Editorial Preface

From the Desk of Managing Editor…

It may be difficult to imagine that almost half a century ago we used computers far less sophisticated than current home desktop computers to put a man on the moon. In that 50 year span, the field of computer science has exploded.

Computer science has opened new avenues for thought and experimentation. What began as a way to simplify the calculation process has given birth to technology once only imagined by the human mind. The ability to communicate and share ideas even though collaborators are half a world away and exploration of not just the stars above but the internal workings of the human genome are some of the ways that this field has moved at an exponential pace.

At the International Journal of Advanced Computer Science and Applications it is our mission to provide an outlet for quality research. We want to promote universal access and opportunities for the international scientific community to share and disseminate scientific and technical information.

We believe in spreading knowledge of computer science and its applications to all classes of audiences. That is why we deliver up-to-date, authoritative coverage and offer open access of all our articles. Our archives have served as a place to provoke philosophical, theoretical, and empirical ideas from some of the finest minds in the field.

We utilize the talents and experience of editor and reviewers working at Universities and Institutions from around the world. We would like to express our gratitude to all authors, whose research results have been published in our journal, as well as our referees for their in-depth evaluations. Our high standards are maintained through a double blind review process.

We hope that this edition of IJACSA inspires and entices you to submit your own contributions in upcoming issues. Thank you for sharing wisdom.

Thank you for Sharing Wisdom!

CONTENTS

Sentiment-Driven Forecasting LSTM Neural Networks for Stock Prediction-Case of China Bank Sector

Shangshang Jin
Department of Art and Science, Johns Hopkins University, Washington, D.C., United States

Abstract*—This study explores the predictive analysis of public sentiment in China's financial market, focusing on the banking sector, through the application of machine learning techniques. Specifically, it utilizes the Baidu Index and Long Short-Term Memory (LSTM) networks. The Baidu Index, akin to China's version of Google Trends, serves as a sentiment barometer, while LSTM networks excel in analyzing sequential data, making them apt for stock price forecasting. Our model integrates sentiment indices from Baidu with historical stock data of significant Chinese banks, aiming to unveil how digital sentiment influences stock price movements. The model's forecasting prowess is rigorously evaluated using metrics such as R-squared (R^2), Root Mean Square Error (RMSE), Mean Absolute Error (MAE), Mean Absolute Percentage Error (MAPE), and confusion matrices, the latter being instrumental in assessing the model's capability in correctly predicting stock up or down movements. Our findings predominantly showcase superior prediction performance of the sentiment-based LSTM model compared to a standard LSTM model. However, effectiveness varies across different banks, indicating that sentiment integration enhances prediction capabilities, yet individual stock characteristics significantly contribute to the prediction accuracy. This inquiry not only underscores the importance of integrating public sentiment in financial forecasting models but also provides a pioneering framework for leveraging digital sentiment in financial markets. Through this endeavor, we offer a robust analytical tool for investors, policymakers, and financial institutions, aiding in better navigation through the intricate financial market dynamics, thereby potentially leading to more informed decision-making in the digital age.

Keywords*—Machine learning; LSTM; sentiment; forecasting; banking sector

I. Introduction

The digital epoch ushered in a plethora of tools and platforms, with search engines emerging as crucial conduits for gauging public sentiment. Shiller [1] accentuates the importance of grounding research in actual human behavior to comprehend how individuals genuinely think and act. This sentiment concurs with the dynamics of the digital realm, where search query fluctuations concerning financial entities can unveil early signs of shifting public interest or potential concerns. These subtle shifts, characteristic of the digital age, harbor the potential to impact stock market trends [2].

This study endeavors to tap into public sentiment within China's financial market, probing how sentiments harvested from digital platforms can act as a predictive lens for scrutinizing and foreseeing market dynamics. Central to this exploration is the Baidu index, a tool often drawn parallel to China's version of Google, emblematic of the digital transition. Baidu, surpassing its initial function as a search engine, has evolved into a dynamic digital nexus, reflecting the collective sentiment of its extensive user base. This discernment elevates tools like the Baidu index to a significant pedestal in contemporary financial prediction frameworks, particularly against the backdrop of digital transformation sweeping through banks and financial institutions [3].

Banks are pivotal players in China’s economic narrative, entrusted with capital provisioning, trade facilitation, and financial stability maintenance [4]. The banking sphere, headlined by colossal entities like the Industrial and Commercial Bank of China (ICBC) and the Agricultural Bank of China (ABC), commands substantial influence over China's economic fabric. In the digital era, their roles and impact have evolved, with stock performance mirroring not only the health of individual institutions but also the broader economic vitality [5]. Observing the stock trends of these institutions can significantly inform both domestic economic strategies and global financial outlooks. Traditional stock prediction methodologies, shackled by inherent constraints, often grapple with accuracy challenges, paving the path for Neural Networks—specifically, the Long Short-Term Memory (LSTM) networks—renowned for their prowess in time series predictions owing to their capability to process long-term data dependencies.

Nonetheless, the nuanced realm of stock market predictions often finds the exclusive reliance on raw financial metrics inadequate. The digital epoch grants stakeholders a platform to voice their opinions, assumptions, and concerns. Tapping into this vast sentiment reservoir, particularly reflected in search patterns on platforms like Baidu, can unveil precious insights. The fusion of sentiment analysis with LSTM models ushers in a novel frontier for stock prediction, especially within crucial sectors like China's banking domain.

This inquiry embarks on an innovative journey, integrating sentiment indices from the Baidu platform with LSTM neural networks to refine the prediction framework for China's banking stocks. Our scrutiny especially shines a light on stalwarts like Industrial and Commercial Bank of China (ICBC), Agricultural Bank of China (ABC), Bank of Communications (BoCom), CCB (China Construction Bank),

China Merchants Bank (CMB), Shanghai Pudong Development Bank (SPDB), and Industrial Bank (IB). Overlaying sentiment metrics with historic stock data, we endeavor to ascertain the predictive potency of sentiments, gauged via the Baidu index, in molding future stock valuations within the banking sector.

This endeavor distinctively enriches the literature by elucidating the intertwined roles of banks in financial stability, regulatory landscapes, investor interests, and the digital transformation of the banking sector. Accurate forecasting of bank stock prices enhances our comprehension of impending financial scenarios and vulnerabilities. By leveraging sentiment analytics, we aim to foresee shifts in the continually evolving regulatory labyrinth banks traverse, equipping stakeholders with insights into potential policy alterations. Recognizing the magnetic appeal the banking sector exudes for investors, our model strives to equip them with precise forecasting tools. Additionally, as the banking sector navigates through transformative digital innovations, our sentiment-driven approach seeks to decipher public perceptions, offering insights into how fintech advancements might reshape bank stock trajectories.

Our exposition is organized as follows: Section II delves into pertinent literature, mapping the journey of sentiment-imbued stock predictions. Section III unravels our methodology, elucidating the integration of Baidu's sentiment indicators with LSTM networks. In Section IV, we disseminate our empirical findings, accentuating the merits and limitations of our model. Finally, Section V encapsulates a reflective summary and contemplates potential directions for future exploration in this domain.

II. Related Work

Research posits that investor sentiment plays a predictive role in cross-sectional stock returns, suggesting that the collective mood of investors can drive stock price fluctuations and impact their anticipated returns [6, 7, 8]. Moreover, an increasing body of literature is exploring the influence of Internet search activities on financial markets, delving into how online information-seeking behaviors may reflect or shape investor sentiment and, in turn, market dynamics.

Li et al. [9] marked one of the initial strides into understanding how financial news articles sway stock prices. Their contention was that while many had mapped the influence of news in a bag-of-words paradigm, the more profound underlying sentiment—bridging the chasm between lexical patterns and stock fluctuations—remained an undercharted territory. By implementing sentiment dictionaries, their work enriched the sentiment space, and the results affirmed that sentiment-infused models yield superior accuracy over the conventional bag-of-words counterparts.

Pivoting to the realm of digital social interactions, Guo et al. [10] embarked on an exploration capitalizing on user comments from Xueqiu, a focal social networking site in the Chinese stock market landscape. Their research sought to dynamically unravel the web of interactions between investor sentiment and the stock market. One salient revelation was that sentiment data's efficacy as a predictive tool is tethered to the degree of public attention the stock garners. This insight underscores the dynamism and contingent nature of sentiment's predictive power.

Smales in [11] delved deeper into the mechanics of how investor sentiment could cause asset prices to deviate from their fundamental equilibrium. He asserted that understanding these deviations is paramount, given their potential ramifications on capital allocation and its costs. Through a comprehensive analysis spanning a quarter-century, he demonstrated that sentiment indicators, exemplified by the Volatility Index (VIX), forge a robust bond with stock returns. Further granularity revealed that some stocks, especially those in tech or smaller capitalization brackets, display heightened susceptibility to sentiment fluctuations. Intriguingly, recessional periods amplify this sentiment-driven volatility.

Bringing sophisticated machine learning into the fold, Xing et al. [12] championed the sentiment-aware volatility forecasting (SAVING) model. Their venture sought to elucidate the bidirectional dance between asset prices and market sentiment. This synthesis of deep learning and sentiment analysis manifested in results that eclipsed traditional forecasting tools and rival neural network architectures in terms of precision.

Lastly, the ubiquity of social media platforms in shaping stock predictions has witnessed academic spotlight. Swathi et al. [13] echoed the notion that platforms like Twitter, given their massive user engagement, have metamorphosed into sentiment barometers. By fusing the Teaching and Learning Based Optimization (TLBO) technique with Long Short-Term Memory (LSTM) frameworks, they demonstrated an unprecedented accuracy in forecasting stock price movements based on social media sentiment.

III. Methodology

This section elucidates the systematic approach employed to forecast the stock prices of significant Chinese banks, leveraging sentiment analysis and LSTM Neural Networks. We initiate with an introduction to LSTM and its aptness for time series forecasting and subsequently incorporate sentiment data derived from the Baidu Index. Acknowledging the latent impact of sentiment on stock market behavior, the Baidu Index is introduced as a lagged variable. Employing grid search, the model's hyperparameters are optimized. Evaluation metrics such as R^2, RMSE, MAE, and MAPE are then utilized to determine the model's predictive accuracy.

A. Long Short-Term Memory (LSTM) Networks

LSTM (Long Short-Term Memory) networks, proposed by Hochreiter and Schmidhuber [14], are a specialized subset of Recurrent Neural Networks (RNN), meticulously crafted to grasp long-term dependencies within sequential datasets. Their intrinsic capability to retain patterns across extended sequences renders them particularly proficient for tasks such as stock price prediction.

Refer to Fig. 1 for a visualization of the LSTM model, structured as follows:

- 1 Input Layer: Accepts the sequence of stock prices and sentiment indices.

- 2 Hidden Layers: Composed of LSTM units that can remember patterns in data over long periods.
- 1 Output Layer: Produces the predicted stock price.

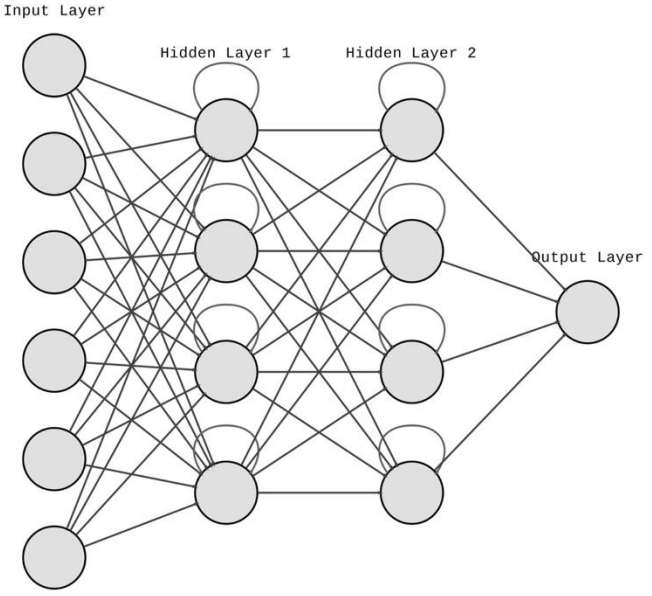

Fig. 1. LSTM structure.

Mathematically, the operations of an LSTM unit are encapsulated as:

$$\begin{aligned} f_t &= \sigma\big(W_f \cdot [h_{t-1}, X_t] + b_f\big) \\ i_t &= \sigma(W_i \cdot [h_{t-1}, X_t] + b_i) \\ \tilde{C}_t &= \tanh(W_C \cdot [h_{t-1}, X_t] + b_C) \\ C_t &= f_t \times C_{t-1} + i_t \times \tilde{C}_t \\ o_t &= \sigma(W_o \cdot [h_{t-1}, X_t] + b_o) \\ h_t &= o_t \times \tanh(C_t) \end{aligned} \tag{1}$$

where:

- $f_t, i_t, \tilde{C}_t, C_t, o_t, h_t$ are the forget gate, input gate, cell candidate, cell state, output gate, and hidden state at time t respectively.
- W_f, W_i, W_C, W_o and b_f, b_i, b_C, b_o are the weights and biases for the respective gates.
- σ is the sigmoid function.

B. Sentiment Index

In this paper, the Baidu index, a popular sentiment index in China, gauges the public sentiment by analyzing search query frequencies and user behaviors on the Baidu search engine. To harmonize the scale between stock prices and the Baidu Index during pre-processing, Min-Max scaling is applied. Recognizing the potential latency in sentiment influence on stock prices, a time-lagged version of the Baidu Index is integrated. This latency captures the inherent delay in investor reactions, attributable to the time taken to interpret and act upon sentiment-driven information, thereby encapsulating market inertia.

For model input augmentation, at each time step t, our LSTM model receives a concatenated input vector, represented as:

$$X_t = [P_t, B_t] \tag{2}$$

Where:

- P_t is the stock price at time t.
- B_t represents the Baidu Sentiment Index at time t.

The LSTM, characterized by its inherent memory, updates its cell state c, factoring in both the stock prices and sentiment index, thereby accounting for sentiment influence across sequences. During the LSTM's forward propagation, this merged input not only impacts immediate outputs but also modifies the hidden states. Consequently, the sentiment information guides predictions and tweaks the LSTM's internal memory. The chosen loss function, Mean Squared Error (MSE), benchmarks model forecasts against real stock prices. During backpropagation, the gradients, inherently influenced by the Baidu Index, fine-tune the model's weightings throughout its training phase.

C. Grid Search Optimization

Grid search is an exhaustive search approach employed for hyperparameter tuning, ensuring optimal model performance. By systematically working through multiple combinations of hyperparameter sets, it evaluates which combination gives the best performance based on a scoring technique [15, 16].

In the optimization process of the LSTM model, several pivotal hyperparameters are meticulously evaluated. The batch size, dictating the number of samples processed before a model update, emerges as a key factor under consideration. The efficacy of various optimizers, notably RMSprop and Adam, is also examined [17]. These algorithms adjust the model's weights in alignment with the data and its corresponding loss function. To fortify the model against overfitting, dropout layers are integrated within the LSTM's architecture [18]. The dropout rate specifies the percentage of neurons randomly nullified during each training phase, enhancing model generalizability. A detailed visualization of the grid search, illustrating the synergy of these hyperparameters and their bearing on model performance, is provided in Fig. 2.

D. Forecasting Evaluation Criterias

To gauge the accuracy and reliability of the model's forecasts, followed by Paudel et al, [19], several statistical metrics are employed:

R^2 (Coefficient of Determination):

$$R^2 = 1 - \frac{\sum_{i=1}^{n} (Y_i - \hat{Y}_i)^2}{\sum_{i=1}^{n} (Y_i - \bar{Y})^2} \tag{3}$$

RMSE (Root Mean Squared Error):

$$RMSE = \sqrt{\frac{1}{n}\sum_{i=1}^{n} \left(Y_i - \hat{Y}_i\right)^2} \tag{4}$$

MAE (Mean Absolute Error):

$$MAE = \frac{1}{n}\sum_{i=1}^{n} \left|Y_i - \hat{Y}_i\right| \tag{5}$$

MAPE (Mean Absolute Percentage Error):

$$MAPE = \frac{100}{n}\sum_{i=1}^{n}\left|\frac{Y_i - \hat{Y}_i}{Y_i}\right| \quad (6)$$

where Y_t is the actual value at time $t, \hat{Y}_t$ is the predicted value at time , and $\bar{Y}$ represents the mean of the actual values.

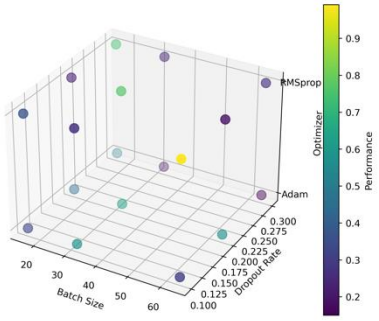

Fig. 2. 3D visualization of grid search.

E. Summary

The proposed technique for predicting stock prices by incorporating the Sentiment Index employs a systematic process, seamlessly integrating the power of Long Short-Term Memory (LSTM) networks and the insights from the Sentiment Index.

Initially, input data comprising of stock prices and a one-day lagged Sentiment Index is collected. This data undergoes normalization to ensure that the range of values is consistent, thereby facilitating effective training. A time-series dataset is then constructed to ensure sequences of data are fed to the LSTM network, aiding in the capture of temporal dependencies.

The dataset gets bifurcated into training and test sets. The LSTM model, designed with two LSTM layers and a dense output layer, is structured to efficiently incorporate and process this information. The first LSTM layer, activated by the tanh function and equipped with dropout, returns sequences which are fed into the second LSTM layer. This layer not only processes the sequences but also integrates the Sentiment Index data. The dense layer at the end aids in producing the final prediction.

Upon constructing this model, it undergoes compilation wherein various aspects like optimizer, loss function, and evaluation metrics are defined. To determine the most optimal parameters for training, a grid search technique is employed. This process considers parameters such as optimizer choice, dropout rate, and batch size, ensuring the model's robustness and accuracy. The model, trained with the best parameters identified by the grid search, is then used to make predictions on the test set.

Once predictions are made, they are de-normalized to revert them to their original scale. Finally, these predictions are evaluated using several metrics to determine the model's efficacy. The metrics include RMSE, MAE, MAPE, and R^2.

The entire technique, encapsulated in the flowchart (see Fig. 3), presents a comprehensive approach to effectively predict stock prices by harnessing the dual power of LSTM networks and sentiment indices.

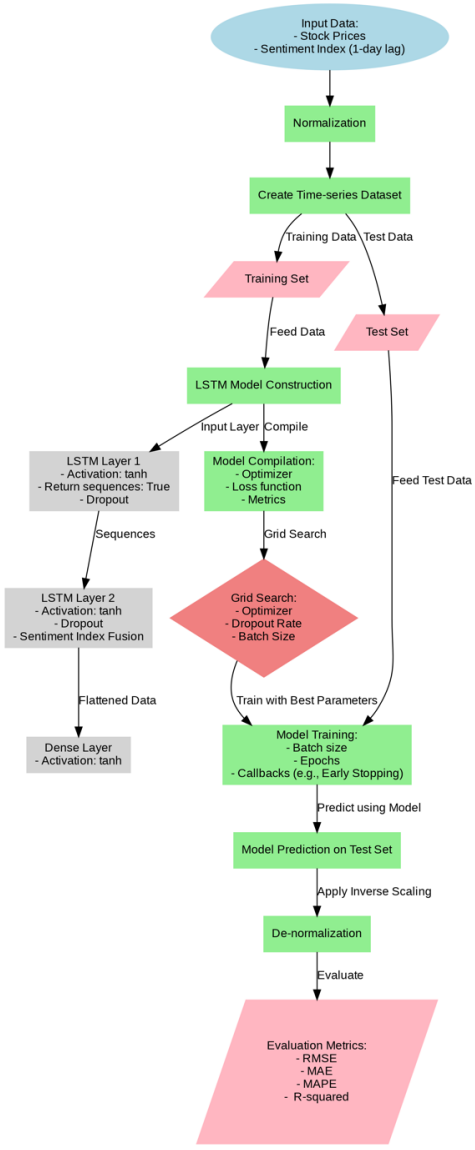

Fig. 3. Flowchart of the proposed technique.

IV. Numerical Results

A. Data Description

The study employs daily stock prices from August 1, 2022, to August 1, 2023, of seven eminent banks listed on the Shanghai Stock Exchange, including ICBC, ABC, BoCom, CCB, CMB, SPDB, and IB (see Fig. 4). This data, sourced from Yahoo Finance, assures precision. Considering Baidu's significant presence in China, its index is a robust reflection of the public's sentiment towards these banks, sentiment indicators is derived from the Baidu index specific to each bank depicted in Fig. 5. For modeling purposes, the data is split: 80% for training and 20% for testing. Preprocessing steps involve data normalization to ensure consistency.

Fig. 4. Stock price.

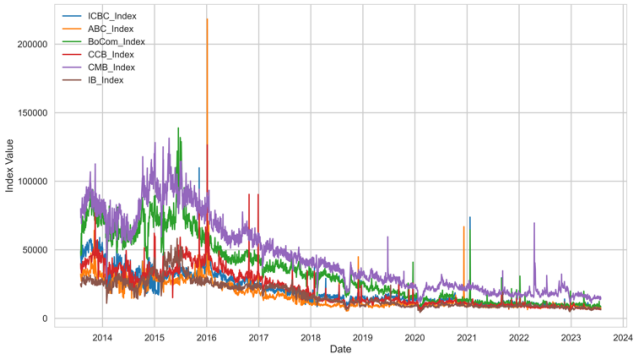

Fig. 5. Stock sentiment index.

B. Hyperparameter Determination

Using grid search, various combinations of batch size, dropout rate, and optimizer type are examined. Each bank's data undergoes this analysis individually, catering to the distinct behavior of each bank's stock prices. The optimal hyperparameters obtained are delineated below in Table I.

C. Forecasting Performance

Table II showcases the forecasting performance of both the LSTM and Sentiment-integrated LSTM (SB-LSTM) models for each bank. For ICBC, the SB-LSTM model exhibits a remarkable increase in R^2 by 6.67% compared to the standard LSTM, and the RMSE also drastically reduces from 0.0510 to 0.0107. In the case of ABC, the R^2 in the SB-LSTM model increases by 2.01% and sees a significant reduction in RMSE from 0.0411 to 0.0185. BoCom's results indicate that the SB-LSTM has an RMSE of 0.0338, an improvement from 0.0553 as observed in the standard LSTM.

Interestingly, for CCB, the standard LSTM outperforms the SB-LSTM in terms of R^2 and RMSE metrics. This suggests that the integration of sentiment does not consistently lead to improved forecasts for every stock. For CMB, the SB-LSTM model dramatically reduces the RMSE from 0.7648 to 0.2316. Similarly, IB's forecasting with the SB-LSTM exhibits a substantial enhancement in R^2, marking an increase of 7.29% compared to the LSTM.

TABLE I. OPTIMAL HYPERPARAMETERS FOR EACH BANK

Stock	Hyperparameter	LSTM	SB-LSTM
ICBC	Batch Size	16	16
	Dropout rate	0.3	0.1
	Optimizer	Adam	Adam
ABC	Batch Size	16	16
	Dropout rate	0.1	0.2
	Optimizer	Adam	Adam
BoCom	Batch Size	16	16
	Dropout rate	0.3	0.3
	Optimizer	Adam	Adam
CCB	Batch Size	16	16
	Dropout rate	0.1	0.3
	Optimizer	Adam	Adam
CMB	Batch Size	16	16
	Dropout rate	0.1	0.3
	Optimizer	Adam	Adam
IB	Batch Size	16	16
	Dropout rate	0.1	0.2
	Optimizer	Adam	Adam

TABLE II. MODEL PERFORMANCE

Stock	Model	R^2	RMSE	MAE	MAPE
ICBC	LSTM	93.03%	0.0510	0.0410	0.9805%
	SB-LSTM	99.70%	0.0107	0.0091	0.2197%
ABC	LSTM	97.48%	0.0411	0.0295	1.0268%
	SB-LSTM	99.49%	0.0185	0.0171	0.6091%
BoCom	LSTM	98.69%	0.0553	0.0379	0.8234%
	SB-LSTM	99.51%	0.0338	0.0320	0.7278%
CCB	LSTM	95.99%	0.0598	0.0419	0.7625%
	SB-LSTM	93.35%	0.0771	0.0767	1.4282%
CMB	LSTM	98.55%	0.7648	0.5662	1.5184%
	SB-LSTM	99.87%	0.2316	0.1973	0.5328%
IB	LSTM	92.66%	0.3340	0.2675	1.6014%
	SB-LSTM	99.95%	0.0274	0.0229	0.1372%

In essence, while the SB-LSTM model generally showcases superior accuracy and precision in forecasting for most stocks, there are notable exceptions, such as CCB. This underscores the idea that sentiment integration typically enhances prediction capabilities, but the individual characteristics of stocks must be taken into account.

D. Classification Analysis

Fig. 6 delineates the confusion matrices for the LSTM and SB-LSTM models across six prominent banks: ICBC, BoCom, ABC, CCB, CMB, and IB. For the ICBC stock, the LSTM model yielded 138 true negatives and 84 true positives but was marred by 131 false positives and 132 false negatives.

Conversely, the SB-LSTM showed a marked improvement, boasting 247 true negatives, 212 true positives, and significantly fewer false positives and negatives. A similar trend was observed for BoCom, where the SB-LSTM displayed enhanced accuracy with 232 true negatives and 227 true positives, overshadowing the LSTM's 134 true negatives and 102 true positives. ABC's LSTM model presented 166 true negatives and 58 true positives, but the SB-LSTM again outperformed by producing 242 true negatives and 189 true positives. This pattern of SB-LSTM superiority persisted with CCB, where the LSTM's 144 true negatives and 86 true positives were eclipsed by the SB-LSTM's 251 true negatives and 210 true positives. For CMB, while the LSTM model recorded 144 true negatives and 111 true positives, the SB-LSTM surged ahead with 257 true negatives and 220 true positives. Lastly, IB's results from the LSTM, comprising 132 true negatives and 96 true positives, were also surpassed by the SB-LSTM's impressive 257 true negatives and 225 true positives.

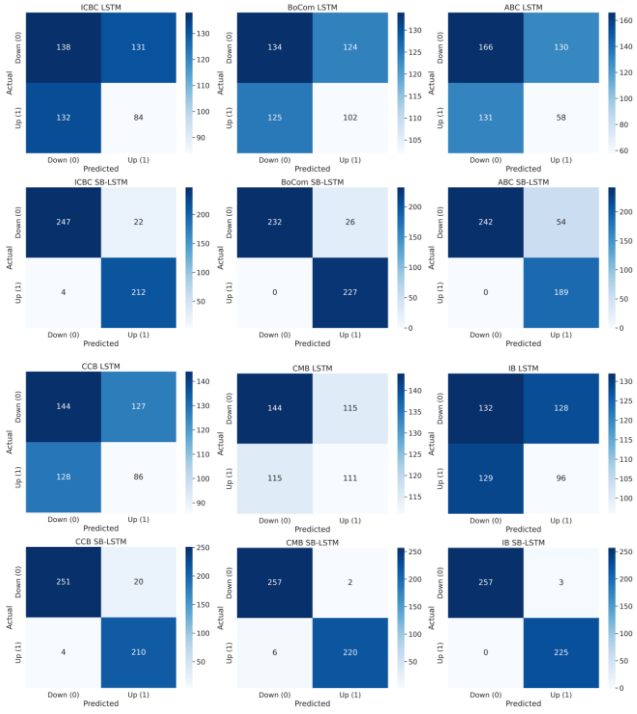

Fig. 6. Confusion matrix.

In summary, the SB-LSTM models consistently demonstrated higher classification accuracy across all stocks when juxtaposed with the LSTM models, emphasizing their superior capability in predicting stock price movements.

V. Conclusion

This study ventured into the realm of sentiment-driven stock prediction, specifically within China's banking sector, utilizing a Sentiment-integrated LSTM (SB-LSTM) model. Our findings predominantly showcased the SB-LSTM model's superior accuracy over traditional LSTM in forecasting stock prices, echoing the potential of sentiment analysis in financial forecasting as suggested by previous studies [20, 21, 22]. Particularly, the use of the Baidu Index highlighted how sentiment data can enhance predictive accuracy. The consistent enhancement in classification accuracy across most stocks by the SB-LSTM models further corroborates the promise of integrating sentiment analysis with LSTM networks for more precise stock price forecasting. While the use of the Baidu Index effectively demonstrated how sentiment data can enhance predictive accuracy, a key limitation lies in the reliance on a single sentiment data source, which may not capture the full spectrum of market sentiments. Additionally, the model's efficacy outside the Chinese banking sector remains untested, suggesting the need for further research to evaluate its applicability across different sectors and geographical regions. This endeavor not only enriches the literature but also paves the way for future explorations in leveraging unstructured sentiment data for financial forecasting amidst the digital transformation sweeping across the financial sector. This transformation is increasingly recognized as crucial in the evolving landscape of financial analytics.

Semantic Sampling: Enhancing Recommendation Diversity and User Engagement in the Headspace Meditation App

Rohan Singh Rajput*, Christabelle Pabalan*, Akhil Chaturvedi*, Prathamesh Kulkarni, Adam Brownell
Headspace
Los Angeles, USA

***Abstract*—In this paper, we present a clever approach to enhance the performance of sequential recommendation systems, specifically in the context of meditation recommendations within the Headspace app. Our method, termed "Semantic Sampling", leverages the power of language embeddings and clustering techniques to introduce diversity and novelty in the recommendations. We augment the Time Interval Aware Self-Attention for Sequential Recommendation (TiSASRec) model with semantic sampling, where the next recommended item is randomly sampled from a cluster of semantically similar items. Our empirical evaluation, conducted on a sample set of 276,700 users, reveals a statistically significant increase of 2.26 % in content start rate for the treatment group (TiSASRec with semantic sampling) compared to the control group (TiSASRec alone). Furthermore, our approach demonstrates improved coverage and rarity, indicating a broader range of recommendations and higher novelty. The results underscore the potential of Semantic Sampling in enhancing user engagement and satisfaction in recommendation systems.**

***Keywords*—Information retrieval; machine learning; recommender system.**

I. Introduction

Recommendation systems have become an indispensable part of modern digital applications, providing users with personalized content and product suggestions [1]. These systems are especially important in the realm of wellness applications, where personalization can enhance user engagement and satisfaction significantly. Headspace, for instance, offers a rich variety of content covering meditation, sleep, focus, and music, among others [2].

However, a common challenge for these systems is the 'long tail problem'. A significant number of items are rarely recommended, resulting in limited diversity in the recommendations [3]. This lack of diversity can curb user exploration and engagement, especially in areas where exploring new content is beneficial. In the context of wellness applications like Headspace, users gain exposure to a diverse range of content, aiding them in discovering new techniques, sustaining interest, and deepening their practice.

Unlike platforms like TikTok or YouTube, where content consumption can be sporadic and unplanned, Headspace users often embark on sequential mindfulness journeys through the content. Recognizing this unique behavior, we found TiSASRec, a sequential recommendation system built on the transformer architecture, to be an apt baseline for our approach [4]. While TiSASRec outperformed earlier models, it started to loop back to repetitive content recommendations after extended training. This tendency to lean towards shorter, frequently accessed content over longer, seldom accessed content limited the scope of recommendations and potentially restricted user exploration.

To amplify recommendation diversity while retaining relevance, we integrated semantic sampling into the TiSASRec model. Semantic sampling involves extracting language embeddings from the titles and teasers of content using sentence transformers. After these embeddings are secured, we compute their cosine similarities. Instead of merely relying on TiSASRec's recommendations, we select content from the cluster of the N most semantically similar items [5]. This approach not only broadens the array of recommendations but ensures they remain pertinent to the user, enhancing the discovery experience.

By melding sequential recommendations with semantic sampling, we present a robust solution to the long tail problem. This strategy augments the diversity of recommendations while ensuring their relevance to individual users. By blending the strengths of both sequential recommendation systems and semantic sampling, our goal is to elevate the user experience in wellness platforms like Headspace.

II. Method

To tackle the long-tail problem in recommendation systems, we introduced a technique called semantic sampling. This approach leverages language embeddings and cosine similarity to offer diverse and engaging content recommendations. We conducted extensive online A/B testing, evaluating various metrics to validate the efficacy of our approach. The results from the A/B test provided crucial insights into the real-world performance of our recommendation system.

A. Headspace App

Headspace is a popular mindfulness and meditation app that offers a wide variety of content to its users. The content is organized into different modules, each focusing on a specific topic or theme. The app provides recommendations to users on the "Today" tab, which is the main landing page of the app. The recommendations are personalized based on the user's past interactions and preferences [6].

*Corresponding authors.

The app also provides recommendations in specific modules. For example, in the "Sleep" module, the app recommends sleep-focused content, while in the "Meditation" module, it recommends meditation-focused content. The goal of these recommendations is to provide users with content that is relevant and engaging, enhancing their overall experience with the app. This is further exemplified in Fig. 1.

B. Semantic Sampling

Semantic sampling is an approach we introduced to enhance the diversity of recommendations. The method employs the extraction of language embeddings from content titles and teasers using the Language-agnostic BERT Sentence Embedding (LaBSE) transformer model [7].

LaBSE is a multilingual sentence encoder, trained on a broad corpus of bilingual sentence pairs. It produces language-agnostic sentence embeddings, ensuring that sentences with equivalent meanings across different languages are proximal in the embedding space [7]. Such a property becomes invaluable for our use case, enabling the comparison and identification of similarities between content, irrespective of language barriers.

Our choice of LaBSE was driven by its excellent performance in paraphrasing similarity tasks, vital for our objective of discerning semantically similar content pieces. The illustration of Semantic Sampling workflow is explained in the Fig. 2.

Semantic sampling proceeds through the following stages:

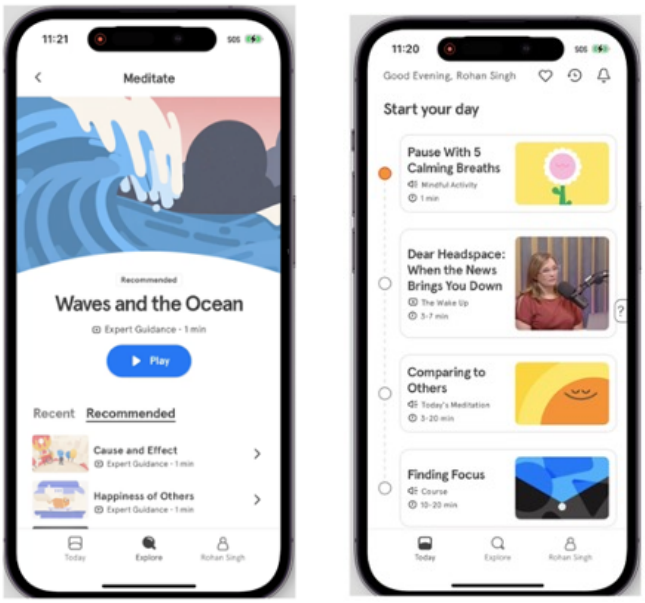
Content Embedding: We commence by extracting the language embeddings from content titles and teasers using LaBSE. This yields a high-dimensional vector representation for every content item.

Similarity Calculation: Cosine similarity between these embeddings is computed. This metric quantifies the cosine of the angle between two vectors, representing a measure of their alignment and, by extension, their similarity. Its value spectrum ranges from -1 (entirely dissimilar) to 1 (perfectly similar).

Recommendation Refinement: Instead of directly using the recommendation produced by the TiSASRec model, we assess the similarity of this chosen content with all other content items. Content pieces falling below a cosine similarity threshold of 0.75 to the chosen content are filtered out. From the remaining, more similar content pieces, one is selected randomly. For this process, there's an 80% likelihood that the content will be resampled using semantic sampling.

The TiSASRec model underpins our recommendation system. A transformer-centric model, it has been empirically validated to adeptly capture users' sequential behaviors [8]. The model utilizes the transformer framework, rooted in self-attention mechanisms, to emulate the sequential tendencies of users. This endows it with the capability to understand both immediate and extended user preferences, rendering it apt for our application.

For our endeavors, the TiSASRec model was the source of initial recommendations, which subsequently received enhancement through our semantic sampling technique.



(a) Recommended Meditation (b) Today Tab

Fig. 1. Screenshots of the Headspace app showcasing our recommendation system. (a) The 'Recommended for You' section in the Meditation module displays personalized suggestions. (b) The 'Today Tab' features dynamic content shelves, each filled with diverse recommendations from our system for an engaging experience.

$$\text{Semantic Sampling}(c) = \arg\max_{c' \in C} \frac{1}{N} \sum_{i=1}^{N} \text{sim}(c, c'_i) \quad (1)$$

Here, c symbolizes the content piece put forth by the TiSASRec model, C embodies the collection of all content items, N stands for the count of the most similar items taken into account, and $\text{sim}(c, c'_i)$ signifies the cosine similarity between the embeddings of content pieces c and c'_i.

By leveraging this methodology, we facilitate a richer spectrum of recommendations. This not only bolsters the user's exploratory experience but also ensures the continued relevance of recommendations to individual users.

C. Metrics for Evaluation

In the context of recommender systems, research has traditionally focused on the precision of the recommendations. However, it has been recognized that other recommendation qualities—such as whether the list of recommendations is diverse and whether it contains novel items—may have a significant impact on the overall quality of a recommender system. Consequently, the focus of recommender systems research has shifted to include a wider range of 'beyond accuracy' objectives [9]. These metrics include coverage, entropy, rarity, and intra-list diversity (ILD).

1) Coverage: Coverage is a measure of the proportion of items in the catalog that the recommender system can suggest. It provides an understanding of how well the recommendations cover the available items. A higher coverage indicates that the recommender system is capable of suggesting a wider

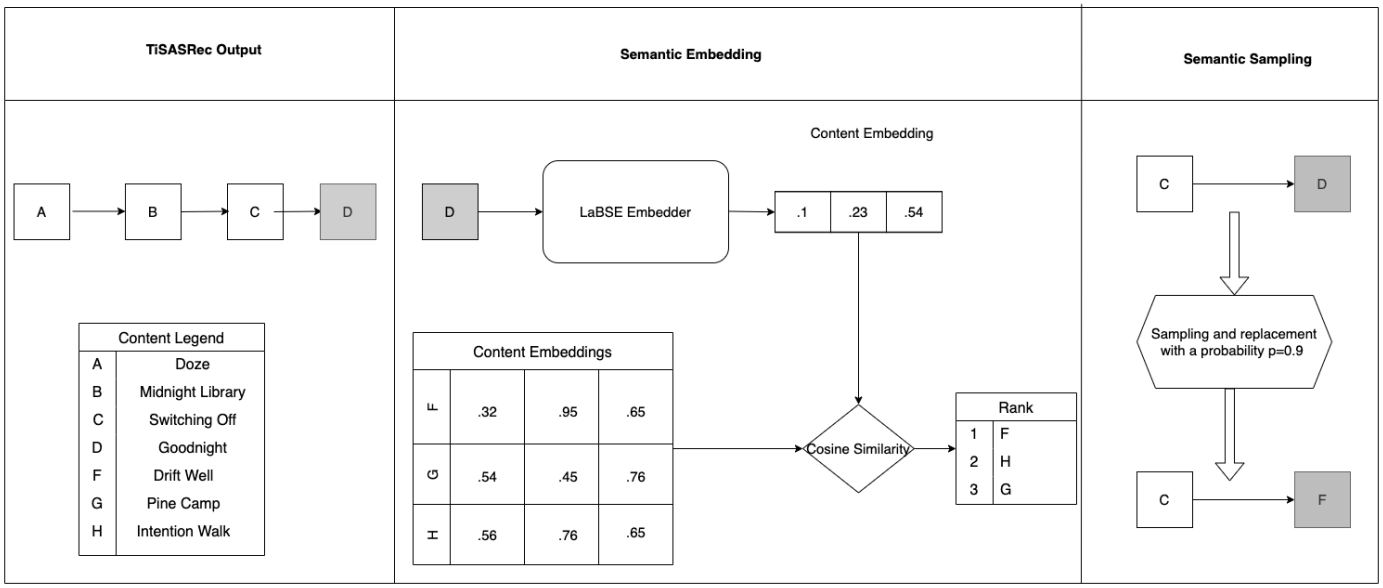


Fig. 2. Semantic Sampling Workflow. (a) The left side illustrates the input-output sequence of the TiSASRec model. (b) The central block depicts the generation of the LaBSE Embedding. (c) The right block demonstrates the replacement of the TiSASRec output with content that has been semantically embedded and sampled.

variety of items, which can contribute to a more diverse and personalized user experience [10]. It can be calculated as follows:

$$Coverage = \frac{|I_{rec}|}{|I|} \tag{2}$$

where, I_{rec} is the set of items recommended and I is the total set of items.

2) Entropy: Entropy is a measure of the unpredictability or randomness of the recommendations. It is derived from information theory, where it is used to quantify the amount of information contained in a set of data. In the context of recommender systems, a higher entropy indicates a more diverse set of recommendations, as it suggests that the recommendations are spread out over a larger number of different items. Optimal entropy is achieved when the recommendation distribution is uniformly distributed, therefore, an increase in entropy signifies an improvement for the long-tail problem [11]. It can be calculated as follows:

$$Entropy = -\sum_{i=1}^{|I|} p(i) \log p(i) \tag{3}$$

where, $p(i)$ is the probability of item i being recommended.

3) Rarity: Rarity is a measure of how uncommon or unique the recommended items are. It is defined as the inverse of normalized popularity, with 0 being our most viewed content and 1 being our least viewed content. A higher rarity score indicates that the recommender system is suggesting more unique or less popular items, which can contribute to a more diverse set of recommendations [12]. It can be calculated as follows:

$$Rarity = 1 - \frac{pop(i)}{max_{j \in I} pop(j)} \tag{4}$$

where, $pop(i)$ is the popularity of item i, and $max_{j \in I} pop(j)$ is the popularity of the most popular item.

4) Intra-List Diversity (ILD): Intra-List Diversity (ILD) is a metric that measures the average dissimilarity between all pairs of items within a recommendation list. It is a measure of the diversity of the recommendations and is defined as follows:

$$ILD(L) = \frac{2}{|L| \cdot (|L| - 1)} \sum_{i=1}^{|L|} \sum_{j=i+1}^{|L|} d(i, j) \tag{5}$$

where, L is the list of recommended items, $|L|$ is the number of items in the list, and $d(i, j)$ is the dissimilarity between items i and j. The dissimilarity between items can be calculated using various methods, such as cosine distance in the embedding space. A higher ILD value indicates a more diverse set of recommendations [13].

5) Content Click-Through Rate: Content Click-Through Rate (CTR) is a measure of user engagement with the recommended content. It is defined as the number of times users initiate interaction with the content divided by the number of times the content is displayed to the users. This metric directly reflects the user's interaction with the recommended content, providing a clear measure of the effectiveness of the recommendations. An increase in this rate is indicative of users finding the recommendations more engaging and relevant [14]. It can be calculated as follows:

$$CTR = \frac{Clicks}{Impressions} \tag{6}$$

where $Clicks$ is the number of times users initiate interaction with the content, and $Impressions$ is the number of times the content is displayed to the users.

D. Online Analysis

For our online analysis, we conducted an A/B test on 138.4K control users (TiSASRec only) and 138.3K treatment users using the StatSig platform. StatSig is a platform that provides robust statistical analysis for A/B testing, ensuring that our results are statistically significant and reliable. This A/B test was run for a period of 42 days.

A key metric we focused on was the change in average content starts across the entire Headspace App. The content start rate, a widely accepted measure of user engagement, is defined as the number of times users initiate interaction with the content divided by the number of times the content is displayed to the users. This metric was chosen because it directly reflects the user's interaction with the recommended content, providing a clear measure of the effectiveness of the recommendations. An increase in this rate is indicative of users finding the recommendations more engaging and relevant [14].

To gain a deeper understanding of the changes in diversity brought about by our semantic sampling approach, we also calculated the entropy, ILD, coverage, and rarity for the clicks originating from both TiSASRec and the treatment model. These metrics were computed for the entire app, providing a comprehensive evaluation of the impact of semantic sampling on the quality of recommendations as described above.

This comprehensive online analysis allowed us to assess the real-world performance of our semantic sampling approach, providing valuable insights into its effectiveness in enhancing the diversity of recommendations while maintaining user engagement which is our primary goal.

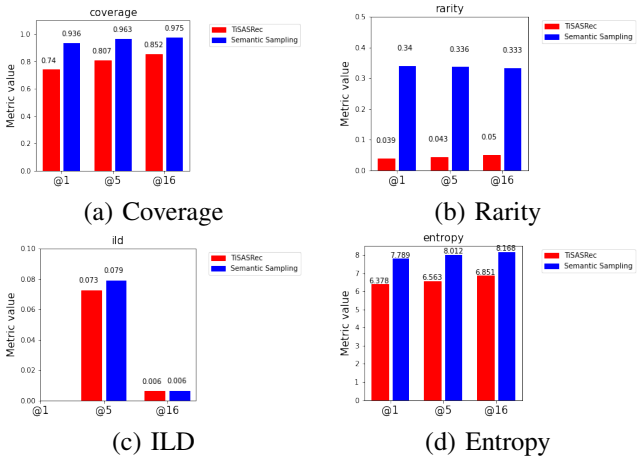
III. Results

In this section, we present the results of our study comparing the performance of the baseline TiSASRec model with the enhanced approach using semantic sampling. We evaluated the two models across various metrics to assess the impact on recommendation diversity and user engagement. Additionally, we discuss the findings from the online A/B test, which provided insights into the real-world effectiveness of our semantic sampling approach to solve the long tail problem.

A. Semantic Sampling Improves Recommendation Diversity

We conducted extensive evaluations to compare the performance of TiSASRec with our semantic sampling approach based on results from the online experiment. The results of these comparisons across different metrics are exemplified in Table I and Fig. 3.

1) Coverage: We first examined the coverage metric, which measures the proportion of items in the catalog that the recommender system is able to suggest. The results showed that the semantic sampling approach significantly outperformed TiSASRec across all top-k rankings (Coverage@1, Coverage@5, and Coverage@16). For example, at Coverage@1, semantic sampling achieved a coverage of 0.936, representing a substantial increase of 26.67% compared to TiSASRec's coverage



(a) Coverage (b) Rarity

(c) ILD (d) Entropy

Fig. 3. Four figures depicting various recommender system metrics. (a) Coverage illustrates the algorithm's range of potential recommendations. (b) Rarity indicates the uniqueness of recommendations. (c) ILD represents the average dissimilarity between recommended items. (d) Entropy quantifies the information in a stochastic process.

of 0.740. This indicates that the semantic sampling approach recommended a wider variety of items to users, enhancing their opportunity for content discovery and engagement.

2) Entropy: The entropy metric measures the unpredictability or randomness of the recommendations. Higher entropy values suggest a more diverse set of recommendations. Our results revealed that the semantic sampling approach significantly increased the entropy of recommendations compared to TiSASRec. For instance, at Entropy@1, the mean entropy of semantic sampling was 7.789, which was 22.09% higher than TiSASRec's mean entropy of 6.378. Similarly, at Entropy@5 and Entropy@16, semantic sampling demonstrated improvements of 22.09% and 19.23%, respectively. These results indicate that the semantic sampling approach generated more diverse and less predictable recommendations, fostering a richer and more engaging user experience.

3) Rarity: The rarity metric measures how uncommon or unique the recommended items are. A higher rarity score indicates that the recommender system suggests more unique or less popular items, contributing to a more diverse set of recommendations. The semantic sampling approach significantly increased the rarity scores compared to TiSASRec for all top-k rankings (Rarity@1, Rarity@5, and Rarity@16). For example, at Rarity@1, semantic sampling achieved a score of 0.340, representing a remarkable increase of 765.88% compared to TiSASRec's score of 0.039. These results further confirm that semantic sampling effectively promotes the discovery of less frequently recommended content items.

4) Intra-List Diversity (ILD): Intra-List Diversity (ILD) quantifies the average dissimilarity between all pairs of items within a recommendation list. Our semantic sampling approach achieved a modest improvement in ILD at top-k ranking values of ILD@5 and ILD@16, with a 8.82% and 2.84% increase, respectively. These results indicate a positive impact on the diversity of recommendations.

TABLE I. COMPARISONS BETWEEN TISASREC AND SEMANTIC SAMPLING ACROSS DIFFERENT METRICS

	TiSASRec		Semantic Sampling		% Change (Mean)
Metric	Mean	Std	Mean	Std	Mean
Coverage@1	0.740	0.015	**0.936**	0.008	**+26.670%**
Coverage@5	0.807	0.010	**0.963**	0.004	**+18.520%**
Coverage@16	0.852	0.008	**0.975**	0.002	**+13.550%**
Entropy@1	6.378	0.039	**7.789**	0.026	**+22.090%**
Entropy@5	6.563	0.026	**8.012**	0.019	**+22.090%**
Entropy@16	6.851	0.019	**8.168**	0.013	**+19.230%**
Rarity@1	0.039	0.001	**0.340**	0.007	**+765.880%**
Rarity@5	0.043	0.001	**0.336**	0.006	**+688.120%**
Rarity@16	0.050	0.001	**0.333**	0.006	**+562.830%**
ILD@1	NaN	NaN	NaN	NaN	NaN
ILD@5	0.073	0.000	**0.079**	0.000	**+8.820%**
ILD@16	0.006	0.000	**0.006**	0.000	**+2.840%**

TABLE II. A/B TESTING EXPERIMENT RESULTS

Metric	**Control**	**Treatment**
Members	138.4K	138.3K
Average Content Starts	15.57	15.92
Delta % (Content Starts)	**+2.26%**	
p-value	**0.004**	

B. Online A/B Test Results

To validate the real-world impact of our semantic sampling approach, we conducted an A/B test involving a substantial user base of 276,700 members. The test compared the control group, which used the baseline TiSASRec model, with the treatment group, which experienced the enhanced model with semantic sampling. These results are shown in Table II.

1) Average Content Starts: As a media-oriented app, one of the primary metrics we focused on in the A/B test was the average content starts per user during the experimental period. This metric measures how frequently users initiated interactions with the recommended content. The treatment group, which used the semantic sampling approach, exhibited an average content start rate of 15.92 starts per user, while the control group, using the baseline TiSASRec model, had an average content start rate of 15.57 starts per user.

The 2.26% lift in content starts for the treatment group compared to the control group was statistically significant (p-value ¡ 0.05), indicating that the increase in user engagement with the recommended content was not due to random chance. This result highlights the effectiveness of the semantic sampling approach in encouraging users to interact more frequently with the content suggested by the recommender system.

IV. DISCUSSION

The results of our study demonstrate the effectiveness of the semantic sampling approach in enhancing the diversity of recommendations and increasing user engagement in the Headspace app. The evaluation of diversity metrics from the online experiment showed significant improvements in coverage, entropy, rarity, and intra-list diversity, indicating that the semantic sampling approach successfully addressed the long tail problem in recommendation systems. By suggesting more diverse, unique, and less predictable content to users, the semantic sampling approach enriches users' discovery experience, encouraging them to explore a wider range of content.

The online A/B test further validated the real-world impact of the semantic sampling approach, showing a statistically significant lift of 2.26% in average content starts for the treatment group. This indicates that users in the treatment group found the recommendations generated using semantic sampling to be more engaging and relevant, leading to increased interactions with the recommended content.

A. Explanation of Increased Diversity and Relevance

The success of the semantic sampling approach in enhancing diversity and relevance can be attributed to two key factors:

Semantic Understanding: The use of language embeddings allowed the system to better understand the semantic meaning of content items. By capturing the inherent relationships between content titles and teasers, the approach could identify and group together semantically similar pieces. This understanding enabled the recommendation system to present a broader range of content options to users, encompassing items that share similar themes or topics.

Random Sampling: The introduction of random sampling from the cluster of semantically similar items injected diversity into the recommendation process. Instead of being confined to a fixed set of items, users were presented with randomly selected content pieces with similar meanings. This randomness allowed for serendipitous discoveries and introduced novelty, making the user experience more exciting and diverse.

Enhanced Relevance: Despite the introduction of diversity through random sampling, the semantic sampling approach ensured that the recommended items remained highly relevant to each individual user. By selecting items from the cluster of semantically similar content, the approach ensured that the recommendations retained a certain level of thematic coherence and alignment with users' preferences. This balance between diversity and relevance led to a more personalized and engaging experience for users, as they received a mix of both familiar and novel content that resonated with their interests.

Overall, the semantic sampling approach struck a delicate balance between increasing diversity and maintaining relevance, making it a powerful tool in addressing the long-tail

problem in recommendation systems. By leveraging semantic understanding and random sampling, the approach provided users with a diverse and personalized set of recommendations that enriched their discovery experience while ensuring the content remained highly relevant to their individual tastes and preferences.

B. Limitations

While the semantic sampling approach offers a promising solution to the long-tail problem and has demonstrated significant improvements in diversity and user engagement, it does have certain limitations that should be considered:

Limited Diversity Boost for Extremely Niche Content: The semantic sampling approach relies on identifying semantically similar content items to enhance diversity. However, for extremely niche or specialized content items that have limited semantic similarities with other items in the system, the approach may have limitations in boosting their diversity. This could lead to less diverse recommendations for such niche content.

Language Embedding Quality: The effectiveness of the semantic sampling approach is highly dependent on the quality of language embeddings obtained from models like LaBSE. Any limitations or biases present in the language embedding model can impact the accuracy of semantic similarities and, consequently, the diversity of recommendations. Ensuring the high quality and representativeness of language embeddings is critical for the success of the approach.

Impact of Sampling Parameters: The semantic sampling approach involves selecting a certain number of most semantically similar items (N) from which to sample recommendations. The choice of N can influence the level of diversity and relevance of the recommendations. Suboptimal values of N may lead to underemphasizing or overemphasizing certain content clusters, affecting the overall quality of recommendations. Careful experimentation and tuning of the sampling parameters are necessary for optimal results.

The semantic sampling approach represents a notable advancement in recommendation systems, with the potential to enhance diversity and user engagement in the wellness content domain. Ongoing research and refinement can address its limitations and further amplify its impact.

V. Conclusion

In this study, we introduced a semantic sampling method tailored for wellness recommendation systems, with an emphasis on the Headspace app. Online A/B testing involving over 276,700 users revealed that our method yielded a 2.26% uptick in the average content start rate—a clear indication of elevated user engagement.

In terms of diversity metrics, our method surpassed the TiSASRec baseline consistently. There were marked gains in metrics such as coverage, entropy, and rarity. Notably, the semantic sampling method ensured a broader range of engaging content recommendations without sacrificing user-specific relevance. Furthermore, increased content diversity did not detract from the start rate, underscoring the method's capability to harmonize between tailored recommendations and content variety.

From a practical standpoint, semantic sampling amplifies the value proposition of content-rich platforms like Headspace. It fosters an environment where users are more inclined to explore diverse content, leading to a dynamic and individualized user journey. Future investigations might delve into refining similarity clustering methodologies and probing the long-term user satisfaction for lasting effects.

In summation, our research underscores semantic sampling's potential in augmenting both diversity and engagement in wellness recommendation systems, solidifying user satisfaction, and ensuring sustained app interaction.

Acknowledgment

This work was funded through Headspace's internal research and development budget. We thank Rachel Stevenson and Setu Shah all of whom are current employees of Headspace Health, for their feedback and contributions to this paper.

Data Availability

For this study, we used a dataset of Headspace App's user analytics events, specifically pertinent to content starts, plays, and completes on recommended content on all tabs and subsections of the app. This data is not publicly available due to privacy reasons and to safeguard Headspace's in-house analytics data.

***Abstract*—A Question Answering System (QAS), also known as a chatbot, is a Natural Language Processing (NLP) application that automatically provides accurate responses to questions posed by humans in natural language. Intent Detection and Classification are crucial elements in NLP, especially in a task-oriented dialogue system. In this paper, we conduct a systematic literature review that will perform a comparative analysis of different techniques or algorithms that are being implemented for intent detection and classification with slot filling. The goals of this paper are to identify the distribution, methodology, techniques or algorithms, and evaluation methods, that can be used to develop and construct a model of intent detection and classification with slot filling. This paper also reviews academic documents that have been published from 2019 to 2023, based on a four-step selection process of identification, screening, eligibility, and inclusion, for the selection process. In order to examine these documents, a systematic review was conducted and four main research questions were answered. The results discuss the methodology that can be used for the implementation of intent detection and classification with slot filling, along with the techniques, algorithms and evaluation methods that are widely used and currently implemented by other researchers.**

Keywords*—Intent detection; intent classification; slot filling; question answering system

I. Introduction

A Question Answering System (QAS) is a group of natural language texts or a pre-structured database which are used to automatically provide correct and accurate responses to questions posed by humans in human natural language [1, 2]. A QAS is more capable and more efficient in answering the user query than most search engines such as Google, Yahoo, Live.com, Ask, YouTube, Facebook, and Microsoft Bing [3].

Search engines have a remarkable capability; however, the engines provide lists of related websites and resources including documents that match the user's query [2] without regard to their real intention or what the real question asked is. Hence, instead of the user having to search for the most relevant website or result to their query provided by the search engines, a QAS makes it easier for the user since it just displays the necessary information and results by detecting, recognizing, and classifying the intents of the user via their human natural language, thus providing them with a corresponding yet accurate response and result directly [2, 4]. Natural Language Processing (NLP) is one of the branches of Artificial Intelligence (AI) that studies human-computer interactions [5]. AI has two subsets, which are Natural Language Understanding (NLU) and Natural Language Generation (NLG). Being able to detect the intent of an utterance has been a keen issue in NLU [6] since it uses syntactic and semantic analysis of the text and speech to determine the meaning of a sentence.

Intent Detection (ID) and Classification (IC) act as critical elements in human language or NLU, especially in a task-oriented dialogue system [1, 6, 7, 8]. In particular, ID is usually related to the keywords of utterance, entities or slots, and intent. ID mainly aims to identify the user's true intent from a given utterance [8] in which, according to [9], the user's true intention sometimes does not settle the meaning of their utterance, and vice versa.

Entities or slots refer to the extraction of the associated arguments of the utterance in which every word in the utterance has its entity or slot. The most usual way of its representation is the IOB representation [10], where the initial "B" in the label indicates the beginning of the slot, the "I" indicates an extension of the "B", and lastly "O" refers to a null label, and it commonly labels the other general words in an utterance. The slots or entities that are constructed are identified by the researchers, hence it is meaningful and easy to be understood by humans.

The intent that is detected by the ID model is another crucial part that defines the context of the text, whereby these intents are the ones that classify and capture the true intention of the user, what they are trying to search for or what they are trying to convey [11] to the application or the system. There are numerous possible intents, depending on the utterance, and for an example of an utterance related to books, some of its intent might be SearchBook, PurchaseBook, BookAuthor, BookGenre, and so on. Many researchers have investigated intent recognition in the English language with very good accuracy. However, to the best of our knowledge, there has been little work done on the Malay language for question answering, with exceptions such as [12].

Within this paper, several methods and methodologies have been identified and proposed for developing ID and IC with a slot-filling model. For instance, [11] has performed several experiments on ID and IC by using various techniques such as Seq2seq, Slot-Gated, Capsule NLU, SF-ID, StackPropagation, SlotRefine, GL-GIN, and Joint-BERT. In addition, a model of ID and IC has been proposed with slot filling of JointBERT and Conditional Random Forest (CRF), called JointIDSF, whereby both XLM-R and PhoBERT were used as the utterance encoder [1]. This paper will contribute to better understanding, and thus developing and implementing, the methods of ID and IC with slot filling in various fields.

In addition, we review the existing literature on the development and implementation of ID and IC with slot filling in this paper in which our main objective is to explore which methods or techniques are the most suitable and can achieve higher accuracy in terms of IC performance. The following are the contributions of our review.

- The previous research that has been published regarding ID and IC with slot filling is investigated.
- The methodologies or approaches proposed by previous research are identified and discussed.
- The techniques or algorithms that can be implemented on ID and IC with slot filling are identified.
- A discussion on the validation process and main results of the previous research is conducted.

Furthermore, many previous research articles have been published and have discussed the researcher's implementation on the topic of ID and IC with slot filling. Papers [1, 8, 15, 16, 17, 18, 19, 20, 21, 22, 23, 24, 25, 26, 27, 28, 29, 30, 31, 32, 33, 34, 35, 36, 37] have discussed and presented their approach or implementation on developing ID and IC with slot filling using various frameworks, methodologies, and techniques. Various frameworks, methodologies, approaches, techniques and algorithms have been implemented by these researchers, whereas for instance, [19, 22, 24, 26, 27, 28, 31, 34, 35, 36] have implemented techniques of Bidirectional Long Short-Term Memory ID (BiLSTM) with Conditional Random Forest (CRF) in their implementation of ID and IC with slot filling.

On the other hand, [8, 15, 17, 20, 24, 26, 28, 31, 33] have implemented integration techniques of Bidirectional Encoder Representations from Transformers (BERT) with various other techniques such as CRF, LSTM, BiLSTM, Convolutional Neural Networks (CNN), Recurrent Neural Networks (RNN), or Regular Expressions (RE). On top of that, there are also published papers with comprehensive reviews [50-51, 53, 55]. The aim of [50-51] is to conduct a literature review about Intents, Intention Mining, and IC and focuses on the review of algorithms, models, and tools that have been implemented in Intention Mining. A review paper on the ID methods in the human-machine dialogue system seeks to advance the study of multi-intent detection methods based on Recurrent Neural Networks [52] and deep neural networks [53]. This paper primarily analyses compares, and summarizes the deep learning methods used in the research of ID in recent years. It also considers how to apply deep learning models to multi-intent detection tasks. The third paper [55] introduces the methods of two tasks ranging from the independent model to the joint model. It focuses on joint modelling methods based on deep neural networks and analyzes current problems and future development trends of two sub-tasks.

Therefore, one of the aims of this paper is to focus on conducting a systematic literature review about ID and IC with slot filling in which we are not focusing on the implementation, but we are going deeper into the investigation and discussion of the framework, methodology, and techniques or algorithms that can be implemented in ID and IC with slot filling. Furthermore, what we are reviewing differs from [51, 53, 55], which reviews the topic of intention mining, ID methods in the human-machine dialogue system, and methods of two tasks from the independent model to the joint model, respectively.

This paper is divided as follows: Section II presents the conducted systematic review methodology that consists of the definition of research questions, search phases, inclusion and exclusion criteria, and paper eligibility screening. Section III presents the results of the systematic review consisting of answers to the research questions, and finally, the conclusion of the systematic review and our thoughts on directions for future work are presented in Section IV.

II. Research Method

The systematic review (SR) in this paper was conducted by implementing the preferred reporting items for an SR and meta-analysis (PRISMA) approach as done in [13], in which PRISMA is an evidence-based minimum set of items used to guide the development and structure of SRs and other meta-analysis. According to [14], PRISMA is designed to help researchers to perform literature reviews systematically and transparently. and report how the review was done in a manner which leads to the findings. Thus, by implementing the PRISMA approach in our paper, the reviewing protocol includes three steps, namely definition of the research questions, search phases, and specification of inclusion and exclusion criteria. The specification of these steps is described in the following sections.

A. Definition of Research Question

This SR is organized to encompass the range of research examined by classifying and evaluating previous related articles. To correctly explain the coverage rate of existing works, the research questions must first be defined. We can gain various insights by examining comparable works, which can subsequently assist researchers in coming up with new insights. Table I lists the research questions that were considered in our SR.

B. Search Phase

Defining the information sources is the initial stage in conducting our SR. As shown in Table II, several academic databases, digital libraries, and open-access search engines have been consulted. In order to locate publications that are pertinent to our setting, the following stage entails creating procedures for examining the scientific and technical documentation that these searches produced. The process is built around these two steps: (i) it is necessary to first

determine the search phrases from the earlier research questions in order to create a list of keywords; (ii) it is necessary to create the queries that will be used to locate and gather all connected results, thus the Boolean operators AND/OR will be used to find and gather all related results in accordance to ID and IC with slot filling. About 221 papers were found overall in the first phase with search terms that might be most pertinent in the title. The search terms used for this paper are shown in Table III.

TABLE I. RESEARCH QUESTION

Research question	Motivation
RQ1. What is the distribution per year, domain application, and publisher of the published papers related to ID and IC with slot filling?	The answer to this question allows us to identify the work's domain, when, and where the research studies have been conducted.
RQ2. What is the methodology used to develop ID and IC with slot filling?	The answer to this question illustrates the steps and phases in developing ID and IC with slot filling.
RQ3. What are the techniques or algorithms that can be used to implement ID and IC with slot filling?	The answer to this question helps to identify the most suitable techniques or algorithms that can be adopted into the implementation of ID and IC with slot filling.
RQ4. Which evaluation method was used and what are the main results that have been drawn based on the evaluation method used?	The answer to this question identifies the methods used to evaluate the performance of ID and IC with slot filling and presents the main results or outcomes of the studied works.

S5 (intent AND classification AND slot filling)
S6 (intent AND detection AND classification AND slot filling)

C. Inclusion and Exclusion Criteria

We employed a set of inclusion criteria and exclusion criteria to identify pertinent papers and to narrow search results (see Table IV). Papers that do not address the exclusion criteria are disregarded, and a screening procedure is used to identify papers that are pertinent to our setting. The following three inclusion criteria phases form the basis of the screening procedure:

1) An abstract-based step: It using details and keywords from publication abstracts, we eliminate irrelevant results. Articles were kept for additional screening if their abstracts met at least 60% of the inclusion criteria.

2) Full-text-based step: We eliminate any results that did not address or make reference to the research terms listed in Table III, i.e., any publications that only cover a small portion of the search terms mentioned in their abstracts.

3) Quality-analysis-based step: We perform quality analysis on the remaining results and discard any that do not meet the requirements listed below:

- C1: The paper discusses a comprehensive approach and methodology to ID and IC with slot filling.
- C2: The paper includes the technical implementation of the proposed solution.
- C3: The paper references additional works.
- C4: The paper discusses the outcomes that were found.

TABLE IV. LIST OF IC AND EC

Inclusion Criteria	Exclusion Criteria
Studies published within the period 2019-2023.	Studies that are not written in English.
Studies should meet at least one of the search terms.	Duplicated papers.
Studies should be published/in-press at a journal or conference.	Studies with missing full text.
Studies should provide answers to the research questions.	Papers that are not directly relevant to the ID and IC with slot-filling topics.
The search is performed based on the title, abstract, and full text.	

D. Systematic Search Strategy Procedure

The PRISMA systematic search-strategy procedure includes four core processes which are identification, screening, eligibility, and inclusion were used to choose the pertinent publications for this review. In the identification procedure initially got 221 records (n=221). After the screening procedure, the results were pared down to 149 (n= 149) after duplicates were eliminated. Next subjected to eligibility criteria based on the title and abstract, acquiring 69 (n-69); finally, eligibility criteria based on the complete text allowed us to acquire 25 pertinent studies. To glean the findings reported in the next part, a thorough analysis of these 25 studies was conducted.

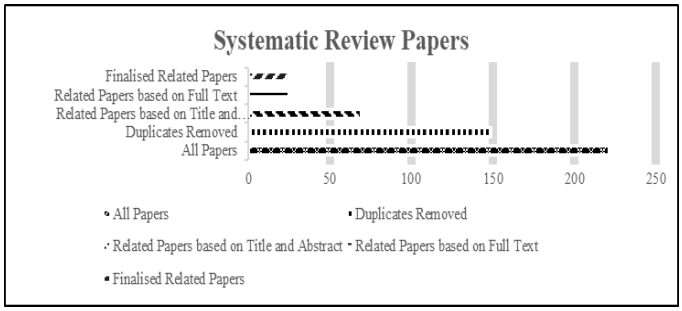

Fig. 1. Related papers reviewed.

Of the 25 papers that had been screened from the review process, all of these papers discussed the ID and IC with slot-filling topics by using various techniques or algorithms. Fig. 1 illustrates the number of papers from each stage in the SR process in a graphical representation of the papers that have been reviewed.

III. Results And Discussion

This section includes a discussion of the review's findings about the earlier proposed research questions. This review is made up of 25 publications that were carefully chosen to address the topic of ID and IC with slot filling. These answers help us to know the related recent literature, methodologies used, techniques or algorithms that can be used to implement ID and IC with slot filling, as well as the methods that can be used to evaluate the performance of the model.

Answer to research question RQ1: What is the distribution per year, domain application, and publisher of the published papers related to ID and IC with slot filling?

The papers that have been gathered and which relate to ID and IC with slot filling originated from several domains, including medical, education, electrical, music, economy, and airline. Fig. 2 and Fig. 3 display the distribution of the selected papers by publication year and source respectively.

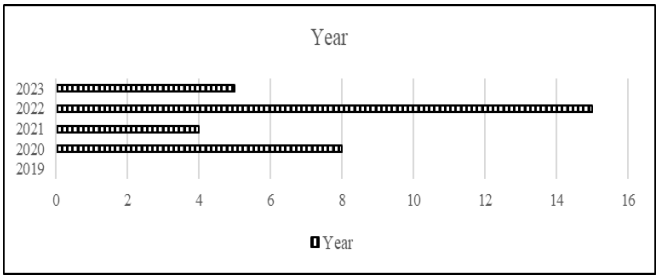

Fig. 2. Distribution of selected papers by publication year.

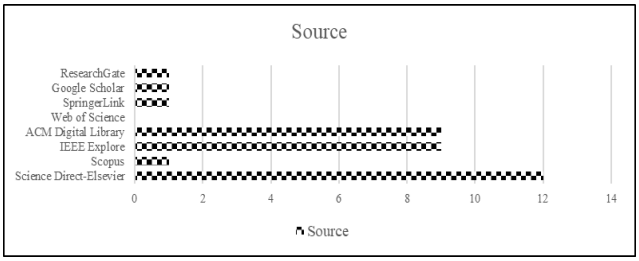

Fig. 3. Distribution of selected papers by source.

Answer to research question RQ2: What is the methodology used to develop ID and IC with slot filling?

Numerous methodologies were used for developing ID and IC with slot-filling phases in which Table V displays the list of methodology names and the phases that are involved in developing ID and IC with slot-filling. After reviewing and analyzing all of the papers, we identified that the majority of the papers integrate several methods resulting in a new methodology or approach. Papers 1, 22, and 25 have integrated Bidirectional Long Short-Term Memory (BiLSTM), Bidirectional Encoder Representations from Transformers (BERT), and Joint BERT with Conditional Random Forest (CRF) respectively. In addition, since there are various and multiple ways in which ID and IC with slot filling have been implemented, almost all of the papers' implementations differ from one another, even though they might seem similar.

The second paper implements a novel non-aggressive joint model, and the fourth paper implements a GloVe approach in their implementation. Some papers implement a unique methodology or approach such as paper 9 which implements a Capsule Network or Capsule-NLU, paper 13 implements a Multi-level Shared-private Framework, paper 14 implements a Deep Concurrent Multi-Task Paradigm, a Dual pseudo-labelling and dual learning methods approach by Paper 16, a Generative and Classification-based approach is implemented by paper 17, and paper 23 implements an Attention-based RNN and Slot-Gated mechanism. Meanwhile, the remaining methodologies implemented by the remaining papers may be further viewed in Table V and Table VI.

In addition, we removed papers [38-47, 54] and [2-15, 49-50, 56-70] from the list due to their related survey paper status. Furthermore, papers [2-15, 49, 56-70, 81] were removed due to their unrelatedness to ID and IC with slot filling or QAS topic relevance.

Answer to research question RQ3: What are the techniques or algorithms that can be used to implement ID and IC with slot filling?

There are several techniques or algorithms that can be implemented for ID and IC with slot filling. According to Table V, these 25 papers have implemented various techniques. Some papers have similarities in their approach with one another but still differ and report unique results.

Initially, Long Short-Term Memory often referred to as LSTM networks are an extension of Recurrent Neural Network (RNN) whereas RNN is a type of neural network that is specially designed for sequence prediction problems since it imposes an order on the observations that must be preserved when training models and making predictions [72]. The LSTM architecture consists of a set of recurrently connected subnets that are also known as memory blocks, which can be thought of as a differentiable version of memory chips in a digital computer [73]. Not only that, LSTM has been primarily implemented for problems such as speech modelling and language translation [72] and it has achieved state-of-the-art performance for IC and slot filling [74]. In addition, an LSTM network is a special variant of an RNN such that it overcomes stability bottlenecks encountered in traditional RNNs, thus

enabling its practical application [72]. Furthermore, an LSTM can also utilize its internal memory in such a way that its predictions are conditional on the recent context in the input sequence, not what has just been presented as the current input to the network. As an example, an LSTM model can show one observation at a time sequentially, and it can learn what observations it has seen previously and which are relevant. From there, it will think and train on how prediction can be done based on their observations made earlier [72].

Furthermore, Bidirectional Long Short-Term Memory (BiLSTM) is a further refinement of LSTM [24] which integrates the forward hidden layer and the backward hidden layer [71], which can acquire and access both the previous and subsequent contexts. Since LSTM exclusively exploits the historical context, unlike BiLSTM, as a result, BiLSTM is better than LSTM at resolving the sequential modelling problem [71]. LSTM and BiLSTM have been used to classify texts and have achieved some progress [19, 22, 24, 26-28].

According to our review, the majority of the papers implement BiLSTM whereas this technique was implemented by 10 papers - 7, 10, 12, 14, 15, 16, 19, 22, 23, and 24. In addition, these papers have integrated BiLSTM with various other techniques which include Conditional Random Forest (CRF), Concurrent Neural Network (CNN), and Bidirectional Encoder Representations from Transformers (BERT) to perform both ID and IC with slot-filling tasks. Some of these papers only implement BiLSTM such as papers 15 and 23 as their main technique. In addition, papers 7, 22, and 24 have integrated BiLSTM with CRF, papers 10 and 14 have integrated BiLSTM with CNN, and are followed by papers 12 and 16 which have integrated BiLSTM with BERT respectively. However, there is also a paper that integrates BiLSTM with two more techniques, and paper 19 has integrated BiLSTM with both CNN and BERT to perform ID and IC with slot filling. The integration between two to three techniques may help to improve the proposed model's performance.

TABLE V. LIST OF PROPOSED FRAMEWORK AND TECHNIQUES

Reference	Proposed Framework	Technique(s) Used
Paper 1 [1]	JointIDSF	JointBERT+CRF
Paper 2 [8]	SlotRefine	BERT+CRF
Paper 3 [15]	Neural Network-Regular Expressions (NN-RE)	RE+CNN+RNN+ BERT+LSTM
Paper 4 [16]	Computational Linguistics with Deep-Learning-Based Intent Detection and Classification (CL-DLBIDC)	Deep Learning Modified Neural Network (DLMNN) +Mayfly Optimization (MFO)
Paper 5 [17]	SLIM	BERT
Paper 6 [18]	BART+MS+I	BART
Paper 7 [19]	Bi-confidence-frequency cross-lingual transfer framework (BiCF)	BiLSTM+CRF
Paper 8 [20]	MultiLingual MultiTask (MLMT)	BERT+CRF
Paper 9 [21]	Capsule ISNP	NER
Paper 10 [22]	Real-time Pilot-controller Voice Communications (PCVC)	Convolutional Neural Network (CNN) + BiLSTM

Paper 12 [24]	No specific methodology name mentioned	Hierarchical Encoder, Context-Aware Graph Convolutional Network, Intent and Dialogue Act Classification, Adaptive Fusion Layer for Slot Filling, Multi-Task Training
Paper 13 [25]	Multi-level Shared-private Framework	Shared-Private Syntactic Encoder, Domain-Aware Sentence-Level Transfer for Intent Detection, Task-Aware Token-Level Transfer for Slot Filling, Joint Training
Paper 14 [26]	Deep concurrent multi-task paradigm	Intelligent Word Embedding Formulation, Contextual Sentence Representation Formulation, Dialogue Act Classification, Intent Detection, Slot Filling, Query Response Retrieval
Paper 15 [27]	Encoder-decoder model	Encoding Layer, Word Embedding, Bi-LSTM Layer, Slot Filling, Intent Detection Layer
Paper 16 [28]	Dual pseudo-labeling and dual learning methods	Sentence Encoding, Intent Classification, Slot Tagging, Semantic-to-Sentence Generation: Encoder, Decoder, Dual Semi-Supervised NLU, Dual Learning Model
Paper 17 [29]	Generative and Classification-based	Encoder, Slot Filling, Intent Detection, Joint Training, Decoder
Paper 18 [30]	No specific methodology name mentioned	Intent Classifier, Slot Classifier, Slot Value Predictor, Value Refiner
Paper 19 [31]	Multitasking Learning	LSTM-CNN Layer, Bi-LSTM + Attention Layer, WordNet Knowledge Base, Joint Optimization, Adaptive Moment Estimation
Paper 20 [32]	Rule-based and Model-based	Text Matching, Encoding, Intent Detection, Slot Filling, Rules Fusing, Joint Optimization
Paper 21 [33]	Weakly-Supervised Dual-Model Learning	Encoder, Word Embedding, Intent Detection-LSTM Layer, Attention Layer, Linear Layer, Joint Optimization
Paper 22 [34]	BiLSTM and CRF Model	Word Embedding, Named Entity Recognition (NER), Semantic Tagging (SemTag), Bi-LSTM+CRF Layer
Paper 23 [35]	Attention-based RNN and Slot-Gated Mechanism	BiLSTM Layer, Intent Attention Layer, Slot Attention Layer, Slot Sequence, Joint Optimization
Paper 24 [36]	Novel Bi-directional Interrelated Model	BiLSTM Layer, Slot Attention, Intent Attention, SF Subnet, SF Iteration Mechanism, ID Subnet, ID Iteration Mechanism, CRF Layer
Paper 25 [37]	JointBERT and CRF Model	BERT Layer, Softmax Layer, WordPiece Tokenizer, CRF Layer, Joint Optimization

In recent times, the BERT framework has been investigated for jointly identifying the intent and slots of an utterance [74, 75]. The model architecture of BERT is a multi-layer bidirectional transformer encoder that is based on the original Transformer model [74, 76-77] whereby it jointly conditions both left and right contexts in the Transformer [75, 77]. Furthermore, the input representation for BERT is a concatenation of WordPiece embeddings [8], positional embeddings, and segment embedding [74].

The BERT model is pre-trained with two strategies on large-scale unlabeled text which refers to Masked Language Model (MLM) and Next Sentence Prediction (NSP) [74-75, 77]. In addition, MLM's function is to randomly mask in order to avoid a token observing itself in a multi-layered context and on the other hand, NSP aims to capture useful information for sentence pair-oriented tasks [75]. Nonetheless, BERT models greatly contribute to enhancing NLP and it is the most commonly used transformer architecture [78]. Furthermore, the BERT model can be fine-tuned with just one additional output layer to create state-of-the-art models for a wide range of tasks such as in QAS and language inference, without substantial task-specific architecture modifications [77-78,80].

The most implemented technique other than BiLSTM is Bidirectional Encoder Representations from Transformers known as BERT in which BERT has been implemented by nine papers - 2, 3, 5, 8, 12, 14, 16, 19, and 21. These papers

have also integrated BERT with CRF, LSTM, BiLSTM, CNN, RNN, or Regular Expressions (RE). Firstly, paper 5 has implemented BERT as its sole technique for ID and IC with slot filling. However, of the remaining papers, papers 2 and 8 have integrated BERT with CRF, paper 21 has integrated BERT with LSTM, and paper 12 has integrated BERT with BiLSTM. Papers 14 and 19 have integrated BERT with BiLSTM and CNN meanwhile paper 16 has integrated BERT with BiLSTM and CRF. There is also a paper that has integrated BERT with four more techniques, making a total of 5 techniques including BERT. Paper 3 has integrated BERT with LSTM, CNN, RNN, and Regular Expressions (RE).

In addition, BERT can be extended into several extensions such as JointBERT, RoBERTa, KoBERT, mBERT, and KLUE-RoBERTa. Even though these techniques are extensions of BERT, they still differ and are different in terms of performance, whereas JointBERT has been implemented by papers 1, 11, 17, and 25. Paper 11 only implements JointBERT in its implementation, meanwhile, papers 1 and 25 have integrated JointBERT with CRF, and paper 17 has integrated JointBERT with RoBERTa. This is followed by RoBERTa which has been implemented by papers 13 and 17 and finally, paper 18 has integrated KoBERT, KLUE-RoBERTa, and mBERT in their ID and IC with slot filling implementation.

The remaining papers (3, 4, 6, 9, and 20) have implemented a technique that is not vastly and widely implemented such as some of the papers have implemented Concurrent Neural Networks (CNN), Recurrent Neural Network (RNN), Deep Learning Modified Neural Network (DLMNN), Mayfly Optimization (MFO), Named Entity Recognition (NER) in their implementation of ID and IC with slot filling. More details on each of these paper's implementation of techniques or algorithms can be further viewed in Table V.

Answer to research question RQ4: Which evaluation method was used and what are the main results that have been drawn based on the evaluation method used?

There are various ways of evaluating the performance of a model after it has been implemented by using various techniques. However, there are several main evaluation metrics or methods that are generally used to evaluate the performance of an ID and IC with a filling model. Such methods include accuracy, F1-score, precision, and recall which is mainly applied for both ID and slot filling task, respectively. Besides that, there are also other evaluations conducted within the 25 papers such as sentence accuracy, semantic error, G-measure, and so on. Technically, model evaluation is crucial to check and validate whether the model is well-functioning and works correctly according to the specifications and the requirements or not.

The majority of these papers evaluate the performance of their ID and IC with slot filling model by using accuracy and F1-score for both intent, sentence and slot performance.

Initially, accuracy is the most used empirical measure and it can be defined as a ratio of accurately classified data items to the total number of observations [48, 80], making it one of the most suitable methods to evaluate the performance of ID and IC. Despite it being the most used technique for testing, however, accuracy does not distinguish between the number of correct labels of different classes [79] and is valid only when the evaluation of classification is well-balanced and is not skewed, and there is no class imbalance. Hence, it is not the most appropriate performance metric in some situations especially in a case where the target variable classes in the dataset are unbalanced. This is because, when the model predicts that each point belongs to the majority class label, the accuracy will be high but the model is not accurate because of the imbalances.

Next is a precision technique which is a measure of correctness that is achieved in true prediction, or it also means how many predictions are positive out of all the total of positive predictions. Precision is calculated by the ratio of the total number of correctly classified positive classes divided by the total number of predicted positive classes [68, 80]. However, precision can only work properly and accurately when the FP is higher than the FN [48, 68, 79] and is usually suitable for a system that has a yes or no, true or false result such as e-mail spam detection.

The following evaluation technique is a recall technique which is measured as the actual observations which are predicted correctly. Recall can also be called sensitivity and is the most suitable evaluation technique to be used when the researcher wants to capture as many positives as possible [48, 68, 80]. Recall is a ratio of the total number of correctly classified positive classes divided by the total number of positive classes, or in other words, out of the observations that are positive, how many of them have been predicted by the algorithm [48].

On the other hand, the F1-score, also known as the F-measure, uses both precision and recall and is one of the best evaluation techniques to calculate the performance of an algorithm [48, 80], especially in the evaluation of text classification and identification tasks [59, 80], because it balances out the precision and recall, whereby if the precision is low, the F1 is low and if the recall is low, then the F1 is also low. Plus, the F1score evaluation method has been generally used to evaluate the performance of the slot-filling task.

Therefore, in this paper, we have identified the evaluation methods used in these papers, and Table VII depicts the list of evaluation methods and their results.

TABLE VII. LIST OF EVALUATION METHODS AND THEIR RESULTS

Paper 1 [1]	ATIS	Airline	Vietnamese
Paper 2 [8]	ATIS, SNIPS	Airline, General	English
Paper 3 [15]	KVRET, FRAMES	In-Car Assistant, Hotel and Travel-Booking	English
Paper 4 [16]	SNIPS	General	English
Paper 5 [17]	ATIS, SNIPS	Airline, General	English
Paper 6 [18]	Policy-aware Explainable Abuse Detection (PLEAD)	Human Abuse	English
Paper 7 [19]	Self-established ID-WOZ	Restaurant, Hotel, Taxi, Attraction	Indonesian
Paper 8 [20]	ATIS, TRAINS, SNIPS, and FRAMES	Airline, Trains, General, In-Car Assistant, Hotel and Travel-Booking	Hindi, Bengali
Paper 9 [21]	ATIS, SNIPS	Airline, General	English
Paper 10 [22]	Self-Collected Pilot-Controller Voice Communications (PCVC)	Airline	Chinese, English
Paper 11 [23]	PILs Model Repository	Drugs / Medicine	Italian
Paper 12 [24]	ATIS	Airline	English
Paper 13 [25]	MTOD, ASMixed (ATIS, SNIPS)	Alarm, Reminder, Weather, Airline, General	English
Paper 14 [26]	ATIS, TRAINS, FRAMES	Airline, Trains, Hotel and Travel-Booking	English
Paper 15 [27]	ATIS, DSTC5 (The Fifth Dialog State Tracking Challenge)	Airline, State	English
Paper 16 [28]	ATIS, SNIPS	Airline, General	English
Paper 17 [29]	ATIS	Airline	Tamil
Paper 18 [30]	In-Vehicle Domain Dialogue Data	Vehicle	Korean
Paper 19 [31]	ATIS, SNIPS, FRAMES, TRAINS	Airline, General, Hotel and Travel-Booking, Trains	English, Hindi, Bengali
Paper 20 [32]	Self-Collected Music and Non-Music Field of the Human-Machine Dialogue System	Music	English
Paper 21 [33]	ATIS, SNIPS, MIT Restaurant	Airline, General, Restaurant	English
Paper 22 [34]	ATIS, MIT Restaurant, MIT Movie	Airline, Restaurant, Movie	English
Paper 23 [35]	ATIS, SNIPS	Airline, General	English
Paper 24 [36]	ATIS, SNIPS	Airline, General	English
Paper 25 [37]	ATIS, SNIPS	Airline, General	English

In addition, each work's dataset, domain, and language used for the implementation are also written in Table VIII whereby most of the works are developed in English. Therefore, few papers have developed this topic on low-resource languages other than English, such as Bengali [20, 31], Chinese [22], Hindi [20, 31], Indonesian [19], Italian [23], Korean [30], Tamil [29] and Vietnamese [1].

IV. CONCLUSION

This paper summarizes the distribution of papers per year, domain application, and source of the published papers related to ID and IC with slot filling along with the proposed frameworks, techniques or algorithms used, the methodology that has been implemented research, as well as the methodology phases, in each paper. In addition, a systematic review has been conducted using the PRISMA approach, and its selection process of identification, screening, eligibility, and inclusion was reported in detail. A total of 25 works were selected from the 221 works that have been initially extracted, based on their relevance to the four main research questions we have developed. In addition, from the review, we discovered that the techniques and algorithms that are generally and widely used to implement ID and IC with slot filling are Bidirectional Long Short-Term Memory (BiLSTM), Bidirectional Encoder Representations from Transformers (BERT), and Conditional Random Forest (CRF). Not only that, for the evaluation methods, we have looked at various evaluation techniques for ID and IC with slot filling, and we have identified that the majority of the past works' models have been evaluated by the accuracy and F1-score evaluation methods. Therefore, our review on this topic has led us to conclude that ID and IC with slot filling are still crucial and indeed still in need of evolution especially for the low-resource languages other than English such as Malay, Chinese, Tamil, or Vietnamese. Hence, the development of ID and IC with slot filling for low-resource languages requires further studies, implementation, and optimization, in order to provide timely future work opportunities for researchers who are interested in this integrative field.

In the future, this research on intent and slot-filling recognition aims to make these systems more accurate, adaptable to different domains, and responsive in real-time interactions. The focus will be on combining various data sources, like text, speech, and images, to better understand user intents, making conversations more natural. Personalizing models for individual user preferences and ensuring ethical considerations, such as minimizing biases, will be crucial. Additionally, efforts will be directed toward making models interpretable and capable of handling multiple languages seamlessly.

ACKNOWLEDGMENT

The authors express their sincere appreciation to the reviewers for their valuable feedback. The funding for this research was provided by Universiti Teknologi MARA under the Young Talent Research Grant (600-RMC/YTR/5/3 (023/2020).

***Abstract*—This research pioneers a ground-breaking system meticulously engineered to swiftly detect vehicular accidents and dispatch immediate alerts to both emergency services and pre-assigned contacts. This symphony of cutting-edge technologies includes an accelerometer sensor attuned to detect acceleration in any vector, a dynamic Liquid-Crystal Display (LCD) display for rapid alert dissemination, an assertive buzzer for resonant alarms, a Global System for Mobile (GSM) module for the swift transmission of distress messages, and pinpoint location data provided by a Global Positioning System (GPS) module. A user-friendly 'cancel' button acts as an escape hatch from potential false alarms. Orchestrated by the dexterity of an Arduino Uno microcontroller, this ensemble orchestrates a harmonious ballet of safety. This solution boasts cost-effectiveness, steadfastness, and unparalleled efficiency. Rigorous testing across diverse scenarios confirms its precision and robustness. By enhancing accident detection accuracy, expediting emergency responses, and facilitating rapid location dissemination, this innovation serves as a vital lifeline, empowering both passengers and rescue services upon accident initiation. With location data as its guiding star, emergency services gain a swift navigational edge, offering a beacon of hope in the battle against accident-related casualties.**

***Keywords*—Vehicle accident detection; microcontroller-based system; accelerometer sensor; Global Positioning System (GPS) localization; Global System for Mobile (GSM) communication; emergency response; safety innovation**

I. INTRODUCTION

The innovative vehicle accident detection and alert system described in this article addresses a crucial gap in the existing safety mechanisms for vehicles. While traditional safety features like airbags and seatbelt tensioners have been valiant in their efforts, they often fall short in preventing accidents and lack the capability to swiftly relay critical information to emergency services and the victim's loved ones.

The gap lies in the need for a comprehensive solution that not only detects accidents promptly but also initiates an immediate response. The current safety mechanisms, though effective to a certain extent, do not harness advanced technology to redefine accident prevention and response.

To address the existing gap in vehicle safety, our research focuses on three pivotal questions. Firstly, we explore the integration of advanced technology to surpass traditional safety measures and enhance overall vehicle safety. Secondly, we delve into the identification of key components and features essential for a comprehensive vehicle accident detection and alert system. Lastly, we examine methods to ensure the system's capability to provide immediate and accurate alerts to both passengers and emergency services in the event of an accident.

Aligned with these questions, our research objectives are multifaceted. Our primary objective is the design of a cutting-edge vehicle accident detection and alert system. This system will incorporate a range of technologies, including a microcontroller, accelerometer sensor, LCD display, buzzer, GSM module, GPS technology, and a cancel button. Subsequently, our research aims to implement and rigorously test this system across various scenarios, ensuring its accuracy, timeliness, and reliability. In addition, we aspire to provide a cost-effective solution applicable to all types of vehicles, making advanced safety technology more accessible. Finally, our overarching goal is to enable immediate alerts for passengers and emergency services, facilitating a rapid response that holds the potential to save lives. These research objectives collectively contribute to advancing the field of vehicle safety and addressing critical gaps in current safety mechanisms.

The significance of this research lies in its ability to fill the existing gap in vehicle safety measures. By introducing a comprehensive and efficient solution, we aim to redefine accident prevention and response, ensuring a safer and more secure transportation environment. The research contributes to the advancement of technology in vehicle safety, with potential implications for reducing accident-related fatalities and injuries. This innovative system has been designed with a focus on cost-effectiveness and reliability, making it widely applicable and impactful in enhancing overall road safety.

The remainder of this paper is organized as follows: Section II delves into a discussion of related works, presenting an overview of existing research in the field. Section III described the system implementation and testing. Section IV describes the results and analysis meanwhile the conclusion is described in Section V. Lastly; future works is mentioned in Section VI.

II. Related Work

In the pursuit of safer roads and more efficient accident prevention, previous research has primarily focused on conventional safety measures such as airbag deployment and seatbelt tensioners. While these measures have made significant strides in enhancing vehicle safety, they face limitations in effectively detecting and preventing accidents, especially in real-time scenarios. This literature review explores the evolution of accident detection and response systems, leading to the proposed innovative method that leverages advanced technology to address the critical challenge of accurate and timely accident detection.

Historically, vehicle safety measures centered around passive systems like airbags. However, these traditional approaches, while valuable in mitigating accident consequences, fall short in their ability to proactively prevent accidents or provide swift alerts to relevant parties in the event of an incident. Anand Gunadal's pioneering research harnessed MEMS accelerometers and GPS tracking to monitor vehicle behavior, particularly during accidents. These accelerometers, both analog and digital, detected changes in velocity and acceleration. The analog-to-digital conversion process allowed for precise analysis of these changes. Gunadal's work laid the groundwork for advanced accident detection systems, focusing on crucial alterations in vehicle motion for improved safety [1] [2].

The pursuit of smarter road safety gave rise to early innovations, such as the use of MEMS accelerometers and GPS tracking to monitor vehicle behavior and detect accidents. These systems demonstrated the potential to enhance accident detection by assessing acceleration forces and vehicle movements. Giriraj Gurjar's research introduced a discreet accident monitoring system that concealed equipment within vehicles. This system utilized GSM communication to transmit comprehensive accident reports, including temperature, smoke conditions, vehicle speed, and accident time [3]. It featured a MEMS accelerometer for continuous vehicle motion detection. During an accident, the MEMS accelerometer sensed the vehicle's movement and relayed this information to a microcontroller. GPS technology was employed to pinpoint the accident location, with graphical representation displayed on an LCD screen. Gurjar's work enhanced accident detection and reporting capabilities [4].

Purushotham and Kumar's research introduced a novel approach by utilizing GPS technology to track vehicles. Their system compared GPS data with pre-defined checkpoints and mapped the location on platforms like Google Earth [5]. This innovative approach streamlined the task of locating accident sites for rescue teams. Additionally, their system incorporated an ultrasonic wave sensor, which measured echo return time, providing valuable insights for accident detection. By combining GPS tracking, innovative sensing mechanisms, and location mapping, their project offered a comprehensive solution that enhanced both accident detection and efficient rescue operations [6].

Kassem and Jabr's research in [7] explored the diverse benefits of automotive black box systems. These systems, they noted, hold the potential to enhance vehicle design, aid accident victims' treatment, assist insurance providers in collision investigations, and influence traffic conditions to reduce fatalities. Their study emphasized the importance of effectively collecting vehicle data, achieved through a combination of basic components and sensors. Data was presented in real-time graphics and saved in an Excel file for further analysis. The hardware comprised sensors and a black box within the vehicle, recording data, including speed. Additionally, their research underscored the significance of analyzing vehicle lights, such as brake lights and flashers, to gain insights into accident investigations. Their adaptable Black Box system, applicable to various vehicles, initiated data recording upon engine startup, providing comprehensive insights [8]. Buyers received detailed reports containing all relevant data. Kassem and Jabr's work illustrated the potential of automotive black box systems in enhancing vehicle safety, accident investigations, and traffic management [9].

Watthanawisuth, et al.'s study aimed to develop a wireless black box system tailored for monitoring motorcycle accidents. It featured a MEMS accelerometer and GPS tracking, enabling accident type detection, post-crash posture assessment, and GPS ground speed determination using accelerometer signals and a threshold technique. In case of an accident, the system promptly triggered an alarm, sending concise alert data via the GSM network and a text message to a designated contact with GPS location information. Real-time monitoring distinguished between falls and accidents based on motorcycle speed and a limit algorithm. The device also logged track and acceleration data one minute before and after an accident, facilitating comprehensive accident analysis [10] [11] [12].

Ritwik Chinmaya Pandia's study focuses on a project designed to capture vital information such as vehicle speed and position during accidents. The system employs a GSM modem to trigger an accident alarm and send the vehicle's current location to a pre-programmed cell phone upon detecting a crash. It utilizes efficient voltage transformation with transformers, rectifiers, and a microcontroller (ATmega16) for communication and control. A piezo sensor is employed as a key sensory element, and the programming is accomplished using AVR Studio and AVR Dude [13]. This study significantly enhances accident data capture and reporting, blending hardware components and microcontroller technology for improved accident information retrieval [14] [15].

Prabha et al. [16] have made a big contribution to enhancing travel safety, utilizing GSM and GPS technology for real-time accident detection and notification. This project places a strong emphasis on travel security by developing an automatic vehicle accident detection and notification system. It enables immediate SMS alerts in the event of an accident and maintains accurate vehicle positioning through GPS technology [17].

The research by Krishna Kanth et al. [18] Singh focuses on the prompt detection of accidents in any location, enabling swift ambulance response through GPS and GSM networks. Their innovative automotive accident detection module integrates GPS, GSM, and MEMS technology. A standout feature of this project is the capability to send notifications to accident locations when authorized individuals place a missed

call to the GSM module at that site. This approach streamlines vehicle identification in accident scenarios, utilizing robust tracking technology. Overall, this study emphasizes the vital role of GPS, GSM, and MEMS in enhancing accident detection and vehicle tracking for improved road safety and emergency services [19].

Anita Kumari et al. [20] focused on a car tracking system that utilizes a GSM module to capture GPS data and send it to a designated mobile or laptop. It highlights the significance of Vehicle Tracking Systems, which use GPS to locate and monitor vehicles, relaying position data to a central monitoring center. The research emphasizes the increasing popularity of vehicle monitoring systems and describes the process of converting GPS data to RS232 format for transmission to the GSM module via a microcontroller and MAX232. It also mentions the system's potential in mitigating accidents, including collisions and in-vehicle fires [21] [22].

The study conducted by Anil Kumar et al. [23] aims to enhance vehicle security and raise driver awareness through IoT technology. It continuously analyzes vehicle performance and driver behavior using various sensors, including a breath analyzer, accelerometers, and distance sensors between other vehicles. In addition, it features a push and panic button for data input into the vehicle's black box. The system monitors alcohol intake levels and alerts emergency contacts when the limit is exceeded. In the event of an accident, the system uses GSM and GPS to monitor the vehicle's location and communicates this information to hospitals and the police. The IoT-based controller is designed to be power-efficient, enabling real-time applications. The project employs a range of sensors, including breath analyzers, accelerometers, and ultrasonic sensors, to ensure driver and merchant safety. It also detects alcohol gas concentrations between 0.05 mg/L to 10 mg/L. When an accident occurs, the GPS module activates and transmits the location via GSM to local authorities [24].

The project conducted by Ranjitha et al. [25] focuses on using a GPS module to precisely locate road accidents and promptly send this position to a pre-programmed phone number via GSM SMS. The project utilizes an Arduino board, offering easy access to input/output and analog ports, as well as the capability for programmed burning and uploading. The GPS module continuously updates the Arduino with the vehicle's longitude and latitude coordinates. This data is then transmitted through the GSM module, which can send the precise latitude and longitude as an SMS to a pre-programmed phone number. Additionally, the system incorporates a limit switch, which, when subjected to a particular amount of pressure, prompts the Arduino to retrieve the GPS module's latitude and longitude and transmit this information to the GSM module. The system also includes an alcohol detector that alerts the Arduino when alcohol is detected, prompting it to send a message to the GSM module, which in turn transmits the message to the designated recipient [26].

In conclusion, the reviewed literature and studies present commendable advancements in accident detection and response systems. However, a critical analysis reveals potential gaps in scalability, accuracy, privacy, data security, system robustness, response time, AI integration, and pedestrian safety. Further exploration and innovation in these areas could significantly contribute to the development of more comprehensive and effective solutions for road safety and emergency services. Addressing these identified gaps will be crucial for advancing the field and ensuring the broader applicability and reliability of accident prevention and response technologies.

Table I shows a comprehensive comparison between existing works in the field, focusing on the evaluation of fall detection systems across different tasks. In the presented years, the tasks include linear and non-linear falls, normal rides, traversing bumpy surfaces, and sudden braking situations. The test times for each task are specified, and the outcomes are categorized into instances where an alarm was triggered and where it was not. The current work in 2023 demonstrates a fall detection system with a test time of 50 units for each task, consistently triggering alarms for falls and maintaining accuracy for other activities. A comparative analysis with previous works from 2012 to 2018 reveals varying performances, with differences in alarm accuracy for non-linear falls and sudden braking scenarios. This comprehensive overview aids in understanding the evolution and effectiveness of fall detection systems over time, providing valuable insights for further advancements in this critical domain.

TABLE I. COMPARISON BETWEEN EXISTING WORK

Year	Task	Test Time	Alarm	Not Alarm	Reference
2023	Linear fall	50	50	0	This work
	Non-Linear fall	50	50	0	
	Normal Ride	50	0	50	
	Bumpy surface	50	0	50	
	Brake Suddenly	50	0	50	
2012	Linear fall	100	100	0	[3]
	Non-Linear fall	100	99	1	
	Normal Ride	50	0	50	
	Bumpy surface	50	0	50	
	Brake Suddenly	50	2	48	
2012	Linear fall	100	100	0	[5]
	Non-Linear fall	100	99	1	
	Normal Ride	50	0	50	
	Bumpy surface	50	0	50	
	Brake Suddenly	50	2	48	
2014	Linear fall	100	100	0	[7]
	Non-Linear fall	100	99	1	
	Normal Ride	50	0	50	
	Bumpy surface	50	0	50	
	Brake Suddenly	50	1	49	
2016	Linear fall	100	100	0	[9]
	Non-Linear fall	100	100	0	
	Normal Ride	50	0	50	
	Bumpy surface	50	0	50	
	Brake Suddenly	50	0	50	
2018	Linear fall	100	100	0	[11]
	Non-Linear fall	100	100	0	
	Normal Ride	50	0	50	
	Bumpy surface	50	0	50	
	Brake Suddenly	50	0	50	

III. THE SYSTEM IMPLEMENTATION AND TESTING

The Vehicle Accident Detection and Alert System (VADAS) represent a critical innovation in road safety. With the increasing number of vehicles on the roads, ensuring the

safety of drivers and passengers has become a paramount concern. Traditional safety measures have been effective to some extent, but there exists a pressing need for more proactive and responsive systems that can promptly detect accidents and summon assistance. This section provides an overview of the VADAS, which utilizes a combination of cutting-edge technology components to enhance accident detection and emergency response.

These integral elements include the Arduino Uno Microcontroller, which serves as the central control unit, orchestrating module, and sensor interactions. The accelerometer sensor detects abrupt impacts or changes in acceleration, providing critical data to ascertain accident occurrences. An LCD display conveys crucial accident details such as location and time, promptly informing passengers and drivers. An audible alert system in the form of a buzzer plays a pivotal role in notifying vehicle occupants in the event of an accident. The integration of a GSM module enables seamless communication with emergency services and predefined contacts, facilitating message transmission and call requests for assistance. Precise location information is provided by the GPS module, expediting emergency responders' arrival at the accident scene. To minimize false alarms, the system incorporates a cancel button, allowing users to deactivate emergency calls and messages when necessary.

The operational framework of the VADAS is illustrated in Fig. 1. The system is centered around the Arduino Uno microcontroller, which coordinates the activities of the various components. The accelerometer sensor continuously monitors vehicle acceleration and based on this data, alerts the microcontroller to potential accidents. Upon accident detection, the microcontroller activates the alarm, sends emergency messages, and calls, and displays alerts on the LCD screen. Importantly, users have the option to cancel these alerts via the cancel button.

Fig. 2 presents the operational flow of the VADAS. It begins with the microcontroller's vigilant monitoring of the accelerometer sensor for sudden acceleration changes that may signify an accident. If such an event is detected, the microcontroller activates the alarm, alerting vehicle occupants. Simultaneously, it triggers the LCD display to convey the accident notification.

Subsequently, the microcontroller communicates with the GSM module, which sends emergency messages, including the accident's location, to predefined contacts. Notably, users could cancel these messages by utilizing the cancel button. If not cancelled, the system proceeds to notify emergency services, ensuring swift assistance. Following an accident, the microcontroller continues to monitor for any subsequent incidents. The VADAS represents a significant advancement in road safety technology, providing a proactive approach to accident detection and emergency response. In the subsequent sections, we will delve into the technical intricacies of this system and present the outcomes of its testing and validation.

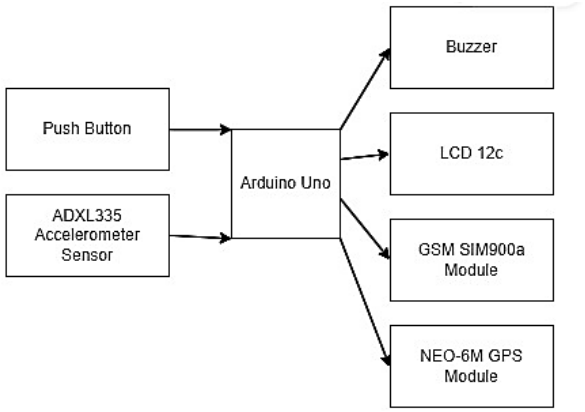

Fig. 1. Block diagram for vehicle accidental tracking system using micro-controller.

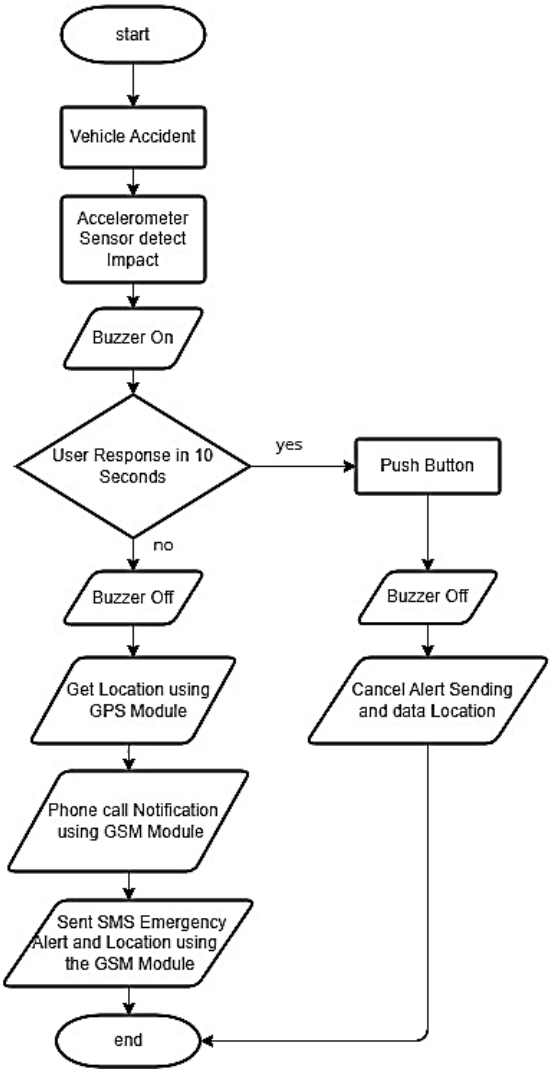

Fig. 2. Flowchart for vehicle accidental tracking system using micro-controller.

A. Hardware Implementation

The hardware implementation of the vehicle accident detection system comprises several key components:

1) Arduino Uno: At the heart of the system, the Arduino Uno takes center stage, featuring the ATmega328P microcontroller. With its array of digital and analog pins, this powerhouse proves its versatility across a spectrum of applications [27]. From LEDs to motors, sensors, and beyond, the Arduino Uno establishes seamless connections, all orchestrated through the user-friendly Arduino IDE. Its innate compatibility with shields amplifies its prowess, transforming it into the ideal candidate for ventures in robotics, home automation, and data logging projects. The Arduino Uno isn't just a board; it's a canvas for creativity — an open-source hardware masterpiece that beckons customization and replication with open arms [28].

2) ADXL 335 Accelerometer Sensor: Enter the realm of motion sensing with Analog Devices' 3-axis accelerometer, a silent guardian detecting shifts in acceleration, a pivotal role in the realm of accident detection. Thriving on low power (3V to 5V), it unveils a measurement prowess with a range of +/- 3g. The ADXL335 doesn't just measure; it brings stability to the temperature dance and hushes into a realm of low noise, making it the unsung hero for delicate applications like airbag deployment systems and the vigilant guardian for vibration monitoring adventures [29] [30].

3) GSM Module (SIM900A): Step into the world of connectivity with the SIM900A GSM/GPRS module from SIMCOM, a communication maestro that bridges the gap with emergency services and predetermined contacts. Boasting a built-in TCP/IP stack for seamless internet connectivity, it not only supports the quintessential SMS and call functionalities but also harmoniously integrates audio capabilities into its repertoire [31]. This wizardry, navigated through the realm of AT commands, finds its place not only in remote-control systems but also dances into the domains of data loggers and the enchanting world of home automation [32].

4) GPS Module (NEO-6M): The NEO-6M GPS module from Ublox provides accurate location, velocity, and time information. It can track up to 22 satellites simultaneously and supports multiple navigation modes, including GPS, GLONASS, and Galileo. With its small form factor and low power consumption, it's used in navigation systems, drones, and robotics.

5) LCD I2C: The LCD I2C is a cost-effective liquid crystal display that uses the I2C communication protocol. It simplifies displaying text and graphics, handling most display functionalities. It comes in various sizes (e.g., 16x2 or 20x4) and is widely used in data logging and temperature monitoring applications.

In the implementation of the vehicle accident detection system, the Arduino Uno serves as the central hub, orchestrating the interactions between the various components. The ADXL335 accelerometer is strategically positioned within the vehicle to continuously monitor acceleration changes. When a significant deviation is detected, suggesting a potential accident, the Arduino Uno triggers the SIM900A GSM module to initiate communication with emergency services and preconfigured contacts, alerting them to the situation. Simultaneously, the NEO-6M GPS module is activated to provide accurate location data, aiding in the quick dispatch of assistance [33]. The LCD I2C display acts as the user interface, conveying relevant information about the accident and the system's status. The modularity of the Arduino Uno allows for seamless integration and communication between these components, creating a cohesive and efficient accident detection and alert system for vehicles [34].

B. Software Implementation

The software implementation of the vehicle accident detection system encompasses various essential components and tools:

1) Arduino IDE: Step into the dynamic realm of creativity with the Arduino IDE (Integrated Development Environment), a software maestro empowering user to craft, upload, and debug code for the Arduino platform. Tailored to streamline the art of programming and device control, from microcontrollers to sensors and actuators, it spreads its wings across Windows, macOS, and Linux, offering a universal embrace. Rooted in Java and nurtured in the fertile grounds of the Processing development environment, the Arduino IDE unfolds its magic through a user-friendly interface adorned with a code editor, serial monitor, and library manager. Speaking the languages of C/C++ and Python, it extends its charm with an extensive library collection, turning every project into a masterpiece [35]. Embraced by hobbyists, educators, and professionals alike, it dances through the realms of robotics, home automation, and the vast expanse of IoT devices. A tool that evolves with the times, adorned with regular updates and a continual infusion of features, it remains a beacon for the creative spirits of our world [36].

2) Proteus: Developed by Labcenter Electronics, Proteus is a comprehensive software package tailored for computer-aided design of electronic circuits. This UK-based software combines schematic capture, simulation, and PCB layout tools, facilitating the design, testing, and layout of electronic circuits before physical construction. Proteus boasts an extensive library of simulation models, covering microcontrollers, microprocessors, sensors, actuators, and communication modules, enabling users to assess circuit behaviour and identify errors through simulation. The software also incorporates a PCB layout editor with features like auto-routing, 3D visualization, and support for surface mount and through-hole components, streamlining circuit board design, error checking, and manufacturing file generation. Proteus is widely embraced in both industry and education, catering to various microcontroller families like AVR, PIC, 8051, ARM, and supporting multiple communication protocols like I2C, SPI, UART, USB, and Ethernet. It is available in student and professional versions and operates within the Windows operating system.

3) SolidWorks: Crafted by the ingenious minds at Dassault Systems, SolidWorks emerges as a luminary in the realm of 3D mechanical CAD (Computer-Aided Design) software, weaving its expertise in solid modeling to breathe life into precise 3D models of parts and assemblies. A virtuoso in simulating their intricate dance of behavior and properties, SolidWorks steps into the limelight across an eclectic array of industries—from mechanical engineering and aerospace to the pulsating realms of automotive and consumer goods. Here, within the digital tapestry it weaves, users find the tools to sculpt 3D masterpieces of parts, intricate assemblies, and complex structures. This digital maestro, adorned with a rich palette of features, not only births vibrant 3D wonders but also unleashes tools for crafting intricate 2D drawings, orchestrating simulations of motion and stress, and orchestrating the symphony of data management. At its core lies the magic of parametric modeling, offering the fluidity of dynamic design changes and the allure of real-time updates. Detailed drawings, pulsating with dimensioning and tolerancing, are born effortlessly, accompanied by simulations donned in the garb of finite element analysis and motion simulations. SolidWorks, the polymath, extends its embrace to robust data management tools—from the meticulous bill of materials to the guardianship of revision control and the spirit of data sharing. In the hands of engineers, designers, and manufacturers, SolidWorks becomes not just a tool but a companion, navigating the intricate landscapes of creation and simulation. An educator at heart, it imparts wisdom to students, arming them with the prowess to sculpt precise designs and orchestrate simulations of grandeur [37]. In its digital wardrobe, SolidWorks adorns itself in multiple versions—Standard, Professional, and Premium—each tailored with its own tapestry of features and functionalities, a harmonious symphony compatible with the Windows operating system [38].

In the implementation phase, the vehicle accident detection system benefits from the synergy of these software tools. The Arduino IDE is utilized to write and upload the code that governs the behaviour of the Arduino Uno, the central control unit of the system. This includes the integration of code for processing data from the ADXL335 accelerometer, communication with the SIM900A GSM module, and handling data from the NEO-6M GPS module. Proteus comes into play by allowing simulation of the electronic circuitry, ensuring that the components interact seamlessly and function as intended. This pre-implementation testing minimizes errors and optimizes the performance of the system. SolidWorks is employed to create accurate 3D models of the physical components, aiding in the design and assembly of the hardware. The software's simulation features assist in predicting potential stress points or motion-related issues. The collective use of these software tools ensures a well-coordinated implementation of the vehicle accident detection system, minimizing errors, optimizing performance, and streamlining the development process [39].

IV. Result and Discussion

A. Hardware Development

Fig. 3 illustrates the system's circuit, offering a visual representation of its hardware components and connections. The hardware development stage is a pivotal component of the vehicle accident detection and alert system's creation.

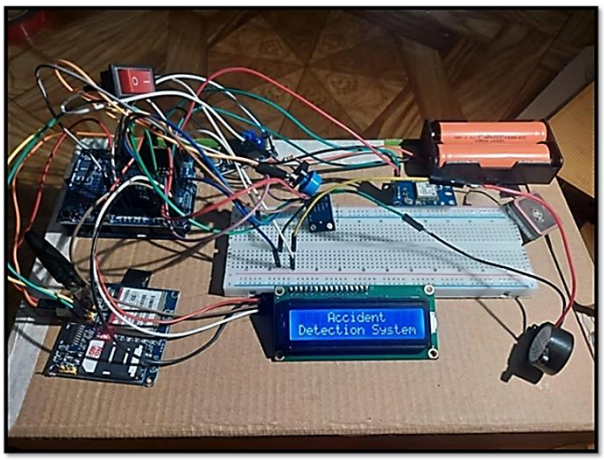

Fig. 3. The hardware connection.

The first crucial step in hardware development involves the careful selection of a microcontroller. The Arduino Uno stands out as the ideal choice due to its renowned ease of use, extensive community support, and rich library ecosystem. This microcontroller serves as the central processing unit for the accident detection and alert system.

To accurately detect accidents, a three-axis accelerometer sensor is integrated into the system. This sensor, capable of measuring acceleration in any direction, seamlessly connects to the Arduino Uno via analog input pins. Its precise measurements form the foundation for identifying potential accidents.

For displaying alerts and critical information, a standard 16x2 character LCD display is chosen. This display interfaces with the microcontroller through digital pins, providing a user-friendly interface to convey important messages related to detected accidents.

An appropriately loud buzzer is incorporated into the system to deliver audible alerts in the event of an accident. The buzzer connects to one of the Arduino Uno's digital pins, ensuring an immediate and attention-grabbing notification.

Facilitating emergency messages and calls is made possible through the integration of a GSM module. Chosen for compatibility with the Arduino Uno and its support for emergency communication, the GSM module interfaces with the microcontroller via serial communication pins.

Accurate location information is achieved through the inclusion of a GPS module. This module, selected based on its compatibility with the Arduino Uno, communicates with the microcontroller through serial communication pins, providing precise location data during emergencies.

A simple push button serves as the emergency cancel mechanism, allowing users to deactivate emergency alerts when necessary. This button connects to one of the microcontroller's input pins, providing a straightforward means to stop alerts and enhance user control.

Ensuring correct wiring of all components is vital to prevent damage. The system is powered by the vehicle's battery, with a voltage regulator employed to maintain a stable power supply. This meticulous approach to wiring and power management ensures the reliability and longevity of the hardware components.

By systematically following these hardware development steps, the vehicle accident detection and alert system's components are assembled cohesively. The resulting system is not only capable of accurately detecting accidents but also excels in promptly initiating emergency messages and calls, providing precise location information, and offering users a convenient means to deactivate emergency alerts when needed. This comprehensive approach enhances the overall usability and reliability of the system in real-world scenarios.

Fig. 4 illustrates the schematic diagram created using Proteus, providing a visual representation of the project's electronic components and their interconnections. This diagram serves as a valuable reference for understanding the system's design and layout.

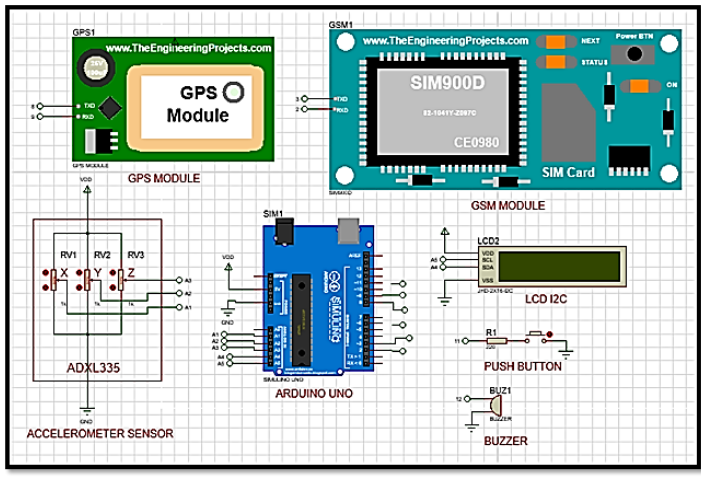

Fig. 4. Schematic diagram using proteus.

B. Prototype Design

The prototype design for the vehicle accident detection and alert system is a critical aspect. It involves careful placement and integration of various components, ensuring they are accessible, functional, and user-friendly. The following describes the design from different views:

Front View: The front view of the prototype prominently features the LCD screen, which serves as the primary interface for displaying alarms and information. The LCD display is strategically positioned within the vehicle to ensure easy visibility by the driver. Adjacent to the display, the cancel button is thoughtfully placed, making it easily reachable for the driver to deactivate emergency alerts if needed.

Side View: The side view showcases the placement of the microcontroller, an Arduino Uno, which serves as the central control unit. The microcontroller is positioned in a convenient location within the vehicle, ensuring accessibility for programming and debugging purposes. Additionally, the side view reveals the placement of the accelerometer sensor, which can be mounted on either the dashboard or the vehicle's floor, enabling accurate accident detection.

Top View: The top view of the prototype highlights the location of the buzzer, responsible for sounding alarms in case of accidents. The buzzer is positioned strategically to ensure that its sound is easily audible to the driver, enhancing the system's effectiveness. Furthermore, the top view reveals the placement of both the GSM module and the GPS module. These modules are situated for easy access within the vehicle, facilitating the rapid sending of emergency messages and calls, along with accurate location data.

Isometric View: The isometric view offers a comprehensive outlook on the overall layout of the system, encompassing all key components such as the microcontroller, accelerometer sensor, LCD display, buzzer, GSM module, GPS module, and the cancel button. The design prioritizes compactness and simplicity to ensure straightforward installation within a vehicle. Consideration is given to the power supply and the establishment of connections between components to maintain system functionality.

By adhering to this prototype design, the vehicle accident detection and alert system can effectively detect accidents, promptly initiate emergency messages and calls, and provide precise location information. The incorporation of the cancel button offers users a convenient means to deactivate emergency alerts in the event of a false alarm, optimizing usability and accessibility. The design ensures that all components are thoughtfully positioned, easy to access, and user-friendly.

Table II shows the prototype design using SolidWorks encompasses a comprehensive visualization presented through various views, including front, side, top, and isometric perspectives. SolidWorks, a powerful computer-aided design (CAD) software, allows for the creation of detailed and accurate three-dimensional models. The front view provides a frontal representation, the side view offers a profile perspective, the top view illustrates the design from above, and the isometric view presents a three-dimensional, angled depiction. These views collectively provide a holistic understanding of the prototype's geometry, dimensions, and features, aiding in the evaluation and refinement of the design before actual production.

C. The Proposed Work's Integration

Vehicle accident detection systems are vital for rapid response to accidents, minimizing injuries and property damage. This project integrates various components into a cohesive system designed to detect accidents and alert emergency services, with provisions for user control. The integration process involves several key steps:

TABLE II. PROTOTYPE DESIGN USING SOLIDWORKS

View	Image
Front View	
Side View	Top View	Isometric View	
1) Hardware connections: The initial step is to establish hardware connections, linking essential components to the Arduino Microcontroller using jumper wires. These components include the accelerometer sensor, LCD display, buzzer, GSM module, and GPS module, each serving a specific function in the system. A button is also integrated, connected to a digital input pin on the microcontroller, enabling user interaction.

2) Accelerometer sensor: The accelerometer sensor continuously provides data to the Arduino Uno, monitoring changes in acceleration. The Arduino program continuously reads and stores accelerometer data, allowing the microcontroller to detect abrupt acceleration changes that could indicate an accident.

3) Accident detection algorithm: An accident detection algorithm is implemented, involving the setting of a threshold value for accelerometer data. If the data surpasses this threshold, it triggers an "accident" event, signifying a sudden acceleration change. The threshold value's adaptability allows customization for different vehicle types and accident detection requirements, minimizing false alarms.

In Fig. 5(a), the display indicates the phrase "Crash Detected." This message is a critical notification to the driver and passengers that the system has detected an accident or a significant impact event. Displaying "Crash Detected" serves as an immediate alert, prompting occupants to take necessary actions and ensuring they are aware of the situation.

In Fig. 5(b), the display provides information related to the magnitude of the impact. This information helps convey the severity of the accident or impact event. Displaying the magnitude of impact can aid emergency responders in assessing the situation and providing appropriate assistance. It can also provide valuable data for post-accident analysis and insurance claims.

(a) (b)

Fig. 5. Display information (a) Crash detected and (b) Magnitude of impact.

These display messages play a crucial role in keeping the vehicle occupants informed about the detected accident and its severity. This real-time feedback contributes to improved situational awareness and facilitates appropriate responses to ensure safety and well-being.

4) Emergency response: Upon detecting an accident event, the Arduino responds by activating the buzzer and initiating SMS messaging via the GSM module. A pre-determined emergency contact receives an SMS containing the vehicle's GPS location and an accident notification. The GPS module determines the vehicle's precise location, facilitating emergency service response to aid potential accident victims.

In Fig. 6(a), the system is initiating an emergency call using the GSM module. This step is crucial for alerting emergency services about the accident or impact event promptly. The emergency call ensures that help is on the way to the location of the incident.

Fig. 6(b) displays an alert message along with location information. The alert message informs the recipient (likely an emergency contact or service) that an accident has occurred. Location information, likely obtained from the GPS module, is included. This information is vital for accurately pinpointing the vehicle's whereabouts. Providing location information helps emergency services quickly locate the vehicle, reducing response times and potentially saving lives.

Fig. 6(c) shows the location information obtained by the GPS module. GPS technology provides precise geographic coordinates, allowing emergency services to pinpoint the exact location of the vehicle involved in the accident. Accurate location data is essential for efficient and effective emergency response. These figures illustrate the critical steps of alerting emergency services, conveying accident information, and providing precise location details. Together, these actions are instrumental in ensuring a rapid and effective response to accidents, ultimately enhancing the safety of vehicle occupants.

5) LCD Display: The LCD display serves to relay system status messages and information. It communicates events such as "Accident detected" and "Emergency message sent," providing transparency regarding system actions to vehicle occupants.

Fig. 7 shows the LCD display and it is like a small screen in your vehicle that tells you what's happening. It shows messages such as "Accident detected" or "Emergency message sent," so you know what the system is doing. This way, you can stay informed about important events while you're in the car. The display makes it easy for you to understand what's going on and helps you feel more confident and safe.

6) Cancel call and message: A dedicated button allows users to cancel initiated calls and messages in instances of false alarms or resolved emergencies. This feature minimizes unnecessary notifications and reduces false alarms.

Fig. 8 demonstrates the importance of user-friendly features like a dedicated push button for canceling alerts. It provides users with a straightforward way to manage the system and prevent unnecessary emergency calls and messages, contributing to the system's reliability and user satisfaction.

7) System loop: The Arduino program operates in a continuous loop, perpetually monitoring for accident events. The system continually assesses accelerometer data for changes in acceleration. In the event of an accident detection or button press, the system responds accordingly.

Fig. 8. (a) Alert cancellation and (b) Push button.

D. Analysis of Limitations of the GPS Module and Magnitude of Impact

1) Limitations of the GPS module: The GPS module plays a crucial role in providing accurate location information for the vehicle accident detection and alert system. However, it is essential to understand and analyze its limitations, which can impact the system's performance. The following limitations of the GPS module have been identified:

Table III shows the performance of GPS modules is influenced by the surrounding environment, leading to distinct limitations in various settings. In open areas such as fields, the GPS module excels with clear sightlines, facilitating strong signal reception from satellites. When mounted on moving vehicles, the constant motion aids the antenna in searching for optimal signals, enhancing location accuracy. However, challenges arise in indoor environments where thick walls and building materials can weaken or block GPS signals, making it difficult to obtain reliable location data inside structures. Similarly, natural obstacles like trees and hills in outdoor settings, as well as the presence of tall buildings in urban canyons, can lead to weakened or blocked signals, rendering the GPS module less effective or even nonfunctional in these specific environmental conditions. These limitations highlight the need for alternative positioning technologies in scenarios where GPS signals are compromised.

TABLE III. LIMITATIONS OF THE GPS MODULE

Location	Limitation Signal	Reason
Open Area	Signals Reached	An open area with minimal obstructions, such as trees or buildings, allows the GPS module to receive strong signals from GPS satellites. The clear line of sight enhances signal reception.
Moving Vehicle	Signals Reached	Mounting a GPS module on a moving vehicle can improve reception. The constant movement of the vehicle helps the antenna continuously search for better signals.
Indoor Environment	Signals Weaken/Blocked	GPS signals can be blocked or weakened by thick walls, roofs, and building materials, making it challenging to obtain a reliable signal inside buildings.
Natural Environment	Signals Weaken/Blocked	Natural features like trees, hills, and other obstacles can block or weaken GPS signals, rendering them unreliable or unavailable in specific outdoor environments.
Urban Canyons	Signals Weaken/Blocked	Tall buildings and skyscrapers in urban areas can block or weaken GPS signals, leading to unreliable or unavailable signals in densely populated urban environments.

2) Analysis of magnitude of impact: Table IV show the magnitude of impact is a critical measurement provided by the accelerometer sensor. It quantifies the force experienced by the system in the event of an accident. In a 3-axis accelerometer, which measures acceleration along the x, y, and z axis, calculating the magnitude of acceleration is essential to assess the severity of the impact.

TABLE IV. ANALYSIS MAGNITUDE OF IMPACT

Times of Impact	X-Axis	Y-Axis	Z-Axis	Magnitude
Impact 1	43	86	69	118.35
Impact 2	64	30	42	82.22
Impact 3	38	68	50	92.56
Impact 4	100	64	99	154.59
Impact 5	22	57	59	84.94

The formula to calculate the magnitude of a 3-axis vector (ax, ay, az) is:

$$||(ax, ay, az)|| = \sqrt{}(ax^2 + ay^2 + az^2) \quad (1)$$

This formula calculates the Euclidean norm or magnitude of the acceleration vector by taking the square root of the sum of the squares of the individual components (ax, ay, az). Analyzing the magnitude of impact is of paramount importance for several critical reasons. Firstly, it aids in assessing the severity of accidents, with higher magnitudes indicating more forceful impacts, potentially signaling more severe accidents. Secondly, it plays a pivotal role in determining the need for emergency responses, such as alerting authorities or sending

emergency messages, based on the impact's magnitude. Additionally, understanding the magnitude of impact ensures that appropriate actions are promptly taken to safeguard the well-being of vehicle occupants and minimize injuries. Furthermore, it significantly contributes to enhancing the overall reliability of the accident detection system by ensuring that alerts are triggered when significant impacts occur. In essence, the analysis of impact magnitude empowers the system to make informed decisions about the activation of emergency response measures, thereby bolstering the system's effectiveness in mitigating the consequences of accidents.

E. Arduino Codes

1) Accelerometer integration: Fig. 9 shows the ADXL335 accelerometer, connected to the Arduino Uno, serving as the system's motion sensor. Utilizing the Adafruit_ADXL335 library, the Arduino continuously monitors changes in acceleration. The loop function computes the total acceleration magnitude and, upon surpassing a predefined threshold, triggers the emergency response function. This function, sendEmergencySMS (), initiates communication with the GSM module for alerting emergency services and predefined contacts about a potential accident.

```
#include <Wire.h>
#include <Adafruit_Sensor.h>
#include <Adafruit_ADXL335.h>
Adafruit_ADXL335 accel = Adafruit_ADXL335(12345);
void setup() {
  Serial.begin(9600);
  if(!accel.begin()) {
    Serial.println("Could not find a valid ADXL335 sensor, check
wiring!");
    while(1);
  }
}
void loop() {
  sensors_event_t event;
  accel.getEvent(&event);

  float acceleration = sqrt(event.acceleration.x*event.acceleration.x +
event.acceleration.y*event.acceleration.y +
event.acceleration.z*event.acceleration.z);

  if (acceleration > THRESHOLD_VALUE) {
    // Accident detected, trigger emergency response
    sendEmergencySMS();
  }
  delay(1000);  // Adjust delay based on your application's requirements
}
```

Fig. 9. Accelerometer integration codes.

2) GPS integration: Fig. 10 shows the NEO-6M GPS module interfaces with the Arduino Uno through SoftwareSerial to provide accurate location data. Using the TinyGPS++ library, the Arduino decodes NMEA sentences from the GPS module in the loop function. Upon validating a location fix, the system calls the sendGPSData function to store or transmit the GPS coordinates. This location data is crucial for emergency responders to locate the vehicle involved in the accident. The integration enhances the overall effectiveness of the accident detection system by providing precise location information.

```
#include <TinyGPS++.h>
#include <SoftwareSerial.h>

TinyGPSPlus gps;
SoftwareSerial ss(10, 11); // RX, TX

void setup() {
  Serial.begin(9600);
  ss.begin(9600);
}

void loop() {
  while (ss.available() > 0) {
    if (gps.encode(ss.read())) {
      if (gps.location.isValid()) {
        // GPS location available, store or send for emergency response
        sendGPSData(gps.location.lat(), gps.location.lng());
      }
    }
  }
}
```

Fig. 10. GPS integration codes.

3) GSM module integration: Fig. 11 shows the SIM900A GSM module facilitates communication with emergency services and predefined contacts. Utilizing SoftwareSerial, the Arduino continuously checks for incoming data in the loop function, employing AT commands to process SMS and call functionalities. In the event of an accident, the Arduino triggers the sendEmergencySMS function. This function uses AT commands to format and transmit an emergency SMS to specified contacts, containing information about the detected accident, including the location obtained from the GPS module.

```
#include <SoftwareSerial.h>

SoftwareSerial gsmSerial(7, 8);  // RX, TX

void setup() {
Serial.begin(9600);
gsmSerial.begin(9600);
}

void loop() {
if (gsmSerial.available()) {
// Process incoming SMS or calls
processIncomingData();
}
}

void sendEmergencySMS() {
// Use AT commands to send an emergency SMS
gsmSerial.println("AT+CMGF=1");  // Set SMS mode to text
delay(1000);
gsmSerial.print("AT+CMGS=\"");  // Set the recipient's phone number
gsmSerial.print(EMERGENCY_CONTACT_NUMBER);
gsmSerial.println("\"");
delay(1000);
gsmSerial.print("Accident detected at location: ");  // Send location
information
gsmSerial.println("LAT, LNG");
delay(1000);
gsmSerial.write(26);  // Send Ctrl+Z to indicate the end of the message
delay(1000);
}
```

Fig. 11. GSM module integration codes.

4) LCD display integration: Fig. 12 shows the I2C LCD display, connected to the Arduino Uno, offers a visual interface for real-time information. Using the LiquidCrystal_I2C library, the LCD is initialized in the setup function with a welcome message. In the loop function, the LCD is continuously updated with relevant information, such as current acceleration data and GPS coordinates. This integration provides an on-the-spot visual indication of the system's status, aiding users, and emergency responders in understanding the situation at a glance. The display serves as an essential component for user interface and system monitoring.

```
#include <Wire.h>
#include <LiquidCrystal_I2C.h>

LiquidCrystal_I2C lcd(0x27, 16, 2);  // I2C address 0x27, 16 column and 2
rows

void setup() {
  lcd.begin(16, 2);  // initialize the lcd
  lcd.print("Vehicle Monitor");
}

void loop() {
  // Display relevant information on the LCD
  lcd.setCursor(0, 1);
  lcd.print("Accel: ");
  lcd.print(acceleration);
  lcd.print(" GPS: ");
  lcd.print("LAT, LNG");
  delay(1000);
}
```

Fig. 12. LCD display integration codes.

V. Conclusion

In conclusion, the proposed vehicle accident detection and alert system, employing a microcontroller, accelerometer sensor, LCD display, buzzer, GSM module, GPS module, and cancel button, has proven to be effective in accurately detecting accidents, promptly alerting both passengers and emergency services, and providing vital location information in case of an accident. This system represents a robust and efficient solution, capable of enhancing response times during accidents and augmenting the overall safety and security of vehicle occupants.

To further enhance its capabilities, future development should focus on integration with complementary systems, such as cameras, voice recognition modules, or navigation systems, to provide more comprehensive accident information and assistance. Additionally, incorporating a cancel button for false alarm mitigation demonstrates attention to usability. The system effectively addresses the critical issue of accident detection and rapid alerting of emergency services, which holds great potential for reducing accident-related fatalities and injuries. It stands as a reliable and efficient system with scope for improvement and expansion in various directions. One noteworthy area for improvement lies in enhancing object detection accuracy, potentially through the implementation of Non-Maximum Suppression, leading to more precise region identification. The addition of a larger number of pre-trained models would also enhance performance. Furthermore, transitioning the system to a cloud-based platform would facilitate data storage and accessibility, allowing user guardians to access generated data and potentially integrating localization features for tracking user movement. In summary, the vehicle accident detection and alert system presented here offers a promising solution for enhancing road safety and emergency response, with ample room for future enhancements and broader applications.

VI. Limitation and Future Works

The vehicle accident detection and alert system, utilizing an Arduino microcontroller, accelerometer sensor, LCD display, buzzer, GSM module, GPS module, and cancel button, stands as a reliable and efficient system poised to enhance response times in accident scenarios while bolstering the safety and security of vehicle occupants. However, there exist several promising avenues for future improvements in the system's functionality and performance. One prospective area of development involves the integration of the system with other complementary technologies, such as cameras or navigation systems. This integration would significantly enhance the system's capabilities by providing additional information in the aftermath of an accident. For instance, a camera could capture vital images of the accident scene, while a navigation system could offer directions to the nearest hospital or emergency services. Another promising frontier for advancement is the implementation of machine learning algorithms to elevate the accuracy of accident detection. Machine learning algorithms, proficient in discerning patterns within sensor data, hold the potential to identify anomalous behavior effectively, thereby reducing the occurrence of false alarms and enhancing system precision. Furthermore, there is a possibility to imbue the system with remote monitoring functionality. This would enable real-time tracking of the vehicle's location and status, facilitating the dispatch of emergency alerts to a remote monitoring center. Such a feature would empower vehicle owners and emergency services alike to promptly locate and respond to accidents, potentially saving lives. Finally, the system's power efficiency can be optimized through the adoption of low-power components and the implementation of power-saving techniques like sleep mode and power management. These optimizations would extend the system's battery life, rendering it more practical for sustained use in vehicles. In summation, the vehicle accident detection and alert system already represents a potent and efficient solution for enhancing accident response times and improving the safety of vehicle users. Yet, with continued development and innovation, the system holds the potential to become even more robust and indispensable.

Design of University Archives Business Data Push System Based on Big Data Mining Technology

Zhongke Wang, Jun Li
Chengdu Technological University
Chengdu, Sichuan Province, 611730, China

***Abstract*—Aiming at the problems of low accuracy, recall, coverage and push efficiency of university archives business data, a university archives business data push system based on big data mining technology is designed. Firstly, the overall architecture and topological structure of the university archives business data push system are designed, and then the functional modules of the system are designed. Using big data mining technology to mine user behavior, modeling according to user behavior sequence, and designing a model to predict user behavior sequence based on hidden Markov model theory. Finally, the user behavior sequence is analyzed, and the factors such as user collaboration, similarity of user behavior sequence and data timeliness are comprehensively considered to push university archives business data for users. The experimental results show that the proposed method has high data push accuracy, recall, coverage and push efficiency, and can effectively push the required business data for users.**

Keywords*—Big data mining technology; system design; business data pus; hidden markov model; similarity

I. INTRODUCTION

With the rapid development and popularization of information technology, the student file management information system in colleges and universities mainly manages the information related to student files. Relying on the basic platform of campus network, it plays an increasingly important role in teaching and management applications. As a powerful tool, big data mining technology can help university archives departments to better manage and analyze massive data, and discover hidden laws and knowledge from it. The traditional student file management information system generally adopts the client/server architecture mode or browser/server architecture mode, and adopts the centralized management mode. All the information is stored in a database, and the scale is getting larger and larger in colleges and universities. Many colleges and universities have multiple campuses. This mode obviously cannot meet the requirements of improving the efficiency of college student file management. With the rapid development of Internet technology, the data produced and faced by Internet users are increasing, which makes people face the dilemma of "information ocean". Therefore, the recommendation system came into being and became the first choice to help users filter effective information from massive information [1], [2]. When the recommendation system is applied to the data push process of archives business in colleges and universities, users' experience is not good because of the sparse data of archives business, one-sided similarity calculation of users or items and poor real-time recommendation results [3]. Therefore, it is of great significance to study and design an effective data push system for university archives business. The design goal of the push system is to provide an efficient, flexible and intelligent data push platform to help university archives departments manage and utilize data better. The system analyzes and mines the archives business data of colleges and universities through big data mining technology, thus providing valuable information and insight. We will also customize the push content for each user according to individual needs to ensure that users can get the most relevant information in time.

Pan, H et al. [4] proposed a five-layer push system framework, which is divided from bottom to top: the perception layer, the filter layer, the sorting layer, the rule layer and the application layer. At the same time, context awareness technology is applied to the data push process to achieve the push of business data. This method has the problem of low accuracy of data push. Zheng, Y et al. [5] reduced the initial data set by using the characteristics of static Sky-line points. Then, according to the characteristics of the searcher moving in the obstacle space, a distance intersection model is constructed, and a pruning strategy is proposed by using the model and the attributes of the data object. According to the pruning strategy, the data objects that have no influence on the query results when the inquirer moves are filtered, so as to reduce redundant data and get the filtered candidate data set. Finally, according to the non-spatial attributes of data objects and the characteristics of mutual dominance, the events that affect the candidate data set are determined, and these events are used to refine the candidate data set, further reducing redundant calculations and obtaining the result set at the current moment. Jelodar, H et al. [6] established an automatic data recommendation system based on user interest classification. The system includes offline module and online module. The offline module processes and cleans the historical storage data, extracts the user's interest characteristics, and forms the user's interest database submodule; The online module uses the recommendation engine to cluster and correlate the information in the user interest database sub-module, and finds the book information similar to the user interest data, forming a preliminary recommendation set sub-module. This method takes a long time to push data. Moreover, the pushed data is too single, which leads to the problems of low push efficiency and low coverage. Panda et al. [7] proposed to realize effective access control of medical data with forward and backward confidentiality, and medical service providers stored patients' electronic medical records in the cloud to provide high-quality

medical services. Attribute-based encryption is a promising encryption technology, which can realize fine-grained access control of outsourced encrypted data. In this paper, an attribute-based encryption scheme is proposed to support the update of access policy, and it also provides forward security, backward security and user revocation. Performance analysis shows that the scheme has high communication and computing ability, and is suitable for devices with limited resources, but the push accuracy of this method is low. Nour et al. [8] proposed the access control mechanism in the named data network, and the information center network was recently proposed as an important candidate for the future Internet architecture to solve the problems existing in the current Internet host-centric communication model based on TCP/IP. This paper provides a detailed and comprehensive investigation of access control mechanism in named data network. The access control in named data network is studied by comprehensive method. Firstly, the paradigm of information center network is summarized, the change from channel-based security to content-based security is described, and different encryption algorithms and security protocols in named data network are introduced. Then, we divide the existing access control mechanisms into two categories: access control based on encryption and access control independent of encryption. Each category is classified according to the working principle of access control. Finally, the experience and lessons of the existing access control mechanism are summarized, and the challenges of access control based on named data network are pointed out, and the future research direction is emphasized, but the push recall rate of this method is low. Zhang et al. [9] put forward the monitoring of industrial sewage outlet water pollution based on web crawler and remote sensing interpretation technology, and took Luanhe River basin as the experimental point, combined with web crawler and remote sensing interpretation technology, put forward a feasible and efficient method to obtain sewage outlet data. Grab industrial information and spatial location data on the Internet, and get the location of industrial sewage outlet through remote sensing image interpretation. The distribution of main industrial sewage flowing into the tributaries of Luanhe River basin is simulated. By comparing the results with the actual data collected during the field investigation, the accuracy and reliability of the developed method are verified, but the push coverage rate of this method is low.

In order to solve the problems in the above methods, a design method of university archives business data push system based on big data mining technology is proposed. This method designs the overall architecture and topological structure of the university archives business data push system, and analyzes the functional modules of the system. Using big data mining technology to mine user behavior, modeling according to user behavior sequence, and designing a model to predict user behavior sequence based on hidden Markov model theory. On this basis, the user behavior sequence is analyzed, and the factors such as user collaboration, similarity of user behavior sequence and data timeliness are comprehensively considered to push university archives business data for users. The research shows that the proposed method has high data push accuracy, recall, coverage and push efficiency, and can effectively push the required business data for users with good push effect.

II. System Design

A. Overall System Architecture

The client side of the university archives business data push system adopts the client server mode, namely C/S, and the system adopts the B/S (Browser/Server) mode on the browser side. In general, it follows the classic three-tier architecture, which includes the presentation layer, application layer, and data layer. The system architecture of the university archives business data push system is shown in Fig. 1.

As it can be seen from Fig. 1, that the presentation layer is mainly the university archives business data push mobile terminal and PC browser. The application layer, situated in the middle of the three-tier architecture, consists of the control layer, the business logic layer, and the basic service layer. At the bottom is the data layer, including the data access layer and the data storage layer.

The display layer is mainly Android mobile terminal and PC terminal browser, which respectively displays user login interface and administrator login interface. The user end views the file business by logging into the Android mobile APP. The implementation method mainly uses the Android Activity and Fragment drawing interface, and the implementation architecture mainly relies on the Android operating system. The PC terminal mainly manages the system by logging in to the WEB page, which is realized by JavaScript+HTML. The execution architecture consists of a browser and an operating system.

The application layer is the main part of the data push system, which includes three parts to complete different operations. The control layer includes the control of terminal access, which is mainly composed of parameter analysis and session management. The control layer analyzes the file business type, and hands over specific operations to the business logic layer for processing; The business logic layer includes the specific services of user management, data publisher management, data management, intelligent push management and other functional modules. The basic service layer includes resource caching, resource access control, web crawler and vectorization processing, as well as data processing services and data analysis services. The functional modules of the business logic layer are implemented based on the construction in the basic service layer. The basic services offered provide functional support for the aforementioned business operations. The mobile terminal is realized through MVP mode, and the PC terminal is realized through Spring+Spring MVC+MyBatis. The execution architecture is composed of browser and operating system.

The data layer is composed of two components: the data access layer and the data storage layer. It mainly stores user data, archive business publisher data, business data, comment data, etc. of the system. The operation of structured data in the system is completed by MySQL database. Unstructured data is stored in files by data preprocessing.

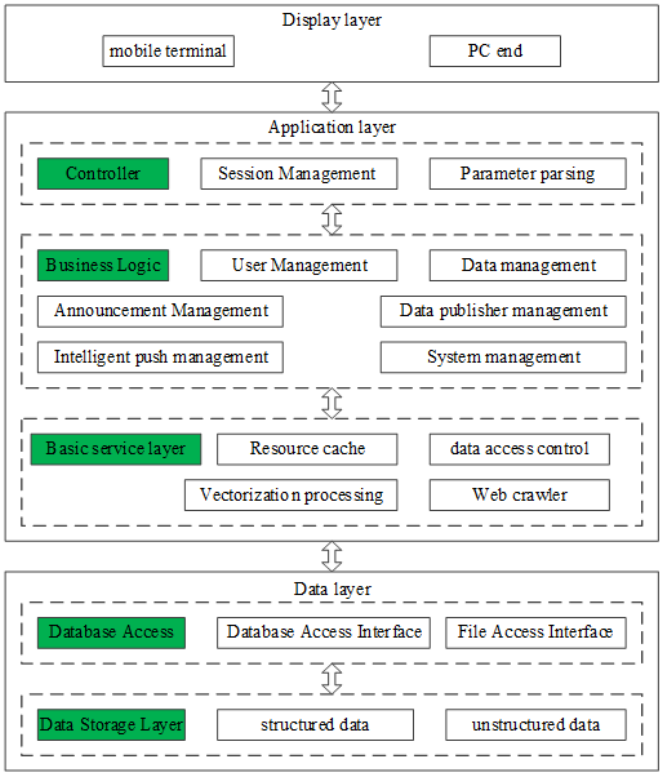

Fig. 1. Overall architecture of university archives business data push system.

In order to maintain the complete extensibility of the system, the system is divided into Controller layer, Business layer, Service layer and DAO layer when implementing the PC side in combination with the specific SSM framework. The business publisher logs in to the system through the browser, accesses the JSP page, and calls the service of the Service layer through the Controller layer.

The request sent by the business publisher to the server first enters the Controller layer. Through the controller layer's control of different businesses, dif-ferent businesses can be distributed to the Business layer to call specific business logic code. The Busi-ness layer encapsulates the database operation ser-vice and the interface provided by the Service layer to the outside. The database operation service can directly call the DAO encapsulated by Mapper. The specific SQL execution statement is implemented in XML. The results are returned to the browser for dis-play through the database operation service.

B. System Topology

Since the university archives business data push system is aimed at users in different geographical locations, the business publisher on the PC side also publishes business in different work areas [10], [11]. The work nodes are distributed in different locations, so the university archives business data push system designed by the proposed method adopts a star to-pology structure, as shown in Fig. 2.

The topological structure of this system is mainly divided into three parts: the network segment where the university archives business data push system is located, the network segment where the third-party organization is located, and the part that communi-cates directly with the Internet. The system is set up inside a communication, with separate WEB server and database server. The WEB server completes the request and response of PC end business publishers and mobile terminal users to the system functions. The database server stores the data information used in the system, including relational data and non-relational file data. At the same time, to ensure concurrent access to the system, the proposed method uses Alibaba Cloud's nginx load balancing to connect to multiple WEB servers. In this network segment, the three roles of system administrator, business administrator and communicator are divided to manage the business information and user information of the system. The roles in the system are connected to the system through the firewall. External users do not need to go through the firewall to access the system, which ensures the speed of external users' access and the security of the internal network.

Through this topology design, different access modes are set for various roles in the system.Whether tourists or registered users, authenticate users [12], [13], use mobile terminals to register and log in to the sys-tem through wireless settings, and complete corresponding queries and other operations. There are three types of file business publishers: correspondent, organization publisher, and individual publisher. The communicator is in the system network segment, the organization publisher is in the third-party organization Ethernet, and the individual publisher is free and can be directly connected to the Internet. The system administrator and news administrator are in the LAN of the system layout to manage user information and file business information.

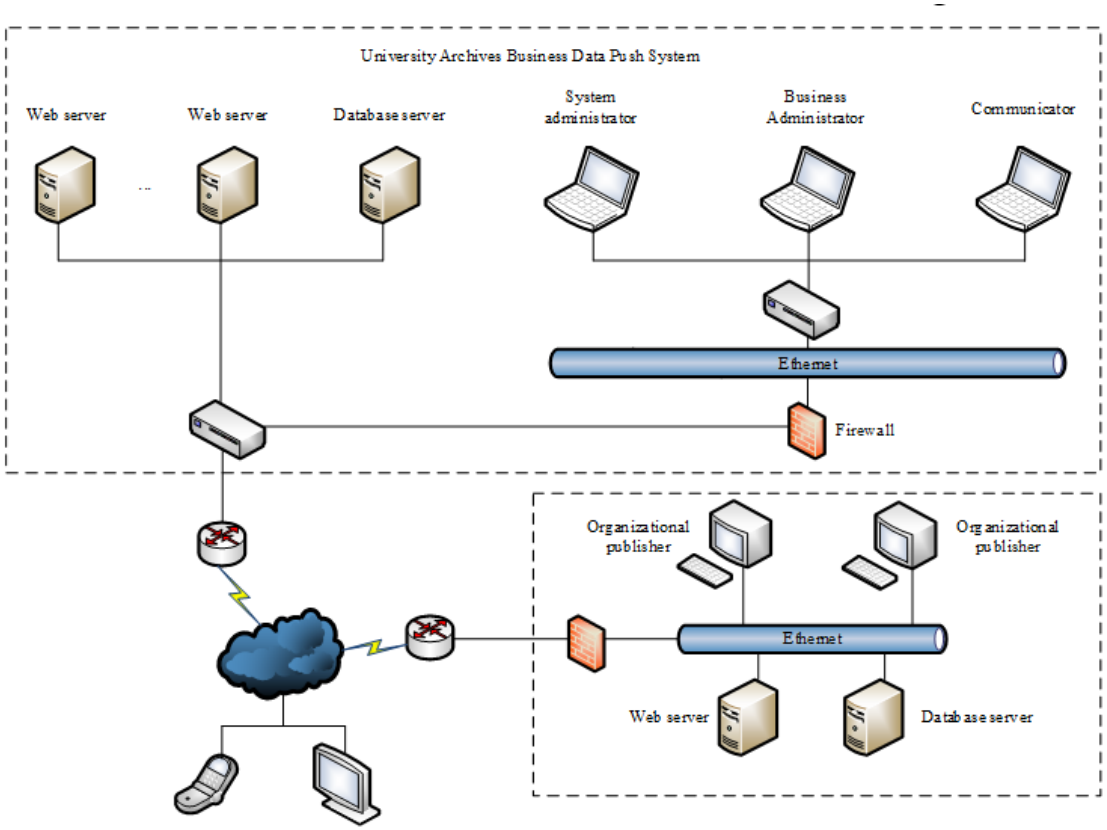

Fig. 2. System network topology.

C. System Function Module

According to the requirements of archives business in colleges and universities, the functional modules of archives business data push system in colleges and universities are divided, and the specific steps are as follows:

Step 1: Demand analysis: It deeply understand the specific needs of university archives business, including interviews with university archives managers, questionnaires or research on existing business processes, with the goal of clarifying the specific requirements and objectives that the system needs to meet.

Step 2: Function identification: Based on the demand analysis, identify the core functions required by the data push system of university archives business to meet the daily operation and management needs of university archives business.

Step 3: Module division: It group and modularize the identified functions. The division of modules should follow the principle of high cohesion and low coupling, so as to ensure that the functions of each module are relatively independent but can work together. The function of the data push system of university archives business is shown in Fig. 3.

1) Push management: You can query the push task records of push users and the records of accessing push pages; Users can also manually add push accounts to the policy server; At the same time, the user can also query the push task record of the active push customer and the record of accessing the push page [14].

2) White list management: This module is mainly responsible for adding users to the white list if they do not want to receive page push reminders, and then adding and deleting the white list if they do not want to be pushed in the future.

3) Customized push management: This module is responsible for adding and modifying the customized push task of the recommendation file business, and is responsible for performing association rule function analysis [15], [16] in the background, and applying the results to the foreground to batch add or delete users of customized recommendation products, and formulating push rules.

4) Push statistics: This module is mainly used to make statistics and analysis on the business data records of each push file in the push system, and present the results to the administrator in the form of a summary table.

5) System management: The system management function module primarily encompasses various functions such as system department management, user management, authority management, password modification, role management, and log query.

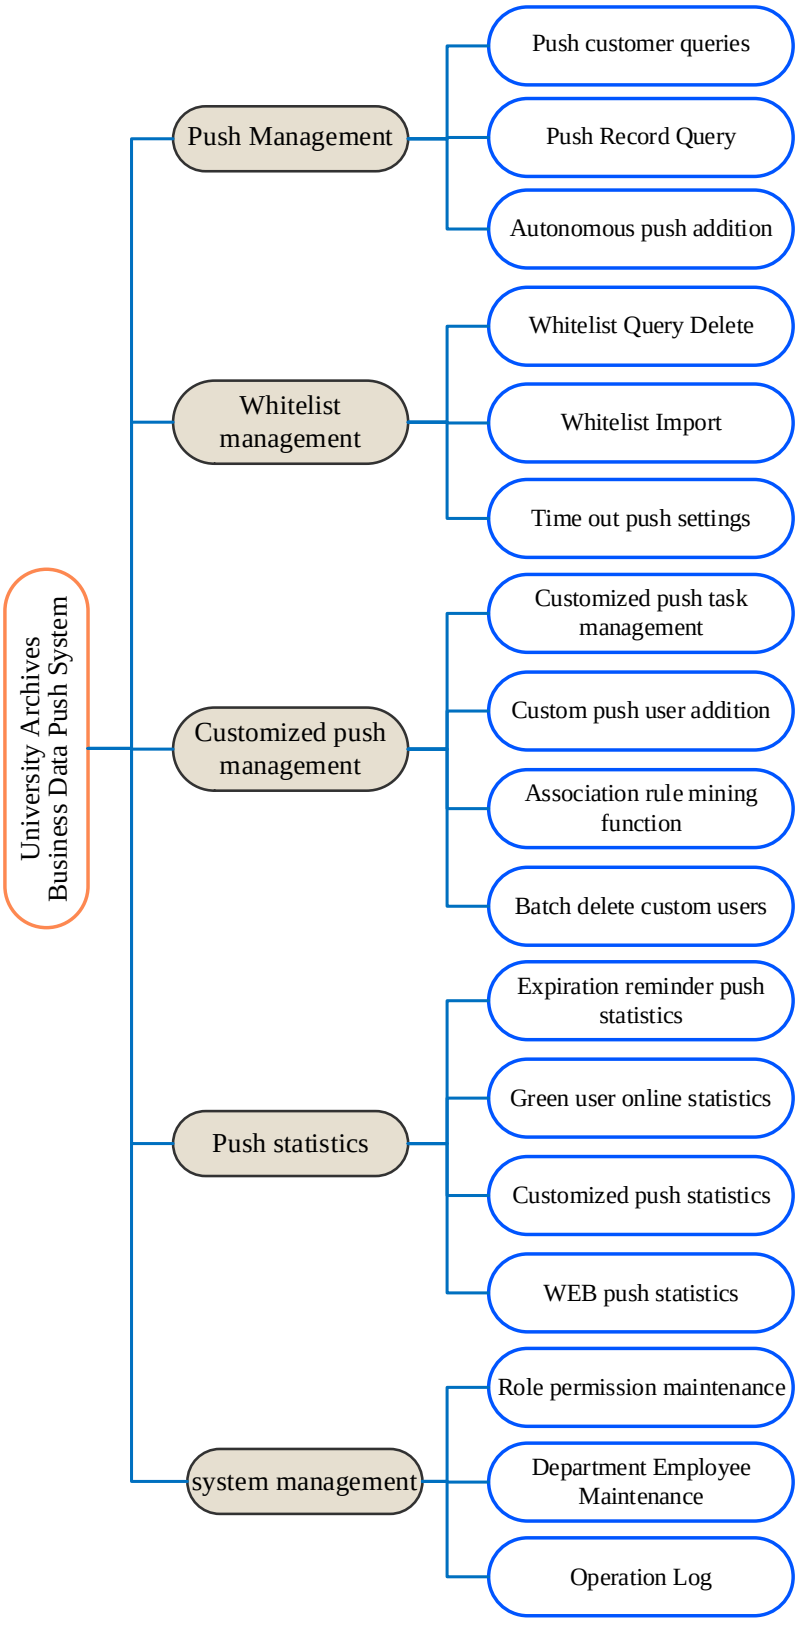

Fig. 3. Function division of college archives business data push system.

III. The Method and Implementation of College Archives Business Data Push

A. User Behavior Analysis

Considering that each user behavior sequence may represent a certain "interest" of the user, and the "entity" of the "interest" is the university file business page pointed to by the behavior sequence. Therefore, user behavior templates are used to record various "interests" of users and their corresponding behavior sequences. The generation rule is to take the user identifier as the name of the file. Each line in the file records a behavior sequence and the identifier of the file business that the behavior sequence points to. This file can be generated synchronously in the process of user behavior sequence extraction.

B. Similarity Calculation

The university archives business data push system designed by the proposed method mainly adopts the idea of user collaborative filtering [17], [18]. The recommendation system based on collaborative filtering needs to find the collection of items or users' nearest neighbor points through similarity calculation, and then carry out the next recommendation work according to the relevant information of these nearest neighbor points. The search of recommended file business data is divided into the following two steps:

- Find the nearest neighbor user of the current user through user feature similarity calculation;
- From the behavior sequences of these neighboring users, we can calculate the similarity of user behavior sequences to find the file business data that the current user may be "interested" in.

1) User feature representation and user feature file: The main data input that the system relies on is the various "filtering and provocation" selected by the user when searching, so that users and data, users and users, and data and data in the system can be associated through user behavior sequences, which can reflect the characteristics of users or data. Therefore, the proposed method takes the user behavior sequence as the original data, uses the vector space model to represent the user, and converts the feature vector β expressed as:

$$\beta = \{(g_1, w_1), (g_2, w_2), \cdots, (g_n, w_n)\} \quad (1)$$

Among them, w_i is the i feature items weight of g_i, indicating that the current user's behavior sequence or behavior template the appears times of g_i ; Characteristic item $g_i$indicates a behavior included in the user behavior sequence; n indicates the type of user behavior in the system.

In order to improve the efficiency of user collaborative search, the proposed method records the feature vectors of all historical users in the form of feature files. This file is a text file, each line of which is composed of the historical user feature vector exported from the user behavior template and the number of this behavior template.

2) User similarity calculation: The common vector-based similarity calculation methods in recommendation systems are as follows:

a) Cosine similarity: Cosine similarity is a commonly used method in information retrieval for measuring the similarity between two documents [19], [20]. It involves treating the feature vectors of the documents as vectors. The cosine similarity is determined by the angle between these two vectors, with a smaller angle indicating a higher degree of similarity, the more parallel they tend to be, and parallelism means they are completely similar. The calculation formula is as follows:

$$s_{im}(u_a, u_b) = \frac{\beta \times \sum_{i=1}^{n} w_{ai} \times w_{bi}}{\sqrt{\sum_{i=1}^{n} w_{ai}^2 \times \sum_{i=1}^{n} w_{bi}^2}} \quad (2)$$

Among them, u_a, u_b represent users eigenvector of a, b; w_{ai},w_{bi} respectively represent eigenvectors u_a,u_b of elements i.

The advantage of cosine similarity is that it is not affected by the size of vector module and the calculation is simple. However, when encountering high-dimensional sparse vectors, the accuracy of similarity calculation will decline.

b) Pearson correlation coefficient similarity: In cosine similarity calculation, two user feature vectors are regarded as two independent variables, but in reality, there may be some connection between them. Especially in the scoring vector based on "user item", there is a certain relationship between different users' ratings of items. Therefore, Pearson correlation coefficient is proposed to measure the approximation of two users [21]. The calculation formula is as follows:

$$s_{im}(u_a, u_b)' = \frac{\beta \times \sum_{s \in S_{ab}} (w_{as} - m_a) \times (w_{bs} - m_b)}{\sqrt{\sum_{s \in S_{ab}} (w_{as} - m_a)^2 \times \sum_{s \in S_{ab}} (w_{bs} - m_b)^2}} \quad (3)$$

Among them, S_{ab} indicates the user a, b subscript set of common features; s express an element in S_{ab} ; w_{as} , w_{bs} respectively represent eigenvectors u_a, u_b of elements s; m_a, m_b respectively represent the average weight of u_a, u_b.

Considering that in the process of college archives business data push, the feature vector of online users is extracted from a behavior sequence, and a behavior sequence contains fewer repeated behaviors, the obtained feature vector of online users is basically a binary vector. Therefore, the similarity calculated by Pearson correlation coefficient is basically equivalent to cosine similarity in effect, but its calculation process is obviously more complex than cosine similarity, so the proposed method uses the cosine value of the vector as the similarity of user characteristics.

3) Similarity calculation of behavior sequence: In general, the number of items found through the current user's nearest neighbor set is still quite considerable, and through previous analysis, it can be seen that each user's behavior sequence is associated with at least one university file, and different behavior sequences of the same user may reflect the user's more subtle interests and preferences. Therefore, the current

user's interest preferences can be more accurately predicted under the direction of the adjacent user's behavior sequence.

An action sequence mainly contains two aspects of information: the relative order in which the user actions in the sequence occur and the value of the actions. Therefore, the similarity of two behavior sequences can be measured from two perspectives, namely, behavior similarity and behavior value similarity.

Define S a behavior sequence the behavior state string of B, which only contains the name of the behavior in B, without the value of the corresponding behavior. Meanwhile in S, the string representing a behavior name is regarded as a state, which is an atomic weight and is indivisible. The calculation formula of the behavioral sequence B_1, B_2 of the behavior similarity of $X_{simseq}(s_1, s_2)$ is as follows:

$$X_{simseq}(B_1, B_2) = \frac{max[L_{len}(B_1), len(B_2)]}{max[L_{len}(B_1, B_2)]} \times sim(u_a, u_b)' \quad (4)$$

Among them, B_1, B_2 represents a common subsequence; $L_{len}(\cdot)$indicates the number of states contained in the behavior state string; $max[\, L_{len}(B_1, B_2)]$ express the number of states s_1, s_2 contained in the maximum common subsequence of.

Values of the same behavior are comparable, and the relative order factors between states should also be included in the scope of value similarity. So, the behavior sequence B_1, B_2 value similarity of $S_{simvalue}(B_1, B_2)$ is based on the maximum common subsequence of s_1, s_2, the calculation formula is as follows:

$$S_{simvalue}(B_1, B_2) = \frac{max[(X_{simseq}(B_1, B_2)]}{max[S_{subseqcount}(B_1, B_2)]} \quad (5)$$

Among them, $S_{subseqcount}(B_1, B_2)$ express the number of the same public status values of B_1, B_2.

Finally, the behavior sequence B_1, B_2 the similarity of $S_{simb}(B_1, B_2)$ given by the linear combination of behavior similarity and value similarity, set parameters $z = \frac{\sigma \times L_{len}(s_1)}{max[L_{len}(s_1), L_{len}(s_2)]}$, the calculation formula of $S_{simb}(B_1, B_2)$ is as follows:

$$S_{simb}(B_1, B_2) = (1 - z)S_{simseq}(s_1, s_2) + S_{simvalue}(B_1, B_2) \quad (6)$$

Among them, σ is a constant between 0 and 1, used to adjust z. Because according to practical experience, the importance of value similarity and behavior similarity is related to the ratio of the number of two behavior states. Generally, the closer the number of behavior states is, the greater the component of value similarity.

C. User Behavior Prediction

The user behavior prediction of the proposed method is mainly based on a set of hidden Markov models [22], [23]. First, relevant machine learning methods are used offline to train the prediction model parameters of various behaviors from historical data; Then, according to the partial behaviors of current online users, a finite step Markov process prediction is performed to obtain a relatively complete sequence of user behaviors; Finally, this behavior sequence is used to guide the push of university archives business data.

1) Prediction model of user behavior sequence: The user behavior sequence prediction model of the proposed method is a model systemcomposed of multiple "single two-layer" mixed state hidden Markov models designed on the basis of hidden Markov model theory [24], in which each sub model is independent of each other and deals with the prediction task of different types of user behavior sequences.

The difference between the "single two-layer" mixed state hidden Markov model and the traditional hidden Markov model is that its state set$S$the contained state elements can be divided into two categories: ordinary state elements and double-layer state elements. The double-layer state is mainly introduced to simulate the double-layer condition in the "filter condition". The detailed description of the model is as follows:

a) Status and observations: In the model, the name of a behavior in the user behavior sequence is regarded as a state, and the behavior value is regarded as the output value of the state. Corresponding to the front search function page of the college file business data push system, the type of the "filter condition" tag is considered as the status, and the "filter condition" represented by the "filter condition" tag is the output value of the corresponding status.

b) Transition probability and initial state vector: In order to reduce the complexity of model calculation, when designing the transition probability matrix, the two-layer state is reduced to a common state, and the root state is used as its representative [25], [26]. From any state$i$transfer to a two-layer state$j$transition probability ofa_{ij}. It can be calculated by the following formula:

$$a_{ij} = \sum_{s \in S_j} p_{is} \times S_{simb}(B_1, B_2) \quad (7)$$

Among them, s is j substatus collection for an element in S_j ; p_{is} is status $i$transfer to status$j$sub state of probability of s. Similar to the transition probability matrix, in the initial state vector, the two-level state is reduced to a common state for processing.

c) Probability vector of observation value: For the double-layer state, the observed values are also divided into two layers. For the root state, all its sub states are regarded as its observed values [27], [28]. Therefore, the double-layer state i of k output probability of observation values $b_i(k)$ is:

$$b_i(k) = \sum_{i=1,k=1}^{m} v_{ik}(j) \times a_{ij} \quad (8)$$

Among them, $v_{ik}(j)$ indicates a sub state k of j the probability of output values.

2) Prediction of user behavior sequence: The prediction of user behavior sequence is to start from a given state, predict the subsequent states and the output values of the states in a limited step, and generate a more complete sequence of user behavior [29]. According to the finite stage optimal decision theory of Markov process, the prediction process is to find the starting point from the specified state in the transfer matrix n step state transfer to obtain the maximum utility of the

transfer path. Define the utility that can be obtained in each step of decision-making, and the predicted result of user behavior sequence is:

$$\gamma(i,j) = a_{ij} \times max[b_i(k)] \quad (9)$$

D. Historical Project Recommendation

Historical project recommendation is to push the university file business data related to historical users to current users. The recommended method is top-N. First, the recommended item set is found by combining user collaborative filtering and user behavior sequence search[30]; Then use the relevant sorting strategy to sort the data in the file business data set according to its sorting weight; Finally select N business data is pushed to users.

1) Historical item search: The search of historical items is to use the similarity between the characteristics of the current user and the historical user, and the similarity between the behavior sequence of the historical user and the behavior sequence of the current user as a clue to filter out the item set that may meet the interests of the current user from the historical items. The specific process is divided into the following steps:

a) User behavior prediction: Use the prediction model to predict backwards n step according to the behavior sequence entered by the current user, to get a more complete sequence of user behaviors s. The size of n is related to the number of behavior states entered by the current user, the more states there are, the small the n is. The maximum number of states contained in a user behavior sequence in the system is ϑ, then the calculation formula of n is as follows:

$$n = \begin{cases} \vartheta - \gamma(i,j) & \vartheta > \gamma(i,j) \\ 0 & \vartheta \le \gamma(i,j) \end{cases} \quad (10)$$

b) Finding user behavior template based on user feature similarity: According to the current user behavior sequence s, generate the user's feature vector, calculate the cosine similarity between the historical user and the current user's feature vector, and take out the similarity greater than the threshold σ_1 user behavior template file. σ_1 can be adjusted by the experimental feedback data.

2) Ranking of recommended items: The ranking of recommended items comprehensively considers factors such as feature similarity between users, behavior sequence similarity, popularity of business data and timeliness of business data, calculates the ranking weight of business data, sorts it, and finally generates *N* list of recommended items of file business data. The specific process is divided into the following steps:

a) Calculate the total feature similarity of users associated with data: One file may be related to multiple users, so the overall feature similarity of file business data $simusers(c,S)$ is the user behavior sequence s similarity between the generated characteristics of the current user and those of all neighboring users containing the data $A_{sim}(c,u_i)$ which is calculated as follows:

$$S_{simusers}(c,S) = n \times S_{simusers}(c,S) \times A_{sim}(c,u_i) \quad (11)$$

b) Calculate the total similarity of the behavior sequence associated with the data: One file business may be related to multiple user behavior sequences, so the similarity of one file business behavior sequence $S_{simstrings}(s,Q)$ is the behavior sequence and prediction sequence associated with s the similarity $S_{simb}(s,q_i)$ which is calculated as follows:

$$S_{simstrings}(s,Q) = \sum_{q_i \in S} S_{simb}(s,q_i) \quad (12)$$

c) Calculate the popularity of data: Count the number of different users associated with each file business, and calculate the popularity of each data. The calculation method is as follows:

$$Z(i) = exp\{ m / \sum_{j=1}^{m} \delta(i,j)\}^{-1} \quad (13)$$

where, $Z(i)$ indicates file business data i popularity, m is the total number of related users.

The values of function $\delta(i,j)$ is as follows:

$$\delta(i,j) = \begin{cases} 1 & m_i \in I_j \\ 0 & m_i \notin I_j \end{cases} \quad (14)$$

where, I_j represents a collection of items contained in a user behavior template.

d) Calculation data timeliness: The timeliness of data is determined by the online time and current time of archive business data. The greater the timeliness, the more innovative the data. The calculation method is as follows:

$$T(i) = exp[\,(t_c - t_i)/\phi] \times Z(i) \times \delta(i,j) \quad (15)$$

Among them, $T(i)$ represent data i timeliness; t_c represents the current time; t_i represent data i online time; ϕ represents a constant greater than 0.

e) Calculate the sorting weight of data: Based on the above factors, the ranking weight of a university's archive business data is:

$$W(i) = \xi_1 \times S_{simusers} + \xi_2 \times S_{simstrings} + \xi_3 \times Z(i) + \xi_4 \times T(i) \quad (16)$$

Among them, ξ_i is the influence factor of each factor, which is set through experimental effect feedback or artificial experience.

f)Generate recommendation list: According to the sorting weight of file business data, the data is sorted from the largest to the smallest, and is selected the first *N* to generate recommendation lists to return to the user.

IV. Experiment and Discussion

In order to verify the overall effectiveness of the design method of university archives business data push system based on big data mining technology, it is necessary to test it. Before the test, prepare three virtual machines and modify the corresponding host names to mini0l, min02, and mini03. Next, set their network mode to NAT and modify their IP addresses [31]. Then modify the hosts file of each machine to configure the mapping relationship between the host name and IP address. Close the firewall of each machine and restart the machine. Finally, configure ssh password free login between virtual machines. Now the Linux environment is ready.

Set five datasets, labeled as Dataset 1, Dataset 2, Dataset 3, Dataset 4, and Dataset 5, specifically, it includes the following contents:

Data set 1: Student file data: This data set contains students' personal information, such as name, gender, date of birth, home address, contact information, etc. It also contains academic information, such as enrollment date, major, course results, rewards and punishments, etc.

Data set 2: Staff file data: This data set contains personal information of staff, such as name, gender, date of birth, contact information, etc. It also contains professional information, such as position, employment date, education, work experience, etc.

Data set 3: School business data: This data set contains various business data of the school, such as school curriculum arrangement, examination arrangement, activity arrangement, etc.

Data set 4: User behavior data: This data set contains the behavior data of users (students and faculty) in the system, such as login times, pages visited, time spent on pages, links clicked, etc.

Data set 5: System log data: This data set contains the running logs of the system, such as error logs and operation logs.

Use the proposed method, reference [4] method, reference [5] method, and reference [6] method to conduct business data push test in the Linux environment, and use the accuracy rate $Precision$, recall rate Z_{Recall} , coverage rate C_{ov} as an evaluation indicator of the method. Accuracy can measure the accuracy of pushed data, recall can measure the integrity of pushed data, and coverage can measure the satisfaction of pushed data to users' needs.

Accuracy P_{re} indicates the ratio of the number of test sets contained in the recommended data list to the number of all recommended items. The calculation formula is as follows:

$$P_{re} = \frac{A}{B} \times 100\% \quad (17)$$

where, A indicates the number of correctly predicted samples, B indicates the number of recommended samples for all users obtained from the test set.

It can be seen from the analysis of Fig. 4 that when the data push test is carried out under the same test environment, the data push accuracy of the proposed method is the highest and relatively stable. The data push accuracy of the reference [4] method and reference [5] method fluctuates greatly, and the data push accuracy of reference [6] method is stable but relatively low overall.

Recall rate Z_{Recall} indicates the ratio between the number of user recommendations and the number of items that users have acted in the test set:

$$Z_{Recall} = \frac{A}{C} \times 100\% \quad (18)$$

where, C indicates the number of samples that all users in the test set have had historical behaviors.

According to the test in Fig. 5, compared with the test results of the method in reference [4], the method in reference [5] and the method in reference [6], the recall rate of the proposed method is higher, indicating that the proposed method has good recommendation ability in the field of large-scale business data push.

Coverage rate C_{ov} represents the ratio of the number of recommended items to the total number of items, and its expression is as follows:

$$C_{ov}=\text{B/D}\times 100\% \quad (19)$$

Where, Drepresents the number of samples in the entire dataset.

It can be seen from Fig. 6 that under different data sets, the data push coverage of the proposed method is more than 90%, which indicates that the proposed method includes many types of data pushed by users with full coverage, and the coverage of the reference [4] method, reference [5] method and reference [6] method is low, which indicates that when the above methods are used to launch data push, the pushed data is relatively simple and cannot meet the needs of users.

The time required for the proposed method, reference [4] method, reference [5] method and reference [6] method in the process of data push test is shown in Table I.

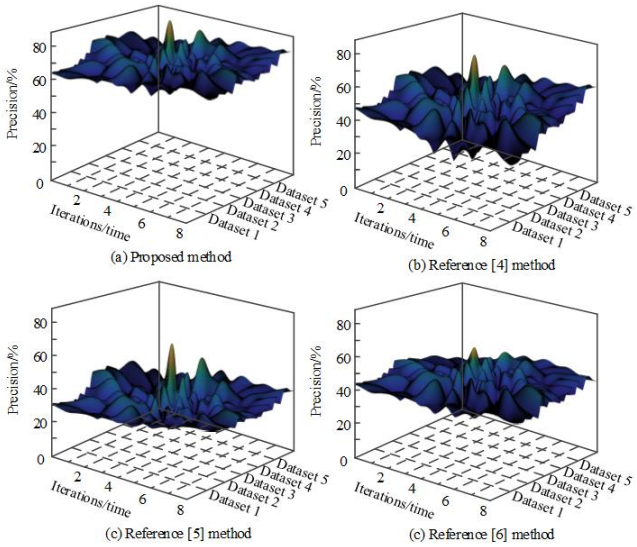

Fig. 4. Accuracy test results.

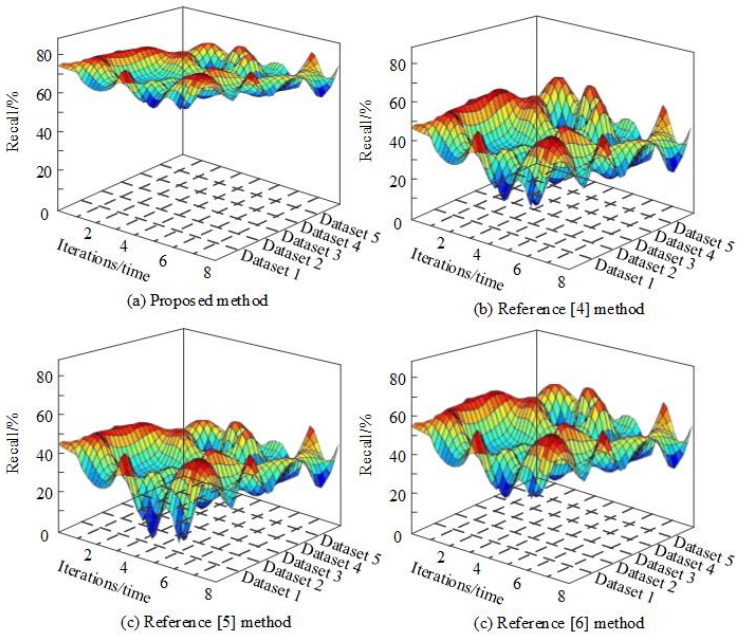

Fig. 5. Recall rate test results.

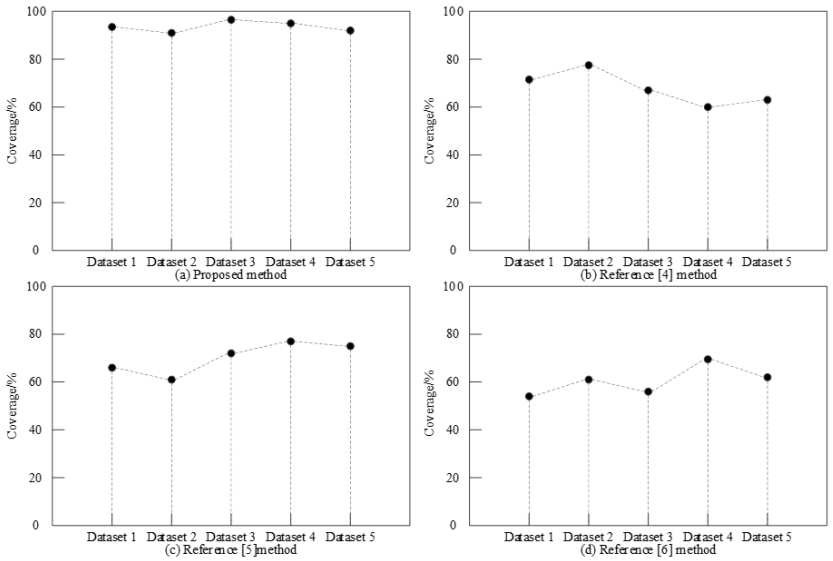

Fig. 6. Coverage test results.

TABLE I. DATA PUSH TIME OF DIFFERENT METHODS

Data samples/piece	Data push time/s			
	Proposed method	***Reference [4] Method***	***Reference [5] Method***	***Reference [6] Method***
100	5.2	9.8	7.6	8.8
200	5.8	10.5	8.3	9.6
300	6.3	11.3	8.9	10.5
400	6.9	12.2	9.7	11.2
500	7.4	13.0	10.4	12.7
600	7.7	14.9	11.7	13.5
700	8.2	15.4	12.6	14.4
800	8.6	16.6	13.7	15.6
900	9.1	17.3	14.9	16.8
1000	9.5	18.1	15.6	17.3

Analysis of the data in Table I shows that the da-ta push time of the proposed method, the reference [4] method, the reference [5] method and the refer-ence [6] method increases with the increase of the number of data samples, but under the same data samples, the push time of the proposed method is far lower than the other three methods, indicating that the proposed method has high data push efficiency.

To sum up, when the data push test is carried out in the same test environment, compared with the methods in [4], [5] and [6], the data push accuracy of the proposed method is the highest and relatively stable; The recall rate is high, the data push coverage rate is above 90%, and the push time required is much lower than the other three methods, which shows that the proposed method has high data push efficiency, and the data pushed for users contains more types and covers all the fields, and it has good push ability in the field of large-scale business data push.

V. CONCLUSION

On the one hand, it takes a lot of time to screen the data, and it is difficult to find the data you need from a large number of data; On the other hand, it will make a lot of redundant information become "hidden information" in the network, which cannot be obtained by ordinary users. In this context, a data push system is proposed. At present, there are some problems in the design method of data push system, such as low push accuracy, low recall, low coverage and low push efficiency. Therefore, a design method of university archives business data push system based on big data mining technology [31] is proposed, which is of great significance and provides decision-making and management support for university management departments. Through the data push function, timely and accurate data transmission and information sharing can be realized, and the efficiency and quality of university archives business can be improved. In this paper, the overall architecture and functional modules of the system are designed, and according to the characteristics of users' behavior, the push of university archives business is realized. It is verified that the data push accuracy of the proposed method is the highest and relatively stable. The recall rate is high, the data push coverage rate is above 90%, and the push time required is much shorter than the other three methods, which can effectively push the required business data for users in a short time. Provide more intelligent and scientific decision-making and management support for university management departments, and improve the efficiency and quality of university archives business.

The prospect of future research work can be carried out from the following aspects:

1) Dig deep into the archives business data of colleges and universities: In the future, we can further expand the data sources, including students, faculty, courses, scientific research projects and other dimensions, in order to obtain more comprehensive data information. Mining hidden rules and trends in data can help university management departments make better decisions and management.

2) Data security and privacy protection: In future research, we need to pay more attention to data security and privacy protection. Explore how to use emerging technologies such as blockchain to ensure the security and credibility of data, and study the methods and technologies of privacy protection to protect sensitive information of individuals and institutions.

***Abstract*—Augmented Reality Software Development Kits, or as they are commonly called AR SDKs, are useful for developers to build digital objects in AR. This paper presents a comparative study of AR SDKs. This comparison is based on several significant criteria, to select the most suitable SDK. The evaluation used the Preferred Reporting Items for Systematic Reviews and Meta-Analysis (PRISMA) method. Based on a comparative analysis of the features and virtual elements available for application development with the AR SDK, researcher suggests that the main functions of the AR SDK were to be able to offer AR application Editing Platform and facilitate software creation without requiring knowledge of algorithms. Besides that, it is possible to establish some general observations regarding the benefits and limitations of the AR SDK. The result of this research is expected to provide with the clear framework for processing the data that has been collected, summarized, and tested from case study so the researcher will be able to reach useful conclusions. From the literature study has been conducted, it was concluded that among many SDK tools, there are 15 of them which were the most employed by AR developers. These 15 tools were selected based on certain main attributes and support platforms. At the end of this research, it also presents the advantages and limitations of these 15 tools.**

Keywords*—Augmented reality; software development kits; AR SDK; platform; framework; AR technology

I. INTRODUCTION

Augmented Reality Software Development Kits, or AR SDKs, are useful for developers to build digital objects [1]. By utilizing devices like gadgets or tablets, digital objects can be incorporated into the real world through augmented reality (AR). The advantages of the features provided by the AR SDK are the functions for image recognition, 3D object tracking and other multi-tracking, providing simultaneous visual localization and mapping, and many other additional features. This allows developers to create a wide range of digital experiences. AR engineers can leverage this SDK to develop mobile applications, integrate with various CAD platforms, create marketing experiences, develop educational applications, and explore many other possibilities [2]. The AR SDK can generally be used for hardware with certain frameworks [3]. From the results of the literature review, it is also known that several AR SDKs are very flexible to use, so they can be applied to many systems. This makes it easy for AR developers to build AR applications across platforms.

This study presents a comparative study of several AR SDKs. The aim of the comparison that will be carried out is so that AR developers can choose the SDK that best suits their needs so that it can be adapted easily. There are several important criteria that will be explained in the SDK comparison carried out. This research is expected to add value because it has been collected, summarized, and tested from the case study samples that have been carried out so that it can reach useful conclusions for this research.

As we know, AR and virtual reality (VR) have different ways of working. Therefore, AR SDK and VR SDK are also different. The main benefit in the AR SDK category is the functionality of creating AR experiences that can be integrated with various operating systems and various other hardware [1]. Basically, there are three steps in the AR system: recognition, tracking, and blending. At the recognition stage, visual identification occurs in the form of images, whether images of objects, faces, bodies, other body parts, or space will be recognized as virtual objects [4]. The tracking stage is carried out to get real-time visual results in the form of images, objects, faces, bodies, or places such as space so that videos, 3D images, 2D images, text, and others can be added to the AR application [5]. In marker-based AR systems, symbols are used as reference points for overlaying computer graphics. The camera used in this system will continue to search for and identify the target object and then process the image data, starting from the position, orientation, and movement of the visual display that appears. The marking system has a problem, namely that if the lighting is not good, the focus will decrease, and resulting in the image disappearing from the screen, so AR services will not be optimal when using this system [6].

It is different from the AR system without markers [7]. This system uses a combination of electronic devices, such as accelerometers, location data (GPS), compasses, and others, that can determine position in the physical world. With this marker-less AR system, objects can be identified from the direction where the camera is pointing or on which axis the device used operates to obtain the location [6]. This location data determines what the device sees by comparing it to a database, allowing data or computer graphics to appear on the screen. This technological approach sparked the idea of the emergence of 'mobile 'augmented reality' on smartphones, tablets, gadgets, and other mobile technology devices [8].

II. LITERATURE REVIEWS

AR technology is applied in many fields, and AR Software Development Kits ("SDK") have been entered into various applications such as gaming, media and entertainment, automotive, retail, health, education, manufacturing, and others. In the gaming industry, the success of AR technology is that it can offer immersive and interactive experiences that will increase the adoption of AR in the gaming industry. With the success of Pokémon Go, the game company has extensively expanded the technology for games and other applications. For example, the game Ingress Prime adapts the idea of Pokémon Go, where players can go out of the house, travel around, and meet face-to-face with other players. Ingress Prime maximizes the rapid development of AR technology, as seen from the presence of a feature that can make players place a 3D map of a location on the dining table or living room table to set a strategy. Previously, the available portal locations were only numbered in the hundreds of thousands, but now Ingress Prime offers millions of locations spread across the globe [9].

For the media and entertainment industries, the advantage of AR technology is that it can provide real-time experiences. For example, in November 2019, Samsung Electronics launched the Samsung TV True Fit. Using smartphones, both Android and iOS, consumers can see exactly what Samsung's widescreen TV will look like on the wall before buying it. This AR application produced by Samsung can combine futuristic technology with the future of retail shopping and virtual product display. Its main goal is to give consumers the opportunity to choose the right TV at the right size and have a pleasant shopping experience [10].

In the retail industry, AR also offers a promising role. Its ability to provide product and service details tailored to customer needs via smartphones with 3D effects has an impact on market growth. For example, Walmart has used AR so that its customers get shopping experience by scouring supermarket aisles for Waffles + Mochi characters to unlock AR content. After scanning a QR code with a smartphone, image recognition technology allows consumers to search for nine different characters hiding in grocery aisles. As shoppers discover each character in the store, they will earn badges and gain access to unlock more games, recipes, stories, and clips from the Walmart app [11].

In the healthcare sector, there is also an increasing demand for AR because it helps with simulations for surgery, training, and patient care. For example, the Mayo Clinic is the best hospital in the world to develop treatments using AR technology. The past decade has seen tremendous growth and expansion in innovative efforts to address the unmet needs of patients, providers, and care systems. To facilitate this effort, the Mayo Clinic Cardiovascular Medicine established a virtual reality innovation group at the Mayo Clinic in Rochester, Minnesota [12].

In the field of education, the results of a study entitled "Investigating Student Attitudes toward Augmented Reality" found that students have positive attitudes towards AR applications, as seen from the increased interest and motivation in an active and interactive learning environment through AR [13]. This proves that AR technology is able to make applications more interesting to use and increase user interest in learning something [14]. In manufacturing, AR is applied to product design and development, quality control (QC) processes, logistics, employee training, equipment maintenance, and more. With the adoption of AR applications, manufacturers can increase productivity, lower costs, and work faster. For example, AR technology and the Internet of Things (IoT) will allow manufacturing systems to self-assess deficiencies or errors that occur in the system [24].

According to a market analysis perspective by International Data Corporation (IDC), the latest projections estimate the AR market will reach $60.55 billion by 2023 [15]. AR is not just an IT technology; it is a link between the digital and physical worlds and becomes a new interface between humans and machines. The world's leading IT companies, such as Amazon, Facebook, Mayo Clinic, US Navy, and others, have implemented AR, and they are seeing the huge impact AR has on quality and productivity for their companies. The main advantage that AR offers to various fields that use it is the power of AR in processing information so that humans can experience unforgettable immersive experiences. With this immersive power, humans can use their five senses to access information at different speeds. From the research results, it is known that vision provides 90% of the information humans obtain through sight. However, accessing information is not easy because it requires mental capacity that is able to absorb and process information [17]. Therefore, cognitive load, as a demand on human capacity, requires mental effort. Like reading instructions from a computer screen, carrying out calculations, and thinking about the information obtained, all of this provides a greater cognitive load compared to listening to the same instructions because the letters must be translated into words. Words must then be represented so that there is a distance or gap between the presentation of information and its understanding in the context of applying the information [18]. For example, when a driver refers to a smartphone and looks for directions while driving, this requires its own focus. The steps that must be taken are that the driver must read the information from the screen, then memorize the information in his memory, look at the screen, and translate the directions from the screen to the physical environment in front of him. Then follow the instructions when operating the vehicle. There is a lot to do, and there is a cognitive gap between the digital information on the screen and the physical reality on the ground where the information must be applied. The combination of the speed of conveying and absorbing information and the cognitive distance involved in its application is like the term "a picture is worth a thousand words"[16]. When humans view the physical world, they absorb vast amounts of information. The information received is almost immediately absorbed. In the same way, an object or image overlaid with information about the physical world places it in context for human knowledge. This can reduce cognitive distance and minimize cognitive load. This reason can explain why AR can become a trend and is in an important position. There is no better graphical user interface than the physical world we see around us when enhanced with a digital overlay of relevant data and guidance on where and when it is needed. AR eliminates reliance on 2D

information that is out of context and difficult to process on pages and screens, while enhancing humans' ability to understand and apply information in the real world [19].

III. Research Methods

The papers used in this study were collected from a bibliographic database of Scopus and academic publications, such as ERICS, IEEE, Science Direct, Taylor and Francis Journal, and Google Scholar. The required articles were those published between January 2019 and October 2023. The following search keywords resulted in 15,900 papers being collected:

"Augmented" AND "Reality" AND "SDK"

"AR" AND "SDK"AND "Technology"

"AR" AND "Framework" AND "Development"

After selection, there were 235 suitable articles.

The evaluation used the Preferred Reporting Items for Systematic Reviews and Meta-Analysis (PRISMA) method with five stages used to conduct a literature review, namely defining eligibility criteria, defining information sources, selecting literature, collecting data, and selecting data items as shown in Fig. 1. Meanwhile, for the presentation of the results of the literature review that has been carried out, it can be seen in Table I below:

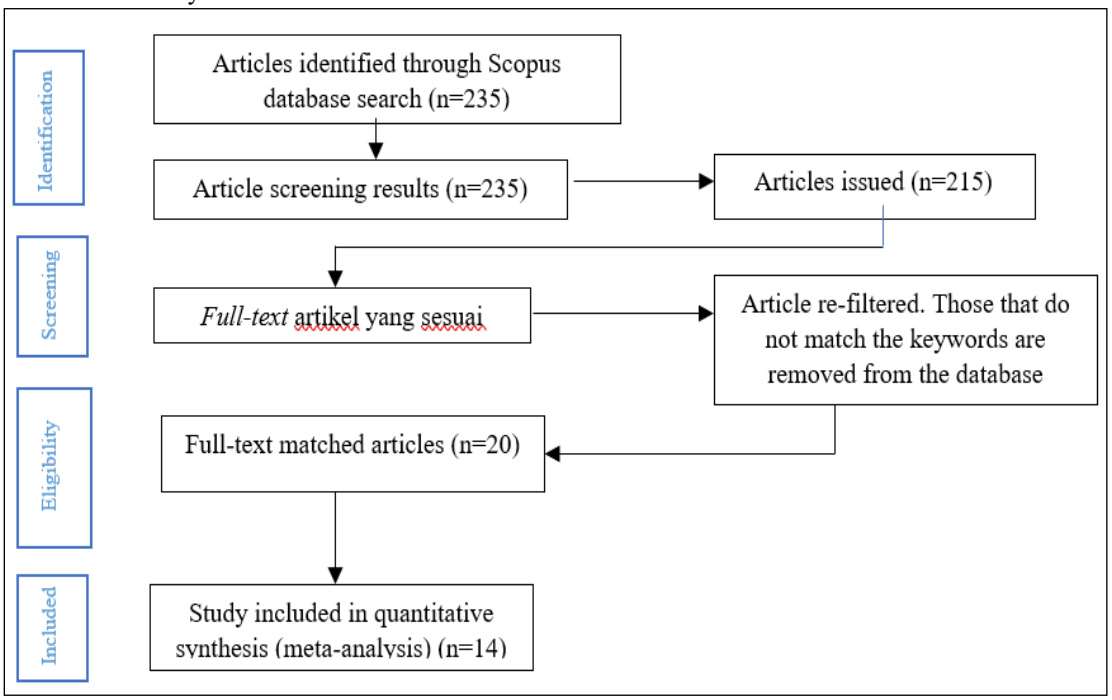

Fig. 1. PRISMA diagram (adapted from Moher et al (2009)).

IV. Analysis of Frameworks and Platforms

From the results of a literature study on AR development tools to explore the functionality and applications used by AR, 15 tools were found that can be used to perform analysis and testing. The data obtained for the development of AR resources is shown in the table below:

1) ARToolkit: Currently for developing AR applications. ARToolkit has the most libraries and the most users. The main advantage of ARToolkit is that it is open source, offers other supporting features, and allows multi-platform use. Its open-source nature allows ARToolkit to continue to develop, and its advantages in tracking planar targets, geolocation, and several other targets can develop along with the needs of AR developers [20][21].

2) Realitykit: The main advantage of Realitykit is rendering realistic photos, creating animations, physics, providing camera effects, and more that are created specifically for AR frameworks. Realitykit makes AR development easier than other tools due to its Native Swift API, ARKit integration, spatial audio, highly realistic physics-based rendering, animation frameworks and transformations, and spatial audio and physics rigid objects, all of which support AR development [2].

3) Aurasma: Aurasma offers an AR platform for education and personal use for free. With support for creating its own mobile applications and web-based platforms, it allows AR developers to transform objects, images, and places. This advantage provides new interactive opportunities using graphic, animation, video, audio, text, and 3D content, enabling planar target tracking and geolocation, as well as tracking via cloud storage in the form of 3D AR [1].

4) BlippAR: The main advantage of BlippAR is that users can register their own bookmarks and connect with many dynamic and interactive visual assets for smartphones. BlippAR supports deep learning algorithms with artificial intelligence, allows users to use cloud technology to track

planar targets, and supports learning of various things that AR developers may need [1][2].

5) CraftAR: The main advantage of CraftAR is that it has a multi-platform SDK, offers mobile applications and a web-based platform, tracks planar images through the cloud, and registers their own bookmarks in various forms such as 3D models, images, audio, video, and more [3].

6) EasyAR: The main advantage of EasyAR is that it has simple and efficient features, is easy to use, and has advanced functions that AR developers have long awaited, such as dynamic target recognition loading, screen recording functions, hard decoding, and more than 1000 types of local target recognition. Apart from that, the web-based platform is also an advantage because it can make it easy for users to register their projects and obtain the necessary licenses. This license is useful for testing and releasing user applications and offers some planar target tracking functionality [1].

7) Kudan: This framework offers an SDK that can be exported to various platforms. Additionally, Kudan has extensive documentation and practical examples and has a support forum for fellow communities. SLAM is also available, allowing the tracking of fewer markers [22] [23].

8) LayAR: Developers can use many features on LayAR, such as adding buttons for social media, web pages, phone calls, email, downloading, voting, shopping, and adding contacts. The programming language used is Java, with back-end XML, PHP, MySQL, and others that support the JSON format. For use on iOS, the iPhone is LayAR's mainstay for integration with specific SDK hardware requirements [2].

9) PixLive: Using PixLive allows the use of media such as images, 3D models, 360-degree images, audio, and video. Developers can also add buttons to social media, web pages, and PDF files and use images and text as buttons. To create scenes and buttons or timers to navigate between scenes, PixLive allows the use of resources for drawing applications and the use of geolocated resources [3].

10)Vuforia: Vuforia is one of the most popular platforms for developing AR. Vuforia provides a web-based environment where users can create and manage their bookmarks and obtain the necessary licenses. Licenses are required to test and publish their applications. Vuforia can also be used to track planar targets, geolocation, multiple targets, text, and 3D objects. Cloud technology can also be used on Vuforia to store data locally on the user's device. Vuforia even enables marker less tracking through two technologies, namely extended tracking and smart terrain.

11)Wikitude: The main advantage of Wikitude is the ability to track planar markers, 3D objects, geolocation markers, multiple targets, and the use of marker less SLAM technology. This platform is paid and offers a web-based 3D AR display and management platform to mobile users. Bookmarks can be created by users and linked to 3D models and other virtual elements.

12)Metaio: A library for creating AR mobile applications. Metaio can perform pattern tracking which will then be compared with existing references. In Metaio, the AR application design has embedded four marker tracking methods to carry out the marker recognition process. These methods have a threshold in the process of recognizing markers[23].

13)D'Fusion: A development platform for building Augmented Reality applications that provides tools for creating all kinds of immersive augmented reality experiences. The platform can also manipulate 3D visuals, combine marker less and gesture recognition, and easily set up and deploy complex AR. More than 300 parameters in advanced functionality are available in this graphical configuration for object recognition and beyond [2].

14)ARMedia: A platform that can help develop Augmented Reality applications effectively and efficiently. This SDK can be used to track unique 3D models from simple AR projects to very complex ones. The SDK provides recognition tools and includes 3D Object, Planar, Location, and Motion Tracking. ARmedia is not only able to recognize planar images and locations, but also 3D objects regardless of size and geometry. The ARMia SDK supports building advanced applications and systems that serve across a wide range of application domains. ARmedia SDK with any 3D Engine and Writing Environment like Unity 3D and Open Scene Graph[1].

15)ARCore: ARCore is a platform for building AR that focuses on mobile devices. The advantage of ARCore is that it can use different APIs; the user's device can observe and receive information about its environment and interact with that information [20][1].

Apart from these 15 tools, there are other tools such as ARUco, ZapWorks, Augment, HP Reveal, PTAM, HandyAR, ARGON, Amazon Sumerian, Mixare and others. It's just that based on the many tools, these 15 tools are the most widely used in research that has been done previously. For tracking target the main attributes in this classification follow a set of criteria that will be used to compare in each SDK. The analysed attributes are:

1) Text recognition: It is used to recognize words and/or groups of words for analysis.

2) Image recognition: It is used to benchmark its planar image recognition.

3) 3D object recognition: It is used to track cylindrical, conical, and general 3D real objects as investigated landmarks.

4) Multi-target recognition: It is used to track multiple targets simultaneously for analysis.

5) Geolocation recognition: It is used to test and verify which tools support geolocation targets.

6) Marker-free recognition: It is used to identify marker-free AR platforms.

From the results of previous research, it is known that there are several support platforms that support the AR SDK including Windows, Linux, OSX, Android, IOS, MAC OS or OSX, Smart Glasses and the Web. From the results of the study conducted by the researcher, the data shown in Table I below was taken:

TABLE I. ANALYSIS OF FRAMEWORKS AND PLATFORMS

Tools	Extension/ Platform	Text Recognition	Image Recognition	3D Object	Multi Targets	Geo-location	Marker less
ARToolKit	Windows, Mac OS, Linux, iOS, Android, Unity Package, Smart Glasses	x	✓	x	✓	✓	x
RealityKit	App (Android, iOS, Windows, Mac)	x	✓	x	x	x	x
Auras-ma	App (Android, iOS)	x	✓	x	x	✓	x
Blipp-AR	App (Android, iOS)	x	✓	x	x	x	x
CraftAR	App (Android, iOS), Unity Package, Apache Cordova	x	✓	x	x	x	x
EasyAR	Windows, Mac OS, Android, Unity Package	x	✓	x	✓	x	x
Kudan	Android, iOS, Unity Package	x	✓	x	✓	x	x
LayAR	App (Android, iOS e BlackBerry)	x	✓	x	x	x	x
PixLive	App (Android e iOS), Apache Cordova e Google Glass	x	✓	x	x	✓	x
Vuforia	Android, IOS	✓	✓	✓	✓	✓	✓
Wiki-tude	App (Android e iOS), Unity Package, Cordova, Titanium, Xamarin e Smart Glasses.	x	✓	x	✓	✓	✓
Metaio	Android, iOS, Unity Package	x	✓	✓	✓	✓	✓
D'Fu-sion	Windows, iOS, Android, Smart Glasses, Unity Package	x	✓	✓	✓	✓	✓
AR-Media	Android, iOS, Unity Package	x	✓	✓	✓	✓	✓
ARCore	Android, iOS, Unity Package	x	✓	✓	✓	✓	✓

In general, AR SDK has similar features, but if we look deeper, each AR SDK has main differences and makes each SDK have specializations that differentiate it from other SDKs. For example, there are some SDKs that have advantages in tracking, but other SDKs excel in recognizing objects. The main feature advantage of all the SDKs studied in this research is their tracking system. Tracking can be done in various ways and each solution offered has its own advantages and disadvantages in the AR experience to be created. There are four main geographic characteristics as seen in Fig. 2 below.

The explanation of Fig. 2 above is as follows:

1) Plane tracking is the localization of one or both ny of the translational offset (X, Y, Z) with rotational orientation (roll, pitch, yaw) in an object with respect to the origin. In AR, the point of origin is usually a mobile device with an embedded camera and almost all AR SDKs have plane tracking although individual results vary.

2) SLAM typically uses Apple ARKIT and Google ARCore as AR SDKs that perform marker less tracking.

3) A common example of face tracking technology is facing tracking with Snapchat AR lenses which uses algorithms to accurately track a user's face. Apart from tracking faces, this technology can also add digital makeup such as eye shadow or lipstick. For game creation, players can become avatars. Face tracking AR SDKs include Vuforia, DeepAR, and Aurasma.

4) Object recognition allows the AR system to identify objects in the real world. This process is still in development but can already display digital information about objects into the field of view and penetrate various areas of life such as education, manufacturing, construction, and design as well as health care.

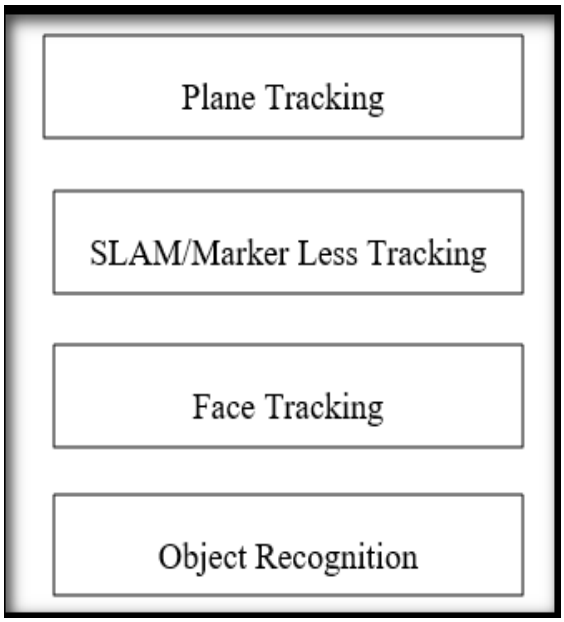

Fig. 2. AR SDKs and Tracking.

V. Result Discussion

Based on a comparative analysis of the features and virtual elements available for application development with the AR SDK, researcher suggests that the main functions of the AR SDK where to be able to offer AR application Editing Platform and facilitate software creation without requiring knowledge of algorithms. Besides that, it is possible to establish some general observations regarding the benefits and limitations of the AR SDK in this study as shown in Table II.

TABLE II. Analysis of Advantages and Limitations of Augmented Reality SDK

	Advantages	Limitations
ARToolKit	- These tools can create AR applications for iPhone and iPad. - ARKit helps developers develop AR applications that can support two devices to share the same virtual item thereby making the AR experience more engaging.	- In less accurate tracking even when the camera and markers are stationary (It does not support location-based). - Free access to AR Library but its development documentation is quite limited.
RealityKit	- High-performance 3D simulation and rendering experiences.	- No Concave Models - No Transparency or Opacity - No Videos - No Shaders
Aurasma	- Allows the association of touching actions on the screen, to start and end the app and after a determined amount of time. - Doesn't required the knowledge to implement algorithms.	- The lack of a control group with which to compare the participants fidelity of videos.
BlippAR	- No coding skills are required. This tool is free for educational use for the next 3 months. - Allows detection of markers and entities. - Allows for a reasonable amount of graphical rendering and animation. - Supports 3D markers for standard shapes.	- Not support marker less AR, though this will be supported soon. - Not support real-time shadows for rendering at present; this will need to be 'faked' by the content creator
CraftAR	- This SDK is most used by iOS apps in the Magazines & Newspapers genre, followed by the Book genre. - Doesn't required the knowledge to implement algorithms.	- Expensive and must be updated to recognize more targets or produce different behaviour.
EasyAR	- EasyAR is an SDK that lives up to its name. The features are simple, easy to use, and efficient. The functions of this SDK are quite advanced according to the needs of AR developers, including hard decoding, dynamic target recognition loading, screen recording functions, and a superior function, namely the recognition of more than 1000 local targets.	- Not free, pricing and payment details are listed on the EasyAR SDK product page. A free trial for EasyAR SDK Pro is provided. Each application will be given a limited time in the trial period.
Kudan	- Kudan is faster than other frameworks. This tool helps mobile AR applications to map multi-polygon models and import 3D models from any of the modelling software packages. - For the number of image recognition is not limited and requires less memory to store files on the device.	- This framework manual is brief and requires additional information. - Limited built-in functionality without direct access to OpenGL.
LayAR	- Offer interactive interactions to users in the context of a brand. Instead of instructing users to download the Screen App, users can bring LayAR interactivity directly into the app without needing to code everything themselves.	- SDK screen is NOT free. A 30-day Trial Period to play with the SDK before proceeding with purchases. But during this trial period users can use the SDK without any restrictions.
PixLive	- Multi-directional recognition and faster synchronization. - Doesn't required the knowledge to implement algorithms.	- Does not provide marker less and offline recognition.
Vuforia	- Enable to maintain tracking even when the target is out of view and view them from greater distance. - Cloud database allows storing thousands of image targets.	- The downside of the Vuforia SDK for Android is that the database is limited; it can only support 100 target images and does not feature any utility functions for loading 3D models, making it difficult for AR developers to create image formats.
Wikitude	- AR Content can be programmed using basic HTML5, JavaScript and CSS. - Enables the use of media such as images, video and 3D models. Allows the insertion and edition of text and buttons for social media. - Doesn't required the knowledge to implement algorithms.	- The SDK component could be a bit heavy, in terms of size. - Tracking of object sometimes was getting reset.
Metaio	- Powerful 3D rendering engine with capability load 3D model of .obj format. - No limit on number of trackable objects depends on device memory.	- Rendering 3D objects is very difficult using this SDK, and it is not easy to carry out developments related to the size of the model to be created.
D'Fusion	- To create high-quality 3D content, this SDK makes it easy to create several different 3D object formats. - Provide encrypted media to prevent privacy or tampering risks. - More than 300 parameters in advanced functionality are available to meet your needs with this graphical configuration tool for object recognition and tracking.	- Video file supported but audio associated with video can't be played.
Armedia	- Depth camera calibration provided which created more immersive experience	- Doesn't support all type of textures for 3D objects.
ARCore	- Its advantages are in motion capture, environmental perception, and light source perception.	- Sometimes it is difficult to scan big virtual object.

VI. CONCLUSION

From the results of the analysis and comparison of features in the AR SDK and virtual elements that have been carried out, the researchers suggest that the main function of the AR SDK is that it can be a platform for editing AR applications and makes it easy to create AR applications without needing to know algorithms or have knowledge of algorithms. The main attributes and supporting platforms were also examined in this study so that they could provide developers especially for the beginners with AR application knowledge. The results of this study showed that the main functions of the AR SDK were to be able to 1) offer an AR application Editing Platform and 2) facilitate software creation without requiring knowledge of algorithms. Developers and especially AR beginners do not need to write any code for the algorithm. These two functions could be in Aurasma, BlippAR, CraftAR, LayAR, PixLive, and Wikitude.

VII. SUGGESTION

Regarding the future perspective, this paper suggests conducting more investigations of the framework, AR functionality and features which required in AR development.

Automatic Extractive Summarization using GAN Boosted by DistilBERT Word Embedding and Transductive Learning

Dongliang Li*, Youyou Li, Zhigang ZHANG
College of Artificial Intelligence, Jiaozuo University, Jiaozuo, 454000, China

***Abstract*—Text summarization is crucial in diverse fields such as engineering and healthcare, greatly enhancing time and cost efficiency. This study introduces an innovative extractive text summarization approach utilizing a Generative Adversarial Network (GAN), Transductive Long Short-Term Memory (TLSTM), and DistilBERT word embedding. DistilBERT, a streamlined BERT variant, offers significant size reduction (approximately 40%), while maintaining 97% of language comprehension capabilities and achieving a 60% speed increase. These benefits are realized through knowledge distillation during pre-training. Our methodology uses GANs, consisting of the generator and discriminator networks, built primarily using TLSTM - an expert at decoding temporal nuances in timeseries prediction. For more effective model fitting, transductive learning is employed, assigning higher weights to samples nearer to the test point. The generator evaluates the probability of each sentence for inclusion in the summary, and the discriminator critically examines the generated summary. This reciprocal relationship fosters a dynamic iterative process, generating top-tier summaries. To train the discriminator efficiently, a unique loss function is proposed, incorporating multiple factors such as the generator's output, actual document summaries, and artificially created summaries. This strategy motivates the generator to experiment with diverse sentence combinations, generating summaries that meet high-quality and coherence standards. Our model's effectiveness was tested on the widely accepted CNN/Daily Mail dataset, a benchmark for summarization tasks. According to the ROUGE metric, our experiments demonstrate that our model outperforms existing models in terms of summarization quality and efficiency.**

***Keywords*—Extractive text summarization; generative adversarial network; transductive learning; long short-term memory; DistilBERT**

I. Introduction

In the digital era, there is an overwhelming amount of online information. Manually extracting insights from this vast data is challenging. Automatic Text Summarization (ATS) is a solution that extracts essential details efficiently. Summarization involves creating a concise version of text from one or multiple sources, capturing the main information for specific users or purposes [1].

There is a plethora of approaches for extractive summarization. Some lean on machine learning techniques such as support vector machines [2] and clustering [3], optimization algorithms [4-7], while others adopt graph-based strategies [8], where sentences are portrayed as graphs, the nodes represent words, and edges signify the relationship between those words. As deep learning evolves, it is becoming more dominant in natural language processing, overshadowing conventional machine learning techniques. Thanks to its complex architecture, deep learning autonomously discerns word, sentence, or document attributes. However, even with numerous deep learning-driven summarization techniques, many grapple with extractive summarization intricacies. Crucial aspects of summarization, like sentence evaluation and choice, often present hurdles. Many existing methods tend to be overly selective, meaning after picking a valuable sentence, they might overlook its relevance in subsequent selections, reducing the overall efficacy of the summary.

Generative Adversarial Networks (GANs) are advanced machine learning tools that consist of a generator and a discriminator. The generator strives to create lifelike outcomes, such as images or text. In contrast, the discriminator tries to discern between genuine and fabricated content [9]. GANs hold potential for optimizing sentence selection in extractive text summarization. When generating a summary, they evaluate the entirety of the document, giving the generator a holistic grasp. Such understanding helps the generator pick subsequent sentences more judiciously, recalling previously identified important sentences and ensuring better summary quality. Adversarial Training significantly boosts the GANs' capability to address the issue of biased sentence selection. The discriminator offers critical insights into the generator about the cohesiveness and quality of the formed summary, allowing the generator to refine its methods. This results in selecting impactful sentences that also harmonize with earlier pivotal sentences. Thanks to adversarial training, GANs adeptly address the risk of omitting key sentences, delivering more unified summaries.

LSTM has been fundamental in numerous sequence-oriented tasks, such as video categorization, machine interpretation, and text summarization [10, 11]. However, standard LSTMs, rooted in inductive learning, shape a universal model from all training datasets. This can sometimes neglect nuances within the data, potentially hampering the adaptability of the model. TLSTM introduces a solution by incorporating a transductive learning method. This approach emphasizes performance improvement around novel data points, accentuating localized nuances. In the structure of TLSTM, this is accomplished through a tailored weighting system, adjusting weights concerning their closeness to the assessment data. Closest data points to the test get a higher

weightage, ensuring optimal performance in those areas. By combining the strengths of LSTM with the adaptability of transductive learning, TLSTM offers a more tailored time-series prediction method. It captures long-term dependencies while addressing overlooked data nuances, making it suitable for intricate time-series challenges [12].

The BERT model in [13] is a notable NLP tool with many parameters. Larger models, while effective, increase computational and environmental costs. DistilBERT [14], a streamlined transformer model, is a distilled version of BERT. It functions 60% swifter and requires 40% less parameters compared to BERT, as evidenced in the GLUE benchmark. In comparison with predecessors like BERT and RoBERTa [15], DistilBERT is a more streamlined variant.

The paper presents an extractive summarizer, founded on DistilBERT word embedding, GAN, and attention mechanism-based TLSTM. GANs are made up of two generator and discriminator components that compete in a process. In this context, the generator's goal is to rate each sentence of the document, while the goal of the discriminator is to distinguish the real from the fake summary, which enhances the performance of the generator. In a non-greedy way, the generator determines the possibility of the presence of sentences in summary at once. The contributions of this article are as follows:

- Using GAN for summarization, the generator improves based on feedback from the discriminator, incorporating both real and fake summaries.
- We use TLSTM to design the generator and discriminator, enhancing accuracy in text summarization.
- By introducing varied noise levels during training and testing, we produce diverse summaries, with a voting system determining the final summary.
- Our proposed model utilizes DistilBERT word embedding to automatically learn and extract complex and meaningful text representations from the input data.

The remainder of the paper is structured as following. Section II covers some related works, while Section III introduces our proposed text summarization method. Section IV presents experimental results, and Section V concludes the paper.

II. Related Works

Abstractive summarization methods, a notable strategy in NLP, aim to produce summaries that don't merely pick and reorganize existing sentences or phrases [16]. These techniques endeavor to grasp the essence of the text and formulate new, succinct, and cohesive statements that reflect the main ideas of the original content [17]. Abstractive summarization seeks to produce summaries with a human-like touch, capturing the heart of the source material without restricting itself to direct extractions. By discerning the core semantics, connections, and subtleties of the document, abstractive methods can potentially craft summaries that are richer, more concise, and linguistically smooth. To realize this, such techniques frequently utilize advanced tools like neural networks and natural language generation models [18, 19]. These models employ methods such as sequence-to-sequence frameworks, attention systems, and reinforcement learning to craft summaries that hold semantic significance and flow smoothly. By grasping the underlying context and essence of the text, abstractive summarization models can reword and restructure the original material, introducing fresh phrases, reshaping statements, and even creating unique expressions to highlight the primary details. This capability to transcend basic extraction allows abstractive summarization to deliver shorter summaries that still encapsulate the primary intent of the original text. Yet, this approach comes with its set of challenges. The crafted summaries must walk the fine line of being brief yet informative, ensuring logical flow and upholding the truthfulness of the source. Moreover, abstractive techniques often demand vast training data and intricate models to effectively decipher the subtleties and variances in natural language [20].

Numerous extractive summarization methods, spanning graph-based to deep learning techniques, have been explored [21, 22]. LeClair et al. [23] delved into code summarization advancements via Graph Neural Network (GNN) application, enhancing summary insightfulness. Zhong et al. [24] derived word features from documents and then determined sentence scores based on word scores. Yousefi et al. [25] scored sentences using the cosine similarity between them and their topics. Cao et al. [26] employed recurrent neural networks for sentence ranking, treating sentences as trees with words as leaves, and deriving sentence scores from a non-linear procedure. Rosca et al. [27] utilized reinforcement learning for summary creation, where sentence coherence was the reward. The policy was crafted as a multilayer perceptron assigning scores to sentences. Abdi et al. [28] showcased a deep learning methodology for creating opinion-focused multi-document summaries. This involved components like sentiment analysis embedding space (SAS), text summarization embedding spaces (TSS), and an opinion summarizer module (OSM) [29]. The SAS uses an RNN with LSTM to capture sequential data, and the TSS applies linguistic knowledge for improved word embeddings. Fitrianah and Jauhari [30] employed LSTM and GRU models in their approach for ETS summarization, leveraging feature engineering techniques. Hin et al. [31] presented LineVD, a deep learning model that identifies vulnerabilities using a Graph Neural Network (GNN) and notably omits vulnerability status in its analysis. Nallapati et al. [32] introduced Summarunner, an RNN-based model, where two RNN layers embed words and sentences, followed by logistic regression for sentence classification. Kobayashi et al. [33] proposed a method centered on embeddings and document-level similarities, representing words through embeddings, treating sentences as word collections, and documents as sentence collections. Chen et al. [34] introduced a deep reinforcement learning technique and an encoder-extractor framework for single-document summarization, extracting sentences post key feature selection [35]. Mikael et al. [36] leveraged continuous vector representations in RNN and achieved top results on the Opinosis dataset. Yin et al. [37] devised a unique sentence selection strategy ensuring a balance

between sentence significance and diversity after developing an unsupervised CNN for phrase representation learning.

In recent times, there has been a transformative shift in the realm of natural language processing, largely attributed to BERT. BERT, a model based on the transformer architecture, has brought about a significant evolution in the domain of NLP by introducing contextual comprehension of words and sentences. In contrast to prior models that processed sentences in a linear manner, BERT takes into account both antecedent and subsequent words, thereby capturing a deeper insight into contextual interdependencies present within the text. This bidirectional approach empowers BERT to construct word representations that carry more profound significance, accurately reflecting their contextual applications. The integration of BERT has yielded notable enhancements across diverse NLP tasks, encompassing aspects such as text classification, identification of named entities, evaluation of sentiment, and particularly, condensing texts. By incorporating BERT into frameworks for text summarization, researchers have achieved summaries that are not only more precise but also informed by the context. BERT's proficiency in grasping linguistic intricacies and generating comprehensive portrayals has led to a paradigm shift in the way we handle and comprehend natural languages. This has, in turn, paved the way for the development of more intricate and efficient NLP applications. As influence of the BERT model continues to stimulate progress in language modeling and comprehension, it carries immense potential for further reshaping the landscape of natural language processing. Koto et al. [38] introduced techniques for probing discourse at the document level, which were utilized to detect connections between documents and appraise the performance of pre-trained language models. They employed BERT, BART, and RoBERTa as model choices to assess the outcomes derived from their assessment. In a separate study, Abdel-Salam and Rafea [39] conducted an evaluation of diverse variations of BERT-based models intended for text summarization. They introduced an unsupervised strategy for creating summaries from multiple documents, leveraging the transfer learning capabilities of the BERT sentence embedding model. The researchers adjusted the BERT model through supervised intermediate tasks extracted from GLUE benchmark datasets. This adjustment included the use of both single-task and multi-task fine-tuning methodologies to enhance the learning of sentence representations. In a different context, Srikanth et al. [40] harnessed the potential of the BERT model to produce extractive summaries through the clustering of sentence embeddings using K-means clustering. Alongside this, they introduced a dynamic approach to ascertain the suitable quantity of sentences to be chosen from the clusters.

A considerable portion of prior deep learning methods face a constraint during sentence selection. They often exhibit an inclination to excessively prioritize the selection of the sentence with the highest score, neglecting its pertinence within the context of subsequent sentence selection. As a result, this methodology contributes to a reduction in the overall excellence of the produced summary.

III. The Proposed Method

To tackle our research challenge, we have combined the strengths of DistilBERT for word embeddings and TLSTM for analyzing temporal data.

DistilBERT, a streamlined variant of BERT, excels in converting words into pertinent vectors. It mirrors BERT's bidirectional transformer architecture but is more efficient due to fewer layers, resulting in quicker computations. Notably, its training employs dynamic rather than static masking.

TLSTM excels at handling sequential data by grasping both short and long-term patterns. Its unique gating mechanism modulates data retention and recall over time.

We have also harnessed GANs for text summarization to boost extractive techniques and combat issues like greediness. Our GAN setup includes a generator, which creates synthetic data, and a discriminator that distinguishes between authentic and fabricated content. We've further enhanced our model by conditioning it on sentence features, allowing more accurate and relevant outputs. Integrating noise into the document representation lets our generator craft varied but consistently high-quality summaries.

In the following, the details of each component are explained.

A. DistilBERT-based word Embedding

The objective of word embedding is to transform words into vectors for utilization in deep learning algorithms. Word embedding has demonstrated its credibility in generating reliable vectors for words, drawing from the surrounding context. Diverse methodologies for word embedding have been introduced, each designed to produce substantial representations suitable for deep models. These approaches encompass Skip-gram [41] and matrix factorization techniques such as GloVe [42].

BERT stands as a profound bidirectional language model, capable of furnishing contextual portrayals. It is frequently subjected to fine-tuning through a hefty neural network layer tailored to various classification undertakings. Its training data encompasses extensive datasets such as Wikipedia. The initial, broadly applicable significance acquired during pre-training can be effectively harnessed to capture context- or issue-specific nuances through the process of fine-tuning, also readying it for classification purposes. BERT adopts a bidirectional transformer architecture, wherein representations are concurrently influenced by both preceding and subsequent context, spanning all tiers. This distinctive characteristic distinguishes BERT from models like GloVe and Word2Vec, which offer embeddings in a singular direction that disregards the contextual intricacies.

DistilBERT integrates the concept of information distillation, wherein a condensed system, the student, learns from a more expansive system's patterns, labeled as the teacher. The student system's learning curve is shaped by a specific loss criterion, reflecting the teacher's probability benchmarks:

$$L_{ce} = \sum_i t_i * \log\ (s_i) \quad (1)$$

Here, t_i and s_i represent the probabilities obtained from the teacher and student techniques, respectively. DistilBERT employs a structure akin to that of BERT, yet with fewer layers. DistilBERT exhibits a 40% reduction in width, operates with 60% enhanced speed, while still retaining 97% of the performance capabilities inherent to BERT. The core aim of the distillation process lies in approximating the comprehensive output distributions of BERT by means of a more condensed model, exemplified by DistilBERT. Consequently, the quantity of layers within the BERT architecture has been curtailed from 12 to 6. The pre-trained model encompasses a total of 66 million parameters, a comparison to the 110 million presents in the BERT model. Notably, DistilBERT's training duration amounts to 3.5 GPU days (using 8 × V100), in contrast to BERT's 12 GPU days (also with 8 × V100). DistilBERT, much like BERT, undergoes training using a dataset of 16 GB sourced from English Wikipedia, specifically the Toronto books corpus. During the training process of DistilBERT, a substantial batch size is employed in conjunction with gradient accumulation. This methodology entails the local amalgamation of gradients from multiple mini-batches prior to the modification of trainable parameters in each phase. Additionally, the training regimen of DistilBERT does not incorporate objectives such as next-sentence prediction and segment embedding learning, which are observed in BERT training. Moreover, the dynamic masking technique employed during inference replaces the static masking mechanism used in the BERT model.

B. TLSTM

LSTM has risen in prominence as a widely embraced and potent method applied to sequence data across diverse domains. Its inherent aptitude to apprehend extended temporal relationships and manage sequential information renders it exceptionally fitting for tasks involving time series analysis and prognosis [43]. An eminent virtue of LSTM lies in its capacity to unravel intricate temporal structures and seize the fluid dynamics of systems that undergo time-driven fluctuations. By dissecting the inherent motifs and inclinations embedded within the data, LSTM architectures can unveil nuanced interconnections that may not be readily discerned using established statistical or machine learning methodologies.

LSTM networks possess the capability to grapple with input sequences of varying lengths, thereby endowing them with adaptability for scenarios involving sequence data wherein the historical data's length may fluctuate across instances [44]. This adaptative trait proves invaluable when confronted with diverse systems or equipment beset with differing operational states or maintenance schedules. Furthermore, LSTM's prowess in dealing with both brief and extensive dependencies within sequence data sets it apart. Traditional methods like autoregressive models or moving average approaches might falter in capturing prolonged trends or subtle intricacies concealed within the data fabric [45]. In contrast, LSTM's memory cells empower it to retain information over extended intervals, thereby empowering the model to apprehend dependencies spanning multiple time increments [46, 47].

The groundbreaking concept of LSTM was originally developed by Hochreiter and Schmidhuber [48]. From its genesis, an array of methods aimed at enhancing its performance have been introduced [49]. In this research, we put into practice the well-accepted architecture advanced by Gers et al. [50], a blueprint that has been leveraged in a multitude of academic endeavors, including [51, 52]. The LSTM mechanism revolves around a gating system which regulates how information is retained over time, skillfully overseeing how long it is stored and determining the appropriate moment for its access through the memory cell. This paper places particular emphasis on the scrutiny of the LSTM cell, as expounded in Graves' work [51]. LSTM employs three gates to optimize information processing. Let i_t, f_t, o_t, c_t, and h_t symbolize the input gate, forget gate, output gate, memory cell, and hidden state at the sequence time t, respectively. When x_t represents the system's input at the same time, the architecture of the LSTM cell can be described as follows [51, 53]:

$$i_t = \sigma(W_{xi}x_t + W_{hi}h_{t-1} + W_{ci}c_{t-1} + b_i) \quad (2)$$

$$f_t = \sigma\left(W_{xf}x_t + W_{hf}h_{t-1} + W_{cf}c_{t-1} + b_f\right) \quad (3)$$

$$c_t = f_t c_{t-1} + i_t tanh(W_{xc}x_t + W_{hc}h_{t-1} + b_c) \quad (4)$$

$$o_t = \sigma(W_{xo}x_t + W_{ho}h_{t-1} + W_{co}c_t + b_o) \quad (5)$$

$$h_t = o_t tanh(c_t) \quad (6)$$

The sigmoid function, σ(.), acts as an activation function. The logistic sigmoid and hyperbolic tangent are applied element-wise. Weight matrices, W_{xk} and W_{ck}, are linked to the input, forget, output gates, and memory cell. The number of neurons in these gates is preset, with Eq. (2) to Eq. (6) affecting each neuron separately. If n represents the neuron count, then $\{i_t, f_t, c_t, o_t, h_t\}$ are in $R^{n\times 1}$. In discussing the LSTM model, we use w_{lstm} and b_{lstm} for weights and biases. The LSTM equations are presented as follows:

$$\begin{cases} c_t = f(c_{t-1}, h_{t-1}, x_t; w_{lstm}, b_{lstm}) \\ h_t = g(h_{t-1}, c_{t-1}, x_t; w_{lstm}, b_{lstm} \end{cases} \quad (7)$$

Considering Eq. (2) through (6), we derive $g(\cdot)$ and $f(\cdot)$. Assuming $z(\eta)$ represents an unseen series, the state space depiction of the T-LSTM is expressed as:

$$\begin{cases} c_{t,\eta} = f(c_{t-1,\eta}, h_{t-1,\eta}, x_t; w_{lstm,\eta}, b_{lstm,\eta}) \\ h_{t,\eta} = g(h_{t-1,\eta}, c_{t-1,\eta}, x_t; w_{lstm,\eta}, b_{lstm,\eta} \end{cases} \quad (8)$$

In Eq. (8), the model structure markedly deviates from what is outlined in Eq. (7). While in Eq. (7) the model parameters remain stable irrespective of the evaluation point, in Eq. (8) they are molded by the feature vector of that specific evaluation point. The subscript η is introduced to underscore the variation in model parameters resulting from the inclusion of data point z(η). It is imperative to underscore that the evaluation label is presumed to be undisclosed. Throughout the training phase, the primary purpose of the evaluation point is to ascertain the relevance of training data points by examining the affinity between their feature vectors and the vector of the evaluation point.

C. Model

In this research, we use adversarial generating networks for extractive summarization. We employ this network to improve the problems of previous methods, including greed. We will first have a description of this network, and then the proposed model is presented.

Generative adversarial networks (GANs) were first proposed by Goodfellow et al. [54]. These networks consist of two separate networks that are similarly trained: the generator and discriminator networks. The purpose of the generator is to produce data such as images, text, etc., which are structurally similar to real data but are fake. On the other hand, the task of the discriminator network is to strengthen the generator.

These two networks play a two-player min-max game with a value function $V(D, G)$ as follows:

$$min_G\, max_D\, V\,(D.G) = E_{x\sim p_{data}(x)}[\log(D(x))]+ E_{z\sim p_z(z)}[log(1 - D(G(z)))] \quad (9)$$

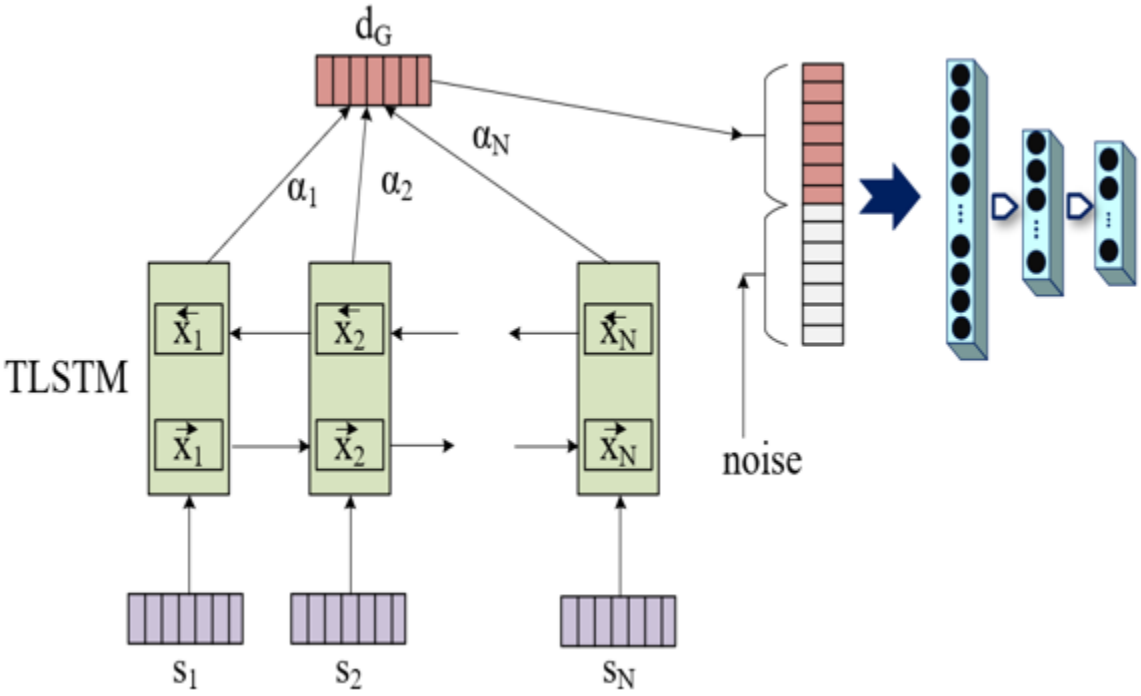

Fig. 1. Generator architecture.

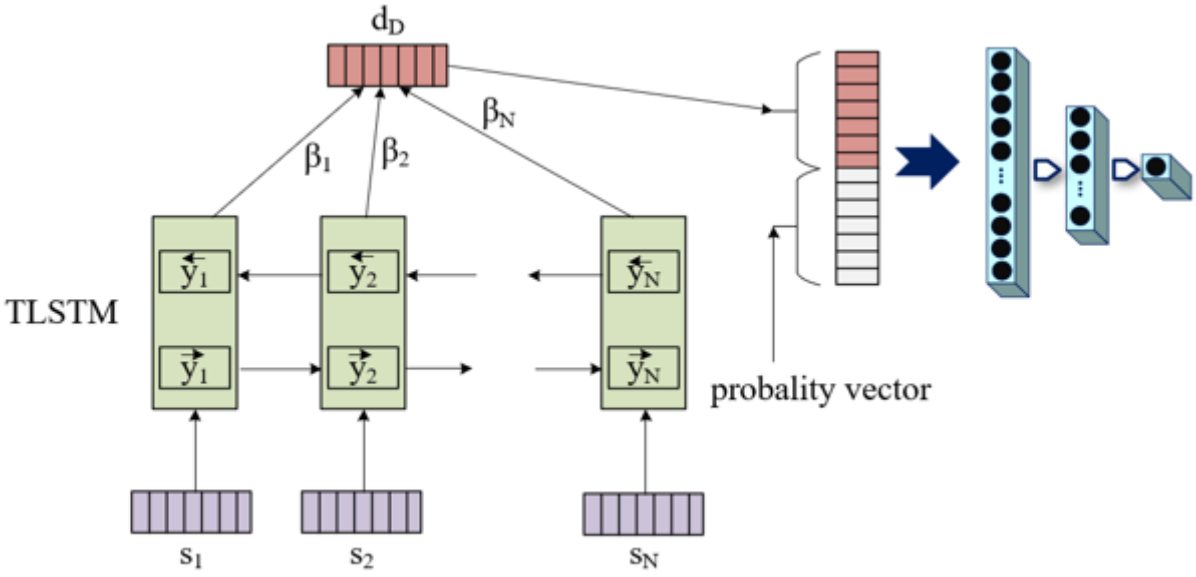

Fig. 2. Discriminator architecture.

Where x and z are input data and noise, respectively. G and D mean the generator and discriminator, respectively. $p_{data}(x)$ and $p_z(z)$ represent the input data distribution and the noise distribution, respectively. E is mathematical expectation.

Generative adversarial networks can be extended to a conditional model If condition y is added to the generator and discriminator input. The value function, in this case, changes as follows:

$$min_G\, max_D\, V\,(D.G) = E_{x\sim p_{data}(x)}[\log(D(x|\boldsymbol{y}))]+ E_{z\sim p_z(z)}[log(1-D(G(z|\boldsymbol{y})))] \quad (10)$$

The proposed generator and discriminator model are shown in Fig. 1 and Fig. 2, respectively. We use sentence features as a condition in the generator and discriminator. Let $D = \{s_1.s_2 \ldots .s_N\}$ represents the document, where the $s_i \in \mathbb{R}^d$ is the extracted features of the i-th sentence. N is the length of document D, which is equal to the number of restricted sentences in each document. The attention mechanism calculates the representation vector of the document in the generator and the discriminator according to the following equations:

$$d_G = \sum_{i=1}^{N} \alpha_i\, [\overleftarrow{x}_i.\vec{x}_i] \quad (11)$$

$$d_D = \sum_{i=1}^{N} \beta_i\, [\overleftarrow{y}_i.\vec{y}_i] \quad (12)$$

where, $\overleftarrow{x}_i \in \mathbb{R}^{d_1}$, $\overleftarrow{x}_i \in \mathbb{R}^{d_1}$, $\overleftarrow{y}_i \in \mathbb{R}^{d_2}$, $\vec{y}_i \in \mathbb{R}^{d_2}$ are the output of step i in BLSTM. α_i and β_i are the coefficients of attention for the i-th sentence in the generator and the discriminator, respectively, which are formulated as follows:

$$\alpha_i = \frac{e^{u_i}}{\sum_{i=1}^{N} e^{u_i}} \quad (13)$$

$$\beta_i = \frac{e^{v_i}}{\sum_{i=1}^{N} e^{v_i}} \quad (14)$$

$$u_i = tanh(W_u[\overleftarrow{x}_i.\vec{x}_i] + b_u) \quad (15)$$

$$v_i = tanh(W_v[\overleftarrow{y}_i.\vec{y}_i] + b_v) \quad (16)$$

where, $W_u \in \mathbb{R}^{2.d_1}.b_v \in \mathbb{R}$, $W_v \in \mathbb{R}^{2.d_2}$, and $b_v \in \mathbb{R}$ are the parameters of the attention mechanism for documents.

In Fig. 1, the document's representation vector is linked with the noise vector, entering a feed-forward neural network. The final layer of this network computes the likelihood of each sentence's presence. The introduction of noise prompts the generator to generate diverse outputs. Each document undergoes multiple iterations of summarization by the generator, with varied noises, leading to distinct outputs. The generator aims to create varied yet similarly high-quality summaries for each document. This process empowers the generator to identify diverse sentence combinations suitable for crafting the summary. Consequently, sentences that might lack individual significance for the summary can contribute to a quality summary when positioned alongside other sentences.

Within the discriminator network, the probability vector of sentences interfaces with the document's representation vector (see Fig. 2). In this context, the probability vector of sentences represents the count of sentences within a document, and each element assumes a value of either zero or one.

1) Real summary: In a typical GAN framework, the output of the generator functions as synthetic data for training the discriminator. Moreover, an authentic target is garnered for each individual sample. In this study, to acquaint the discriminator with quality summaries, more than one summary is drawn from each document, displaying similar levels of quality. Simultaneously, several summaries of inferior quality are generated for each document. Given that actual summaries are text and unsuitable as target data, a method is required to represent the presence or absence of each sentence in a summary as a numerical value. To serve this purpose, a vector with N elements is designated for every document, where N signifies the sentence count. Each element of this vector holds a value of either zero or one, with a value of one indicating the inclusion of the sentence in the summary. This vector is constructed employing a greedy approach as delineated in Fig. 3. Initially, a vector of length N with M ones is generated, where M corresponds to the sentences within the summary. The ones are distributed randomly throughout the vector. Sentences associated with a value of one are then concatenated within this vector to compose a summary, and the quality is assessed using the ROUGE metric.

Subsequently, a one is selected at random and transformed into zero, while a randomly selected zero is converted to one. The ROUGE score is recalculated, and if it surpasses the prior value, the alteration is retained. This sequence is reiterated Itr times, culminating in the selection of the most favorable vector throughout the process, which is then designated as the outcome. It is important to note that for the generation of any genuine target, the algorithm must be restarted from the beginning. The procedure for devising a synthetic target closely mirrors that of a real target, with the exception that if the ROUGE score is lower, the vector supersedes the previous one. The length of all documents is confined to N sentences, with longer documents being truncated to N sentences and shorter ones being padded with zeros.

2) Loss function: The Loss function is calculated based on the discriminator output for the generator as follows:

$$Loss_G = E_{i\sim Dataset}\left[E_{z\sim p_{z(z)}}\left[log\left(1-D\big(G(z|y_i)\big)\right)\right]\right] \quad (17)$$

where, *Dataset* is a set of documents, y_i is features of sentences in document i, and E is the mathematical expectation. The Loss function for the discriminator is computed based on the generator output, real and fake summaries as follows:

$$Loss_D = E_{i\sim Dataset}[\,E_{z\sim p_{z(z)}}[log(1-D(G(z|y_i)|\,y_i))] + E_{k\sim p_{Fake_i}}\big[log\big(1-D(k|y_i)\big)\big] + E_{k\sim p_{Real_i}}[log(D(l|y_i))]] \quad (18)$$

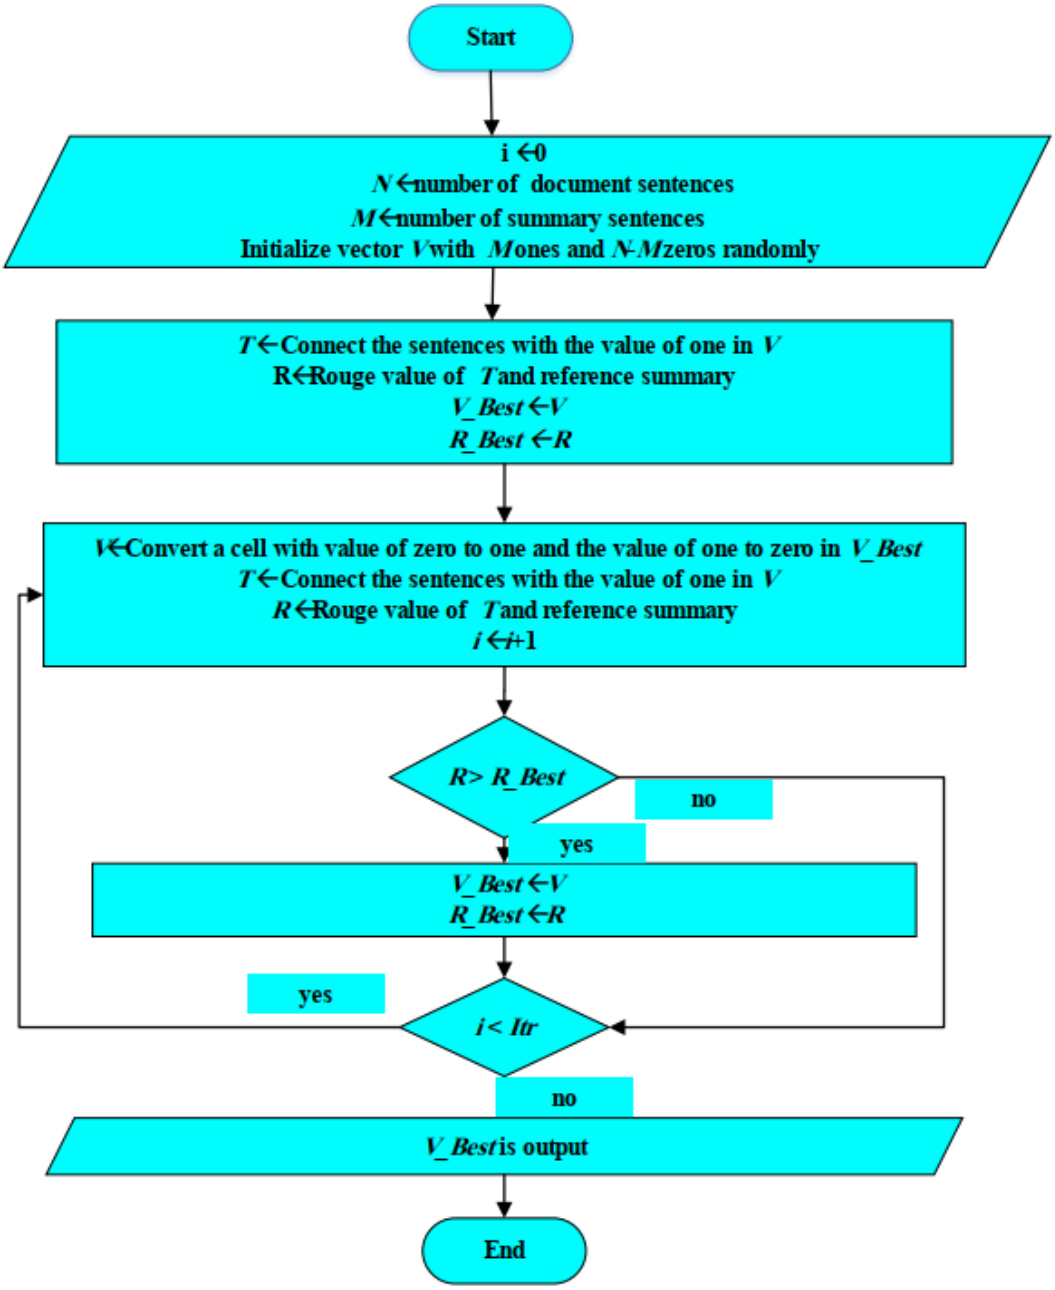

Fig. 3. Generate a real summary for the document.

where, p_{Real_i} and p_{Fake_i} show the distribution of real and fake summaries for the document *i*. Eq. (18) forces the discriminator to learn a set of high-quality and low-quality summaries. On the other hand, be sensitive to the summaries produced by the generator and force the generator to produce a high-quality summary.

IV. Empirical Evaluation

A. Dataset

For our assessments, we employ a familiar dataset known as CNN/Daily Mail. This dataset amalgamates two distinct datasets devised for comprehension, extractive, and abstractive tasks, and it has garnered notable attention from researchers in the domain of automated summarization in recent years. The CNN/Daily Mail dataset is comprised of 287,226 documents earmarked for training, 13,368 for validation, and 11,490 for testing. Within the training data, the average document encompasses approximately 28 sentences. On average, each document's reference summary spans 3 to 4 sentences, and the mean word count per document in the training dataset is approximately 802 words [34]. You can delve into additional particulars outlined in Table I. This dataset exists in two versions: the first version features the replacement of all entities with specific words, while the second version retains the original data. For our model, we choose to adopt the second version of the dataset.

TABLE I. STATISTICS OF THE CNN / DAILY MAIL DATASET

	Train	Validation	Test
Pairs of data	287,113	13,368	11,490
Article length	749	769	778
Summary Length	55	61	58

TABLE II. THE PARAMETERS OF THE MODEL

Parameter	value
batch size	128
embedding dim	60
max sentence length	100
real summary per document	40
fake summary per document	40
activation fun (tlstm & dense)	relu
dense hidden layer	8

B. Detail of Model

For the execution of this study, the Python programming language and the PyTorch library have been harnessed for implementation purposes. The Jupyter environment has been employed as the platform to execute project codes. Additionally, the NLTK library, an instrumental component, has been utilized. This particular library furnishes an assortment of classes and methods dedicated to processing natural language within the Python context. Its capabilities span a broad spectrum of natural language processing tasks.

The model architecture incorporates a dual-layer bidirectional TLSTM structure. Within generative adversarial networks, the discriminator tends to converge at a quicker rate than the generator, often impeding the generator's convergence. In light of this, we have designed a training strategy wherein the discriminator is trained once for every 15 iterations of generator training. Moreover, due to the interconnection of vectors within the two networks, we implement batch normalization prior to data entry into the feed-forward neural network. The parameter values are detailed in Table II.

C. Metrics

We employ the ROUGE (Recall-Oriented Understudy for Gisting Evaluation) package [55] as an evaluation metric in our experiments. This metric calculates the similarity between the generated summary and the reference summary by counting the number of common units. Rouge-n recall between an extracted summary and a reference summary is calculated as follows:

$$\text{Rouge-}n = \frac{\sum_{s \in \{ref\ sum\}} \sum gram_n \in s\ Count_{match}\ (gram_n))}{\sum_{s \in \{ref\ sum\}} \sum gram_n \in s\ Count\ (gram_n))} \quad (19)$$

where, n stands for the length of n-ngram, $Count_{match}\ (gram_n)$ is the maximum number of n- gram co-occurring in the extracted summary and the reference summary. Rouge-1 and Rouge-2 are special cases of Rouge-n in which n = 1 or n = 2. R-L calculates the length of the longest common subsequence between the reference summary and the extracted summary. Based on previous works, Rouge-1(R-1), Rouge-2(R-2) and, Rouge-L(R-L) are most widely used in summarization. For this reason, we use these three metrics in all our experiments.

D. Experimental Results

In the execution of our project, we utilized a Windows operating system that runs on 64-bits, accompanied by 64 GB of RAM and an integrated GPU. For the CNN/Daily Mail dataset, the optimal model emerged after running through 50 epochs. Remarkably, the entirety of our training duration spanned a mere four hours.

Our innovative approach was subjected to a comparative analysis against various methodologies. These included three methodologies rooted in graph algorithms: BGSumm [56], TextRank [57], and EdgeSumm [8]. Additionally, we compared against seven methodologies anchored in deep learning paradigms: SummaRunner [32], RENS with Coherence [58], SHANN [59], HSSAS [60], T5 [61], BART [62], and DeepSumm [63]. Lastly, a foundational model, TLSTM, was part of our comparison. It's noteworthy to mention that the TLSTM model is exclusively reliant on the generator component we devised. To visualize the assessment results for our system using the CNN/Daily Mail dataset, please refer to Table III.

TABLE III. NUMERICAL COMPARISON OF THE PROPOSED METHOD AND OTHER METHODS ON THE CNN / DAILY MAIL DATASET

Model	R-1	R-2	R-L
BGSumm	33.20	12.50	31.74
TextRank	32.16	11.10	29.21
EdgeSumm	34.26	13.10	32.90
DeepSumm	42.91	18.18	37.95
SummaRunner	39.65	16.26	35.39
RENS with Coherence	41.29	18.90	37.79
SHA-NN	35.46	14.74	33.26
HSSAS	42.32	17.81	37.65
T5	42.48	18.08	37.77
BART	36.51	15.14	31.26
TLSTM	26.46	8.48	6.25
Proposed	44.51	18.46	38.90

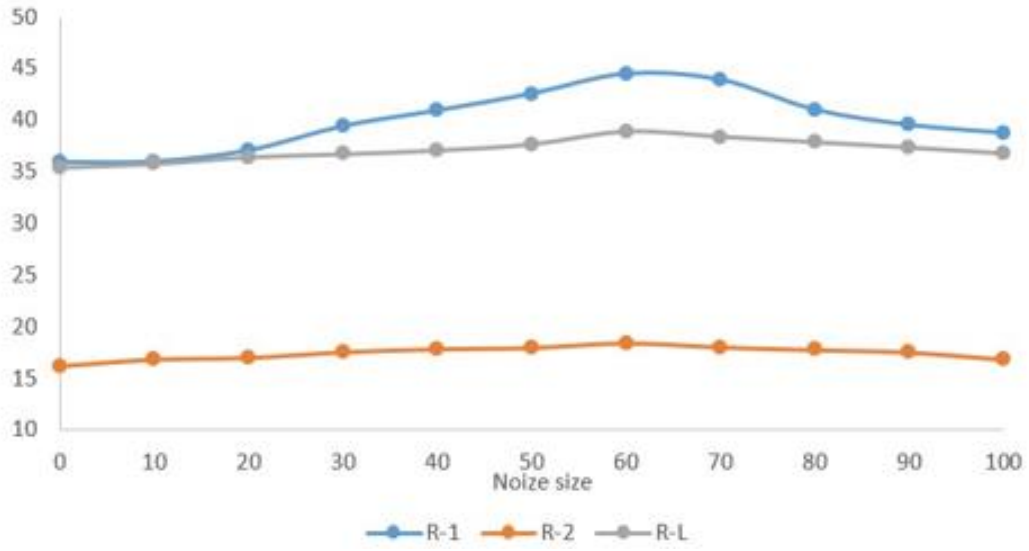

Fig. 4. Results of the proposed model for different noises on the CNN / Daily Mail dataset.

Drawing insights from the graph-centric models, the EdgeSumm model conspicuously outperformed its peers, inclusive of BGSumm, across all evaluated benchmarks. To quantify, EdgeSumm decreased errors by magnitudes of more than 33%, 32%, and 30% for the three primary metrics: R-1, R-2, and R-L, respectively. Intriguingly, even though BGSumm demonstrated its efficiency on a medical dataset, it couldn't replicate its performance for the CNN/Daily Mail dataset. Surpassing even the robust EdgeSumm model, our pioneering model showcased error enhancement rates of approximately 24.29%, 24.30%, and 25.41%. As many would anticipate, models anchored in deep learning exhibited greater efficacy than those rooted in graph algorithms. The RENS with Coherence approach, despite its integration of sentence coherence, didn't match the precision of our model. Among the pantheon of deep learning models, DeepSumm emerged as the frontrunner. However, even DeepSumm lagged behind our proposed model, registering weaker performance metrics of 25.28%, 25.39%, and 26.47%.

1) Explore noise: We undertook additional experimental trials to ascertain the impact of varying noise intensities on the generator's functionality. In these trials, we introduced noise of diverse magnitudes to the generator to observe its effect. The outcomes, specifically for metrics R-1, R-2, and R-L pertaining to the CNN/Daily Mail dataset, are graphically presented in Fig. 4. A noteworthy observation was that elevating the noise level to 60 improved the aforementioned metrics: R-1, R-2, and R-L. However, a declining trend in performance was evident when the noise level ranged between 60 and 100. From our analysis of this dataset, it appears that the optimal noise magnitude stands at 60. It is evident from the findings that the generator's efficiency is enhanced when noise is incorporated, with our proposed model displaying superior results in the presence of noise.

2) Word embedding: Word representations play a pivotal role in the realm of deep learning models. This is primarily because these models interpret input data as vectors; therefore, if there is any discrepancy or error in the embedding process, it could potentially misguide the model. In this research, we have employed the DistilBERT model for word embeddings, which is considered one of the latest advancements in this domain.

TABLE IV. RESULTS OF DIFFERENT WORD EMBEDDINGS ON THE MODEL

Model	R-1	R-2	R-L
One-Hot encoding	23.45	8.11	27.80
CBOW	35.86	12.01	30.80
Skip-gram	36.04	12.14	31.11
GloVe	39.30	15.26	35.39
FastText	40.14	16.98	36.89
BERT	43.40	17.33	37.44
DistilBERT	44.51	18.46	38.90

To rigorously assess the efficacy of various word embedding techniques in tandem with our model, we introduced five different embeddings for our evaluation: One-Hot encoding, CBOW, Skip-gram, GloVe, FastText, and the original BERT model [45]:

- One-Hot Encoding: This basic yet foundational technique is essential for translating categorical variables into a format that can be fed into deep learning models, thereby optimizing prediction and classification outcomes. The essence of this approach lies in representing each unique category with a distinct binary code, ensuring only one bit is "hot" or set to '1' for every class representation.
- CBOW and Skip-gram: These are sophisticated models that employ neural networks to associate words with their respective embedding vectors. Their operational methodologies might differ, but they share a common goal.
- GloVe: This unsupervised learning model taps into the aggregated co-occurrence data of global word pairs from a given corpus, providing a distinctive representation for words.
- FastText: Pioneering an evolution of the Skip-gram model, FastText takes a novel approach by encoding words as letter n-grams rather than representing them as unique vectors.

For a comprehensive understanding of our results, one should consult Table IV. It was anticipated, and the results confirmed, that One-Hot encoding lagged behind other embeddings, registering suboptimal performance. The improvement metrics for our proposed model using this method were approximately 62.70% (R-1), 9% (R-2), and 18% (R-L). Intriguingly, CBOW and Skip-gram, given their analogous architecture, exhibited similar performances, with both overshadowing the GloVe embedding. Among the lot, the BERT model emerged as the most competent word embedding technique. However, its effectiveness diminished slightly when juxtaposed with the DistilBERT model. In comparison to BERT, DistilBERT demonstrated a reduction in errors by 11% (R-1), 10% (R-2), and 19% (R-L).

The real summary is, “A Canadian doctor says she was part of a team examining Harry Burkhart in 2010, Diagnosis: autism, severe anxiety, post-traumatic stress disorder and depression, Burkhart is also suspected in a German arson probe, officials say, Prosecutors believe the German national set a string of fires in Los Angeles”.

3) Examples: Using a practical illustration of the generator's functionality, we've provided three sentences from a document within the CNN/Daily Mail dataset. These sentences, as extracted by the generator, can be viewed alongside their corresponding reference summary in Fig. 5. Upon inspection, it is evident that sentences sharing a greater number of words with the reference summary tend to receive elevated scores. This showcases the generator's ability to prioritize and assign higher scores to sentences that align more closely with the central themes or keywords present in the reference summary.

rank	Sentence	Score
1	Stancheva said she and other doctors including a psychiatrist diagnosed Burkhart with ”autism, severe anxiety, posttraumatic stress disorder and depression.”	0.95
2	Burkhart, a 24-year-old German national, has been charged with 37 counts of arson following a string of 52 fires in Los Angeles	0.86
3	A medical doctor in Vancouver, British Columbia, said Thursday that California arson suspect Harry Burkhart suffered from severe mental illness in 2010, when she examined him as part of a team of doctors.	0.76

Fig. 5. Three sentences extracted by the generator for the CNN / Daily mail dataset.

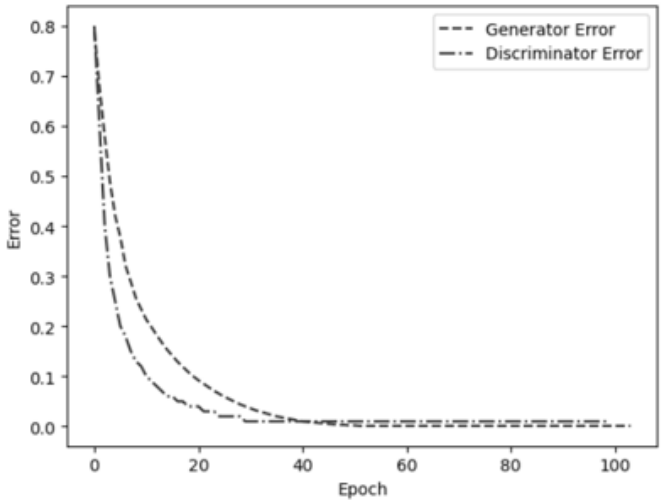

Fig. 6. Comparative diagram of error dynamics.

4) Discussion: This paper unveiled a groundbreaking approach to extractive text summarization, blending a multitude of advanced techniques. Our introduced methodology synergizes the power of a GAN-centric framework, the precision of DistilBERT word embeddings, and the adaptability of TLSTM. Central to efficacious summarization is the interplay between two components within the GAN architecture: the generator and the discriminator. The generator's primary task is to gauge the significance of each sentence in a prospective summary. In contrast, the discriminator's role is to critique and ascertain the caliber of the summaries generated. Such a dynamic within the GAN structure empowers the generator, encouraging it to sift through an array of sentence permutations. As a result, this culminates in the creation of summaries that are both concise and of superior quality. Adding another layer of sophistication is TLSTM, which harnesses the power of transductive learning. Transductive learning is distinctive in its approach, as it assigns augmented weights to data samples that are proximate to a specific test point. This ensures that the most relevant and closely aligned data samples exert greater influence, optimizing the summarization process.

Fig. 6 presents error diagrams for both the generator and discriminator in a GAN across various epochs. Initially, the generator's error is markedly higher at 0.789, revealing its challenges in generating samples mimicking the true data distribution. Yet, as training progresses, the error of the generator exhibits a clear decreasing trend. This suggests the generator is progressively getting better at simulating genuine data, capturing intricate patterns within the dataset. Simultaneously, the discriminator, starting with a slightly lower error of 0.8, undergoes its own evolution. Its role is to differentiate between real and synthetic data. Over the epochs, its error also reduces, though not as sharply as the generator. This indicates that even as the discriminator becomes more skillful, the generator is advancing at a slightly faster pace, producing ever more convincing samples. The interplay between these adversarial elements is crucial to the convergence of the GAN. A diminishing error for both entities across epochs implies a harmonious convergence in the GAN training. The generator refines its outputs, drawing them closer to real samples, while the discriminator sharpens its evaluative abilities. This consistent drop in error highlights the stability and continuous advancement of the GAN in training. The model aptly leverages the adversarial dynamic between its components to enhance performance over epochs. In essence, Fig. 5 underscores the iterative refinement in GAN training, each step bringing the system closer to generating more credible synthetic data distributions.

The paper touts the proposed model's preeminence, substantiating its claims through performance metrics derived from the ROUGE evaluation on the CNN/Daily Mail dataset. Nevertheless, this evaluation is tethered to just one dataset, raising questions about the model's adaptability across a spectrum of diverse datasets. To genuinely encapsulate the model's prowess, it would be prudent to undertake assessments across a myriad of datasets. Relying solely on the CNN/Daily Mail dataset might pave the way for dataset-specific biases. The rationale behind this exclusive dataset choice warrants elucidation, and an exploration into the model's versatility across varied datasets is imperative. Multiple datasets inherently encapsulate nuances in linguistic style, domain specificity, and content diversity, which undeniably bear implications on the outcomes of text summarization. A more holistic evaluation, spanning multiple datasets, would invariably render a more nuanced understanding of the model's capabilities.

The paper touts the proposed model's preeminence, substantiating its claims through performance metrics derived from the ROUGE evaluation on the CNN/Daily Mail dataset. Nevertheless, this evaluation is tethered to just one dataset, raising questions about the model's adaptability across a spectrum of diverse datasets [64]. To genuinely encapsulate the model's prowess, it would be prudent to undertake assessments across more datasets. For this, we can use datasets presented in [65]. Relying solely on the CNN/Daily Mail dataset might pave the way for dataset-specific biases. The rationale behind this exclusive dataset choice warrants elucidation and an exploration into the model's versatility across varied datasets is imperative. Multiple datasets inherently encapsulate nuances in linguistic style, domain specificity, and content diversity, which undeniably bear implications on the outcomes of text summarization. A more holistic evaluation, spanning multiple datasets, would invariably render a more nuanced understanding of the model's capabilities [66].

GANs are built upon a novel framework where two neural networks, the generator and the discriminator, work in tandem. The generator's primary goal is to produce outputs that are indistinguishable from real data, while the discriminator's objective is to differentiate between actual data and the data generated by the generator. This adversarial process, though powerful in theory, presents several practical challenges, particularly during the training phase. One primary concern is the issue of convergence. Given the dynamic nature of the adversarial relationship, ensuring that both networks converge to an optimal solution is not straightforward. If not carefully managed, the training can end up in a loop where each network

constantly tries to outdo the other without reaching a stable equilibrium. This oscillatory behavior can make GANs particularly sensitive to hyperparameters, initialization, and the chosen architecture, often requiring extensive experimentation and fine-tuning. Additionally, the delicate balance between the generator and discriminator can easily be disrupted. If the discriminator becomes exceptionally adept early on in training, it can stifle the generator's ability to learn. The generator, facing constant rejection from the discriminator, may struggle to make any meaningful progress, leading to a stagnation in learning and potentially resulting in mode collapse, where the generator produces limited or repetitive outputs. On the other hand, if the generator dominates the learning process and continually manages to deceive the discriminator, the discriminator may fail to provide meaningful feedback. This can result in generated summaries that, while convincing at first glance, might stray from the original content's essence, compromising the quality and relevance of the output. Given these challenges, there's a growing consensus in the research community about the need for more refined training strategies for GANs [67]. Techniques such as gradient penalty [68], spectral normalization [69], and modified loss functions [70] have been proposed to stabilize GAN training.

Transductive learning is a unique learning paradigm that seeks to make predictions specifically for the given test set without generalizing to the broader population. By concentrating on samples near the test point, it can produce highly optimized results for a specific set of data. However, this precision comes with its own set of challenges, primarily related to model generalization [71]. The inherent nature of transductive learning to prioritize certain instances over others can inadvertently lead the model to capture noise or idiosyncrasies present in the training data. Such a model would be finely tuned to a particular dataset, but might falter when introduced to new, unseen data. This phenomenon, known as overfitting, means that while the model performs exceptionally well on its training data, its performance significantly drops on new, unfamiliar data. In practical scenarios, especially in dynamic environments like news summarization, social media analytics, or customer feedback systems, data distributions can shift rapidly. A model trained with a strong transductive bias might not adapt well to these changing scenarios, thus compromising its effectiveness and reliability. It would continuously require retraining or fine-tuning on new data points, which is resource-intensive and not always feasible. Addressing these challenges necessitates a more balanced approach to learning. One potential avenue is the incorporation of regularization techniques [72]. Regularization, in essence, adds a penalty to the loss function, discouraging the model from fitting too closely to every data point and, in turn, mitigating overfitting. Techniques such as L1 and L2 regularization or dropout [73] can be applied to ensure the model retains a level of generality. Furthermore, blending transductive learning with inductive learning offers another promising solution. While transductive learning focuses on specific test points, inductive learning aims to find a general pattern or hypothesis that can be applied to any input. By combining these two paradigms, one could harness the precision of transductive learning while maintaining the broader applicability provided by inductive learning. Such a hybrid approach would not only cater to specific data instances but also ensure that the model remains versatile and adaptable to a range of data distributions.

V. CONCLUSION

In the research presented, we introduce an innovative approach to extractive text summarization, leveraging a blend of GAN, the DistilBERT word embedding technique, and an attention-centric TLSTM methodology. Utilizing DistilBERT, we crafted a feature vector for each sentence, which was subsequently fed into the generator to deduce the likelihood of that sentence being part of the final summary. In tandem, a discriminator was employed to scrutinize the summaries churned out by the generator, thus honing its capabilities. We further innovated by designing a unique loss function tailored for the training of the discriminator. This function meticulously considers the output of the generator, as well as both authentic and contrived document summaries. An intriguing facet of our methodology is that each document is paired with distinct noise during both training and testing phases. Such a strategy empowers the generator, equipping it to explore a vast array of sentence amalgamations, laying the groundwork for the creation of superior quality summaries. Empirical evaluations conducted on the CNN/Daily Mail dataset lend weight to the efficacy of our model. The results not only underscore the effectiveness of our novel methodology but also highlight its superiority, outpacing other established text summarization techniques in performance metrics.

In forthcoming research endeavors, we intend to focus on enhancing the coherence among sentences within our model. Coherence plays an instrumental role in ensuring that the summarized text is not just a collection of sentences, but a fluid and cohesive narrative that is easy for readers to follow and understand. Addressing this aspect can significantly elevate the quality and readability of the generated summaries. One possible approach to achieve this would be to prioritize coherence during the construction of our target summaries. By doing so, the model would be trained to select sentences that not only contain critical information but also seamlessly connect with one another, ensuring a natural flow of ideas. Additionally, another promising avenue to explore is the incorporation of coherence as a loss function within the generator. By integrating coherence into the loss function, the generator would be incentivized to produce summaries where the sentences logically follow one another, leading to more cohesive and contextually relevant outputs. Introducing such modifications could provide dual benefits: improving the intrinsic quality of the summaries and enhancing the user experience, as coherent and logically structured summaries are more easily comprehensible. This, in turn, would further cement the model's applicability and usefulness in real-world scenarios, catering to a wider range of text summarization needs.

Security in Software-Defined Networks Against Denial-of-Service Attacks Based on Increased Load Balancing Efficiency

Ying ZHANG, Hongwei DING*

***Abstract*—The goal of software-oriented networks (SDNs), which enable centralized control by separating the control layer from the data layer, is to increase manageability and network compatibility. However, this form of network is vulnerable to the control layer going down in the face of a denial-of-service assault because of the centralized control policy. The considerable increase in events brought on by the introduction of fresh currents into the network puts a lot of strain on the control surface when the system is in reaction mode. Additionally, the existence of recurring events that seriously impair the control surface's ability to function, such as the gathering of statistical data from the entire network, might have a negative impact. This article introduces a new approach that uses a control box comprising a coordinating controller, a main controller that establishes the flow rules, and one or more sub-controllers that establish the rules to fend off the attack and avoid network paralysis. It makes use of current (when needed). The controllers who currently set the regulations are relieved of some work by giving the coordinating controller management and supervision responsibilities. Additionally, the coordinator controller distributes the load at the control level by splitting up incoming traffic among the controllers of the flow rules. Thus, a proposed method can avoid performance disruption of the flow rule setter's main controller and withstand denial-of-service attacks by distributing the traffic load brought on by the denial-of-service attack to one or more sub-controllers of the flow rule setter. The results of the experiments conducted indicate that, when compared to the existing solutions, the proposed solution performs better in the face of a denial-of-service assault.**

Keywords*—Security; open balance; denial-of-service attacks; software-oriented networks

I. INTRODUCTION

The next-generation network approach, known as a software-oriented network (SDN), allows for programmable control of the network and makes network management easier by separating network transmission from control operations [1]. The Open_ Flow protocol has been utilized the most out of all the tools that are currently available to actualize the software-oriented network [2]. The flow rules that the controller installs in the flow tables of the switches direct the network traffic in an Open_ Flow network. The controller can generate flow rules using either the proactive method or the reactive way, respectively [3]. In the pre-active method, before launching the software-based network, the controller installs the flow rules in the switches based on the predetermined strategy [4]. No special flow rules are put in the switches beforehand when using the reaction technique [5]. A table loss event occurs for each new flow that does not match the installed flow rules [6]. In response, an Open_ Flow request is delivered to the controller, and the controller chooses a new flow rule based on this request. The reactive technique, which is flexible, is typically employed in software-based networks [7].

Even though Open_ Flow has many benefits for streamlining network management and expanding its adoption, its reactive approach to installing flow rules makes it simple for DoS attacks on the controller to succeed because the controller must deal with all the packets generated by the absence of the table in [8]. The Open_ Flow network may receive a high number of transient phony flows that were created by a hacked host. Many flow requests (packet_in packets) are made to the controller when the Open_ Flow switch receives these malicious flows because they cause events linked to the loss of the table. Consequently, these high-frequency current requests deplete the controller's resources, interfering with regular functioning [9].

A denial-of-service attack on the Open_ Flow network often has the following effects: a) overloading of switches; b) congestion in the data plane and control plane communication channel; c) overloading of the controller; and d) overflowing of switch flow tables [10]. While the anomaly connected to the controller's service might cause disruption and failure of the entire network, overloading the switches and overflowing the switch flow tables only endanger the victim switch. As a result, the majority of threats from a denial-of-service attack in the Open_ Flow network are brought on by the emergence of congestion in the communication channel of the data level with the control level and overloading of the controller [11].

The suggested approach for the control level of the software-based network has been utilized in this article to strengthen the security of the network against denial-of-service attacks and boost its availability [12]. In order to increase the availability of the software-based network against significant changes in the events brought on by the arrival of new flows (due to the temporal and spatial characteristics of the network traffic) and the existence of repeated events, the proposed method consists of a control box [13]. It is intended to gather statistical data from the entire network, which overburdens the controller. A coordinating controller, a primary controller of the current setter, and one or more (as required) sub-controllers of the current setter are all included in this control box [14].

The current installation controllers' job is essentially decreased by giving the coordinating controller responsibility for managing and monitoring the software-based network. It is the responsibility of flow controllers to install flow rules in line with the network applications that are operating on them in order to configure the data level of the software-oriented network [15].

Additionally, the coordinator controller will categorize the incoming traffic in a statistical manner after activating one or more (as necessary) sub-controllers in response to the network's increased traffic load, which can be brought on by a denial-of-service assault [16]. Each of them receives a portion of the incoming traffic that the flow controller divides into known categories. This results in the flow controller's controllers sharing the load of incoming traffic, which lessens the effort of all of the flow controller's controllers. In the suggested method, the redundancy of the controllers and the division of labor among them are used to distribute the traffic caused by the denial-of-service attack to one or more sub-controllers, taking into consideration the multi-controller capability offered in Open_ Flow Specification 1.2. The software-based network controller will experience less of an impact from the attack thanks to the flow installer, and the software-based network will be more resilient to unexpected and severe fluctuations in network traffic. In summary, the article presents a solution to improve the security and resilience of SDNs against DoS attacks. The proposed approach, utilizing a control box with coordinating and sub-controllers, is shown to be effective in managing traffic during attacks and reducing response times. However, the article acknowledges the need to address resource consumption and scalability in future work.

In short, the contribution of the authors in this research is as follows:

- Introducing a new approach: A new approach has been introduced to increase the security and resilience of Software Defined Networks (SDN) against Denial of Service (DoS) attacks. It lies in the creation of a "control box" consisting of coordinating, main and sub-controllers.
- They also contribute to this field by comparing the proposed solution with four other existing methods for mitigating DoS attacks in SDN, including Ryu controllers with different mechanisms. Through this comparison, they show that their approach consistently outperforms these alternatives and provides a more effective way to counter DoS attacks.

The article's structure is described in the paragraphs that follow. The work that has been done to fortify the software-based network's control level against denial-of-service assaults has been mentioned in Section II. The software-based network controller's input load has been looked into in Section III. Section IV describes the suggested technique for enhancing the security of the software-based network control level. In Sections IV and V, it was examined, respectively, how denial-of-service assaults would affect the proposed approach and how a saturation attack on the control surface by the data surface would affect it. The effectiveness of the suggested approach against a denial-of-service attack is contrasted with that of many other solutions in Section VI, and conclusions and recommendations for further work are provided in Section VII and Section VIII respectively.

II. Related Works

Studies on data-level protection and control-level protection that aim to lessen the effects of denial-of-service attacks on software-based networks fall into these two groups. In order to fight against assault, data layer protection focuses on enhancing data layer functionality or adding new features [17]. In order to keep the controller from becoming overloaded with requests, OF-Guard uses a data-level cache. The strategy, however, lacks flexibility because it is uncertain whether such a cache will be established at the data level. The implementation of SYN Proxy is proposed in AVANT-GUARD [18] as a unit that performs the TCP Handshake in the switches before sending the incoming TCP stream to the network. The pressure on the switch buffer is increased using this unit, and there is also a cap on the number of proxy ports. Because LineSwitch can arbitrarily proxy flows from the same IP source that it has already established a TCP handshake with, it is suggested that LineSwitch will enhance AVANT-GUARD [19]. Another AVANT-GUARD-based solution is SDN-Shield, which employs a number of NFV-based attack mitigation units to counter distributed denial-of-service attacks at the software-oriented network data level. However, none of these SYN Proxy-based techniques work with other network protocols.

In order to sustain network policy enforcement, Flood-Guard offers a pre-active flow rule analyzer that can examine the source code of an Open_Flow-based application and generate several pre-active rules via running time monitoring of each application's global state. To produce based on the protocol, Flood-Guard stores the remaining packets caused by table loss in a cache at the data level. The source code analyzer, however, is extremely complicated and unable to be deployed across a network. Additionally, the same attack flow protocol was utilized by additional benign flows, so the data level cache cannot ensure fair behavior against them.

Enhancing the security of the controller policies and implementing detection and filter techniques to lessen denial-of-service attacks are the main goals of control level protection [20]. In Flow Ranger, the controller employs a rating algorithm to recognize typical users and pre-process packets with a higher priority. In order to distinguish malicious communication, SGuard introduces an access control system that leverages six items as feature vectors in the classification unit [21]. Researchers in [22] have suggested a scheduling policy for the proposal controller that divides the flows into various queues. The controller manages each queue based on round-robin scheduling, and each queue corresponds to a switch that is situated on the denial-of-service attack path. MLFQ creates an equitable sharing of control resources between the server and hosts in the network by utilizing a number of expandable and collapsible request queues [23]. Potentially hostile traffic is diverted to the intrusion detection system by SDN-Shield, and the impact of a denial-of-service attack is lessened by appropriately building the flow rules.

In order to lessen channel congestion between the victim switch and the controller, Flood Defender suggests a technique for distributing packets related to table loss from the victim switch to its surrounding switches. Additionally, for the purpose of detecting sporadic attacks, Flood Defender employs a two-stage filter and briefly archives packet_ in packets. To handle new benign flows, the packet_ in packet buffer introduces a significant delay. Additionally, the surrounding switches that are being flooded may suffer damage from the packet distribution caused by the absence of the table. In order to counter the denial-of-service attack, FMD employs a technique based on flow migration at the software-oriented network control level slow. The master controller, to which fraudulent requests with a high volume are delivered, is replaced in this technique by a slave controller. The master controller handles all typical Open_ Flow requests. In order to safeguard the channel of communication between the victim switch and the master controller, FMD sends the threatening Open_ Flow requests to the slave controller after identifying a denial-of-service attack. The migrated requests are briefly kept in the slave controller and transferred to the master controller for additional processing at a limited rate [24] to prevent the master controller from becoming overloaded. SGS is offered to defend the control plane from denial-of-service assaults, and its key component is the clustered deployment of several controllers in the control plane. The abnormal traffic detection and controller dynamic defense units make up the SGS procedures. Anomalous traffic detection uses quadratic feature vectors to separate phony flows from real ones by focusing on switches that already exist at the data level. The impact of the denial-of-service assault at the control level is minimized by the controller's dynamic protection, which involves remapping the controller and sending the access control message to the switch. As it was already indicated, the majority of the techniques for data layer protection include modifying Open_ Flow switches or incorporating unique features into the data layer. However, all techniques in the second category (control level protection) work to reduce the number of resources that a denial-of-service assault uses up. In reality, the controller cannot manage the rate of receiving Open_ Flow packets. Additionally, the main cause of the denial-of-service attack in the control level is the congestion of the communication channel connecting the data level with the control level, which is of the TCP or TLS type. Source in [42] has demonstrated the capacity to enhance networks and withstand DDoS attacks. Thus, the purpose of this survey is to review 65 articles about DDoS attack detection in SDN. As a result, each reviewed article's systematic reviews of the suggested methodology are examined. This work additionally analyzes the performance metrics and their best assault detection accomplishments from each research publication. Furthermore, this work reviews the reduction technique applied in each paper.

In this study, an architecture to handle service source attacks is developed in order to address the restrictions indicated above. A suggestion is to have flow rule setter sub-controllers that are multiples of the main flow rule setter controller and assign incoming traffic from denial-of-service attacks to them regardless of the protocol used, as well as from the channel connecting the data level with the level. Control is comprehensive since it guards against congestion and shields the main flow rule controller from denial-of-service attacks to minimize their negative effects on good new flows. Additionally, the concept is transparent because it does not require any adjustments to the network's infrastructure or application programs to be used.

III. Examining the Software-based Network Controller's Input Load

As depicted in Fig. 1, within a software-oriented network made up of Open_Flow switches, the Open_Flow controller periodically sends multi-part messages [25] to the switches under its control. These messages serve to collect statistical data from the switches, contributing to the construction of the network's information base (NIB). The controller can have a comprehensive view of the entire network under his control based on the information in this network's information base. The initial packet of each flow that reaches the input switch is examined to determine whether it complies with the rules set up in the switch's flow table. Suppose the switch's flow table does not contain a match for the packet. In that case, a packet-in message is provided to the controller containing the lowest priority flow entry that is compatible with any incoming flow (flow entry absent from the table). The request in this message is to begin planning a path for the incoming stream. The Open_Flow controller determines the appropriate route for the incoming flow based on information from the network information base. The route is established by installing the appropriate flow rules in the flow tables of the switches along the route, and as a result, all flow packets are directed to their intended destination. Eq. (1) determines the input load to the controller resulting from the input currents with the input speed of the current per second in a data center with N switches, assuming the average number of switches located in the path is [N/2] and for each flow in the flow table of switches located in the path of two flow rules (to forward in two directions) installed.

$$L_{arrival-flows} = \lambda \times (\lceil m_{pi} \rceil + \lceil m_{po} \rceil + \left\lceil \frac{N}{2} \right\rceil \times 2 \times \lceil m_{fm} \rceil) \quad (1)$$

where, m_{fm} stands for the size of the flow_mod packet, which is the packet delivered from the controller to the Open_Flow switches to install a new flow rule. Additionally, m_{pi} and m_{po} stand for the sizes of the packets in and out, respectively. As a result, there is a chance that the controller will become overloaded by increasing the speed at which fresh currents enter the input switch in the reaction mechanism chosen for each incoming current to be passed into the controller.

The input load brought on by gathering statistical data at the network level is another element that overburdens the software-based network controller. Important statistical data that can be gathered from existing Open_ Flow switches in a data center includes data about the ports connected to servers and data about the flows set up in the switches' flow tables. Eq. (2) can be used to determine the input load to the control level in a data center as a result of gathering statistical data from Open_ Flow switches.

$$L_{statistics} = N \times (([m_{portreq}] + H \times [m_{portrep}] + [m_{flowreq}] + F \times [m_{portrep}])) \times [\frac{1}{T}] \quad (2)$$

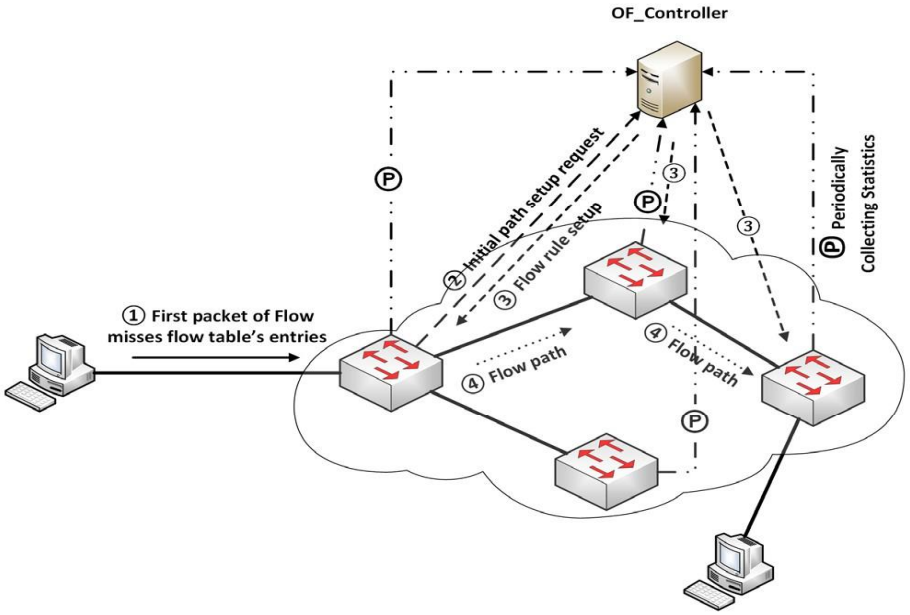

Fig. 1. The software-oriented network's controller operation mechanism creates a path for a new flow.

TABLE I. THE VARIABLES THAT ARE USED TO CREATE THE INCOMING TRAFFIC TO THE DATA CENTER

Name	Model	Parameters
New flow arrivals	Poisson	$\lambda(t) = 192$
Internal rack flow ratio	Bernoulli	$R_{int} = 0.8$
TCP flow ratio	Bernoulli	$R_{tcp} = 0.85$
Flow duration, Dn	Pareto	$a_p = 1.504$ $M_p = 1.0001$
Flow transmission rate, Yn	Gaussian	$E[Y_n] = 4303.69$ $Var[Y_n] = 69936.37$
Flow size, Sn	$Y_n \times D_n$	$E[S_n] = 8517.97$

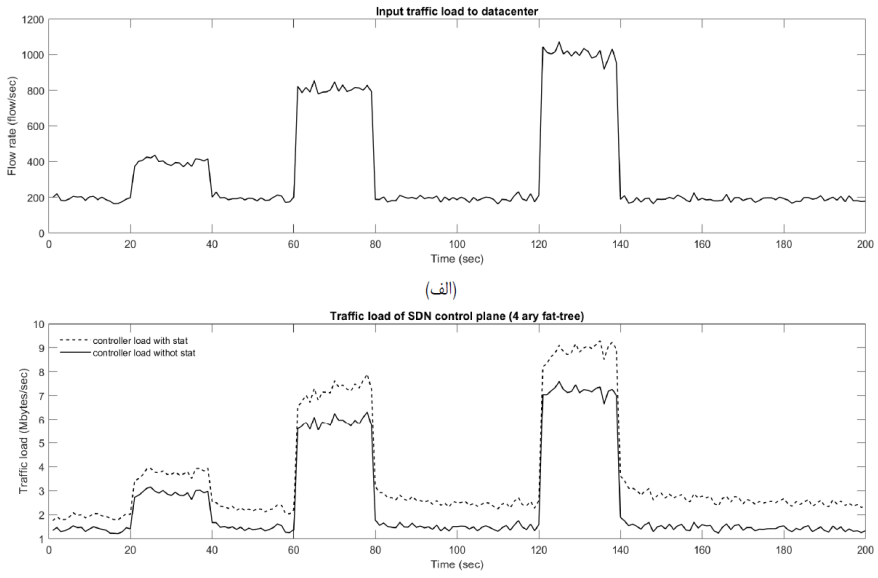

Fig. 2. (a) Incoming traffic to the data center and (b) Incoming load to the controller in a data center with _Ary_Fat_tree4 structure ((-- -) with the load resulting from the collection of statistical information and (-) without it.

where, H is the total number of switch ports linked to servers, and N is the total number of Open_ Flow switches in the data center. F is the number of installed currents in the switches, and T is the controller's periodic request for statistics data. A simulation has been run in MATLAB 2022b to show the impact of the load brought on by the gathering of statistical data (Relation 2) and the admission of fresh flows into the data center (Relation 1) on the software-based network controller.

The data center in this simulation has an Ary Fat_tree 4 structure. The data center's incoming traffic is generated based on the findings of Yoonseon Han and his associates [26], who used the values in Table I. Fig. 2 displays the simulation outcome based on (1) and (2), as well as the relationships offered by Bong-yeol Yu and his associates [27]. As seen in Fig. 2(a), the data center receives 192 flows per second of incoming traffic in the usual state. This amount is in the intervals to observe the impact of speeding up this flow rate on the amount of incoming load to the software-based network controller. There has been an increase in the current per second from 20 to 40 seconds, 60 to 80 seconds, and 120 to 140 seconds, respectively. The input load to the software-based network controller of a data center with an _Ary_Fat_tree4 structure is shown in Fig. 2(b) in two states: (-) with the load brought on by gathering statistical data and (-) without it. As might be predicted, as the pace of incoming traffic to the data center grows, so does the input load on the controller. The important feature in Fig. 2's lower portion is the sizeable input load brought on by the controller's statistical data collection, which has a significant impact on the occurrence of interference with the transmission of basic controller messages (such as current installation), delays the arrival of information to the controller, and ultimately lowers the controller's efficiency. Therefore, packet_in can improve the controller's efficiency and availability by separating the load arising from the gathering of statistical data from the load resulting from the arrival of packages.

IV. Suggestion for Enhancing the Security of SDN Control Levels

In software-based networks, the controller is not just in charge of performing the functions of a straightforward switch to transfer flows throughout the network in order to take advantage of its central management. It is required to gather statistical data from the network level in order to implement efficient programs, such as balancing the load on communication lines and servers in the network or quality control of service provided to flows system by system. For successful and integrated management, software-oriented networks need the controller to be highly available.

There are two ways to provide high availability for Open_ Flow controllers in software-based networks [28]. Reduce the load on controllers as the initial step in the approach. The Open_ Flow controller communicates with the Open_ Flow switches frequently, particularly while running in reactive mode, as was covered in the preceding section. The controller has become overwhelmed. As a result, making it is unable to process incoming messages. The second option is to replace one controller with many controllers to add redundancy.

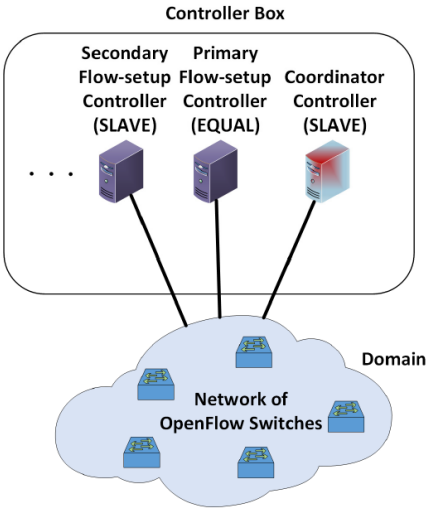

Fig. 3. The recommended approach for software-based network controllers' structure.

Both of the aforementioned methods are taken into account in the proposed control box, which is employed in the proposed method to increase the availability of Open_ Flow controllers in software-based networks (see Fig. 3). One of the controllers in this control box serves as a coordinator, connecting to Open_ Flow switches only to gather statistical data from them. Additionally, there is a main controller and one or more (depending on the demand) sub-controllers in this control box that are in charge of adding flow rules to the flow tables of Open_ Flow switches. So, in addition to lessening the strain on the controller, more controllers have been deployed by splitting the work between the coordinating controller and the controllers that establish the flow rules. It is necessary to employ several controllers to control Open_ Flow switches, which are accessible in Open_ Flow version 1.2 and later, in order to implement the control box concept in software-based networks. Since Open_ Flow version 1.2, it has been possible to have numerous controllers, each of which can control Open_ Flow switches in one of the three modes of SLAVE, MASTER, or EQUAL. The MASTER and EQUAL modes have complete access to the switch and can receive all asynchronous communications (such as packet-in) from the switch, among the other two modes [29].

Each Open_ Flow switch is permitted to communicate with one MASTER controller but numerous EQUAL controllers. In SLAVE mode, the controller can only read from the switches through its access to them; it is, therefore, unable to receive any other asynchronous messages than the answer of the multi-part message containing the switch's status. Each controller can modify its state by sending the switches the OFPT_ROLE_REQUEST message [30]. The switch transmits the OFPT_ROLE_REPLY message to the controller after receiving this message.

The other controllers of that switch will convert to the SLAVE state if the switch gets a message from it instructing it to change the controller state to MASTER. Due to the switch's ability to have several Open_ Flow channels, it is not necessary to re-establish the channel in the event that one of the

controllers connected to it fails. Open_ Flow switches are able to transmit packet-in messages solely to the controller whose ID is in the matching table entry by giving each of the flow rule set controllers in the control box a distinct ID. Their direction of flow is known. Utilizing the Nicira features integrated within the RYU network operating system; this capability is possible [31]. The NXTSetControllerId function is used to accomplish this by giving each flow rule controller a special identification number. The number of flow rule set controllers that can be used in the control box will thus no longer be constrained. As a result, the control box is expandable, allowing the number of active controllers that establish the flow rules to grow as necessary. This boosts the availability of the control level of the software-oriented network by dividing the load associated with packet-in messages among the controllers of the flow rules and reducing their individual loads.

A. Coordinating Controller

All Open_ Flow switches in the domain are connected to the coordinator controller that is operating in SLAVE mode. As seen in Fig. 4, the coordinating controller has a variety of components for regulating the operation of the controllers that establish the flow rules and for keeping an eye on the network. Allocating incoming traffic to the flow controller's sub-controller is the primary responsibility of the coordinating controller. When the coordinating controller notices that the main controller is on the verge of overflowing, this is what happens. By doing this, the existing installation's main controller's traffic load is lessened, and it is once again able to function.

In order to prevent the overload of the controller controllers as the amount of incoming traffic to the network increases, the coordinating controller repeats this process by turning on new flow controller sub-controllers and allocating the overload of incoming traffic to them (see Fig. 5). On the other hand, by lowering the load of traffic entering the network, the coordinating controller transfers all of the traffic load entering the network to the main controller of the flow setter while deactivating the sub-controller of the flow setter. The description of the coordinating controller's role as well as information on each of its component parts, are provided below.

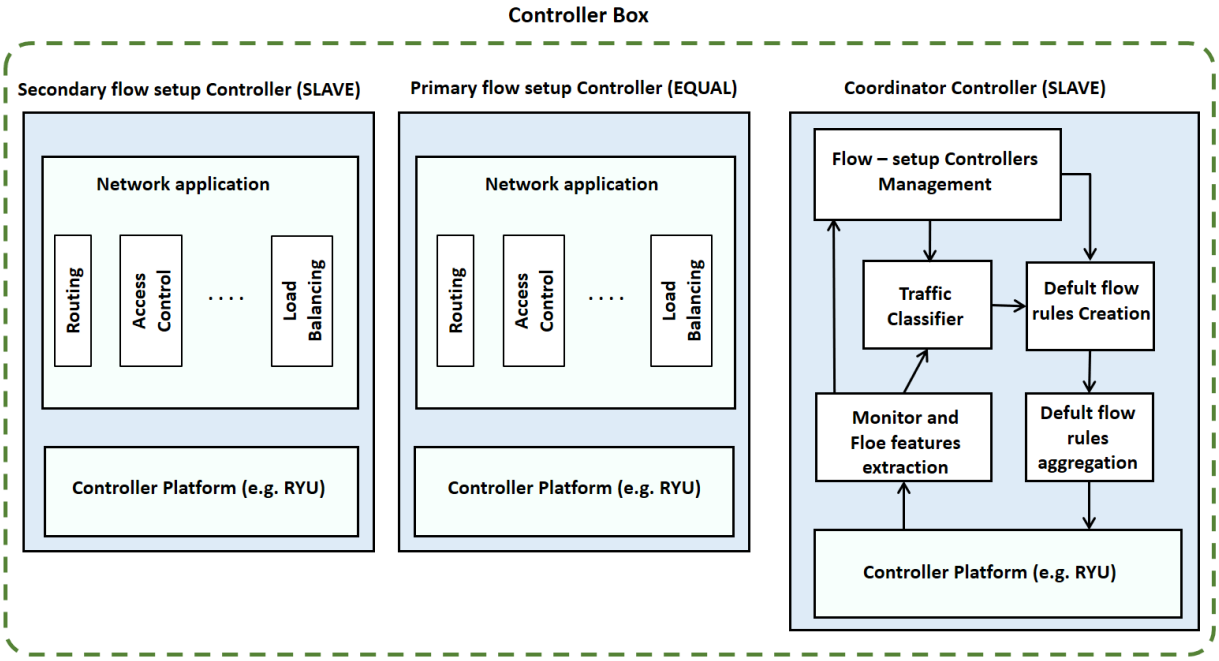

Fig. 4. Block diagram of the components of the proposed method.

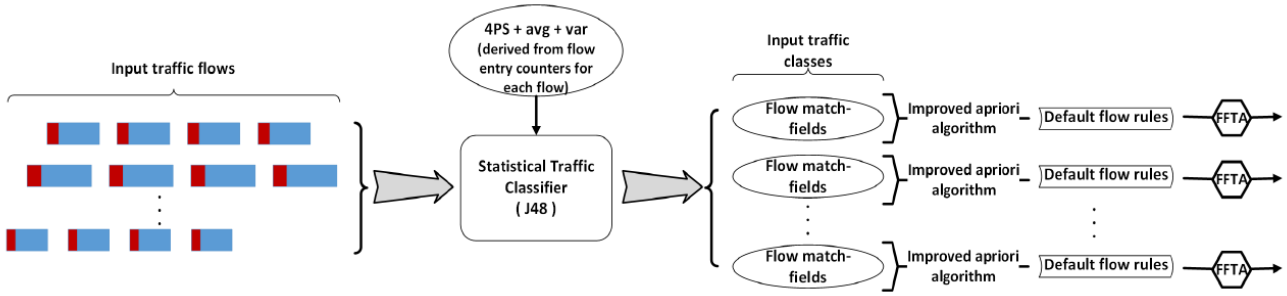

Fig. 5. The process of creating default flow rules and statistically classifying incoming network traffic.

B. How to Switch the Sub-controller On and Off

The main controller of the current installation may become overloaded as a result of changes in the rate at which traffic enters the network. The current setter's sub-controller is activated by the coordinating controller when it notices that the main controller is on the verge of overload as shown in Fig. 6(a). The flow controller's sub-controller receives the be-Active signal from the coordinating controller in order to accomplish this. The sub-controller of the flow installer sends the OFPT_ROLE_REQUEST message to all the Open_ Flow switches attached to it to alert them that its state has changed to EQUAL after receiving the be-Active signal. The sub-controller of the flow installer enters EQUAL mode after receiving the OFPT_ROLE_REPLY signal from the Open_ Flow switches. The coordinating controller changes its state from SLAVE to EQUAL upon receiving the activated signal from the flow controller's sub-controller, and after implementing the default flow rules related to one of the traffic categories entering the network, the output of the controller's classification algorithm. The gate switches activated current controller switches back to SLAVE mode.

The sub-controller of the current setter is deactivated once again by the coordinating controller when it notices that the main controller of the current setter is no longer in overload mode as shown in Fig. 6(b). The coordinating controller delivers the be-passive signal to the current setter sub-controller after switching the mode from SLAVE to EQUAL and removing the default flow rules connected to the active current setter sub-controller from the gateway switches. A remark is sent. The coordinating controller then reverses its state, going back from EQUAL to SLAVE. The flow installer's sub-controller sends Barrier request messages to all of the switches connected to it upon getting the be-passive signal, causing these switches to complete processing all of the messages they had been receiving from the flow installer's sub-controller. The flow controller sub-controller then sends the OFPT_ROLE_REQUEST message to all the switches connected to it, changing their status from EQUAL to SLAVE. The current regulator's sub-controller is rendered inactive as a result.

C. Investigating How the Proposal is Affected by a Control-Level Saturation Attack at the Data Level

A UDP flood attack was applied against three scenarios (the first scenario: using one controller, the second scenario: using a desaturation controller and a number of flow rule set controllers, and the third scenario: using the proposed architecture) in order to demonstrate the impact of redundancy on the availability of the proposed architecture. This experiment was carried out using the structure depicted in Fig. 7 and implemented in the Mininet 2.2.2 emulator environment [32]. According to Table II, this implementation uses OpenVSwitch [33] software switches for the Open_ Flow switches and the RYU platform [34] for the controllers. Additionally, the iPerf [35] tool has been used to produce UDP flood attack traffic in order to test the scenarios. The attacker launches a UDP flood assault on the Open_ Flow switch while a client is corresponding with the load balancer between servers at a consistent pace of 50 flows per second. In this experiment, the round-trip time (RTT) of client requests collected by running the ping command has been used to assess the performance of various scenarios. The round-trip time of client requests has been observed for all three situations, as seen in Fig. 8, despite the fact that the speed of the UDP flood attack rises linearly up to 800 packets per second (PPS). Fig. 8 shows that the proposal approaches saturation when the attack speed hits 800 packets per second, whereas for scenarios 1 and 2, this happened at 450 and 500 packets per second, respectively. In fact, the controllers of the flow rules are out of reach and are unable to install a new route on the Open_ Flow switch in exchange for the arrival of fresh flows once the attack speed surpasses the saturation point of each of the scenarios. The results show that the proposal has a high availability compared to alternative scenarios and is particularly resistant to the assault of saturating the control surface due to the usage of redundancy in the flow rule controllers.

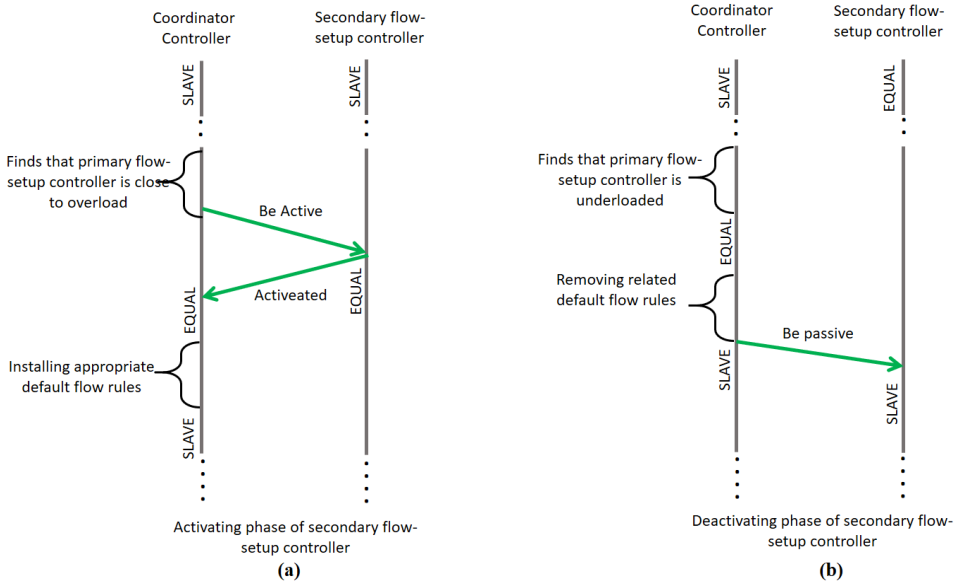

Fig. 6. How to modify the proposal's state of the existing regulator's sub-controller: a) activation and (b) deactivation.

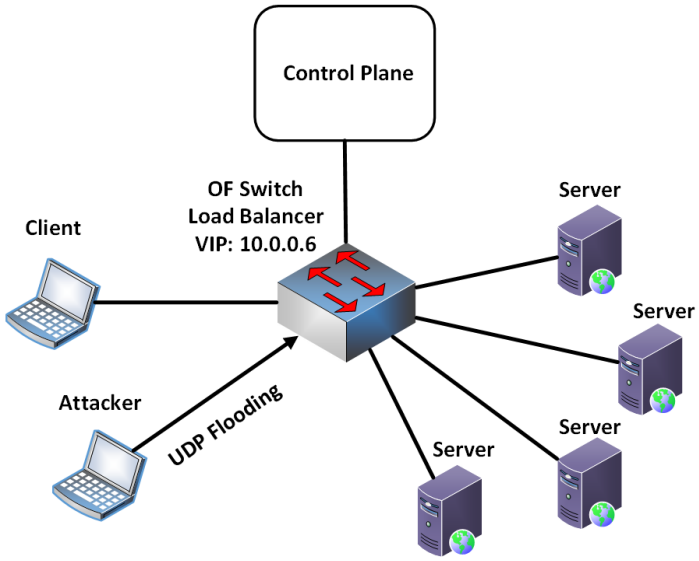

Fig. 7. A structure that was utilized for the UDP flood assault test.

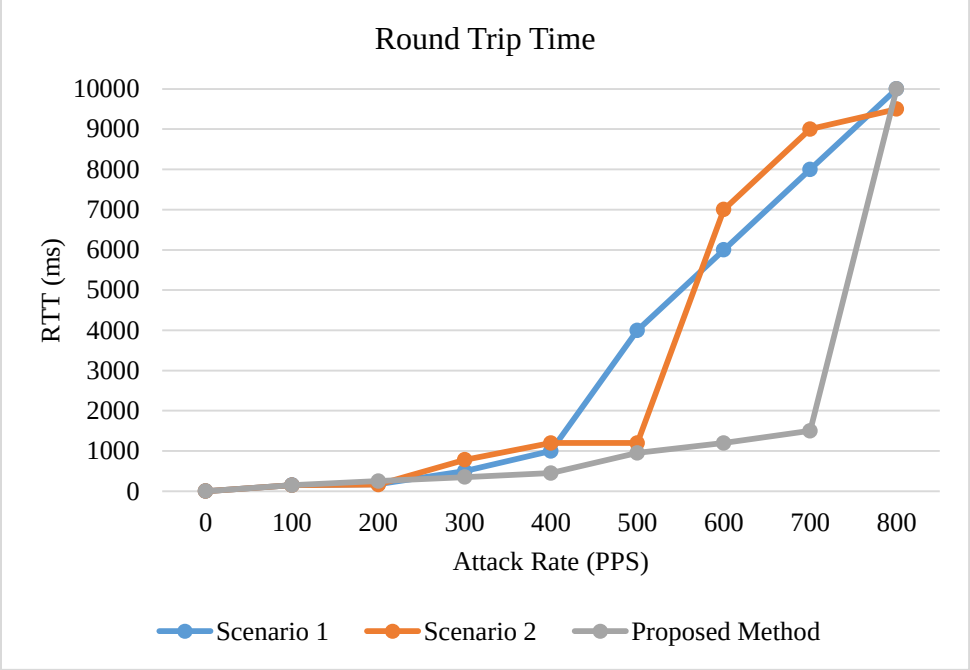

Fig. 8. Determining, during the flood attack, the turnaround time for client requests for proposals and scenarios 1 and 2. a) The first scenario: using one controller, (b) the second scenario: using a coordinating controller and a number of controllers that set the flow rules, and (c) the third scenario: using a proposed method.

TABLE II. LABORATORY PARAMETERS FOR THE PROPOSED EVALUATION

Virtual Machine	Oracle VM VirtualBox (Version 5.1.10 r 112026)
Guest OS	Ubuntu 16.04
CPU	Intel core i7-4720hq cpu@2.60ghz
RAM	16GB
Emulator	Mininet 2.2.2
Network Operating System	RTU 4.15
Open_Flow Switch	OpenVSwitch 2.4.0
Network Traffic Generator	iPerf 2.08b

V. Analyzing How Denial-of-Service Attacks Affect the Proposal

One of the elements affecting the availability of software-based networks is denial-of-service attacks. This section has researched how three different denial-of-service attacks affect the proposal. These attacks include ICMP/Ping flooding, UDP flooding, and TCP.SYN flooding. These attacks, which are a subset of volume denial-of-service attacks, were created using the Hyenae tool version 0.36 [36]. In this section, experiments were carried out utilizing the topology depicted in Fig. 7 that was constructed using the.222 Mininet simulator [37] and [38].

Additionally, the attacker conducts denial-of-service assaults on the Open_ Flow switch while a client is interacting with it (the switch is an Open_ Flow load balancer between servers) at a constant speed of 50 flows per second. The intended parameters in this test are the input load on the controllers in the proposed method, the round-trip time (RTT) of customer requests, and the impact of denial-of-service attacks on the proposed method's availability and performance. The ping command is used in conjunction with the 062bwm-ng v. utility to acquire these parameters. These attacks and the outcomes of their use have been addressed in the paragraphs that follow.

A. Study of the ICMP / Ping Flood Attack's Effects

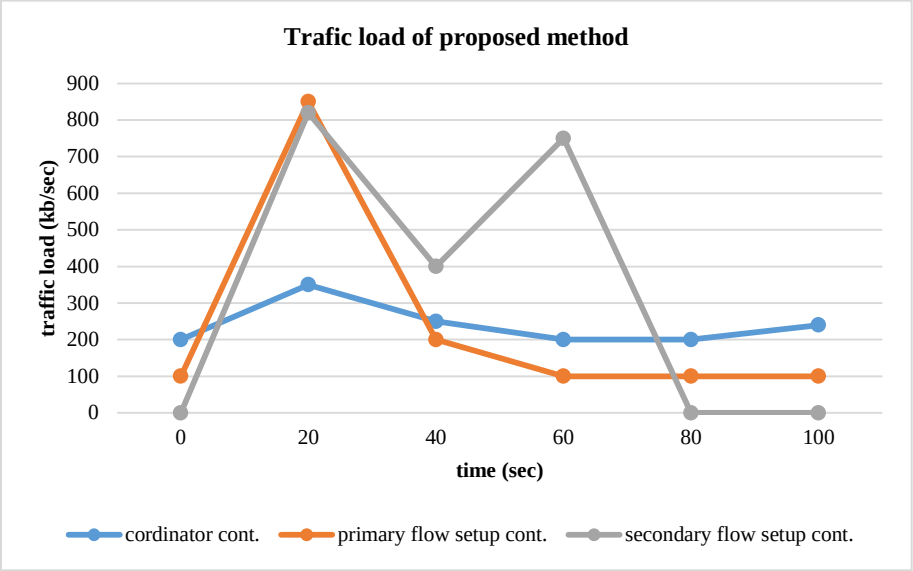
This kind of attack involves the attacker bombarding the target with ICMP echo requests, which interfere with other services that the target's other programs rely on. This kind of attack requires the attacker to rapidly transmit to the victim a large number of echo_request packets that appear to be coming from various sources and have random addresses. By having many flows, the attacker can interfere with the network. Each time a new packet-in is generated when an attacker attacks a victim using many sources with random addresses, the controller will experience a significant increase in traffic. The controller begins to sink when it receives a lot of packet-in packets, and after some time, it begins to disregard fresh incoming packets. The amount of production traffic described in terms of bytes, packets, or streams can be used to identify this kind of assault. Fig. 9 displays the outcomes of an ICMP/Ping flood assault conducted on the software-oriented network using the suggested technique, whose topology is depicted in Fig. 7. The volume of incoming traffic using the suggested method before, during, and after the attack is depicted in Fig. 9(a). Fig. 9(b) also depicts the duration of back-and-forth for client inquiries. The ICMP/Ping flood attack begins at 10 seconds and ends at 40 seconds, as can be shown. As soon as the attack begins, the time it takes for the customer's requests to move back and forth dramatically increases due to the main controller of the flow rules being overloaded and unable to handle requests entered as packet-in packages. The amount of incoming traffic load to the main controller of the flow rules setter is decreased by the activation of the sub-controller of the flow rules setter by the coordinating controller due to the detection of overloading of the main flow rules setter controller and the allocation of additional load resulting from the attack on it. The amount of incoming traffic to the main controller of the flow rules is decreasing, and as a result, this controller is once more able to handle and process requests that are received as packet-in packages. As a result, the amount of time required to go back and forth for customer requests returns to a reasonable value. This test demonstrates that the proposed method's availability is unaffected by an ICMP/Ping flood attack, save for a brief period of time (the time needed for the coordinating controller to notice that the main controller of the flow rules setter is overloaded before activating the sub-controller and adding additional load to it).

B. Investigating the Effect of UDP Flood Attack

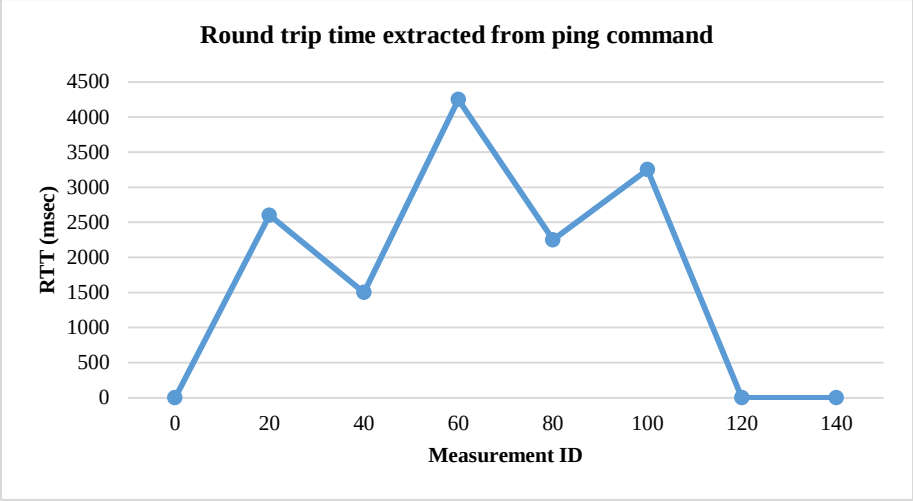
A UDP flood assault aims to bombard the target with a large volume of UDP packets. A host employs a huge number of bogus sources IP addresses when launching a UDP flood attack. The buffer overflow occurs in the victim as a result of a huge quantity of UDP packets arriving at the victim. Since sending a large number of bytes to the victim is the primary characteristic of UDP flood attacks, they produce the most traffic among denial-of-service attacks. In this attack, bogus source IP addresses are used to produce UDP packets that appear to send the target a lot of fresh streams per second. As a result, the software-based network controller starts pouring new flows after a given amount of time. The results of a UDP flood assault on a software-based network using the suggested technique, whose structure is depicted in Fig. 7, are displayed in Fig. 10. The volume of incoming traffic using the suggested method before, during, and after the attack is depicted in Fig. 10(a).

Additionally, Fig. 10(b) displays the amount of time spent responding to client inquiries. The UDP flood attack begins at 10 seconds and stops at 50 seconds, as can be shown. As soon as the attack begins, the time it takes for the customer's requests to move back and forth dramatically increases due to the main controller of the flow rules being overloaded and unable to handle requests entered as packet-in packages. Fig. 10(b) shows that this increase in time is caused by the software-based network controller receiving more incoming traffic than during the ICMP/Ping flood attack.

The amount of incoming traffic load to the main controller of the flow rules setter is decreased by the activation of the sub-controller of the flow rules setter by the coordinating controller due to the detection of overloading of the main flow rules setter controller and the allocation of additional load resulting from the attack on it. The main flow rule controller's ability to handle and process requests received in the form of packet-in packets is restored with the reduction of incoming traffic load, and as a result, the time required for the customer's requests to move back and forth to its reasonable value. Therefore, in this instance, similar to the ICMP/Ping flood attack, the UDP flood attack has no impact on the proposed method's availability other than for a brief time (the time needed for the coordinating controller to detect the main controller of the flow rules setter's load before activating the sub-controller and allocating additional load to it).



(a)



(b)

Fig. 10. (a) The amount of incoming traffic in the proposed method before the UDP flood attack, during the attack and after it and (b) the round trip time (RTT) of the client's requests.

C. Investigating the Effect of TCP_SYN Flood Attack

A TCP_SYN flood attack bombards the target with bogus SYN requests that were generated using fictitious source IP addresses. The victim never gets an answer to their SYN/ACK packets because the source IPs are faked. As a result, the attack's port is still open unnecessarily. All of the victim's ports are blocked as a result of several bogus SYN requests, making it impossible for the victim to connect to trustworthy people. It only takes a small amount of bandwidth for this kind of attack to keep the false connections open and render the victim unreachable. Hyenae tool version 0.36 was used [39] to develop a TCP_SYN flood attack, which begins by sending the victim a large number of low-speed streams containing TCP_SYN packets.

Additionally, the Open_Flow load balancing switch only distributes a load of incoming traffic across three servers to analyze the effect of the TCP_SYN flooding attack on the software-based network controller. From the fourth server, the round-trip time is measured. Customer requests are employed in (RTT). The software-based network controller can see a significant number of flows in this assault since random source IPs are being used to produce flow towards the target. This significantly hinders the efficiency of the software-based network controller by adding a lot of traffic to it.

The results of the TCP_SYN flooding assault on the software-based network using the suggested technique, whose structure is depicted in Fig. 7, are displayed in Fig. 11. The volume of incoming traffic using the suggested approach before, during, and after the attack is depicted in Fig. 11(a). Fig. 11(b) also depicts the duration of back-and-forth travel in response to customer demands. The TCP_SYN flood assault begins in three seconds and concludes in 45 seconds, as can be shown. As soon as the attack begins, the time it takes for the customer's requests to move back and forth dramatically increases due to the main controller of the flow rules being overloaded and unable to handle requests entered as packet-in packages. Due to the software-based network controller receiving far less incoming traffic than the UDP flood attack, the time increase seen in Fig. 11(b) is noticeably reduced. The amount of incoming traffic load to the main controller of the flow rules setter is decreased by the activation of the sub-controller of the flow rules setter by the coordinating controller due to the detection of overloading of the main flow rules setter controller and the allocation of additional load resulting from the attack on it. The main controller of the flow rules can once again handle and process requests that are received in the form of packet-in packets by reducing the amount of incoming traffic. As a result, the time it takes for the customer's requests to go back and forth returns to a reasonable value. As a result, in this instance, similar to ICMP/Ping and UDP flood attacks, the TCP_SYN flood attack has no effect on the proposed method's availability other than for a brief period of time (the time needed to detect the coordinator controller loading the main controller of the flow rules and then the activation of the installer) Flow rules and allocation of additional load to it.

VI. Comparing the Effectiveness of the Proposed Solution to those Already in Use

This section compares the effectiveness of the proposed strategy with four different ways of preventing denial-of-service attacks. The four options are as follows: Ryu controller [40] without any protection method, Ryu controller [41] with MLFQ mechanism, Ryu controller [18] with Flood Defender mechanism, and Ryu controller [40] with FMD-ARA system. The method used by the researchers in [19] provides the basis for this comparison. Fig. 12 (implemented in the Mininet 2.2.2 emulator) depicts the network structure utilized to conduct this comparison [36], [37].

The control layer network in this experiment was out-of-band (a different network from the data layer network), in contrast to the prior tests where the control layer had an in-band network (using the data layer network to communicate with switches and other controllers).

As seen in Fig. 12, in the scenario taken into consideration for the test, 2h interacts with 3h, and 7h communicates with 8h while attackers 1h and 5h perform a UDP flood attack and steadily speed up this attack. Response Request Time (RRT) is measured at about 2h with 3h and 7h with 8h as a standard to evaluate the effectiveness of each solution. RRT is the average response time from the controller and demonstrates the efficiency of the controller in producing network connections. Yes, that is doable. The response request time in Fig. 13 is in relation to 2h and 3h demonstrates the effectiveness of the approach against the denial-of-service attack. The coordinating controller speeds up the attack until it reaches 1000 packets per second (PPS), at which point it activates the sub-controller of the flow rules setter and sends the traffic produced by the UDP flood attack to it. As demonstrated in Fig. 13, this operation has significantly lowered the average response time to legitimate and safe requests to build the flow by reducing the traffic load on the main controller that establishes the flow rules. Fig. 13's findings, derived from the researchers' article from [20], indicate that while the efficiency of the other four techniques improved as the attack speed increased, so did their average response times. The control level is resistant to denial-of-service attacks and performs better thanks to its unique structure (the presence of sub-controllers that determine the flow rules in the main and coordinating controllers).

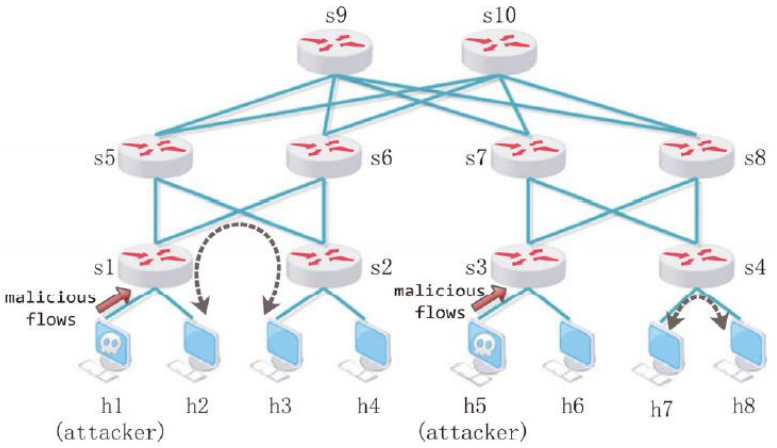

Fig. 12. Network architecture consisting of Open_Flow switches to evaluate the proposed efficiency against denial-of-service attacks.

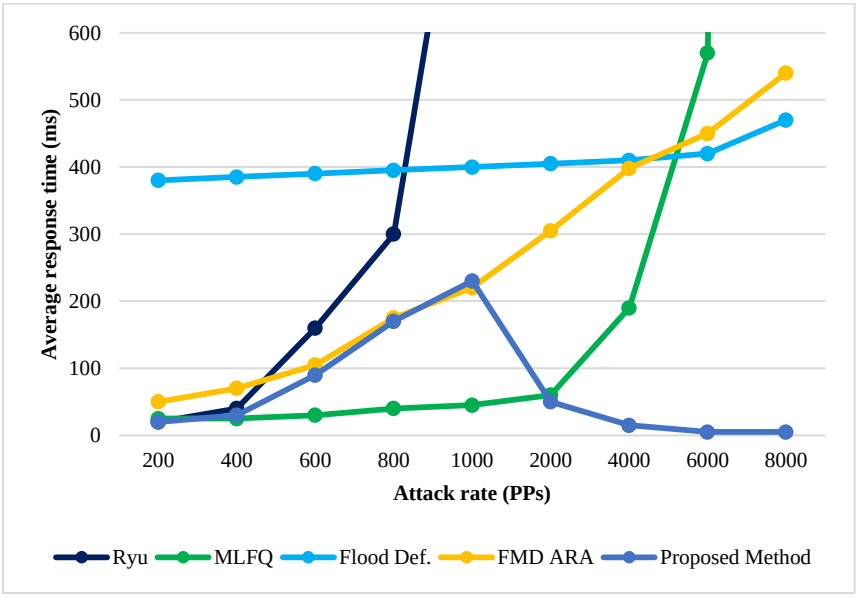

Fig. 13. For current approaches, the typical reaction time is between 2 and 3 hours.

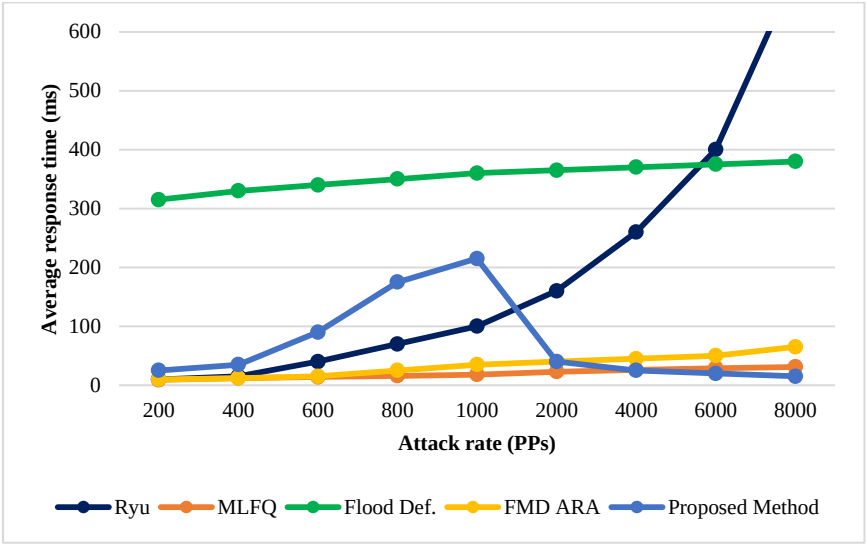

Fig. 14. Based on current techniques, the average reaction time in communication is between 7 and 8.

Fig. 14 illustrates the typical response time for communications between 7 and 8 hours. In contrast to the previous instance, a connection is established between two hosts not directly linked to the switch targeted in the attack. In this instance, the recommended efficiency is not much different from the prior state. Among the four solutions, with the exception of Flood Defender, which relies on a pre-processing system and must temporarily store each new Open_Flow request in a packet buffer before reacting to it, all show better performance than the previous setup. This situation results from the fact that the main factor causing an increase in the reaction time delay in the three solutions, MLFQ, Ryu, and FMD-ARA, is the presence of congestion in the communication channel of the switch with the controller. If, as proposed, the switch's communication channel with the main controller of the flow rules becomes congested and the main controller becomes overloaded, increasing the response time delay, the additional load that caused the congestion is sent through a different communication channel to the main controller. The set of flow rules acts as a guide for a sub-controller. The coordinating controller activates the sub-controller of the flow rules when it notices that the main controller of the flow rules is overloaded. This not only overloads the main controller but also creates a separate communication channel between the sub-controller and the switch. To avoid clogging up the main controller's communication channel with the switch.

The key findings of the study highlight the effectiveness of a novel approach to enhance the security and resilience of software-defined networks (SDNs) against denial-of-service (DoS) attacks. The introduced "control box" solution, consisting of coordinating, main, and sub-controllers, successfully manages and distributes incoming traffic during DoS attacks, reducing response times and maintaining network availability. Experimental validation, using various DoS attack scenarios, demonstrates the method's superiority over existing solutions. Furthermore, comparisons with alternative methods, including Ryu controllers with various mechanisms, consistently show that the proposed approach outperforms them. While the solution offers promising results, the study acknowledges the need for further research to address resource consumption and scalability issues, paving the way for more resource-efficient and scalable network security solutions in the future.

VII. Conclusion

In this article, a new solution for the control layer has been developed with the aim of increasing access to software-based networks by increasing the security of its control layer. The control box is the main part of the proposed method. This control box consists of a main controller that adjusts the flow rules, one or more sub-controllers that adjust the flow rules, and a coordinating controller. The task of the coordinator controller is to monitor the controllers that define the flow rules and monitor the network by collecting statistical data from the Open_Flow switches. Controllers that install flow rules are also responsible for installing flow rules. Based on network information base (NIB) data obtained from the coordinating controller, these flow rules are generated by network programs running on the controllers that install the flow rules. Based on the traffic load entering the network, the coordinating controller also coordinates the operation of the main and sub-controllers of the flow rules. The high tolerance of the proposed method for attacks that lead to the saturation of the control plane by the data plane of SDN networks is due to the redundancy of flow rule set controllers in the method. In summary, the importance of the proposed solution to increase the security and resilience of Software Defined Networks (SDN) against Denial of Service (DoS) attacks is emphasized. They highlight the unique contribution of their "control box" approach, which effectively manages and distributes incoming traffic during DoS attacks, thereby reducing response time and maintaining network availability. The following are the limitations and future works.

The proposed solution, while effective in reducing DoS attacks, requires the deployment of additional resources, which can lead to increased energy consumption and cost. This limitation highlights the need for further optimization to reduce the resource overhead associated with the approach. This article also mentions a limitation on the number of available switch ports for adding sub-controllers to a flow rules installation. This scalability limitation needs to be addressed to ensure that this approach can be applied to larger and more complex SDN environments.

VIII. Future Work

1) Resource efficiency: Future research should focus on optimizing the proposed solution to reduce resource requirements, making it more resource efficient and environmentally sustainable.

2) Scalability solutions: Addressing scalability limitations is a priority. Researchers could explore ways to scale the approach to accommodate larger SDN deployments, possibly through innovations in controller communication and load distribution techniques.

3) Security extensions: Expanding research to cover a wider range of cyber threats and security challenges in SDNs would be valuable. This could include exploring ways to increase security against other types of attacks beyond DoS, ensuring comprehensive network protection.

Optimization of Unsupervised Neural Machine Translation Based on Syntactic Knowledge Improvement

Aiping Zhou
Department of Fundamental Courses, Southeast University Chengxian College, Nanjing, 210088, China

***Abstracts*—Unsupervised Neural Machine Translation is a crucial machine translation method that can translate in the absence of a parallel corpus and opens up new avenues for intercultural dialogue. Existing unsupervised neural machine translation models still struggle to deal with intricate grammatical relationships and linguistic structures, which leads to less-than-ideal translation quality. This study combines the Transformer structure and syntactic knowledge to create a new unsupervised neural machine translation model, which enhances the performance of the existing model. The study creates a neural machine translation model based on the Transformer structure first, and then introduces sentence syntactic structure and various syntactic fusion techniques, also known as the Transformer combines grammatical knowledge. The results show that the Transformer combines grammatical knowledge paired with Bi-Long Short-Term Memory proposed in this research has better performance. The accuracy and F1 value of the combined model in the training dataset are as high as 0.97. In addition, the time of the model in real sentence translation is controlled within 2s, and the translation accuracy is above 0.9. In conclusion, the unsupervised neural machine translation model proposed in this study has better performance, and its application to actual translation can achieve better translation results.**

I. Introduction

With the progress of globalization and the increasing frequency of information exchange, machine translation, is an important artificial intelligence technology, plays an important role in connecting different languages and cultures [1-2]. Machine Translation (MT) is the process of using computer software to convert text or speech from one natural language to another. MT, as a branch of computer-assisted translation, aims to achieve barrier-free language communication between people. Unsupervised Neural Machine Translation (UNMT) belongs to one kind of MT, and the use of UNMT model to carry out translation tasks can not only improve the translation speed and save the cost, but also be able to deal with multiple languages at the same time, which is an important value of language utilization. As a research direction that has been developing rapidly in recent years, the main purpose of UNMT is to provide the best solution to the problem in the field of unsupervised translation, and to provide the best solution to the problem. Its main purpose is to carry out automatic translation without parallel corpus, so as to improve the speed and accuracy of machine translation [3-4]. Currently, the traditional UNMT model is still facing a series of challenges, for example, in the environment without parallel corpus, UNMT is often difficult to obtain effective linguistic correspondences, thus affecting the quality and accuracy of translation [5]. Against this background, the emergence of the Transformer structure has revolutionized the field of machine translation, especially its demonstrated efficiency in sequence-to-sequence learning [6]. At the same time, how to better integrate grammatical knowledge into the UNMT model has become an urgent challenge. Based on the above problems and challenges, this study aims to deeply explore and propose a novel UNMT model, which not only incorporates the advantages of the Transformer structure, but also the theoretical features of grammatical knowledge. The newly constructed UNMT model aims to achieve higher translation quality and effect, and at the same time solve the technical and theoretical problems of the traditional UNMT model in machine translation, so as to provide certain technical reference value for the field of machine translation.

In order to facilitate readers to better understand the content of the article and the framework of the article, this research divides the article into a total of six sections, which are the introduction, literature review, method design, result analysis, discussion and conclusion chapters. Section I mainly introduces the background of the study, the current status of the study, the research methodology, and the significance of the study. The literature review chapter mainly analyzes and summarizes the related studies of others so as to prove the novelty of this research which is mentioned in Section II. The research methodology in Section III mainly explains how to build the optimized UNMT model and introduces some related machine translation techniques. The result analysis section mainly tests the performance and practical application effect of the UNMT model, so as to prove the effectiveness of the model which is mentioned in Section IV. The discussion in Section V is mainly to further analyze and summarize the reasons for the better performance of the model according to the experimental results. The conclusion in Section VI is a concise summary of the whole paper.

II. Related Work

UNMT is an approach to MT whose main feature is to translate without a parallel corpus. Currently, it has been optimised by a number of experts in combination with deep learning. In order to address the drawback that remotely supervised relational reminding is seriously affected by

mislabelling in practical applications, Xiao et al. proposed a Transformer module for remotely supervised relational reminding with multi-instance learning using a hybrid attention mechanism. On the remote supervised relational reminding task, experimental results demonstrated that the method developed by the research performed better than the state-of-the-art algorithms at the time [7]. The Transformer concept has additionally been used in the machining sector. The a priori knowledge of the target text could not be fully utilised by the conventional automatic speech mistake detection systems, according to Zhang et al. Therefore, Zhang et al. proposed to apply the Transformer model to it, and the results of this study showed that the method could obtain a relative improvement of 8.4% on the F-1 scoring metrics, which is advancing significance for the optimisation of automatic speech error detection methods [8]. Li et al. concluded that the existing anomaly detection methods in the power industry do not fully exploit the potential value of the data. Therefore, an anomaly detection model based on graph attention and Transformer was proposed. Li et al. designed experiments based on power data in a region of China [9]. Li et al. argued that current neural TTS models suffer from robustness problems thus leading to audio anomalies. In order to construct a Neural network (NN) model capable of synthesising both natural and stable audio, thus a Transformer based TTS model called RobuTrans was proposed in [10]. Through experiments, it was found that the model solves the robustness problem that exists in the TSS model. According to Xiao et al., the current entity and relation extraction suffers from noise labelling issues and is unable to recognise the relationship between relations and phrases. This led to the proposal of a hybrid depth NN model based on Transformer and other models. The outcomes of many experiments demonstrated that the model was superior at entity and relation extraction and could filter noisy words [11].

As a posteriori regularisation technique to direct the training efficiency of unsupervised MT models during repeated reverse translation, Ren et al. presented a phrase-based statistical MT model. This study jointly optimises the SMT and NMT models under a unified expectation maximisation framework and gradually improves the performance of both models during the iterative process. The results of the study show that the proposed scheme can achieve two advantages. Filtering the noise in the phrase table by SMT can promptly mitigate the negative impact of errors during iterative back translation. Meanwhile, NMT can make up for the inherent lack of fluency in SMT [12]. Li et al. utilised spatio-temporal maps obtained from videos and the spatial and temporal interactions of objects to facilitate potential spatial alignment and remove translation ambiguity in UNMT. The designed model employs multimodal backtranslation and feature pseudo-visual hubs, and learns a shared multilingual visual-semantic embedding space that fuses visual hub subtitles as additional weak supervision. The proposed model is validated on the VATEX Translation 2020 and HowToWorld datasets for translation in sentences and words with good generalisation performance [13]. Sun et al. empirically investigated the performance of four different languages (French, German, Chinese, and Japanese) on the English UNMT model. In addition, a simple general method is proposed for improving the translation performance of these four language pairs. To address the shortcoming that different language pairs have significant delayed convergence in the denoising process, Sun H et al. proposed a pseudo-data based UNMT [14].

In summary, a number of scholars have carried out a series of studies on Transformer structure and UNMT model. Among them, the research on Transformer structure mainly focuses on the detection of various abnormal signals and data, while the research on UNMT model focuses on the optimisation of model translation effect. Based on the above background, this research innovatively fuses the Transformer structure with GK and uses the fused model in the field of UNMT, aiming at better extraction of English grammatical error features and detection of its incorrect grammar.

III. UNMT Model Construction Based on GK Improvement

The emergence of neural MT models has led to the gradual replacement of end-to-end single MT, and the continuous optimisation of neural MT models has also made the translation effect of various small language translation models closer and closer to that of human translation. In this research, the traditional Long Short-Term Memory (LSTM) and the neural MT model under the Transformer structure are firstly introduced, and then it is optimised by combining with the GK structure, and a new UNMT model is proposed.

A. Research on Neural MT Modelling Based on Transformer Structure

With the continuous combination of deep learning and MT technology, the neural MT model has become the most mainstream intelligent translation model. The biggest advantage of Recurrent Neural Network (RNN) in English translation is its ability to remember the historical information of a sentence, to expand the individual words in a sentence in time steps, and to check its grammar [15]. RNN automatically corrects grammatical errors by transforming the input natural language text into the output of the RNN so that grammatical errors can be corrected automatically. The standard expression form of the RNN is shown in Eq. (1) and Eq. (2).

$$h_t = \varphi_h\left(W_h x_t + U_h h_{t-1} + b_h\right) \tag{1}$$

In Eq. (1), x_t denotes the input of the time step at moment t and $t = [1, 2, \cdots m]$. h_t denotes the implied state of the output of the time step at moment t. W_h, U_h, and b_h denote the relevant parameters of the output implied state, respectively. φ_h, on the other hand, denotes the nonlinear activation function of the output implied state [16].

$$y_t = \varphi_y\left(W_y h_t + b_y\right) \tag{2}$$

In Eq. (2), y_t denotes the output of the network at the moment t. W_y and b_y are the relevant parameters of the output state of the network, respectively. φ_y denotes the nonlinear activation function of the network output. Researchers optimised the RNN and designed new loop units

by adjusting the nonlinear activation function in the network. The common LSTM gradually gets new applications in MT problems. The unit structure of LSTM is shown in Fig. 1.

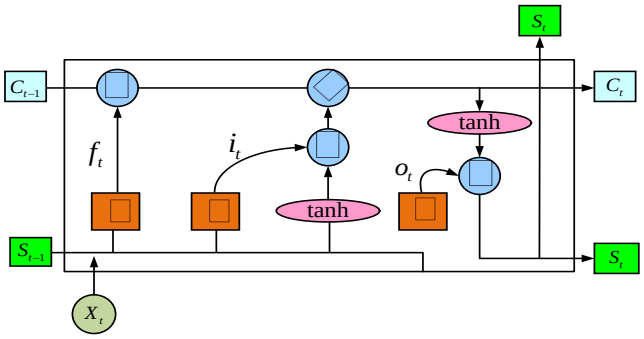

Fig. 1. LSTM cell structure diagram.

In Fig. 1, the LSTM consists of three gate structures, and selectively receives information through memory units. Where X_t denotes the input data of the input layer at the moment t. S_t denotes the neuron state of the hidden layer at the moment t. C_t denotes the memory unit at the moment t. The three σ in Fig. 1 indicate the three gate structures in LSTM from left to right. f_t, i_t, and o_t indicate the parameters of the three gates, respectively [17].

$$f_t = \sigma' W_x^f \cdot X_t + W_s^f \cdot S_{t-1} + b_f \tag{3}$$

In Eq. (3), W_x^f, W_s^f denotes the weight matrix, b_f denotes the input gate bias vector. σ' denotes the input gate. f_t denotes the input gate parameters.

$$i_t = \sigma'' W_x^i \cdot X_t + W_s^i \cdot S_{t-1} + b_i \tag{4}$$

In Eq. (4), W_x^i and W_s^i denote the weight matrix, b_i denotes the forgetting gate bias vector. σ'' denotes the forgetting gate. S_{t-1} denotes the neuron state at the moment of $t-1$. i_t denotes the forgetting gate parameter.

$$o_t = \sigma''' W_x^o \cdot X_t + W_s^o \cdot S_{t-1} + b_o \tag{5}$$

In Eq. (5), W_x^o, W_s^o denotes the weight matrix, b_o denotes the output gate bias vector. σ''' denotes the output gate. o_t is the output gate parameter.

$$\tilde{c}_t = \tanh\left(W_x^c \cdot X_t + W_s^c \cdot S_{t-1} + b_c\right) \tag{6}$$

In Eq. (6), $\tilde{c}_t$ is the output of the memory cell obtained by the forgetting gate parameter i_t after the calculation of the tanh function. W_x^c and W_s^c denote the weight matrix. b_c denotes the bias vector of the forgetting gate after the calculation of the tanh function.

$$c_t = i_t \square \tilde{c}_t + f_t \square c_{t-1} \tag{7}$$

In Eq. (7), $\square$ denotes the Hardman product.

$$S_t = o_t \square \tanh(c_t) \tag{8}$$

Eq. (8) is the equation for the neuron state of the hidden layer at moment t.

Since both RNN and LSTM are prone to the problems of gradient vanishing and gradient explosion when performing parameter updates, the study builds a small language translation model by combining the Transformer structure. Transformer is an NN structure used for sequence-to-sequence learning, which is better able to deal with the problem of long text. The structure of Transformer is shown in Fig. 2.

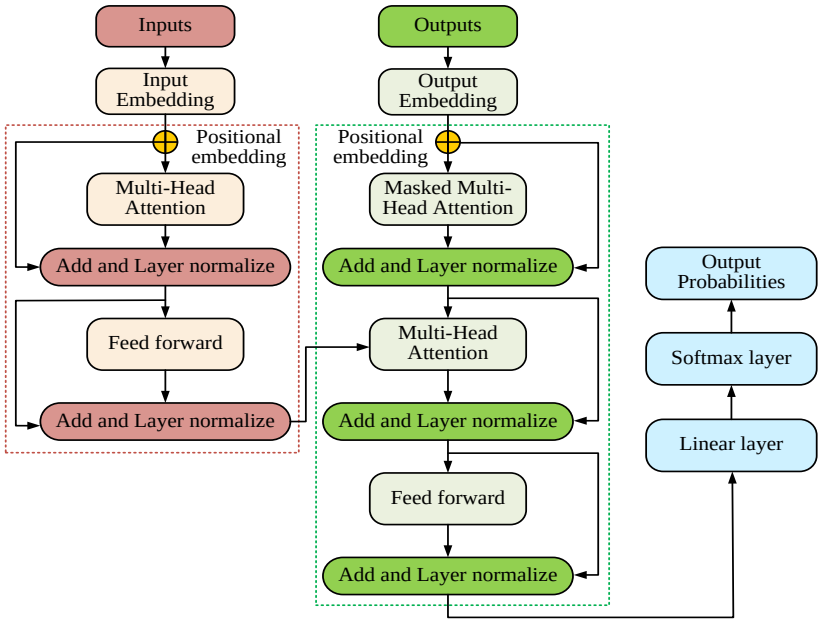

Fig. 2. Structure of the transformer model.

Fig. 2 depicts the Transformer model's structural layout. The operation flow of the encoder and decoder is shown in Eq. (9) and Eq. (10) [18].

$$e_1, e_2, \cdots, e_m = encoder\left(X1, X2, \cdots, Xm\right) \quad (9)$$

In Eq. (9), $e_1, e_2, \cdots, e_m$ denotes a string of input text sequence. $encoder\left(X1, X2, \cdots, Xm\right)$ denotes the encoder for encoding.

$$Y_t = decoder\left(e_1, e_2, \cdots, e_m, Y1, Y2, \cdots Y_{t-1}\right) \quad (10)$$

In Eq. (10), Y_t denotes the probability distribution vector of the decoded data, which is obtained by calculating the SoftMax function. $decoder\left(e_1, e_2, \cdots, e_m, Y1, Y2, \cdots Y_{t-1}\right)$ denotes the decoding operation on the probability distribution vector.

B. Study of UNMT Modelling Incorporating the Transformer Structure and GK

Since the traditional Transformer model tends to ignore the semantic information of the sentence in the translation process, which leads to the translation result deviating from the actual meaning, this study further proposes an optimized UNMT model based on the traditional Transformer structure combined with GK, notated as Transformer combines grammatical knowledge (TCGK). Traditional UNMT is an approach for training in MT tasks without using parallel corpus, i.e., corresponding sentence pairs between source and target languages. Fig. 3 depicts the UNMT model's fundamental structure.

Fig. 3 depicts the UNMT model's overall structure. Two monolingual semantic repositories, a language modelling board, and a reverse translation board are the primary components of the UNMT architecture shown in Fig. 3 [19]. When the words in the two monolingual semantic repositories are input into the model, they first need to be initialised. In the initialisation process, the main purpose is to encode the words, phrases and words so that each word can be recognised by the UNMT model, thus achieving the purpose of training the model. After the initialisation process, language modelling is required. In the modelling process, the encoder-decoder structure is used for denoising and at the same time allowing the encoder to learn the semantic information of the monolingual data. The mathematical expression for language modelling is shown in Eq. (11).

$$L_{\min} = E\left[-\log P_{s\to s}\left(x\middle|C\left(x\right)\right)\right] + E\left[-\log P_{t\to t}\left(x\middle|C\left(x\right)\right)\right] \quad (11)$$

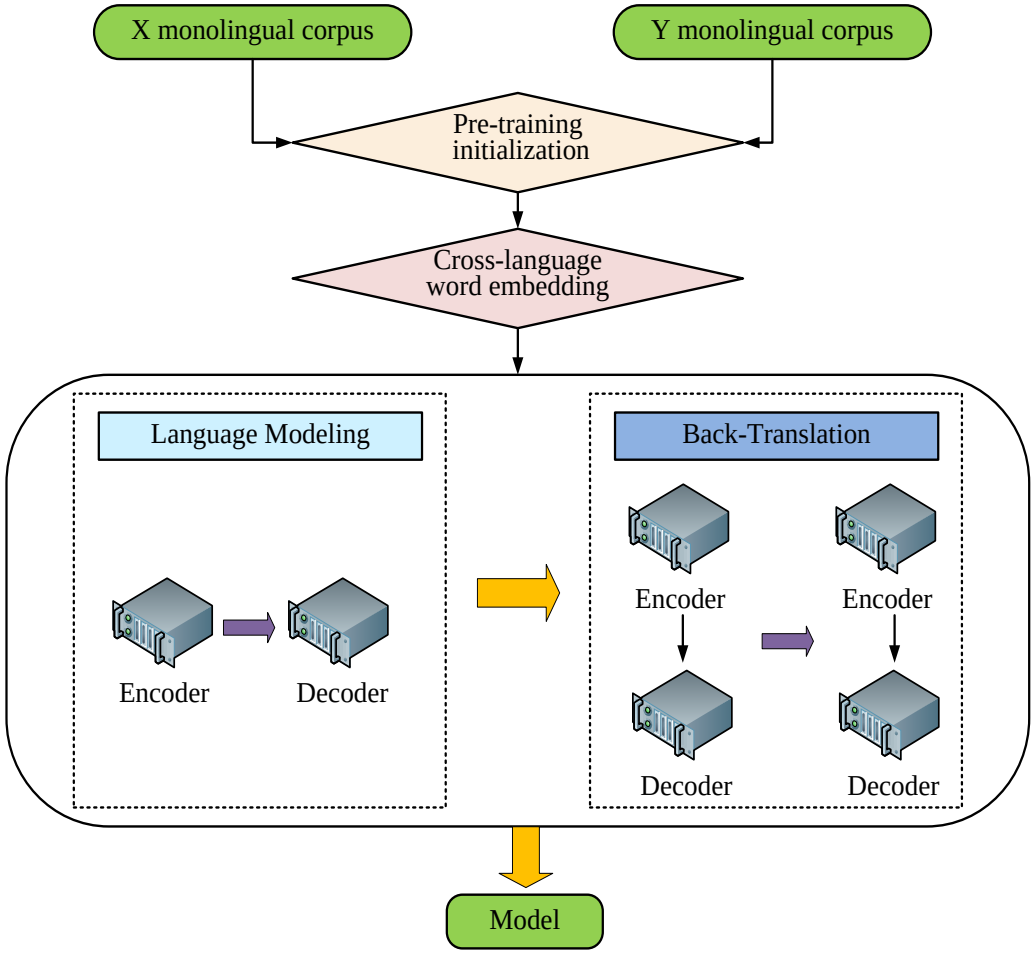

Fig. 3. Unsupervised neural machine translation model structure.

In Eq. (11), $L_{\min}$ denotes the minimum loss in the modelling process. C denotes the noise model. x denotes the sentence in the X monolingual semantic base. $P_{s\to s}$ denotes the source-side encoder-decoder combination. $P_{t\to t}$ denotes the target-side encoder-decoder combination. E denotes the energy consumption in the modelling process. The mathematical expression for reverse translation is shown in Eq. (12).

$$L'_{\min} = E\left[-\log P_{s\to t}\left(y\middle|u*(y)\right)\right] + E\left[-\log P_{t\to s}\left(x\middle|v*(x)\right)\right] \quad (12)$$

In Eq. (12), $L'_{\min}$ denotes the minimum loss in the reverse translation process. y denotes a sentence in the Y monolingual semantic base. $u*(y)$ denotes translating the source language according to the target language. $v*(x)$ denotes translating the target language according to the source language. $P_{s\to t}$ denotes the direction of translation from the target language to the source language. $P_{t\to s}$ denotes the direction of translation from the source language to the target language.

In order to learn the translation relationships between the source and destination languages, neural MT models typically need a sizable parallel corpus for training that comprises corresponding sentence pairs between the two languages. However, UNMT does not rely on parallel corpus, but is trained by using monolingual corpus. The UNMT model is obtained by optimising the encoder-decoder structure, and the basic idea is to learn the correspondence between source and target languages through self-supervised learning of monolingual corpus, so as to achieve the MT task. This study takes GK and syntactic structure into account for the model's optimisation on the basis of the conventional UNMT model in order to give the UNMT model a better translation effect that can accurately translate according to the syntactic structure and be close to the actual semantic environment. Firstly, the sentence syntactic structure is introduced, as shown in Fig. 4.

Fig. 4 shows the syntactic tree structure diagram of the sentence. To translate a complete sentence according to the actual context and grammatical structure, it is necessary to split its sentence syntactic structure first [20]. In Fig. 4, it can be seen that a complete sentence is composed of sentences or phrases. For phrase structure, its extracted syntactic labels contain constituent categories and phrase structure information. The hierarchical output of the phrase structure syntax contains the information of the various categories of words and the attributes of the words.

In order to allow unsupervised MTs to have a better knowledge of syntax, this research decided to use the results of the syntactic analysis to optimise the translation results of the model. After linearising these results and extracting their syntactic labels, and then combining them with the corresponding sentences, the combined data is used to train the source side of the denoising autoencoder. In this way, sentences and syntactic information can be jointly encoded into a new vector, thus creating a language model that incorporates syntactic information. The process of training the model with fused syntactic knowledge is shown in Fig. 5.

A flowchart of the model training process incorporating syntactic knowledge is demonstrated in Fig. 5. In Fig. 5, the optimised model has adapted the inputs of the denoising autoencoder, and multiple encoders are used to process the monolingual corpus, lexicality, phrase structure, and dependency syntax, respectively. During training, the model absorbs lexical and syntactic information and optimises the shared encoder and decoder parameters to better capture the implicit syntactic information in sentences. When decoding, the model utilises semantic, lexical and syntactic information to assist in the predictive generation of target words. By incorporating lexical and syntactic knowledge, the challenge of not being able to explicitly learn syntax can be addressed and the accuracy of the translation can be improved.

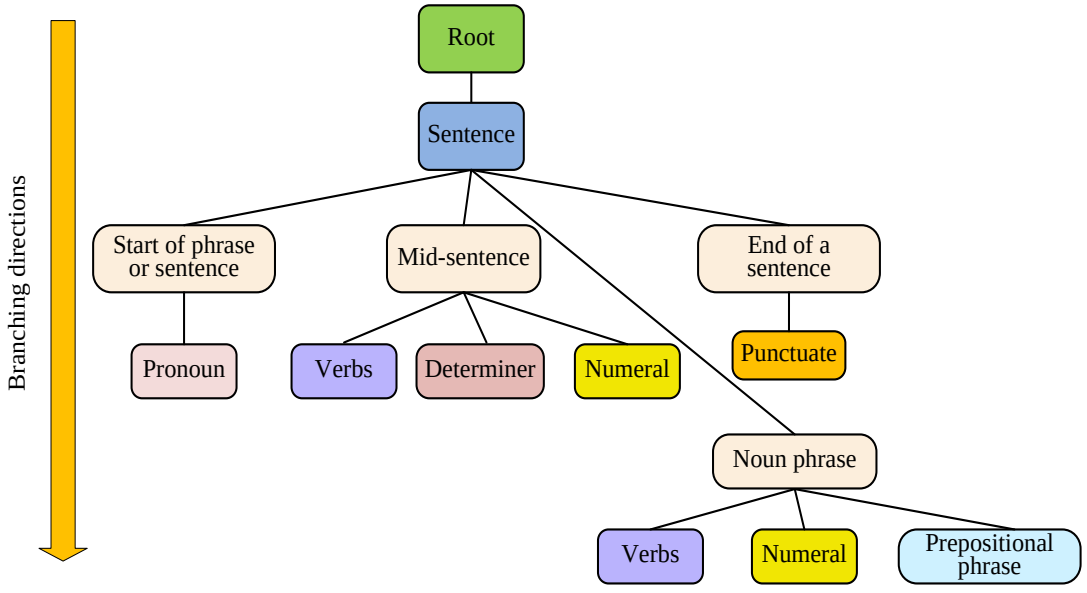

Fig. 4. Sentence syntactic tree structure.

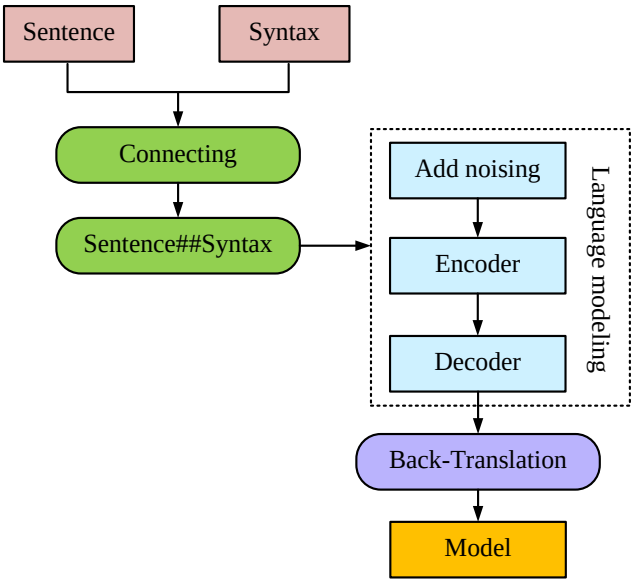

Fig. 5. Flow chart of model training incorporating syntactic knowledge.

In addition to adopting the approach of fusing syntactic knowledge in Fig. 5, the study also uses Bi-Long Short-Term Memory (Bi-LSTM) in NN to extract vectors of features for syntactic analysis sequences and splice them with sentence vectors to obtain a vector containing semantic and syntactic information, and uses this vector to train TCGK, so as to improve the translation quality of the TCGK model. The flow chart of Bi-LSTM extraction of syntactic vectors is shown in Fig. 6. The flowchart of Bi-LSTM for extracting syntactic vectors is shown in Fig. 6.

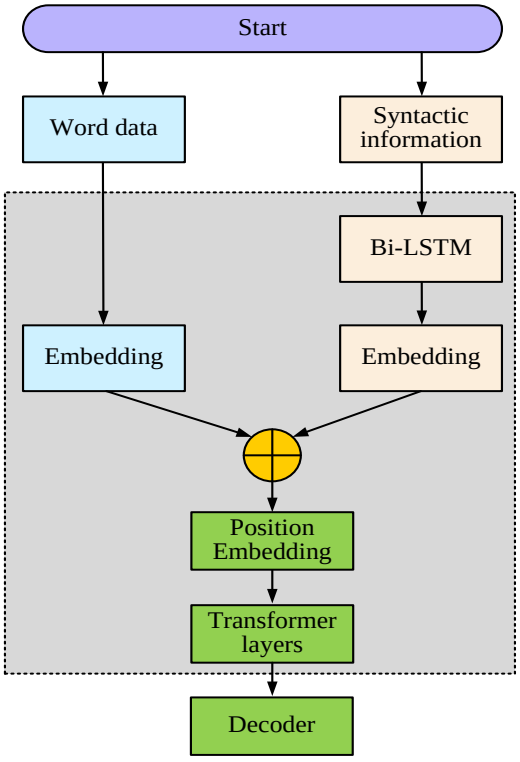

Fig. 6. Flow chart of sentence normal vector extraction under Bi-LSTM.

As shown in Fig. 6, Bi-LSTM is used to extract syntactic vectors. In order to more closely combine monolingual sentences and explicit syntactic information, the syntactic tree sequence is first linearised. At the input of Transformer, this study combines sentence vectors with syntactic vectors processed through Bi-LSTM to form new fusion vectors. The syntactic features are first transformed into high-dimensional vectors through the word embedding layer of the NN and then spliced with the sentence vectors, and this resulting integrated feature vector does not involve modifying the syntactic content. Using this fused vector, the encoder-decoder starts iterative training and stops iterative training until the model has better translation results.

IV. Performance Analysis of UNMT Models using Transformer Structure and GK

The result analysis section tested the performance of various types of translation models before testing the UNMT model created in the aforementioned study. This demonstrated that the translation performance of the model used in this study was superior through the indicators of detection accuracy, change of loss curves, and F1 value. In addition, the study further compares the translation effect of each translation model in practical applications. The results of the study found that the UNMT model combined with Bi-LSTM has higher translation accuracy and teacher-student satisfaction.

A. Performance Analysis of Different Translation Models

The News Crawl dataset was first chosen as the experimental dataset, and Newstest2020 and Newstest2021 were chosen as the experimental training dataset and test dataset, respectively, to test the performance of the model under the Transformer structure. In Newstest2020 and Newstest2021, there were 5000 corpora each. The corpus for Newstest2020 and Newstest2021 is 5000. Table I displays the settings for the experimental model's parameters.

The basic network parameters in the Transformer model are given in Table I, including the number of its encoder-decoder layers, the number of layers of the multi-head attention mechanism, the dimensions of the word embedding and hidden layers, and the learning rate. The detailed composition of the Newstest2020 and Newstest2021 experimental dataset information is shown in Table II.

Table II shows the details of the Newstest2020 and Newstest2021 experimental datasets, describing the source of the datasets, the composition of the language pairs, the number of samples, and the purpose of the dataset usage, respectively. In addition to utilizing the Newstest2020 and Newstest2021 experimental datasets for testing, the study also selected some public language datasets for testing. In order to compare the performance of the two syntactic fusion methods in the model TCGK, this study notated the syntactic fusion approach in Fig. 5 as TCGK+Common coding, and the syntactic fusion approach in Fig. 6 as TCGK+Bi-LSTM, and introduced the traditional Transformer model as well as the LSTM model for the comparison of the model translation performance. The detection accuracy of the four models in different datasets is shown in Table III.

TABLE I. PARAMETER SETTING OF THE EXPERIMENTAL MODEL

Transformer model parameters	Parameter values
Number of encoder and decoder layers	4 layers
Number of layers of multi-head attention mechanism	8 layers
Dimension of word embedding and hidden layers	1024
Learning rate under Adam's optimization method	0.001
Batch Size	32
Model regularization Dropout	0.1

TABLE II. EXPERIMENTAL DATA SET INFORMATION TABLE

Data set information	introduce
Source	It mainly contains news texts, which are sourced from various news websites and agencies.
Language pair	These two datasets cover multiple language pairs. For example, English to German, English to French, English to Chinese, etc.
Sample size	The number of corpus in Newstest2020 and Newstest2021 is 5000.
Aim	Evaluate the translation performance of machine translation models.

In Table III, a total of five public datasets, Newstest2020, Newstest2021, Para Crawl, Europarl, and Common Crawl, are selected for testing. Europarl: dataset is a dataset based on the records of the European Parliament, covering 21 European languages. Common Crawl is a multilingual aligned dataset based on web crawling. Para Crawl is a multilingual parallel corpus for large-scale web crawling. As shown in Table III, the detection accuracies of LSTM in Newstest2020, Newstest2021, ParaCrawl, Europarl, and Common Crawl are 0.78, 0.77, 0.71, 0.66, and 0.69, respectively. Transformer in Newstest2020, Newstest2021, ParaCrawl, Europarl, and Common Crawl with detection accuracies of 0.82, 0.83, 0.75, 0.71, and 0.72, respectively. TCGK+Common coding in Newstest2020, Newstest2021, Para Crawl, Europarl, and Common Crawl were 0.88, 0.89, 0.86, 0.82, and 0.83, respectively. The detection accuracy of TCGK+Bi-LSTM in Newstest2020, Newstest2021, Para Crawl, Europarl, Common Crawl are 0.96, 0.97, 0.91, 0.92, and 0.93, respectively. Among them, the TCGK+Bi-LSTM model is able to achieve the highest detection accuracy in the datasets Newstest2020 and Newstest2021. The translation performance of the four models will be further tested in combination with the datasets Newstest2020 and Newstest2021.

In Fig. 7, the incorrect syntax detection accuracy values for the various translation models in the training dataset and test dataset are displayed. Fig. 7(a) and Fig. 7(b) among them illustrate the detection accuracy of the four translation models for the training dataset and the test dataset, respectively: LSTM, Transformer, TCGK+Common Coding, and TCGK+Bi-LSTM. The four translation models' detection accuracies for faulty grammar samples exhibit an increasing trend as the number of detected samples rises, as shown in Fig. 7(a) and Fig. 7(b). The four translation models, LSTM, Transformer, TCGK+Common coding, and TCGK+Bi-LSTM, each have detection accuracy scores in the training dataset that are 0.78, 0.82, 0.90, and 0.97, respectively. In the testing dataset, the highest detection accuracy values of the four translation models, LSTM, Transformer, TCGK+Common coding, and TCGK+Bi-LSTM, are 0.78, 0.82, 0.90, and 0.97, respectively. coding, and TCGK+Bi-LSTM, the highest detection accuracy values of the four translation models are 0.77, 0.81, 0.88, and 0.96, respectively.

The graphs of the variation of loss values for different translation models are shown in Fig. 8. Among them, all the figures in Fig. 8 show the actual loss curves and the specific changes of the training loss curves of the four translation models, namely, LSTM, Transformer, TCGK+Common coding, and TCGK+Bi-LSTM, in the training process, respectively. Comparing the loss change curves of the four models, it can be found that compared to the other three models, the training loss curve and the actual loss curve of TCGK+Bi-LSTM basically overlap during the training process, so the stability of this model is better during the training process, and there will not be large data fluctuations.

The variance of F1 values for various translation models in the training dataset and test dataset is depicted in Fig. 9. The study introduces F1 values for testing to better represent the detection performance of each model. The F1 values obtained by the four models in the training dataset and test dataset are displayed in Fig. 9(a) and Fig. 9(b), respectively. In Fig. 9(a), the highest F1 values of the four translation models, LSTM, Transformer, TCGK+Common coding, and TCGK+Bi-LSTM, are 0.76, 0.81, 0.90, and 0.97, respectively. In Fig. 9(b), the highest F1 values of the four translation models, LSTM, Transformer, TCGK+Common coding, and TCGK+Bi-LSTM, the highest F1 values of the four translation models are 0.75, 0.80, 0.89, and 0.96, respectively.

TABLE III. DETECTION ACCURACY OF FOUR MODELS IN DIFFERENT DATA SETS

Model	Data set type				
	Newstest2020	Newstest2021	ParaCrawl	Europarl	Common Crawl
LSTM	0.78	0.77	0.71	0.66	0.69
Transformer	0.82	0.83	0.75	0.71	0.72
TCGK+Common coding	0.88	0.89	0.86	0.82	0.83
TCGK+Bi-LSTM	0.96	0.97	0.91	0.92	0.93

B. Analysis of the Effectiveness of the Application of Different Translation Models

The results of the analysis of the above performance indicators show that TCGK+Bi-LSTM has better performance compared with the other three translation models. TCGK+Bi-LSTM not only has better error grammar recognition accuracy values and F1 values, the change of the loss curve of this network during training is also basically the same as the actual change. To test the effectiveness of the four models in real English sentence translation, the study randomly selected 10 English utterances from a high school English textbook for testing. The translation accuracy and translation time of the two optimised UNMT models in real translation are shown in Fig. 10.

The translation accuracy and translation time of TCGK+Common coding and TCGK+Bi-LSTM in different English utterances are demonstrated in Fig. 10. Fig. 10(a) and (b) shows the translation accuracy and translation time of TCGK+Common coding and TCGK+Bi-LSTM, respectively. Comparing the translation effects of the two models in ten English utterances, it can be seen that the highest translation accuracies of TCGK+Common coding and TCGK+Bi-LSTM are 0.93 and 0.99, respectively. The shortest translation times of TCGK+Common coding and TCGK+Bi-LSTM take 3.2s and 0.5s, respectively. In addition, the translation accuracies of TCGK +Common coding model has a large change in the accuracy value during the translation process, and its translation elapsed time fluctuates more. Therefore, compared with TCGK +Common coding, TCGK +Bi-LSTM has better translation effect in practical applications.

(b) Translation accuracy and translation time for ten sentences under model TCGK+Bi-LSTM

Fig. 10. Translation accuracy and translation time of the two translation models in practice.

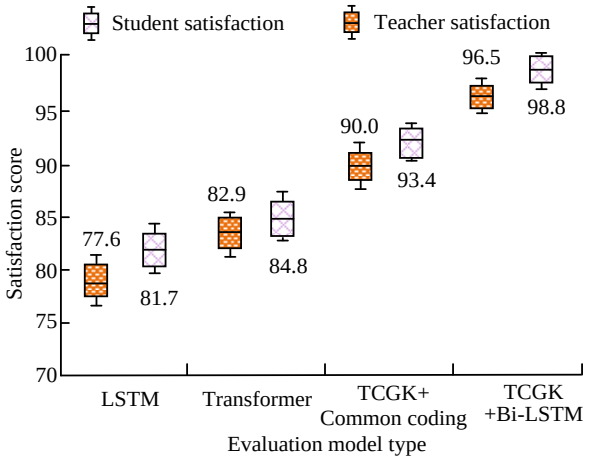

Fig. 11. Satisfaction of university teachers and students with the four translation models.

Fig. 11 shows the satisfaction scores of university students and teachers for the four translation models in practical applications. As shown in Fig. 11, the satisfaction scores of university students for the four translation models LSTM, Transformer, TCGK+Common coding, and TCGK+Bi-LSTM are 77.6, 82.9, 90.0, and 96.5, respectively. The satisfaction scores of university teachers for the four translation models LSTM, Transformer, TCGK+Common coding, and TCGK+Bi-LSTM are 81.7, 84.8, 93.4, and 98.8, respectively. In conclusion, TCGK+Bi-LSTM not only have better translation performance in practical applications, but also have higher satisfaction of university teachers and students for this model.

V. Discussion

In order to improve the accuracy and efficiency of machine translation, this research combines the fusion of Transformer structure and grammar knowledge to optimize the unsupervised neural machine translation model, and finally builds the TCGK+Bi-LSTM translation model. By comparing and analyzing the performance of various types of models as well as their practical application effects, the following discussion is derived from this research.

From the experimental results of error syntax detection accuracy, it is obvious that the TCGK+Bi-LSTM model has better error syntax detection effect compared to LSTM, Transformer, and TCGK+Common coding. The TCGK+Bi-LSTM model outperforms the other three models in terms of test accuracy and F1 value in both the training dataset and the test dataset. The reason behind the high detection accuracy and F1 value of the TCGK+Bi-LSTM model is that the combination of the deep self-attention mechanism of the Transformer structure and the Bi-LSTM network enables the model to better capture long-distance dependencies and complex syntactic structures in sentences. In addition, the TCGK+Bi-LSTM model has a better loss profile compared to LSTM, Transformer, and TCGK+Common coding, which further illustrates that the Transformer structure and the Bi-LSTM network can improve the stability of the model during the training process, which enables the model to obtain more accurate test values.

In addition, although translation accuracy is the primary index of the machine translation task, fast translation speed is also very critical in practical applications. Especially in situations where a large number of translations are required, such as online services or real-time translation applications, efficient translation speed can greatly improve the user experience. The TCGK+Bi-LSTM model also has a significant advantage in translation time compared to the other three models. This is because the introduction of the Transformer structure and the Bi-LSTM network enables the model to process the information features faster, thus achieving fast translation. Finally, the TCGK+Bi-LSTM model was also able to achieve a high level of teacher and student satisfaction in real-world applications, thus proving the value of this technique in real-world applications.

Although this study provides valuable insights into the performance of the proposed model in Chinese-English translation tasks, there are some limitations. First, the experiments were mainly conducted based on specific datasets and specific tasks, and the performance of the proposed model should be further validated on more datasets and multiple language pairs in the future. In addition, although this experiment examined the performance of several models, there are still more existing and emerging modeling approaches that deserve further exploration and comparison. Based on the current findings, future research can further examine the performance of the models on other language pairs or larger datasets. In addition, it can also explore how to further optimize the structure or parameters of the model to improve its performance in specific tasks or scenarios. In summary, this study provides valuable insights into unsupervised neural machine translation models that incorporate Transformer structural and syntactic knowledge, and provides useful directions for future research.

VI. Conclusion

This research utilizes the knowledge of Transformer structure and syntax to construct a new UNMT model that aims to improve the performance and translation accuracy of existing translation models. The results of the study show that the proposed TCGK+Bi-LSTM model model significantly outperforms the other three models in terms of detection accuracy and F1 value on both training and testing datasets. In addition, the TCGK+Bi-LSTM model exhibits higher translation accuracy and translation speed than the TCGK+Common Coding model in real translation tests involving English sentences. Finally, the TCGK+Bi-LSTM model gained high satisfaction among university teachers and students, further validating its effectiveness. Since this study mainly focused on the performance of the model in Chinese-English translation tasks, it does not have comprehensive coverage, and subsequent studies should further extend the scope of the study to examine the performance of the model on more language pairs.

***Abstract*—In order to ensure the security of university teachers and students using cyberspace, a machine learning based university cyberspace security defense model is constructed. Adopting a compression perception based data collection method for university cyberspace, the data information collection of university cyberspace is completed through sparse representation, compression measurement, and recovery reconstruction. Combining the advantages of Convolutional Neural Network (CNN) model in spatial feature extraction of data and Long Short Term Memory (LSTM) model in sequential feature extraction of data, extract the features of university network spatial data. After completing the multi feature dimensionality reduction processing of university network data based on the non-negative matrix decomposition algorithm, the feature dimensionality reduction processing results are input into the ConvLSTM-CNN model. After convolution calculation and integration, the security threat detection results of university network space are output. Based on the results of security threat detection, corresponding network attack defense measures are selected to ensure the security of the university's cyberspace. The experimental results show that the average attack interception rate of the model after application can reach 97.6%. It has been proven that building a model can accurately detect security threats to the university's cyberspace and achieve defense against various network attacks in different environments.**

I. INTRODUCTION

The development of computer technology has accelerated the process of information popularisation. By utilising the Internet, various services such as electronic banking, online teaching, and video conferencing can be provided to the public, gradually increasing people's dependence on the Internet in their daily lives, studies, and work. Currently, the Internet is also widely used in various universities. The university network has the characteristics of spatial freedom, large distribution scale, and relatively opens, but at the same time, there are also security risks in the university network. The rapid development of the Internet has led to a large number of intrusion behaviours, posing a huge threat to the network security of universities. Therefore, achieving a comprehensive perception and defense of the university's cyberspace attack events is significant for building a complete network security defense system [1]–[3].

The research on secure and reliable defense methods for network-blocking attacks has become an urgent issue to be solved, and many relevant experts and scholars have achieved fruitful research results on this topic. Wang et al. designed a network active security defense system based on the K-means algorithm [4]. However, this method is greatly affected by attackers during maintenance and is easily exploited by them, and its defense ability needs to be improved. Oliveira et al. proposed an intelligent network attack detection and classification method for network-based intrusion detection systems [5]. However, the effectiveness of this method in network security situational awareness is relatively low, and it cannot solve some low perception network attacks. The research in [6] constructed an integrated learning model for detecting botnet attacks in IoT networks. However, this method does not take into account the changes in feature quantities that exist in university networks. Zhang et al. proposed a network security attack detection method for the network Physical system based on deep learning [7]. However, this method addresses a relatively single type of network attack, and its defense effectiveness against different network attacks is not outstanding. Tonkal et al. proposed a machine learning method with neighborhood component analysis for detecting DDoS attacks in software defined networks [8]. Gurumanapalli et al. [9] proposed a state-of-the-art generalized Feistel network-assisted Shannon condition and dynamic key based SSPN (GFS-SSPN) lightweight encryption system for IoT security to achieve high attack resilience. Majeed et al. [10] used intelligent machine learning methods to design IoT assisted drones. This method will provide an intelligent network security system that helps detect network security threats using blockchain. However, due to the processing of multi-dimensional data for network attacks, this method did not undergo dimensionality reduction processing, and the accuracy of network attack detection needs to be improved. Although the above methods have achieved attack defense, they still have issues such as inadequate defense capabilities, low perceptual efficiency, and lack of consideration for feature changes, single attack type resolution, and insufficient dimensionality reduction processing.

Machine learning aims to train computers to perform certain operations through data to train "learning" in datasets and enable computers to make improved decisions in the future. Machine learning is widely used in data mining, which involves searching for unknown or hidden patterns through a large amount of data. Machine learning can be divided into two categories: supervised and unsupervised. In the supervised

learning dataset, all training and test data are assigned a value, that is, a label, which can be a numeric or a character value. Labels of unknown data can be learnt and predicted through machine learning algorithms. In unsupervised learning, data does not have labels and machine learning algorithms are needed to find out the data patterns and predict unknown data. Therefore, in response to the university's network attacks, this paper constructs a security defense model of the university's cyberspace through machine learning, implements effective defense of attack data, and ensures the safe and stable operation of the university's cyberspace. The proposal of this model will provide innovative solutions for university cyberspace security, improving the resilience and accuracy of cyberspace security defense. The main research structure of this article is as follows:

1) Construction of a security defense model for university cyberspace: This section includes several parts: university cyberspace data collection based on compressed sensing, university cyberspace security threat detection based on machine learning, university cyberspace data feature extraction based on ConvLSTM-CNN model, and university cyberspace security defense methods.

2) Experimental analysis: This section verifies the defense effectiveness of the constructed model from different perspectives.

II. Construction of a Cyberspace Security Defense Model for Universities

While operating the security defense model for the university's cyberspace, this paper conducts network security threat defense through three stages: data collection, threat detection, and defense generation. The specific process is as follows:

A. University's Cyberspace Data Collection based on Compressed Sensing

In order to meet the actual application needs of the university's cyberspace [11], this paper implements the university's cyberspace data collection through the principle of compressed sensing. The core goal of the data acquisition method based on the principle of compressed sensing is to ensure the high accuracy of data. Therefore, on the basis of analysing the core theory of compressed sensing and combining it with the specific characteristics of the university's cyberspace monitoring data, it should study practical and feasible data collection methods for the university's cyberspace that meet the needs.

As a whole, the operating status of each node in the university's cyberspace will be interrelated and affect each other [12], which indicates that there must be a strong correlation between the data of each node and data with strong correlation must have a lot of redundancy and data containing redundancy can be expressed from another perspective through simple information. The large quantity and variety of data in universities' online space can be expressed by relatively simple information in a certain space, which shows sparsity in that space. This processing method of transforming data acquisition into information acquisition is one of the core ideas of compressed sensing. Therefore, the collected data from the university's cyberspace can be compressed using the principle of compressed sensing.

The speed and accuracy of monitoring data collection are crucial for the safe operation of a university's cyberspace. The data acquisition method based on the compressed sensing principle includes three processes: sparse representation, compressed measurement and recovery reconstruction, as shown in Fig 1. By studying and improving each process of the collection method, the accuracy of data collection can be further improved.

The starting point of this paper is the co-domain sampling of the university's network spatial data, and its research focuses on the sparse representation of data (the supporting theory of co-domain sampling). According to Fig. 1, improving the sparsity of data can improve the accuracy of data collection methods and reduce the errors introduced when restoring the original monitoring data using the feature data of monitoring quantities; Data recovery requires knowing the compressed measurement sampling value y and sparse basis matrix Ψ at the other end of the communication channel. The amount of data transmitted between the two ends, y and Ψ, determines the speed of the data collection method.

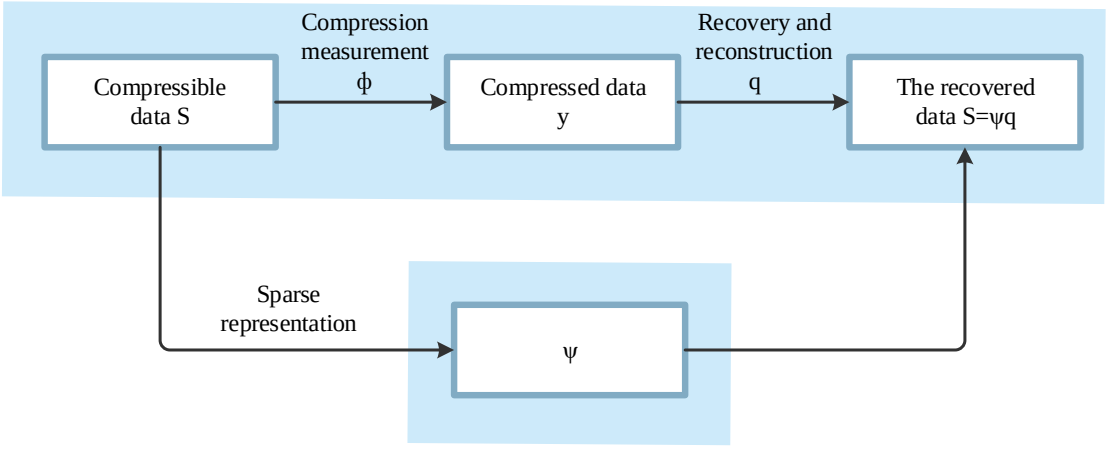

Fig. 1. Compressed sensing flow of monitoring data.

1) Theoretical basis of compression perception algorithm: In compressed sensing [13], the K-means Singular Value Decomposition (K-SVD) dictionary learning algorithm is an adaptive data sparse method. Due to the fact that data collected in a university's cyberspace can always be sparsely represented in an unknown space, and the excellent adaptive characteristics of the K-SVD dictionary enable it to adapt to the collected data in the university's cyberspace through dictionary learning algorithms, so as to effectively find a sparse space suitable for university's cyberspace data and achieve sparse representation of university's cyberspace collected data.

The mathematical model of the K-SVD dictionary learning algorithm is as follows:

$$\begin{cases} D, \theta = argmin\{\|s - D\theta\|_r^2\} \\ s.t. \forall i, \|\theta_i\|_0 \le T_0 \end{cases} \quad (1)$$

where, s represents monitoring data containing different data types within a sampling period; θ is sparse coefficient vector; T_0 is the upper limit of the number of non-zero components in sparse coefficients; the dictionary is $D = [d_1, d_2, \cdots, d_k] \in R^{n \times k}$, where each column d_k represents an atom; r is the norm.

The data s parasitisation steps based on the K-SVD dictionary learning algorithm are as follows.

Initialise the dictionary. Randomly select K data samples from the general data samples as the atoms of dictionary D. This paper takes the monitoring data S as the initial atom of D, and its standardisation process is as follows:

$$d_i^* = \left| \frac{d_i}{\sqrt{\sum_{i=1}^{N} d_i 2}} \right| \quad (2)$$

where, N is any length of compressible discrete real value data.

a) Sparse encoding. Under the condition that the dictionary D is fixed, it can solve the optimisation model of the above equation using the Orthogonal Matching Pursuit(OMP) to obtain the sparse coefficient θ′ of the collected data S.

b) Dictionary update. Update the dictionary column by column. When updating the k -th column d_k of the dictionary, make E_k the error generated by removing d_k from the data, that is:

$$E_k = s - \sum_{j \ne k} d_j \theta_T^j \quad (3)$$

In the equation, θ_T is the jth line of θ. Then perform singular value decomposition on the error to obtain the updated d_k and θ.

c) Repetitive sparse encoding and dictionary updates. If the termination condition is met, the output data is based on the adaptive sparse dictionary D of the K-SVD dictionary learning algorithm.

In the application of data collection in the university's cyberspace, based on the K-SVD dictionary learning algorithm, every atom of the optimal dictionary D of signal S is identical, and the coefficient vector θ decomposed on this dictionary is 1-sparse, ensuring the high sparsity of data S. This shows the feasibility and progressiveness of the K-SVD dictionary learning algorithm applied to a sparse representation of monitoring data in university network space.

2) Compression measurement: For the compression measurement of the university's cyberspace data, data x is compressed to obtain a measurement vector y with a length of $M(M \times N)$, which is expressed as:

$$y = \Phi x \quad (4)$$

Compression measurement no longer uses the method of measuring the university's network spatial data X itself first and then compressing it. Instead, a measurement matrix $\Phi \in R^{M \times N}$ is used to directly compress and measure data X, converting data sampling into sampling of M projections on the measurement matrix Φ.

3) Compression reconstruction: For the restoration and reconstruction of the university's cyberspace data, it is the process of restoring the original data x from vector y. In this process, the measurement vector y is represented as:

$$y = \Theta\theta \quad (5)$$

In the equation, Θ is the perception matrix and satisfies the isometric constraint criterion. The goal of the university's cyberspace data recovery and reconstruction is to find the optimal sparse coefficient vector θ, which can be expressed as an optimisation problem under the l_1 norm, namely:

$$\begin{cases} \theta = \arg\min \|\theta\|_1 \\ s.t. \quad y = \Theta\theta \end{cases} \quad (6)$$

Finally, the optimal recovery value x of the original data can be obtained. And then, the space data collection of the university's network using compressed sensing is realised. Based on the above compression perception, compression measurement, and compression reconstruction processes, data collection and output of university cyberspace security threat detection results are shown in Table I:

TABLE I. SECURITY THREAT DETECTION RESULTS OF UNIVERSITY CYBERSPACE

B. Machine Learning-based Threat Detection for University's Cyberspace Security

1) Theoretical basis of ConvLSTM-CNN model: A CNN is a deep feedforward neural network with a large number of convolution calculation processes. Different from the conventional neural network model, the neurons in each layer of CNN are arranged three-dimensionally. A two-dimensional data's length and width are the neurons' length and width, while the depth represents the third dimension used to activate the data volume. It is precisely because of this characteristic of the CNN model that it can better obtain the spatial features of university network data [14].

At present, CNN models have been widely applied in the field of cyberspace security in universities, such as intrusion detection systems and situational awareness. The structure diagram of a typical CNN model is shown in Fig. 2. Convolutional neural networks are typically composed of input, hidden, and output layers, with hidden layers typically including convolutional, pooling, and fully connected layers.

The data is first input in the input layer, and then the university's network data perceived in Section II (A) is preprocessed. By normalising the data, it is then passed into the hidden layer for calculation.

The first layer to enter is the convolutional layer, which is the core of the CNN model structure. It has multiple convolutional kernels inside and can extract features from the input data. After the convolutional layer, there is usually a pooling layer, which appears alternately in the convolutional neural network. Each convolutional layer corresponds to a pooling layer. The fully connected layer in convolutional neural networks has a similar network structure to conventional neural networks, where each neuron structure constructs connections with all neurons in the previous layer, playing the role of a "classifier" in the entire network, integrating and mapping local sample information into the corresponding space.

Compared with other neural network models, CNN has better automatic feature extraction ability [15] and is widely used in computer vision, natural language processing, cyberspace security and other directions. It has made much progress and can be used for attack classification, image recognition, target segmentation, and other fields. In this paper, we utilised the advantages of CNN models in the perceptual extraction of spatial dimension features and optimised their structure to make them more suitable for modelling traffic time series in the field of cyberspace security situational awareness in universities.

Although the CNN model has obvious advantages in data space feature extraction, it is not good at feature extraction for sequence data such as network traffic. Therefore, it needs to be optimised based on fully utilising its advantages.

LSTM model is a special Recurrent Neural Network (RNN) model which has the ability to store the long-term state of data. Sometimes, due to the long data sequence length, the training process of ordinary RNN models is prone to the problem of vanishing or exploding gradients. The LSTM model performs better in training longer sequence data than this.

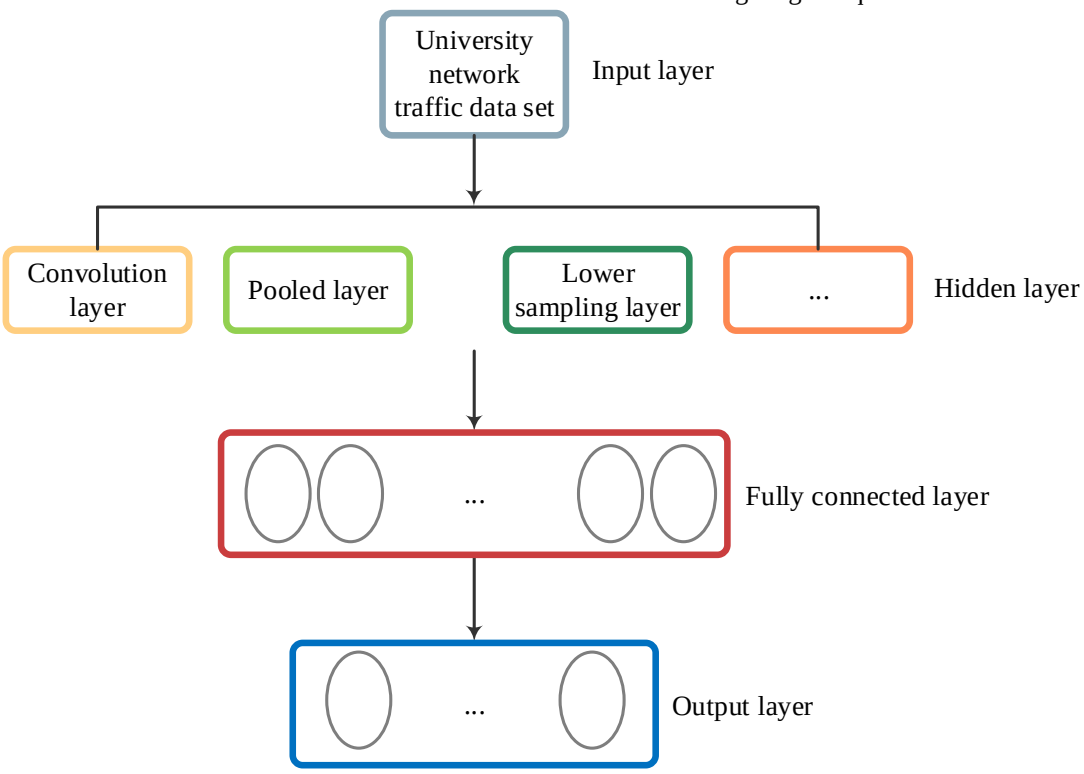

Fig. 2. Schematic diagram of convolutional neural network model.

In order to control the cell state, three gates are designed in the LSTM model to control or delete the added unit state information, namely the forgetting gate, memory gate, and output gate:

a) Forgetting gate: It used to forget or discard part of attribute information, accept a short-term memory output from the previous unit module, and decide which part to retain and forget.

b) Memory gate: It determines the information stored in the cellular state. For the attribute relationships discarded in the forgetting gate, it can find and fill in the corresponding new attribute information in this unit module to supplement the attribute information discarded by the forgetting gate.

c) Output gate: It determines the output value based on the cell state.

The working principle of the LSTM model is shown in Eq. (7):

$$\begin{cases} i_t = \sigma(W_{xi}x_t + W_{hi}h_{t-1} + W_{ci} \circ c_{t-1} + b_i) \\ f_t = \sigma(W_{xf}x_t + W_{hf}h_{t-1} + W_{cf} \circ c_{t-1} + b_f) \\ c_t = f_t \circ c_{t-1} + i_t \circ tanh(W_{xc}x_t + W_{hc}h_{t-1} + b_c) \\ o_t = \sigma(W_{xo}x_t + W_{ho}h_{t-1} + W_{co} \circ c_t + b_o) \\ h_t = o_t \circ tanh(c_t) \end{cases} \quad (7)$$

where, i_t、f_t、c_t、o_t、h_t represents input gate, forgetting gate, cell state, output gate, and transmission state; $\circ$ is the multiplication of the corresponding elements of the matrix, also known as Hadamard product, and σ is the sigmoid function; W is the weight matrix, and b is the bias top.

The LSTM model, especially for high-dimensional time series data such as network data, can effectively analyse the logical relationships between input features and the complex temporal correlations between information. Meanwhile, compared to the CNN model, the LSTM model can better simulate human thinking patterns and cognitive processes and exhibits better processing ability for complex tasks closely related to time series. Therefore, this paper will use the temporal features extracted from LSTM network data combined with the spatial features extracted from CNN network data as the result of feature extraction for university network data.

2) Multi-feature dimensionality reduction processing of university's network data based on non-negative matrix decomposition algorithm

Due to the multi-dimensional problem of obtaining the features of the university's network data in Section II (B) (1), in order to improve the accuracy of threat detection in the university's network space security, a non-negative matrix decomposition algorithm is used to perform multi-feature dimensionality reduction on university network data [16]. The non-negative matrix decomposition algorithm has the advantages of simple decomposition implementation and small space occupation. The specific process of multi-feature dimensionality reduction for university network data based on the non-negative matrix decomposition algorithm is as follows:

Fuzzy classification of university network data features is carried out, and the initial value of the non-negative matrix decomposition base matrix to be composed of the classification centroid is set [17]. In contrast, the non-negative matrix decomposition rank is the number of classifications. The feature set of university network data is set to $\lambda = [\lambda_1, \lambda_1, \cdots, \lambda_n]$, where n represents the number of samples in the feature set of university network data. After fuzzy l classification, the set is $F = [F_1, F_2, \ldots, F_l]$, where l represents the number of feature classifications of university network data. While the membership degree of the university's network data features to the fuzzy vector is expressed by U_{ij}, the membership degree matrix representation is expressed as $U = [U_{ij}]_{l \times n}$. It should be noted that U_{ij} meets $\sum_{i=1}^{l} U_{ij} = 1$, and the membership degree update function is specified as:

$$U_{ij} = \begin{cases} 0 & \|\lambda_j - z_i\|_2 > 0 \\ 1 & \|\lambda_j - z_i\|_2 = 0 \\ \left[\sum_{a=1}^{l} (\|\lambda_j - z_i\|_2 / \|\lambda_j - z_a\|_2)^{2/(\omega-1)}\right]^{-1} & \|\lambda_j - z_i\|_2 < 0 \end{cases} \quad (8)$$

where, λ_j represents the jth university network data feature; z_i represents the i-th clustering centre; z_a represents the initial clustering centre; ω represents the fuzzy weighted index.

Thus, the cluster centre set is determined as follows:

$$Z_i = \frac{\sum_{j=1}^{n} (U_{ij})^{\omega} \lambda_j}{\sum_{j=1}^{n} (U_{ij})^{\omega}} \quad (9)$$

The objective function is:

$$D = \sum_{i=1}^{l} \sum_{j=1}^{n} (U_{ij})^{\omega} \|\lambda_j - z_i\|_2^2 \quad (10)$$

If the above equation calculates the result $D < \tau$ (threshold), then the iteration stops, and the initial value of the base matrix P in non-negative matrix decomposition is set to be composed of the cluster centre set z_i.

According to the non-negative matrix decomposition algorithm, the feature matrix $\lambda_{m \times n}$ of university network data is decomposed into two non-negative matrices $Q_{m \times n}$ and $P_{m \times n}$, and the product between them infinitely approximates the original non-negative matrix, namely $P_{m \times n} \approx Q_{m \times n}$. Where, $P_{m \times n}$ represents the base matrix; $Q_{m \times n}$ represents the coefficient matrix, using minimising the remaining Frobenius as the objective function, and the expression is:

$$\min_{P,Q} F(P, Q) = \frac{1}{2} \sum_{i=1}^{n} \sum_{j=1}^{n} (\lambda_{ij} - (PQ)_{ij})^2 \quad (11)$$

When, $\lambda = PQ$, the value is 0.

Before the convergence of the objective function, fuzzy classification is used to obtain the centroid initialisation basis matrix, and the matrices P and Q are alternately updated. The matrix iteration rules are expressed as follows:

$$\begin{cases} P_{ia} \leftarrow P_{ia} \sum_j \frac{\lambda_{ij}}{(PQ)_{ij}} Q_{ai} \\ P_{ia} \leftarrow \frac{P_{ia}}{\sum_i P_{ia}} \\ Q_{aj} \leftarrow Q_{aj} \sum_i \frac{\lambda_{ij}}{(PQ)_{ij}} \end{cases} \quad (12)$$

After repeated iterations, the base matrix and coefficient matrix are finally obtained as P_t and Q_t. The coefficient matrix Q_t is used to replace the original sample matrix, thus achieving multi-feature dimensionality reduction of university network data.

3) ConvLSTM-CNN-based threat detection model for university's cyberspace attacks: As mentioned earlier, traditional CNN models cannot fully consider the sequence characteristics of data, and using LSTM models alone cannot fully consider the spatial characteristics of data and the correlation relationships between various features. Therefore, this paper intends to introduce the idea of the ConvLSTM model to model the problem of situational awareness of cyberspace security threats in universities from the dimensions of time and space features. Considering the limited computational performance of the ConvLSTM model and the higher computational cost and longer training time of each layer compared to convolutional layers, this paper proposes a ConvLSTM-optimized CNN model. It applies to the field of cyberspace security threat situational awareness in universities.

ConvLSTM was first proposed in 2015 and has shown good performance in predicting spatiotemporal data with both temporal and spatial features. This model extends the fully connected LSTM to have a convolutional structure in both input-to-state and state-to-state transitions, as shown in Fig. 3, which is the ConvLSTM network architecture diagram.

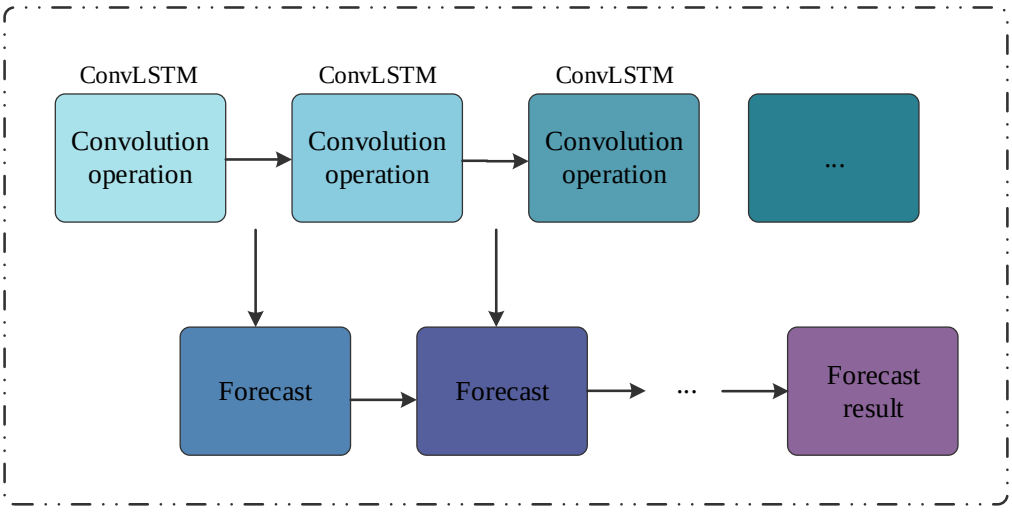

Fig. 3. Internal architecture of ConvLSTM model.

The working principle of ConvLSTM is shown in Eq. (13):

$$\begin{cases} i_t = \sigma(W_{xi} * \chi_t + W_{hi} * H_{t-1} + W_{ci} \circ c_{t-1} + b_i) \\ f_t = \sigma(W_{xf} * \chi_t + W_{hf} * H_{t-1} + W_{cf} \circ c_{t-1} + b_f) \\ c_t = f_t \circ c_{t-1} + i_t \circ tanh(W_{xc} * \chi_t + W_{hc} * H_{t-1} + b_c) \\ o_t = \sigma(W_{xo} * \chi_t + W_{ho} * H_{t-1} + W_{co} \circ c_t + b_o) \\ h_t = o_t \circ tanh(c_t) \end{cases} \quad (13)$$

In the equation, i_t, f_t, c_t, o_t, H_t represents input gate, forgetting gate, cell state, output gate, and transmission state, respectively; $\circ$ is the multiplication of the corresponding elements of the matrix, also known as Hadamard product, and σ is the sigmoid function; W is the weight matrix, and b is the bias top. Unlike LSTM, where χ, c, H, i, f, o represents three dimensions, f and o represent the information of data rows and columns.

For the classification and prediction requirements of spatiotemporal sequence data, such as university's cyberspace data, the ConvLSTM model has the memory storage and computing ability for long-time sequences [18]. Therefore, this paper uses a combination of the ConvLSTM and CNN models to construct the ConvLSTM-CNN model, with the specific structure shown in Fig. 4.

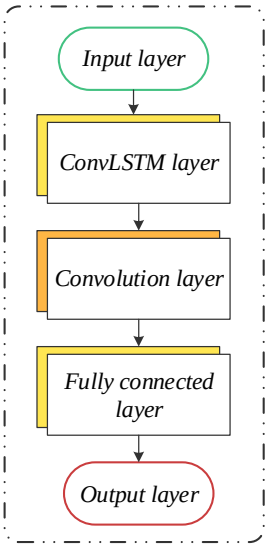

Fig. 4. Structure diagram of ConvLSTM-CNN model.

a) Input layer: First, encode the labels of input data in the input layer, convert them from textual data to continuous numerical variables, fit the data, and then perform standardisation and normalisation processing. Next, convert the data into a specific dimensional matrix that can be accepted by the next ConvLSTM layer.

b) ConvLSTM layer: The first layer to enter after the input layer is the ConvLSTM layer [19], which identifies the time dimension and spatial dimension of data, captures the spatiotemporal characteristics of data, and has a long memory function for solving the problem of serial data modelling with a long time. At the same time, unlike the feedforward fully connected form between the input and each gate in the LSTM model, the model's weight is convolutionally calculated and connected using the convolutional form, which allows for the acquisition of spatial features of the data while considering temporal features.

c) Convolutional layer: After capturing the spatiotemporal features of the data, it enters the convolutional layer for calculation. By utilising the typical sparse connection characteristics of the convolutional layer, it can effectively extract data features while shortening the convergence time of the model [20]. In forward fully connected neural networks, every element in the matrix needs to participate in computation, which undoubtedly increases the computational time and complexity of the algorithm. In this layer, the parameters of each convolutional kernel can be shared with each other, allowing only one operation to be performed on the same parameters in the university network model, which not only improves the runtime but also preserves its advantages in spatial feature extraction [21]. In the design of this model, the number of convolutional layers is set to 3, with a gradually decreasing number of convolutional kernels.

d) Fully connected layer: Located at the last layer of the entire network structure, it is used to integrate the feature information output from the previous layer.

e) Output layer: make classification and probability mapping for the model output and map it to the corresponding labels.

4) Optimisation parameter selection: In a neural network, the key work to enable it to solve the nonlinear problem of a sparse matrix, such as a university's cyberspace security situation awareness, is how to select and use appropriate activation functions, introduce nonlinear factors, retain and map the features of some activated neurons, and remove redundant and irrelevant features in the data, so as to enable neural networks to have hierarchical nonlinear mapping learning capabilities that linear models do not possess [22]. After completing the construction of the neural network model, it is necessary to search for the optimal solution for the model and select a suitable optimiser. Usually, the idea of gradient descent is used to calculate the loss and gradient of the model in order to obtain the parameters of each layer of the university's cyberspace security threat detection model and generate the optimal solution.

a) Activation function: In the structure and calculation process of ConvLSTM, similar to LSTM, there is a tanh operation in the related calculations of its input and output gates, which is used to generate candidate memories. As shown in Eq. (14), the calculation equation for the tanh function is shown. It can be seen that the tanh function requires a fourth power operation during the calculation process, and more power operations may be performed during its backpropagation differentiation, which undoubtedly increases the computational complexity of the ConvLSTM layer. Meanwhile, the tanh function may also cause gradient saturation during model training, which is a major reason for its low computational efficiency.

$$tanh(x) = \frac{e^{x} - e^{-x}}{e^{x} + e^{-x}} \tag{14}$$

where, e is a function.

In order to reduce the computational load of the security threat detection model of the university's cyberspace and solve the gradient saturation problem in ConvLSTM, this paper introduces the linear rectification function (ReLU) as the activation function in ConvLSTM-CNN and CNN layers and Eq. (15) is the calculation equation of ReLU function.

$$\mathrm{ReLU}(x) = max(0, x) \tag{15}$$

In the full connection layer, the activation function [23] is not used by default; that is, each layer only performs simple matrix multiplication. In this layer, the design and use of appropriate activation functions can play the role of adding nonlinear factors to neurons and the entire network structure, making neurons approach nonlinear networks. Therefore, this paper uses Softmax as the activation function in the full connection layer to obtain the probability value of each sample corresponding to the input so as to achieve the purpose of data classification. The calculation equation for the sigmoid function is shown in Eq. (16).

$$\text{soft}\,max(x) = \frac{e^{x}}{\sum_{x=1}^{T} e^{x}} \tag{16}$$

where, T is the number of types of samples.

b) Optimiser: After the establishment of the threat detection model for cyberspace security in basic colleges and universities, multiple iterations is needed to continuously optimise the model, find appropriate parameters, reduce the value of the loss function as much as possible, and improve the accuracy of the threat detection model for cyberspace security in colleges and universities. In order to adjust the parameters of the university's cyberspace security threat detection model during the training process and find the optimal solution, we introduced an optimiser to calculate and update the network parameters that could affect the training and output of the university's cyberspace security threat detection model, so that the results of the university's cyberspace security threat detection model can approximate or achieve the best [24], [25]. In this paper, the Adaptive Time Estimation Method (Adam) is introduced to calculate the adaptive learning rate of each parameter in the university's cyberspace security threat detection model. Adam algorithm

has higher convergence speed and more efficient computational efficiency than other adaptive learning rate algorithms. At the same time, it also has a lower occupancy rate of system computing resources and is more suitable for situations such as sparse gradients or high gradient noise. The Adam algorithm has made improvements such as bias correction and gradient algorithm optimisation on the basis of AdaGrad and RMSProp. Still, it retains its advantage of dynamically and adaptively optimising the learning rate. The calculation process of the Adam algorithm is shown in Eq. (17), which includes storing the exponential decay average value v_t of the historical square gradient and maintaining the exponential decay average value m_t of the historical gradient.

$$m_t = \beta_1 m_{t-1} + (1-\beta_1) g_t$$
$$v_t = \beta_2 v_{t-1} + (1-\beta_2) g_t^2 \quad (18)$$

where, β is the learning rate, and g_t is the fitness function.

The calculation process of the Adam algorithm after introducing the deviation correction step is shown in Eq. (18) to reduce the impact of deviation on the early training of the university's cyberspace security threat detection model.

$$m_t' = \frac{m_t}{1-\beta_1^t}$$
$$v_t' = \frac{v_t}{1-\beta_2^t} \quad (18)$$

After correcting the deviation, as shown in Equation (19), it can adaptively calculate the updated step size η_t from the perspectives of gradient mean m_t' and gradient square v_t'.

$$\eta_t = \eta_{t-1} - \alpha * m_t / (\sqrt{v_t} + \varepsilon) \quad (19)$$

where, α is the Lagrange multiplier and ε is the relaxation variable.

C. Defense Methods for Cyberspace Security in Universities

According to the ConvLSTM-CNN threat detection model in Section II (B), security threats in the university's cyberspace are detected, and the university's cyberspace security defense is carried out through the following methods.

1) Security defense against DNS attack threats: For example, the Domain Name System (DNS) denial of service attack threat is prevented in the network blocking attack detected by the ConvLSTM-CNN threat detection model. DNS denial of service attack threat security defense requires a detailed record of the number of DNS requests and hit rate in the time window. Based on the network attack threat detected by ConvLSTM-CNN, threat detection is performed on DNS attack data [26]. The attack data is divided into a blacklist. Normal data is divided into a whitelist and efficient network space inside the socket is used to transfer data information from the two lists so that it is assigned to filtering work, to filter attacks and redirect them, and implement constraints on the number of DNS requests that each source IP passes through per unit time to achieve security defense. The specific approach is as follows:

a) Prohibit DNS requests from the blacklist;

b) For whitelist lists, IP can be allowed to pass through a large number of DNS requests;

c) For non-whitelist lists, it constrains the number of DNS requests that IP passes through, where the allowed non-frequent DNS requests per unit time (1-2 requests) can be limited by using the *tc* tool. To provide commonly used domain name responses on behalf of servers in cases where there are a large number of DNS requests and to randomly discard some requests that are not included in the DNS frequency list, filters can be set in front of the attacked server. The security defense model steps for network blocking attack threats are shown in Fig. 5.

A filter function is mounted on the NetFilter framework chain of the Linux kernel to discard DNS requests with the source IP on the blacklist. In university's cyberspace data packets, using this framework can achieve the application of custom behaviour. Blocking IP addresses on the blacklist improves filtering efficiency and compensates for the missing functionality of the original DNS protocol [27].

The created queue is set on the output port and constraints university network traffic reasonably based on routing selection. Filters, queues, and classifications together form the *tc* tool. The following is the operation process:

a) Create CBQ queues and apply them to network physical devices;

b) Create the classification in the CBQ queue;

c) Create filters for each category, and the filters need to be created based on the routing;

d) Routing tables can be created by matching filters.

Usually, only one queue needs to be created, with each queue containing a root classification that includes subcategories. The smaller the classification number is, the more effective it becomes. If a certain classification rule is met, the data packet can be sent using that classification, and subsequent classifications will lose effectiveness. This completes the security defense against DNS attacks that threaten the cyberspace of universities.

2) Security defense against DDoS attack threats: The essence of security defense is how to defend against DDoS attack threats detected through the ConvLSTM-CNN threat detection model [28]. In SDN networks, OpenFlow flow tables can be used for implementation. As shown in Fig. 6, in the SDN network, when an attacker controls the botnet to launch a DDoS attack against the server, the attacking university's network space traffic first reaches the edge switch S1 and S1 detects whether there is a flow table matching the flow label in the university's network traffic space. If there is one, it will be forwarded directly according to the flow table rules. If not, it will upload the flow information to the controller and wait for the controller to make a decision. After receiving the flow information, the controller executes the

ConvLSTM-CNN threat detection model to detect the traffic in the university's cyberspace and determines whether the flow is DDoS attack traffic. If it is not, it calculates forwarding and sends a flow table containing routing information to the switch. The switch forwards according to the flow table rules; If so, the controller issues a table containing discarded instruction flows to the switch, and then the switch will discard this DDoS attack. In order to avoid the overflow of switch flow table space caused by excessive traffic in the university network space, a soft timeout time for the university's cyberspace traffic is set. Since DDoS attacks on university network space traffic are usually instantaneous, the soft timeout time is set to 1 second, which means that the flow table will delete itself if it is not matched for more than a second. This completes the security defense against DDoS attacks that threaten the cyberspace of universities.

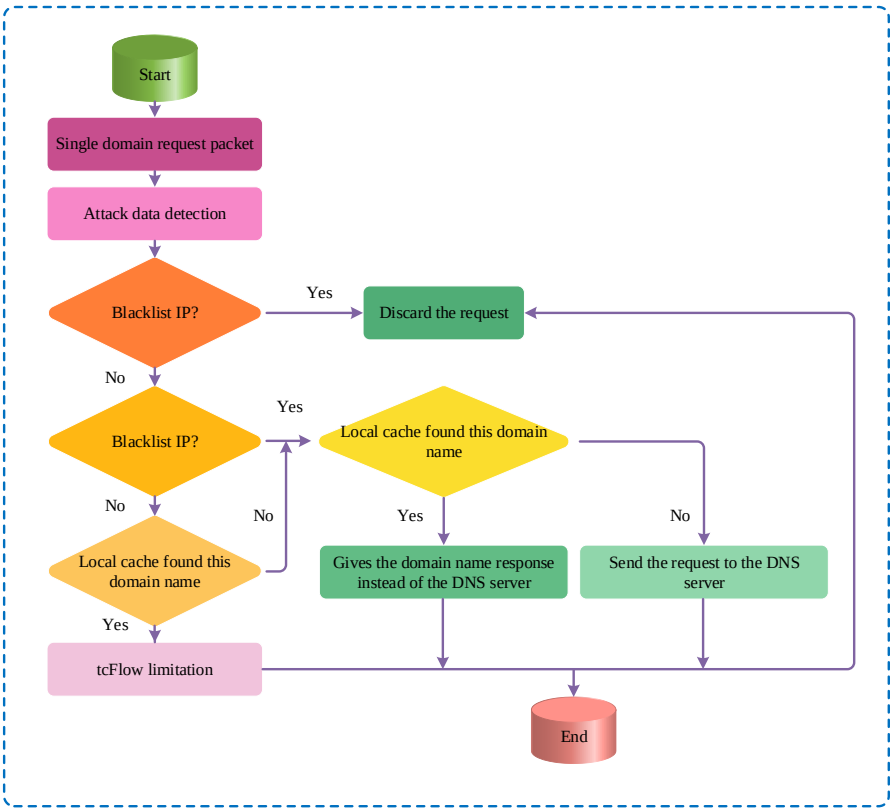

Fig. 5. Steps for defending against network blocking attacks.

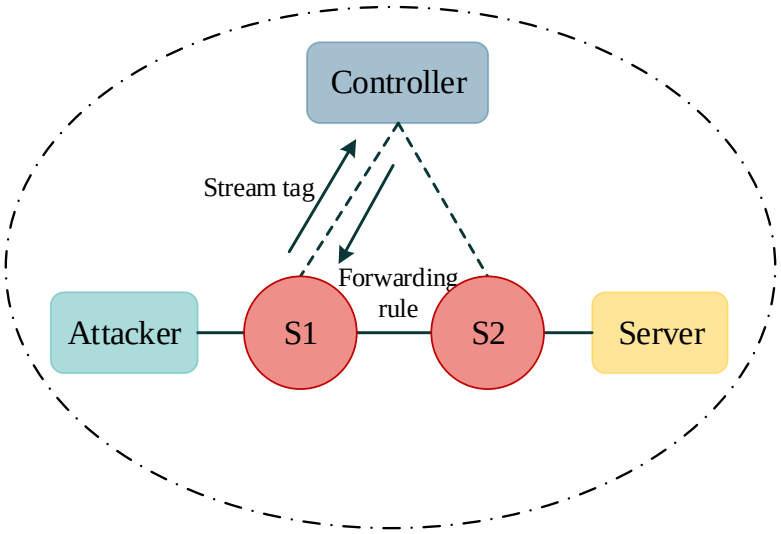

Fig. 6. Network diagram.

III. Experimental Analysis

Taking a certain university's cyberspace as the experimental object, based on big data analysis technology operating parameters, the control centre selects the Mininet+POX platform, simulates the virtual university's cyberspace environment through Mininet, follows the custom remote network interaction process, and runs the POX controller within the platform as the core selection. Based on the connectivity of remote university's cyberspace attacks, six switches are used to connect with each other. Among them, one switch is used to connect to the remote subnet, and another attack host is prepared. The other four are the teaching building, library, experimental building, and cafeteria of a certain university, and the topology of the university's network space attack is completed based on the remaining operating bandwidth of the switch. Using the built-in traffic generation tool Trafgen to attack university network space, the attack host's attack traffic is generated. Based on the attack traffic source IP address and source port number parameters, the attack content in the host file is continuously configured, and iPerf3 is used to generate and configured attack packet-related parameters. The environmental design scheme is described in Fig. 7.

After building the attack topology structure, it simulates the running environment of the university's big data analysis technology using the background traffic in the attack package to call Scapy on the normal host and complete the writing of the main function code of big data analysis technology. Based on the instructions sent and the actual response interactions generated, the traffic in the network space of attacking universities within the topology structure is resolved into multiple protocols that support attack instructions, which can control the attacking host, form identity mapping, generate mapping requests with attacking instructions, extract query ports generated by port access, and use them as fixed identity numerical markers to debug the remote attack process between the attacking host and other hosts.

To ensure the effectiveness of the experiment, the parameters of the proposed method are set as follows:

CNN model parameters: Convolutional kernel size is 3 × 3. The step size is 1, and the activation function is ReLU.

LSTM model parameters: The hidden layer size is 256, and the activation function is tanh.

Non negative matrix decomposition algorithm parameter: Select to retain the first 50 features as the dimensionality reduction result.

CNN model: Convolutional layer 1 has 32 convolutional kernels, with a kernel size of 3x3 and a step size of 1. Convolutional layer 2 has 64 convolutional kernels, with a kernel size of 3×3 and a step size of 1. The activation function is ReLU.

LSTM model: The LSTM layer has 64 hidden layer units.

Fully connected layer: The output layer has two neurons, representing the categories of normal and attack.

Loss function: Using cross entropy loss function.

The selected comparison methods use the parameters during their testing period, and will not be listed here.

The DDoS attack and DNS attack are used to verify the security defense capability of the model in this paper against the network space security of colleges and universities. At the same time, the network active security defense model based on the K-means algorithm in reference [4], the network security defense model based on the improved particle swarm optimisation algorithm in reference [5], the network security defense model oriented to digital transformation based on endogenous security framework in reference [6], the network security defense decision-making model based on timing game in reference [7], and the network data resource security defense model based on cloud computing in reference [8] are tested as a comparison method for the model in this paper. The test results are shown in Table II.

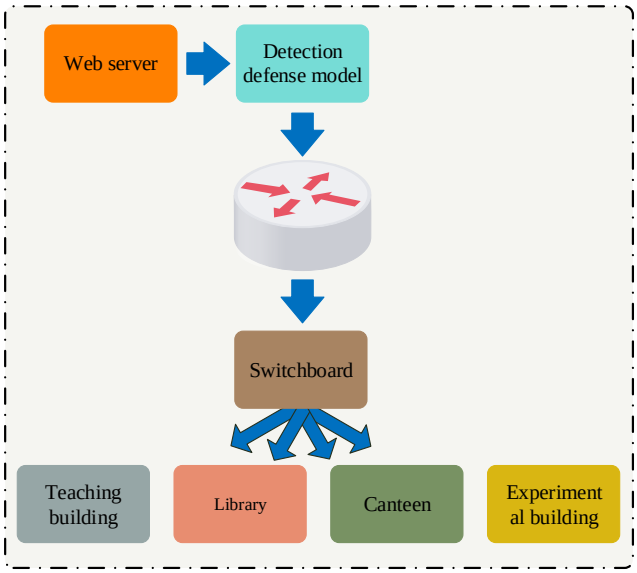

Fig. 7. Design of security defense model environment for cyberspace attacks in universities.

TABLE II. SECURITY DEFENSE RESULTS OF DIFFERENT ENVIRONMENTS IN UNIVERSITY NETWORK SPACE

Host		Teaching building	Library	Canteen	Experimental building
Model in this paper	DDoS attack	Success	Success	Success	Success
	DNS attack	Success	Success	Success	Success
Reference [4] Model	DDoS attack	Failure	Success	Success	Failure
	DNS attack	Failure	Failure	Failure	Failure
Reference [5] Model	DDoS attack	Failure	Failure	Success	Failure
	DNS attack	Success	Failure	Failure	Failure
Reference [6] Model	DDoS attack	Failure	Failure	Failure	Success
	DNS attack	Success	Success	Success	Success
Reference [7] Model	DDoS attack	Failure	Success	Success	Failure
	DNS attack	Success	Success	Success	Failure
Reference [8] Model	DDoS attack	Success	Success	Success	Failure
	DNS attack	Success	Failure	Failure	Failure

From Table II, it can be seen that in the simulated cyberspace attack environment outside a certain university's teaching building, library, cafeteria, and experimental building, the models in reference [4] and the reference [5] only successfully defended two times when they attacked DDoS and DNS cyberspace eight times, while the other six times failed. The defense effect of the models in reference [6], reference [7], and reference [8] are better than the first two models, the defense against threat attacks is above 50%, but it has not achieved the desired security defense effect. And through the model in this paper, the defense against DDoS and DNS network space attacks is all successful, indicating that the model in this paper can achieve security defense in network space under different network attacks in different environments and has strong security defense capabilities.

The experiment sets the attack host traffic value between 200-1200MB to ensure the accuracy of the test results. In this attack traffic mode, the fixed controller has 18 running windows. Based on the running window values and attack traffic parameters, it completes the statistical work of the actual intercepted traffic data of the defense software. Then it calculates the attack interception rate of the defense software.

Equation $F = (AR + TN) \div (TA + TN + FA + AR) \times 100\%$ is used to represent numerical relationships. Among them, F represents the interception rate of defense software attacks; AR represents the number of attack data correctly intercepted by the defense software, TN indicates successful tagging of attack data traffic; TA represents the number of intercepted windows supported by the controller, FA represents the set attack traffic value; traffic interception rate statistics for defense software attacks can be conducted based on different traffic attacks. The results are shown in Table III.

Based on the numerical relationship between different attack interception values, statistical analysis is conducted on the attack interception rates of the models in reference [4], reference [5], reference [6], reference [7], reference [8], and the defense software in this paper. The average is read for the attack interception rates under different supply scales. From Table III, it can be seen that the average attack interception rates of the defense software in reference [5] model and reference [6] model are 77.7% and 77.2%, respectively, indicating weak defense capabilities against university cyberspace security; The average attack interception rates of the defense software for reference [4] model, reference [7] model, and reference [8] model are 85.2%, 85.4%, and 87.9%, respectively, indicating an improvement in defense capabilities; The average attack interception rate of the defense software designed in this model is 97.6%, which is the strongest defense capability for university cyberspace security compared to the other five models.

Based on two types of network attack methods, DDoS attack and DNS attack, the congestion status of the university's cyberspace is tested for six attack defense models. The network space attack defense models of reference [4], reference [5], reference [6], reference [7], and reference [8] are used as comparative models. Fig. 8 shows the network congestion rate results of the six models for the university's cyberspace attack defense.

TABLE III. INTERCEPTION RATES OF UNIVERSITY'S CYBERSPACE ATTACKS USING DIFFERENT MODELS (%)

Host attack traffic	Reference [4] Model	Reference [5] Model	Reference [6] Model	Reference [7] Model	Reference [8] Model	Model in this paper
200	82.1	79.2	75.6	82.6	89.2	97.6
400	86.2	77.5	76.8	84.3	86.9	98.9
600	85.6	79.4	79.5	85.9	88.4	96.4
800	87.1	75.3	77.9	87.5	86.1	97.7
1000	85.2	76.1	78.2	86.7	89.4	98.3
1200	84.9	78.7	75.3	85.3	87.5	96.9

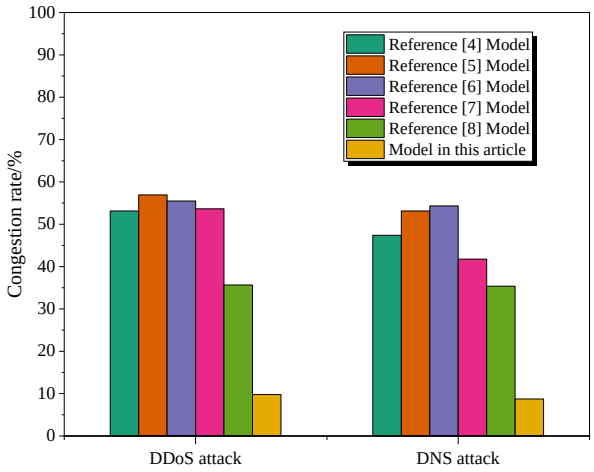

Fig. 8. Comparison of defense congestion rates of different defense methods.

Analysing Fig. 8, it can be seen that after being defended by six different network space security defense models, the congestion rate of DDoS attacks and DNS attacks is less than 60%. However, for the two different attacks, DDoS attacks and DNS attacks, the congestion rate of the model in this paper is the lowest, below 10%. The university's cyberspace security defense model proposed in this paper can effectively reduce the congestion rate of the university's cyberspace and protect the security of the university's cyberspace; the model in this paper can defend against different types of attack methods and has excellent defense capabilities against network space blocking attacks in universities.

In order to verify the effectiveness of the university's cyberspace security threat detection model in this paper and compare the impact of different numbers of feature quantities on detecting the university's cyberspace security threats, the number of feature quantities is set to 5, 10, 15, 25, 25, 30, 35, 40, and 45. The security threat detection accuracy of the university's cyberspace is obtained on different numbers of feature quantities, and the detection results are shown in Fig. 9.

From Fig. 9, it can be seen that through the feature extraction of the university's cyberspace using this model, as the number of features continues to increase, the model's accuracy in detecting security threats in the university's cyberspace has also improved. When the number of features is 35, the model has the highest accuracy in detecting security threats in the university's cyberspace, at around 0.98. However, when the number of features exceeds 35, the detection accuracy of the model in this paper for threats to the security of the university's cyberspace has begun to decline. Therefore, the model in this paper is used to reduce the dimensionality of the features in the university's cyberspace, setting the feature amount to 35, laying the foundation for the next step of the university's cyberspace security detection and improving detection accuracy.

In order to further verify the detection performance of the model in this paper for university's cyberspace security threats, DDoS attacks, DNS attacks, and DoS attacks are set as attack sources. The detection accuracy of the models in reference [4], reference [5], reference [6], reference [7], reference [8], and the model in this paper for university's cyberspace security threats are used as evaluation indicators and compared. The detection results are shown in Table IV.

From Table IV, it can be seen that the average detection accuracy of the model in reference [8] for DDoS attacks, DNS attacks, and DoS attacks is 0.76, which is relatively low in detection accuracy; The average detection accuracy of the models in reference [4], reference [5], reference [6], and reference [7] for three different network attacks is 0.82, 0.83, 0.80, and 0.80, all of which are above 0.8. Compared with the model in reference [8], the detection accuracy has been improved; the model in this paper has the highest detection accuracy for these three different types of network attacks, with an average detection accuracy of 0.98. The detection accuracy for each network attack is 0.97 or above, indicating that the model in this paper is the most effective in detecting security threats in the university's cyberspace and ensuring the security of the university's cyberspace.

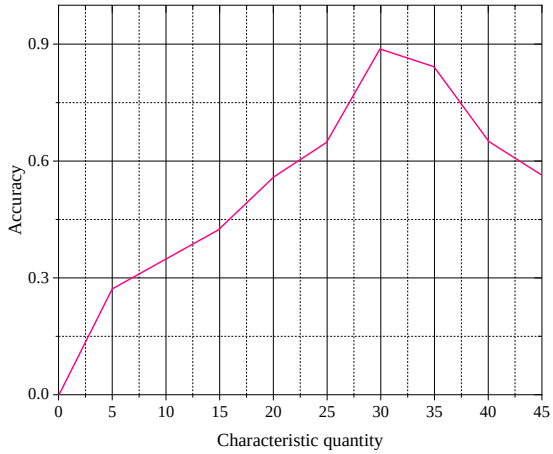

Fig. 9. University network security detection accuracy of different characteristic quantities.

TABLE IV. ACCURACY OF SECURITY DETECTION IN UNIVERSITY'S CYBERSPACE BY DIFFERENT MODELS

Model	DDoS	DNS	DoS
Reference [4] Model	0.85	0.79	0.83
Reference [5] Model	0.84	0.80	0.85
Reference [6] Model	0.79	0.81	0.81
Reference [7] Model	0.83	0.76	0.82
Reference [8] Model	0.73	0.77	0.79
Model in this paper	0.97	0.98	0.98

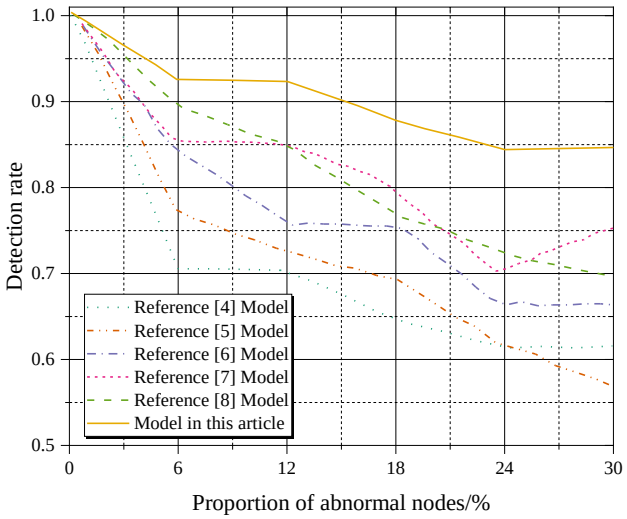

Fig. 10. Comparison of data detection rates collected by different models.

The core goal of the data collection model based on the compressed sensing principle is to ensure the high accuracy of the data. Distinguishing whether there is a threat to the security data nodes in the university's cyberspace is an important indicator to measure the model in this paper. Based on the model oriented towards the university's cyberspace security threat data in this paper, the detection rate of the algorithm is defined as the proportion of the detected university's cyberspace security threat data nodes to the total data nodes. In order to verify the effectiveness of the model proposed in this paper in detecting threats to the university's cyberspace security, 200 sensor nodes are set up in the experiment. The detection rates of the model proposed in this paper are compared with those of models in reference [4], reference [5], reference [6], reference [7], and reference [8] under different abnormal node ratios. The results are shown in Fig 10.

As shown in Fig. 10, as the proportion of nodes posing security threats to the university's cyberspace increases, the detection rates of the models in references [4], [5], [6], [7], [8] and this paper all show a downward trend. However, the detection rates of this paper are all above 0.9, while the detection rates of other models are all below 0.9. In comparison, the model in this paper has the highest detection rate. This model can effectively distinguish the types of efficient cyberspace security threat data nodes, provide decision-making support for data reliability collection, and improve the detection rate of cyberspace security threats in universities. Based on the above experimental results, it can be seen that the machine learning based university cyberspace security defense method proposed in this article has achieved significant results in practice. Compared with previous studies, the method proposed in this paper not only enhances existing research results, but also provides innovative solutions and improvement strategies.

Firstly, the method proposed in this article has achieved certain results in the defense of cyberspace security in universities. The model in this article combines data collection based on compressed sensing, security threat detection based on machine learning algorithms, and optimization parameter selection, providing comprehensive security defense support for university cyberspace.

Secondly, the method results presented in this article demonstrate novelty that was not discovered in previous studies. By introducing a compression aware data collection method, this article extracts effective information from large-scale network data, avoiding the related problems of storing and transmitting all the original data in traditional methods. Meanwhile, by using different machine learning models and feature selection methods, this article can accurately detect and prevent security threats in university cyberspace from multiple perspectives.

Finally, the research findings of this article provide new ideas and insights for the field of cyberspace security in universities. By effectively combining machine learning algorithms with knowledge in the field of network security, this method not only improves security defense capabilities, but also improves the accuracy and efficiency of security threat detection. These innovative achievements not only have significant academic significance, but also provide specific guidance and reference for the practice of cyberspace security in universities, and provide new solutions for network security protection in practical applications.

IV. Conclusion

The security threats and defense issues of university cyberspace are not only related to campus security but also closely related to the daily lives of teachers and students. There is a large amount of data, such as network traffic, log information, and system signals, in the cyberspace of universities. This study proposes a new method for university cyberspace security defense through the comprehensive application of compressed sensing based data collection method and deep learning model. After experimental verification, the model has achieved significant results in attack interception rate and provided effective protection for the security of university cyberspace. These results demonstrate the innovation and feasibility of the model, providing new ideas and insights for research and practice in the field of cyberspace security in universities. Due to the large amount of attack data, more types of data will be added to the model in the future, such as network traffic data, log data, user behavior data, etc., to improve the breadth and accuracy of security detection.

V. Data Availability

The raw data supporting the conclusions of this article will be made available by the authors, without undue reservation."

VI. Conflicts of Interest

The authors declared that they have no conflicts of interest regarding this work."

***Abstract*—Soil is a vital requirement for agricultural activities providing numerous functionalities restoring both abiotic and biotic materials. There are different types of soils, and each type of soil possesses distinctive characteristics and unique harvesting properties that impact agricultural development in various ways. Generally, farmers in the olden days used to analyse soil by looking at it visually while some prefer laboratory tests which are time-consuming and costly. Testing of soil is done to analyse the features and characteristics of the soil type, which results in selecting a suitable crop. This in turn results in increased food productivity which is very beneficial to farmers. Hence, to recognize the soil type an automatic soil identification model is proposed by implementing Deep Learning Techniques. It is used to classify the soil for crop recommendation by analysing accurate soil type. Different Convolution Neural Networks have been applied in the proposed model. They are VGG16, VGG19, InceptionV3 and ResNet50.Among all those techniques it is analysed that better results were obtained with ResNet50 having an accuracy of about 87% performing Multi-classification that is Black soil, Laterite Soil, Yellow Soil, Cinder soil & Peat soil.**

Keywords*—Agricultural; convolution neural network; soil classification deep learning; VGG16; VGG19; InceptionV3; multi-classification; ResNet50

I. Introduction

Soil stands as a vital agricultural resource, housing a plethora of nutrients essential for crop cultivation. Each region possesses its unique soil composition, giving rise to diverse soil types worldwide. Serving as Earth's outer layer, soil encompasses various minerals, organic matter, living organisms, and water. Acting as a bridge between the planet's internal layers and its surface, soil plays a pivotal role in facilitating plant growth. The availability of nutrients and water in the soil determines the growth of a plant, making it a crucial factor for analysis. In the current era, effective plant management holds paramount importance to ensure human sustainability. The global population have been steadily increasing, thus there is a growing need to enhance food, fabric, and medicine production. Consequently, improving the agricultural sector becomes imperative, as it stands as a primary source capable of meeting these escalating demands.

The growth of different types of crops is influenced by diverse factors such as the availability of nutrients, water, and oxygen in the soil, balancing both environmental and physical conditions to achieve a good yield. Among all these resources the current work concentrates on the different classifications of soil to identify the specific category of soil which ultimately determines a selective crop. Each region is determined with different types of soils like black soil, peaty soil, alluvial soil, red soil, desert soil, forested soil, laterite soil, and many more. For soil classification various Deep Learning techniques are implemented as they are categorized based on the considered soil images. To classify soil types, a variety of features such as hue, saturation, texture, colour, intensity, and other relevant characteristics are extracted and utilized.

Deep learning is an architecture comprising a large number of layers that enables the transformation of raw data into meaningful features. This process is often referred to as feature engineering in the context of deep learning models. Various types of CNNs are used for classification. Some of the existing models are implemented using both Machine Learning and Deep Learning Techniques [1]. The author implements a model using K-NN Classifier and SVM Classifier on different types of soil image datasets [2] [9] [14]. The author implements a model using an SVM classifier. The research in [3] [13] proposed a technique designed using an SVM classifier and ResNet50, CNN while the author in [4][17], employs a range of neural network models, including CNNs, DBNs, LSTMs, Multilayer Perceptron, and Autoencoders. These architectures serve various purposes such as image processing and feature extraction within the study. The study in [5] [16] proposed a technique implementing an, Network Model (CNN), SVM classifier and StoolNet. The research in [15] [6], the author implemented a Network Model based on Convolutional Neural Networks (CNN). This model was designed to filter images using five different types of masks: spot, wave, level, ripple, and edge. These masks are utilized as filtering techniques in image processing, helping to extract specific features or enhance certain characteristics in the images. The application of these masks within a CNN framework suggests that the study focuses on leveraging convolutional operations to analyses and process images for a particular purpose, such as texture analysis or pattern recognition [10]. A model has been proposed by the author that combines Naive Bayes and Artificial Neural Network (ANN) techniques. This hybrid approach is utilized to analyze physical parameters like water content and dry density, as well as soil parameters such as internal friction angle, cohesion. Simultaneously in [6] the study employs a Gabor Filter for edge detection, followed by Std, skew, Mean, and kurtosis and other sinusoidal measures

to retrieve images. The classification task involves using the CNN algorithm for land and soil images. Additionally, a Visual Transformer for image classification is introduced, showcasing superior accuracy compared to CNN, SVM, ResNet-50 and subsequent machine learning models as stated in study [3].

Therefore, in this paper, a model developed is determined using VGG16, InceptionV3, VGG19 and ResNet50associated with Transfer Learning resulting in better and more accurate soil classification. The main objective of this model is to do multi-classification that is yellow soil, Laterite Soil, Cinder soil, Black Soil and Peat soil. The general workflow of the proposed model is explained and continued with the Literature Survey in Section II and Section III provides a diagrammatic approach for the developed model. Section IV covers the experimental evaluation. Section V presents the conclusion of the proposed paper.

II. Literature Survey

Rahman Zaminur proposed a system that utilized the K-NN Classifier, a machine learning algorithm, for classifying soil texture. The research recommended Support Vector Machine as the most effective classifier. The approach involved Bootstrap resampling and a stacked decision tree ensemble classifier. The study encompassed nine different soil types and also explored alternative algorithms such as Artificial Neural Network and GAtree [1].

Navya and Vijay E V proposed a system the image classification process, employing diverse methods including, Sub-pixel Classification, Artificial Neural Network Classification and Maximum Likelihood Classification. They opted for SVM due to its versatility and suitability for comparison purposes. The research utilized a range of pre-processing methods to identify patterns, leading to improved classification analysis [2].

Jagetia Aaryan underscored the significance of precise soil classification, substantiated by multiple parameters such as void ratio, moisture content, liquid limit, clay content, specific gravity and plasticity. Employing the Visual Transformer, an advanced technique for image classification, resulted in impressive accuracy rates of 98.13% during training and 93.62% during testing [3].

Prabhavathi V's research is cantered on Utilizing deep learning algorithms to classify soil, particularly highlighting an inventive deep learning model. The investigation delves into a range of deep learning algorithms, encompassing CNNs, DBNs, LSTM, Autoencoders and Multilayer Perceptron CNNs, in particular, exhibit remarkable accuracy when it comes to Identifying soil through the analysis of hyperspectral bands derived from satellite data and categorizing aggregates using stereo-pair images [4].

Srivastava Pallavi research proposal investigates soil classification techniques through computer vision and the utilization of image processing. colour and soil texture are determined employing methods such as the Munsell colour chart, elutriation, pipette, decantation, The model incorporates StoolNet, which attains a remarkable 100% accuracy in classifying burozem soil and yellow soil [5].

Aparna Yerrolla examines the International Soil Reference and Information Centre dataset, which includes various soil images belonging to different classes. Feature extraction is performed using the Gabor filter to capture attributes like entropy, standard error, and mean. The analysis places significant importance on soil colour extraction. Texture characteristics are extracted using the Laws mask method, involving filtering images with five different mask types: edge, ripple, level, wave and spot. The application of Convolutional Neural Networks (CNNs) with three-layered hidden layers enables the algorithm to effectively classify land images and soil, distinguishing between categories such as Clayey peat, Silty sand, Clay, Humus clay, Peat, Sandy clay and Clayey sand [6].

Barkataki Nairit introduced a deep CNN model designed for automatic soil classification through non-invasive techniques such as ground penetrating radar (GPR). A fabricated dataset was created through the use of gpr-Max for both training and validation. Through a 5-fold cross-validation, the model demonstrated exceptional performance, achieving an impressive accuracy rate of 97% in classifying seven distinct soil types based on ground penetrating radar (GPR) B-Scan images [7].

Khullar Vikas puts forward an effective soil classification system by leveraging deep learning techniques. The study incorporates a diverse set of algorithms, including Random Forest, KNN, Ada-Boost, SVV Machine, Quadratic Discriminant Analysis, Logistic Regression, Decision Tree, Extra Trees, Gaussian Naïve Bayes, and Histogram Gradient Boosting. Additionally, the use of VGG16 and InceptionResNetV2 deep networks for soil classification enhances the categorization process, yielding robust and dependable results that outperform prior state-of-the-art methodologies [8].

Greema S Raj describes a survey done on soil classification using different techniques. Decision tree predictions are made using a binary tree model, known for its speed and accuracy. Naïve Bayes classifiers utilize the Bayes theorem for predicting unrelated features within a class. Parameter estimation is performed using maximum likelihood or Bayesian methods. SVM is a heuristic algorithm employed for supervised learning, determining the optimal hyperplane to separate two classes [9].

Ladan Samadi's research focuses on soil classification using machine learning algorithms, namely ANN and Naïve Bayes. Neural networks are effective in establishing relationships between input variables and target parameters. The Unified Soil Classification System (USCS) is employed for soil classification based on and particle size analysis Atterberg limits. Naïve Bayes and ANN algorithms are utilized for classification, considering particle size analysis and Atterberg limits. The objective is to develop an Artificial Neural Network model that predicts soil classification based on soil conditions and collected data on soil mechanics parameters [10].

Rakesh Kr Dwivedi's Deep learning process, using K-means clustering, aids farmers in classifying soil based on its texture, clay, silt, sand concentrations, and pH value. Soil

image classification utilizing machine learning involves three steps: image segmentation, feature extraction, and classification [11].

Abhinav Pandey utilizes a deep CNN methodology for satellite image classification, concentrating on the classification of soil types using chemical and physical properties as criteria. Using the DGX-2, the trained deep CNN achieves an average accuracy of 0.67 and a maximum accuracy of 0.80 in five runs when utilizing images with vegetation removed. However, accuracy decreases to 0.41 due to vegetation fluctuation over time. The desert soil class shows the highest confidence, while the black soil class exhibits the lowest. The average classification accuracy during testing is 0.72, indicating the effectiveness of the model in classifying different soil types from satellite images [12].

The existing methods were implemented mostly on one type of soil from various soil images, based on their respective parameters. This research works aims to classify different types of soil like black soil, yellow soil, laterite, cinder and peat soil with more efficient CNN models.

III. Proposed Model

The suggested model uses the input photos to determine the type of soil. Several varieties of convolution neural networks, which are a part of deep learning techniques, are used in this instance to automatically classify data. Several unseen layers are stacked upon each another in a specific order to create CNN, feed-forward neural network which is multi-layered, which extracts features that are displayed as patterns. The pre-processed input data is then sent through many CNN types, such as ResNet50, InceptionV3, VGG16, and VGG19, to further aid in the classification of the picture of soil under consideration. Fig. 1 illustrates the suggested model's workflow.

The collection of images in the dataset is divided into four categories: images of black soil, yellow soil, peat soil, cinder soil, and laterite soil. It is gathered from offline and internet sources. When putting them into the model, they are mainly divided into Train and Test data images and are pre-processed utilizing techniques for image transformation. Pre-processing procedures, which involve the implementation of Data Augmentation Techniques, are executed in this context. During data augmentation, specific circumstances are applied, such as rotating the image at a ninety-degree angle and modifying it horizontally and vertically. This is done in order to capture more photographs and view it from various perspectives. Images are resized simultaneously to change their aspect ratio and size to a standard 220x220x3 format.

Every image has a specific label applied to it and is mapped for additional classification. As a consequence, pre-processed train and test image data are obtained. Thus, the acquired trained dataset is used to train the model, and the test dataset is used to assess the model.

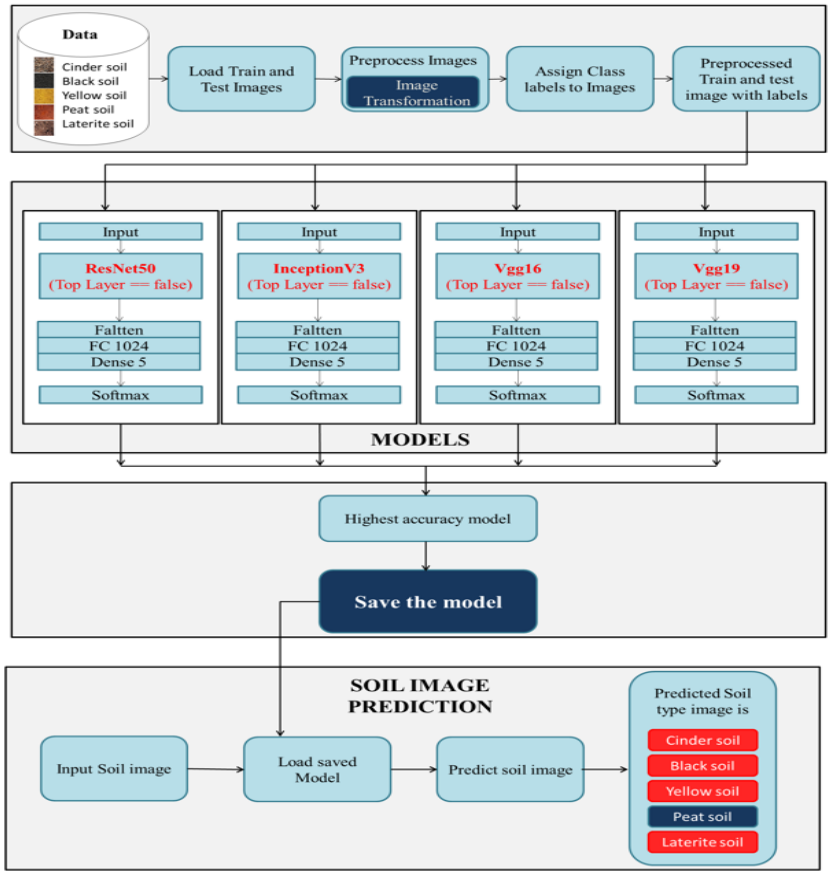

Fig. 1. Workflow of the proposed model.

The acquired data undergoes processing through several CNNs, namely Inception V3, ResNet50, VGG16, and VGG19. Each neural network's individual layer operates on the input data, extracting distinct patterns crucial for classifying the particular soil type under examination. CNNs stand out as highly efficient architectures for image recognition and classification owing to their pattern recognition capability, significantly aiding in the prediction and classification of input image data and yielding the highest achievable accuracy. Standard CNNs typically comprise three fundamental types of layers, often referred to as "building blocks": convolutional, pooling, and fully connected layers. The initial two layers, convolution and pooling, primarily focus on feature extraction, while the third, the fully connected layer, translates these identified features into the final output, such as a classification. Within a CNN, which functions as a sequence of mathematical operations, the convolution layer plays a pivotal role, providing a specialized version of linear operations. Digital images are represented as an array of integers or a two-dimensional (2D) grid capturing pixel values. A kernel, serving as an optimizable feature extractor, is applied at each position across the image, allowing for the extraction of essential features.

We use Transfer learning technique to Connect base model with fine-tuned model Fully Connected Layers. Subsequently, layer freezing is carried out employing the trained data images for the model's first run. When knowledge is taken from an established model and applied to a newly proposed model, transfer learning plays a significant role. Every item listed above The Transfer Learning Mechanism is the foundation upon which CNNs operate. The epochs, learning rate, optimizer and batch size are among the many parameters that are changed for each Convolutional Neural Networks, to classify the photos of dirt, save the model and run it.

Plots of loss percentages and accuracy have been made in accordance with the outcomes of the designed model. One indicator used to assess the model's performance in an understandable manner is accuracy. A metric called loss indicates how well the model performs following each optimization step. In order to anticipate the provided input soil input, we must load the saved model weights concurrently with the input picture path of the testing image, and then predict the input image using the loaded model. Class label assigned determines the index of output, which is based on the index of the maximum element within an array along a specified axis.

Algorithm: Implementation of Model:

Input: Images of different kinds of soil

Output: Prediction of image (Peat, Yellow, Laterite, Black and Cinder Soil images)

Step 1.Importing all training and testing images corresponding to soil categories into the dataset.

Step 2. Preprocessing the Images.

- Enhancing all training and testing images through the application of data augmentation techniques.

Step 3.Associating class labels with their respective images by creating a mapping.

Step 4.Generating the pre-processed dataset after performing all necessary transformations, including data augmentation, and mapping class labels with their corresponding images.

Step 5.Utilizing ResNet50, InceptionV3, Vgg16, and Vgg19 models as the base models for further analysis or processing.

Step 6.Integrating a fine-tuned model into Vgg16, InceptionV3, ResNet50, and Vgg19 by customizing the top layers. Steps

- Configuring the model with specific parameters such as epochs, batch size and learning rate to train and optimize the neural network.
- Incorporating a flattened and fully connected layer into the base model architecture.
- Appending a dense layer with five units (for the number of classification classes) and applying the “SoftMax” activation function to the model.

Step 7. Implementing transfer learning by connecting the base model with fine-tuned fully connected layers to leverage the pre-trained features and optimize the model for the specific classification task.

Step 8. Freezing the layers to maintain their pre-trained weights and prevent them from being updated during the initial execution of the model.

Step 9. Training the model by fitting the training data images to it.

Step 10. Saving the model weights after training for future use or further analysis.

Step 11. Plotting accuracy and loss percentages to visualize the performance of the designed model during training and evaluation phases.

Step 12. The classification of images has been successfully completed using the trained model.

1) VGG16: The utilization of Very Deep Convolutional Networks in Large-Scale Image Recognition showcases the impact of network depth on accuracy within extensive image

identification scenarios. The primary focus is a comprehensive analysis of networks with incrementally deeper layers, employing an architecture using (3x3) convolution filters which is relatively small. This study reveals that increasing the depth to a range of 16–19 layers significantly enhance performance compared to current configurations. Our team participated in the 2014 ImageNet Challenge, leveraging these discoveries, leading to our team securing top two places in the localization and classification tracks, respectively. This success underscored the adaptability of our representations across diverse datasets, consistently yielding state-of-the-art results. To encourage continued exploration of deep visual representations in computer vision, our two most impactful ConvNet models available for research purposes.

2) VGG19: The depth of convolutional networks affects their accuracy in large-scale image identification contexts. It employs an architecture with (3x3) convolution filters, just like VGG19, and shows that going deeper to 16–19 weight layers can yield a discernible improvement over the current configuration. When using this VGG19, we have more hidden layers, which yields the best outcomes.

3) InceptionV3: Convolutional networks are the foundation of most state-of-the-art computer vision systems for various workloads. Since its debut in 2014, very deep convolutional networks have made considerable progress in a number of benchmarks. We investigate strategies for scaling up networks that leverage factorized convolutions and aggressive regularization to make the most efficient use of the extra processing. While it's often true that larger model sizes and increased computational resources lead to improved performance in various tasks, provided there is a sufficient amount of labelled data for training, we are exploring methods to efficiently scale up neural networks. This involves applying strong regularization techniques and optimizing convolutions through appropriate factorization, ensuring that the additional computation is used as efficiently as possible, these methods are compared to the state of the art using ILSVRC 2012 automation challenge validation set and find notable improvements: For single frame evaluation, a network with less than 25 million parameters and a computational cost of 5 billion multiply-adds per inference produced errors of 21.2% top-1 and 5.6% top-5. Using an ensemble of four models with multi-crop assessment, we report a 17.3% top-1 error and a 3.5% top-5 error on the validation set and 3.6% error on the test set.

4) ResNet50: Deep residual networks have emerged as a category of highly extensive architectures, demonstrating exceptional accuracy and attractive convergence behaviours. The analysis delves into the propagation formulations fundamental to the residual building blocks, suggesting that both forward and backward signals can be seamlessly transmitted from one block to any other block, specifically when utilizing identity mappings as skip connections followed by activation after addition. Numerous ablation experiments confirm the significance of these identity mappings, which, in turn, serve as the inspiration behind our introduction of a novel residual unit. This new unit not only enhances generalization but also streamlines the training process.

Deep residual networks represent a class of highly extensive architectures known for their exceptional accuracy and favourable convergence behaviours. This analysis explores the propagation formulations within the residual building blocks, particularly when employing identity mappings as skip connections along with post-addition activation. It indicates the direct transferability of both forward and backward signals between various blocks. Numerous ablation experiments further affirm the significance of these identity mappings. As a result, this serves as the driving force behind our proposal for a novel residual unit, aiming to streamline training processes and enhance generalization.

IV. Experimental Analysis

In this paper, the system has been tested with 4 deep-learning keras API models using different optimization techniques with 203 soil images of five categories: Laterite Soil, Peat Soil, Black Soil, Yellow Soil and Cinder Soil.

There are 47 tests done where nine images for each category all the images in the dataset are divided into eight batches. Each image has its own 30 iterations along with various features optimizers that belong to Adam and SGD. There are 156 training images of are done for each model.

For the VGG16 and VGG19 systems recorded mean accuracies are 100% & 100% and loss error rates are 0.0032 & 0.0019, for InceptionV3 system recorded a mean of 87% and the mean loss value is 0.4747.

By using the SGD optimizer technique with the ResNet50 System recorded highest accuracy is 100% and the loss error rate is 0.0013 using the Adam optimizer technique with the ResNet50. From all the above models ResNet50 with the Adam optimizer system is a bit higher than the remaining models.

To compute accuracy, we utilize the confusion matrix, which consists of four categories: True Positives, True Negatives, False Positives, and False Negatives. This matrix enables the calculation of various valuable metrics.

$$\text{Accuracy} = (TP + TN) / (TP + TN + FP + FN)$$

TABLE I. Measuring Accuracy using the Presented Techniques

Models	VGG16	VGG19	Inception V3	ResNet50
Validation Accuracy	1.0000	1.0000	0.8750	1.0000
Validation Loss	0.0032	0.0019	0.4747	0.0013
Training Accuracy	0.8871	0.9355	0.5645	0.8750
Training Loss	0.9862	0.5171	1.0490	0.9059

The graphs below illustrate the accuracy and loss metrics obtained from different models, including VGG16, InceptionV3, VGG19 and ResNet50.

As illustrated from Fig. 2, the accuracy values ranging from 0.0 to 1.0 is represented on X-axis and the number of epochs (100) executed in the model is represented on Y axis. Throughout the study, 100 epochs were conducted, and the optimal accuracy was achieved at 26 epochs, accompanied by a loss rate of 0.0032. The blue line on the graph corresponds to the training data, while the orange line represents the validation data. It is important to note that 20% of the images were randomly selected from each class for testing purposes, ensuring a representative evaluation of the model's performance.

As illustrated from Fig. 3, the accuracy values ranging from 0 to 70 is represented on X-axis and the number of epochs (100) executed in the model is represented on Y axis. The graph illustrates the loss corresponding to the accuracy of the VGG16 model. The optimal result was achieved at 26 epochs with a minimal loss rate of 0.0032. The blue line in the graph represents the training data, and the orange line represents the validation data. It's important to note that 20% of the images were randomly selected from each class for testing purposes, ensuring a representative evaluation of the model's accuracy and loss.

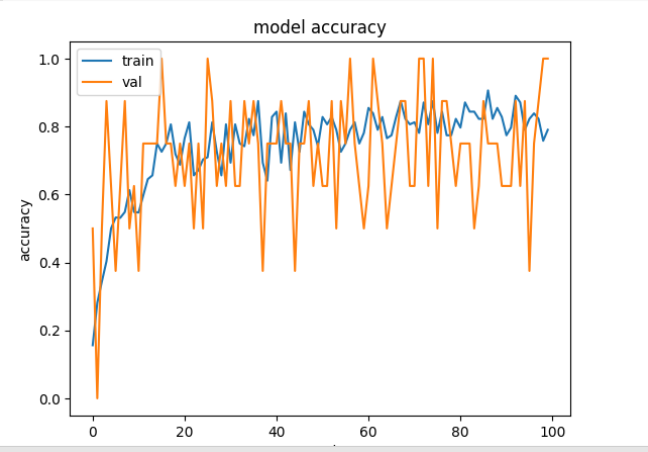

Fig. 2. Accuracy of VGG16.

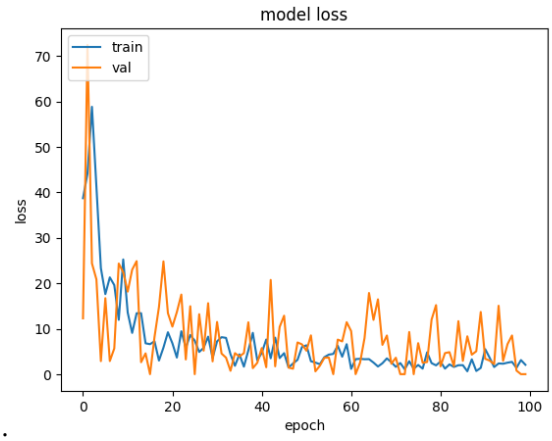

Fig. 3. Loss of VGG16.

As illustrated from Fig. 4, the accuracy values ranging from 0.3 to 1.0 is represented on X-axis and the number of epochs (100) executed in the model is represented on Y axis. In the course of this study, 100 epochs were conducted, and the highest accuracy was achieved at 58 epochs, with a minimal loss rate of 0.0019. The blue line on the graph corresponds to the training data, while the orange line represents the validation data. It's worth noting that 20% of the images were randomly selected from each class for testing purposes, ensuring a representative evaluation of the model's performance.

The blue line is representative of the training data, while the orange line signifies the validation data. Notably, for testing, 20% of images were randomly selected from each class.

As illustrated from Fig. 5, the accuracy values ranging from 0 to 60 is represented on X-axis and the number of epochs (100) executed in the model is represented on Y axis. The graph illustrates the loss corresponding to the accuracy of the VGG16 model. The lowest loss rate was achieved at 58 epochs, with a value of 0.0019. The blue line in the graph represents the training data, while the orange line represents the validation data. It's important to note that 20% of the images were randomly selected from each class for testing, ensuring a reliable evaluation of the model's accuracy and loss.

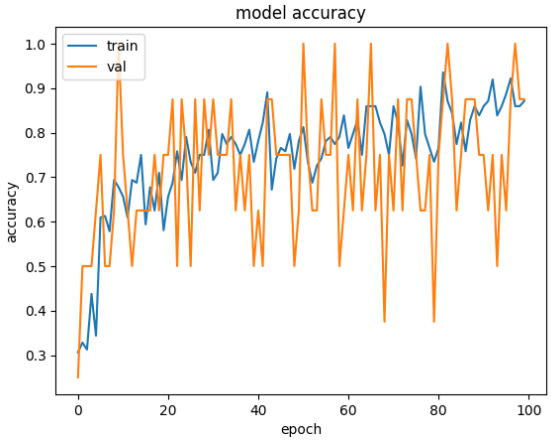

Fig. 4. Accuracy of VGG19.

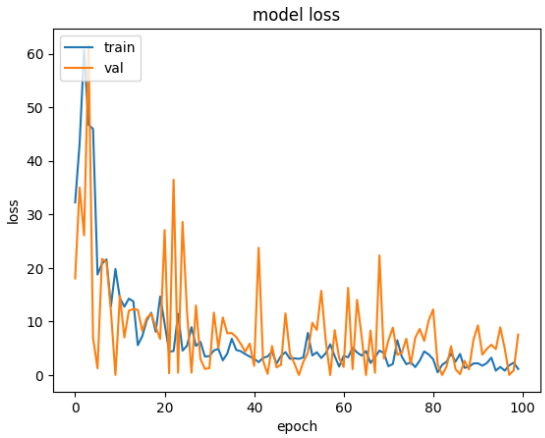

Fig. 5. Loss of VGG19.

As illustrated from Fig. 6, the accuracy values ranging from 0.0 to 0.8 is represented on X-axis and the number of epochs (100) executed in the model is represented on Y axis. During the study, the model was trained for 100 epochs, and the highest accuracy, 87%, was achieved at 52 epochs with a corresponding loss rate of 0.4747. The blue line on the graph represents the training data, while the orange line represents the validation data. It's important to note that for testing purposes, 20% of the images were randomly selected from each class, ensuring a representative evaluation of the model's performance.

The blue line corresponds to the training set, while the orange line represents the validation set. Notably, for testing purposes, 20% of images were randomly selected from each class.

As illustrated from Fig. 7, the accuracy values ranging from 0 to 80 is represented on X-axis and the number of epochs (100) executed in the model is represented on Y axis. The graph illustrates the loss corresponding to the accuracy of the VGG16 model. The lowest loss rate was achieved at 52 epochs, with a value of 0.4747. The blue line on the graph corresponds to the training data, while the orange line represents the validation data. It's important to note that for testing purposes, 20% of the images were randomly selected from each class, ensuring a representative evaluation of the model's accuracy and loss.

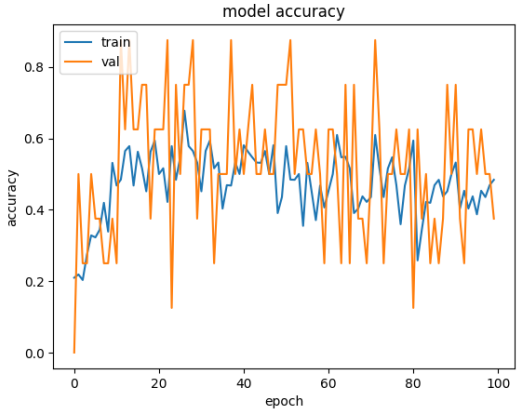

Fig. 6. Accuracy of inceptionV3.

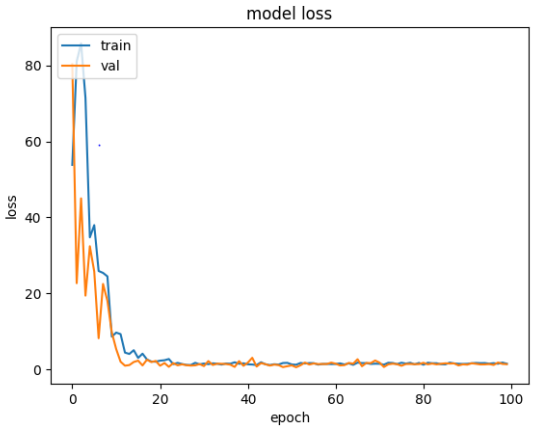

Fig. 7. Loss of inceptionV3.

As illustrated from Fig. 8, the accuracy values ranging from 0.4 to 1.0 is represented on X-axis and the number of epochs (100) executed in the model is represented on Y axis. Throughout the study, the model had been trained for 100 epochs, and the highest accuracy, achieved at 22 epochs, was recorded at 0.0013 loss rate. The blue line on the graph corresponds to the training data, while the orange line represents the validation data. It's important to note that 20% of the images were randomly selected from each class for testing purposes, ensuring a representative evaluation of the model's performance.

The training data is represented by the blue line, while the validation data is indicated by the orange line. Notably, 20% of images from each class were randomly chosen for testing.

As illustrated from Fig. 9, the accuracy values ranging from 0 to 40 is represented on X-axis and the number of epochs (100) executed in the model is represented on Y axis. The graph illustrates the loss corresponding to the accuracy of the VGG16 model. The lowest loss rate was achieved at 22 epochs, with a value of 0.0013. The blue line in the graph illustrates the training data, while the validation data is depicted by the orange line. It's important to note that for testing purposes, 20% of the images were randomly selected from each class, ensuring a representative evaluation of the model's accuracy and loss.

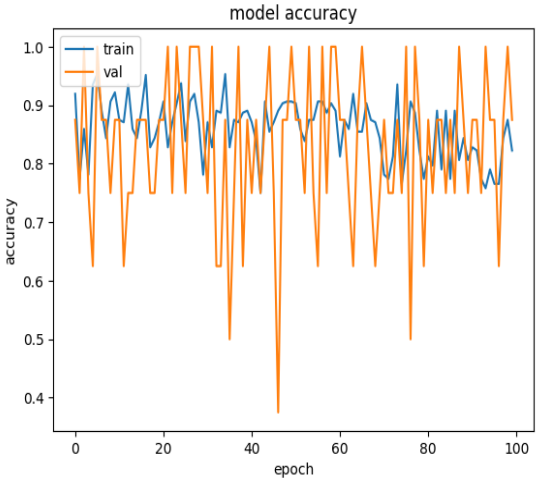

Fig. 8. Accuracy of ResNet50.

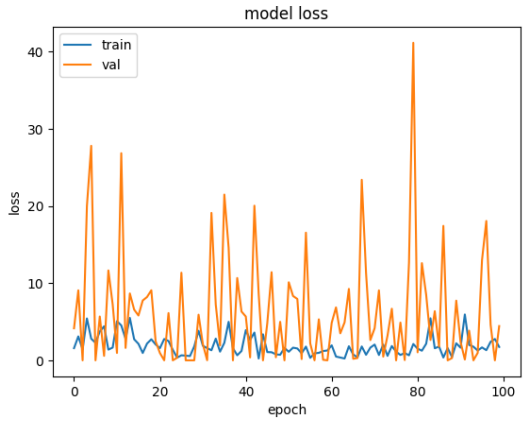

Fig. 9. Loss of ResNet50.

Out of the listed models, namely InceptionV3,VGG16, ResNet50 and VGG19 the ResNet50 model stands out, exhibiting the highest accuracy with minimal loss. Furthermore, in addition to accuracy and loss metrics, the output includes Soil Image and the subsequent soil classification as described below.

Fig. 10 shows the output of the model which is name of the soil here the classification of soil type is Yellow Soil, list of values in array and the image which is given as input to the model with height 220 and width 220.. Out of the listed models such as VGG16, VGG19, InceptionV3, ResNet50 , the ResNet50 got highest accuracy with less loss. So model taken ResNet50 for execution and identified as Yellow Image.

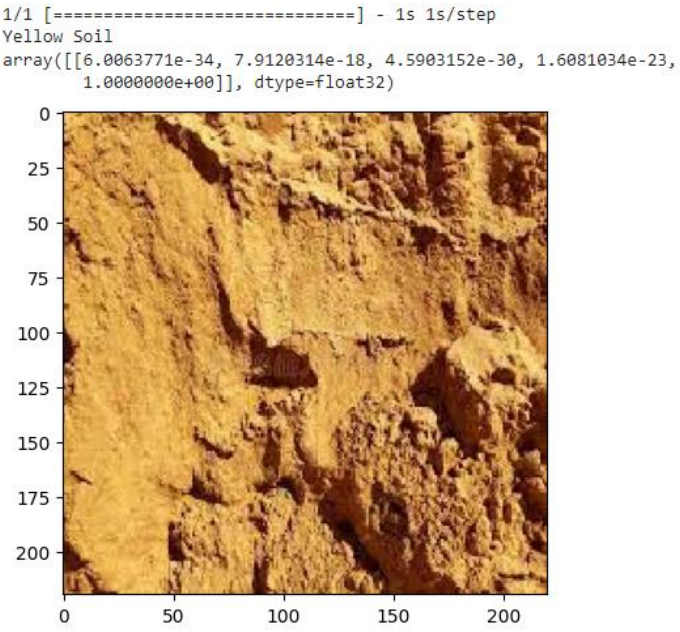

Fig. 10. Soil classification.

ResNet50 achieves high accuracy and minimal loss due to its 50-layer architecture utilizing a bottleneck design for building blocks. The bottleneck residual block incorporates 1×1 convolutions, called a "bottleneck," reducing parameters and matrix multiplications. This design enables faster training of each layer. Unlike the traditional two-layer approach, ResNet50 employs a stack of three layers, contributing to its superior performance.

V. Conclusion

Soil classification holds significant importance as it aids in the analysis of soil nutrients and minerals. This analysis enables precise crop management, leading to enhanced productivity and meeting the growing food demands. Deep Learning Techniques are employed to address challenges encountered in the manual soil classification process. This project emphasizes the utilization of Deep Learning and Image Processing for classifying soils, focusing on key soil characteristics such as particle size, texture and color. These techniques aim in replacing the traditional manual soil inspection methods. The proposed model incorporates four different Convolutional Neural Networks (CNNs) – ResNet50, VGG16, VGG19, and InceptionV3 – for multi-class classification, categorizing soils into Yellow, Peat, Cinder, Laterite and Black Soils respectively. Among these neural networks, ResNet50 outperformed the others, achieving a minimal error rate of 0.13% and a flawless accuracy of 100%. Although the model was tested with a limited dataset, expanding the dataset could potentially improve accuracy further. Additionally, incorporating pH values into the dataset and integrating crop recommendations could enhance the model's capabilities in extracting soil nutrients and minerals. This model can be enhanced by using large dataset, to get nutrients and minerals from soil by adding pH values to the dataset and also for crop recommendation.

***Abstract*—e-Commerce today is a remarkable experience. However, finding and purchasing a right quality product based on numerous product reviews and manual rating in the e-commerce websites utilize much time among the consumers. This paper presents the problems faced by the consumers when buying products in e-commerce websites and a solution to solve the problems. Thus, the idea of an automated product rating system would be very useful for the consumers in which it rates the products automatically based on the reviews given by the buyers. To do this, a technique called Sentiment Analysis is used. It also ranks the products in order based on the product rating that is generated automatically. It would provide a way for the consumers to purchase their desired product within minutes. Surveys and interviews were conducted to find out the problems faced by consumers when purchasing a product online through e-commerce websites. There was also research conducted to study the product rating and product review section on the current e-commerce websites. To conclude, this automated product rating system eventually eases the consumers' effort and time from reading numerous reviews and trusting inaccurate product rating to find a best quality product for them.**

Keywords*—*e-commerce website; sentiment analysis technique; manual product rating; automated product rating; product review

I. Introduction

As technology advances, everything is becoming more digital and automated. In this digitalized world, all of us now can buy anything on e-commerce websites and have it delivered without having to go to a store physically. There is almost nothing that we cannot find on e-commerce websites. However, judging a product solely based on its pictures and reviews is difficult and requires extensive research. Online buyers will always look for reviews of a product before buying to avoid purchasing low quality products. For them to look for the right product to be purchased, they must look for the products from different shops and compare those products. Reading numerous reviews and selecting the best product from a sea of similar items is a time-consuming process. Every review must undergo a thorough examination. The buyers had to scroll through and analyze thousands of reviews to buy a product online. Not only that, even when there is a rating provided for the product, it is not accurate enough as the buyer can just rate simply and not everyone knows the reason behind the rating that is given. Some reviews and ratings that are available in certain e-commerce websites are not even related. The reviews may be written in a positive way, but the rating given may be too low and vice versa. This makes the other buyers confused to look whether to refer to the reviews or the ratings. They would be frustrated in looking for that kind of unmatching reviews and ratings. Furthermore, the arrangement of the products is unstructured. Even though a product has many good reviews or ratings, it is shown at the bottom of the page. We are not sure how many people would scroll till the bottom to find a perfect product for them. They will only be going a certain mile to find the products and read the reviews. So, by the time the buyer does not reach the product that has a good review, they are losing the chances of buying the good ones. Thus, an advanced Sentiment Analysis for Product Rating system is developed to speed up finding the best products online using Sentiment Analysis technique. In addition, the system is also able to detect the hidden sentiments in the reviews and rate the product accordingly in which it will be done automatically by the system. Using the rating that is given for each review, an overall rating is assigned for each product. Based on the overall rating, it will rank the products from the highest to lowest product rating when displaying the products. By doing this, the true customer sentiment will be shown in the form of rating, and the correct and best product can be purchased by the consumer easily. To understand better, an effort was made to look for pertinent papers, research papers, reports, and documents that are related to the topic.

II. e-Commerce

Electronic commerce refers to the buying, selling, and exchanging of goods and services over the internet. e-commerce is a contemporary business that caters to the needs of organizations and the customers able to purchase products when the prices drop, when the product quality improves and the delivering services pace enhances [1]. Moreover, Abdullah et al. [2] portrayed e-commerce as the use of Internet, computer and shared software technology to exchange the product details and visuals, offers and purchasing information and any other information that requires to be communicated to customers, suppliers or the society. Online store sales are roughly equivalent to the physical stores and this trend would continue without a stop [3]. To add on to the previous point, Franco & Regi [4] claimed that the customers can easily compare the products that they wanted to be purchased

without burdening themselves to drive from shop to shop. Armando & Alberto [5] mentioned that there was a massive shift in spending towards e-commerce. The shopping rate is also hugely elevated. However, the customers always wanted and always rely on the reviews or ratings that a product has before they decide to purchase the product. This is because when buying products online, the product cannot be touched or sensed physically, therefore the only way to make the customers trust and buy a product is the feedback or reviews given by the other customers who have bought the product earlier. Nellutla et al. [6] mentioned that a typical customer goes to the website, selects a product, inspects the prices and ratings, reads the reviews, and then proceeds with the transaction. However, e-commerce has its own set of issues. One of them is the rating of the products. Thus, we can tell that e-commerce is consistently growing and becoming more significant to businesses as technology constantly advances and it is something that needs to be taken advantage of and implemented. Customers are playing a vital role in purchasing products online as their honest reviews or the information that they are spreading are eventually influencing other customers who want to purchase a product online.

III. Product Rating and Review

Product rating and review are becoming more important in the customer decision making process nowadays. Buyers are relying on the reviews and ratings that are posted by the other buyers who have bought the product. As a result, the customer ratings and reviews have the power to significantly influence the sales of the product [7]. According to Fawzy et al. [8], the product rating is critical in ascertaining whether a product or service is in a good quality as publicized and can be trusted. In addition, Fan & Fuel in [9] mentioned that 94% of customers read reviews before deciding to do any online purchasing. To add on, Wang & Chen [10] also stated that reviews in e-commerce websites are a valuable resource and play a vital role in purchasing a product. Customers decide either to proceed with the transaction or drop down based on the reviews in the e-commerce websites. In addition, Lackermair et al. [11] stated that 104 of customers in Germany reported that roughly 85% of the customers view and read all the product reviews very frequently before purchasing a product. To conclude, ratings and reviews aid the customers as they help them to get a better and clear idea of a product before buying it. Before deciding whether a product is worth purchasing, the customers analyze the reviews and ratings in the comment section and make themselves clear. Unfortunately, the product ratings are inaccurate to resemble the quality of the products as some of the customers simply put some random ratings without having a proper rationale behind it.

IV. Sentiment Analysis Technique

To solve the problems such as unmatched product ratings with the reviews and inaccurate product ratings, Natural Language Processing (NLP) was decided to use as it has the power of measuring sentiment from a text. NLP is a branch of machine learning (more specifically the branch of Artificial Intelligence) that is concerned with a computer's ability to comprehend, analyze, manipulate, and possibly generate human language [12]. In NLP, there is a technique called Sentiment Analysis which suits well to achieve the objective of this topic. To use the Sentiment Analysis technique, some other NLP techniques or processes needed to be used so that the objective of Sentiment Analysis can be achieved (will be discussed in the upcoming section). Based on the research that is made, there are no other techniques that are used to analyze a review. The only technique that has been introduced to analyze the sentiment of a review is Sentiment Analysis. There are many reasons why Sentiment Analysis is decided to be used for analyzing the product reviews and generating product rating in accordance with the reviews. Those are described in the next subsection.

V. Sentiment Analysis in e-Commerce Website

Nowadays, people place a lot of importance on online shopping because it allows them to complete their purchases faster and with less effort. According to Jha et al. [13], Sentiment Analysis is used to ascertain what customers think of the product. This helps other customers in making decisions on buying a product. Textual reviews, star ratings, and emojis are all used to express opinions. Thus, Sentiment Analysis is used to examine the vast amounts of data that assist retailers or the buyers in meeting their objectives. Sentiment Analysis, a cognitive process for eliciting a user's feelings and emotions. As the internet-based applications have increasingly evolved, it has resulted in a huge number of personalized reviews for many types of information on the Web. Sentiment Analysis is also known as a mighty tool for extracting relevant and needed information including aggregating the sentiments of the reviews for the users. It requires a training set for its performance and its quality is utmost important in evaluating a text accurately [14]. Besides that, Jabreel et al. [15] stated that the main goal of Sentiment Analysis is to predict whether a text's overall sentiment is positive, negative, or neutral. It has numerous variations. One method is to assign a rating scale from the reviews, such as 1 = "worst" to 5 = "best". According to Vyas & Vijayasundaram [16], big data from customer reviews, e-commerce sites and other sites are nearly impossible to manage. An automated system that calculates the overall tendency of belief and intensity to units like agencies, manufactured items, events, and their components is Sentiment Analysis. Sentiment Analysis is necessary for a greater understanding of the product. Furthermore, the simplest way to analyze the reviews is by calculating the feedback rating using Sentiment Analysis with word count. The rating can be predicted by the customer feedback. After receiving the sentiment analysis output, the customer can read all the feedback as fast and efficiently as possible in terms o [17].

Not only that, Haque et al. [18] mentioned that there are so many reviews that an effective method of analysis is needed. Customers must read through thousands of reviews manually to purchase a product in e-commerce. The volume of reviews is stored like a mountain which requires some effective classifier to identify valuable information from text. Sentiment Analysis can be useful in determining customer behavior by analyzing and examining customer reviews in e-commerce. Customers express their feelings by providing a subjective judgment about the products in e-commerce [19].

Additionally, Sentiment Analysis aids in categorizing the unstructured text as positive, negative, or neutral, which summarizes customer opinions and helps us better understand how other customers feel about a given product and retailer [20]. To summarize, Sentiment Analysis plays an essential role in analyzing the hidden and true sentiment of customers based on the feedback or reviews given by them.

VI. Comparison on Existing e-Commerce System

A comparison on some existing e-commerce websites such as Shopee, Lazada and Amazon in some aspects of their product ratings are also made. Those are shown in Table I.

TABLE I. Comparison of the Existing e-Commerce Websites with Product Rating Feature

Criteria to assess	Shopee	Lazada	Amazon	Proposed system
Existence of product rating feature	Yes	Yes	Yes	Yes
Automated product rating based on product review	No	No	No	Yes
Technique used in product rating	No technique used	No technique used	No technique used	Sentiment analysis will be used to analyse the true sentiment of the customers based on the product review given by them
Matchiness of product rating and product review	Not match sometimes	Not match sometimes	Not match sometimes	Will be matched as the product rating will be automated based on the product review given
Arrangement of products based on product rating	Random	Random	Random	Will be orderly arranged automatically based on the product ratings (from high to low)

VII. Method

Interviews and surveys were conducted to find out the problems faced by consumers when purchasing a product online through e-commerce websites.

A. Interview

The interview was conducted with two frequent users of e-commerce websites who are X, regular user of Shopee and she is a student who's running a small jewelry business and another interviewee is Y, active user of Lazada and she is a businesswoman who's having her own boutique. The interviews were conducted by asking open-ended questions without providing any options. This is because answering open-ended questions will reveal the truth of interviewees' problems so that all their pains and challenges of purchasing products online can be understood well. By using qualitative method, the interviewees' problems were clear-cut. It creates an opportunity to understand the interviewees in depth. Not only that, but the behavior of the interviewees was also easily observed during the interviews. This was helpful to understand them especially their pains and gains because those were expressed through their expressions and their body languages. In addition, 'WH' questions were asked to the interviewees to uncover deeper meaning and to identify the problems that the interviewees had but never realized its existence. Furthermore, it was effective enough to immerse in the interviewees' experience by purchasing products online through the e-commerce website together with them. The prepared questions were asked and there were some extra questions added based on the response given by the interviewees. The online interview sessions were conducted for 20 to 45 minutes.

B. Survey

Besides, a simple online short survey was conducted through Google form with a set of questionnaires. Since this issue involves e-commerce website users which are also known as consumers, the survey has been conducted among the people who actively use e-commerce websites to purchase their desired products. Based on the survey, there are a total of 20 respondents that have answered the questionnaire.

C. Sentiment Analysis Process

Since it involves the Sentiment Analysis technique, there are some processes that have performed so that it automatically analyzes the reviews for the sentiment of the consumers and rate according to it. Those processes are as below.

D. Data Collection

Dataset was collected from the Kaggle platform. The dataset is about clothing reviews with its product ratings and some relevant information. It is the raw data. And it is in the .csv format.

E. Data Reading

After collecting the dataset from the Kaggle platform, the data has to be read for the upcoming process. Then, the number of rows, the number of columns and the number of data were read. For this project, the amount of data for every star-rating has been read and displayed which will be useful for the upcoming processes.

F. Data Cleaning

Data cleaning was done so that the data will be accurate, consistent and complete. Data cleaning or cleansing is the process of cleaning datasets by accounting for missing values, removing outliers, and smoothing noisy data (removing the meaningless data, renaming the meaningless column names and removing duplicated data) [21]. At the end, only the product reviews column and product ratings column were retained.

G. Data Preprocessing

Data preprocessing is the process of transforming raw data into a useful, understandable format. Raw data usually has inconsistent formatting, human errors, and can also be incomplete [22]. In data preprocessing, firstly, tokenization process was implemented. Tokenization is a process that will break the raw text into small chunks which helps in understanding the context or developing the model for the NLP [23]. It also helps in interpreting the meaning of the text by analyzing the sequence of the words. Then, special characters such as punctuations were eliminated as those characters are less important for training and testing models later on. Next, stop words were removed in which it removes the words that occur commonly across all the documents in the corpus. Typically, articles and pronouns are generally classified as stop words. Moreover, stemming process was also performed. It is also known as data filtering. It is a process of reducing a word to its word stem that affixes to suffixes and prefixes or to the roots of words known as a lemma.

H. Feature Extraction

Feature extraction is a process that will convert text into a matrix (or vector) of features. For this, we will be using a technique called TF-IDF technique in which it stands for term frequency-inverse document frequency. It highlights a specific issue which might not be too frequent in our corpus but holds great importance [24]. The TF– IDF value increases proportionally to the number of times a word appears in the document and decreases with the number of documents in the corpus that contain the word. It is composed of two sub-parts, which are Term Frequency (TF) and Inverse Document Frequency (IDF). Term Frequency (TF) specifies how frequent a term appears in the entire document while the Inverse Document Frequency (IDF) is a measure of whether a term is rare or frequent across the documents in the entire corpus. The formula of TF-IDF is:

$$\text{TF}(t, d) = \frac{number\ of\ times\ t\ appears\ in\ d}{total\ number\ of\ terms\ in\ d} \quad (1)$$

$$\text{IDF}(t) = \log\frac{N}{1+df} \quad (2)$$

$$\text{TF-IDF}(t, d) = \text{TF}(t, d) * \text{IDF}(t) \quad (3)$$

where, d refers to a document, N is the total number of documents, df is the number of documents with term t.

TF-IDF is word frequency scores that highlight the words that are more interesting. The scores have the effect of highlighting words that are unique in a given document.

I. Data Balancing

Data balancing is used to balance the imbalanced data. There are two methods to be used to solve the imbalanced data. One is a random under sampling method, and another is a random oversampling method. Random under sampling method aims to randomly choose and eliminate samples from the majority class, thereby reducing the number of examples in the majority class in the transformed data whereas random oversampling involves choosing random examples from the minority class with replacement and adding multiple copies of this instance to the training data, so it's possible that a single instance will be chosen more than once [25].

J. Model Building (Sentiment Classification Analysis)

There are several Machine Learning based classification algorithms available using supervised and unsupervised learning approaches. The supervised methods make use of a large number of labeled training documents while the unsupervised methods are used when it is difficult to find these labeled training documents. For this proposed system, supervised learning method is chosen as it has a labeled dataset and a training process, therefore, several models were used such as Gaussian Naïve Bayes Classifier, Multinomial Naïve Bayes Classifier, Bernoulli Naïve Bayes Classifier, Random Forest Classifier, Logistic Regression Classifier, Decision Tree Classifier, Support Vector Classifier and K-neighbors Classifier. All these mentioned models were decided to use as they are capable of scalability. Using all these models, accuracy of each model was then identified. From there, the highest accuracy model was chosen and the dataset using the chosen model was trained.

K. Sentiment Analysis

With the highest accuracy model, Sentiment Analysis is then carried out to analyze the sentiments in each review and provide appropriate rating to it.

VIII. Results and Discussion

The results of the interviews and survey are discussed in this section.

A. Interview

In the first interview, X mentioned that she uses Shopee because it is user-friendly. In Shopee, she normally browses the same products in distinct shops and compares the price and the quality of the products by looking at the reviews and ratings. She often does online shopping in Shoppe (twice a week) to buy things for herself and for her business. She said it takes almost two to three days to view all the product features and compare them with other sellers because the same product from other shops has different kinds of reviews. Before she decides to purchase a product, she normally goes through the product features, product rating and the product reviews. As for her, purchasing a product online consumes her time as it takes time to compare the products with different shops and choose the right product. She also mentioned that she will not purchase a product if she found the product has a huge number of negative reviews and even if it has an equal number of positive and negative reviews. Furthermore, she found some of the ratings are displayed as high but portrayed bad about the product when reading the reviews. She said that seeing and reading a ton of reviews are really time consuming, as a result, she will not be in the mood to shop most of the time.

In the second interview, Y said that she uses Lazada because it is easier for her to use, and it was recommended by her friend. In Lazada, she usually buys her desired products, reads reviews of her desired product before purchasing and sees the ratings of the product. Y mentioned that she does online shopping in Lazada once a week mainly to buy some

necessary items for her business. She said it takes almost a day to make a purchasing decision. This is because she always trusts the people's views, thus, she will always read the reviews before purchasing anything and she also said that some of the products have a ton of reviews which is time consuming. Before she wants to buy anything, she usually looks for people's thoughts in the review section. As for her, purchasing a product online consumes more time because she must go through a lot of reviews. She also mentioned that if she found the product has a huge number of negative reviews and even it has an equal number of positive and negative reviews, she normally will not buy the product in that shop and will find another shop that sells the same product which has more positive reviews. In addition, trusting too much on the product reviews including the product rating before purchasing a product became a bigger problem for her because she often confused with the product reviews and ratings as they both will not be correlated and she does not know which one to trust, therefore, she will move to other shop to purchase the same product. Furthermore, she found that there are unmatching reviews and ratings of a product in which the rating is low for positive reviews and vice versa. She said that seeing and reading a ton of reviews are really time consuming. As a result, her excitement of buying the product will be lessened in that shop and will decide to shop in different shops.

B. Survey

There are roughly 15 questions in the survey, but the result of this survey will be displayed only for some questions that are important for achieving the objective of this project. Those are as below:

Fig. 1 shows a bar chart of the e-commerce websites that are used by the respondents daily. Based on this bar chart, 18 of the respondents use Shoppe websites, 20 of the respondents use Lazada websites and 11 of them use Amazon websites. Since Shopee, Lazada and Amazon are the three highest e-commerce websites used by the respondents, that's why a comparison of those three e-commerce websites was made in the previous section (see Table I).

Fig. 2 shows a bar chart of the activities that are carried by the respondents in the e-commerce websites. It is clearly be seen that reading other users' reviews of a product and looking at the rating of a product have the highest counts which means the respondents always look for the reviews and ratings when they shop.

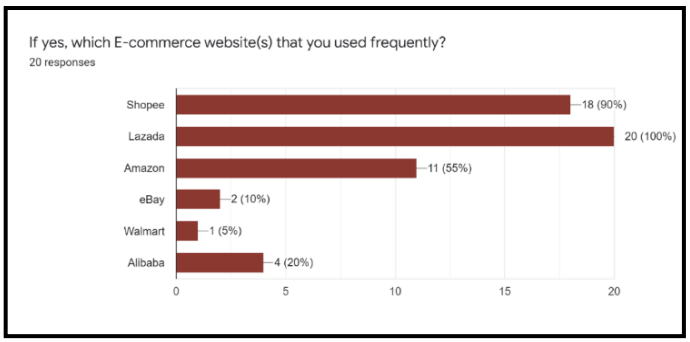

Fig. 1. Frequently used e-commerce website(s).

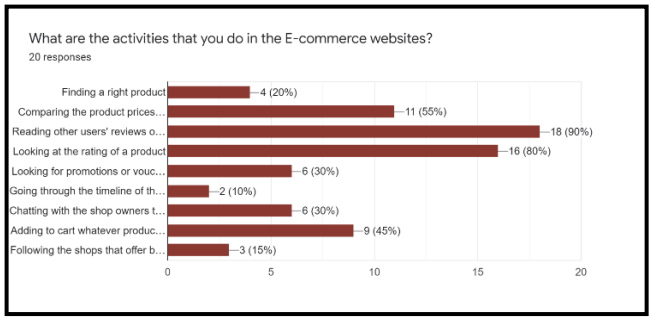

Fig. 2. Activities carried out in e-commerce websites.

Fig. 3 shows a pie chart on the time taken to make a purchasing decision while shopping online by the respondents. Around 40% of the respondents took more than five hours to decide while 25% of the respondents took more than 1 day to decide and followed by the rest. From here, it is obvious that spending more than five hours or one day is too much for a person to decide on a product to purchase. Even the respondents would not spend that much time when they shop physically. It would take only 10-15 minutes to buy physically. Tons of reviews to be read might be one of the reasons why most of the respondents spend too much of their time to make decision.

Fig. 4 shows a bar chart on the criteria(s) that are considered by the respondents before they proceed with purchasing a product. From this chart, reading the product reviews and looking at the product ratings have the same count which is 19 and both are the highest among the other criteria. Thus, it is crystal clear that reviews and ratings are playing a major role when purchasing a product in e-commerce websites.

Fig. 3. Time taken to make a purchasing decision.

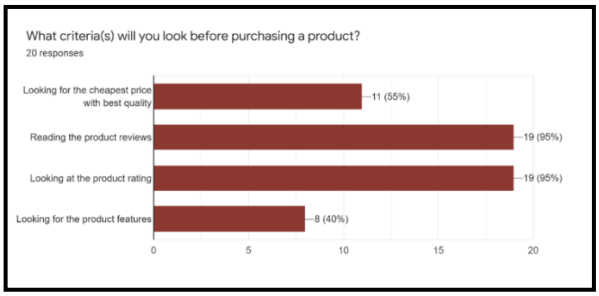

Fig. 4. Criteria(s) that are considered before purchasing a product.

Fig. 5 shows a pie chart on the time taken the respondents took to read all the related reviews of a product. 60% of the respondents took more than one hour to read the reviews.

There are also some respondents who voted for 10 – 30 mins and 30 mins - 1 hour. This is mainly because of the number of reviews a product has. The more the reviews a product has, the more the time taken to read the reviews one by one.

Fig. 6 shows a pie chart to know whether the respondents experience unmatched product reviews and ratings. All the respondents voted for 'Yes' which means all of them experienced seeing unmatched product reviews together with manual product ratings. This is meant by, either they have seen a good review with low product rating or a bad review with a high product rating which both do not make sense at all. The reviews and ratings should be related with each other to avoid creating distrust among the other consumers who firstly visited a particular shop.

Fig. 7 and Fig. 8 show pie charts on difficulty and time consumption in finding and purchasing a right product. All 20 respondents agreed that finding and buying the best product for them is really time consuming and very difficult. This is maybe because finding a product that has the highest product rating on an unordered products arrangement consumes more time and a mixture of positive and negative reviews of all the similar products from different shops make the consumers think in depth to proceed with the purchasing decision.

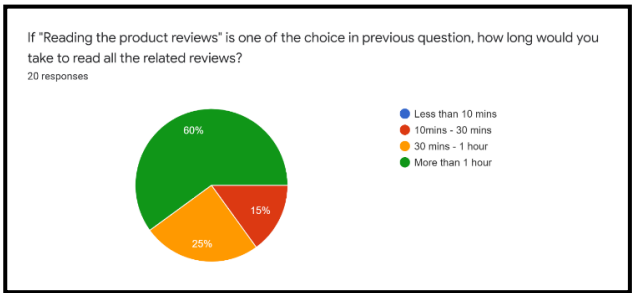

Fig. 5. Time taken to read all the reviews.

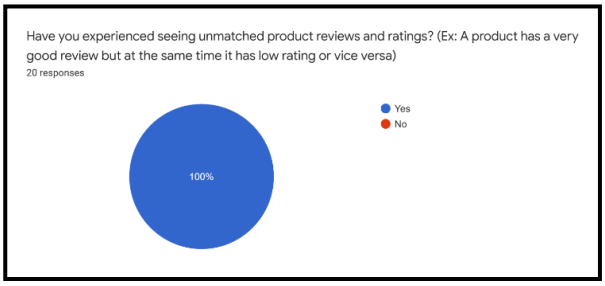

Fig. 6. Experience of seeing unmatched product reviews and ratings.

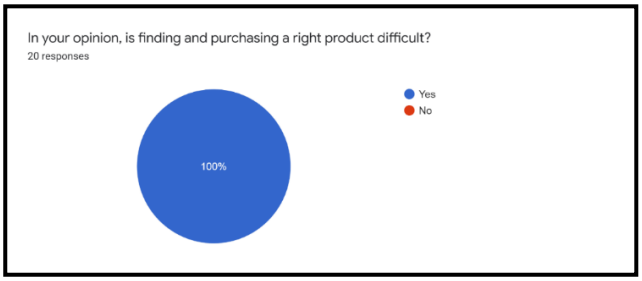

Fig. 7. Difficultness in finding and purchasing a product.

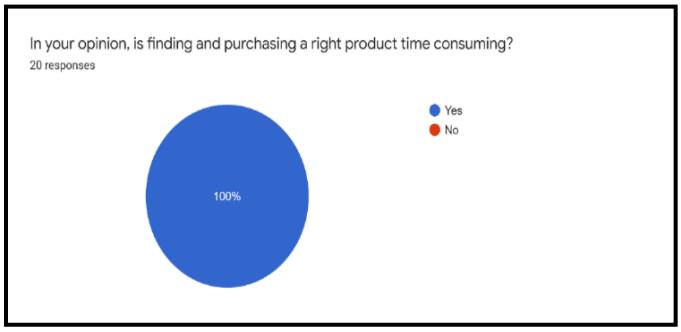

Fig. 8. Time consumption in finding and purchasing a product.

C. Sentiment Analysis Process

The result of each process mentioned in the previous section is discussed as below.

D. Data Collection

Clothing Reviews dataset was collected from Kaggle platform in .csv format that has the columns named product review and product rating.

E. Data Reading

The number of rows, the number of columns and the number of data counts of every rating value were read using pandas library (python)

F. Data Cleaning

The null values, duplicated values and unwanted columns are removed to make the data accurate and consistent. Additionally, the column names were renamed with meaningful names. All these were done using the drop (columns = […]) method, rename (columns= […]) method, dropna () method and drop_duplicates () method.

G. Data Pre-Processing

In this process, label encoder is used to encode the rating value of 1,2,3,4,5 to 0,1,2,3,4,5. Then, using the NLTK library, stop words are imported so that it can remove the stop words found in the dataset. All the unwanted characters like special characters were removed. And made the reviews all in small characters. Moreover, the review was also tokenized into small chunks. And finally, the suffixes and prefixes of a word in the review were removed and only holds the root word.

H. Feature Extraction

Feature extraction technique was used to find the frequency and the importance of the words that are present in the corpus. Here, the TF-IDF technique was implemented from the sklearn library by importing TfidfVectorizer from the feature extraction.text module.

IX. Data Balancing

Upon visualizing the product review with its rating in the dataset, it is found that the number of product reviews for all the product ratings (1-star to 5-star) is not balance as shown in Fig. 9.

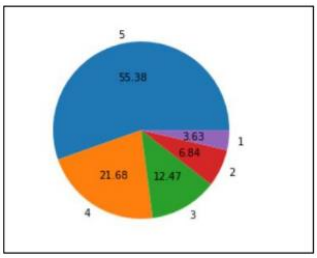

Fig. 9. Pie chart of the number of product reviews for all the product ratings in Clothing review dataset.

This is known as imbalanced data. When the machine learning models are trained using this imbalanced data, the models will be well trained for only 5-star rating reviews as it holds a bigger amount of product reviews compared to the other star ratings. In this case, even a bad review could make the models to interpret the review as a good one and could create a good rating since the product rating of 1-star, 2-star, 3-star have a smaller amount of review data compared to 5-star reviews and it will not be trained as how 5-star product review do. Thus, out of two methods that were mentioned in the previous section which are random oversampling and random under sampling, the random under sampling method is chosen because the random under sampling method gives the accurate result compared to the random oversampling method. This was identified by running both methods and observed the accuracy of the product rating that was generated by the system upon analyzing the reviews that were submitted in the review section.

A. Model Building (Sentiment Classification Analysis)

To find out which classifier suits the dataset the best, we implemented our dataset on multiple classification models namely Multinomial Naive Bayes Classifier, Bernoulli Naive Bayes Classifier, Gaussian Naive Bayes Classifier, Support Vector Classifier, K Nearest Neighbour Classifier, Decision Tree Classifier, Logistic Regression Classifier and Random Forest Classifier.

```
For  Support Vector Classifier
Accuracy -  0.4776910616993079
Time taken -  10.018787860870361

For  K-Neighbors
Accuracy -  0.31438668826387867
Time taken -  10.443702697753906

For  Multinomial Naive Bayes

```

Fig. 10. Accuracy and time taken of each classifier.

The accuracy and time taken of each machine learning model were identified to train the model using each classifier that was mentioned, as shown in Fig. 10. In Fig. 10, it is clear that the Multinomial Naïve Bayes model holds the highest accuracy compared to other models.

B. Sentiment Analysis

The highest accuracy model, which is Multinomial Naïve Bayes model, was selected to analyze the sentiments on each review given and provide an appropriate rating to it.

X. Conclusion

It is true that reading numerous reviews, finding a right product for a longer time, and having unmatched reviews and ratings are the top issues among the consumers and there is a dire need to solve them. These are the key reasons to have an automated product rating system and different from the existing e-commerce websites. It uses Sentiment Analysis technique as it has an ability to analyze the hidden sentiment of the consumers in the review section. In addition, this system can also rank the products based on the rating in which it will reduce the time taken for the consumers to scroll the page down till they find the right one for them. On top of that, the unmatched reviews and ratings can be avoided as the rating will be given automatically based on the reviews, hence helps the consumers shorten their time searching for the best products within minutes.

Future Works

A fundamental challenge in e-commerce research comprehends the idea of Artificial Intelligence (AI). According to our research, e-commerce product ratings based on customer reviews have primarily been taken into consideration by researchers. Researchers can contribute AI to e-commerce research in the future. This will assist in precisely analyzing data and forecasting e-commerce activity through the use of AI platform algorithms. Having this clarification would help avoid misunderstandings between AI and business analytics and intelligence in e-commerce. Additionally, it would make it easier to distinguish between AI as a social actor and AI as a computing technology capable of cognitive tasks. Context is a second fundamental problem with AI research in e-commerce. Based on the output of an e-commerce system that is relevant in the real world, an AI system would be able to interpret the message that the user communicated or sought using the same data. Hence, rather than making broad assertions about product prices, researchers would need to work with practitioners to better understand and define contexts of inquiry. Lastly, to provide more information about the methodology, such as sample size, demographics, and questions asked during interviews and surveys.

***Abstract*—The paper presents a simplified yet innovative computational framework to enable secure routing for sensors within a vast and dynamic Internet of Things (IoT) environment. In the proposed design methodology, a unique trust evaluation scheme utilizing a modified version of Ant Colony Optimization (ACO) is introduced. This scheme formulates a manifold criterion for secure data transmission, optimizing the sensor's residual energy and trust score. A distinctive pheromone management is devised using trust score and residual energy. Concurrently, several attributes are employed for constraint modeling to determine a secure data transmission path among the IoT sensors. Moreover, the trust model introduces a dual-tiered system of primary and secondary trust evaluations, enhancing reliability towards securing trusted nodes and alleviating trust-based discrepancies. The comprehensive implementation of the proposed integrates mathematical modeling, leveraging a streamlined bioinspired approach of the revised ACO using crowding distance. Quantitative results demonstrate that our approach yields a 35% improvement in throughput, an 89% reduction in delay, a 54% decrease in energy consumption, and a 73% enhancement in processing speed compared to prevailing secure routing protocols. Additionally, the model introduces an efficient asynchronous updating rule for local and global pheromones, ensuring greater trust in secure data propagation in IoT.**

Keywords*—Internet of things (IoT); secure IoT routing; manifold criterion trust evaluation; ant colony optimization (ACO); bioinspired computing; pheromone management

I. Introduction

Sensors are an integral part of the IoT landscape. They acquire environmental data and perform real-time transmission over the hosted IoT network [1]. These compact electronic devices can sense various environmental attributes, such as chemical composition, motion, sound, light, pressure, humidity, and temperature, depending on their application or the environment in which they are deployed [2–5]. In the context of IoT, sensors acquire information from the physical world and forward it to a sink node for analysis [6]. This acquired information might be used for research purposes or to trigger specific actuators for automated actions [7–10]. However, despite their capabilities, these sensors often have limited processing and computing abilities, and ensuring their extended lifespan remains challenging [11].

Among the various issues associated with sensors, security is the most critical concern for IoT sensors [12]. The first issue is data privacy, ensuring data is stored securely and transmitted to the intended terminal without unauthorized access [13]. The second pertains to vulnerabilities in IoT devices; sensors often fall prey to cyber-attacks due to unpatched vulnerabilities, outdated software, or weak passwords [14]. The third challenge relates to malware attacks in the form of Trojans, worms, and viruses, which can hinder data transmission, steal data, or corrupt device functionalities [15]. Physical security represents the fourth concern; unauthorized access to a sensor can lead to data tampering, malware introduction, or functionality disruption [16]. The fifth challenge involves Distributed Denial-of-Service (DDoS) attacks, where overwhelming traffic incapacitates sensors, disrupting their communication or services [17]. The sixth pertains to Man-in-The-Middle attacks, where attackers can intercept and potentially modify or steal data [18]. Numerous studies have proposed security mechanisms for IoT to address these vulnerabilities [19–23], but comprehensive solutions that tackle all these challenges remain elusive, with each approach having its strengths and weaknesses.

Securing routing in IoT has become a complex endeavor in today's landscape, marked by an ever-increasing array of known and emerging threats [24, 25]. One core challenge arises from the use of resource-constrained devices in IoT, characterized by limited battery life, memory, and computing power. This limitation precludes the deployment of robust cryptographic algorithms on such devices [26]. The dynamic topology of IoT, where devices can spontaneously join or leave the network, further complicates security protocols. Incorporating diverse IoT devices with specific service requirements complicates implementing universal security protocols. Challenges also arise from issues with mobility and localization; accurate localization information is hard to obtain, and the legitimacy of mobile nodes is difficult to verify. The need for standardization in IoT devices and security protocol management further complicates matters. Most current IoT security research is conducted in controlled environments, distinct from real-world scenarios. Thus, the reliability of their applications in practical deployments remains to be determined.

The manuscript is structured as follows: Section II delves into current methodologies for secure routing in IoT, emphasizing various bioinspired approaches and their

contributions. Section III outlines the research problem identified from insights gleaned from these existing methodologies. The proposed methodology to address these issues is detailed in Section IV. An analysis of the results is presented in Section V, while Section VI concludes the paper.

II. Existing Approaches

Over time, several schemes have been developed to investigate secure routing within IoT. Among these, trust-based schemes have emerged as an essential tool for a simplified defense against security breaches [27, 28]. Liu *et al.* [29] devised a secure aggregation model for a Wireless Sensor Network (WSN), ensuring increased trust when operated with a single mobile sink node. Additionally, some research has focused on optimizing trust factors through bioinspired approaches. For instance, Mangalampalli *et al.* [30] employed a whale optimization scheme for enhancing task scheduling. Muzammal *et al.* [32] introduced a trust-based protocol to counter blackhole attacks in static and mobile IoT environments. However, these approaches often need to pay more attention to the dynamic nature of IoT networks and may not be efficient in real-time scenarios.

Awan *et al.* [33] embraced a blockchain-based model for secure routing in WSN, aiming to refine trust management. Notably, their model incorporated the Rivest Shamir Algorithm to safeguard data propagation. However, blockchain's inherent latency issues could limit its practicality in specific IoT setups. Nagaraju *et al.* [34] combined energy optimization with a traditional hybrid approach for secure IoT routing within heterogeneous WSNs. While energy-efficient, such models might compromise on real-time response. Bakhtiari *et al.* [35] proposed a two-way trust strategy using Bayesian learning automata for fog computing in IoT. It improves efficiency, reduces latency, and enhances trust calculations compared to existing methods. However, it's sensitive to initial trust accuracy, potentially impacting performance in dynamic networks. Also, implementing this two-way trust management strategy may introduce increased computational complexity as a potential limitation. Concurrently, Rakesh and Sultana [36] designed a neural network-empowered quantum scheme for mobile sink selection, employing the sailfish optimization approach for enhanced route security. However, this approach might demand more computational resources, impacting resource-constrained IoT devices. Additionally, its effectiveness may vary based on network conditions and the presence of malicious nodes, with reliance on initial trust assessments potentially limiting performance in dynamic environments. Gladkov *et al.* [37] championed a novel routing technique merging the residual number of redundant systems with a secret sharing scheme. However, the complexity associated with such hybrid approaches might lead to higher computational overheads. These diverse strategies enhance security in IoT and WSNs, but careful consideration of their computational requirements and adaptability to dynamic networks is crucial during implementation. Balancing security with resource constraints remains an ongoing challenge in these technologies.

Ramaswamy and Norman [38] introduced a trust model targeting network longevity and internal attacks in IoT. The exploration of bioinspired methods for secure IoT routing has seen algorithms like ACO applied in secured routing (Wang [39], Saleem & Ahmad [40]), decentralized traffic management (Nguyen and Jung [41]), electric vehicle selection (Ajinappa and Prabhakar [42]), and malware detection (El-Ghamry *et al.* [43]). While ACO's adaptive nature is commendable, it may struggle with large-scale, dynamic IoT environments due to its iterative nature. Particle Swarm Optimization (PSO), as documented by Alterazi *et al.* [44], Lin *et al.* [45], and Rajeshwari & Ramakrishnan [46], has also been harnessed for secure data transmission. Other notable bioinspired techniques include the Mayfly Optimization Algorithm (MOA) by Janani and Ramamoorthy [47], the Dragonfly Algorithm (DA) by Hosseinzadeh *et al.* [48], and Glowworm Swarm Optimization (GSO) by Selvaraj *et al.* [49]. Although these bioinspired strategies offer unique solutions, their scalability and adaptability in diverse IoT ecosystems might be limiting factors. The summary of strength and weakness of the reviewed literature is presented in Table I to state that existing methodologies towards secure routing in IoT is associated with beneficial features as well as shortcomings, which are required to be addressed in future upcoming series of research work.

TABLE I. Summary of Existing Schemes

Author	Problem	Methodology	Advantage	Limitation
Liu *et al.* [29]	Security in WSN, IoT	Trust-based secure data aggregation	• Trust-based secure data aggregation mechanism. • Real-time and accurate data acquisition. • Robust aggregation tree algorithm for efficient data gathering. • Enhanced network performance, including improved accuracy and reduced delay.	• Possibility of contradiction in indirect trust. • Scalability challenges in large-scale Industrial Internet of Things (IIoT) settings. • High implementation complexity. • Limited consideration for mobile sensor nodes. • Need more focus on energy efficiency.
Mangalampalli *et al.* [30]	Task scheduling with trust	Whale Optimization	• Enhanced task scheduling efficiency. • Reduced makespan. • Lower energy consumption. • Improved quality of service. • Increased trust in cloud service providers.	• Parameter sensitivity. • Implementation complexity. • Scalability issues. • Input data dependency. • Workload-driven performance variations. • Setup-specific fine-tuning. • Lack of real-world validation.

Muzammal *et al.* [31,32]	Resisting routing attacks	Trust-based protocol	• Improved security against Routing Protocol for Low-Power and Lossy Network (RPL) attacks. • Tailored for mobile IoT environments with trust and mobility metrics. • Superior performance in packet loss rate, throughput, and topology stability. • Meets consistency, optimality, and loop-freeness requirements. • Better throughput.	• Increased computational resource demands. • Sensitive to network size and setup. • Limited real-world IoT testing. • Protocol implementation complexity. • Requires further assessment in highly dynamic IoT scenarios. • Relies on trust and mobility metrics' accuracy.
Awan *et al.* [33]	Secure data transmission	Trust model, Asymmetric encryption	• High delivery ratio. • Enhanced security through blockchain-based authentication. • Extended network lifespan and reduced packet loss. • Effective malicious node detection and removal. • Secure routing based on residual energy and trust. • High packet delivery ratio in simulations.	• Increased key size. • Blockchain dependency may add complexity. • Scalability issues in more extensive networks. • Lack of real-world validation. • Computational resource demands. • Limited scope beyond trust assessment. • Latency potential in real-time applications. • Ongoing trust monitoring is required.
Nagaraju *et al.* [34]	Security, energy issues	Multipath link routing, hybrid protocol	• Satisfactory network lifetime. • Improved energy efficiency in heterogeneous WSNs. • Enhanced network lifetime. • Secure routing for confidential IoT data. • Load balancing capability. • Improved data storage capacity.	• Cannot sustain dynamic threats. • Limited real-world validation. • Dependence on specific routing protocols. • Possible sensitivity to network dynamics. • Lack of consideration for scalability in large-scale deployments.
Bakhtiari *et al.* [35]	Trust issues in Fog and IoT	Bayesian-based learning automata	• Faster response time. • Improved energy consumption. • Efficient network usage. • Reduced latency. • Enhanced trust management.	• Induces complexity for an extensive network. • Limited real-world validation. • Possible sensitivity to network dynamics. • Dependence on specific trust management methods. • May require fine-tuning for different IoT applications.
Rakesh and Sultana [36]	Trust issues	Sailfish optimization, Neural Network	• Can mitigate multiple attacks. • Improved node reliability with the introduction of a mobile sink. • Secure routing implemented using the sailfish optimization algorithm. • Data encryption for increased data security.	• Consumes higher memory to retain trust values. • Limited real-world validation and scalability considerations. • Network dynamics and computational resource dependencies. • Complexity in implementation. • Emphasis on specific optimization algorithms.
Gladkov *et al.* [37]	Routing reliability	Secret sharing scheme	• Highly adaptive. • Enhanced speed and reliability in data transmission. • Improved security through Secret Sharing Schemes (SSS). • Enhanced fault tolerance and reliability. • Adaptive multipath secured transmission for route attack prevention.	• No consideration of energy constraints. • Possible complexity in implementing SSS and RRNS. • Dependency on adaptive multipath secured transmission. • Scalability needs to be fully addressed. • Limited evaluation in dynamic heterogeneous networks.
Ramaswamy [38]	Energy issues	Trust model	• Secured clustering	• Extensive analysis is needed further.
Wang [39], Saleem and Ahmad [40], Nguyen and Jung [41], Ajinappa and Prabhakar [42], El-Ghamry *et al.* [43]	Security issues in IoT	ACO	• Higher accuracy	• Inferior convergence speed.
Alterazi *et al.* [44], Lin *et al.* [45], Rajeshwari [46]	Trust/security in IoT	PSO	• Faster performance	• High dimensional space issue needs to be addressed.

Janani and Ramamoorthy [47]), Hosseinzadeh *et al.* [48], Selvaraj *et al.* [49]	Secure data transmission in IoT	MOA, DA, GSO	• Flexible performance	• Highly iterative scheme leading to complexity.

From the highlights of the methodologies, their advantages, and limitations in the table above, it can be noted that existing secured routing methodologies are associated with various shortcomings in the perspective of deployment in an IoT environment. Following are some of the significant research problems related to the existing methods towards secure routing in IoT:

- Issues in Trust-based IoT Security: Various trust-based secure routing schemes are formulated in existing systems. Most of these techniques offer better throughput; however, the majority are also witnessed by their non-sustainability towards dynamic threats. Furthermore, the existing trust management schemes are usually designed considering the predefined information of adversaries. This makes the model robust in one environment but not applicable if the adversary environment is altered.
- Imbalance between Energy and Security Demands: Existing approaches favor energy or security retention. The security schema presented in existing schemes uses various sophisticated operations that can offer more security but at the cost of uncertain resource consumption. There has yet to be a benchmarked study model to prove this in the presence of the dynamic environment of IoT.
- Usage of Bioinspired Approach: The adoption of bioinspired approaches towards secure routing is less abundant in archives of technical publications. However, the available publications on the use of bioinspired strategies contribute towards findings of the secured path by adopting the varied cognitive principles of organisms to attain optimal security. Unfortunately, the issues related to premature convergence and higher sensitivity towards parameters by conventional bioinspired approaches have not yet been addressed. Moreover, there is no report of any study model where novel features of organisms' cognitive behavior have been attempted to be modified and investigated.
- Non-inclusion of Constraint in Trust Management: The existing trust management scheme needs to be more reportedly designed considering the restricted resources in IoT, e.g., processing power, energy, etc., which makes it quite challenging even to execute the sophisticated security protocols in sensors. This yet-to-solve challenge acts as a potential impediment to computing and establishing trust between all the entities and IoT devices in large and dynamic environments. For secure routing to occur correctly, it is necessary to formulate a better form of constraint modeling with a clear definition of the attributes that need to be added to the existing system.
- The tradeoff between Model Effectiveness and Scalability: Scalability is a different set of problems in IoT to be resolved. It demands a smart and highly planned processing for secure routing in IoT. Unfortunately, none of the existing study models has been designed considering its optimization parameter or problem space mapping with the large environment of an IoT with more interconnected devices. For this purpose, the outcome of model effectiveness doesn't match the sensors' scalable performance in increased traffic flow over an IoT.

From the above-stated highlights of the identified research problem, it can be inferred that trust modeling is one of the complex issues that demand the inclusion of various intrinsic and extrinsic attributes and effective constraint modeling. Apart from this, it is necessary to optimize the problem space to increase the change of optimal outcome of the secured path. Bioinspired algorithms are a potential alternative to address this problem, but they demand a novel inclusion of characteristics that can balance security and resource demands. The proposed solution addresses all these research issues, and its associated methodology towards implementation is discussed next.

III. Research Problem

The rapid proliferation of the IoT heralds both transformative opportunities and notable security challenges. With its expansive network of devices, IoT underscores the urgency for reliable, secure routing. Emerging as a promising avenue, trust-based secure routing strategies aim to buttress IoT's security framework. However, IoT's dynamic and resource-limited nature has often rendered traditional trust-based methods inadequate.

A significant limitation of extant trust-based IoT security methodologies is their inability to adapt to evolving threats, often designed around known adversarial models. The quest to harmonize energy conservation with security amplifies this challenge, as current systems lean towards one, often sacrificing the other. This compromise becomes more palpable when high-security measures, despite their efficacy, devour substantial resources.

The contemporary research landscape needs to display bioinspired strategies for secure IoT routing. Drawing inspiration from natural systems to fortify security, these approaches appear promising. Nevertheless, prevalent bioinspired models grapple with issues like early convergence and parameter sensitivity. This highlights a pressing need to refine and adapt these methods, tailoring them for IoT's unique challenges.

Further complicating the scenario is the design of trust management systems. The intrinsically limited resources of IoT devices, in terms of energy and processing power, hinder the execution of comprehensive security protocols. This challenge intensifies in the sprawling IoT ecosystems, where fostering trust amongst various devices is vital and daunting.

Scalability further accentuates these problems. While effective in a controlled setting, an approach might need to be revised under IoT's expansive and interconnected structure, especially when encountering unexpected traffic surges.

While trust modeling offers a promising foundation for IoT security, its practical deployment is beset with multifaceted challenges. This study aspires to address these gaps, employing the bioinspired ACO technique to architect an adaptive and secure IoT routing paradigm adeptly poised to navigate the intricate challenges of IoT.

IV. Materials and Methods

The prime agenda of the proposed study model is to introduce a novel computational model that ensures robust trust-based security while transmitting data among the sensor nodes in IoT. The prime basis of the proposed study model is based on the fact that the severity degree of security threat for sensor nodes deployed in an IoT environment is comparatively higher in contrast to conventional WSN. Therefore, the security aspect of WSN deployed in IoT is subjected to improvement by balancing the demand for increased security along with energy consumption. Hence, various criterion-based schemes is implemented, harnessing ACO along with constraint consideration towards secure trust evaluation.

From the exhibited methodology in Fig. 1, it can be noted from the declaration of the proposed scheme that it uses a manifold criterion modeling towards trust-based secure routing in an IoT environment. Adopting an optimization agenda towards manifold criteria is simultaneously challenging due to the surfacing possibilities of various conflicts. Moreover, unlike managing unit criterion-based routing improvement strategy, the multiple criterion schemes usually seeks to obtain compromised outcomes, yet another sub-optimal solution towards secure routing. Therefore, the proposed system constructs a manifold criterion-based trust modeling in IoT to address the issue of energy drainage and security threats as follows:

$$arg_{max}\varphi(t) = [\varphi_1(t)\varphi_2(t)] \quad (1)$$

In Eq. (1), the manifold criterion function $\varphi(t)$ is represented by two sub-criteria, i.e., $\varphi_1(t)$ and $\varphi_2(t)$, representing the mean criterion for remnant energy and the mean value of trust of the sensor nodes associated with the routing path in IoT. Two processes follow for this purpose:

- The above expression is required to be satisfied for its remnant energy score $R_i(t) > 0$ for the i^{th} the sensor at t instance of time such that acquired data by the sensor is $AD_{ij}(t) > 0$ from the i^{th} sensor to the j^{th} sensor while forwarding data $FD_{ji}(t) > 0$ from the j^{th} sensor to the i^{th} sensor.
- This task is carried out considering $0 < t < t_{max}$. From Eq. (1), it can be noted that the proposed scheme considers
  - $\varphi_1(t)$ as a function for mean remnant energy,
  - $\varphi_1(t)$ as a function for trust score that is considered towards the selection of an optimal path,
  - Multiple constraints as a maximal time of communication t_{max}, the quantity of forwarding data $FD_{ji}(t)$, the quantity of acquired data $AD_{ij}(t)$, and remnant energy $R_i(t)$.

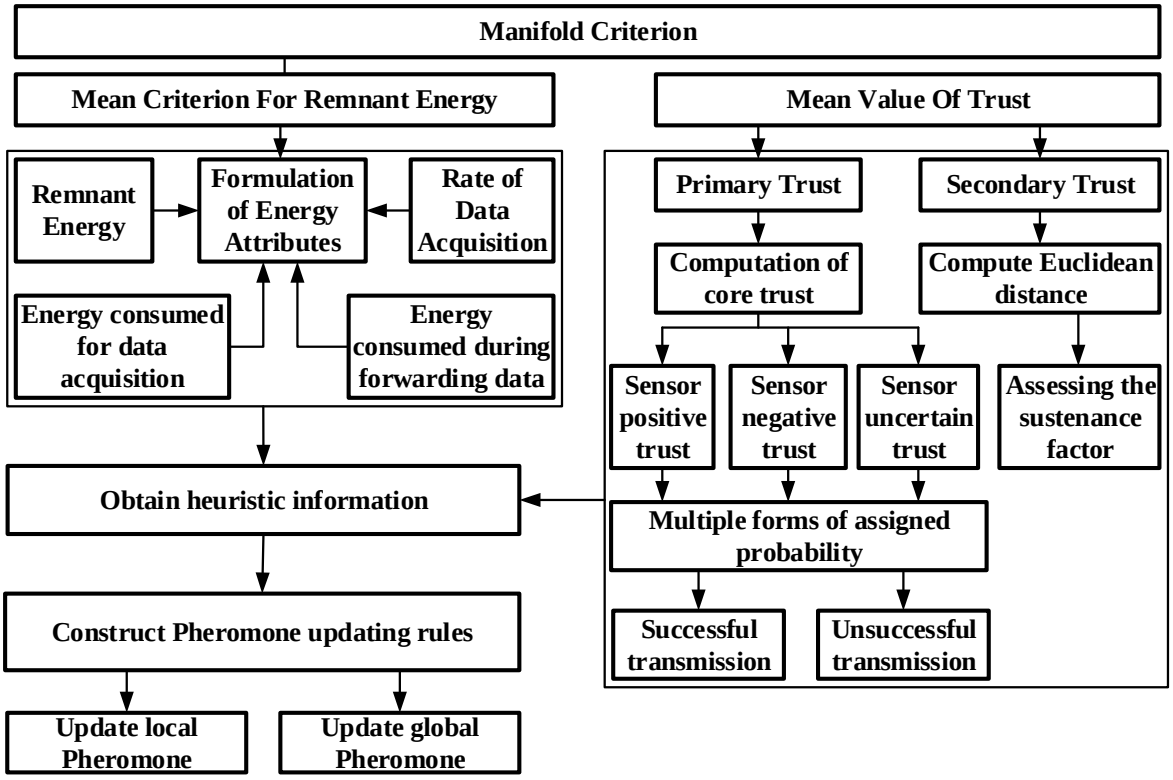

Fig. 1. Proposed methodology.

The complete formulation of the proposed study is based on two essential functions toward meeting the objectives, i.e., $\varphi_1(t)$ and $\varphi_2(t)$ towards energy and trust, respectively. It also includes four conditions of constraint. It should be noted that adopting these two essential functions is deployed for opting for the best path for data propagation, where the performance of nodes is selected as an indicator. This section further elaborates on the formulation of the proposed scheme. Further discussion of the formulation of the proposed modeling is carried out in subsequent sections.

A. Formulation of Manifold Criterion

Energy is one of the essential attributes considered in the proposed scheme whose consumption is generally recorded for multiple events of a sensor being in an idle state, sleep state, or either in receiving or transmission state. The formulation of energy attribute $R_i(t)$ is carried out as follows:

$$R_i(t) = \eta_1 + \eta_2 \tag{2}$$

To obtain information on the consumed energy of IoT nodes, any conventional mechanism can be adopted considering software and hardware components. The proposed scheme considers this an energy input value and contributes towards further optimized routing. Besides energy, the proposed method chooses to initiate its design implementation considering any conventional trust evaluation scheme that can vary based on application and use case. However, the system relies not much on device-specific trust computation mechanisms but more on behavioral analysis based on historical reports of security breaches, violations /adherence to security protocols, and compliance with access control protocols. Like the consumed energy metric, the proposed scheme also considers this trust score to act as an input to its model toward working in the direction of proof-of-concept. In Eq. (2), the computation of energy attribute $R_i(t)$ is carried out using two sub-entities, i.e., η_1 and η_2.

$$\eta_1 = R_j(t-1) - \lambda_{ij}(t).R_j^{\lambda}(t) \tag{3}$$

As shown in Eq. (3), the formulation of η_1 is carried out by differentiating the product of $\lambda_{ij}(t)$ and $R_j^{\lambda}(t)$ from $R_j(t-1)$, where the entities $R_j(t)$ and $R_j(t-1)$ represent remnant energy of the j^{th} sensor at instant t and $(t-1)$, respectively. The entity $\lambda_{ij}(t)$ represents the data acquisition rate from the i^{th} sensor to the j^{th} sensor. In contrast, $R_j^{\lambda}(t)$ represents the energy consumed for data acquisition for the j^{th} node at the t-instance.

$$\eta_2 = \lambda_{ij}(t).R_j^{C}(t) - R_j^{C}(t) \tag{4}$$

On the other hand, the formulation of η_2 shown in (4) is carried out by differentiating energy dissipated by the j^{th} sensor, $R_j^{C}(t)$ from the product of the data acquisition rate from the i^{th} sensor to the j^{th} sensor, $\lambda_{ij}(t)$ and energy consumed while forwarding data for the j^{th} sensor, $R_j^{C}(t)$. Therefore, the criterion function for mean energy associated with the path of routing considering α number of sensors in IoT can be represented as:

$$\varphi_1(t) = \sum {R_j(t)}/{\alpha} \tag{5}$$

In Eq. (5), the suffix j resided between (1, α). After formulating the energy attribute, the next task is developing the trust attribute of a sensor deployed in an IoT environment. The notion of trust attribute represents the degree of consistency in data packet transmission and receiving by the sensors when exposed to different severity levels of attacks in IoT (e.g., DDoS). The trust attribute is computed based on the evidential traces furnished by the neighboring sensors or by observing trust attributes from the adjacent sensors. Therefore, the proposed scheme formulated two types of trust attributes, i.e., primary and secondary.

1) Evaluation of primary trust: The primary trust is the value obtained directly from the i^{th} sensor to the j^{th} sensor. In contrast, the secondary trust is the value obtained from the i^{th} node to different relay sensors, and then it reaches the j^{th} sensor. The initial assessment towards the trust modeling is carried out for primary trust that considers that every possibility of evaluation of the sensor's trust consists of information associated with the degree of consistency associated with data transmission, rate of transmission, and rate of acquiring the data packet. The proposed scheme considers the evaluation of the core trust score γ_{ij} of the target i^{th} sensor on the j^{th} sensor to be assessed at t-instance of time as follows:

$$\gamma_{ij}(t) = \left[spt_{ij}(t), snt_{ij}(t), sut_{ij}(t)\right] \tag{6}$$

In Eq. (6), the computation of core trust γ_{ij} is carried out based on sensor positive trust, sensor negative trust, and sensor uncertain trust represented by $spt_{ij}(t)$, $snt_{ij}(t)$, and $sut_{ij}(t)$, respectively. It can be noted that all these three types of trust variables are equivalent to probability factors associated with multiple forms of assigned probability $\omega_{ij}^{c}(\pi)$, $\omega_{ij}^{c}(-\pi)$, and $\omega_{ij}^{c}(\pi,-\pi)$, where π represents a possible secured route for data propagation. It will eventually mean that the variable $\gamma_{ij}(t)$ represents the summation of the success rate of data acquiring, i.e., $\lambda_{ij}^{s}(t)$. In contrast, the success rate of data forwarding $F_{ij}^{s}(t)$ and $\beta_{ij}^{s}(t)$ denotes consistency in data packet transmission. Therefore, the expression in Eq. (6) can now be rewritten as:

$$\gamma_{ij}(t) = [\omega_{ij}^{c}(\pi), \omega_{ij}^{c}(-\pi), \omega_{ij}^{c}(\pi,-\pi)] \tag{7}$$

where, $\omega_{ij}^{c}(\pi) = [\theta_1.\lambda_{ij}^{s}(t) + \theta_2.F_{ij}^{s}(t) + \theta_3.\beta_{ij}^{s}(t)]$

$\omega_{ij}^{c}(-\pi) = [\theta_1.\lambda_{ij}^{us}(t) + \theta_2.F_{ij}^{us}(t) + \theta_3.\beta_{ij}^{us}(t)]$

$\omega_{ij}^{c}(\pi,-\pi) = [1 - spt_{ij}(t) - snt_{ij}(t)]$

In Eq. (7) in its expanded form, the power variable of the expression, i.e., s and us, represents successful and unsuccessful transmission in the IoT environment, while the variables θ_1, θ_2, and θ_3 represent weight values associated with different modes of transmission, which are subjected to training using first-order iterative optimization to arrive at the local value of the defined function. With the aid of Eq. (7), the formulation of the primary trust PT_{ij} between the i^{th} sensor and j^{th} sensor can be carried out as follows:

$$PT_{ij}(t) = [P1_{ij}(t), P2_{ij}(t), P3_{ij}(t)] \tag{8}$$

$$= [\omega_{ij}(\pi), \omega_{ij}(-\pi), \omega_{ij}(\pi, -\pi)]$$
$$= h_1 + h_2$$

In Eq. (8), the variables $P1$, $P2$, and $P3$ are primary values of trust, which are nearly similar to the notion of the variables $spt_{ij}(t)$, $snt_{ij}(t)$, and $sut_{ij}(t)$, while the variables h_1 and h_2 are empirically represented as follows:

$$h_1=\left[(1-\eta).\gamma_{ij}(t)\right]$$
$$h_2=\left[\eta.\gamma_{ij}(t)(t-1)\right] \quad (9)$$

From Eq. (9), the variable η further represents the temporal attribute of adaptivity used to evaluate the significance of heuristic data over the existing routing data to assess the trust among the sensors while deployed in an IoT environment.

2) Evaluation of secondary trust: The next part of the implementation is associated with formulating secondary trust $ST_{ij}(t)$, which is essentially meant to process any form of conflict. The empirical formulation of the secondary trust $ST_{ij}(t)$ is expressed as:

$$ST_{ij}(t) = [S1^l_{ij}(t), S2^l_{ij}(t), S3^l_{ij}(t) \quad (10)$$
$$= [\omega^l_{ij}(\pi), \omega^l_{ij}(-\pi), \omega^l_{ij}(\pi, -\pi)]$$

From Eq. (10), it can be seen that the formulation of secondary trust bears a similar strategy as noted in Eq. (8) for primary trust computation, including a variable l representing the common sensor node that resides within the transmission region for both the i^{th} and j^{th} sensors. A closer look into Eq. (10) for secondary trust evaluation will show that it is an n-ary circled times operation between two primary trusts, i.e., $ST_{ij}(t) = PT_{i,1}(t) \otimes PT_{1j}(t)$. The variables $S1^l_{ij}(t)$, $S2^l_{ij}(t)$, and $S3^l_{ij}(t)$ represent secondary positive trust, secondary negative trust, and secondary uncertain value of trust, respectively. These are also corresponding to $\omega^l_{ij}(\pi)$, $\omega^l_{ij}(-\pi)$, and $\omega^l_{ij}(\pi, -\pi)$.

Fig. 2 highlights the pictorial representation of primary and secondary trust evaluation. As the secondary trust evaluation is carried out by the other relay nodes, which are neither source nor destination nodes, there is always a possibility of evolving contradiction in the trust computation. Therefore, the next part of consecutive implementation is associated with evaluating the conflicts in the secondary trust. For this purpose, the proposed scheme constructs a reference matrix towards assessing the equivalency of the trust attributes of secondary trust where the variable μ represents the steadiness score between two secondary trusts and hence $\mu_{a,b}$ indicates the steadiness score for a^{th} and b^{th} relay sensors with a Euclidean distance of $dis_{a,b}$ between two secondary values of trust of ST^{lb}_{ij} and ST^{la}_{ij}, where la and lb represent common a and b sensors between i^{th} transmitting sensor and j^{th} receiving sensor. Empirically, it will be designated as follows:

$$dist_{ab} = |sqrt\left[\left(ST^{lb}_{ij} - ST_{ij}\right)^2 + \left(ST^{la}_{ij} + ST_{ij}\right)^2\right]| \quad (11)$$

After evaluating distance in Eq. (11), the next task is to assess the sustenance factor of secondary trust σ_a, which is obtained by summing up all steadiness scores, i.e., $\mu_{a,b}$. Further, towards attaining secondary trust value, there is a need for one more dependable attribute, i.e., indicative weight g_a, which is obtained from the standard weight of secondary trust (i.e., $ST^{l)}_{ij}$, i.e., O_a. This variable of normal weight of ST^l_{ij} is obtained by dividing sustenance score σ_a with the cumulative sustenance score of secondary trust, i.e., $\sum \sigma_a$. Therefore, the suggested indicative weight of secondary trust, i.e., g_a, is obtained by dividing the normal weight O_a with $arg_{max}(O_a)$. Thus, the final empirical expression towards attaining the value of secondary trust is as follows:

$$ST^l_{ij}(t) = [b_1, b_2, b_3] \quad (12)$$

In Eq. (12), the computation of secondary trust $ST^l_{ij}(t)$ is carried out using three dependable attributes, i.e., b_1, b_2, and b_3 representing $[g_a.S1^l_{ij}(t)]$, $[g_a.S2^l_{ij}(t)]$, and $[1 - g_a.(S1^l_{ij}(t) + S2^l_{ij}(t))]$ respectively.

$$ST^l_{ij}(t) = [(g_a.S1^l_{ij}(t)), (g_a.S2^l_{ij}(t)), (1 - g_a.(S1^l_{ij}(t) + S2^l_{ij}(t)))] \quad (13)$$

Finally, the primary and secondary trust (shown in Eq. (13)) values are combined to yield the joint trust score. It should be noted that the computation of primary trust is carried out directly between the two communicating nodes. In contrast, the secondary trust is evaluated using associated neighboring nodes, as shown in Fig. 2.

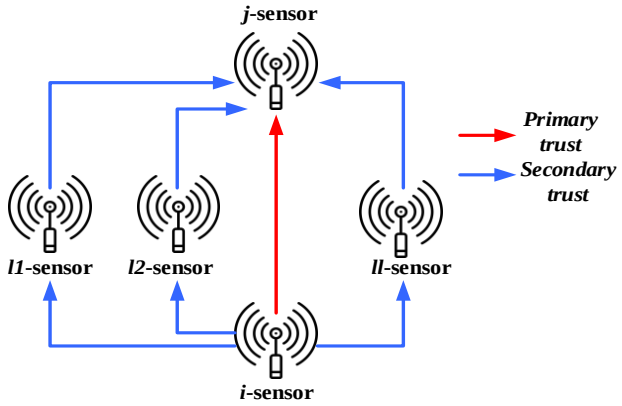

Fig. 2. Primary and secondary trust evaluation.

B. Formulation of Proposed ACO

After the trust computation, the next part of implementing the proposed scheme consists of applying the ACO scheme to arrive at an optimal solution for enhancing network lifetime and accomplishing a higher degree of resiliency from varied threats in the IoT environment. It should be noted that the proposed scheme introduces dual criteria and optimal solutions to amend the conventional ACO scheme to be used in secured routing in IoT. The novelty of the proposed ACO approach is that it constructs logic of manifold heuristic data and manifold pheromones to accomplish the discussed concept of manifold criterion in IoT routing by sensor nodes. The proposed scheme makes use of the idea of crowding distance to boost the algorithm to yield optimal solution diversity. The idea of the proposed ACO approach using crowding distance is to perform

an optimal selection of solutions required for the next generation to map with secure and energy-efficient routing among the sensors in IoT. If the crowding distance is more for a specific set of solutions, then the algorithm considers that set of solutions further for the next generation. Therefore, the proposed ACO approach offers a diversified and optimal solution to accomplish both secured trustworthy routes for data transmission with higher residual energy. According to the proposed scheme, the first set of operations is towards selecting the j^{th} sensor by k number of ants in the form of the i^{th} sensor present in the next hop. This computation offers the probability of change from one state to another. The proposed scheme constructs dual heuristic information that is associated with remnant energy and trust value, which can be empirically exhibited as follows:

$$\sigma_{ij}^{1}(t) = R_j(t) \text{ and } \sigma_{ij}^{2}(t) = \pi_j(t) \quad (14)$$

From Eq. (14), it should be noted that the first heuristic information $\sigma_{ij}^{1}(t)$, i.e., $R_j(t)$, is evaluated considering energy dissipated by the data acquired divided by the initialized energy of the sensor. In contrast, the second heuristic information $\sigma_{ij}^{2}(t)$ depends on a set of candidate routes for optimal data transmission performance with higher trust. The proposed scheme implements two types of pheromone information to fit the model with two heuristic information. The idea is to jointly study the value of trust and the associated remnant energy of a sensor. When an ant constructs a candidate solution using Eq. (15), the scheme instantly updates the pheromone associated with each heuristic. The following are the empirical expressions:

$$\left[\rho_{ij}^{1}(t), \rho_{ij}^{2}(t)\right] = [\chi_1, \chi_2] \quad (15)$$

In Eq. (15), the first attribute of pheromone, i.e., $\rho_{ij}^{1}(t)$, is associated with the criterion for remnant energy, i.e., χ_1. In contrast, the second attribute of pheromone, i.e., $\rho_{ij}^{2}(t)$, is related to the criterion for the mean value of trust, i.e., χ_2. It should be noted that the maximization of the pheromone score is relative to the mean quantity of resource availability and trust score associated with the propagation routes. The inference is that increased resource availability on the communication routes can only ensure a higher degree of pheromone retention. The conclusive remark of this logic is that nodes with reported higher value of trust and resources will eventually have higher feasibility to be opted as participating routing nodes. However, this empirical expression is in abstract form, and it demands more clarity in terms of the actual updating mechanism of pheromone in ACO, which is given as follows:

$$\rho_{ij}^{n}(t+1) = funct(e, \rho_{ij}^{n}) \quad (16)$$

In Eq. (16), the updating of local pheromone ρ_{ij}^{n} is stated considering the unique function $funct$ of coefficient of pheromone evaporation e mainly. The function $funct$ performs extractions of two operators using arguments of e and ρ_{ij}^{n}, i.e., i) $(1-e).\rho_{ij}^{n}(t)$ and ii) $e.\Delta\rho_{ij}^{n}(t)$, where the values of suffixes i and j are associated with π, while the value of power variable n is (1, 2) owing to consideration of two heuristic information. The variable $\Delta\rho_{ij}^{n}(t)$ is incremented, further proportional to the heuristic information of mean trust and energy score. The prominent inference of this implementation concept is that the maximum score of the function χ_1 associated with mean remnant energy will mean higher retention of pheromone on the routing path. It will also mean that if the value of the function χ_2 associated with the mean trust value is found to be maximal, then it will mean that a large quantity of pheromone will be retained. Hence, the routing operation in IoT will always choose only those sensors with a higher value of remnant energy and higher trust. The implementation concept of updating the local pheromone is completed when the data reaches the sink node, followed by further updating of enhanced crowding distance by sub-optimal solutions in the sink node. The system finally yields a backward-moving ant from the forward-moving ant upon completion of the local updating operation of the pheromone.

Finally, the proposed scheme performs updating of the global pheromone by subjecting all the sub-optimal solutions presented by the sink node. The backward-moving ant in the proposed ACO approach carries out this task of updating the sub-optimal solution. An empirical expression for this global pheromone updating is similar to that of Eq. (12) only with the difference of $\Delta\rho_{ij}^{n}(t)$ equivalent to $1/\varsigma$, where the variable ς represents the quantity of the sensors traversed by the k number of backward-moving ants considering a set of sub-optimal solutions as routing paths to update the global pheromone.

The contributions of this methodology can be seen by two significant results: (a) The primary contribution of the proposed method is to design and develop a simplified yet robust secure data propagation scheme in IoT. It is simplified as it doesn't consist of any sophisticated mechanism or involve a higher number of complex processing routing schemes. It is robust as the method can realize the dynamic vulnerabilities present in links connecting IoT nodes without any dependencies on the apriori information of an attacker. The scheme is highly secured as the formulation of the system is carried out considering manifold criteria in the form of an essential function associated with trust and resources of IoT nodes as well as various practical constraints related to time, forwarding, and receiving data, and remnant resources of IoT nodes, (b) The second prime contribution is associated with the mechanism of deploying an ACO approach where novel pheromone management is presented. The credibility of the data propagation and exchange among the IoT nodes is carried out by proposed ACO-based routing, where the selection of cost-effective and secured routes is based on heuristic and pheromone information of manifold type. It should be noted that the proposed scheme considers heuristic information and pheromone information derived from remanent information and the trust score of IoT nodes. The main contributions of the study can be briefly summarized as:

1) The proposed scheme balances trust computation with the selection of optimal nodes possessing substantial residual energy, ensuring they have the requisite resources for extensive secure data propagation within IoT.

2) The trust evaluation mechanism of the proposed system is scalable and viable for both compact and expansive IoT environments. Its resilience is evident as it can function even

in the presence of unknown-origin attackers. This resilience stems from the fact that, regardless of an attacker's strategy, the proposed scheme ensures all standard sensors compute an optimal solution that remains inscrutable to potential intruders.

3) The proposed ACO approach addresses and rectifies the traditional issues of slow convergence and parameter sensitivity, which plague conventional ACOs. By providing a broader problem scope, it aptly aligns with the expansive nature of IoT.

The ensuing section delves into the results derived from implementing the proposed scheme.

V. RESULT

This section presents the results achieved after implementing the proposed model. Since the proposed implementation introduces a novel ACO-based secure routing method, emphasis has been placed on investigating data transmission performance. Additionally, the trust management scheme has been executed for the system. The primary objective of the result analysis is to establish an extensive test environment using variable performance metrics. This is done to gauge the impact of the proposed secure routing conducted by sensors within the IoT environment. The results are then analyzed to provide insights into how the model's performance compares to existing secure routing schemes.

A. Assessment Strategy

The entire implementation is conducted in MATLAB on a standard 64-bit Windows machine. The simulation environment selected for the experiment spans an area of 1000x1000 m^2, with the specific simulation parameters detailed in Table II. This environment replicates a smart city setting where numerous clusters of wireless sensor nodes are interconnected, facilitating data aggregation with a predetermined energy level. While the initial energy assigned to each node is 10 J, it can be adjusted based on the specific IoT application in use. Thus, the proposed simulation environment offers considerable flexibility, accommodating modifications to parameter values to fit various scenarios.

TABLE II. SIMULATION PARAMETERS ADOPTED FOR ASSESSMENT

Parameters	Values
No. of Sensors	500-1000
Initialized energy	10 J
Rate of data transmission	400 kbps
Data packet size	5000 byes
Communication Radius	200 m
Antenna	Omni-directional
MAC	802.11
Simulation Time	100 s

To gauge the effectiveness of the proposed scheme, a benchmarked analysis against existing secure routing schemes in the IoT environment is essential. This comparative analysis examines specific performance metrics across the proposed and existing secure routing schemes. The conventional secured routing schemes selected for comparative analysis in IoT include:

- Routing Protocol for Low-Power and Lossy Network (RPL): This standard IoT routing scheme is tailored for networks with lossy features and low-powered nodes. Its secure variant, Secure RPL (SRPL), employs authentication of messages and encryption operations to ensure data freshness, integrity, and confidentiality [32].
- Routing using 6LoWPAN: Another conventional IoT routing method closely aligned with RPL, this protocol leverages the IPv6 scheme for routing. It adopts 6LoSec, primarily designed to guard against replay attacks and ensure data integrity and confidentiality [50].
- Secured routing using Zigbee Cluster Library (ZCL): Zigbee's prevalence in IoT-based wireless communication systems is notable. However, ZCL is designed to provide secure routing exclusively for Zigbee-based networks. This scheme uses authentication and encryption to ensure authentic communication, data integrity, and confidentiality [51].
- Secure routing using Constrained Application Protocol (CoAP): This protocol facilitates data transmission for resource-constrained devices within the IoT framework. It incorporates Datagram Transport Layer Security (DTLS) to provide authentication, data integrity, and confidentiality [52].

The aforementioned secure routing schemes and proposed method have been implemented in comparable test environments and under similar simulation parameters. Moreover, the conventional ACO and PSO algorithms have been employed to evaluate the performance enhancements ushered in by the proposed scheme relative to existing bioinspired approaches.

B. Discussion of Result

The initial performance metric examined is network throughput, calculated as the volume of data packets transmitted from one node to another within the IoT environment over a specific time. A detailed examination of the proposed secure routing scheme reveals that it encompasses various mathematical and logical operations based on the manifold criterion-based model. This design ensures a robust defense against manipulation or unauthorized access. Given these intricacies, potential delays or added computational demands might impact throughput. Consequently, benchmarking based on throughput provides a clear insight into whether the inherent security operations compromise network performance and data transmission. Additionally, thorough throughput assessment can highlight potential bottleneck areas within the routing path.

Fig. 3 presents the average throughput observed during a series of evaluations over specified simulation duration. It indicates that the proposed scheme outperforms existing methods in terms of throughput. The RPL protocol emerges as the next best performer in current systems, primarily due to its dynamic path selection capabilities. However, it needs help to balance traffic load during dynamic events within the IoT landscape. Following RPL, conventional ACO, PSO, and

CoAP algorithms rank next in terms of throughput. It's worth noting that traditional ACOs have a limitation, needing help to provide optimal solutions amidst heavy traffic flow. PSO faces a similar challenge, grappling with increased memory dependencies as traffic surges, reducing throughput. The CoAP protocol, because it utilizes User Datagram Protocol (UDP), is prone to packet loss, primarily when data packets are transmitted in an unordered sequence within IoT.

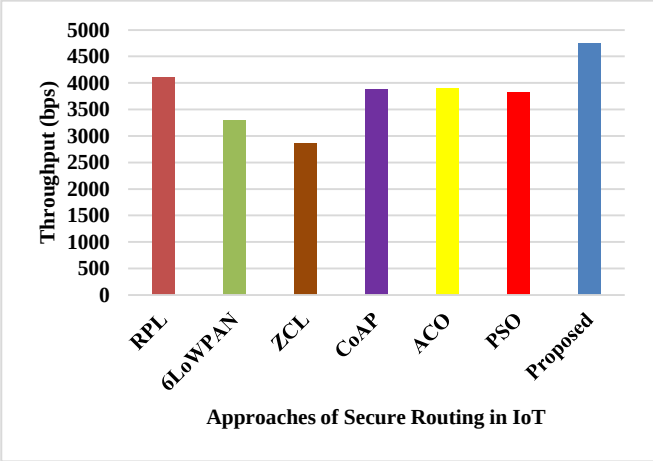

Fig. 3. Comparative analysis of throughput.

Moreover, 6LoWPAN and ZCL underperform in throughput within the IoT environment due to complexities arising from header compression. In contrast, the proposed system remains unaffected by such challenges. Its constraints concerning energy and trust, combined with its modeling, are adept at identifying vulnerabilities and pinpointing alternative optimal paths for propagation based on the manifold criterion. Consequently, even without encryption, the proposed scheme achieves superior secure data transmission throughput compared to conventional secure IoT routing strategies that predominantly depend on encryption and authentication.

The subsequent performance metric evaluated is a delay, calculated as the latency encountered during the data bit transmission across the network from one sensor to another within the IoT framework. Evaluating delay is paramount for secure data transmission, given the diverse applications and services housed within the IoT environment. It's essential to highlight that the proposed scheme incorporates several mathematical procedures for trust calculation, where local and global parameters play pivotal roles. Conversely, most extant secure routing schemes lean heavily on encryption and message authentication to ensure data security. Thus, it becomes imperative to ascertain that these intrinsic security processes don't detrimentally influence network performance by augmenting delay. For optimal network efficiency, it's crucial to maintain low delay, as extended latency often signals network bottlenecks or areas compromised by security vulnerabilities, consequently impinging on data transmission durations.

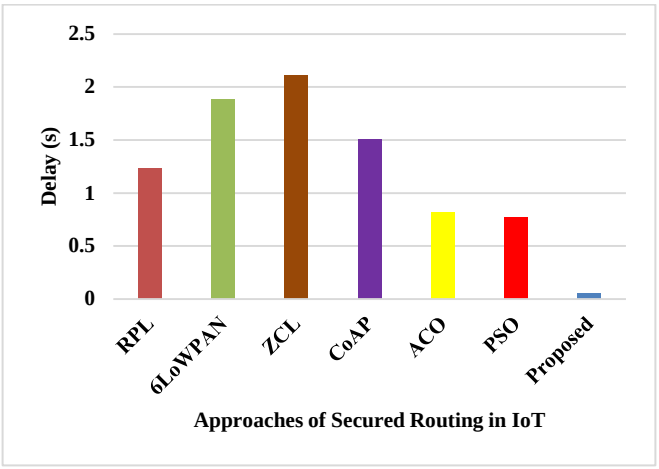

Fig. 4. Comparative analysis of delay.

Examining Fig. 4 reveals that the proposed scheme considerably reduces delay compared to existing systems. ZCL displays a higher delay due to its conventional architecture's slower transmission rate tailored to meet Zigbee transmission requirements. 6LoWPAN outperforms ZCL in delay, but it sacrifices some security; it possesses a weaker immunity to interference. A significant cause of delay in 6LoWPAN is its repeated retransmissions due to packet loss from IPv6 data chunks. CoAP, being optimized for peer-to-peer communication, has an inevitable delay. However, RPL shines the best in reducing delay compared to other secure transmission methods. This is attributed to its auto-configuration capabilities and dynamic path selection, vital for large-scale IoT devices with resource-constrained sensors. Yet, RPL's delay becomes significant in IoT's mobile environments. Conventional ACO and PSO also underperform due to i) increasing iteration counts as they seek optimal solutions in constrained problem areas and ii) premature convergence resulting in sub-optimal routing paths, leading to increased delay. In contrast, our proposed scheme excels in delay performance, being more progressive, less iterative, and encompassing a broader problem area, thereby reducing the effort needed for optimal solutions and achieving a superior delay score.

The third performance metric is energy consumption. The rationale behind selecting this metric hinges on two factors: i) our mathematical model prioritizes residual energy as a primary constraint, with manifold criterion modeling also considering residual energy apart from the trust attribute as a heuristic. This necessitates evaluating the model's impact on energy consumption, and ii) our scheme primarily focuses on sensors as essential IoT devices. Given their limited energy resources, it becomes crucial to ascertain the energy expended during secure data transmission in IoT. The objective is to balance trust-based security and energy efficiency, ensuring a prolonged network lifespan. Here, "energy" denotes the power expended on cumulative sensor operations, which encompasses data transmission and reception, data processing, and internal circuit functions. We rely on the first-order radio energy model [53] to assess this, which provides a comprehensive formula for sensors' total energy consumption.

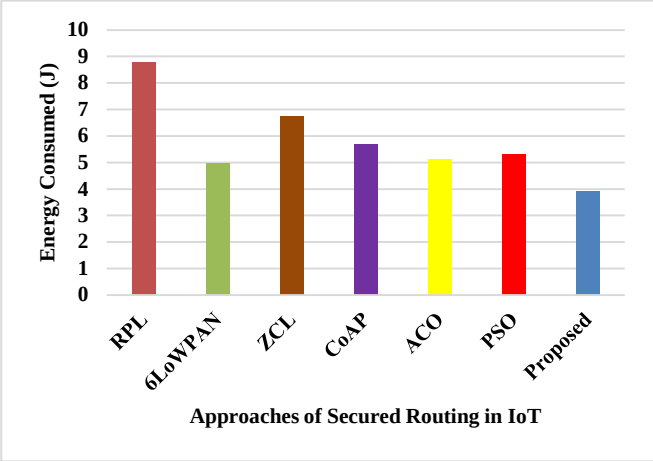

Fig. 5. Comparative analysis of energy consumption.

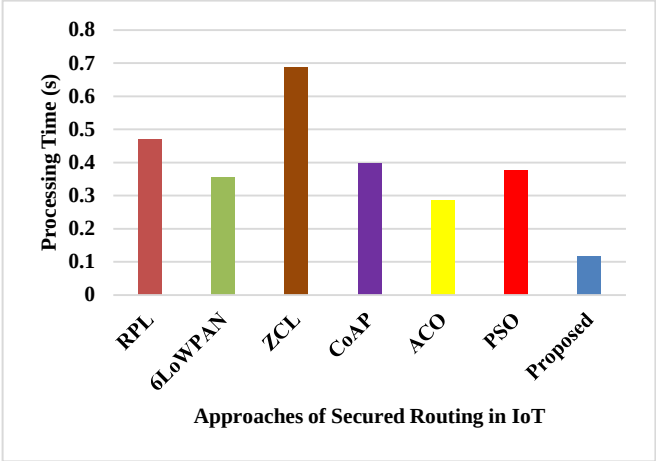

Fig. 6. Comparative analysis of algorithm processing time.

The data presented in Fig. 5 reveals that our proposed scheme significantly reduces power consumption compared to most existing systems. What stands out is that both conventional ACO and PSO demonstrate slightly higher energy consumption. The main reasons for this are: i) the increased use of attributes to achieve higher convergence performance and ii) a stronger focus on the local search optimization problem, often at the expense of global search space. The distinction between the proposed ACO and the conventional ACO lies in the former's formulation of pheromone management based on multiple criteria intertwined with an adaptive operational principle. A detailed examination of our ACO scheme further shows that their functionalities are mostly preserved despite the utilization of numerous parameters. The only variation arises from their use cases to enhance trust and energy retention. Due to the calculated global update formulation, local operatives' reliance on extensive operations diminishes as simulation time increases, leading to energy conservation. IoT secure routing schemes, such as RPL, ZCL, CoAP, and 6LoWPAN, incorporate encryption in their security variants. This inclusion demands a significant energy allocation for the ciphering and deciphering processes, which our proposed secure routing scheme avoids.

The final performance metric assessed for the proposed scheme is the processing time, an essential measure that reflects the time complexity inherent in algorithmic processing during secure routing. This metric is determined by evaluating a sensor's time to complete its operations. An efficient system model, especially one with lightweight characteristics, should display reduced processing times. If the processing time is extensive, the security scheme in use might benefit from some refinement to boost its overall efficiency. It is also crucial to note that, given sensors' limited computational capabilities, their processing time can increase when more complex operations are introduced. As a result, gauging the system's efficacy in terms of computational complexity by assessing its processing time becomes vital.

Fig. 6 illustrates that the proposed scheme significantly reduces processing time compared to other secured routing schemes. The processing time for ZCL is notably higher, as this scheme necessitates performing extensive iterative operations for massive data transmission in IoT. On closer examination, 6LoWPAN, CoAP, and conventional PSO performance reveal similar processing times. This similarity arises because these approaches segment and chunk data into smaller portions, leading to packet loss in a heterogeneous IoT network that necessitates retransmission. Additionally, the conventional PSO requires iterative computation of particles and velocities to identify optimal results. While this is effective for homogeneous systems, it is less so for heterogeneous ones, causing them to amalgamate all data packets and conduct routing. Such operations demand significant processing time and deliver sub-optimal data quality.

Furthermore, RPL displays a longer processing time, slightly more than CoAP. This is attributed to RPL's formation of a directed acyclic graph, eventually resulting in a singular link from the leaf node to the route. While this might be suitable for smaller IoT networks, the RPL graph operation must be repeated to achieve data transmission within the context of more extensive IoT networks. This repetition expends excessive resources and consumes considerable processing time for data transmission. Therefore, the proposed scheme promises minimal processing time, primarily due to diminished resource dependencies and fewer iterative operations, as emphasized in the proposed mathematical modeling.

VI. Conclusion

The landscape of the IoT is both exciting and challenging, marked by tremendous opportunities and, in parallel, considerable security vulnerabilities. In the modern age, when digital interconnectedness is both a boon and a bane, the urgency to fortify IoT against burgeoning threats cannot be overstated. The paper has addressed this urgency, providing a novel and streamlined approach that leverages a modified version of ACO toward achieving optimal security in the vast and dynamic IoT ecosystem. This bioinspired approach symbolizes our attempt to mimic nature's intuitive problem-solving methodologies. Through our process, not only is data

transmission secured, but the dual challenges of optimizing sensor energy and ensuring high trust scores are simultaneously addressed. A particular innovation in our work is the unique pheromone management system, which holistically considers residual energy and trust scores. Coupled with our manifold criterion and the dual-tiered trust evaluation system, the methodology provides an unparalleled framework for IoT security. Our research has showcased its merits, delivering impressive performance metrics compared to prevailing secure routing protocols. With a 35% improvement in throughput, 89% reduction in delay, 54% decrease in energy consumption, and 73% surge in processing speed, the approach is theoretically sound and practically efficacious. The current work, however, has its limitations. While it has achieved a balance between energy conservation and security, nuances to this balance need exploration. The inherently dynamic nature of IoT means that newer devices with diverse capacities are continually entering the ecosystem, presenting evolving challenges for security protocols. The future work of this study model will be to formulate a hybrid modeling of a bioinspired approach to optimize the security and resource management performance in a large IoT environment. Furthermore, integrating Artificial Intelligence and Machine Learning algorithms could further enhance our initial results. These can help the system to adaptively learn from emerging threats and respond proactively, ensuring a more agile and dynamic security mechanism.

ACKNOWLEDGMENT

The authors express their appreciation for the effort of Ms. Gousia Nissar in proofreading and editing the paper.

Analyzing Sentiment in Terms of Online Feedback on Top of Users' Experiences

Mohammed Alonazi
Department of Information Systems, College of Computer Engineering and Sciences,
Prince Sattam bin Abdulaziz University, Al-Kharj, 16273, Saudi Arabia

Abstract*—Since most businesses today are conducted online, it is crucial that each customer provide feedback on the various items offered. Evaluating online product sentiment and making suggestions using state-of-the-art machine learning and deep learning algorithms requires a comprehensive pipeline. Thus, this paper addresses the need for a comprehensive pipeline to analyze online product sentiment and recommend products using advanced machine learning and deep learning algorithms. The methodology of the research is divided into two parts: the Sentiment Analysis Approach and the Product Recommendation Approach. The study applies several state-of-the-art algorithms, including Naïve Bayes, Logistic Regression, Support Vector Machine (SVM), Decision Tree, Random Forest, Bidirectional Long-Short-Term-Memory (BI-LSTM), Convolutional Neural Network (CNN), Long-Short-Term-Memory (LSTM), and Stacked LSTM, with proper hyperparameter optimization techniques. The study also uses the collaborative filtering approach with the k-Nearest Neighbours (KNN) model to recommend products. Among these models, Random Forest achieved the highest accuracy of 95%, while the LSTM model scored 79%. The proposed model is evaluated using Receiver Operating Characteristic (ROC) - Area under the ROC Curve (AUC). Additionally, the study conducted exploratory data analysis, including Bundle or Bought-Together analysis, point of interest-based analysis, and sentiment analysis on reviews (1996-2018). Overall, the study achieves its objectives and proposes an adaptable solution for real-life scenarios.

Keywords*—Sentiment analysis; product review; machine learning; recommendation system; collaborative filtering; exploratory data analysis

I. Introduction

In this era of modern computational technology, technological advancement can be seen everywhere; even the business sector is taking the initiative to enhance its revenue in computing and technology [1]. The term sentiment analysis has extensively been utilized to track out social media, allowing businesses to extract hidden information from the recorded data or identify critical information before coming into the limelight [2]. Thinking about giant tech companies such as Facebook, Google, Apple, and Microsoft, they have a huge amount of datasets. Every day, lots of data is being recorded to their central database. Besides, manually analyzing these data is time-consuming [3]. With a massive amount of dataset, it is quite difficult to manually extract meaningful insights that can help them make a business oriental decision. Turning into a product-based company, it can be stated that the product-based company tends to develop its product and launch it into the market [4]. If the thing is grocery or jewelry items so in this case, users will be giving their opinion based on the items whether the product is caught their attention or not. Suppose the clients explore a large e-commerce platform like Amazon.com. In this case, it is noticeable that the end-users threw their comments or reviews related to a specific item. Other individuals take themselves towards the advertisement phenomenon [5]. In turn, this brings us to a big question, whether it or not possible to handle such massive amounts of ratings manually and extract the business insights. So, the automated system can be the possible solutions to overcome these issues [6]. Thus, the impact of information on user sentiment and physical environments is not limited to modern technology.

The computational approach can be taken into consideration. Nowadays, machine learning algorithms have widely been utilized in biomedical imaging, forecasting things or even critical disease prognosis [7]. For the case of product analysis, it has shown their promising performance beforehand. Researchers are now using computing power to take their analysis to a satisfactory level from where meaningful insights can be extracted easily by analyzing a large number of datasets [8]. The priority of this research is to analyze the product sentiment using machine learning algorithms and propose a recommendation system for the stakeholder to make a better decision while doing online business. In this research, conventional Machine Learning (ML) algorithms were adopted to analyze the online product, and our study will significantly contribute to the research community. This is the motivation of this proposed study.

On the other hand, there are three contributions have been addressed in this study, and these are following:

- Three types of data analysis have been completed and through which business owners can make a variety of decisions towards their product.
- Various machine learning algorithms were applied to check their credibility to analyze the Sentiment, and satisfactory accuracy was turned out to be successful. This research also ensures the robust machine learning pipeline that achieved a good accuracy, and the concentrated model can be deployed to a webserver to achieve sustainable goals.
- The different assessment pointers bend assessed the proposed show, and at long last, a proposal framework has been submitted by coordination overall sifting strategy. By taking after the proposal framework, the

This study is supported via funding from Prince Satam bin Abdulaziz University project number (PSAU/2023/R/1444).

partner will be able to supply important data to their enlisted client, which can improve the request for specific things.

The manuscript is classified into six interconnected sections. Section II presents the exciting works with research gap analysis. Section III depicts the overall methodology of the proposed system with proper discussion. Section IV shows the results associated with our proposed solutions, including data-driven analysis and approaches. Section V represents the observations and discussion on the results. Finally, the conclusion of the research with future work will be discussed in Section VI.

II. LITERATURE REVIEW

This section illustrates the background study of the previous works related to the proposed model. In this section, the research gaps have been extracted with proper discussion. Many great contributors have traced fruitful online product contributions or sentiment analysis contributions.

The authors of the paper in [9] worked on an efficient way to optimize the accuracy of the sentiment analysis in Egyptian Arabic. The proposed work was identically based on the conventional semantic orientation and machine learning techniques, and the authors had achieved the highest accuracy of 92.98% while working with Support Vector Machine (SVM). The purpose of the article in [10] was to examine the attitudes of buyers regarding electrical devices by analyzing various sale tweets. The experimental results of the proposed research will be valuable to a variety of business organizations in making business decisions that will ultimately increase the sales of the products they offer. The author of the paper also claimed that they had achieved the highest accuracy of 86%, 91%, and 91% with the Logistic Regression (LR) in the phone, laptop, and television, respectively.

The paper in [11] aimed to extract the text features into the semantics of words. The authors adopted a Word Sense Disambiguation (WSD) technique to extract the features from the reviewing sentences. A supervised learning approach has been adopted to analyze the product reviews and utilized 10-fold cross-validation to validate the results. The authors had significantly optimized the performance by 10.6%, while precision was 10.9% higher and recall was 9.2% higher than baseline approaches. The author of the paper in [12] had presented a significant comparison among several conventional deep learning-based models for word embedding in product sentiment analysis. Thus, they adopted data augmentation techniques to enrich the dataset and classify it into identical classes. The research also claimed they found the highest accuracy of 96% while working with CNN-RNN based BI-LSTM algorithms.

In paper [13] proposed an Adaptive Neuro-Fuzzy Inferences System (IANFIS) model to produce a way of analyzing the sentiment of online products. The method is identically based on natural language processing to track the user's opinion. The authors classified the dataset into three interconnected parts: contents, grades, and collaborations. Then, they applied deep learning algorithms to make a prediction on the negative and positive comments from the users. The research also performs a comparison among the existing solutions. The paper in [14] aimed to implement a model for analyzing the sentiment of the users in movie reviews. The authors extracted the feeling and feedback from existing text patterns. The models had the ability to detect several types of feeling like negative, positive, and even neutral. To accomplish this goal, they utilized different machine learning algorithms and classifiers, and mechanisms of natural language processing.

The authors in [15] have presented a machine learning-based online product sentiment analysis. In this work, they showed the labeled product reviews in several websites with the help of supervised and unsupervised (lexicon-based) based algorithms. The models were then applied to the iPhone 5s reviews collected from the existing popular online shops. The authors further extracted the combination of unigram and bigram features, which placed the best results while dealing with machine learning-based classifiers.

Paper in [16] identified three subtasks that must be addressed: the definition of the target; the separation of good and bad news content from good and bad sentiment expressed on the target; and the analysis of clearly marked opinion that is defined explicitly, without the need for interpretation or the use of world knowledge. The authors in [17] created a new strategy that combines previous approaches to provide the best coverage results and competitive agreement. They had also proposed iFeel, a free Web service that provides an open API for retrieving and comparing findings from several sentiment methods for a given text. In paper [18], researchers categorized movie reviews using features based on these taxonomies paired with traditional "bag-of-words" features, and reported 90.2 percent accuracy. Furthermore, they discover that some types of assessment appear to be more critical for sentiment classification than others.

The contributions of the papers in [19] had only focused on the development of a notable features selection on online product sentiment analysis. But the researchers didn’t focus on the correct terms of algorithms and algorithm tuning to optimize sentiment analysis accuracy level. In sharp contrast, the manuscript presented three forms of data analysis. These analyses will allow business owners to make several judgments regarding their specific products. Various machine learning methods were used to check their reliability and determine adequate accuracy. This research also assures a robust machine learning pipeline that the condensed model can be deployed to a webserver to fulfill long-term objectives for product sentiment analysis.

Based on the literature review, several studies have been conducted to improve sentiment analysis and product recommendation using machine learning techniques. The authors of one study achieved the highest accuracy of 92.98% in sentiment analysis of Egyptian Arabic using Support Vector Machine. Another study analyzed buyer attitudes towards electronic devices through sale tweets and achieved high accuracy of 86%, 91%, and 91% for phone, laptop, and television respectively using Logistic Regression. One study aimed to extract text features through Word Sense Disambiguation and achieved a significant performance

improvement compared to baseline approaches. Lastly, a study compared several deep learning-based models for word embedding in product sentiment analysis and achieved an accuracy of 96% using a CNN-RNN based BI-LSTM algorithm.

Overall, the studies show the effectiveness of machine learning techniques in sentiment analysis and product recommendation. These approaches can help businesses make data-driven decisions to improve sales and customer satisfaction. However, there is still room for further research to optimize the accuracy and efficiency of these techniques.

III. METHODOLOGY

This section presents the overall design of the proposed model, including the illustration. Fig. 1 illustrates a block diagram of the proposed research through which this study was conducted. By looking at Fig. 1, it can be observed that this research was carried out through three interconnected stages. The experimental dataset was collected and preprocessed to model the data in the first stage. In the second phase, product sentiment analysis was accomplished. Finally, in the third stage, a recommendation system is proposed as the priority of this research is to provide a model that can analyze the product sentiment and transform the traditional business into a data-driven approach.

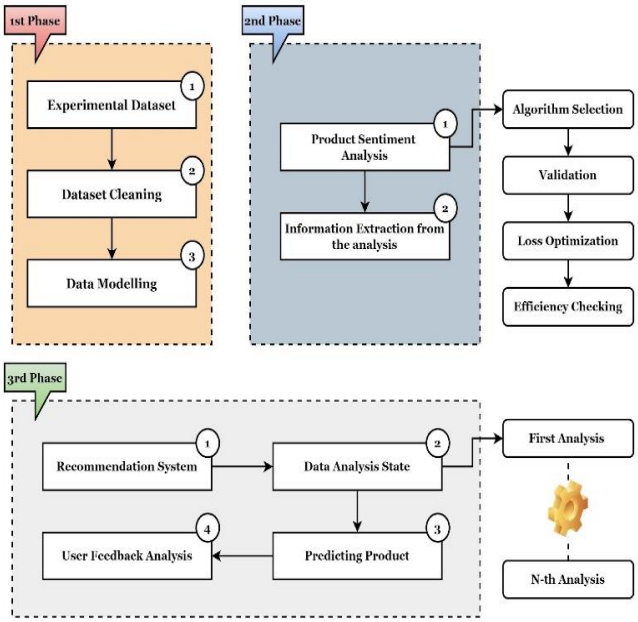

Fig. 1. Block diagram of the proposed research, including the experimental analysis to product recommendation approach.

A. Sentiment Analysis Approach (SAP)

This section explains the steps of approach, including experimental data, data preparation and concentrated research algorithms in more details.

1) Experimental dataset: From May 1996 through July 2018, Amazon's "Clothing, Shoes, and Jewelry" category received 2.5 million product ratings and information from 2.5 million customers. This collection includes reviews (scores, description, and sentiment comments), product metadata (descriptions, controls and monitors, pricing, branding, and image attributes), and links [20].

2) Data preparation: Perusing different JSON records from a single JSON record, 'ProductSample.json,' and including them in the list in such a way that each list of the list has the substance of a single JSON record [21]. Following that, iterate over the list, loading each index as JSON, extracting the data from each index, and creating a list of Tuples containing all the data from the JSON files. Again, each cycle begins with a clean JSON file converted to the right JSON format using some substitutions. Finally, a data frame is created using the list of Tuples obtained in the previous step.

3) Concentrated research algorithms (CRA): The Concentrated Research Algorithms (CRA) indicates the suggested model that has been adopted in this study to analyze the research data [22]. It is to be specified that various conventional techniques were applied in this investigation; among them, the Naïve Bayes and Decision tree algorithms were found to be satisfactory [23]. So, the mathematical interpretation and model optimization procedure were highlighted in this section. These models have a benchmark performance that appeared in the previous research. In addition, model performance is depending on the data distribution, furthermore, the Naïve based and Decision tree are capable enough to handle the product sentiment analysis data.

- Naïve Bayes Algorithm: Nave Base Classifier is a classification-type machine learning algorithm [24]. This algorithm is based on the Base Theorem. Simply put, the base theorem is a method of determining the probability of one event (X) occurring and another event (Y) occurring. If clouds are seen in the sky, there is a possibility of rain. The base theorem can be mathematically written as,

$$\frac{P(y)P(y)}{P(X)} \tag{1}$$

The above equation is a simple base equation used to determine probability in the case of a conditional event only. In practice, most datasets are multivariate, in which case the equation becomes a bit more complicated. Then we can write the equation like this:

$$P(y \mid x_1, \ldots, x_n) = \frac{P(x_1|y)P(x_2|y)\ldots P(x_n|y)P(y)}{P(x_1)P(x_2)\ldots P(x_n)} \tag{2}$$

A few of the highlights of Naïve Base Classifier: It is exceptionally simple to execute and works moderately quick, works well indeed on small datasets, gives a small less exactness than other calculations, and all traits in Naïve Base are considered commonly autonomous but within the genuine world Isn't.

- Decision Tree: Both classification and regression problems can be solved with the classification and regression tree or CART algorithm [25]. In short, many people call it the Decision Tree. The decision tree looks

a lot like the branches of a tree, which is why the word 'tree' is associated with its name. The decision trio starts from the 'root node' just as the tree starts from the root. From the root node, the branches of this tree spread through different decision conditions; such nodes are called decision nodes, these nodes are called leaf nodes after making a final decision. Other Parameters of the Decision Tree: Splitting - The process of moving a dataset across a series of variables, starting from the root node, is called splitting [26]. Entropy - Entropy is the amount of chaos. When the tree is split, the amount of data of the same type/class in each node is purity. All the data in a pure node are of the same class. The lower the purity, the higher the entropy. Again, the lower the entropy, the higher the purity. Information Gain - The measure of righteousness is information gain [27]. The higher the information gain, the purer nodes the tree can create. Guinea Index - Guinea is the probability of all node members being in the same class. This value ranges from 0 to 1. Guinea value 0 means all the members of that node belong to the same category, and Guinea value 1 means the members of that node are randomly distributed or of different classes, i.e., entropy is much higher. If the value of Guinea is 0.5, then the members of the two classes are equal (if the number of classes is 2) [28].

$$Entropy = p(A)log(p(A) - p(B)log(p(B \quad (3)$$

Information Gain= Entropy Before Split - Entropy After Split

$$Gini\ Index\ = 1 - \sum(P(x = k))\text{^}2 \quad (4)$$

B. Product Recommendation Approach (PRA)

This section highlighted the product recommendation procedure. It can be said that the PRA is vital towards business transformation because user behavior and pattern cannot easily be identified if the stakeholder did not design any recommendation system. By looking at Fig. 2, it is noticeable that a flow chart has been proposed in terms of the recommendation system. The collaborative filtering approach is selected that will filter out the user ID based on age, gender, location and rating score etc. After having all of that information, the system will make a comparison set for the specific users. However, the detailed sequence and consequences are shown in Fig. 2. The diagram in Fig. 2 suggests that the proposed pipeline aims to improve e-commerce and enhance customer experience by using a collaborative filtering method for item recommendation. It implies that the pipeline could help businesses identify the most relevant products for their customers, thus improving their overall shopping experience. The use of collaborative filtering suggests that the pipeline may leverage the behavior of similar users to provide personalized recommendations, ultimately leading to increased customer satisfaction and potentially higher sales. Overall, the diagram title hints at a promising approach to improving the online shopping experience and driving business growth.

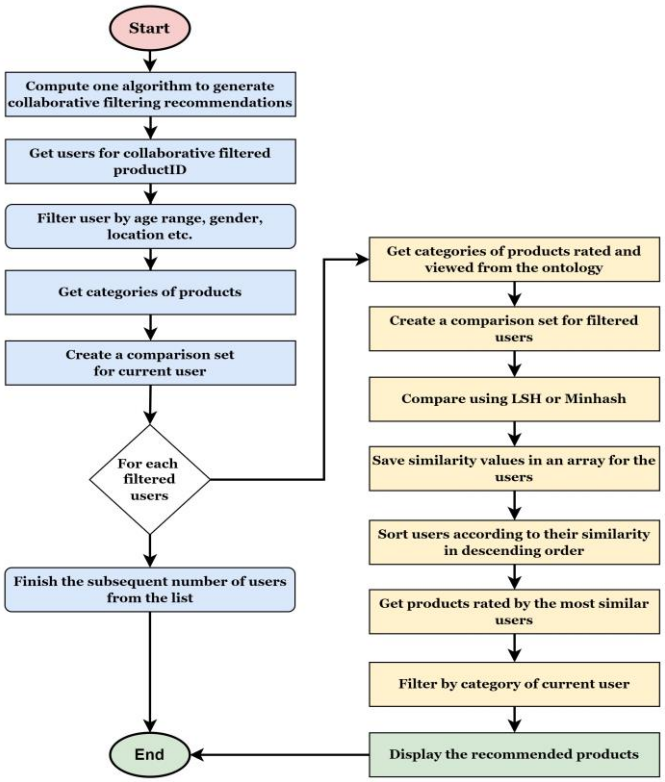

Fig. 2. Efficient pipeline for the item proposal approach towards commerce change and client design acknowledgment through the collaborative sifting method.

The research system utilizes several methods like K-Nearest Algorithm (KNN) [29], the Jaccard's coefficient, the Dijkstra algorithm, and the cosine similarity. The aim is to suggest based on users' behavior patterns. In recommendation systems, the most common types are the Collaborative Filtering Method (CFM), the Content-Based Filtering Approach (CFA), and Hybrid Recommendation System (HRS) [30]. This filtering approach generally focuses on collecting and analyzing user experience information, behaviors, or interests and predicting what they would like based on similarity with other users. The collaborative sifting approach's imperative advantage is that it does not depend on machine analyzable substances and can accurately prescribe complex things without requiring an "understanding" of the thing itself.

A typical recommendation engine processes data over the following four steps: selection, storage, analysis, and filtering. We have applied the K-Nearest Algorithm (KNN), the Jaccard's coefficient, the Dijkstra algorithm, and the cosine similarity to forecast the shortest path from the user's current location to the user's desired destination and as well as to suggest places to the users based on the rating. In Figure 3 a) shows the corresponding KNN's cluster filtering working procedure and b) shows the Dijkstra algorithm 's workflow.

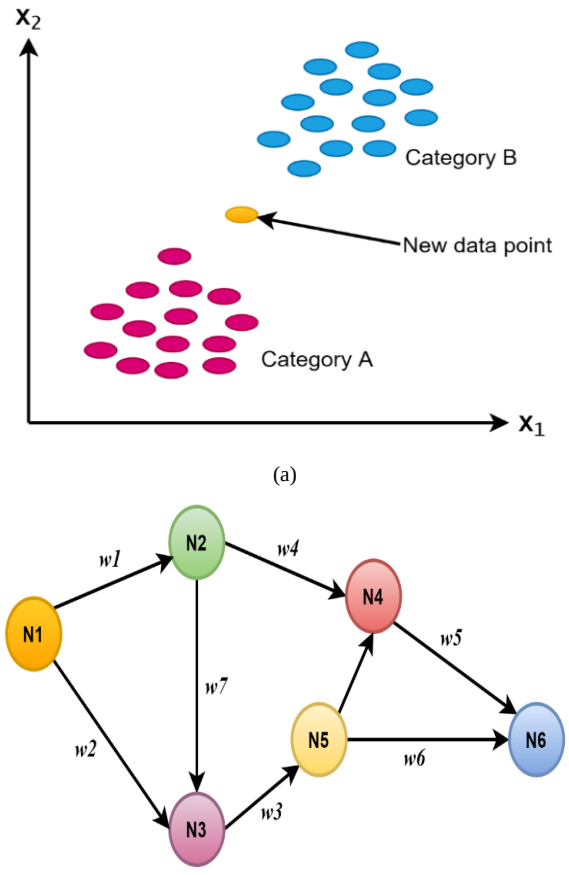

Fig. 3. a) Perform K –nearest algorithm's cluster filtering, b) Dijkstra algorithm.

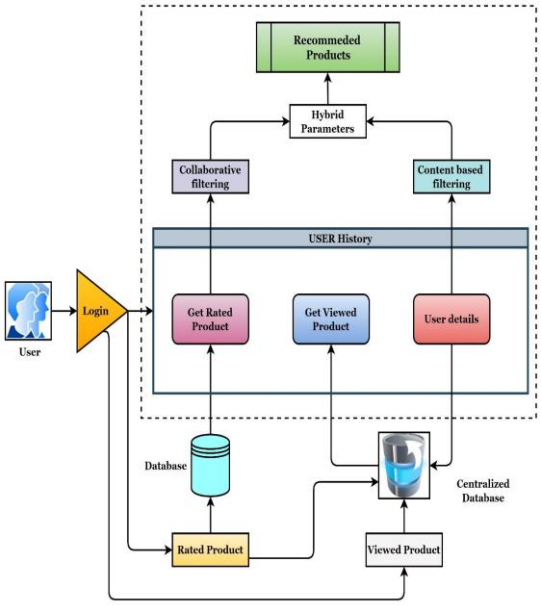

Fig. 4. Architecture diagram of the product recommendation system using various filtering methods.

In Fig. 4, it can be stated that the suggested recommendation engine is the result of a number of interconnected methodologies being used. In order to utilize the system, the user must first complete their registration before being allowed to proceed. After logging into a system, a log file will be created automatically to keep track of the user's patterns of behavior. At this point, we have implemented a cooperating filtering method as well as a content-based filtering approach. Users' comments and product ratings will be taken into consideration by the recommendation system, which will take action based on both forms of data. After obtaining all of the necessary parameters, the system will proceed to the next stage of proposing a specific product to a user who has expressed interest in it. The architecture also assures that collaborative and content-based filtering are the middle layer of this architecture that are the responsible for the product sentiment analysis. However, the hybrid parameters will then send to the model for identifying the sentiment.

IV. Result Analysis

The result analysis section is categorized into several parts: Classification Metrics Interpretation (CME), Measuring the Efficiency, Interpretation of Sentiment Analysis, Observation & Discussion. The precision of expectations from the classification calculations is evaluated by applying a classification report. The report illustrates the exactness, review, and f1-score of the key classification measurements per lesson. These measurements are computed by utilizing genuine and untrue positives and genuine and wrong negatives. The measurements comprise of four components: genuine positive, untrue positive, genuine negative, wrong negative, and wrong negative. The taking after Condition (1), (2), (3), and (4) was considered for finding the exactness, review, and f1-score. In Table I, the classification report of the machine learning calculation, is depicted. In this table, we can clearly observe that the machine learning algorithms like Random Forest (RF) and Logistic Regression provide better results, such as 95% and 94%, compared to the other algorithms like LSTM and CNN_LSTM. This is because for this dataset, we have found that low-cost classifiers work far better at deep computation because of the small size of the dataset. Thus, we have achieved the highest accuracy from conventional classifiers.

Precision: It is the relationship between the true positive estimate of the model and the overall positive estimate (both accurate and wrong) .It is articulated as:

$$Precision\ (P) = \frac{TP}{TP+FP} \tag{5}$$

Recall / Sensitivity: The probability of being capable of predicting is a positive ratio. It is given in mathematical form as:

$$Recall\ (R) = \frac{TP}{TP+FN} \tag{6}$$

F1-score: As a general rule, the harmonic mean for Accuracy and Review provides a much better; a significantly better; higher; a stronger and more enhanced gauge than the Precision Metric of the incorrectly categorized occurrences. It is given, mathematically, as:

$$F1-\text{score} = 2 \cdot \frac{Precision.Recall}{Precision + Recall} \tag{7}$$

Accuracy: It is the sum of all the cases in which the predictions were right. It is given as:

$$Accuracy\ (A) = \frac{TP+TN}{TP+TN+FP+FN} \quad (8)$$

TABLE I. CLASSIFICATION REPORT OF THE CONCENTRATED ALGORITHMS

Algorithm	Accuracy (%)	Precision (%)	Recall (%)	F1-score (%)
Naïve Bayes (NB)	93	92	93	93
Logistic Regression (LR)	94	93	94	94
SVM	93	93	93	93
Decision Tree (DT)	91	89	89	90
Random Forest (RF)	95	94	95	95
BI-LSTM	76	70	71	70
CNN_LSTM	77	77	75	76
Stacked LSTM	76	76	76	76
LSTM	79	78	78	77

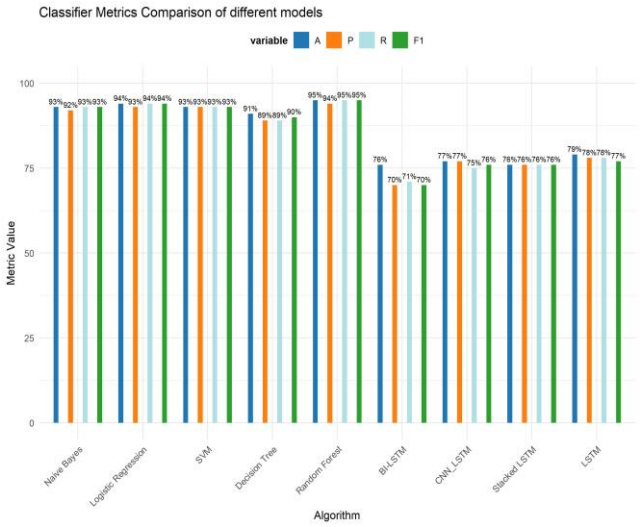

Fig. 5. Performance analysis from the different models.

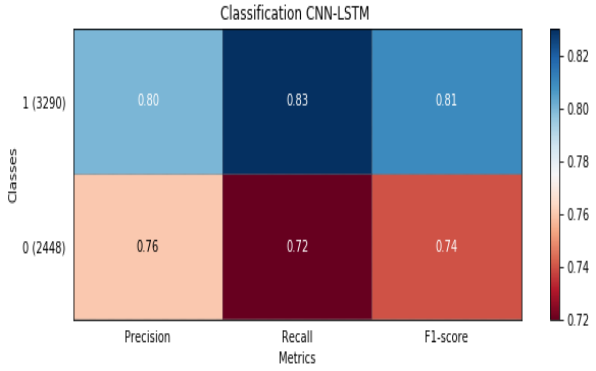
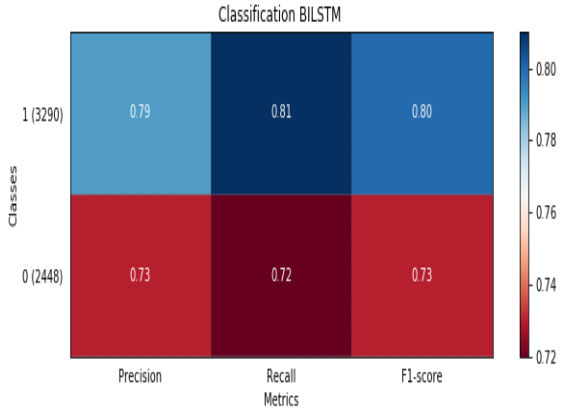
On the other hand, Fig. 5 highlights the confusion matrix on top of the Random Forest and LSTM model. The confusion matrix consists of four values: TP, TN, FP, and FN. We can identify the total sensitivity and specificity ratio by following the Confusion matrix. This is another model evaluation indicator, and in the field of data science, this matrix has been utilized extensively to measure a specific model. The confusion matrix consists of four values, True positive, True negative, False positive, and False negative are the four values in the confusion matrix. Fig. 6 (a) and (5) illustrates the significant proportion of true positive and false negative values.

ROC-AUC curve is used to determine how good a model is. This evaluation indicator distinguishes the positive and negative data points from the dataset. If the ROC curve goes to 1.0, the model can accurately differentiate the positive and negative data points. Fig. 7 (a) and (b) are almost close to 1.0 or the area under the curve. It can be stated that this model is applicable to use in real life.



(a)



(b)

Fig. 7. (a) Evaluating curve on top of the Random Forest model (b) Measuring the model and visualizing the ROC-AUC curve on top of the LSTM model.

A. Interpretation of Sentiment Analysis

This analysis is divided into three stages: Sentiment analysis on reviews (1996-2018), exploratory analysis on product reviews (1996-2018). This is of particular note since it is the one with the greatest number of prior sales on Amazon, as determined by an examination of "Bundles" or "Bought-Together."

B. Analysis 1: Sentiment Analysis on Reviews (1996-2018)

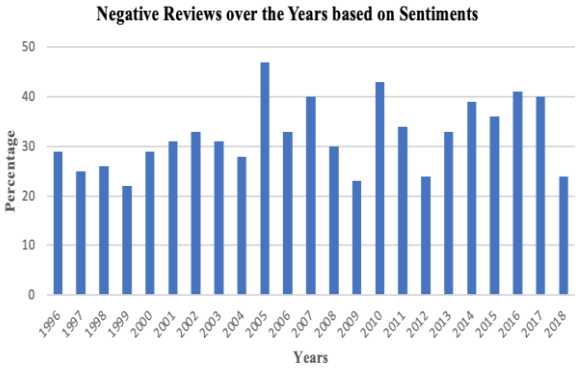
Fig. 8 indicates the exploratory product data analysis in terms of user feedback. In Fig. 8 (a) and Fig. 8 (b), the sentiment analysis on user reviews have been demonstrated for the year of between 1996 to 2018. It is noticeable that, the year 2000 was the least number and 2001 reach out at the highest number of negative product reviews based on the sentiment. At the same time, the year 2000 was the top year where significant number of positive reviews based on the users sentiment was recorded. After that, the percentage was decreased and remained same for the next consecutive years. Besides, Fig. 7 (c) and (d) shows the word cloud visualization based on the positive and negative reviews where it the keywords are tagged and, in this way, it would be convenient to find out the negative and positive keywords from the dataset.

For Positive Word Cloud, some well-known terms such as adored, idealized, decent, wonderful, best, outstanding, and so on were used to describe the goods. A large number of people who were polled were pleased with the prices of things sold on Amazon. Bra, coat, bag, and outfit are some of the most commonly discussed goods. Disappointment, terrible fit, horrible deformity, return and etc. are some of the well-known adjectives used to describe the things. Some of the most talked-about goods were shoes, binoculars, bras, batteries, and so on. Predominant item in terms of how others feel about it. There are 953 positive reviews for the Speak Unisex Chuck Taylor Classic Colors Sneaker. There are 672 positive reviews for the Talk Unisex Chuck Taylor All-Star Howdy Best Dark Monochrome Sneaker. There are 65 negative reviews for the Yaktrax Walker Footing Cleats for Snow and Ice. There are 44 negative reviews for the Speak Unisex Chuck Taylor Classic Colors Sneaker. Welcome to the Best Dark Monochrome Sneaker, with a total of 247 honest reviews. [31], which state achieved that 72.7 % was positive, 5 % was negative, and 22.3 % was neutral. Overall, Sentiment for reviews on Amazon is on the positive side as it has very few negative sentiments.

The drift for Rate of Audit over a long time, positive surveys rate has been lovely reliable between 70-80 all through a long time. Negative surveys have been diminishing recently since final three a long time; possibly they worked on the administrations and issues.

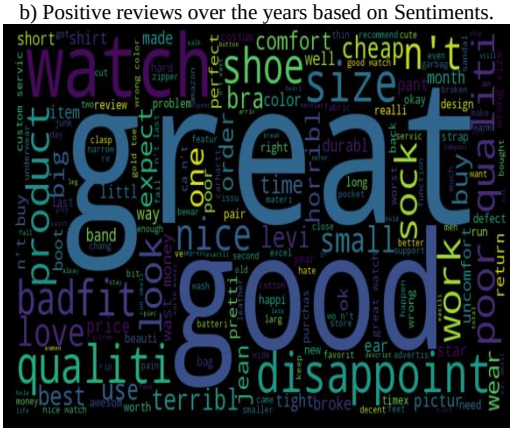
C. Analysis 2: Point of Interest-based Analysis

The lexical density of a language is a concept in computational linguistics that measures the structure and complexity of human conversation in [31]. Functional and content words are used to calculate a written or spoken composition's lexical density.

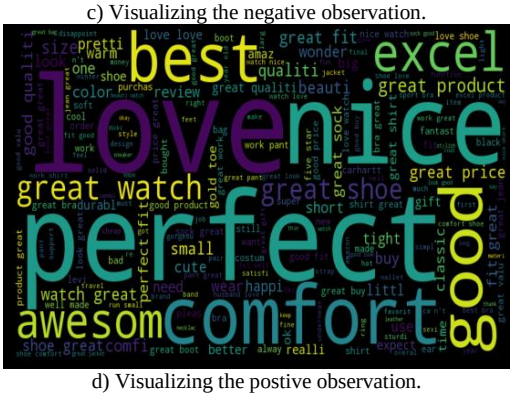


a) Negative reviews over the years based on sentiments.

b) Positive reviews over the years based on Sentiments.



c) Visualizing the negative observation.



d) Visualizing the postive observation.

Fig. 8. a) Negative reviews over the years based on the Sentiment (b) Positive reviews based on the Sentiment (c) Visualizing the negative observation through the word cloud visualization approach (d) Illustrating the positive observation with the help of word cloud visualization.

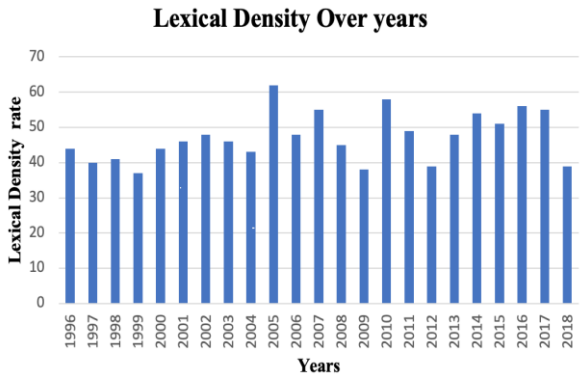


Fig. 9. Lexical density over years.

By looking at the Fig. 9, it can be observed that lexical density over years have been displayed. In 2018, the significant amount just over the 40 but in 1996, there is a downward trend at nearly 36 and remained steady for the next subsequent years.

D. Analysis 3: Bundle' or 'Bought- Together' based Analysis

In the Table II, Bundle or Bought together based analysis has been interpreted in terms of up vote, helpful rating, total votes, and percentage. Based on the reviewer ID, it is clearly demonstrated the helpful rating, and these has been illustrated owing to the fact that for the case of analysis, product sentiment analysis and review records are considerably required so that essential information can be extracted.

Taking a close look at the Fig. 10, helpfulness and average length have been displayed. The findings show that the effectiveness of review length is influenced by product category; longer evaluations are more helpful for think products. Furthermore, review helpfulness is linked to the degree of consistency between individual review ratings and total product ratings. In contrast the Fig. 11 shows the data analysis with correlation between the ASIN.

E. Analysis 3: Exploratory Data Analysis

1a) The common survey rating for the foremost commonly checked items is between 4.5 and 4.8, with little variation. 1b) Whereas there's a little converse affiliation between the recurrence level of ASINs and regular audit appraisals for the primary four ASINs, this relationship isn't critical since the normal survey for the prior four ASINs is evaluated between 4.5 and 4.8, which is respected greatly by and large audits. 2a) As illustrated within the bar chart (beat), ASINs with lower frequencies have much more change in their routine survey evaluations on the point-plot chart (foot), as demonstrated by the length of the vertical lines. As a result of the tall fluctuation, we accept that our research's normal audit evaluations for ASINs with lower frequencies are not imperative. 2b) On the other hand, we assume that the lower frequencies for ASINs are inferable to lesser quality items. 2c) Moreover, the final four ASINs have no change due to their significantly lower frequencies. Whereas the survey appraisals are a culminate 5.0, we ought not to consider these audit appraisals' significance due to the lower recurrence as shown in 2a). Based on our information examination between ASINs and audits. Rating, we have taken note that numerous ASINs with the common event had huge fluctuations; in this way, we decided that these moo event ASINs are not imperative in our think about due to the little test measure. Additionally, we found nearly no interface between ASINs and surveys. Rating in our relationship considers which is reliable with our findings.

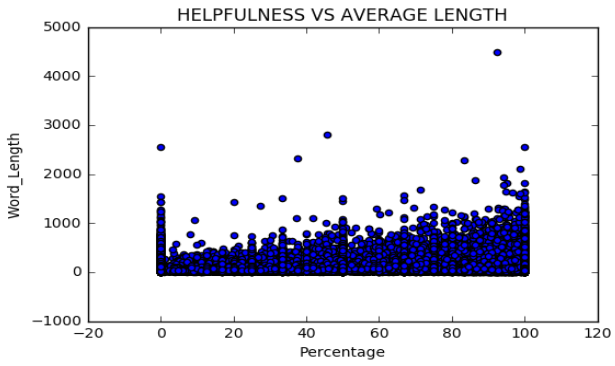

Fig. 10. Helpfulness and average length.

TABLE II. EXPLORARYTORY DATA ANALYSIS WITH THE DATASET AND THEIR FEATURES

Reviewer ID	Rating helpful	Upvote	Total Votes	Percentage	Rating
A2XVJBSRI3SWDI	5.0	0.0	N/A	0.0	N/A
A2G0LNLN79Q6HR	4.0	1.0	0.0	N/A	N/A

Fig. 11. (a) Exploratory data analysis on top of the ASIN (b) Correlation analysis between ASIN.

V. Discussions

The foremost regularly looked into products have routine audits within the 4.5 to 4.8 extend, with small fluctuation. Even though there's a slight converse relationship between the ASINs recurrence level and normal audit evaluations for the primary 4 ASINs, this relationship is immaterial. The normal survey for the prior 4 ASINs is evaluated between 4.5 to 4.8, which large surveys consider great. For ASINs with lower frequencies, we see that they're comparing normal audit evaluations on the point-plot chart (foot) have an essentially bigger change, as appeared by the length of the vertical lines. As a result, we recommend that the normal audit appraisals for ASINs with lower frequencies are not critical for our examination due to high variance.

On the other hand, due to their lower frequencies for ASINs with lower frequencies, we recommend that this result from more second-rate quality items 2c). Moreover, the final 4 ASINs have no fluctuation due to their altogether lower frequencies. Even though the audit evaluations are a culminate 5.0, we ought not to consider the centrality of these review evaluations due to lower recurrence. I am able to see that certain items have much more reviews than others based on the ASIN investigation, proposing a greater deal for those items. Ready to see that the ASINs have "right-tailed" dissemination, demonstrating that specific things have bigger deals, which can be connected to the higher recurrence of ASINs within the audits. Moreover, we took the log of the ASINs to normalize the information so that we seem to get a more nitty-gritty to see each ASIN and see that the dissemination is still "right-tailed." In our study, product sentiment analysis has been carried out towards in the year between 1996 to 2018. Three types of data analysis have been completed and through which business owners can make a variety of decisions towards their particular product. The different assessment pointers bend assessed the proposed show, and at long last, a proposal framework has been submitted by coordination overall sifting strategy. By taking after the proposal framework, the partner will be able to supply important data to their enlisted client, which can improve the request for specific things.

VI. Conclusion and Future Work

Nowadays, product sentiment is very important because, when a business is run online, it is important for every user to recommend their various products through pattern recognition. In order to use cutting-edge machine learning and deep learning algorithms to evaluate online product sentiment and make recommendations, a thorough pipeline is needed. This research proposes a pipeline for analyzing the online product. Also, a recommendation system has been presented through which a similar product can be filtered out for users. The study approach comprises two distinct components, namely the sentiment analysis approach and the product recommendation approach. The study uses appropriate hyperparameter optimization techniques to apply a number of cutting-edge algorithms, such as Naïve Bayes, Logistic Regression, Support Vector Machine (SVM), Decision Tree, Random Forest, Bidirectional Long-Short-Term Memory (BI-LSTM), Convolutional Neural Network (CNN), Long-Short-Term Memory (LSTM), and Stacked LSTM. The k-Nearest Neighbors (KNN) model is combined with the collaborative filtering approach in the study to make product recommendations. Of these models, the Random Forest model had the highest accuracy (95%), followed by the LSTM model (79%). The Area under the ROC Curve (AUC), also known as the Receiver Operating Characteristic (ROC) curve, is used to evaluate the proposed model. In addition, the study carried out exploratory data analysis on reviews (1996–2018) using point-of-interest-based analysis, sentiment analysis, and bundle or bought-together analysis. Overall, the study meets its goals and suggests a flexible fix for practical situations.

Different machine learning and deep learning algorithms were applied to analyze the sentiment in this research. The Random Forest was found to be satisfactory through the investigation and can recommend any product effectively. In addition, three types of analysis have been carried out in this study. This research has several limitations, such as experimenting with just one dataset, but experimenting on multiple datasets was required, which we will complete in the future. In addition, a software system will be developed where a recommendation system will be integrated. Also, various loss optimization formulas will be applied to ensure model efficiency. Evaluation indicator approaches will later justify the type of model followed for recommendation in this phase.

Automatic Model for Postpartum Depression Identification using Deep Reinforcement Learning and Differential Evolution Algorithm

Sunyuan Shen[1*], Sheng Qi[2], Hongfei Luo[3]
Department of Applied Engineering, Zhejiang Business College Hangzhou 310053, People's Republic of China[1, 3]
Institute of Electronic Commerce, Zhejiang Business College Hangzhou, 310053, People's Republic of China[2]

***Abstract*—Postpartum depression (PPD) affects approximately 12% of new mothers, posing a significant health concern for both the mother and child. However, many women with PPD do not receive proper care. Preventative interventions are more cost-effective for high-risk women, but identifying those at risk can be challenging. To address this problem, we present an automatic model for PPD using a deep reinforcement learning approach and a differential evolution (DE) algorithm for weight initialization. DE is known for its ability to search for global optima in high-dimensional spaces, making it a promising approach for weight initialization. The policy of the model is based on an artificial neural network (ANN), treating the categorization issue as a policymaking stage-by-stage process. The DE algorithm is used to acquire initial weight values, with the agent obtaining samples and performing classifications in each step. The habitat provides an award for every categorization activity, considering a greater award for identification of the minor category to encourage precise detection. By using a particular compensatory technique and an encouraging learning system, the operator eventually decides the most excellent method for achieving its goals. The model's efficiency is evaluated by analyzing a set of data acquired from the population-based BASIC study carried out in Uppsala, Sweden, which covers the period from 2009 to 2018 and consists of 4313 samples. The experiential results, identified by known analysis criteria, indicate that the sample achieved better precision and correctness, making it suitable for identifying PPD. The proposed model could have significant implications for identifying at-risk women and providing timely interventions to improve maternal and child health outcomes.**

Keywords*—Postpartum depression; deep reinforcement learning; differential evolution algorithm; weight initialization; artificial neural network

I. Introduction

PPD is a common condition in Sweden, affecting 8% to 15% of new mothers annually [1]. It manifests as mild to severe depressive episodes either during pregnancy or within the first year after giving birth [2, 3]. The exact cause of PPD remains unknown but is thought to result from a combination of psychosocial, psychological, and biological factors. Biologically, inflammation, the withdrawal of allopregnanolone, and genetic factors play roles. Psychosocially, factors like ongoing stress, prior depression, relationship difficulties, and significant life changes contribute to PPD risk. The consequences of PPD can be severe, impacting both mother and child. Mothers may struggle with forming emotional bonds with their child, doubt their caregiving abilities, and even have harmful thoughts towards the child [4]. Efforts have been made to predict PPD during the prenatal period. Still, currently, there is no reliable method to accurately identify women at risk of experiencing depressive symptoms after giving birth [5].

Conventional statistical methods typically analyze the relationship between two variables while factoring in other variables [6, 7]. In contrast, machine learning (ML) techniques allow for the simultaneous analysis of many interconnected variable relationships, leading to the creation of data-driven predictive models [8]. These models can then be assessed to find the most effective predictor. ML can handle complex nonlinear relationships and integrate various data types from different sources. Over the past ten years, the application of ML has expanded across medical fields including oncology, cardiology, hematology, critical care, and psychiatry. In PPD, which poses a moderate risk of a serious psychiatric condition with reasonably accurate prediction of symptom onset, ML can be highly valuable given the societal impact of PPD. Despite its potential benefits, it is impractical to monitor every individual for early PPD symptoms. A more efficient strategy is to target high-risk groups during postpartum checks by healthcare professionals like midwives or nurses, rather than the broader population. In Sweden, with its 120,000 annual births and the myriad of post-childbirth adjustments women undergo, and a typical PPD prevalence of around 12%, this targeted approach proves especially advantageous for personalized, cost-effective maternal and perinatal mental care.

Machine learning can face issues with feature extraction, affecting generalization, processing time, and precision [9]. The rise of deep learning, particularly Multi-Layer Perceptron (MLP), offers improved classification capabilities [10]. MLP, designed for nonlinear XOR problems, is versatile for various tasks, from image processing to optimization [11]. It functions like human neurons, where each node in ANN processes inputs and uses an activation function to produce an output. In MLP, nodes are interconnected across different layers, without intra-layer connections.

Medical classification poses significant challenges due to imbalanced data, where negative instances far outnumber positive ones, leading to decreased performance [9, 12, 13].

Measures can be employed at both the algorithm and data levels to address this issue. At the level of the data, downsampling, upsampling, or a mixture of both techniques can be utilized to alleviate the negative impact of imbalanced classification [14, 15]. On the other hand, algorithmic approaches involve assigning greater weight to the minority class [16, 17]. Moreover, deep learning methods offer potential solutions for tackling imbalanced classification [12, 18]. Huang et al. [19] have proposed a process to identify distinctive features in imbalanced data while maintaining inter-cluster and inter-class margins. Similarly, Yan et al. [16] have suggested a technique using the bootstrapping method to balance data in convolutional networks across mini-batches.

Population-based training can be utilized to select the most optimal solution from a population of generated models in order to optimize neural networks [20-22]. This approach mitigates the risk of being trapped in local optima, a common challenge in traditional training methods [23]. Surprisingly, a straightforward evolutionary algorithm has proven comparable to stochastic gradient descent in terms of the effectiveness of neural network training [24, 25]. Jaderberg et al. [26] successfully applied population-based training to cutting-edge models in deep reinforcement learning, machine translation, and generative adversarial networks, yielding consistent accuracy, training time, and stability enhancements. In related studies [27] and [28], effective weight training for neural networks was achieved through the adoption of differential evolution-based strategies [29] and the employment of the ABC (Artificial Bee Colony) method [30, 31], respectively.

This paper introduces a novel approach for identifying PPD by combining deep Q-learning and the DE method to initialize the load. The categorization task is formulated as an estimating challenge within an RL framework, treating it as a Markov decision process. The environment state is represented by a sample, and the agent is an ANN. To initiate the game, we explore the application of the DE algorithm to find an optimal weight initialization for the ANN. The agent classifies each sample, and its classification is awarded accordingly by giving the right choices positive awards and wrong decisions getting negative awards. For tackling dataset imbalance, the minority class is given a higher absolute value of the reward. The operator aims to amplify the accumulative awards by accurately classifying the samples throughout the policymaking procedure. Significantly, our research is pioneering in utilizing a population-based methodology that leverages an extensive and varied dataset, incorporating a wide range of clinical, psychometric self-report, and medical journal-derived variables. The performance of our proposed model on this dataset demonstrates its supremacy over alternative methods depending on initializing the arbitrary load. The primary contributions of the paper can be outlined in the following manner:

- Formulating the classification task as a guessing game within an RL framework, treating it as a Markov decision process.
- Using DE to find an optimal weight initialization for the ANN, initiating the guessing game.
- Rewarding correct and incorrect decisions positively, addressing dataset imbalance by giving higher rewards to the minority class.
- Demonstrating the superiority of the proposed model over alternative approaches that rely on random weight initialization through its performance on the dataset.

The organization of this paper is outlined below: Section II reviews relevant literature, Section III delves into the DE algorithm, and Section IV describes the proposed model. Results and their analysis are discussed in Section V. The paper concludes with a summary in Section VI, along with recommendations for future investigations.

II. Related Work

In recent years, the field of medical science has witnessed an unprecedented surge in the application of machine learning techniques to forecast and categorize a plethora of health concerns, with PPD standing out as a significant area of interest [32]. To understand the evolution and progression of these methodologies, a series of pioneering studies have been meticulously evaluated to shed light on the practices adopted and the degree of precision achieved in their PPD classification endeavors [33].

Zhang et al. [34] placed their bet on SVM and FFS-RF, emphasizing these as the most promising tools for PPD prediction. They embarked on a comprehensive longitudinal survey, engaging 508 women as respondents. The Edinburgh Postnatal Depression Scale (EPDS) served as their choice of instrument to gauge PPD risk. Delving further into their work, Zhang et al. [35] opted for EHR datasets, focusing on the detection of PPD in perinatal women. Their findings were intriguing; while logistic regression fortified with L2 regularization emerged as the top contender for data leading up to childbirth, the post-childbirth data saw MLP taking the lead. Jasiya et al. [36] proposed a machine learning system to identify risk factors and prevalence of postpartum depression in Bangladesh. Utilizing modified questions from EPDS and PHQ-2 scales and socio-demographic queries, data from 150 women was analyzed. The most effective model was identified as Random Forest. Amit et al. [37] presented a Gradient Boosting Machine (GBM)-based approach to PPD depression risk using electronic health records from 266,544 UK women between 2000 and 2017. The model assessed socio-demographic and medical variables and was evaluated alongside the standard EPDS questionnaire for improved screening accuracy. Park et al. [38] suggested an evaluation of methods to reduce bias in clinical machine learning models. Health data from the IBM MarketScan Medicaid Database, focusing on females aged 12 to 55 years with a live birth record from 2014 to 2018, was analyzed. The study examined logistic regression, random forest, and extreme gradient boosting models for postpartum depression and mental health service utilization, assessing racial disparities. Bias reduction methods like reweighing and Prejudice Remover were also explored.

Diversifying the landscape, Shin et al. [39] ventured to harness the PRAMS 2012-2013 dataset and the PHQ-2 questionnaire. Their objective was clear: to tap into various

machine learning algorithms and decipher the prevalence of PPD. Their rigorous analysis crowned Random Forest as the algorithm par excellence for PPD prediction. In a similar vein, Andersson et al. [40] crafted multiple machine learning prototypes, drawing data from Swedish hospitals. Their study, vast in its scope, found the Extremely Randomized Trees model to be unmatched in performance.

Dipping into another significant contribution, Tortajada et al. [41] embarked on a study, leveraging data accumulated from hospital settings. Their research, hinging on MLP, showcased an impressive accuracy rate of 81% in PPD prediction. On the other hand, De Choudhury [42] ventured into the realm of digital platforms, conducting a longitudinal online survey. This study examined an array of regression models, paving the way for new insights. In another noteworthy study, Nataranjan et al. [43] showcased a comparative analysis of algorithms like Functional-gradient boosting, Decision-trees, Naive Bayes, and SVM. Their work, rooted in a longitudinally curated dataset, championed Functional-gradient boosting as the superior method. Lastly, Wang et al. [44] married EHR data with machine learning techniques, with their research revealing SVM as the most fitting algorithm for their dataset.

However, while these advancements are commendable, it is essential to recognize the challenges that come with them. The sheer diversity of algorithms means that selecting the optimal one requires rigorous testing, often demanding substantial resources. Moreover, discrepancies in datasets across different studies might lead to varying conclusions, underscoring the need for standardized and universally accepted data collection methods. Additionally, the robustness of these models in real-world scenarios remains a topic of debate, necessitating further in-depth research and validation.

III. Differential Evolution

Differential Evolution (DE) [29] is an optimization algorithm that stems from populations and finds frequent applications in addressing optimization problems. It falls under the umbrella of evolutionary algorithms, drawing inspiration from the natural progression of evolution. DE is widely acknowledged for its straightforwardness and effectiveness in handling optimization problems involving continuous variables. In addition to its broad range of applications, DE has proven valuable in the realm of machine learning, particularly within the domain of training artificial neural networks. An essential aspect of neural network training revolves around weight initialization, a pivotal factor influencing convergence, generalization capabilities, and the capacity to learn intricate patterns. Traditional weight initialization methods, such as random initialization or fixed values, often grapple with the challenge of striking an optimal balance between avoiding vanishing or exploding gradients and achieving efficient learning. DE can be employed to initialize neural network weights by treating weight values as variables to be optimized. The objective is to identify an optimal set of weight values that minimize the objective function, representing network performance or error on a training dataset. Through the strategic reimagining of weight initialization as an optimization quandary, DE can adeptly navigate and investigate weight configurations that serve as a catalyst for bolstering network performance. DE offers several benefits for weight initialization in machine learning [10]:

- Exploration of Solution Space: The DE algorithm facilitates the exploration of the solution space by generating diverse candidate solutions. This is particularly advantageous for weight initialization as it helps to avoid getting stuck in local optima and enables the algorithm to search for better-performing weight configurations.
- Efficient Optimization: The DE algorithm optimizes the weights by iteratively updating them based on the difference between the target and current solutions. This efficient optimization process aids in finding suitable initial weights that can contribute to faster convergence and improved learning algorithm performance.
- Robustness to Noise: The DE algorithm is known for its robustness to noisy fitness evaluations. In weight initialization, this robustness helps to handle uncertainties and variations in the data, leading to more reliable and stable initial weight configurations.
- Flexibility and Adaptability: The DE algorithm allows for flexibility and adaptability in weight initialization. It can be customized to handle specific problem domains or constraints, such as imposing bounds on weight values or incorporating prior knowledge. This adaptability enhances the algorithm's ability to initialize weights suitable for the given learning task.

The primary procedures of DE are as follows:

- Initialization: The method begins with creating a beginning populace of chosen resolutions called "individuals." Each individual represents a potential solution to the optimization problem and is usually represented as a vector of real numbers.
- Mutation: In each iteration of the algorithm, the individuals in the population are subjected to mutation. Mutation is the process of generating new candidate solutions by perturbing existing ones. In DE, the mutation is performed by creating a trial vector for each individual using the difference between two randomly selected individuals from the population.
- Crossover: After mutation, a crossover operation is applied to combine the trial vector with the original individual. Crossover is a process that blends the information from the trial vector and the original individual to create a new candidate solution. The crossover operation in DE is typically performed using a binomial crossover scheme, where each component of the new solution is selected either from the trial vector or the original individual with a certain probability.
- Selection: The new candidate solution produced by crossover is compared with the original individual, and the better one is selected to proceed to the next iteration. The selection process ensures that only the fitter individuals survive and propagate their traits to the next

generation. This step helps in driving the search towards better solutions over time.

- Termination: The algorithm continues to iterate through mutation, crossover, and selection until a termination condition is met. The termination condition can be a maximum number of iterations, reaching a desired level of solution quality, or any other criteria defined by the problem.

IV. Model Architecture

To address our research challenge, we turned to the capabilities of DE for weight initialization and RL for imbalanced classification, particularly because existing models fall short in several aspects. Traditional models often rely on random weight initialization, which can lead to prolonged training times and the possibility of converging to suboptimal solutions. Many existing algorithms struggle with imbalanced datasets, leading to biased predictions that often overlook the minority class.

By using DE for weight initialization, we can ensure a diverse and potentially more optimal starting point for our learning algorithm. This can lead to faster convergence and potentially superior solutions compared to traditional methods.

RL is a type of machine learning wherein an agent learns to decide by taking actions in an environment to maximize a cumulative reward. It has especially apt for imbalanced classification tasks because it can be tailored to place greater emphasis on the minority class by suitably adjusting the reward mechanism. In scenarios where traditional supervised learning faces challenges because of insufficient representative data for all classes, RL can more effectively explore the decision space and devise strategies that prioritize the accurate classification of underrepresented classes. This addresses another critical limitation of many existing models: their inability to adapt to and accurately classify instances from underrepresented categories.

A. Pretraining

Weight initialization is crucial in neural network training, influencing convergence, generalization, and pattern learning. In this article, the DE algorithm treats weights as variables and minimizes the objective function, representing performance or error. DE effectively explores the weight space by iteratively evaluating and updating weight configurations through evolutionary operators. The goal is to refine weights for better convergence, reduced error, and improved generalization. Incorporating DE in pretraining enhances weight initialization, improving overall network performance.

In this article, the power of the DE algorithm is leveraged to initiate the weights of the MLP. The weights are encoded by meticulously arranging them into a vector, representing them within the DE algorithm. It should be noted that finding the most appropriate layout can be intricate, requiring persistent efforts and a multitude of experiments. Undeterred by the complexity, an optimal encoding strategy was devised through extensive trials and refinements. To provide a visual depiction of this process, Fig. 1 is presented, offering a clear illustration of how all the weights and bias terms are meticulously gathered and assembled into a comprehensive vector. This vector, acting as a candidate solution within the DE algorithm, encapsulates the essential components necessary for weight initialization. By organizing these elements thoughtfully and strategically, the stage is set for the DE algorithm to unleash its optimization prowess, guiding the MLP toward enhanced performance and increased learning capability.

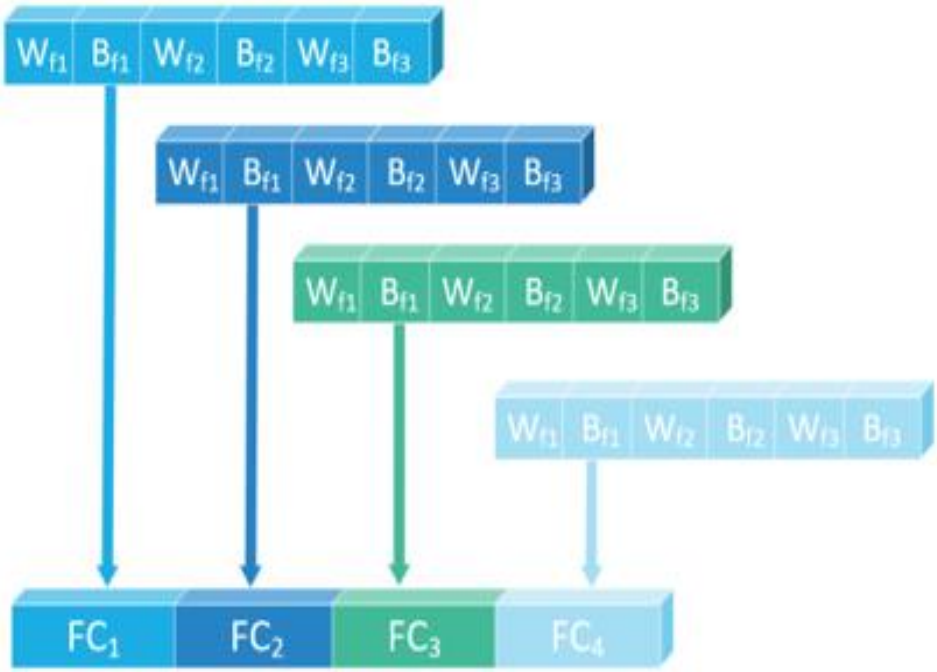

Fig. 1. Encoding strategy used in the proposed algorithm.

The efficacy of a chosen resolution is comprehensively assessed by describing and establishing athleticism performance as a crucial metric. Within the context of the specific problem domain, the quality and performance of the solution are quantified through this function, which serves as a vital tool. The fitness function is meticulously crafted to capture the essential aspects and criteria that govern the success and effectiveness of the candidate solution. The fitness or suitability of the solution can be objectively measured through the careful consideration of relevant factors and parameters, allowing informed decisions to be made and the optimization process to be guided towards optimal outcomes. The fitness function is defined as:

$$Fitness = \frac{1}{\sum_{i=1}^{N}(y_i - \tilde{y}_i)^2} \quad (1)$$

Here, N shows the whole count of train demos, where y_i represents the goal value of the i-th sample and $\tilde{y}_i$ shows the corresponding output predicted by the model.

B. Prediction

To further improve our method of calling the problem of unbalanced classification caused by unequal data volumes in our two classes, we implemented a consecutive policymaking procedure using an RL method. This involved training an ANN model to act as an agent, making informed classifications for each instance, and effectively handling the challenges associated with imbalanced datasets. In the sequential decision-making process, each instance in the train dataset represented a distinct habitat state. The ANN model, acting as the operator, made a categorization sequence for every instance. Simultaneously, as the operator predicted the category name, for instance, it took an act denoted as a_t. At each time-step t, the agent observed an instance representing the current state of the environment, labeled as s_t. The environment provided a reward, r_t, in response to the agent's actions, aiming to guide its behavior. To address the class imbalance issue, the reward values were carefully crafted. Samples from the majority class received lower absolute reward values, while relatively higher absolute reward values were assigned to samples from the minority class. This reward design aimed to encourage the agent to prioritize the correct classification of minority class samples, contributing to mitigating the impact of imbalanced data. In this article, the reward function is defined as:

$$r_t(s_t, a_t, y_t) = \begin{cases} +1\,, a_t = y_t \; and \; s_t \in D_S \\ -1\,, a_t \neq y_t \; and \; s_t \in D_S \\ \lambda\,, a_t = y_t \; and \; s_t \in D_H \\ -\lambda\,, a_t \neq y_t \; and \; s_t \in D_H \end{cases} \quad (2)$$

where D_S, and D_H represent the minority and majority categories in order. Incorrectly/correctly categorizing a demo of the major category gains an award of $+\lambda/-\lambda$, where $0 < \lambda < 1$. We aimed to incentivize the agent to give greater attention to the minority class and mitigate the bias caused by imbalanced data by providing differential rewards based on class distribution. Through this reinforcement learning approach, the agent learned an optimal classification strategy that considered both the inherent difficulty of classifying the minority class and the importance of accurate predictions overall. During training, the agent continuously refined its decision-making capabilities and updated its policies and strategies based on the rewards received. By leveraging reinforcement learning techniques, we aimed to achieve a more balanced and effective classification performance, particularly for the underrepresented class. This novel sequential decision-making process enabled us to overcome the limitations imposed by imbalanced datasets and successfully address the challenges of imbalanced classification. As a result, we achieved improved accuracy and fairness in predictions by combining the power of artificial neural networks and reinforcement learning.

V. Experimental Results

A. Data Sources

The data used for developing the prediction models were acquired from the "Biology, Affect, Stress, Imaging and Cognition during Pregnancy and the Puerperium" (BASIC) study [45]. BASIC is a prospective cohort study conducted at the Department of Obstetrics and Gynaecology in Uppsala University Hospital, Uppsala, Sweden, and it involves a population-based approach. Between September 2009 and November 2018, pregnant women who fulfilled specific eligibility criteria were invited to take part in the study. The criteria included being 18 years of age or older, not having concealed identities, possessing sufficient proficiency in reading and comprehending Swedish, and not having been diagnosed with bloodborne infections or non-viable pregnancies based on routine ultrasound examinations. In the BASIC study, data collection primarily relied on online surveys and questionnaires administered to women at various stages: during pregnancy at the 17th and 32nd week of gestation, as well as at 6 weeks, 6 months, and 12 months after giving birth. These surveys and questionnaires were designed to gather information from participants during these specific time points. The surveys consisted of inquiries regarding various background characteristics, encompassing sociodemographic variables, psychological assessments, medical details, reproductive history, lifestyle factors, and sleep patterns. All questionnaires were completed by the participants themselves and were conducted online. Information was additionally sourced from medical journals. The study had a participation rate of 20%, but the cohort experienced a comparatively low dropout rate, as 71% of the participants remained in the study during the 12-month follow-up period. The study obtained approval from the Research Ethics Board in Uppsala (Dnr 2009/171, with amendments). Prior to their inclusion in the study, all participating women provided written informed consent. The research methods adhered to applicable guidelines and regulations.

B. Model Performance

Our project utilizes a 64-bit Windows operating system, complemented with 64 GB of RAM and a 64 GB GPU. Table I presents the hyperparameters applied to the proposed model.

TABLE I. HYPERPARAMETER SETTING FOR THE PROPOSED MODEL

Hyperparameter	Value
Epoch	256
Batch size	64
Learning rate	0.02
Dropout rate	0.5
Discount factor	0.3

TABLE II. HYPERPARAMETER SETTING FOR MACHINE LEARNING METHODS

Algorithm	Parameter	Value
Naïve Bayes	α (Lidstone smoothing parameter)	0.5
KNN	*k* (Number of neighbors)	5
	Distance Metric	Euclidean (p=2), Manhattan (p=1)
SVM	Kernel	polynomial
	γ (Kernel coefficient)	0.5
Random Forests	Number of trees	20
	Max depth of tree	10
Logistic Regression	C (Inverse regularization strength)	0.3
	Solver	liblinear
Decision Tree	Criterion	entropy
	Max depth	10

In the evaluation process, the suggested model underwent rigorous comparison with six distinct machine learning models: Naïve Bayes [46], KNN [47], SVM [48], Random forests [49], Logistic Regression [50], and Decision tree [51]. In the evaluation process, the suggested model underwent rigorous comparison with six distinct machine learning models: Naïve Bayes [46], KNN [47], SVM [48], Random forests [49], Logistic Regression [50], and Decision tree [51]. Table II shows the parameters applied to these models.

Additionally, two modified versions were included in the analysis to explore different variations of the proposed model. The first modified version, proposed+random weights, adopted a similar foundational architecture to our model but employed random weights for initialization. This alternative initialization method allowed for a comparative investigation of the impact of weight initialization on the performance of the model. The second modified version, Proposed+random weights+RL, incorporated RL techniques for classification. This integration of RL aimed to enhance the ability of the model to make accurate predictions and improve its overall performance. Standard metrics were employed to assess these models' performance, with particular emphasis on the geometry average and F-measure due to their suitability for unbalanced info [52]. The results, which can be found in Table III, clearly demonstrate the superiority of the proposed model over all other models, including the previously recognized top performer, Decision Tree. The evaluation results are shown schematically in Fig. 2 to understand the results better. Across all evaluation criteria, the proposed model consistently outperformed its counterparts. Notably, the proposed model achieved remarkable error reductions over 65%; plus, 29% in the G-averages and F-measure metrics, orderly. These substantial improvements illustrate the effectiveness of the proposed model in tackling the challenges posed by imbalanced data and its ability to generate more accurate predictions. Contrasting the offered sample with the modified versions, Offered+arbitrary loads+RL and Offered+arbitrary loads, the significance of the integration of DE and RL approaches becomes apparent. Our model demonstrated an impressive decrease in the error rate of approximately 62% when compared to these modified versions. This finding underscores the critical role played by DE and RL in enhancing the model's performance and highlights their importance in developing state-of-the-art machine learning models.

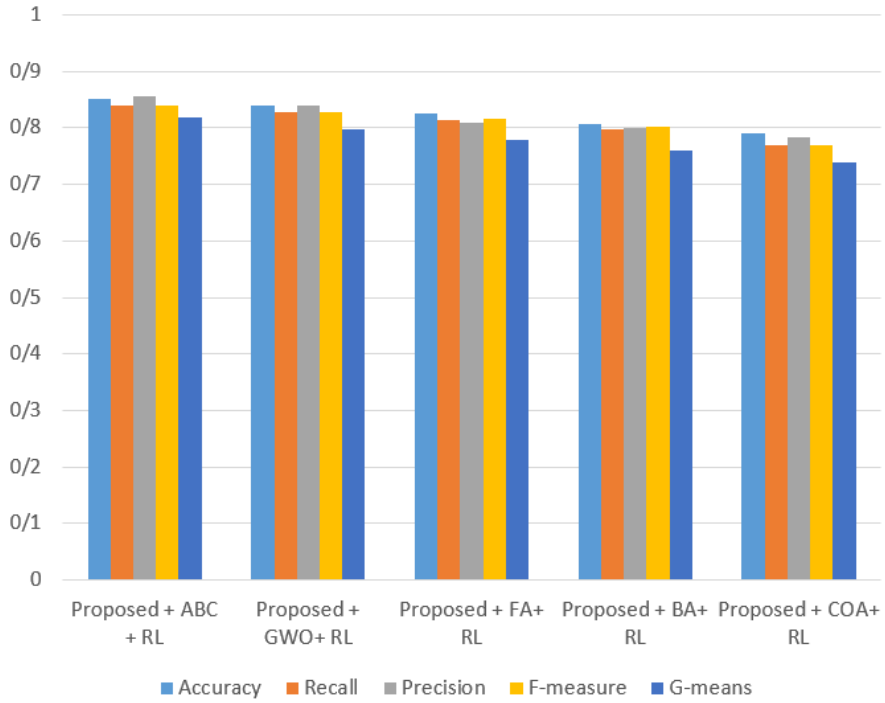

Fig. 3. Graphical comparison of various classification algorithms.

A detailed analysis was conducted in the subsequent experiment to compare the DE algorithm with various well-established metaheuristic optimization algorithms. To ensure a fair comparison, different metaheuristics were employed to derive the initial weights while keeping the remaining components of the model consistent. The evaluation encompassed six distinct algorithms, namely ABC [53], GWO [54], FA [55], BA [56], and COA [57]. For every algorithm, both the population size and the count of function evaluations are configured to 200 and 3,000, respectively. The default configurations are detailed in Table IV. The results of this comprehensive experiment were systematically presented in Table V and Fig. 3, providing valuable insights into the performance of each algorithm. Notably, the findings highlighted the remarkable achievement of DE, which demonstrated a significant reduction in error of approximately 52% when compared to the ABC algorithm. Furthermore, the DE algorithm outperformed other well-known algorithms, including GWO and BA. This outcome solidified the position of the DE algorithm as a leading contender among the considered metaheuristic optimization approaches.

C. Award Operation Effect

The rewards given to the majority and minority classes for correct and incorrect classifications are +1 and ±λ, in order. The λ value is determined by the scale of major to minor demos, and by increasing this scale, the ideal value of λ is expected to decrease. For researching the λ effect, we assessed the offered demo's efficiency through various λ on a scale of 0 to 1 (in increments of 0.1) as saving the bonus for the major category. The outcomes are represented in Fig. 4. By the time the λ is 0, the major category's effect gets insignificant, while at λ = 1, both categories have the same effects. The findings reveal the model performs optimally when λ is set to 0.4 for every measured criterion, recommending that the optimum λ value is on the scale of 0 to 1. We should notice that when it is crucial to diminish the major category's effect by adjusting λ, adjusting it to a lower level might have a detrimental effect on the overall model performance. The results indicate that the choice of λ has a substantial impact on the performance of the model. The optimal value of λ depends on the relative proportions of the majority and minority samples, underscoring the significance of careful selection to achieve the best possible outcomes.

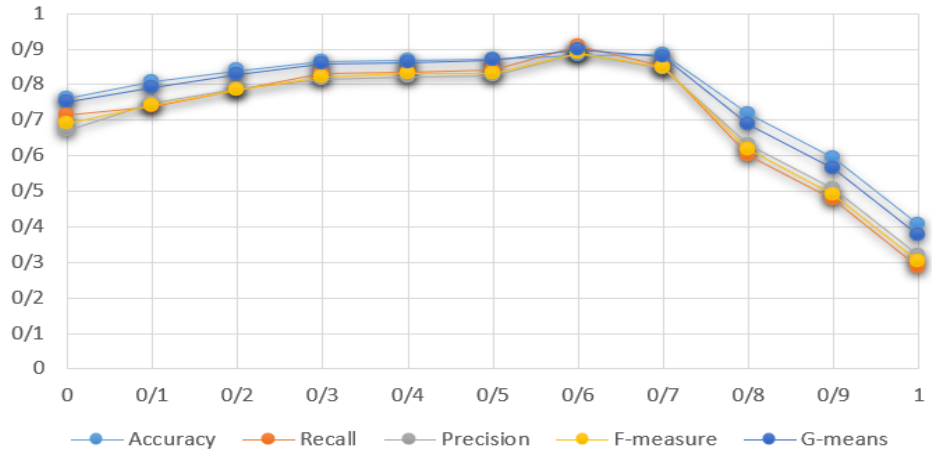

Fig. 4. Visual depiction showcasing the alteration in performance parameters caused by fluctuations in the value of λ.

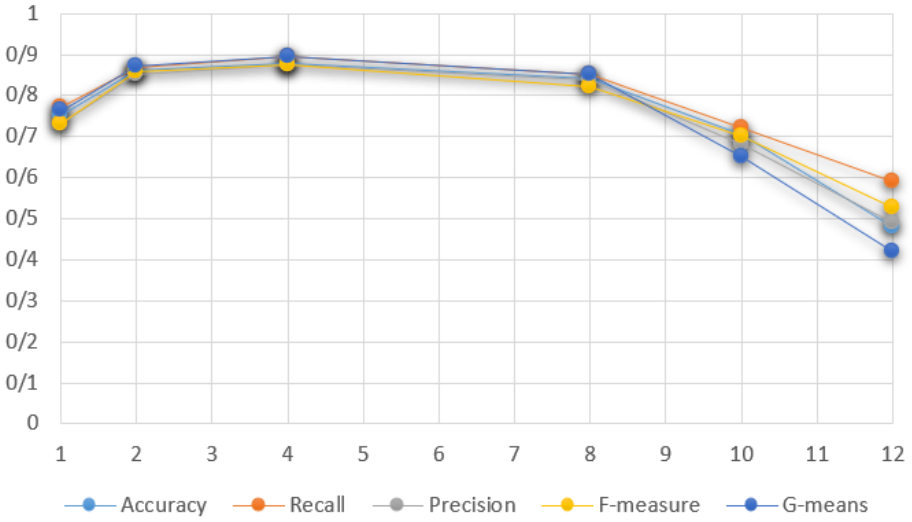

Fig. 5. The plotted performance metrics as a function of the MLP layers.

D. Impact of the MLP Layers

The article emphasizes that increasing the number of layers in an MLP leads to a higher model complexity, which in turn increases the risk of overfitting. On the other hand, having too few layers may limit the ability of the model to capture important features in the training data. In our proposed approach, we conducted experiments with six different values (1, 2, 4, 8, 10, 12) for the number of layers in the MLP to examine its impact on model performance. The results, presented in Fig. 5, demonstrate a decreasing trend in performance as the number of layers is in the 1 to 4 range, next to a rising trend for 4 to 12 values. This suggests that having four layers in the MLP yields optimal performance and achieves the best results.

E. Impact of the Loss Function

Various techniques are available to tackle data imbalances in machine learning models, including adjusting data augmentation methods and selecting an appropriate loss function. Among these techniques, the choice of loss function plays a crucial role in enabling the model to learn from the minority class effectively. To assess the efficacy of different loss functions, we examined five specific functions: WCE [58], BCE [59], DL [60], TL [61], and CL [62]. BCE and WCE commonly use loss functions that equally treat positive and negative examples. However, in the case of imbalanced datasets where the emphasis needs to be placed on the minority class, these loss functions may not be suitable.

On the other hand, DL and TL loss functions are better suited for imbalanced datasets as they yield improved performance ojn the minority class. As a promising loss function, CL is particularly beneficial for applications involving unbalanced data. By adjusting the weights of the loss function, CL can assign lower importance to simple examples and focus more on learning complex samples. To evaluate the effectiveness of these loss functions, we conducted experiments and presented the results in Table 6 and Fig. 6. The findings demonstrate that the CL function surpasses the TL function, resulting in a 25% reduction in the error rate for the accuracy metric and a 39% reduction for the F-measure metric. However, it is worth noting that the CL function performs 60% worse than the FL function, which is a specialized loss function specifically designed for binary classification tasks. It is important to consider these results in

the context of the specific problem at hand and the nature of the dataset. While the CL function outperforms the TL function, it falls short when compared to the FL function. Further investigation is required to understand the factors contributing to these differences in performance and to explore the potential of customized loss functions specifically tailored to address the challenges posed by imbalanced datasets. Additionally, research can focus on developing novel loss functions or adapting existing ones to strike a balance between emphasizing the minority class and maintaining overall classification accuracy across various classification tasks and datasets.

F. Discussion

The findings presented in this study have important implications for PPD identification and intervention. Developing an automated model using a deep reinforcement learning approach and a DE algorithm for weight initialization shows the potency of advanced ML approaches for addressing the challenges associated with PPD identification. One of the key advantages of using the DE algorithm for weight initialization is its ability to explore high-dimensional spaces and find optimal weight values effectively. This ensures that the model is initialized in a manner that enables it to make accurate predictions and classify PPD effectively. By leveraging an ANN and treating the categorization issue as a policymaking stage-by-stage process, the sample considers the complexity and nuances of PPD, enhancing its predictive capabilities. Using an encouraging learning system and a particular compensatory technique further enhances the model's performance. By assigning a higher reward for identifying the minority class, the model is incentivized to focus on precise detection, addressing the challenge of identifying at-risk individuals. This approach acknowledges the importance of early identification to provide timely interventions and support to those most in need. The evaluation of the model's performance using a comprehensive dataset acquired from the population-based BASIC study in Uppsala, Sweden, strengthens the validity of the findings. With a large sample size of 4313 samples spanning a significant period, the study provides robust evidence of the high accuracy of the model in identifying PPD. This accuracy underscores the potential effectiveness of the model in real-world applications for identifying at-risk women. The implications of this research are far-reaching. By accurately

identifying women at risk for PPD, healthcare professionals can provide timely interventions and support, thus improving maternal and child health outcomes. Preventative interventions targeted at high-risk individuals have been shown to be more cost-effective, making the automated model a valuable tool in resource allocation and optimizing healthcare services.

To offer a more in-depth assessment of our model's capabilities, we reached out for external expert opinions. By teaming up with seasoned professionals, possessing extensive experience in the field, we embarked on a comprehensive qualitative review of the model's performance. These experts, hailing from diverse backgrounds and having a rich tapestry of experiences in similar research areas, thoroughly scrutinized the model's underpinnings, methodologies, and outcomes. Their rigorous evaluations and constructive feedback painted a clear picture. Their collective insights resoundingly echoed our preliminary findings, particularly highlighting the model's unparalleled precision, steadfast reliability, and robust adaptability. When our model was placed side by side with pre-existing algorithms for a comparative analysis, it distinctly stood out, showcasing its superior design and performance. The external validation from such esteemed professionals not only fortified our confidence in the model but also underscored its potential for real-world applications and future research endeavors.

However, it is important to acknowledge the limitations of this study and consider avenues for future research. Firstly, the dataset used in this study was acquired from a specific population-based study conducted in Uppsala, Sweden. While this provides valuable insights into the model's performance within that particular context, it raises questions about the generalizability of the findings to diverse populations and settings [63]. Variations in cultural, socioeconomic, and healthcare factors may influence the prevalence and presentation of PPD, potentially impacting the model's performance [64]. Therefore, future studies should aim to validate the model using datasets from different regions and populations to ensure its applicability across various contexts [65].

Additionally, while the model demonstrates high accuracy in identifying PPD, assessing its performance in real-world clinical arrangements is crucial [66]. The controlled environment of the study may not fully reflect the complexities and challenges faced by healthcare professionals in their daily practice.

Evaluating the model's effectiveness in a clinical setting, where multiple factors can influence the identification and treatment of PPD, would provide valuable insights into its practical utility. Longitudinal studies tracking patient outcomes and the impact of the model's predictions on treatment decisions and health outcomes would further enhance our understanding of its clinical relevance. Furthermore, expanding the scope of research beyond the model accuracy is essential. While accuracy is a crucial metric, evaluating other performance measures such as sensitivity, specificity, positive predictive value, and negative predictive value is equally important [67]. These metrics provide a more comprehensive assessment of the model's diagnostic capabilities and ability to identify individuals at risk and those not at risk for PPD. Understanding the model performance across these measures can guide healthcare professionals in effectively utilizing its predictions and making informed interventions and resource allocation decisions.

Moreover, assessing the impact of the model on patient outcomes is a critical aspect that requires further investigation [68]. While timely identification of at-risk women is essential, evaluating whether the interventions based on the model predictions lead to improved maternal and child health outcomes is equally vital [69]. Conducting studies that measure the effectiveness of interventions guided by the model, such as targeted support programs or personalized treatment plans, would provide valuable evidence of the model's potential to impact patient outcomes positively.

Finally, it is important to consider the ethical implications and potential challenges associated with the implementation of an automated model for PPD identification [70]. Issues such as privacy, data security, and the potential for biases in the model's predictions need to be thoroughly examined and addressed. Ensuring transparency, fairness, and accountability in developing and deploying such models is essential to maintaining trust among healthcare professionals and the wider public [71].

VI. CONCLUSION

In this study, we have developed an automated model to identify PPD using a deep reinforcement learning approach combined with a DE algorithm for weight initialization. The DE algorithm is renowned for its ability to effectively explore high-dimensional spaces and find optimal weight values, making it well-suited for weight initialization in our model. Our approach utilizes an ANN and treats the PPD classification problem as a policymaking stage-by-stage process. At every stage, the operator acquires samples and employs classifications, while the habitat maintains rewards for every classifying activity. For inspiring precise detection, a greater award is determined for recognizing the minor category. Through a particular compensatory technique and an encouraging learning system, the operator learns and chooses the most effective method for achieving the goals. To evaluate our sample's efficiency, we analyzed a comprehensive set of data obtained from the population-based BASIC study conducted in Uppsala, Sweden, spanning from 2009 to 2018, and comprising 4313 samples. The experiential results were assessed by known analysis criteria, revealing our sample achieved greater precision and correctness, demonstrating its suitability for identifying PPD. These findings carry significant implications for identifying at-risk women and providing timely interventions to improve maternal and child health outcomes.

Reinforcement learning algorithms often face the challenge of striking a balance between exploration and exploitation. Future research can delve deeper into exploring effective strategies for addressing this trade-off in the context of PPD identification. Techniques such as adaptive exploration policies, multi-objective optimization, or

incorporating domain knowledge can help optimize the model's performance in identifying at-risk women while minimizing false positives and negatives. Moreover, investigating the potential of transfer learning and domain adaptation techniques can contribute to improving the generalization capabilities of the PPD identification model. By leveraging knowledge gained from related domains or pre-trained samples, the sample's efficiency can be enhanced when applied to different populations, cultures, or healthcare settings. This research direction can help address the challenges of model generalizability and make the automated PPD identification model more robust.

***Abstract*—With the increasing demand for remote operations and the challenges posed during the COVID-19 pandemic, industries across various sectors, including logistics, manufacturing, and education, have adopted virtual solutions. Cloud-based robot control has emerged as a viable approach for enabling safe remote operation of robots. However, along with the benefits, there are also risks associated with cloud-based robots. In this study, a secure cloud-based robot control system using a blockchain system was developed. The robot utilizes supervisory control to navigate via the internet. The communication system of the robot relies on the ThingsSentral cloud-based IoT platform; enabling communication between the user via a GUI developed using Python Tkinter and the local robot over the internet. To facilitate internet communication, the robot in this study incorporates an ESP32 microcontroller, which provides a low-cost and low-power system capable of connecting to Wi-Fi. However, cloud-based control systems are susceptible to cyberattacks, prompting the use of blockchain cybersecurity in this study to mitigate the risks. The data sent by the supervisor is stored within a private blockchain developed using Python, simultaneously being transmitted to the cloud platform. The developed security system addresses the risks associated with cloud-based robot control systems, such as data tampering and unauthorized misuse, by leveraging the Proof of Work (PoW) and hashing mechanisms.**

Keywords*—Internet of Things (IoT); robot control; cloud computing; cybersecurity; blockchain

I. Introduction

Industries from a variety of sectors have adopted virtual ways of conducting business in these challenging times due to the enormous problems posed by social distance measures. As a result, there is a huge increase in demand for robots that can be operated safely and remotely for practical research in academic settings. The ability to securely and easily control robots from a distance has become possible thanks to cloud-based interconnection, assuring the continuity of hands-on learning experiences [1].

Cloud-based robot control refers to the practice of remotely controlling robots through cloud computing infrastructure. In order to enable effective and scalable control of robotic systems, it includes utilizing the cloud's capabilities and resources [2]. The robot offloads some duties or calculations to the cloud, which can offer improved computational capabilities, storage, and network connectivity, as opposed to merely depending on onboard processing and control systems [3]. Nowadays, autonomous vehicles or cloud-based robots are mostly used in the service sector. There are many different kinds of service robots, including robots for cleaning [4], [5] and housekeeping [6], surveillance [7], entertainment [8], rehabilitation [9], and so forth [10]. In Malaysia, service robots have been widely used in restaurants to deliver food to customers' tables [11].

These days, residential robots are also substantially included in service robots. In smart homes, restaurants, and hospitals, it is crucial [12], [13]. Roombas [14], vacuum cleaners [5], [15], lawnmowers [16], [17], waiter robots [18], security robots, and sentry robots [19], [20] are a few examples of residential robots. Domestic service robots are becoming more and more common because of how convenient they are and how much time they can save homeowners for other things. To improve their usefulness and performance, they frequently make use of cutting-edge sensors, artificial intelligence, and cloud connectivity. Service robots are becoming more and more popular, which will lead to concerns regarding their security.

Because robot systems are networked and rely on software control, guaranteeing cybersecurity is essential in this field. However, because they are primarily focused on other issues, many initiatives fail to take into account how susceptible robot control systems are to cyberattacks. Frequently, projects create their own cloud connections without paying enough attention to security, potentially creating holes in coding frameworks and other parts. Robots are integrated with the Internet as cyber-physical systems, making them vulnerable to different cybersecurity threats like malware, phishing schemes, and illegal access [21]. Businesses and individuals must prioritize cybersecurity precautions, such as using safe passwords, keeping software updated, and utilizing antivirus and anti-malware software, in order to reduce these risks.

Robots that are autonomous and connected to the cloud have the risk of being misused by authorized users in addition to being exploited by hackers. Robots connected to the cloud execute user-issued orders. A security measure needs to be implemented on the robot to ensure that the commands being delivered are coming from the intended user. Blockchain technology can assist in tracking the actions taken in response to commands provided through the system's digital ledger. The technology of blockchain is now gaining a lot of interest and may help with IoT security challenges. Due to its decentralized architecture, ability to provide data immutability, and non-repudiation services, blockchain technology appears to be a

promising approach for securing IoT and protecting user/data privacy.

The advantages of blockchain technology are dependability, security, and efficiency. By limiting access to authorized users, it guarantees the timeliness and accuracy of information for users within a members-only network. A blockchain transaction cannot be changed after it has been recorded, not even by administrators. Time-consuming reconciliations are no longer necessary thanks to the distributed ledger, and smart contracts automate transaction execution [22]. Block-based transactional data is stored in decentralized databases called blockchains. Before being uploaded to the blockchain, each transaction is first checked for accuracy and encrypted by the parties involved or trusted nodes. Depending on the access and encryption methods used, blockchains can be either public or private [23]. There are lots of public blockchain used currently, mainly used in cryptocurrency transactions such as Bitcoin [24] and Ethereum [25] while Hyperledger Fabric [26] is an example of private blockchain.

In this paper, we present a secure cloud-based robot control using blockchain. The robot's control system allows it to navigate toward a designated and specified location while having a security system to prevent cyberattacks such as data breaches and misuse by authorized users. The paper is organized as follows: The next section explains related works on the types of robot control system and cybersecurity of cloud-based robot. The following section presents the steps taken to complete this study, the IoT platform used in this paper (The ThingsSentral), and the development of a supervisory control system. Then, the following section covers the implementation and testing of the cloud-based robot control system, and a performance test analysis of the supervisory control system using blockchain technology. The last section gives the conclusion and future work of the research.

II. Related Works

A. Robot Control Systems

There are numerous ways to control service robots. The control system that is chosen depends on the particular needs of the service robot application for which it is intended. For instance, on-board control systems, LAN control systems, and cloud-based control systems can all be utilized to operate service robots [27]–[29]. The types of control systems and a few instances of their use are presented in Fig. 1.

1) On-board control system: A control system called an on-board control system is one that is built into the robot's hardware. The robot has the ability to operate without external systems. This kind of control system is widely used by autonomous service robots, which are robots that can travel and do tasks on their own thanks to sensors and algorithms. Restaurant robots, cleaning robots, logistic robots, and social robots are a few examples of robots with on-board control systems.

In comparison to cloud-based service robots, on-board control systems can offer real-time reactivity, a high degree of autonomy, less latency or buffering, and better security. To execute the command without error, applications of service robots employing on-board control systems must be controlled without buffer [6], [30]. ROS has some restrictions even though it can be used as an on-board control system. Fully autonomous robots may have several advantages for the user [31], although initial setup may be laborious. The kinematics computation may be aided by the use of coding, such as MATLAB [32], to carry out a command, such as grabbing an object with a robotic arm.

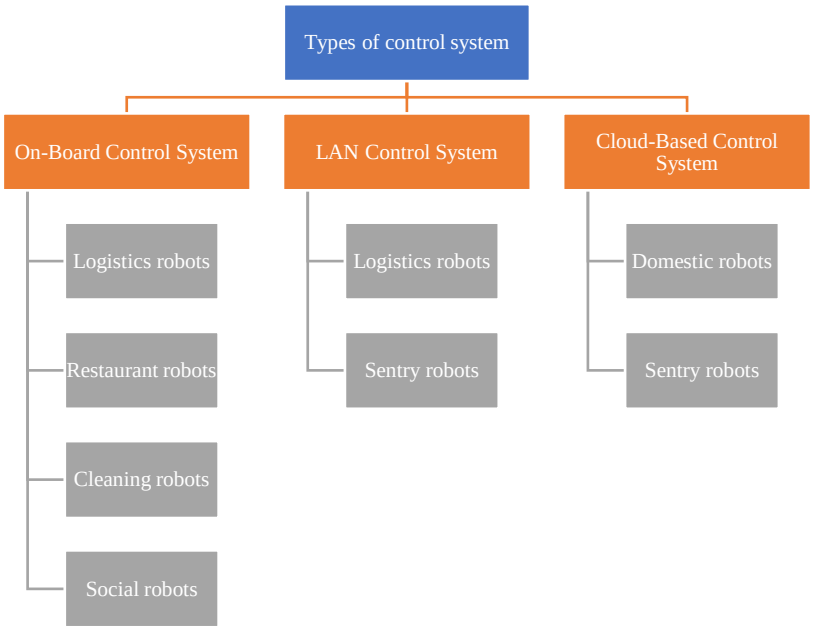

Fig. 1. Types of robot control system.

2) LAN control system: In a LAN (Local Area Network) control system, the robot is connected to a control station or a remote device over a local area network. This approach is frequently used by industrial robots and mapping sentry robots [28]. The robot receives commands from the control station via the LAN and reacts with sensor data and status updates.

LAN management mechanism service robots are machines with remote controls connected to a local network. Due to their connection to a single network, LAN control system service robots may have various benefits over cloud-based and on-board control systems, including reduced latency, high levels of autonomy, and improved security. However, the drawbacks of using LAN to control the service robot are limited external connectivity and unreliable network conditions [33]. This can be avoided by sending data to the server across multi-layered networks or by adding additional relay nodes [34], [35]. This strategy could be laborious, though, as the system's complexity and price will skyrocket.

3) Cloud-based control system: In order to remotely control and manage the behaviour of a service robot, the control system uses cloud computing technology. Domestic robots and sentry robots are a couple of the uses for cloud-based service robots [29]. By fusing the robot's control system with cloud-based servers, this approach enables the robot to quickly access and process enormous amounts of data.

The use of cloud computing in standalone and remotely networked mobile robot systems is the current focus of robotics research. Real-time robot path planning with cloud-based, computationally expensive evolutionary algorithms [36]. Recent studies show that cloud-based control system using IoT platform is increasingly popular. 46 IoT platforms have been described as open, whereas 25 systems are deemed to be open by some research but not by the platforms themselves [37]. In this study, the cloud platform used is The ThingsSentral cloud platform [38]. ThingsSentral is a cloud platform developed by the CAISER research group at the Faculty of Engineering and Built Environment (FKAB), Universiti Kebangsaan Malaysia (UKM).

B. Robot Cybersecurity

Service robot cyber security refers to the safeguarding of service robots against cyberthreats such as malware, hacking, and other cyberattacks. As service robots become more tightly connected to the internet and other devices, the potential of hacks increases [39]. Cyberattacks can take many different forms. DDoS is the most typical [40]. The cloud robot will cease operations if a DDoS attack is launched against its server, which could cause a significant loss [41]. When building service robots [42], secure coding techniques ought to be applied to minimize the risk of vulnerabilities.

1) Authentication: Strong authentication mechanisms should be used to increase the security of service robots [43]. It is essential to make sure that these robots are only accessible to those who are allowed. Passwords, biometric authentication [44], face recognition [45], and other authentication techniques can all be used. Users must supply a legitimate password or passphrase for password-based authentication in order to prove their identity. Biometric identification verifies users by using distinctive biological traits like fingerprints or iris patterns. To authenticate people, face recognition technologies compare and evaluate facial traits. Service robots can build strong security standards, prohibiting unwanted access, and guaranteeing that only authorized users can control and interact with the robots.

2) Encryption: Data encryption is another method to improve the cyber-security of service robots in addition to authentication. Communication between service robots and their control systems should be encrypted to prevent unauthorized data interception [46]. Secure communication technologies that can be used for this include SSL/TLS and VPN. The usage of service robots involves the use of numerous sensors to collect a lot of data, some of which could be sensitive. Through the cloud service, the data is sent to a communication protocol [47]. In order to lower the danger of cyberattacks, data transfer encryption must be robust. Users' sensitive data can be well-protected by using encrypted data.

3) Blockchain: There is only a few research that has been done on cloud-based service robots with blockchain technology as the complexity of the system is high. However, robotics and cloud computing relate highly to one another and are becoming increasingly important as both technologies evolve in the IR4.0 applications. Robotic system management and deployment platforms can be made available by cloud computing. Robotic systems can be centralized handled and watched, allowing for real-time changes and upgrades, by leveraging cloud-based software platforms. Some of these applications are in the domains of smart city and smart industry [48]. Therefore, we can also say that blockchain and cloud computing relate to one another with blockchain and robotics.

Blockchain is used in cloud computing to build decentralized storage solutions that are safe [49]. Blockchain-based storage, in contrast to conventional centralized cloud storage, eliminates single points of failure and potential hacker targets [50]. Blockchain improves security and attack resilience by dispersing data across a decentralized network. Blockchain makes it possible to create secure and open identity management systems in the context of robotics and cloud computing [51]. Users can securely validate their identities when using cloud services through decentralized and tamper-proof records [52], [53]. Blockchain's incorporation into cloud computing provides greater data security, less chances of data tampering, and improved identity verification processes. Fig. 2 shows the basic operation of Blockchain.

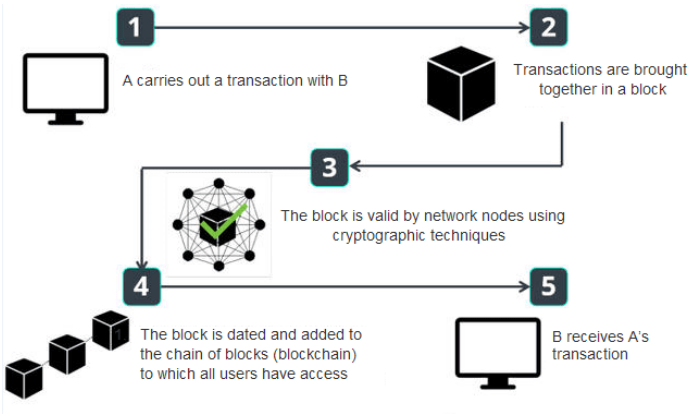

Fig. 2. Basic process of blockchain adopted from (URL:- https://www.centralcharts.com/en/gm/1-learn/1-cryptocurrency/42-trading/699-definition-of-blockchain).

III. Methodology

Fig. 3 depicts the main flowchart of this study. The study begins with the construction of robot using microcontroller, actuators, sensors and power supplies. This study continues with the development of the robot communication system with the cloud platform ThingsSentral. After achieving satisfactory result of the testing of communication system developed, this study continues to the development of GUI control system. The results achieved in this study depend on the GUI developed and also the cybersecurity implemented in this study.

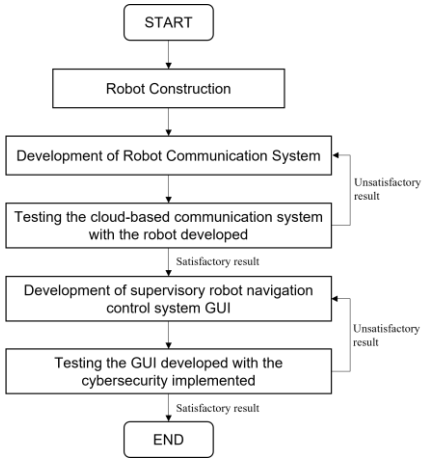

Fig. 3. Flowchart of the study.

A. Development of Robot Communication System

This study uses cloud-based control system as its main communication system. The robot developed, which is located at FKAB, UKM must have the ability to be controlled from a base station located elsewhere. This study uses ThingsSentral cloud platform to send the command from the base station to the robot. The data sent from the supervisor is stored inside the blockchain at the same time it is sent towards the cloud platform. This ensures the command sent by the supervisor as blockchain transactions. Supervisors can also read data from cloud platform such as latest data or distance. The robot reads the data from cloud and sends sensor data to ThingsSentral to be read by the supervisor. Fig. 4 shows the framework of this study.

The software used to develop the communication system between the robot and ThingsSentral cloud platform is Arduino IDE and Python. Both the Arduino IDE and Python software communicate to ThingsSentral web application using Web API. Fig. 5 shows the ThingsSentral web application that was used in this study.

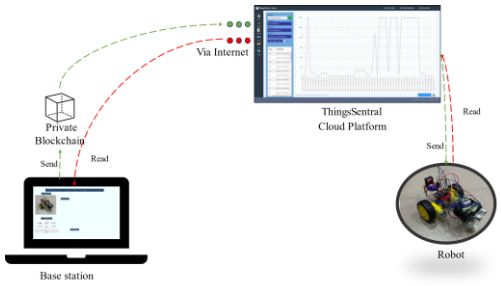

Fig. 4. Framework of the study.

Fig. 5. ThingsSentral web application.

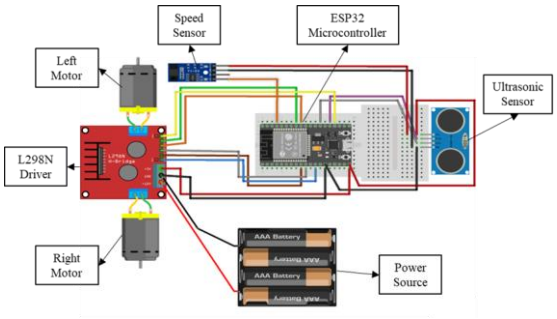

Fig. 6. Schematic diagram of robot.

The robot developed in this study relies on batteries or direct current as its primary power source. The batteries supply power to activate the motors, which are connected to the tires, microcontroller, and sensors. The microcontroller chosen for this research is the ESP32, which utilizes program memory and data memory to store commands and data. Fig. 6 illustrates the schematic diagram of the robot utilized in this study, featuring the ESP32 microcontroller, actuators, and sensors such as ultrasonic and speed sensors. For communication between the robot and the user as a supervisory control system, the ThingsSentral platform is employed. This cloud-based control system allows the robot to be moved remotely and wirelessly. To facilitate control over the robot, a web GUI application has been developed using Python software. This application enables the user to control the robot's actuators and obtain real-time sensor data from the robot.

The data exchange between the ESP32 microcontroller and the cloud platform ThingsSentral is facilitated through an intermediary platform—a GUI developed using Python. This communication system allows for the sending and receiving of data via ThingsSentral. The adoption of cloud-based control systems for service robots is dependent on the specific requirements and constraints of each application. ThingsSentral offers a security system to users, ensuring that the communication mechanism between the user and the robot can be safely controlled without the risk of unauthorized manipulation by attackers.

Moreover, ThingsSentral enables users to control the developed robots over a different network. This means that the robot can be operated from various locations, regardless of the user's distance, as long as there is a stable internet connection [54]. In this study, a cloud platform is essential for the communication system between the robot and the controller because it provides a dedicated static IP address for sending and receiving user data. This differs from a local area network (LAN) control system, as the robot requires its own IP address to ensure proper functioning of the communication system when a cloud platform is not available to assign the IP address. However, it is important to note that the availability of static IP addresses for the robot is limited, which presents some limitations to this solution.

Cloud-based control systems offer numerous advantages, but they also come with drawbacks, including latency and dependence on external networks. The focus of this study is on addressing the security and privacy concerns associated with such systems. While ThingsSentral provides a security system for users, it is still susceptible to misuse by authorized individuals. Hence, the objective of this study is to develop a cybersecurity system to prevent the misuse of the control system by authorized users. In this study, the chosen cybersecurity solution is Blockchain. The reason for selecting Blockchain is its inherent immutability and permanence. Transactions recorded in a Blockchain system cannot be altered or deleted, as they are permanently stored within the system. This ensures the accuracy of every transaction, and users are unable to assign blame to other parties for commands issued by themselves. By leveraging Blockchain, the study aims to enhance the security and integrity of the control system.

B. Secure Cloud-based Robot Control Implementation and Testing

Fig. 7 illustrates the robot prototype utilized in this study, which was developed based on the schematic diagram depicted in Fig. 6. The communication of data is facilitated through the ESP32 microcontroller, serving as the processor for communication between the robot and the ThingsSentral cloud platform. The robot itself is equipped with two tires, each connected to a DC motor, an L298N driver responsible for motor direction control, sensors including an encoder and an ultrasonic sensor, and AA batteries serving as the power source. The microcontroller handles the reading and sending of data to the ThingsSentral web application. To enable this transmission, an intermediary (API) is required to establish a connection between the gateway and the internet.

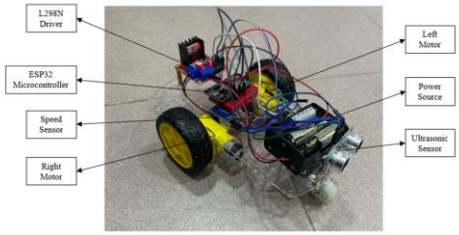

Fig. 7. Robot prototype used in this study.

In this study, HTTP protocols are utilized for both data transfer and data ingestion from ThingsSentral. The sensor nodes receive the transmitted data, which includes the distance measured by the ultrasonic sensor and the motor speed obtained from the encoder. The Arduino IDE software is employed to facilitate data transmission from the sensor nodes to the ThingsSentral cloud platform, as the data is stored within the ESP32 microcontroller. Through programming, the data collected by the sensor nodes can be transmitted to ThingsSentral using URLs and internet networks.

C. Development of Supervisory Control System GUI

Fig. 8 showcases the developed supervisory control system created using Python Tkinter in this study. The graphical user interface (GUI) includes buttons that have been programmed to transmit data values to ThingsSentral, which serve as instructions to control the robot's motors. For example, when the "Stop" button is pressed, it sends a command value of 0. Each motor will be assigned a value of 0 and 1 depending on the state of the motor after the command value is sent. This command value is then utilized by the ESP32 microcontroller to instruct the motors to halt the robot's movement. Each button on the GUI corresponds to a different command value, enabling control over the robot's navigation.

Furthermore, in addition to the buttons used to send command values for robot navigation, the developed GUI also displays the most recent sensor readings obtained from the node sensor via the ThingsSentral cloud platform. The node sensor, located at the bottom right of Fig. 8, represents the ultrasonic sensor. To obtain and display the latest sensor reading, the HTTP Get protocol is employed to retrieve data from ThingsSentral. The ultrasonic reading provides information to the user regarding the distance between the

robot and any obstacles in front of it. An example of the value sent by the GUI to the ThingsSentral cloud platform is presented in Table I.

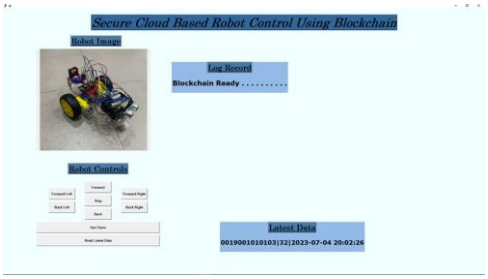

Fig. 8. Supervisory control system.

IV. Results and Discussion

A. Results

The timestamp provided in Table I depicts when the command value was received by ThingsSentral cloud platform. However, the time may differ from when the command value was sent by the supervisory GUI as buffer is present when controlling the robot through cloud-based control system. The difference in time depends on factors such as internet speed and the load sent by the GUI. Additionally, Fig. 9 presents a graphical representation of the command values for each motor plotted against the timestamp.

After successfully testing the supervisory control system's performance, the security of the robot control system underwent evaluation. Employing Python's hashlib module, this study crafted a blockchain system. The command payload from the supervisory control system is incorporated into a block generated by the module. This block includes an index indicating its position in the chain, the block's hash, the timestamp of the sent payload, the payload data specifying the robot's movement command, proof of work, and the previous block's hash. Utilizing the SHA-256 algorithm in the hashlib module, the block's validity, determined by its hash, proof of work, and the previous block's hash, is verified.

TABLE I. Command Value of each Motor

#	Desired Navigation	Command Value	Left Motor	Right Motor	Timestamp
1	Stop	0	0	0	28/6/2023 17:11:24
2	Forward	1	1	1	28/6/2023 17:11:26
3	Forward Left	5	0	1	28/6/2023 17:11:28
4	Forward	1	1	1	28/6/2023 17:11:30
5	Stop	0	0	0	28/6/2023 17:11:32
6	Backward Right	4	-1	0	28/6/2023 17:11:34
7	Backward	2	-1	-1	28/6/2023 17:11:37
8	Stop	0	0	0	28/6/2023 17:11:39
9	Forward Right	3	1	0	28/6/2023 17:11:47
10	Stop	0	0	0	28/6/2023 17:11:50

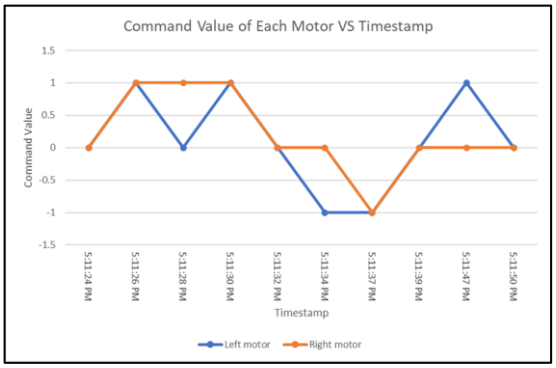

Fig. 9. Graph of command value of each motor Vs timestamp.

The GUI allows for the display of the chain by pressing the "Get Chain" button, as depicted in Fig. 10. The chain is presented on the right side of the GUI, showcasing the total length of the chain and listing the blocks. Each block includes information such as the index number, timestamp, payload (determined by the button pressed to navigate the robot), PoW, and the previous hash. The latest data on the bottom right of Fig. 10 indicates the latest ultrasonic data read from ThingsSentral cloud platform. This data depicts the distance between the robot and an obstacle in front of it.

Fig. 10. Blockchain system in this study.

B. Discussion

The supervisory control system, developed using Python software, is connected to the ESP32 microcontroller through programmed code using Arduino. This connection is facilitated by making ThingsSentral serve as an intermediary. The control system sends data to the cloud, which is then read by the robot via the microcontroller to execute the issued commands. The value of the data sent by the GUI determines the direction of the robot's navigation, instructing the motor driver to activate the robot's motors. The communication of data between the robot and the ThingsSentral cloud platform is achieved using the HTTP GET protocol. Upon receiving the command value, the ESP32 utilizes it as an instruction to engage the motor driver, which controls the robot's movement by directing the motor's speed and rotational direction.

Every command value corresponds to a specific action for the motors, determining the robot's movement or halt according to the intended navigation. For example, if the supervisor instructs the robot to move forward, each motor will be assigned a value between 0 and 1, depending on the desired direction. A positive value indicates forward movement, while a negative value signifies backward motion. Table I provides

an overview of the command values assigned to each motor based on the desired navigation.

The security system developed in this study is based on Blockchain technology. Blockchain offers data tampering and breach prevention mechanisms through its Proof of Work (PoW) and hashing mechanisms. PoW serves as a consensus mechanism in Blockchain networks, creating a robust barrier against data breaches. To modify a block within the blockchain, an attacker would need to alter the block's contents and recalculate the hash, which is computationally expensive and time-consuming due to PoW. Additionally, rewriting the entire blockchain would require an attacker to possess the majority of the network's computational power, making it highly improbable.

The blockchain system developed in this study utilizes the hashlib module in Python software. This module provides a universal interface for various secure cryptographic hash and message digest algorithms. Each hash algorithm has its designated constructor method, creating a hash object with a straightforward interface. The hashlib module supports several hash algorithms, including Secure Hash Algorithm 1 (SHA-1), SHA-224, SHA-256, SHA-384, SHA-512, and MD5. These functions generate fixed-size hash values, known as the hash value or digest, based on the input data they receive.

V. Conclusion

This research presents the development of a secure cloud-based robot control system incorporating blockchain technology. Utilizing an ESP32 microcontroller and Wi-Fi connectivity to ThingsSentral, the robot aims to navigate specific desired locations through a cloud-based control system. The implementation involves Python Tkinter for a user-friendly GUI with dedicated buttons, serving as controllers for robot navigation. The GUI facilitates data transmission to the microcontroller via ThingsSentral, serving as an intermediary cloud platform. However, inherent risks of data tampering and misuse in cloud-based control systems are acknowledged. To counter these concerns, the study introduces a blockchain security system, leveraging hashing, Proof of Work (PoW), and transaction records. Through these mechanisms, the study aims to mitigate the identified risks and enhance overall cybersecurity in the cloud-based robot control system. While this study provides valuable insights, limitations include exclusive use of private blockchain technology visible only to certain organization members, raising concerns about potential transaction payload changes that may impact user confidence in system security. Future research may explore leveraging public blockchains like Ethereum for enhanced transaction verification, offering transparency and validation through universal observation by a diverse user base.

Acknowledgment

The authors would like to thank Universiti Kebangsaan Malaysia for supporting this research. We would also like to thank the Faculty of Engineering and Built Environment and the Institute of IR4.0, UKM for providing the research facilities.

An Edge Computing-based Handgun and Knife Detection Method in IoT Video Surveillance Systems

Haibo Liu, Zhubing HU*
Department of Electrical and Electronics Engineering, Hebei Petroleum University of Technology, Chengde 067000, China

***Abstract*—Real-time handgun and knife detection on edge devices within the Internet of Things (IoT) video surveillance systems hold paramount importance in ensuring public safety and security. Numerous methods have been explored for handgun and knife detection in video-based surveillance systems, with deep learning-based approaches demonstrating superior accuracy compared to other methods. However, the current research challenge lies in achieving high accuracy rates while managing the computational demands to meet real-time requirements. This paper proposes a solution by introducing a single-stage convolutional neural network (CNN) model tailored to address this challenge. The proposed method is developed using a custom dataset, encompassing model generation, training, validation, and testing phases. Extensive experiments and performance evaluations substantiate the efficacy of the proposed approach, which achieves remarkable accuracy results, thus showcasing its potential for enhancing real-time handgun and knife and knife detection capabilities in IoT-based video surveillance systems.**

***Keywords*—Real-time detection; handgun and knife detection; edge devices; IoT video surveillance; deep learning; convolutional neural network**

I. Introduction

Video Surveillance Systems (VSS) have gained tremendous significance in various domains due to their ability to monitor and analyze activities in real-time [1, 2]. With the advent of the Internet of Things (IoT), these surveillance systems have become even more versatile and effective [3]. The integration of IoT technology into video surveillance systems has opened up new avenues for efficient data collection, analysis, and decision-making in diverse applications ranging from security and safety to healthcare and industrial automation [4, 5].

In the realm of IoT-based video surveillance, a pivotal role is played by edge computing devices [6]. These devices, situated at the edge of the network, are responsible for processing data closer to the data source, thereby reducing latency, conserving bandwidth, and enabling real-time analytics [7]. Edge computing enhances the capabilities of IoT video surveillance systems by enabling rapid data processing and timely response to detected events.

One specific and critical application in this context is real-time detection on edge devices [8]. The ability to detect firearms in real time has significant implications for enhancing public safety and security measures [9, 10]. Achieving accurate and rapid handgun detection on edge devices requires sophisticated methods that can handle the computational constraints posed by these devices while maintaining high levels of accuracy.

Deep learning-based approaches have garnered substantial attention in the realm of real-time handgun detection due to their remarkable capabilities in handling complex visual patterns and achieving high accuracy [11, 12]. These methods utilize deep neural networks to automatically learn intricate features from images and videos, thus enabling accurate object detection tasks [13]. This has led to a surge in research efforts exploring deep learning-based methodologies for real-time handgun detection compared to traditional methods.

Despite the advancements, there exist certain limitations and research challenges in the realm of deep learning-based approaches for handgun detection [14]. Pursuing high accuracy while maintaining real-time performance demands innovative solutions [15, 16]. Addressing these challenges necessitates further investigation and exploration of novel methodologies to ensure the efficacy of real-time handgun detection systems.

In this study, we propose a deep learning method utilizing single-stage convolutional neural network (CNN) architecture to address the requirements of handgun detection. The adopted deep learning approach is justified by its ability to balance accuracy and real-time constraints, making it a promising candidate for the addressed research challenge. The proposed model is trained, validated, and tested using a custom dataset, allowing for robust evaluation of its performance.

This research contributes to the field in three key ways. Firstly, a custom dataset is generated specifically designed for the challenge of handgun detection. Secondly, an efficient deep-learning method is proposed for accurate and real-time handgun detection on edge devices. Lastly, extensive experiments and performance evaluations are conducted to validate the effectiveness of the proposed method, shedding light on its potential contributions to the domain of IoT-based video surveillance and public safety.

II. Related Work

The author in [11] presented a method for automatic handgun detection using deep learning in video surveillance images. The approach involves training a deep neural network on a labeled dataset of surveillance images containing handguns. The network utilizes convolutional layers to extract features and make predictions. The method achieves promising results in detecting handguns in real-time video streams. However, there are some limitations to consider. The accuracy of detection can be influenced by variations in lighting, object occlusions, and different camera angles. Additionally, the

model's performance might degrade when faced with new environments or different handgun types not well-represented in the training data. Further research is needed to enhance the robustness of the method and address these challenges effectively.

The paper in [17] introduced a technique for handgun detection using human pose information. The method involves utilizing pose estimation models to extract key human joint positions from images. By analyzing the spatial relationships between these joints, potential handguns can be identified. The approach demonstrates effectiveness in identifying handguns in various poses. However, limitations include potential false positives due to similar joint configurations and the reliance on accurate pose estimation, which may suffer in challenging scenarios such as low-resolution or occluded images. Further refinement of the method and addressing these limitations are essential for real-world application.

The paper in [18] presented TYOLOV5, a real-time handgun detection system for videos based on quasi-recurrent neural networks. The method integrates YOLOv5 architecture with temporal information to enhance detection accuracy. It successfully detects handguns in video streams, but it may face challenges with complex backgrounds and rapid motion, leading to false positives or missed detections. Further improvements are needed to optimize its performance in dynamic scenarios and mitigate limitations related to occlusions and varying lighting conditions.

The author in [19] focused on enhancing handgun detection by combining visual features with body pose-based data. The method involves extracting both appearance-based features and human body joint positions from images. By integrating these features, the detection algorithm achieves improved accuracy in identifying handguns. However, challenges like limited effectiveness in cases of occlusion and varying poses, as well as potential false positives from similar joint configurations, need to be addressed for robust real-world deployment.

The author in [20] presented the CCTV-Gun benchmark for handgun detection in CCTV images. The method involves curating a dataset with labeled images containing handguns to assess detection algorithms. Various state-of-the-art models are evaluated using this benchmark, demonstrating their effectiveness. However, limitations include potential biases in the dataset and a focus on handguns only, neglecting other potential threats. To address these limitations, future work should encompass a more diverse range of objects and consider broader contextual factors to ensure comprehensive video surveillance.

The paper in [13] introduced a deep-learning framework for handgun and knife detection using edge devices with indoor video surveillance cameras. The method employs a neural network model optimized for edge computing to identify handguns and knives. While achieving real-time detection, limitations arise from potential constraints of edge devices, such as limited processing power and memory. Additionally, the model's performance might be affected by variations in lighting conditions and camera angles, warranting further research to enhance robustness and adaptability to diverse scenarios.

III. Research Methodology

A. Dataset Preparation

The dataset creation process involves two distinct variations: augmented and non-augmented. Augmentation entails the application of transformations such as rotation, scaling, and flips to the original images. These alterations expand the dataset's diversity and complexity, enabling the model to comprehend a broader array of scenarios. Rotation introduces images from various angles, scaling accounts for size variations, and flips reflect different orientations. Rotation is one of the key augmentation techniques, and it entails rotating the original images at different angles. This introduces images from various perspectives, allowing the model to learn from different viewpoints and orientations. For example, in a dataset of handwritten digits, rotating the images can help the model recognize numbers written at various angles, just like how humans can read numbers whether they are upside down or sideways. This augmentation enriches the dataset by simulating real-world variability, enhancing the model's adaptability when confronted with novel situations. Scaling, another important augmentation technique, takes care of size variations. This means resizing the images to different scales, which can simulate scenarios where objects appear closer or farther away in the real world. For instance, in an image dataset for object recognition, scaling can help the model recognize objects that are either close up or in the distance.

Flips are yet another augmentation technique and involve creating mirror images or reversing the orientation of the original images. This mimics situations where an object or scene is seen from a different perspective or orientation. For instance, in image recognition for self-driving cars, flips can help the model adapt to objects that are seen in the rearview mirror or through the side mirrors

As shown in Table I, in terms of dataset composition, it adheres to a structured distribution of 70-20-10, allocated for training, validation, and testing, respectively. This distribution is strategically designed to ensure that the model learns extensively, validates its performance, and rigorously tests its capabilities. With 70% of the data devoted to training, the model grasps underlying patterns and learns to recognize handguns and knives under differing conditions. The 20% validation subset enables performance evaluation during training, allowing fine-tuning and parameter adjustment. Lastly, the 10% testing fraction evaluates the model's generalization on entirely new, unseen data, objectively assessing its practical applicability.

Incorporating these assumptions into the broader context underscores the importance of assembling a dataset that encapsulates the intricacies of real-world scenarios. The diversity of images featuring handguns and knives, captured from multiple angles, lighting settings, and backgrounds, emulates the complexity of actual situations. To empower the model for precise detection and classification, annotations encompass bounding box coordinates and class labels. This information equips the model to not only identify the presence of handguns and knives but also understand their spatial arrangement within the images. The combination of data augmentation techniques, well-structured dataset distribution,

and comprehensive annotations collectively fortifies the model's ability to generalize effectively, paving the way for robust performance across diverse real-world settings.

B. YOLO-based Model Setup

Fig. 1 shows the structure of the proposed method. As shown in Fig 1, the YOLO-based handgun and knife detection models are configured by adapting key parameters in the model's architecture and hyperparameters. This involves selecting the appropriate YOLO variant or backbone, setting the number of classes to 2 for handguns and knives, and specifying a consistent input image size of 416x416 pixels. Anchor box sizes are tailored based on object statistics, enhancing object localization accuracy. Hyperparameters like learning rate, weight decay, and loss function weights are meticulously fine-tuned through iterative experimentation to optimize accuracy while accounting for computational efficiency. Table II shows the model configuration for Yolo-based models in the proposed method.

TABLE I. NO AUGMENTED IMAGES IN A DATASET

Number of Images	Train (70%)	Valid (20%)	Test (10%)
965	676	193	96

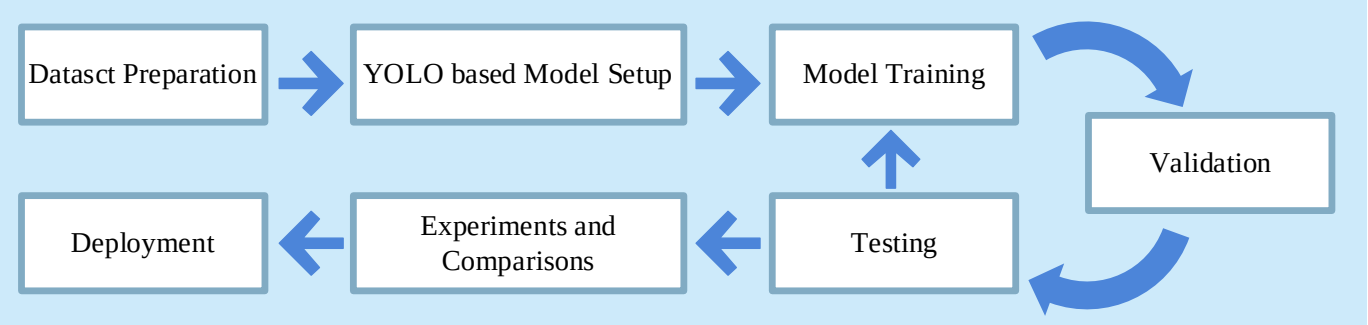

Fig. 1. The structure of the proposed method.

TABLE II. MODEL CONFIGURATION IN THE PROPOSED METHOD

```
model:
  # Choose an appropriate variant: 'n'
  type: YOLOv5  # Or CSPDarknet53 for backbone
nc: 2  # Number of classes: handguns and knives
# Input image size
img_size: 416
# Anchors - Adapt these based on your dataset statistics
anchors:
  - [10,13, 16,30, 33,23]
  - [30,61, 62,45, 59,119]
  - [116,90, 156,198, 373,326]
# Hyperparameters - Fine-tune these based on experimentation
hyp:
  lr0: 0.001  # Initial learning rate
  lrf: 0.2  # Learning rate reduction factor
  momentum: 0.937  # SGD momentum
  weight_decay: 0.0005  # Weight decay
  giou: 0.05  # GIoU loss weight
  cls: 0.58  # Classification loss weight
  cls_pw: 1.0
  obj: 1.0
  obj_pw: 1.0
  iou_t: 0.20  # IOU threshold for objectness loss
  anchor_t: 4.0  # Anchor-multiple threshold
  fl_gamma: 0.0  # Focal loss gamma
  hsv_h: 0.0138
  hsv_s: 0.678
  hsv_v: 0.36
```

As shown in Table II, in the YOLOv5 configuration, the model type is specified by the type parameter, which can be 'YOLOv5' or 'CSPDarknet53', determining the core architecture and feature extractor. The nc parameter sets the number of classes, denoting handguns and knives, while img_size standardizes input image dimensions at 416x416 pixels. The anchors parameter encompasses anchor box sets, vital for object localization, and should be adapted to object aspect ratios and scales. The hyperparameters, central to model optimization, include lr0 for the initial learning rate, lrf for learning rate reduction, momentum for optimization acceleration, and weight_decay for regularization. Parameters like giou, cls, and obj influence loss functions, while iou_t and anchor_t dictate object detection thresholds. Fine-tuning factors like cls_pw, obj_pw, and fl_gamma, along with hsv_h, hsv_s, and hsv_v for augmentation, are also pivotal. It's crucial to iteratively fine-tune these parameters based on experimentation and evaluation to strike the right balance between accuracy and computational efficiency in the context of handgun and knife detection using YOLO models.

C. Training

Training a YOLOv5 model for handgun and knife detection involves several crucial stages that collectively contribute to its accuracy and adaptability. Firstly, during the data loading and augmentation phase, the model's script meticulously processes images and annotations sourced from the training dataset. Augmentation techniques, encompassing random rotations, scaling, flips, and color adjustments, are strategically applied. This augmentation strategy enhances the model's robustness, allowing it to handle a diverse array of real-world scenarios. By exposing the model to a wider range of training examples through augmentation, it gains the capacity to discern objects across varying angles, scales, and lighting conditions.

Subsequently, in the loss calculation step, the model embarks on each training iteration by predicting bounding box coordinates and class probabilities for every object within the images. The pivotal loss function comes into play, which amalgamates crucial components, including localization loss (measured by the Generalized Intersection over Union or GIoU metric), objectness loss, and classification loss. This calculated loss acts as a gauge of the dissimilarity between the model's predictions and the factual annotations, thereby steering the optimization process toward convergence. The calculated losses provide feedback that guides the model in adjusting its internal parameters to align with ground truth annotations more accurately.

As the training unfolds, the process of backpropagation and optimization plays a central role. The computed loss is propagated backward through the model's layers, influencing the gradient updates of the model's weights and biases. The optimization method employed here is stochastic gradient descent (SGD), a foundational algorithm in machine learning. The learning rate and momentum parameters within the optimization process directly impact the extent of weight updates, influencing the model's capacity to navigate the optimization landscape. Furthermore, to finely tune the training procedure, learning rate scheduling is introduced. By incorporating the lr0 parameter and the reduction factor lrf, the learning rate gradually diminishes across training epochs. This dynamic learning rate adjustment facilitates a controlled convergence process, enhancing the accuracy and precision of the model's predictions.

D. Validation and Testing

Validation and testing are essential steps in generating accurate models for handgun and knife detection using the YOLO models. These phases ensure that the trained models not only perform well on the training data but also generalize effectively to unseen scenarios.

During the validation phase, a separate subset of the dataset is used to assess the model's performance as it undergoes training. This helps prevent overfitting, where the model becomes overly specialized to the training data and struggles to perform on new data. The validation dataset consists of images the model hasn't seen before, and the annotations for these images are used to evaluate the model's predictions. By comparing the predicted bounding box coordinates and class probabilities to the ground truth annotations, metrics such as mean average precision (mAP) are calculated. mAP quantifies the model's accuracy across different object categories and various confidence thresholds. This validation process aids in fine-tuning hyperparameters, adjusting learning rates, and making decisions on model checkpoints that offer the best trade-off between precision and recall.

The testing phase evaluates the model's performance on entirely new and unseen data, further confirming its generalization capabilities. A distinct testing dataset is used to assess how well the model can detect handguns and knives in real-world scenarios it has not encountered during training or validation. Similar to validation, the model's predictions are compared to the ground truth annotations to calculate metrics like mAP, offering insights into the model's accuracy on unfamiliar data. Testing validates the model's readiness for real-world deployment and gives an indication of how well it will perform in live environments.

IV. Results And Discussion

This section presents the visual representation of our experimental results and performance evaluation. Fig. 2 demonstrates a visual representation of our experimental results for Yolo models. Moreover, for performance evaluation, standards performance evaluation metrics, including precision, recall, and F- score, are employed inspired by [21, 22]. The details of performance evaluation are discussed in the following sections.

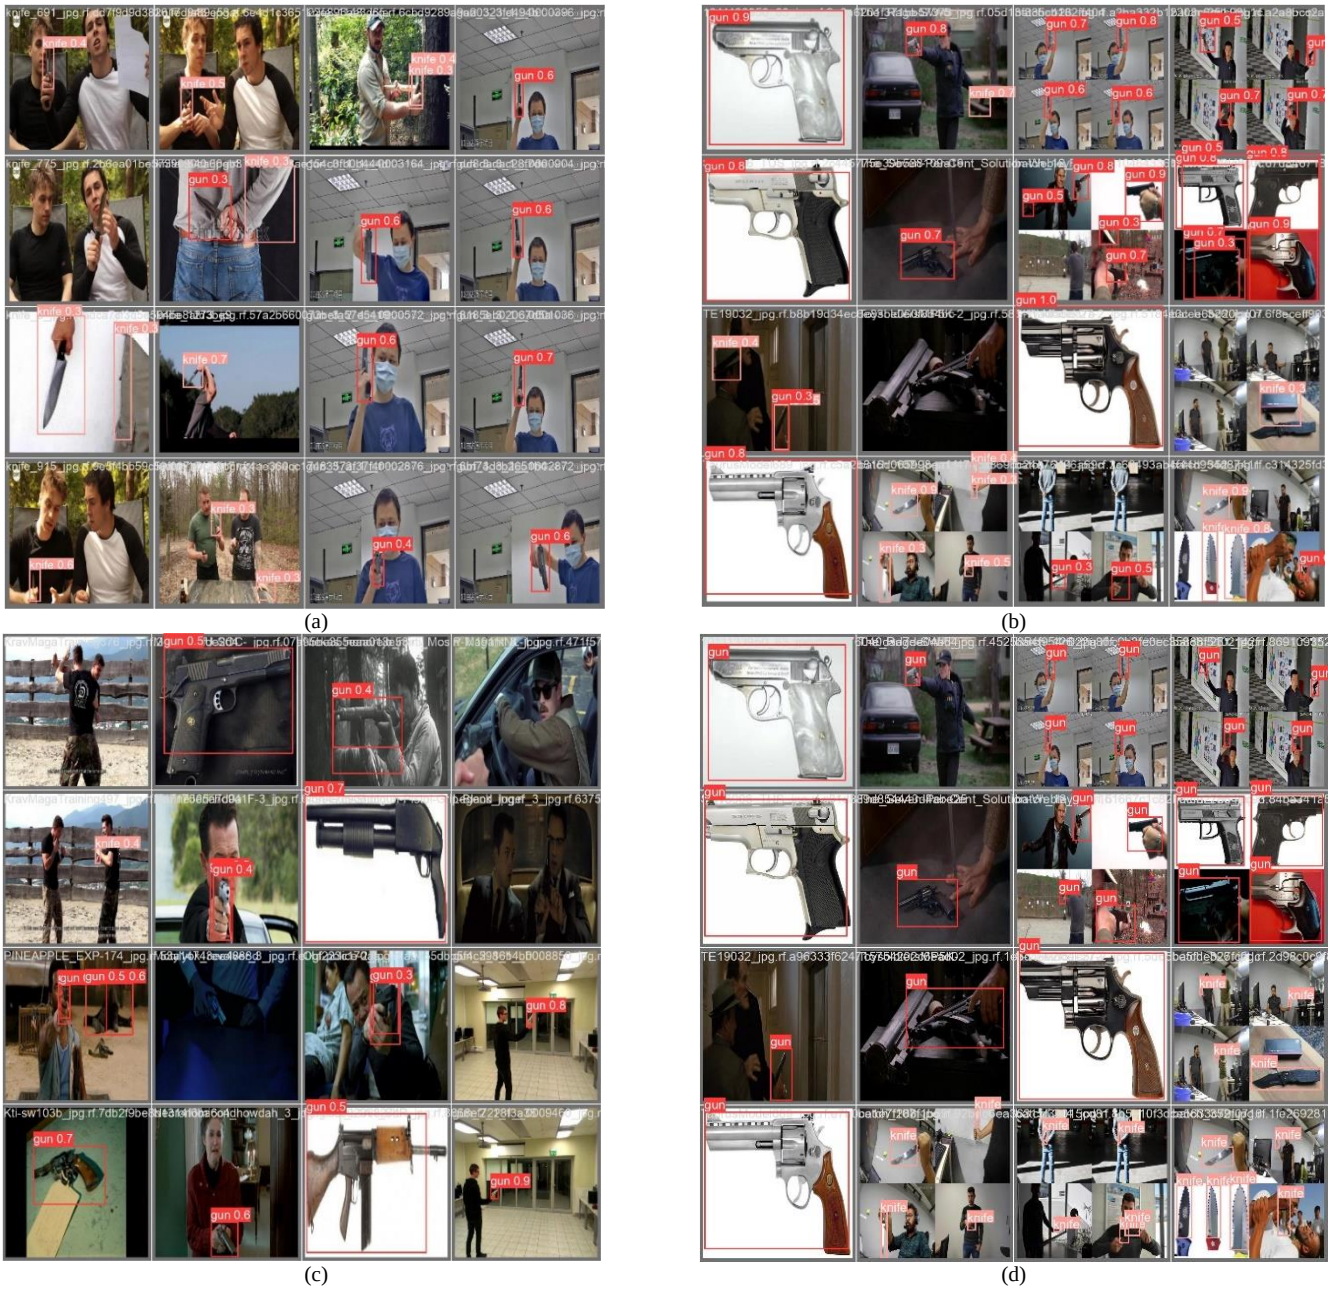

Fig. 2. Visual illustration of experimental results, (a): YOLOv5n-no-aug, (b): YOLOv5n-aug, (c): YOLOv8n-no-aug, (d): YOLOv8n-aug.

V. Performance Evaluations

A. Performance Evaluations of YOLOv5n with No Augmentation Results

In this study, we first employed the YOLOv5 model for the specific task of handgun and knife detection. Notably, we chose to conduct our experiments without incorporating any data augmentation techniques into the dataset. This decision was made to assess the inherent capability of the model without any external modifications to the training data. After training, we rigorously evaluated the model's performance using standard metrics such as precision, recall, and F1-score. These metrics provide a comprehensive view of the model's ability to correctly identify instances of handguns and knives in the test dataset. The absence of augmentation allowed us to directly gauge the model's performance on the original dataset, shedding light on its raw detection capabilities and potential strengths or weaknesses. Fig. 3 shows the results of the performance evaluation of the generated YoloV5 model with no augmentation.

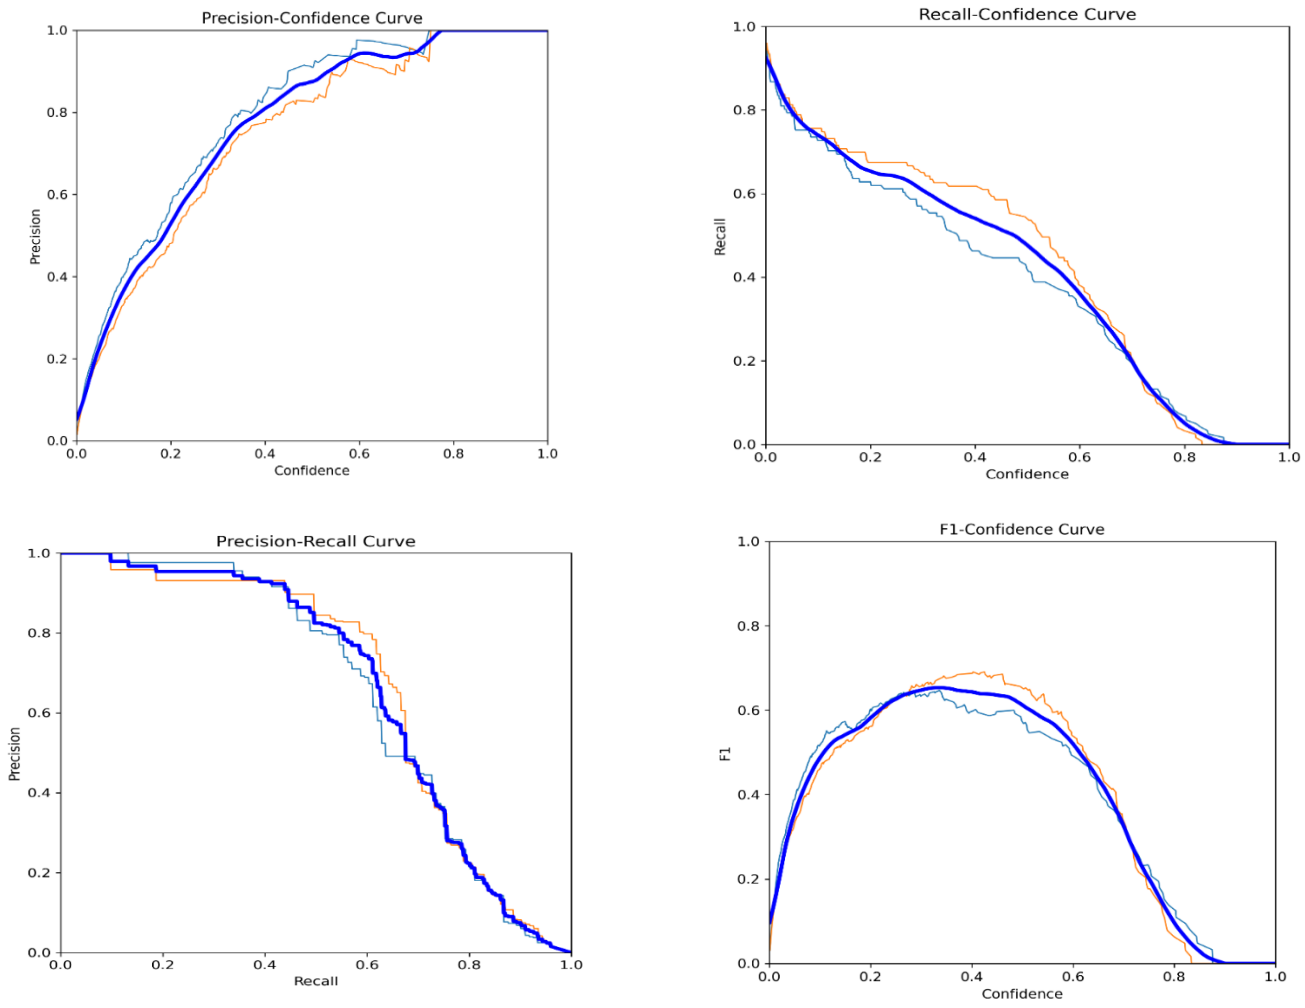

Fig. 3. The result of YOLOv5n on no-augmented dataset.

As depicted in Fig. 3, the evaluation of our YOLOv5 model using precision, recall, PR-curve, and F1-score has provided insightful results that showcase its effectiveness, even in the absence of data augmentation. The average precision (P-curve) of 0.77 for gun detection and 0.92 for knife detection suggests that the model is capable of correctly identifying a significant portion of relevant instances within these classes. Similarly, the high average recall (R-curve) of 0.65 indicates the model's proficiency in capturing a considerable proportion of actual positives within the dataset.

The PR-curve, with an average value of 0.66, illustrates a balanced trade-off between precision and recall. This implies that the model strikes a commendable equilibrium between minimizing false positives and maximizing true positives. Moreover, the F1-score of 0.65 signifies a harmonious blend of precision and recall, indicating the model's strong performance in terms of both accuracy and completeness.

Considering these metrics collectively, the YOLOv5 model demonstrates its reliability and suitability for real-time applications. Despite the absence of data augmentation, the model maintains a consistent and respectable level of performance across multiple evaluation criteria. The high recall values suggest that the model effectively captures instances of handguns and knives, essential for accurate detection in scenarios where prompt identification is critical. Furthermore, the balanced PR-curve and F1-score underscore the model's potential for reliable and precise detection, making it a promising candidate for real-time applications where accurate and swift identification of these objects is paramount.

B. Performance Evaluations YOLOv5n with Augmentation Results

Secondly, we developed a YOLOv5 model for handgun and knife detection. Through dataset augmentation, we diversified the training data with rotations, scaling, and flips. This improved the model's adaptability to real-world scenarios. We evaluated the model using precision, recall, and F1-score, highlighting its capacity to identify instances accurately. The augmentation-enhanced model showcases potential for effective real-time applications, addressing dataset limitations and fostering improved detection performance.

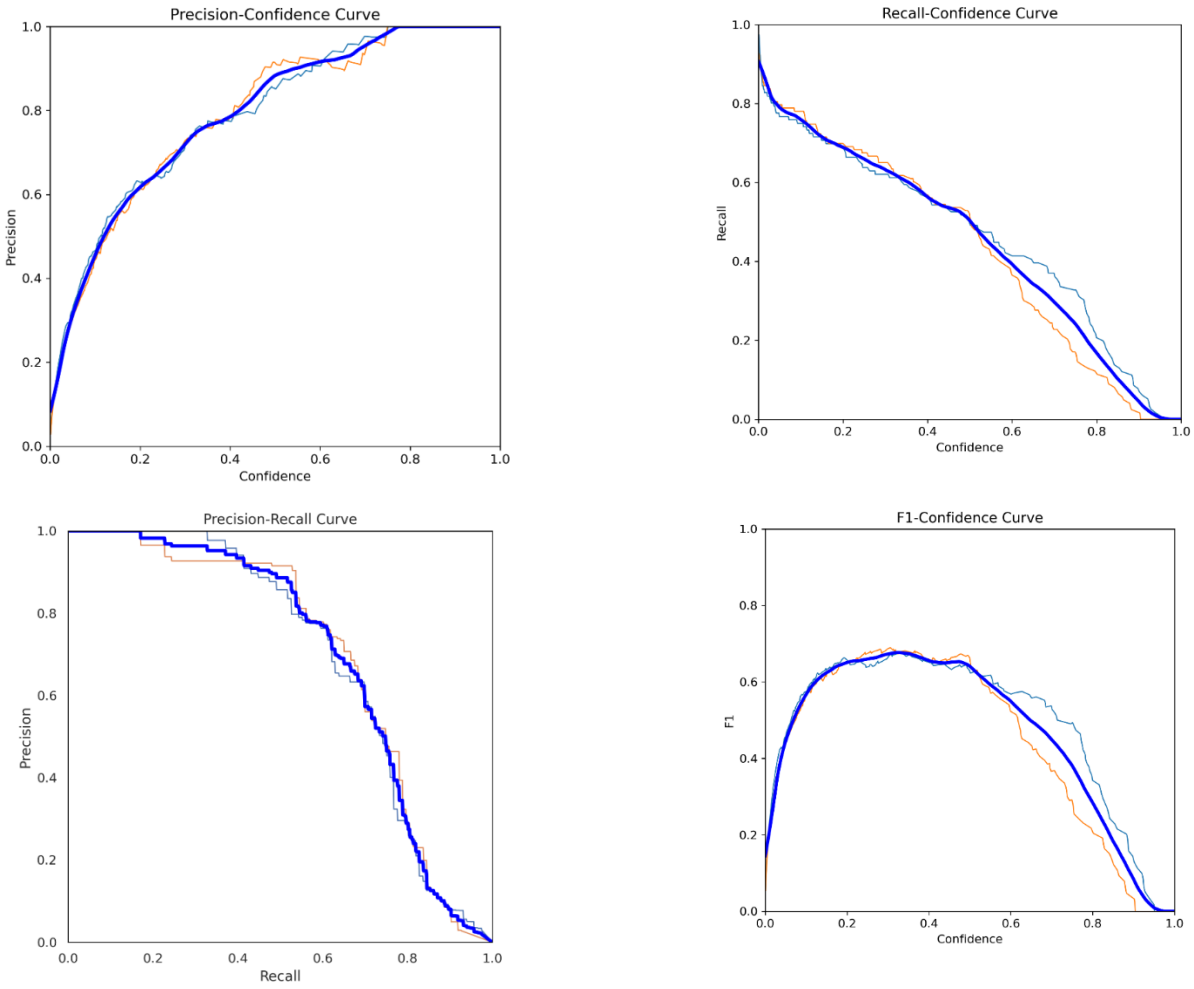

Fig. 4. The result of YOLOv5n on the augmented dataset.

As illustrated in Fig. 4, the evaluation results of the YOLOv5 model for handgun and knife detection, enriched with dataset augmentation, highlight its improved performance compared to the version without augmentation. The higher average precision values of 0.77 for gun and 0.91 for knife detection imply that the augmented model excels in correctly pinpointing instances of these objects. Moreover, the substantial average recall of 0.69 underscores its proficiency in capturing a noteworthy portion of actual positives within the dataset.

The PR-curve's average value of 0.69 signifies that the model effectively balances precision and recall, indicating its capacity to minimize false positives while maximizing true positives. This indicates the model's heightened accuracy in distinguishing relevant instances from the background. The F1-score of 0.68, combining precision and recall, reflects the model's improved overall performance and ability to harmonize between precise detection and comprehensive coverage.

These enhanced metrics collectively demonstrate that the augmented model presents a substantial advancement. Augmentation has expanded the model's understanding of different object appearances and contexts, enabling it to generalize better to unseen scenarios. This has led to heightened accuracy in identifying handguns and knives. Consequently, the augmented YOLOv5 model holds greater potential for real-time applications, where the improved precision, recall, and balanced performance make it a more reliable tool for swift and accurate object detection in dynamic environments.

C. Performance Evaluations YOLOv8n with No Augmentation Results

Thirdly, we developed a YOLOv8n model specifically designed for the detection of handguns and knives. Notably, our experimentation followed a no-augmentation approach, where the dataset remained unaltered. We aimed to evaluate the model's performance in its raw form without the influence of external data modifications. Subsequently, the model underwent a comprehensive evaluation, utilizing precision, recall, and F1-score as the primary metrics. These metrics allowed us to assess the model's precision in identifying instances accurately, its ability to capture actual positives, and the balance between these two factors. Through this evaluation, we sought to gain insights into the model's intrinsic detection capabilities when subjected to real-world scenarios without the aid of dataset augmentation techniques.

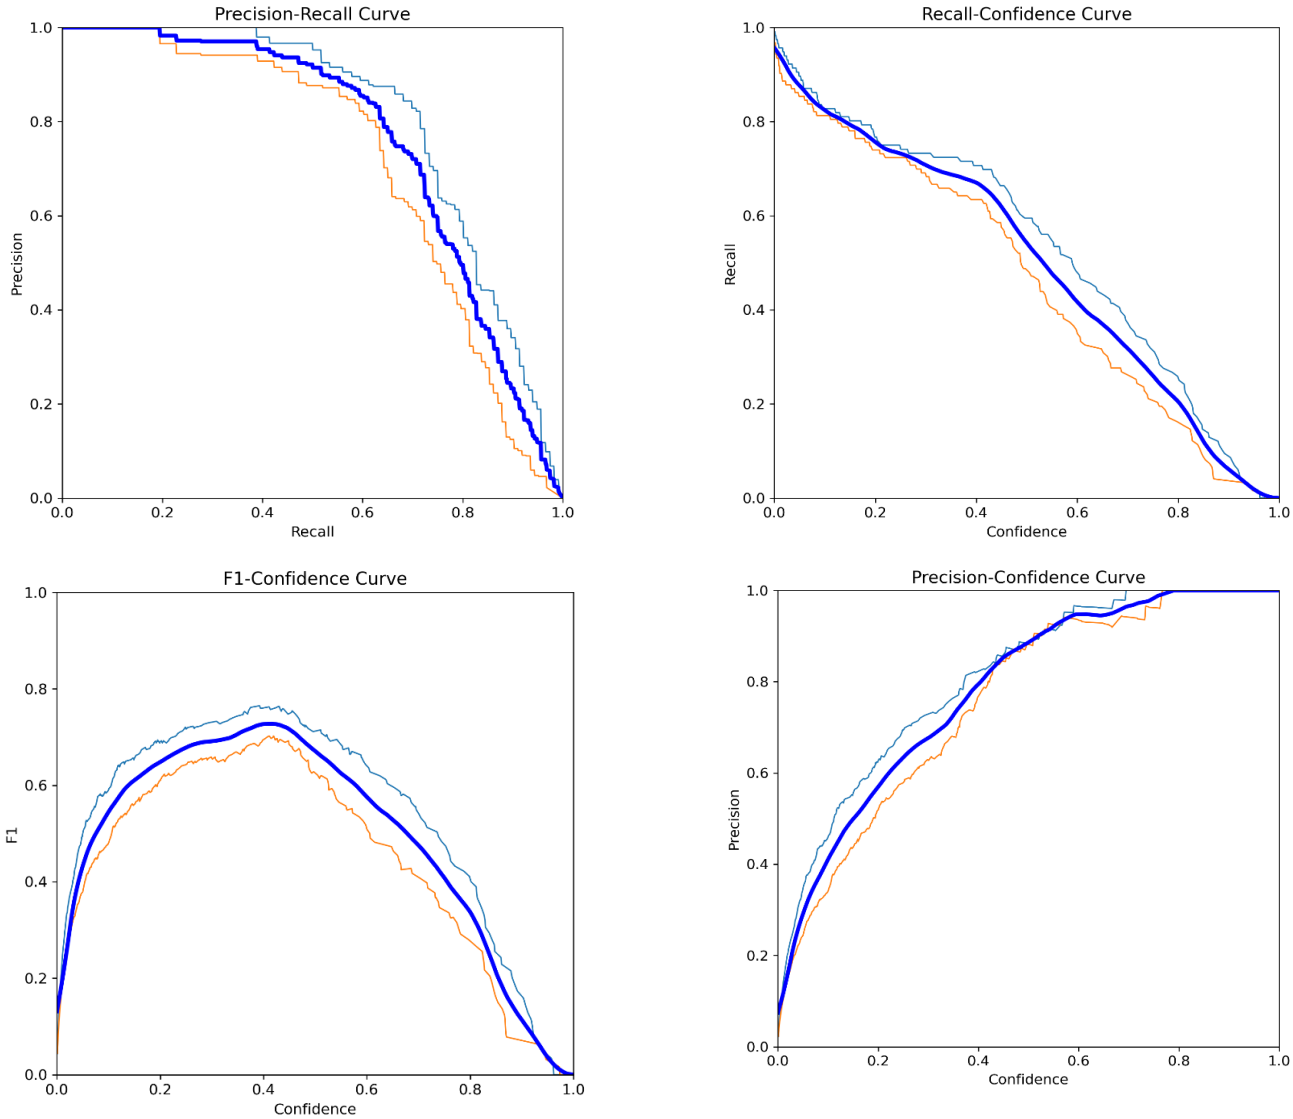

Fig. 5. The result of YOLOv8n on no-augmented dataset.

As shown in Fig. 5, the evaluation results of the YOLOv8n model in handgun and knife detection are highly promising. With an average precision of 0.79 for gun detection and an impressive 0.96 for knife detection, the model showcases its accuracy in correctly identifying instances within these specific classes. These values indicate that the model's predictions are consistently precise, minimizing the occurrence of false positives and boosting its reliability in distinguishing objects of interest.

The average recall of 0.80 is a testament to the YOLOv8n model's exceptional ability to capture a significant proportion of true positives, thereby avoiding missed detections. This indicates that the model effectively identifies and localizes instances of handguns and knives in a wide range of scenarios. The high recall value reflects its proficiency in comprehensively covering the target classes, which is vital for real-time applications where objects might appear in various orientations and scales.

The PR-curve's average value of 0.76 highlights the balanced trade-off between precision and recall achieved by the YOLOv8n model. This equilibrium suggests that the model can achieve high levels of accuracy in identifying relevant instances while maintaining a strong ability to capture true positives. A balanced PR-curve is especially advantageous in scenarios where minimizing false alarms and maximizing detections are critical, making the model suitable for real-world applications.

The F1-score of 0.73 reflects the YOLOv8n model's capacity to integrate precision and recall harmoniously. This indicates that the model is not only precise but also exhibits comprehensive coverage of relevant instances. The F1-score is particularly valuable as it provides a single metric that considers both false positives and false negatives, offering a holistic assessment of the model's performance in a real-world context.

Comparing the YOLOv8n model's performance with the YOLOv5 model, both without augmentation and the augmented YOLOv5 model, reveals distinct trends. While the YOLOv5 model without augmentation had lower precision, recall, PR-curve, and F1-score values, the augmented YOLOv5 model showcased improved performance. However, the YOLOv8n model consistently outperformed both counterparts, excelling in all metrics. This superiority can be attributed to the unique architecture and design choices of YOLOv8n, allowing it to capture object features and contexts better, ultimately resulting in higher accuracy, recall, and balanced performance.

D. Performance Evaluations YOLOv8n With Augmentation Results

Lastly, we developed a YOLOv8n model tailored specifically for handgun and knife detection. Contrasting with the no-augmentation approach, we expanded the dataset through augmentation techniques, effectively diversifying the training data. Similar to the generated YOLOv5 model with augmentation, we aimed to enhance the model's ability to generalize across a broader range of real-world scenarios by introducing variations like rotations, scaling and flips. Our experimentation involved a comparison of the augmented dataset against the original one to evaluate the model's performance under different conditions. This allowed us to gauge the impact of augmentation on the model's detection capabilities, assessing its potential for improved accuracy and robustness when faced with varying object orientations, scales, and backgrounds.

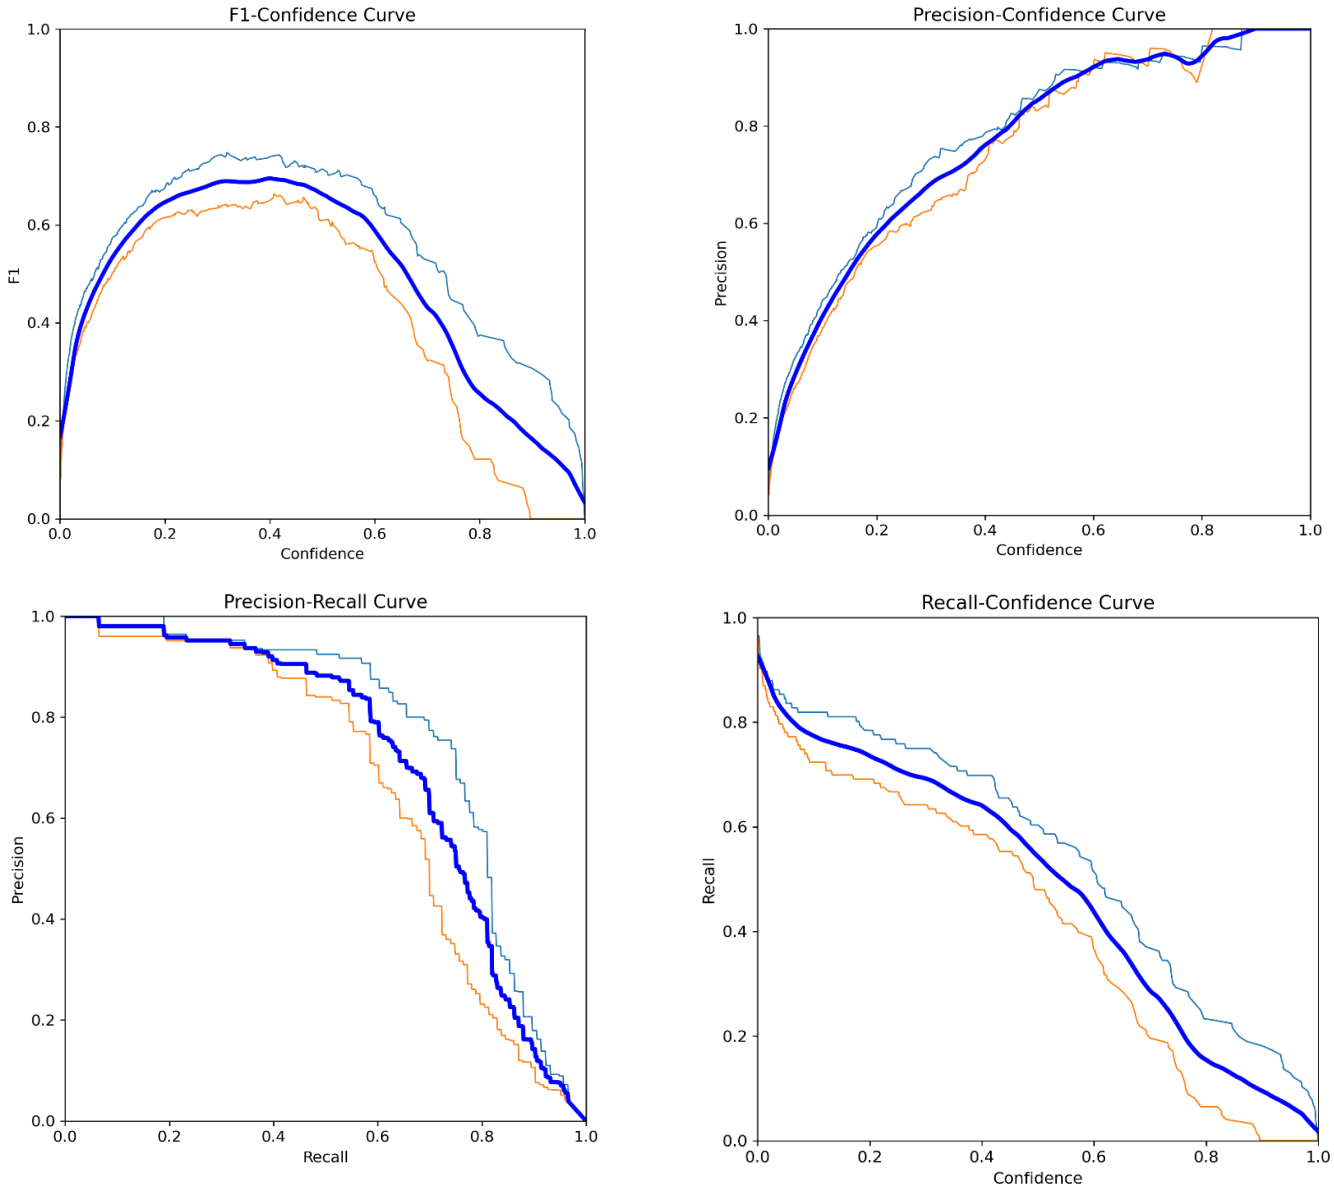

Fig. 6. The result of YOLOv8n on the augmented dataset.

As illustrated in Fig. 6, the evaluation results of the YOLOv8n model with augmentation underscore its remarkable performance, with average precision values of 0.89 for guns and 0.93 for knives. These values suggest that the model accurately identifies instances within these classes, indicating a notable improvement compared to YOLOv8n without augmentation. Additionally, the impressive average recalls of 0.76 highlights the model's proficiency in capturing a significant portion of true positives, further affirming its robustness.

The PR-curve's average value of 0.71 reflects the YOLOv8n model with augmentation's ability to achieve an effective balance between precision and recall. This balance is pivotal in real-time applications, ensuring that the model minimizes false positives while maximizing the identification of true positives. Similarly, the F1-score of 0.69 signifies the model's success in harmonizing precision and recall, which is crucial for maintaining high accuracy and comprehensive coverage.

When comparing the YOLOv8n model with augmentation against its no-augmentation counterpart, the improvements in precision, recall, PR-curve, and F1-score affirm the value of dataset augmentation. Augmentation techniques introduce diversity to the training data, enabling the model to better adapt to real-world variations in object appearance, background, and orientation. This results in enhanced detection performance and better prepares the model for challenges it might encounter in dynamic environments. To ensure fair and objective comparisons between the proposed methodology and other popular methods discussed in the manuscript, a rigorous and standardized evaluation protocol must be employed. By adhering to a transparent and reproducible evaluation framework, the manuscript can provide a clear and credible basis for comparing the proposed approach against existing methods.

In comparison to YOLOv5 without augmentation, the YOLOv8n model with augmentation consistently outperforms it across all metrics. This indicates that YOLOv8n's architecture, combined with augmentation, provides a more effective framework for handgun and knife detection tasks. The YOLOv5 model, although renowned, demonstrates limitations in terms of precision and recall in comparison to both versions of YOLOv8n, reinforcing the advantages of the latter. Fig. 7 shows the comparison of performance results of different experiments.

As depicted in Fig. 7, when contrasting with augmented YOLOv5, the YOLOv8n model maintains its superiority. This suggests that YOLOv8n's architectural enhancements, coupled with augmentation, result in a more refined and adaptable model. While augmentation does enhance YOLOv5, the performance boost offered by YOLOv8n is still apparent, showcasing its advanced capabilities in handling object detection tasks.

Ultimately, the YOLOv8n model with augmentation emerges as the optimal choice for handgun and knife detection in real-time scenarios. Its superior performance across multiple metrics attests to its accuracy, versatility, and robustness. Augmentation proves to be a crucial factor, as it empowers the model to handle diverse and challenging situations, making it more reliable and effective in real-world applications where timely and accurate detection is essential.

As a result, the combination of YOLOv8n's architecture and dataset augmentation yields a powerful model that excels in handgun and knife detection tasks. Its superior precision, recall, PR-curve, and F1-score values, when compared to both YOLOv8n without augmentation and YOLOv5 models, demonstrate its efficacy. This model is well-equipped to address the intricacies of real-time applications, offering heightened accuracy, adaptability, and efficiency in identifying handguns and knives.

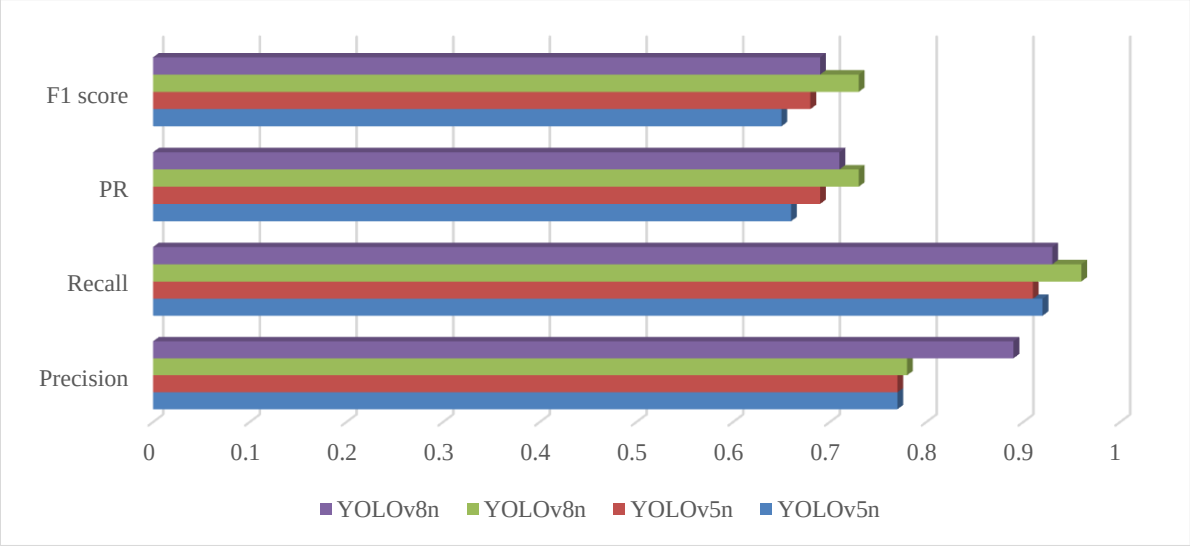

Fig. 7. Comparison of performance results of different experiments.

Moreover, to ascertain the scalability and efficacy of the proposed dataset creation methodology, it is imperative to conduct a comprehensive evaluation of the results obtained. This evaluation process should involve comparing the performance of models trained on augmented and non-augmented datasets across various real-world scenarios and challenges. By using the augmented dataset, the model's ability to adapt to different angles, sizes, and orientations can be thoroughly tested, allowing for a more robust assessment of its capabilities. Metrics such as accuracy, precision, and recall should be considered, along with real-world benchmarks and use cases. The results of this evaluation will not only validate the significance of the augmentation techniques but also demonstrate the dataset's utility in enhancing the model's generalization and adaptability, making it a crucial step in ensuring the success of the proposed work in various practical applications.

VI. CONCLUSION

Real-time handgun and knife detection on edge devices are paramount for enhancing the effectiveness of IoT video surveillance systems. This paper addresses the significance of accurate and timely firearm detection in such systems, highlighting the various methods explored in video-based surveillance contexts. Deep learning-based approaches have demonstrated superior results in handgun and knife detection due to their ability to learn intricate patterns, yet they face challenges concerning accuracy and computational efficiency for real-time operation. This study proposes a solution by introducing a single-stage convolutional neural network model tailored to address the aforementioned research challenge. The proposed method involves model generation through a custom dataset and encompasses comprehensive training, validation, and testing phases. Experimental results and performance evaluations validate the effectiveness of the proposed approach in achieving accurate firearm detection, demonstrating its potential impact on IoT video surveillance systems. Two potential avenues for future research stem from the findings of this study. Firstly, considering the evolving nature of IoT technologies and edge computing, exploring methods to optimize the computational efficiency of the proposed single-stage convolutional neural network model would be valuable. Addressing the current challenges of high computation costs while maintaining real-time capabilities could lead to more scalable and practical implementations. Secondly, delving into the integration of multi-modal sensor inputs, such as audio and environmental data, with the proposed handgun and knife detection model could enhance its robustness and accuracy in complex real-world scenarios. By incorporating additional contextual information, the proposed approach could offer more reliable and comprehensive firearm detection outcomes in diverse IoT video surveillance applications.

Advanced Seismic Magnitude Classification Through Convolutional and Reinforcement Learning Techniques

Qiuyi Lin, Jin Li*
School of Architectural Engineering, Chuzhou Polytechnic, Chuzhou 239000, Anhui, China

***Abstract*—Earthquake Early Warning (EEW) systems are crucial in reducing the dangers associated with earthquakes. This paper delves into the realm of EEWs, focusing on rapidly determining earthquake magnitudes (EMs). Traditional methods for swift magnitude categorization often grapple with challenges such as data disparity and cumbersome processes. Our research introduces an innovative EEW model, employing a 7-second seismic waveform record from three different components provided by the China Earthquake Network Center (CENC). This empirical, quantitative study pioneers a method combining dilated convolutional techniques with a novel mutual learning-based artificial bee colony (ML-ABC) algorithm and reinforcement learning (RL) for EM classification. The proposed model utilizes an ensemble of convolutional neural networks (CNNs) to simultaneously extract feature vectors from input images, which are then amalgamated for classification. To address the imbalances in the dataset, we implement an RL-based algorithm, conceptualizing the training process as a series of decisions with individual samples representing distinct states. Within this framework, the network operates as an agent, receiving rewards or penalties based on its precision in distinguishing between the minority and majority classes. A key innovation in our approach is the initial weight pre-training using the ML-ABC method. This technique dynamically optimizes the "food source" for candidates, integrating mutual learning elements related to the initial weights. Extensive experiments were carried out on the selected dataset to ascertain the most effective parameter values, including the reward function. The findings demonstrate the superiority of our proposed model over other evaluated methods, highlighting its potential as a robust tool for EM classification in seismology. This research provides valuable insights for both seismologists and developers of EEW systems, offering a novel, efficient approach to earthquake magnitude determination.**

Keywords*—Earthquake early warning; the magnitude of the earthquake; imbalanced classification; artificial bee colony; reinforcement learning

I. Introduction

The importance of earthquake prediction research is increasing globally, aiming to mitigate earthquake impacts. Early warning systems can drastically reduce casualties and damages from severe earthquakes [1]. These systems, endorsed by the United Nations, detect seismic activities and issue alerts rather than predicting earthquakes. Utilizing the time difference between primary and secondary seismic waves, they send warnings once an earthquake is detected. This allows immediate actions like unlocking building exits, managing power grids, and adjusting operations in critical facilities like hospitals and nuclear power plants [2].

The EEW system has gained significant attention in seismology research, particularly focusing on the "excellent period method" introduced by Nakamura et al. [3] and refined by Allen and Kanamori [4], which estimates earthquake magnitude from the initial three to four seconds of P-wave data. Despite its promise, this method shows notable variability in its estimates. To improve it, Kanamori [5] applied wavelet analysis for a more detailed time-frequency analysis of seismic data, but the problem of variability remained. Lancieri and Zollo [6] proposed an alternative, the "peak ground motion displacement Pd method," which uses peak displacements measured shortly after the P- and S-waves to estimate magnitude. Like its predecessors, this method also suffers from dispersion issues. Overall, current methods for magnitude estimation offer some level of estimation capability but are often limited by significant dispersion and lack of universal applicability.

Class imbalance, where one category has more data than the other, can adversely affect the performance of classification models [7]. The challenge is greater with minority classes due to their smaller size and variability. To address this, two main strategies are employed: data-level and algorithmic-level adjustments. At the data level, one can balance classes by over-sampling the minority class or under-sampling the majority class, but these methods risk information loss and overfitting [7, 8]. While these techniques are promising, their success varies depending on the dataset and application at hand, making it crucial to consider the specific characteristics of the imbalance and the needs of the application when choosing a method [9, 10]. Deep Reinforcement Learning (DRL) [11] has shown promise in improving classification by reducing noise and enhancing features, despite increasing computation time due to complex agent-environment interactions [12, 13]. DRL has been used to improve classifiers and in ensemble pruning, yet its application in addressing class imbalance has not been sufficiently explored by researchers [14].

Deep learning models have revolutionized multiple fields with their ability to fine-tune internal parameters through learning algorithms, particularly using backpropagation [15-18]. This method adjusts the weights of the model to minimize errors, but it can suffer from problems like sensitivity to initial weight settings and getting stuck in local minima, particularly

in classification tasks [19]. To overcome these issues, researchers are looking into meta-heuristic algorithms such as the ABC algorithm [20], which searches the solution space more broadly and is thus less likely to fall into local minima. However, the ABC algorithm itself has challenges in choosing the optimal food source or solution [21]. A new approach, ML-ABC, has been developed to enhance the standard ABC [22]. This method promotes mutual learning between different elements of the algorithm, improving adaptability and possibly resolving the weight initialization issues that affect gradient-based methods [23]. By fostering information exchange within the optimization process, ML-ABC can avoid local minima and find better solutions [24].

This research presents a deep learning model designed for EEW systems, which can accurately detect seismic events with magnitudes of 4 or higher using data from the first 7 seconds after the P-wave arrival from a single seismic station. The model uses dilated convolutional layers for feature extraction, which are then used for classification into two categories: EM ≥4 or EM <4. The data is skewed, with the EM ≥4 category being overrepresented, which adversely affects the model's performance. To tackle the data imbalance, the study applies a RL approach, where an agent iteratively learns from the environment to make binary classifications, receiving rewards for correct predictions and penalties for mistakes. A higher reward is given for correctly predicting the underrepresented class to address the imbalance. The agent aims to maximize classification accuracy and cumulative reward. The paper also addresses the issues of gradient-based training methods, which are sensitive to initial weight settings. The innovative ML-ABC method is introduced as a solution. It dynamically adjusts the optimization process by mutual learning from the initial weights, which improves the model's robustness. The model demonstrates outstanding performance in EEW tasks, with classification accuracy exceeding 90%. The paper highlights the effectiveness of combining DL with RL and the novel ML-ABC method for addressing data imbalance and initialization sensitivity in classification tasks. Below is a succinct summary of the primary themes explored within this paper:

- The article addresses the issue of imbalanced classification by introducing a sequential decision-making RL algorithm.
- Rather than relying on random weight assignments for model parameters, an enhanced ABC algorithm is adopted to establish initial values and a coding strategy for these parameters.
- A unique reward mechanism is integrated into the approach, incentivizing accurate decisions while penalizing errors. This mechanism assigns higher rewards to the minority class, prompting the model to allocate adequate attention to less common data. This strategic adjustment fosters a more equitable and balanced classification process.

The subsequent sections of the paper are organized as follows: Section II presents related works, while Section III provides an in-depth exploration of the proposed approach, detailing the core methodology. Section IV presents the empirical results and their subsequent analysis. In Section V, concluding remarks are provided, along with potential directions for future research.

II. Related Work

As the pool of seismic activity data grows, deep learning is becoming a cornerstone in the development of EEW systems. Ren et al. [25] capitalized on this by implementing CNNs to estimate earthquake magnitudes, treating the process as a classification problem. Their innovative model analyzes 4-second waveform segments from individual seismic channels to determine the potential impact of an earthquake. This approach has been validated through its successful application to distinct earthquake events, such as the clusters in Changning and Tangshan, proving its effectiveness in practical scenarios. Beyond academic validation, the model has seen real-world application, having been adopted by the China Earthquake Network Center (CENC) for real-time seismic data analysis, thus contributing to more timely and reliable earthquake warnings. Wang et al. [26] proposed a sophisticated deep learning model using long short-term memory (LSTM) neural networks to enhance onsite EEW systems. By analyzing the initial P waves to predict destructive S waves, this approach aims to mitigate the limitations of fixed-threshold single indicators, addressing complex nonlinearities due to varying travel paths and site effects. The LSTM model's proficiency was validated by testing it with recent seismic events in Taiwan, achieving remarkable accuracy with a 0% missed alarm rate and a mere 2.01% false alarm rate.

Expanding the scope of DL in EEW, Hu and Zhang [27] have designed a DL model that predicts the range of earthquake magnitudes with greater precision and reliability than traditional models. Despite its sophistication, this model could be prone to overfitting when faced with limited or noisy data, which might limit its application to new seismic events. Wang et al. [28] have pushed the boundaries further with DLcav, a CNN model aimed at predicting the cumulative absolute velocity (CAV) from seismic waveforms. DLcav stands out for enhancing the prediction of earthquake-induced damage, which is a crucial component of EEW. Datta et al. [29] introduced DeepShake, a novel deep spatiotemporal recurrent neural network designed for forecasting shaking intensities using real-time ground-motion data. This network-based model predicts future shaking across an array of stations without prior knowledge of their locations, learning from data on wave propagation patterns. Tested in the 2019 Ridgecrest earthquake sequence, DeepShake successfully alerted for significant shaking events with an equal error rate of 11.4%, indicating its potential as a reliable one-step early warning system for earthquakes.

Kavitha et al. [30] advanced the field of EEW through their development of the 3S-AE-CNN model, a novel innovation in deep learning applications. This model excels in quickly assessing crucial earthquake parameters, such as size and location, immediately after detecting the initial P-wave. The integration capabilities of this model with Internet of Things (IoT) technology could revolutionize the responsiveness of EEW systems. In a similar vein, Yanwei et

al. [31] have presented EEWNet, a cutting-edge deep learning framework that promises to rapidly and accurately predict earthquake magnitudes by analyzing raw P-wave data from single seismic stations. This model is particularly adept at dealing with earthquakes in the magnitude range of 4.0 to 5.9, offering a considerable improvement over existing empirical method.

Meanwhile, Meng et al. [32] have introduced an EEW model that leverages a DenseBlock structure with a Bottleneck and Multi-Head Attention mechanism to classify earthquake magnitudes from 7-second seismic data snippets. However, the model performance could be compromised by the issue of imbalanced data, which poses a risk to its predictive capabilities, especially for less frequent but critical earthquake magnitudes. Lastly, Lin et al. [33] have developed a CNN tailored for magnitude prediction, utilizing just 3-second windows of seismic data and conceptualizing the task as a classification problem, reinforcing the trend towards integrating advanced DL techniques in EEW for enhanced magnitude estimation accuracy. Münchmeyer et al. [34] proposed TEAM-LM, a hybrid model integrating CNN and Transformer architectures for simultaneous magnitude and location prediction using 10 seconds of data. While demonstrating promise within EEW systems, its computational intensity and multi-parameter predictions could impact overall accuracy.

III. Materials and Methods

The structure of the proposed model is shown in Fig. 1. The proposed model is particularly designed to enhance the classification process in seismic data analysis, where the intricacies of imbalanced classes and the necessity for precise initial weight settings are crucial. The adoption of ML-ABC and RL within our model directly addresses these critical areas where existing models fall short. Traditional algorithms often fail to offer a systematic method for initial weight selection, which can hinder the learning phase by causing slower convergence and the risk of settling on suboptimal minima. This can be particularly problematic in seismology, where the timeliness and accuracy of predictions are paramount.

Moreover, current models are not adequately equipped to deal with class imbalance, a frequent issue in seismic data where large magnitude events are rare. These models tend to be biased towards the majority class, resulting in a significant oversight of minority classes which are often the most critical to detect accurately in the context of earthquake early warning systems. Our approach, through ML-ABC, provides a carefully considered and diverse set of initial weights, enhancing the model's ability to escape local minima and converge more efficiently to a global solution.

Furthermore, the RL component of our model is tailored to assign a higher reward to the correct classification of the minority class, effectively shifting the model's focus towards these critical predictions. This is a substantial improvement over traditional supervised learning methods, which may not have sufficient representative data to train effectively across all classes. RL's adaptability in the learning policy allows for a more balanced exploration of the decision space, leading to strategies that favor the accurate classification of underrepresented classes. This adaptive nature of RL in our model sets it apart from existing methods, equipping it to overcome the inherent limitations faced by conventional classification approaches in the context of EEW systems.

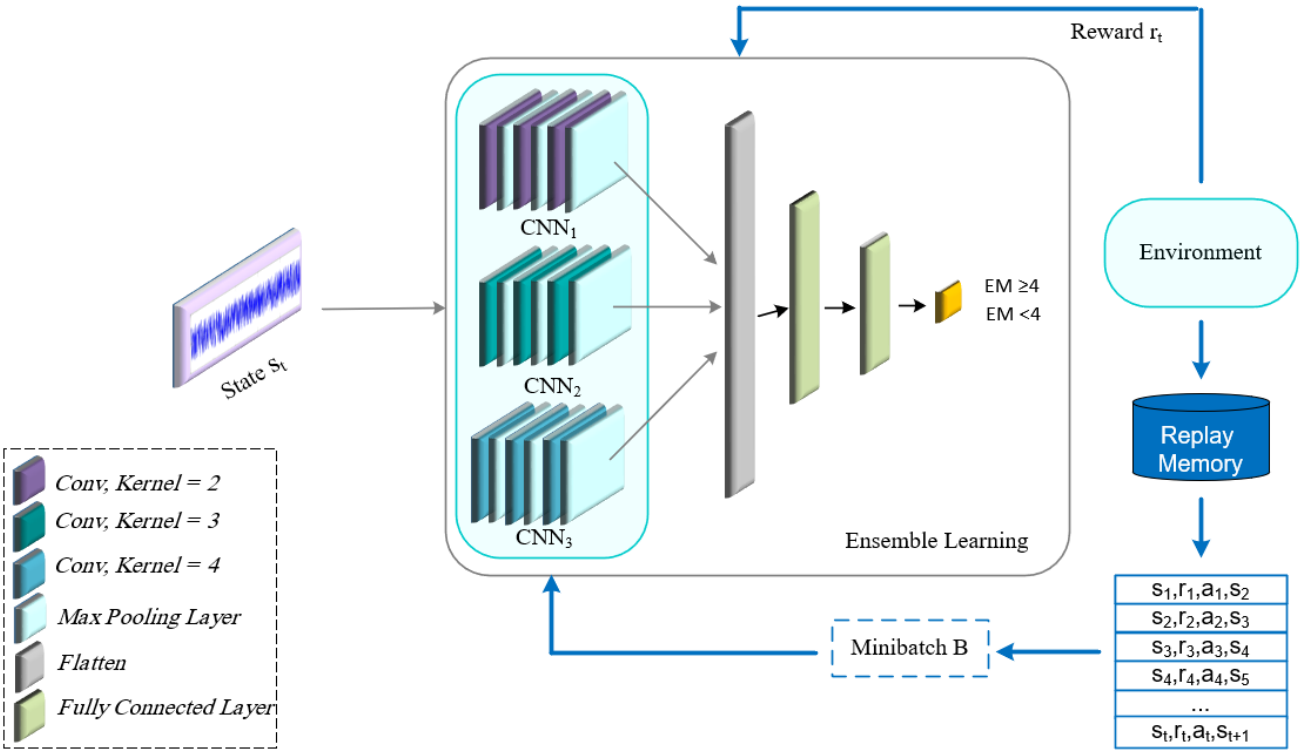

Fig. 1. The proposed model.

A. Pre-training Phase

The accuracy of network weights' initial values holds significant importance for deep models. If these initial settings are inaccurate, their repercussions can cascade throughout the model's training process, potentially leading to challenges related to convergence. Acknowledging the pivotal role of weight initialization, the initial phase of this study embarks on establishing the optimal configurations for both the CNN and the feed-forward neural network. To address the predicament of weight initialization, we introduce a groundbreaking approach called the ML-ABC technique. This strategy seeks to revolutionize the conventional process of determining initial values for network weights. In typical scenarios, the selection of initial weights relies on various methods, often incorporating heuristic or random techniques. However, the ML-ABC method introduces a higher level of intelligence into this process. By combining the principles of artificial bee colony optimization with the concept of mutual learning, the ML-ABC approach draws inspiration from the cooperative behaviors observed in natural bee colonies. This innovative approach aims to generate optimal initial weight seeds by enabling the network to learn and evolve collaboratively through the exchange of insights and knowledge. This facilitates a more informed and efficient weight initialization process.

1) The ML-ABC algorithm: The ABC algorithm, drawing inspiration from the intricate behaviors of honeybees when foraging for food, mirrors the collective intelligence and intricate actions observed in nature. This algorithm provides a methodical and intuitive approach to solving optimization problems. At its core, the ABC algorithm comprises four essential components:

a) Worker Bees: Functioning as the initial explorers, these bees venture into a designated area or target zone to identify potential food sources. Their actions are not random but are guided by their knowledge of previous sources, evaluating the quantity and quality of nectar available. After gathering information, they return to the hive to share their findings.

b) Observer Bees: Situated within the hive, observer bees absorb and analyze the information brought by the worker bees. Their decisions are based on shared information, particularly the quality and quantity of nectar discovered. If a worker bee's dance (used to communicate food source information) is compelling and suggests a rich source, observer bees are influenced to visit that location. This dance-based decision-making process ensures the swift exploitation of promising food sources.

c) Scout Bees: These bees act as adventurers, stepping in when a food source becomes depleted or no longer viable. Rather than relying on dance-based information, scouts explore the surroundings to find fresh food sources in a stochastic manner. Their role ensures the hive's adaptability and resilience to changing conditions.

d) Food Sources: Representing potential solutions to the optimization problem, each food source possesses a nectar quantity that reflects the quality or fitness of the associated solution. The collective aim of the worker bees, observer bees, and scouts is to maximize nectar accumulation, analogous to seeking optimal solutions in a computational context.

The brilliance of the ABC algorithm lies in its adaptability. By mimicking the foraging behaviors of honeybees, it achieves a balance between exploring new solutions and exploiting known ones. This intricate interplay of roles and responsibilities, guided by nature-inspired principles, positions the ABC algorithm as a robust tool in the realm of optimization [35].

Eq. (1) elucidates the process of generating a new position, utilizing spatial information from the worker bee. If the nectar found at the new position surpasses the quality of the previous location, the bee will adopt the new position, abandoning the former one. Conversely, if the quality of the nectar is subpar, the bee retains the memory of its previous location.

$$v_i^j = s_i^j + \varphi_i^j (x_i^j - x_k^j) \tag{1}$$

The equation employs the index i to represent the i-th position, where each solution s_i comprises a set of D parameters. The parameter D signifies the count of parameters subjected to optimization, while k signifies an alternative random solution distinct from i. The variable φ_i^j is randomly chosen from the interval [0, 1]. Introducing a change to one parameter of s_i generates a novel solution v_i, which may differ from the original one.

During an optimization process in "D" dimensions, a dimension is randomly selected, and its value is adjusted, with the fitness value determining the superior outcome in each iteration. As indicated in Eq. (1), the novelty and irregularity of the fresh food source v_i^j stem from its dependence on two variables, s_i^j and s_k^j.

To create a food source with enhanced fitness, we leverage knowledge derived from mutual learning between the present and adjacent food sources. This aspect is pivotal in the ABC algorithm, as it necessitates a food source with a heightened fitness value [36].

$$v_i^j = \begin{cases} s_i^j + \varphi_i^j (s_k^j - s_i^j), & Fit_i < Fit_k \\ s_k^j + \varphi_i^j (s_i^j - s_k^j), & Fit_i \geq Fit_k \end{cases} \tag{2}$$

where, Fit_i and Fit_k denote the fitness values of the neighboring and current food sources, respectively. The variable φ_i^j is a uniformly distributed random integer ranging from 0 to F, where F represents a positive mutual learning factor. Novel solutions enhance their fitness by evaluating nearby and current food sources and gravitating toward superior choices. If the current food source offers better fitness, the candidate solution aligns with it; otherwise, the solution moves toward a neighboring source. The stability of food positions hinges on the value of F, which must be a non-negative positive number yielding improved solution.

As the value of F incrementally rises from zero to a specific threshold, the disturbances observed in the corresponding point diminish. This signifies that the fitness value of the alternative food source is converging to, or

closely approaching, the higher fitness value. However, an elevated F value disrupts the delicate balance between exploration and exploitation. In order to illuminate the potential solution in the ML-ABC algorithm, our research's encoding technique vectorizes the CNN and feed-forward weights. It is challenging to provide precise weights, but through several attempts, we devised a method of encoding that strives for the utmost accuracy. An example of encoding a feed-forward network with three hidden layers and a CNN network with three layers, each layer comprising three filters, is shown in Fig. 2. The array's weight matrices are all referenced as rows, and this is crucial information to remember.

For the purpose of determining how effectively a solution fits into the developed DE algorithm, the fitness factor is constructed as follows:

$$Fitness = \frac{1}{1+\sum_{i=0}^{N}(y_i-\tilde{y}_i)^2} \quad (3)$$

The y_i and $\tilde{y}_i$ represent the target and projected labels, respectively, for the i-th dataset, while *N* indicates the total number of cases.

B. Deep Reinforcement Learning

DRL presents a robust approach within the realm of deep learning, where an agent dynamically engages with its environment to optimize rewards. This dynamic learning process equips the agent to navigate uncertain situations and make a sequence of decisions, proving particularly valuable in diverse domains like robotics, healthcare, and finance [37]. DRL's competence in handling tasks necessitating sequential decisions and its adaptability to unpredictable scenarios underscore its versatile, practical applicability. A primary challenge in tasks involving categorization arises from imbalanced datasets, where one category significantly outweighs others. This imbalance can lead to biased learning, as conventional categorization methods tend to prioritize the dominant category heavily, consequently hindering the recognition of less prominent ones. In such cases, DRL emerges as a more efficacious strategy for training neural networks compared to conventional methods. DRL tackles the uneven categorization issue by incorporating a reward-based system. By judiciously assigning rewards, the agent's attention can be steered towards instances from less prevalent categories, thereby enhancing the accurate identification of these infrequent groups. This incentive-driven model establishes a comprehensive decision-making approach, giving prominence to the detection and categorization of rare incidents or less common categories.

In the domain of deep Q-learning, the agent's objective is centered on selecting actions that maximize the potential rewards in forthcoming situations. The rewards expected in future scenarios, denoted by the reward value, decrease over time with the discount rate γ, as depicted in Eq. (3). In this context, T represents the final time step of an episode.

$$R_t = \sum_{t'=t}^{T} \gamma^{t'-t} r_{t'} \quad (4)$$

Q-values stand for the measure of state-action interactions' effectiveness and symbolize the predicted result of policy π when action a is taken in state s. This calculation is illustrated in Eq. (4).

$$Q^{\pi}(s,a) = E[R_t|s_t = s, a_t = a, \pi] \quad (5)$$

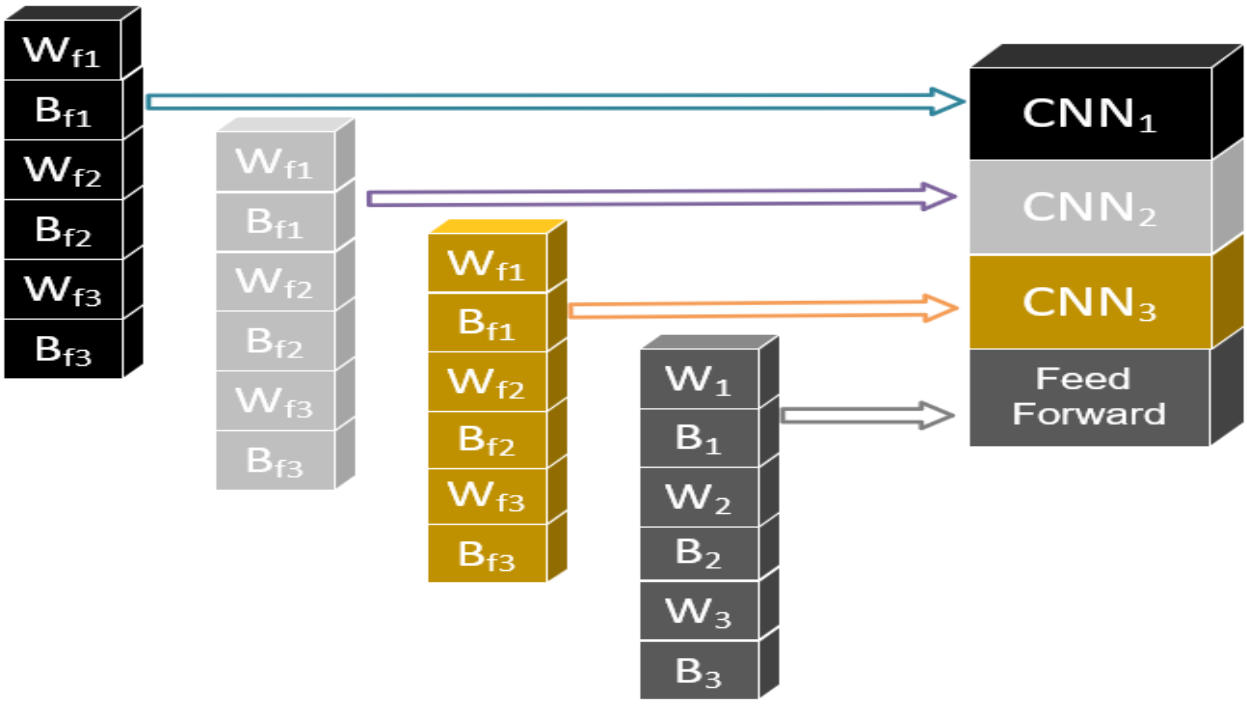

Fig. 2. Strategy for encoding employed in the algorithm being suggested.

The action-value function that yields the maximum expected reward among all strategies following the observation of state s and the execution of action a is computed as illustrated in Eq. (5).

$$Q^*(s,a) = max_\pi\, E[R_t|s_t = s, a_t = a, \pi] \quad (6)$$

The function applies the Bellman equation [38], which asserts that the highest expected result for a specific action is the combination of the current action's rewards and the maximum expected outcome from subsequent actions in the following step. This idea is illustrated in Eq. (6).

$$Q^*(s,a) = E[r + \gamma\, max_{a'} Q^*(s',a')|s_t = s, a_t = a] \quad (7)$$

The calculation of the optimal action-value function is conducted in a step-by-step manner utilizing the Bellman equation, as demonstrated in Eq. (7).

$$Q_{i+1}(s,a) = E[r + \gamma\, max_{a'} Q_i(s',a')|s_t = s, a_t = a] \quad (8)$$

During the training process, as the network encounters state s, it generates a corresponding action for that state. Subsequently, the environment provides a reward r and transitions to the next state s'. These variables are combined into a tuple (s, a, r, s'), which is then stored in memory M. Collections of these tuples, referred to as Batches B, are selected to perform gradient descent. The formula to compute the loss is described as shown in Eq. (8).

$$L_i(\theta_i) = \sum_{(s,a,r,s') \in B} (y - Q(s,a;\theta_i))^2 \quad (9)$$

In this context, θ represents the weights of the model, while y represents the estimated target for the Q function. This estimation involves summing the reward associated with the state-action combination and the discounted highest Q value in subsequent time steps, as demonstrated in Equation 9.

$$y = r + \gamma\, max_{a'} Q(s', a';\ \theta_{k-1}) \quad (10)$$

It is worth highlighting that the Q value assigned to the terminal state is set to 0. The magnitude of the gradient for the loss function at iteration i can be computed using Eq. (10).

$$\nabla_{\theta_i} L(\theta_i) = -2 \sum_{(s,a,r,s') \in B} (y - Q(s,a;\theta_i)) \nabla_{\theta_i} Q(s,a;\theta_i) \quad (11)$$

Through executing a gradient descent iteration on the loss function, the model's weights are updated as per Eq. (11). This adjustment aims to reduce the disparity, with α representing the learning rate that governs the degree of progress in the optimization process.

$$\theta_{i+1} = \theta_i + \alpha \nabla_{\theta_i} Q(s,a;\theta_i) \quad (12)$$

In this paper, our emphasis lies in applying the RL-driven algorithm in the realm of EEW. The following explanation elucidates the functioning of the methodology and imparts comprehension of each constituent element:

- State $\boldsymbol{s_t}$: This corresponds to the image observed at the time step t.
- Action $\boldsymbol{a_t}$: The classification performed on the image is treated as an action. This represents a decision made by the network based on its existing understanding of the goal.
- Reward $\boldsymbol{r_t}$: A reward is provided for each classification, designed to guide the network toward precise categorization. The formulation of this reward mechanism is presented as follows:

$$r_t(s_t, a_t, y_t) = \begin{cases} +1\,, a_t = y_t \text{ and } s_t \in D_O \\ -1\,, a_t \neq y_t \text{ and } s_t \in D_O \\ \lambda\,, a_t = y_t \text{ and } s_t \in D_N \\ -\lambda\,, a_t \neq y_t \text{ and } s_t \in D_N \end{cases} \quad (13)$$

Here, D_O and D_N respectively refer to the majority and minority classes. Accurately/incorrectly categorizing a sample from the majority class results in a gain/loss of $+\lambda/-\lambda$. The proposed method directs the network towards prioritizing the precise classification of instances from the rarer class, assigning a higher absolute value as a reward. Simultaneously, incorporating the majority class and a versatile reward parameter within the interval of $0 < \lambda < 1$ introduces intricacy to the reward structure, enabling precise tuning of the network's emphasis between the more prevalent and less common classes.

IV. Empirical Evaluation

A. Dataset

The data utilized in this investigation consists of three-component waveform data sampled at a frequency of 100 Hz. These data were collected by CENC from 1104 stations located in China over the time span from 2009 to 2017 [32]. As seismic waves propagate, their energy weakens as the distance of propagation increases. Consequently, the characteristics of waveforms tend to deteriorate. To address this, we have chosen seismic waveforms with epicentral distances shorter than 200 km. These waveforms might display disruptions and overlaps due to issues like network communication anomalies and equipment malfunctions. Therefore, we employ the "obspy" library to reprocess the data in this study. The composition of the training and test sets is presented in Table I.

TABLE I. Waveform Distributions for the Unbalanced Dataset Presented by CENC

Magnitude range	Waveforms in the CENC dataset
1-2	214963
2-3	91206
3-4	14080
≥4	4017

B. Metrics

We employ various metrics such as Accuracy, F-measure, and G-means, which are defined as follows:

$$\text{Accuracy} = \frac{TP+TN}{Total\ number\ of\ samples} \quad (14)$$

$$\text{Precision} = \frac{TP}{TP+FP} \quad (15)$$

$$\text{Recall} = \frac{TP}{TP+FN} \quad (16)$$

$$Specificity = \frac{TN}{TN+FP} \quad (17)$$

$$\text{G} - \text{means} = \sqrt{\text{Recall} \times Specificity} \quad (18)$$

Here, TP represents the true positives, or the count of actual positives accurately identified by the model. TN denotes the true negatives, referring to the actual negatives that the model correctly predicts. FP stands for false positives, which are the actual negatives that the model erroneously labels as positive. Lastly, FN indicates the false negatives, meaning the actual positives that the model incorrectly classifies as negative.

C. Comparator Models

During the evaluation phase, a comprehensive comparative analysis was conducted to assess the performance of our proposed model in comparison to five distinct deep learning frameworks: SeisNet [25], EEWMagNet [32], MagEstNet [39], QuakeClassNet [40], QuakeNet [41]. This rigorous examination aimed to offer a holistic perspective on our model's efficacy in relation to contemporary methodologies. To further explore various adaptations of our proposed model, two modified versions were introduced into the analysis. The first variant, referred to as "Proposed with RL," maintained an architectural design akin to our original model while excluding the application of the ML-ABC technique. Conversely, the second variant, "Proposed with ML-ABC," omitted the use of the RL technique for classification. To thoroughly evaluate the performance of these models, established metrics were employed, with a specific focus on metrics like the F-measure and geometric mean, known for their suitability in cases of skewed data distributions.

D. Results

The outcomes of this evaluation, as detailed in Table II, distinctly showcase the superior performance of our proposed model when compared to all other contenders, even including well-established models such as EEWMagNet and SeisNet. Across all evaluation criteria, our model consistently demonstrated its superiority over its counterparts. Remarkably, the model achieved substantial reductions in errors, showcasing improvements of 25% and 10% in the F-measure and G-means metrics, respectively. These noteworthy enhancements underscore the model's ability to effectively address challenges posed by imbalanced data distributions and its proficiency in delivering more accurate predictions.

A particularly illuminating comparison emerges when we consider the model's modified versions - "Proposed with RL" and "Proposed with ML-ABC". The advantages inherent in the integration of ML-ABC with the RL approach become evident. Our primary model achieved a substantial reduction in errors, nearly 30%, relative to its modified versions. This emphasizes the pivotal roles of both ML-ABC and RL in augmenting the model's performance, underscoring their significance in advancing the development of cutting-edge deep learning systems.

TABLE II. PERFORMANCE METRICS OF THE PROPOSED MODEL VERSUS COMPARATOR DEEP MODELS

	Accuracy	**F-measure**	**G-means**
EEWMagNet	0.8914±0.1405	0.8622±0.2001	0.8515±0.0104
SeisNet	0.8510±0.1553	0.7471±0.1054	0.8002±0.0402
MagEstNet	0.8105±0.1404	0.7302±0.1404	0.8006±0.1201
QuakeClassNet	0.7901±0.1006	0.5502±0.0953	0.6505±0.2502
QuakeNet	0.6703±0.1205	0.6702±0.2103	0.7503±0.0051
Proposed with RL	0.8104 ± 0.0627	0.7918 ± 0.1623	0.8303 ± 0.2622
Proposed with ML-ABC	0.8615 ± 0.0243	0.8506 ± 0.0517	0.8609 ± 0.0921
Proposed	0.9217 ± 0.0384	0.8814 ± 0.0297	0.9066 ± 0.0423

Table III presents a comparative analysis of the performance metrics for various deep learning models, including the proposed model, across two classes: EM <4 and EM ≥4. In the EM <4 class, the proposed model exhibits a superior performance with an accuracy of 0.9012±0.0450, indicating its robustness in this category. This performance is notably higher than that of EEWMagNet and SeisNet, which have accuracies of 0.8714±0.1210 and 0.8616±0.1020, respectively. MagEstNet and QuakeClassNet show moderate performance, while QuakeNet trails with the lowest accuracy in this class. For the EM ≥4 class, the proposed model again leads with an impressive accuracy of 0.9415±0.0056, significantly outperforming all comparator models. EEWMagNet, with an accuracy of 0.9012±0.0255, follows as the second most accurate model. SeisNet and MagEstNet show relatively similar performances, while QuakeClassNet and QuakeNet lag behind, indicating potential challenges in accurately classifying instances in this higher EM category. The consistency in the leading performance of the proposed model across both classes underscores its effectiveness and

reliability in binary classification tasks within this context. This superiority is particularly notable in the EM ≥4 class, where the margin of its lead suggests a higher degree of precision and confidence in its predictive capabilities. These results highlight the potential of the proposed model as a robust tool for classification in the studied domain.

Fig. 3 depicts the receiver operating characteristic (ROC) curves for the techniques outlined in Table I. The primary metric employed for assessing the effectiveness of classifiers is the area under the curve (AUC). An AUC value of 1 signifies perfect differentiation, while a value of 0.5 indicates performance equivalent to random chance. Among the various models, SeismoNet stands out with an impressive AUC score of 0.81. This remarkable result showcases its exceptional ability to distinguish between positive and negative outcomes, providing further evidence of the method's robust predictive prowess.

In contrast, both EEWMagNet and SeisNet demonstrated average AUC scores of 0.69 and 0.51, respectively, falling short of the performance achieved by our proposed model. The remaining models, including QuakeNet, QuakeClassNet, and QuakeNet, yielded less favorable results, exhibiting AUC scores ranging from 0.48 to 0.51. Notably, the performance of the QuakeNet model was notably lower, achieving a meager AUC of 0.48, just slightly surpassing the threshold for random prediction. The ROC curves vividly illustrate the disparities in performance across the evaluated methods, with our proposed model showcasing superior performance in discriminating between different outcomes.

Fig. 4 illustrates the error progression observed in the proposed model over a span of 500 epochs. Commencing with an initial error measurement of 10, a consistent downward trajectory becomes evident as the epochs advance. This sustained decline in error validates the model's ability to adapt and enhance its predictive capabilities with the accumulation of training iterations.

It is noteworthy that the most significant reduction in error occurs during the earlier epochs, gradually tapering off as the epochs accumulate. This pattern suggests diminishing returns in terms of error reduction as training prolongs, particularly after approximately the 425th epoch. Around this point, the error stabilizes, maintaining a relatively constant value of approximately 4.2962 across subsequent epochs. This plateau implies that continuing training beyond this juncture might not yield substantial performance improvements, implying the likelihood of the model reaching convergence.

Furthermore, this stability could serve as an indicator of potential overfitting, especially if there is no subsequent improvement observed on external validation or testing datasets. This underscores the importance of monitoring the model's behavior and performance to strike the right balance between training duration and preventing overfitting.

TABLE III. PERFORMANCE METRICS OF THE PROPOSED MODEL VERSUS COMPARATOR DEEP MODELS BY CLASS

Model / Class	EEWMagNet	SeisNet	MagEstNet	QuakeClassNet	QuakeNet	Proposed
EM <4	0.8714±0.1210	0.8616±0.1020	0.7914±0.2356	0.8015±0.1148	0.7014±0.1263	0.9012 ± 0.0450
EM ≥4	0.9012±0.0255	0.8423±0.1026	0.8216±0.1462	0.7726±0.1065	0.6425±0.1105	0.9415± 0.0056

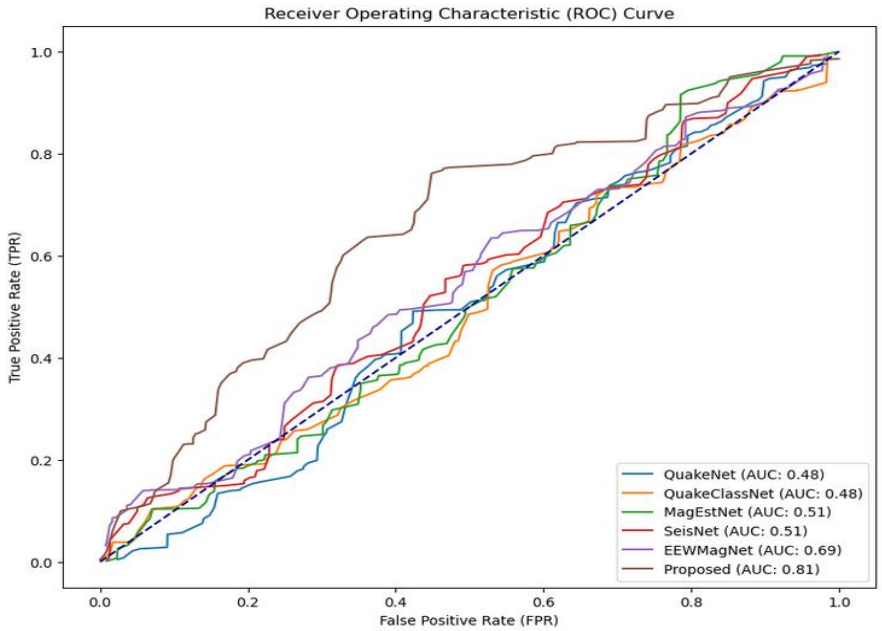

Fig. 3. The ROC chart illustrates the ROC curves for the proposed model and other benchmark techniques. The blue dashed line on the graph represents the ROC curve corresponding to random guessing.

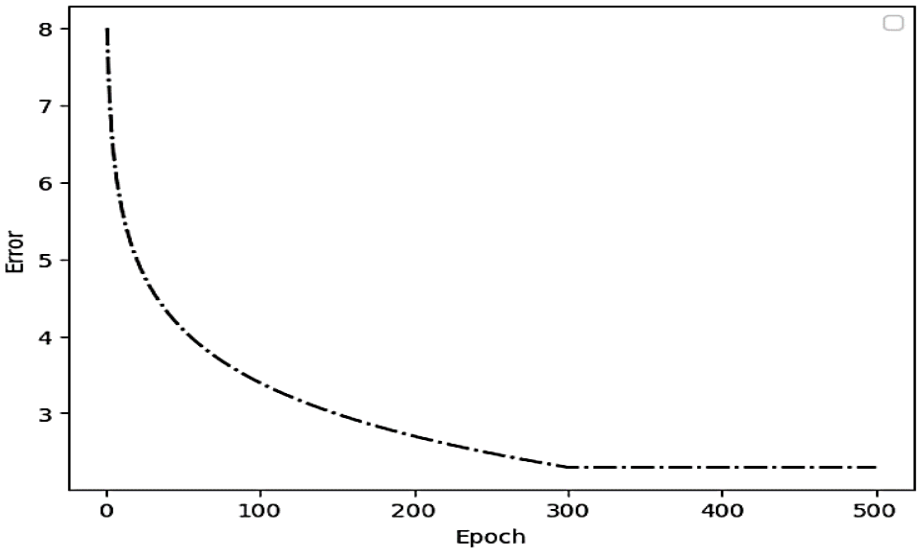

Fig. 4. Diagram illustrating the comparative dynamics of errors.

1) Impact of the reward function: Within our devised model, we introduced a reward mechanism to handle class imbalances effectively. In the case of the majority class, correct predictions were rewarded with a score of +1, while incorrect ones incurred a penalty of -1. For the minority class, accurate predictions garnered rewards of +λ, while incorrect ones resulted in penalties of -λ. The specific value of λ was adjusted based on the ratio between majority and minority samples. Notably, as this ratio increased, the optimal λ tended to decrease.

To explore the impact of λ, we thoroughly analyzed the model's performance across a spectrum of λ values ranging from 0 to 1, incrementing by intervals of 0.1. Throughout this analysis, the reward for the minority class remained consistent. The findings are presented in Fig. 5. At λ = 0, the influence of the majority class was minimal, while at λ = 1, both classes carried equal significance.

The data underscores that the model's most optimal performance is achieved when λ is set to 0.6, according to all evaluation criteria. This indicates that the most suitable value for λ resides between the extremes of 0 and 1. It is essential to recognize that while adjusting λ to diminish the dominance of the majority class is essential, setting it too low can potentially undermine the overall model performance.

This investigation highlights the critical role that the choice of λ plays in shaping the model's outcomes. Determining the ideal value of λ hinges on the relative frequency of majority and minority samples, emphasizing the significance of meticulous parameter adjustments to attain optimal result.

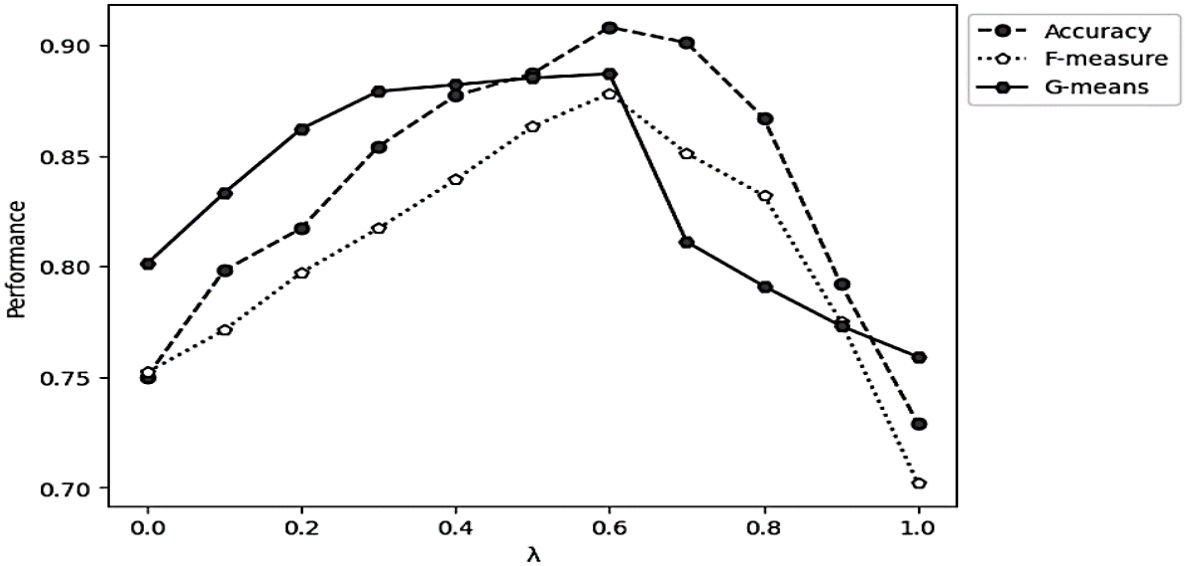

Fig. 5. Generating graphs illustrating the performance metrics of the proposed model as they vary in response to different λ values incorporated within the reward function.

2) Impact of the loss function: A wide array of strategies is available to tackle data imbalances within the realm of machine learning [42]. These encompass enhancements in data augmentation methodologies as well as the careful selection of an appropriate loss function. The pivotal role of the chosen loss function in enabling the model to capture the intricacies of the underrepresented class comprehensively cannot be overstated. Our investigation delved into the effectiveness of five distinct loss functions: Weighted cross-entropy (WCE) [43], balanced cross-entropy (BCE)] [44], Dice loss (DL) [45], Tversky loss (TL) [46], and Combo Loss (CL) [47].

While both WCE and BCE commonly utilized loss functions that treat positive and negative instances with equal weight, their performance may falter when faced with datasets exhibiting significant imbalances that heavily favor the minority class. On the contrary, DL and TL emerge as more suitable choices for datasets characterized by pronounced imbalances, showcasing notably improved results in relation to the minority class. Among these, CL takes a distinctive position as an exceedingly effective loss function, particularly tailored to datasets characterized by skewed distributions. Through judicious adjustments of the loss function's weights, CL elevates the significance of intricate samples, thereby conferring them a greater influence than straightforward ones.

Our meticulous analysis of these loss functions has been meticulously detailed in Table IV, yielding illuminating insights. The outcomes of this study underscore the exceptional performance of CL in comparison to TL, leading to an impressive 13% reduction in error rate accuracy and a substantial 25% enhancement in the F-measure, a pivotal metric for model evaluation. However, it is imperative to note that, despite its remarkable achievements, CL falls short by 20% when measured against our proposed model, which has been intricately designed to tackle binary classification challenges. This underscores the context-specific nature of model design and the need to tailor solutions to the particular problem at hand.

TABLE IV. COMPARISON OF THE PERFORMANCE METRICS BETWEEN THE SUGGESTED MODEL AND THE EMPLOYED LOSS FUNCTIONS

	Accuracy	F-measure	G-means
WCE	0.7432± 0.1132	0.7215± 0.0130	0.7510± 0.1255
BCE	0.8001± 0.1021	0.7622± 0.0102	0.8025± 0.0101
DL	0.8042± 0.2033	0.7992± 0.0106	0.826± 0.1000
TL	0.8320± 0.1203	0.8148± 0.0436	0.8450± 0.2062
CL	0.8630± 0.0247	0.8440± 0.0152	0.8639± 0.0152

3) Impact of the number of CNNs: The proposed architecture employs multiple CNNs to derive feature vectors from input images concurrently. The quantity of these CNN-based feature extractors significantly influences the model's performance. Utilizing an insufficient number of CNNs can lead to subpar feature extraction, while an excessive number might result in overfitting or the inclusion of redundant information. Both these extremes have the potential to undermine the efficacy of the model. To identify the ideal number of CNNs, an evaluation of the proposed model was conducted across a range of one to seven CNN feature extractors.

The outcomes of this investigation reveal that the model attains its peak performance when equipped with three CNNs, as clearly depicted in Fig. 6. Interestingly, the model's performance exhibited a decline when six and seven CNNs were employed. Strikingly, these cases even yielded results inferior to those obtained using a solitary CNN. This finding underscores the delicate balance required in selecting the number of CNNs for optimal performance, where an excess can prove detrimental rather than beneficial.

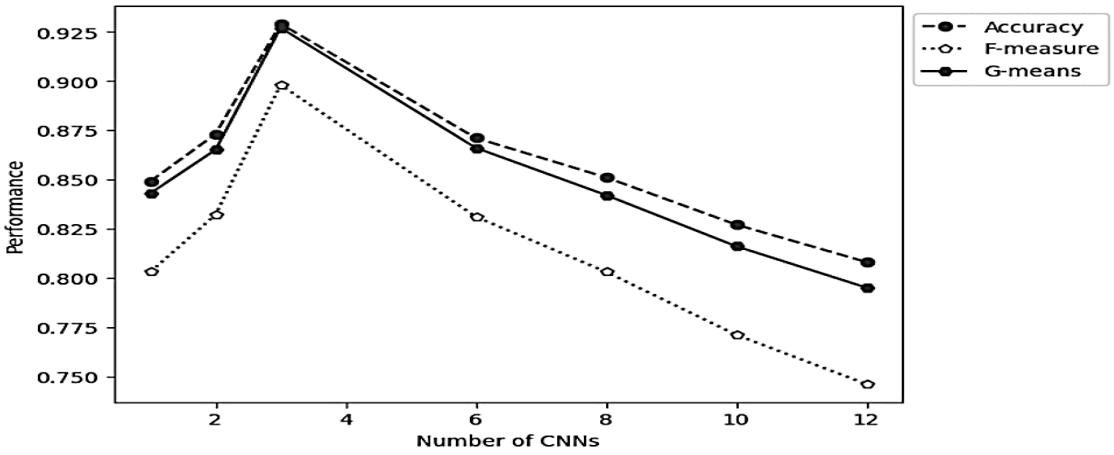

Fig. 6. Graphing the performance measurements of the suggested model concerning changes in the count of convolutional feature extractors.

4) Discussion: The study unveiled an innovative EEW model that was specifically designed to classify earthquake magnitudes rapidly. This classification was achieved through the analysis of a 7-second, three-component seismic waveform record acquired from the CENC. This novel model architecture featured a distinctive incorporation of three concurrent dilated convolution layers. These layers played a pivotal role in extracting crucial feature vectors that were subsequently employed for effective classification tasks.

Addressing the inherent challenges tied to data imbalances often encountered in conventional EEW models, the research integrated an algorithm based on RL. This strategic approach aimed to enhance the accuracy of sample classifications by providing appropriate rewards to the model. In the training process, individual samples were visualized as distinct states within a sequence of interconnected decision points. Functioning as an agent, the neural network received rewards or penalties based on its performance in accurately distinguishing between various classes.

To initiate the weight pre-training of the model, a unique approach known as ML-ABC was introduced. This pioneering technique dynamically adjusted the optimal "food source" for candidate solutions, encompassing components of mutual learning that were intricately linked to the starting weights. This innovative initialization process contributed to the ability of the model to learn and adapt during subsequent training phases.

The model proposal, crafted using seismic waveform records obtained from the CENC, exhibits potential limitations when attempting to extend its applicability to various global datasets. Its fundamental design, intricately linked to the distinct seismic characteristics unique to the CENC, raises substantial concerns regarding its performance when applied to regions such as California, renowned for the San Andreas Fault, or Japan, a significant participant in the Pacific Ring of Fire [48]. This potential challenge unfolds in two aspects: firstly, the model might internalize and overly emphasize the particular attributes of the CENC dataset, and secondly, it could inadvertently absorb any biases inherently present within that dataset. Such an excessively specialized adaptation could significantly hinder the capacity of the model to adapt to broader, more diverse contexts, impeding its generalization capabilities [32].

Furthermore, while the algorithms incorporated within the proposed model, such as RL and dilated convolution layers have been meticulously fine-tuned to accommodate CENC data, their flexibility when applied to unfamiliar datasets, remains questionable. A common issue observed with specialized algorithms is their susceptibility to overfitting on the training data, rendering them less adaptable and responsive when presented with previously unseen data. Take the RL algorithm, for instance, which has been structured with reward mechanisms tailored to the unique attributes of the CENC dataset [49]. This design might lead to challenges when confronted with datasets that possess distinct seismic event distributions. Similarly, the dilated convolution layers, optimized specifically to decipher intricate patterns inherent in CENC data, could either overlook or misinterpret vital features originating from divergent geographic regions [50].

The complexities inherent in seismic data are multifaceted, and the presence of noise or anomalies can wield substantial influence over the accuracy and dependability of any predictive model [51]. In regions marked by dense urbanization or significant industrial undertakings, the vibrations stemming from everyday human activities like traffic movement, construction endeavors, or even the operations of underground subway systems can introduce supplementary signals into the seismic data. Likewise, natural geophysical disturbances such as volcanic eruptions, landslides, or even robust winds and oceanic waves can engender disturbances that might be misconstrued as seismic activity by a model that hasn't been primed to contend with such factors [52].

The susceptibility of the proposed model to such extraneous signals takes on heightened concern when pondering the repercussions of erroneous alerts or missed predictions. The occurrence of false alarms, where the model inaccurately forecasts a seismic event due to noise, holds the potential to induce unwarranted panic and economic disruptions and erode public trust in the reliability of the system. Conversely, if the model fails to identify a genuine seismic event owing to its confusion with noise, the ramifications could be gravely severe, encompassing loss of lives and property.

Furthermore, managing noise isn't merely a matter of filtering out undesired signals; it also necessitates the ability to discriminate between noise and legitimate seismic activities that might exhibit similar characteristics. The challenge lies in striking a delicate equilibrium wherein the model remains attuned to authentic seismic events while discarding irrelevant data. Achieving this equilibrium mandates the training of the model on diverse datasets that encapsulate a broad spectrum of noise scenarios and authentic seismic patterns.

Moreover, it is imperative to recognize that the refinement and fine-tuning of the model should remain an ongoing process. This is particularly significant due to the dynamic nature of noise sources, which can evolve over time. As cities expand, infrastructure undertakings progress and the landscape of human activity evolves, the nature of noise embedded within seismic data will inevitably undergo transformations. This dynamic characteristic underscores the necessity for the model to be adaptable rather than static, prepared to accommodate and surmount the challenges that emerge from evolving noise profiles [53].

V. CONCLUSION

This manuscript introduces SeismoNet, an innovative EEW model that capitalizes on a 7-second, three-component seismic waveform record sourced from the CENC. The architecture of the model is characterized by the inclusion of three concurrent dilated convolution layers, which play a pivotal role in the extraction of feature vectors. These vectors are subsequently amalgamated to facilitate the classification process. In response to the challenges stemming from data imbalances within the realm of EEW models, an RL-based

algorithm has been seamlessly integrated. This algorithm rewards the model agent more prominently for precise sample classifications, thereby enhancing its learning process.

The training mechanism of the model is visualized as a sequence of interconnected decision points, with each individual sample treated as a discrete state. Within this framework, the neural network assumes the role of an agent, and its performance in distinguishing between the minority and majority classes is met with corresponding rewards or penalties.

For the initial weight pre-training of the model, a groundbreaking ML-ABC technique is introduced. This method exhibits dynamic adjustments to the optimal "food source" for candidate solutions, ingeniously incorporating mutual learning components that are intricately linked to the initial weights. This innovative initialization process lends the model adaptability and enhances its capacity to learn and adapt during subsequent training phases.

A comprehensive suite of experiments has been conducted using the designated dataset to discern optimal parameter values, including the formulation of the reward function. The outcomes of these experiments resoundingly underscore the efficacy of our proposed methodology when juxtaposed with alternative approaches that were explored within the confines of this study. This affirmation further solidifies the viability and potential of the proposed model as a robust solution for Earthquake Early Warning systems.

Information Retrieval System for Scientific Publications of Lampung University by using VSM, K-Means, and LSA

Rahman Taufik, Didik Kurniawan*, Anie Rose Irawati, Dewi Asiah Shofiana
Dept. of Computer Science, University of Lampung, Bandar Lampung, Indonesia

***Abstract*—The Lampung University repository system is a repository of data related to study, community service, and other scientific works, currently has 37242 documents accessible through repository.lppm.unila.ac.id. Despite the amount of data, its optimal use as an information retrieval remains unrealized, hindering the effective promotion of Lampung University's scientific publication excellence. Recognizing the limitations of existing information retrieval systems that are limited to specific methods for topic identification through clustering, this study aims to develop a retrieval system for Lampung University's repository using Vector Space Model (VSM), K-Means and Latent Semantic Analysis (LSA) that generates clusters and study expertise at the level of study program, faculty and Lampung University. The methodology includes data collection, preprocessing, modeling, evaluation and system deployment. The results show that the number of clusters obtained for the university level is 7 clusters, for the faculty level are 6, 7, 8 and 10 clusters, and for the program level are 3 to 5 clusters. In addition, the finding topic identification indicate that the expertise topics at Lampung University, which are agriculture, soil, education, plants, learning, society, Lampung. This study contributes to optimizing the information retrieval system, promoting academic excellence, and advancing the understanding of study expertise at Lampung University.**

Keywords*—Information retrieval; Vector Space Model (VSM); k-means; Latent Semantic Analysis (LSA); clustering; topic identification; scientific publication information

I. INTRODUCTION

The Lampung University repository system is a data repository accessible to all lecturers and the academic community through the address repository.lppm.unila.ac.id. According to Google index data, the publication data already contains 37242 documents. Additionally, the University of Lampung Repository System is utilized to store lecturer data related to study activities, publications, community service, and other achievements. All data stored in this repository is traceable based on divisions at the University of Lampung, namely faculties, study programs, authors and years of study. The data stored in this repository can serve various purposes, including as a source of information, for literature reviews, accreditation, self-evaluation, institutional achievements, and other *tri dharma*-related purposes.

However, the data in the repository has not been effectively utilized as meaningful information due to the inadequacy of the system in accessing and managing data in an informative manner. Consequently, units within Lampung University encounter difficulties when searching for relevant scientific publications in their areas of expertise. Furthermore, understanding the strength of study fields based on the obtained information is crucial to assess the excellence of study at the University of Lampung.

One of the technologies that can be used to extract information from a repository system is an information retrieval system. Several studies such as Information Retrieval for Digital Library [1], Information Retrieval for Faculty Study Repositories [2], Information Retrieval for Bibliographic Control and Institutional Repositories [3], Multilingual Information Retrieval [4], have proven that information retrieval systems can effectively collect and determine information from various repositories. In study [1], they improved the existing digital library system, namely Sowiport, by integrating heterogeneous databases through an information retrieval system approach. As a result, they obtained 513,000 data entries from 25 different thesauri, enhancing keyword search capabilities. In addition to digital library system [1], there are other studies related to educational repositories which are studies [2][3]. The study [2] aims to evaluate faculty study repositories used in higher education institutions. One aspect of the evaluation is to identify relevant articles from nine academic databases using an information retrieval system approach. The results indicate that the evaluated and redesigned system improves the preservation of scientific study results. While study [3] improves the quality of their data, metadata, and semantic data through an information retrieval system approach, the results support their control over the bibliography, including a repository that is rich and clean. In terms of diversity of information data, compared to other studies that collect data in various languages through information retrieval systems [4], they successfully gathered over 77 thousand Wikipedia queries in 18 languages. This supports improvements in data retrieval across multiple languages.

*Corresponding Author

The implementation of an information retrieval system must be accompanied by the utilization of techniques. The follow-up regarding the application of techniques can be observed in studies [5] [6] [7]. Study [5] employs data mining techniques to enhance information retrieval within their digital institutional repository, yielding personalized profiles specific to each user group in their repository. In study [6], an information retrieval system and data mining techniques were employed, specifically an Expertise Recommender System. This approach was utilized to develop a prototype system aimed at identifying and recommending thesis advisors for specific subjects. Unfortunately, specific data mining methods used in studies [5] [6] are not mentioned. On the other hand, study [7] developed an information retrieval system using hybrid deep fuzzy hashing algorithm to address issues related to similarity measurement procedures. Experimental result showed that the proposed model achieved higher retrieval accuracy compared to conventional models, although it is limited in feature selection.

Additionally, other approaches, such as Natural Language Processing (NLP), can be employed, as demonstrated in study [8] [9]. Study [8] developed an information retrieval system using NLP techniques to address employee queries based on knowledge from their internal site. The results showed that the queries were successfully responded to with relevant answers, although there is potential for further acceleration in the process. Furthermore, study [9] developed a search system by implementing information retrieval system techniques, Jaccard and cosine similarity matrix techniques. These methods were utilized to clean and standardize data and information related to academic documents. The results indicated that the system could be utilized to recommend documents, albeit with limitations in searches based on divergence metrics.

Despite significant advancements in the utilization of information retrieval systems across various domains [1] [2] [3] [4], there appears to be a noticeable gap in explicit discussions or study concerning the optimization of data generated by information retrieval systems. Several studies [5] [6] [7] [8] [9] mention the use of data mining techniques and NLP, but specific methods for topic identification through clustering have not been proposed. The implementation of clustering for topic identification is crucial, particularly in the context of academic data.

The present study aims to develop an information retrieval system for scientific publications of Lampung University using the Vector Space Model (VSM), K-Means and Latent Semantic Analysis (LSA). We propose VSM to obtain the similarity in vector representations, K-Means to cluster study topics, while LSA is used to generate the identification of study topics. The use of Vector Space Model (VSM) method can improve the information obtained from information retrieval systems. A number of studies have developed information retrieval system that applied VSM to determine information [10] [11]. The study in [10] proposed the combination of two methods, namely VSM and description logic for concept extraction, which increases the level of similarity between documents and certain concepts in information retrieval systems. While, the study [11] proposed VSM based on TF-IDF weights and word vectors to calculate semantic similarity for implicit citation detection problem. On the other hand, studies such as [12] [13] show that K-means method can be proposed for clustering scientific publication documents. The study [12] proposes a multi-verse optimizer and k-means algorithm for extracting topics from clustered documents. K-means can be used especially in cases where the dataset is normally distributed such as scientific publication documents [13]. Furthermore, regarding LSA, study [14] proposed a method for information retrieval systems using LSA method to retrieve important information from questions asked by users or mass documents, and the results showed a positive contribution. Therefore, the selection of VSM, K-means, and LSA is proposed based on a literature review [10] [11] [12] [13] [14], given their effectiveness in addressing the specific aspects required for the study, the use of alternative methods may not align with our objectives.

The objective of this study is to develop an information retrieval system that generates clusters and study expertise at the level of study program, faculty and Lampung University. The study is driven by the following three research questions: (1) How to develop the information retrieval system for scientific publications using the Vector Space Model (VSM), K-Means and Latent Semantic Analysis (LSA)? (2) How many clusters are formed based on data generated by the information retrieval system? (3) What is the most dominant study topics based on the results of the information retrieval system? Answers to these study questions are provided and discussed in the remaining sections of this paper, particularly in the results and discussion section. We aim to contribute to the ongoing discourse on information retrieval system development and provide practical insights on VSM, K-Means and LSA implementation to determine study expertise.

II. STUDY METHODOLOGY

In developing the information retrieval system (see Fig. 1), various stages are proposed, which include data collection, preprocessing, modeling, evaluation, and system distribution. Initially, 37242 scientific publication documents from lecturers were collected from the repository of the Institute for Study and Community Service (LPPM), University of Lampung. After collection, the data was preprocessed by keyword extraction, cleaning, language detection, translation, stemming, and stopword removal. The data was then modeled to achieve clustering and classification of study topics. The evaluation was done using clustering test methods such as Silhouette score [15], Calinski-Harabasz score [16], and Davies-Bouldin score [17]. Finally, the obtained study data on clusters and scientific publication expertise were distributed as meaningful information for Lampung University.

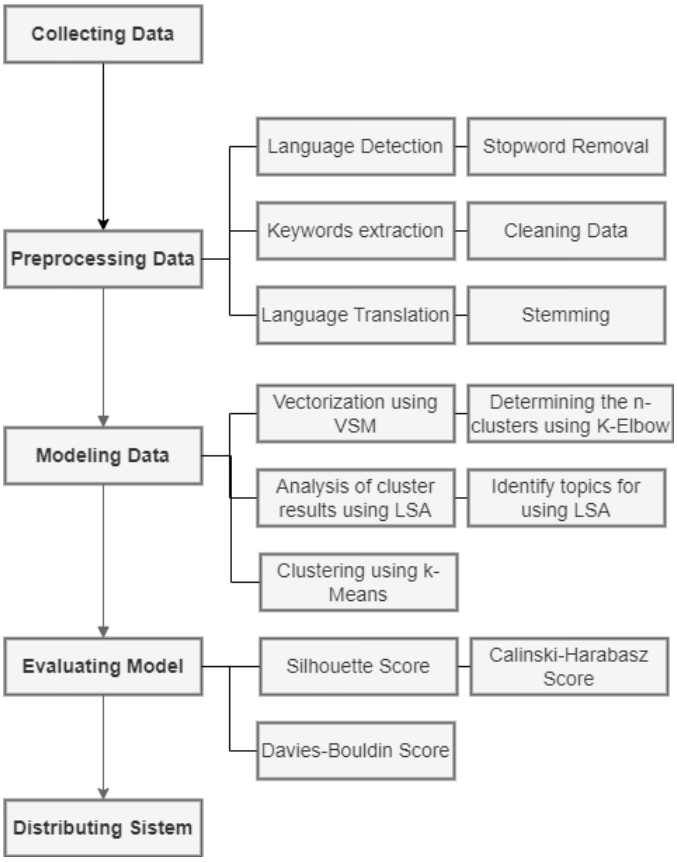

Fig. 1. Stages of information retrieval system development.

III. Results and Discussion

A. Data Collection

The first stage in the development of the Lampung University Lecturer Publication Information Retrieval System is literature study and data collection. Data collection is done by first creating a program using the Python programming language which can be seen in Fig. 2. This program was created to retrieve raw data from the Lampung University's LPPM repository (http://repository.lppm.unila.ac.id/) into collection data. The rest, this program is used to collect data from each URL that has been registered, clean the data collection and convert it into csv.

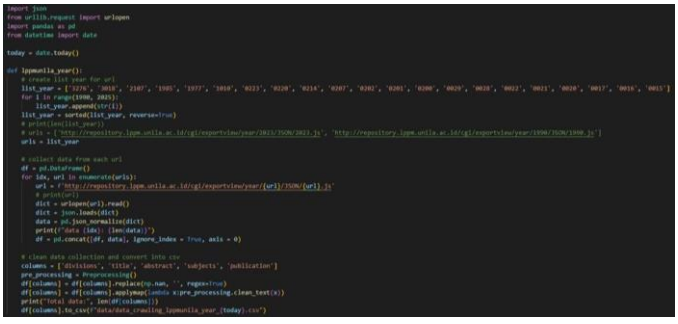

Fig. 2. Code of the study publication data collection program.

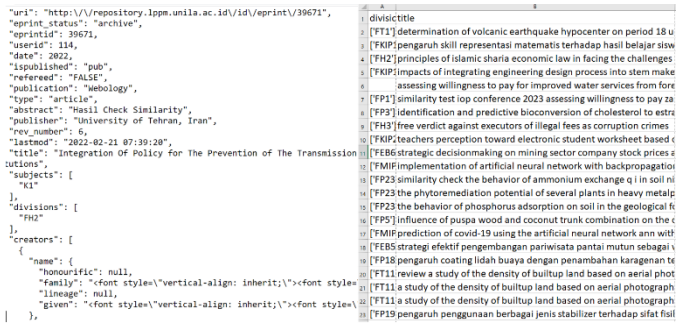

Fig. 3. Data collection of study publication.

Using the above program, 37242 data were retrieved. These data are scientific publication data of Lampung University lecturers, including division, title, abstract, subjects, publication, publisher, date, keywords. Fig. 3 shows raw data from Lampung University's LPPM repository and collection data in the form of .csv files processed by the program.

B. Data Preprocessing

The next step is data preprocessing. This stage aims to clean the collection data prepared for data modeling. This stage includes several activities, including keyword extraction, data cleaning, language detection, language translation, stemming, and stopword removal. These preprocessing stages are performed sequentially.

The collection data obtained from the Lampung University's LPPM repository does not have good consistency, some data have keywords and some do not, so the first preprocessing stage performed is the separation of keywords from abstract data using the Python library and regex. After the keywords data are obtained, the title and abstract data are cleaned by separating some unimportant characters and symbols. In addition to inconsistencies related to keywords, the collection data obtained is also inconsistent regarding language, therefore the next stage is to detect the language, and if there is data in English then it is translated into Indonesian. After all the data is in Indonesian, the next data is stemming which converts a word to its root word by removing the phrase prefix [18]. The last preprocessing stage performed is stopword removal; this stage is performed to remove unimportant words. The stopword removal can be seen in Fig. 4. Furthermore, the preprocessing results of keywords, abstract and title data are combined into a feature that is ready to be used for data modeling.

Fig. 4. The stopword removal to remove unimportant words..

C. Data Modeling

The next stage is data modeling which is the core of the development of this information retrieval system. Data modeling in this study is aimed at obtaining clustering and topic classification from study data using various machine learning methods. The modeling stages include text vectorization using the VSM model, determining the number of clusters using the k-elbow method, clustering using the k-means method, visual analysis of cluster results using the Umap library and the LSA method, and topic classification using the LSA method. This data modeling stage is performed on three different types of data, first for university level data, second for faculty data and third for study program data.

The collection data are preprocessed and then converted into vector form using VSM. One of the VSM methods used is TF-IDF (Term Frequency - Inverse Document Frequency). TF-IDF produces a vector value based on measuring the authenticity of a word by comparing the number of occurrences of a word in a document with the number of occurrences of a document containing that word. The vector results obtained from the University of Lampung study data have vector dimensions (37242, 3094428). The result of the vector is then used to determine the number of clusters and the clustering process, k-elbow and k-means methods are proposed in this case. In the results, the number of clusters obtained for the university level is 7 clusters, while for the faculty level is 6, 7, 8 and 10 clusters, while for the study program level is 3 to 5 clusters. The details for the faculty and study program levels can be seen in Tables I and II. In addition, the results of clustering at the university level can be seen visually in Fig. 5.

TABLE I. FACULTY-LEVEL CLUSTERING INFORMATION

Faculty	Total Data	Cluster Number	Topic
FKIP (Faculty of Teacher Training and Education)	4710	8	student, learning, teacher, education, teaching, Lampung, language,class
FMIPA (Faculty of Mathematics and Natural Sciences)	5042	7	plant, orchid, plant, extract, method, acid, virus
FEB (Faculty of Economics and Business)	2207	8	business, work, Lampung, indonesia, employee, consumer, tax,money
FT (Faculty of Engineering)	4401	6	land, water, city, oil, material, earth
FP (Faculty of Agriculture)	9022	10	plant, forest, agriculture, fertilizer, tree, food, water, plant, food,Lampung
FISIP (faculty of Social Sciences and Political Sciences)	2912	7	lampung, village, community, travel, tourism, group, work, district
FK (Faculty of Medical)	6569	8	patient, health, mind, development, behavior, school
FH (Faculty of Law)	2466	7	law, custom, community, protected, Lampung, tax, data

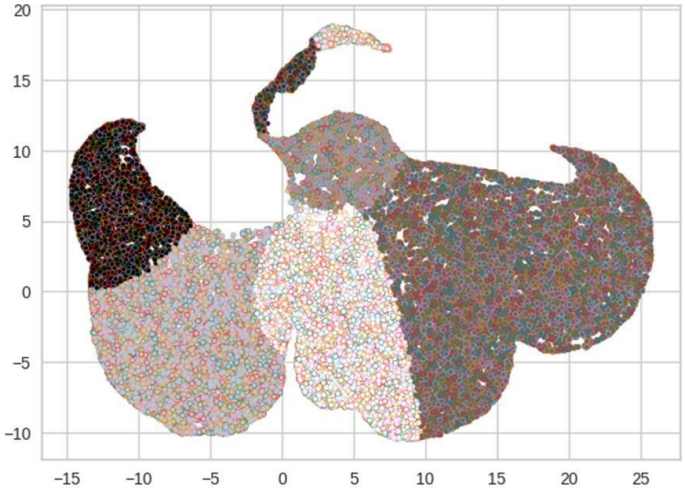

Fig. 5. Visualization of University-level clustering.

In addition to clustering, the results of this study also generate a set of topic identification from each clustering obtained. These topics identifications are generated using the LSA method. For each topic identification from the clusters obtained, then a topic is selected that is very relevant in the context of the topic in manually, for example from the Faculty of Agriculture 2 clusters are produced, the first cluster has classified topics including study, results, farming, while the second cluster is soil, processing, farming, then from the first cluster the topic taken is farming and the second cluster the topic taken is soil. This is because the topic represents the cluster; in addition to the words farming and soil have a context related to the study topics of the Faculty of Agriculture. The results of topic classification for the university level include agriculture, soil, education, plants, learning, society, Lampung. As for faculties and study programs can be seen in Table I and Table II.

D. Data Evaluation

The next stage is model evaluation. The model evaluation stage is used to test the quality of the clustering results of the proposed model. Several methods are used to obtain the evaluation results, including Silhouette score, Calinski-Harabasz score, and Davies Bouldin score. The Silhouette score with a value close to 1 means that the data point is in the correct cluster, close to -1 means that the data points is in wrong cluster [15]. While in Calinski-Harabasz calculations, the higher the value, the better the grouping is [16]. On the other hand, for the Davies Bouldin score, the smaller the value produced, the more optimal the clustering model [17]. The clustering model evaluation results obtained for the university level are 0.53 for the Silhouette score, 107298.36 for the Calinski Harabasz score, and 0.60 for the Davies Boulding score. The plot of these scores shows that the cluster model formed is quite good. Meanwhile, the results of the clustering model evaluation for the faculty and study program levels can be seen in Table III and Table IV.

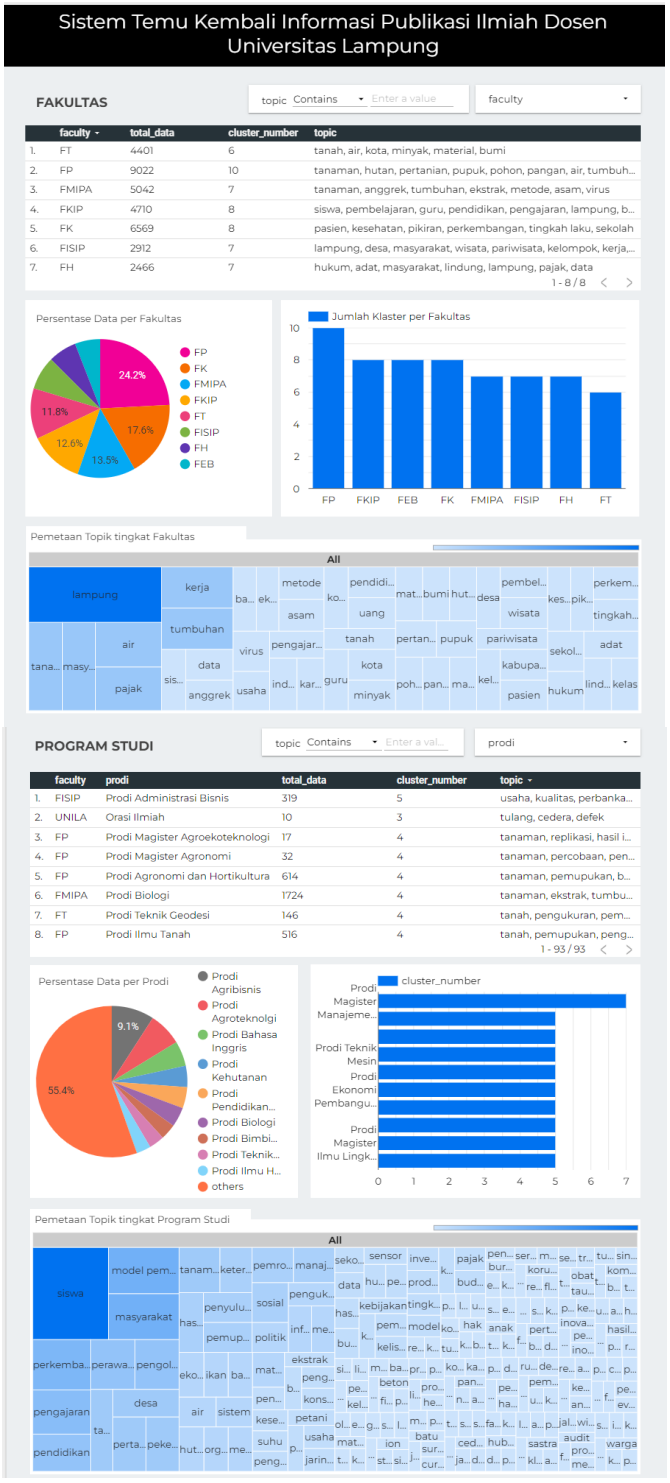

Fig. 6. Dashboard of information retrieval development.

E. Data Distribution

The last stage in the development of this information retrieval system is system distribution. The purpose of this stage is to make it easier for users to access the information generated by the developed information retrieval system.

This system distribution is in the form of a dashboard developed using Google Looker. The information contained in this dashboard consists of general information about this information retrieval system, clustering and classification of topics in the form of detailed data and visualizations. In addition, users can control the menu available on this dashboard and select specific information based on the faculty and study program level. The appearance of this system can be seen in Fig. 6.

F. Analysis Results

From the results of the development of this information retrieval, clustering, topic identification and model evaluation values for each clustering at the University, Faculty and Study Program levels were obtained. For the university level, 7 clusters were obtained with topic classifications including agriculture, soil, education, plants, learning, society, and Lampung. For the faculty level, 6 clusters were obtained for FT, 7 clusters for FMIPA, FISIP, FH, 8 clusters for FKIP, FEB, FK, and 10 clusters for FP.

For the study program level, the most clusters were obtained, namely 5 clusters, this cluster was owned by Master of Government Science study program, Bachelor of Education in Indonesian and Regional Languages and Literature, Bachelor of Education in Drama, Dance and Music, Bachelor of State Administration, Bachelor of Agricultural Engineering, Bachelor of Communication, Bachelor of Agribusiness, Bachelor of Mechanical Engineering, Master of Agricultural Extension and Communication, Diploma in Civil Engineering, Master of Environmental Science, Bachelor of Physical Education, Health and Recreation, Bachelor of Computer Science, Bachelor of Physics. Most of the clusters in this study program belong to study programs with faculties FISIP, FKIP, FT, FMIPA and FP. The amount of data is not always directly proportional to the number of clusters, for example at the faculty level it can be seen that the smallest number of clusters is FT, which is 6, but the amount of data is greater than FEB, FISIP and FT, as well as at the study program level.

Furthermore, the evaluation results of the clustering model obtained for the university level are 0.53 for the Silhouette score, 107298.36 for the Calinski Harabasz score, and 0.60 for the Davies Boulding score. As for the faculty level, the optimal value for Silhouette score is 0.514 which is obtained by FISIP, the optimal value for Calinski Harabasz score is 19386.733 which is obtained by FMIPA, the optimal value of Davies Bouldin score is 0.518 which is obtained by FT. As for the study program level, the optimal value for the Silhouette score is 0.945 which is obtained by the Doctor of Agricultural Science Study Program, the optimal value for the Calinski Harabasz score is 7450.063 which is obtained by the Agribusiness Study Program, the optimal value of the Davies Bouldin score is 0.058 which is obtained by the Doctor of Agricultural Science study program. All study programs obtain the optimal value are come from FP.

In addition, based on the optimal scores obtained from the three clustering evaluation methods used, there are variations in results between faculties and study programs, which indicate the formation of study relationships. Therefore, this study also examined the study relationships between faculties and/or study programs, the results of which can be seen in Table V. FP is the faculty with the highest number of study

relationships, namely 11 relationships. The relationships owned by the Faculty of Agriculture include relationships between study programs in FP, FH, FT, FISIP, and FK.

TABLE V. STUDY RELATIONSHIPS BETWEEN FACULTIES AND STUDY PROGRAMS

Faculty	Faculty relationship	Number of Relationships
FKIP (Faculty of Teacher Training and Education)	[['FKIP1', 'FKIP14'], ['FKIP19', 'FKIP20', 'FKIP21'], ['FKIP23', 'FMIPA3'], ['FK1','FKIP1']]	4

FH (Faculty of Law)	[['FH1', 'FP1'], ['FEB3', 'FH1', 'FH3']]	2

IV. CONCLUSION

This research aims to develop an information retrieval system that generates clustering and expertise in study fields at the program, faculty, and university levels of Lampung University.

The development stages of this information retrieval system include data collection, data preprocessing, data modeling using VSM, K-Means, and LSA, data evaluation, and system distribution. To address the first research question, VSM is used to obtain text similarity in vector form, K-Means is used for data clustering, and LSA is used to identify study expertise based on the obtained clustering. The analysis results of this information retrieval system development include the number of clusters, the scores from the model evaluation, and the topics identified according to the number of clusters. The obtained cluster numbers for the university level are 7 clusters, while for the faculty level there are 6, 7, 8, and 10 clusters, and for the program level there are 3 to 5 clusters. These cluster numbers answer the second research question. Furthermore, based on the number of clusters, study relationships, and cluster model evaluation scores, study clustering occurs predominantly in programs and faculties of FP, FISIP, FMIPA, FT, and FKIP. Research question number three is addressed by identifying topics based on the number of clusters identified as the most dominant study expertise at Lampung University, including agriculture, soil, education, plants, learning, society, and region Lampung.

Although the topic identification in this research uses Latent Semantic Analysis, the number of identified topics with the number of clusters is still manually selected. Therefore, further research is needed to develop information retrieval systems that can automatically expertise topics based on a set of identification topics. Nevertheless, the development of information retrieval system in this research addresses the needs related to the excellence of study fields at Lampung University.

Adaptive Gray Wolf Optimization Algorithm based on Gompertz Inertia Weight Strategy

Qiuhua Pan
Institute of Mathematical Sciences, Shanghaitech University, Shanghai 201210, China

***Abstract*—To solve the problems that the Gray Wolf Optimizer (GWO) convergence speed is not fast enough and the solution accuracy is not high enough, this paper proposes an Adaptive Gray Wolf Optimizer based on Gompertz inertia weighting strategy (GGWO). GGWO uses the characteristics of the Gompertz function to achieve nonlinear adjustment of the inertia weight, which better balances the speed of global search and accuracy of local search of the GWO algorithm. At the same time, the Gompertz function is used to realize the adaptive adjustment of the individual gray wolf's position and to better update the gray wolves' position according to the fitness values of different gray wolf individuals. Use 6 classic test functions to compare the performance of GGWO in optimization and 10 other classic or improved swarm intelligence algorithms. Results show that GGWO has better solution accuracy, stability, and faster convergence than all other 10 swarm intelligence algorithms.**

***Keywords*—Gray wolf optimization algorithm; inertia weight; adaptive; Gompertz function; swarm intelligence algorithm**

I. INTRODUCTION

The world is full of unknowns, and there are many uncertain problems in the unknown world. There is a lot of uncertain information that needs to be processed. To represent and process uncertain information, many optimization problems arise. Many optimization algorithms have emerged as the times require. In the fields of applied mathematics and engineering, there are a large number of optimization problems, and the computational solutions of these problems are located in a complex solution space. Therefore, finding new optimization methods with fast computation speed and strong convergence ability is of great practical significance. With the development of digitization and informatization, more and more meta-heuristic algorithms are being applied in the fields of science and engineering. Metaheuristic algorithms have the characteristics of self-organization, compatibility, parallelism, holism, and coordination. Their working principle is to initialize a set of random solutions and then perform repeated feedback iterations to approach the expected goal. In this search mechanism, the algorithm only needs to know the objective function and search range and can obtain the target solution regardless of whether the search range is continuous and differentiable. Metaheuristic algorithms are mainly divided into three types: biological evolution, natural phenomena, and species' living habits. The swarm intelligence optimization algorithm can specifically represent unknown information. The swarm intelligence algorithm is a model with optimization as its task. The swarm intelligence algorithm is generally based on imitating the living methods and behavioral habits of natural organisms and can optimize problems and methods with special methods. The iterative process of swarm intelligence algorithms is generally based on feedback from individuals within the population, such as particle swarm optimization, where all individuals in the population refer to the position information of the globally optimal individual to move. The cuckoo algorithm simulates the behavioral habits of cuckoo chicks and updates position information based on Levy flight. The grey wolf optimization algorithm is based on the hunting behavior habits of the grey wolf population, and the position updates of all individuals in the population are based on the globally optimal positions of three grey wolves. Researchers have proposed many solutions and drawn many important conclusions and achievements in exploring the performance improvement of swarm intelligence algorithms.

In the expansive domain of optimization algorithms, methodologies that diligently seek optimal or near-optimal solutions have demonstrated their indispensable value across a spectrum of disciplines and fields. These algorithms are not merely instrumental in enhancing the efficiency and performance of systems, designs, or models but also play a pivotal role in decision-making, resource allocation, and quality improvement. In various domains, such as machine learning, engineering, economics, logistics, biology, and computer science, optimization algorithms facilitate optimal parameter adjustments, design, resource distribution, and experimental design, thereby crafting a robust platform for interdisciplinary communication and collaboration. While these instances merely skim the surface regarding the application of optimization algorithms across disciplines, their profound impact and extensive connections undeniably propel the continuous progression and development of scientific technology. Transitioning from the general landscape of optimization algorithms, the Gray Wolf Optimizer (GWO) warrants specific attention, presenting its unique methodology in the rich field of optimization.

Researchers have been inspired by long-term observations of the social interactions, lifestyles, and biological behaviors of organisms such as fish, ants, elephants, wolves, and bees in nature, and have developed a series of related optimization algorithms to solve many practical problems such as engineering optimization and power dispatch. The GWO algorithm is implemented by utilizing the intelligence of gray wolves and their collective hunting characteristics. The GWO algorithm simulates a group of wolves following a specific hierarchical pattern, with different categories of wolves (named alpha, beta, delta, and omega) playing different roles

in the hunting mechanism to achieve search and hunting purposes.

II. Literature Review

GWO is a swarm intelligence optimization algorithm proposed by Mirjalili. This algorithm is derived from the hunting mechanics and leadership levels of gray wolves in the natural world. Mirjalili [1] used GWO to train the multi-layer perceptron (MLP). It's found that GWO has higher accuracy and is competitive in avoiding local optimality. Mohanty [2] completed the maximum power point tracking design of photovoltaic PV systems by GWO. Mirjalili [3] proposed the multi-objective gray wolf optimizer (MOGWO) in 2016, which is very effective in solving multi-objective optimization problems. Emary [4] proposed a binary version called bGWO for better feature selection. Heidari [5] integrated Levy flight and greedy algorithms to obtain a new LGWO algorithm to improve optimization performance. Faris [6] also discussed different versions of GWO optimization in detail, divided them into modified versions, hybrid versions, and parallel versions, and analyzed their role in the main application fields. Kohli [7] introduced chaos theory into GWO, which greatly improved the global convergence speed. Gupta [8] proposed an improved algorithm called RWGWO rooted in random walks to solve optimization problems in life. Nadimi [9] proposed an efficient gray wolf optimizer (I-GWO) based on the dimensional learning hunting (DLH) search strategy. Al [10] combined GWO with PSO to implement a new BPSOGWO binary algorithm to find the best feature subset.

GWO transcends its foundational application in mathematical function optimization, demonstrating utility across diverse domains. Altan [11] used GWO to optimize the intrinsic model function output and efficiently utilize wind energy. Zhao [12] used GWO to search feature sets to improve the diagnostic accuracy of patients with paraquat poisoning. Jayabarathi [13] also used GWO to solve economic dispatch problems. Sulaiman [14] applied GWO to solve the power deployment problem (ORPD) in the power system. Shariati [15] created a model combining a hybrid extreme learning machine with GWO to forecast the strength of concrete if replaced partially by cement. Jino [16] applied optimization algorithms like GWO in advanced image processing fields. Ramakrishnan [17] uses MRG-GWO for segmentation in an estimate of the CT brain tumor images. The GWO algorithm can help find optimal or suboptimal scheduling solutions, Jiang [18] used GWO to solve cases of scheduling Job Shop and Flexible Job Shop. Wei [19] improved SVM by using GWO and applied it in predicting the second major. Yang [20] used grouped GWO to optimize the parameters of wind turbines and improve the maximum power and obstacle-breaking capability.

GWO has more application scenarios including machine learning, image processing, and engineering design.

Within the machine learning sphere, SVM's (Support Vector Machines) potential is often bound by the intricacies of parameter optimization. Zhou's research [21] in 2021 elucidated this challenge by introducing two models. While both models aimed at earthquake forecasting, the latter, harnessing the capabilities of GWO, showcased commendable performance. This reinforces GWO's capability for effective exploration and exploitation in parameter optimization.

In the domain of image processing, particularly image segmentation, achieving a synergy of quality and efficiency remains pivotal. Khairuzzaman's work [22] in 2017 offers a paradigm in this regard. By leveraging GWO for multilevel thresholding, the research underscored GWO's adaptability in delivering quality segmentation with computational expediency.

Transitioning to engineering design, particularly in wind energy optimization, the nuances of turbine efficiency stand paramount. Yang's 2017 study [20] on the optimization of Maximum power points for wind turbines, specifically those operating on doubly-fed induction generators, provides a testament to GWO's efficacy. The introduction of Grouped GWO in this context exemplifies the optimizer's finesse in adaptive parameter adjustments for enhanced energy outputs.

Beyond its established domains, GWO has shown remarkable adaptability in addressing various complex optimization problems, encompassing both classical combinatorial issues and cutting-edge applications.

A quintessential example is the Traveling Salesman Problem (TSP). Given the complexity of determining the shortest possible route that visits each city exactly once and returns to the origin, Panwar's contribution is notable. In 2021, Panwar [23] employed a discrete GWO approach, paving the way for efficient solutions to symmetric TSP instances. This application not only accentuates GWO's versatility but also underscores its potential in combinatorial optimization.

Furthermore, in the domain of software engineering, predicting software defects based on metrics data is a crucial task. GWO's application in Software Defect Prediction (SDP) focuses on optimizing both feature selection and classifier parameters. One intriguing application by Kermadi [24] highlighted GWO's efficacy in designing an efficient photovoltaic array hybrid maximum power point tracker, specifically tailored for intricate local shading conditions in SDP.

Multi-objective optimization problems (MOP) present another challenging arena, where the goal is to find non-inferior solutions across multiple objectives. Wu's research in 2020 [25] exemplifies this by integrating GWO with other objective optimizations for wind speed forecasting. This innovative approach, leveraging GWO's capabilities, orchestrates harmony among various objectives, generating superior solutions.

It further reveals novel applications of GWO in electrical and control systems. Lakum [26] employed GWO for optimally placing and sizing active power filters in radial systems, especially amidst nonlinear-distributed generation. Arora's work [27] ventured into algorithmic hybridization, combining GWO with the Crow Search Algorithm (CSA) for enhanced function optimization and feature selection. Sun's research [28], on the other hand, utilized GWO for the intricate task of feedback control optimization in PM hub motors. Moreover, Eltamaly's study [29] stands out in

harnessing GWO-FLC to track dynamic maximum power points (MPP) for PV systems under variable shading conditions. Jamal employs the Improved Grey Wolf Optimization (IGWO) algorithm to optimize overcurrent relay coordination, demonstrating its enhanced efficiency and reliability over conventional methods [30]. Telugu utilizes the Chaos-enhanced Grey Wolf Optimization Algorithm (CGWO) for designing a two-stage CMOS Differential Amplifier, achieving significant improvements in reducing circuit size and power dissipation compared to traditional optimization methods [31].

The diverse applications of GWO demonstrate its adaptability and robustness across various research arenas, addressing distinct challenges and expanding its applicability in optimization landscapes. Its multifaceted use across sectors showcases its versatility in delivering optimal solutions. However, current improvement ideas often blend multiple algorithms, facing issues like low accuracy, slow convergence speed, and poor stability. This article suggests a streamlined and efficient enhancement plan solely based on the GWO algorithm, aiming to tackle these issues.

Section III introduces the background and basic principles of the GWO algorithm; Section IV introduces the two strategies of inertia weight and adaptive weight respectively, and uses them for GWO position update, thereby obtaining an adaptive algorithm based on Gompertz inertia weight(GGWO); Section V uses simulation experiments to compare and analyze the convergence performance, convergence speed, stability and time complexity of 11 algorithms including GWO and GGWO from three dimensions and six test functions; finally Section VI summarizes the full text and looks forward to the diverse application scenarios of GGWO in the future.

III. Gray Wolf Optimization Algorithm

GWO simulates the hunting mechanism and leadership levels of gray wolves by dividing these wolves into four layers according to the characteristics of gray wolves. The first layer is the α layer, the leaders of the population, in charge of leading the rest wolves to hunt prey, which is interpreted as the optimal solution in the algorithm. The second layer is the β layer, responsible for assisting the α layer wolf pack, and this layer interprets the sub-optimal solution in GWO. The third layer is the δ layer, which should obey any orders or decisions made by the previous two α and β and they have to investigate more etc. The grading mechanism of gray wolf packs is not static. Some of the α and β with poor fitness will degenerate to δ. The fourth layer is called the ω layer, which updates its position according to the previous three α, β, or δ. Furthermore, these four layers of wolves α, β, δ, and ω cooperate in the hunting. There are in total three main stages of gray wolf hunting, and they are simulated specifically as surrounding prey, chasing prey, and attacking prey.

In the first stage of surrounding the prey, the gray wolf will update its position based on the position information of the prey and gradually surround the prey, as shown in Eq. (1):

$$\overrightarrow{X}(t+1) = \overrightarrow{X_p}(t) - \vec{A} \cdot \vec{D} \quad (1)$$

where X stands for the position vector of the gray wolf, t represents the number of iterations, X_p

is the position vector of the prey, and the parameters A and D as shown in Eq. (2), (3):

$$\vec{A} = 2\vec{a}\vec{r_1} - \vec{a} \quad (2)$$

$$\vec{D} = |\vec{C} \cdot \overrightarrow{X_p}(t) - \vec{X}(t)| \quad (3)$$

Among them, $\vec{a}$ linearly decreases from 2 to 0 during iteration, $\vec{r_1}$ is a random vector on $[0,1]$, and

the parameter C is as follows in Eq. (4):

$$\vec{C} = 2\vec{r_2} \quad (4)$$

where is a random vector.

While hunting prey, the behaviors of all the gray wolves are guided by α, β and δ gray wolves and these three layers of wolves may also cooperate with ω gray wolves in hunting. To better simulate and reproduce the hunting strategy of gray wolves, we suppose that α, β, and δ have a better idea of the potential position of prey. Via sorting the fitness values of all the wolves, the best three layers of wolves are chosen as α, β, and δ respectively. The specific gray wolf location update steps are as follows:

First, the corresponding $\vec{D}_\beta$ and $\vec{D}_\delta$ are as shown in Eq. (5):

$$\vec{D}_\alpha = |\overrightarrow{C_1} \cdot \overrightarrow{X_\alpha} - \vec{X}| \ \vec{D}_\beta = |\overrightarrow{C_2} \cdot \overrightarrow{X_\beta} - \vec{X}| \ \vec{D}_\delta = |\overrightarrow{C_3} \cdot \overrightarrow{X_\delta} - \vec{X}| \quad (5)$$

Then, solve the position vector $\vec{X}(t+1)$ of the current gray wolf in the next iteration, as shown in Eq. (6) and (7):

$$\overrightarrow{X_1} = \overrightarrow{X_\alpha} - \overrightarrow{A_1} \cdot \overrightarrow{D_\alpha} \quad \overrightarrow{X_2} = \overrightarrow{X_\beta} - \overrightarrow{A_2} \cdot \overrightarrow{D_\beta} \quad \overrightarrow{X_3} = \overrightarrow{X_\delta} - \overrightarrow{A_3} \cdot \overrightarrow{D_\delta} \quad (6)$$

$$\vec{X}(t+1) = \frac{\overrightarrow{X_1} + \overrightarrow{X_2} + \overrightarrow{X_3}}{3} \quad (7)$$

In summary, this algorithm outlines a structured process for GWO, iterating through defined steps to ascertain optimal solutions by emulating the hierarchical and behavioral dynamics of gray wolves.

IV. Adaptive Gray Wolf Optimization Algorithm based on Gompertz Inertia Weight Strategy

A. Gompertz Inertia Weight Strategy

The Gompertz function [32] is monotonic, and its function expression is as shown in Eq. (8):

$$y = -e^{-e^{-x}} + 1 \quad (8)$$

Draw the graph of the Gompertz function as shown in Fig. 1:

As shown in Fig. 1, the Gompertz function curve is characterized by slow growth in the initial and final stages and rapid growth in the middle section. The image of the

Gompertz function tends to decrease as the abscissa increases, which is related to the iterative process of swarm intelligence algorithms. In the early stages of swarm intelligence algorithm iteration, the population is prone to falling into local optima, so it is necessary to give a larger step size initially. Giving a larger inertia weight can increase the step size of individual gray wolf movements, thereby helping the population to better conduct global search. As the algorithm iterates, the needs of individual populations gradually shift from global optimization to local optimization. In the later stages of the algorithm, some individuals need to strive to explore global optima within a small range, so giving a smaller step size in the later stages of the algorithm can help the algorithm perform local optimization. The Gompertz function has this feature, as its value decreases as the abscissa increases, which helps our algorithm balance global optimization and local optimization. This article uses it to improve the inertia weight of the GWO. The Gompertz inertia weight ω used in this article is as follows in Eq. (9):

$$w = -e^{-e^{\frac{t}{M}}} + 1 \tag{9}$$

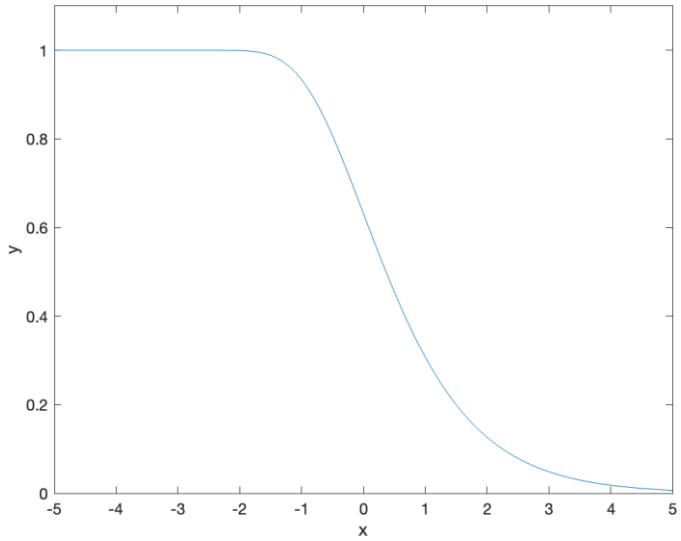

Fig. 1. Gompertz function.

The graph of selecting the right side of the y-axis as the inertia weight ω of the GWO algorithm is shown in Fig. 2:

As shown in Fig. 2, the Gompertz inertia weight remains large in the early stages of iteration, which is conducive to maintaining a large search range of the algorithm, making the algorithm less likely to fall into the local optimal solution; as the number of iterations of the algorithm increases, the curve in the middle section will decrease rapidly and eventually stabilize at a smaller value, which will help the algorithm have a smaller inertia weight in the later stages of the iteration, which will help find the optimal solution more thoroughly in local area and during long periods.

B. Gompertz Adaptive Position Update Strategy

Gompertz function is used to construct the adaptive weight Φ_i strategy as shown in Eq. (10):

$$\Phi_i = -e^{\frac{f_i}{f_{avg}}+1} - e^{\frac{f_i}{f_{avg}}} + 1, (i = 1, 2, 3) \tag{10}$$

Among them, f_1, f_2, and f_3 represent the fitness of the α, β and δ layer wolves respectively. f_{avg} is as shown in Eq. (11):

$$f_{avg} = \frac{f_1 + f_2 + f_3}{3} \tag{11}$$

Gompertz adaptive weight Φ_i is shown in Fig. 3:

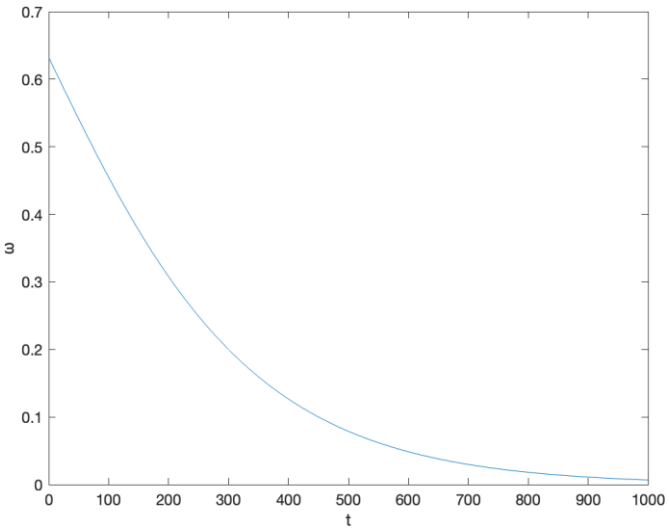

Fig. 2. Gompertz inertia weight.

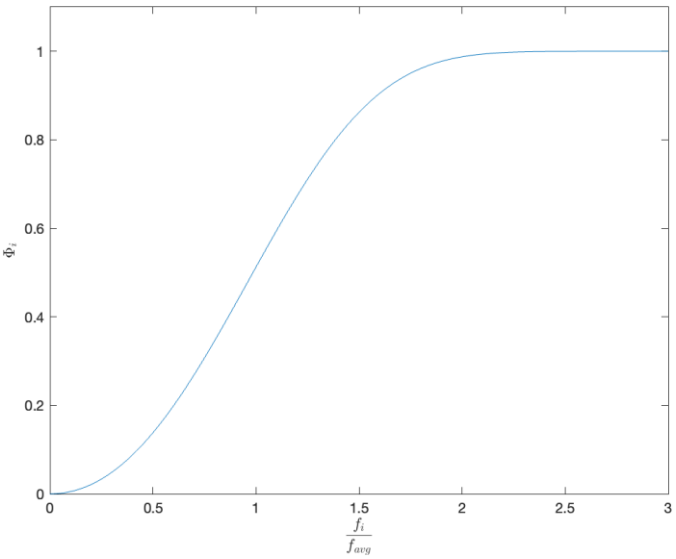

Fig. 3. Gompertz adaptive weight strategy.

As shown in Fig. 3, the Gompertz adaptive weight is close to 0 when the corresponding wolf fitness value is relatively small, indicating that the wolf is close to the prey. This step control is extremely small, which is conducive to more thoroughly finding the optimal value locally; As the corresponding wolf fitness value ratio increases, it indicates that the wolf is far away from the prey, so the Gompertz adaptive weight increases rapidly to prevent falling into the

local optimum, and the step size increases, which is conducive to searching for the optimum in the global scope.

C. Adaptive Gray Wolf Optimization Algorithm based on Gompertz Inertia Weight Strategy

Based on the Gompertz inertia weight strategy, the position update formula is modified as Eq. (12):

$$\overrightarrow{X_1} = w \cdot \overrightarrow{X_\alpha} - \overrightarrow{A_1} \cdot \overrightarrow{D_\alpha} \quad \overrightarrow{X_2} = w \cdot \overrightarrow{X_\beta} - \overrightarrow{A_2} \cdot \overrightarrow{D_\beta}$$
$$\overrightarrow{X_3} = w \cdot \overrightarrow{X_\delta} - \overrightarrow{A_3} \cdot \overrightarrow{D_\delta} \tag{12}$$

Based on the Gompertz adaptive weight strategy, the new gray wolf position $\overrightarrow{X}$ is obtained as shown in Eq. (7), (13):

$$\overrightarrow{X_1} = \Phi_1 \cdot \overrightarrow{X_1} \quad \overrightarrow{X_2} = \Phi_2 \cdot \overrightarrow{X_2} \quad \overrightarrow{X_3} = \Phi_3 \cdot \overrightarrow{X_3} \tag{13}$$

The steps of the GGWO algorithm are as follows:

1) Set the relevant parameters $\vec{a}$, $\overrightarrow{r_1}$, $\overrightarrow{r_2}$, $\overrightarrow{A}$, $\overrightarrow{C}$ according to Eq. (2), (3) and (4);

2) Define α, β and δ wolves;

3) Initialize the position of the population;

4) Calculate the fitness value according to Eq. (5) sort the fitness value from large to small, and filter out the top three D_α, D_β and D_δ corresponding to α, β and δ wolves respectively;

5) Update the positions of α, β and δ wolves according to Eq. (12) by adding inertia weight ω;

6) Then update the positions according to Eq. (7), (13) by adding an adaptive weight Φ_i and performing boundary check;

7) If the maximum number of iterations is reached, the algorithm stops and the optimal value is output; otherwise, return to step 4.

The flow chart of GGWO is shown in Fig. 4:

As shown in Fig. 4, the basic parameters of the GGWO algorithm are set to initialize the wolves, and then start iteration. In the process of continuous iteration, the position of the wolves is updated through various strategies like inertial weight, adaptive weight, and bounds check. Finally, after reaching the maximum number of iterations, the optimal value is output. The algorithm in this article uses the Gompertz inertia weight strategy and adaptive position update strategy to balance the global search and local search of the gray wolf population, which can effectively consider all information during the iteration process. Gompertz inertia weight strategy calculates the iteration of the algorithm, giving the same inertia weight value to all gray wolf individuals. This is to balance the global and local search performance of all gray wolf individuals from a global perspective. The adaptive position update strategy allows all gray wolf individuals to give different position update schemes to different gray wolf individuals when the number of iterations is fixed. This reflects the different fitness values of different particles and should be given different inertia weights, which is very scientific and necessary. The unity of the Gompertz inertia weight strategy and adaptive position update strategy can use all particles in the population to have targeted inertia weights and position update adjustment strategies, which is a non-multiplicative and scientifically reasonable solution.

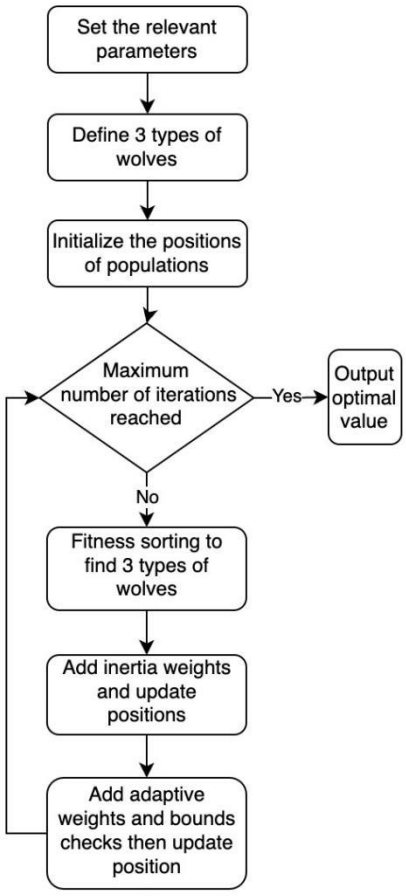

Fig. 4. The flow chart of GGWO.

V. Simulation Experiment and Result Analysis

Simulation environment: MacOS, memory: 256GB, machine frequency 3.49GHz, MATLAB R2022a.

A. Test Function and Parameter Settings

The six test functions used in the simulation experiments of this article are shown in Table I:

Table I introduces the expressions, upper and lower limits, and optimal values of the six test functions used in this simulation.

As shown in Table I, $f_1(x)$ is a simple sum of squares function, which is smooth and convex. It is typically used to assess the basic performance of an optimization algorithm. $f_2(x)$ combines a linear sum component and a multiplicative component, introducing both global structure and local minima. It tests an algorithm's ability to handle non-separable and multimodal functions. $f_3(x)$ is a nested sum of squares, adding complexity by testing the algorithm's performance on hierarchical problems where optimization at one level depends on the optimization at another. $f_4(x)$ is a maximization

function that tests the algorithm's ability to find the largest element in a vector, which can be useful for problems that require selection from a set of alternatives. $f_5(x)$ is reminiscent of the Rastrigin function, which introduces a large number of local minima, making it a challenge for algorithms to find the global minimum. $f_6(x)$ resembles a modified Schwefel function with a sinusoidal component, which is very challenging due to its complex landscape with many local optima.

TABLE I. TABLE OF TEST FUNCTIONS

Test Functions	Expressions of Functions	Domian	Optimal
F1	$f_1(x)=\sum_{i=1}^{n} x_i^2$	[-100,100]	0
F2	$f_2(x)=\sum_{i=1}^{n}\lvert x_i\rvert+\prod_{i=1}^{n}\lvert x_i\rvert$	[-10 ,10]	0
F3	$f_3(x)=\sum_{i=1}^{n}(\sum_{j=1}^{i} x_j)^2$	[-100,100]	0
F4	$f_4(x)=\max_i\{\lvert x_i\rvert, 1\le i\le n\}$	[-10,10]	0
F5	$f_5(x)=\sum_{i=1}^{n}[x_i^2-10\cos(2\pi x_i)+10]$	[-5.12,5.12]	0
F6	$f_6(x)=\frac{1}{4000}\sum_{i=1}^{n} x_i^2-\prod_{i=1}^{n}\cos(\frac{x_i}{\sqrt{i}})+1$	[-600,600]	0

B. Experimental Results Analysis

1) Comparison of average convergence curves of 11 algorithms

Select 8 classic swarm intelligence optimization algorithms [33-40], and then add the three algorithms improved in this article, which are Gray Wolf Optimization Algorithm Adding Inertia Weight (GIGWO), Gray Wolf Optimization Algorithm Adding Self-adaptive Weights (GSGWO) and Adaptive gray wolf optimization algorithm based on Gompertz inertia weight strategy (GGWO) for a total of 11 optimization methods. The average convergence curves of these 11 algorithms in three dimensions on 6 test functions are shown in Fig. 5 to 10:

In Fig. 5 to10, the abscissa reflects the number of current iterations, and the ordinate represents the logarithm of the fitness value. In low dimension (D=30) and high dimension (D=200, 300), As the iteration proceeds, the other eight algorithms except GIGWO, GSGWO and GGWO converge slowly and easily fall into local optimal, the evolution curve of the GGWO algorithm is the unique algorithm with the most obvious decline, the highest solution accuracy, and the fastest convergence speed, and will not fall into the local optimal.

Except for the initial convergence speed of the F2 test function in high dimensions, the other eight swarm optimization algorithms are close to the optimized algorithm GIGWO, GSGWO, and GGWO. However, they will easily fall into local optimality when the number of iterations grows, and the convergence speed and accuracy are also far inferior to those of the optimized ones. In addition, the standard GWO algorithm based on GIGWO, GSGWO, and GGWO, such as the high-dimensional F6 test function, has slightly lower accuracy and convergence speed than WDO. However, after the optimization, the convergence speed of the three algorithms GIGWO, GSGWO, and GGWO are all much higher than that of WDO, which shows that the optimization strategy in this article is quite effective.

And the convergence speed and solution accuracy of GIGWO and GSGWO are far better than GWO. The convergence speed of the GGWO algorithm on F1-F4 test functions is much higher than that of the GIGWO and GSGWO algorithms, indicating that both Gompertz inertia weight and adaptive optimization strategies are effective. On F4 and F5, the convergence speed of GGWO is far better than that of GIGWO and slightly better than GSGWO. The solution accuracy of the three algorithms is close and far better than the other eight algorithms, reflecting that the superposition of the two optimization strategies is still effective because the convergence results of GGWO are better in more cases.

As can be seen from Fig. 5 to 10, the GGWO has the fastest decline rate and the smallest final fitness value. In the high-dimensional case of F4, although GIGWO is not completely stuck in the local optimum, the curve is stable at first, indicating that it is still stuck in the local optimum at the beginning of the iteration, which makes it impossible to search for the global optimal solution as quickly as possible. Similarly, although GSGWO has not completely stuck into the local optimal solution in the F2 high dimension, the curve gradually stabilizes as the iterations proceed, indicating that it has fallen into the local optimal, which is also not conducive to the search for the global optimal.

The optimization performance and stability of 11 algorithms in low dimension (D=30) and high dimension (D=200, 300) are shown in Tables II to IV:

In Tables II to IV, the optimization performance and stability of 11 algorithms in low dimension (D=30) and high dimension (D=200, 300) are reflected by calculating the mean and variance. Among them, the bold data is the minimum value of the mean or standard deviation among the 11 algorithms.

2) Comparison of global optimal values of 11 algorithms

Whether it is high-dimensional or low-dimensional, GGWO has the smallest mean or standard deviation, which shows that GGWO has extremely strong optimization performance and stability. On the two test functions F5 and F6, GIGWO, GSGWO, and GGWO found the global optimal solution 0 in every experiment. The performance of GWO is lower than that of WDO, but after adding Gompertz inertia weight or adaptive weight, the performance and stability are much higher than that of WDO, which shows that the optimization strategy for GWO is quite effective.

In conclusion, the stability and convergence performance of GGWO is also the best among the 11 algorithms.

C. GGWO Time Complexity Analysis

The time complexity of GWO is $O(nmD)$, where n is the gray wolves' total number of in populations, m is the maximum number of iterations, and D is the dimension of the corresponding optimization problem. Moreover, GWO has one of the smallest time complexity among the eight algorithms in this article because the time complexity of other algorithms such as FA and GSA is as high as $O(n^2mD)$. GGWO uses Gompertz inertia weights and adaptive weights to update the position in the algorithm, which is essentially equivalent to linearly multiplying a constant in the formula during each iteration of the standard gray wolf optimization algorithm. Therefore, GGWO does not increase the time complexity of the original algorithm GWO, which means the time complexity of the improved algorithm GGWO in this article is also the smallest, $O(nmD)$.

GGWO greatly improves the algorithm's convergence speed, ability to jump out of local optima, and stability without additional increase in time complexity. In comparison with the other 10 population intelligent optimization algorithms, it clearly shows that the optimization performance far exceeds that of other algorithms.

VI. CONCLUSION

An adaptive gray wolf optimization algorithm based on the Gompertz inertia weight strategy is proposed, which uses the Gompertz function to improve the inertia weight and position update formulas. By comparing the simulation experiments, 11 different swarm intelligence algorithms were used on 6 test functions to draw the average convergence curve, and the average value of 10 runs was taken as the final display result. Experimental results show that GGWO has the smallest variance in the test functions, proving that it has the best stability. In addition, the average convergence curve of GGWO decreases the fastest, indicating that it has the fastest convergence speed. Moreover, the time complexity of GGWO is $O(nmD)$, which has a certain application potential. From the comparative analysis of standard deviation, convergence curve, time complexity, and other angles, the experimental results show that the improved algorithm GGWO has the characteristics of good stability, fast convergence speed, and high solution accuracy.

Although GGWO has made certain improvements in solution accuracy, speed, and stability, there are still some areas for future improvements. GGWO's work mainly focuses on adjusting inertial weights; we can consider other position update formulas in the future. In addition, the population initialization of GGWO is too random. Due to this, Latin hypercube sampling will be considered to initialize the population operation. Besides, while GGWO improved sharply on the simple or unimodal test functions, for processing some complex test functions or data, the effect might not greatly improved. Based on various industrial applications, GGWO can be an efficient optimization tool that can be used to deal with many practical optimization problems. In the future, GGWO will be used in some practical problems, such as medical image recognition, fault detection, UAV path planning, quantum neural network optimization, and other issues.

DATA AVAILABILITY

The data supporting the findings of this study are available from the GGWO repository at this link: GGWO

Optimizing Shuttle-Bus Systems in Mega-Events using Computer Modeling: A Case Study of Pilgrims' Transportation System

Mohamed S. Yasein[1], Esam Ali Khan[2]
The Custodian of the Two Holy Mosques Institute of Hajj and Umrah Research, Umm Al-Qura University, Makkah, KSA[1, 2]
Electrical Engineering Department - Faculty of Engineering, Port-Said University, Port-Said, Egypt[1]

***Abstract*—Mega-events are held in a city, or more, during a limited time, which requires special attention to the infrastructure and the offered services. The Hajj event, hosted in Makkah - Saudi Arabia, is considered as an excellent example of religious mega-events. The field of computer modeling and simulation is one of the main technical tools that help in developing and understanding the risks of crowds and studying the safety means during organizing of many major events in the world. This paper focuses on using computer simulation to optimize the pilgrims' shuttle-bus transportation system in Holy Sites (Mashaaer), as a case study of optimizing shuttle-bus Systems in Mega-Events using computer modeling. The objective of paper is to develop a model of the shuttle-bus transport system to give insights of the advantages of the use as an alternative for transporting pilgrims as well as to provide decision makers with a tool that could be used to select the best parameters of the system for the most efficient operation. For this purpose, pilgrims' evacuation time, traffic congestion and average trip time, from Arafat to Muzdalifa, are identified as the performance measures for evaluating the proposed transport system. The conducted simulation can be used to assess the current systems, recommend changes to the systems, and offer indicators and readings to assist decision makers.**

Keywords*—Computer modeling; simulation; optimization; shuttle-bus systems; mega-events; hajj

I. INTRODUCTION

Mega-events are considered as large-scale events attended by huge numbers of visitors. In addition, they have been getting much attention as key ingredients in tourism for many destinations [1]. Organizing a mega-event has a great impact on the hosting cities, which requires special attention to the infrastructure and the offered services [2].

In order to classify an event as a mega event, different criteria can be considered, such as duration, scale, number of visitors and importance of the event. Among the famous events that can be considered as mega-events are the Olympic Games, the World Expo and the Football World Cup [3], in addition to some religious festivities.

The Islamic pilgrimage (Hajj) event, which occurs once a year and is hosted in Mecca KSA, is an excellent example of religious mega-events.

The Hajj organizers aim at allowing the best possible number of Muslims to perform Hajj to the fullest; and providing the best services before, during and after their visit to Mecca. Transportation is an important service that is offered throughout the entire year and especially during Hajj days. Improving the quality of transportation services requires the use of modern techniques to raise the efficiency of operations and improve services.

Hajj is a set of rites unchanged for 14 centuries that takes place from the 8^{th} to 12^{th} (or in some cases 13^{th}) of Dhul al-Hijjah, the 12^{th} month of the lunar year. On the 8^{th} of Dhul al-Hijjah, pilgrims confirm their intention to make the pilgrimage. After Fajr prayer on the 8^{th} of Dhul al-Hijjah, the pilgrims proceed to Mina where they spend the whole day. The next morning (The 9^{th} of Dhul al-Hijjah), they leave Mina to go to Arafat, where they supplicate and seek mercy of Allah. Pilgrims leave Arafat for Muzdalifa after sunset. After returning from Muzdalifa, the pilgrims perform symbolic stoning of the pillars (Ramy al-Jamarat). On the same or the following day, the pilgrims revisit the Haram Mosque in Makkah for Tawaf al-Ifadah. The night of the 10^{th}, 11^{th}, and 12^{th} of Dhul al-Hijjah are spent back at Mina, where the same process of stoning of the pillars takes place. Finally, before leaving Mecca, pilgrims perform a farewell tawaf called Tawaf al-Wadaa. Fig. 1 illustrates the route taken by pilgrims on their journey and the relative proximity between the Holy sites.

The constraints of time (from the 8^{th} to 12^{th}/13^{th} of Dhul al-Hijjah) and area (Haram, Mina, Muzdalifa, and Arafat) pose different challenges for Hajj authorities responsible for controlling traffic and crowd movements of pilgrims. Such challenges further increase with the steady increase in the number of pilgrims each year.

The restricted times for pilgrim movements between Holy sites suggest that carefully planned pilgrim services are required to be aligned in accordance with such movements. In particular, one of the most important pilgrims' services is transportation.

During the past Hajj seasons, many transportations operational strategies, including regular buses, shuttle-bus, train, or on foot (walking), were successfully experimented between the Holy sites in Makkah.

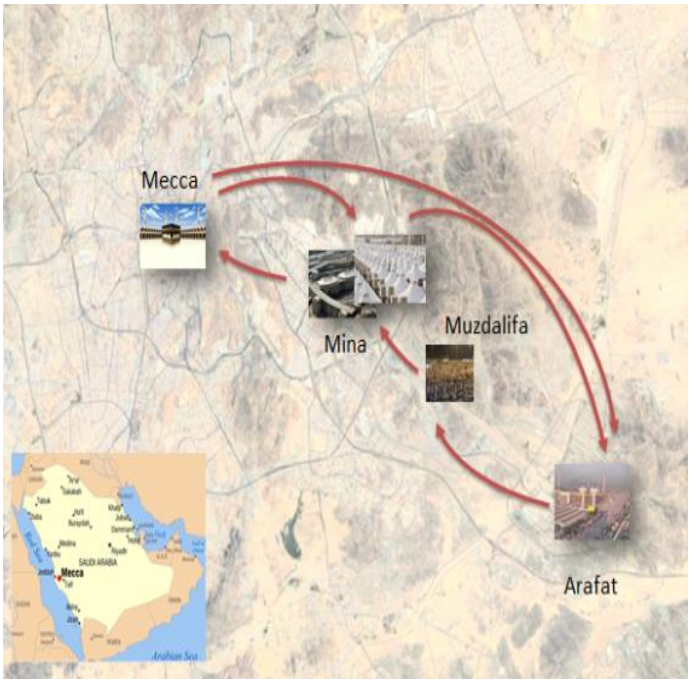

Fig. 1. The route of Hajj journey.

The Saudi Ministry of Transportation first reported on the idea of using shuttle-buses to transport pilgrims between Arafat and Muzdalifa. In the following years, the shuttle-bus project was extended to include the Muzdalifa–Mina roadway and presently continues to operate on the two segments of Arafat–Muzdalifa and Muzdalifa–Mina [4].

Due to the steady increase of number of pilgrims, which may reach five million by 2030, an optimized transportation system is of a high importance. This paper aims at utilizing computer modeling and simulation to study the effectiveness of the pilgrims' shuttle-bus transportation system in Mashaaer Holy Sites. It focuses on using computer modeling to optimize pilgrims' shuttle-bus transportation system for the path from Arafat towards Muzdalifa (Nafrah). More specifically, the paper focuses on the path of pilgrims of Turkey and Muslims of Europe, America, and Australia. This model can be used for the planning and analyzing all Hajj transportation operations. The results of the simulation may be used to assess the effectiveness of the current system and to suggest changes that might be made. Hence, the designed model can be used for optimizing the pilgrim's transportation system with respect to different parameters.

The paper is organized as follows. Section II discusses the literature review. Section III presents the proposed computer modeling of the shuttle-bus system, while results and discussions are presented in Section IV and V respectively. Conclusions are drawn in Section VI.

II. Literature Review

Several research studies investigated the research issues associated with pilgrims' transportation planning and the deployed shuttle-bus project [5], [6].

In [7], an integrated solution to the problem of pilgrimage transportation control while tracking the shuttle-bus from its starting point till its final destination was proposed. The system is designed to work in an environment where vehicle and passenger identification is required, namely at check points, in order to speed up the checking process with best quality services. In the designed system, buses are identified using RFID tags, while passengers boarding or getting off the bus are identified on the basis of RFID cards they have and finger identification.

In study [8, 9], a tool was created to assist in planning the shuttle-bus service operation configuration during Hajj using an analytical approach. With the use of this tool, the shuttle service between Arafat and Muzdalifa can be run with the fewest possible buses and cycles. It uses GPS data to gather information about the shuttle-bus service, including pick-up and drop-off timings, travel times along the path, and the number of pilgrims.

The research reported in [11] presents a simulation study of the 1422H Hajj season shuttle-bus transportation system using the Arena simulation system, with the goal of understanding of the characteristics and limitations of the system, by examining bus routes, dispatching mechanisms, and loading/unloading scenarios on system performance. During this Hajj season, approximately 160,000 pilgrims used the shuttle-buses, and 542 buses were used to transport pilgrims from Arafat to Muzdalifa. The paper suggested that in order to maintain a reasonable evacuation time, the number of buses should not be decreased below a limit of about 500 buses.

An approach in [12] is based on a stochastic simulation model to design a shuttle-bus system to transport pilgrims along the entire Arafat and Muzdalifa segment roadway, using logistics features of ProModel simulator. The model is used to estimate the number of buses needed to transport pilgrims at the shortest possible evacuation time with the least amount of congestion, as well as the number of bus stops needed to accommodate pilgrims. To evacuate Arafat in six hours, the study offered an expanded plan with 3160 buses and 740 bus stations.

A number of research papers addressed the optimization of shuttle-bus systems. The research in [14] examined the optimization of a local shuttle route. It creates a solution to the optimal routing design problem in order to minimize overall cost, which includes user and supplier costs, while taking budgetary restrictions and demand for passenger traffic into account. Both a genetic algorithm (GA) and a depth-first search algorithm (DFS) are used to accomplish this.

A hybrid genetic algorithm is used in [15] to solve a shuttle-bus route optimization model. The travel time reliability estimation approach is based on back propagation (BP) neural networks, and the optimization model is built with operational reliability maximization as its primary goal.

A structure for an optimization model that maximizes the general satisfaction of users and public transit businesses was presented in [16]. A hybrid intelligent optimization technique is utilized to solve the optimization model, which is based on

meeting the passenger journey time requirements and reducing the cost-of-service operations.

On a case study of a university shuttle-bus, the research in [17] employs the Artificial Neural Network and Support Vector Machine algorithms for the optimum journey time prediction with a lower error rate. It is also used to suggest appropriate pathways for the selected scenario.

In study [18], an optimization modeling approach based on simulation to assist airport shuttle operators in deploying electric vehicles efficiently was suggested. In order to achieve predefined objectives, the suggested approach uses an event-driven simulation model, Airport Shuttle Planning and Improved Routing Event-driven Simulation (AS-PIRES) [19], to propose an optimization model that determine the battery capacity, charging power, and number of chargers.

In study [10], a transport planning approach that is adopted for the Summer Olympic Games (SOG) and identifies lessons learned for planning of the Hajj/Umrah was explored. It described the context for each event and the nature of transport demand and supply and outlines the transport planning approaches used.

When planning a community shuttle service, the optimal stop location and route can help to reduce the walking distance of passengers and the route length. In study [13], a discrete optimization problem was proposed to make a trade-off between the walking distance of passengers and route length.

III. Modeling the Shuttle-Bus Transportation System in Arafat-Muzdalifa Area

A. Problem Formulation

The issue addressed in this study focuses on computer modeling of the shuttle-bus transportation system for pilgrims on the route from Arafat to Muzdalifa (Nafrah), in particular the route taken by Muslims from Turkey and other parts of Europe, North America, and Australia. Fig. 2 depicts the shuttle-bus route from Arafat to Muzdalifa that is taken into account in the proposed model.

The shuttle-bus transportation system in Arafat-Muzdalifa area is responsible for transporting the pilgrims from loading stations in Arafat (L_{SN} loading bus-stations) to unloading stations in Muzdalifa (U_{SN} unloading bus-stations). In Arafat, the pilgrims are moved to the bus stops in groups, each of fifty pilgrims, and loaded into the bus at that stop. When the Nafrah starts, the first group of buses departs Arafat taking pilgrims towards Muzdalifa and the following group is released to the bus stops. In Muzdalifa, buses unload the pilgrims at the pre-assigned bus stops. The shuttle-bus transportation network utilizes a dedicated two-lane bus road, where bus stops are constructed on the roads' shoulders.

The goal is to complete the evacuation of the designated number of Turkish pilgrims - roughly 240000 pilgrims - within the Nafrah's allocated time frame, maintaining the bus-stations capacity.

In order to complete evacuating the designated number of pilgrims, there is a need for a buses batch size (N), which is the overall number of buses dedicated for the transportation of pilgrims. The number of buses in a batch should be kept to a minimum both economically and to prevent excessive traffic congestion on the roads. In addition, the total time for completing the evacuation (T) should be kept within the time allotted for the Nafrah (T_A).

The different parameters that affect the shuttle-bus transportation system are as follows:

- The interarrival time for buses entering the system (I_T), which is the time interval between bus arrivals in the system. A small interarrival time may appear to speed up the evacuation operation for pilgrims because the entire bus batch size (N) begins doing their job more quickly, however, it may actually lead to traffic jams and causes overload in Arafat bus-stations, as the number of buses exceeds their capacity. Therefore, it's important to maintain a balance between the level of congestion and the rate at which buses enter the route. Using less bus interarrival time causes overload in Arafat bus-stations, as the number of buses exceeds their capacity.

Fig. 2. The path of shuttle-bus from Arafat to Muzdalifa.

- The bus trip time during Nafrah (B_T), which depends on the following parameters:
  - The pilgrims' loading time in Arafat (L_T).
  - The pilgrims' unloading time in Muzdalifa (U_T).
  - The buses' speed (B_S).
- The maximum number of cycles (loops) that each bus completes across the system before departing for the parking area (C_N). Apparently, a higher number of cycles require less bus batch size (N), but bus drivers may be more tired as they spend more time driving.

The following performance metrics can be used to assess the efficiency of shuttle-bus transportation system:

- The number of bus trips reached Muzdalifa (M_N). As mentioned earlier, for each bus trip, a group of fifty pilgrims are evacuated. Therefore, the number of bus trips is considered an indicator of the number of pilgrims that are evacuated. Moreover, another type of city-bus can be utilized, which allows evacuating a group of eighty pilgrims per bus trip.
- Total number of buses exists in the system at a certain time (N_{CB}), which is considered an indicator of the total time for completing the evacuation (T).

Moreover, traffic congestion is taken into consideration for evaluating the transportation system efficiency.

Table I summarizes the parameters used in this work to model the shuttle-bus pilgrims transportation system.

TABLE I. PARAMETERS OF THE SIMULATION MODEL

Parameter	Description
Buses batch size (N)	The overall number of buses dedicated for the transportation of pilgrims.
Nafrah time (T_A)	Time allotted for the Nafrah (the available time to finish the evacuate pilgrims from Arafat to Muzdalifah)
Total evacuation time (T)	Total time for completing the evacuation process
Interarrival time (I_T)	The time interval between bus arrivals in the system.
Bus trip time (B_T)	Total time for a bus to travel from Arafat to Muzdalifah
Loading time (L_T).	Pilgrims' loading time in Arafat
Unloading time (U_T)	Pilgrims' unloading time in Muzdalifa
Bus speed (B_S).	Average speed of a bus during the trip from Arafat to Muzdalifah
Number of cycles (C_N)	The maximum number of cycles (loops) that a bus completes across the system before departing for the parking area
Number of bus trips (M_N)	Total number of bus trips reached Muzdalifa
number of buses (N_{CB})	Total number of buses exists in the system at a certain time

B. Setting up the Model of the Shuttle-Bus System

The first step in the computer modeling operation is the data collection of system specifications, input variables, as well as performance of the existing shuttle-bus system. This is done by observing the actual transportation system performance during Hajj seasons. Based on the actual data collected from the field during Hajj seasons, the values of the following parameters were determined as:

- The interarrival time for buses entering the system (I_T) is 10 seconds. This means that six buses enter the system every minute.
- The number of loading stations in Arafat (L_{SN}) is 80 stations.
- The number of unloading stations in Muzdalifa (U_{SN}) is 32 stations.
- The pilgrims' loading time in Arafat (L_T) was taken as a triangular distribution function as triangular (6, 8, 10), with the min value of 6 min., max value of 10 min., and most likely value of 8 min.
- The pilgrims' unloading time in Muzdalifa (U_T) was taken as a triangular distribution function as triangular (4, 6, 8), with the min value of 4 min., max value of 8 min., and most likely value of 6 min.
- The buses' speed (B_S) was taken as 70 km/h, unless other values are tested.
- The maximum number of loops (C_N) was taken as 6 loops, unless other values are tested.
- The typical time of Nafrah (T_A) is about seven hours.

C. Building the Model of the Shuttle-Bus System

The next step is model construction by developing schematics and network diagrams of the shuttle-bus system, abstracting the essential features of the system, and programming the system operations that characterize the system.

This model architecture was built using Anylogic, which is a multi-method simulation tool with an intuitive GUI. It is completely written in Java and enables combining process modeling, system dynamics and agent-based modeling in one model. Moreover, it has a built-in Road Traffic Library. On one hand, Anylogic seems to be a perfect tool for our research since a microsimulation model of traffic flow can be created directly in Anylogic. On the other hand, several difficulties had to be overcome due to the fact that the tool is not primarily intended for shuttle-bus transportation systems. In order to make sure that the designed model is an accurate representation of the real system, a model validation is performed. This is done by using actual data collected from the field during Hajj seasons. The typical duration of Nafrah is about seven hours.

The model is carried out using an exclusive two-lane bus road. The processes' general structure of the model is shown in Fig. 3. In this modeled environment of roads in Mashaaer Holy Sites (especially Arafat-Muzdalifa area), concurrent groups of simulated agents interact with potential to enable direct acquisition of statistics and indications.

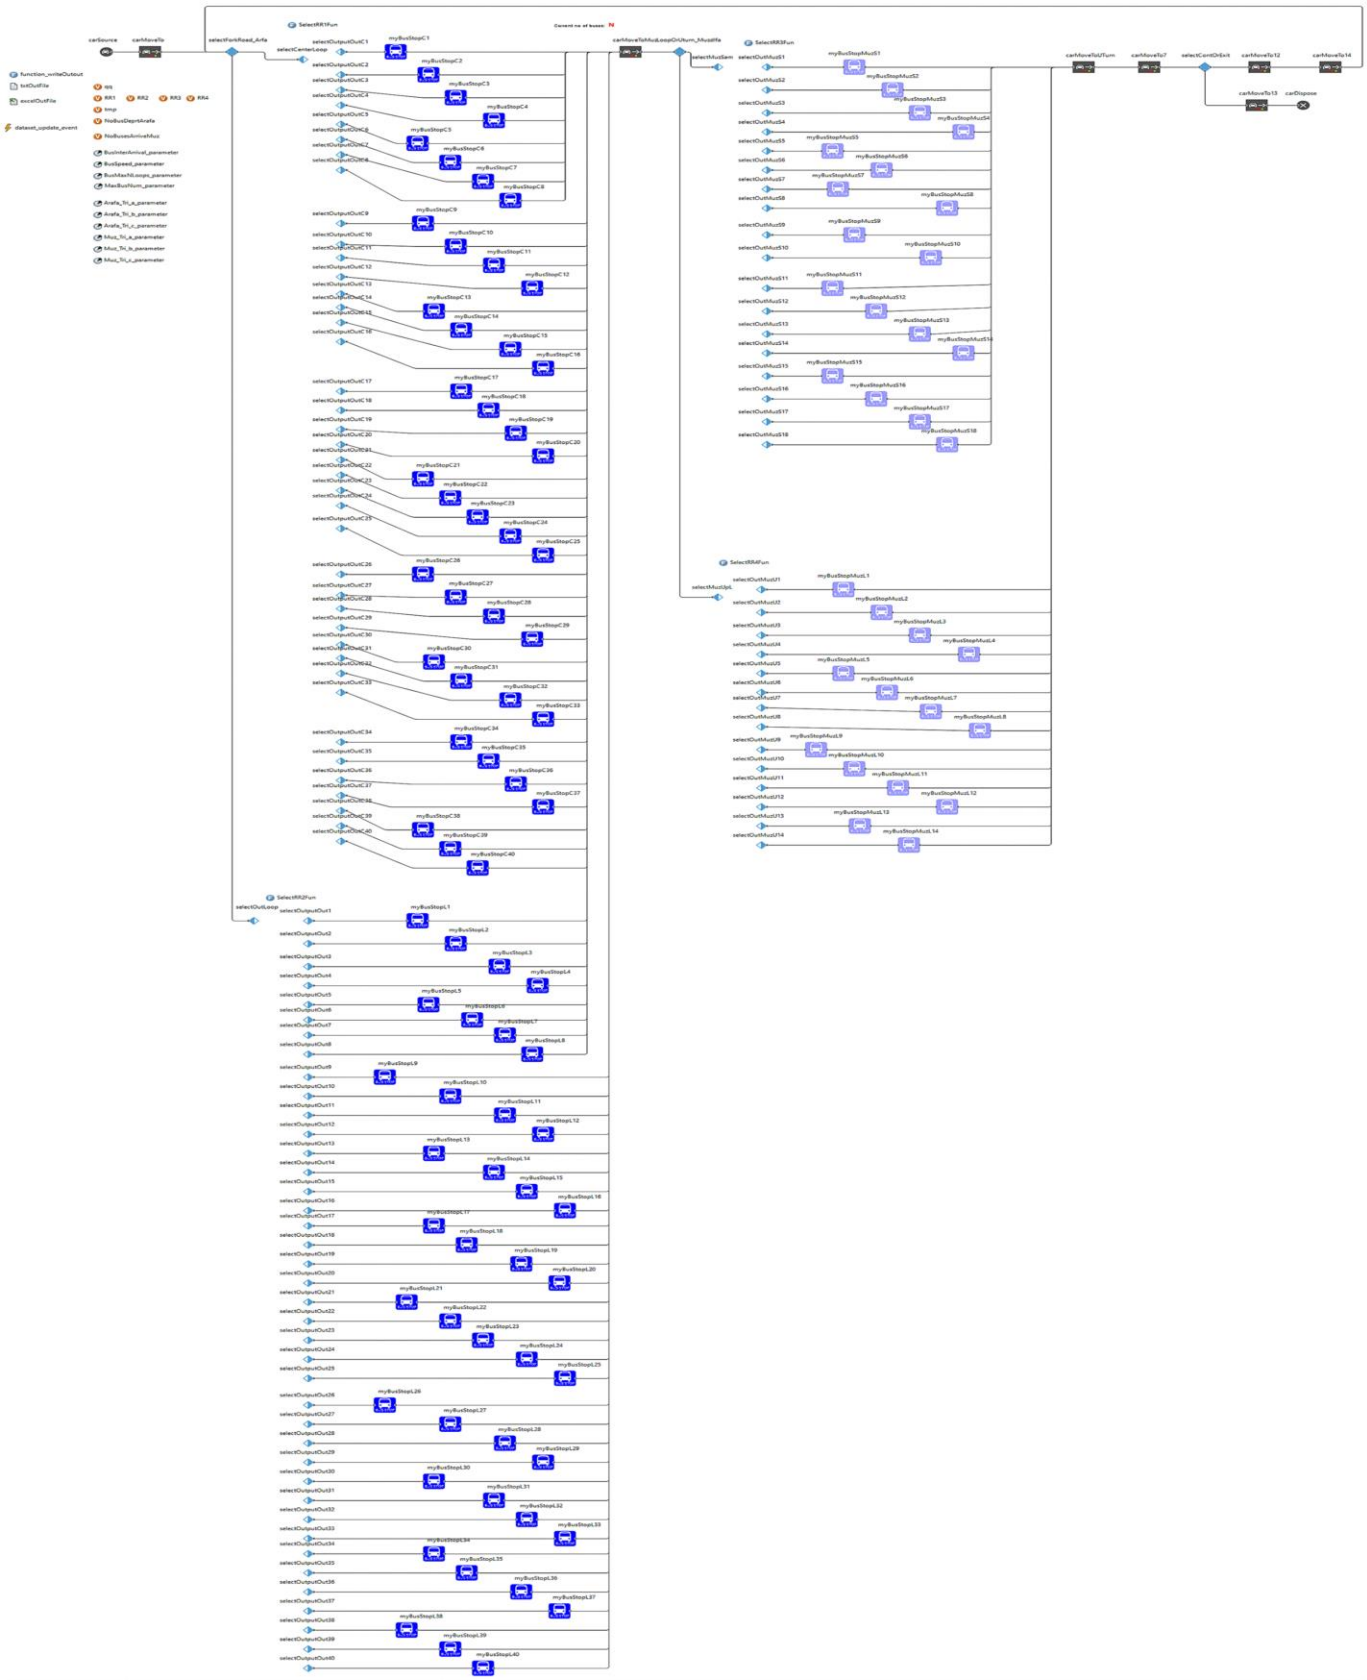

Fig. 3. The processes structure of the model.

The main processes of the model include:

- CarSource: It generates cars (buses) and tries to put them into the specified location inside a road network.
- CarMoveTo: It controls the car movement by calculating the way from its current location to the specified destination.
- SelectOutputIn and SelectOutputOut: For routing agents (buses) to different flowchart branches (bus stations).
- Delay: Delays agents (buses) for a given amount of time.
- CarDispose: Removes a car (bus) from the model.

The system parameters can be controlled through some input-fields in the starting screen of the proposed simulation system. These model parameters include:

- BusInterArrival_parameter: It controls the interarrival time for buses entering the system (in min.).
- Arafa_Tri_a_parameter, Arafa_Tri_b_parameter, and Arafa_Tri_c_parameter: It controls the loading time in Arafat.
- Muz_Tri_a_parameter, Muz_Tri_b_parameter, and Muz_Tri_c_parameter: It controls the unloading time in Muzdalifa.
- BusSpeed_parameter: It controls the speed of a bus.
- BusMaxNLoops_parameter: It controls the maximum number of cycles (loops) that a bus travels before leaving the system.

The simulation screen has some active camera viewports. Examples of the cameras that the system has include:

- Arafat area Cam: A camera that follows the loading bus stations in Arafat site.
- Muzdalifa area Cam: A camera that follows the unloading bus stations in Muzdalifa site.

A screenshot of the simulation screen (at time = 60 min.) is shown in Fig. 4.

D. Validation of the Model of the Shuttle-Bus System

Comes next an important operation, which is model verification. This is to ensure the correctness of the logical structure of the model and the correctness of the represented form in the computer.

In order to make sure that the designed model is an accurate representation of the real system, a model validation is performed. This is done by comparing the results of the simulation model with actual data collected from the field during Hajj seasons.

In the following section, an example of a simulation scenario is shown, which has been used to prove that our model gives realistic results compared to the actual data already collected.

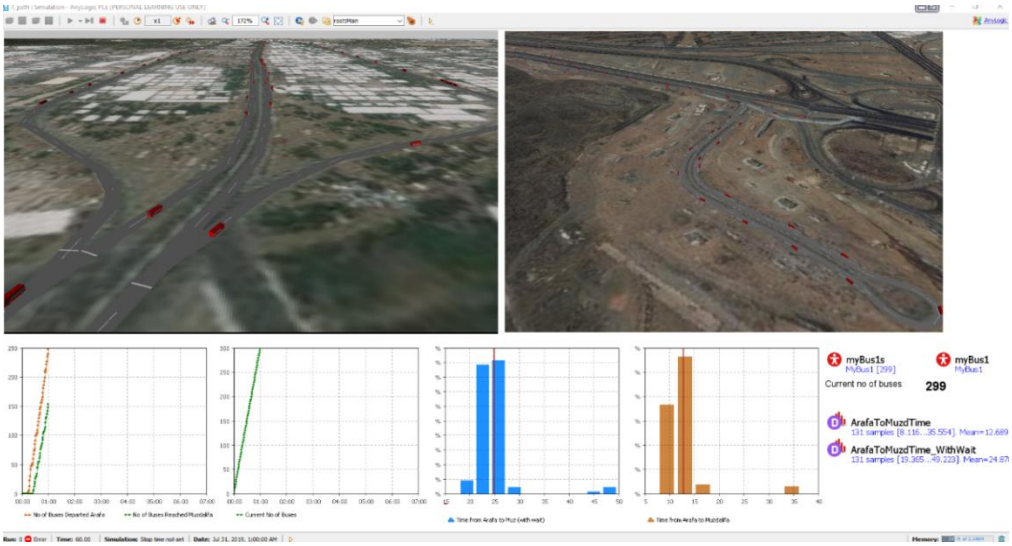

Fig. 4. A screenshot of the simulation screen.

IV. Simulation Results

Through a series of simulations, the model's behavior, and the effects of changing various parameters on the shuttle-bus transportation system are examined. An example of a simulation scenario is provided in this section.

After running the simulation experiment using the aforementioned parameters for a long duration of time, the simulation results were observed. It was found that the average trip time B_T, from Arafat to Muzdalifa, is about 21 min. The total number of buses that existed in the system and the number of trips departed Arafa and arrived Muzdalifa were observed as can be shown in Fig. 5. It can be seen in the figure that using an interarrival time of 10 seconds, the buses batch size (N) increases gradually and reach a number of 700 buses during around 114 min. (point B in the figure). In addition, using this buses batch size, and with a maximum number of loops (C_N) of 6 loops, buses start to depart to the parking area (point C in the figure) after 4 hours and 15 min., hence, the

number of buses existed in the system starts to decrease until all buses finish their job. By the time of around eight hours, the number of trips departed Arafa and arrived Muzdalifa was 4200 (point D in the figure), which means that around 210000 pilgrims were successfully evacuated to Muzdalifa, or around 336000 pilgrims were successfully evacuated, when the type of 80-passenger city-bus is used.

In Fig. 6, the results of a simulation experiment that examines the effect of tuning the maximum number of cycles (C_N) are shown. The figure shows the number of trips arriving in Muzdalifa and the total number of buses existing in the system for different number of loops, using a bus batch size N = 600. It can be depicted from the figure that:

- For C_N = 6, a total of 3600 trips (180000 pilgrims, or 288000 when the type of 80-passenger city-bus is used) were able to reach Muzdalifa within 7 hours and 20 minutes. In addition, the total duration for completing the evacuation (whole buses batch were able to leave the system to the parking area) was 7 hours and 42 minutes.
- For C_N = 7, a total of 4200 trips (210000 pilgrims, or 336000 pilgrims when the type of 80-passenger city-bus is used) were able to reach Muzdalifa within 8 hours and 26 minutes. In addition, the total duration for completing the evacuation was 8 hours and 48 minutes.
- For C_N = 8, a total of 4800 trips were able to reach Muzdalifa within 9 hours and 20 minutes. In addition, the total duration for completing the evacuation was 9 hours and 54 minutes.

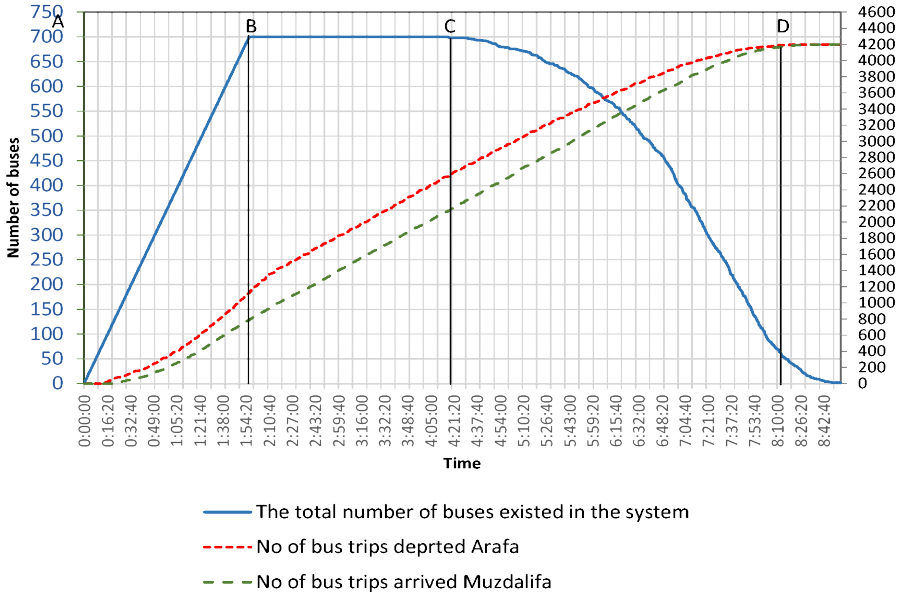

Fig. 5. The total number of buses existed in the system and the number of trips departed Arafa and arrived Muzdalifa for (700 batch of buses and 6 loops).

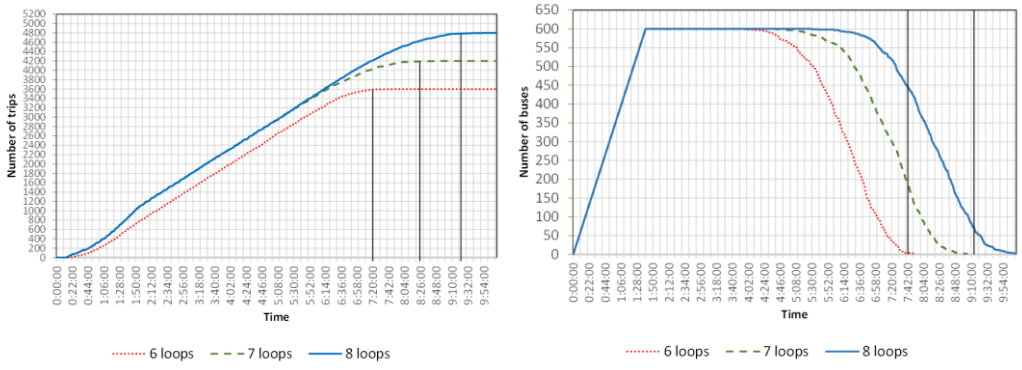


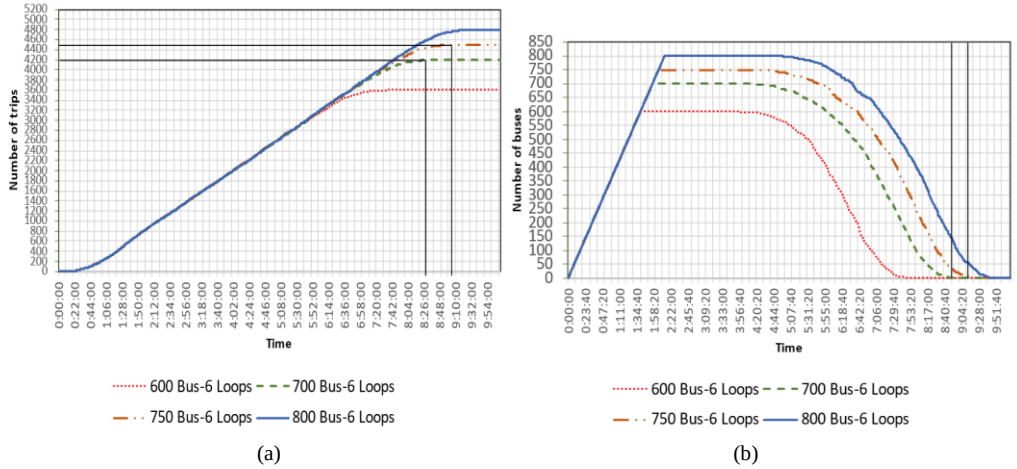
(a) (b)

Fig. 6. The effect of tuning the maximum number of cycles (C_N): (a) The number of trips arrived Muzdalifa for different number of loops; (b) The total number of buses existed in the system for different number of loops.

The results of another simulation experiment that examines the effect of tuning different bus batch sizes (N) are shown in Fig. 7. The figure shows the number of trips arriving in Muzdalifa and the total number of buses existing in the system for different N. It can be depicted from the figure that:

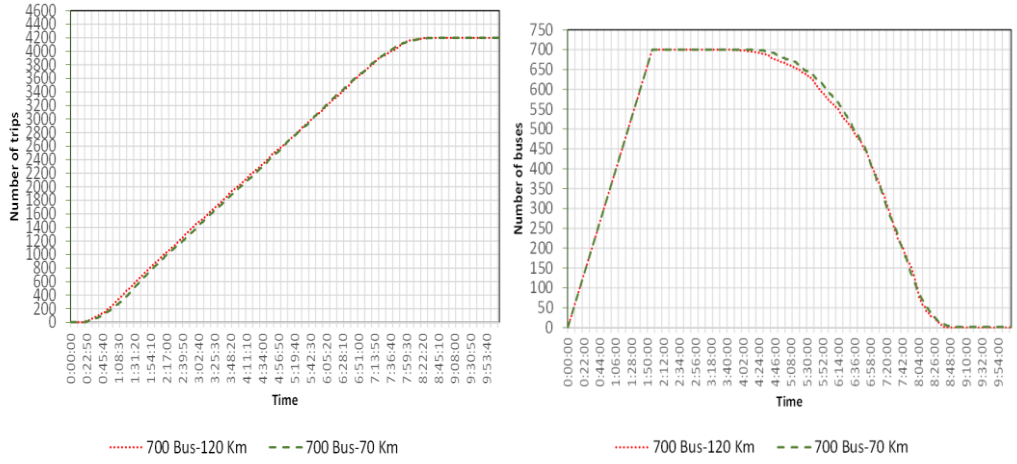
- for N = 600, a total of 3600 trips (180000 pilgrims, or 288000 pilgrims when the type of 80-passenger city-bus is used) were able to reach Muzdalifa within 7 hours and 20 minutes. In addition, the total duration for completing the evacuation (whole buses batch were able to leave the system to the parking area) was 7 hours and 42 minutes.
- for N = 700, a total of 4200 trips (210000 pilgrims, or 336000 pilgrims when the type of 80-passenger city-bus is used) were able to reach Muzdalifa within 8 hours and 26 minutes. In addition, the total duration for completing the evacuation was 8 hours and 48 minutes.
- for N = 750, a total of 4500 trips (225000 pilgrims, or 360000 pilgrims when the type of 80-passenger city-bus is used) were able to reach Muzdalifa within 9 hours. In addition, the total duration for completing the evacuation was 9 hours and 10 minutes.
- for N = 800, a total of 4800 trips (240000 pilgrims, or 384000 pilgrims when the type of 80-passenger city-bus is used) were able to reach Muzdalifa within 9 hours and 32 minutes. In addition, the total duration for completing the evacuation was 9 hours and 40 minutes.

While not always applicable and for the sake of experimenting, buses with faster speed (120 km/h) were tested. The calculated statistics, after running the simulation, are shown in Fig. 8. It can be seen in the figure that increasing the bus speed does not help in increasing the arrival rate in Muzdalifa, as the results are similar to the results when using bus speed of 70 km/h.



(a) (b)

Fig. 7. The effect of tuning different bus batch sizes (N): (a) The number of trips arrived Muzdalifa for different bus batch sizes; (b) The total number of buses existed in the system for different bus batch sizes.



(a) (b)

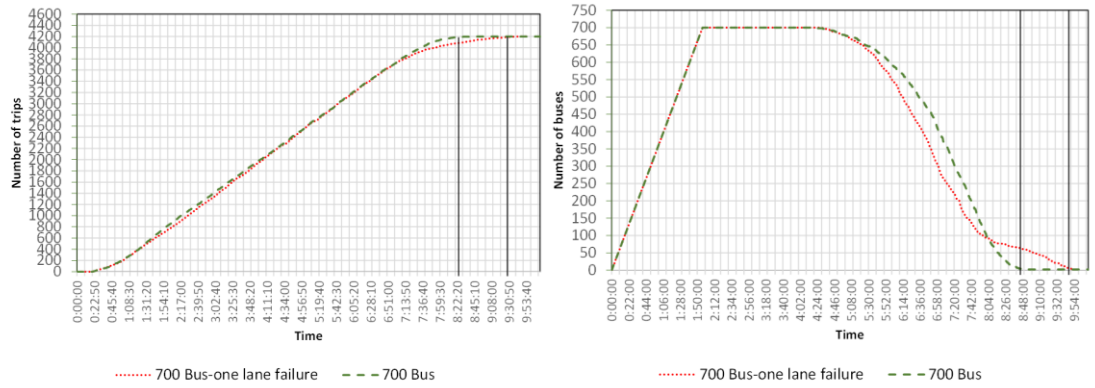
Fig. 9. The effect of tuning the interarrival time for buses entering the system (IT): (a) The number of trips arrived Muzdalifa for different Bus interarrival times; (b) The total number of buses existed in the system for different Bus interarrival times.



(a) (b)

Fig. 10. The impact of a failure that might occur in one of the road lanes: (a) The number of trips arriving in Muzdalifa; (b) The total number of buses existing in the system.

The results of another simulation experiment that examines the effect of tuning the interarrival time for buses entering the system (I_T), are shown in Fig. 9. It can be seen in this figure that using I_T = 10 seconds, the buses batch size (700) increases gradually and reach a number of 700 buses during around 114 min, and after 4 hours and 15 min., buses start to depart to the parking area. On the other hand, using I_T = 20 seconds, the buses batch size (700) increases gradually and reach a number of 700 buses during around 3 hours and 55 min. and at that time buses start to depart to the parking area, as several buses have already reached the maximum number of cycles. The results of the simulation showed that using I_T = 10 seconds was a suitable choice as it maintains a good balance between the level of roads congestion and the rate at which buses enter the route.

Fig. 10 depicts the results of another simulation experiment that investigates the impact of a failure that might occur in one of the road lanes. The figure depicts the number of trips arriving Muzdalifa and the total number of buses in the system in two scenarios: a scenario with no failure and another scenario with one-lane failure. The figure shows that the presence of one-lane failure causes a slight delay in the movement of the buses. However, the delay is minor because using dedicated roads for traffic helps to keep the level of congestion low.

V. Optimization of the Shuttle-Bus Transportation System in Arafat-Muzdalifa Area

In the optimization process, the results of simulation experiments that include all possible combinations of parameters are registered. As mentioned earlier, the parameters include:

- the overall number of buses dedicated for the transportation of pilgrims (N),
- the maximum number of cycles (loops) that each bus completes across the system before departing for the parking area (C_N),
- the total amount of time for completing the evacuation that all buses spend in the system before departing for the parking area (T), and
- The total number of bus trips that reach Muzdalifa (N_{Trips}).

The objective of our optimization problem is to determine the optimal solution with respect to one or more of the above parameters. This could be the minimum N, the minimum C_N, the minimum T, or the maximum (N_{Trips}). In general, N_{Trips} = N * C_N; hence, maximizing N_{Trips} while minimizing N indicates that C_N must be maximized.

The objective function can be formulated as $\min_{(N,C_N,T,N_{Trips})} S_\omega$, where S_ω is a weighted function that includes the system parameters. This function can be re-written as a weighted function of the parameters as:

$$S_\omega = \omega_1 N + \omega_2 C_N + \omega_3 T + \omega_4 \frac{1}{N_{Trips}} \quad (1)$$

However, the values of the system parameters in the above equation are not within close ranges. Therefore, to have a consistent formula for S_ω , the system parameters in the equation are normalized by dividing each one by its possible maximum value. Such maximum values are clearly determined from the set of all possible combination of parameters that are used in the simulation experiments. Hence, a normalized parameter is obtained as

$$\hat{p} = p/p_{Max}\,, \quad (2)$$

where, p is a parameter value, $\hat{p}$ is a normalized parameter value, and p_{Max} is the maximum possible value of the parameter. The weighted summation function in Eq. (1) is, therefore, reformulated as,

$$S_\omega = \omega_1 \hat{N} + \omega_2 \widehat{C_N} + \omega_3 \hat{T} + \omega_4 \widehat{\frac{1}{N_{Trips}}} \quad (3)$$

To be accepted as a possible solution, the obtained parameters shouldn't exceed predefined limits (the available number of buses, the maximum number of cycles, and the target time for completing the evacuation). In addition, the target number of bus trips that reach Muzdalifa should be satisfied. In the considered system (the shuttle-bus transportation system for pilgrims on the route from Arafat to Muzdalifa (Nafrah)), the parameters are determined using a range of (500 to 850) for N, a range of (3 to 8) for CN, and a range of (1500 to 6800) for NTrips. Table II illustrates the targeted values of the system parameters.

An excerpt of the outcomes from simulation experiments that looked at every possible combination of parameters is shown in Table III.

Eq. (3) can be used either to optimize one parameter or to find an optimal solution with respect to more than one parameter. In the former case, the weight of the targeted parameter is set to 1, while the weights of the other parameters are set to 0. In the latter case, the weights of the selected parameters are set to 1, while the other weights are set to 0. The following experiments illustrate how different sets of weights are used for the optimization process:

- For the maximum number of buses (N), the weights are set to the values of ($\omega_1 = 1, \omega_2 = 0, \omega_3 = 0, \omega_4 = 0$), hence, only the effect of $\hat{N}$ is considered in S_ω. The optimized result of S_ω in this case is 0.59. This optimized result gives a number of possible solutions. The best of them in terms of total evacuation time gives the following values: N=500, C_N = 4, N_{Trips} = 2000, T = 294.92 min. However, this solution is not an acceptable as it doesn't satisfy the target number of bus trips that reach Muzdalifa. The best solution that complies with the predefined limits has the following values: N=500, C_N = 6, N_{Trips} = 3000, which results in a total time (T) of 395.87 min.
- When the optimization process is performed to fine the minimum number of cycles (C_N), the weights are set to the values of ($\omega_1 = 0$, $\omega_2 = 1$, $\omega_3 = 0$, $\omega_4 = 0$), where the effect of $\widehat{C_N}$ is only considered in S_ω. The optimized parameters, in this case, were determined as N=500, C_N = 3, N_{Trips} = 1500, and the total amount of time for completing the evacuation (T) was found to be 240.27 min. Although this solution minimizes the number of cycles, this is not an acceptable solution as it doesn't satisfy the target number of bus trips that reach Muzdalifa. The first solution that complies with the predefined limits has the following values: N=720, C_N = 4, N_{Trips} = 2880, which results in a total time T of 378.88 min.
- To minimize the total amount of time for the evacuation process (T), the weights are set to the values of ($\omega_1 = 0, \omega_2 = 0, \omega_3 = 1, \omega_4 = 0$), which means only the effect of $\hat{T}$ is considered in S_ω.

TABLE II. THE TARGETED VALUES OF THE SYSTEM PARAMETERS

N	≤ 800 buses
C_N	≤ 8 cycles
T	≤ 480 min.
N_{Trips}	≥ 2820 (around 225600 pilgrims, when 80-passenger city-bus is used)

TABLE III. AN EXCERPT OF THE SIMULATION EXPERIMENTS RESULTS

N	C_N	T	N_{Trips}	$1/N_{Trips}$	$\hat{N}$	$\widehat{C_N}$	$\hat{T}$	$\widehat{1/N_{Trips}}$
500	4	294.92	2000	0.000500	0.59	0.50	0.37	0.75
510	4	298.44	2040	0.000490	0.60	0.50	0.37	0.74
530	4	302.33	2120	0.000472	0.62	0.50	0.38	0.71
520	4	314.95	2080	0.000481	0.61	0.50	0.39	0.72
500	5	356.44	2500	0.000400	0.59	0.63	0.44	0.60
500	3	240.28	1500	0.000667	0.59	0.38	0.30	1.00
510	3	242.13	1530	0.000654	0.60	0.38	0.30	0.98
540	4	319.03	2160	0.000463	0.64	0.50	0.40	0.69
520	3	248.80	1560	0.000641	0.61	0.38	0.31	0.96
510	5	366.51	2550	0.000392	0.60	0.63	0.46	0.59
530	3	251.00	1590	0.000629	0.62	0.38	0.31	0.94
⋮	⋮	⋮	⋮	⋮	⋮	⋮	⋮	⋮

- In this case, the optimal solution gives the values of N=500, C_N = 3, N_{Trips} = 1500. The total amount of time for completing the evacuation (T) in this case was

found to be 240.27 min. Although this solution resulted in the minimum time, the solution is not acceptable because it doesn't satisfy the target number of bus trips that reach Muzdalifa. The first solution that complies with the predefined limits has the following values: N=720, C_N = 4, N_{Trips} = 2880, which results in a total time T of 378.88 min.

- To satisfy the target number of bus trips (N_{Trips}), a possible scenario is to find the maximum N_{Trips}. Here, the weights are set to the values of ($\omega_1 = 0, \omega_2 = 0, \omega_3 = 0, \omega_4 = 1$), to allow the effect of $\widehat{\frac{1}{N_{Trips}}}$ to be only considered in S_ω. The results of this case were determined as N=850, C_N = 8, N_{Trips} = 6800, in which the total amount of time for completing the evacuation (T) was found to be 801.30 min. Although this solution achieves a large number of bus trips that reach Muzdalifa, it consumes lots of resources, in terms of the number of buses dedicated for the transportation of pilgrims (N), in addition to the maximum number of cycles (loops) that each bus completes across the system. Moreover, the required time for completing the evacuation is long. Hence, this is not an acceptable solution. The first solution that complies with predefined limits has the following values: N=750, C_N = 5, N_{Trips} = 3750, which results in a total time T of 476.75 min.

In order to maintain the effects of all parameters, the weights are set to the values of ($\omega_1 = 1, \omega_2 = 0, \omega_3 = 1, \omega_4 = 1$). The reason for having the value $\omega_2 = 0$ is to solve the contradiction in (4), by omitting the effect of C_N. The optimized parameters, in this case were determined as N=500, C_N = 6, N_{Trips} = 3000, and with these parameters the total amount of time for completing the evacuation (T) was found to be 395.87 min. This can be considered as an accepted solution that achieves the targets while maintaining the system resources within the available limits.

Table IV summarizes the results of the above experiments.

In fact, the values of weights used in Eq. (3) can be chosen to define the significance of each parameter in S_ω. In our experiments, we used equal weights to indicate equal importance of the parameters. However, unequal values of weights will give some parameters more importance than others.

TABLE IV. A SUMMARY OF THE EXPERIMENTS ILLUSTRATING EFFECTS OF VARYING THE WEIGHTS IN THE OPTIMIZATION PROCESS

weights	N	C_N	T	N_{Trips}
$\omega_1 = 1, \omega_2 = 0, \omega_3 = 0, \omega_4 = 0$	500	6	395.87	3000
$\omega_1 = 0, \omega_2 = 1, \omega_3 = 0, \omega_4 = 0$	720	4	378.88	2880
$\omega_1 = 0, \omega_2 = 0, \omega_3 = 1, \omega_4 = 0$	720	4	378.88	2880
$\omega_1 = 0, \omega_2 = 0, \omega_3 = 0, \omega_4 = 1$	750	5	476.75	3750
$\omega_1 = 1, \omega_2 = 0, \omega_3 = 1, \omega_4 = 1$	500	6	395.87	3000

VI. CONCLUSIONS

In this paper, a computer modeling of pilgrims' shuttle-bus transportation system in Mashaaer Holy Sites, were presented. The model was designed using a multimodal modeling and simulation tool developed by AnyLogic to include operations during the pilgrims' transport from Arafat to Muzdalifa via shuttle-buses. The proposed model can be used for optimizing the pilgrim's transportation system with respect to different parameters since the results of the simulation may be used to assess the effectiveness of the current system and to suggest changes that might be made. In our experiments, we used equal weights to indicate equal importance of the parameters. In future work, unequal values of weights of parameters can be set to give more importance of some parameters than others. In addition, this paper focused on one of the paths of the hajj shuttle bus system. As a future work, the simulation model may be extended to include other paths.

***Abstract*—Nurses are professionals who provide health services using a scientific process called nursing. In nursing, problem-solving uses the nursing process which is a critical thinking method, nurses must analyze the data found in patients to diagnose and determine the results and appropriate intervention plans. Prospective nursing students are required to be able to apply the nursing process in carrying out nursing care according to existing nursing standards, of course, with supervision by nursing experts to improve the quality of medical services. This study aims to develop an android application with the help of an expert system as a nursing diagnosis tool, which helps nursing students learn the nursing process and helps lecturers monitor the nursing process carried out by nursing students. This research uses 116 symptom data, 22 diagnosis data, 60 intervention data, 8 type data, and 864 description data. The results of this research are in the form of an expert system with an android-based forward chaining method that has been tested using the black box testing method.**

***Keywords*—Classification; expert system; forward chaining; blackbox testing; android; flutter; nursing process**

I. INTRODUCTION

Nursing service is a way for nurses to provide professional services, both emotional and otherwise, to individuals, families, groups, and communities, for the healthy and the sick. [1]. Nursing services are part of health services, and the quality of nursing services in general determines the quality of health services [2]. Nurses are professionals who provide medical services using a scientific process called nursing, problem-solving using the nursing process. The nursing process is used as a tool for nurses to practice nursing systematically in solving nursing problems [3]. Nurses provide care according to established standards. This standard was developed by the Indonesian National Nurses Association (PPNI). RI Law No. 36 of 2009 concerning Health has mandated that health workers are obliged to meet professional standards and respect patient rights [4]. The relationship between quality and standards are two things that are very closely related, because through these standards it can be measured that service is improving or even getting worse [5].

The standards ensure that nurses make appropriate and rational decisions and perform interventions that are safe and legally responsible [6]. Nursing students are prospective nurses according to their expertise, they must be able to apply the nursing process in the performance of nursing care, therefore vocational nurses (D3) and nurses are equipped with knowledge of the nursing process in education. Students can utilize expert system applications to support the learning process of nursing diagnoses and appropriate interventions by the Indonesian Nursing Diagnosis Standards (SDKI). In the diagnostic process, experienced experts are needed to provide the correct conclusions [7].

An expert system is a computer-based system that uses knowledge, facts, and reasoning techniques to solve a particular problem which normally can only be solved by experts in their field [8]. The nursing process Expert System is designed to be able to assist nurses in analyzing patient data so that interventions and outputs can be determined according to the conditions and circumstances of the patient.

There are several studies on diagnostic expert systems but for expert systems that produce nursing diagnoses to help nursing students there is still no. Research in [9] discusses the creation of an expert system to diagnose eye disease with the android-based certainty factor method. This Android-based expert system has 75% accuracy results with details of 15 diseases and 52 symptoms of eye disease.

In the study [10] built an android-based expert system to detect dental and oral diseases. The data used is 13 diseases and 44 symptoms. This dental and oral disease detection expert system has an accuracy of 100% if tested with black box testing, while the test results of the User Acceptance test have an accuracy of 93.03%.

Then in the study [11] built an android-based expert system to detect liver disease. This study used 64 test data. The method used in this study is Fuzzy Tsukamoto to diagnose liver disease. The test data was then tested and has an accuracy of 96.87%.

Furthermore, the study [12] built an expert system to diagnose diseases in chili plants. The data used is in the form of 37 symptom data, 10 chili disease data, and 10 rules. The method used is forward chaining, testing carried out using black box testing gives the expected results from each test class. As for the test results from the User Acceptance Test obtained an average of 84%.

In research [13], the researcher developed an expert system that can identify stroke symptoms using the naive

*Corresponding Author

bayes method. In this study using data from patient consultation results at Dr. M Hatta Bukittinggi Brain Hospital for seven months in 2021. Drs. M Hatta Bukittinggi for seven months in 2021. The research has an accuracy of 100% in identifying the type of stroke disease from 10 data samples used.

Based on previous related research, the expert system to improve the quality of nursing quality still does not exist. Meanwhile, in the era of the Industrial Revolution like now, nursing students must be able to adapt to existing technological advances. In research [14], it is said that technological developments really need further development to get better results, in order to get accurate results. Therefore, this research aims to develop an information system for information system for monitoring the nursing process with the addition of an expert system that uses the forward chaining method as a nursing diagnosis tool based on android application, to help nursing students in learning and improving the ability of the nursing process as well as assisting lecturers in monitoring the process carried out by prospective students. Students will enter input first by analyzing the symptoms that have occurred, and the expert system that will be developed will save the results of the student's work. Furthermore, lecturers will be able to monitor and see whether students have correctly analyzed or not.

II. Materials and Methods

The workflow of this research is divided into two stages, namely the 1st stage of building an expert system for nursing diagnoses, and the 2nd stage of implementing the android application using the waterfall system development method. This research workflow can be seen in Fig. 1.

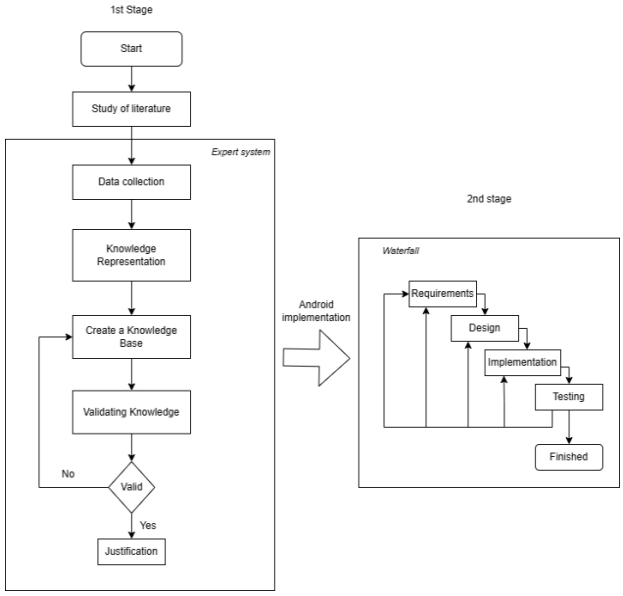

Fig. 1. Research workflow.

A. Building an Expert System

At the expert system development stage, several steps are carried out as follows.

1) Data collection: It was carried out by conducting literature studies and interviewing experts in the field of nursing. The results of the collection are in the form of data needed by expert systems such as symptom data, results of nursing diagnoses, interventions, and descriptions of interventions. In addition, an overview of the system requirements to be built is also obtained.

2) Representing knowledge: The goal at this stage is to represent the knowledge that has been collected to build a knowledge base. Examples of knowledge in this study are symptoms. Each of these symptoms has a different code and has its score as well. Scores on symptoms ranging from a score of 1 to 5 are obtained from interview data with nursing experts, which will later be used in the diagnosis process, where the diagnosis will only be made if the total number of selected overall scores is more than 4 scores. The symptom data can be seen in Table I.

Table I is part of the symptom data collection needed in this study. Symptom data is denoted by the letter "G", and this symptom data has 116 data. After collecting symptom data, then the next step is to collect diagnosis data to enter the next stage. The following are some of the diagnosis data used in this study.

Table II is some data from the results of diagnosis data collection. Diagnosis data has a total of 22 data. Diagnosis data is symbolized by "D" to simplify the running of the system. From the diagnosis data above, researchers also need intervention data. Here is some intervention data used in this study.

TABLE I. Symptom Data

Code	Symptoms	Score
G1	Cough is not effective	5
G2	Can't cough	4
G3	Excess sputum	3
G4	Wheezing, and or dry rhonchi	2
G5	Meconium in the airway (in neonates)	1
G6	Use of accessory muscles of respiration	5
G7	Abnormal breathing pattern	4
G8	The expiratory phase is prolonged	3
G9	Pursed lip breathing	2
G10	Vital capacity decreases	1
G11	Complain of nausea	5
G12	Feeling like vomiting	4
G13	Not interested in eating	3
G14	Sour taste in the mouth	2
G15	Increased saliva	1
G16	Complain of pain	5
G17	Looked grimaced	4
G18	Being protective (positioning to avoid pain)	3
G19	Nervous	2
G20	Focus on yourself	1

TABLE III. DIAGNOSIS DATA

Code	Diagnosis
D1	Ineffective airway clearance
D2	Ineffective breathing pattern
D3	Nausea
D4	Acute pain
D5	Childbirth pain

TABLE IV. INTERVENTION DATA

Code	Intervention
A1	Effective coughing exercises (A)
A2	Airway management (B)
A3	Respiration monitoring
A4	Airway management
A5	Respiration monitoring

Table III above is some data from the intervention in this study. Intervention data has a total of 80 data. The diagnosis data will be coded with the letter "A" to facilitate the running of the system.

3) Creating a knowledge base: The knowledge representation from an expert that the system needs to solve certain problems. The knowledge that has been obtained is made into rules; these rules consist of relationships between existing data such as symptoms, diagnosis results, type interventions, and intervention descriptions.

4) Validate the knowledge: Validate the knowledge base by experts so that there is no mission of interpretation between an expert's knowledge and the knowledge base created.

5) Justification: The final stage, namely justification, the system can already provide the results of nursing diagnoses based on existing symptoms and descriptions of interventions that are suitable for the results of these diagnoses.

B. Implementation of Android Applications

The development of an Android application is carried out using the Flutter framework. The method used in the manufacture of the system is the "waterfall" method, which takes a systematic approach starting from the stage: Requirement, Design, Implementation, until Testing. The following describes each stage.

1) Requirement: The requirement is the stage of identifying the needs of the system to be built and being a reference in determining what functions need to be developed. Here are the system requirements in research that can be seen in Fig. 2.

In the use case diagram, it has been shown that there are two levels of users, namely students, and lecturers. In the use case diagram, limitations have also been given on what each type of user can do on the system. Students can perform the nursing process on patients and lecturers can monitor the results of the nursing process carried out by their students.

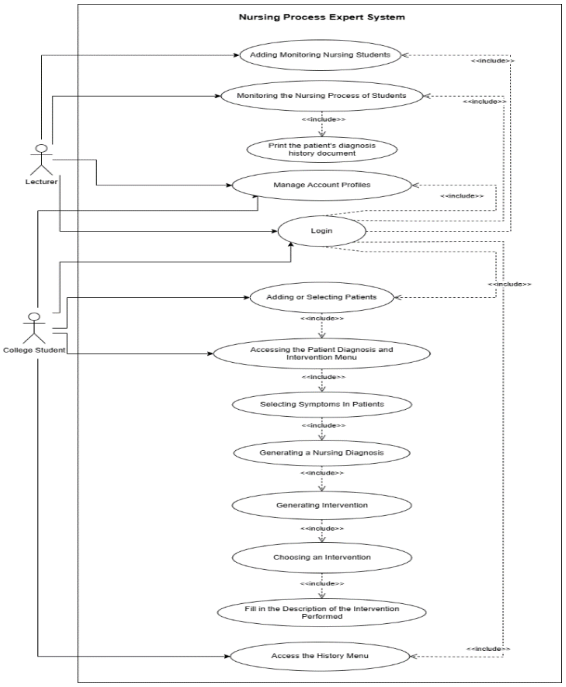

Fig. 2. Use case diagram.

2) Design: The next stage is to make a system development plan into design forms such as ERD designs and activity diagram designs. The following is the ERD system which will be shown in Fig. 3.

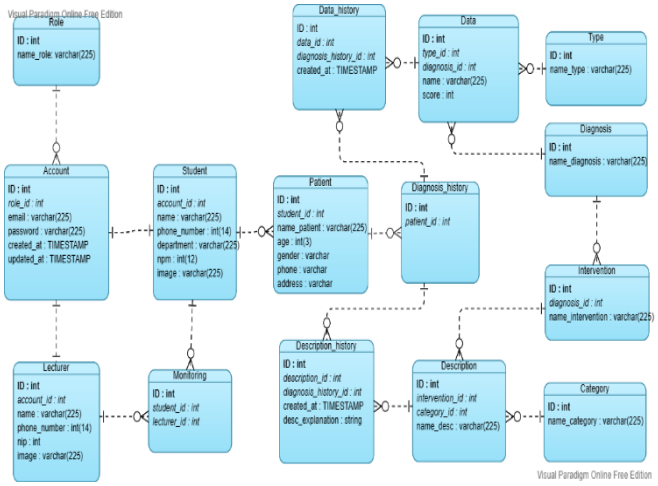

Fig. 3. Entity relationship diagram.

Entity Relation Diagram explains the relationship between tables in the database that the system uses. In the tables, some data is used in expert systems. These data consist of 116 symptom data, 22 diagnosis data, 60 intervention data, 8 type data, and 864 description data. The activity design for students explains how the system flows if the logged-in user is a student, students can carry out the patient nursing process from determining the type of diagnosis, selecting symptoms, generating diagnoses, selecting interventions, and filling out appropriate intervention descriptions for patients. The following activity design for nursing students can be seen in Fig. 4.

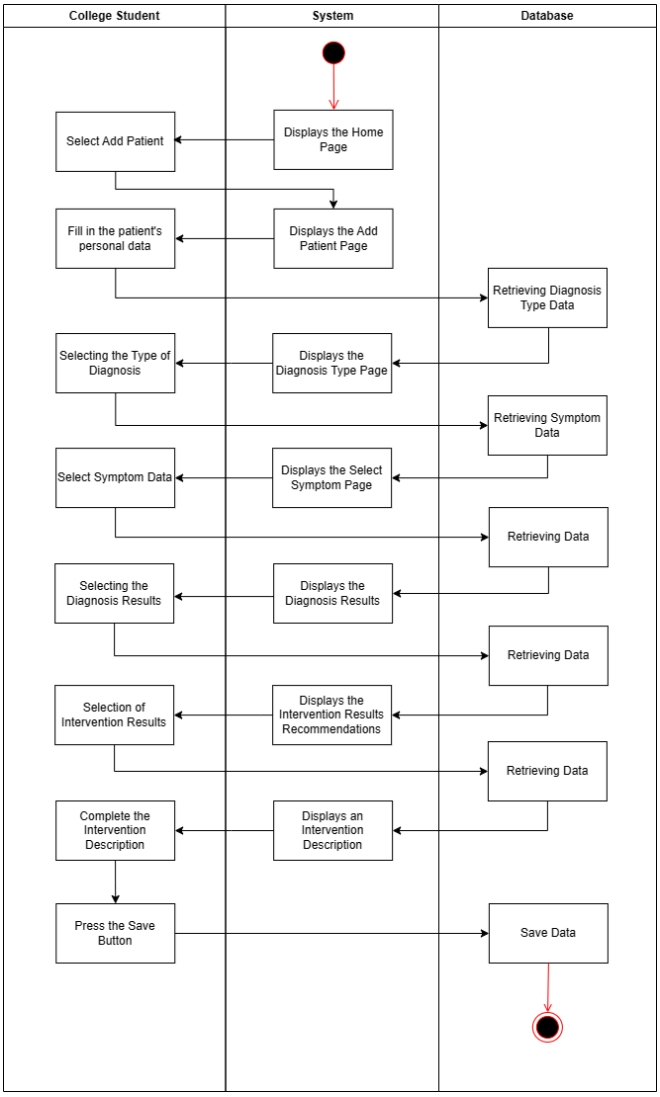

Fig. 4. Nursing process activity by nursing students.

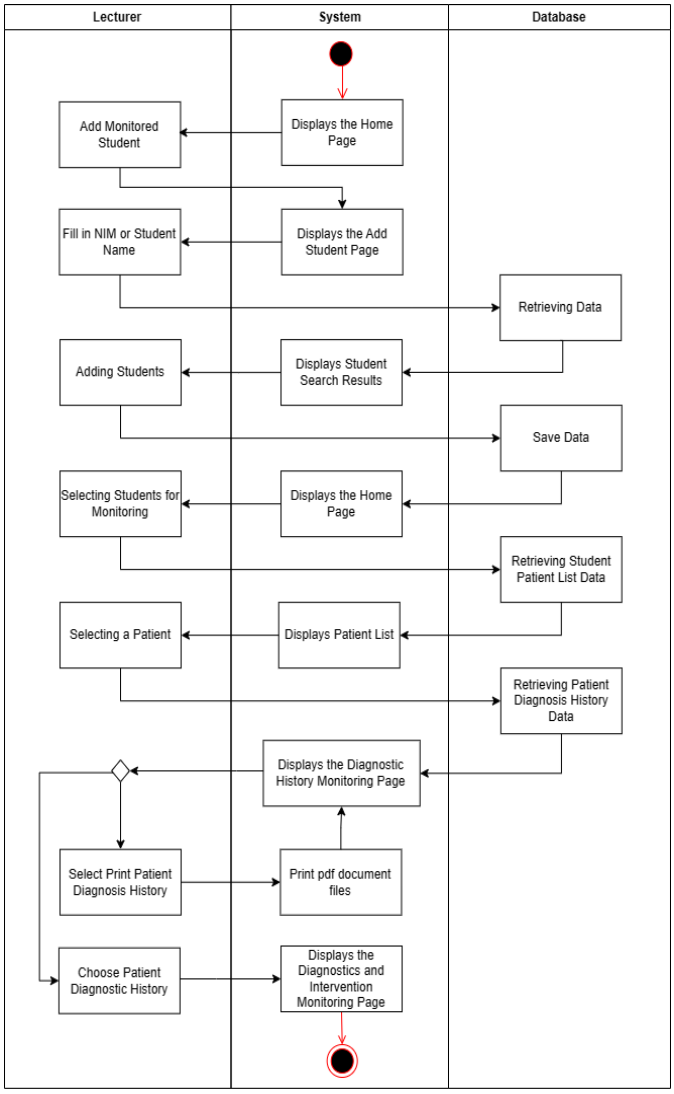

Fig. 5. Activity monitoring nursing process.

Fig. 4 explains the flow of how students diagnose patients, starting from students adding patients first by filling in the data of the patient to be diagnosed, followed by students starting to diagnose from symptoms to the end until the system saves patient data that has been diagnosed by students. The activity plan for the lecturer explains the flow of how the system runs if the user who login is a lecturer, lecturers can monitor the results of the nursing process carried out by their students, starting from a nursing process carried out by their students starting from adding a student to being monitored. Students, who are monitored, view all patient lists who have been treated by students, to see all the history of the nursing process that has been carried out. The following activity plan for lecturers can be seen in Fig. 5.

Fig. 5 explained the flow of how lecturers monitor the results of their student nursing process, starting from lecturers adding students to the system of displaying the history of the patient's nursing process by students.

3) Implementing: All system designs that have been created including expert system functions to help students learn in the nursing process into the form of program code built using dart language, with the help of Flutter frameworks to build android applications and Laravel8 frameworks to build system database APIs.

4) Testing: After implementation, the next stage is testing. Testing will be done using the Black-Box Testing method. In addition to testing the system using black-box, user acceptance testing of the built system is also carried out, the target of system users, namely students and nursing science lecturers.

IV. Result and Discussion

A. Knowledge Base

The knowledge base is the core of the expert system, which is a representation of knowledge from experts. The knowledge base shown in Table IV is a description of the relationship between symptom data and other data contained in the database. Here is the knowledge base that can be seen in Table IV.

TABLE V. Expert System Knowledge Base

Type	Symptom	Diagnosis Results	Intervention	Description
T1	G1 G2 G3 G4 G5	D1	A1	U1, U2, U3, U4, U6, U10, U5, U7, U8, U9
			A2	U12, U13, U14, U 15, U16, U17, U18, U19, U20, U21, U22, U23, U24, U25
			A3	U26, U27, U28, U29, U30, U31, U32, U33, U34, U35, U36, U37, U38, U39, U40
	G6 G7 G8 G9 G10	D2	A4	U41, U42, U43, U44, U45, U46, U47, U48, U49, U50, U51, U52, U53, U54
T2	G11 G12 G13 G14 G15	D3	A6	U55, U56, U57, U58, U59, U60, U61, U62, U63, U64, U65, U66, U67, U68, U69, U70
			A7	U71, U72, U73, U74, U75, U76, U77, U78, U79, U80, U81, U82, U83, U84, U85, U86, U87, U88, U89
	G16 G17 G18 G19 G20	D4	A8	U90, U91, U91, U93, U94, U95, U96, U97, U98, U99, U100, U101, U102, U103, U104, U105, U106, U107, U108
			A9	U109, U110, U111, U112, U113, U114, U115, U116, U117, U118, U119

Table IV above is part of the expert system knowledge base consisting of the data used, for symptoms coded with the letter "G", for diagnoses coded "D", interventions coded "A", types coded "T" and descriptions coded "U". The results of the system diagnosis will appear if the main requirements are met, namely if the total score of the selected symptoms is more than equal to 5 scores (∑Symptom Score ≥ 5). After the results of the system diagnosis appear and are selected, the results of the intervention and description of the intervention will appear following the options.

1) User interface: The user interface is part of an information system that requires user interaction to create input and output for the system [15]. The User Interface is used to provide an overview of the appearance of the application that will be used by the user.

B. System Testing Results

System testing is carried out by testing the system functionally using the black-box testing method and non-functionally, the system aims to determine the response and assessment of users of the system created.

1) Black-box testing: Black-box testing is a software testing technique that focuses on the functional specifications of software [16]. This test is carried out by examiners as well as application users consisting of lecturers and nursing students. All test results obtained from the examiner are successful for each test case carried out.

2) User acceptance testing: This test is carried out with a focus on the non-functional attributes of the system. The main goal is to develop software that can meet user requirements. Not only meets system specifications and can be used but also to find out whether the system is acceptable to users or not [17]. Technical testing was carried out by the way respondents downloaded and ran the application, after using the application respondents were directed to fill out the questionnaire. Here are the results of the questionnaire in this test.

TABLE VI. User Acceptance Test Results

No.	Question	Index (%)
1	The application is easy to understand how to use it	**87,83%**
2	The application interface display is good and easy to understand	**85,22%**
3	The images and icons used in the application display are easy to understand	**86,96%**
4	The instructions in the application are clear and easy to understand	**86,1%**
5	I feel comfortable while using the app	**81,74%**
6	The application helps nursing students in making nursing diagnoses	**86,96%**
7	The diagnostic results given are by the facts	**81,74%**
8	The application helps nursing students in nursing learning	**86,96%**
9	This application can assist lecturers in monitoring the nursing process of students	**73,33%**
Average Index		**84%**

Table V is a summary of the test results conducted by each user. Testing was carried out by students and lecturers, 22 students and three lecturers. Testing is done with nine questions that must be filled in by each user whether the features in the system are running properly; the functionality of each feature will be tested by students and lecturers. The results of the test show that this research has an average index value of 84% which means that the system built has a "Very Good" value.

V. Conclusion

In this study, the expert system for the learning process of nursing students is considered capable of helping nursing students to properly analyze the diagnosed patients and can assist lecturers in monitoring every nursing process carried out by students. The expert system application that was successfully built using the Flutter framework has a test value of "Very Good" with an average value obtained of 84%.

Recommendations for future researchers are that future researchers can add and complete data that is in accordance with SDKI (Indonesian Nursing Diagnosis Standards) and SIKI (Indonesian Nursing Intervention Standards), add assessment features, corrections and notes for lecturers on each treatment result carried out by students, add features to replace lecturers for students, add features to remove students from the monitoring list for lecturers, add features for students to be able to add patient progress notes and add features for lecturers to evaluate the patient care process carried out by students.

ACKNOWLEDGMENT

We would like to express our deepest thanks to LPPM Lampung University for providing research funding for this project. The financial support provided has enabled us to obtain the data and resources necessary to complete this research.

***Abstract*—The emotional state is an essential factor that affects mental health. Electroencephalography (EEG) signal analysis is a promising method for detecting emotional states. Although multiple studies exist on EEG emotional signals classification, they have rarely considered processing time as a metric for classification model evaluation. Instead, they used either model accuracy and/or the number of features for evaluation. Processing time is an important factor to be considered in the context of mental health. Many people commonly use smart devices, such as smartwatches to monitor their emotional state and such devices require a short processing time. This research proposes an EEG-based model that detects emotional signals based on three factors: accuracy, number of features, and processing time. Two feature extraction algorithms were applied to EEG emotional signals: principal components analysis (PCA) and fast independent components analysis (FastICA). In the classification process, ensemble method classifiers were adopted due to their powerful performance. Three ensemble classifiers were used: random forest (RF), extreme gradient boosting (XGBoost), and adaptive boost (AdaBoost). The experimental results showed that the RF and XGBoost achieved the best accuracy, i.e., 95%, for both methods. However, XGBoost outperformed RF in terms of the number of features; it used 33 components extracted by PCA within 14 seconds, while RF used 36 within 4 seconds. AdaBoost was the worst in terms of both accuracy and processing time in the two experiments.**

Keywords*—*Electroencephalograph; mental health; feature extraction; random forest; extreme gradient boosting; adaptive boost

I. Introduction

Mental health is a source of concern due to its significant impact on an individual's quality of life and on society, where poor mental health can lead to multiple health and financial losses, in addition to suicide in critical cases. Mental health issues are increasing due to different factors such as social media, social state, and financial state. Additionally, natural disasters and global epidemics affect an individual's mental health, such as what is caused by the Covid-19 pandemic [1]. In 2011, the World Health Organization predicted that depression would be the leading cause of the global illness burden by 2030 [2]. Twenty-five percent of people worldwide have mental health problems [3]. Hence, it is essential to pay attention to this field and find solutions to mitigate the expected impacts of poor mental health.

Furthermore, personal emotions primarily affect people's mental health [4]. EEG signals contain brain electrical activity information gathered from the scalp by electrodes [5]. Thus, several studies have been concerned with conducting experiments classifying emotions using EEG signals. Multiple previous studies have focused on classification accuracy and the number of features. The previous experiments achieved high accuracy with an appropriate number of components in the EEG signal classification process [6], but ignored processing time. On the other hand, limited studies have considered time to be an essential factor for the model evaluation. However, their results have shown that the processing took a relatively long time, impairing the model's efficiency. A short processing time is a required factor in mental health data processing, enabling smart devices to adopt these models and allowing their users to monitor their emotional states through them directly. Moreover, fast processing to detect personal emotions contributes to preventing critical cases, such as suicide due to depression.

This gap encouraged us to propose a model that classifies emotional signals considering accuracy, number of features, and processing time. PCA and FastICA were used in the extraction feature stage due to their speed in the extraction, while RF, AdaBoost, and XGBoost were implemented to classify the emotions.

The contributions of this study are summarized as follows:

- Implementing three ensemble classification algorithms on EEG signals using two feature extraction algorithms.
- Defining the best combination of feature extraction and classification algorithms based on three factors: accuracy, number of features, and processing time.
- Comparison of the proposed model results with several studies that used the same dataset.

II. Literature Review

Table I shows a summary of related works in terms of the dataset, features extraction algorithm, number of features, best accuracy, and processing times. As shown in the table, few studies have been concerned with the models' processing times. On the other hand, various datasets and algorithms were used.

TABLE I. SUMMARIZATION OF RELATED WORK

The emotions-state dataset was used in several studies; it contained 2548 features and classified the emotions into three classes: negative, positive, and nature [7]. For instance, Bird et al. [7] used the dataset to propose a work that included biological inspiration used in all implementation steps rather than being limited to the classification stage. Additionally, they explored deep learning and tuning using long short-term memory (LSTM). Moreover, they have tested AdaBoost using two different models.

The system implements an evolutionary optimization of a multilayer perceptron (MLP) to estimate the network's best hyperparameters. The model extracted 500 features and tested them with several classifiers: deep evolutionary multilayer perceptron (DEvo MLP), LSTM, AdaBoost deep evolutionary multilayer perceptron (AdaBoost DEvo MLP), and AdaBoost LSTM. The accuracy results were 96.11%, 96.86%, 96.23%, and 97.06%, while the training times were 16.66, 65.11, 32.88, and 594.55 seconds, respectively. In study [8], the authors implemented four feature extraction methods: One Rule (OneR), Bayes Network (BN), Info-Gain, and Symmetrical Uncertainty. This study conducted a classification using single and ensemble methods on a dataset to determine the best result. The single models were: OneR, RT, Sequential Minimal Optimization (SMO), Naive Bayes (NB), BN, Logistic Regression (LR), and MLP. In contrast, the ensemble models were RF, Vote, and AdaBoost of random forest (AdaBoost RF). In the single model, MLP with Info-Gain achieved the highest accuracy by 94.89%. Simultaneously, RF with Info-Gain gained the best accuracy in ensemble methods by 97.89%. On the other hand, this experiment [9] converted the EEG signs to 2D and 3D convolutional neural network (CNN) images. In the beginning, the authors used three feature selection methods: Kullback-Leibler Divergence, OneR, and Symmetrical Uncertainty. The best results for each feature selection of 2D CNN were 98.22%, 97.28%, and 97.12%. In contrast, the accuracy of 3D CNN was 97.28%, 96.97%, and 97.12%, respectively.

On the other hand, multiple studies used a popular dataset called SEED [22]; the signals were collected from 15 participants using 15 Chinese film clips. Each participant experimented three times, and they classified the films into three classes: negative, positive, and neutral. Authors in [10] used the SEED dataset to propose a model called (STRNN) which integrated spatial and temporal dependencies with a recurrent neural network (RNN). The proposed approach had

two layers: a multi-direction spatial RNN (SRNN) and a bi-direction temporal RNN (TRNN) layer. These layers captured spatial and temporal information within the sequence signal. The accuracy of this experiment was 89.50%. While Asadur Rahman et al., in [11] used PCA and t-statistics to extract five channels and used them with four classifiers: support vector machine (SVM), artificial neural network (ANN), linear discriminant analysis (LDA), and k-nearest neighbor (KNN). The classification accuracy was 85.85%, 86.57%, 82.50%, and 73.42%, respectively.

DEAP [23] dataset signals were collected from 32 participants; each participant watched 40 music videos for one minute per video. The participants classified the videos based on their levels of valence, arousal, liking, dominance, and familiarity. It is another common dataset used broadly in the state of the art. For instance, Doma and Pirouz in [12] used the DEAP dataset with PCA, and without PCA, with several classifiers: SVM, logistic regression, decision tree, KNN, and naive bayes. The classifiers achieved accuracy ranging from 55% to 75% and an F1 score between 70% and 86%. The better F1-score was 84.73% obtained by SVM with PCA of arousal classification. However, Hemanth in [13] used a Kohonen neural network (KohonenNN) with several modifications to achieve better accuracy. The modified KohonenNN I and II improved the accuracy by 1% to 2%. The best accuracy was achieved using KohonenNN I, which was 87%. In this study [14] suggested a novel model called ECLGCNN. ECLGCNN consists of three layers. The first layer is a graph convolutional neural network (GCNNs) devoted to calculating the relationship between two channels of EEG signals and extracting the graph domain features from differential entropy. The second layer is LSTM, which handles memorizing the changes between two EEG channels. The final layer is the dense layer, which focuses on classifying the emotions. The study conducted two experiments; the first experiment was subject-dependent, and it achieved 90.45% and 90.60% for valence and arousal. The second experiment was subject-independent and achieved lower accuracy, which was 84.81% and 85.27%. In this study [15], authors suggested using an empirical mode decomposition (EMD) to decompose the signals. Then they extracted the features using second-order difference plots (SODP), which are the mean, area, and measure of central tendency. The experiment used an SVM and two-hidden layers of MLP to classify the multi-class emotions. MLP achieved good results in each classification. However, the best accuracy was 100% for high and low of arousal. Another study [16] carried out several feature extraction algorithms: power, entropy, fractal dimension, and statistical. Additionally, they used several classifiers: SVM, KNN, and decision tree. They adopted PCA to select features. The system achieved the overall best accuracies of 78.96%, 77.62%, and 77.60% for arousal, valence, and dominance, respectively, using SVM with statistical features.

Some studies have used multiple emotional datasets. For instance, Cheng et al. [24] used the DEAP and DREAMER [17] datasets. The authors used the deep forest to extract spatial and temporal information from these two datasets. Both experiments achieved good results. The accuracy of the first dataset was 97.69% and 97.53% for valence and arousal, respectively. In contrast, the second dataset's accuracies were 89.03%, 90.41%, and 89.89% for valence, arousal, and dominance, respectively. This study considered the running time; the experiment took 693.4861 seconds in the first experiment and 1307.406 seconds in the second experiment. In contrast, another study [18] used SEED and DEAP datasets to implement their model. The research used a flexible analytic wavelet transform (FAWT) with information potential (IP) to extract the features. The experiment was tested using two classifiers: RF and SVM. SVM was better than RF, where it achieved 59.06% accuracy on DEAP and 83.33% accuracy on the SEED database. Additionally, authors in [19] used the same two datasets; they used three algorithms to extract the EEG signals. The three algorithms are variance, discrete wavelet transform (DWT), and fast Fourier transform (FFT). DEAP and SEED were used to validate the model. The DEAP dataset contains four states: valence, arousal, dominance, and liking. In contrast, the SEED has three states: negative, positive, and neutral. The classifier used spiking neural networks (SNNs), which achieved 78%, 74%, 80%, and 86.27% accuracy, respectively, on the first dataset, while on the second dataset, it achieved 96.67% accuracy.

On the other hand, some studies have used a different dataset. For example, authors in [20] used Indian films to classify emotions into happy, sad, fear, and relax. The study worked in two stages to remove the noise of the dataset. The first stage used empirical mode decomposition (EMD), while the second stage used variational mode decomposition (VMD). A Multi-class least squares SVM (MC-LS-SVM) classifier was used to classify the emotions alongside the morlet wavelet (MW) kernel function. This model's best accuracies were 92.79%, 88.98%, 87.62%, and 93.13% for happy, sad, fear, and relaxed emotions, respectively. Seal et al. in [21] used a dataset that classified the EEG into four categories: sad, fear, happy, and neutral. The experiment used a discrete wavelet transform and an extreme learning machine (ELM). The best accuracy was 94.72% from the FP1-F7 channel in the subband of gamma.

III. METHOD

In this section, we present the proposed model's method, as shown in Fig. 1. We experimented on the emotional state dataset used by some researchers, as mentioned in the literature review section [7]. The database classified a person's emotional state into positive, negative, and neutral. Data were collected from one man and one woman using electrodes via an EEG headband while watching six clips for one minute per clip. Three films stimulated positive emotions, while the other three stimulated negative emotions. Six minutes were recorded for each person in a neutral or normal state. This experiment resulted in a dataset of 2,549 attributes and 2,132 rows. Two algorithms of the feature extraction stage, PCA and FastICA, were applied in this experiment. In addition, three ensemble classifiers were included in the classification stage: RF, XGBoost, and AdaBoost. Moreover, each experiment was tested using 10-cross-fold validation accuracy. Each experiment will be discussed in detail in the following subsections.

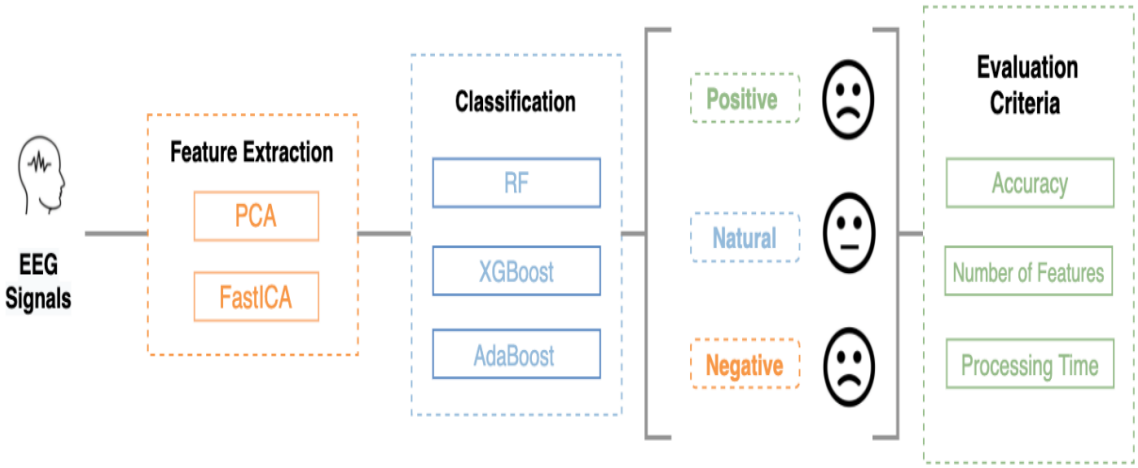

Fig. 1. Research Methodology. The research methodology included three main steps. The first step was the feature extraction step, which contained two methods: PCA and FastICA. The second step was the classification step, which consisted of three classifiers: random forest, XGBoost, and adaptive boost. Finally, the third step was the evaluation step, which was based on three criteria: the accuracy of the model, the number of features, and the processing time.

A. Feature Extraction

This model used two feature extraction algorithms to extract the most important EEG signals of emotions: PCA and FastICA. Several studies used different extraction feature algorithms based on several specifications. In this study, we used PCA for its fast-processing capabilities [25]. Similarly, FastICA is a fast version of ICA and is suitable for large datasets [26]. The two following subsections will discuss the two selected extract feature algorithms.

1) Principal component analysis: The main concept of principal component analysis is dimension reduction by transforming the correlated variables into new uncorrelated components, which maintain a maximum variation of the original components [27]. Based on [28], there are some steps to extracting the features using a PCA, which are presented as follows:

a) Suppose there is a matrix of m × n size.

b) Convert the matrix to an N dimension vector with input data x as $x_0, x_{0,1}, \ldots, x_{m,n}$.

c) Calculate the mean vector as follows:

$$X_{mean} = \left(\frac{1}{N}\right) \sum_{i=1}^{N} X_i \quad (1)$$

d) Calculate the covariance matrix.

e) Compute the eigenvalues and eigenvectors.

f) Select the components using k-eigenvectors of the highest eigenvalues, then construct a w matrix of $d \times k$ dimensions.

g) Construct the principal components using the w matrix to transform the samples into a new subspace.

In this study, PCA was used with each classifier algorithm to obtain a good result. Based on multiple experiments, we have seen that the best selections were 36 components with RF, 33 components with XGBoost, and 28 components with AdaBoost.

2) Fast independent component analysis: Fast independent component analysis is a type of ICA algorithm responsible for separating the unknown mixed signals to obtain useful independent signals using the source signal's independent and non-Gaussian nature [29]. An algorithm of FastICA works faster and is iteratively used at constant points with a simple structure and fast convergence [30].

To implement FastICA, some steps follow, as mentioned in [31]:

a) Remove the mean of x by centralization.

b) Transform x linearly to obtain an uncorrelated vector called z. Thus, the covariance matrix of z will be: $E\{zz^T\} = I$.

c) Construct an operation matrix called w, which satisfies: $\|w\| = 1_{\circ}$.

d) Update the separation matrix w, then iterate it based on the Newton iteration method to obtain w^*.

e) Normalize w^* to be $w = w^*/\|w^*\|_{\circ}$.

f) Judge the coverage of w. If it is good, then the best estimate of the source signal $wx_{\circ}$; if not, go back to step 3.

In FastICA experiments, we selected 33 components with RF and 31 components with AdaBoost and XGBoost.

B. Classifiers

This subsection shows the three classifiers used in this study. We focused on using ensemble classifiers based on their powerful performance. RF and AdaBoost were selected based on their good performance in classifying the EEG signals in some studies [32] [33]. Additionally, we used XGBoost due to its effective label classifications and fast computation [34]. The following subsections will discuss the selected classifiers.

1) Random forest: RF consists of multiple decision trees. Each decision tree makes a classification separately and then provides its result. The final result was identified based on the voting of all the decision trees [35]. The RF algorithm describes the steps according to Evans et al., in [36] as follows:

a) Construct iterative N bootstraps of n size sampled from z population.

b) Grow an RF tree T_b randomly at each node and define m variables from M to permute over each node to know the best split using the Gini entropy index.

c) Use out-of-bag data to validate every tree T_b.

d) Produce several RF trees:

$$\{T_b\} = \frac{B}{1} \quad (2)$$

To predict a new observation x_i, $\hat{C}_b(x)$ be a class prediction of Bth RF tree, then:

$$\hat{C}_{rf}^{B}(x) = majorityvote\{\hat{C}_b(x)\}\frac{1}{B} \quad (3)$$

In this study, we tuned parameters where the best parameters of RF with PCA and Fast ICA are illustrated in Table II.

2) Extreme gradient boosting: Extreme gradient boosting (XGBoost) is a robust algorithm based on a gradient boosting system [37]. It is a tree-boosting system; however, there is a major difference between RF and gradient-boosted machines (GBM): RF trees are built independently. In contrast, the GBM added a new tree to complete the previously built ones [38]. According to Duan et al. [39], the general points of XGBoost algorithms are presented as follows:

- Assume $D = \{(x_i, y_i)\}$ is a dataset of n samples and m features ($D = n, x_i \in R^m, y_i, \in R$).
- The model uses z additive functions to approximate the response of the system, as follows:

$$\hat{y}_i = \phi(x_i) = \sum_{z=1}^{z} f_z(x_i), f_z \in F \quad (4)$$

where, F is the regression trees space, and it is defined as:

$$F = \{f(x) = w_q(x)\}(q: R^m \to T, w \in R^T) \quad (5)$$

where, q stands for the tree structure, T indicates the number of leaf nodes, and the w represents the weights. Besides, f_k is a function that illustrates that w and q are compatible with an independent tree.

Table III illustrates the parameters we used with the XGBoost classifier with PCA and FastICA based on the tuning parameters process.

3) Adaptive boost: Adaptive boost (AdaBoost) is an algorithm that improves learners' accuracy by changing the sample weight distribution [40]. As mentioned in [41] AdaBoost works to reduce the exponential loss greedily. Eq. (6) shows that:

$$FT(X) = \sum_{t=1}^{T} f_t(x) \quad (6)$$

where, ft indicates to a weak learner and x is the object used.

$$FT(X) = \sum_i E\left[F_{t-1}(x_i) + \alpha_t\, h(x_i)\right] \quad (7)$$

where, h(x_i) is the hypothesis made by a weak learner, and αt is the parameter of it to minimize the sum of error in training.

In this experiment, AdaBoost was used two times, first with PCA while the second was with FastICA. The parameters we have used in the two experiments are shown in Table IV.

C. Performance Measures

The proposed model was evaluated in terms of accuracy, number of features, and processing times. The formulation of accuracy is presented as follows:

$$Accuracy = \frac{TP + TN}{TP + TN + FP + FN} \quad (8)$$

where:

- True Positive (TP): means when the actual class was positive, and the model was predicted to be positive.
- True Negative (TN): means when the actual class was not positive, and the model was predicted to be not positive.
- False Positive (FP): means when the actual class was not positive, but the model was predicted to be positive.
- False Negative (FN): means when the actual class was positive, but the model was predicted to be not positive.

TABLE II. PARAMETERS USED BY RF SELECTED BASED ON PARAMETERS TUNING

PARAMETERS	BOOTSTRAP	MAX_DEPTH	MAX_FEATURES	MIN_SAMPLES_LEAF	MIN_SAMPLES_SPLIT	N_ESTIMATORS

PARAMETERS	BOOTSTRAP	MAX_DEPTH	MAX_FEATURES	MIN_SAMPLES_LEAF	MIN_SAMPLES_SPLIT	N_ESTIMATORS
PCA	TRUE	20	AUTO	1	2	2000
FASTICA	TRUE	20	AUTO	1	2	800

TABLE IV. PARAMETERS USED BY ADABOOST SELECTED BASED ON PARAMETERS TUNING

Parameters	Algorithm	Learning_Rate	n_Estimators
PCA	SAMME	0.01	2000
FastICA	SAMME	0.3	1600

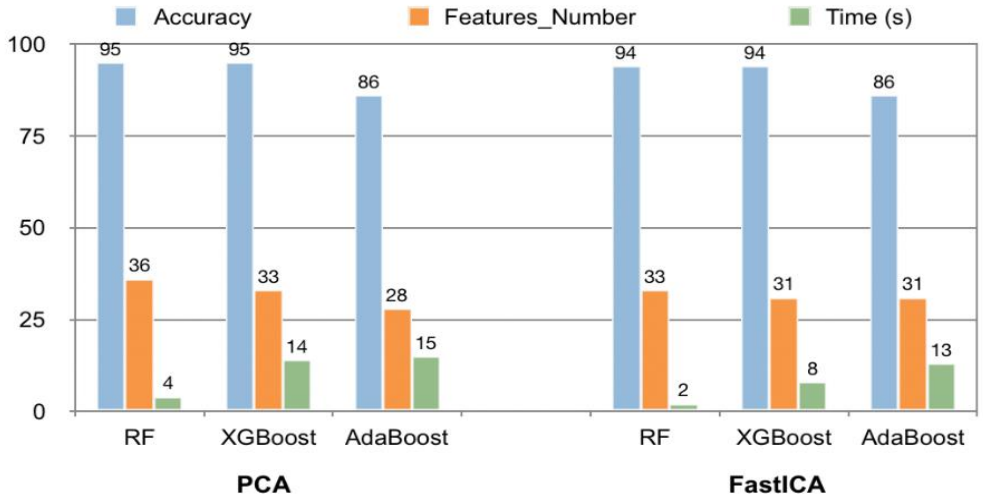

Fig. 2. Proposed model results.

To achieve scientific accuracy, we tested each classifier ten times with PCA and FastICA, avoiding biased results of the classifier accuracy. Then, we calculated the average of these experiments.

Additionally, several measures were calculated to give complete view of the results, namely precision, recall, and F1-score.

Precision was calculated as follows:

$$Precision = \frac{TP}{TP + FP} \quad (9)$$

This means the percentage of the relevant results. Recall was calculated as follows:

$$Recall = \frac{TP}{TP + FN} \quad (10)$$

This indicates the average of precision and recall.

IV. Result and Discussion

One of the goals of this study was to reduce the number of features to fewer than 63, which is the lowest number of features achieved by previous studies that used the same dataset [8]. We succeeded in reducing it by 48%, which equals 33 features using PCA with an accuracy equal to 95% using the XGBoost classifier. On the other hand, FastICA decreased the features by 51%, which is 31 features using the XGBoost classifier with 94% accuracy. According to the time, we noticed that all classifiers' processing times were between 2 seconds and 15 seconds. Notably, all classifiers take a short time to process; thus, we decided to take time as the third factor in the evaluation process. However, RF was the faster algorithm; it took just four and two seconds of processing time with PCA and FastICA.

On the other hand, AdaBoost had the lowest accuracy, achieving 86% in the two experiments. Additionally, AdaBoost was the slowest algorithm in both experiments. The highest accuracy achieved in the experiments was 95% using the XGBoost classifier, with 33 features extracted by PCA. In contrast, the same accuracy was achieved by RF using PCA, but with 36 features. Fig. 2 shows the results of the three classifiers for the three evaluation criteria. The figure shows the performance of the three classifiers with PCA and FastICA. The accuracy of the RF and XGBoost were high and equal in both experiments. However, RF outperformed in the time processing criteria, while XGBoost outperformed in the number of features. AdaBoost was the lowest and slowest classifier in this work. Table V shows the results of each measure of the three emotions in all experiments.

Generally, some existing works achieved better accuracy than this experiment, but with more features, such as [7]. However, we think 95% is not a bad percentage, especially within a short processing time of 14 seconds. Table VI presents a performance comparison of the proposed work and existing works that used the same emotional dataset.

TABLE V. Classification Performance

Feature Extraction	Classifier	Class	Precision	Recall	F1-score
PCA	RF	Negative	0.96	0.98	0.97
		Natural	0.95	0.95	0.95

		Natural	0.94	0.96	0.95
		Positive	0.92	0.88	0.90
	AdaBoost	Negative	0.82	0.94	0.87
		Natural	0.94	0.89	0.91
		Positive	0.76	0.67	0.71

TABLE VI. PERFORMANCE COMPARISON BETWEEN THE MODELS USING THE SAME DATASET IN THIS WORK

Ref	Number of features	Best accuracy	Time (s)
[7]	500	97.06%	595
[8]	63	97.89%	-
[9]	-	98.43%	-
Proposal model: XGBoost with PCA	33	95%	14
Proposal model: XGBoost with FastICA	31	94%	8

V. CONCLUSION

This paper presented an EEG signals emotion prediction model that concerns three factors: accuracy, number of features, and processing time. PCA and FastICA were used to extract the features from the signals. RF, XGBoost, and AdaBoost have been used to classify the signals. The XGBoost results were the best in the two experiments. The best accuracy of this work was 95% using 33 features extracted by PCA; the classification process took 14 seconds. In contrast, RF achieved the same accuracy in the PCA experiment but used 36 features within four seconds. AdaBoost achieved the lowest accuracy and longest time in both experiments. XGBoost was the fastest classifier in both experiments. This model can be adopted in smart devices, such as smartwatches that offer dynamic monitoring of mentally patients to protect them from the probable implications. In future work, the authors will utilize other methods and techniques to obtain better accuracy with fewer features and processing time.

Selection of a Trustworthy Technique for Fraud Prevention in the Digital Banking Sector

Bandar Ali M. Al-Rami Al-Ghamdi
Faculty of Computer Studies, Arab Open University, Riyadh 11681, Saudi Arabia

***Abstract*—Digital banking fraud poses a threat to the global economy and fintech applications. Sustainable models are essential to address this issue and minimize its economic impact. Hybrid methods have been developed to assess strategies for preventing digital banking fraud, aiding global stakeholders in making well-informed judgments. However, many of these models concentrate on the numerical features of digital banking ratios while overlooking crucial financial fraud protection qualities. This paper introduces a computational method for discovering and measuring the influence of digital banking fraud prevention strategies on sustainable fraud prevention. This innovative approach combines intuitionistic fuzzy set theory and the analytical network process for decision-making. Initially, an intuitionistic fuzzy expert system prioritizes crucial indices based on the preferences of financial decision-makers. This technique is then compared to alternative decision-making models across multiple variables. Empirical data demonstrate the superiority of the intuitionistic fuzzy-based decision-making system, outperforming other models and facilitating the recognition of financial statement fraud in global banking networks. Consequently, it offers a sustainable fintech solution. The findings of this study are pertinent to fintech scholars and practitioners engaged in the global battle against digital banking fraud.**

***Keywords*—Digital banking fraud; analytical network process; intuitionistic fuzzy sets; fraud prevention and detection**

I. Introduction

Fraudsters in Saudi Arabia have rapidly adapted to modern technological systems, leaving old brick-and-mortar institutions behind [1–2]. Criminal techniques are constantly evolving, posing a threat to the entire payment ecosystem and prompting regulatory attention across all banks, regardless of their level of digital transformation [3–4].

The adoption of online banking in Saudi Arabia is expected to rise by 16.7% from 2024 to 2028 [5], indicating significant growth in KSA's digital banking. After fifteen years of continuous growth, the online banking rate is predicted to peak at 68.16 percent in 2028. It is noteworthy that Saudi Arabia has consistently increased internet banking penetration in recent years, demonstrating a persistent trend of people using digital banking services for financial interaction and management.

The growing digitization of global banking has necessitated an evaluation of hybrid decision-making (DM) methods to combat digital banking fraud [6–8]. Digital banking fraud encompasses phishing, spoofing, identity theft, account fraud, and transaction fraud. Phishing and spoofing, involving unwary recipients receiving misleading emails, phone calls, and texts from seemingly reputable sources, are common occurrences [9–10]. These attempts aim to steal sensitive data or gain access to computer networks, resulting in financial losses and identity theft.

Given the severity of these frauds, Saudi business boards must implement stronger and more effective fraud prevention measures. Fraud detection and mitigation are not only cost-effective but also essential for reputation protection. Saudi Arabian specialists use multiple characteristic decision-making (MCDM) methods to evaluate digital banking fraud prevention technologies [5–7]. The Analytical Network Process (ANP) serves as a suitable model for comparing characteristics to solutions. However, due to decision-makers' subjectivity and uncertainties in input data, a more realistic strategy that effectively addresses these uncertainties is needed.

The intuitionistic fuzzy ANP emerges as a better and more realistic method for evaluating alternative solutions to Saudi Arabia's digital banking fraud problem. It assists decision-makers in choosing actions that align with goals by considering user expertise and historical perspectives on the issue. By incorporating the views of Saudi Arabian subject-matter experts, the intuitionistic fuzzy-ANP model addresses local fintech differences effectively.

This research enhances the evaluation of fraud prevention models in the financial accounts of Saudi Arabian fintech applications using the intuitive fuzzy-ANP methodology. The study has two objectives: first, to understand the drivers of Saudi fintech apps and digital banking fraud, and second, to assess how well the intuitionistic fuzzy-ANP utilizes these characteristics to prevent wrongdoing. The study recommends a systematic and integrated approach to investigation and prevention to identify abnormalities and conduct comprehensive fraud assessments [8–12]. These early investigations lay the groundwork for further analyses and in-depth inquiries to resolve the issue.

This article analyzes past trends and statistics to provide readers with a brief introduction to fraud analysis and prevention in fintech apps. The next section is a literature overview of pertinent studies by earlier researchers. The final section discusses features used to evaluate digital banking fraud models and suggests a hierarchical architecture for Saudi Arabian fraud detection and prevention. The study employs intuitionistic fuzzy-ANP to numerically deconstruct the hierarchical problem. The discussion will include a comparative study after presenting the findings. The paper concludes with a summary of the complex discussion and outlines study limitations.

II. PREVENTING DIGITAL BANKING FRAUDS

Saudi Arabia needs a comprehensive digital banking fraud prevention strategy to guide managers and key departments in recognizing, assessing, and responding to possible fraud [13-15]. This well-developed strategy details each organization's function and its duties. Its success depends on senior management's active participation in its formulation. Effective communication between decision-makers, managers, law enforcement agencies, customers, and external organizations helps develop robust risk analysis, prediction, and DM procedures and fosters seamless collaboration.

Comprehensive training for the entire team is necessary to accurately apply the policy and handle situations in accordance with the fraud prevention strategy [16-17]. Before preventing fraud, this training is required. To ensure efficacy, the fraud prevention plan should be thoroughly examined, rehearsed, and checked for flaws. This rigorous preparation is necessary since the fraud prevention plan executes activities and ensures fraud detection and prevention. The organization's nature, size, and operating environment have all played a significant role in shaping the Saudi strategy.

Before establishing the best decision support tools, Saudi Arabia needs a well-defined network to manage its many fraud prevention techniques. Fraud in digital banking applications is diverse; thus, decision support systems should be tailored to the individual difficulties [5-6]. The following paragraph examines the fundamental principles of a proactive preventative strategy and its components. The following paragraph elaborates on this strong discussion and analysis.

A. Fraud Prevention Planning

Upper management's active involvement across all business units and their unwavering support underpin the plan's concepts in Saudi Arabia [15]. It has four main steps, as explained below. After refining with Saudi-specific examples, the process was reduced to four parts. The organization's management, fraud risk assessment, views of fraud detection, and a complete fraud prevention policy for stakeholders are covered in these phases. Each phase is interdependent, and sub-processes are carefully structured to match. The hierarchical design in Fig. 1 shows how to build a fraud prevention plan model. Organizational management subprocesses include management attitude, integrity, policy commitment, and strict enforcement. Below is a full description of each subprocess:

1) Organization's management: Any fraud prevention plan begins with a thorough management structure review. Senior management must be involved in organisational units while developing a fraud prevention strategy. This involvement should be regular to be effective. The top of the firm oversees all plan execution processes as a protective cover. This level includes management's thinking, unshakable dedication to integrity policies, and rigorous implementation. Fig. 1 shows the complex interaction of these mechanisms [4–5].

2) Fraud risk assessment: Any comprehensive fraud protection plan's second crucial step is a thorough analysis of digital banking fraud risk. This phase assesses the like-lihood of illegal activity. It involves creating specialised teams, mitigating risks, and monitoring and controlling the strategy. This step includes the creation of the risk as-sessment team, the creation of a rigorous risk assessment methodology, and the im-plementation of compliance monitoring measures [9–12]. Fig. 1 shows the fraud risk assessment procedure in steps.

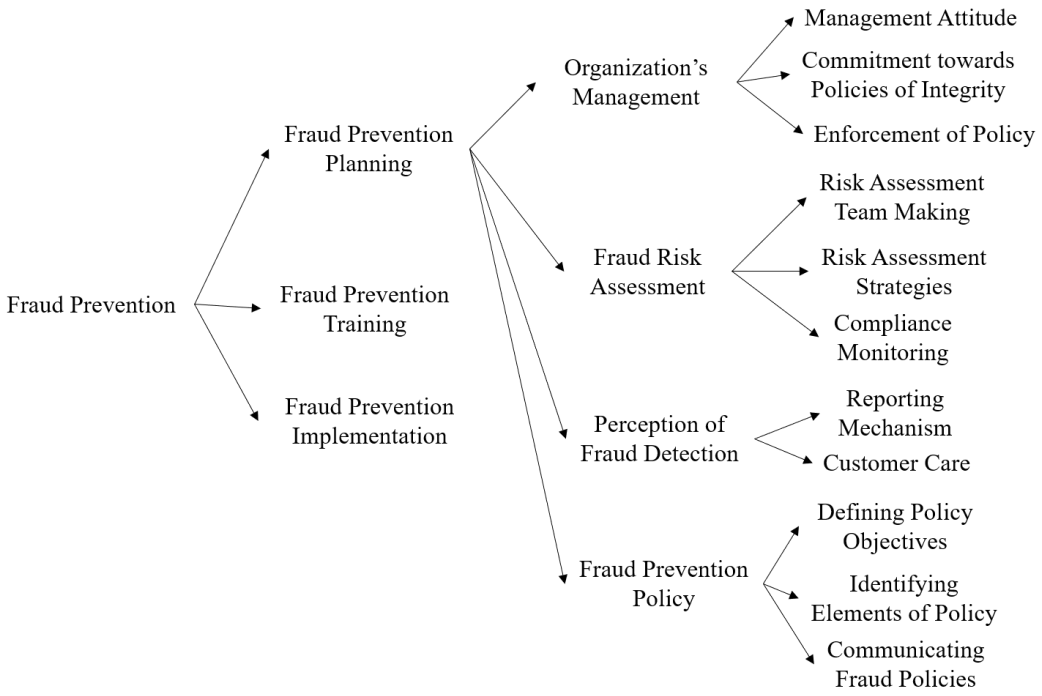

Fig. 1. Basic characteristics.

3) Perception of fraud detection: This phase includes all fraud detection efforts [16–17]. Customer service and fraud reporting are key to this level. Fig. 1 shows that fraud detection and its subsidiary procedures are the fundamental processes in this situation.

4) Fraud prevention policy: The methodical process an organisation follows to create and implement a digital banking fraud prevention policy is called the "fraud prevention policy." This process involves identifying essential fraud policy elements, developing effective communication mechanisms, and rigorously documenting the policy [17]. Fig. 1 shows the three essential subprocesses of creating policy objectives, identifying critical fraud prevention policy elements, and disseminating the fraud policy. It also shows the first step in the fraud prevention policy process.

B. Fraud Prevention Training

Saudi Arabia simulates the fraud prevention approach in this planning phase. At this level, fraud prevention plans and methods are tested and practiced. This involves developing testing processes, creating test scenarios, and carefully assessing the fraud protection plan's performance. Management must also train their Saudi Arabian staff and agents to effectively implement the fraud prevention plan [17].

C. Fraud Prevention Implementation

Saudi Arabian enterprises need comprehensive fraud detection and prevention solutions due to the rising frequency of financial crimes, cyberattacks, and digital fraud. The main goal is to reduce the damage or costs from these illegal operations [17]. Financial crimes, hacking, and digital fraud are on the rise in Saudi Arabia. Organizations can avoid the high costs and consequences of unchecked fraud by implementing efficient fraud detection and prevention methods. This strategic approach protects Saudi Arabian organizations from unbridled fraud [17].

Fraud prevention must be integrated into a comprehensive plan to identify and prevent fraudulent transactions or banking activities in Saudi Arabia, preventing financial and reputational harm to clients and financial institutions. This approach helps identify fraudulent transactions and banking activity and prevent them from harming the Saudi financial sector.

III. Methodology

The proposed methodology for selecting dependable visual analytics tools tailored for medical data analysis in the context of Saudi Arabia is a multifaceted approach encompassing three key phases [5-6]. The methodology commences with the meticulous establishment of a comprehensive network encompassing all variables potentially impacting the problem at hand. This entails a rigorous examination of the entire chain under consideration, with a keen focus on identifying any potential vulnerabilities. Subsequently, the outcomes are categorized based on shared attributes, following the delineation of intersections. This procedural step warrants periodic reevaluation, especially when significant alterations within the chain transpire.

In the subsequent phase, the methodology involves the assignment of weights to the criteria, a crucial step in the process. Intuitionistic fuzzy ANP is the chosen method for this purpose, incorporating the valuable input of domain experts. Within this framework, the criteria are diligently assessed under specific key categories.

The third phase of the methodology encompasses the scrutiny of results derived from multiple criteria evaluations. This comprehensive analysis aids in the identification of key patterns, trends, and insights essential for informed DM.

Finally, the fourth step of the methodology is pivotal in determining the organization’s readiness to employ raw materials. To facilitate this DM process, the intuitionistic fuzzy TOPSIS technique is employed. This step serves as the culmination of the methodology, shaping the organization’s course of action.

In adapting this methodology to the unique landscape of Saudi Arabia, it is paramount to consider the distinct contextual factors, healthcare requirements, and societal aspects that underpin the nation's healthcare sector. The utilization of a reliable knowledge-based fuzzy expert system within this framework holds substantial promise in advancing medical data visualizations, enhancing patient care, and contributing to the evolving healthcare landscape of Saudi Arabia.

A. Intuitionistic Fuzzy ANP

Intuitionistic fuzzy ANP is an extension of ANP that seamlessly incorporates intuitionistic fuzzy set theory into its framework [5-7]. In intuitionistic fuzzy ANP, intuitionistic fuzzy scales are a key part of showing how different parts of different criteria compare in terms of how intense they are. Consequently, this approach enables the creation of an intuitionistic fuzzy decision matrix, with intuitionistic fuzzy quantities representing the ultimate scores assigned to the alternatives [8-10]. By applying specific algebraic operators to these intuitionistic fuzzy integers, the optimal solution is derived, effectively encapsulating the entirety of weight vectors and the judgment matrix.

To gauge the relative importance of one criterion compared to another, intuitionistic fuzzy ANP employs intuitionistic fuzzy numbers in the formulation of an intuitionistic fuzzy judgment matrix for each measure [12-13]. These evaluation vectors, in tandem with the intuitionistic fuzzy pairwise comparison matrix, facilitate the allocation of relative significance to each criterion. The representation of linguistic expressions as intuitionistic fuzzy integers is elucidated in Table I, while Table II delineates the computation of the consistency ratio (CR) through the utilization of the random index (RI). Furthermore, the intuitionistic fuzzy membership function for linguistic terms in both criteria and sub-criteria is visually depicted in Fig. 2.

It is crucial to acknowledge that the final weightings result from a meticulous process of organizing, modifying, and reviewing linguistic term assignments, frequently with the help of expert consensus. By using intuitionistic fuzzy ANP in the context of Saudi Arabia, this method is likely to improve the evaluation of a reliable knowledge-based intuitionistic fuzzy

expert system for medical data visualizations that fits the unique needs of the Saudi healthcare system.

TABLE I. SCALE

Numeric Value	Verbal Value	Intuitionistic based Triangular Fuzzy Number (TFN)
1	Equally significant	1, 1, 3
3	Less significant	1, 3, 5
5	Very significant	3, 5, 7
7	Incredibly Essential	5, 7, 9
9	Extremely Essential	7, 9, 11

TABLE II. SCALE OF RANDOM INDEX

Size (n)	1	2	3	4	5	6	7	8
RI	0	0	0.52	0.89	1.11	1.25	1.35	1.40

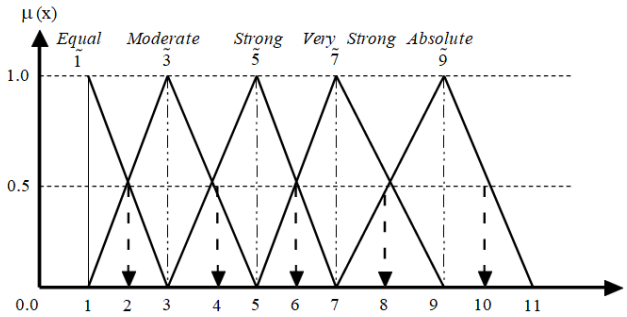

Fig. 2. Function of fuzzy membership.

B. Intuitionistic Fuzzy TOPSIS

Applying intuitionistic fuzzy ANP and intuitionistic fuzzy TOPSIS entails the following three procedures: One must first discover what elements are having an impact on the DM procedure, then perform the calculations for the intuitionistic fuzzy ANP, and finally utilize the intuitionistic fuzzy TOPSIS and Table III to rank the options.

In Saudi Arabia, using intuitionistic fuzzy ANP and intuitionistic fuzzy TOPSIS requires a structured approach that includes three integral procedures. These procedures are delineated as follows: initially, the identification of influential factors affecting the DM process; subsequently, the execution of calculations employing intuitionistic fuzzy ANP; and ultimately, the utilization of intuitionistic fuzzy TOPSIS, along with the insights presented in Table III, to ascertain the ranking of available options.

TABLE III. RATING SCALE

Verbal Values	Equivalent TFNs
Very Poor (VP)	1, 1, 3
Poor (P)	1, 3, 5
Medium (M)	3, 5, 7
Good (G)	5, 7, 9
Very Good (VG)	7, 9, 11

In the initial phase, the identification of potential attributes for the foundational system is conducted. Criteria that hold significance in impacting the DM process are identified, and a hierarchical structure is established to facilitate informed DM. This pivotal phase culminates with the approval of the DM chain of command by the team of decision-makers. An inherent strength of the proposed methodology lies in its adeptness at addressing ambiguity, particularly in terms of criteria and resources. Several key strategies are employed within this method to mitigate or eliminate uncertainty:

Alignment of variables across different facets of the model to gauge the problem-solving capabilities of field experts effectively.

Replacement of numerical data with descriptive terminology through the application of distinct intuitionistic fuzzy membership functions, which are aptly suited for resolving the discussed issues.

Consideration of multiple weighted sources relevant to the subject matter, thereby enhancing the reliability of medical data.

Employing a two-module structure that accommodates varying levels of granularity and uncertainty inherent in medical data sources, encompassing precise qualitative and intangible quantitative medical data, as well as tangible quantitative medical data and data derived from field surveys.

The intuitionistic fuzzy TOPSIS technique demonstrates remarkable efficacy in addressing real-world application challenges within an intuitionistic fuzzy environment. Rooted in traditional multi-attribute-based DM systems, TOPSIS [17] operates on the principle that the alternative selected should be the one farthest from both the positive ideal solution (PIS) and negative ideal solution (NIS). Additionally, TOPSIS features a flexible and user-friendly calculation methodology, enabling the concurrent consideration of multiple criteria with differing units [17]. The procedural steps of the intuitionistic fuzzy ANP-TOPSIS assessment are elaborated below.

Step 1: Determine the relative importance of each criterion for evaluation. In this study, the intuitionistic fuzzy ANP is used to determine preference weights.

Step 2: Build the intuitionistic fuzzy decision/performance matrix and use the criteria to select the right linguistic variables for the different options as shown in Eq. (1) and Eq. (2).

$$\widetilde{DA} = \begin{bmatrix} F_1 \\ F_2 \\ \vdots \\ F_m \end{bmatrix} \begin{bmatrix} f_{11} & f_{12} & \dots & \dots & f_{1n} \\ f_{21} & f_{22} & \dots & \dots & f_{2n} \\ \dots & \dots & \dots & \dots & \dots \\ \dots & \dots & \dots & \dots & \dots \\ f_{m1} & f_{m2} & & & f_{mn} \end{bmatrix} \quad (1)$$

i=1,2,3,….m and j=1,2,…n

$$x_{ij} = \frac{1}{K}(x_{ij}^{-1} \oplus \dots \oplus x_{ij}^{-k} \oplus \dots x_{ij}^{-K}) \quad (2)$$

Where x_{ij}^{-k} is performance rating of attribute $A_i$with respect to C_j evaluated by kth expert and $\tilde{x}_{ij}^{k} = (l_{ij}^{k}, m_{ij}^{k}, u_{ij}^{k})$.

Step 3: Next step is constructing the intuitionistic fuzzy decision matrix. The unprocessed medical data are then

normalized by employing a linear scale conversion in order to bring the scales of the different criteria into a comparable format. The intuitionistic fuzzy decision matrix for the attributes $(\widetilde{DA})$ is built as follows Eq. (3) to Eq. (5).

$$(\widetilde{DA}) = [\tilde{d}_{ij}]_{m\times n} \quad (3)$$

Where i=1,2,3,….m and j=1,2,…n

$$\tilde{d}_{ij} = \left(\frac{x_{ij}}{z_j^*}, \frac{y_{ij}}{z_j^*}, \frac{z_{ij}}{z_j^*}\right) \text{ and } z_j^* = \max_i z_{ij} \quad (4)$$

$$\tilde{d}_{ij} = \left(\frac{x_j^-}{z_{ij}}, \frac{x_j^-}{y_{ij}}, \frac{x_j^-}{x_{ij}}\right) \text{ and } z_j^* = \max_i z_{ij} \quad (5)$$

Step 4: Build the weighted and normalized matrix.

Multiplying the weights (wj) of calculating criteria by the normalized intuitionistic fuzzy decision matrix is how one arrives at the weighted normalized matrix (wj) for criteria.$\tilde{d}_{ij}$ see Eq. (6).

$$\tilde{V} = [v_{ij}]_{m\times n} \quad \text{i=1,2,….n ; j=1,2,3……m where } v_{ij} = \tilde{d}_{ij}(\cdot)W_j \quad (6)$$

Note that $\tilde{v}_{ij}$ is a TFN represented by $(\tilde{x}_{ijk}, \tilde{y}_{ijk}, \tilde{z}_{ijk})$

Step 5: Following is the calculation that is used to determine the intuitionistic fuzzy PIS and intuitionistic fuzzy NIS of the attributes as shown in Eq. (7) and Eq. (8):

$$F^* = (\tilde{v}_1^*, \tilde{v}_2^* \dots \dots . \tilde{v}_n^*) \text{ where } \tilde{v}_j^* = (\tilde{z}_j^*, \tilde{z}_j^*, \tilde{z}_j^*) \ \tilde{z}_j^* = \max_i\{\tilde{z}_{ij}\} \quad (7)$$

$$F^- = (\tilde{v}_1^-, \tilde{v}_2^- \dots \dots . \tilde{v}_n^-) \text{ where } \tilde{v}_j^- = (\tilde{x}_j^-, \tilde{x}_j^-, \tilde{x}_j^-) \ \tilde{x}_j^- = \min_i\{\tilde{x}_{ij}\} \quad (8)$$

i=1,2,3…..m; j=1,2,….n

Step 6: The subsequent step is to determine the distance between individual attributes.

The distance (d_i^+, d_i^-) of individual weighted alternative i=1,2,3……m from the intuitionistic fuzzy PIS and intuitionistic fuzzy NIS is computed as per the following in Eq. (9) to Eq. (11):

$$d_i^+ = \sum_{j=1}^n dv(\tilde{v}_{ij}, \tilde{v}_j^+) \quad i = 1, \dots \dots, m \quad (9)$$

$$d_i^- = \sum_{j=1}^n dv(\tilde{v}_{ij}, \tilde{v}_j^-) \quad i = 1, \dots \dots, m \quad (10)$$

$$d(\tilde{A}, \tilde{B}) = \sqrt{\frac{1}{3}((x_A - x_B)^2 + (y_A - y_B)^2 + (z_A - z_B)^2)} \quad (11)$$

Step 7: This step is computation of the closeness coefficient $ClCo_i$ of individual alternative

The closeness coefficient $ClCo_i$ symbolizes the distances to the intuitionistic fuzzy PIS (d^+) and the intuitionistic fuzzy NIS (d^-) concurrently. The closeness coefficient of separate attribute is measured as in Eq. (12):

$$ClCo_i = \frac{d_i^-}{(d_i^+ + d_i^-)} \quad (12)$$

Step 8: Next step is to rank the attributes

In step 8, the values of the maximum closeness coefficient are used to rank or choose the different attributes in decreasing order.

IV. Results

The author evaluates hybrid DM methods for combating digital banking fraud in Saudi Arabia in this part. The author implements intuitionistic fuzzy ANP and shows how it solves selection through hybrid multi-criteria decision-making. The author created and constructed a network of digital fraud prevention model variables and conducted a case study using Saudi-based digital banking applications to evaluate the intuitionistic fuzzy-ANP technique. In addition, the ANP method establishes characteristic weights in phases. 147 Saudi decision-makers and experts evaluated the qualities and options. Three important features, four level 1 characteristics, and eleven level 2 characteristics are compiled from the literature review. After reviewing Saudi Arabian literature and industry standards, the author chose decision network of Fig. 1.

Planning, training, and implementation of fraud prevention are the primary evaluation characteristics. Saudi Arabia's organizational management fraud prevention plan includes fraud risk assessment, perceptions of fraud detection, and fraud prevention policies. Management sub-characteristics include attitude, integrity, and policy implementation. Sub-characteristics of fraud risk assessment include risk assessment teams, methodologies, and compliance monitoring. Customer service and reporting models are fraud detection sub-characteristics. A complete fraud prevention strategy should include planning, training, and implementation. Saudi Arabia uses a matrix to weigh each criterion and alternative.

Consequently, the primary objective of this study is to conduct a case study involving five alternatives (digital fraud prevention models), exploring the attributes that determine their suitability for selecting trustworthy fraud prevention models for the digital banking sector. The chosen approach encompasses a comprehensive set of potential identifiers, each accompanied by rating evaluations. This approach was determined before the commencement of the investigation. The selection of these five digital fraud prevention models as alternatives for comparative trustworthiness evaluation was based on consensus among domain owners and subject matter experts, ensuring a robust evaluation process. To enhance the productivity and reliability of this study, we have conducted an ANP-TOPSIS analysis within an intuitionistic fuzzy framework. This evaluation is centred on assessing the ideality of a hybrid medical expert system for selecting a trustworthy fraud prevention model for the digital banking sector, following the equations detailed in the methodology section, ranging from Eq. (1) to Eq. (12).

After converting linguistic expressions into numerical values Steps 1 to 4 and Eq. (1) to Eq. (6) these values were refined within the intuitionistic fuzzy framework (see Step 5) into clear numerical values. Subsequently, numerical computations were performed to construct a pairwise comparison matrix, with the results summarized in Table IV, as detailed below. The algorithm progressed by introducing intuitionistic fuzzy integer values and then transitioning into crisp numerical values within an intuitionistic fuzzy framework

to present the final results in Table IV. Following that, numerical calculations were executed to generate a pairwise comparison matrix, and the summarized results, which are displayed in Table IV and presented below, are elaborated in the subsequent paragraph.

The method was changed to include intuitionistic fuzzy wrappers as in Eq. (1) to Eq. (5), triangular number estimation, and the degree of possibility in order to get the final results shown in Table V. Ultimately, the experts established the pairwise comparison matrix using Eq. (7) to Eq. (8). Table V showcases the defuzzified values of the group's characteristics, computed using Eq. (9), and the Table V and Fig. 3 were constructed accordingly. Table VI displays the normalized weights of the group's characteristics after calculating local priority vectors, weighted super matrix, and super matrix formation. The comprehensive findings of this investigation are concisely summarized below for reference. After that, numerical calculations were done to figure out the absolute weight vector for row values and figure out which traits were the most important, as shown in Eq. (10) to Eq. (12). The intuitionistic fuzzy data from the judgment matrices were put together to make a pairwise contribution matrix. Table VII and Fig. 4 shows the results of the network as a whole.

TABLE IV. WEIGHTS OF THE CHARACTERISTICS AND THE SUB CHARACTERISTICS

	Characteristics Weight	Sub Characteristics at Level 2	Characteristics Weight	Sub Characteristics at Level 3	Characteristics Weight	Final Weight (CW*SCW3)

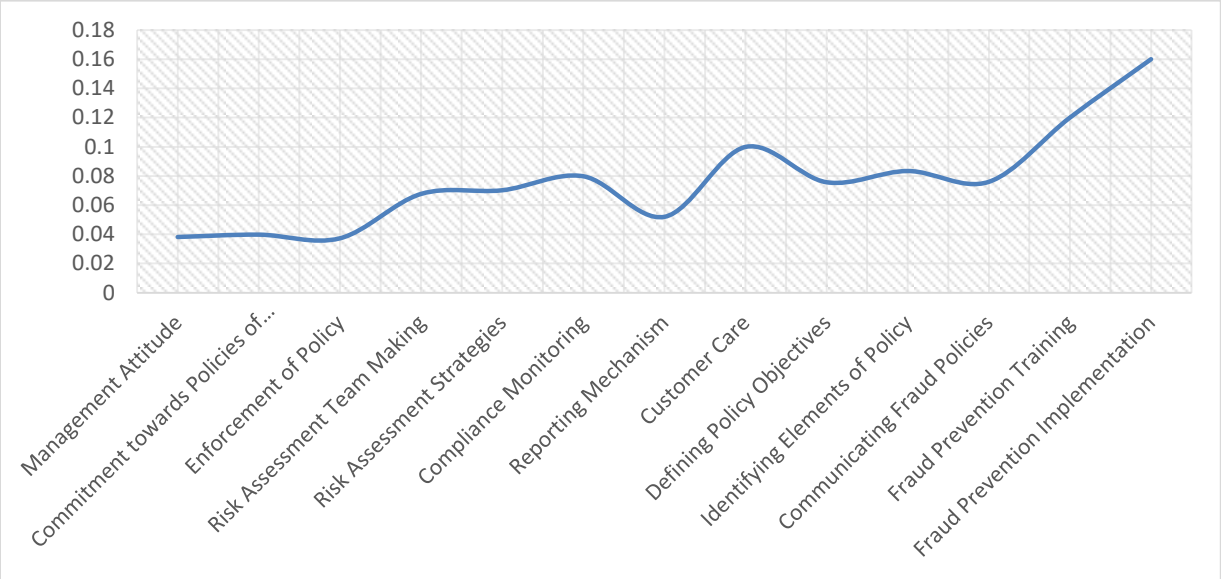

Fig. 3. Graphical representation of characteristics.

Subsequently, the following section of this study will provide a practical assessment of the findings, focusing on the evaluation of a trustworthy fraud prevention model for the digital banking sector. To accomplish this, an ANP approach was applied under conditions of fuzziness to derive the composite weights of features. Subsequently, the intuitionistic fuzzy TOPSIS method was employed to determine the overall ranking of competing alternatives, utilizing the feature weights obtained earlier. It is important to note that these evaluations are particularly relevant in the context of Saudi Arabia.

After completing several intermediary steps, we obtained the normalized intuitionistic fuzzy decision matrix for five fraud prevention models: Riskified [1], Nudata Security [2], GBG Services [18], Feedzai [19], and Featurespace [20]. The results of our analysis are encapsulated within this matrix. To calculate the normalized performance values of the intuitionistic fuzzy decision matrix, we utilized Eq. (8) to Eq. (9). Table VI presents the definitive findings, computed by applying Eq. (10) to Eq. (11) to establish the positive and negative idealness of each alternative concerning each characteristic. These equations were combined to ascertain the ideality of each alternative. The presentation of these results follows the chronological order in which they were obtained.

Furthermore, Eq. (12) were employed to calculate the relative closeness score for each choice, which was then used to determine the degree of satisfaction [21]. The results of this computation can also be found in Table VII and Fig. 4. This additional calculation serves as a valuable post-analysis assessment to provide a comprehensive view of the findings. These evaluations are essential for informed DM in the Saudi Arabian context.

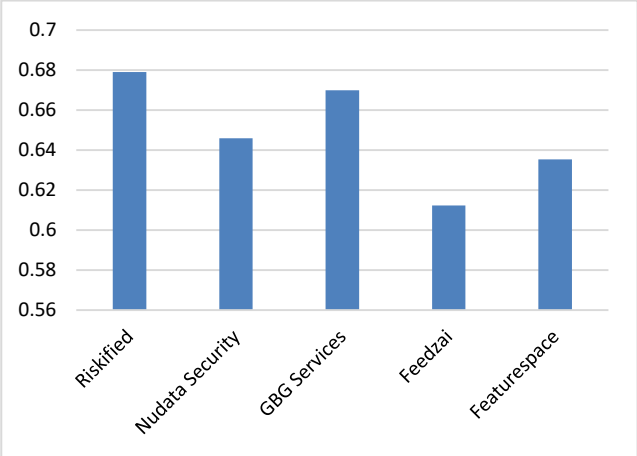

Fig. 4. Impact of alternatives.

The investigation was conducted on five distinct alternatives within the digital banking applications, revealing that categorization is a preferable and successful approach to addressing issues related to fraud prevention in the context of Saudi Arabia. The evaluation was based on the selected characteristics chosen to serve as the foundation for assessment in the Saudi Arabian digital banking landscape.

The relative weights assigned to each of the numerous factors used for selection have a significant impact on the presentation order of various choices. Careful adjustments to the proportional weights of the selection characteristics are essential in the Saudi context to avoid potential ranking changes as a direct consequence of these adjustments. The authors followed a sensitivity analysis approach outlined in [5] to assess the level of confidence in the findings, allowing them to validate their results within the Saudi digital banking environment. By progressively adding a 5% penalty to the weights of each selection criterion one by one, the authors evaluated the sensitivity of the final outcomes to performance variations in Saudi Arabia. These steps enable an exploration of the sensitivity of the results, specifically in the Saudi context. The conclusions derived from the sensitivity analysis are graphically represented in Table VIII and Fig. 5, included for the sake of clarity and convenience for Saudi stakeholders. The results unequivocally demonstrate the ongoing consistency of their practices within the Saudi digital banking sector.

V. Conclusion

This study sheds light on the profound impact of financial theft on Saudi Arabia's economy and culture, underscoring the considerable financial strain it places on individuals. The complex business landscape in the Kingdom of Saudi Arabia (KSA) poses challenges for traditional methods of digital banking fraud detection. Our research set out with several objectives, with a primary emphasis on developing robust DM models within the Saudi financial sector, specifically geared toward effective fraud detection and prevention. Through the application of a novel intuitionistic fuzzy-based DM approach, we aimed to create models capable of assessing fraud detection and prevention in Saudi digital banking systems. The outcomes presented in this paper highlight the efficacy of our proposed approach in detecting and preventing fraud in Saudi Arabian digital banking applications, surpassing the performance of both fuzzy ANP and conventional ANP models. As a final recommendation, we advocate for the implementation of an artificial intelligence (AI) DM program to mitigate fraud in Saudi Arabia. Given the hybrid nature of DM processes in Saudi Arabia, such an algorithm holds promise for significantly enhancing effectiveness and application, ultimately playing a vital role in fortifying fraud protection within the dynamic landscape of KSA's digital banking ecosystem.

Arabic Regional Dialect Identification (ARDI) using Pair of Continuous Bag-of-Words and Data Augmentation

Ahmed H. AbuElAtta, Mahmoud Sobhy*, Ahmed A. El-Sawy, Hamada Nayel
Department of Computer Science-Faculty of Computers and Artificial Intelligence,
Benha University, Egypt

***Abstract*—Author profiling is the process of finding characteristics that make up an author's profile. This paper presents a machine learning-based author profiling model for Arabic users, considering the author's regional dialect as a crucial characteristic. Various classification algorithms have been implemented: decision tree, KNN, multilayer perceptron, random forest, and support vector machines. A pair of Continuous Bag-of-Word (CBOW) models has been used for word representation. A well-known data set has been used to evaluate the proposed model and a data augmentation process has been implemented to improve the quality of training data. Support vector machines achieved a 50.52% f1-score, outperforming other models.**

***Keywords*—Dialect identification; continuous Bag-of-Words; data augmentation; text classification.**

I. Introduction

The Arabic language presents a captivating and challenging duality. Its source stems from its historical significance, the strategic importance of its native speakers and their region, along with its abundant cultural and literary legacy. Simultaneously, its complex linguistic framework poses difficulties [1]. More than 330 million people speak Arabic as their native tongue, and as a Semitic language, it has several distinctive linguistic features such as right-to-left writing, and the presence of a dual number of nouns. One of the most prominent features observed in Semitic languages, including Arabic, is the utilization of both female and male genders alongside the root. This aspect stands out significantly and distinguishes these languages [1].

The various Arabic dialects that exist today are together referred to as the Arabic language. There is one "written" form that is used to write Modern Standard Arabic (MSA), while numerous "spoken" variants based on the regional dialect have been used. Due to its use in official settings and written communication, the sole variant undergoes standardization, regulation, and formal instruction in educational institutions. When compared to MSA, regional dialects, which are mostly employed for spoken communication and daily interactions, are still slightly absent from written communication. The same letters used in MSA and the same (mainly phonetic) spelling conventions of MSA can, however, be utilized to create Dialectal Arabic (DA) text [2].

The possible data source is of importance to two key sectors, the commercial sector where marketing intelligence places a larger value on client information including age, gender, nationality, and native language, and the security industry is responsible for guarding against crimes like plagiarism and identity theft, among others, on the internet. As a result, the research community encourages scientists to find and create efficient procedures and methodologies in related disciplines like plagiarism detection and author profiling [3].

The use of DA is prevalent on social media platforms. Computational linguists could generate vast datasets that could be employed in statistical learning environments by gathering information from such sources. It is a challenge to differentiate and separate the dialects from one another; as all Arabic dialects share the same character set and a large portion of their vocabulary. There are six main Arabic regional dialects in addition to MSA, which is typically not commonly spoken as a primary language. Fig. 1 shows the regional dialects of Arabic world.

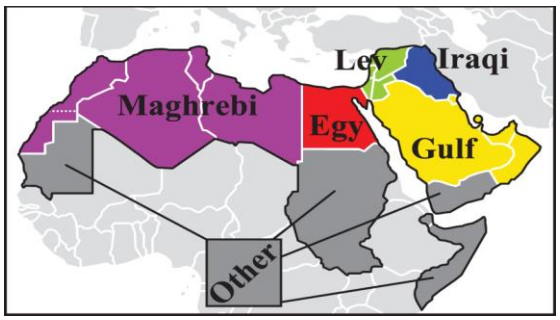

Fig. 1. Regional dialects of Arabic world [2].

- Egyptian: The dialect that is most generally known and understood, due to Egypt's strong film and television industries. As well as it's significant influence through-out a significant portion of the 20th century [4].
- Levantine: A group of dialects linked to Aramaic that sound somewhat different and have different intonations but are substantially comparable when written [5].
- Gulf: The regional dialect that is most like MSA as the current version of MSA is developed from an Arabic dialect that originated in the Gulf region. Compared to other variants, the Gulf dialect has retained a greater portion of MSA's verb conjugation, despite the variances [6].

- Iraqi: Although it has distinctive qualities of its own in terms of prepositions, verb conjugation, and sound, it is occasionally regarded as one of the Gulf dialects [6].
- Maghrebi: French and Berber had a big influence on this dialect. In spoken form, the western-most dialects may be incomprehensible to speakers from other Middle Eastern countries [7].

Due to the complexity of the Arabic language's morphology, the dearth of datasets, and most of the available datasets are imbalanced. Arabic research obtained little attention in its primary phases, especially regarding dialect identification. There are many challenges caused by the high similarity of dialects, particularly in short phrases, such as:

- The same word might have similar meanings in different dialects, for example, the word "**كتاب**" (pronounced "Ketab") means book.
- For the same dialect, there are different short phrases with the same meanings. For example, in Egyptian dialect, the words "**طيب**" (pronounced "Tayb"), "**حاضر**" (pronounced "Hader"), "**عنيا**" (pronounced "Enya"), "**انت تؤمر**" (pronounced "Enta To'mor"), "**إشطه**" (pronounced "Eshta") means "ok".

Effective dialect identification improves the performance of different applications and services, such as machine translation, Automatic Speech Recognition (ASR), remote access, e-commerce, e-learning, and exposing forensic evidence. Arabic dialect identification has been performed at the regional-level (e.g., Levant, Gulf) [8], country-level (e.g., Egypt, Saudia Arabia) [9], and province-level (e.g., Cairo, Al-Madinah) [10]. This work concentrates on the challenge of Arabic Regional Dialect Identification (ARDI) for social media users. We propose machine learning-based classification models to perform ARDI for Arabic tweets. A word embedding model has been used for word representations and a data augmentation process has been applied to improve the quality of data. In the classification step, Decision Tree (DT), K-Nearest Neighbor (KNN), Multi-Layer Perceptron (MLP), Random Forest (RF), and Support Vector Machines (SVM) algorithms were used.

The remaining portions of the paper are structured as follows: Related work is introduced in Section II. Section III describes the dataset that has been used for model development. Section IV introduces the general architecture of the proposed model. The results obtained by the proposed model presented in Section V. The detailed explanation of the results is represented in Section VI, while Section VII concludes the paper.

II. Related Work

There are major efforts that have been carried out for ARDI; some of these works will be described in this section. The First Nuanced Arabic Dialect Identification Shared Task (NADI 2020) has been presented in [11]. This shared task includes the identification of Arabic countries as subtask-1, and the identification of Arabic provinces as subtask-2. The dataset for NADI 2020 covers 21 Arab countries including 100 provinces obtained from Twitter. The baseline, Google's mBERT, model was fine-tuned with 50 tokens as a sequence's maximum length and 8 batches. Various approaches have been applied for NADI such as Machine Learning (ML) approaches and Deep Learning (DL) approaches, and the best performed model achieved a 26.78% f1-score for the first subtask and 6.39% for the second subtask. NADI 2021 was the second shared task that aimed at identifying the linguistic diversity of brief texts based on small geographical regions of origin in Arabic dialects [10]. In NADI 2021, an unlabeled corpus for 10M tweets has been added for optional use. The same baseline model for NADI 2020 was fine-tuned in addition to the ML and DL approaches. The best winner model reported 22.38%, 32.26%, 6.43%, and 8.60% f1-score for country-level-MSA, province-level-MSA, country-level-Dialectal Arabic, and province-level-Dialectal Arabic, respectively. Another NADI shared task in 2022 [9] aimed at the identification of Arabic country-level dialects. Three baselines were finetuned in NADI 2022, Baseline-mBERT, Baseline-XLMR, and Baseline-MARBERT in addition to some pre-trained models based on the BERT model. The top systems reported 36.48% and 18.95% f1-score for Test-A and Test-B sets respectively.

Antoun et al. [12], introduced the AraBERT model which trained on a large Arabic corpus and achieved state-of-the-art on various Arabic NLP tasks, including sentiment analysis, named entity recognition, and question answering. The BERT-base configuration was 12 encoder blocks, 768 hidden dimensions, 12 attention heads, 512 maximum sequence length, and a total of 110M parameters. The model outperforms the multilingual version of BERT and other previous approaches. Another transformer-based model designed for Arabic language understanding was introduced by Abdul-Mageed et al. [8]. They introduced ARBERT and MARBERT, bidirectional transformers for Arabic language processing, focusing on MSA and Arabic Dialects respectively. A random 1B Arabic tweets were selected to train MARBERT, and a dataset of about 6B tweets was formed. Tweets greater than two Arabic words were only included. MARBERT was trained for 36 epochs with 256 batch size and 128 sequence length and achieved high scores in various Arabic dialects datasets.

Talafha et al. [13] used BERT architecture for NADI and achieved a 26.78% f1-score. Also, Gaanoun and Benelallam [14] presented an Arabic-BERT model combined with ensemble methods and data augmentation for NADI. The Arabic-BERT model was trained on the provided training data; then data augmentation was performed by splitting the training data into three parts and mixing them for each country. The augmented data was used to train multiple models, including the "Mix" model, which showed good performance and obtained an f1-score of 23.26% and 5.75% for country-level and province-level respectively. A combination of BERT and N-GRAM characteristics was presented in [3]. The authors investigated the task for the identification of dialects at the national and provincial levels. They introduced an ensemble model that achieved promising results. M-NGRAM uses TF-IDF with character and word n-grams and a Stochastic Gradient Descent (SGD) classifier. The ensemble method achieved a f1-score of 25.99% and 6.39% for country-level identification and province-level identification, respectively.

The contributions of this paper include: (1) develop five classification models based on a pair of Continuous Bag-of-Words model (CBOW) for ARDI, (2) build a new corpus from various datasets to use for building our CBOW model, (3) apply the data augmentation process to enhance the quality of training data.

III. DATA

The dataset that has been used in this research is ArSarcasm [8]. Which is a collection of Arabic sentiment analysis datasets called SemEval 2017 [15] and ASTD [16]. The dataset contains 10,547 tweets modified by adding dialect labels. The distribution of the train set, and test set over all classes is shown in Table I.

TABLE I. DISTRIBUTION OF TRAINING SET AND TEST SET IN EACH CLASS OF ARSARCASM DATASET

Arabic Region	Number of documents in train set	Number of documents in test set
msa	5652	1410
egypt	1904	479
levant	439	112
gulf	414	105
maghreb	28	4
Total	8,437	2,110

The dataset contains the following fields:

- tweet: the text of the original tweets.
- sarcasm: a Boolean value indicating whether a tweet is sarcastic.
- sentiment: the new annotation's sentiment (good, neutral, or negative).
- source: the original tweet's SemEval or ASTD source.
- dialect: the Arabic regional dialect used in tweets, msa, egypt, levant, gulf, and maghreb, which were shown in Section I.

IV. METHODOLOGY

The proposed model uses classic ML-based classifiers integrated with a data augmentation approach for word representation. As shown in Fig. 2, the proposed system is divided into five primary phases, including data augmentation, text preprocessing, feature extraction, classification, and evaluation.

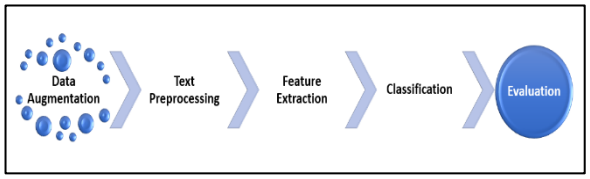

Fig. 2. General architecture of the proposed system.

In the data augmentation phase, the training data was augmented with extra Arabic text from itself and other datasets. Some text cleaning steps and adjustments were applied in the text preprocessing phase. In the feature extraction phase, all documents have been represented based on the embeddings of words in each document. In the classification phase, we classify each vector in the feature vectors to its correct class. Finally, the proposed model has been evaluated by measuring its performance in the evaluation phase. All steps are explained in the following sections.

A. Data Augmentation

- Data augmentation basically allows one to artificially increase the training set by making updated copies of training samples using existing data [17]. It involves modifying the dataset slightly or creating new data points using deep learning approaches. Data augmentation is used for several purposes; (1) to prevent overfitting; (2) when the initial training set is insufficient; (3) to increase the accuracy of models; and (4) to handle the unbalanced dataset. As shown in Table I, the training data is unbalanced as “msa” and “egypt” classes were much bigger than the other classes, as well as the portion of class “maghreb” is too small. In this work, several text augmentation approaches have been used, like:
- Rearranging words or sentences in a random manner.
- Substituting words with their synonyms.
- Rephrasing sentences using the same meanings.
- Insertion or deletion of words at random.

Furthermore, to increase the quality of the dataset, the original training data has been augmented with other datasets in the same domain. In this step, we selected some datasets which have the same Arabic dialect texts as our dataset. Especially, we selected records of data with the same regions in our dataset. The first external dataset is NADI 2022 [9] which focused on nuanced Arabic dialect identification at country-level for Arabic tweets and covers 18 dialects (a total of approximately 20K tweets). The second external dataset is NADI 2021 [10], which covers MSA and DA. The dataset contains a training set of 21,000 tweets, a development set of 5,000 tweets, and a test set of 5,000 tweets. Habibi is the third external dataset [18] which is the earliest Arabic song lyrics corpus. More than 30,000 Arabic song lyrics by vocalists from 18 different Arabic countries are included in the corpus, which includes songs in six Arabic dialects.

TABLE II. DISTRIBUTION OF TRAINING SET FOR EACH CLASS BEFORE AND AFTER THE AUGMENTATION PROCESS.

Class (Arabic region)	Number of documents before augmentation	Number of documents after augmentation
msa	5652	5652
egypt	1904	6187
levant	439	4227
gulf	414	4484
maghreb	28	3554
Total	8,437	24.104

More than 500,000 sentences (song verses) and more than 3.5 million words make up the lyrics [18]. The benefit of this corpus is that all words are written in DA not in MSA. After the data augmentation step was done, the dataset became balanced somewhat and the next step was data preprocessing. Table II shows the distribution of training data in each class before and after the augmentation process.

B. Text Preprocessing

To get the data ready for training, light preprocessing has been used which preserves a true representation of the text that naturally appears. Emojis, Latin letters, URLs, mentions, numerals, and non-Arabic characters were all excluded from the data because Arabic texts, particularly those found on social media, are unstructured and exceedingly loud. In addition, the following steps have been implemented.

- Convert the various forms of Arabic characters into their unique forms, such as "ة " (pronounced as Haa) and " ه " to be " ه".
- Deleting extraneous Arabic forms, such as," ال " (pronounced "al") and it operates as a determiner.
- Deleting punctuation marks such as {'?'; '.'; '!'; '$'} which make more unnecessary features that can expand the dimension of the feature space.
- Reducing the letter repetition since Arabic tweets tend to be less structured. Clearing the letters from the extraneous tokens helps in reducing feature space. In this work, we considered the letter, which is repeated more than twice as redundant. For example, the word "كاااامل" "(pronounced as "Kamel") which means "complete" will be decreased to "كامل", also the word "رهيييب"(pronounced as "Rahib") which means "awesome") will be reduced to "رهيب ".

C. Feature Extraction

In this phase, all tweets are represented as feature vectors, each of which contains an embedding for each word in the tweet. A variety of approaches are employed to get the word embedding vector from the context in which the words are found. In this study, a pair of Word2vec models has been used. Google has suggested the Word2vec neural network [19] to analyze text input. The Word2vec model is a neural network with three layers: an input layer, an output layer, and a hidden layer without activation function. Additionally, the number of neurons in the hidden layer is the same size as the word embeddings' vector's dimensions. The Word2Vec model makes use of huge datasets during training to precisely capture the semantic and syntactic structure of the words, allowing for the efficient measurement of word similarity [19].

Continuous Bag of Words (CBOW) and Skip-gram are the two learning models included in Word2Vec: CBOW predicts the word given its context, while Skip-gram predicts the context given a word as shown in Fig. 3. The window size and vocabulary size are two hyperparameters that are shared by the two methods. The window size indicates the number of words in the context. Given the near future and historical words, the CBOW technique classifies the projected middle word using a log-linear classifier.

The number of words in the context is equal to the size of the sliding window; for example, if the sliding window is seven words, then there are six words in the context. Additionally, while predicting a word, the context of the preceding three words and the succeeding three words of the middle word must be considered.

The first Word2Vec model that has been used was built using UNLABELED-10M, a set of 10 million unlabeled Arabic tweets provided by NADI [9] in the form of tweet IDs. A ready implementation of Word2Vec model, gensim [20], using CBOW has been used to generate word vectors of size 300.

Nevertheless, the embedding vectors for words in the first model were not enough to cover all the words in the dataset. So, we created another Word2Vec model. We employed CBOW to generate the word vectors as it has higher computing speed, and it is more efficient with frequent words than Skip-gram [21]. The vocabulary has been built from the entire training data and some external aforementioned datasets, NADI 2021 shared task dataset [10], and Habibi corpus [18]. Previously, if the embedding vector did not exist in the corpus, the vector was set randomly. Now, it is obtained from the second corpus, and this increases the correctness of the vector. Following the training phase, a vector is used to represent each word.

Next, we construct the high dimension matrix. Rows in the matrix represent the training tweets and columns represent words. The classification phase, which is described in the following section, follows the creation of the feature vector matrix for all training instances.

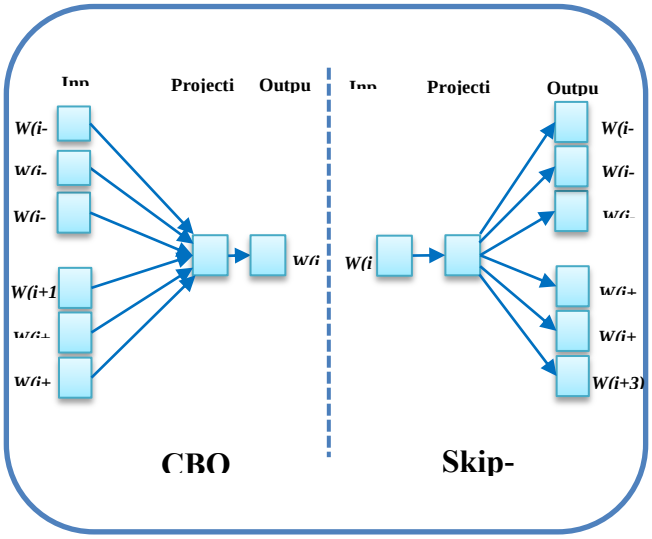

Fig. 3. The architecture of CBOW model.

D. Classification

Five classification algorithms, DT, KNN, MLP, RF, and SVM, were used in this study. To improve the performance of these classifiers, their hyperparameters were utilized.

The SVM is a linear classifier that uses training samples close to the borders of classes [22]. The SVM model uses kernel functions for classifying non-linear data such as linear,

sigmoid, and Radial Basis Function (RBF) kernels, which were used in this work. The KNN algorithm assumes that the new sample and the available samples are similar, and it places the new sample in the category that resembles the available categories [23]. The DT classifier [24] utilizes the decision tree as a model for making pre-dictions based on observations about the items that are represented in the tree's branches to inferences about the target value of items that are represented in the decision tree's leaves.

The RF is an average-based meta-estimator that is used to increase predictive accuracy and reduce overfitting by applying several decision tree classifiers to various dataset sub-samples [25]. The MLP is a completely connected class of feedforward Artificial Neural Network (ANN) [26]. A typical MLP has an input layer, a hidden layer, and an output layer, which make up together less than or equal to three layers of nodes. Every node uses a nonlinear activation function, apart from the input nodes.

E. Evaluation

All algorithms mentioned in the paper that were evaluated on the ArSarcasm dataset. The evaluation metrics that have been used are Accuracy (Acc), Precision (P), Recall (R), and f1-score [27]. Accuracy measures the number of truly classified tweets divided by all tweets. Precision is another metric that calculates the number of correctly classified tweets divided by all classified tweets. Another metric is Recall, which calculates the number of correct correctly classified tweets divided by all correct tweets. The macro-averaged f1-score is the official metric for most NLP tasks as it is the most basic aggregation for the f1-score. The macro-averaged f1-score is the unweighted mean of the f1-scores determined for each class. The formula for macro f1-score [27] is:

$$f1\text{-}score = 2 * \frac{R*P}{R+P} \quad (1)$$

V. Experimental Results and Discussion

To evaluate the proposed model, several experiments have been carried out using different parameters as shown in Table III.

TABLE III. Parameters of Some Proposed Models.

Algorithm	Parameters
SVM	Kernel functions = {linear, sigmoid, RBF}
KNN	Number of neighbors (*n*) = {30, 40, 50}
MLP	Number of hidden layers (*h*) = {5, 10, 20}

The proposed models have been tested using two variations of word embedding models. The results of the proposed models with the first embedding (UNLABELED-10M) without augmentation and with augmentation are shown in Table IV and Table V respectively. The results of the proposed models with the second embedding model (CBOW) without augmentation and with augmentation are shown in Table VI and Table VII respectively.

As shown in Table I above, the test data were unbalanced; the number of documents with the label (msa) is 1410, whereas it was only 4 with the label (maghreb). This was a big challenge to classify at least two documents with the label (maghreb) correctly. Fig. 4 shows the confusion matrix plot for the SVM (RBF) classifier, which has the best results.

It is clear that, the SVM (RBF-kernel) with the augmentation of data and the pair of Word2Vec models outperformed all other classifiers. Table IV shows the results of using the CBOW model, UNLABELED-10M, without data augmentation. The SVM classifier with RBF kernel function has achieved the highest accuracy, precision, and f1-score while MLP with five hidden layers has achieved the highest recall. Table V shows that the SVM classifier with RBF kernel function has achieved the highest accuracy, and F1-score, while MLP with five hidden layers has achieved the highest precision and the highest recall has achieved by MLP with 10 hidden layers.

TABLE IV. Performance of using UNLABELED-10M Model (without augmentation).

Algorithm	Parameter	P	R	f-score	Acc
SVM	linear kernel	46.683	39.737	41.902	77.014
	sigmoid kernel	39.296	35.618	36.684	70.900

KNN	n = 30	47.853	38.152	40.250	77.014
	n = 40	48.833	37.947	40.057	77.156
	n = 50	48.261	37.777	39.198	76.730
DT		32.024	32.815	32.365	64.739
RF		43.333	33.292	35.057	76.398
MLP	h = 5	44.125	45.456	42.512	74.041
	h = 10	47.568	**47.453**	44.542	73.652
	h = 20	48.225	47.342	**44.654**	72.850

TABLE V. Performance of using UNLABELED-10M Model (with Augmentation).

Algorithm	Parameter	P	R	f-score	Acc
SVM	linear kernel	48.195	45.783	43.214	75.877
	sigmoid kernel	39.896	42.723	40.115	69.384
	RBF kernel	**56.008**	46.530	**46.050**	**78.341**
KNN	n = 30	48.460	38.436	40.570	77.204
	n = 40	47.262	37.287	40.900	69.005
	n = 50	46.334	36.564	38.152	68.512
DT		35.701	36.096	35.849	67.915
RF		43.420	30.964	32.567	75.450
MLP	h = 5	49.105	46.466	43.758	75.071
	h = 10	48.940	**48.403**	45.655	74.739
	h = 20	47.334	47.042	44.259	73.791

In Table VI, the results of using two CBOW models, UNLABELED-10M, and our own CBOW model, without data augmentation. This table shows that the SVM classifier with RBF kernel function has achieved the highest accuracy and

recall while MLP with five hidden layers has achieved the highest f1-score and precision. Table VII shows the results of using the same pair of CBOW models in Table V after the data augmentation process was done. This table shows that the SVM classifier with RBF kernel function has achieved the highest performance for all metrics.

TABLE VI. PERFORMANCE OF USING PAIR CBOW MODELS (WITHOUT AUGMENTATION).

Algorithm	Parameter	P	R	f-score	Acc
SVM	linear kernel	49.159	44.001	45.777	77.488
	sigmoid kernel	38.310	35.141	36.059	70.900
	RBF kernel	**55.018**	41.684	44.556	**78.863**
KNN	n = 30	48.460	38.436	40.570	77.204

MLP	h = 5	47.185	50.548	46.610	75.640
	h = 10	49.018	52.481	47.272	75.924
	h = 20	46.714	54.902	46.545	74.313

TABLE VIII. F1-SCORE OF OUR BEST MODEL AND PREVIOUS MODELS.

Algorithm	F1-score
mBERT [8]	43.81
XLM-R_L [8]	41.83
AraBERT [8]	47.54
SVM-RBF-With-Augmentation	**50.53**

Table VIII compares the performance of the proposed model and state-of-the-art in terms of f1-score. The results show that the proposed model outperformed the state-of-the-art models using low resources than those previous models which use huge resources to train language models using billions of words; as the proposed model depends on two embeddings and augmented data.

Fig. 4 shows the change in the values in the confusion matrix with the three attempts we made in the augmentation step. Let's focus on the true and predicted values of maghreb. In Fig. 4(a), without augmenting training data, the four test samples were misclassified. In Fig. 4(b), after the augmentation of the training samples of the maghreb class, 25% of the test samples were correctly classified. In Fig. 4(c), after the augmentation of all training samples, 50% of the test samples were correctly classified.

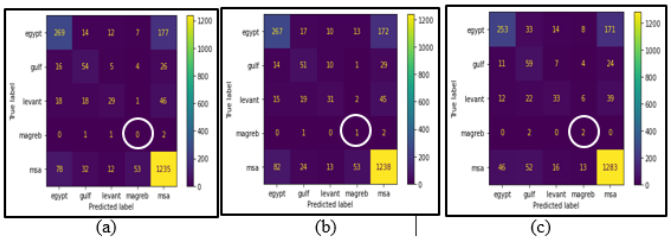

Fig. 4. Confusion matrix of classes after applying SVM with RBF kernel: (a) without augmentation; (b) with augmentation of magreb documents only; (c) with augmentation of documents of all classes.

I. CONCLUSION

Due to its complexity, ARDI becomes a challenge. This work proposed a machine learning-based model that implements DT, KNN, MLP, RF, and SVM for ARDI. A pair of CBOWs has been used for data representation and a data augmentation approach has been implemented to overcome the problem of imbalanced data. SVM reported 50.53% f1-score which was higher than previous work. The results proved that using a pair of CBOW models is better than using only one and proved that data augmentation was very useful for improving the quality of data. In future work, different representation models can be used to improve the performance of ARDI such as BERT models.

Advanced Metering Infrastructure Data Aggregation Scheme Based on Blockchain

Hongliang TIAN, Naiqian ZHENG, Yuzhi JIAN
School of Electrical Engineering, Northeast Electric Power University, Jilin 132012, China

***Abstract*—Smart grid stands as both the cornerstone of the modern energy system and the pivotal technology for addressing energy-related challenges. Advanced Metering Infrastructure constitute a critical component within the smart grid ecosystem, providing real-time energy consumption data to power utility companies. Advanced Metering Infrastructure enables these companies to make timely and accurate decisions. Hence, the issue of data security pertaining to Advanced Metering Infrastructure assumes profound significance. Presently, Advanced Metering Infrastructure data confronts challenges associated with centralized data storage, rendering it susceptible to potential cyberattacks. Moreover, with the burgeoning number of electricity consumers, the resultant data volumes have swelled considerably. Consequently, the transmission of this data becomes intricate and its efficiency is compromised. To address these issues, this paper presents a lightweight blockchain data aggregation scheme. By integrating fog computing and cloud computing, a three-tier blockchain-based architecture is devised. Initially, digital signatures are employed to ensure the validity and integrity of user data. The innate attributes of blockchain technology are harnessed to safeguard the security of electricity energy data. Through secondary data aggregation, the privacy-sensitive user data is efficiently compressed and subsequently integrated into the blockchain, thereby mitigating the storage pressure on the blockchain and enhancing data transmission efficiency. Ultimately, through rigorous theoretical analysis and simulated experimentation, the paper demonstrates that, in comparison to existing methodologies, lightweight blockchain data aggregation scheme exhibits heightened security. Additionally, lightweight blockchain data aggregation scheme holds a competitive advantage in terms of computational and communication costs.**

***Keywords*—Smart grid; blockchain; advanced metering infrastructure; data aggregation**

I. Introduction

Smart grid epitomizes the evolution and transformation of the power and energy industry, constituting a pivotal platform for the execution of new energy strategies and the optimization of energy resource allocation. Functioning as an intelligent power network, the smart grid is constructed upon the foundation of an integrated and high-speed bidirectional communication network. Leveraging cutting-edge sensing and measurement technologies, advanced equipment methodologies, sophisticated control techniques, and state-of-the-art decision support systems, the power grid is imbued with traits of reliability, safety, cost-effectiveness, efficiency, environmental consciousness, and user security [1]. The deployment of the smart grid has notably catalyzed interaction between users and power utility companies, fostering a two-way exchange of power and data that has substantiated substantial economic and societal gains. The amalgamation of distributed generation, user-oriented energy consumption management, and remote monitoring has been actualized [2]. The realization of these outcome rests upon the bedrock of essential components like smart meters, the proliferation of which has engendered a prodigious volume of corresponding power data. The effective transmission and processing of this data stands as a vital prerequisite for the smart grid's success, as underscored by computational and communication cost considerations [3]. Moreover, the security and confidentiality of this data are of paramount importance, given its role in shaping customer electricity billing and guiding the decisions of power utility companies. Data security concerns encompass tampering, data falsification, and database attacks. In this context, blockchain technology, a decentralized data processing paradigm, emerges as a robust safeguard, with all network nodes being collectively responsible for data storage, thus ensuring comprehensive data security. In tandem with the continuous advancement of blockchain technology, numerous countries have synergistically integrated smart grid infrastructures with blockchain [4]. Within the smart grid domain, Advanced Metering Infrastructure (AMI) store substantial volumes of private user data, thereby adopting blockchain to fortify AMI data protection and storage within the blockchain, effectively mitigating the potential repercussions of data breaches [5]. Simultaneously, leveraging its distributed architecture, fog computing facilitates computations at the network's edge. In comparison to cloud computing, fog computing holds distinct advantages in processing smart meter data [6]. Notably, within smart meters, fog nodes can expedite the processing of user privacy data [7]. Given the shared architectural underpinnings of fog computing and blockchain, their integration holds great potential. Building upon prior research, this paper introduces a lightweight data aggregation schema (LDAS-BC), amalgamating fog computing, blockchain technology, and the Paillier homomorphic encryption algorithm. This schema refines the Paillier encryption system and employs a two-tier aggregation model to achieve granular data aggregation. Moreover, the scheme leverages the lightweight, one-way irreversible properties of hash algorithms to authenticate components, thereby minimizing computational and communication overheads. Overall, the primary contributions of this endeavor are as follows:

1) The introduction of cloud computing and fog computing in a three-tier architecture—comprising the user layer, fog layer, and cloud layer—attenuates performance

limitations arising from the constrained storage and computing resources of network edge devices. The intermediary fog node routinely collects user data from smart meters and significantly enhances data transmission efficiency through secondary aggregation operations.

2) The LDAS-BC scheme harnesses blockchain technology and harnesses fog nodes to formulate a fog chain. This dual-pronged approach not only permits fault tolerance for select fog nodes via consensus and master node selection algorithms but also furnishes clouds with stable and dependable data services.

3) By synergizing improved additive homomorphic encryption techniques, the schema presents a lightweight data aggregation mechanism predicated on blockchain to ensure the privacy of aggregated and transmitted data. Simultaneously, digital signatures founded on hash algorithms underwrite data integrity and validity during transmission.

The ensuing sections delineate the research structure: Section II reviews pertinent literature; Section III expounds upon the network model of the schema; Section IV introduces the master node algorithm tasked with electing a master node from the entire pool; Section V elaborates on the blockchain-rooted data aggregation mechanism. Section VI is dedicated to simulation experiments and performance analyses, culminating in a final comparison of data. Lastly, Section VII encapsulates this paper's findings and outlines potential future directions.

II. Related Work

In recent years, several privacy-conscious data aggregation methodologies have emerged, aiming to safeguard the confidentiality of transmitted data within the smart grid context. Chen et al. [8] introduced a data aggregation scheme founded on the Paillier homomorphic encryption algorithm. Nevertheless, this scheme neglected the constrained computational capabilities of smart meters and was incapable of executing pairing operations. Liang et al. [9] proposed a protocol centered on total homomorphic encryption, yet the intricate implementation of total homomorphic encryption posed a challenge. Gope et al. [10] devised a gradual data aggregation scheme that employed an aggregation tree to consolidate users' energy consumption data. The mechanism required all smart meters to partake in the aggregation process to ensure scheme accuracy. Despite this safeguard against aggregation interruption due to smart meter failure through Ping tests and third-party aggregator (TPA) involvement, the scheme incurred substantial communication overhead. Furthermore, excessive reliance on TPA engendered issues of trust and single points of failure. Singh et al. [11] proposed a privacy-ensuring data aggregation model integrating deep learning and homomorphic encryption to mitigate the adverse effects of flash memory workload on predictive model accuracy. The model facilitated secure data aggregation at low computational costs. However, it failed to account for data volume and suffered from sluggish transmission efficiency.

And in the context of blockchain. Guan et al. [12] introduced a blockchain-based methodology for privacy protection and secure, efficient data aggregation. The scheme employed pseudonyms to mask user identities and maintained data on a private blockchain. Identity authentication primarily relied on Bloom Filters within this framework. Chen et al. [13] advanced a dual blockchain-supported secure and anonymous data aggregation protocol named DA-SADA. The scheme formed a three-tier data aggregation structure via fog computing, incorporating secure and anonymous data aggregation mechanisms involving Paillier additive homomorphic encryption, aggregate signatures, and anonymous authentication, with minimal computational overhead. Faiza et al. [14] conceived PrivDA, a blockchain and homomorphic encryption-based privacy-preserving IoT data aggregation approach, enabling consumer users to create smart contracts to stipulate terms of service and requested IoT data. Cristina et al. [15] innovated a privacy-enhancing distributed security protocol leveraging blockchain and homomorphic encryption for data aggregation, employing homomorphic encryption for data encryption and blockchain smart contracts for aggregation. Bao et al. [16] advanced the BBNP paradigm, a blockchain-grounded model employing data aggregation protocols to safeguard data privacy and communication confidentiality, deploying identity authentication mechanisms for data integrity, and employing the subjective logical reputation model for consensus to address single point of failure. Zhang et al. [17] presented a potent blockchain-oriented multidimensional data aggregation framework using the Byzantine consensus mechanism to designate master nodes for data aggregation and secret sharing-based user management. Zhao et al. [18] introduced a blockchain-rooted privacy protection billing framework underpinned by the BGN encryption scheme, safeguarding users' private billing data. Notwithstanding, none of these solutions offered comprehensive data protection within the smart grid milieu. Yu et al. [19] proposed a privacy-preserving data aggregation and quality assessment protocol driven by smart contracts, storing data on the Inter Planetary File System (IPFS), deriving summary outcomes to evaluate data quality, and allocating rewards based on data quality.

In smart grid and edge computing scenarios. Lu et al. [20] introduced an edge blockchain-aided lightweight privacy-protecting data scheme dubbed EBDA within the smart grid context. Zhang et al. [21] devised LPDA-EC, a lightweight privacy-preserving data aggregation framework tailored for edge computing, ensuring data confidentiality and privacy. Fan et al. [22] introduced DPPDA, a distributed privacy-protecting data aggregation methodology for the smart grid, uniting master node algorithms, the Paillier encryption system, Boneh-Lynn-Shacham short signatures, and SHA-256 capabilities to meet security and privacy requisites for data aggregation in a fledgling grid, ensuring equitable and secure smart grid communications.

III. Smart Grid Network Model Based on Blockchain

A. Main Objectives of the System Model

Currently, substantial challenges persist in ensuring data privacy within the smart grid framework. Firstly, at the user level, the possibility of malevolent entities fabricating spurious data for transmission to fog nodes or tampering with data conveyed by smart meters poses a threat to data validity and

integrity. Consequently, data source verification becomes imperative to establish the authenticity and integrity of transmitted data. Secondly, the issue of raw data exposure remains prominent, as malicious actors could potentially gain access to such data. To mitigate this, encryption of original data is necessary, safeguarding data security from the inception of transmission through storage. Thirdly, the quandary pertains to data storage methodology. The conventional practice of storing data on fog node servers renders it susceptible to malevolent infiltration, jeopardizing power data confidentiality. To counter this, blockchain serves as a robust solution, averting single points of failure and safeguarding against server attacks by storing data in a decentralized manner. Lastly, as user numbers proliferate, so does the voluminous power consumption data. This exponential data growth necessitates data compression to curtail transmission duration, enhance efficiency, and facilitate swift decision-making at the cloud computing center. In light of these challenges, this paper introduces the LDAS-BC scheme, chiefly targeting data integrity, validity, and privacy, while also addressing the efficacy of data storage and transmission.

B. System Model

This section introduces the blockchain-centered smart grid network model, as proposed within the scope of this paper. The schematic representation of this network model is depicted in Fig. 1. The blockchain-based smart grid network model comprises three distinct strata: the user layer, the fog layer, and the cloud layer.

1) User layer: This layer predominantly encompasses an extensive array of smart meters, which, in alignment with their geographic distribution, establish connections with adjacent fog nodes. Concurrently, each smart meter dispatches encrypted data in the form of user reports to the respective area's fog node.

2) Fog layer: Comprising fog nodes endowed with computational capabilities, this layer undertakes the verification of received user reports. Once confirmed as accurate, these nodes perform primary aggregation operations on the ciphertext received from the user layer. Subsequently, an elected master node oversees secondary aggregation, culminating in the storage of the resultant aggregated data onto the blockchain, followed by data transmission to the cloud.

3) Cloud layer: The cloud layer is chiefly responsible for system initialization, data retrieval, decryption, storage, and analysis, among other functionalities. The cloud server is capable of disseminating electricity consumption reports, deduced via analysis, to the associated fog nodes. This facilitates low-latency real-time electricity consumption data queries for users.

The crux of the network model comprises three core entities: the smart meter (SM), the fog node, and the measurement data management system (MDMS). Within this intricate network framework, the Advanced Metering Infrastructure (AMI) network is methodically subdivided into 'm' distinct subregions. Each such subregion encompasses 'n' smart meters, primarily tasked with the collection of users' energy consumption data. $SM_{ij}\left(0 \le i \le n, 0 \le j \le n\right)$ is the i-th smart meter in region j, and smart meters form a user layer. In each region of the user layer, a fog node is strategically positioned for deployment. These fog nodes undertake the pivotal role of data concentration and possess the capability to aggregate the collected data. Spatially situated at the network's periphery, these fog nodes bridge the gap between the user layer and the cloud infrastructure. The measurement data management system resides within the cloud environment, equipped with the capacity to access aggregated data residing on the fog chain. Upon retrieval, this system is proficient in decryption procedures, thereby enabling analysis of the decrypted data. The outcomes of this analysis are subsequently harnessed to formulate pertinent supply strategies. Notably, the MDMS encompasses functionalities akin to cloud servers and reputable third-party entities, thereby encapsulating multifaceted roles within its purview.

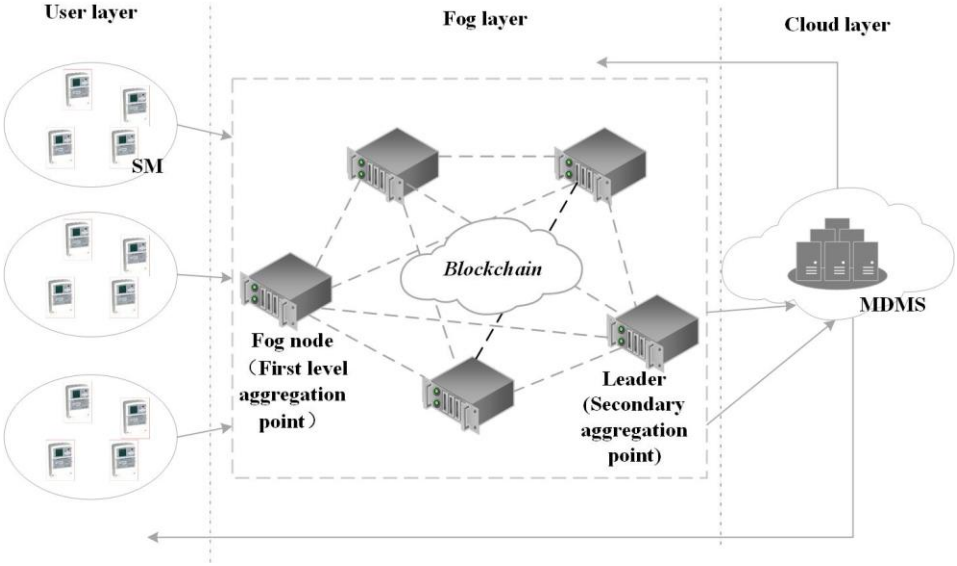

Fig. 1. Network model of LDAS-BC.

IV. Election of the Leader Node

In the realm of blockchain technology, the master node assumes a pivotal role as a fundamental component within the blockchain network. Its principal functions encompass the verification of operations executed by other nodes, the preservation of blockchain integrity, and the packaging of transactions into fresh blocks for incorporation into the blockchain. Within the context of fog nodes, the role of a primary node becomes essential in performing analogous tasks. This section sets forth a novel approach for the election of a primary node, designated to undertake the aforementioned operations.

Algorithm1 Election of the Master Node

1 When $n > 3f + 1$, $DC_i \rightarrow Follower(i \in 1,2,...,n)$, where f is the number of faulty nodes;
2 Set the term number to 0, that is $TN_{DC_i} = 0(i \in 1,2,...,n)$;
3 Set the initial vote number to 0, that is $N_v = 0$;
4 Start timing and express as $Times$;
5 Set a time threshold, that is T_{out};
6 While $Times > T_{out}$ do;
7 $Follower \rightarrow Candidate$;
8 $TN + 1$;
9 $Times$ reset to zero and restart the timer;
10 $N_v + 1$;
11 Send voting requests to other nodes and wait for responses;
12 if the replies from other nodes are received, then the cumulative number of votes N_v is calculated;
13 if $N_v > n/2 + 1$, Where n is the number of nodes, then $Candidate \rightarrow Leader$;
14 end If
15 else (Primary node has been identified);
16 $Candidate \rightarrow Follower$;
17 else
18 Repeat steps 7-11 to start a new election;
19 end If
20 end While

The master node, pivotal in linking aggregated data, subsequently transmitting this data to the cloud, is underscored by three distinct states within each fog node: candidate (sole initiator of the election), follower (participant in the voting process), and master node (sole entity authorized to modify operations). The algorithm governing the master node unfolds across three phases, as delineated below, and is encapsulated in the steps presented within Algorithm 1.

1) Preparation stage: In cases where a primary node is non-existent, the primary node election process is activated. All fog nodes are initialized with a term of 0, and the initial vote tally stands at 0.

2) Voting stage: Upon exceeding the designated time threshold, all nodes transition from follower nodes to candidate nodes, thereby heralding the commencement of the voting process.

3) End stage: Upon the vote count of a given node exceeding half of the total votes, that node ascends to the status of primary node. Subsequently, this node broadcasts its identity as the primary node. Other candidate nodes, in turn, assume the status of followers.

This method ensures the seamless selection of a primary node, vital for executing essential operations within the fog node domain.

V. Data Aggregation Mechanism Based on Blockchain

This section elucidates the LDAS-BC scheme delineated in this paper, which ingeniously amalgamates blockchain technology with Paillier homomorphic encryption technology. The scheme encompasses four integral components: system initialization, user report generation, fog chain generation, and data reading and analysis. A visual representation of these components is visually depicted in Fig. 2.

A. System Initialization

Select *k* as the system security parameter, and compute the Paillier algorithm, public key $(n = p \cdot q, g)$, private key $(\lambda = lcm(p-1, q-1), \mu)$, where p, q are large prime numbers satisfying the $|p| = |q| = |k|$ condition, let $g = N + 1$, ensure that $\mu = \left(L\left(g^{\lambda} \bmod N^2\right)\right)^{-1} \bmod N$ exists. The system randomly selects $r \in Z_N^*$ and calculates $s = r^N \bmod N^2$. Define the function $L(u) = u - 1/N$ and select the safe hash function $h: \{0,1\}^* \rightarrow \{0,1\}^l$.

B. Generation of User Reports

The energy consumption data acquired from smart meters inherently harbors users' confidential information, necessitating the encryption of such data during the collection process. For contextual clarity, this paper postulates a scenario where the private data gathered by a smart meter is transmitted to a fog node in 15-minute intervals. It's worth noting that the smart meter employs encryption mechanisms to secure the energy consumption data every 15 minutes, ensuring data integrity and privacy through digital signatures. During a designated timeframe, each fog node undertakes the aggregation of data submitted by individual smart meters.

1) SM_{ij} generates the corresponding energy consumption data, which is represented by Formula 1, including user ID_{ij}, energy consumption data d_{ij} and time stamp T_p.

$$m_{ij} = ID_{ij} \| d_{ij} \| T_p \tag{1}$$

2) Use the corresponding key (g, n, s) to calculate ciphertext C_{ij}, which can be expressed as Formula 2.

$$C_{ij} = g^{d_{ij}} \cdot s = (N+1)^{d_{ij}} \cdot s = (1 + d_{ij} n) \cdot s \tag{2}$$

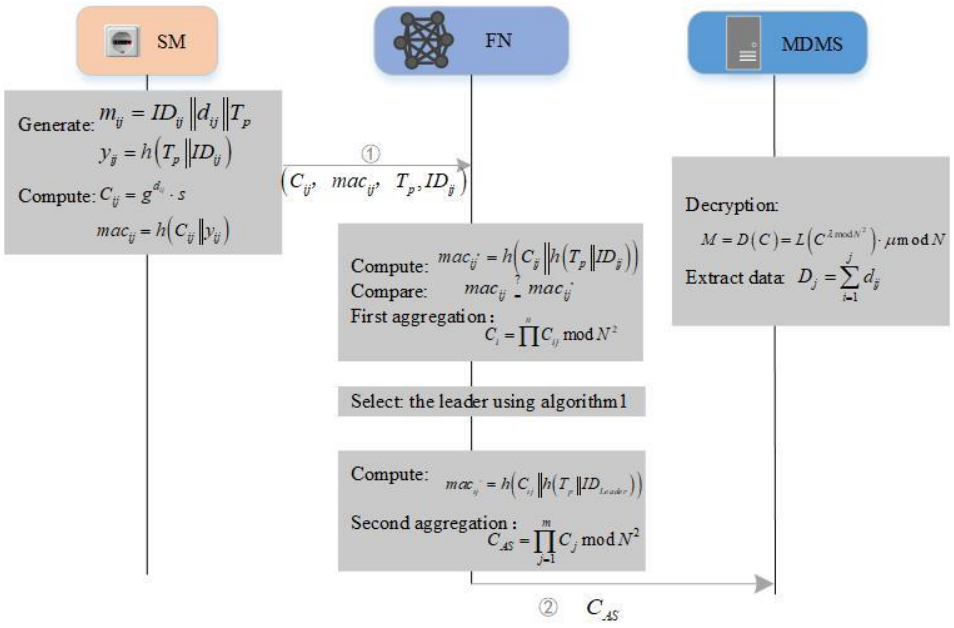

Fig. 2. LDAS-BC working flowchart.

3) After data encryption is completed, SM_{ij} uses hash function h to calculate the digital signature, which can be expressed as Formula 3, where $y_{ij} = h(T_p \| ID_{ij})$.

$$mac_{ij} = h(C_{ij} \| y_{ij}) \tag{3}$$

4) SM_{ij} sends the user report $(C_{ij}, mac_{ij}, T_p, ID_{ij})$ to the fog node.

C. Generation of Fog Chain

This section unfolds across five primary stages, each uniquely handling data in distinct ways. The algorithmic representation of state transitions for each fog node is illustrated in Algorithm 1. During the initial three stages, all fog nodes actively engage, while subsequent to the selection of the primary node, only the fog node designated as the primary node partakes in the final two stages.

1) Data verification: Upon the receipt of a user report, the fog node conducts digital signature computation, incorporating its own identity information. This process can be formally represented as Eq. (4). Subsequently, a comparison is made with the baseline condition, expressed as $mac_{ij} \stackrel{?}{=} mac_{ij}'$. If the equation holds true, the verification process is deemed successful, warranting further progression. Conversely, if the comparison fails to satisfy the condition, the received user report is deemed invalid and subsequently rejected.

$$mac_{ij}' = h(C_{ij} \| h(T_p \| ID_{ij})) \tag{4}$$

2) Initial data aggregation: Within the purview of this stage, every fog node orchestrates the aggregation of ciphertext originating from all smart meters under its jurisdiction. The resultant aggregated ciphertext is delineated by Formula 5. The generation of the corresponding signature for this aggregated ciphertext is elucidated through Formula 6. Where $y_j = h(T_p \| ID_j)$.

$$C_i = \prod^{n} C_{ij} \bmod N^2 \tag{5}$$

$$mac_j = h(C_j \| y_j) \tag{6}$$

3) Primary node election: In an endeavor to curtail the risk of regional data loss and data compromise stemming from single points of failure, and to mitigate the concentration of processing numerous data streams originating from fog nodes via the measurement data management system, the algorithmic methodology outlined in Algorithm 1 is harnessed for primary node selection. Each of the participating fog nodes is equipped with the prospect of ascending to the role of a master node.

4) Subsequent data aggregation: Following the receipt of the aggregation report denoted as (C_j, mac_j, T_p) dispatched by the respective fog node, the master node undertakes a sequence of actions. Initially, the master node initiates the verification process of the aggregation report. Subsequently, it computes the digital signature, as depicted in Formula 7. In contrast to $mac_{ij} \stackrel{?}{=} mac_{ij}'$, if the equation is valid and T_p is within the validity period, then the verification passes. Then, the master node will perform a secondary aggregation of the aggregation report, and the second-level aggregation ciphertext is C_{AS}, as shown in Formula 8.

$$mac_{ij}' = h(C_{ij} \| h(T_p \| ID_{leader})) \tag{7}$$

$$C_{AS} = \prod_{j=1}^{m} C_j \bmod N^2 \tag{8}$$

5) Creation of new block: The master node is tasked with the creation of transaction $T_x = \left(C_{AS}, Leader_{fog_j}, T_p\right)$. In the network model outlined within this section, all fog nodes bear the responsibility of upholding and overseeing the fog blockchain. However, the role of generating blocks is solely entrusted to one and only one master node. The architectural blueprint of this process is succinctly represented in Fig. 3. Upon the master node's encapsulation of the transaction within a block, it disseminates the block across the network, transmitting it to all nodes. Upon receipt of acknowledgments from over a third of the nodes, the block is seamlessly integrated into the longest blockchain, ensuring its enduring persistence and security.

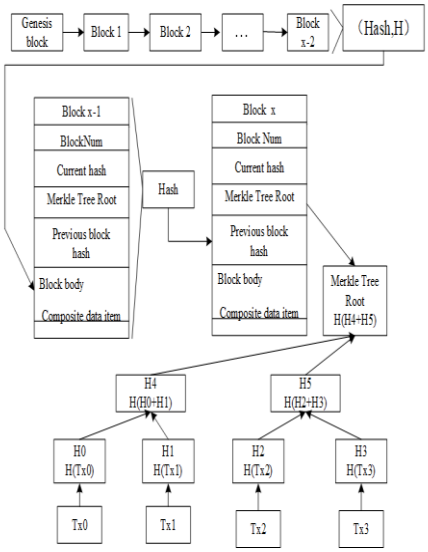

Fig. 3. Block structure and connections.

D. Data Reading and Analysis

Algorithm2 Extraction of Regional Data

Input： M and R

Output： $\left(D_1, D_2, ..., D_n\right)$

1 Set $x_0 = M/R$; $a_1 = R^1, a_2 = R^2, ..., a_m = R^m$; $x_0 = D_1 + R^1 D_2 + ... + R^{m-1} D_m$;

2 For $j = m$; $j > 1$; $j--$ do;

3 $D_j = x_{j-1} \bmod R$;

4 $x_j = x_{j-1}/R$;

5 End for;

6 return $\left(D_1, D_2, ..., D_n\right)$.

The measurement data management system possesses the capability to retrieve information from the fog chain at η minute intervals. Commencing this process, the system initiates the decryption of the second-level aggregate ciphertext through the utilization of the Paillier homomorphic decryption algorithm. To streamline this decryption process for the aggregated ciphertext, certain definitions are introduced:

$$M = a_1 \sum_{i=1}^{n} d_{i1} + a_2 \sum_{i=1}^{n} d_{i2} + ... + a_n \sum_{i=1}^{n} d_{in} \tag{9}$$

$$R = \prod_{j=1}^{n} r_j \tag{10}$$

The ciphertext can then be converted to the form of Formula 11.

$$C = g^M \cdot R^N \bmod N^2 \tag{11}$$

The final aggregated ciphertext still follows the Paillier encryption algorithm, so the measurement data management system can perform Paillier decryption using the private keys λ and $L(\mu)$ to obtain the aggregated plaintext M:

$$M = D(C) = L\left(C^{\lambda \bmod N^2}\right) \cdot \mu \bmod N \tag{12}$$

The ultimate goal of the measurement data management system is to obtain the fine-grained power consumption of each region. In order to achieve this goal, the region data can be obtained through algorithm 2 and $D_1, D_2, ..., D_n$ can be extracted from M:

$$D_j = \sum_{i=1}^{j} d_{ij} \tag{13}$$

VI. Simulation Experiment and Performance Analysis

A. Performance Test

This paper uses Hyperledger Caliper to test the performance of the deployed blockchain network, mainly measuring transaction throughput, transaction latency, and docker container volume. The host hardware parameters used were as follows: The experiment was carried out on an Apple M1 CPU@4*3.2GHz+4*2.064GHz computer.

This paper builds a blockchain network based on Hyperledger fabric v2.4, and the test network consists of two organizations, each with two nodes. A workload named AMI DATA is used to simulate the reading and writing of AMI data, and the performance of the blockchain is evaluated by controlling the number of transactions sent. The test results are shown in Table I.

TABLE I. Performance of Parameters of AMI Data Transaction

AMI data	Maximum delay (s)	Handling capacity (TPS)
1000	1.12	75.4
2000	1.20	79.4
3000	2.05	80.5
4000	1.08	81.6
5000	1.08	98.2

According to the experimental results, with the increase of the number of transactions, the maximum delay basically does not change and remains at about 1S, and the whole system is in

a fairly stable state. The blockchain system can process all the AMI data in a very short time. It can meet the time requirements of smart grid data processing. The throughput changes from 75.4TPS to 98.2TPS, which is a small change and uses less system resources. It can meet the needs of daily power grid equipment. As shown in Fig. 4, the throughput changes with the number of AMI devices. It can be seen that with the increase of AMI devices, the throughput gradually becomes stable. The growth rate is smaller. The changes in throughput are shown in Fig. 4.

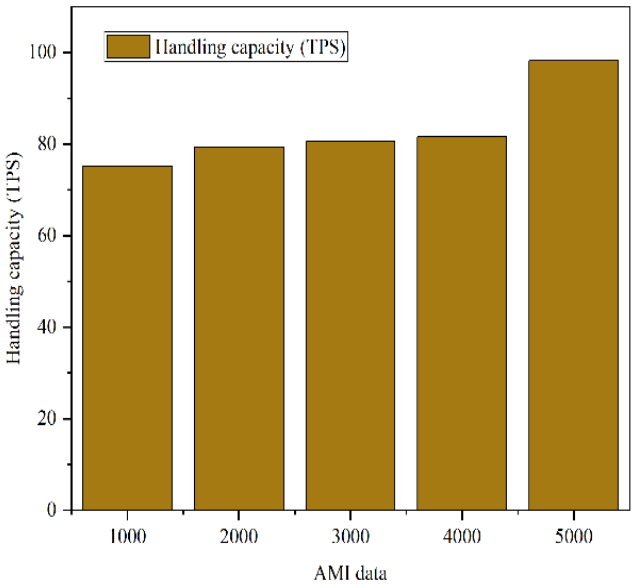

Fig. 4. Changes in throughput.

B. Calculation of Cost

Within this section, a comprehensive analysis of the overall system's computational cost is undertaken. In this analysis, it is posited that the number of fog nodes traverses a spectrum ranging from 5 to 50, which is $m \in [5,50]$. Each of these fog nodes governs jurisdiction over 20 smart meters, which is $n = 20$. For the sake of facilitating a comprehensive performance evaluation of the proposed scheme, a comparative analysis was conducted involving other proposed schemes such as EBDA [20] and LPDA-EC [21]. This comparative assessment aims to provide a robust understanding of the proposed scheme's relative merits and performance attributes in contrast to these alternative approaches. Define T_{E_1} as the exponential operation time in $Z_{n^2}^*$, T_{E_2} as the exponential operation time in G , T_M as the multiplication operation time, and T_P as the pairing operation time. Within this section, the execution of each aforementioned operation is carried out leveraging a pair-based encryption library (PBE). To ensure comparability across experiments, the operation times stipulated in study [13] are adopted. Table II presents the diverse operations alongside their corresponding execution times. Notably, due to the significantly minute time allocation for hash operations relative to other operations, these hash-related procedures are deemed negligible and thus omitted from the computational cost assessment.

TABLE II. TIME TO RUN THE OPERATION

Notations	Descriptions	Time cost （ms）
T_{E_1}	Exponentiation operation in $Z_{n^2}^*$	1.60
T_{E_2}	Exponentiation operation in G	1.62
T_M	Multiplication operation	0.06
T_P	Pairing operation	17.70

At the user level, computing ciphertext C_{ij} requires $2mn$ multiplication T_M . In the fog layer, each fog node performs the first data aggregation, then the entire fog layer requires a total of mn times multiplication operation, that is, mn times T_M . The master node performs a second data aggregation, requiring the m multiplication operation T_M . When the measurement data management system in the cloud needs to read the contents of the fog chain, the operation of Formula 12 is performed, which requires a power operation T_{E_1} and a multiplication operation T_M . In summary, the total calculation cost of the proposed scheme is $(3mn+m+1)T_M + T_{E_1}$. Table III shows a comparison of calculated costs.

TABLE III. COMPARES THE CALCULATED COSTS

Option	Calculate the cost
LPDAEC	$m\left[2nT_{E_1} + 4nT_M + (3n+1)T_{E_2}\right] + 2mT_P + 2mT_{E_1}$
EBDA	$m\left[nT_{E_1} + 2(n+1)T_M\right] + (m+1)T_P + (m+1)T_M + T_{E_1}$
LDASBC	$(3mn+m+1)T_M + T_{E_1}$

Fig. 5 provides a comparative illustration of the cumulative computational costs associated with the three schemes under examination. Evidently, the proposed scheme presented in this paper markedly exhibits significantly lower computational costs in comparison to the other two schemes. This advantageous performance differential becomes even more pronounced with the escalation in the number of smart meters within the system. By comparing the graphs, it can be concluded that LDAS-BC can significantly reduce the computational cost of AMI data and has strong scalability.

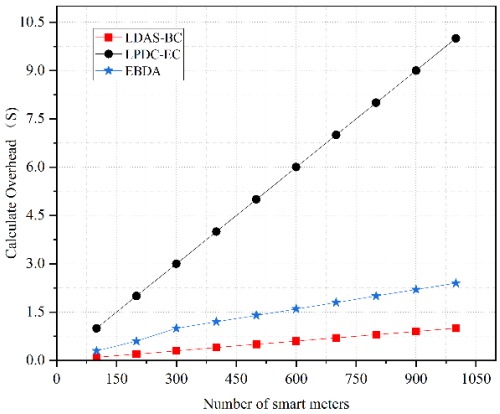

Fig. 5. Calculated cost comparison.

C. Communication Cost

The communication cost within the proposed scheme encompasses two primary components: the communication between the smart meter and the fog node, and the subsequent communication between the fog node and the master node. First, the smart meter generates a user report $\left(C_{ij}, mac_{ij}, T_p, ID_{ij}\right)$ and sends it to the fog node, assuming that $\left|N^2\right|$ is 2048*bit*, $|p|$ is 160*bit*, $|ID|$ and $\left|T_p\right|$ are 160*bit*, then $S_{user\to fog} = \left|C_{ij}\right| + \left|mac_{ij}\right| + \left|T_p\right| = 2368bit$. The fog node then sends $\left(C_{ij}, mac_{ij}, T_p, ID_{ij}\right)$ to the master node, which has $S_{fog\to Leader} = \left|C_{ij}\right| + \left|mac_{ij}\right| + \left|T_p\right| = 2368bit$. As a consequence of the aggregation operation, the aggregate communication overhead remains unaffected by the number of smart grids. This intrinsic property signifies that even as the quantity of smart grids escalates, the communication overhead between the fog node and the master node remains consistent. Table IV tabulates the communication costs associated with the three alternatives.

TABLE IV. COMPARISON OF COMMUNICATION COSTS

Option	Communication Cost
LPDA-EC	$mn\left(\left\|C_{ij}\right\|+160+\left\|T_p\right\|+160\right)+(m-1)\left(\left\|C_j\right\|+\left\|ID_j\right\|+\left\|\sigma_j\right\|+T_p\right)$
EBDA	$mn\left(\left\|C_{ij}\right\|+\left\|h_{ij-s}\right\|+\left\|mac_{ijs}\right\|\right)+(m-1)\left(\left\|C_j\right\|+\left\|ID_j\right\|+\left\|\sigma_j\right\|\right)$
LDAS-BC	$mn * S_{user\to fog}+(m-1) * S_{user\to Leader}$

Fig. 6 presents a comparative analysis of the communication costs inherent in the three schemes. The visual depiction highlights that the proposed scheme boasts a marginal advantage over the other two alternatives in terms of communication costs. This advantage is poised to intensify as the Advanced Metering Infrastructure (AMI) scale expands during subsequent stages. Through the comparison of the figures, it can be concluded that LDAS-BC can significantly reduce the cost of AMI data transmission, and after secondary aggregation, the effect is more obvious.

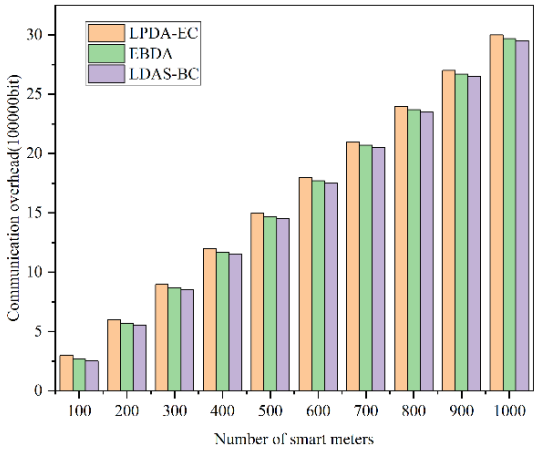

Fig. 6. Calculated cost comparison.

To sum up, compared with existing schemes, LDAS-BC has great advantages in terms of data security, data privacy, data aggregation, as well as computational costs and communication costs. LDAS-BC is a lightweight, low-risk secondary aggregation scheme for blockchain data.

VII. CONCLUSIONS

With the objective of enhancing the data transmission efficiency within the context of advanced measurement systems, as well as curtailing computational and communication overhead, this study introduces the LDAS-BC data aggregation scheme predicated on blockchain technology. This scheme ingeniously amalgamates the Paillier homomorphic encryption algorithm to achieve the aggregation of ciphertext, significantly mitigating the risk of breaching user privacy data. Furthermore, the scheme incorporates the tenets of fog computing and cloud computing, effectively addressing issues tied to computational limitations and restricted storage resources associated with network edge devices. The integration of blockchain technology further reinforces the security and reliability of on-chain data. The proposed LDAS-BC scheme's efficacy is substantiated through theoretical analysis and experimental simulations, which collectively validate its safety and dependability. Comparative experiments additionally underscore the scheme's heightened advantages in comparison to alternative approaches. In the future work, we should consider the selection of consensus algorithm, the mutual authentication among different levels, and the calculation cost and communication cost of these problems need to be calculated. Finally, it is envisaged to extend this scheme to the scenario of Internet of Things data. This will become the focus of the later research work.

***Abstract*—Quantifying student academic performance has always been challenging as it hinges on several factors including academic progress, personal characteristics and behaviours relating to learning activities. Several research studies are therefore being conducted to identify the factors so that appropriate measures can be conducted by academic institutions, family and the student to boost his/ her academic performance. The present study investigates personal characteristics, psychological factors, behavioural factors, social factors and learning capabilities, that directly or indirectly affect student's academic performance, which was tapped by administering a self-designed questionnaire. The data was collected from 214 undergraduate students studying in various streams of the University of Delhi and post that semi-structured interview was conducted to get in- depth information. The result proved the correlation between the aforementioned factors and the learning capabilities of the students. Using the results of analysis a machine learning model based on k-nn algorithm was formed to predict student performance. A chatbot is also proposed to provide guidance to students in strenuous situations, motivate them and interact with them without having personal bias.**

Keywords*—Academic performance; machine learning; chatbot; educational data mining; learning analytics

I. Introduction

In today's era of the information revolution, learning analytics, predictive analytics, educational data mining, and machine learning techniques has become a hot area of research [1, 2] as it is beneficial for Teachers, administrators, family and the student him/herself to provide a timely remedy. We found that students have frequent mood swings, internal conflicts and issues that keep them distracted. They are often not comfortable to share their problems with their family members and friends. Accumulation of these issues causes stress and anxiety. In such a situation students become pessimistic, spend more time on social media or get involved in substance use. It is therefore important to identify academic and non-academic parameters that affects a student's performance. Using these parameters, we need a ML model to predict a new student's performance so that teachers and mentors can address their concerns at the earliest and provide them every help to grow with a stable mind.

Supervised learning algorithms are being used to analyse student's learning behaviours in order to predict and classify the students' performance [13,17]. However, the challenging task is to find the optimal algorithm that gives best results. Machine learning algorithms like k-nn, Naïve Bayes, ANN, logistic regression, SVM, decision tree, random forest, etc are used for prediction but the accuracy of results obtained from each model depends on the size and quality of data [11,12].

In this paper, we have used data analytics to identify personal, behavioural and academic factors that affect student's learning capability and empirically proved that there exists a relationship between the identified factors and the learning capability. Then, an AI model is created which when fed with identified factors as input, predicts the how quick learner a student is using the k-nn algorithm. Moreover, to handle the mental health issues which in turn affects student's academic performance as well as their learning capability, an NLP based chatbot model has been proposed to interact and guide them especially in strenuous situations.

The paper is divided into six sections. The first section introduces the title of the paper. The second section presents a summarization of research already done in this area. In section, data science and data analytics have been used to mine information from the dataset and visually represent crucial numbers using tables and charts. The results of analysis are interpreted and explained in Section IV. The section also proposes an AI based solution to find a solution to the issues identified in Sections III and IV. Section V proposes an AI based machine learning model that can accurately predict a new student's future performance by analysing certain parameters and comparing them with data already stored in the database. The paper is finally concluded in Section VI.

II. Literature Review

The drop-out students' ratio from higher education institutions results in immense loss/resource wastage. It also affects the evaluation and assessment processes of these institutions. New technologies like data mining, machine learning should therefore be used to perform simple and effective analysis of student-performance data that could help to improve learning procedures and atmosphere [3,4].

In [5], researchers have explained the use of Bigdata methods for learning analysis that can be used for system performance prediction, visualization of data, student skills estimation, risk detection, course recommendation, grouping of students and collaboration with other students. Predictive analysis is done on student achievements, behaviour, and skill prediction.

During the forecast of student performance [6] data-mining techniques were used to build a predictor framework for the final-marks based on students' achievements and features including features, non-courses variables, out of class student conduct, video watching and post-school tutoring.

Researchers in [7] have evaluated students at the beginning of an academic session to forecast their achievements using collaborative filtering technique that is based on their academic history. Going further, in [8], the author has used historical academic data of students to evaluate a students' performance. The study relied on a factorization of low-range-matrixes and dispersed linear model.

In [9], a student classification system was developed using naive Bayes and decision tree algorithms that used features like the occupation of parents to enhance the correctness of the grade-prediction framework. The Decision Tree classifier performed better than the naive Bayes Classification in terms of accuracy [10].

III. Data Analysis

In the first stage, the raw datasets are collected from 214 students studying different courses in the University of Delhi. The data was then pre-processed to transform categorical data into numerical. Data analytics techniques were then applied using programming languages R and Python. The observations are reported in Table I.

TABLE I. Queries and Corresponding Responses

Query	Response	Query	Response
When you listen to a spiritual leader / motivational speaker, what are your topics of interest?	36.4% for Handling Relationships 66.3% for Enhancing Concentration 57.3% for overcoming anxiety 72.4% for staying motivated 12% do not listen to any spiritual leader	How many hours do you spend on social media per day?	13.1% spend less than 1 hour daily 31.8% spend 1 to 2 hours daily 35.5% spend 2 to 3 hours daily 19.6% spend more than 3 hours daily
How many close friends do you have?	11.7% have no close friend 65.4% have 1 to 3 close friends 15.9% have 4 to 5 close friends 7% have more than 5 close friends	How frequently do you meet your friends in a week?	8.4% meet once in a week 5.1% meet twice in a week 6.1% meet thrice in a week 26.2% meet more than three times 54.2% meet them occasionally
Do you discuss your personal issues with your close friends?	50.5% says certain issues not all 35% feel free to discuss 14.5% do not share	How frequently do you have mood swings?	36.4% experience mood swings multiple times in a day 15.4% once in a day 13.6% once in a week 28.5% once every fortnight Rest occasionally
What is the state of your mind in general?	43.3% varies frequently 24.3% calm 16.8% happy 14.9% highly frustrated and disappointed	How many hours do you devote every day for self-study?	16.8% spend less than 1 hour daily 36.9% spend 1 to 2 hours daily 29% spend 2 to 3 hours daily 12.6% spend 3 to 4 hours daily 4.7% study for more than 4 hours daily
Which method of study do you prefer the most?	59.3% Reading Books or any other sort of Reading Material 29.9% Watching Videos 7.5% Group Studies with Friends 2.3% Listening Audio Podcasts Rest Educational Programs on TV	Who is your role model?	43% Family Member 42.5% have no role model 4.7% sees their teacher as their role model 6.5% sees Sportsperson / army / any eminent person from history as their role model 3.3% sees Actor / Actress as their role model
How do you find your classes?	15.9% find them Boring and unproductive 50% Not boring but putting extra burden 34.1 %Exciting and triggering my thought process	Has your learning capabilities been affected due to the pandemic?	41.6% Badly affected 51.4% Slightly affected 3.3% Not at all affected 3.7% Have become better than before
Were you comfortable with online teaching?	29.9% Yes 41.6% No Rest was unsure	Which mode of teaching do you prefer now?	10.7% Online 47.7% Offline 41.6% Hybrid
Did your learning capabilities improve with digital technology?	53.7% Yes 20.6% No 25.7% are unsure	Did any of the cases given below affect your learning capabilities in the last 2 years?	71.4% were affected due to Stress and Anxiety 21.9% were affected due to Death in the Family 44.8% were affected due to Strained Financial Conditions 63.08% were affected due to Problems in Relationships 72.4% were affected due to Increased exposure to Electronic Gadgets

			18.69% were affected due to All of the above
During pandemic, your studies were affected the most due to which of the following reasons?	46.77% Lack of personal space 20.56% Inadequate ventilation 25.7% Power Cut 54.7% Noise from surroundings 62.14% Technical Issues 77.17% Disturbed routine 42.05% Unhealthy eating habit	Which activity do you practice to keep your mind stable?	27.57% practice Yoga 39.71% practice Meditation 58.4% practice Singing 54.2% practice Dancing 31.7% get involved in Sports Activities
Do you want any type of counselling to handle your stress?	57.5% Yes Rest No	What do you do to burst your stress?	64.4% prefer Talking to someone who is close to me 65.8% prefer Keeping Quiet and Sitting Alone 35.9% prefer Reading Shopping 33.17% prefer Eating too much 68.2% prefer Watching TV or Web Series 54.2% prefer Walking or any Physical Activity
As a student, when was your level of motivation and attention higher?	49.5% Pre-pandemic times 7.5% During pandemic times 14.5% post-pandemic times Rest opted for Never 24.3% Always the same	Do you feel that your memorizing capabilities have been adversely affected due to COVID-19?	52.8% Yes 24.3% No Rest believes Maybe
During online classes, was your learning affected due to any of the following reasons?	28.03% Classes were not conducted on online platform regularly 61.68% Recording of lecturers were not available 50% Sessions were not interactive 70.09% Could not interact with other students in the class 51.8% Could not attend due to poor net connection 42.98% Did not have enough devices to attend classes 35.98% Study material was not available 80.8% Difficult to concentrate online beyond a certain limit	Are you facing self-regulation challenges?	40.65% Often miss the deadlines given by teachers 52.33% Did not get appropriate help during online classes 48.5% Lack the ability to control my own thoughts, emotions, and actions during classes 63.08% Have limited preparation before a class. 60.28% have poor time management skills during online classes. 55.14% fail to properly use online peer learning strategies (i.e., learning from one another to better
Do you face Technological literacy and competency challenges?	27.10% Lack competence and proficiency in using various interfaces or systems 21.49% resist learning technology. 30.37% are distracted by an overly complex technology. 19.6%I have difficulties in learning a new technology. 22.42% lack the ability to effectively use technology to facilitate learning. 23.83% lack knowledge and training in the use of technology. 20.09% are intimidated by the technologies used for learning. 28.5% resist and/or am confused when getting appropriate help during online classes. 30.84% have poor understanding of directions and expectations during online learning. 29.43% perceive technology as a barrier to getting help from others during online classes		

IV. Data Interpretation

When we analysed the data collected, we observed an alarming situation. 90% of the students admitted that their learning capabilities have been affected due to the pandemic. Out of these, 71.4% of the students were affected due to Stress and Anxiety and 41.6% of these students were never comfortable with online teaching.

49.5% students believe that their level of motivation and attention was higher in pre-pandemic times and 52.8% feel that their memorizing capabilities have been adversely affected due to COVID-19.

During online classes, learning abilities of the students were affected as their classes were not conducted on online platform regularly (28.03%), recorded lecturers were not available (61.68%), teaching sessions were not interactive (50%), no interactions with peer group (70.09%), poor net connection (51.8%) and lack of concentration (80.08%). In fact, every student experienced Student isolation challenges (SIC). Due to this, students feel emotionally disconnected or isolated and uncomfortable during online classes. They preferred face-to-face interaction with teachers and traditional classroom methods for socialization [11]. This is evident from the graph shown in Fig. 1.

During pandemic, studies were affected majorly due to lack of personal space (46.77%), noise from surroundings (54.7%), technical Issues (62.14%), disturbed routine (77.17%) and unhealthy eating habits (42.05%). In fact, the students admitted that during exams, they experienced anxiety issues when appearing for interviews or viva. So, they preferred to have offline teaching for better outcomes (refer Fig. 2).

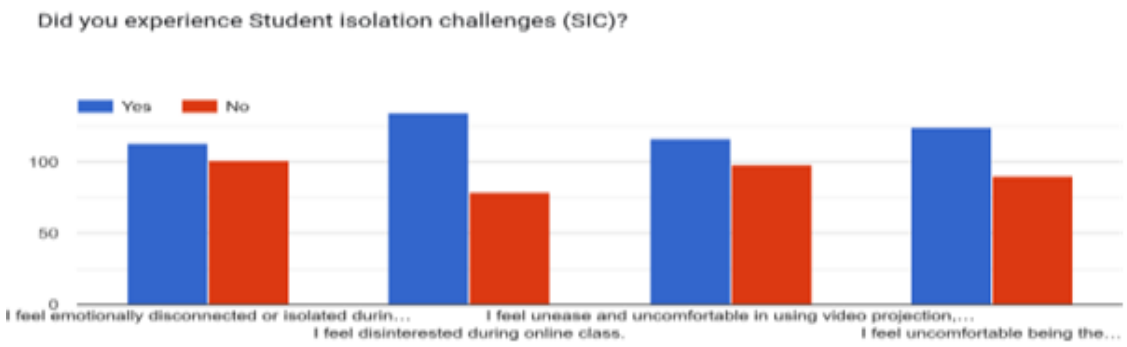

Fig. 1. SIC issues.

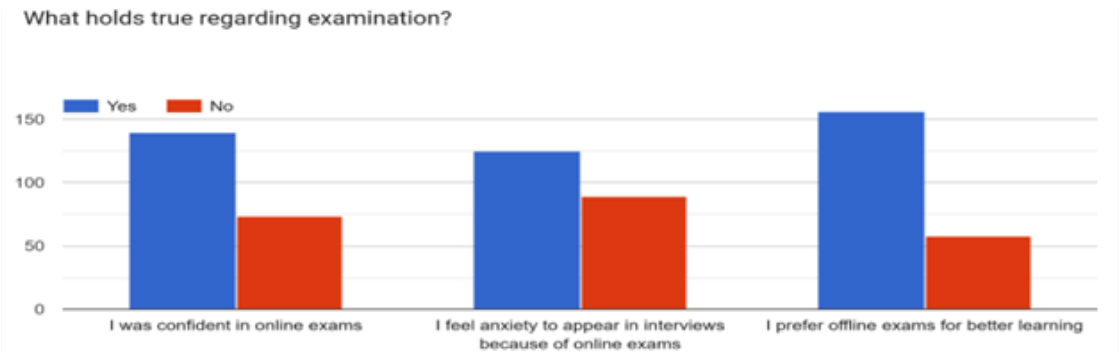

Fig. 2. Mindset regarding examination.

40.65% of the students feel disappointed as they often miss the deadlines given by teachers and 48.5% find it difficult to control their thoughts, emotions, and actions during classes. However, after the colleges reopened post COVID, the situation has become little better. More than 76% of the students agreed that a personal eye contact with the teacher is required for effective learning [12] (refer Fig. 3).

In fact, after colleges started in offline, only 8.9% of the students stated that small intra-class as well as inter-class competitions will not help to augment effective learning.

A. *Stress and Anxiety Hampers Success*

The students accepted that due to stress and anxiety they are unable to perform to their maximum potential. 51.8% of students experience mood swings at least once in a day [13]. 43.3% believes that their state of mind is not calm and happy. Rather, it varies frequently. The situation is worsened as 14.9% of students accept that they are highly frustrated and disappointed.

42.5% of students do not have a role model. This may not be a good sign for their sound mental health. 50% of students feel that their classes add an extra burden to their daily lives. 57.8% students admitted that they need counselling to handle their issues. When asked additional questions related to their mental health, students' responses were recorded as shown in Fig. 4.

To handle such a strenuous situation, students are taking measures to overcome factors affecting their studies, which are in line with other research studies. They are listening to spiritual and motivational speakers for enhancing concentration and overcoming stress as well as anxiety. As evident from the pie chart shown in Fig. 5, more than 75% of the students have expressed that they listen to a spiritual/ motivational speaker at least once in a week. 58.4% practice Singing and 54.2% of the students practice Dancing to keep stress at bay. In extreme strenuous conditions, 64.4% prefer talking to a close friend/relation, 65.8% prefer keeping quiet and sitting alone, 68.2% watch TV or Web Series and 54.2% prefer walking or any other physical activity, which helped improve the mood and reduce stress among students [14].

Fig. 3. Importance of teachers and competitions in effective learning.

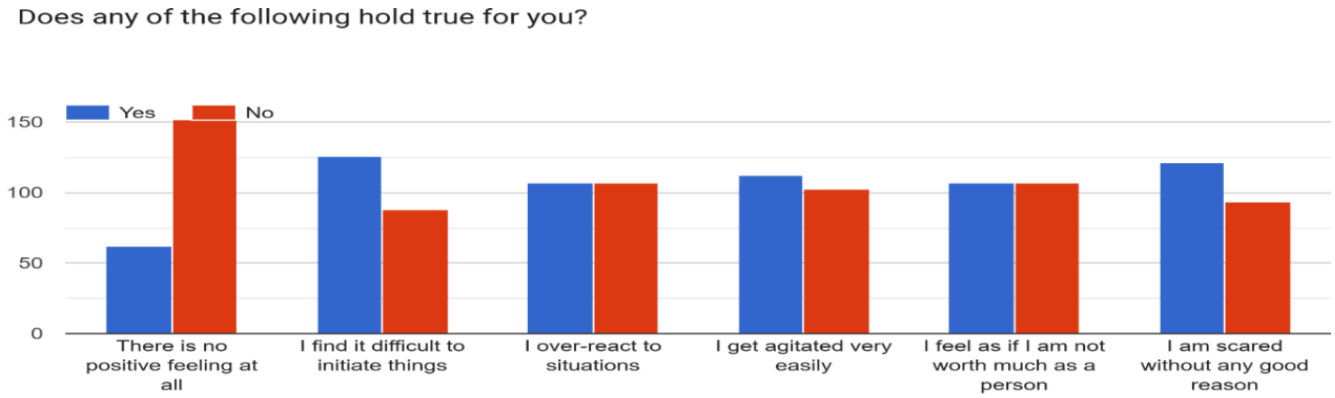

Fig. 4. Analysing mental health of students in post-pandemic times.

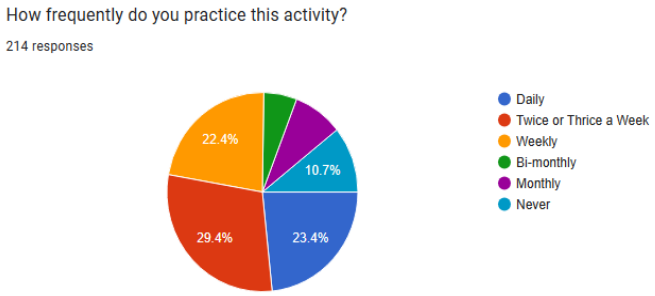

Fig. 5. Frequency of listening to spiritual / motivational speakers.

B. Solution Proposed to Boost Learning Capabilities

In the study, it was observed that 65.4% of the students have 1 to 3 close friends but 54.2% of them meet them occasionally. Moreover, 65% of the students admitted that they feel uncomfortable to discuss issues that disturb them with their close friends.

Moreover, in the post-pandemic times, more than 56% of the students are facing issues due to fatigue. And only 37% of the students are finding their studies interesting. Rest feels overwhelmed due to stress and thus feel fatigued after studying for few minutes.

To help students handle their stress and anxiety issues, we have proposed a chatbot based on the model depicted in Fig. 6. The role of this chatbot is to provide guidance to students in strenuous situations, motivate them and interact with them without having personal bias. Our study reveals that students are not comfortable discussing their personal issues even with their close friends. In such a scenario, they can at least share their feelings with an AI assisted chatbot that can communicate like a human and provide counselling or guidance.

C. Data Exploration to Build the Model

Before designing the machine learning model to make predictions, we first need to explore data to understand the relationships that exists between different parameters [15]. Therefore, we calculated co-relation between some key variables. The co-relation values between two variables are given in Fig. 7. The same values when plotted using a heatmap can be visualized.

From the heat map plotted, it is very clearly evident that there is a strong relationship between Hours_of_Self_Study and Optimistic, Consistent_Learner and Quick_Learner, Stable_Mind and Optimistic, Stable_Mind and Hours_of_Self_Study. To study their underlying relationship in depth, we have plotted bar graphs. Identifying relationships between the variables and their impact on being quick and consistent learner is important, as a successful student has to be quick to learn and learn consistently. The conclusion that a consistent learner is quick to learn and vice versa has been drawn from the heatmap.

We observed that students who believe in group studies with friends are not quick and consistent learners. Quick and consistent learners prefer to study from books or any sort of reading material. Few of them also prefer to learn by watching educational videos on the World Wide Web. A quick and consistent learner spends at least 1 to 3 hours daily (refer Fig. 8) and spends majority of the time reading books/ study material followed by watching educational videos (refer Fig. 9). Even in the digital age, students prefer to read hard bound books or printed text material. They watch videos only for certain topics that they find too hard to understand. Moreover, in a country like India students find difficult to understand terminologies of hard-core English language, so they watch videos in local languages to understand as well as validate their understanding. One more interesting thing that we concluded from our studies is that negligible number of students prefers watching educational programs on Television and listen to podcast for effective learning.

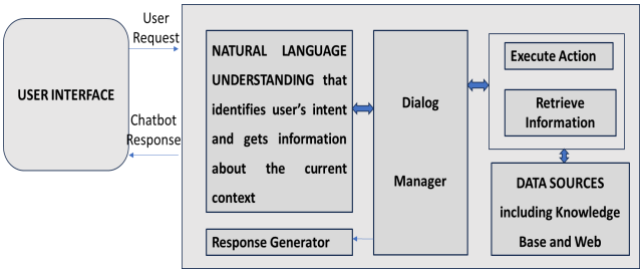

Fig. 6. Proposed chatbot model.

	Hours_SelfStudy	Method_Study	Optimistic	ConsistentLearner	Stable_mind	Quick_Learner
Hours_SelfStudy	1.000000	-0.039559	0.174594	-0.023668	0.098585	-0.015722
Method_Study	-0.039559	1.000000	-0.023559	-0.005205	-0.068424	0.014068
Optimistic	0.174594	-0.023559	1.000000	-0.043759	0.089492	-0.101285
ConsistentLearner	-0.023668	-0.005205	-0.043759	1.000000	0.019614	0.124775
Stable_mind	0.098585	-0.068424	0.089492	0.019614	1.000000	0.022564
Quick_Learner	-0.015722	0.014068	-0.101285	0.124775	0.022564	1.000000

Fig. 7. Correlation matrix and heatmap.

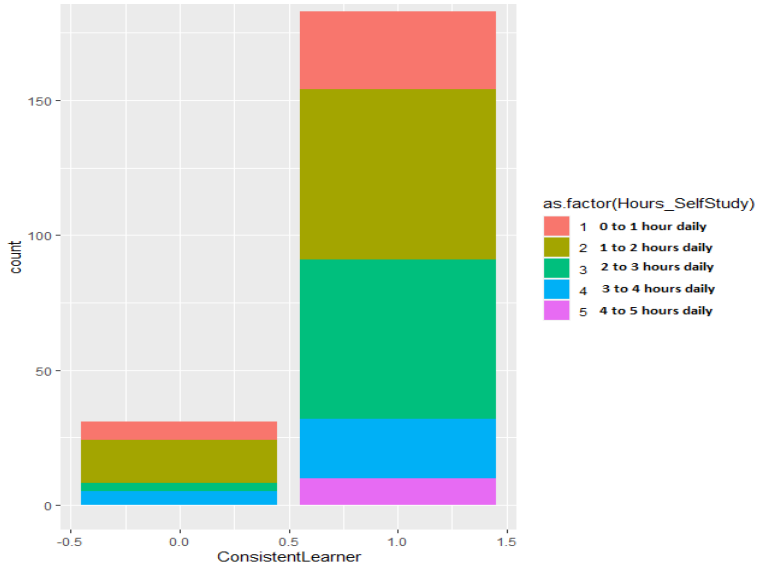

Fig. 8. Relationship between consistent learner and hours of self-study.

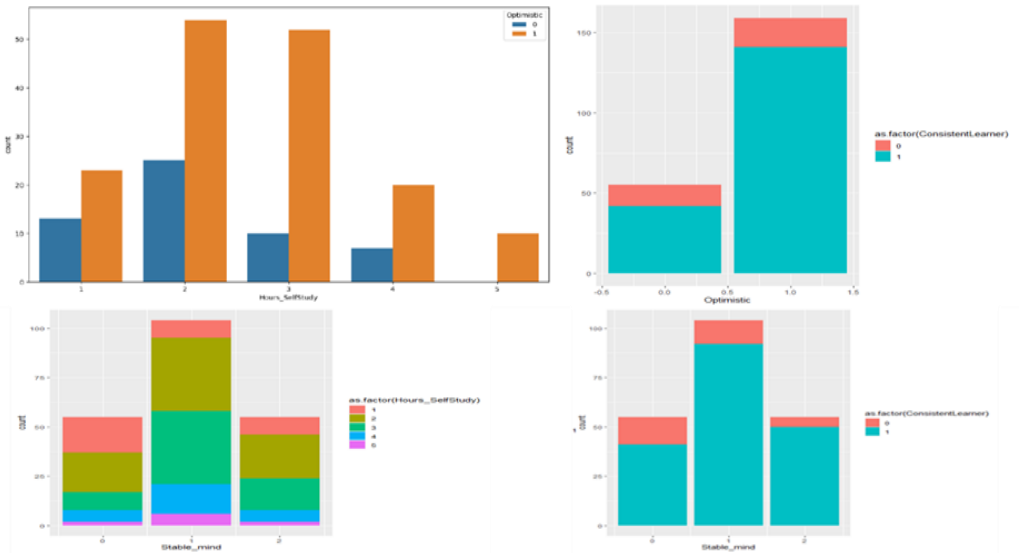

Fig. 9. Relationship between method of study and hours of self-study.

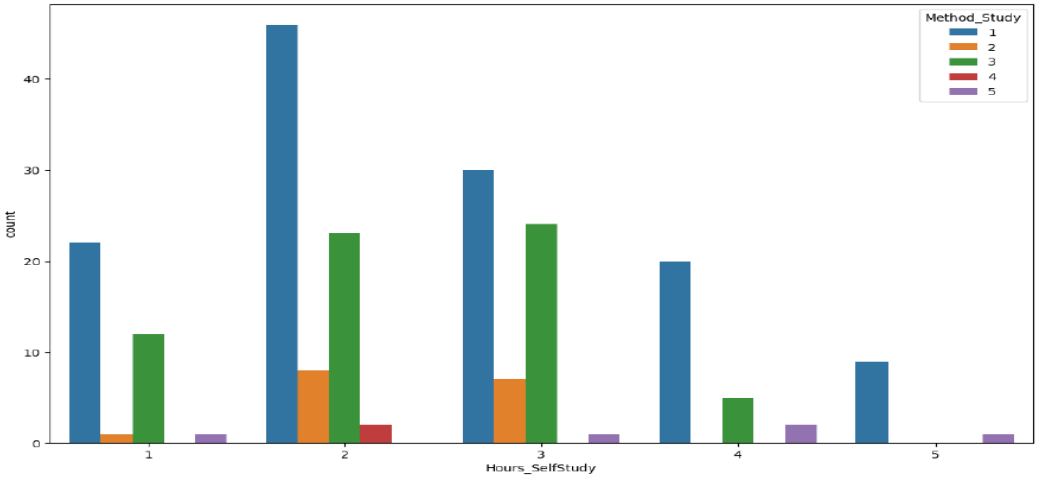

Fig. 10. Relationship between stable mind, optimistic, consistent learner and hours of self-study.

For effective learning, a quick and consistent learner devotes 1 to 3 hours daily. Studying beyond 3 hours does not add to their learning productivity. Research has indicated a favourable correlation between study duration and scholastic achievement [16]. A specific amount of study time will be reached before the grade no longer demonstrates a discernible shift. A quick and consistent learner experience less stress and anxiety and therefore has a stable mindset and is usually optimistic. Optimistic student prefers self-study using books or study material and is not dependent on peer group for learning. These numbers are evident from graphs given in Fig. 10.

V. Proposed ML Model to Predict Learning Capabilities

Using these conclusions, we can create a machine learning model (refer Fig. 11). The model divides the entire data set into two groups- training dataset and testing dataset. While training dataset has 70% of the data records chosen randomly from the original dataset, testing data set on the other hand has rest of the 30% records. The training dataset is utilized in the learning phase of the machine learning model. Correspondingly, the testing dataset is used in the evaluation phase to predict values for the 30% rows in the dataset. The ML model classifies a student either as a Quick Learner or a Slow Learner. Values predicted are then compared with actual values. The number of correctly predicted values are then compared with those predicted wrongly to determine the accuracy of the model. Higher the accuracy, higher is the probability that a new student will be accurately classified being a quick and consistent learner.

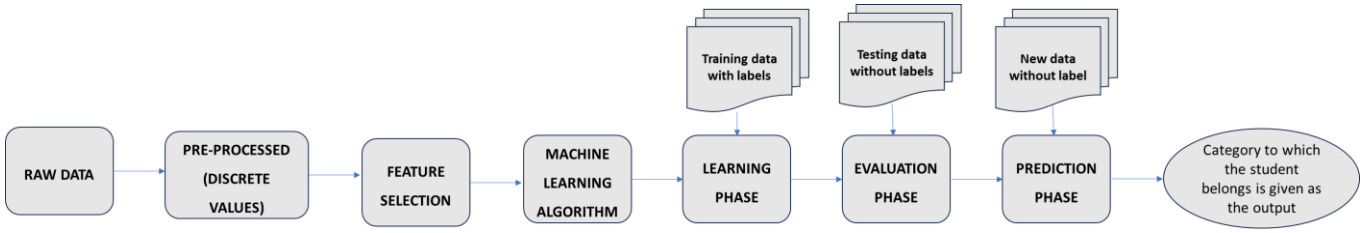

Fig. 11. Proposed ML model.

An accurate machine learning model will help the teachers to focus on inconsistent and slow learners and at the same time plan certain activities or assignments to further polish and accelerate the learning of quick and consistent learners.

The proposed machine learning model uses K Nearest Neighbour Classification algorithm. We also designed ML model using Naïve Bayes algorithm but accuracy of predictions was higher in case of knn algorithm [17]. For better and efficient results, we had done hyper parameter tuning. The confusion matrix of the k-nn algorithm is given in Fig. 12.

Accuracy (all correct / all) = (TP + TN) / (TP + TN + FP + FN).

Accuracy = (26 + 23) / (26 + 23 + 11 + 3) = 49 / 63 = 0.7777.

Misclassification (all incorrect / all) = (FP + FN) / (TP + TN + FP + FN).

Misclassification = 14 / 63 = 0.2222

Precision (true positives / predicted positives) = TP / (TP + FP)Precision = 26 / 37 = 0.7027.

Sensitivity aka Recall (true positives / all actual positives) = TP / (TP + FN).

Recall = 26 / 29 = 0.8965

Specificity (true negatives / all actual negatives) =TN / (TN + FP).

Specificity = 23 / 34 = 0.6764

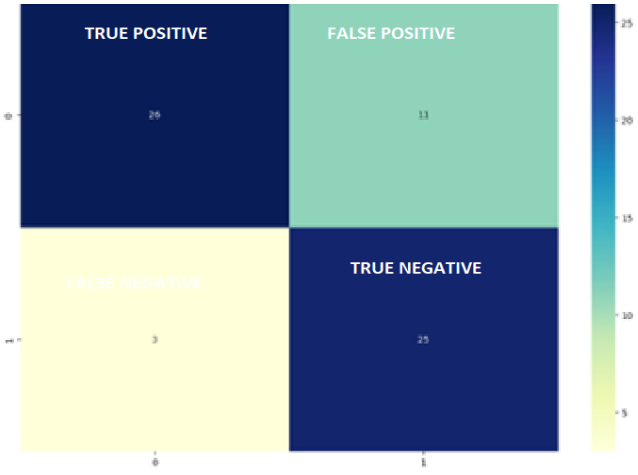

Fig. 12. Confusion matrix.

VI. Conclusion and Future Scope

The paper presents a study on 214 students in Higher Education. Several questions were asked to get an insight into their learning capabilities, behaviour, mental health, academic profile and their study habits. It was observed that students are facing issues including loneliness, stress, anxiety, resistivity to learn new things, lack of confidence, competence and proficiency. The students are aware about these challenges and are trying several techniques to deal with them and stay motivated as these issues are impacting their learning capabilities and success.

In the paper, we have proposed an AI Chatbot based on Natural Language Processing to interact with the students, guide them and motivate then whenever they feel low. The paper also proposes a machine learning model using knn algorithm that could classify a new student as a quick learner or a slow learner based on several factors related to mental health, hours of self-study, and preferred way to study. The model could predict data with an accuracy of 78%. In our subsequent study, we shall try to improve the accuracy by collecting more data about these factors affecting a student's academic performance. Since data is the fuel of AI applications, more the data better are the results.

Sentiment Analysis Predictions in Digital Media Content using NLP Techniques

Abdulrahman Radaideh[1], Fikri Dweiri[2]
Engineering Management, University of Sharjah, UAE[1]
Industrial Engineering and Engineering Management, University of Sharjah, UAE[2]

***Abstract*—In the current digital landscape, understanding sentiment in digital media is crucial for informed decision-making and content quality. The primary objective is to improve decision-making processes and enhance content quality within this dynamic environment. To achieve this, a comprehensive comparative analysis of NLP for tweet sentiment analysis was conducted, revealing compelling insights. The BERT pre-trained model stood out, achieving an accuracy rate of 94.56%, emphasizing the effectiveness of transfer learning in text classification. Among machine learning algorithms, the Random Forest model excelled with an accuracy rate of 70.82%, while the K Nearest Neighbours model trailed at 55.36%. Additionally, the LSTM model demonstrated excellence in Recall, Precision, and F1 metrics, recording values of 81.12%, 82.32%, and 80.12%, respectively. Future research directions include optimizing model architecture, exploring alternative deep learning approaches, and expanding datasets for improved generalizability. While valuable insights are provided by our study, it is important to acknowledge its limitations, including a Twitter-centric focus, constrained model comparisons, and binary sentiment analysis. These constraints highlight opportunities for more nuanced and diverse sentiment analysis within the digital media landscape.**

***Keywords*—Sentiment analysis; digital media; decision-making; quality assurance; NLP**

I. Introduction

In the contemporary era, digital media has permeated nearly every facet of daily life, fundamentally altering communication, information consumption, and our interaction with the world. From the rapid expansion of social media platforms to the continuous accessibility of online news and entertainment, the digital media landscape has evolved into an omnipresent force shaping public discourse, impacting consumer behavior, and facilitating global connectivity[1].

Central to this profound digital shift is the role of sentiment—the collective emotional undercurrent that flows through the vast sea of digital content. Sentiment in digital media encompasses a spectrum of emotions, from jubilation and enthusiasm to anger and disillusionment [2]. It is the pulse that drives conversations, sparks movements, and dictates the success or failure of digital content, brands, and ideas.

It is also known as opinion mining, refers to the automated process of identifying, extracting, and evaluating sentiments and attitudes expressed within textual data. This process is integral for understanding public perception, consumer sentiment, political discourse, and market trends. It provides valuable insights that guide businesses in crafting effective marketing strategies, aids policymakers in gauging public sentiment on critical issues, and empowers researchers to delve deeper into the intricacies of human communication in the digital age.

The influence of sentiment in the realm of digital media cannot be overstated. Sentiments expressed by users on social media platforms can quickly escalate or deflate public interest in a topic, product, or event. News articles and opinion pieces, often dissected through sentiment analysis, can sway public opinion and even influence political decisions. Understanding and harnessing this dynamic interplay of sentiments within digital media are essential endeavors in an increasingly interconnected and digitized world [3]. Traditionally, sentiment analysis relied on rule-based and statistical approaches, which had their merits but often struggled to capture the subtleties of human language. These methods proved ill-suited for the ever-evolving digital discourse, where slang, context, and linguistic nuances abound. The limitations of conventional sentiment analysis methods have become increasingly evident in the face of the dynamic, multilingual, and culturally diverse nature of digital content [4].

In this context, artificial intelligence (AI) emerges as a transformative force. AI-powered sentiment analysis utilizes advanced Natural Language Processing (NLP) techniques, Machine Learning (ML), and Deep Learning (DL) to decipher the intricacies of language and context, providing unprecedented accuracy and adaptability. The advent of AI has paved the way for a new era in sentiment analysis, characterized by its ability to discern sentiments across various domains, languages, and platforms[5].

The research paper explores the symbiotic relationship between sentiment analysis and artificial intelligence, introducing a novel AI-powered approach that navigates the complexities of sentiment identification and classification in the digital age. The aim is to unravel the intricacies of sentiment analysis [6], elucidating its historical context, traditional methodologies, and the paradigm shift brought about by AI-driven solutions [7].

The aim of this research is to revolutionize decision-making processes and quality assurance within the dynamic realm of digital media by utilizing a groundbreaking AI-powered approach to sentiment analysis [8]. This comprehensive investigation delves into the integration of traditional statistical methodologies, such as the machine learning model, and cutting-edge deep learning architectures, including ML and DL, to discern their respective impacts and

potential synergies in the context of sentiment analysis. With a primary focus on real-time Twitter sentiment data, our aim is to unlock valuable insight that inform strategic decision-making and elevate the standards of quality assurance in digital media [9].

A. Objectives

1) To Evaluate Traditional and DL-Based Sentiment Analysis Models.

2) To Assess the Influence of Twitter Sentiment Analysis: Analyze the impact of real-time Twitter sentiment data on decision-making processes and quality assurance in digital media, emphasizing the added value it brings to sentiment analysis.

3) To Explore Feature Extraction and Sequence Retention: Investigate the ability of the ML and DL architecture to extract intricate features from digital media content while retaining essential temporal sequences, thereby enhancing the accuracy of sentiment analysis.

4) To Conduct a Comparative Analysis: Conduct a rigorous comparative analysis to discern the strengths and limitations of each approach, elucidating the trade-offs and opportunities they present in the context of decision-making and quality assurance.

5) To Provide Practical Recommendations: Offer concrete recommendations and insights for practitioners and stakeholders in digital media, guiding them in leveraging sentiment analysis as a potent tool for informed decision-making and robust quality assurance.

These objectives collectively drive our endeavor to advance the understanding of sentiment analysis's transformative potential and its pivotal role in shaping the future of decision-making and quality assurance within digital media.

In the contemporary landscape dominated by digital media, this research aims to redefine the boundaries of sentiment analysis by introducing a novel and comprehensive AI-powered approach. Unlike traditional sentiment analysis methodologies, which often struggle to adapt to the evolving nature of digital discourse, this work stands out through the integration of both established statistical techniques and cutting-edge deep learning architectures. This distinctive fusion allows for capturing the intricacies of sentiment in a dynamic, multilingual, and culturally diverse digital environment.

B. Contributions of the Research

1) Hybrid methodology integration: One of the primary novelties of this approach lies in seamlessly integrating traditional statistical methodologies, such as machine learning models, with advanced deep learning architectures. This unique hybrid methodology capitalizes on the strengths of both approaches, providing a more robust and adaptable sentiment analysis framework.

2) Real-time twitter sentiment analysis impact: Extending beyond conventional sentiment analysis, this research places particular emphasis on the real-time analysis of sentiment in the context of Twitter data. This distinctive focus allows for exploring and quantifying the immediate impact of sentiments on decision-making processes and quality assurance in digital media.

3) Temporal sequence retention in feature extraction: Addressing a critical gap in existing literature, this study delves into the temporal dynamics of sentiment by investigating the ability of ML and DL architectures to extract intricate features from digital media content while retaining essential temporal sequences. This novel approach enhances the accuracy of sentiment analysis, especially in capturing the temporal evolution of sentiments over time.

Through these novel contributions, this research advances the understanding of sentiment analysis's transformative potential, setting a new standard for decision-making processes and quality assurance within the ever-evolving realm of digital media.

II. Literature Reviews

The intersection of sentiment analysis and digital media has garnered significant attention in recent years, reflecting the growing recognition of the pivotal role sentiments play in shaping online discourse, content quality, and decision-making processes [10]. This literature review provides an overview of the historical context, key methodologies, and prior applications of sentiment analysis in the realm of digital media, highlighting the evolving landscape of this interdisciplinary field [11].

A. Historical Context of Sentiment Analysis in Digital Media

The roots of sentiment analysis can be traced back to the early days of NLP and ML [12]. Early sentiment analysis efforts primarily focused on binary sentiment classification, distinguishing between positive and negative sentiments in textual data. As digital media evolved, sentiment analysis adapted to accommodate the nuanced and multifaceted nature of sentiments ex-pressed in online content [13].

The advent of social media platforms in the early 2000s marked a significant turning point [14]. Researchers and organizations recognized the potential of sentiment analysis to extract valuable insights from the vast volumes of user-generated content on platforms like Twitter and Facebook. Since then, sentiment analysis has matured into a sophisticated field, incorporating advanced NLP techniques and machine learning models to capture sentiments in real time across a wide array of digital media sources [15].

B. Key Methodologies and Technologies in Sentiment Analysis

Sentiment analysis methodologies have evolved in tandem with advancements in NLP and AI technologies [16]. Early approaches relied on lexicon-based sentiment analysis, using predefined lists of words and phrases associated with positive and negative sentiments. While effective to some extent, these approaches struggled with con-text and sarcasm [17].

Machine learning techniques, particularly supervised learning, revolutionized sentiment analysis by enabling models to learn sentiment patterns from labeled datasets. Techniques such as SVM, Naive Bayes NB, and more recently DL models like RNN and Transformers, have significantly improved sentiment analysis accuracy [18]. Pre-trained language models, such as BERT and GPT-3, have further elevated sentiment analysis by capturing contextual nuances and domain-specific sentiment [19].

C. Prior Applications of Sentiment Analysis in Decision-Making and Quality Assurance within Digital Media

The applications of sentiment analysis within digital media are multifaceted and extend across various domains:

1) Content creation and optimization: Content creators use sentiment analysis to gauge audience reactions to their articles, videos, or social media posts. In-sights from sentiment analysis inform content optimization strategies, helping creators tailor content to audience preferences [20].

2) Engagement strategies: Organizations leverage sentiment analysis to identify viral content and trends. By understanding sentiment patterns, they can craft engagement strategies that resonate with their target audience and enhance brand loyalty [21].

3) Quality assurance: Sentiment analysis plays a crucial role in maintaining content quality. It assists in content moderation by identifying inappropriate or harmful content and helps fact-checkers and journalists identify misinformation and fake news [22].

4) Advertising and marketing: Marketers analyze sentiment to measure the effectiveness of advertising campaigns. They also use sentiment insights to personalize ad targeting and messaging.

5) News and journalism: Sentiment analysis aids news outlets in understanding public sentiment towards news stories, political events, and social issues. This information can influence editorial decisions and story selection.

6) Public opinion and policy making: Governments and policymakers monitor online sentiment to gauge public opinion on policy issues and to respond proactively to emerging trends or concerns [23].

The literature reviewed underscores the transformative potential of sentiment analysis in digital media [18]. It has evolved from a binary classification task to a sophisticated field empowered by AI and machine learning, offering valuable insights for decision-makers, content creators, and quality assurance processes [24].

D. Gap Analysis

In our research, notable gaps emerge, urging further exploration in the realm of sentiment analysis in digital media [25]. These include the integration of multi-modal data sources, the development of real-time decision support systems, cross-platform sentiment analysis, ethical considerations, and user-centric sentiment analysis [26]. Closing these gaps promises to enhance the depth and breadth of sentiment analysis applications, ensuring its ethical use, and fostering personalized, real-time decision-making in the dynamic digital media landscape [27] (see Table I).

TABLE I. GAPS ANALYSIS

Year	Technique	Dataset	Accuracy Achieved	Application	Pros	Cons
2017	Approaches Using Machine Learning and Lexicons	Twitter dataset	83.3%	Sentiment analysis of tweets	Machine learning can analyze text without feature engineering	Traditional methods require feature engineering
2018	Long Term Memory (LSTM) and Convolutional Neural Networks (CNN)	English language tweets	88.5%	Sentiment analysis of tweets	Efficient and reliable technique	-
2019	Convolutional, recurrent, neural networks, unsupervised, and mixed neural networks, as well as deep reinforcement learning	-	-	Sentiment analysis of texts	Can recognize new complex features	Less accurate than supervised techniques
2020	Algorithms for supervised machine learning, such as Support Vector Machines and Artificial Neural Networks	User-created texts	88.5%	Sentiment analysis of texts	Can extract users' feelings from their writing	Slow and take a long time to train
2021	Support vector machines (SVM) and Universal Language Model Fine-tuning (ULMFiT)	-	-	Sentiment analysis of texts	Powerful deep learning architecture	-
2022	ELMO and CNN	Twitter dataset	-	Clustering in service discovery	Effective discovery of the best service	-

III. METHODOLOGY

The study utilized a dataset obtained from the Kaggle website, comprising around 160,000 tweets from the Twitter blog categorized into three groups: positive, negative, and neutral. Initial analysis involved applying various pre-processing techniques to cleanse and prepare the tweets for feature extraction. Subsequently [28], the database was split into a training set and a test set. Features were extracted from tweets using diverse techniques, and machine learning algorithms were trained for tweet polarity classification, including support vector machine, naive Bayes, decision tree, and K-nearest neighbor approaches [29]**.** The performance of these classifiers was then assessed on the test set across all extraction techniques to compare their impact on the sentiment analysis process, using multiple performance evaluation measures. Following this evaluation, a model was proposed, specifically a recurrent neural network employing Long Short-Term Memory (LSTM). The results obtained from this model were then compared with the outcomes of the previous classifiers [30] (see Fig. 1).

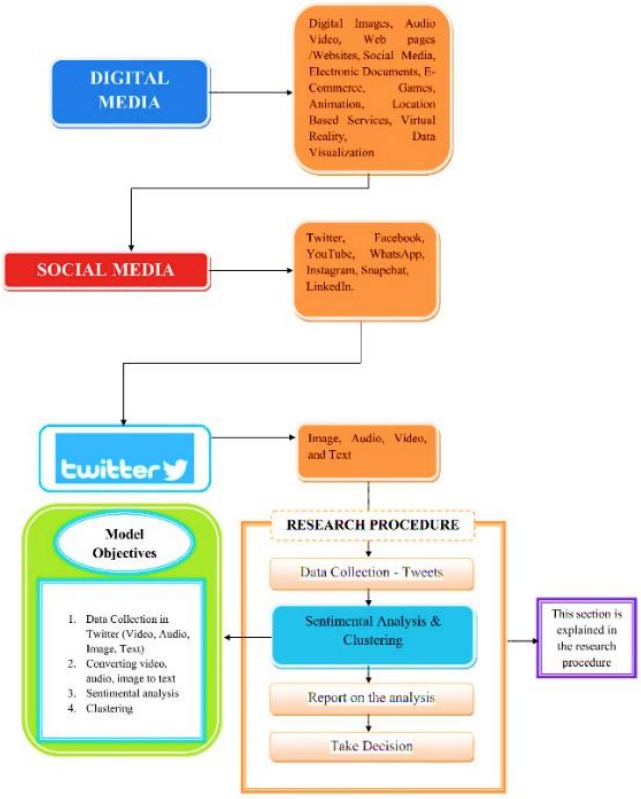

Fig. 1. General framework.

A. Tools and Resources

To accomplish the task of sentiment analysis, various tools and resources are necessary. The required tools and resources for analyzing the sentiment of tweets are discussed below:

1) Programming language: Python, a high-level general-purpose programming language, proves to be an excellent tool for artificial intelligence, machine learning, and deep learning. Python will be used for creating and training models. Several Python libraries will be employed for sentiment analysis, including Pandas, Numpy, Scikit Learn, NLTK, Re, Keras, PyTorch, and Transformers.

2) Software: Anaconda, a Python distribution platform, will be utilized, providing access to many built-in packages. Within Anaconda, Jupyter Notebook will serve as the primary environment for developing and training machine learning and deep learning models.

3) Twitter API: After developing and evaluating the machine learning and deep learning models, the Twitter API will be employed to extract new tweets and test the model's performance. Twitter allows the use of 3rd party Python packages like Tweepy to extract tweets based on query words and date range, facilitating the entire process.

4) Hardware: Given that various machine learning and deep learning models will be trained, the minimum system requirements are as follows: Core i5 Processor, 16 GB of RAM, Nvidia GPU with a minimum of 6 GB of V-RAM, and 100 GB of HDD space.

B. Machine Learning-Based Models

Through this model, we will initially process the data, extract the features, and then classify them based on machine learning algorithms. Fig. 2 shows the work steps.

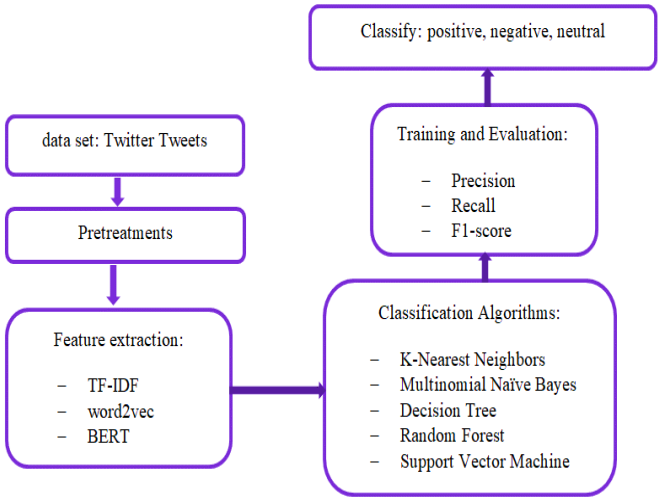

Fig. 2. Framework of model.

The model involves several steps, including pre-processing the data, feature ex-traction using techniques such as TF-IDF, word2vec, and BERT, and classifying the tweets using various algorithms such as k-nearest neighbors, multinomial Naïve Bayes, decision tree, random forest, and support vector machine. The model will be trained and evaluated using performance metrics such as precision, recall, and F1-score.

C. Features Selection

1) Data pre-processing: Since machines do not understand spoken or written natural language, data pre-processing is a very important step for sentiment analysis and a necessary process before training machine learning models. Data pre-processing aims to make it easier to train and test

classifiers by performing an appropriate set of transformations on the data. We did the pre-processing using the NLTK library in Python. Because we work with text data from Twitter. Tweets contain different parts that are not necessary or important to understanding the meaning of a tweet. Where we can extract the semantic meaning of the tweet by getting rid of all the unnecessary words and symbols by pre-processing the data. The tweets were pre-processed by selecting features that were likely to be relevant for sentiment analysis. In general, when selecting features for sentiment analysis, some common criteria researchers consider include relevance, in-formativeness, redundancy, computational efficiency, and interpretability. The pre-processing of the data follows the following steps: remove punctuation, remove stop words, remove URLs, remove emoji, remove hash marks, and drop all word wrapping, derivation, and markup. The data is now clean and ready for feature ex-traction. Fig. 3 shows the steps for data pre-processing.

2) Data preprocessing: The steps involved in pre-processing include converting letters to upper/lower case, tokenizing the text into individual units, removing unwanted characters and stopwords, normalizing the text, stemming to remove affixes, and lemmatization to reduce words to their base form. Finally, the pre-processed text is vectorized to convert the text data into numerical form that can be utilized by machine learning models.

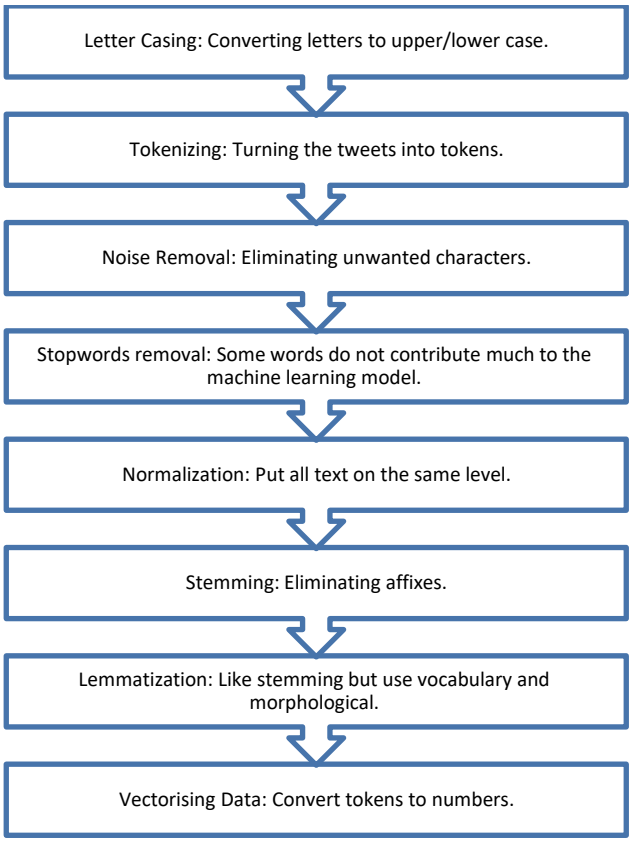

Fig. 3. Data pre processing.

3) Feature extraction: The study employed three techniques to extract features from text data:

a) TF-IDF algorithm (term frequency-inverse document frequency): is a statis-tical measure that evaluates how relevant a word is to a document in a collection of documents. This is done by multiplying two metrics: how many times a word appears in a document and the inverse document frequency of the word across a set of documents. To implement the TF-IDF technique, the implementation of the TF-IDF technique utilized a class from the sklearn library.

b) word2vec: is a predictive model for computing a continuous radial representation of quantities in large data sets. The given models use two alternative models to get a high dimensional vector for each word:

- PCA: A technique focused on reducing the dimensions of words that directly impact how the original set of vectors transforms into a new set.
- t-SNE: A technique for nonlinear dimensionality reduction and data visualization. It combines words from a higher dimension with ones from a lower dimension. The Gensim library was used to construct word vectors using word2vec, with parameters like tokenized words and mincount set accordingly.

c) BERT: is a pre-trained language model for deep, bidirectional representations of unlabeled text by co-adapting on both the left and right context in all layers. BERT can be used in a variety of language tasks, with only a small layer added to the base model. BERT was used in two ways:

- Use the hugging face BERT model to fine-tune our sentiment analysis.
- Use the BERT model for fine-tuning and training on our dataset.

D. Machine Learning Algorithms

Various machine learning can be used to accomplish the task of sentiment analysis. The following machine learning algorithms are used:

The sentiment analysis task involved the utilization of a diverse set of machine learning and deep learning algorithms:

1) K-Nearest Neighbors (KNN): Identify the group to which a new data point (tweet) belongs based on training data. If a new tweet is close to a negative group, it is classified as negative; if close to positive or neutral, the prediction is made accordingly.

2) Multinomial Naïve Bayes: Determine the probability of a tweet being positive, negative, or neutral based on its contents or words.

3) Decision tree: Classify a tweet based on its features, i.e., the words it contains.

4) Random forest: Constructed from multiple decision trees to provide a more accurate and stable prediction. Operates as an ensemble, potentially offering improved results compared to a single decision tree.

5) Support vector machine: Utilize a non-linear Support Vector Classification model to categorize a tweet into positive, negative, or neutral classes.

6) Voted classifier: Ensemble approach incorporating KNN, Multinomial Naïve Bayes, Random Forest, and Support Vector Machine to enhance sentiment analysis predictions.

7) LSTM: Leverage deep learning with LSTM, specifically effective for sequential data like text. LSTM's capacity to remember long-term dependencies in words contributes to its success in handling text sequences.

8) Transformer network: Implementation of an encoder-only transformer model and the use of a pre-trained transformer model for sentiment analysis.

9) K-Means clustering: Segregate groups with similar traits and assign them into clusters.

E. Model Training and Evaluation

- Training: Model training is an integral part of the whole process. It is very important to set the hyper-parameters of the models to the right ones to achieve good results.
- Evaluation: As we compare different machine learning models for sentiment analysis, various evaluation metrics will be employed to determine the model's performance.
- Confusion Matrix.

1) Precision.
2) Recall.
3) F1 Score.
4) AUC-ROC Curve.

F. Model Testing

After training and evaluating the model, the best-performing model will be selected for testing with new tweets from Twitter. This process can be implemented using the Twitter API to create a user-friendly web server. Users can enter a keyword and date range, and the server will display the corresponding tweets along with their polarity. This provides organizations or individuals with valuable insights into what people are tweeting about their products or themselves.

G. Comparative Analysis

A comparative analysis is provided for various sentiment analysis models and techniques applied to the digital media dataset. The objective is to assess and contrast the performance of these models in terms of their ability to accurately classify sentiment, computational efficiency, and practical applicability in real-world scenarios.

IV. Result and Discussion

All models underwent training on 80% of our dataset, with the remaining 20% reserved for validation. Accuracy was employed as the performance metric during training, focusing on the validation accuracy of the models. The results are presented in Table II.

From the table above, it's evident that the BERT pre-trained model significantly outperformed even the LSTM model. Among the machine learning models, the random forest exhibited superior performance compared to others, including the voting classifier.

TABLE II. Validation Accuracy

Model	Validation Accuracy
K-Nearest Neighbors	55.36%
Multinomial Naïve Bayes	65.18%
Decision Tree	66.55%
Random Forest	70.82%
Support Vector Machine	65.98%
Voted Classifier	69.86%
LSTM	81.12%
BERT	94.56%

A. Evaluation

Additional metrics, such as Confusion Matrix, Recall Score, Precision Score, and F1 Score, were employed to evaluate and compare the sentiment analysis models. The evaluation results for the aforementioned algorithms based on these criteria are presented in Fig. 4 and Table III.

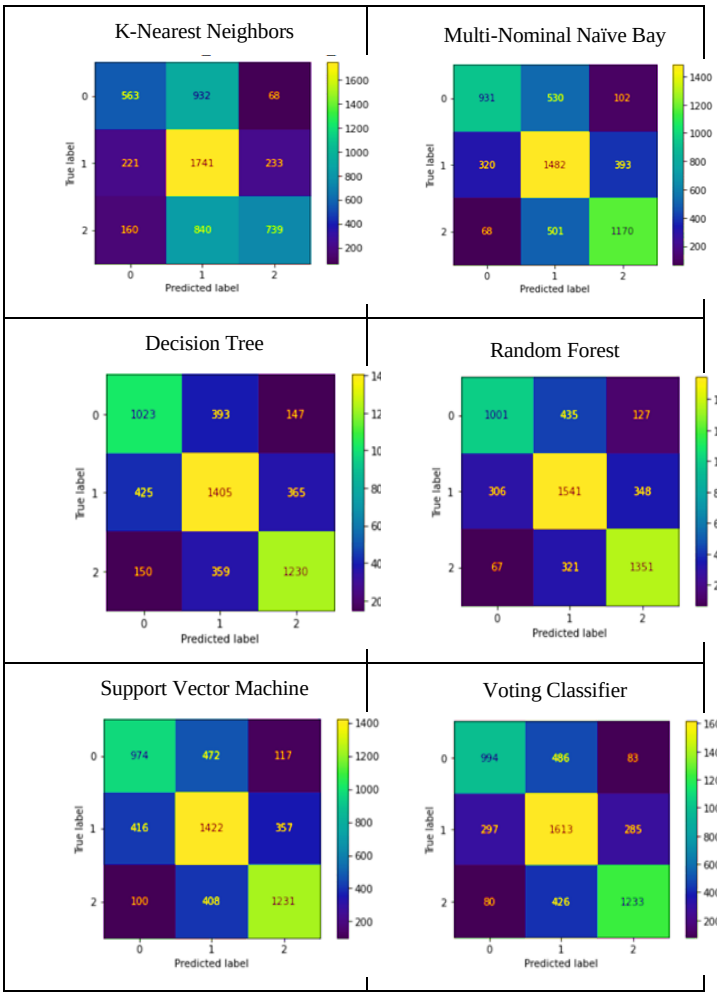

Fig. 4. Confusion matrix.

TABLE III. RECALL, PRECISION, F1 SCORE OF ALL ALGORITHMS

Model	Recall	Precision	F1 scores
K-Nearest Neighbors	0.5536	0.5923	0.5436
Multinomial Naïve Bayes	0.6518	0.6584	0.6321
Decision Tree	0.6655	0.6655	0.6509
Random Forest	0.7082	0.7091	0.6904
Support Vector Machine	0.6598	0.6609	0.6566
Voted Classifier	0.6986	0.7049	0.6921
LSTM	0.8112	0.8232	0.8012
BERT	0.9455	0.9551	0.9499

From the confusion matrix, it can be seen that most of the algorithm is best at classifying neutral tweets and they have a tendency to classify other tweets as neutral also.

The table shows how well different machine learning algorithms performed on a task, based on three metrics: recall, precision, and F1 score. The LSTM and BERT models had the highest scores, indicating they were the most effective algorithms.

B. Proposed Method-based Deep Learning Algorithm (RNN-LSTM)

This method aims to enhance the preceding approach through an exploratory analysis of data to extract features, followed by the application of a deep learning algorithm to classify tweets into positive, negative, or neutral categories. Fig. 5 illustrates the proposed framework for sentiment analysis. The improved method will be applied to the existing data for comparative evaluation with the previous approach, assessing the effectiveness of the proposed method.

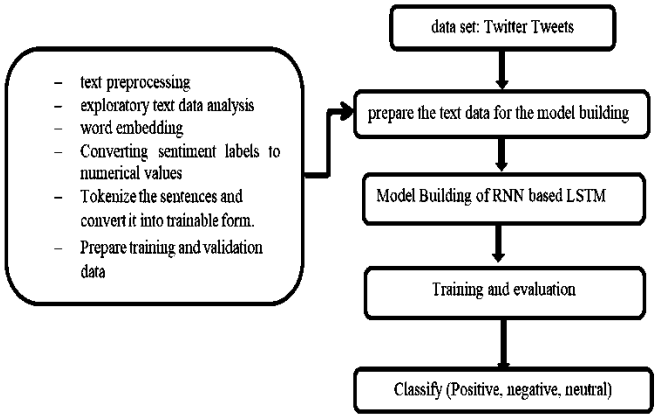

Fig. 5. Framework for proposed model.

C. Algorithms

Step 1: prepare the text data for the model building

1) Pre-processing of text. It represents the initial phase of NLP projects. Some of the pre-processing to use a text cleaning procedure to clean all the content: Stop words, URLs, and punctuation such as! $() *% @, lowercase, stemming, tokenization, and lemmatization have been removed.

2) Exploratory text data analysis is a straightforward yet incredibly informative method. In order to better understand the basic traits of the text data, it comprises (word frequency analysis, sentence length analysis, average word length analysis, distribution of the number of words, etc.). For instance:

- The distribution of the number of words for each sentiment. So that we will use these features in the model training process.
- Distribution of the number of letters for each sentiment.
- The count of the most frequent words in the entire text is essential for reinforcing the analysis in the feature extraction phase.

3) Apply word embedding to improve the model accuracy.

A word embedding is a type of learned representation of text in which words with the same meaning are represented similarly. It is regarded as one of the key developments in deep learning of document and word encoding for challenging natural language processing problems.

Word embedding is a method where individual words are represented as real-valued vectors in a specified vector space. Since each word is assigned to a distinct vector and the vector values are learned similarly to a neural network, the technique is frequently referred to as deep learning. Through the use of word embedding techniques, a corpus of literary works is used to learn a real-valued vector representation for a preset set-sized vocabulary. Other tasks, such as document categorization, include either unsupervised learning using document data or learning in conjunction with a neural network model. The word embedding method was developed using the Gensim library's keyed vectors library.

4) After loading the data, transform the sentiment into a numerical representation. All of the target categorical values must be converted to numerical format because the model will train on numbers and understand numbers better. Therefore, the model will be able to very effectively learn the target. The Python tools offer a number of methods that can be used to convert categorical data into appropriate numerical values; we utilized TensorFlow from the Gensim module**.**

5) Eliminating superfluous columns and compiling a text list with the target sentiment.

6) Tokenize the statements and modify them so that they can be trained.

- Tokenization is the process of breaking up a long block of text into tokens. Words, letters, or sub words can all be tokens in this context. So, there are three main categories of tokenization: word, character, and sub-word (n-gram characters). Take the phrase "Never give up" as an illustration.
- Tokens are most frequently created based on space. The tokenization of the statement yields three tokens, Never-give-up, assuming space as a delimiter. Every token is a word; hence it serves as an illustration of Word tokenization.

7) Prepare the embedding matrix as well as the training and validation data.

- A sample of data is used to unbiased evaluate how well a model fits a training dataset while modifying model hyperparameters is known as a validation dataset. The evaluation becomes more skewed when skill from the validation dataset is added to the model setup.
- A list of all words and their accompanying embeddings is called an embedding matrix. The embedding matrix is prepared by importing the train-test-split from Sklearn.

Step 2: Model Building

LSTMs employ a number of "gates" that regulate how data in a sequence enters, is stored in, and leaves the network. A typical LSTM has three gates: an output gate, an input gate, and a forget gate. Each of these gates is a separate neural network and may be thought of as a filter.

In order to avoid overfitting, the Dropout layer randomly sets input units to 0 with a frequency of rate at each step during training. Keep in mind that the Dropout layer only functions when the model's training is set to true, preventing any values from being dropped during inference.

A dense layer is densely connected to the layer above it is one in which every neuron in the layer is coupled to every other neuron in the layer above. The majority of artificial neural network networks employ this layer.

The values are unrolled starting with the last dimension when using the flatten operator.

Dropout layers: Since a dropout layer doesn't have any weights, it lacks parameters. A dropout layer only increases the likelihood that a neuron won't be tested by 1%. In a dropout layer, nothing more needs to be configured. We successively import layers, constants, dense, embedding, flatten, and initializers from keras in order to build the model.

Step 3: Model Training

The number of samples that must be processed before the internal model parameters are changed is determined by the hyperparameter known as batch size. A for-loop is a type of batch that makes predictions while iterating through one or more samples. At the end of the batch, the predictions are compared to the expected output variables, and an error is then calculated. This issue is fixed using the updated algorithm, for instance by lowering the gradient of the error. The number of epochs hyperparameter controls how many times the learning algorithm will run through the entire training dataset.

For every sample in the training dataset, the internal model parameters changed once throughout an epoch. An era is made up of one or more batches. For instance, a single-batch epoch is described by the batch gradient descent learning process.

Step 4: Model Accuracy

Model accuracy is a measure of the proportion of correct predictions made by a model out of the total number of predictions produced. This metric is commonly used to assess a model's performance, although other metrics may also be considered. We found that this model can get 96% accuracy and this is better than our previous analysis.

Step 5: Plotting and Displaying Results

From Fig. 6, during the sentiment analysis model's training phase, the loss and AUC metrics are shown for the training and validation sets. During the first 10 epochs, the loss is greatly reduced while the precision is noticeably improved.

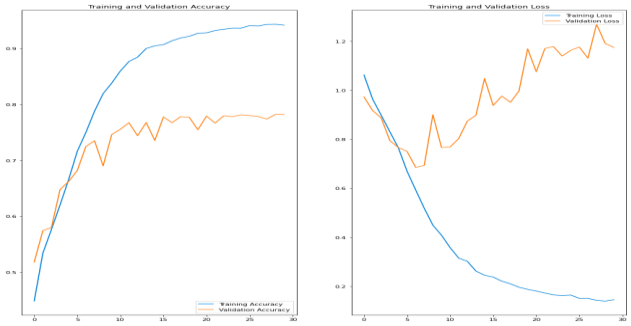

Fig. 6. Plot of results of RNN model.

Step 6: Based on their shared characteristics, various data subsets are segmented through clustering. Python offers a wide array of useful cluster analysis tools, and the choice of strategy depends on the specific task and the nature of the available data. Commonly utilized techniques in Python include Gaussian mixture models, spectral clustering, and K-means clustering. In this scenario, the K-means clustering method is employed. K-means clustering, a type of unsupervised machine learning, exclusively trains on inputs without generating outputs. It identifies distinct clusters of data points that are closest to each other. Once the data is partitioned into clusters, each point is assigned to the cluster whose mean is closest to that specific data point. We employ K-means clustering to create sentiment-based clusters from our data. For the implementation of sentiment analysis on the tweet data, a comprehensive pipeline has been developed. The model assigns different tweets to each of our clusters, encompassing three distinct sentiment labels (see Fig. 7 and 8).

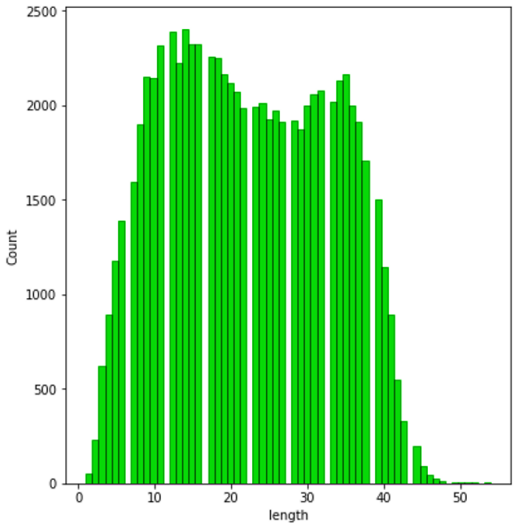

Fig. 7. Positive sentiments tweets.

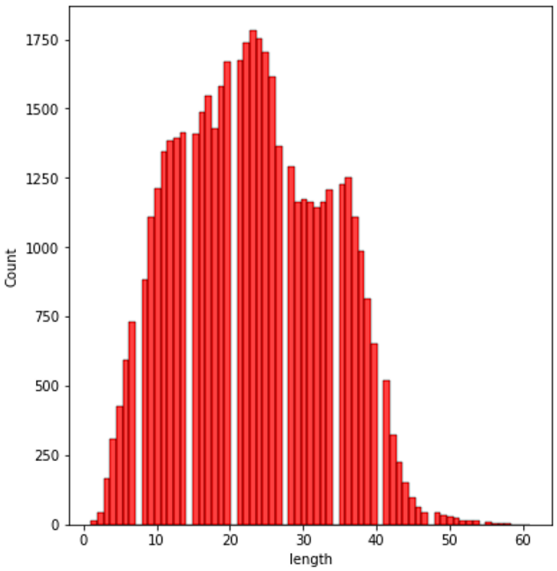

Fig. 8. Negative sentiments tweets.

So, the clustering algorithms assign a numerical value to each of the labels and assign a cluster based on its text context.

D. Summary of Results

The following are the main conclusions from the comparison of machine learning and deep learning algorithms for tweet sentiment analysis:

1) The BERT pre-trained model outperformed the LSTM model, achieving the greatest accuracy of 94.56%. This demonstrates that transfer learning for text classification problems can be quite successful when employing pre-trained language models.

2) With an accuracy rate of 70.82%, the Random Forest algorithm outperformed the other machine learning models. The method used in K Nearest Neighbours has the lowest accuracy, 55.36%.

3) The LSTM model received the greatest ratings for Recall, Precision, and F1, with values of 81.12%, 82.32%, and 80.12%, respectively, suggesting that it performed the best overall.

4) By achieving 96% accuracy, the suggested RNN-LSTM model with word embedding, dropout, and clustering proved the value of deep learning for sentiment analysis.

5) The model performance was evaluated thoroughly and rigorously utilizing confusion matrices, recall, precision, and F1 scores.

In conclusion, for tweet sentiment analysis, deep learning techniques, particularly the LSTM and BERT models, outperformed machine learning algorithms. To create more reliable and generalized models, more study is necessary.

V. Conclusions

Utilizing a range of machine learning and deep learning techniques on Twitter data, our aim was to enhance decision-making and content quality in the dynamic digital media landscape. Key findings highlight BERT's exceptional 94.56% accuracy, showcasing transfer learning's effectiveness. Noteworthy results include the Random Forest algorithm (70.82% accuracy) and the LSTM model, excelling in Recall, Precision, and F1 scores. Deep learning, exemplified by the RNN-LSTM model, demonstrated exceptional potential with a 96% accuracy, establishing LSTM and BERT as tweet sentiment analysis frontrunners. Future research should focus on refining models for real-world applications, exploring optimization, alternative architectures, and dataset expansion. Acknowledging study limitations points toward opportunities for a more nuanced approach within the digital media landscape.

In summary, this study lays the foundation for leveraging advanced sentiment analysis techniques, emphasizing the pivotal role of deep learning models, while recognizing the evolving nature of research in this domain.

An Enhanced Approach for Realizing Robust Security and Isolation in Virtualized Environments

Rawan Abuleil[1], Samer Murrar[2], Mohammad Shkoukani[3]
Department of Computer Science, Philadelphia University, Amman, Jordan[1]
Department of Computer Science, Applied Science Private University, Amman, Jordan[2, 3]

***Abstract*—Transitioning into the next generation of supercomputing resources, we're faced with expanding user bases and diverse workloads, increasing the demand for improved security measures and deeper software compartmentalization. This is especially pertinent for virtualization, a key cloud computing component that's at risk from attacks due to hypervisors' integration into privileged OSs and shared use across VMs. In response to these challenges, our paper presents a two- pronged approach: introducing secure computing capabilities into the HPC software stack and proposing SecFortress an enhanced hypervisor design. By porting the Kitten Lightweight Kernel to the ARM64 architecture and integrating it with the Hafnium hypervisor, we substitute the Linux-based resource management infrastructure, reducing overheads. Concurrently, SecFortress employs a nested kernel approach, preventing outerOS from accessing mediator's memory, and creating a hypervisor box to isolate untrusted VMs' effects. Our initial results highlight significant performance improvements on small scale ARM-based SOC platforms and enhanced hypervisor security with minimal runtime overhead, establishing a solid foundation for further research in secure, scalable high- performance computing.**

***Keywords*—Virtual Machine (VM); High-Performance Computing (HPC); cybersecurity; hypervisor security**

I. INTRODUCTION

Advances in computing technology have ushered in a paradigm shift in how computational resources are deployed and utilized in recent decades. The rapid growth and adoption of virtualization technologies are at the forefront of this transition [1]. By abstracting the physical hardware from the software, virtualization enables the creation of multiple isolated Virtual Machines (VMs) that can run concurrently on a single physical machine, resulting in significant improvements in resource utilization and cost efficiency [1].

However, as with any technology, virtualization brings with it new challenges, most notably in the area of security [1]. The hypervisor, the abstraction layer that allows the creation of VMs, is a lucrative target for attackers [2]. If an attacker successfully compromises the hypervisor, they may gain control of all VMs running on the system, resulting in a significant security breach [3]. Furthermore, while the isolation of VMs from each other and the host system is beneficial for security, it can also be used by attackers to conceal malicious activity [3].

This necessitates the development of enhanced security solutions capable of effectively protecting the hypervisor and the virtual machines that run on it [4]. Several technologies have been developed to this end, providing various mechanisms for securing virtualized environments [4]. Hafnium, ARM TrustZone, and SecFortress, for example, provide unique security solutions that can significantly improve the security of virtualized environments [1, 2, 5].

Hafnium is a microkernel-based VM monitor that provides secure isolation between virtual machines [5]. It enables each VM to run in its own isolated environment, memory-separated from other VMs [5]. This means that even if an attacker gains control of one VM, they cannot access the memory of other VMs [5]. Hafnium also ensures control flow integrity (CFI), which prevents unauthorized changes to a VM's control flow [5]. Fig. 1 depicts the default hafnium system architecture. Hafnium, as illustrated in the diagram, relies on a primary VM to make scheduling decisions and explicitly invoke context switches to secondary VMs via a privileged hyper-call interface.

ARM TrustZone, on the other hand, provides a secure execution environment within a processor that allows sensitive tasks to be run in a separate environment from the rest of the system [1]. ARM TrustZone can protect the system from both external and internal threats by ensuring that only authenticated and verified code is allowed to run within this secure environment [1].

SecFortress approaches security differently. Its goal is to protect the hypervisor by isolating it from the rest of the operating system [2]. SecFortress ensures that an attack on one VM or the outer operating system does not compromise the hypervisor or any other VMs by providing each VM with its own dedicated hypervisor box and preventing direct interaction between the hypervisor and the outer operating system [2]. Fig. 2 presents the architecture of SecFortress.

Each of these technologies offers a distinct solution for securing virtualized environments, but their full potential may be realized only when they are integrated into a unified security framework. The purpose of this paper is to investigate the integration of these technologies into a multi-layered security solution for virtualized environments, with the goal of providing comprehensive protection against both external and internal threats [3].

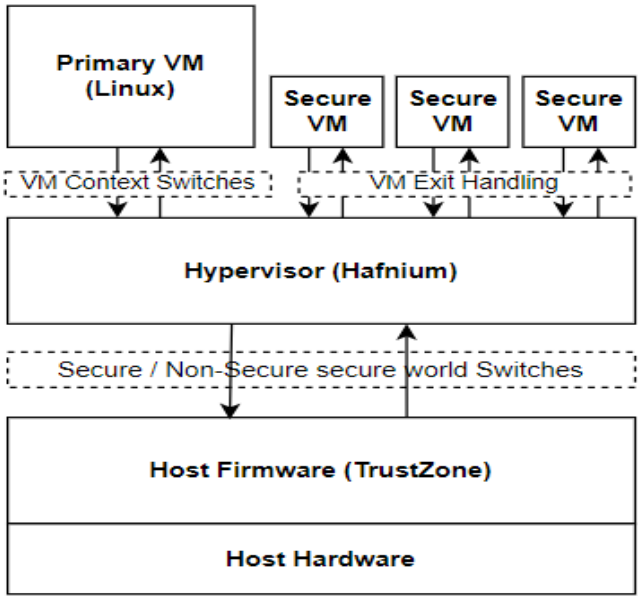

Fig. 1. Hafnium VM configuration.

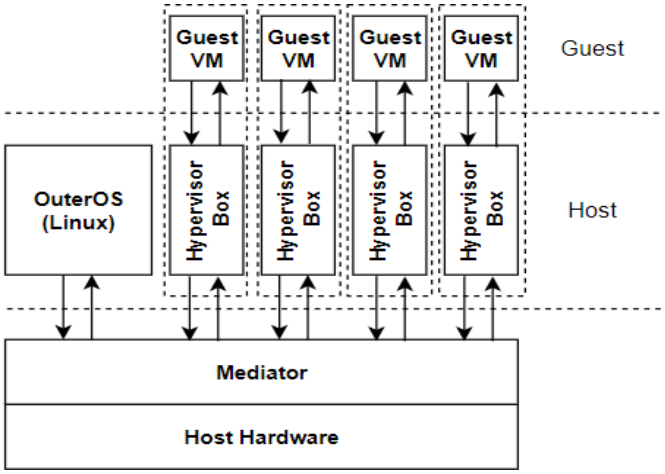

Fig. 2. SecFortress architecture.

The complexities of integrating various security mecha isms, the potential performance overheads of multiple security layers, and the requirement for ongoing updates to address new security vulnerabilities all present significant challenges to the implementation of such a framework. These challenges, however, can be addressed with careful planning and design, paving the way for a more robust and secure computing environment in the virtualization era.

II. Background

Virtualization, enabled by lightweight kernels or hypervisors, has transformed computing by allowing multiple virtual machines (VMs) to run on a single physical host [5]. This operation is enabled and managed by a hypervisor, a key component of the virtualization stack. Despite playing an important role in resource management and VM isolation, hypervisors are vulnerable to security threats from both guest VMs and the host environment [5]. As a result, the design and implementation of secure, lightweight hypervisors are critical to protecting VMs and ensuring system security [5].

The ARM TrustZone is a hardware-based security extension for ARM processors [1], and Hafnium is a lightweight security isolation layer for virtual machines on ARM platforms [5]. The TrustZone technology creates a Trusted Execution Environment (TEE) by partitioning the system into secure and non-secure worlds, whereas Hafnium isolates VM memory and provides a unique security-focused virtualization solution [1]. Hafnium's minimalist design reduces potential attack surfaces, allowing it to be a lightweight hypervisor focused on memory isolation between VM instances while leaving performance and availability guarantees to the host OS [5].

The nested kernel concept takes a different approach to security by embedding a small, lightweight, and isolated kernel within a larger one [2]. This strategy achieves logic isolation by tracking all changes to the virtual-to-physical mapping and removing sensitive instructions from untrusted components, protecting physical memory and lowering the Trusted Computing Base (TCB) in complex systems [2].

Securing our digital infrastructure remains critical in the era of virtualization and cloud computing. Building upon the strengths of Hafnium, ARM TrustZone, and SecFortress, this paper proposes a new multi-layered security strategy to fortify security at both the VM and hypervisor levels, thereby protecting against both internal and external threats. While promising, the combination of these technologies presents certain challenges, including the complexity of managing the various security mechanisms, potential performance overhead due to multiple security layers, and the necessity for continuous updates to counter newly discovered security vulnerabilities [3, 4].

The successful integration of these security solutions into an organization's infrastructure necessitates careful design, comprehensive implementation strategy, and meticulous planning. Despite the obstacles, such an approach holds the potential to significantly enhance the security posture of virtualized and cloud computing environments, making them more resilient against potential attacks [6, 7].

As we forge ahead, extensive testing, performance optimization, and continuous updates will play pivotal roles in overcoming these challenges. By harnessing the unique advantages provided by Hafnium, ARM TrustZone, and SecFortress, we can lay the groundwork for a more secure, robust, and resilient virtualized environment. The path to achieving this goal is strewn with difficulties, but by working collaboratively, we can hope to stay one step ahead of evolving cybersecurity threats and secure our virtualized infrastructure effectively [7].

III. Related Works

Various approaches have been proposed to secure the run-time of hypervisors. HyperLock and DeHype, for instance, deconstruct KVM by assigning a separate isolated hypervisor instance to each VM, similar to the isolated context each VM has in SecFortress [4]. However, unlike SecFortress, they don't protect the hypervisor against a compromised host OS. SecFortress also differs from systems like MultiHype, which supports running multiple hypervisors on a single physical

platform, in that it ensures a smaller Trusted Computing Base (TCB) and stronger isolation by creating a single hypervisor box for each VM [8].

Nexen, SecVisor, and SeL4, along with SecFortress, utilize the nested kernel to reconstruct the virtualization platform [9]. However, they have their limitations; Nexen doesn't consider the security vulnerabilities in its shared service domain, SecVisor focuses on kernel integrity protection within guest VMs rather than isolation among different VMs, and SeL4, being a formally verified microkernel, doesn't include common OS components [9]. Another memory isolation implementation, Hyper Wall, requires support from specific hardware like FPGA, contrasting with SecFortress's ability to be deployedon commercial x86 platforms [9].

Hardware-based defense technologies have also emerged. Intel TDX, for instance, isolates VMs from the hypervisor by adding a secure arbitration mode [10]. AWS Nitro Enclaves and Arm CCA offer different approaches to creating isolated VM execution environments [11]. However, these systems either focus on protecting the guest from an untrusted hypervisor or applications rather than the entire VM, which differs from SecFortress's target of bidirectional isolation protection between VMs and the hypervisor.

In this paper, we have furthered the research into secure HPC OS/Rs by presenting preliminary results of our approach and an initial proof-of-concept implementation [12]. We have identified several potential research directions, such as evaluating our approach on more realistic systems and workloads, designing I/O mechanisms that maintain secure system isolation without imposing significant performance overheads, and investigating dynamic partitioning approaches for secure partitions and VM images [12].

Also, while we have used the Hafnium hypervisor as a starting point for secure virtualization in HPC, we are still evaluating its long-term suitability [12]. The necessary modifications to support HPC workloads, the need for a potential new hypervisor architecture tailored to HPC environments, and the upcoming ARM platform (ARMv9) which introduces significant security, isolation, and trusted computing features, are all factors that could impact the direction of future researchin this area [11, 12].

IV. Proposed Model

A. Design

The TrustZone-Assisted SecFortress solution is a pain stinkingly designed architecture aimed to improve security in a virtualized environment. The innovative design combines TrustZone technology's robust isolation capabilities with the SecFortress hypervisor's flexible and comprehensive security services. As a result, hypervisors and their associated virtual machines benefit from a powerful combination of hardware and software-enforced security mechanisms.

The secure boot mechanism is at the heart of our design. We ensure a trustworthy startup process by utilizing Trust- Zone technology, which allows only authenticated software to launch. This significantly reduces potential threats from unauthorized or malicious software, allowing the system to operate in a trusted state from the start.

Our solution embeds a trust anchor within TrustZone's secure world to establish a root of trust within the system. This provision has important implications for improving hypervisor security and supporting other security functions such as cryptographic key management and secure storage. It ensures a higher level of trust in the system, essentially laying the groundwork for all subsequent security protocols to operate on.

Our design addresses the difficult challenge of securely handling interrupts and I/O operations. The SecFortress solution includes a mediator component that acts as a go-between for the hypervisor and the rest of the system. The mediator significantly reduces potential vulnerabilities that could be exploited during these operations by managing and securely handling interrupts and I/O operations.

Inter-VM communication can be a security risk if not properly managed. Our design ensures secure communication between VMs via the SecFortress solution's mediator. This intermediary validates each communication request to ensure it comes from a reliable source before it reaches its intended destination. This feature prevents unauthorized access and potential data leaks, thereby strengthening the system's overall security.

To provide a secure environment for sensitive processes and applications, our solution design makes use of Trust- Zone's hardware-based isolation capabilities to create a secure execution environment within the hypervisor. This strategic inclusion effectively insulates these processes from potential threats in the 'normal' world, thereby protecting the integrity of our secure world.

The comprehensive isolation of hardware and software components is a critical aspect of our design. This is accomplished through TrustZone's hardware-level isolation, which creates two distinct environments: one for the hypervisor and one for the VMs and outerOS. This hardware isolation is supplemented by the SecFortress's mediator's software-level isolation. As a result, our design fortifies the hypervisor's shell, effectively isolating it from the rest of the system and potentialattack vectors.

Our design also prioritizes system integrity and resilience in the face of a variety of potential attacks. TrustZone technology protects the integrity of the hypervisor by preventing unauthorized changes to its code. SecFortress' security services, which validate the integrity of data and communication channels within the system, add to this. In terms of resilience, the secure boot feature ensures that the system starts up in a trusted state, while the isolation provided by TrustZone and the mediator makes the system difficult to compromise, increasingits resistance to potential threats.

The way we design prioritizes secure communication and data handling. SecFortress' mediator is at the heart of all communication between the VMs, the outerOS, and the hypervisor, validating the origin and destination of each communication request. TrustZone technology protects data integrity and confidentiality by isolating sensitive data within a

secure world. This two-pronged approach significantly reduces the risk of data exposure or tampering from malicious processes.

The TrustZone-Assisted SecFortress solution design promotes adaptability. The solution is designed to be compatible with a wide range of hardware platforms and hypervisors with minimal modifications, allowing it to be widely deployed across a wide range of systems. The design's scalability, which is further enhanced by its modularity, enables it to protect systems of various sizes, from individual servers to large data centers, without compromising security.

The TrustZone-Assisted SecFortress solution is also optimized for efficiency and performance. With the SecFortress solution's mediator minimizing overhead in handling communication between the VMs, the outerOS, and the hypervisor, and TrustZone ensuring efficient use of hardware resources, optimal system performance is guaranteed.

The solution design incorporates built-in fail-safe mechanisms to ensure that the system remains secure even if a component fails. For example, if the mediator component detects an error, it activates built-in fail-safe routines to prevent a system-wide failure. Similarly, TrustZone technology ensures that any breaches in the normal world do not impact the secure world, adding an extra layer of security.

The solution is designed to work seamlessly with a wide range of systems, taking into account both modern and older systems that may not have built-in security measures. It is compatible with various system architectures and hypervisor types, giving it versatility in securing various systems. The design also includes recovery and maintenance measures capable of detecting potential security threats, initiating protective actions, and allowing for easy system updates and patches. This not only ensures long-term security but also improvesthe system's overall security capabilities.

The TrustZone-Assisted SecFortress solution is designed for the future, combining scalability, robustness, compatibility, efficiency, and fail-safe mechanisms. Its comprehensive and adaptable design supports a variety of system architectures and hypervisors, as well as a wide range of virtual machines and can handle increasing load and traffic. Because of its adaptability, it is an effective security solution for complex virtualized environments. Furthermore, the solution reduces costs while maintaining security by leveraging TrustZone's existing hardware security features and SecFortress's minimalistic design. Also, our design considers future developments in the cybersecurity landscape. It is easily upgradable to handle new types of security threats or to incorporate advancements in hypervisor and virtualization technology. This foresight distinguishes our solution, making it a comprehensive, robust, and scalable option for securing hypervisor environments today and in the future.

The TrustZone-Assisted SecFortress solution is divided into several layers or levels, as illustrated in Fig. 3, and are as follows:

Level 1 - Hardware Layer: This includes the actual hardware platform. At this level, the TrustZone technology creates two distinct environments: the secure world' and the 'normal world'. The most sensitive processes and data reside in the secure world.

Level 2 - TrustZone Technology: TrustZone technology primarily operates at this level, providing fundamental hardware- based isolation capabilities and establishing a root of trust within the system. It also manages the secure boot mechanism, which ensures that only authenticated software can run.

Level 3 - Mediator Component: At this level, the mediator component operates, providing a layer of software-based isolation on top of TrustZone's hardware-based isolation. It also handles interrupts, I/O operations, and inter-VM communications securely, acting as a liaison between the hypervisor and the rest of the system.

Level 4 - Hypervisor: At this level, the SecFortress hypervisor operates. It communicates directly with TrustZone technology to take advantage of hardware-based isolation capabilities for enhanced security. It is also the location of the secure execution environment for sensitive processes and applications.

Level 5 - Virtual Machines (VMs) and outer OS/Primary VM using Kitten lightweight kernel: At this level, virtual machines and the outer / Primary VM operating system operate. They communicate with the hypervisor and the mediator, enabling secure communication and operations.

These components interact in a variety of ways to form a comprehensive, secure, and adaptable system. TrustZone technology, for example, serves as the foundation for system security by creating a secure execution environment and managing the secure boot process. The SecFortress hypervisor, in turn, relies on this secure environment to run VMs and manage their communication via the mediator component.

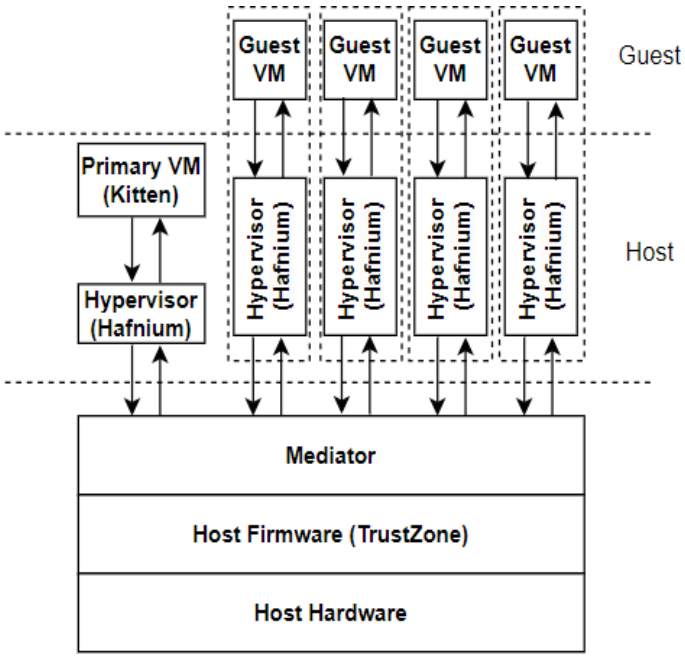

Fig. 3. Proposed model trustzone-assisted secfortress solution architecture.

B. Implementation

The implementation of the TrustZone-Assisted SecFortress solution begins with configuring the ARM-based System-on-a-Chip (SoC) to use TrustZone technology. This process begins with the system boot-up, during which the Secure World is configured before any other system components are initialized.

To establish a clear demarcation between the Secure and Non- Secure Worlds, the memory layout and IRQ controllers must be carefully adjusted. TrustZone's Monitor Mode is set up as an extra execution level within the Secure World to host the mediator software, which manages secure transitions between the two worlds.

After properly configuring the Secure and Non-Secure Worlds, we proceed to integrate the Hafnium hypervisor into the system's Non-Secure World. The isolation capabilities of Hafnium are critical to the system's security. It is intended to create isolated partitions for each virtual machine (VM), effectively isolating them from one another and from the hypervisor itself. The configuration of Hafnium is meticulously adjusted during this phase to manage VMs, enforce memory access policies, and control inter-VM communication. Fig. 4 depicts the memory access view of each SecFortress component. For example, the left-most large box represents the VM's memory access view. That is, each VM has complete access to its own memory but no access to the memory of others. The mediator has access to all memory and controls the page tables to determine the memory view of each component. Illegal memory accesses across components will result in pagefaults, which will be detected by the mediator.

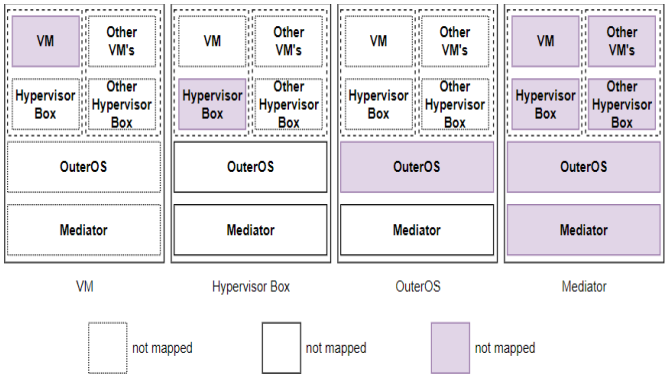

Fig. 4. Memory access view of VM, Hypervisor Box, outerOS, and mediator.

We integrate the Kitten lightweight kernel into the Hafnium hypervisor after it has been established. The Kitten kernel is the foundation of our hypervisor layer. It is designed to be extremely efficient in high-performance computing environments. The integration of the kernel entails prioritizing the optimization of memory management, task scheduling, and I/O operations, which improves overall system performance.

We begin development of the mediator software after successfully integrating the Hafnium hypervisor and Kitten kernel. The use of programming languages compatible with the ARM architecture and the TrustZone environment is required for this task. Memory protection, instruction protection, and control flow management are among the critical security services enforced by the mediator software. It is also intended to intercept and manage VM exits, ensuring safe context switchesbetween system components.

The addition of VM image integrity checks and encryption measures improves system security even further. Before each startup, VM image integrity checks are performed to ensure that the VM images have not been tampered with. Furthermore, the VM images are encrypted with strong encryption algorithms, ensuring the data stored within the VMs' security. The cloud provider's key management service secures the encryption keys.

We chose to implement software updates for the TrustZone- Assisted SecFortress virtualization layer via offline install packages in order to maintain system security. This method gives us more control over the software versions that are running on the system. System administrators install these updates manually, lowering the risk of online threats.

We employ several strategies to reduce performance overhead, ensuring that the system remains operational and does not impair overall performance. The use of a nested MMU extension to create memory protection domains, efficient memory management with the mediator's internal allocator, hard coding of sensitive instruction entry points during system bootup, and the minimization of memory mapping updates within the hypervisor box are among these strategies [13].

Implementing the TrustZone-Assisted SecFortress solution is a meticulous process that includes system initialization, hypervisor setup, kernel integration, mediator software development, VM security measures, software update procedures, and performance overhead reduction strategies. The end result of this comprehensive implementation process is a robust and secure virtualization environment suitable for secure cloudcomputing applications [13, 14].

V. Results and Evaluation

This section describes the TrustZone-Assisted SecFortress solution's results thorough evaluation and security analysis, including protection against mediator tampering, the level of isolation and confidentiality, denial-of-service (DoS) mitigation, performance assessment, and the results of practical attack scenarios.

A. Security Analysis

The TrustZone-Assisted SecFortress solution's comprehensive security analysis begins with protection against mediator tampering. Because the mediator plays such an important role in the system, its integrity is critical. As a result, its security is ensured by secure boot and code integrity checks during system boot, which is a process that protects the mediator's code by write-protecting it, preventing attackers from tampering with it. This writes protection extends to dynamic checks within non-TCB components, protecting sensitive instructionsand code from bypass attacks.

Effective isolation and confidentiality are critical security objectives of the TrustZone-Assisted SecFortress solution, which it achieves by isolating hypervisor boxes from the

outerOS and other hypervisor boxes. Memory access control and paging mechanisms are used to restrict access to sensitive memory regions. OuterOS is prevented from accessing the memory of the hypervisor boxes by unmapping hypervisor box-related memory regions in the kernel master page table. Additionally, zeroing physical pages before assigning them to hypervisor boxes strengthens the integrity defense against attacks.

In terms of Denial-of-Service (DoS) attacks, the TrustZone-Assisted SecFortress solution defends itself by meticulously checking the memory and registers of guest VM states before returning control to them. While this comprehensive measure reduces the possibility of crashes or interference with other VMs by addressing any state mishandling, it does not completely prevent DoS attacks from originating from the host.

B. Performance Evaluation

A performance evaluation was carried out to determine the overhead and efficiency of the combined solution. The solution was tested using various performance benchmarks on Pine A64-LTS SBC and Ubuntu 18.04.5 with Linux 5.2 for Intel VT platforms. The benchmarks focused primarily on CPU and memory performance, with consistent results demonstrating minimal overhead for virtualization and secure isolation. Even when lightweight kernels and ARM TrustZone-based mechanisms were used, there was no significant performance degradation.

A series of tests, including Stream and Random-Access micro-benchmarks, were used to assess memory and I/O performance. These tests revealed that Hafnium and ARM TrustZone introduced minor overhead in some scenarios, but overall performance was satisfactory.

The combined solution was then put through its paces with application performance benchmarks like the HPCG mini-app and a subset of the NAS Parallel Benchmark suite. These tests demonstrated that the solution was capable of running a full mini-app benchmark with minimal overhead and of providing secure isolation for HPC applications and workloads.

C. Practical Attack Evaluation

The TrustZone-Assisted SecFortress solution was subjected to realistic attack scenarios in order to validate the effectiveness of the security measures. CVE analysis for Linux/KVM vulnerabilities was included in these scenarios. The evaluation revealed that the security mechanisms of the solution were effective in preventing privilege escalation, information leakage, memory corruption, and denial-of-service attacks from compromised outerOS or malicious VMs. In essence, the combined solution's isolation was critical in mitigating the impact of compromised components and safeguarding sensitive data andmemory regions.

Finally, the TrustZone-Assisted SecFortress solution combines lightweight kernels, Trusted Execution Environments (TEEs), the Hafnium hypervisor, and ARM TrustZone to achieve robust security isolation in virtualization environments. It effectively addresses both security and performance concerns, thereby assisting in the development of more secure and efficient virtualized systems. Comprehensive security and performance evaluations confirm its resistance to common attacks and ability to handle high-performance computing workloads with minimal overhead. As virtualization technology evolves, it promises to be a solid foundation for secureand high-performance virtualization environments.

VI. Conclusion

In this paper, we presented an enhanced to secure hypervisor runtime and a new use case for Lightweight Kernels as resource management services in securely isolated HPC systems. As part of this effort, we integrated the ARM64-ported Kitten LWK with the Hafnium hypervisor in our SecFortress solution to support secure virtual machine instances on a compute node. SecFortress partitions the virtualization platform strategically into a trusted mediator, an isolated outerOS, and multiple restricted hypervisor box instances, improving security isolation in high-performance computing platforms. The new approach prevents the outerOS from accessing the hypervisor's memory, with each hypervisor box instance limited to the least amount of memory access. As a result, even if one instance is compromised, the integrity and confidentiality of other instances are not jeopardized. We have provided an initial proof of concept implementation and preliminary evaluation, which show that our approach has no significant performance overheads on a variety of HPC benchmarks. SecFortress' experimental results show that it can defeat exploits against the host OS and VMs with negligible performance overhead, implying that SecFortress could be an effective solution for improving both virtual machine security and performance. This work has also identified a number of future challenges and made a compelling case for security isolation and trusted computing as key features of next-generation HPC platforms. Fully supporting security isolation in a scalable and performant manner will most likely pose a significant challenge for HPC OS/R architectures, necessitating future research. Our integrated solution, we believe, provides a promising foundation for the evolution of more secure and efficient virtualized systems.

Efficient Evaluation of SLAM Methods and Integration of Human Detection with YOLO Based on Multiple Optimization in ROS2

Hoang Tran Ngoc*, Nghi Nguyen Vinh, Nguyen Trung Nguyen, Luyl-Da Quach
FPT University, Can Tho 94000, VietNam

***Abstract*—In the realm of robotics, indoor robotics is an increasingly prominent field, and enhancing robot performance stands out as a crucial concern. This research undertakes a comparative analysis of various Simultaneous Localization and Mapping (SLAM) algorithms with the overarching objective of augmenting the navigational capabilities of robots. This is accomplished within an open-source framework known as the Robotic Operating System (ROS2) in conjunction with additional software components such as RVIZ and Gazebo. The central aim of this study is to identify the most efficient SLAM approach by evaluating map accuracy and the time it takes for a robot model to reach its destinations when employing three distinct SLAM algorithms: GMapping, Cartographer SLAM, and SLAM_toolbox. Furthermore, this study addresses indoor human detection and tracking assignments, in which we evaluate the effectiveness of YOLOv5, YOLOv6, YOLOv7, and YOLOv8 models in conjunction with various optimization algorithms, including SGD, AdamW, and AMSGrad. The study concludes that YOLOv8 with SGD optimization yields the most favorable outcomes for human detection. These proposed systems are rigorously validated through experimentation, utilizing a simulated Gazebo environment within the Robot Operating System 2 (ROS2).**

I. Introduction

With the rapid advancement of Artificial Intelligence (AI) and the continuous evolution of sensor technologies, coupled with the introduction of the Robot Operating System (ROS) and its latest iteration, ROS 2 [1], the development of indoor robots has become more accessible than ever before. Mobile robots have yielded substantial economic benefits across various sectors, including industry, warehousing, and logistics [2]. Notably, robots are no longer confined to industrial applications; they are increasingly being deployed in the realm of mental healthcare, where they assist therapists in caring for the elderly and children struggling with depression [3]. In light of these developments, our objective is to create a pet robot designed to serve the purposes mentioned above. Within the realm of developing such a robot, we consider two fundamental tasks of paramount importance: Navigation and Human Detection. This article aims to compare different methods and put forth the most optimal approaches for accomplishing these critical tasks.

Sensors play a crucial role in how robots and autonomous vehicles perceive their surroundings. The choice and installation of sensors have a significant impact on the specific results of observation and also influence the complexity of SLAM problems. Based on the primary type of sensor used, SLAM can be categorized into Visual-SLAM and LiDAR-SLAM. Visual SLAM remains a particularly challenging task due to inherent difficulties. Moreover, vision cameras struggle to extract features from texture less areas, which limits the applicability of Visual SLAM. On the other hand, LiDAR SLAM primarily relies on LiDAR technology for environmental sensing. The relative movement and pose changes of the laser radar are determined by comparing point clouds captured at different moments. LiDAR SLAM offers advantages in terms of stability, simplicity, precise map data, and lower computational requirements compared to Visual SLAM. Numerous investigations have explored LIDAR-SLAM techniques in the literature [4]-[9].

This research primarily centers on evaluating Slam techniques through the utilization of ROS2, with a primary emphasis on assessing their performance based on the resulting maps. The evaluated methods fall within the category of 2D LIDAR Slam techniques designed for indoor settings, including GMapping, Cartographer SLAM, and Slam-Toolbox. In addition, we have integrated a LIDAR-SLAM technique with a human detection system. The methods we evaluated and tested for this integration include YOLOv5 [10], YOLOv6 [11], YOLOv7 [12] and YOLOv8 [13], using multiple collected datasets. Ultimately, this research aims to develop an optimized system for indoor robotic operations, ensuring precise localization and robust human detection capabilities within indoor spaces. This system is designed to facilitate avoidance maneuvers and ensure safety during robot operations.

II. Related Work and Our System

A. Related Work

Recent advancements in the field of mobile robot navigation have enabled robots to operate effectively in various environments, including warehouses, retail stores, and crowded pedestrian areas. A plethora of navigation solutions have been proposed to address these challenges [14]. One of these solutions introduced a navigation system and environmental representation that utilized 3D data obtained from tilting 2D laser scanners for navigation. Initially, conventional methods such as A* and DWA were employed

*Corresponding Author.

for path planning and obstacle avoidance. However, the prevalence of cost-effective 3D depth cameras and laser scanners has gradually overshadowed the use of tilting 2D laser scanners. Some aspects of these approaches were customized to account for the specific geometry, limited accuracy, and characteristics of 2D tilting laser setups. Furthermore, the emergence of sparse multi-beam laser scanners has rendered traditional raycasting methods ineffective in clearing free space, especially in dynamic environments. In response to this challenge, Sparse Traversability Volume (STVL) has emerged as a scalable alternative suitable for various types of sparse and long-range sensors, replacing traditional techniques effectively [15].

The Robot Operating System (ROS) Navigation has historically been one of the most popular navigation solutions built on top of ROS. However, with the introduction of ROS2, Navigation2 was developed as a successor to build upon the success of ROS Navigation. Navigation2 incorporates a behavior tree for orchestrating navigation tasks and utilizes novel methods designed to handle dynamic environments, making it applicable to a wider range of modern sensors. SLAM is a critical technology in mobile robotics, allowing robots to map unknown environments while simultaneously determining their own position based on the created map. Several SLAM algorithms have been proposed, categorized into two groups: earlier algorithms employing Bayes-based filter approaches like GMapping [16], and newer ones using graph-based methods such as Cartographer [17], Karto SLAM [18], and Slam Toolbox [19].

For our human detection task, we have chosen to leverage the YOLO (You Only Look Once) framework for several compelling reasons. Among the numerous object detection algorithms available, YOLO stands out due to its exceptional combination of speed and accuracy. It excels in rapidly and accurately identifying objects within images, making it an ideal choice for real-time applications. YOLO has gained prominence as a central system for real-time object detection in various domains, including robotics, autonomous vehicles, and video monitoring, demonstrating its reliability and versatility in a wide range of applications [20]. The YOLO family of object detection models has undergone a series of iterations, evolving from the original YOLOv1 to the most recent YOLOv8. Each iteration has built upon the foundation of its predecessors, aiming to address limitations and enhance overall performance in object detection tasks. However, in our research paper, we will specifically focus on evaluating human detection using YOLO versions ranging from YOLOv5 to YOLOv8. This selective approach allows us to assess the advancements and capabilities of these more recent YOLO iterations in the context of human detection, which is a pivotal aspect of our study.

B. Our System

In this study, we are using an open-source robotic middleware ROS 2. Inheriting from ROS, the libraries provided by ROS 2 used in this project make robotic programs and development more flexible and easier. ROS 2 also offers the capability to obtain hardware abstractions of the robot model, encompassing sensors, motors, and actuators which can be used for navigation and are accessible through URDF and XACRO files. Additionally, we utilize other open-source software in conjunction with ROS 2, namely Gazebo and RVIZ 2. Gazebo functions as simulation software, enabling the virtual simulation of robots through the use of plugins. This allows us to construct a simulated environment represented as URDF and WORLD files, facilitating the simulation of the robot within the Gazebo world, as depicted in Fig. 1. In this article, the robot model used is a mobile robot with two wheels, equipped with several sensors including a 360° 2D LIDAR and a camera. These sensors play a crucial role in tasks like navigation and human tracking. The detailed illustration of this robot model is shown in Fig. 2. RVIZ 2 serves as a data visualizer tool for robot data, presenting various data types, including laser scans, maps retrieved from the map server, and grid displays. As well as ROS, RVIZ 2 also provides navigation goals and poses estimation functionalities, which are inherited from RVIZ in order to accomplish the Robot's navigation in the ROS 2 virtual environment.

In order to make the autonomous robot navigate in its environment safely without encountering collisions with either static or moving obstacles, the assistance of SLAM is required. Different SLAM algorithms can be used for mapping such as Karto SLAM, Cartographer SLAM, Gmapping SLAM, and Hector SLAM, but in this paper, we want to compare the package provided by ROS 2 (SLAM_toolbox).

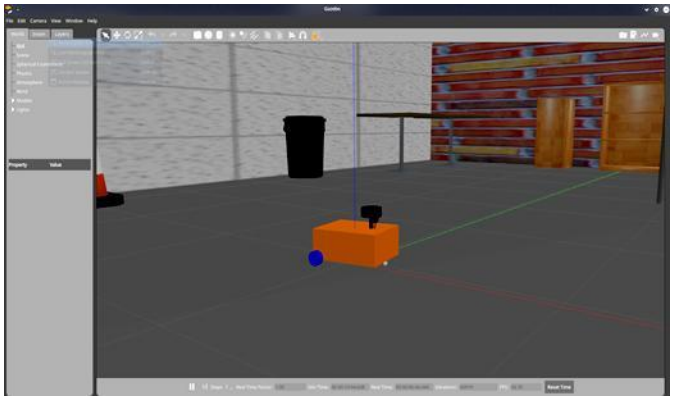

Fig. 1. Robot model in Gazebo virtual world.

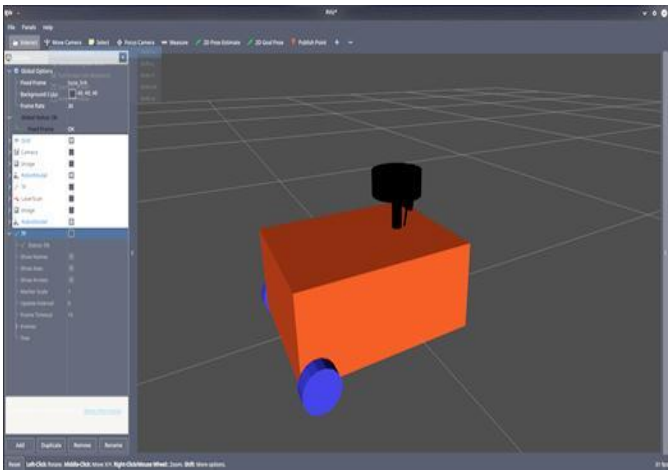

Fig. 2. Robot description on Rviz 2.

III. METHODOLOGY

A. LIDAR 2D SLAM Algorithms

In this section, an analysis of SLAM algorithms in the ROS2 environment will be conducted. Among the available open-source laser scanner SLAM algorithms, Cartographer is a graph-based algorithm that manages a graph representing robot poses and features. It offers resource efficiency, especially for constructing large-scale maps. It consists of a front-end responsible for tasks like scan matching, trajectory building, and submap generation, as well as a back-end that handles loop closure procedures, using the Google Ceres graph solver. Cartographer provides a pure localization mode for users with existing maps and supports data serialization for storing processed sub-maps. However, it has encountered challenges, such as the discontinuation of maintenance and support by Google, leading to its abandonment. This algorithm divides a large single map into smaller sub-maps by integrating two separate 2D SLAM techniques. One method focuses on local operations, while the other deals with global aspects, and both employ a LiDAR sensor. These two methods are optimized independently. In the local SLAM process, sub-maps are created by collecting and arranging data, involving the alignment of multiple scans relative to the initial position. These sub-maps are grids with defined resolutions, with each grid point indicating occupancy probability based on prior measurements updated as new sub-maps are generated. An algorithm optimizes sub-map positioning for alignment, aiding extrapolation. The second part, global SLAM, leverages feedback from these sub-maps, which are associated with robot positions. This enhances maps and reduces accumulated SLAM errors, a process known as loop closure [24]. The well-known optimization technique called Spare Pose Adjustment (SPA) [23] [38] is utilized in Cartographer SLAM, and a map-scanner is activated whenever a sub-map is generated to close the loop and incorporate that sub-map into the graphic. Two formulas are provided to determine whether a cell is classified as busy, empty, or transitioning to an empty state within a map cell, enhancing comprehension.

$$M_{new}(cell) = F^{-1}(F(M_{old}(cell)\ F(f_{hit}))) \quad (1)$$

where: $M_{old}(cell)$ is the old probability of the cell which could be an error, f_{hit} is the probability function that represents a map cell is busy, and $F = \frac{F}{1-F}$.

Scan matching process goes through a minimization of the following function:

$$\arg_{\delta}\min \sum_{k=1}^{K} (1\text{-}M_{smoothen}(T_{\delta}s_k))^2 \quad (2)$$

where, $M_{smoothen}$ represents the value of a cell that has been smoothed using its neighboring values, s_k denotes the laser scan reading involves to the cell, T_{δ} is the matrix transformation that displaces the point h_k to δ, and δ is the posture vector $(\delta_x, \delta_y, \delta_\theta)$.

Additionally, Cartographer may struggle to create suitable maps for annotation and localization when integrated with other robotic platform localization software that lacks exceptional odometry. Its complexity can hinder modifications and resolution of seemingly straightforward issues, limiting its suitability for many applications.

GMapping Slam is widely used within the Robot Operating System (ROS) and stands out for its frequent adoption. GMapping employs the Rao Blackwellized Particle Filter (RBPF) [21] technique for map generation. However, it's important to note that GMapping has limitations when applied to large environments and struggles with precise loop closure in industrial-scale spaces. The idea of the RBPF for SLAM, first introduced by Murphy [22] in 1999, is to estimate the joint posterior $p(x_{1:t}, m \mid z_{1:t}, u_{1:t-1})$ of the map where m is the map and the trajectory $a_{1:t} = a_1, \ldots, a_t$ of the robot. The $z_{1:t} = z_1, \ldots, z_t$ is the given observations and the odometry measurements is $o_{1:t-1} = o_1, \ldots, o_{t-1}$. These both can be obtained by the robot's data. The fully RBPF factorization for SLAM is representing below:

$$p(m, a_{1:t} \mid z_{1:t}, o_{1:t-1}) = p(m \mid a_{1:t}, z_{1:t})\ p(a_{1:t} \mid z_{1:t}, o_{1:t-1}) \quad (3)$$

Nonetheless, filter-based approaches such as GMapping encounter difficulties when attempting to achieve seamless reinitialization across multiple sessions.

The SLAM Toolbox is a versatile mapping solution that efficiently covers large areas using standard mobile Intel CPUs commonly found on robots. It simplifies space mapping through automation and supports session serialization, enabling users to easily improve existing maps. What makes it unique is its preservation of complete raw data and pose-graph, enabling various innovative tools like manual pose-graph manipulation and kinematic map merging. The SLAM Toolbox provides three primary operational modes: synchronous mapping for high-quality maps, asynchronous mapping for real-time performance, and pure localization for adapting to dynamic environments.

Significant enhancements to the OpenKarto SLAM library [19], [38] have boosted its speed and adaptability, making it a valuable tool for robot navigation and mapping tasks. The SLAM Toolbox has been effectively integrated, tested, and utilized on diverse robotic platforms around the world by both professionals in the industry and researchers. It serves as the default SLAM solution in ROS 2, replacing GMapping. Incorporated into the ROS 2 Navigation2 project, it enables real-time positioning in changing environments, facilitating autonomous navigation. Its user-friendly interface empowers both experts and non-experts to map extensive spaces in real time, establishing its significance in robotics and autonomous system development.

To evaluate a Slam algorithm, two criteria such as the accuracy of the generated map based on comparing the ground truth and the map generated or its feature locations, and the time taken for the robot to navigate and get to its destination for each environment are considered. In order to investigate the map's quality, we created three different simulation environments on the Gazebo simulator, and we added the robot model to those simulation worlds that we created. The robot model has laser scanner sensors (LIDAR 360) that supply data crucial for map creation when implementing three

SLAM techniques in RVIZ 2. The data were transmitted to the scan topic for the map, to generate and then visualize it on RVIZ 2; afterward, map topics were activated. The higher the map fits the ground truth the better the map quality. Fig. 3 shows RVIZ 2 and Gazebo when launching our virtual world from their respective directories. In Fig. 4, we illustrate three maps generated by three different SLAM methods within a simulated environment.

These maps are saved in PGM file format and have been compared with ground truth data. To create these maps, the robot navigated through the simulated environment using a control framework called "ros2_control," which is a reimplementation of the "ros_control" framework used in ROS.

After mapping each environment using different SLAM techniques with their default parameters, the resulting maps were saved as YAML files. Notably, we observed that the SLAM_toolbox method exhibited higher accuracy. The map generated by this SLAM method had less noise and better alignment with the ground truth. Detailed evaluations of these SLAM methods will be discussed further in the experimental section.

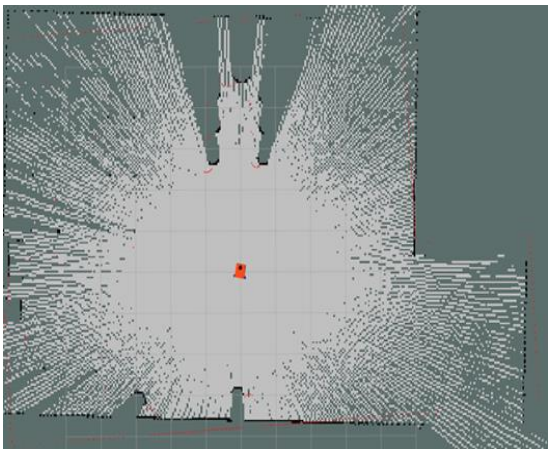

Fig. 3. Robot model creating the map of the environment.

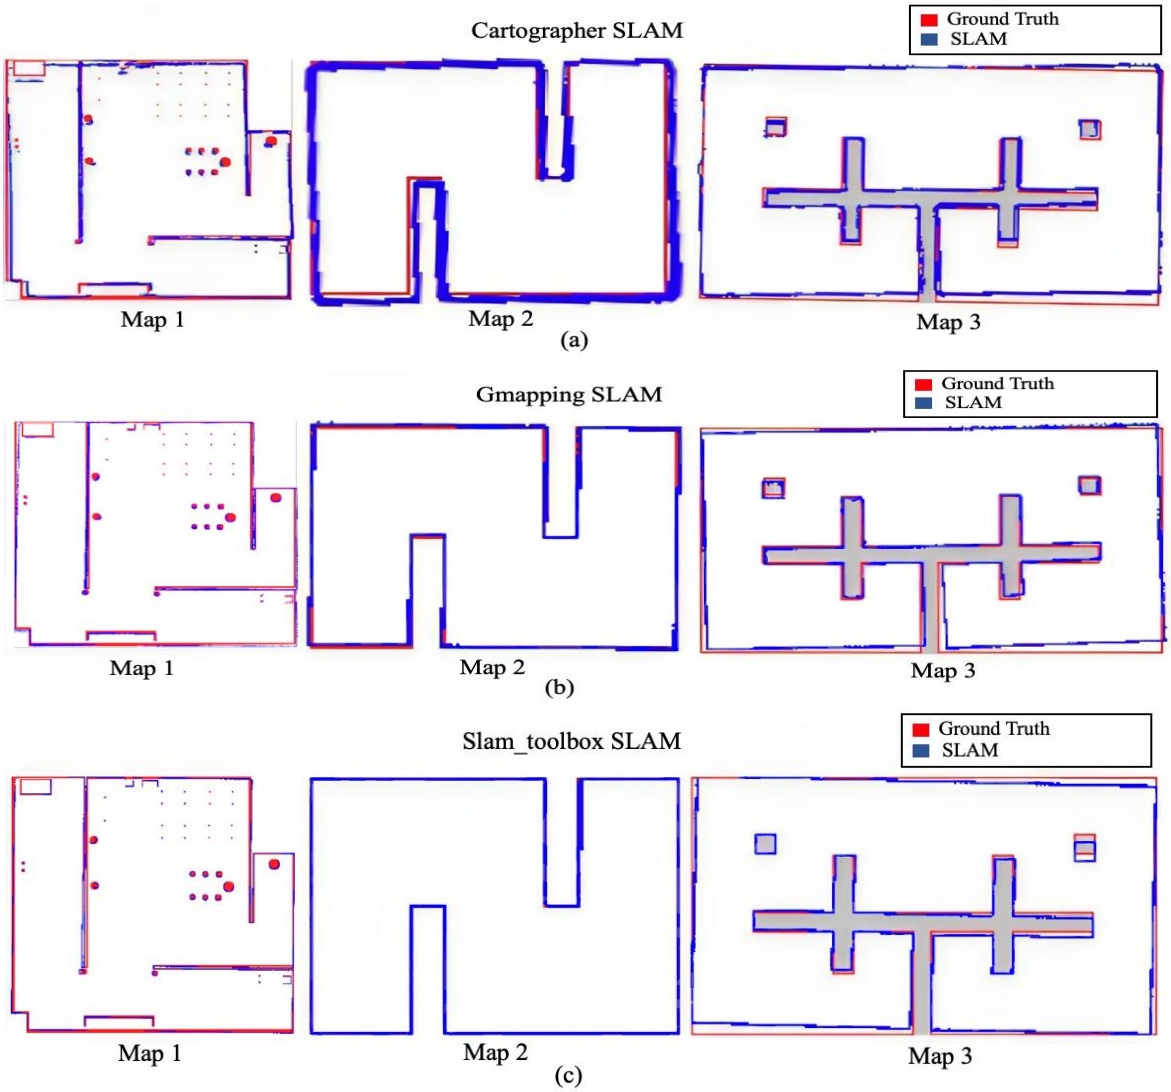

Fig. 4. Generated map results compared to ground truth with: (a) Cartographer SLAM, (b) Gmapping SLAM, (c) Slam_toolbox SLAM.

To enable autonomous navigation of the robot, the robot received a generated map of each algorithm as an input. The AMCL (Adaptive Monte Carlo Localization) algorithm employs a probabilistic localization model that aids the movement of the robot between different positions using a "2D Navigation Goal" provided by RVIZ 2 to reach each destination; and "2D Pose Estimator" that allows the position of the robot model to be set within an environment.

B. Human Detection Algorithm

In this section, we scrutinize and assess the human detection algorithm, aiming to propose an optimal model for indoor robots. This model is designed to help robots in tasks like obstacle avoidance and ensuring operational safety. Among the many algorithms for object detection, the YOLO (You Only Look Once) framework has gained recognition for its exceptional blend of speed and accuracy, enabling rapid and reliable object identification in images. Over time, the YOLO family has gone through multiple iterations, with each new version building upon the previous ones to address shortcomings and enhance performance.

In 2020, Ultralytics introduced YOLOv5 [10]. Unlike YOLOv4, which utilized Darknet, YOLOv5 was developed using Pytorch and incorporated various improvements. YOLOv5 also integrated an AutoAnchor algorithm, a pre-training tool that evaluates and adjusts anchor boxes to better suit the dataset and training parameters, including image size. Initially, it applies a k-means function to dataset labels to establish starting conditions for a Genetic Evolution (GE) algorithm.

In September 2022, the Meituan Vision AI Department introduced YOLOv6 [11]. Its network design features an efficient backbone PAN topology neck, which utilizes RepVGG or CSPStackRep blocks. It uses an efficient decoupled head with a hybrid-channel strategy. Furthermore, a new quantization technique was proposed to achieve faster and more accuracy.

YOLOv7 [12] was published in July 2022. At the time of its release, it outperformed all known object detectors in terms of speed and accuracy, achieving frame rates ranging from 5-160 FPS. It was trained only on the MS COCO dataset without pre-trained backbones. YOLOv7 brought forth numerous architectural modifications and a range of improvements, which boosted accuracy without affecting inference speed, albeit increasing training time.

In January 2023, Ultralytics, the organization responsible for YOLOv5, released YOLOv8 [13]. It has the capability to handle multiple vision-related tasks, including classification, object detection, segmentation, pose estimation, and tracking.

In Table I, we compare the structure and loss functions employed in various versions of YOLO. Fig. 5 illustrates the structure of the human detection model using YOLOv8-N, which we propose for adoption. With its compact size and high accuracy, YOLOv8-N is well-suited for deployment in resource-constrained hardware robots. Our evaluations indicate that YOLOv8-N outperforms other models. The results of our indoor detection capabilities will be presented in the experimental section.

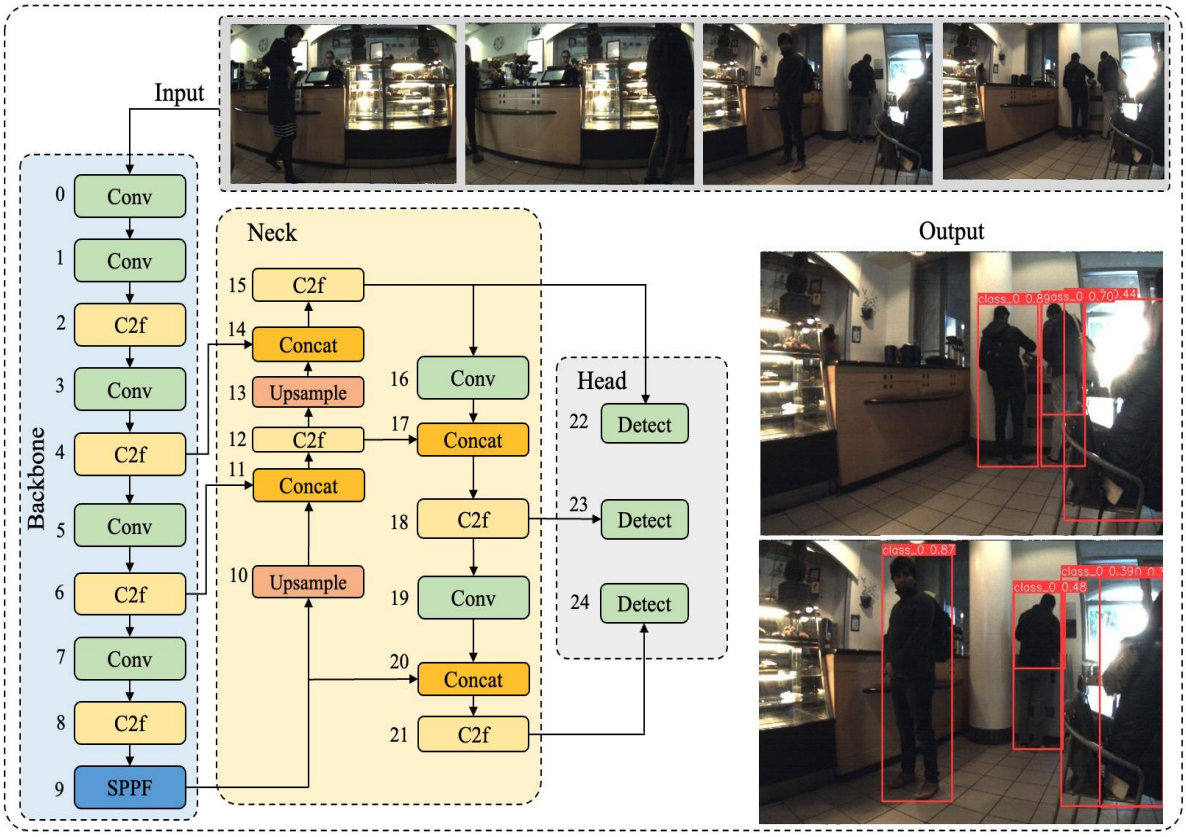

Fig. 5. The structure of the human detection model using YOLOv8-N.

TABLE I. ARCHITECTURE OF YOLO'S VERSION

	YOLOv5-N	YOLOv6-N	YOLOv7-Tiny	YOLOv8-N
Backbone	CSP Darkent53 [30]	RepVGG [31] and CSPRepStack [32]	EELAN [12]	CSPDarkent53 [30]

IV. EXPERIMENTAL RESULTS

A. SLAM Performance and Results

After utilizing the three SLAM techniques, Cartographer, GMapping, and SLAM_toolbox, the map was successfully generated with the highest level of precision using the SLAM_toolbox method, as depicted in Fig. 4. To assess the impact of map accuracy, we recorded the time taken by the robot to navigate and reach its destination in various environments. We divided the time measurement process into three segments for each map, conducted multiple test runs, and subsequently computed the average duration.

The first two phases of testing were conducted on Map_2 and Map_3, as illustrated in Fig. 6. In each of these navigation scenarios, a map generated by one of the three SLAM algorithms was utilized. Table II presents the time taken by the robot to reach its destination on the maps generated by Cartographer SLAM, GMapping, and SLAM_toolbox. For map 2, the goal point coordinates were set as (x = 4.0, y = 2.0), while for Map_3, they were set as (x = 0.0, y = 6.0), with the z-axis being maintained at 0.

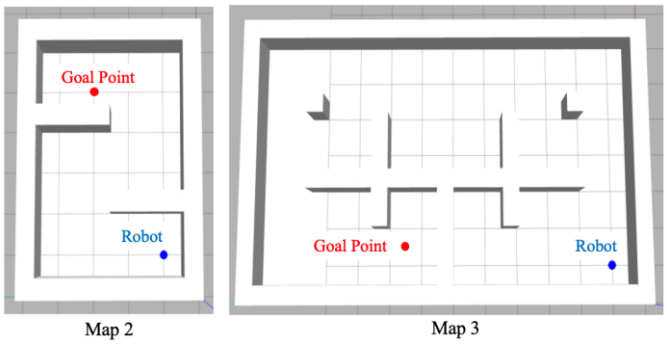

Fig. 6. Map 2 and 3 with their goal point.

TABLE II. THREE SLAM METHOD TRAILS FOR THE SECOND AND THIRD MAP

	Cartographer (s)		Gmapping (s)		Slam_toolbox (s)	
	Map_2	Map_3	Map_2	Map_3	Map_2	Map_3
Test 1	25.90	72.64	25.73	70.72	**24.29**	**70.11**
Test 2	26.10	70.15	26.10	72.17	**24.45**	**70.12**
Test 3	26.24	72.45	26.12	72.66	**24.71**	**70.07**
Average	26.08	71.75	25.983	71.85	**24.483**	**70.1**

Upon examination of Table II, it becomes apparent that when the robot is in operation with the SLAM_toolbox map, it achieves a quicker trajectory completion compared to the two other methods. This phenomenon is attributed to the SLAM_toolbox's capacity to produce maps characterized by a higher degree of precision and reduced noise levels. Consequently, the robot's operational stability is significantly improved.

A wide and intricate map with numerous obstacles was tested, as shown in Map_1. Fig. 7 illustrates the map when the robot navigates to its destination, with the green line indicating the path that the robot model must follow to reach its destination. The destination is set using RVIZ's 2D Goal Pose tool and is represented by a green arrow.

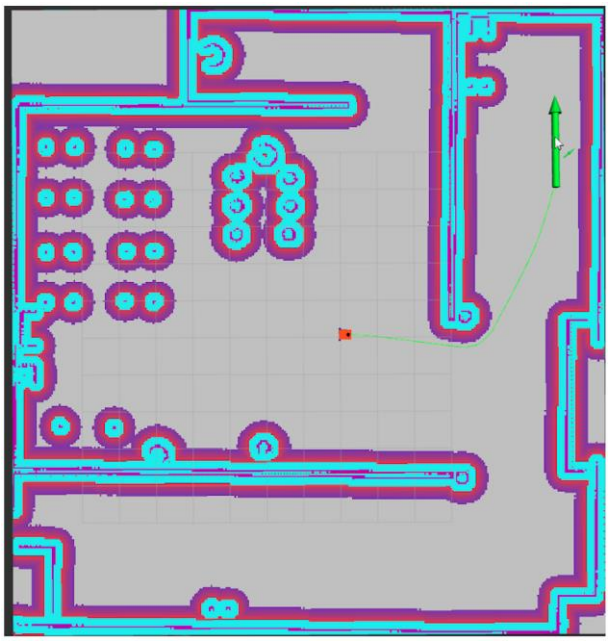

Fig. 7. Robot navigates to its destination in Map_1.

The last part was tested on Map_1 with three goal points. Each of these navigation tasks is executed using a map generated by its respective SLAM algorithm. The coordinates for point 1 is (x = 7.5, y = -2.0, z = 0.0); point 2: (x = 4.0, y = -8.0, z = 0.0); point 3: (x = -5.0, y = 0.0, z = 0.0). Fig. 8 shows Map_1 and the three goal points where the robot will move to, each represented by specific coordinates.

Fig. 8. The Map_1 with 3 different goal points.

Table III presents the duration it took for the robot to reach its destinations on the maps created by each method. It was observed that the map created using Slam Toolbox is more accurate than GMapping and Cartographer SLAM. To calculate the accuracy percentage of the point on the created map compared to the point we give before, we use the following Eq. (4):

$$Accuracy\ (\%) = [1 - (\frac{Error}{Range})] * 100 \quad (4)$$

where: Error is the Euclidean distance between actual goal points and the robot location after navigating, Range is the maximum possible distance between the two points, which is the distance between the actual point and the origin (0, 0) on Gazebo virtual world. Although the travel times to the destination points being relatively close for the use of maps in all three methods, Table IV shows the robot movement of the SLAM_toolbox method is more accurate to the virtual world than the other. The reason is Gmapping uses a particle filter to build grid maps from 2D lidar data and primarily relies on LIDAR data for mapping which is not well suited for expansive environments and struggles to accurately complete loop closures on an industrial scale, and the Cartographer relies on incorporating LIDAR and IMU data for highly accurate mapping because of its complexity in algorithm (IMU is not used in this robot model). Based on the empirical evidence from our conducted experiments, we readily infer that the utilization of the SLAM_toolbox for SLAM mapping is demonstrably superior.

B. Human Detection Results

The experiments were conducted to train and evaluate YOLO's versions using two distinct datasets. The training model was executed on an Ubuntu 20.04 platform, utilizing an Intel Core i7 processor and 16 GB of RAM. Firstly, we train YOLO's versions 20 epochs with the same hyparameters on a small dataset to choosing up the best optimal version for our work. After that we train chosen version 50 epochs on larger dataset with different optimizations such as SGD, AdamW [33], and AMSGrad [34]. Performance was assessed based on metrics such as Recision, Recall, and mAP(0.5-0.95).

1) Datasets and Evaluation Metrics:

a) Datasets: The research paper ultilizes three datasets created by using framework FiftyOne [35] to spliting human images, bounding box from the MSCOCO dataset [36], and JRDB dataset [39]. The small dataset contains 12.6K images with 10K for train and 2.6K for validation. The large dataset ontains 66.6K images with 64K for train and 2.6K for validation. Moreover, we also use augmentation methods on each of those dataset before training. Augment methods used are Blur, MedianBlur, ToGray, CLAHE.

TABLE III. THREE SLAM METHOD TIME RECORDED FOR THE FIRST MAP

	Cartographer (s)			**Gmapping (s)**			**Slam Toolbox (s)**		
	1st destination	2nd destination	3rd destination	1st destination	2nd destination	3rd destination	1st destination	2nd destination	3rd destination

b) Evaluation metrics: In object detection challenges and scientific research, various annotated datasets are used, and the primary metric for assessing the accuracy of object detections is the Average Precision (AP). AP relies on four fundamental concepts:

- True positive (TP): Accurately identifying a real bounding box in line with the ground truth.
- False positive (FP): Incorrectly identifying a non-existent object or inaccurately placing an existing object's detection.
- False negative (FN): Failing to detect a bounding box that matches the ground truth.
- True Negative (TN): Nevertheless, in the realm of object detection, the concept of True Negative (TN) is not relevant.

To address this, the intersection over union (IOU) metric is commonly employed. IOU is a measurement based on the Jaccard Index, which quantifies the similarity between two sets of data. In object detection, IOU calculates the overlap between the predicted bounding box (Bp) and the ground-truth bounding box (Bgt), dividing it by the area of their union. This provides a more suitable and informative metric for evaluating object detection performance, particularly in scenarios where True Negatives are not relevant [37].

In our research, we will primarily evaluate the performance of our model using the mean Average Precision (mAP) metric over a range of IoU thresholds (0.5 to 0.95). This mAP score considers the integral of mAP across these different IoU thresholds, providing a comprehensive assessment of detection accuracy. Additionally, we will also utilize the Precision metric to evaluate the percentage of correct positive predictions made by our model and the Recall metric to assess the percentage of correct positive predictions among all the ground truth annotations. These metrics collectively offer a well-rounded evaluation of our model's performance in object detection tasks.

The equation of those metrics is shown below:

$$\text{IoU} = \frac{\text{area of overlap}}{\text{area of union}} \tag{5}$$

$$\text{Precision} = \frac{\text{TP}}{\text{FP+TP}} \tag{6}$$

$$\text{Recall} = \frac{\text{TP}}{\text{FN+TP}} \tag{7}$$

2) Results and discussion: Fig. 9 to Fig. 11 illustrate the mAP (0.5-0.95), precision, and recall, while Table V presents the final results of training models on our dataset. In this set of results, two models, YOLOv8 and YOLOv6, outperform YOLOv5 and YOLOv7, with mAP@0.5:0.95 scores of 0.438 and 0.503, compared to 0.424 and 0.407, respectively. Notably, YOLOv6 demonstrates superiority across these metrics, as evidenced by its leading performance in Fig. 9 with the highest mAP score.

However, despite YOLOv6's impressive performance, we decided to exclude it from further consideration due to two critical factors. Firstly, it boasts a substantial number of parameters, totaling 4.3 million, which can strain computational resources. Secondly, its convergence appears to plateau within the first 20 epochs, suggesting that other models might potentially achieve even higher performance with prolonged training. Thus, we have opted for a trade-off between processing speed and accuracy in our model selection process.

Furthermore, YOLOv8, while not particularly outstanding in the initial 20 epochs, is our preferred choice. This decision is rooted in its consistent convergence, indicating that with more training time, it can potentially outperform other models. Additionally, as referenced in [13], YOLOv8 currently boasts superior processing speed compared to its counterparts, making it well-suited for real-time object detection applications.

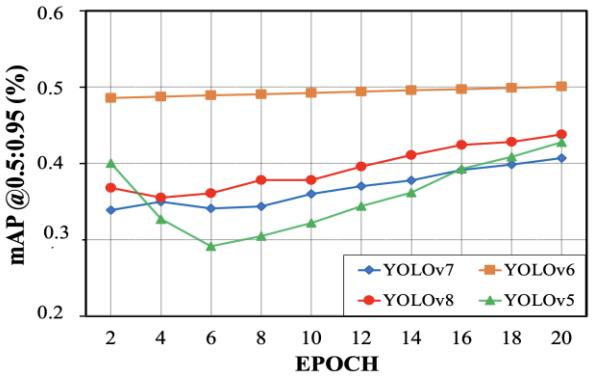

Fig. 9. mAP@0.5:0.95 of YOLO's versions.

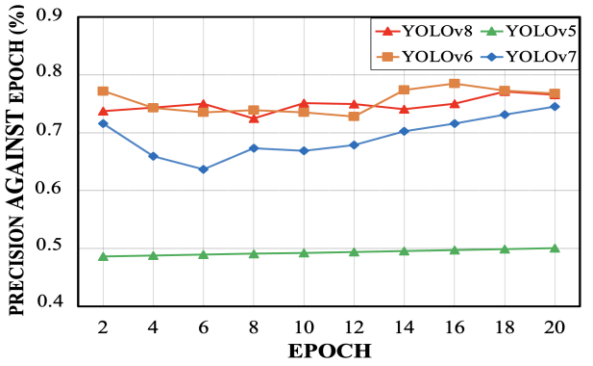

Fig. 10. Precision of YOLO's versions.

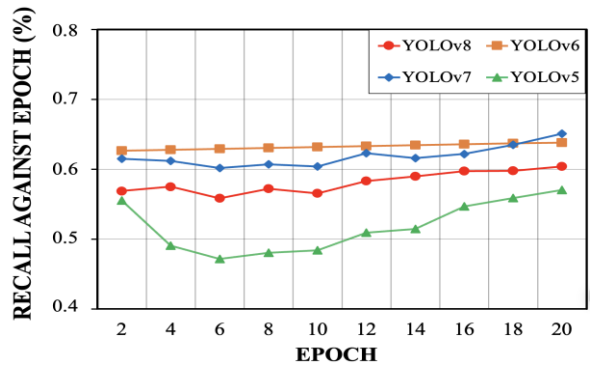

Fig. 11. Recall of YOLO's versions.

TABLE V. LAST RESULT OF FIRST EXPERIMENT

	Precision	Recall	AP (IoU=0.5)	AP (IoU=0.5:0.95)
YOLOv5	0.503	0.58	0.696	0.424
YOLOv6	0.768	0.651	0.791	0.503
YOLOv7	0.725	0.679	0.664	0.407
YOLOv8	0.766	0.604	0.728	0.438

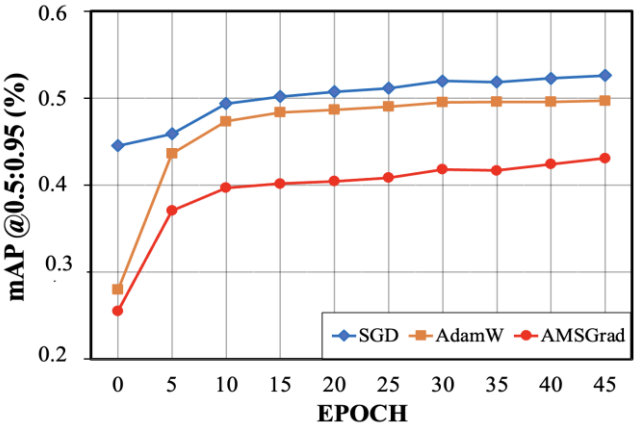

Fig. 12. mAP@0.5:0.95 of YOLOv8 with optimizers.

In the second experiment, we conducted training for 50 epochs using YOLOv8 on a dataset larger than the first with 66.6K images, employing various optimizers, including SGD, AdamW, and AMSGrad. The results from the last epoch are presented in Table VI. Notably, the SGD optimizer demonstrated superior performance across precision, recall, and mean Average Precision (mAP) with 0.794 Precision, 0.657 Recall, and 0.527_mAP@0.5:0.95. It has shown an increase over the original YOLOv8 model in [13] with only smaller than 0.4 mAP@0.5:0.95, which is obvious because here the parameters are trained to focus exclusively on human detection compared to numbers of class up to 80 in the original model. In Fig. 12, 13, and 14, we provide insights into the mAP@0.5:0.95, precision, and recall results throughout the 50-epoch training process. Remarkably, SGD consistently outperformed the other optimizers. Nonetheless, it's worth highlighting that even at the 50th epoch, all three methods exhibited ongoing improvement. This suggests that they have not yet reached their maximum potential, indicating that AdamW and AMSGrad might still have untapped strengths.

In Fig. 15, we conducted another evaluation to assess the human detection capability of the YOLOv8-SGD framework that we propose for the task of detecting individuals, particularly humans, within the JRDB dataset. This evaluation involved detecting individuals in various indoor settings, such as shopping centers, train stations, and cinemas.

V. Conclusion

We have successfully compared currently commonly used state-of-the-art methods for each task such as SLAM, Navigation, and Human detection. Furthermore, we have also provided analysis and evaluation of the experimental results.

Our findings align with our expectations, and we have identified potential areas for enhancement. We utilized the maps generated by each algorithm in both RVIZ 2 and Gazebo for guiding the robot to three distinct destinations. We repeated this process in five trials. The average values obtained from these tests were then used to create graphs that depict the time taken for various destinations, as shown in the table. The comparison revealed that the map generated with the Slam Toolbox exhibits greater precision compared to GMapping and Hector SLAM. The robot's motion aligns more accurately with the virtual world when using Slam Toolbox, in contrast to the others. However, the choice between these SLAM solutions depends on your specific project requirements, familiarity with the tools, hardware capabilities, and the complexity of your robot's operating environment. Each of these options has its strengths and weaknesses, and the better choice will vary depending on the context of your application.

As for human detection, the experimental results returned were quite surprising as the YOLOv8 model did not have outstanding results compared to older models; however, we see it still has potential for development, so we still choose it. Furthermore, because our initial goal was to apply to mobile robots with small microprocessors, this trade-off between processing speed and accuracy was extremely reasonable.

After this article, our next direction is to research more deeply into other more advanced tasks such as tracking, determine people's location, movements and behaviors of using 3D point cloud, etc. It will have some challenges such as privacy, security, fairness, scalability, and interdisciplinary collaboration will be addressed to ensure ethical and impactful innovation. But we hope that we can further apply modern technology to contribute to improving human happiness in today's society.

Abstract*—Protecting data and computer systems, as well as preserving the accessibility, integrity, and confidentiality of vital information in the face of constantly changing cyberthreats, requires the vital responsibility of detecting network intrusions. Existing intrusion detection models have limits in properly capturing and interpreting complex patterns in network behavior, which frequently leads to difficulties in robust feature selection and a lack of overall intrusion detection accuracy. The drawbacks of current methods are addressed by a unique approach to network intrusion detection presented in this paper. This framework discusses the difficulties presented by changing cyberthreats and the critical requirement for efficient intrusion detection in a society growing more networked by the day. Using a Hybrid Adaptive Neuro Fuzzy Inference System and African Vulture Optimization model with Min-Max normalization and data cleaning on the NSL-KDD dataset, the methodology outlined here overcomes issues with complex network behavior patterns and improves feature selection for precise identification of potential security threats. This approach meets the need for an effective intrusion detection system. Python software is used to implement the suggested model since it is flexible and reliable. The results show a notable improvement in accuracy, with the Hybrid Adaptive Neuro Fuzzy Inference System and African Vulture Optimization model surpassing previous approaches significantly and obtaining an exceptional accuracy rate of 99.3%. The accuracy of the proposed model was improved by African Vulture Optimization, rising from 99.2% to 99.3%. When compared to Artificial Neural Network (78.51%), Random Forest (92.21%), and Linear Support Vector Machine (97.4%), this amazing improvement is clear. When compared to other techniques, the suggested model exhibits an average accuracy gain of about 20.79%.

Keywords*—Network intrusion; cyberthreats; normalization; African vulture optimization; data cleaning

I. Introduction

The Internet has smoothly merged into the framework of everyday life in the rapidly changing digital age, acting as a vital resource for both people and businesses. It now serves as the foundation for keeping records, company operations, and connectivity. The safety and confidentiality of online transactions, nevertheless, are an increasing worry brought on by this previously unheard-of dependence on the World Wide Web. Because of this, cybersecurity has become a crucial area of concern for both business and academics, motivating the commitment of significant funds to protect contemporary web-based networks from possible dangers and abnormalities [1]. Several cyber security issues have emerged, posing several potential hazards to the online lives [2]. Attackers frequently use the flaws in well-known software to target computer systems on networks. These attackers' damage may result in significant issues like service interruptions or even substantial financial losses [3]. In modern linked world, NIDSs are imperative for protecting the accessibility, security, and reliability of data [4]. The two primary types of methods used by NIDSs to do this are signature-based detection and anomaly-based detection [5]. In order to be very effective in recognizing assaults using widely recognized signatures and structures, signature-based NIDSs rely on predefined attack patterns [6]. Nevertheless, their susceptibility to novel attacks is a serious obstacle because they are unable to adjust to new dangers without foreknowledge. Fig. 1 shows the Network intrusion detection system.

There is still much space for enhancement of NIDS efficiency, despite major improvements. The enormous amount of information about network traffic produced, the rapidly changing technical environment, the sizeable collection of features that make up data sets for training and the requirement for actual intrusion detection provide difficulties [7]. The efficacy of NIDS and the speed of training models can both be hampered by unnecessary or redundant characteristics [8]. Because of this, improving the effectiveness of machine learning -based detection models require careful features subset selection and tuning. By defining and explaining what makes up usual network behavior, anomaly-based detection systems, on the other hand, can be used to discover assaults that are unknown or novel.

Both methods have advantages, but to handle the always changing network security concerns, constant advancements are needed [9]. Thus, in order to improve the accuracy of machine learning (ML)-based detection models, careful data subset selection and parameter optimization are required [10].

Different methods were used to fortify network defenses, each with their own advantages and disadvantages. By detecting known attacks using predetermined sequences of attacks, signature-based detection systems act as the initial line of protection [11]. It is impossible to overstate how successful they have historically been at identifying popular hazards. Nevertheless, because they rely on historical signatures for identification, these tools fail when faced with fresh, never-before-seen threats [12]. Anomaly-based Identification systems are skilled at identifying unidentified dangers based on models created around typical actions since they focus on the recognition of abnormalities from standard procedures [13]. As they may be able to identify new threats that signature-based systems overlook, these systems add a key layer of security [14]. Systems for detecting intrusions now depend heavily on machine learning techniques [15]. The focus of conventional methods is on implementing feature engineering and selection, which can be computationally demanding and could only collect deep characteristics, leading to subpar recognition rates. With the promise for higher precision and fewer positive results, artificial intelligence techniques have become widely used to detect fraudulent network traffic [16]. RNNs, CNNs and DRL are a few examples of deep learning techniques that have shown promise in overcoming the drawbacks of conventional machine learning.

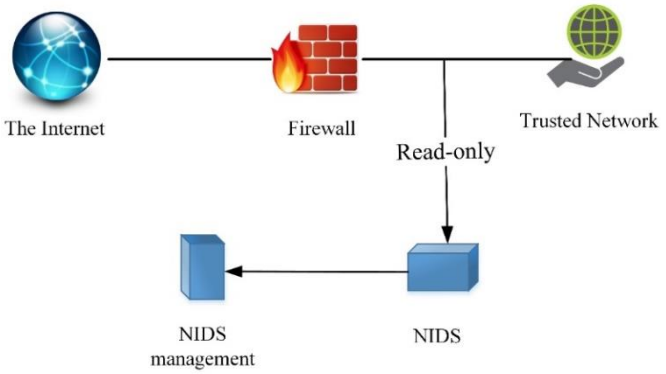

Fig. 1. NID system.

Ongoing improvements in NIDS are required due to the explosive growth of the Internet and the resulting rise in security threats [17]. To develop reliable and effective techniques and systems that precisely detect and react to unwanted or harmful actions within a computer network is the overarching problem statement for network intrusion detection. To safeguard the network's resources from many types of assaults, like as intrusions, infections with viruses, compromises of data, and denial-of-service attacks, this entails differentiating between normal network traffic and suspicious or malicious behavior. Key contributions of this work as follows:

- Data cleaning and Min-Max normalization are included in the study's thorough pre-processing procedure. These methods guarantee the dataset's dependability and quality, which improves the accuracy of subsequent intrusion detection analysis.
- African Vulture Optimization (AVO) provides a novel feature selection method based on the scavenging habits of vultures. By shrewdly determining the most pertinent features for network intrusion detection, it greatly improves model performance and interpretability.
- The Hybrid ANFIS (Adaptive Neuro-Fuzzy Inference System) Model is the central component of the research. The effective capturing of complex patterns in network behavior is made possible by the Hybrid ANFIS. In order to achieve accurate and exact intrusion detection, the model adapts and fine-tunes fuzzy rules through backpropagation.

An outline of the research is given in Section I. The Section II analyses the material that has already been written and highlights the need to handle particular modifications in Network Intrusion detection. Concerning the complexity of Network Intrusion detection, Section III defines the main research issue. Data collection, preprocessing, feature selection, and Hybrid ANFIS are described in Section IV of the paper. The research's importance in detecting Network Intrusion Detection is emphasized in Section V, which gives empirical findings, compares classifier performance, examines consequences and Section VI summaries the conclusion of the paper.

II. Related Works

An essential component of ensuring cybersecurity is intrusion detection and the capability to identify attacks. The aim of this study is on defending against assaults on cyberattack detectors built using machine learning. Here, an approach for adversarial machine learning detection was developed by Pawlicki, Choras, and Kozik [18]. In actuality, the confrontational nature of the surroundings in which they are used has not been taken into consideration while designing modern machine learning algorithms. Therefore, a variety of attacks are currently being directed towards machine learning systems. By constructing adversarial attacks using the four currently proposed approaches, this work assesses the potential of degrading the effectiveness of an intrusion recognition process at test time and then provides a mechanism to identify such assaults. Both artificial neural networks and four techniques for creating adversarial attacks have the necessary historical data. The five separate classifiers' outputs are contrasted, and a thorough explanation of the new detecting technique is provided. In this work intrusion detection systems have not yet been extensively studied in terms of identifying confrontational attacks on false neural networks. And also, it has high false positive rate.

Detecting network intrusions is crucial for maintaining digital security on the network. The primary analysis technique employed in the area of NID is the identification and evaluation of aberrant traffic by extracting statistical

aspects of flow. However, because these features must be created and retrieved individually, the original flow data is frequently lost, which reduces the effectiveness of the detection process. In this study, instead of explicitly designing the process's features directly collected the flow's actual data details for evaluation. The deep hierarchical network, which incorporates the enhanced LSTM and LeNet-5 neural network is developed by Zhang et al. [19]. Instead of retraining a pair of networks independently, a feasible network cascade approach was designed to train the suggested hierarchical network simultaneously. A unique traffic collection system can need a lot of resources, including specialized hardware, software, and committed employees, to build and maintain. Managing large amounts of real-world traffic data might put a burden on the facilities available due to computational and storage needs. This strategy could cost a lot to implement in terms of infrastructure setup and ongoing maintenance.

The advancement of network infrastructure and technology has advanced quickly in the past few decades, and Internet services have extended throughout all industries. The prevalence of infringement has increased, and many contemporary systems have been breached, making the advancement of technology for information security to identify new attacks essential. An IDS that uses deep and machine learning algorithms to identify irregularities in network traffic is the greatest vital security-related technologies. Employing a deep neural network techniques and an outstanding network efficiency for network intrusion detection was proposed by Maithem and Al-sultany [20]. The primary purpose of this study is to use advanced IDS to find unidentified attack packages. In this model, detection of attacks is carried out in two different ways (binary categorization and several classes' classification). With regards to the high accurateness with multiclass categorization and with dual classification), the suggested system has demonstrated interesting results. It suggests that the research used deep learning approaches to detect network assaults with excellent classification accuracy. A number of significant flaws and restrictions demand attention. In order to make sure that these networks fail to biased in a specific dataset like the KDD Cup 99. For a viable implementation, it is also essential to handle data imbalance and address computational scalability difficulties.

The potential attack area for cyber hackers is expanding as additional gadgets with internet access come online. Many intrusion detection systems look for identified breaches using network communications characteristics. Despite depending on these fingerprints, investigators have recently employed a machine learning techniques to identify network threats. For an intrusion detection system that is ready for the market, these methods often have a high false-positive rate. Atefinia and Ahmadi [21] proposed a deep neural network model in this study to decrease the incidence of intrusion detection systems that overreact in response to anomalies. The trials make use of the CSE-CIC-IDS2018 dataset, and the models that emerge from them can be included into IDS to produce alerts or thwart upcoming assaults. Though seeking to reduce alarms that are unfounded, the creation of a modular deep neural network for intrusion detection has a number of possible downsides and difficulties. Complexity and interpretability problems can be introduced by modular neural networks. It might be demanding of resources and difficult to apply custom feature extractors and datasets to various contexts. Increasing the amount of training with large data systems carries the danger of over fitting, and there may be issues with data privacy and security.

The reviewed research papers bring up some of the shortcomings and difficulties that intrusion detection systems face, especially when dealing with large false-positive rates and aggressive attacks on neural networks. Handling large amounts of real-world traffic data can put a burden on resources and result in high maintenance and infrastructure expenditures. The reliability of these systems depends on the careful handling of notable problems such bias, data imbalance, and computing scalability. When working with big datasets, modular neural networks can add complexity and interpretability issues, requiring resources and putting data privacy at risk. The aforementioned studies highlight the necessity of continued investigation to surmount these constraints and augment the efficacy of intrusion detection systems with regard to the dynamic landscape of cyber threats.

III. Problem Statement

From the above literature reviews, the necessity to improve intrusion detection system's effectiveness as well as efficacy in order to safeguard computer networks and data against cyberattacks is the central issue in the arena of intrusion detection. Identifying earlier unidentified and changing attack strategies, maintaining sizable and imbalanced data sets, assuring real-time detection and response, and enhancing the comprehensibility of detection models are some of the current issues [21].

IV. Network Intrusion Detection using Hybrid ANFIS and AVO-based Predictive Analysis

The main measures made to improve the precision and effectiveness of the intrusion detection system was described in the methodology section of the network intrusion detection study. The NSL-KDD dataset, a labeled network intrusion detection dataset with a wide variety of network traffic scenarios, was the primary dataset used in this study. It commenced a thorough pre-processing step to guarantee the dataset was prepared for analysis. In order to standardize the data and prepare it for further analysis, this required data cleaning and Min-Max normalization. The process of feature selection, a crucial factor in determining the effectiveness of intrusion detection systems, forms the basis of the methodology. It used the ground-breaking African Vulture Optimization (AVO) method to address this. AVO provides a clever way to choose the most pertinent characteristics, optimizing the feature subset for better model performance and interpretability. It is inspired by the scavenging activity of vultures. After selecting features, the Hybrid Adaptive Neuro-Fuzzy Inference System (ANFIS) was put into use to detect intrusions. Fuzzy logic and neural networks are used with ANFIS to capture complex patterns in network behavior. It achieves accurate intrusion detection by fine-tuning fuzzy rules through backpropagation. By lowering false positives and increasing detection precision, this methodology seeks to

strengthen network security in the end. Compared to alternative methods, this thorough framework exhibits an exceptional accuracy rate of 99.3%, proving its efficacy through rigorous experimentation. Fig. 2 shows the Overall Framework for Hybrid ANFIS and AVO-based Network Intrusion Detection.

A. Data Collection

The labeled network intrusion detection dataset known as NSL-KDD was utilized in numerous assignments to test various deep learning-based methods for developing various IDS techniques. Four types of characteristics—basic, time-based, content-based and host-based traffic features—can be distinguished among the 41 characteristics included in the NSL-KDD dataset. These traits' worth is mainly determined by their constant, separate, and symbolic nature. Five bout classes, including Normal Denial-of-Service (DoS), Root to Local (R2L), Probe, and Unauthorized to Root (U2R), are included in the NSL-KDD dataset. The attributes associated with each NSL-KDD data can be used to determine these attack classifications [22].

B. Pre-processing with Data Cleaning and Min-Max Normalization

Data preparation modifies the data ranges in an NSL-KDD dataset to improve information gathering and operation. The dataset's maximum and minimum ranges exhibit high contrast variance. The normalization of data during this phase lessens an algorithm's challenges.

Data cleaning procedures are used to eliminate data redundancy, noise, mistakes, and undesirable information from the dataset. Only the pertinent data may be processed subsequently in this process.

The normalization role, which contains a least and extreme algorithm and transforms the remaining data value between [-1, 1] and [0, 1], heavily relies on data scalability. The normalization formula is given in Eq. (1).

$$I'^{*} = \frac{D*'-D*'_{min}}{D*'_{max}-D*'_{min}} \quad (1)$$

The phrase I' in Eq. (1) denotes the value of the input that has been transformed (or, more specifically, normalized). The terms D'_{max} *and* D'_{min} stand for the supreme and lowest values of the input variable D', respectively, whereas the term D' stands for actual value [23].

C. Feature Selection using African Vulture Optimization

African Vulture Optimization, an innovative metaheuristic strategy based on the behavior of African Vultures, has become a popular choice for feature selection in network intrusion detection. The world's most common bird species, vultures, are usually carnivorous. They are dependent on scavengers to dissect carcasses because they are incapable of doing so themselves. African vultures have been reported to soar above 11,000 meters and to circle over great distances in search of possible food sources. However, once they locate a food supply, they have trouble getting to it quickly. The stronger vultures are frequently encircled by the less powerful ones, which delays the feeding process. The less dominant vultures gradually start looking for food when the dominant ones get tired. This distinctive scavenging behavior has prompted the creation of a novel metaheuristic method designed to tackle feature selection problems in the field of network intrusion detection [24].

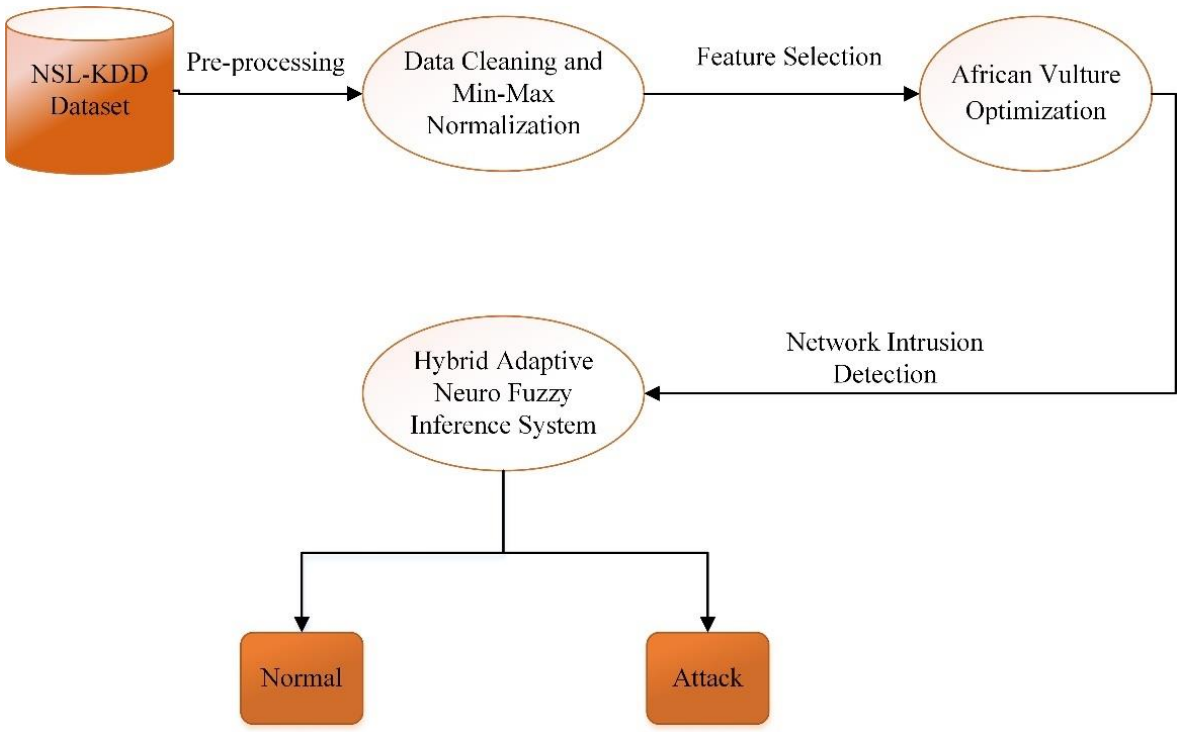

Fig. 2. Overall framework for hybrid ANFIS and AVO-based network intrusion detection.

Step 1: To ensure that every feature is given equal weight in the first stage of feature selection for network intrusion detection, try to increase the number of possible characteristics. Finding the highest-performing characteristics within a particular group is the main goal. Eq. (2) gives the description of this operation.

$$S(I) = \begin{cases} best\ vul_1, if\ Z_l = F_1 \\ best\ vul_2, if\ Z_l = F_2 \end{cases} \quad (2)$$

Here, F_1 and F_2 are parameters that were assessed before to optimization; they both have to be between 0 and 1, with the requirement that $F_1 + F_2 = 1$.

Step 2: Finding the features' "famine rate" is the focus of this step. Characteristics are rated according to how well they can advance the optimization, just like actual vultures fly in pursuit of food. Eq. (3) accurately depict this process mathematically:

$$V = (2 \times \tau + 1) \times n \times \left(1 - \frac{iter_l}{max_{iter}}\right) + I \quad (3)$$

In Eq. (3), τ denotes a random number between 0 and 1. The current iteration is indicated by $iter_l$, the total number of iterations is shown by max_{iter}r, and n is a constant that directs the optimization process through its stages of investigation and processing. There are restrictions on the variable d that fall between -2 and 2. If n is less than zero, it means that a feature is scarce, like vulture hunger, and if n is greater than one, it means that a trait is abundant, like a well-fed vulture.

Step 3: In order to facilitate feature selection, vultures are outfitted with random feature subsets that provide two possible configurations and a variable r_1 that has a range of zero to one. Eq. (4) and Eq. (5) provide the following mathematical breakdown of the technique used to choose the best feature set:

$$If\ r_1 \geq randr_1$$
$$S(l+1) = BV(l) - T(l) \times S \quad (4)$$
$$If\ r_1 < randr_1$$
$$S(l+1) = BV(l) - S + rand_2 \times ((ub - Ib) \times rand_3 + Ib \quad (5)$$

S here stands for the unique feature subsets that were selected at random when searching for the best features. The best-performing feature subsets are stored in BV, while the lower and upper bounds for feature values are represented by Ib and ub. Two random variables, rand2 and rand3, have values ranging from 0 to 1.

Step 4: The selected features are represented by the value of |S|, which splits this step into two halves. Both segments include rotational flights when 0.5 < |S| < 1. An active feature can be identified if |S| is greater than or equal to 0.5. During this stage, less significant features try to use the stronger ones to improve their performance. The position of the new feature set, designated as S(k+1), is found by applying Eq. (6), Eq. (7), and Eq. (8).

$$S(l+1) = \frac{best_1 + best_2}{2} \quad (6)$$

$$b_1 = best\ vul_1(l) - \frac{best\ vul_1(l) \times S(l)}{best\ vul_1(l) - S(l)^2} \times S \quad (7)$$

$$b_2 = best\ vul_2(l) - \frac{best\ vul_2(l) \times S(l)}{best\ vul_2(l) - S(l)^2} \times S \quad (8)$$

In the field of network intrusion detection, African Vulture Optimization (AVO) feature selection is a new method. Using a dynamic optimization process that imitates vulture foraging activity, AVO enhances intrusion detection systems' effectiveness by selecting pertinent features. The technique improves detection accuracy and reduces false positives by utilizing AVO, which guarantees that the most important characteristics are taken into account. This adds to the general stability and dependability of the network security configuration.

D. Employing Hybrid Adaptive Neuro-Fuzzy Inference System for Intrusion Detection

A hybrid ANFIS system for intrusion detection combines the features of fuzzy logic and neural networks to produce a flexible and adaptive solution for identifying network intrusions while reducing false positives. ANFIS contains of five layers, as shown in Fig. 3.

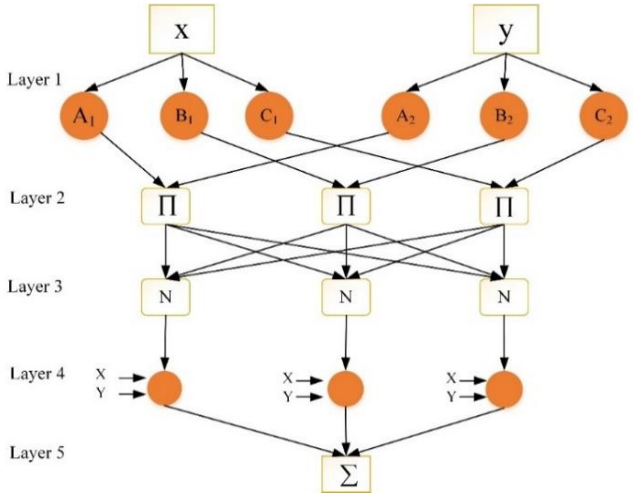

Fig. 3. ANFIS architecture.

The fuzzification layer is represented by Layer 1. It computes the membership function as follows in Eq. (9) and Eq. (10):

$$\lambda_{ai}(y) = \frac{1}{1 + \left[\left(\frac{y - c_{ai}}{\alpha_{ai}}\right)^2\right]^{\beta_{ai}}} \quad (9)$$

$$\lambda_{bi}(z) = \frac{1}{1 + \left[\left(\frac{z - c_{bi}}{\alpha_{bi}}\right)^2\right]^{\beta_{bi}}} \quad (10)$$

Where, the bell function parameters are c_{ai}, c_{bi}, α_{ai}, α_{bi}, β_{ai}, and β_{ai}.

Layer 2 establishes the rules layer. Each node's firing power is represented by the output in Eq. (11):

$$\omega_i = [\lambda_{ai}(y)] \times [\lambda_{bi}(z)] \quad (11)$$

The normalization layer is designated as Layer 3. It adjusts the computed firing strength to be normal by Eq. (12).

$$\overline{\omega_i} = \frac{\omega_i}{\omega_1+\omega_2} \quad (12)$$

Hybrid ANFIS and AVO Algorithm	
Load the input data	
Perform preprocessing operation	//Data Cleaning and Min-Max Normalization
Select feature using AVO	
Calculate the fitness of vultures	
If s ≥ 1then	
Upgrade vulture location using Eq. (5)	
Otherwise	
Upgrade vulture location using Eq. (6)	
Network Intrusion Detection	//Hybrid ANFIS
Calculate RMSC of each particle	
If goal achieved	
Apply Optimal Particle Position	
End	

The consequent layer is represented by Layer 4. This layer's output is the result of multiplying the polynomial resulting from fuzzy rules by the normalized firing strength of Eq. (13):

$$\overline{\omega_i}F_i = \overline{\omega_i}(p_i y + q_i z + r_i) \quad (13)$$

where, p_i, q_i and r_i are the consequent parameter sets.

The defuzzification layer was designated as Layer 5. The ANFIS output as a whole is what it produces by Eq. (14).

$$F = \sum_i \overline{\omega_i}F_i = \frac{\sum_i \omega_i F_i}{\sum_i \omega_i} \quad (14)$$

The learning algorithm must adjust each adjustable parameter in order for the initial training data to match the output of the ANFIS. The RMSE (Root Mean Square Error) between projected values and actual measurements is trained into the ANFIS model to get the lowest possible value. RMSE is characterized by Eq. (15):

$$RMSE = \sqrt{\frac{1}{N*}\sum_{i=1}^{N*}(y-z)^2} \quad (15)$$

In Eq. (15), N* is the number of samples, y represents the actual measurement, z the forecasted value.

When optimizing Network Intrusion Detection with a Hybrid Adaptive Neuro-Fuzzy Inference System, the parameters of the African Vulture Optimization algorithm play a crucial role. In feature selection, AVO is essential to the intrusion detection system's overall efficacy. The optimization procedure is directly impacted by the particular parameters of the AVO algorithm, such as population size, convergence criterion, and number of iterations. The Hybrid ANFIS and AVO-based system's accuracy and efficiency are greatly impacted by fine-tuning these parameters, which improves predictive analysis. Through their interaction, AVO and the Hybrid ANFIS model provide a synergistic approach that successfully addresses the difficulties associated with network intrusion detection and highlights the significance of parameter tuning for obtaining better outcomes in cybersecurity applications. Overall process of the proposed model is given in Fig. 4.

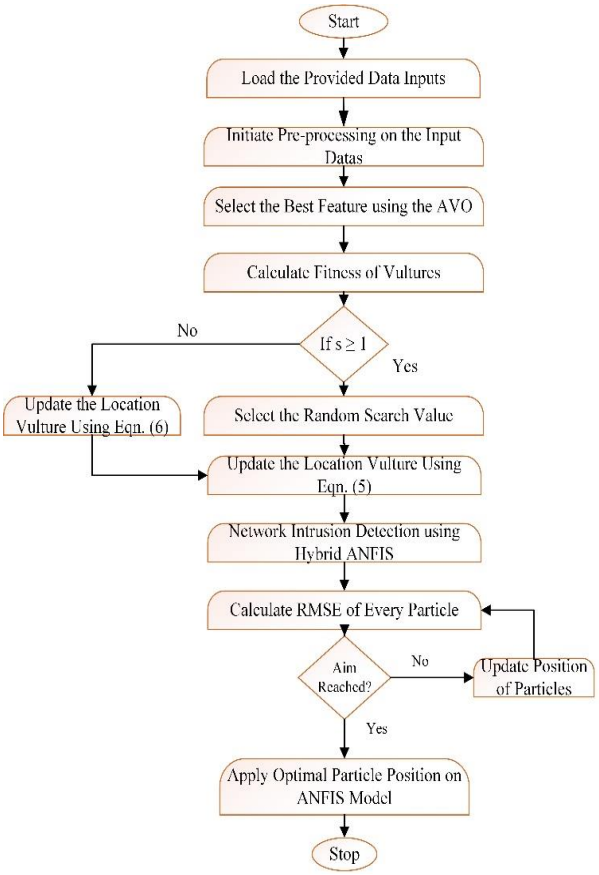

Fig. 4. Overall flowchart of proposed hybrid ANFIS and AVO.

V. Results and Discussions

The results of this extensive technique should be presented in the network intrusion detection study's results section. First, describe in detail how we trained and tested our intrusion detection system using the NSL-KDD dataset. Examine the pre-processing findings after the first round of data collection, emphasizing how much data cleaning and Min-Max normalization improved the dataset's analytical fit. Then the key feature selection procedure, where the African Vulture Optimization (AVO) approach was used. This data shows how well AVO performs in terms of identifying the most pertinent characteristics, refining the feature subset, and enhancing interpretability and performance of the model. The Hybrid Adaptive Neuro-Fuzzy Inference System (ANFIS) is an effective tool for intrusion detection. Its ability to capture complex patterns in network behavior is one of its most important applications. ANFIS optimizes fuzzy rules to provide extremely accurate intrusion detection through its backpropagation technique. The results show that this approach significantly improves detection precision while also lowering false positives, which strengthens network security in the end. Robust testing has generated empirical confirmation, demonstrating the framework's improved performance at a remarkable 99.3% accuracy rate—quite an accomplishment in comparison to other well-established methodologies. This method's effectiveness is confirmed by these results, which also highlight how much better network intrusion detection systems could become.

A. Training and Validation Accuracy of Hybrid ANFIS and AVO

Using 80% of the data for training and 20% for validation was the proposed strategy. The accuracy level and loss rate fluctuation graphs for the complete Hybrid ANFIS and AVO model procedure are shown in Fig. 5 and Fig. 6. When the training intervals of the Hybrid ANFIS and AVO model reach 100, the overall graph of the accurateness ratio and loss ratio stabilizes.

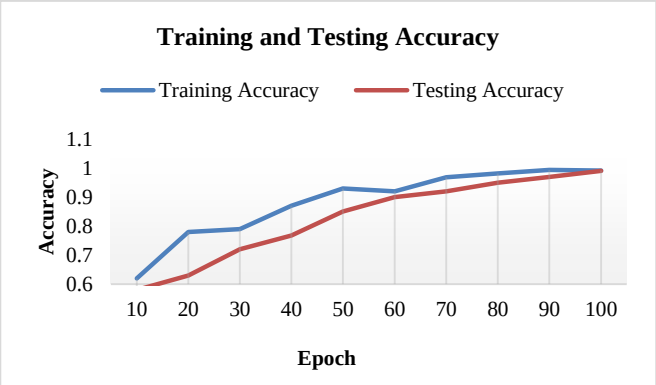

Fig. 5. Accuracy of training and testing values.

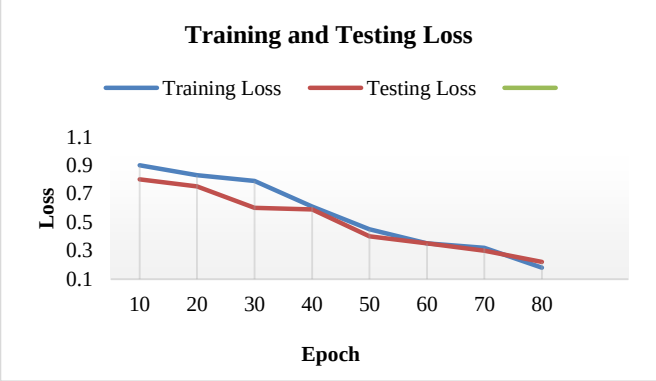

Fig. 6. Loss of training and testing values.

B. Evaluation of Performance

Recall, F1-score, precision, and accuracy were employed as comparison evaluation criteria. The model was evaluated using these parameters. They are shown below:

Accuracy: The prediction accuracy used to evaluate classification performances, as given in Eq. (16), is used to evaluate the classifier's overall performance.

$$A = \frac{TP\prime+TN\prime}{TP\prime+TN\prime+FP\prime+FN\prime} \quad (16)$$

Precision: The degree to which a collection of outcomes approve with one another is referred to as precision. The example is in Eq. (17).

$$P = \frac{TP\prime}{TP\prime+FP\prime} \quad (17)$$

Recall: To determine, below a convinced set of molds, a particular dependent variable, recall analysis, as illustrated in Eq. (18). This process is carried out within predetermined bounds that depend on one or more factors in the incoming data.

$$R = \frac{TP\prime}{TP\prime+FP\prime} \quad (18)$$

True positive pixels are denoted by TP', true negative pixels by TP', false positive pixels by FP', and false negative pixels by FN'.

F1-score: Recall and accuracy are related in the classification task. The F1-score definition is shown in Eq. (19).

$$F1-score = 2 * \frac{Pre*Re}{Pre+\mathrm{Re}} \quad (19)$$

The assessment results of the created Network intrusion detection system employing the combined strategy are shown in Table I.

TABLE I. PERFORMANCE METRICS OF HYBRID ANFIS AND AVO MODEL

Metrics	Values (%)
Accuracy	99.3
Precision	96.8
Recall	98.5
F1-Score	99.1

The performance indicators demonstrate the efficiency of the proposed model in detecting network intrusions, which is quite encouraging. With an astounding accuracy rate of 99.3%, the classification of network activity is classified with a high degree of overall accuracy. The system's precision in reducing false positives is demonstrated by the impressive score of 96.8% obtained by precision, a metric that gauges the model's ability to properly categorize incursions. Recall, which measures how well the model can identify real incursions, is also quite significant at 98.5%. A robust 99.1% is reached by the F1-Score, which balances recall and precision and highlights the system's well-balanced performance.

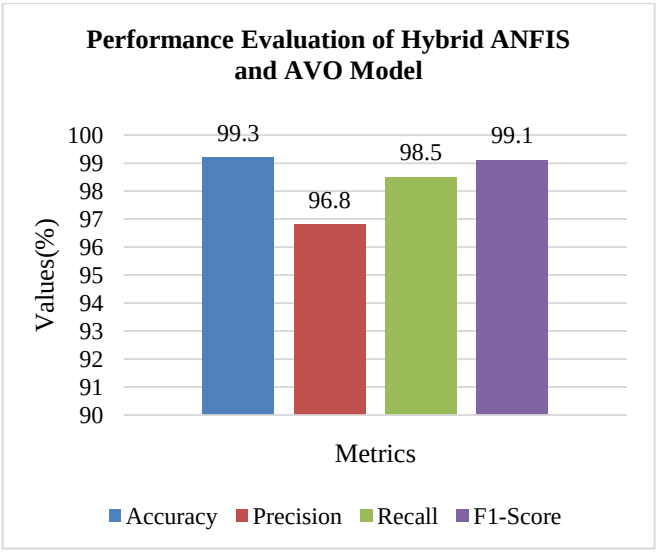

Fig. 7. Performance evaluation of hybrid ANFIS and AVO model.

These results demonstrate accurate and trustworthy anomaly detection with high values across key performance measures. The performance evaluation of the proposed Hybrid ANFIS and AVO model is shown in Fig. 7.

Table II shows the Accurateness, Recall, Precision and F1-score of the proposed approach with existing methods. The accuracy of the suggested method Hybrid ANFIS and AVO model (99.3%) is higher than the existing approaches ANN (78.51%), Random Forest (92.21%) and Linear SVM (97.4%).

Fig. 8 depicts the graphic depiction of the performance metrics of proposed with existing approaches. The precision of the suggested method Hybrid ANFIS and AVO model (96.8%) is higher than the existing ANN (96.6%), Random Forest (96.8%) and Linear SVM (97%). The recall of the suggested method Hybrid ANFIS and AVO model (98.5%) is higher than the existing approaches ANN (62.05%), Random Forest (61.5%) and Linear SVM (97%). The F1-score of the suggested method Hybrid ANFIS and AVO model (99.1%) is higher than the existing approaches ANN (75.5%), Random Forest (75.2%) and Linear SVM (97%).

The suggested model's graph shows how, as it reached a point of consistency using the provided hyperparameters, the accuracy of the training and validation sets rose quickly over a shorter period of time.

Before optimization the value of accuracy for proposed Hybrid ANFIS and AVO model is 99.2%. The accuracy achieved after optimization using Hybrid ANFIS and AVO model is 99.3%. The fitness of Hybrid ANFIS and AVO model is depicted in Fig. 9.

C. Discussion

This paper highlights the relevance of the results through a thorough analysis, including a comparison with existing methods, by combining African Vulture Optimization (AVO) with the Hybrid Adaptive Neuro-Fuzzy Inference System (ANFIS) for network intrusion detection. Using well-known performance indicators like recall, F1-score, accuracy, and precision, the validity and training accuracy of the new approach are carefully assessed. The Hybrid ANFIS and AVO model performs exceptionally well, outperforming existing models in the field with a 99.3% accuracy rate. The fitness improvement graph of the AVO model, which shows the efficiency of the optimization process and the ongoing improvement of feature selection over time, supporting the superiority of the model, provides evidence. Reducing false positives and improving detection precision is emphasized as a critical component of strengthening network security. The comparative analysis with traditional methods shows that the study's findings strengthen and advance the field of network intrusion detection. The methodology not simply performs better than other conventional ways like Random Forest (92.21%) [25], Artificial Neural Network (78.51%) [25], and Linear SVM (97.4%) [25], but it also shows potential for greatly enhancing the efficacy and dependability of intrusion detection systems. This verifies the methodology's applicability and offers solid solutions to the problems facing network security today.

TABLE II. PERFORMANCE METRICS OF PROPOSED METHOD

Methods	Accuracy (%)	Precision (%)	Recall (%)	F1-score (%)
ANN [25]	78.51	96.6	62.05	75.5
Random Forest[25]	92.21	96.8	61.5	75.2
Linear SVM [25]	97.4	97	97	97
Hybrid ANFIS and AVO model	99.3	96.8	98.5	99.1

VI. Conclusion and Future Work

The integration of the Hybrid Adaptive Neuro-Fuzzy Inference System (ANFIS) with African Vulture Optimization (AVO) in this network intrusion detection system has produced remarkable outcomes. This novel approach is carefully assessed and contrasted in the discussion part, which also highlights its overall effectiveness, training correctness, and validity. This proposed model outperforms existing models in the industry with an accuracy rate of 99.3% after a thorough review utilizing key performance measures like recall, F1-score, precision, and accuracy. The fitness improvement of the AVO model is represented graphically, which highlights the efficacy of the optimization process by showing how feature selection is improved over time and how this leads to an improvement in the overall performance of the model. Especially, this approach solves a critical network security issue by decreasing false positives and improving detection accuracy at the same time. The comparison with current models demonstrates the significant advancements made in network intrusion detection. This strategy not only performs better than conventional techniques, but it also has the potential to greatly improve intrusion detection systems' dependability and effectiveness. These results validate the applicability of the approach to modern network security problems. This study's shortcomings include differences in the dataset's properties, which raise questions about how well-suited it is to different network contexts and the possibility of bias resulting from the traits unique to the dataset. Future research will concentrate on improving the hybrid ANFIS and AVO-based system's real-time deployment by implementing deep learning techniques. The strategy will be modified to handle new network security issues, especially those related to 5G and Internet of Things networks. The methodology will be expanded to handle scenarios involving multi-class intrusion detection, guaranteeing its relevance in a variety of dynamic cybersecurity environments.

***Abstract*—The goal of artistic style translation is to combine an image's substance with an equivalent image's spirit of innovation. Current approaches are unable to consistently capture complex stylistic elements and maintain uniform stylization over semantic segments, which results in artefacts. Also suggest a novel approach which blends subjective loss algorithms using deep networks of neurons with segmentation using semantics to address these issues. By guaranteeing contextually-aware design distribution together with information preservation, the combination improves general aesthetic correctness during the styling transmission process. With this technique, perceptive components are extracted using both the subject matter and the style photos using previously trained deep neural systems. These components combine to provide perceptive loss coefficients, which are subsequently included into the design of a Generative Adversarial Network (GAN). For offering the representation a better grasp of the meaning contained in any given image, an automatic segmenting module is subsequently implemented. This historical data directs the style transferring process, producing an additional precise and sophisticated transition. The outcomes of our experiments confirm the efficacy of this method and demonstrate improved visual accuracy over earlier approaches. The use of semantic segmentation and loss of perceptual information algorithms together provide a significant 95.6% improvement in visual accuracy. This method effectively overcomes the drawbacks of earlier approaches, providing precise and trustworthy transference of style and constituting a noteworthy advancement in the field of imaginative style transfer. The final output graphics further demonstrate the importance of the recommended approach by deftly integrating decorative elements into functionally significant places.**

Keywords*—Artistic style transfer; Generative Adversarial Networks (GANs); semantic segmentation; visual fidelity; deep Convolutional Neural Networks (deep-CNN)

I. INTRODUCTION

A compelling method called creative style transfer blends the subject matter of a single image with the aesthetics of another to create unique and visually appealing artworks. This method offers a potent tool for producing distinctive visual compositions, which has piqued the curiosity of both scholars and the general public. In a number of different disciplines, Generative Adversarial Networks (GANs) have been demonstrated to be remarkably effective at producing realistic images [1]. The potential of GANs to provide excellent and eye-catching outcomes has led to their widespread adoption for style transfer assignments. Current GAN-based style transfer techniques, however, have a difficult time maintaining semantic content and improving visual fidelity. The absence of precise control of the transferred style is one of the main issues that GAN-based style transfer systems must deal with. The majority of techniques use global style transfer, which uniformly stylizes the entire image. Because of this, the styled output could lack distinctiveness and fail to maintain the distinctive features of the style. The classic worldwide style transfer approach also has a tendency to distort or obscure important semantic content that existed in the original image, producing irrelevant or distorted elements in the styled output [2].

Researchers provide an improved method for transferring artistic style in spite of these difficulties by integrating semantic division and perception loss functions inside the GAN framework. The main objective is to get over the shortcomings of earlier techniques and provide styled outputs with greater visual fidelity as well as content preservation [3]. Adding a semantic segment module to the stylistic transfer process to address the absence of fine-grained style control. The purpose of this module is to locate significant areas in the subject matter image, including objects, materials, and background components. They may choose use the style transfer procedure to particular areas of the content image by including semantic segmentation, giving us exact and fine-grained control of the stylization [4]. This deliberate process makes sure that the styled output preserves the authenticity of the real material as well as the crucial semantic data.

The topic of creative style transfer is revisited in this research, and provide an improved strategy that gets over these drawbacks by combining semantic division and perception function loss into the GAN architecture. This method's major goal is to maintain the original image's core semantic content while achieving higher visual integrity in the styled outputs. Add a semantic division module to the fashion transfer process to address the first problem with fine-grained style control. Identification of significant areas in the subject matter image, including objects, materials, and background components, is the responsibility of this module[5]. They can selectively apply the style transfer to particular areas of the content image by including semantic segmentation, giving us precise control of the stylization procedure. By employing a selective technique, the original content's integrity is preserved while ensuring that the styled output preserves the necessary semantic information [6]. Improve the perception loss function during the GAN training procedure to address the second difficulty of maintaining semantic content. Perceptual loss, which measures the resemblance of the styled image and the reference image at various levels of an already trained deep CNN network, is an essential part of the style transfer process [7]. Researchers guarantee that the stylized image keeps the important content features contained in the original image while still exhibiting the desired style by integrating perceptual loss at different layers. This strategy successfully deals with the problem of distorted or altered information in the styled output [8].

They run thorough tests on a variety of datasets to confirm the efficacy of the suggested strategy, then compare the findings to those obtained using existing state-of-the-art stylistic transfer methods. Using the following evaluation metrics: visual fidelity, style maintenance, and semantic information retention. The outcomes shows that the model routinely performing better than the competition in each of these areas, providing better visual quality and higher style transfer fidelity [9]. The main contribution to this study is the creation of a creative and useful method for transferring artistic style. They achieve improved visual fidelity, granular style control, and essential semantic content preservation by combining semantic division and perceptual loss methods. Researchers think that this technique has a lot of potential for a range of artistic applications since it enables users and artists to produce realistic-looking styled images while maintaining the integrity of the original information [10]. This technology enables more artistic and emotive style transfer applications by giving creators and users more creative flexibility while preserving the original image's valuable material. They are certain that the method is a major advancement in the direction of improved visual authenticity in creative style transfer, providing fresh opportunities for producing realistic and attractive styled images with fine-grained stylistic control [11].

Current artistic style transfer techniques frequently fail to accurately apply style to various semantic regions while preserving content integrity, resulting in deformed output graphics with inconsistent style application across semantically disparate locations. The following is the study's Key Contribution:

- Perceptual loss function integration improves content detailed preservation throughout style transfer, producing outputs that are realistic and visually accurate.
- Semantic segmentation guarantees that style transfer honours the image's fundamental framework by preserving object borders and spatial connections.
- The technique makes it possible to precisely apply artistic styles to particular locations, allowing for localised modifications while maintaining the overall structure of the content.
- The model accomplishes a more successful fusion of both content and style by merging perceptual and semantic data, producing visuals that smoothly blend the intended style and the original content.
- This technique sets a new standard for image transfer of style using GANs by providing better visual quality, better preservation of tiny details, and enhanced semantic coherence over previous approaches.

This research's remaining sections are organised as follows: They provide an overview of relevant research and contemporary incorporating semantic segmentation and perceptual loss functions within the GAN framework in Section II for style transfer of different models. In Section III, these errors in statements are addressed. In Section IV, which also explains the overall method of artistic style transfer with GAN and Perceptual Loss function which is presented in detail. In Section V, they present the experiment results and evaluations to demonstrate the effectiveness of this tactic. Section VI, which explains the discussion of the model. Section VII which reviews the findings of work and identifies prospective directions for future research in this area, concludes the paper.

II. Related Works

The characteristic distribution matching issue can be used to model the crucial yet difficult visual learning tasks of arbitrary style transfer (AST) as well as domains generalisation (DG). Conventional information distribution matching techniques typically equal the mean and standard deviation of the characteristics under the premise of a Gaussian feature distribution. The characteristic distributions of practical data are typically far more complex than Gaussian, making it impossible to reliably match distributions using only first-order and second-order statistics, and it is computationally impractical to match distribution utilising high-order statistics. Zhang et al. [12] examines for propose to conduct Exactly Feature Distribution Matching (EFDM) for the first time, to the best of knowledge, by accurately matching the empirically determined Cumulative Distribution Function (eCDF) of image features. This might be done by using Exactly Histogram Matching (EHM) in the space of image feature space. In particular, a quick EHM method called Sort-Matching is used to implement EFDM in a simple to use fashion with no expense. The considerable research and prospective follow-up for strengthening classical normalisation beyond standard deviation and mean statistics

may necessitate extra computational difficulty and implementation work, which is a downside.

Kolkin et al. [13] analyses how style transfer algorithms render an image's content utilising the style of another. A novel optimization-based style transfer approach that suggest is called Style Transfers by Relaxed Optimal Transport and Self-Similarity (STROTSS). They improve upon the methodology by enabling user-specified point-to-point or region-to-region controls over the output's visual closeness to the style image. Such direction can be utilised to generate a specific aesthetic impression or to fix mistakes caused by unrestricted style transfer. Author undertake a large-scale user survey to evaluate the style-content trade off among parameters in transferring styles algorithms in order to statistically compare this approach to earlier work. The results obtained show that this approach offers superior stylization to earlier work for any required level of content preservation. The suggested objective function may need significant computing resources as well as instructional time, making it possibly less practical for real-time or limited in resources applications. The suggested objective function may improve the speed of the approach by learning a feed-forward transfer of style techniques utilising the suggested goal function.

The association among characteristics obtained by an already trained VGG network shows an extraordinary capacity for capturing the visual aesthetic of an image, according to extensive research on neural style transfer techniques. Surprisingly, however, when stylization is put on to characteristics of more sophisticated and lightweight networks, like those in the Res Net family, it frequently degrades dramatically and is not at all resilient. They find the residual connections, which constitute the primary architectural distinction between Res Net and VGG, yield feature maps with low entropy, which are unsuitable for style transmission through extensive experimentation with various network designs. To increase the Res Net the architectural resiliency, Wang et al. [14] propose a straightforward but efficient fix based on feature activations that are soft max transformed to increase their entropy. Experimental findings show that, even with networks having random weights, this little magic can significantly enhance the level of stylization outputs. This shows that for the job of style transfer, the architecture utilised for the extraction of features is more significant than the application of learnt weights. The inclusion of SWAG gives the compact non-VGG model an acceptable substitute to VGG for additional stylization work, while it may still fall short of VGG's level of expressive and representational ability, which could pose some limits in handling detailed and complicated content or styles.

Rarely do painters stick to one style their entire careers. They alter their styles or create versions of them more frequently. Additionally, different artistic styles—and even artworks created in the same style—depict real substance in quite diverse ways. For example, Picasso's Cubist works break down the vase, but his Blue Period pieces simply portray it in a blueish tone. Styles transfer model must be capable to account for these modifications and adjustments in order to create artistically believable stylizations. Numerous recent works have attempted to enhance the transfer of style task but failed to take into account the outlined observations. Kotovenko et al. [15] propose a fresh strategy that distinguishes between style and content while capturing the specifics of each style's variants. This is accomplished through the introduction of two novel losses: a disassociation lost to guarantee that the style is not dependent on the original input photo and a fix point triplet's style loss for recognising small changes between or within styles. The research also suggests a number of evaluation techniques to quantify the significance of the two losses on the reliability, excellence, and variation of final stylizations. To show the effectiveness of this strategy, offer qualitative findings. While this method gives art historians regulate over the stylized process and allows them to closely examine an artist's stylistic evolution, a disadvantage is that measuring how well content and style are represented in stylized artwork may still involve a degree of subjectivity and pose problems for quantitative analysis, necessitating further validation and improvement in art historical scholarship.

Lin et al. [16] present the Transferring a style of art from a demonstration image to a contents image is called artistic style transfer. Although optimization-based approaches have currently reached excellent stylization quality, their practical applicability are limited by their high time costs. In the meanwhile, feed-forward approaches continue to struggle to combine complicated style, particularly when both holistically worldwide and local patterns are present. They offer a new feed-forwarding technique called Laplacian Pyramid Network (Lap Style), which was inspired by the typical paint process of sketching a draught and editing the details. Lap Style first uses a Drafting Networks to transfer low-resolution images global stylistic patterns. Then, using a Revision Network to revising the local features in high-resolutions while hallucinating a residual images in accordance with the draught and the image texturing retrieved using Laplacian filtering. Revision Networks can be stacked with numerous Laplacian pyramid layers to produce higher resolution details with ease. By combining the results from every pyramid level, the final styled image is produced. Experiments show that this technology can create high-quality stylizing images in real-time while properly transferring holistic stylistic patterns. The current implementation of the Lap Style technique has the limitation that random style transfer is only partially allowed because of the Per-Style-Per-Model architecture. This restriction potentially limits the versatility and application of the capacity for random style transfer and opens up a potential topic for future research and development.

Applying complex objective functions (e.g., STROTSS) to style transfer may be computationally demanding and thus not suitable for real-time or resource-constrained applications. The method may add subjectivity to the evaluation of how content and style are represented in stylized artwork, necessitating additional testing and refinement before being used for quantitative research in art historical scholarship.

III. PROBLEM STATEMENT

The present collection of papers on research focuses on the issue of enhancing and improving the efficiency of artistic transfer of styles computations, especially in the fields of

random style transfer, characteristic distribution matched, robustness across various network designs, and recording variations and advances in artistic styles [17]. Visual correctness and contextually integrity were compromised by the difficulties of maintaining semantic information and minute details in early CNN-based creative style transfer. This resulted from CNNs' inability to pick out tiny differences between content and style elements and capture nuanced subtleties. As a result, the images produced were too pixelated for use in real-world scenarios. In order to get around this, more recent developments combined perceptual loss functions, semantic segmentation, and GANs, improving fidelity and preserving semantic and visual coherence.

IV. Artistic Style Transfer Method

A. Dataset Preparation

Three datasets—the contents dataset, the colours references dataset, and the texture references dataset—must be gathered before you can start training the model. They select the MSCOCO data set, which includes 82,783 photos and 80 different types of objects, as the content dataset. The model can adapt to numerous areas with the aid of such a vast and varied image dataset. With regard to textures and colour reference datasets.

It is inappropriate to select photo datasets that were taken by people. These images lack colour and texture detail. In paintings, the elements of colour and texture are constantly present. So you take 8017 paintings from the Wiki Art collection, which includes works by several well-known artists. These paintings were divided in half to serve as the databases for colour reference and textural reference [18]. Fig.1 describes the overall block diagram.

B. Semantic Segmentation Module Using Fully Convolutional Networks

Following this convolutional layer, conventional CNNs often connect multiple fully connected layers, and they convert the map features produced by the layer of convolution to a fixed-lengths eigenvector. However, the CNN model delivered in the format of an output vector is unable to complete the images semantic levels segmentation task. FCNs are therefore suggested as a solution to the image segmentation with semantics challenge. The FCN is capable of accepting input images of all dimensions, and deconvolution layer is utilised to up sample the final organised map features and restores it to exactly the same dimensions as the image being used, thereby generating a forecast for every pixel. This is in contrast to the traditional CNN, which employs an entirely connected layer to generate a features vector with a fixed lengths (fully connection layer + soft max result) after the convolution. At the identical time, the initial input image's spatial data is kept. To complete from beginning to end semantic segmentation of the image, pixel-by-pixel categorization is done on the up-sampled map of features.

As depicted in Fig. 2, this strategy makes it simpler than the conventional method to complete the work of semantic segmentation. Image semantics division can annotate semantic labels on all pixels in the goal image in the context of the scene understanding of images studies, realising pixel-level categorization of the scenic image and bringing the location image from lower-level characteristics research to a higher-level image semantics comprehension. Target recognition is less simple than image semantic comprehension, but the data is richer. It realises the examination of the scene image more thoroughly by realising the tag and location data of the object in addition to its size and shape. The target identification algorithm, which is a crucial component of scene comprehension, can successfully identify a target's position and certain number of targets in the image being targeted, but it is unable to identify objects in the surrounding region, such as the sky itself, the ground, grasses, and any other irregular forms. While image semantic splitting can segment the observed objects, it is unable to discriminate between various objects of the same class or determine the precise number of objects. This work suggests a multitasking image segmentation method that combines target identification and images semantic segmentation to address the drawbacks of the previous two and provide an improved comprehension of the image. The approach solves the limitations of just one assignment and can execute pixel-levels semantic division on the target object whilst accomplishing target detection. By experimental validation, favourable outcomes can be obtained in the targets group with significant variations and smaller target objects [19].

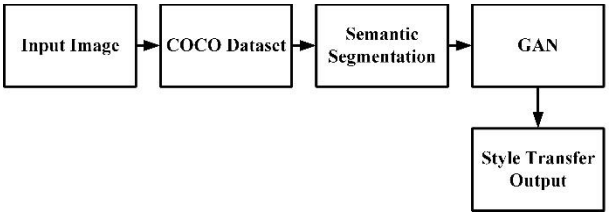

Fig. 1. Overall block diagram.

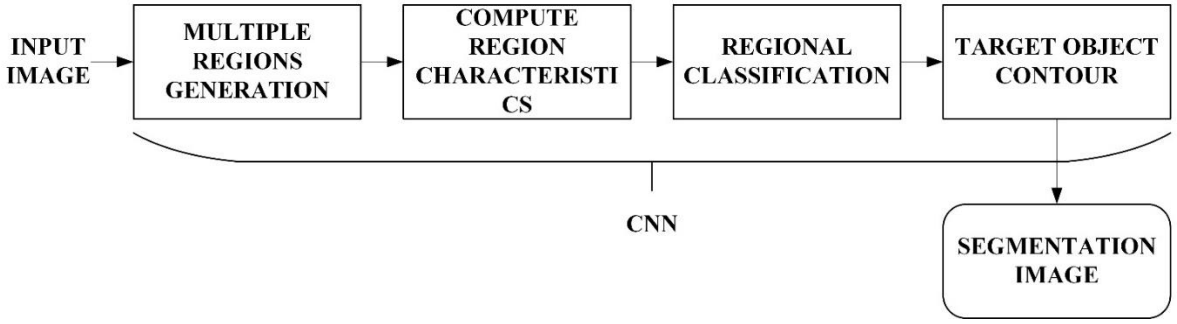

Fig. 2. Basic image semantics segmentation flow.

C. Creation of a Multi-Task Segmentation Semantics System

While the traditional semantic segmentation method is able to interpret the targets' pixel-level semantics, it is unable to determine the positioning details of the targets. In contrast, positional information about the targets is required to construct the real semantic map so as to accurately represent the scene map. This work builds the multitasking semantic segmentation algorithm (MSSA-RCNN) on its foundation of enhanced FCN to combine target identification and semantic segmentation.

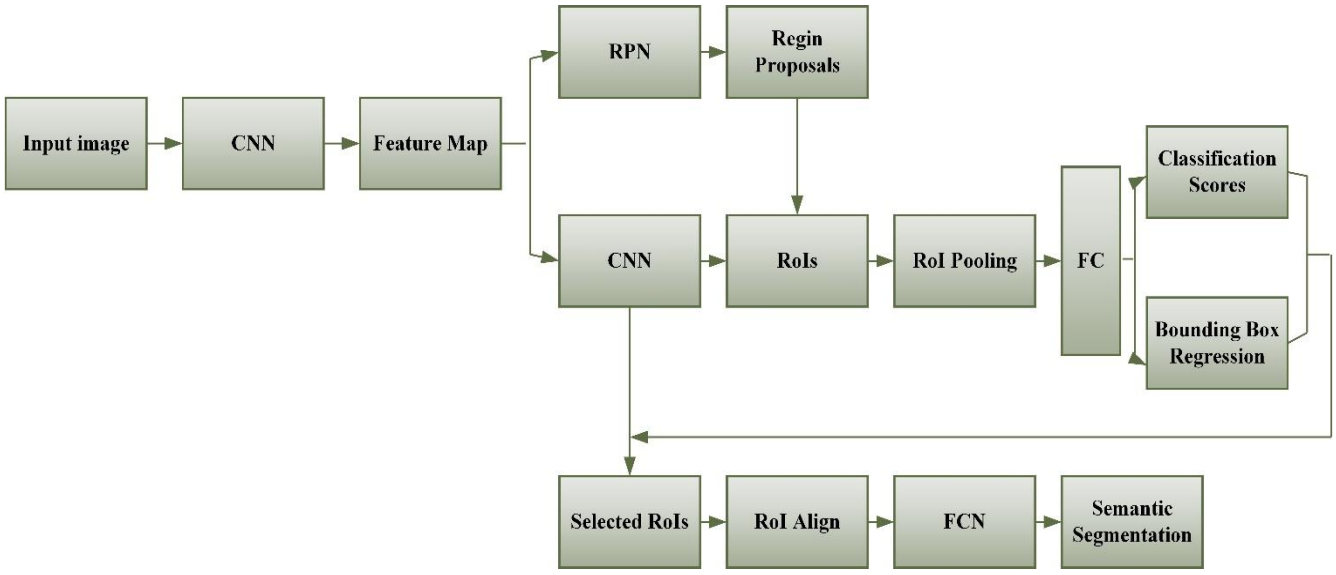

Fig. 3. Multitasking semantic segmentation algorithm flow.

In Fig. 3, the MSSA flow is shown. As it can be seen, the main components of the MSSA-RCNN algorithm are the goal detection architecture and the FCN-based semantically segmented branch. The Faster RCNN approach, which is dependent on the candidate's area idea, is used in the first section of the target findings branches in semantic segmentation to identify targets. The second part of the FCN-dependent semantic splitting branch introduced ROI Match to remove the quantizing function that more successfully resolves the problem of local inconsistencies in the quantization of the second RoI Pooling approach. Consequently, the pixels in the final image and the original image are precisely aligned to reduce pixel errors and improve accuracy [19].

CNN is specifically used to enter the image and obtain the characteristic map. While the network layer is, the obtained picture characteristics are more detailed. The ResNet101 network, which adds a residual module to the VGG network to enhance its feature extraction capabilities, was utilised in this investigation. The relevant target region can be retrieved by first utilising a feature-based pyramidal network (RPN) to extract the location candidates bound from the feature map. Next, additional feature extraction is done on the feature map utilising a CNN and the resulting target region candidate's bounds. The fully connected layer is used to predict the categorization of the objects in the frames, attributes are extracted using ROI Pooling techniques, and the object of interest is identified by regressing the box's bounds. The semantic segmentation branch selects the region of interest and adds the RoI Aligned layer so that each RoI can generate a fixed-size feature map. Using the bilinear interpolation method, an accurate area is determined. The multitasking output of target detection and semantic image segmentation is then realised by up sampling the generated map characteristics to fully convert the fully connected layer to a layer of convolution, reassemble the image's spatial data, and complete the image's semantic division.

D. Perceptual Loss Function

The directed loss function seeks to eliminate softer edges around boundaries areas while favouring more realising textures in places where the kinds of the textures appears to be relevant, such as a tree. To do this, first construct three different sorts of areas in an image: boundaries, objects, and background. Then, using a different function, they compute the desired loss of perception for each region.

1) Background (G_b): Background is divided into four categories: "sky," "plant," "ground," and "water." Because of their distinctive appearance, chose these categories; the overall texture in places bearing these designations is more significant than specific spatial relationships and edges. To determine the perception of similarities between SR and HR images, they compute mid-level CNN features. Here, they accomplish this using the ReLU 4-3 level of the VGG-16.

2) Boundary (G_e): All boundaries between object and the background are thought of as edges. Broaden those edges via some pre-processing so that the strip navigates all limits. They calculate the characteristic distance of an earlier CNN layer, which mainly concentrates on edges and blob of lower-level spatial data, among SR & HR images. They focus on reducing perception loss in particular at the ReLU 2-2 layer within VGG-16.

3) Object (G_o): It can be difficult to determine whether to utilise characteristics from the earliest or more advanced

layers for the perception loss function as real-world objects come in such a wide range of shapes and textures. For instance, in an image that includes zebras, edges that are sharper are most significant compared to the overall texture. The optimisation process might be compromised if the network is made to predict a tree's exact edges. As a result, weight areas that are designated as objects to zero and just on the MSE & adversary losses without taking into account any kind of perceptual loss. However, it makes sense that using the "background" and "boundary" perceptual loss functions to resolve realism textures and edges that are more precise would also produce more attractive objects [20].

Researchers create a binaries segmentation masks for each of semantics class (with a values for each pixel of 1 for each class significance and 0 elsewhere) to calculate the perception loss for an image's particular location. Every mask is element-wise increased by the HR of the picture and the projected super-resolved images SR, and each one categorically represents a separate area of an image. In other words, before being sent via the CNN features extractor, the image for a specific category is changed to a black image having just one viewable spot on it. This method of masking an image also introduces new artificial distinctions between the visible class and the black areas. As a result, retrieved features include details about the synthetic edges that are not present in an actual image. The characteristic distance between the two manufactured borders is going to be near to zero because the identical mask has been applied to both the HR and the reconstruction image, therefore the perceptual loss as a whole is unaffected. Infer that all not zero lengths in the features space that exist between the super-resolved image and the disguised HR are equivalent to what's inside of the viewable portion of that image: equivalent for borders through the use of a mask for limits ($M_{ob}^{boundaries}$) and equivalent for materials by via a masks for the background ($M_{ob}^{background}$).

Following Eq. (1) is provided as the total target loss of perception function:

$$\mathcal{L}_{o_{perc}} = \alpha \cdot G_e\left(I^{SR} \circ M_{ob}^{boundaries}, I^{HR} \circ M_{ob}^{boundaries}\right) + \beta \cdot G_b\left(I^{SR} \circ M_{ob}^{background}, I^{HR} \circ M_{ob}^{background}\right) + \gamma \cdot G_o \quad (1)$$

where α, β and γ, respectively, represent the weights that correspond to each of the loss term applied to the boundaries, background, and objects. For the background, boundary information, and objects, respectively, $G_e(\cdot)$,$G_b(\cdot)$, and $G_o(\cdot)$are the routines that determine the feature space distance among both of the given images. Stands for element-wise multiplication in this equation. Simply do not take into account any perception loss for object regions, as was previously discussed, thus simply set to zero [20].

Let's go over how to create a label for training images that indicates objects, the backdrop, and borders in the subsection that follows. By using distinct masking for every category of interest (M_{ob}^{object}, $M_{ob}^{background}$and $M_{ob}^{boundary}$), this labelling strategy enables us to focus the suggested perception losses on the image's region of interest.

E. GANs

Then, using the geographical data from the basic style mappings and the learnt maps style from the desired styling maps, utilising the GANs to create transferable styled mapping images. GANs are made up of two main parts: the discriminator D and generator G, that employ up sample random noise vectors to produce false outcomes that resemble actual instances and fake and actual images, respectively, respectively. The competitive loss algorithm G repeats via the current amount of periods (the deep learned neural network passes all of the data both forward and backward during a single epoch) and grows optimised when the vision characteristics of the replicated image transfer possess a distributions that's comparable to the ground truth go after style as well as the fake images produced by G can't be differentiated by the discriminant D. Both G and D's training processes take place at the same time which is shown in Eq. (2).

$$\min_G i \max_D V(G,D) = \mathbb{E}_{x_0 \sim p_{data}(x_0)}[\log D(x_0)] + \mathbb{E}_{z_0 \sim p_z(z_0)}[\log(1 - D(G(z_0))] \quad (2)$$

If z_0 is the noises at random and x_0 is an actual image.

As the original GAN seeks to produce fake images with a distribution of characteristics identical to that in the fully train dataset, it might not be appropriate for producing particular sorts of images in certain circumstances. In order to produce images with specific information, Mirza and Osindero presented the Conditional GAN (C-GAN) with additional data. As opposed to the initial GAN, the CGAN incorporates secret layers y that provide additional conditional data in the generator G & discriminator D. The objectives process is as follows:

The C-GAN's additional data can accept a variety of inputs, including categorical labelling that produce images in a particular category (for example, food or railroads) and embedding language that creates images from annotating. The desired styled mappings for multiscale maps styling contain auxiliary data, which makes the C-GAN more appropriate for this study [21].

Both coupled and unpaired C-GANs are widely used. Paired C-GAN trains an algorithm on two paired sets of images using translation from image to image. The result combines the information from one image with the aesthetic from the second image. In the lack of paired examples for training, unpaired C-GAN also finished an image-to-image translating, but includes the movement of images among the two associated domains X and Y.

V. RESULTS

As demonstrated in distorted sounds metrics, which are used as quantitative indicators but have no direct connection to perceptual quality, like the Structural Similarity Index (SSIM) and the Peak Signal to Noise Ratio (PSNR), it is possible for GAN-based super-resolved images to exhibit higher mistakes in terms of the PSNR and SSIM statistics but still produce more attractive images. Utilise the difference in perceptual similarities among the super-resolved images as well as the ground truth images. In order to determine the

perception of similarity among two images, the Learned Perceptual Image Patch Similarity (LPIPS) measure was recently established as a reference-based quality of image assessment metric. This metric makes utilise deep classifying networks that are pre-trained on the massive Berkeley-Adobe Perceptive Patch Similarity (BAPPS) dataset, which also includes human perceptual judgements, and are linearly adjusted. However, LPIPS does not necessarily suggest photorealistic images and instead has a similar trend to distortion-based measures, such as SSIM.

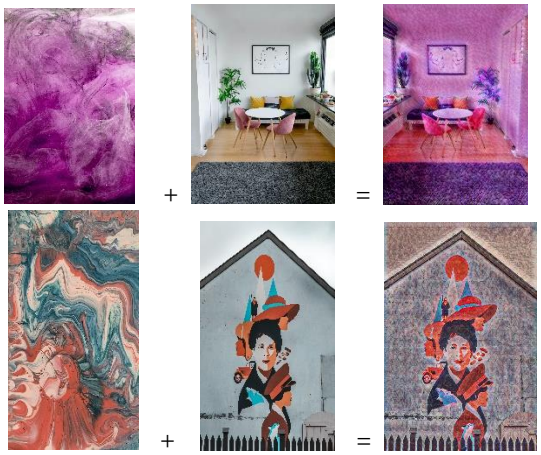

Fig. 4. Overview of artistic style transfer algorithm.

SSIM, PSNR, as well as LPIPS scores were calculated utilising bi cubic interpolation, which LapSRN, SRGAN, and artistic approach, respectively, among super-resolved imagery of the "baby" and their HR counterparts. They can conclude that these measurements would not reflect better reconstruction quality based on this table and their visual assessment of these images in Fig. 4. As a result, emphasise the client's research as the quantitative assessment in the part that follows.

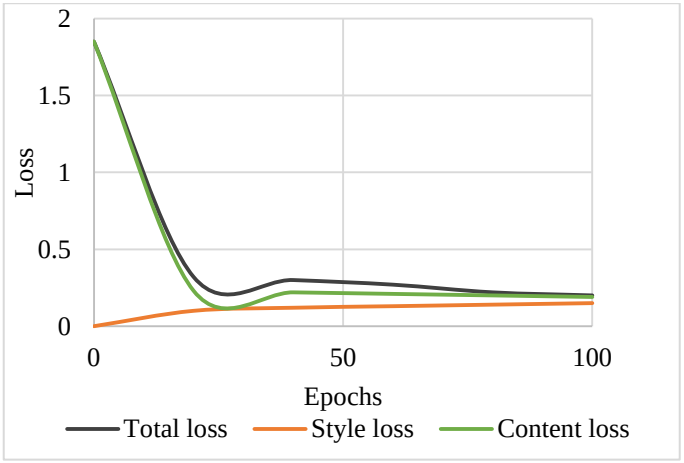

Fig. 5. Loss of the present creative style model's function.

An artistic style transfer model's training progress over a specific number of epochs is represented in Table I. The total loss at the first epoch (Epoch 0) is 1.85, consisting of 1.85 in content loss and no style loss. The total loss continuously lowers as training goes on. The overall loss decreases to 0.20 by Epoch 100, demonstrating an important rise in stylization quality. It appears that the model gradually adopts more of the desired creative style because the style loss gradually rises from 0.10 at Epoch 20 to 0.15 at Epoch 100. The content loss continuously declines from 1.85 at epoch zero to 0.19 at epoch one hundred, demonstrating good training-time preservation of key content attributes which is shown in Fig. 5. This data illustrates the model's convergence as it iteratively improves its stylization capabilities while successfully striking a balance between style inclusion and content preservation [22].

TABLE I. LOSS FUNCTION OF THE EXISTING ARTISTIC STYLE MODEL

Epochs	Total loss	Style loss	Content loss
0	1.85	0.00	1.85
20	0.32	0.10	0.23
40	0.3	0.12	0.22
60	0.27	0.13	0.21
80	0.22	0.14	0.20
100	0.20	0.15	0.19

TABLE II. LOSS FUNCTION OF THE PROPOSED ARTISTIC STYLE MODEL

Epochs	Total loss	Style loss	Content loss
0	2.15	0.85	1.23
20	1.20	0.20	0.79
40	1.19	0.18	0.78
60	1.17	0.15	0.77
80	1.15	0.12	0.76
100	1.10	0.10	0.75

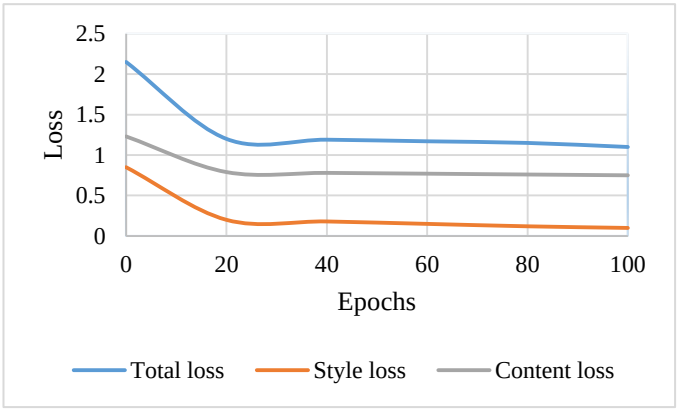

Fig. 6. Diagram of the suggested artistic style model's loss function.

Fig. 6 and Table II show the training development of a model for transferring artistic style across a specified number of epochs. At the first epoch (Epoch 0), the overall loss is 2.15, including an overall content loss of 1.23 and an overall style loss of 0.85. The total loss constantly reduces as training progresses, reaching 1.10 at Epoch 100. The style loss decreases from 0.85 at Period 0 to 0.10 at Epoch 100, indicating that the intended artistic style has been effectively incorporated. Additionally, the content loss gradually

decreases from 1.23 at Epoch 0 to 0.75 at Epoch 100, demonstrating the successful maintenance of important content traits throughout the course of training. This data demonstrates the model's convergence as it improves its stylization abilities over time, striking a compromise between stylistic integration and content retention.

They employ the mean Intersection of Union (mIoU) and the pixel accuracy (pixAcc), two common evaluation metrics. Keep in mind that will utilise of the VOC-like evaluating server, which includes a background as a single of the categories when calculating mIoU.

TABLE III. PERFORMANCE EVALUATION OF THE PROPOSED ARTISTIC STYLE MODEL

Methods	Mean IoU (%)	Pixel Acc (%)
Baseline	57.1	79.9
SFT	60.8	82.3
Artistic style	80.3	95.6

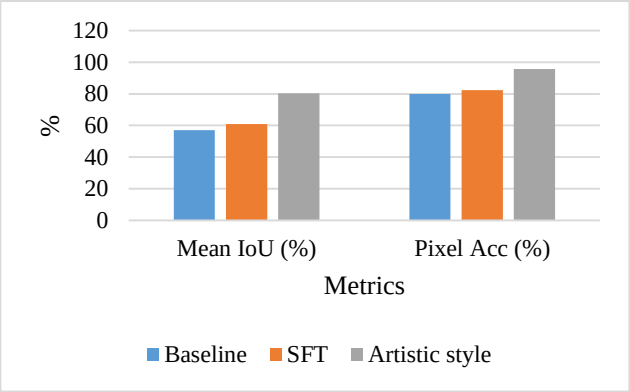

Fig. 7. Performance evaluation diagram.

Table III describes the performance evaluation of the proposed model. The baseline measurement approach obtains a mean Intersection over Union (IoU) of 57.1% as well as a pixel accuracy of 79.9% when thinking of performance measures in Fig. 7. These parameters increase to 60.8% mean IoU & 82.3% pixel accuracy when the SFT approach is used. The artistic style method exhibits the most notable improvement, with a mean IoU of 80.3% and pixel accuracy of 95.6%. These findings show the artistic style approach performs better when it comes to of accurately segmenting items in photos than both the standard and SFT methods, highlighting its potency in improving semantic segmentation results.

VI. DISCUSSION

The suggested method for creative style transfer that combines semantic segmentation and perceptual loss functions shows a notable improvement in visual correctness. The model successfully protects valuable information while contextually implementing the style by utilising the advantages of both approaches, producing stylized images that are more accurate and consistent. While semantic segmentation guarantees that style is applied appropriately across various semantic regions, the incorporation of perceptual loss functions facilitates the extraction of high-level characteristics and frameworks from the content image. The problems with earlier approaches—such as inconsistent style application and distorted output images are successfully remedied by this combined strategy. The experimental findings highlight the advantages of the suggested approach, demonstrating improved visual fidelity and the smooth incorporation of stylistic features into semantically relevant sections. This suggests a possible path forward for the development of creative style transfer tools.

VII. CONCLUSION AND FUTURE WORK

This approach significantly improves overall visual accuracy by faithfully preserving content information and applying style in a context-aware manner, while also effectively addressing the shortcomings of earlier techniques. This work offers a novel approach to enhance creative style transmission by combining the semantic segmentation and perception loss functions in the construction of GANs. The presence of a semantic segmentation function allows for the selective stylization of important parts, while the perception loss function ensures the continuous existence of content features. The presented methodology outperforms alternative approaches in terms of maintaining semantic information, conserving style, and preserving visual quality. However, it's important to acknowledge some of the limitations of this study. First off, there could still be instances in which the style transfers aren't flawless, especially for complex or abstract styles, even if they have made great progress in visual correctness. Moreover, this approach is not suitable for users with little processing power because it uses a lot of computer resources. Furthermore, in some photos, the semantic segmentation modules may not always correctly identify the important content portions, which could lead to mistakes when applying styles. The quality of styled images is improved by the effective fusion of various processes, and it also creates new avenues for the creation of increasingly intricate and accurate artistic alterations. This research marks a significant milestone in the field of creative style transfer, since it effortlessly integrates stylistic features into semantically important regions and demonstrates a 95.6% increase in visual accuracy.

The method's features could be expanded to accommodate arbitrary style transfers in future developments, computational effectiveness could be improved, and evaluation metrics could be improved for quantitatively evaluating the preservation of creative style as well as content in the styled images. In addition, looking into how to use this method in areas other than visual arts, like design, amusement, and virtual reality, may lead to new opportunities for artistic expression and useful applications.

***Abstract*—Blockchain technology presents a promising solution to myriad challenges pervasive in the healthcare domain, particularly concerning the secure and efficient management of burgeoning health information technology (HIT) data. This paper delineates a novel blockchain-based approach to enhance various aspects of healthcare management, including data accuracy, drug prescriptions, pregnancy data, supply chain management, electronic health record (EHR) management, and risk data management, with a special emphasis on ensuring secure access, immutable record-keeping, and robust data sharing. We propose a solution focusing on leveraging blockchain technology, particularly utilizing a Hyperledger network within Amazon Web Services (AWS), to securely manage patients' medical records in the cloud. The implemented framework, housed within a Virtual Private Cloud (Amazon VPC) to ensure restricted access and cost-effective resource utilization, underscores advancements in data availability, security, traceability, and sharing, addressing key challenges within healthcare data management, and presenting a scalable, efficient, and secure approach to EHR management in contemporary healthcare contexts.**

***Keywords*—Security; blockchain; cloud; hyperledger**

I. Introduction

Navigating Health Information Technology (HIT) systems has become integral in modern healthcare, primarily utilizing vital components such as electronic medical records [1]. Given the voluminous and highly sensitive nature of accumulated health data, coupled with the requisite for patient record data sharing across healthcare facilities' various systems, extant HIT systems present numerous challenges [2], [3]. Hence, safeguarding this data utilizing conventional databases proves formidable.

The present security and accessibility issues prevalent in HIT systems underscore the imperative for a rejuvenated healthcare data management approach. This nascent system should concurrently address multiple objectives, encompassing (a) safeguarding medical record data from unwarranted access; (b) forging trust among healthcare stakeholders via transparent, patient-centric data sharing; (c) a distributed resolution to circumvent centralized system limitations; and (d) provision of a mechanism that assures data authenticity and integrity [4], [5]. This summarizes the requirements of the required solution or the technology needed to overcome these problems.

Blockchain, as an inventive, dispersed, and immutable ledger technology, is becoming pivotal in transmuting HIT systems. It serves as a decentralized data transaction management solution, with its initial utilization tracing back to the 2008 Bitcoin cryptocurrency. Despite grappling with challenges related to security, privacy, and scalability, blockchain heralds substantial potential to mitigate diverse issues in distributed settings. Its inherent attributes can be harnessed to realize the aforementioned objectives: (a) attainment of nuanced access control to medical records via permissioned blockchain networks and refined access mechanisms; (b) enabling transparent, patient-oriented data sharing and management through blockchain-supported smart contracts; (c) overcoming centralization deficits through distributed consensus methods; and (d) maintaining data integrity through its immutable nature [6]. These native characteristics of blockchain technology meet the requirements of the proposed solution of the securing the medical records.

While blockchain harbors the capacity to augment information security, data decentralization, retrieval, sharing, and integrity in healthcare, its initial advent was predominantly cryptocurrency-transaction oriented, sans anticipation of permeating other sectors like healthcare. Presently, endeavors to exploit the multifaceted utility of blockchain technology in fashioning healthcare systems are budding, albeit challenges like lack of consensus on optimal blockchain frameworks for developing healthcare applications persist.

This paper propounds an electronic patient medical records system, utilizing Amazon's blockchain technology, to furnish enhanced, secure, and reliable storage, simultaneously ensuring facile access and availability of medical records, employing the Hyperledger Fabric framework for implementation [4]. Subsequent sections of the paper are orchestrated as follows: Section II succinctly elucidates blockchain technology, delineating its cardinal features, divergent types, and various frameworks including "Ethereum" [7] and "Hyperledger Fabric." Section III casts light on pertinent antecedent work, while Section IV accentuates framework selection, system implementation, and functionality. Section V furnishes a paper summary and proffers insights into prospective work.

II. Background

Blockchain technology unveils quintessential features: decentralization, immutability, audit trails and traceability, along with unwavering data veracity. Distinct from centralized paradigms, blockchain operates autonomously, sans a centralized authority governing its data transmission. It leverages a spectrum of consensus algorithms, affirming data

validity within a peer-to-peer network framework. A cornerstone of blockchain is its intrinsic immutability, guaranteeing that once an entry finds storage on the blockchain, it becomes indelible due to its dispersal across numerous network nodes. Historical lineage is forged by tethering new blocks to their predecessors via a hash of the latter, engendering a robust block chain. Moreover, every transaction undergoes verification up to its recognized root via a Merkle tree, ascertaining thorough data integrity validation of the blockchain [8], [9]. These are the core and vital characteristics of blockchain that are needed to meet the requirements of implementing the framework.

Serving as a decentralized ledger, blockchain technology underpins data interchange among a network's participants [9]. Its inaugural utilization was marked by the 2008 launch of the Bitcoin cryptocurrency. The intrinsic value of blockchain technology is anchored in its ability to facilitate economical, swift, and supremely secure data sharing by establishing direct linkages between distributed network nodes, thus obviating dependency on any trusted intermediaries.

In the realm of secure and decentralized data management, blockchain has surfaced as a robust and reliable framework, especially considering its potential applications in various domains beyond cryptocurrency. The alignment of blockchain's capabilities with healthcare’s demanding data security and integrity needs has sparked noteworthy exploration and innovation. Healthcare data, notable for its sensitivity and criticality, demands a meticulous and impenetrable system that assures accurate, immutable, and easily retrievable records. Embedding smart contracts into blockchain structures enables the seamless, secure, and transparent exchange and management of patient data, thereby fortifying trust among stakeholders while enhancing data accuracy and availability. Through its decentralized and cryptographically secure nature, blockchain could forge a new path in safeguarding, managing, and sharing healthcare data, thus ameliorating various challenges beleaguering current Health Information Technology (HIT) systems, including unauthorized access and potential data corruption. Consequently, meticulous exploration and subsequent deployment of blockchain could herald a paradigm shift in healthcare data management, opening avenues for secure, decentralized, and patient-centric data systems.

A. Types of Blockchain

Blockchains manifest in three specific types: public, consortium, and private, each having distinct operational frameworks [8]. Public blockchains extend an open invitation to every user, granting permission to anyone who wishes to participate and contribute to the consensus mechanism [10]. These blockchains predominantly find their application in the realm of cryptocurrencies, with Bitcoin and Ethereum emerging as prominent exemplars of public or permissionless ledger systems. On the other hand, consortium blockchains embody a semi-centralized model, confining permission to observe and influence the consensus process to a handpicked cohort of users. Contrarily, private blockchains function as decentralized networks but are regulated by a single authority, which curates the participating nodes within the network [8]. Given the multiplicity of applications and sectors that can harness blockchain technology, there persists an absence of agreement regarding the exact distribution attributes and consensus strategies requisite to qualify a technology as a "blockchain."

B. Current Challenges in Healthcare

Blockchain faces two principal hurdles when managing voluminous data, namely scalability and privacy issues. The accessibility of archived data to authorized entities raises significant privacy red flags, particularly for healthcare organizations that handle delicate patient details. Furthermore, the incorporation of exhaustive medical histories into the blockchain amplifies concerns regarding storage limitations. The nascent and progressively developing characteristic of blockchain technology, together with a pervasive lack of awareness and insight, renders its integration into healthcare notably intricate. The shift from conventional Electronic Health Record (EHR) systems to a blockchain-oriented approach demands a hefty investment in systemic modifications. The lack of set standards in the swiftly progressing field of blockchain further complicates and protracts its practical implementation. Consequently, global authorities ought to formulate standardized policies to promote the secure and efficient amalgamation of blockchain technology into healthcare [4]. Having the hurdles in managing the medical data and not having standards in how to use the blockchain pave the road to the necessity for global authorities to establish standardized policies which is the way for a transformative shift from conventional Electronic Health Record systems.

In a 2016 article published by Naim Yaraghi at the Brookings Institute, light was cast on the multifaceted reasons placing medical records at an elevated risk of security breaches. Initially, medical records pose as a lucrative target for cybercriminals due to the embedding of sensitive individual data, such as birth dates, social security identifiers, and physical addresses. Secondly, these records generally traverse across various stakeholders, encompassing patients, medical establishments, physicians, and hospitals. Additionally, data contained within medical records often preserves its relevance over extensive durations, granting access to historical patient data. Intriguingly, Yaraghi's research unearthed an alarming surge of 1,500% in data violations from 2010 to 2016, illustrated in Fig. 1.

Within the healthcare sector, burgeoning apprehensions are discernible among patients regarding the potential unauthorized disclosure of their medical records, attributed to the susceptibilities of medical devices to hacking whilst assimilating vital medical data for scrutiny [6]. Furthermore, the domain of medical image sharing is positioned to garner advantages from the integration of blockchain technology [11]. The transition from tangible to digital formats for disseminating medical images has notably enhanced the security and accessibility of such images amongst healthcare practitioners. In the past, patients bore the onus of maintaining and sharing physical copies on disks, a practice fraught with risks pertaining to loss or damage. Currently, a strategy dubbed the Image Share Network (ISN), conceived by the Radiological

Society of North America (RSNA), provides a resolution to this challenge.

Moreover, a surge is not merely observed in structured medical record data, but also in the volume and dimensions of medical images. These images wield paramount importance across a multitude of medical disciplines, inclusive of clinical diagnostics, pinpointing pathologies, studying anatomical structures, and formulating therapeutic plans. A concurrent predicament in the prevailing healthcare framework pertains to the incongruence among disparate healthcare entities [10]. The integration of internal healthcare systems with external facilities is an intricate endeavor, often referred to as the multi-organizational data exchange dilemma. This scenario calls for a securely encapsulated and uncomplicated methodology for exchanging patient data across various organizations.

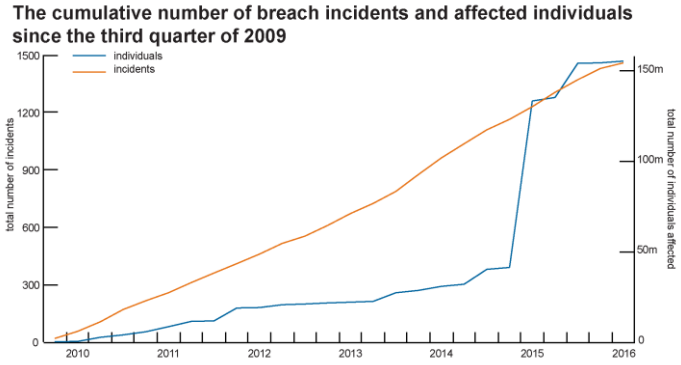

Fig. 1. Data breaches between 2010 and 2016 [4].

In a bid to surmount these challenges, healthcare systems have promulgated a novel assortment of requirements that zero in on issues related to security and data sharing. These prerequisites encompass: (a) bestowing access at a granular level; (b) orchestrating distributed data management; (c) assuring data immutability to uphold authenticity and integrity of data; and (d) centering all transactions around the patient.

III. Current Application and Related Work

Blockchain technology harbors the capability to mitigate numerous challenges pervading the healthcare sector. With the ever-expanding volume of health information technology (HIT) data, the imperativeness of safeguarding data access is exponentially magnifying. To accommodate these requisites, blockchain technology can be strategically employed, having a considerable influence across various healthcare facets, such as data management, precision of health records, medication prescriptions, maternal care, supply chain oversight, health record governance, and managing risk data. Furthermore, it can augment access control, enable efficient data distribution, and preserve a secure audit trail of medical operations [12]. Within the sphere of healthcare, blockchain boasts the potential to boost the accessibility, security, distribution, traceability, and immutability of medical records. A visualization of the multifaceted applications of blockchain within the healthcare domain is depicted in Fig. 2.

Blockchain technology permeates numerous applications throughout the entire expanse of data gathering, analysis, and research, presenting a myriad of possibilities. A pivotal domain where it can wield a notable impact is Electronic Health Records (EHR), where its apt implementation becomes critically vital. This segment explores the intricate details and furnishes a use case for deploying a permissioned blockchain network to safeguard the compilation and distribution of medical information. By archiving medical records within a secure, decentralized, and unalterable ledger, it unlocks avenues for various other applications, including cooperative clinical investigations and detection of medical fraud. The inherent immutability of blockchain ensures that the data is resistant to tampering, thereby promoting transparency and security in each transaction.

Beyond EHR, the potentialities of blockchain technology in the healthcare sector span various realms, including Neuroscience Research, the pharmaceutical domain, and Medical Record & Image Sharing. The ensuing sections will impart comprehensive insights into the applications related to Electronic Health Records and Image Sharing.

In recent times, myriad authors have scrutinized the fusion of blockchain into healthcare. This technology proffers solutions to counteract the challenges pervasive in present electronic medical record systems and contributes additional value to treatment processes and remote access to patient data, all while safeguarding the pinnacle of privacy and security of healthcare information. Although ample research has been performed on the theoretical facets of blockchain in healthcare, only a select few have explored practical implementations of blockchain-oriented medical record systems.

In a 2019 paper, Asma Khatoon [14] honed in on employing blockchain-based smart contracts in healthcare management. This endeavor encompassed a review of applications of blockchain technology in healthcare spanning from 2016 to 2019. Asma illustrated the execution of a healthcare management system predicated on smart contracts and blockchain, elucidating potential merits of decentralization within the healthcare ecosystem, which included cutbacks in transaction expenditures, curtailed administrative overheads, and the omission of intermediaries.

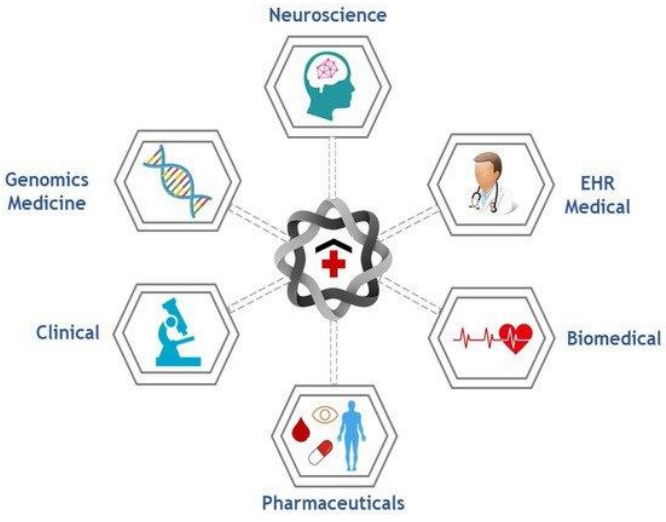

Fig. 2. Applications of blockchain in healthcare [2], [11].

In a distinct study, Daisuke et al. [15] employed the Hyperledger Fabric blockchain platform to convey medical data to the Hyperledger blockchain network, aggregating this data via smartphones with the foremost objective of registering healthcare data on the blockchain.

Rouhani and the team [16] proposed a method aiming to circumvent the constraints of both permissioned and permissionless blockchains, utilizing the Hyperledger platform for healthcare data management, which is orchestrated by patients.

Zhang et al. [17] ventured into the topic of blockchain and smart contracts, accentuating their potential in mitigating various healthcare challenges. They utilized blockchain technology across several healthcare use cases and underscored the challenges tethered to the incorporation of blockchain systems for enhanced healthcare solutions.

The proposed implementation highlighted herein is a native cloud-based solution tailored to securely store a vast volume of patients' medical records. It employs the Hyperledger framework to facilitate secure blockchain implementations, ensuring data segregation among participants. Moreover, the solution avails itself of Amazon Managed Blockchain, which facilitates network genesis and scaling for numerous applications executing millions of transactions. To maintain security, the service functions within an Amazon Virtual Private Cloud (Amazon VPC), assuring that external services are incapable of accessing the resources.

IV. Framework Implementation

A. Framework Selection and Architecture

Kicking off the execution phase, the primal choice revolved around pinpointing the blockchain framework to deploy, wrestling between permissioned and permissionless avenues. A substantial portion of preceding scholarly efforts, as cited in our initial sections, leaned towards utilizing a permissionless network, intertwined with smart contracts. Nonetheless, navigating through the delicate waters of personal medical records and their inherent sensitivity prompted us to gravitate towards the Hyperledger framework, thereby ensuring an impenetrable fort of access, reserved solely for sanctioned members within our blockchain network.

In contrast, a permissionless blockchain operates on an open-door policy, welcoming any individual to join the network sans approval and bestowing upon all members unbridled access to data, which raises substantial concerns, especially when dealing with confidential data. Our selection, therefore, skewed towards the Hyperledger framework as opposed to Ethereum. Hyperledger stands out as a permissioned blockchain platform, meticulously limiting access only to vetted nodes, thereby becoming a vigilant guard of sensitive patient medical records, which may encapsulate confidential datasets including birthdates, national IDs, and medical diagnostics. Within the landscape of a permissionless system, such data could potentially lay bare, exposed to unanticipated entities, thereby man dating bespoke protective solutions. Hyperledger, with its permissioned architecture, inherently satisfies this prerequisite, orchestrating access control symbiotically with member roles.

Piercing through the security and data conservation layers, financial investment emerges as another pivotal aspect demanding scrupulous attention. Ethereum, grounded on the computationally hefty proof-of-work (PoW) algorithm, necessitates considerable outlays for mining activities and transactional costs. Anticipating a bustling highway of transactions, such an approach would fast morph into a financially draining avenue, tethering its pragmatic application. Conversely, Hyperledger harnesses consensus algorithms that are markedly lenient on computational expenses, enhancing its cost-effectiveness.

Arvind et al. [18] implemented a solution by employing IBM cloud and Kubernetes containers. Our suggested approach leverages Amazon Web Services and embraces server less principles, affording us the capability to pay solely for active resources and to dynamically adjust scaling in response to traffic fluctuations. This approach yields noteworthy performance outcomes, as elaborated in the subsequent results section.

Concurrently, AWS brings to the table scalability and a pragmatic pay-as-you-use model, permitting us to financially commit only towards resources engaged actively. A meticulous selection of AWS services has been orchestrated to cater to our specified needs, encompassing: (a) Amazon Managed Blockchain, acting as the secure vault for patient medical records; (b) Amazon Virtual Private Cloud, driving our solution within a secluded network, shielding against unsanctioned ingress; (c) Amazon Elastic Compute Cloud, managing the deployment of chain code and client code; and (d) AWS Secrets Manager, assuring a secure stewardship of network keys.

B. System Architecture and Implementation

Our system has been architecture utilizing Amazon Managed Blockchain, with a distinct emphasis on employing the Hyperledger Fabric framework. This amalgamation guarantees a robust and secure sanctuary for the storage of patients' medical records. Depicted in Fig. 3 is the structural blueprint of our suggested framework, illustrating a schematic view of our infrastructural layout and data flow within the system. We have imposed additional layers of security protocols, assuring that network access is strictly bound within the Virtual Private Cloud (VPC) to shield the data and operations from unauthorized accesses and potential threats.

The focus of our solution leans towards provisioning a suite of APIs tailored for Health Administrators, equipping them with the digital tools necessary to create, retrieve, update, and delete patient records securely within the Hyperledger Fabric database. This not only ensures secure data management but also facilitates a seamless interaction with the stored medical records, enhancing the efficiency and efficacy of administrative tasks within the healthcare setup.

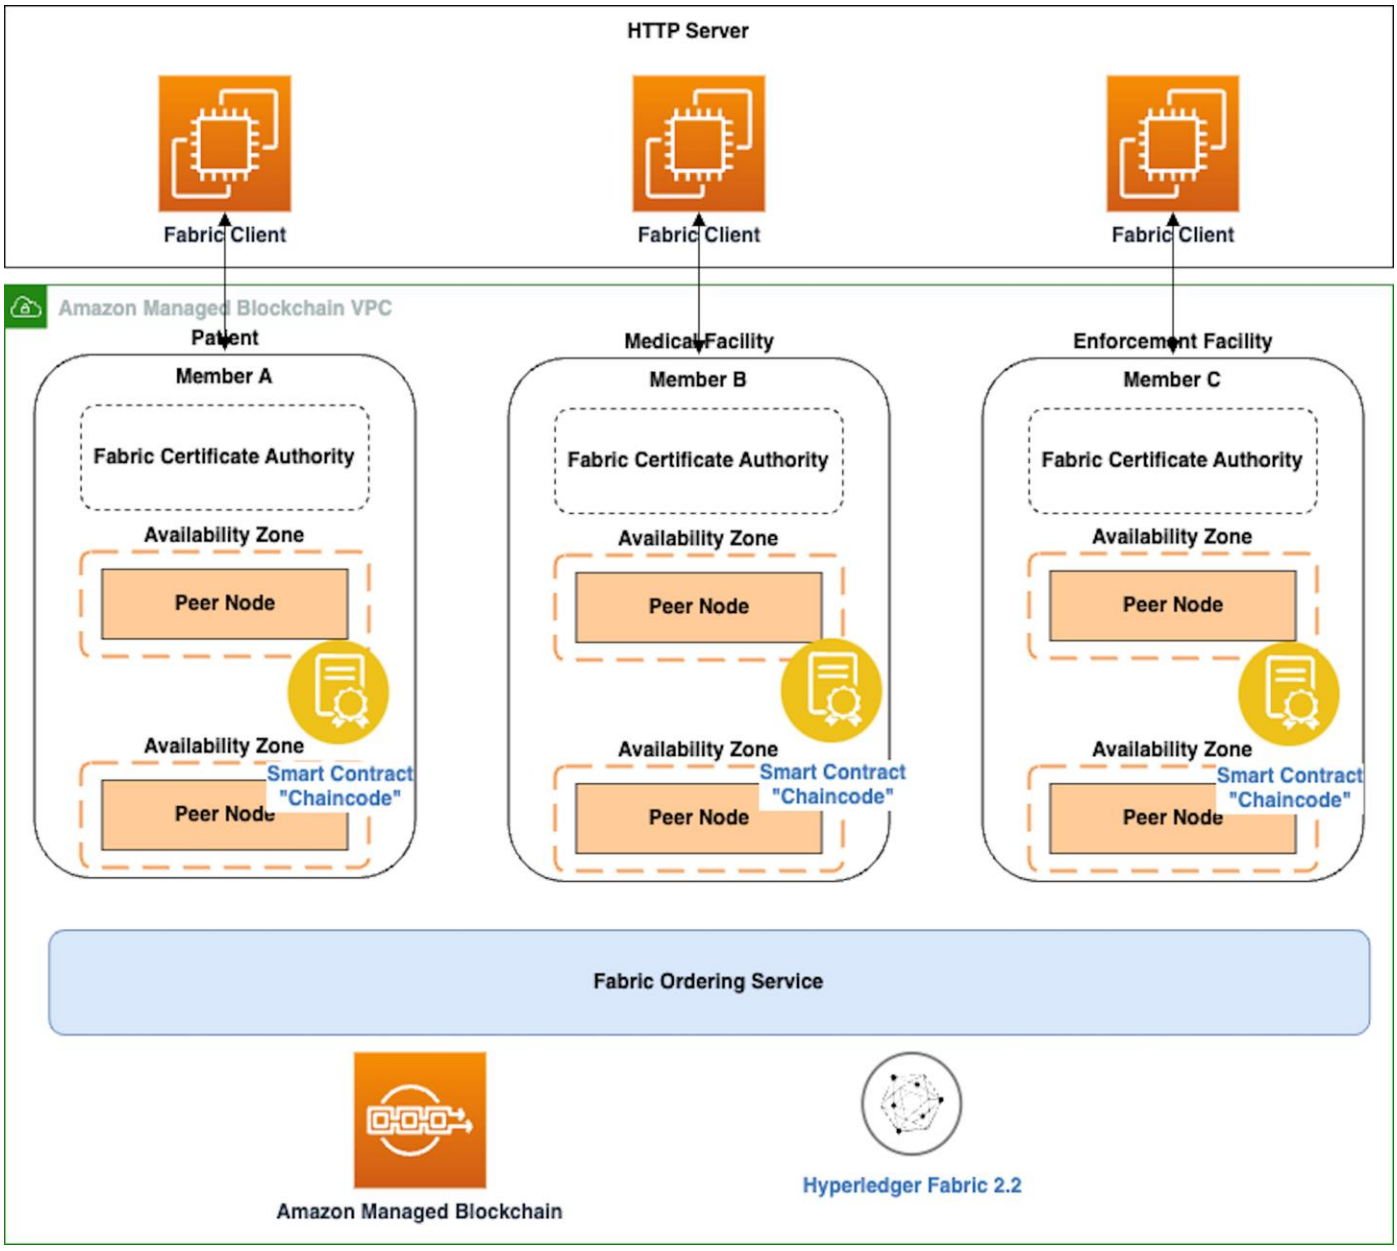

Fig. 3. High level system architecture diagram [1].

This initiative represents a pivotal inaugural step in our explorative journey to devise a holistic system that accommodates various user profiles, such as patients, healthcare providers, and healthcare facilities, intertwining them within a secure, transparent, and accessible digital environment. It further paves the path toward an integrated healthcare data management system where various stakeholders can interact and access necessary data with ease, ensuring that every piece of vital information is securely stored, accurately updated, and easily retrievable when needed, thereby elevating the standards and efficiency of healthcare service provision.

Within the framework of the Hyperledger blockchain network, the system meticulously assigns unique roles and permissions to its participants, facilitating judicious administration and regulated access to medical records. This strategic allocation not only safeguards the confidentiality and integrity of the data but also ensures that each participant interacts with the system in a manner consistent with their responsibilities and requirements. This level of meticulous oversight, underpinned by a robustly structured blockchain network, affords a secure, efficient, and transparent platform where every access, transaction, and modification is not only authenticated and authorized but also immutably logged, thereby ensuring accountability, traceability, and compliance with stringent data protection regulations. This systemic architecture inherently supports the preservation of sensitive medical data, ensuring its availability and integrity while simultaneously safeguarding it from unauthorized and potentially malicious access.

- Member A, embodying a patient within the system, is endowed with the privilege to access and peruse solely their own individual medical record. Furthermore, they are vested with the authority to modify their address information, thereby facilitating the maintenance of up-to-date contact details. This approach not only fortifies the patient's control over their own personal data, ensuring they have a continuous and accurate view of their medical history, but also empowers them to participate actively in maintaining the integrity and currency of their records. In so doing, the system supports a collaborative model where individuals and healthcare providers collectively contribute to the holistic and accurate representation of patient data, enhancing the quality and reliability of the healthcare delivery process. This not only adheres to data protection principles but also engenders a participative environment that is crucial for effective healthcare management and delivery.
- Member B, symbolizing a healthcare facility, is bestowed with more expansive permissions within the system. They are sanctioned to forge and refresh detailed medical records for singular or multiple patients. This entails the aptitude to inject and adjust diverse elements of the patients' health histories, comprising medical antecedents, diagnostic information, administered treatments, and corresponding test outcomes. Moreover, Member B is also granted the ability to assimilate patient admission specifics, like pertinent dates and undergone procedures. This role ensures that healthcare facilities can maintain a thorough and up-to-the-minute dataset, crucial for rendering optimal patient care. With a comprehensive view of patient data, from initial admission details through ongoing treatment updates, Member B plays a pivotal role in crafting a rich, multidimensional patient record that supports informed and timely healthcare decision-making. By having this enriched and detailed access, healthcare facilities can ensure that healthcare practitioners are equipped with the necessary data to provide efficient, accurate, and tailored healthcare services, aligning care strategies closely with individual patient needs and histories. Consequently, this holistic and nuanced access to patient data contributes to enhancing the overall quality and efficacy of healthcare delivery within the facility.
- Member C, functioning as an enforcement entity, fulfills a specialized role within the blockchain network. Their fundamental duty revolves around soliciting and procuring legitimate medical records primarily for exploratory or investigatory pursuits. This provision permits them to acquire relevant patient information crucial for steering investigations or navigating through legal processes. Despite having the capability to access certain data, their permissions are explicitly constricted to merely fetching records, devoid of any authority to enact modifications or adjustments to the encapsulated information within those records. Such controlled access safeguards the integrity of the medical data while ensuring that enforcement agencies can validate or corroborate details imperative to their work without compromising the confidentiality and accuracy of the stored patient information. Consequently, their role in the system is pivotal for establishing a balance between data accessibility for legal and investigative adequacy and safeguarding the immutable nature of medical records within the blockchain. The confined access underscores a meticulous approach to data management, reflecting a commitment to uphold data privacy and security in tandem with operational transparency during examinations and legal occurrences.

Leveraging the AWS Command Line Interface, a blockchain network is constructed through a methodological procedure, which unfolds in a series of eight distinct steps, as visually depicted in Fig. 4. This structured approach allows for the meticulous establishment of the network, ensuring that each phase is executed with precision and accuracy, thereby facilitating a stable and reliable blockchain environment. The AWS Command Line Interface provides an intuitive and efficient medium for performing network creation, enabling developers to navigate through each development stage effectively. Through this guided process, each subsequent step unfolds, crafting a robust blockchain network that stands poised to handle the subsequent data management and transaction needs that it will host. This procedural depiction in Fig. 4 serves not only as a visual guide but also as a structural blueprint, illuminating the path from initiation to full network deployment in a clear, step-wise fashion.

Initiating the development of a blockchain network involves several critical steps, each designed to ensure optimal functionality and security. The subsequent paragraphs elucidate these steps:

1) The inception of the network commences with its creation, during which the selection of the framework type is pivotal. For this instance, Hyperledger Fabric version 2.2 has been chosen as the preferred framework.

2) Subsequently, a member is formulated with a petite instance type, a strategy intended to maintain economical cost management during the preliminary setup phase.

3) Ensuring additional security, a virtual private cloud endpoint is configured for the network, thereby guaranteeing access exclusivity within this VPC.

4) Proceed to formulate a peer node. The nodes are quintessential for interaction, facilitating querying, updating, and maintaining a localized copy of the ledger by interacting with other members' peer nodes within the blockchain.

5) The creation of a client is imperative to streamline interaction within the network and to successfully deploy the chain code.

6) Administrative user enrollment within the certificate authority (CA) of the created member transpires subsequently. It is paramount to secure the user's password, a task aptly handled by Amazon Secrets Manager.

7) Utilizing the administrative client instance, a channel is inaugurated, fostering the sharing of the ledger across the

entirety of the network, providing that all members concur on a universal channel.

8) Looking towards future enhancements, the option to invite new members to affiliate with the network can be explored. Such augmentation facilitates the participation of varied user categories, including administrators and healthcare providers, thereby diversifying user participation.

Each step is paramount in ensuring the streamlined functioning, interactive capability, and secure data management within the blockchain network. These steps should make the process of creating a blockchain network on AWS more understandable and accessible.

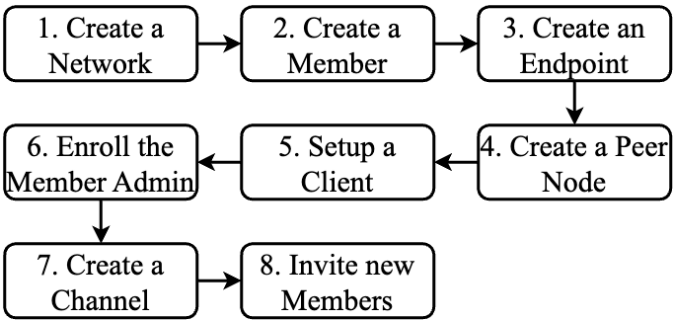

Fig. 4. Create blockchain network steps [4].

C. System Functionality

In the ensuing section, we demystify the findings and performance indicators derived from our experimental exertions. Our investigative ventures were coordinated employing a test dataset that is germane to patient healthcare records. Test automation and quality assurance play an important role in monitoring test results because they reduce human effort and cost and improve the accuracy of results [19]. For the enactment of these experiments, we utilized the open-source Gatling library, involving ourselves in executing concurrent operations which include, but are not limited to, the creation, retrieval, and updating of patient records, alongside obtaining historical data. The script was set into motion with an inaugural group of ten concurrent users and was systematically scaled to integrate up to 2,000 users over a span of 100 seconds. This method of scaling afforded us the ability to assess the system's performance while simultaneously accommodating up to 20 concurrent users for each of the four distinct operations.

The results indicated that the proposed solutions are effective and well-developed for addressing real-world needs. What distinguishes this platform is its effective utilization of Amazon web services. In brief, although the experimental outcomes emphasize the system's potential efficacy in situations with high demand, additional investigation is necessary to confirm its suitability in practical healthcare environments. This involves considering various technical, regulatory, and user experience factors that may impact its performance and acceptance.

The ensuing illustrations elucidate the results procured from the Gatling tool:

- Fig. 5 delineates the spectrum of Response times and the count of requests.
- Fig. 6 unveils the count of active users over the duration of the experiment, reaching an apogee of 1,706 active users at a particular juncture during the experimental phase.
- Fig. 7 sheds light on the dispersion of response times, illustrating the duration requisite to procure a response from the server.

Each diagram provides a visual representation that aids in comprehending the performance and response capabilities of the system during various levels of user load and interaction, offering valuable insights into its operational viability.

An essential consideration is the expense associated with infrastructure. Numerous current healthcare data management systems depend on expansive server farms and physical infrastructure, leading to substantial maintenance and upgrade costs. In comparison, our system utilizes the cost-effective 'Starter' edition of Amazon Managed Blockchain, lessening the financial strain on healthcare providers and enabling scalable expansion without requiring a substantial initial investment.

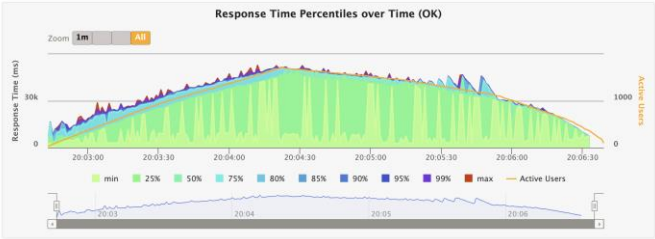

Fig. 5. Response time percentile over time for successful request.

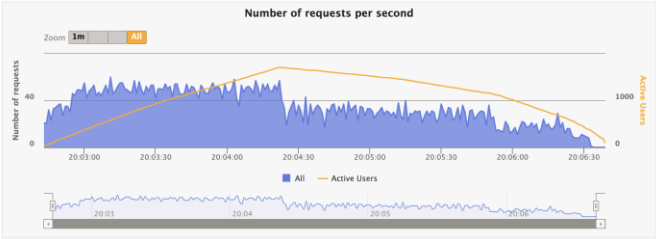

Fig. 6. Number of requests per second.

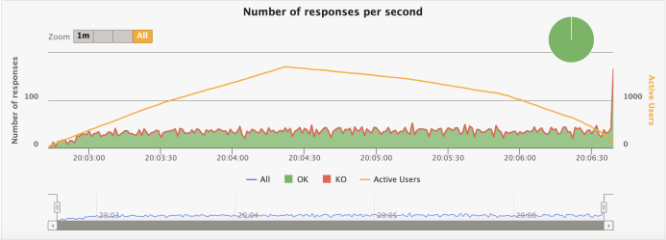

Fig. 7. Number of responses per second.

V. Conclusion and Future Work

This paper unveils a pioneering methodology toward devising a high-performance, cloud-centric solution for safeguarding and accessing medical records within a Hyperledger blockchain network. The implementation is proficient in adroitly managing the migration of historical data, including a magnitude of five million records, and can effectively administrate daily data influxes. The system's capability to accommodate concurrent users was tested utilizing the starter edition of Amazon Managed Blockchain machine type, thereby illustrating its scalability and cohesive integration with AWS services.

Moreover, the paper accentuates the crucial role of testing automation and quality assurance in authenticating experimental outcomes, diminishing human labor and financial expenditure while enhancing precision.

The suggested system is predominantly centered around data storage and analysis, laying a foundation for future enhancements and the integration of novel features to amplify functionality and security. This encompasses potential amalgamation with nascent technologies like artificial intelligence and machine learning to expedite diagnostic processes. Furthermore, enhancements such as multifaceted authentication to secure personal, confidential information and the option to scale to more substantial machine sizes for bolstered performance are contemplated. These prospective enhancements underscore the potential for ongoing system development to cater to the evolving demands of healthcare data management.

School of Information and Control Engineering, Jilin Institute of Chemical Technology, Jilin, China[2, 3, 4]

***Abstract*—This paper introduces an advanced method for enhancing the security of image transmission. It presents a novel color image encryption algorithm that combines hyperchaotic dynamics and deep learning medium and long short-term memory (LSTM) networks. Firstly, the chaotic sequence is generated using the Lorenz hyperchaotic system, then the Lorenz chaotic system is discretized and iteratively processed using the fourth-order Runge-Kutta (RK4) method, and then the deep learning LSTM model is used to transform the chaotic sequence processed by the Lorenz hyperchaotic system into a new sequence for training. Finally, according to the new chaotic signal, the Arnold disruption and Deoxyribo Nucleic Acid (DNA) encoding double disruption diffusion are performed to derive the ultimate encrypted image. Through the analysis of multiple color image simulation experiments, the algorithm presented in this paper can well realize the encryption on color images and can achieve lossless encryption, with strong resistance to differential attack, statistical attack and violent attack. Compared with the literature analysis, the correlation coefficient, information entropy and pixel change rate of this paper are closer to the ideal value, and it has higher security and better encryption effect.**

I. Introduction

With the advancement of information technology, big data, 5G and cloud computing technologies are inseparable from many areas of daily life, such as education, military, medicine and scientific conferences. However, while the Internet has brought great convenience, large amounts of data face numerous challenges, such as espionage, theft, usurpation, and modification, leading to numerous information security incidents. One such area is digital images, where the transmission of image data is an integral part of Artificial Intelligence (AI) systems. Through the use of image encryption technology, images can be encrypted so that they are not easily stolen or tampered with during transmission, thus ensuring the security of transmission. In the field of AI, personal image data, such as face recognition and human posture recognition, plays a significant role. Image encryption technology can be used to encrypt and protect these sensitive image data to ensure the security of personal privacy.

As an important carrier of information, digital image is a two-dimensional image composed of discrete pixels (picture element), each pixel represents a point in the image with specific position, brightness and color information. They can be generated by digital cameras, scanners or computers, and stored and processed in digital form. They contain important information in areas such as defense medicine, and education [1]. To guarantee the security of the transmission process, the most effective way is encryption. Traditional encryption methods include symmetric encryption, which is one of the earliest and simplest encryption methods that performs encryption and decryption operations on plaintext by using the same key, and some of the most commonly used symmetric encryption algorithms include the Advanced Encryption Standard (AES), Data Encryption Standard (DES), Triple Data Encryption Standard (3DES), and others [2]. Symmetric encryption offers the benefits of excellent efficiency and high speed, but it needs to secure the key transmission process. Asymmetric encryption, also known as public key encryption, involves a public key that can be used by anyone to encrypt data, while the private key is retained exclusively by the key holder for decrypting the data. Prominent asymmetric encryption methods encompass Rivest-Shamir-Adleman (RSA) and Elliptic Curve Cryptography (ECC), Digital Signature Algorithm (DSA) [3]. These algorithms are primarily developed for text-based application information and are less efficient in encrypting images with high image pixel correlation and extensive redundancy. It is difficult for traditional image encryption methods to overcome the difficulties in key distribution, resulting in illegal theft of ciphertext and low security. Deep learning algorithms have high complexity, good chaos characteristics and strong parameter sensitivity, and can be applied in the field of image encryption. Therefore, this paper, we investigate image encryption algorithms for chaotic systems with more complex performance and higher security.

II. Current Status of Research

With the dissemination of digital images in the network, the security of digital images has emerged as a significant concern [4]. To enhance data security, numerous image encryption algorithms have been introduced, including those based on chaotic systems [5], compression perception [6], DNA coding [7], S-box transform [8] and transform domain [9]. In the 1960s, Lorenz, a scientist from Massachusetts Institute of Technology (MIT) in the United States, proposed chaotic system for the first time, and attracted widespread attention and research, and scholars from various countries gradually utilized chaotic systems in picture encryption. In 1997, Fridrich pioneered the application of chaotic systems in image encryption for the inaugural time [10]. Usually, chaos-based image encryption algorithm mainly consists of disarray and diffusion, disarray is to diminish the correlation between adjacent pixels in a plaintext picture by changing the spatial

position between pixels, and diffusion refers to changing the pixel value of an image.

Chaotic systems are a class of dynamic nonlinear systems that exhibit non-stationarity, unpredictability and strong sensitivity. Due to their unpredictability and complexity they are widely used in information security and random number generation. Chaotic signal as the core of chaotic image encryption consists of the following two kinds of chaotic systems: one is a one-dimensional chaotic system, a nonlinear dynamical system containing only one independent variable, such as Logistic mapping, Henon mapping, Sine mapping, etc., which is simple in structure, high in operational efficiency, and has different dynamical characteristics, but the system key space is small and vulnerable to attacks, and can be determine the chaotic characteristics by analyzing the bifurcation map, periodicity and so on. Another kind of chaotic system is multi-dimensional chaotic system, which contains multiple variables and has more complex and diversified dynamics characteristics, such as Lorenz system, Chen system, etc. These systems introduce more state variables, have higher complexity and heightened sensitivity to starting conditions, making them prevalent in the realm of image encryption.

In order to enhance the security of image encryption, Alghamdi Yousef and Munir Arslan proposed an encryption algorithm with a nonlinear feedback shift register in their literature [11]. This algorithm improves security through multiple rounds of encryption, row substitution, column substitution, and bit-level substitution, resulting in higher quality and efficiency. The paper provides detailed insights into how the algorithm achieves these improvements. Chen Xin et al. proposed the algorithm of quantum chaos and DNA coding in literature [12], by studying the properties of IEA-QCDC, plaintext attack was used to obtain the key, and DNA coding operation was used to obtain the encrypted image, making full use of the security defects of IEA-QCDC and achieving better encryption effect. Ding Dawei, Wang Jin et al. proposed a fractional-order amnesia-coupled chaotic mapping (MCCM), using internal parameters, to make the system more stable and more conducive to the application in the field of chaotic engineering, through experimental analysis, the system exhibits a heightened level of dynamic complexity, leading to the development of a secure medical picture encryption scheme, which provides technical support for the security of the medical field, with good security and robustness [13]. Liang Qin et al. tackled the problem of insufficient security in one-dimensional chaotic systems. They introduced a novel one-dimensional chaotic system with the aim of bolstering security. They introduced a new one-dimensional chaotic system designed to enhance security. This new system, known as one-dimensional sine-cosine chaotic mapping (SCCM), leverages index mismatch of chaotic sequences in image rows and columns, and incorporates random DNA code selection to enhance the encryption process's resistance against plaintext attacks, resulting in improved encryption effectiveness [14]. Francesco Castro et al. introduced a secure fingerprint authentication image encryption scheme. The primary objective of this scheme is to bolster the security and resilience of safeguarding medical images. To address the issue of medical image insecurity during transmission and safeguard patient privacy, the scheme employs chaotic encryption with a replacement key for encrypting private images. Additionally, it implements a hybrid encryption approach based on the ECC and AES, resulting in improved security [15]. Meanwhile, as deep learning technology continuously advances, more algorithms that utilize the fusion of deep learning and chaotic systems are widely used. Ulises Manuel Ramirez Alcocer et.al introduced a deep learning approach that utilizes the LSTM network to monitor medical processes. This approach has been found to yield improved results in the medical field [16].

To summarize the state of multi-dimensional chaotic systems and the extensive application of deep learning, this paper introduces a novel approach that leverages LSTM networks to generate new chaotic signals. These signals are subsequently applied in chaotic systems and iterated using Lorenz mapping to create pseudo-random sequences. The algorithm further employs the Arnold algorithm and DNA coding for double disruption to enhance security. This leads to an expanded key space and increased resistance to attacks. Compared with the reference [17], the original equalization method using 3D histogram is discarded, and the LSTM model, which has better performance in long sequences, is used to enhance the sequence complexity. The traditional encryption method is only related to the image pixel arrangement, and the encryption is too single and simple, this paper increases the number of parameters through the addition of deep learning LSTM, so that the chaotic system reaches a super chaotic state, and at the same time, constructs the DNA encoding rules, which ultimately affects the factors to increase, and improves the security of the algorithm, as well as the encryption efficiency, and has a higher value of using it in the confidentiality.

III. BASIC THEORY

A. Lorenz Chaotic System

Lorenz chaotic system is a three-dimensional nonlinear system of ordinary differential equations, which is composed of three coupled nonlinear differential equations with good chaotic properties and initial value sensitivity, and is often widely used as a classical pseudorandom generator in the field of image encryption [18]. The Lorenz system is defined as depicted in Eq. (1).

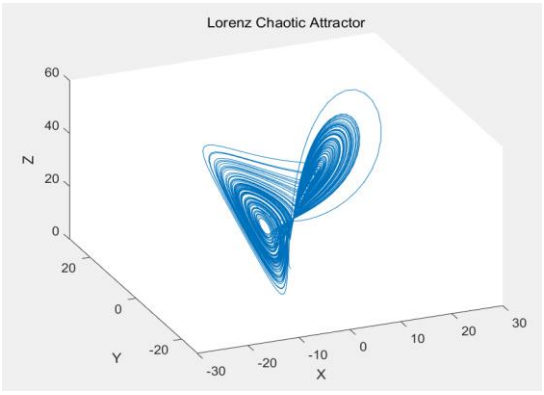

Fig. 1. Phase diagram of hyperchaotic lorenz attractor.

$$\begin{aligned} \dot{x} &= a(y-x)+w, \\ \dot{y} &= cx-y-xz, \\ \dot{z} &= xy-bz, \\ \dot{w} &= -yz+rw, \end{aligned} \tag{1}$$

where, $\dot{x}$, $\dot{y}$, $\dot{z}$, $\dot{w}$ are the chaotic states of the system, for the control parameters a, b, c and r of the Lorenz system, when these parameters satisfy a=10, b=8/3, c=28, and $-1.52 \leq r \leq -0.06$, the system enters a state of hyperchaotic. The attractor phase diagram of the hyperchaotic Lorenz system can be observed in Fig. 1. When the system control parameter r=-1, the Lyapunov exponents in Eq. (1) are as follows in order: 0.3381, 0.1586, 0, and -15.1752. Notably, this sequence contains two Lyapunov exponents greater than zero. The chart of the Lyapunov exponent diagram is shown in Fig. 2.

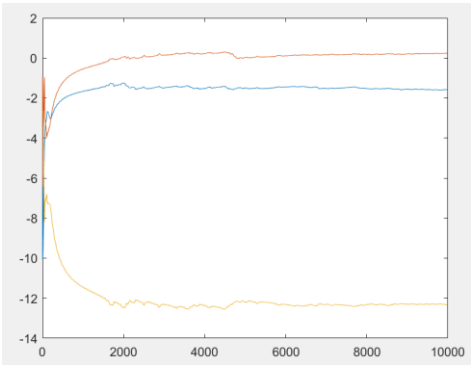

Fig. 2. Lyapunov exponent plot.

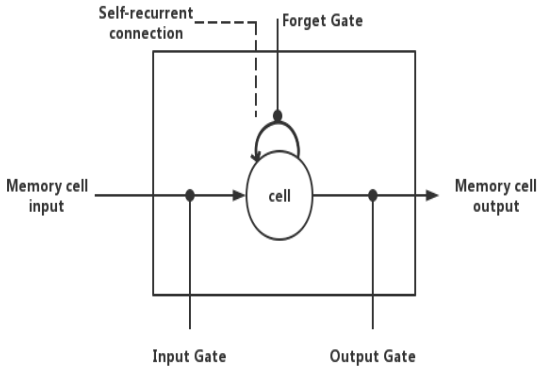

Fig. 3. LSTM model diagram.

B. LSTM Model

LSTM can be viewed as a specialized variant of Recurrent Neural Network (RNN), primarily developed to address the challenges related to gradient vanishing and gradient explosion when training with lengthy sequences [19]. LSTM's unique architecture and memory retention mechanisms make it particularly well-suited for a wide range of applications. RNN is a kind of neural network dealing with sequential data. Based on the RNN model, the LSTM model introduces a gating mechanism (Gates) to solve the short-term memory problem of RNN, which is able to capture long-term dependencies, thus enabling the recurrent neural network to better leverage long-range temporal information and have better performance in longer sequences. The LSTM model includes three key logical control units: the Input Gate, Output Gate, and Forgetting Gate. These units are connected to a multiplication element, forming the core structure of the LSTM model, as illustrated in Fig. 3. These components play a crucial role in controlling information flow and memory retention within the network, allowing it to excel in tasks involving longer sequences.

The cell is a memory unit that represents the memory of the neuron's state, providing the LSTM unit with the capability to store, retrieve, reset, and update long-term information. When the moment t, the LSTM neural network defines the formula as:

$$\begin{aligned} f_t &= \text{sigmid}\left(W_f \cdot [h_{t-1}, x_t] + b_f\right) \\ i_t &= \text{sigmid}(W_i \cdot [h_{t-1}, x_t] + b_i) \\ o_t &= \text{sigmid}(W_o \cdot [h_{t-1}, x_t] + b_o) \\ \tilde{c}_t &= \tanh(W_c \cdot [h_{t-1}, x_t] + b_c) \\ c_t &= f_t \times c_{t-1} + i_t * \tilde{c}_t \\ h_t &= o_t \times \tanh(c_t) \end{aligned} \tag{2}$$

where, f_t、i_t、o_t and c_t denote Forget Gate, Input Gate, Output Gate, and cell, respectively, as mentioned in Fig. 3. W_*, on the other hand, denotes the recursive connection weights of the corresponding gates, respectively, and sigmid and tanh denote the two activation functions.

C. Arnold Mapping

Arnold mapping is a chaotic mapping technique that repeatedly applies folding and stretching transformations within a bounded region, serving as a primary method for permutation. The transformation principle involves performing a shearing transformation along the x-axis, followed by a similar transformation along the y-axis. Finally, a modulo operation is used to implement cut-and-fill operations, altering the layout of image grayscale values by changing the pixel coordinates. The specific transformation formula is:

$$\begin{pmatrix} x_{n+1} \\ y_{n+1} \end{pmatrix} = \begin{pmatrix} a & b \\ c & d \end{pmatrix} \begin{pmatrix} x_n \\ y_n \end{pmatrix} mod \begin{pmatrix} M \\ N \end{pmatrix} \tag{3}$$

D. DNA Coding

In the field of biology, medicine and other applications, the information of many organisms in nature exists in DNA, and DNA can be arranged according to different rules and sequences to achieve the effect of disarray through the disarrangement of rows and columns. DNA consists of four kinds of DNA, which are adenine (A), thymine (T), guanine (G) and cytosine (C). In accordance with the rules of complementary base pairing in biology, A is paired with T, while G is paired with C. In computer systems, the complementarity of the two bases is determined by the fact that they are complementary to each other. In a computer system, the complementary pairing rules are similar to the pairing rules for binary coding, 0 and 1. Therefore, the four varieties of deoxyribonucleotides can be denoted using two binary digits, yielding a sum of 24 feasible codes. However, only eight coding rules, in accordance with DNA coding standards, are retained, as shown in Table I [20]. Every pixel in a grayscale image can be denoted using 8-bit binary numbers consisting of 0 and 1. Similarly, each pixel value can be encoded using a DNA sequence comprising four nucleotides. As an illustration,

the decimal number 232 can be expressed in binary as 11101000, and following the DNA coding rules, this binary sequence can be converted to the DNA sequence TGGA.

In the process of image encryption, DNA arithmetic rules are employed, encompassing DNA addition, DNA subtraction, and DNA dissimilarity operations. Adding and subtracting DNA sequences follow similar principles to traditional algebraic calculations [21], and the rules for these arithmetic operations are provided in Table II and Table III.

TABLE I. DNA CODING RULES

Rule 1	Rule 2	Rule 3	Rule 4	Rule 5	Rule 6	Rule 7	Rule 8

IV. IMAGE ENCRYPTION

A. Encryption Algorithm

The image encryption algorithm presented in the paper follows the traditional rules of disarray and diffusion, and proposes a double disarray by combining Arnold mapping and DNA encoding. During the encryption process, the initial key of the original image P is first obtained using a hash function. Following this, a chaotic sequence is produced using the hyperchaotic Lorenz system, and the system is subjected to discretization and iterative processing using the Runge-Kutta method. The deep learning LSTM model is utilized to leverage temporal features for both training and analyzing the chaotic sequence, ultimately generating a novel chaotic sequence. Finally, double permutation is applied to shuffle and diffuse the pixels, resulting in the ultimate encrypted image. The primary encryption procedure of the algorithm are illustrated in Fig. 4.

B. Encryption Process

1) Key generator: The key for the plaintext image P is determined through the SHA-256 function, which serves as the fundamental component of the key generator. First take the plaintext image P as input, use the function to generate a 64-bit digest, convert it to 256-bit binary as output, and divide it into groups of every 8 bits to get a 32-bit segmented keystream $K = \{k_1, k_2, k_3, \cdots k_{32}\}$, where k_i, $i = 1,2,\cdots 32$ are all 8-bit hash values.

According to the generation rule of key flow, K is processed as follows, according to Eq. (4) to Eq. (7), the initial state parameters of the system $\{x_0, y_0, z_0, w_0\}$ can be computed, and through Eq. (8), we get the key s_0 which is related to the plaintext, and then we generate pseudo-random sequences S_1 , S_2 used for the subsequent Arnold diffusion.

$$x_0 = \left((k_{17} \oplus k_{18}) \oplus (k_{18} \oplus k_{19}) \oplus (k_{19} \oplus k_{20})\right) \times \sum_{j=1}^{j=32} \frac{k_j \times 2^{j-1}}{2^{47}} \quad (4)$$

$$y_0 = \left((k_{21} \oplus k_{22}) \oplus (k_{22} \oplus k_{23}) \oplus (k_{23} \oplus k_{24})\right) \times \sum_{j=1}^{j=32} \frac{k_j \times 2^{j-1}}{2^{47}} \quad (5)$$

$$z_0 = \left((k_{25} \oplus k_{26}) \oplus (k_{26} \oplus k_{27}) \oplus (k_{27} \oplus k_{28})\right) \times \sum_{j=1}^{j=32} \frac{k_j \times 2^{j-1}}{2^{47}} \quad (6)$$

$$w_0 = ((k_{29} \oplus k_{30}) \oplus (k_{30} \oplus k_{31}) \oplus (k_{31} \oplus k_{32})) \times \sum_{j=1}^{j=32} \frac{k_j \times 2^{j-1}}{2^{47}} \quad (7)$$

$$s_0 = \text{zeros}(1, n), n = 2MN \quad (8)$$

2) Preprocessing: The RK4 is a suitable method for solving differential equations. It achieves higher computational accuracy by approximating the differential equations in four discrete steps over a specific time interval of the solution. The discretized equations are as follows:

$$\begin{aligned} x_{n+1} &= x_n + \frac{h}{6}(k_1 + 2k_2 + 2k_3 + k_4) \\ k_1 &= f(t_n, x_n) \\ k_2 &= f\left(t_n + \frac{h}{2}, x_n + \frac{h}{2}k_1\right) \\ k_3 &= f\left(t_n + \frac{h}{2}, x_n + \frac{h}{2}k_2\right) \\ k_4 &= f(t_n + h, x_n + hk_3) \end{aligned} \quad (9)$$

In this method, the subsequent value x_{n+1} is calculated by multiplying the current value x_n with the period h and reckon slope. The slopes are represented as follows: k_1 is the slope at the start of the period, k_2 and k_3 correspond to the slopes in the middle of time, and k_4 indicates the slope at the conclusion of the time period. The Lorenz chaotic system is discretized using RK4 and iterated T+MN times, discarding the first T times to eliminate transient effects and increase safety, four new sequences x_1, y_1, z_1, w_1 are obtained.

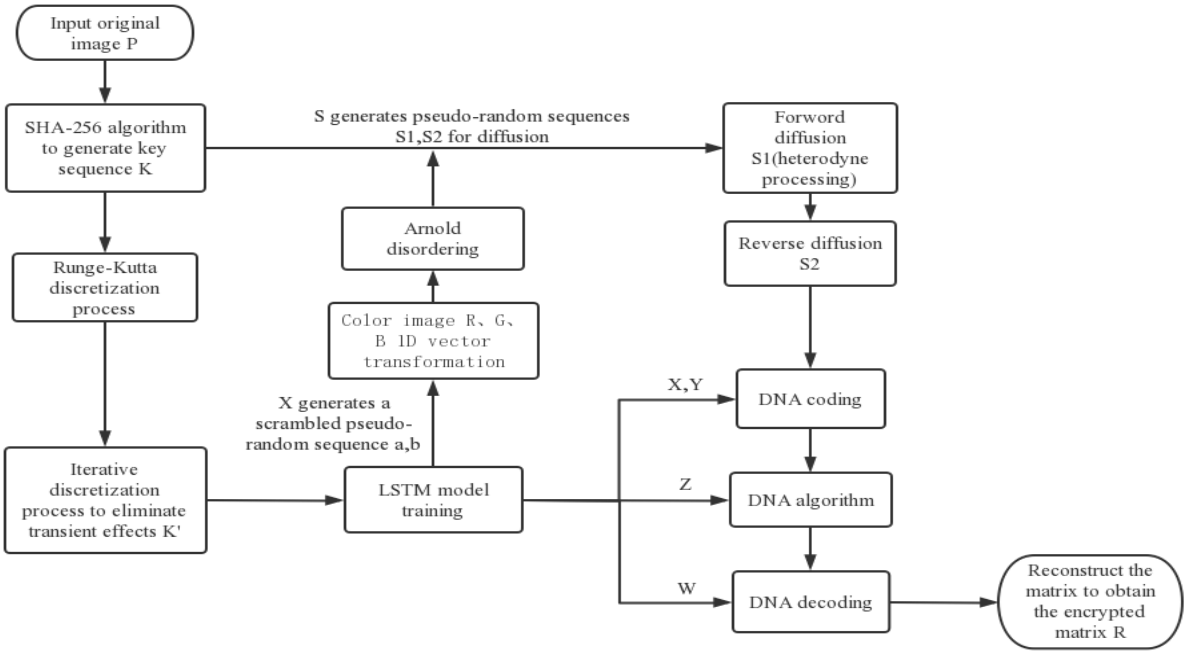

Fig. 4. Encryption flow chart.

3) LSTM training: By configuring the parameters of LSTM, the preprocessed sequences are trained, and a portion of the length l of the pseudo-random sequences x_1, y_1, z_1, w_1 are respectively selected for deep learning. The initial learning rate is represented as 'r', the learning rate decreasing factor is 'p', and the length of the selected training sequences is 'l'. Following the completion of the training process, four novel pseudo-random sequences, namely X, Y, Z, and W, are generated. During the training process, the root-mean-square error (RMSE) serves as a more effective metric for quantifying the disparity between predicted and actual values. It offers heightened sensitivity to anomalous data and is defined as the square root of the average of the squared differences between the predicted and actual values, divided by the number of observations, denoted as n. In Fig. 5, the RMSE is depicted as it evolves with the number of iterations during the training process. As the number of iterations increases, the RMSE becomes smaller and gradually approaches 0, signifying that the model can make more accurate data predictions.

4) Double disorder modeling: The color original image P, with dimensions M×N, is separated into three individual color channels: R, G, and B. The pseudo-random sequences a, b are generated using LSTM generated sequences X. The decomposed channels are initially converted into one-dimensional vectors, and then transformed into the coordinates using a, b to get the transformed coordinates q, as shown in Eq. (10), and then Arnold disambiguation is carried out.

$$\begin{aligned} a &= X(1:M*N) \\ b &= X(M*N+1:2*M*N) \\ q &= mod(b(i)+a(i)*i, M*N)+1 \end{aligned} \tag{10}$$

After disorganization, the key S_1, S_2 obtained in the key generation stage is used for forward and reverse diffusion according to Eq. (11) and Eq. (12) to obtain the new single-channel image. The key S_1 is used for forward diffusion, which is a kind of diffusion processing method based on different-or operation, and S_2 is the key for reverse diffusion, where B_i represents the three channels R, G, B, and B_i' represents the new R, G, B channels.

$$\begin{aligned} B_i &= (B_{i-1}+S_1+P_i) mod 256 \\ C_i &= (C_{i+1}+S_2+B_i) mod 256 \end{aligned} \tag{11}$$

$$B_i' = reshape(C_i, M, N) \tag{12}$$

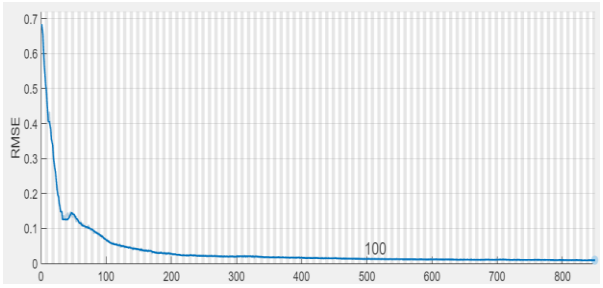

Fig. 5. RMSE variation curve.

Through DNA encoding, the bases A, T, G, C and the binary pixel values are disambiguated according to certain rules, which consumes less time and has a strong disambiguation effect and is highly applicable in image data encryption [22]. Each chunk of the graphic representation P is encoded according to the rules in Table I, and the encoding rules are determined by the pseudo-random sequence X to get the matrix P_i'. The obtained new three single channels are encoded according to Y to get the disarrayed matrix Q_i'. The encoded chunks are subjected to the DNA operation of P_i' and

Q_i' in accordance with the rules established by the sequence Z, and the encrypted matrix Q_i is obtained. Finally, DNA decoding of Q_i is performed using W. Each chunk are combined to create the ultimate encrypted image Q .

C. Decryption Process

The decryption process is the inverse application of the encryption. The individual channels of the encrypted picture are isolated, and the separated image is subjected to DNA coding inverse disambiguation, plus mode inversion, forward inverse diffusion. The Arnold inverse transformation is employed to extract the individual channels from the plaintext image, and subsequently, these channels are reconstructed and combined to obtain the original plaintext P.

V. Encryption Effect Analysis

In this paper, we employ the MATLAB R2022b simulation platform to carry out encryption and decryption operations using the proposed algorithm, and we analyze its performance. The hardware specifications during the experiments include an Intel(R) Core(TM) i5-8265U CPU @ 1.60GHz, 1.80 GH. The experiments were conducted using 512×512 pixel color images of Lena, Baboon, Peppers, Airplane, and Splash color images for simulation testing. And the tests are performed in terms of histogram analysis, adjacent pixel correlation analysis, information entropy, differential attack analysis, robustness analysis and key space analysis. Fig. 6 shows the encryption and decryption effect of the color image, the encrypted image is entirely devoid of any visible information from the original image, making it impossible for an attacker to extract any meaningful data from the image, enough to resist the common means of attack such as differential attack, violence attack, and the algorithm yields a strong encryption effect.

A. Histogram Analysis

Histograms can display image information and offering a visual representation of the arrangement of individual grayscale values in picture. The frequency of occurrence is counted according to the size of the gray values. A better encryption algorithm should ideally render the histogram of the encrypted image so indistinct that a clear distinction cannot be discerned, the histogram can be evenly distributed. Histograms of plaintext images often exhibit clear statistical patterns, and attacks that exploit these patterns are known as statistical attacks [23]. To enhance the ability to resist statistical attacks, the histogram of the encrypted image should tend to a straight line, and there is a big difference between it and the plaintext histogram. For example, Fig. 7 shows the comparison of histograms before and after Lena's encryption.

From the above figure, it is evident that the pixels between the original plaintext images have strong statistical regularity and are more susceptible to statistical attacks, the distribution of elements in the encrypted Lena image exhibits greater uniformity, the encrypted histogram is smoother, and making it difficult to extract information from the encrypted image, thus enhancing security and increasing resistance to statistical attacks by potential attackers.

B. Correlation Analysis

During the image encryption process, the characteristics of image pixels make the correlation between neighboring pixels strong, and at the same time, it can disrupt the correlation between neighboring elements by disambiguating the pixels of the original picture, so as to achieve the purpose of resisting statistical attacks [24]. In a high-quality encryption algorithm, the lower the correlation between adjacent elements post-encryption, the more favorable the outcome. To evaluate an encryption algorithm's ability to withstand statistical attacks more effectively, we randomly selected 5000 pairs of pixel values from the Lena image in various orientations. And then examined the correlation coefficients in the three directions both before and after encryption, separately for the three single channels of the Lena image. The outcomes of this analysis are presented in Fig. 8, 9, and 10. This can be clearly seen from these pictures the strong correlations present in the plaintext image across all directions before encryption. However, post-encryption, the image exhibits a more uniform pixel distribution and scattered throughout the rectangular square matrix, there is no difference in the whole plane leading to a reduction in pixel-to-pixel correlations. The formula for calculating the correlation between two adjacent pixels can be expressed as follows:

$$E(x) = \frac{1}{N}\sum_{i=1}^{N} x_i \tag{13}$$

$$D(x) = \frac{1}{N}\sum_{i=1}^{N} \left(x_i - E(x)\right)^2 \tag{14}$$

$$\mathrm{cov}(x,y) = \frac{1}{N}\left(x_i - E(x)\right)\left(y_i - E(y)\right) \tag{15}$$

$$r_{xy} = \frac{\mathrm{cov}(x,y)}{\sqrt{D(x)}\sqrt{D(y)}} \tag{16}$$

where $E(x)$ and $E(y)$ denote the mathematical expectation of x, y respectively, and $\mathrm{cov}(x,y)$ denotes the covariance of x, y . Through simulation test, compare and analyze the correlation coefficients before and after encryption of Lena and Baboon. Furthermore, a comparison was made with the correlations mentioned in the literature [25] [26], as shown in Table IV. The analysis reveals that the correlation of different channels (R, G, and B) in different directions before encryption is close to 1, indicating a higher correlation. In contrast, the correlation in the post-encryption image approaches the ideal value of 0. This algorithm offers a high level of security and exhibits enhanced resistance to statistical attacks.

TABLE V. INFORMATION ENTROPY

Information entropy	R-channel		G-channel		B-channel	
Imagery	pre-encryption	post-encryption	pre-encryption	post-encryption	pre-encryption	post-encryption
Lena	7.2531	7.9993	7.5940	7.9993	6.9684	7.9993
Baboon	7.7067	7.9993	7.4744	7.9992	7.7522	7.9992
Peppers	7.3388	7.9993	7.4963	7.9993	7.0583	7.9994
Airplane	6.7178	7.9993	6.7990	7.9993	6.2138	7.9993
Splash	6.9481	7.9993	6.8845	7.9992	6.1265	7.9993

C. Information Entropy

Entropy is employed to characterize the intricacy of phenomena, and information entropy serves as a quantitative gauge of the level of randomness within a source, that is, it describes the complexity of a system. This metric can be applied to assess the randomness of an image by quantifying the dispersion of pixels with distinct grayscale values across different color channels. A distribution with higher uniformity indicates higher resistance to statistical attacks. Greater information entropy signifies increased complexity within the picture. An ideal encryption should possess an information entropy of 8. The calculation formula is:

$$H(x) = -\sum_{i=1}^{2N-1} P_i \log_2 P_i \quad (17)$$

In Eq. (17), P_i represents the occurrence rate of message i and $H(x)$ is the information entropy. Table V reveals that the information entropy of different channels in the encrypted image closely approaches the target value of 8. This suggests that the encrypted image significantly differs from the plaintext image and is less susceptible to leakage, thus indicating the algorithm in this paper has a higher level of security.

D. Differential Attack

A differential attack is one type of chosen plaintext attack, for a common method of cracking the ciphertext image, the attacker is able to the relationship between the picture before and after the encryption, to find out the law of the ciphertext image to be deciphered. The anti-differential performance mainly depends on the degree of sensitivity in the plaintext. In the encryption process, the Normalized Pixel Contrast Ratio (NPCR) and Unified Average Changing Intensity (UACI) are two variables to measure the two variables that quantify the disparity between two images and are quantitative tests to analyze the original and encrypted images [27]. NPCR measures the proportion of pixels that differ in the same positions between two images, relative to the total number of pixels in those images. UACI calculates the average magnitude

of changes between the images before and after transformations, and its formula is as follows:

$$NPCR = \frac{\sum_{i=0}^{M-1}\sum_{j=0}^{N-1} D(i,j)}{M \times N} \times 100\% \quad (18)$$

$$D(i,j) = f(x) = \begin{cases} 1, C_1(i,j) \neq C_2(i,j) \\ 0, otherwise \end{cases} \quad (19)$$

$$UACI = \frac{1}{M \times N}\frac{\Sigma(C_1(i,j) - C_2(i,j))}{255} \times 100\% \quad (20)$$

Among them, the ideal NPCR and UACI values are 99.6094% and 33.4635%, respectively. The algorithm's effectiveness in countering differential attacks improves as the measured values approach these ideal benchmarks. In this paper, a comparative analysis is conducted using the literature [28] [29], as illustrated in Table VI. The analysis demonstrates that the NPCR and UACI values in this algorithm closely approach the true values, indicating strong encryption efficacy and enhanced resistance to differential attacks.

TABLE VI. KEY SENSITIVITY

Imagery	NPCR/%	UACI/%
Lena	99.60	33.47
Baboon	99.62	33.45
Peppers	99.62	33.46
Airplane	99.61	33.47
Splash	99.61	33.47
Literature [28]	99.66	33.61
Literature [29]	99.61	33.48

E. Key Space

The key space represents the collection of all potential keys capable of generating an encryption key. The size of the key space is contingent upon the length of the security key, and a sufficiently extensive key space is effective in thwarting brute force attacks. When the key space of the whole algorithm reaches 2^{100}, it can show that the security of the algorithm can be guaranteed [30]. In the chaotic system used in this paper, the initial key is generated by the SHA-256 algorithm. Without considering the influence of other factors, the size of the security key is 256 bits, and the size of the key space is $2^{256} > 2^{100}$, which can withstand brute force attacks and exhibits a high level of security.

F. Robustness Analysis

Images are susceptible to interference from external factors during transmission, and the robustness of an encryption system is to assess how an image performs when subjected to various forms of interference. It is used to judge the encryption and decryption quality of an encryption system, with the aim of determining whether the system can effectively protect the encryption and integrity of the image when confronted with noise interference [31]. Salt and Pepper Noise (SPN) is a familiar type of noise in digital images that can significantly affect image quality, causing it to become unclear or distorted. The image decrypted with various levels of SPN added to the Baboon image is shown in Fig. 11. It is evident from the image that as the intensity of the added SPN increases, from (a) with intensity 0.1 to (c) with intensity 0.3, the quality of the deciphered image deteriorates and becomes increasingly blurry. However, it is still possible to discern the information in the original picture. This suggests that the algorithm introduced in this paper showcases substantial resistance to noise interference.

VI. CONCLUSION

This paper introduces a hyperchaotic image encryption algorithm based on LSTM. It involves processing the chaotic sequence generated by the Lorenz system in order to create new chaotic signals. This is achieved by leveraging the sequence data processing capabilities of the LSTM. Following this, the data undergoes iterative processing using the hyperchaotic system. Simultaneously, the Arnold algorithm, along with DNA coding and arithmetic rules, is applied to perform double diffusion of the data. This enhances the algorithm's complexity. In this paper, the above problems are described in detail and the experiment and analysis are carried out. The experimental results show that the algorithm can effectively ensure the privacy of the image through the encryption and decryption of the color RGB image. Meanwhile, comparisons with other algorithms, and an analysis of the algorithm's performance in terms of histograms, correlations, information entropy, and more, it has been verified that the encryption system exhibits strong resistance to differential attacks, statistical attacks, and brute-force attacks. It efficiently diminishes the correlation among adjacent pixels, thus bolstering the algorithm's complexity, security, and encryption efficacy. The DNA encoding technology employed in the algorithm falls within the realm of bioengineering, which suggests that the algorithm could be combined with biomedical treatments in the future to provide better protection for the transmission of medical data. In fact, there are many applications of deep learning algorithms to images, which can achieve good encryption effects and improve efficiency, which is the direction of future research and improvement.

ACKNOWLEDGMENT

The authors would like to thank the reviewers for taking time to guide the completion of this paper.

Thai Finger-Spelling using Vision Transformer

Kullawat Chaowanawatee, Kittasil Silanon*, Thitinan Kliangsuwan
College of Computing, Prince of Songkla University Phuket Campus, Kathu, Phuket, Thailand

***Abstract*—In this paper, we present a finger-spelling recognition system that is based on Thai Sign Language (TFS) and employs a deep learning model called vision transformer. We extracted the 15 characters of the Thai alphabet from publicly available and our collected datasets to establish the recognition system. To train the learning model, we employed four EVA-02 vision transformer models, each of which showed impressive performance across different model sizes. We conducted four experiments to determine the most effective performance model. In Experiment 1, we directly trained the model to compare its performance. In Experiment 2, we used augmentation techniques to generate additional datasets. Experiment 3 utilized the Test-Time Augmentation (TTA) technique to generate test images with random variations. Lastly, in Experiment 4, we used Pseudo-Labelling (labeling labeled and unlabeled data) in each batch to train the model network. Furthermore, we developed a mobile application that collects user image data and provides helpful information related to finger-spelling, such as meanings, gestures, and usage examples.**

Keywords*—*Thai finger-spelling; vision transformer; deep learning; image recognition

I. INTRODUCTION

Sign language is a method of communication used by individuals who are deaf or hard of hearing. There are two primary types of sign language: vocabulary signs, which use hand shapes, movements, and facial expressions to convey word meanings, and finger-spelling, which uses only hand shapes to spell out technical words, such as names and locations. However, finger-spelling is not commonly used in everyday conversations, so many deaf individuals, especially children, struggle with it. Several finger-spelling recognition research studies have been proposed to help their skills. For instance, A. Deza and D. Hasan [1] used pre-processing techniques such as boosting contrast, edge enhancement, and the Convolution Neural Network (CNN) model to classify the American Sign Language (ASL) finger-spelling dataset. These techniques enabled the authors to achieve a validation accuracy of approximately 77%. R. A. Alawwad et al. [2] introduced Arabic Sign Language (ArSL) recognition systems using a Faster Region-based Convolutional Neural Network (R-CNN). The proposed approach yielded 93% accuracy and confirmed the robustness of background variations. K. R. Prajwal et al. [3] proposed a British Sign Language (BSL) finger-spelling recognition using transformer architecture to train models with noisy labels. Researchers employed a multi-stage training approach to achieve better performance. E. M. Martin and F. M. Espejo in [4] presented a system to interpret the Spanish Sign Language (LSE) finger-spelling. The pre-trained CNN model and Recurrent Neural Network (RNN) have been tested and compared. The CNN obtained a much better accuracy, with 96.42% being the maximum value. V. J. Schmalz [5] applied deep learning and fine-tuning techniques to build an automatic recognition system for Italian Sign Language (LIS) finger-spelling. The proposed CNN and VGG19 models were used for large-scale image and video recognition. The system obtained an accuracy of 99% with VGG19 and 97% with the CNN architecture. E. J. Ong et al. [6] suggested a Sequential Pattern Tree-based (SP-Tree) multi-class classifier for German Sign Language (DGS) and Greek Sign Language (GSL) finger-spelling recognition. Their proposed SP-Tree Boosting algorithm-based recognition model performs better than the Hidden Markov Model (HMM). X. Jiang et al. [7] proposed a novel finger-spelling identification method for Chinese Sign Language (CSL) via AlexNet-based transfer learning and Adam optimizer, which tested four different configurations of transfer learning. Although there has been research on finger-spelling in many languages, Thai Sign Language (TSL) finger-spelling will be the main focus of this work. P. Nakjai et al. [8] investigated a YOLO based on the convolution neural network architecture to localize and classify TSL finger-spelling. The system achieved the mean Average Precision (mAP) of 82.06% under a complex background and 84.99 % under a plain background. S. Lata and O. Surinta [9] proposed an end-to-end TSL finger-spelling recognition based on the YOLOv3 objection detection framework to create the most robust model with high recognition performance. P. Nakjai and T. Katanyukul [10] proposed automatic TSL finger-spelling recognition using CNN-based and Histogram of Oriented Gradients (HOG) based approaches. Experimental results have shown the viability of the proposed method, which achieves mAP at 91.26%. J. Sanalohit and T. Katanyyukul [11] invented MediaPipe Hands (MPH) trained model for hand-keypoint detection. The MPH can satisfactorily address single-hand schemes with accuracy of 84.57%

According to studies, the CNN model is the most commonly employed technology in finger-spelling research. Various model architectures [12], such as Xception, VGG16, InceptionV3, or ConvNeXt, are provided. However, the CNN model has some drawbacks, such as requiring a lot of data and computational resources and being sensitive to spatial distortions and variations. For this reason, a new deep learning technology called vision transformer (ViT) has been introduced for image recognition applications. The ViT offer a different approach by treating images as sequences of patches and applying self-attention to capture global dependencies and contextual information. This allows them to learn from less data and perform very well on image classification tasks. Therefore, we are interested in using the ViT approach due to its advantages in our work for TSL finger-spelling recognition. To find out the most effective performance recognition model. We performed four experiments. In Experiment 1, the model will be trained directly to compare model performance.

Experiment 2 will generate additional data sets using the augmentation technique. Experiment 3 uses the Test-Time Augmentation (TTA) technique to generate test images with random variations. Experiment 4 employed Pseudo-Labelling (labeled and unlabeled data) in each batch to train the model network. We organize the paper as follows. Section II describes the details of the dataset and ViT model. We present the experiment details and results in Section III. Section IV shows the implemented application using the recognition model as its classifier. Finally, we conclude this paper in SectionV.

II. Datasets and Vision Transformer Model for Image Classification

In this section, we first describe the classes of the dataset. Then we describe the details of vision transformer model and it's characteristic.

A. Datasets forTSL Finger-Spelling

This system recognizes 15 letters of TSL finger-spelling (see Fig. 1 and Table I) which use static-single-hand postures. We collected image hand postures from public datasets. The dataset was randomly partitioned into training and test sets, with an 80:20 ratios, resulting in 1,522 and 381 images in the respective subsets.

TABLE I. Static-Single-Hand Posture for TSL Finger-Spelling

Letter	Hand posture
" ก " (Ko kai)	Point the index and middle fingers with a thumb between them.
" ต " (To tao)	Form a fist with your thumb between the middle and index finger.
" ส " (So suea)	Make a fist and put your thumb on top of your fingers.
" พ " (Po phan)	Press your thumb against your middle finger with index pointed.
" ห " (Ho hip)	Stick out your middle and index fingers.
" บ " (Bo bimai)	Hold your fingers together with your thumb across your palm.
" ร " (Ro ruea)	Cross your index finger over your middle finger.
" ว " (Wo waen)	Hold up three fingers and spread them apart
" ด " (Do dek)	Touch your fingertips to your thumb and point.
" ฟ " (Fo fan)	Press your index finger and thumb together with straight fingers.
" ล " (Lo ling)	Form an L-shape with your thumb and index finger.
" ย " (Yo yak)	Stick out your pinkie and thumb.
" ม " (Mo ma)	Hold an invisible ball and poke your thumb through.
" น " (No nue)	Poke your thumb between your middle and ring.
" อ " (O ang)	Make a fist with your thumb pointing up.

B. Vision Transformer Model

The Vision Transformer (ViT) [13] are a type of deep learning architecture that uses the Transformer architecture. This is a significant departure from traditional computer vision architectures that rely on convolutional neural networks (CNNs). The ViT model works by first dividing the image into a sequence of patches. Each patch is then represented as a vector. These vectors for each patch are subsequently fed into a transformer encoder, a stack of self-attention layers. Self-attention is a mechanism that enables the model to learn long-range dependencies between the patches. This is crucial for image classification, as it allows the model to understand how different parts of an image contribute to its overall label. The output of the Transformer encoder is a sequence of vectors representing the image's features. The features are then used to classify the image. The ViTs have emerged as a powerful and promising alternative to CNNs in computer vision. Their ability to capture long-range dependencies, global attention, and data efficiency has made them a preferred choice for various computer vision tasks.

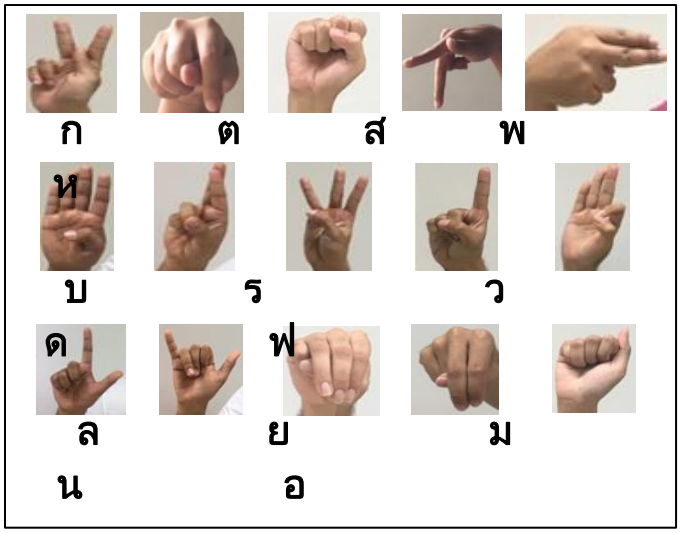

Fig. 1. Static-single-hand posture for TSL finger-spelling.

Currently, the ViT model that is gaining attention is a model named EVA02, presented by Y. Fang et al. [14]. The EVA-02 architecture is designed to be more efficient than previous Transformer-based models, enabling it to process images with greater speed and reduced computational resources. This superior performance makes it a valuable tool for tasks like object detection, semantic segmentation, and visual understanding. There are four variations of the EVA-02 model, with sizes ranging from 6M to 304M parameters. These models perform magnificently in image recognition tasks (see Table II).

TABLE II. Four Variations of EVA-02 Models

EVA-02 Model	Parameters (Million)	FLOPs (Billion)	Top-1 Accuracy on ImageNet (%)
EVA-02 Tiny	10M	0.6	76.2
EVA-02 Small	31M	1.6	77.5
EVA-02 Base	101M	3.3	79
EVA-02 Large	304M	7.6	81.4

III. Experimental Works

Four experiments were conducted to assess the classification performance of TSL finger-spelling recognition as discussed in this section.

A. Vision Transformer Training

In this experiment, we utilized four variations of the EVA-02 model, namely Tiny, Small, Base, and Large. All models

were trained directly on the dataset, with the input image size set to 224x224 pixels. We considered some crucial hyper parameters, including the learning rate of 2e-3, batch size set to 16, cross-entropy loss function, and 30 epochs for training the model. The K-Fold Cross Validation technique in [15] evaluates the predictive model. The dataset is divided into five subsets or folds. The model is trained and evaluated five times, using a different fold as the validation set. This technique aids in model assessment, selection, and hyper parameter tuning, providing a more reliable measure of a model's effectiveness. The model's generalization performance is evaluated using accuracy and weighted F1-score. Accuracy is a simple measure of overall correctness. At the same time, the weighted F1-score is a more sophisticated metric that considers class imbalances. Testing model results are shown in Table III. The large EVA-02 model at 1st fold achieved the best performance at 94.6% accuracy and 94.4% weighted F1-score. Fig. 2 shows the classification results of all 15 classes as a part of class performance analytics. Most errors occur in class "Mo ma" which produces incorrect predictions for classes "So suea" and "To tao" as a consequence of similar hand posture shapes, as displayed in Fig. 3. To improve the model's performance, we will discuss in the next section about the possibility of increasing the number of training examples.

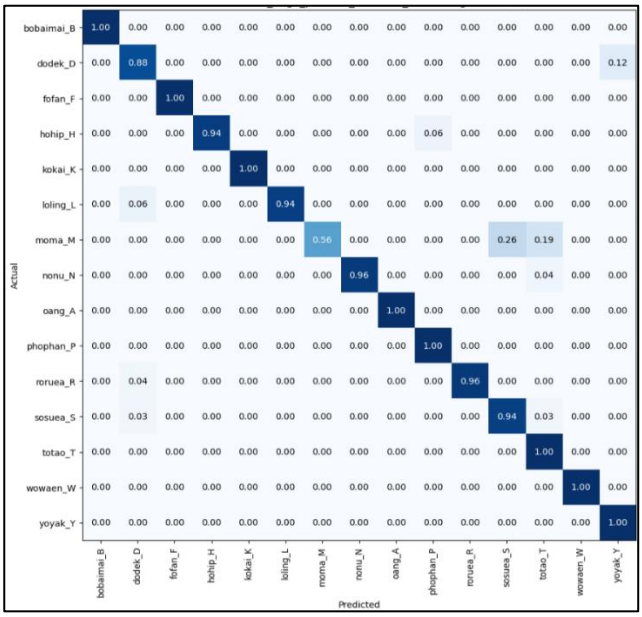

Fig. 2. Confusion matrix of the large EVA-02 at 1st fold.

Fig. 3. Classification error example of the large EVA-02 at 1st fold.

B. Data Augmentation

Data augmentation [16] is typically used during model training that expands the training set with modified copies of samples from the training dataset. This experiment simulates horizontal/vertical flipping, space transformation, random focus, noise addition, and slight rotation to train the model on more generalized data. Fig. 4 shows an example of a dataset after augmentation. Testing model results with the augmentation dataset are shown in Table IV. The large EVA-02 model at 3rd fold achieved the best performance at 94.6% accuracy and 94.5% weighted F1-score. Fig. 5 shows the classification results of all 15 classes as a part of class performance analytics. The model performance was improved when using the data transformation method, especially class "Mo ma"; the accuracy result increased to 70%. Class "So suea" and class "To tao" recognition errors decreased to 15% and 7%, respectively. For other classes, such as class "Po phan" or class "Yo yak", the accuracy dropped to 77% and 94% individually. In addition to augmenting the training dataset to improve the model's performance, we can also increase the number of testing datasets to enhance the accuracy of the model, which we will discuss in the following experiment.

TABLE III. MODEL PERFORMANCE EVALUATION

Model	Fold	Test dataset	
		Accuracy	Weighted F1
Tiny	1	0.6846	0.6693
	2	0.6590	0.6467
	3	0.6692	0.6608

	4	0.7513	0.7364
	5	0.9051	0.9041

C. Test-Time Data Augmentation

Test-Time Data Augmentation (TTA) [17] is a technique that can boost a model performance by applying augmentation to the test dataset. TTA is performed on multiple augmented copies of each image in the test dataset, having the model predict each and then returning an ensemble of those predictions to get a higher overall accuracy. For example, the image in Fig. 6 applies two transformations (rotation and color change) together with the original image. All of these images are passed to the same model and the results are averaged.

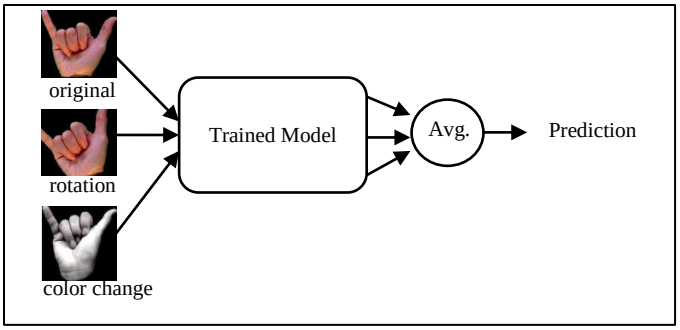

Fig. 6. Test-time data augmentation example.

TTA can be implemented to a model that has already been trained because, unlike training dataset augmentation, no model changes are required. We compared performance results of test dataset without TTA from previous experiment and test dataset using the TTA technique of models. From Table V, the large EVA-02 model at 3rd fold using TTA technique achieved best performance at 95.9% accuracy and 95.8% weighted F1-score. Fig. 7 shows the classification results of all 15 classes as a part of class performance analytics. Class "**Mo ma**" was improved, with accuracy increasing to 77%, while the other classes almost all exceeded 80% accuracy. In the following experiment, we discussed the ways to combine labeled and unlabeled dataset to improve the model's performance.

TABLE V. TEST-TIME DATA AUGMENTATION MODEL PERFORMANCE EVALUATION

Model	Fold	Test dataset without TTA		Test dataset using TTA	
		Accuracy	Weighted F1	Accuracy	Weighted F1
Tiny	1	0.6590	0.6455	0.6744	0.6597
	2	0.7667	0.7521	0.7872	0.7753
	3	0.7231	0.7213	0.7205	0.7152
	4	0.8385	0.8303	0.8538	0.8436
	5	0.7821	0.7755	0.7744	0.7677
Small	1	0.8205	0.8082	0.8282	0.8176
	2	0.7051	0.6923	0.7103	0.7005
	3	0.8051	0.8016	0.8026	0.7965
	4	0.8308	0.8243	0.8333	0.8229
	5	0.8359	0.8270	0.8179	0.8082
Base	1	0.8641	0.8549	0.8769	0.8679
	2	0.9077	0.9034	0.9154	0.9127
	3	0.9231	0.9217	0.9205	0.9196
	4	0.9231	0.9219	0.9359	0.9349
	5	0.8769	0.8714	0.8949	0.8888
Large	1	0.9462	0.9435	0.9513	0.9491
	2	0.9462	0.9428	0.9436	0.9402
	3	0.9462	0.9450	0.9590	0.9586
	4	0.7513	0.7364	0.7718	0.7588
	5	0.9051	0.9041	0.9026	0.9011

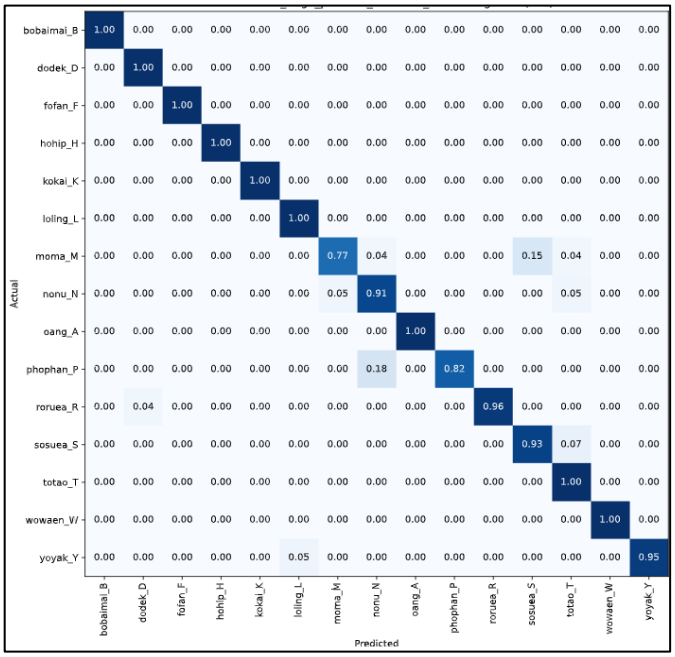

Fig. 7. Confusion matrix of the large EVA-02 at 3rd fold with TTA data augmentation.

D. Pseudo-Labeling

Pseudo labeling [18] is the process of using the trained model to predict labels for unlabeled data. A model has trained with the dataset containing labels and that model is used to generate pseudo labels for the unlabeled dataset. Finally, both the original labels dataset and pseudo labels dataset are combined to retrained the model. In this work, the best performance model from previous experiment is selected to predict labels for unlabeled data. The unlabeled data is collected from our subjects who were asked to stand in front of a white background. The labels dataset and pseudo labels dataset are used to retrain EVA-02 model. Finally, the new retrained model is used to predict the test dataset with TTA technique. Table VI shown performance model using Pseudo labeling. The large EVA-02 model at 1st fold using Pseudo labeling technique achieved best performance at 96.7% accuracy and 96.6% weighted F1-score. Fig. 8 shows the classification results of all 15 classes as a part of class performance analytics. Class "Mo ma" continues to be improved with accuracy increasing to 78%, while for some classes the accuracy has decreased but is still within the acceptable range of at least 80%. This experiment produced good recognition results, as indicated by 11 classes with 100% accuracy, more than any previous experiment. Based on the experiment, the most effective model will be selected as the recognition model which will be used in the program we will develop to recognize TSL finger-spelling recognition. The best EVA-02 model for user will depend on work specific needs. If users are looking for a model that is fast and efficient, then the EVA-02 Tiny or Small models may be a good choice. If user needs the best possible accuracy, then the EVA-02 Base or Large model is the best option.

TABLE VI. PSEUDO-LABELING MODEL PERFORMANCE EVALUATION

Model	Fold	Pseudo-labeling	
		Testing dataset using TTA	
		Accuracy	Weighted F1
Tiny	1	0.7515	0.7332
	2	0.8090	0.7978
	3	0.7885	0.7713
	4	0.8583	0.8509
	5	0.7947	0.7873
Small	1	0.8871	0.8830
	2	0.8604	0.8508
	3	0.8973	0.8942
	4	0.8480	0.8391
	5	0.9014	0.8992

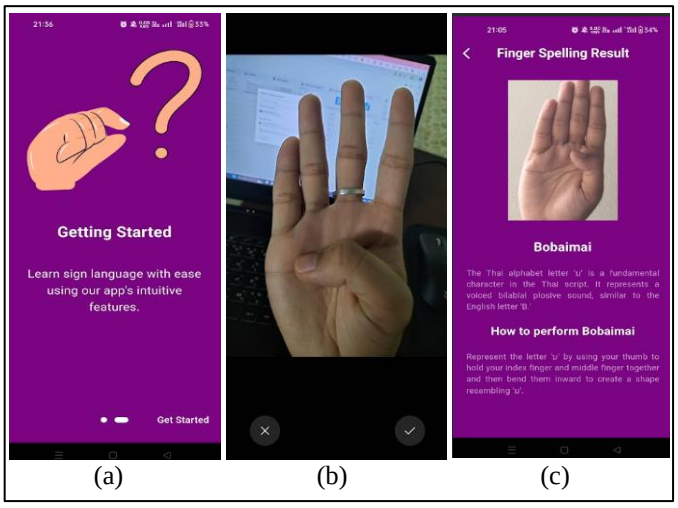
IV. APPLICATION

In this section, we explain our mobile application that users can upload and classify their hand posture images with this application. The application is named "Thai Finger-Spelling Recognition" (see Fig. 9 (a)). We used the Flutter framework to build the front-end part of our mobile application to interact with user, while Python and the Flask framework were employed to develop the backend part to image classification process. The best classification model from experiments is deployed on the server. Users can either capture their own hand posture images or choose from their mobile gallery using the application's main interface (see Fig. 9 (b)). Subsequently, the application uploads the image to the server. The server then prompts the trained model to predict the most likely classes of Thai finger-spelling. The output class retrieves additional details from the database, including example images, class names, alphabet information, and hand posture demonstrations (see Fig. 9 (c)).



(a) (b) (c)

Fig. 9. Thai finger-spelling application: (a) User interface (b) Image capturing (c) Classification information.

V. CONCLUSION

In the study, we proposed training model experiments for Thai sign language finger-spelling recognition. The experiment consisted of vision transformer model training, training with data augmentation, test-time data augmentation, and pseudo-labeling. Our study achieved good performance compared with the experimental phases. In addition, we developed a mobile application. User can upload image data and process from classification to receive useful information related to finger-spelling, such as example image, hand postures, and usage information. For future work, we will collect more data and experiment for several types of Thai finger-spellings such as alphabets, vowels, and tones. Furthermore, we will be testing out other deep learning models like CNN, Capsule Networks, or Generative Adversarial Networks (GANs). The purpose is to compare their recognition performance with the ViT model and reduce model size while maintaining accuracy. This will make it possible to deploy the model in environments with limited resources such as mobile devices or embedded systems.

ACKNOWLEDGMENT

The authors would like to thank College of Computing and Prince of Songkla University, Phuket Campus, Thailand for their support and for providing a working area to test our system.

Investigation of Deep Learning Based Semantic Segmentation Models for Autonomous Vehicles

Xiaoyan Wang*, Huizong Li
School of Computer Science and Technology, Nanyang Normal University, Nanyang, Henan, 473061, China

***Abstract*—Semantic segmentation plays a pivotal role in enhancing the perception capabilities of autonomous vehicles and self-driving cars, enabling them to comprehend and navigate complex real-world environments. Numerous techniques have been developed to achieve semantic segmentation. Still, the paper emphasizes the effectiveness of deep learning approaches because they have demonstrated impressive capabilities in capturing intricate patterns and features from images, resulting in highly accurate segmentation results. Although various studies have been conducted in literature, there is needed for a careful investigation and analysis of the existing methods, especially in terms of two critical aspects: accuracy and inference time. To address this need for analysis and investigation, the research focuses on three widely-used deep learning architectures: ResNet, VGG, and MobileNet. By thoroughly evaluating these models based on accuracy and inference time, the study aims to identify the models that strike the best balance between precision and speed. The findings of this study highlight the most accurate and efficient models for semantic segmentation, aiding the development of reliable self-driving technology.**

Keywords*—Semantic segmentation; autonomous vehicles; deep learning approaches; performance analysis; accuracy; inference time

I. Introduction

Semantic segmentation plays a pivotal role in the realm of computer vision, enabling machines to comprehend visual scenes by assigning each pixel of an image to a specific object category or class [1, 2]. This technique holds immense significance in a plethora of applications, including the navigation of autonomous vehicles [3]. The autonomous driving landscape, characterized by the emergence of self-driving cars, has transformed transportation paradigms [4]. Precise scene understanding through semantic segmentation is paramount in ensuring these vehicles' safe and efficient control in real-time scenarios [5, 6], enabling them to make informed decisions based on the interpretation of their surroundings from video feeds.

Autonomous vehicles, commonly referred to as self-driving cars, are reshaping the future of transportation [7]. Their ability to navigate complex environments autonomously relies on a myriad of technological advancements, and semantic segmentation stands as a linchpin among these. The process of accurately segmenting objects within a scene in real-time video feeds empowers self-driving cars to make split-second decisions [7-9], ensuring pedestrian safety, identifying lane boundaries, and interpreting traffic signals.

Existing methodologies in semantic segmentation for autonomous vehicles have made substantial strides. Deep learning-based approaches, in particular, have garnered significant attention due to their exceptional performance in complex tasks [10, 11]. This preference is attributed to their ability to automatically learn intricate features and patterns from vast datasets, ultimately leading to heightened accuracy [12]. Among the deep learning architectures, ResNet [13], VGG [14], and MobileNet [15] have emerged as frontrunners due to their efficiency in capturing nuanced spatial relationships and features within images [16]. However, despite these advancements, a need persists to identify the most effective and efficient deep learning-based method that strikes a balance between accuracy and inference time, thus optimizing the performance of semantic segmentation for autonomous vehicles.

The statement of the research problem is: How to achieve semantic segmentation for autonomous vehicles and self-driving cars using deep learning models that have high accuracy and low inference time. Correspondingly, the research questions are: What are the strengths and weaknesses of ResNet, VGG, and MobileNet architectures for semantic segmentation? How do these models compare in terms of accuracy and inference time on different datasets and scenarios? Which model(s) can provide the best balance between precision and speed for semantic segmentation?

In this study, we delve into the realm of DL-based models for semantic segmentation in autonomous vehicles, aiming to identify the most effective and efficient solutions. We examine three popular DL architectures: ResNet, VGG, and MobileNet, renowned for their contributions to computer vision tasks. Through a comprehensive analysis, we evaluate these models in terms of foreground accuracy, dice coefficient, and inference time, three crucial performance metrics in the context of autonomous driving systems.

Our findings reveal that certain DL models exhibit notable accuracy and efficiency in semantic segmentation for autonomous vehicles. By conducting an in-depth comparison between ResNet, VGG, and MobileNet architectures, we shed light on their respective strengths and weaknesses. Moreover, we identify the DL models that excel in terms of accuracy and inference time, providing valuable insights for practitioners and researchers in the field. The results of this study serve as a guide to selecting appropriate DL models for real-time semantic segmentation tasks in autonomous vehicles, ultimately contributing to the advancement and reliability of self-driving technologies. By rigorously evaluating these models' performance on video data, this study aims to

contribute insights that advance the state-of-the-art in semantic segmentation for autonomous vehicles. This research endeavors to identify the most effective and efficient deep learning approach through meticulous experimentation and analysis, thereby fostering safer and more reliable autonomous driving systems.

II. Related Works

Ghosh et al. [17] introduced SegFast-V2, an approach to semantic image segmentation tailored for autonomous driving scenarios. Notably, the method prioritizes efficiency by utilizing fewer parameters within deep learning frameworks. With a focus on achieving accurate semantic segmentation, especially in the context of self-driving vehicles, SegFast-V2 presents a solution that balances computational efficiency and performance. The research contributes to advancing the field of autonomous driving by addressing the challenge of efficient and effective semantic segmentation, which is crucial for safe and reliable navigation in complex environments.

Colley et al. [18] investigated the impact of visualizing semantic segmentation in highly automated vehicles on trust, situation awareness, and cognitive load. By examining how providing visual cues of semantic segmentation affects drivers' perceptions and cognitive demands, the research aims to uncover insights into human-vehicle interaction dynamics. By analyzing the implications of semantic segmentation visualization on trust levels, understanding of the driving context, and mental workload, the paper enhances the design and implementation of automated driving systems to optimize driver experience, safety, and overall performance.

Nesti et al. [19] assessed the resilience of semantic segmentation methods employed in autonomous driving scenarios against real-world adversarial patch attacks. Focusing on the critical task of accurately segmenting objects in complex driving environments, the study investigates the vulnerability of these methods to deliberate perturbations introduced by adversarial patches. By subjecting various semantic segmentation models to these real-world attacks, the research endeavors to unravel the potential weaknesses and challenges of such vulnerabilities in ensuring safe and reliable autonomous driving systems. Through meticulous evaluation and analysis, the paper sheds light on the robustness of semantic segmentation techniques under adversarial conditions, offering valuable insights into enhancing the security and performance of self-driving vehicles. The author in Mo et al. [20] conducts a comprehensive review of the latest advancements in semantic segmentation technologies grounded in deep learning methodologies. By critically examining the current state-of-the-art approaches, the study aims to provide an in-depth understanding of the evolution and capabilities of deep learning-based semantic segmentation. Through the analysis of various models, architectures, and techniques, the paper contributes to the field's knowledge by outlining cutting-edge solutions that leverage deep learning for precise object delineation and scene understanding in diverse applications.

Dang et al. [21] presented a lightweight pixel-level semantic segmentation technique based on deep learning for the purpose of detecting and analyzing sewer defects. By leveraging deep learning methods, the approach offers an efficient solution for identifying and classifying sewer system issues through pixel-level segmentation. The study's focus on lightweight architecture signifies a commitment to computational efficiency while maintaining accurate defect identification. This research contributes to the field of sewer infrastructure maintenance by offering a streamlined approach that employs deep learning for detailed and effective defect analysis, enhancing the overall assessment and management of sewer systems.

As results, there are many existing methods for semantic segmentation, but they need to be carefully investigated and analyzed, especially in terms of two critical aspects: accuracy and inference time. Accuracy is the measure of how well the model can correctly segment the image and match the ground truth labels. Inference time is the measure of how fast the model can process the image and produce the segmentation output. These two aspects are important because they affect the performance and safety of the autonomous vehicles and self-driving cars. A model that has high accuracy can provide more reliable and detailed information for the vehicle, while a model that has low inference time can respond more quickly and adapt to changing situations. Therefore, the research paper wants to find the best balance between accuracy and inference time for semantic segmentation.

III. Material and Method

A. Dataset Overview

The Cambridge-driving Labeled Video Database, commonly known as CamVid, is a comprehensive and meticulously annotated dataset designed to advance the field of computer vision, particularly in the context of autonomous driving and scene understanding. The CamVid stands as a vital resource in the realm of computer vision with its diverse and meticulously labeled video sequences. CamVid features a diverse collection of high-resolution video sequences captured from a moving vehicle navigating through urban and suburban environments. These videos encompass a wide range of real-world driving scenarios, presenting challenges such as varying lighting conditions, dynamic traffic, and intricate road layouts. One of the distinguishing aspects of CamVid is its extensive labeling. Each frame of the dataset is meticulously annotated with pixel-level semantic segmentation labels. This means that every pixel in the video frames is categorized, providing a detailed understanding of the objects and structures present in the scenes. Such detailed annotations enable the training and evaluation of advanced machine-learning models for tasks like object detection, semantic segmentation, and instance segmentation. CamVid's applications extend beyond autonomous driving research. The dataset's rich annotations make it highly suitable for projects related to urban scene understanding, environmental monitoring, and general semantic segmentation challenges. The dataset consists of a series of videos, each accompanied by semantic labels that categorize object classes. These labels are accompanied by additional metadata. The database includes accurate reference labels that link every individual pixel to one of 32 predefined semantic categories. Fig. 1 [22] demonstrates the semantic classes of the CamVid dataset.

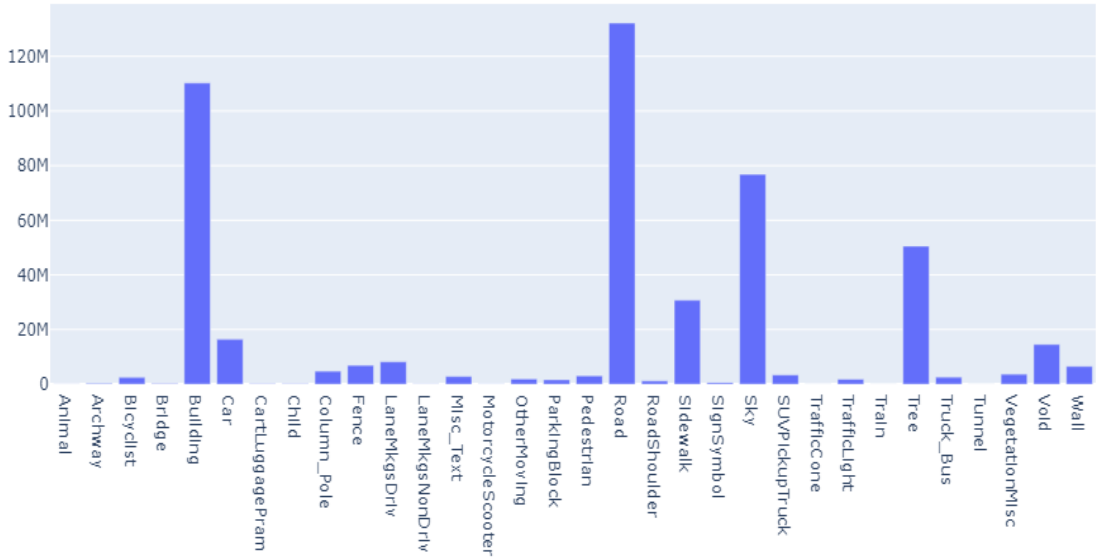

Fig. 1. Semantic classes of the camvid dataset.

B. Model Learning

The proposed model in this study is designed to acquire detailed annotation for each individual pixel within a scene recorded from the perspective of an autonomous agent. The primary task of this model is to classify and isolate every pixel in the given scene into one of 32 specific categories. These categories include items such as roads, pedestrians, sidewalks, and cars, as showcased in the animated image of our product. This enables interaction with any particular image.

The main objective is to understand and interpret the scene with exceptional precision. This understanding is achieved by categorizing each pixel into specific classes, which represent different objects or entities within the scene. For instance, a road, a pedestrian, a sidewalk, a car, and more – all of these are examples of classes that the model identifies. Imagine a picture of a street: the road, the people walking on the sidewalk, the parked cars, and other elements are contained. Our model performs something similar but for each and every pixel in the scene. It determines if a pixel belongs to the road, the sidewalk, a person, a car, or one of the other predefined categories – a total of 32 categories.

C. Backbones

For our initial set of experiments, we opted to employ a straightforward architecture that draws inspiration from the UNet model. This architecture incorporates backbones like ResNet50, VGG19, and MobileNetV2. Despite its simplicity in terms of implementation, this architecture has proven to be remarkably robust in terms of its performance. In other words, it strikes a balance between being relatively easy to create and yielding impressive results in various tasks.

1) ResNet50 Backbone: The UNet architecture is a convolutional neural network (CNN) design that excels in image segmentation tasks. It consists of an encoding path that gradually reduces spatial resolution while capturing features and a decoding path that restores the resolution while refining segmentation maps. In this baseline, we enhance the UNet with a ResNet50 backbone, which is a deep residual network known for its excellent performance in various computer vision tasks. ResNet50 incorporates skip connections to mitigate vanishing gradient issues during training. As shown in Fig. 2 [23], the architecture of ResNet50 is depicted.

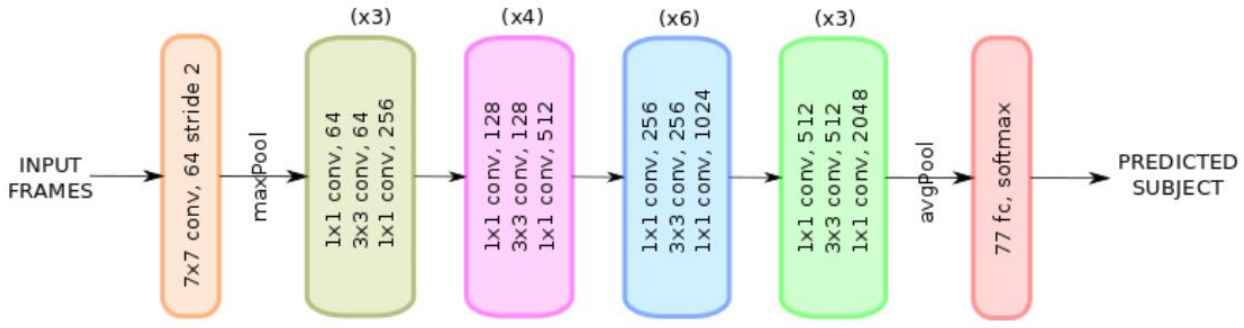

Fig. 2. ReseNet50 architecture [23].

As shown in Fig. 2, the ResNet50 is a specific variant of the ResNet architecture, characterized by its depth of 50 layers. It builds upon the original ResNet's innovation of residual connections, enhancing its capacity to capture complex patterns and features from images. By incorporating a series of residual blocks, ResNet50 enables the efficient training of deeper neural networks while mitigating issues related to vanishing gradients. This architecture has proven highly effective in various computer vision tasks, such as image recognition and segmentation. In the context of enhancing the perception capabilities of autonomous vehicles, ResNet50's depth and feature-extraction prowess contribute to accurate and detailed semantic segmentation, aiding in the vehicles' understanding and navigation of intricate real-world environments.

2) VGG19 backbone: Similar to the previous architecture, this baseline employs a UNet structure but integrates a VGG19 backbone. VGG19 is a deep CNN architecture known for its simplicity and effectiveness. It consists of multiple convolutional layers followed by max-pooling, and it captures progressively complex features through its layers. This backbone enhances the UNet's feature extraction capabilities, contributing to better segmentation performance. Fig. 3 demonstrates the architecture of VGG19.

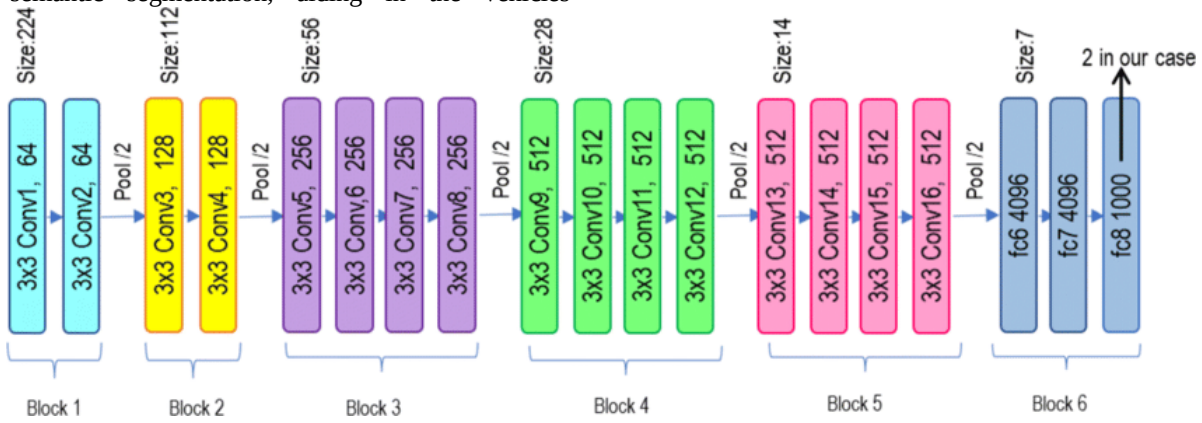

Fig. 3. VGG19 architecture [24].

As shown in Fig. 3, VGG19 is a convolutional neural network architecture renowned for its simplicity and effectiveness in image recognition tasks. With 19 layers, it follows a straightforward design principle of stacking multiple 3x3 convolutional layers, followed by max-pooling layers for down-sampling. This repetitive structure results in a deep network capable of capturing intricate features at different levels of abstraction. VGG19's uniform architecture makes it easy to understand and implement, contributing to its popularity. In the context of enhancing the perception capabilities of autonomous vehicles, VGG19's depth and feature-extraction capabilities play a crucial role in semantic segmentation, enabling the vehicles to accurately perceive and navigate complex real-world scenarios.

3) MobileNetV2 Backbone: The UNet design combined with a MobileNetV2 backbone represents a lightweight yet powerful configuration. MobileNetV2 is optimized for efficiency and speed, making it suitable for real-time applications on resource-constrained devices. It utilizes depthwise separable convolutions to reduce computational complexity while preserving accuracy. Fig. 4 illustrates the architecture of MobileNetV2

The architecture's core component is depth-wise separable convolutions. In these convolutions, the spatial information is decoupled from the channel-wise information, reducing the computational load. Each convolution is divided into a depth-wise convolution, which applies a single convolutional filter to each input channel, followed by a point-wise convolution that merges the outputs into the desired number of output channels. MobileNetV2 also employs skip connections to retain important features, facilitating the flow of gradients during training. These innovative design choices collectively result in a lightweight architecture capable of achieving impressive accuracy on tasks like image classification and semantic segmentation.

D. Hyperparameter Tuning

To enhance the efficacy of our baseline model, a dual focus on both optimal model selection and hyperparameter tuning becomes imperative. The crux lies in identifying not only the most suitable model architecture but also the optimal configuration of hyperparameters for training. To achieve this, we utilize a Bayesian hyperparameter search methodology, a sophisticated technique aimed at systematically exploring the hyperparameter space to unearth the combination that yields the most favorable results.

The essence of this method revolves around minimizing the model's loss function when evaluated against a dedicated validation dataset. By leveraging a Bayesian approach, we dynamically adapt the search process based on previous iterations, progressively honing in on the most promising areas of the hyperparameter space. This method is especially effective in mitigating the challenges posed by high-dimensional and complex search spaces. Ultimately, the outcome of this meticulous hyperparameter search is a refined model configuration that not only aligns with the chosen architecture but also significantly bolsters the model's performance, setting the stage for more accurate and robust predictions.

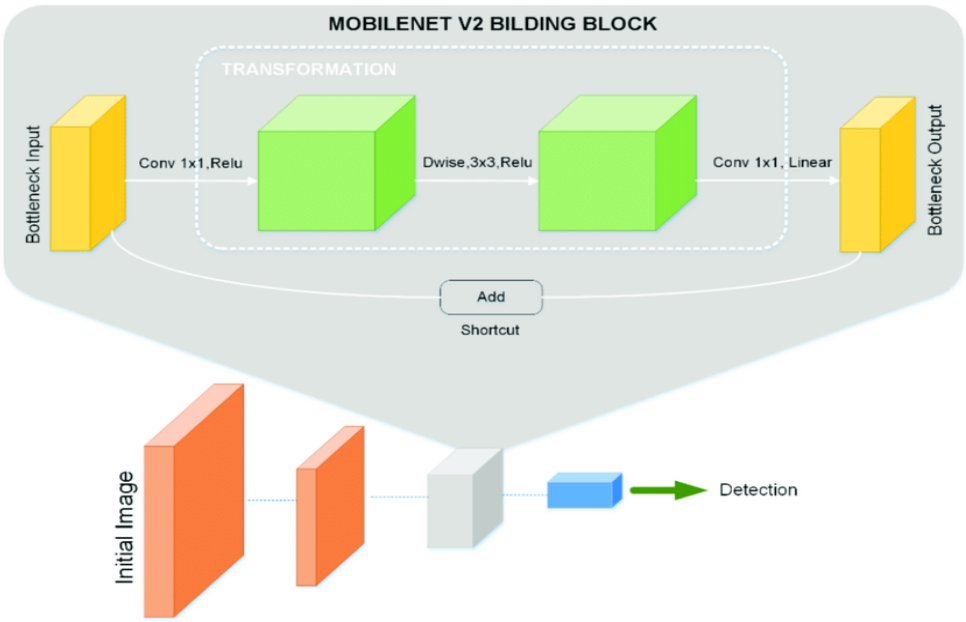

Fig. 4. MobileNetV2 architecture [25].

IV. Experimental Results and Performance Analysis

The forthcoming section delves into the outcomes of our experiments, shedding light on the results obtained through rigorous testing and evaluation. It's important to underscore that for reasons of safety paramountcy, we have prioritized specific classes during the training process. These priority classes encompass entities that play pivotal roles in ensuring safety within various scenarios. The prioritized classes, due to their pronounced safety implications, encompass Pedestrians, Bicyclists, Children, Cars, Heavy Vehicles, and Traffic lights. These categories encapsulate elements that are central to the smooth functioning of urban environments and the safety of both pedestrians and drivers. By focusing on these classes during training, we aim to equip our model with the capability to distinctly recognize and respond to these critical entities.

When evaluating the performance of models in semantic segmentation tasks, two essential metrics that provide valuable insights are Foreground accuracy and the dice coefficient. Foreground accuracy measures the precision with which a model correctly classifies the foreground objects of interest, which is particularly important in scenarios where specific classes carry more significance.

A. Foreground Accuracy

Foreground accuracy, in the context of semantic segmentation, is a metric used to gauge the accuracy of a model's predictions specifically concerning the foreground objects or classes of interest. Unlike overall accuracy, which considers all classes equally, foreground accuracy focuses solely on how well the model correctly identifies and classifies the relevant objects, ignoring the background and other unimportant classes. This metric provides a more insightful evaluation of a model's performance in tasks where certain classes are of greater significance than others, such as object detection or scene segmentation. It is computed by dividing the number of correctly classified foreground pixels by the total number of foreground pixels and can be represented as:

$$Forground\ Accuracy = True\ Positive\ (TP) + False\ Negative(FN) \Big/ True\ Positive\ (TP)$$

B. Dice Metric

The dice coefficient, also known as the F1 score, offers a comprehensive assessment of segmentation accuracy by considering false positives and false negatives. It quantifies the overlap between the predicted segmentation and the ground truth, producing a value between 0 and 1, where 1 indicates perfect alignment. Fig. 5, 6 and 7 show dice metric for the methods. The dice metric is calculated as follows:

$$Dice = 2 * True\ Positive\ (TP) \Big/ 2 * True\ Positive\ (TP) + False\ Positive(FP) + False\ Negative(FN)$$

C. Backbone Experiments

In this section, we delve into the backbone experiments, wherein the focus lies on the fundamental architectural components of our models. These backbone models excel at assimilating contextual information from expansive image regions. This is achieved by adeptly pooling features through a variety of window sizes and seamlessly integrating them using both residual connections and adaptable weights. Our investigation involves subjecting the baseline models to thorough experimentation, including an exploration of different loss functions, to comprehensively understand their performance and capabilities. We present some experiments corresponding to the baselines. Table I presents the experiment name associated with each backbone.

D. Experiments with Hyperparameters

As discussed in Section 5.6, in the process of assessing the effectiveness of models such as ResNet50, VGG19, and MobileNetV2, we harness the capabilities of the Sweep tool. This utility streamlines the execution of a Bayesian hyperparameter search strategy, which is employed to minimize the model's loss on the validation dataset. Sweeps significantly simplify our ability to conduct various experiments while utilizing this search method. The results of foreground accuracy and dice are shown in Fig. 8, 9, 10 and 11.

TABLE I. EXPERIMENT NAME FOR THE BACKBONES

Experiment name	Backbone name
baseline-train-1	ResNet50
baseline-train-2	VGG19
baseline-train-3	MobileNetV2

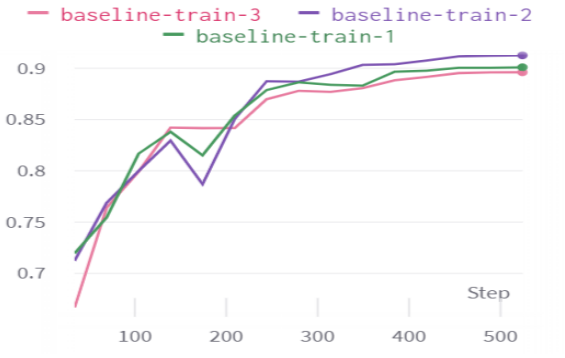

Fig. 5. Foreground accuracy for baseline experiments.

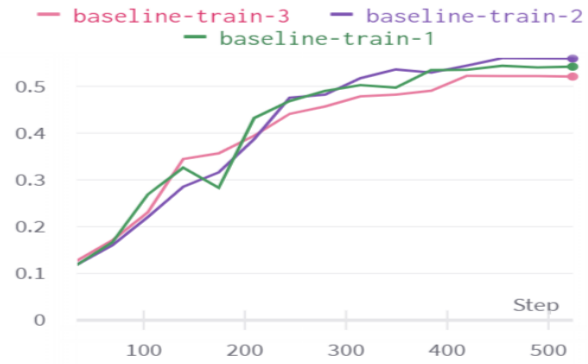

Fig. 6. Dice score for baseline experiments.

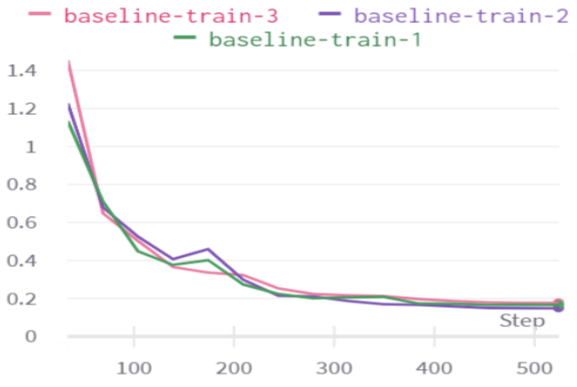

Fig. 7. Validation loss for baseline experiments.

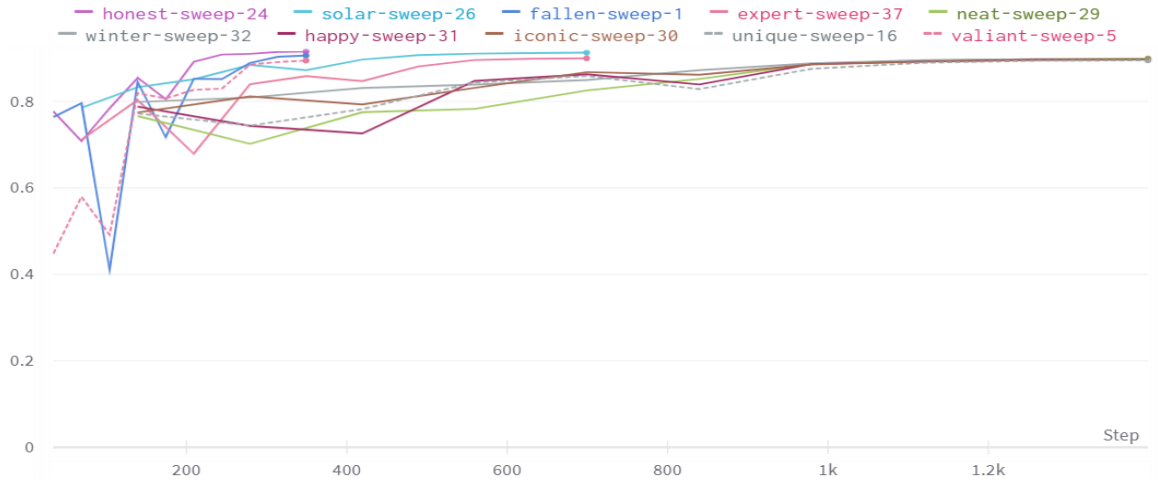

Fig. 8. Foreground accuracy.

Fig. 8 depicts foreground accuracy for various hyper-parameters tuning using Sweep. The provided chart illustrates the Foreground accuracy achieved across ten distinct experiments, offering a comparative analysis of various fine-tuned models. Among these experiments, the recorded accuracy values reveal a hierarchy of performance. Notably, the experiment named "honest-sweep-24" attains the highest accuracy, followed by "solar-sweep-26," "valiant-sweep-5," "solar-sweep-26" once again, and "expert-sweep-37." Conversely, the models "neat-sweep-29," "winter-sweep-32," "happy-sweep-31," "iconic-sweep-30," and "unique-sweep-16" exhibit the lowest accuracy values.

Starting with the highest accuracy achieved in the experiment labeled "honest-sweep-24," it showcases the model's exceptional ability to accurately classify foreground objects. The meticulously tuned parameters of this model contribute to its precision in segmenting relevant classes within the image. This high accuracy score signifies that the model successfully distinguishes and labels the target objects, a crucial feat in tasks like object recognition or scene understanding. The reliability of the "honest-sweep-24" experiment's outcome implies that its fine-tuning process effectively optimized its performance, rendering it a formidable contender in semantic segmentation tasks.

On the other hand, Fig. 9 presents the performances of the models with various backbones in terms of mean foreground accuracy. The backbones involve resnet34, resnet50, Resnet18, vgg19, mobilenetv2_100, mobilenetv3_large_100, mobilenetv3_small_050. The mean foreground accuracy indicates how well the model is performing in correctly classifying instances belonging to the class of interest, often in the context of object recognition or segmentation.

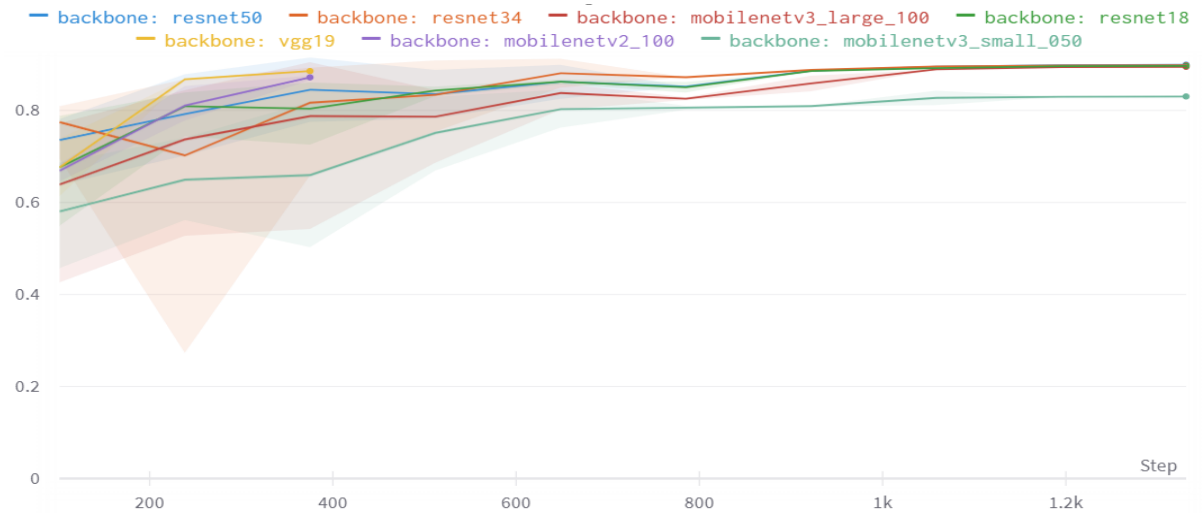

Fig. 9. Mean foreground accuracy for different backbones.

As shown in Fig. 9, among the listed backbone models, "Resnet18" stands out as the best performer, with an accuracy of 89.67%. Resnet18 is a variant of the Residual Network (ResNet) architecture, designed with 18 layers. This architecture utilizes residual blocks, allowing it to efficiently train deep neural networks by mitigating the vanishing gradient problem. Resnet18's success can be attributed to several factors. Firstly, its moderate depth strikes a balance between model complexity and capacity, preventing overfitting while still capturing intricate features in the data. Secondly, Resnet18's residual connections enable efficient gradient flow during training, fostering better convergence and feature representation. Thirdly, Resnet18's design incorporates skip connections, which allow information to bypass certain layers, further enhancing its ability to capture relevant features.

Comparatively, other backbones might struggle due to either excessive complexity leading to overfitting (as with deeper architectures) or limited depth hindering feature extraction (as with shallower architectures). Resnet18 strikes a favorable balance, resulting in its superior mean foreground accuracy. Its intermediate depth, residual connections, and skip connections collectively contribute to achieving a strong balance between capacity and generalization, making Resnet18 a top performer in the comparison.

Finally, the mean dice score presents different backbones, as shown in Fig. 8. It quantifies the similarity between predicted and ground truth segmented regions by measuring the overlap of pixels. This metric's significance lies in its ability to assess the model's capability to accurately delineate object boundaries and capture fine-grained details in complex scenes, providing a comprehensive measure of segmentation quality and performance.

As demonstrated in Fig. 10 presents the mean dice score values collected for different backbone architectures, including "resnet34," "resnet50," "vgg19," "mobilenetv2_100," and "mobilenetv3_large_100." These scores reflect the performance of each backbone on specific tasks or datasets. Notably, "resnet34" emerges as the top-performing architecture with the highest dice scores across multiple columns, followed closely by "resnet50." Both these architectures consistently exhibit superior performance compared to others like "vgg19," "mobilenetv2_100," and "mobilenetv3_large_100." The provided scores reflect the efficacy of these backbones in tackling the given tasks, with "resnet34" standing out as a particularly strong model.

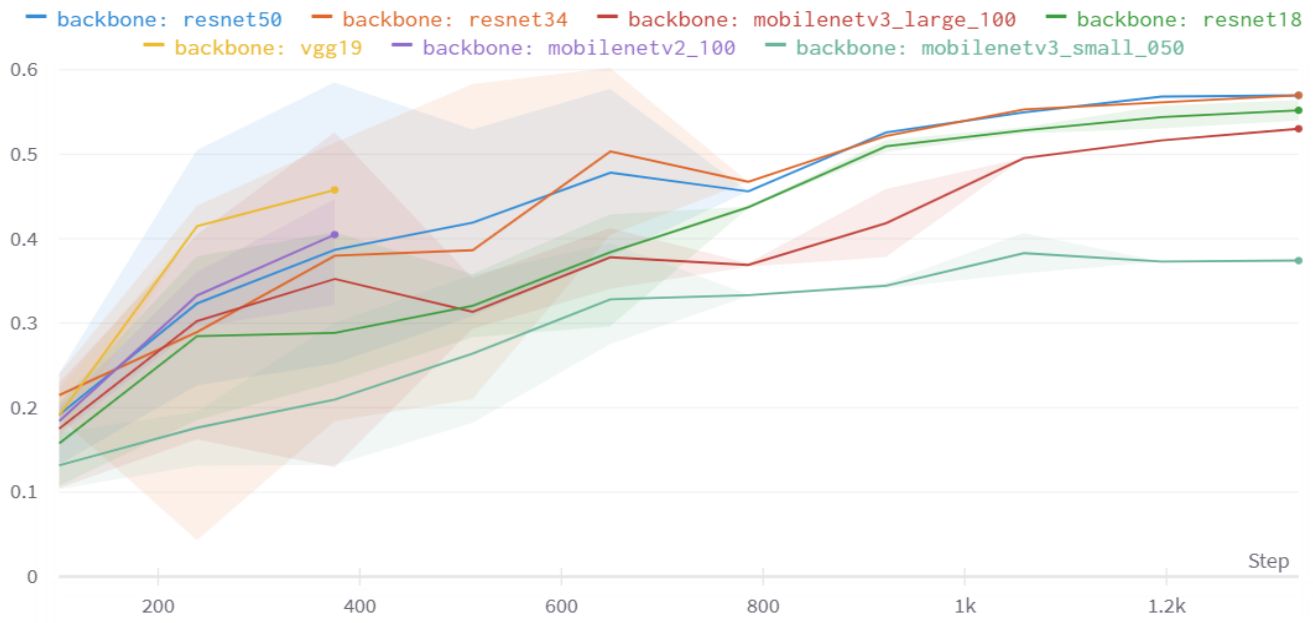

Fig. 10. Mean dice score for the backbones.

E. Inference Time

Inference time refers to the amount of time a model takes to process an input and produce an output prediction. In the context of semantic segmentation models, it measures how quickly a model can analyze an image and generate pixel-wise segmentation results.

The inference times were collected for various backbone models, including "resnet34," "resnet50," "Resnet18," "vgg19," "mobilenetv2_100," "mobilenetv3_large_100," and "mobilenetv3_small_050." Notably, the "Resnet18" model achieved the lowest inference time, while "Vgg19" had the highest.

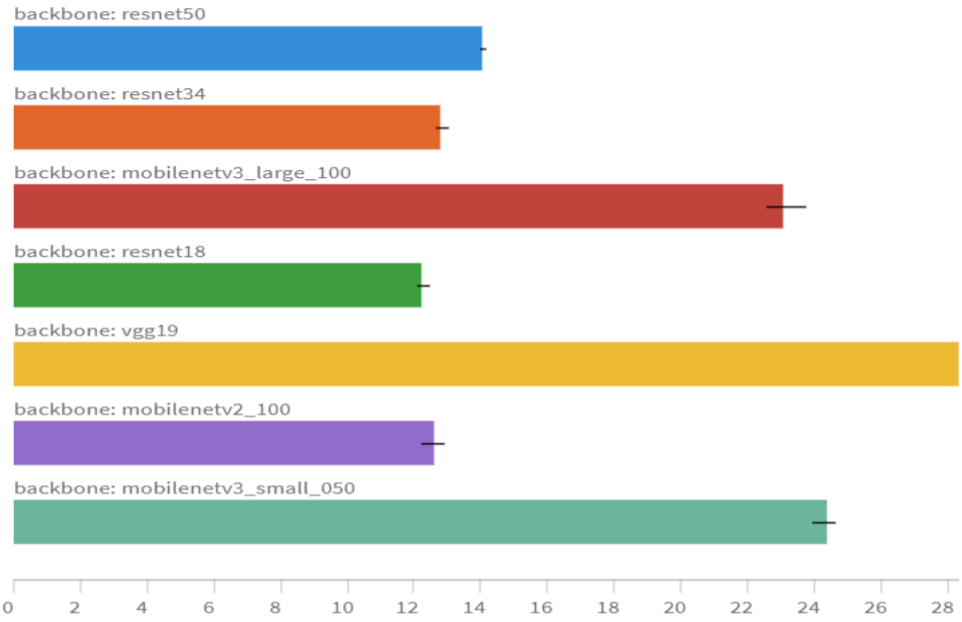

Fig. 11. Inference time of different backbones.

As illustrated in Fig. 11, the superior model in terms of inference time appears to be "Resnet18," which exhibits the lowest processing time among the listed models. This faster inference time can be attributed to Resnet architectural design, which balances depth and complexity, enabling efficient feature extraction while minimizing computational overhead. In contrast, "Vgg19," while offering strong performance, likely incurs higher inference times due to its greater depth and more complex architecture. Therefore, "Resnet18" emerges as the superior choice for applications that prioritize faster semantic segmentation inference times.

V. DISCUSSION

The analysis conducted yields critical insights that significantly inform the optimization of the training process and the selection of backbone architectures for a semantic segmentation model. Firstly, it's evident that employing lower learning rates and weight decay parameters leads to improved foreground accuracy and dice scores. This underscores the necessity of precise parameter tuning to achieve superior segmentation results.

Secondly, the study identifies the batch size and image resize factor as key factors with strong positive correlations to the evaluation metrics. This highlights the pivotal role these factors play in shaping model performance, emphasizing their potential for enhancing accuracy and dice scores.

Additionally, caution is advised against the utilization of VGG-based backbones for the final model. The findings suggest that these architectures are susceptible to vanishing gradients, which can impede gradient propagation during training and hinder optimal model performance.

Ultimately, the analysis underscores the superior performance of ResNet backbones across various metrics. ResNet34 and ResNet50 emerge as optimal choices for the final model due to their impressive performance and quicker inference times compared to other architectures. These insights provide actionable recommendations for refining model training, selecting appropriate backbones, and ultimately improving the efficiency and accuracy of semantic segmentation models.

VI. CONCLUSION

This study extensively explores various deep learning models for semantic segmentation, particularly ResNet, VGG, and MobileNet architectures, aiming to determine the most effective and efficient approach in terms of accuracy and inference time. Through thorough analysis of real-world video data, the research strives to advance semantic segmentation for autonomous vehicles, enhancing their safety and reliability. The investigation's outcomes offer crucial insights into optimizing training processes and selecting backbone architectures, with lower learning rates and weight decay parameters enhancing accuracy, while the batch size and image resize factor positively influence model performance. Caution against using VGG-based backbones due to vanishing gradients is noted, favoring ResNet34 and ResNet50 for their strong metrics and quicker inference times. These findings provide actionable guidelines for refining model training and selecting suitable backbones to enhance the efficiency and precision of semantic segmentation models. For future studies, firstly, researchers could explore hybrid architectures that combine the strengths of ResNet, VGG, and MobileNet for semantic segmentation. This approach seeks to harness the unique features of each architecture to create novel solutions that offer a balance between accuracy, efficiency, and robustness. Secondly, a promising avenue involves enhancing the adversarial robustness of semantic segmentation models. This entails investigating techniques to counter real-world adversarial attacks, particularly in the context of self-driving vehicles. By developing defense mechanisms against such attacks, researchers could contribute to improving the reliability and safety of autonomous driving systems.

Smart Cities, Smarter Roads: A Review of Leveraging Cutting-Edge Technologies for Intelligent Event Detection from Social Media

Ebtesam Ahmad Alomari[1], Rashid Mehmood[2]
Faculty of Computer Science and Information Technology, Albaha University, Albaha, Saudi Arabia[1]
Faculty of Computer and Information Systems, Islamic University of Madinah, Madinah, Saudi Arabia[2]

***Abstract*—The rapidly evolving landscape of smart cities and intelligent transportation systems makes the timely detection of traffic events a critical element for optimizing urban mobility. Furthermore, social media emerges as a valuable source of real-time information, with users acting as active sensors who spontaneously share observations and experiences related to traffic incidents. This review paper offers a comprehensive understanding of the state-of-the-art in traffic event detection from social media. The paper explores leveraging cutting-edge technologies including machine learning, and deep learning with big data technologies and high-performance computing. The discussion unfolds with an in-depth examination of the recent approaches for event detection followed by an exploration of the techniques of spatio-temporal information extraction and sentiment analysis, which are both considered fundamental aspects in enhancing the contextual understanding of traffic events. Further, the review explores the pivotal role of big data technologies in addressing scalability challenges inherent in the vast expanse of social data. The examination encompasses how big data frameworks facilitate efficient storage, processing, and analysis of large-scale social media datasets, thereby empowering machine learning and deep learning models for robust and real-time traffic event detection. Subsequently, the challenges and future directions have been highlighted. Addressing these challenges and leveraging advanced technologies, facilitates the proactive detection and management of these events, paving the way for smart mobility systems.**

***Keywords*—Mobility; smart cities; event detection; social media; big data analytics**

I. Introduction

The importance of detecting traffic events (incidents) cannot be overstated in the context of smart mobility and cities. Efficient traffic event detection lies in its impact on traffic flow optimization, safety enhancement, urban environment functionality and sustainability as well as the overall quality of life in smart cities. Therefore, rapid identification of incidents, such as accidents, road closures, or adverse weather conditions, helps authorities to make timely decisions, minimizing the negative impact of these events and contributing to the seamless operation of transportation systems.

Moreover, social media platforms become vast and decentralized sources of information, with their active users, who function as sensors spontaneously sharing observations, experiences, and updates related to topics in different domains including traffic. Subsequently, Twitter has widely been used to enable smart mobility systems, such as for traffic congestion estimation [1], passenger flow prediction in public metro transit systems [2], understanding taxi traffic dynamics [3], and detecting traffic anomalies caused by traffic accidents, disasters, etc. [4]. Besides, other social media have been used as well, for instance, public geotagged Instagram posts are used to detect an abnormal increase or decrease of the citizen's number in a specific area at a specific time by applying a density-based clustering algorithm [5]. Furthermore, several works have been focused on detecting events using social data, which raises the need for review papers that discuss the significant previous contributions and highlight future directions.

This review paper explores the detection of traffic events through analysis of social media data leveraging artificial intelligence with a specific focus on machine learning, and deep learning techniques in conjunction with big data technologies. The paper begins with examining the approaches of events detection and then investigates the techniques of Spatio-temporal information extraction and sentiment analysis. Furthermore, the review explores using big data technologies. The importance of utilizing big data technology in analyzing social data cannot be overstated, due to the volume, velocity, and variety of data generated on social media platforms, which require scalable and efficient processing frameworks. By leveraging advanced analytics and machine learning on large datasets, big data technology empowers the development of sophisticated models for traffic event detection, ensuring timely and accurate responses to dynamic urban challenges. To the best of our knowledge, only one review paper [6] provides a systematic review of traffic event detection techniques from social data but it does not includes the recent approaches such as using big data technology.

The main contribution of our work can be summarized as follows:

1) Cover the recent approaches including using deep learning and big data technologies as well as provide a taxonomy of the approaches.

2) Discuss the techniques of spatio-temporal information extraction and sentiment analysis, which are both considered

as fundamental aspects in enhancing the contextual understanding of traffic events.

3) Highlight the challenges and future directions to facilitate the proactive detection and management of the events and pave the way for smart mobility systems.

The rest of the paper is organized as follows. Section II reviews the works on traffic-related event detection from social data. Section III discusses using big data technologies in mobility and reviews the works related to traffic event detection using big data platforms and technologies. Section IV discusses the challenges and future directions. Finally, we draw our conclusions in Section V.

II. Social Media in Traffic Event Detection

With the exponential growth of social media platforms, users actively share real-time information, offering a valuable resource for monitoring and responding to traffic-related incidents. In this section, we review the existing work on road traffic analysis and event detection from social media. Fig. 1 depicts the number of reviewed papers in the period between 2012 and 2023. The total number of papers related to traffic event detection from social media included in this review is 61, only 15 of them are using big data technologies and platforms. Moreover, Fig. 2 shows the used social media and the number of reviewed papers that used big data technologies (light blue color) and that do not use them (blue color). It can be seen that most of the works have used Twitter while only one paper has used Instagram.

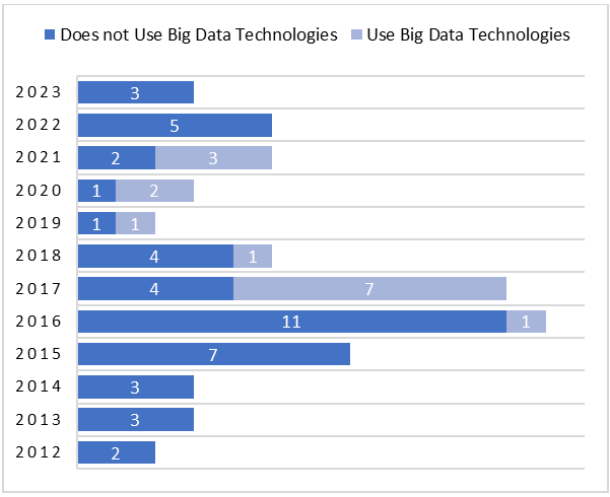

Fig. 1. Number of publications per year.

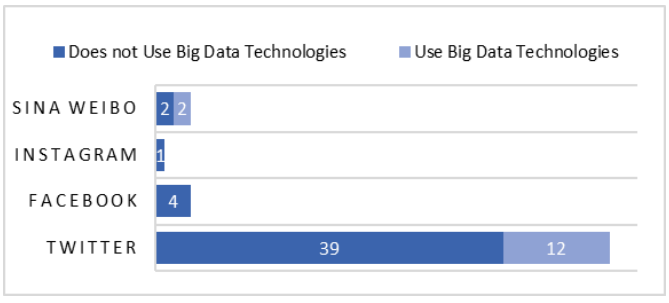

Fig. 2. Number of publications and social media platforms.

Fig. 3 shows the analysis dataset languages that have been used in the reviewed works, which include English, Arabic, Italian, Thai, Indonesian, Japanese, Malay, Korean, French, Spanish and Chinese. The blue color represents the number of papers that do not use big data technologies while the red represents the number of papers that use big data technologies. As depicted in the figure most of the works are focused on the English language.

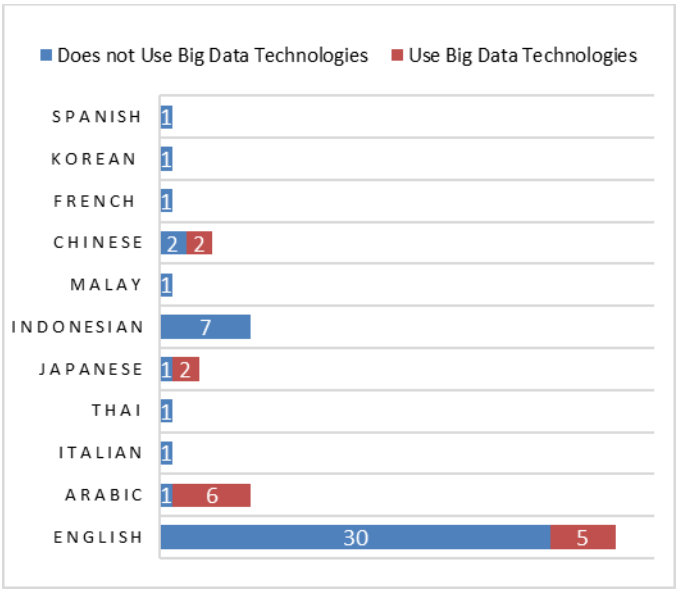

Fig. 3. Number of publications and dataset language.

Moreover, Fig. 4 describes the general workflow of event detection from social data. The main components are Data collection and filtering, Pre-processing, Event detection, Spatio-temporal information extraction, and Evaluation. Firstly, data are collected by using keywords, hashtags, accounts, geo-coordinates or a combination of these approaches. Then, the data are filtered to keep only traffic-related data. Data filtering can be done during data collection or it can be a separate step and various approaches can be used including machine learning algorithms. The next step is data pre-processing. There are common sub-components for pre-processing, which are tokenizer, normalizer, stop-words removal, and stemmer. Several tools and packages are available for pre-processing but mostly they are designed for a specific language. The next step is detecting the events and then extracting the time and location information. Subsequently, sentiment analysis is applied to understand the feelings and emotions regarding the detected events. This step is not mandatory. It depends on the interest of the researcher and the aim of the work. Finally, the tool is evaluated. The evaluation process depends on the method that has been used. For instance, if machine learning algorithms have been used to build classifiers for event detection, there are common evaluation metrics that can be used for evaluation such as accuracy, precision and recall. These are the main common steps that have been followed in literature to detect traffic events, more details about the components can be found in [7].

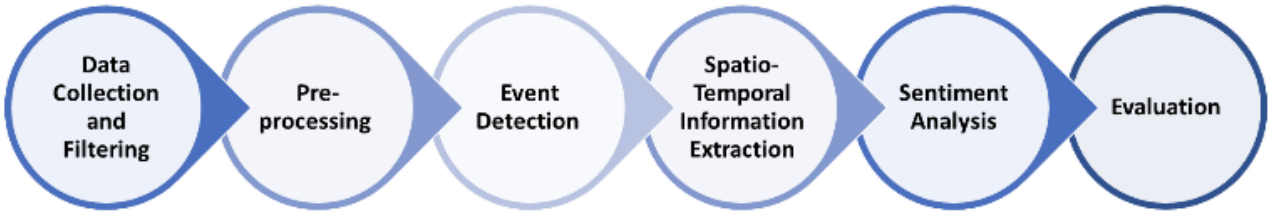

Fig. 4. General workflow of social data analysis for Traffic event detection.

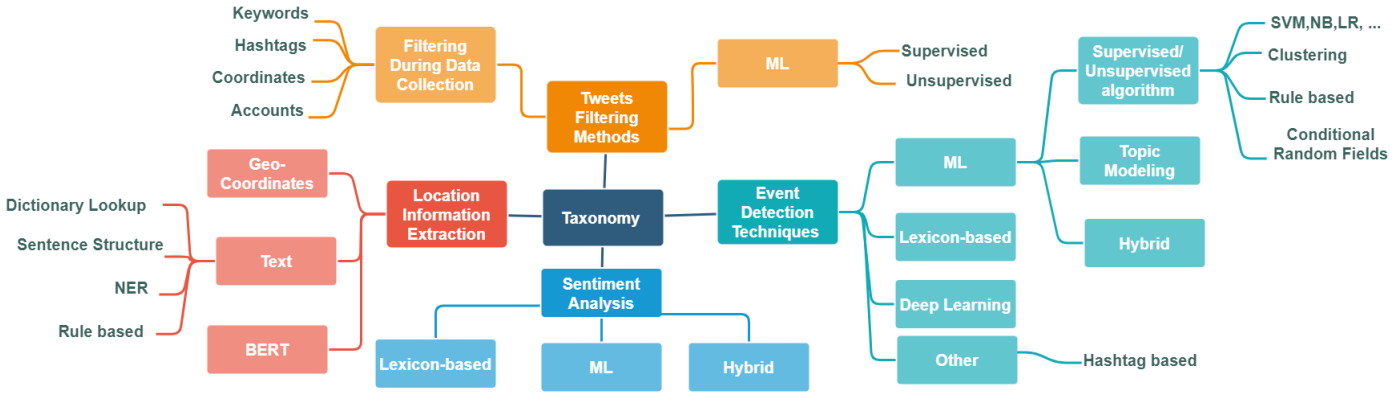

Fig. 5. Taxonomy of traffic events detection techniques from social data.

Fig. 5 shows the taxonomy of the approaches for each component in the general workflow except for the pre-processing component, which mainly depends on the language of the analyzed data and the evaluation component, which depends on the approach that has been used for the event detection. In the next subsection, we review the existing works and organize them based on the approaches that have been used. We started in section A with the event detection approaches because it is the main and the most important component. At the end of section A, we summarized the techniques for data filtering. In section B, we discuss the techniques of Spatio-temporal information extraction. Finally, section C covers the techniques of sentiment analysis

A. Event Detection Techniques

Several techniques have been used for traffic event detection including lexicon-based, machine learning (ML) and deep learning techniques. The next subsections provide a review of the existing works for each technique.

1) Lexicon-based: Istiq et al. [8] built an application to monitor road conditions. They collected road condition information from RSS fed on Facebook and stored them in the MySQL database. After Text Mining, the application categorized the information based on how much connectivity between words by categories. The information is categorized into six types including floods, traffic jams, congested roads, road damage, accidents, and landslides. Daly et al. [9] developed Dub-STAR system to extract the causes of traffic conditions from real-time tweets. They applied a simple dictionary approach to assigning tags to the input messages. The text is classified into classes such as delay, incident, roadwork, or concert. Moreover, Alomari and Mehmood [10] analyzed Arabic tweets related to traffic congestion in Jeddah city. They created custom dictionaries in SAP HANA for the common Arabic keywords about transportation and traffic congestion.

Alkouz and Alghbari [11] proposed a tool called SNSJam for traffic event detection using Arabic and English posts from Twitter and Instagram. They collected 50 million posts but after filtering they got around 2.3 million tweets and 4k Instagram posts. To identify events, they used a list of keywords.

2) Machine learning (ML)

a) Supervised and Unsupervised ML: Researchers in [12] and [13] used the SVM algorithm to classify tweets as relevant and irrelevant to traffic. But they don't detect event types. Dhavase and Bagade [14] provided a classification technique based on a machine-learning algorithm to detect crime-disaster events. Agarwal et al. [15] detected complaints tweets about road irregularities and bad road conditions by employing a rule-based classifier. They extracted the important information; such as the problem and the location, and then the tweets were categorized into useful, nearly-useful and irrelevant complaint reports.

Furthermore, Sakaki et al. [16] detected weather information and heavy-traffic information by classifying tweets into positive class means event-related and negative class means not related to events using the SVM algorithm. Klaithin and Haruechaiyasak [17] applied a machine learning classifier based on Naive Bayes Model. They classified the Thai tweets about traffic into three types: tweets about location, tweets about roads and tweets about traffic status. Kumar et al. [18] built a model to detect road hazards so they

classified the tweets into two classes namely, having negative or non-negative sentiment. They considered that all negative sentiment tweets have road hazard information. They applied three algorithms, which are Naïve Bayes (NB), K-nearest neighbors (KNN), and the Dynamic Language Model (DLM).

Moreover, D'Andrea et al. [19] applied text mining techniques and classified real-time Italian tweets into three classes, which are "traffic due to an external event", "traffic congestion or crash", and "non-traffic". They validated the detection of temporal information by their system using a generated dataset for traffic events from local newspapers and official news websites.

Kurniawan et al. [20] built a machine learning classifier to classify real-time Indonesian tweets into traffic-related and not-related. They used NB, SVM and decision tree (DT) algorithms. They counted the occurrences of all the words in a tweet as features. Then, in the feature selection process, they used only 40 selected words. Nguyen et al. [21] developed a system called TrafficWatch to monitor traffic conditions in Australia using real-time and historical tweets. During the feature selection process, they used serval features including a bag of words, Pattern recognition, Lemma, part-of-speech and a bag of tags. They introduced the NER annotation schema for detecting traffic related entities. Additionally, they trained the model based on Conditional Random Fields (CRFs). The traffic-related entities are implemented as key features to train the ML classification model. Further, they implemented an online clustering algorithm to incrementally cluster the streaming tweets.

Yazici et al. [22] used TF-IDF and NB to detect events from personal and organizational Twitter accounts. They noticed that the tweets from personal accounts do not disseminate traffic incident information in a very structured manner in terms of grammar and spelling compared with the organizational account. On the other side, personal tweets are better in reporting events that have just happened. Besides, Semwal *et al.* [23] and Tejaswin *et al.* [24] predicted the traffic incidents from social media using a random forest classifier. Anantharam et al. [25] developed a framework for extracting city-related events. They created a training set for building a conditional random field (CRF) automatically, by using dictionary-based spotting of event and location terms, to reduce manual tagging effort.

Moreover, Langa and Moeti [26] filtered real-time tweets about congestion in South Africa into traffic-congested-route and non-traffic-congested tweets using the Naïve Bayes algorithm. Subsequently, they developed a mobile application to send notifications to users based on classified tweets about traffic. Suat-Rojas et al. [27] built a classifier to detect accidents from tweets in the Spanish language. They classified tweets into accident and non-accident. For validation, they compared the detected accidents with official data from the Bogota Mobility Secretariat. Subsequently, they found that using doc2vec for feature extraction and SVM for classification helped in achieving good accuracy results.

3) Topic Modeling: One of the popular topic modeling algorithms is Latent Dirichlet Allocation (LDA). It was introduced by Blei et al. [28]. Besides, it is a statistical classification model based on the word-topic frequency distribution. Wang et al. [29] focused on exploring the relationship between traffic conditions in daily matter and urban human events in Toronto, Canada. They developed a tweet-LDA engine to classify tweets into two classes namely, "traffic-relevant" and "traffic-irrelevant". To ensure that no relevant tweets are missed, they filter out traffic-irrelevant tweets using a set of keywords. Moreover, Huang et al. [30] used DBSCAN to build spatiotemporal clusters from the geotagged tweets. Then, the LDA was implemented to the tweets under each cluster to extract the topics. Ali et al. [31] applied OLDA-based traffic event labeling. They used a well-known Web Ontology Language (OWL) tool called Prot´eg´e to develop ontology before using LDA. They generated a list of the most frequent words related to traffic events and then used them to develop ontology-based semantic knowledge.

a) Hybrid (Topic Modeling and Supervised/ Unsupervised ML): Gu et al. [32] collected historical and real-time tweets about traffic in Pittsburgh and Philadelphia Metropolitan. They used Supervised Latent Dirichlet Allocation (sLDA). In addition, the Tweets are classified by a Semi-Naive-Bayes (SNB) classifier. Lau [33] used Latent Dirichlet Allocation (LDA) topic modeling to filter traffic messages in the Chinese language. Additionally, they built SVM, KNN and NB classifiers for traffic events detection.

4) Deep Learning: Chen et al. [34] extracted Chinese traffic information from the Sina Weibo platform. They employed deep neural networks to learn the abstract features and classify them into traffic relevant and irrelevant. Ji et al.[35] measured the similarity of events between texts using meta-path in heterogeneous information networks. Then, to get the best possible meta-path weights, they employed a graph neural network for semi-supervised learning. After that, they designed a clustering algorithm to identify the traffic event categories.

Moreover, Ambastha and Desarkar [36] used different ML algorithms including SVM, Naive Bayes and Random Forest as well as deep learning algorithms including LSTM, CNN, and Universal Language Model FIne-Tuning (ULMFIT). The developed classification models were used to classify the tweet into two categories, namely, "Traffic incident related" or "Non-Traffic incident related". The Transfer Learning approach using ULMFIT was employed to enhance the performance.

Kim et al. [37] classified tweets in the Korean language using NB, RF, SVC, linear SVC, BiLSTM, and TextCNN into six classes: construction, weather, accident, traffic jam, crowded event and others. Rifqi et al. [38] used CNN+Word2Vec, CNN+FastText, and SVM to classify Indonesian tweets into 2 classes, which are tweets about traffic jams and tweets about smooth traffic. Swapnika and Vasumathi [39] applied the DNN and Harris Hawk optimization (HHO) algorithm to detect the following events from Twitter: education, transportation, environment, geospatial and water events. They claimed that they addressed

the challenge of the scalability challenge, but they did not provide a detailed explanation.

Furthermore, Hodorog et al. [42] combined AWD-LSTM and ULMFiT to detect traffic-related events in Cardiff City in the UK. They focused on several events including congestion, accidents, social gatherings, thefts, bus queues, floods and electricity charges. Additionally, they studied the relationship between the events as well as assigned a citizen satisfaction value to each of them. Mehri et al. [43] used BERT to detect subway-related events from tweets in English and French Language. They manually labeled 10381 records in English and 11008 in French to build the training dataset. The finding indicated that BERT in zero-shot surpasses the performance of the baseline models.

TABLE I. EVENT DETECTION TECHNIQUES

Ref.	Detected Event types	Event Detection Technique
Lexicon-based		
[8]	Floods, traffic jams, road damage, accidents, landslides	Based on the connectivity between words
[9]	Traffic congestion causes	Dictionary-based
[10]	Accidents, weather, road works, social events.	Dictionary-based
[11]	Accidents	Dictionary-based
ML		
[14]	Crime and disaster	NB
[15]	Useful, nearly-useful, irrelevant complaint reports	Rule-based classifier
[16]	Related to roads, related to weather	SVM
[17]	Accident, announcement, question, request, sentiment.	NB
[18]	Hazard and non-hazard	NB, KNN, and DLM
[19]	Congestion, crash, non-traffic event, external event.	SVM, NB, C4.5 Decision tree, PART, KNN,
[20]	Traffic and non-traffic	NB, SVM, DT
[21]	Roadwork, queue, accident, activities, breakdown, police.	Conditional Random Fields (CRFs) labeling method.
[22]	Traffic-relevant, traffic-irrelevant	NB, dictionary of frequently occurring words
[23]	Heavy-vehicle, traffic-jam, park-footpath autometer, wrong-side, breakdown, jump-signal, U-turn, no-parking.	Random forest classifier
[24]	Weather	Random forest classifier
[40]	Roadwork traffic jam, freight traffic, road closure, weather, accident	Dictionary, clustering algorithm
[41]	Earthquakes, forest fires, floods, and droughts	Checking a set of predefined weighed keywords, KNN algorithm
[25]	City-related events	CRF model, dictionary-based spotting
[26]	Traffic-congested and non-traffic-congested	NB
[27]	Accident and non-accident	SVM, NB, RF and Neural Networks
[29]	Traffic-relevant, traffic-irrelevant	LDA
[30]	Leisure, sports, music, movies, art, and other	LDA
[31]	Traffic, non-traffic	OLDA
[32]	Roadwork accidents, weather, special events, obstacle vehicles.	sLDA, SNB
[33]	Accidents, traffic jams, weather	LDA, SVM, NB, K-Nearest
Deep Learning		
[34]	Traffic relevant, Traffic-irrelevant	CNN
[35]	Traffic Control, Weather Anomaly, Accident, Congestion, Road Construction, Vehicle Anchorage, Official Occupation, and Normal Traffic.	BS-GCN
[36]	Traffic relevant, Traffic-irrelevant	ULMFiT model
[37]	Construction, weather, accidents, traffic jams, crowded events and others.	NB, RF, SVC, linear SVC, BiLSTM, and TextCNN
[38]	Traffic jams, smooth traffic	CNN+Word2Vec, CNN+FastText, and SVM
[39]	Education, transportation, environment, geospatial and water event	DNN and HHO
[42]	Congestion, accidents, social gatherings, thefts, bus queues, floods, and electricity charges.	AWD-LSTM and ULMFiT
[43]	Incident and non-incident	BERT

5) Other Methods: He et al. [44] proposed MetroScope system which analyzed real-time tweets to detect events related to the Washington D.C. Metro system. They developed a phrase-level algorithm that groups events with similar key phrases into a story. To prioritize urgent events, they performed sentiment analysis and then implemented a function to automatically send emails to authorities regarding emergency events.

Shekhar et al. [45] collected data about traffic conditions from Facebook and Twitter. They constructed a decision tree to display traffic-sensitive optimized routes. After that, they categorized particular streets within a city into three categories, which are Moderate Congestion, Severe Congestion, and No Congestion based on the average user's sentiment on hourly time slots. Further, they detected the possible causes of traffic congestion in a particular area and enabled users to search for the cause of congestion at a particular time. Ni et al. [2] developed a hashtag-based event detection algorithm. To detect events, they examined tweets within a specific area and probe (the subway station and two stadiums) instead of detecting the exact topic of the events.

Table I shows the type of detected events by each of the reviewed papers as well as the techniques that have been used for event detection. Table II illustrates the filtering approaches that have been used to filter out irrelevant posts before detecting the events.

B. Spatio-temporal Information Extraction

Chaniotakis et al. [50] analyzed tweets about the flood and the evacuation in Oroville, California USA. They used the WordNet dictionary to create a corpus to detect discussions concerning the evacuation. Muhammad and Khodra [53] used the conditional random field (CRF) model for event information extracted from Indonesian tweets. They filtered the event-related tweets by combining the rule-based method with the bag of words model. Kumar *et al.* [18] extracted coordinates from geo-tagged tweets. Then, the geographic coordinates are mapped to a specific road or road segment**.** Shekhar *et al.* [45] extracted location names from the text. They assumed that the location is almost preceded by a preposition. So, they created a list of all the prepositions (e.g. in, at, on, etc.). The extracted location name is sent to Google Maps API to return the geographical coordinates. Wang et al. [29] extracted the coordinates from geo-tagged tweets and mapped them to extract location in terms of road, street, and landmark. On the other side, the location information from non-geotagged tweets is extracted either from users' profiles or from tweet content by using semantic analysis to identify the key joint words of "between...and", "from...to" and "exit to...,".

Furthermore, Wang *et al.* [1] extracted the streets, landmarks, and direction information from the text by using a gazetteer. Additionally, for traffic estimation and prediction, they extracted two types of road features, which are physical features (such as the road segment length, the number of lanes and the number of intersections) and point of interest (POI) (such as schools, hospitals, shopping mall, etc.). Sakaki et al. [16] extracted driving information from Japanese tweets and transformed geographically related terms into geographical coordinates. They created a dictionary for the place names in Japan. In addition, they collected pairs of verbs and prepositions, which are dependent on the names of places. Then, they used such pairs to extract the names of places.

Moreover, Daly et al. [9] perform a dictionary lookup to extract location names from SMS messages or tweets. Alifi and Supangkat [12] classified the tweets by using SVM to distinguish between the data that are related and not related to the traffic condition. They suggested methods for extracting location information which is using location vocabulary, using the symbol "-" or based on the structure and words in a sentence. In addition, they obtained useful information from real-time streams involving congestion causes, traffic conditions, as well as weather conditions. They suggested using three approaches: (i) the existence of location words (such as from, to, toward), (ii) the use of the symbol "-" that usually used to link two location points at once, (iii) the location vocabulary (such as street name). Klaithin and Haruechaiyasak [17] extract words or phrases related to traffic information from Thai tweets using lexicon-based and rule-based methods. They extracted traffic information such as road names, locations, and traffic accidents. Hanifah et al. [13] applied a rule-based approach and obtained information regarding the time and date, location and image. Additionally, they employed SVM model for traffic congestion detection from tweets posted in Bandung, Indonesia. The developed model filters the tweets into relevant to traffic congestion and irrelevant.

Dhavase and Bagade [14] proposed an approach to extract location from tweets. They used three different parsers: (i) named location parser (e.g., use gazetteer matching) to check for locations in tweets, (ii) NER parser (like Stanford NER). (iii) street building parser using rule-based pattern matching.

Hasby and Khodra [52] developed an information extraction module to extract time, location, condition, direction, and causes from Indonesian tweets about traffic jam.

The module consists of five elements, which are tokenizer, normalizer, Named Entity Recognition (NER), template element task, information filling and relation extraction. Similarly, Muhammad and Khodra [53] extracted event name, location, time and additional event information using an extractor module that was built up by Tokenizer, NER and POS Taggercomponent.

Moreover, Agarwal et al. [15] applied a combination of NER (Indico Text Analysis API) and GeoCoding (OpenStreetMap API) APIs to obtain the geographical entities from tweets. Gutierrez et al. [40] extracted locations from tweet messages using four NER engines, which are: Alchemy, Stanford NER, OpenCalais and NERD. Further, they used three geolocation external applications, which are: GeoNames, Google Geocoding, and Nominatim. Raymond [33] and Musaev et al. [54] applied the open-source Stanford NER tool to extract the place name. Salas et al. [46] used NER to link a concept to a unique location through a knowledge base such as Wikipedia.

Subsequently, Xu *et al.* [47] proposed a model based on crowdsourcing for describing urban emergency incidents such as storms, fires or traffic jams. They proposed a 5W model for illustrating the data, which provides five basic elements 1) When: temporal information (e.g. the starting/ending time of the event), 2) Where: spatial information (places), 3) What: the semantic information for the event, 4) Who: personal information (e.g., participatory or witness) and 5) Why: the reason information. They extracted location information from the check-in information from Weibo.

Besides, Berlingerio *et al.* [48] developed a system named SaferCity based on a new spatiotemporal clustering algorithm for incident detection from Twitter. Singh [55] extracted location from tweet text. To address the issue of the lack of location information, they suggested using the historical locations of the user to predict the probable location by applying Markov chain model. Yang et al. [51] extracted information form tweets related to the traffic conditions in Malaysia. They suggested extracting the location and direction information from the text using prepositions and words like "from…to", "along", "heading" and etc. Tejaswin et al. [24] extracted location entities using a regular expression parser. After that, entity disambiguation is applied to verify if it is a location and ensure that the address belongs to the correct city. Kim et al. [37] built an algorithm for region extraction to extract keywords from Korean tweets with the help of entity name recognition API based on BERT.

Table III summarizes the techniques for extracting location information. We grouped the approaches for extracting the location information into three main groups, which are: (i) from the coordinates attribute in the geotagged posts (ii) by extracting the location name from the text, and iii) using deep learning models such as BERT. The first approach is not always applicable since not all posts are geotagged because some users turn off location services on their smartphones to protect their privacy. For the second approach, the text will be analyzed using natural language processing (NLP) methods to extract the place name. The common methods that are applied to extract a placename from the text are as follows: i) Dictionary lookup: requires checking the text to discover place names listed in a gazetteer or glossary. ii) Sentence structure: use a list of prepositions (e.g., in, at, on, etc.) iii) Named Entity Recognition (NER): identify and categorize entities from text. iv) Rule-based pattern matching: implement the extraction based on certain written actions.

C. Sentiment Analysis

1) Lexicon-Based: Shekhar et al. in [45] and [41] categorized the users' emotions during a disaster by feeding English text from social media to sentiment analysis method. The users' emotions are sub-categorized as positive, negative, unhappy, depressed and angry. Additionally, they created a dictionary of weighted sentiment ratings for words and used SentiStrength online. SentiStrength [56] is a popular stand-alone online sentiment analysis tool. It uses a dictionary of sentiment words for assigning scores to negative and positive phrases in the text. Salas et al. [46] applied sentiment analysis to classify the tweets into positive, negative, or neutral class. They used TensiStrength for stress and relaxation strength detection.

2) Machine learning: A different sentiment classification method was applied by Kumar et al. [18] to categorize tweets into four sentiment classes: false negative, true negative, false positive and true positive. A true positive indicates that the tweet is accurately categorized as non-hazard whereas a true negative indicates that a tweet is accurately classified as a hazard. The false positive category refers to tweets that include some positive sentiment terms e.g. "awesome" and "enjoy", however, the actual sentiment is negative. On the other side, false negative refers to tweets that are incorrectly categorized as a hazard. They employed three ML algorithms, which are KNN, Naïve Bayes, and DLM.

Ohbe et al. [57] classify Japanese tweets about the local event into three categories: positive, negative, and other. They used a multinomial logistic regression analysis for the classifier. Berlingerio *et al.* [48] used Sentiment140 API for sentiment analysis. Sentiment140 [58] used a trained classifier built on large tweets with emoticons for distant supervised learning. Furthermore, Musaev et al. [54] developed a model to categorize tweets into happy or sad. They applied the Continuous Bag-of-Words and Skip-gram model. To do automatic labeling, they searched for tweets that contain ":-)" and ":-(" emoticons. After that, they utilized the Word2Vec repository to convert the tweets in the training set to their vector representations.

3) Hybrid: Adetiloye and Awasthi [59] applied sentiment analysis for traffic tweets using the lexicon of opinion words (LOWs) and the improved Naïve Bayes algorithms in [60]. Table IV summarizes the techniques for sentiment analysis that have been used in literature for event detection.

D. Big Data Tools and Platforms

The term big data refers to the extremely large amount of data that grows exponentially with time, which makes it difficult to conduct an efficient analysis using conventional IT and hardware solutions within a reasonable amount of time

[61]. Subsequently, the four main characteristics of big data are i) Volume: refers to the size of data that might be measured by Zettabytes (ZB), or Yottabytes (YB) ii)Velocity: which refers to the processing speed and considered as crucial characteristic for the performance. iii) Variety: refers to the diversity of the data, which can be structured, unstructured, or semi-structured. iv) Value: refers to valuable and reliable data.

TABLE IV. SENTIMENT ANALYSIS APPROACHES FOR EVENT DETECTION

Ref.	Lexicon	ML	Hybrid	Categories
[45], [41]	✓			Positive, Negative, Unhappy, Depressed, Angry
[18]		✓		True Negative, False Negative, True Positive, False Positive.
[46]	✓			Positive, Negative, Natural
[57]		✓		Positive, Negative, and other
[48]		✓		Positive, Negative, Natural
[59]			✓	Positive, Negative, Natural
[54]		✓		Sad, Happy

III. BIG DATA TECHNOLOGIES IN MOBILITY

Furthermore, the traditional data storage, processing, and analysis applications are insufficient to address the challenges that come from the massive continuously generated transportation and traffic-related data from various sources such as sensors, digital cameras, and social media. This raises the need for big data platforms and technologies, based on distributed data management and parallel processing. Big data storage solutions, such as NoSQL databases are ideal solutions for the storage issue since they have more flexible and adaptable data models and schemas compared to relational databases. Subsequently, big data platforms have integrated libraries including machine learning, deep learning, or data mining algorithms, which facilitate smart analysis [62].

The next subsection explains the existing approaches for traffic event detection using big data.

A. Traffic Events Detections Using Big Data Technologies

Nguyen and Jung [63] detected events by applying density-based spatial clustering. Additionally, to evaluate the proposed method, they used datasets (about 'FA Cup'' and ''Super Tuesday) employed in a previous study. They evaluated the performance using Hadoop. Khazaei *et al.* [64] proposed a big data analytics platform, named Sipresk that was built over Apache Spark to detect traffic events from different sources including social media, cameras, mobile devices, etc. Lau [33] suggested using topic model-based for text filtering then they built a classifier to identify traffic events such as traffic jams, road accidents, weather, etc. They fed the message corpus to the proposed Latent Dirichlet Allocation (LDA) model for topic learning. Subsequently, they applied the probabilistic language model to estimate the generation probabilities of the labeled message based on a mined unlabeled topic. Further, they implemented ML classifier using Spark Machine Learning (MLib) library.

Salas et al. [46] fetched real-time tweets through Kafka and Flume and stored them in HBase storage. They employed Spark machine learning library to build SVM classifier and filter the tweets into traffic or non-traffic-related tweets. The tweets are processed using Natural Language Processing (NLP) methods before they are passed to the trained classifier.

Suma *et al.* [49] used Apache Spark for spatio-temporal events detection in London City. For the data pool, they utilized the power of the Fujitsu Exabyte File System (FEFS). Further, they installed both FEFS and spark technologies on top of the HPC cluster. Pandhare and Medha [65] analyzed tweets related to traffic and accidents to detect road traffic events using Spark. They used a regular expression filter to separate unnecessary information. Then, they applied some text mining steps including tokenization, creating term frequency vectors by using HashingTF and TF-IDF to reflect the importance of a token in a document. After that, they classified the tweets by employing Logistic regression and SVM algorithms. Kousiouris *et al.* [66] identified large crowd concentration events that might affect the user journey. They used Spark, Apache AVRO and Cloud-based solutions (OpenStack Swift).

Moreover, Alomari and Mehmood [10] developed a lexicon-based approach to filter Arabic tweets about traffic congestion in Jeddah city using SAP HANA. Then, they extended their word and performed sentiment analysis [67]. Subsequently, they developed multiple big data pipelines and architectures for social text event detection using cutting-edge technologies consisting of machine learning algorithms and high-performance computing as well as Apache Spark. Furthermore, they proposed supervised [68], [7] and unsupervised [69] machine learning methods to enable smarter transportation by detecting events using social data in the Arabic language. Subsequently, they detected several events including congestion, roadwork, fire, social events, weather, government measures, and public concern. Additionally, to improve the performance of detecting events from Saudi dialectical Arabic text, they proposed a pre-processing pipeline that includes a tokenizer, irrelevant characters removal, normalizer, stop words removal, as well as an Arabic light stemmer. Also, they built a tool for spatio-temporal clustering and visualization. Furthermore, they proposed methods for validating the detected events through internal sources (Twitter data) and external sources (e.g. official newspaper websites). Moreover, to address the challenges that come from manual labeling of large datasets, they proposed an automatic labeling method [70] using predefined dictionaries for detecting events.

Chen et al. [71] proposed a semi-supervised deep-learning model for detecting traffic events. They built a multi-model feature learning architecture to transform data from sensor time series and Twitter posts into a unified multi-modal feature representation. They built two encoders: the first one to extract features from sensor data using the Recurrent Neural Network (RNN) while the second encoder is designed for social data.

IV. DISCUSSION, CHALLENGES AND FUTURE DIRECTIONS

We illustrated in Section II the general workflow for event detection. In this section, we discuss the challenges for each step in the workflow.

Firstly, for data collection, the existing API such as Twitter API[1] limits the number of collected data for free. Additionally, even though they have paid APIs with fewer restrictions on the number of fetched tweets, it is too expensive. Secondly, for data pre-processing, although there are several tools and packages, most of them are built for the English language. Thus, there is a need for more efficient tools for other languages. Subsequently, there is a need to improve pre-processing and NLP methods to work on the dialectical short text. Thirdly, posts on social media are usually short and thus may not include all the important information about the events. Therefore, finding the exact location or time of occurrence might be difficult. The information might either not exist because users disable the location service for privacy reasons, or it exists but does not reflect the time or the place where the event occurred since people can post about events in other cities and countries. Additionally, in some cases, the post carries more than one location or time information. For instance, the information attached to the posts such as the geo-coordinates and the information users wrote in the text. Thus, the existing approaches for Spatio-temporal information extraction need improvement to consider the different scenarios and extract or predict the right information. Subsequently, recent approaches need to be used including deep learning and Large Language Model (LLM) such as the work in [37].

Moreover, several approaches have been used for traffic event detection including the lexicon-based approach, ML algorithms and deep learning. We divided the works that used ML into four categories. The first category includes works that used the common supervised or unsupervised algorithms such as SVM, Naïve based, clustering, etc. The second category includes the works that used topic modeling algorithms such as LDA. The third category contains the works that applied deep learning. The last category includes the works that used other methods such as hashtags-based techniques. Each approach has it is own challenges. One of the major challenges of using supervised classification is labeling the data for training the model. Manual labeling takes significant time and effort, especially for big data.

Furthermore, supervised classification requires defining the classes and then building and training the models, which means that we need to specify the types of events that we want to detect in advance. Thus, supervised classification is not appropriate if we do not want to limit the detected event types. The other challenge in supervised classification is having an imbalanced dataset where the number of posts in the training dataset for each class label is not balanced. On the other side, topic modeling has its challenges. One of the challenges is understanding the topic and finding the category that belongs to it. Additionally, we need to test different parameters to find the best number of topics and iterations, which is a difficult process and takes a long running time, especially for big data (for more details see [69]). Furthermore, the works in literature that used deep learning for traffic event detection are very limited. Additionally, more work is required to study the feelings and emotions regarding the detected events, which could help the authorities and decision-makers understand the situation and get more involved in addressing the difficulties.

Finally, detecting events from big social data is difficult due to its daunting characteristics -- volume, variety, velocity and veracity. The state-of-the-art on using big data technology for traffic event detection from social media is limited. Therefore, many more works are needed to improve the breadth and depth of the studies in this area regarding the size and diversity of the data, as well as the applicability, accuracy, performance, and scalability of the analysis and detection methods.

V. CONCLUSION

This paper comprehensively reviews recent advancements in the fusion of AI with a specific focus on machine learning, and deep learning techniques in conjunction with big data technologies for traffic event detection from social media. Furthermore, we presented the general workflow, which includes the following steps: Data collection and filtering, Pre-processing, Event detection, Spatio-temporal information extraction, and Evaluation. Before detecting events, data are filtered to keep only traffic-related posts. We found that this process is done either during the data collection phase or after through machine learning algorithms. After that, we divided the techniques for event detection into categories and then discussed the works based on the applied technique. The first technique for event detection is lexicon-based. The second technique is using machine learning including, supervised and unsupervised algorithms, topic modeling, or hybrid. The third technique is using deep learning. The last category includes other techniques such as hashtags-based techniques.

Moreover, we grouped the techniques for extracting location information into two main groups, which are using geo-coordinates attributes in the geotagged posts and extracting location names by text analysis. The first approach is not always applicable since not all posts are geotagged. For the second approach, several methods are applied to extract location from the text including using NER, Dictionary lookup, Rule-based pattern matching, deep learning models and sentence structure by using a list of prepositions.

Furthermore, we classified the existing approaches for sentiment analysis for traffic-related events into three categories, which are lexicon-based, using machine learning, and hybrid approaches. Additionally, we reviewed the works that used big data technology for traffic event detection from social media.

However, the state of the art in this area that uses deep learning, LLM or big data technologies is limited, and thus many more works are needed to improve the breadth and depth of the studies since using them helps to improve the efficiency, scalability, performance, flexibility as well as support multilingual. Subsequently, big data technologies and platforms are very important in this domain due to the characteristics -- volume, variety, velocity, and veracity of the social data. In conclusion, this review consolidates the current state of research, offering a valuable resource for researchers, practitioners, and policymakers seeking to leverage cutting-

A Proposed Roadmap for Optimizing Predictive Maintenance of Industrial Equipment

Maria Eddarhri[1], Mustapha Hain[2], Jihad Adib[3], Abdelaziz Marzak[4]
Industrial Engineering Department AICSE Laboratory, ENSAM University of Hassan II, Casablanca, Morocco[1, 2]
Mathematics and Computer Sciences Department LTIM-Faculty of Sciences, University of Hassan II, Casablanca, Morocco[3, 4]

***Abstract*—Now-a-days, the maintenance management of industrial equipment, particularly in the aeronautical industry, has evolved into a substantial challenge and a critical concern for the sector. Aeronautical wiring companies are currently grappling with escalating difficulties in equipment maintenance. This paper proposes an intelligent system for the automated detection of machine failures. It assesses predictive maintenance approaches and underscores the significance of sensor selection to optimize outcomes. The integration of Machine Learning techniques with the Industrial Internet of Things (IIoT) and intelligent sensors is presented, showcasing the heightened accuracy and effectiveness of predictive maintenance, especially in the aeronautical industry. The research aims to leverage Predictive Maintenance for enhancing the performance of production machines, predicting their failures, recognizing faults, and determining maintenance dates through the analysis and processing of collected data. Employing sophisticated code, the study emphasizes real-time data collection, data traceability, and enhanced precision in predicting potential failures using Machine Learning. The findings underscore the collaboration between sensors and the synergy of Machine Learning with IIoT, ultimately aiming for sustained reliability and efficiency of predictive maintenance in aeronautical wiring companies.**

Keywords*—Predictive maintenance; intelligent system; aeronautical wiring companies; machine learning; IIoT

I. Introduction

Maintenance in aeronautical wiring companies is crucial to ensure the safety and reliability of aircraft electrical systems. Technicians conduct regular inspections, testing, and repairs to meet aviation standards. Adherence to regulations and the adoption of advanced techniques like predictive maintenance are essential for optimal performance and safety. In the previous article [1], a maintenance management model employing machine learning was implemented. This model utilizes an expert system to support diagnostics and generate action plans for repairs based on the type of failure. The expert system reduces maintenance intervention time, minimizes machine downtime, and serves as the foundation for predictive maintenance.

The main objective of this paper is to significantly improve the maintenance approach by integrating intelligent sensors. These sensors ensure seamless communication via the (IIoT) and are connected to a central server to collect real-time data, which is efficiently stored in a database. Machine learning leverages this data to predict potential breakdowns and detect patterns and trends in the state of industrial equipment. With this proactive approach, corrective measures can be swiftly taken to minimize unexpected downtime, reduce high maintenance costs, and ensure continuous reliability and efficiency in the aeronautical industry.

This paper proposes an intelligent system for automatically detecting failures in machines. The initial focus is on presenting and evaluating the maintenance predictive approaches, including the approach detailed in article [1]. Following that, an in-depth discussion ensues regarding various sensor types and their significance in optimizing and predicting outcomes. Emphasis is placed on selecting sensors that support inter-sensor communication, fostering collaboration, and leveraging IIoT to enhance predictive maintenance capabilities, particularly in the aeronautical industry.

Additionally, the integration of Machine Learning techniques with IIoT and intelligent sensors is showcased, illustrating their synergistic impact on improving the accuracy and effectiveness of predictive maintenance processes.

The main contribution of this paper is integrating intelligent diagnostic sensors with Industrial Internet of Things (IIoT) technology and machine learning analysis in aeronautical industries, specifically in wire cutting machines. This integration enables real-time data collection and storage in a centralized database. The ultimate goal is to optimize maintenance procedures, ensuring the long-term reliability and efficiency of cutting cable machines in aeronautical industries.

The structure of this paper is organized as follows: Section II provides a review of existing approaches. Section III presents materials and methods. In Section IV, the proposed model is introduced, and results and discussion are presented in Section V. Finally, the last section concludes by highlighting the main contributions and outlining future work.

II. Review of Existing Approaches

To establish a detailed context for exploration, a comprehensive analysis of predictive maintenance in the industrial sector is undertaken in the following sections. Furthermore, numerous research studies have investigated different facets of intelligent sensor integration for maintenance in smart factories [2].

Specifically, Song et al. [3] focus on smart sensors used to monitor rock bolts' condition and integrity to minimize economic and personnel losses. Jin [4] discusses multifunctional sensors suitable for industrial production, while Feng [5] delves into sensors for intelligent gas sensing. Paidi

[6] examines intelligent parking sensors that utilize machine learning to replace ultrasonic sensors. In addition, Talal and Sony [7] [8] characterize sensors for health monitoring. The concept of combining smart sensors and smart factories, a crucial aspect of Industry 4.0, is commonly found in literature reviews. Lee [9] illustrates the use of smart sensors to evaluate and diagnose individual devices in smart factories.

Expanding the review, Strozzi in [10] emphasizes the actual transition and implementation of large, intelligent factories. Pereira and Álvarez [11] [12] focus on implementing smart factory principles and highlight that effective value creation depends on the chosen method of implementation.

The implementation process, which involves managing technological and organizational changes and desirable competencies, is further addressed by Sousa [13] and Lee et al. [14]. They also draw attention to the gap between recent research and the actual level of deployment.

Regarding maintenance in intelligent factories, several literature reviews revolve around predictive maintenance. Carvalho [15] concentrates on machine learning methods, considering them a promising tool for predictive maintenance. Sakib [16] observes a shift from reactive service activities to proactive, predictive maintenance and relates it to the context of Industry 4.0.

In specific applications, Olesen and Shaker [17] study practical use in thermal power plants, while Fei [18] focuses on predictive maintenance in aircraft systems. As for the approach [1], a maintenance management model utilizing Machine Learning has been proposed to optimize and enhance reliability. The model includes a referential and expert system that aids in diagnosing breakdowns, assigning technicians, and generating detailed repair action plans. The expert system reduces intervention time, minimizing machine downtime, and facilitates predictive maintenance implementation.

So, studies focus on the use of smart sensors to monitor conditions, enhance safety, improve efficiency and implement predictive maintenance techniques, with the aim of minimizing economic and human losses. However, it should be noted that the integration of smart sensors via IIoT and real-time data collection for predictive maintenance in the aeronautical industry, particularly in cable-cutting machines, has not been discussed in these studies.

The current studies primarily concentrate on utilizing smart sensors to monitor conditions, enhance safety, improve efficiency, and implement predictive maintenance techniques, all with the objective of reducing economic and human losses. However, it's crucial to note that the aeronautical industry has not received comprehensive attention in these studies, specifically regarding the integration of smart sensors through the IIoT and real-time data collection for predictive maintenance, especially in the context of cable-cutting machines. This identified gap calls for special consideration to fully exploit the potential benefits of technology in this specific field of aviation. Further research and development in this area can lead to significant advancements and improvements in maintenance practices within the aeronautical industry. Although the proposed expert system successfully reduces technician assignment and maintenance intervention time [1], it faces a notable limitation. The data collected by technicians may be unreliable, which can have adverse consequences on the maintenance process. One major limitation of this approach is its failure to identify the specific nature of equipment failures. Human involvement is still necessary to diagnose the equipment and pinpoint the failed components. However, this manual approach to data collection slows down the maintenance process, resulting in machine immobilization.

The diagnostic aspect is crucial as it allows for accurate identification of the failure and the specific part that requires replacement. Without this information, machine downtime can be prolonged, especially if there is an inadequate stock of spare parts available. Therefore, improvements are needed to enhance data reliability and the system's ability to diagnose failures effectively.

So, the primary goal is to enhance the maintenance approach significantly by employing intelligent sensors specially created for diagnostics. These sensors will communicate through the IIoT, enabling the real-time collection and efficient storage of data in a centralized database. Subsequently, machine learning will analyze the data to predict potential breakdowns. By adopting this proactive strategy, intervention actions can be implemented before issues escalate, thereby minimizing downtime, maintenance expenses, and disturbances in the production process. The ultimate objective is to optimize maintenance, ensuring the reliability and efficiency of industrial equipment.

III. Materials and Methods

A. Introduction to Sensors

The new requirements imposed on industrial systems in their operation and in their production and in the quality of their production, require a very elaborate strategy in the control of these installations. The difficulty is to have relevant and reliable information that allows to generate an effective corrective action. Sensors are these sources of information.

The development of information processing capabilities allows the control and automation of increasingly complex systems.

The calculation possibilities of the controlling parties seem to be limited only by the quantity and quality of the data provided to them. So Sensors play an important role in the automation of any kind of application by measuring and processing the data collected to detect changes in physical things. Fig. 1 illustrates the sensor operation.

Intelligent sensors are multi-component measuring devices that are self-calibrating, self-optimized, and simple to integrate into the environment for high connectivity, according to Eifert [19]. Furthermore, intelligent sensors possess process intelligence and are capable of generating multidimensional data information.

A sensor is a device, module, machine, or subsystem that detects events or changes in its environment and relays the information to other electronics, most commonly a computer processor [20]. A sensor converts the physical parameters into

a measurable digital signal, which can then be presented, read or processed.

Several classifications of sensors exist, established by different authors and experts. There are some that are very simple and others that are very complex. In this classification of sensors, they are divided into two categories: active and passive. Active sensors are those that require an external excitation signal or power signal. In contrast, passive sensors do not need an external power supply and are able to generate an output response directly.

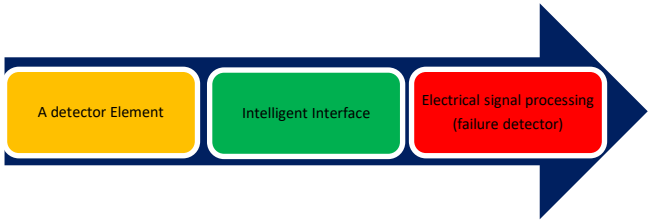

Fig. 1. Illustration view on the working of sensor.

B. *Different types of Sensors*

There are different types of sensors varying from the simplest to the most complex. Sensors are classified according to their specifications, their conversion method, the type of material used, the physical phenomenon of detection, the properties of what it measures and the application field [21].

- Proximity Sensors: Without making direct physical touch, proximity sensors make it simple to determine the location of any adjacent object. It detects the existence of an object by simply looking for any fluctuation in the return signal after emitting electromagnetic radiation, such as infrared. Numerous types of proximity sensors, including inductive, capacitive, ultrasonic, photoelectric, magnetic, and others, are available and are aimed at various purposes. This specific sort of sensor is frequently utilized in applications that demand efficiency and security. This sort of sensor has several applications, including object detection, item counting, rotation measurement, object positioning, material detection, movement direction measurement, parking sensors, and others. The best applications for proximity sensors are found in a variety of industries [21] [22] [23].

- Position Sensors: By sensing motion, the position sensor determines the presence of humans or objects in a specific region. It can be used in home security to track the doors and windows of rooms and appliances from any location. It informs them of the open or closed state at all times and can follow intruders while they are away. It can be used in health care monitoring to track the location of patients, nurses, and doctors in a hospital [24], as well as in agriculture to track the whereabouts of animals [25].

- Pressure Sensors: Liquid or other forms of pressure are used in a variety of devices. These sensors enable the creation of IoT systems that monitor pressure-driven systems and devices. Any variation from the typical pressure range alerts the system administrator to any issues that need to be addressed [26][27] The use of these sensors is beneficial not only in production but also in the maintenance of complete water and heating systems since it is simple to detect any pressure fluctuations or decreases [20] [28] [29].

- Temperature sensors: It primarily used to control air conditioning, freezers and other environmental control devices. Now they are used in manufacturing, agriculture and healthcare. Since a defined ambient and device temperature is required for most equipment in the manufacturing process, this type of measurement can still be used to improve the production process. Soil temperature, on the other hand, is crucial for crop growth in agriculture. It helps the plants to grow properly, which results in optimal results[20].

- Chemical Sensors: In the world, there are various types of chemical sensors, some of which are used to measure the chemical composition of the environment. By monitoring chemical plumes in the environment, a wireless chemical sensor network can monitor air quality [30].

- Occupancy sensors: The presence sensor, also known as the occupancy sensor, detects the presence of individuals or items in a specific area. The sensor can be used to detect numerous characteristics such as temperature, humidity, light, and air from a distance. The authors provide a similar use of these types of sensors in [31].

- With regard to the choice of intelligent sensors in the industrial field for predictive maintenance and specifically for aeronautical cable cutting machines as discussed in the previous article [1], specific criteria for collecting the data needed for early detection of failures need to be taken into account.

- The various intelligent sensors to be installed (temperature, vibration, pressure, etc.) must be able to communicate with each other to share the data collected. In addition, it is essential to check that the sensors are capable of collecting data at an appropriate frequency to enable real-time monitoring and rapid detection of anomalies. It is essential that these intelligent sensors support IIoT-compatible communication technologies, making it easier to collect and analyze data remotely, as well as integrating them into more comprehensive predictive maintenance systems.

It is also important to ensure that these sensors provide useful information that can be easily interpreted to analyze the state of the machine. The data collected must be relevant for predicting breakdowns and contributing effectively to the maintenance planning process.

Another crucial aspect is to ensure that the sensors can be easily integrated into the existing cable-cutting machine without disrupting its normal operation. Successful integration ensures that the sensors fulfil their role without compromising the overall performance of the machine.

C. About PLCs

PLCs are industrial automation devices that perform two main functions: measuring process parameters using sensors and controlling equipment according to specific programs [32].

These specialized systems solve sequential and combined logic problems using programmable configurations. PLCs are used in a wide range of applications due to their ease of programming, accessibility and high reliability. They are equipped with digital or analogue input and output cards. PLCs are programmed using various communication protocols and specialized software [32]. PLC is considered as the brain of the automation setup, controlling and coordinating various industrial processes. The PLC interprets the sensor data to trigger appropriate actions. The seamless integration of sensors with PLCs empowers industries to monitor and regulate processes with enhanced accuracy, efficiency, and safety.

IV. Proposed Work

- Using IIoT, a traceability system has been developed to ensure communication between the PLC and the server through the MQTT communication protocol. Through this integration, a high-performance traceability system has been implemented to ensure real-time data collection and monitoring via a dashboard.
- Firstly, connecting the sensors to the IIoT network allows continuous data collection on various monitored parameters such as temperature, pressure, vibrations, etc. This data is then transferred to a centralized server for storage and analysis.

Data traceability makes it possible to track the complete history of measurements made by the sensors. This provides a complete and detailed overview of how parameters evolve over time, making it easier to identify trends and anomalies.

Real-time data collection enables proactive monitoring of equipment. Sensor values are constantly updated, enabling unusual variations to be detected quickly. This real-time information can be used to make rapid decisions and avoid expensive failures. With an intuitive dashboard, users can view collected data, trends, alerts and predictive maintenance information. The dashboard can display graphs, customized dashboards and notifications when significant thresholds or deviations from normal values are exceeded.

V. Results and Discussion

By using Machine Learning techniques, the collected data can be analyzed to predict potential failures.

Machine Learning algorithms are trained to recognize patterns and warning signals that indicate imminent failure. These predictions enable maintenance activities to be planned proactively, avoiding production interruptions and reducing the costs associated with unexpected breakdowns.

A model will be created by integrating IIoT and artificial intelligence. this model uses sensor connectivity, data traceability, real-time data collection and predictive analysis to improve predictive maintenance. This optimizes operations, minimizes unplanned downtime and delivers significant savings in maintenance and repair costs.

As shown in Fig. 2, the proposed model for maintenance management demonstrates the key role that IIOT & AI play in failure prediction and production line optimization.

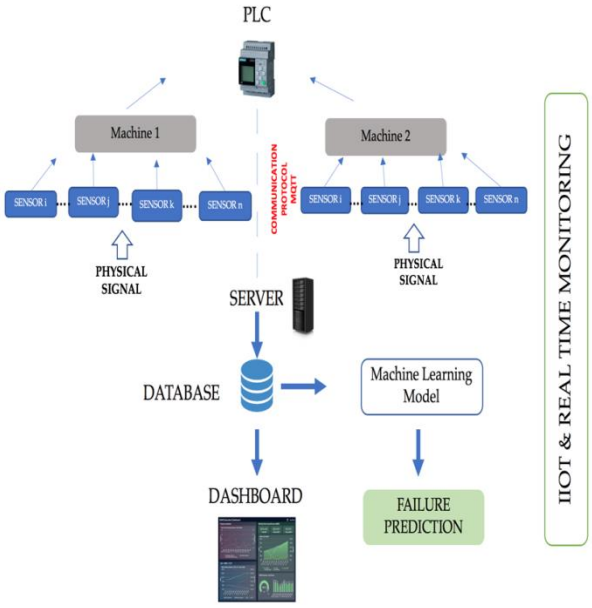

Fig. 2. Modeling of the maintenance process using intelligent sensors.

To implement the maintenance optimization approach, extensive and sophisticated code has been developed. This code plays a central role in the collection, processing and analysis of data from intelligent sensors interconnected via the IIoT (Industrial Internet of Things).

The first step in development was to create a communication interface that enables the sensors to transmit their measurements in real time to the designated data storage server. With this seamless connection, a huge amount of data can be collected from different pieces of industrial equipment, providing a global view of their operating status.

Once the data had been collected, the core of the code was based on the use of machine learning. A predictive model has been trained using advanced machine learning algorithms, capable of detecting patterns, trends, and anomalies in the sensor data. This model is continually refined and updated as new data is collected, allowing it to improve in terms of accuracy and reliability.

The pseudocode that schematically illustrates the main steps in this approach is shown in Figure 3. The pseudocode describes the general logic of the algorithm, including data pre-processing steps, model training, failure prediction techniques, and maintenance decision making.

Using this extensive code and machine learning approach enables the prediction of potential failures with enhanced precision. Anticipating problems before they occur allows proactive planning and execution of maintenance interventions, minimizing unplanned downtime and maximizing the availability and efficiency of industrial equipment.

Fig. 3. Proposed pseudocode.

In summary, the extended code and the methodology illustrated by the pseudocode in Fig. 3 provide a powerful decision-support tool, enabling the maximization of the reliability and performance of these industrial assets while reducing the costs associated with corrective maintenance.

VI. CONCLUSION AND FUTURE SCOPE

In conclusion, the adoption of smart sensors and the Industrial Internet of Things (IIoT) to enhance the maintenance approach represents a significant advancement in the industry. This proactive strategy, based on real-time data analysis through machine learning, provides the opportunity to anticipate potential failures and take action before they escalate into major issues. For aerospace companies, especially those utilizing cable cutting machines, this approach ensures not only optimal performance of their equipment but also precise traceability and real-time monitoring of each operation.

In future work, implementation of predictive maintenance using the proposed model is planned. This approach will further enhance the ability to foresee and prevent failures, thereby contributing to more efficient industrial operations management. By combining technological expertise with a proactive approach, the goal is to ensure continuous and reliable production while optimizing costs and maximizing the lifespan of equipment.

Research on 3D Target Detection Algorithm Based on PointFusion Algorithm Improvement

Jun Wang, Shuai Jiang, Linglang Zeng, Ruiran Zhang
School of Mechanical and Electrical Engineering, Jiangxi University of Science and Technology, Ganzhou, China

***Abstract*—With the continuous development of automatic driving technology, the requirements for the accuracy of 3D target detection in complex traffic scenes are getting higher and higher. To solve the problems of low recognition rate, long detection time, and poor robustness of traditional detection methods, this paper proposes a new method based on PointFusion model improvement. The method utilizes the PointFusion network architecture to input 3D point cloud data and RGB image data into the PointNet++ and ResNeXt neural network structures, respectively, and adopts a dense fusion method to predict the spatial offsets of each input point to each vertex in the 3D selection box point by point, to output the 3D prediction box of the target. Experimental results on the KITTI dataset show that compared with the PointFusion network model, the improved PointFusion-based model proposed in this paper improves the 3D target detection accuracy in three different difficulty modes (easy, medium, and hard) and performs best in the medium difficulty mode. These findings highlight the potential of the method proposed in this paper to be applied in the field of autonomous driving, providing a reliable basis for navigating self-driving cars in complex environments.**

***Keywords*—Neural network; target detection; autonomous driving; PointFusion; deep learning**

I. INTRODUCTION

With the rapid development of computer vision and deep learning technology, driverless vehicles are moving towards the practical stage. However, in intricate road conditions and uncertain traffic scenarios, the safety of automated driving technology is becoming more and more important. How to recognize obstacles efficiently and accurately has become an important challenge in the field of autonomous driving.

Target detection plays an important role in autonomous driving [1, 2]. A large number of methods have been proposed to solve the obstacle recognition problem in autonomous driving. In the field of 3D target detection, depending on the modality of the sensor data used in 3D detection networks, they can be broadly categorized into detection methods based on image, point cloud, and bimodal information fusion of image and point cloud. The SMOKE network model proposed by Liu et al. [3] is an image-based 3D target detection that utilizes feature point estimation and 3D spatial variable regression to determine the spatial location of the target, which has the advantage of a simple data preprocessing stage that improves the detection speed, while the network model solves the effect of noise introduced due to redundancy of 2D detection networks. The 3D-SSD network model proposed by Luo et al. [4] is a one-stage network for target detection based on depth information, and the prediction is realized with multi-scale mapping, the method has a good improvement in small target detection, as well as excellent performance in depth estimation against images. The Mono3D (Monocular 3D) model proposed by CHEN et al. is based on the improvement of the 3DOP model [5], which generates 3D candidate frames, then scores them with 2D image features and classifies and regresses the candidates with high scores, where the 2D image features are generated based on the information of semantic segmentation, instance segmentation, and location a priori. The practice has shown that the accuracy of the 3DOP model is insufficient relative to the estimation of depth, and some scholars have found that more accurate depth information can be obtained by utilizing parallax estimation. In 2019, LI et al. proposed a Stereo R-CNN model [6], which, relative to the 3D-SSD and the 3DOP model, utilizes the parallax estimation method to obtain more accurate depth information. In point cloud-based 3D target detection methods, many researchers rasterize the point cloud and convert it into voxel form representation to easily handle irregular point cloud data. SIMON et al. [7] proposed Complex-YOLO, a point cloud-based 3D real-time target detection network based on YOLO, where the pose of an object is estimated by adding an imaginary and a real number to the regression network in a specific Euler-Region-Proposal Network (E-RPN). The voxel size setting is a difficult problem to be solved in point cloud voxelization. In 2020, M.Y et al. [8] proposed a hybrid voxel network (HVNet) for mixing point clouds with voxels, which solves this problem by fusing voxel features of different scales at the point-level of the point cloud and projecting them into multiple pseudo-image feature maps. Deng et al. proposed a two-stage voxel-based framework Voxel R-CNN network [9], which first generates region proposals based on a bird's-eye view, and then extracts region-of-interest features directly from voxel features using a designed voxel RoI pool. However, the process of transforming the point cloud into either a voxel or bird's eye view projection map form causes some loss of point cloud data. To minimize or avoid this loss, some scholars have investigated the direct processing of the original point cloud. Qi et al. proposed the PointNet network [10], which ensures that the order of the points in the point cloud remains unchanged during the processing, and the structural connection between the points is preserved completely. Lehner et al. introduced a two-stage model, which consists of two VoxelNet [11] based networks, the Region Proposal Network (RPN) and the Local Refinement Network (LRN), for accurate detection and localization of 3D targets from point cloud data. Although different modal data have obvious effects when used individually in some specific scenarios [12], however, a sensor can only acquire a single modal data in the environment, and a large number of

experiments have proved that there are obvious inherent deficiencies in the environment sensing tasks accomplished by relying on only single modal data. The fusion of LiDAR point cloud data and camera image data with complementary relationships to improve the detection of targets in autonomous driving environment sensing tasks has been the focus of researchers [13]. Xu et al. proposed a PointFusion network structure [14], which is one of the typical pre-fusion structures. PointFusion first generates 2D selection frames on the image with a 2D detector projects the point cloud to the image plane, and selects the appropriate target region in the point cloud using the 2D selection frames region, and the selected 2D image data and the 3D point cloud data are used for feature extraction with ResNet [15] and PointNet networks for feature extraction to predict the location of the target in space. The advantage of this method is that the point cloud is directly input as raw data so that the information is preserved. However, the network is limited to dense point cloud data and is poor for sparse point clouds. Inspired by fusion methods such as PointFusion, Sindagi et al. proposed the MVX-Net network architecture for hybrid fusion based on earlier fusion [16], which utilized the Voxel Net network structure introduced at the time to combine two modal data, RGB images, and point clouds. Wang et al. proposed the F-ConvNet network [17], which, unlike the method of fusing voxelized point clouds with images, consists of a set of view cones proposed to be generated from 2D checkboxes, which are used to group the local point clouds, and the view cone features are formed through feature extraction. The VeloFCN network proposed by Li et al. [18] draws on the experience of 2D image detection by projecting a 3D point cloud to a front view similar to a camera image, and the data obtained from this processing is converted to a 2D image form, and the image is detected with a 2D target detector, but the point cloud in this method has multiple points that overlap in the process of projecting to the front view, resulting in loss of information.

In recent years, with the continuous development of computer vision and deep learning, the detection of targets using deep learning techniques has become a popular research direction. Saranya. K.C et al. [19] proposed YOLO v3 to detect pedestrians, using this method reduces the computational resources and speeds up the computation speed based on guaranteeing the detection accuracy, but there will still be misdetection and omission problems for the targets occluding each other, overlapping and so on. Ren S [20] proposed to utilize neural networks instead of selective search and proposed the concept of anchor frames, the highlight of this method is the integration of subsequent steps such as feature extraction in the same network, which leads to an improvement in the overall performance.

However, the current target detection algorithms are still unable to meet the practical needs, and many problems still need to be solved and improved. On the one hand, most of the autonomous driving scenarios are outdoor open scenarios, containing a large number of static and dynamic targets, and the traffic situation is complex; on the other hand, most of the sensors used for target detection in autonomous driving vehicles are more than three types, and the currently designed target detection algorithms have a single task on the network, and the fused sensor data types are fewer, which will deplete the limited arithmetic power of the vehicle control unit when carrying out multiple tasks at the same time. When performing multiple tasks at the same time, it consumes the limited arithmetic power of the vehicle control unit. Therefore, how to recognize obstacles efficiently and accurately is still of great significance in the field of autonomous driving.

The rest of the paper is organized as follows: Section II describes the theoretical approach and optimization process of the proposed improved model, including the relevant parameter settings of the PointNet++ network and ResNeXt network. Section III examines the accuracy of this paper's model on the KITTI dataset, followed by a comprehensive analysis and discussion of the experimental results. Section IV summarizes the main contributions of this paper's model and proposes future research directions.

II. Proposed Method

A. Pointfusion Network Model Optimization

In this paper, we improve the PointFusion architecture based on the PointFusion architecture, optimize the point cloud feature extraction module and the image feature extraction module, introduce the better performing PointNet++ and ResNeXt neural network structures instead of the PointNet module and the ResNet module, and use only the dense fusion structure to predict the 3D selection box point by point from each input point to the 8 corners (i.e., each vertex) of the spatial offsets, and in this way outputs the 3D prediction frame of the target. The structure is shown in Fig. 1.

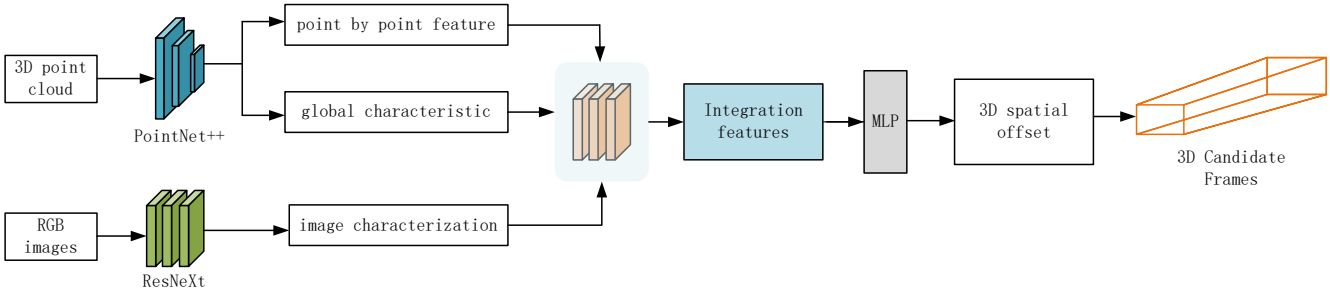

Fig. 1. Improved converged architecture based on PointFusion.

The PointFusion network architecture is a pre-fusion two-stage network structure. The network architecture performs target detection on the image data with a 2D target detector and enhances the point cloud information with the detected 2D target image information. Then the processed RGB image and point cloud image are used as input information, and the corresponding image and point cloud feature extraction network are used to extract features from the input data. Finally, the points in the point cloud of the target area are used as localization anchor points in space and predicted to obtain the 3D candidate frame of the target.

PointFusion uses heterogeneous network architecture to process the input. 3D point cloud data and RGB image data are fed into different branches for feature extraction. A variant model of the PointNet network architecture is used to process the raw point cloud data directly, avoiding the lossy input preprocessing caused by converting the point cloud data into Range maps or voxel forms. However, the PointNet network itself has a poor ability to process sparse point cloud data, which leads to weak detection of sparse point cloud targets in PointFusion itself. In the architecture of PointFusion, on the one hand, the data enhancement of point cloud data is performed with a 2D target detection method before data input, which makes the input point cloud information a cropped dense point cloud, and its network architecture is also trained in the dense region of point cloud, which has a weak adaptive ability to sparse point cloud; on the other hand, when utilizing the point cloud as a spatial localization point, the dense point cloud can be very On the other hand, when using point clouds as spatial localization points, dense point clouds can predict the spatial location of the target, while sparse point clouds cannot predict the spatial location of the target very well using this method.

B. PointNet++ Network

PointNet++ is a deep optimization improvement based on PointNet.PointNet++ is a neural network structure consisting of a combination of multiple individual layers, which applies the PointNet network in feature extraction of the input point set. The PointNet++ network, by calculating the spatial distances between points in space, can follow the change in size between two neighboring layers to extract local features. Moreover, each ensemble sampling layer can be adapted to sample point cloud regions with different densities and can automatically combine feature information at different scales.

PointNet++ employs hierarchical point set feature learning with a hierarchy consisting of multiple ensemble sampling layers. At each ensemble sampling layer, the point cloud sets within a region are first grouped and sampled, then undergo feature extraction and move to the next ensemble sampling layer. In the new ensemble sampling layer, each set of features from the previous layer is combined into a new point cloud element, and the previous operation is repeated until all the features are extracted. The ensemble sampling layer is the core layer and consists of the sampling layer, the grouping layer, and the point network layer. The sampling layer uses the farthest point sampling (FPS) method for sampling, which randomly takes a set of input points as the center of the region, then calculates the distances between other points and that point, and determines the adjacent points based on the distances between the points. The grouping layer constructs the neighborhood of each point cloud based on the distances between spatial points. The PointNet layer focuses on feature extraction of point clouds in the domain, using a simplified version of the PointNet network to extract features from different groups of point clouds in the grouping layer. The PointNet++ structure is shown in Fig. 2.

The input to the ensemble sampling layer is N × (d + C), where d represents the coordinate dimension of the point cloud, C represents the feature vector dimension of each point in the point cloud, and N represents the number of points in each point cloud ensemble. The output of this layer is $N'\times$（d+C'）, where the coordinate dimensions of the points are unchanged, C'represents the eigenvector dimension of each point in the point cloud collection in the input to the next ensemble sampling layer, and N' represents the number of points in each point cloud collection in the input to the next ensemble sampling layer.

A set of points$\{x_1, x_2, \ldots, x_n\}$ is input to the sampling layer, and a set of points $\{x_{i_1}, x_{i_2}, \ldots, x_{i_m}\}$ is found using constant iterative sampling to determine that x_{i_j} is the maximum distance from the set $\{x_{i_1}, x_{i_2}, \ldots, x_{i_{j-1}}\}$. This sampling ensures that all points in the point cloud collection are utilized.

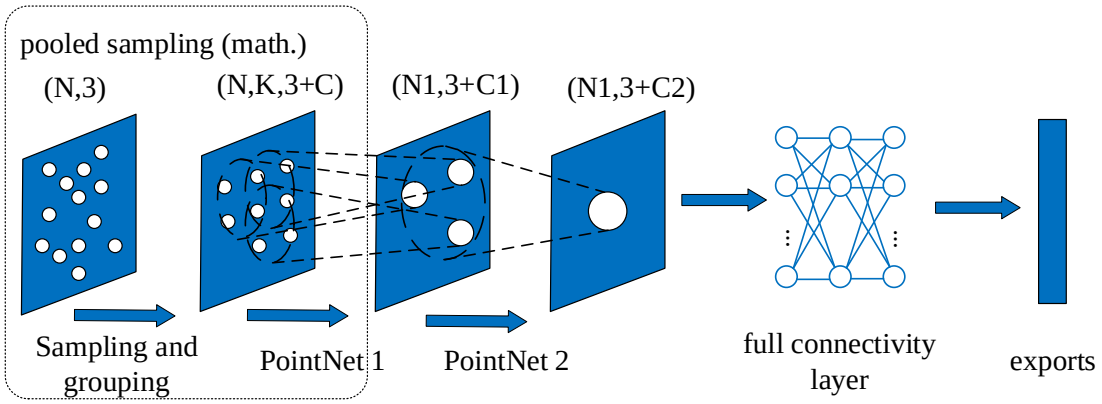

Fig. 2. PointNet++ network structure.

The grouping layer inputs are a point cloud collection and a center of mass collection. The point cloud collection contains the coordinate dimension of the point cloud, the eigenvector dimension of each point, and the number of points in the point cloud; the center of mass collection contains a set of center of mass coordinates. The output of this layer is N'×K×(d+C), with N' denoting the number of neighbors in the set, and K being the center-of-mass points selected in the neighborhood with variable size.

In the PointNet layer, the input is a localized region of N' points of size N'×K×（d+C）, and each localized region in the output is abstracted by its center of mass and local features encoding the neighborhood of the center of mass, with a data size of N'×K×（d+C'）. The PointNet layer is to extract the features of the point cloud data within each neighborhood partitioned by the previous layer, represented by a feature vector of uniform size. The input to this layer is N'×K×（d+C ） and the output is N'×K×（d+C'）.

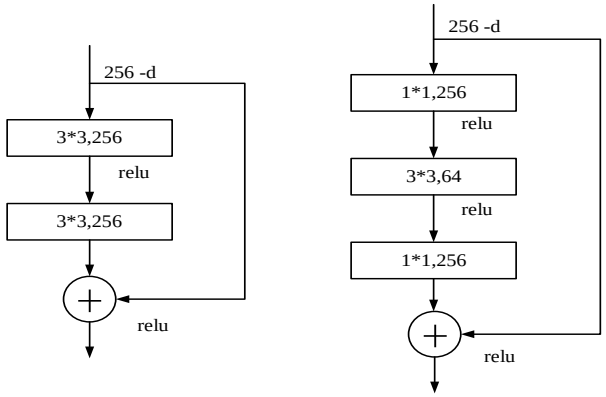
The PointNet++ network structure specifically addresses the problem that when the point cloud is inhomogeneous, the features learned in the dense region may not be suitable for the sparse region, and proposes a multiscale grouping (MSG), where the point cloud data with different densities are grouped into multiple local neighborhoods with different sizes, and these neighborhoods are first feature extracted, and then later the local neighborhood features are extracted by a point cloud feature extraction network to obtain the global features.

C. ResNeXt Network

In the image feature extraction branch, the ResNeXt neural network structure is used, which is developed based on ResNet and combines the experience of classic network structures such as VGG, ResNet, and Inception. It is composed of stacking multiple residual blocks of similar structure and in each block, three convolutional layers are used to realize various transformations from "dimensionality reduction-transformation-upgrading".

The ResNeXt network has been used as the core of many advanced networks for its performance in speed and accuracy in many image vision tasks. Although Resnet can be subdivided into 18, 34, 50, and 101 layers, the main body of the network structure is the same. The starting input of the Resnet network structure is a convolutional layer with 7*7 convolutional kernels, followed by a maximum pooling downsampling layer with 3*3 convolutional kernels, followed by a residual structure with multiple blocks stacked in layers conv2~conv5, and the last layer is an average pooling downsampling layer with 3*3 pooling kernels. The first input of the Resnet network structure is a convolutional layer with 7*7 convolutional kernels, followed by a maximally pooled downsampling layer with 3*3 convolutional kernels, followed by conv2~conv5 layers which are residual structures stacked with multiple blocks, and the last layer is an average pooled downsampling and fully-connected layer, and the result is outputted by softmax. The structure of the ResNeXt network is shown in Fig. 3.

Fig. 3(a) shows the residual module of ResNet-18/34, and Fig. 3(b) shows the residual module of ResNet-50/101/152. Each module consists of a main branch and a shortcut branch, which are output after the convolution operation of the main branch on one hand, and the shortcut branch is directly the input, and then the results of the two branches are summed up and processed by the activation function, so the size and depth of the feature matrices of the shortcut branch and the output of the main branch should be the same. The size of the kernel of convolution and the input/output of the residual module of ResNet-18/34 are the same at each layer, and the size of the kernel of convolution and the input/output of ResNet-50/101/152 is the same, while the size of the convolution kernel of the convolutional layers in the residual module of ResNet-50/101/152 is not consistent. In Fig. 3(b) 1*1 convolution kernel is used for downscaling and upscaling, and it can be seen from the figure that the input of 256 channels in the first layer is output down to 64 channels, while the 64 channels input in the second layer is increased to 256 channels by the output of the third layer. In Fig. 3(b), this structure serves to save more number of convolution kernels. Taking the input of 256 channels as an example, after calculation, there are 1179648 convolutional kernels in Fig. 3(a) and 69632 convolutional kernels in Fig. 3(b), compared to the reduction of 111,016 convolutional kernels, which saves resources and improves the efficiency at the same time.



(a) The residual module of ResNet-18/34 (b) The residual module of ResNet-50/101/152

Fig. 3. PointNet++ network structure.

The improved network uses a dense fusion network structure. The network uses the input spatial points as spatial anchors and predicts the spatial positional offsets of each spatial point to each vertex of the neighboring preselected boxes. An unsupervised approach is utilized to predict a score for each spatial point, and the point with a high prediction score receives a high confidence level. The high confidence point is used as the final prediction point. The unsupervised scoring loss function is:

$$L_{score} = \frac{1}{N}\sum\left(L^{i}_{offset} \cdot c_i - w \cdot log(c_i)\right) + L_{stn} \quad (1)$$

where, w is the weight coefficient, c_i is the confidence level, and L^{i}_{offset} is the spatial angular offset loss at the first spatial point. L_{stn} is the spatial transformation regularization loss. The loss function of the dense fusion network is:

$$L_{dense} = \frac{1}{N}\sum_i smothL\left(x^{i^*}_{offset,} x^{i}_{offset}\right) + L_{score} + L_{stn} \quad (2)$$

where, N is the number of input points, $x_{offset}^{i^*}$ is the offset between the true checkbox vertex position and the ith spatial point, and x_{offset}^{i} is the spatial position offset between the predicted checkbox vertex position and the ith spatial point.

III. Experimental Results

A. Experimental Parameter setting

1) PointNet++ parameter settings: This experiment uses the MSG network (Multi-Scale Network) of the PointNet++ network to set up three ensemble sampling layers, and some of the parameters of each ensemble sampling layer are shown in Table I.

TABLE I. Parameter Settings for each Ensemble Sampling Layer

Ensemble sampling layer	Number of input points	Number of sampling points	Sampling radius	characteristic channel
SA1	1024	512	[0.1,0.2,0.4]	-
SA2	512	128	[0.2,0.4,0.8]	320
SA3	128	-	-	640+3

During model training, batch is set to 24 and epoch is set to 200. The MSG model has three layers SA1, SA2, and SA3 used for point cloud data feature extraction.

1) Ensemble Sampling Layer: The MSG network model has three layers, sa1, sa2, and sa3, which are used for point cloud data feature extraction. The output of this layer mainly has seven-dimensional features. The first-dimensional feature is the number of sampled points; the second-dimensional feature is the radius size, a total of three radius parameters are set, [0.1,0.2,0.4] for the first layer, [0.2,0.4,0.8] for the second layer; the third-dimensional feature is the number of points in the group corresponding to the radius; the fourth-dimensional feature is the number of features or the channel size of the input points; and the fifth to the seventh-dimensional features are corresponding to the three radiuses respectively. The fifth to seventh-dimensional features are the number of feature dimensions corresponding to each of the three radii.

2) ResNeXt parameter settings: The ResNeXt101 network is used in this experiment, where the batch is set to 32, num_workers is set to 4, and epoch is set to 100. The optimizer is ADAM, and the learning rate is 0.001. The parameters of conv2~conv5 of the ResNeXt residual structure are set to {3, 4, 23, 3}.

B. Analysis and Discussion of Results

To test the model precision on the KITTI dataset, to better compare with other target detection methods, the experiment uses the evaluation method provided by the official KITTI dataset, sets the thresholds for cars, cyclists, and pedestrians at 0.7 respectively, and divides the test set among the KITTI dataset into three modes: simple, medium and difficult. The accuracy and recall in the three modes are calculated to obtain the average precision as the evaluation performance metric. According to the method of PointFusion, Fast-Rcnn is used as a 2D target detector with ResNeXt-101 to extract the input image feature information and average over the feature map positions. For each input 2D frame, the image is cropped and resized to 224 × 224, and up to 400 3D point clouds are randomly sampled as input for training and evaluation.

The P-R curves obtained from the experiment are shown in Fig. 4, and the final experimental AP result statistics are shown in Table II.

Table II results show the improved fusion network model detection results. The evaluation results for 3D detection in both evaluation criteria show that the detection accuracy for the automobile class is improved to 79.97% in the simple model; the detection accuracy for pedestrians is still below fifty percent. Some of the visualized test results are shown in Fig. 5.

TABLE II. Model Test Results

objectives	AP_{BEV}(%)			AP_{3D}(%)		
	Easy	**Medium**	**Difficult**	**Easy**	**Medium**	**Difficult**
vehicle	89.10	83.14	71.41	79.97	69.13	58.57
pedestrians	56.52	47.80	43.63	48.65	40.11	35.99
cyclist	71.92	57.99	51.55	65.51	51.33	45.05

The PointFusion model before and after improvement is compared with other state-of-the-art models in Table III. The experimental results show that the improved PointFusion-based model proposed in this paper performs well for the target detection task in general and improves the performance compared to the original model. Among them, the highest improvement is 6.13% in the medium mode, 2.05%, and 5.3% in the easy and difficult modes, respectively. In the medium and difficult modes, the proportion of accuracy improvement before the improvement relative to that after the improvement is larger, indicating that the generalization ability of the improved model to the original model has been improved. The method proposed in this paper reaches or approaches the results of the current state-of-the-art methods in all three difficulty modes, but there is an obvious gap in accuracy compared to AOVD and F-PointNets in the difficulty level. The comparison reveals that both the original model and the improved model based on this paper have poor performance in the difficulty modes relative to the above two models. This indicates that the detection of large occluded targets and small targets needs to be improved.

IV. CONCLUSION

In this paper, we propose to optimize the PointFusion architecture based on the improved PointFusion fusion algorithm by replacing the PointNet module and ResNet module in the point cloud feature extraction module and image feature extraction module with PointNet++ and ResNeXt network structures, respectively, to achieve more accurate 3D target detection. The key difference with the existing methods is that we consider the problems of poor generalization ability of the PointNet network and poor feature extraction in sparse regions of the point cloud. We feature extract image and point cloud information from the input data and use a dense fusion approach to obtain the final prediction, which effectively reduces the number of hyperparameters in the image feature extraction module and improves the computing speed without affecting the accuracy of the final prediction. Finally, we used experiments on the KITTI dataset to demonstrate the effectiveness of the method, and compared with the original prediction model, the model in this paper has the highest improvement among the medium modes, reaching 6.13%. Most of the current neural networks for autonomous driving perception tasks are designed for a single task, which generates a large amount of arithmetic power consumption for the in-vehicle main controller that works on multiple tasks at the same time. How to integrate the networks of different tasks into one main network, optimizing the arithmetic power, and improve the cooperative work of each task will be a future research direction.

Beyond the Norm: A Modified VGG-16 Model for COVID-19 Detection

Shimja M, K.Kartheeban
Department of Computer Science and Engineering, Kalasalingam Academy of Research and Education, Tamil Nadu, India

***Abstract*—The outbreak of Coronavirus Disease 2019 (COVID-19) in the initial days of December 2019 has severely harmed human health and the world's overall condition. There are currently five million instances that have been confirmed, and the unique virus is continuing spreading quickly throughout the entire world. The manual Reverse Transcription-Polymerase Chain Reaction (RT-PCR) test is time-consuming and difficult, and many hospitals throughout the world do not yet have an adequate number of testing kits. Designing an automated and early diagnosis system that can deliver quick decisions and significantly lower diagnosis error is therefore crucial. Recent advances in emerging Deep Learning (DL) algorithms and emerging Artificial Intelligence (AI) approaches have made the chest X-ray images a viable option for early COVID-19 screening. For visual image analysis, CNNs are the most often utilized class of deep learning neural networks. At the core of CNN is a multi-layered neural network that offers solutions, particularly for the analysis, classification, and recognition of videos and images. This paper proposes a modified VGG-16 model for detection of COVID-19 infection from chest X-ray images. The analysis has been made among the model by considering some important parameters such as accuracy, precision and recall. The model has been validated on publicly available chest X-ray images. The best performance is obtained by the proposed model with an accuracy of 97.94%.**

***Keywords*—Covid-19; coronavirus; artificial intelligence; deep learning; transfer learning; VGG-16; performance metrics**

I. Introduction

Since the beginning of December 2019, the Coronavirus Disease 2019 (COVID-19) outbreak has put enormous pressure on the entire world [1]. According to the World Health Organization (WHO), more than five million people have been infected globally to date, and there have been about three lakh confirmed cases of death. A respiratory disease, COVID-19 is brought on by the Severe Acute Respiratory Syndrome Coronavirus 2 (SARS-CoV-2) and is characterized by symptoms such as fever, myalgia, dry cough, headache, sore throat, and chest pain [2]. The infected person may not exhibit all symptoms for up to 14 days.

A severe respiratory condition known as COVID-19 can be cured without the use of antibiotics in affected individuals. Chronic medical diseases like diabetes, chronic respiratory illnesses, and cardiovascular issues increase the chance of spreading this virus. According to the WHO, the COVID-19 symptoms, which include fever, tiredness, a dry cough, shortness of breath, aches, pains, and sore throat, are similar to those of the ordinary flu [3]. Because of these common symptoms, it is difficult to detect the virus in its early stages. There is no chance that antibiotics, which are used to treat bacterial or fungal infections, will be able to halt this as it is a virus.

In medical, scientific, and healthcare laboratories, the coronavirus has been identified using a variety of diagnostic techniques. Indirect methods evaluate antibodies against the virus in a host that has been exposed, whereas direct tests identify the contamination directly by detecting the viral RNA. During a pandemic, a clinical test method should be accurate and sensitive enough to quickly make the right clinical recommendations. The various diagnostic methods for the covid-19 detection are shown in Fig. 1.

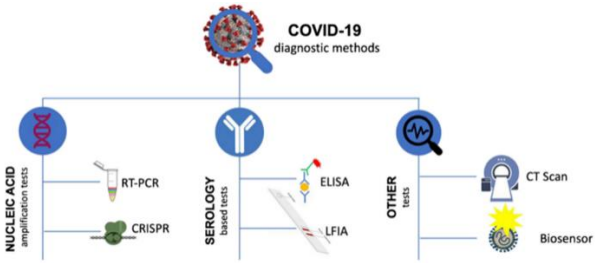

Fig. 1. Diagnostic method for Covid-19 detection [4].

The most dependable and popular technique for COVID-19 detection among the several methods available is RT-PCR [5]. There is sometimes a lack of supplies during pandemic events, including PCR kits. Therefore, having a variety of diagnostic method choices is crucial. Equally crucial are other testing methods and accessories that may be produced locally, even on a small scale. Those platforms would be suitable in environments with restricted resources as well. Because the currently used RT-PCR techniques are expensive, many nations, especially those with poor incomes, cannot afford enough COVID-19 tests to screen a broader population. Screening asymptomatic people throughout the incubation phase still has significant gaps. It is also difficult to accurately predict live virus shedding in healed patients in order to make de-isolation decisions. Several COVID-19 test kits have been recalled in various nations due to questionable quality. The rigorous evaluation of the diagnostic precision of the recently introduced SARS-CoV-2 assays is hampered by the lack of a recognized reference standard, the use of various sample collection and preparation techniques, and a flawed understanding of viral interplay across the time phase of infection.

There is currently no specific medication or treatment for this illness. However, RT-PCR is the technique that is most frequently used to diagnose COVID-19. It has recently been

discovered that medical imaging methods like X-rays and Computed Tomography (CT) are essential for testing COVID-19 instances. The chest radiography images (chest X-ray or CT images) have been extensively investigated since the virus typically infects the lungs [6]. Radiologists manually evaluate these images to look for any visual signs of COVID-19 infection. These visual cues can be used as an alternative screening technique for infected patients.

The WHO has approved the RT-PCR technique as a coronavirus testing method, in which short DNA or RNA sequences are evaluated and replicated or amplified. But it takes more than one test to totally rule out coronavirus in some people. WHO guidelines for laboratory testing state that negative results do not necessarily rule out the possibility that the person is virus-infected. The lack of screening workstations and testing kits to identify COVID-19 makes it incredibly challenging for medical staff and professionals to address the issue. It is incredibly challenging for medical practitioners in this situation to promptly and precisely detect possible COVID-19 cases. Numerous tests are also necessary because of the cases' exponential growth in order to fully comprehend the circumstances and come up with the finest decisions.

Despite the availability of numerous imaging modalities, chest radiography is believed to have a low sensitivity for major clinical findings. Doctors frequently use X-ray imaging technologies to identify pneumonia because they are an essential part of healthcare systems all over the world. The use of chest X-ray equipment is time-consuming in the absence of screening workbenches and kits notwithstanding their simplicity in locating COVID-19 cases. Additionally, there may be situations where individuals receive imaging for a different reason and the results of their scans point to COVID-19. The findings from the chest X-ray images strongly suggest that even in the early stages of COVID-19, the effect can be seen in the lungs, particularly in the lower lobes and posterior segments, with peripheral and subpleural distribution. The lesions diffuse more and more as time passes. The biggest problem, though, is that analyzing each chest X-ray image and determining what information is most important takes a lot of time and the presence of medical professionals. Therefore, to assist in the detection of COVID-19 cases using chest X-ray images, medical personnel need computer assistance.

Although the traditional diagnosing process has sped up somewhat, it still puts medical professionals at great risk. Additionally, it is expensive, and there are only a few diagnostic test kits available. On the other hand, screening based on medical imaging techniques (such X-ray and CT) is often safe, quick, and available. X-ray imaging, as opposed to CT imaging, has been utilized extensively for COVID-19 screening because it is less expensive, requires less imaging time, and is more readily accessible even in rural areas than CT imaging. The larger-scale visual examination of X-ray images by radiologists is time-consuming, labor-intensive, and could result in an incorrect diagnosis because of ignorance of the virus-infected regions. Therefore, the development of automated approaches to acquire a quicker and more precise COVID-19 diagnosis is highly necessary. The most recent automated methods sought to lessen the labor of radiologists while enhancing the power of X-ray imaging using cutting-edge Artificial Intelligence (AI) technologies [7]. Convolutional Neural Networks (CNN), a type of DL model, in particular, have proven to be more efficient than conventional AI techniques and are frequently used to analyze a variety of medical images. CNN has recently been used to successfully identify COVID-19 in chest X-ray images. The major contribution of this paper includes:

- An effective detection model for Covid-19.
- A modified VGG-16 model for Covid-19 detection from chest X-ray images.
- Classification of chest X-ray images into Covid-19 and Normal.

This paper seems to have the following format. The details of the currently used COVID-19 detection techniques are covered in Section II. The methodology is covered in Section III. The experimental findings and conclusions are presented in Sections IV and V respectively. Finally, the future works are presented in Section VI.

II. Literature Review

Saul Calderon-Ramirez et al. [8] introduced COVID-19 detection from chest X-ray images using semi- supervised deep learning methods. Using a semi-supervised deep learning framework built on the Mix Match architecture, chest X-rays are classified into Covid-19, pneumonia, and healthy cases in this paper. When there is a lack of high-quality labeled data, performance levels for Covid-19 identification can be enhanced with the use of the semi-supervised framework. Shamima Akter et al. [9] introduced COVID-19 detection using deep learning approaches. The paper suggested a deep learning-based automated classification model based on a convolutional neural network that exhibits a high COVID-19 detection rate. The COVID-19 symptoms were initially identified utilizing the dataset by applying eleven pre-existing CNN models. A confusion matrix was used to demonstrate how well the models performed. Zehra Karhan and Fuat Akal [10] discussed Covid-19 Classification Using Deep Learning in Chest X-Ray Images. The ResNet50 model was utilized for Covid-19 classification from chest X-ray images. Artificial intelligence allows for fast analysis of chest X-ray images and identification of diseased individuals. It can also be applied when RT-PCR testing and other options are insufficient. Sami Bourouis et al. [11] introduced Bayesian Learning of Shifted-Scaled Dirichlet Mixture Models for Covid-19 detection. In order to distinguish between individuals who are either negative or positive for particular types of viruses and pneumonia, this research introduced a novel statistical framework. The success and reliability of this mixing model in recent image processing applications is encouraging. The established Bayesian framework has the benefit of accounting for uncertainty to precisely estimate the model parameters and the capability to address the overfitting issue. Lightweight deep learning models for detecting COVID-19 from chest X-ray images were discussed by Stefanos Karakanis and Georgios Leontidis [12]. In this paper, a new approach was proposed to detect COVID-19 via exploiting a conditional generative adversarial network to generate synthetic images

for augmenting the limited amount of data available. The study focused on both binary classification for COVID-19 vs Normal cases and multi-classification that includes a third class for bacterial pneumonia.

In study [13], Covid-19 detection using majority voting classifiers are used. This work introduced an automated COVID screening (ACoS) method that identifies healthy, suspicious, and COVID-19-infected patients using radiomic texture descriptors taken from CXR images. The proposed system employs a majority vote-based classifier ensemble comprising five benchmark supervised classification algorithms in a two-phase classification approach (normal vs. abnormal and COVID-19 vs. pneumonia). Tulin Ozturk et al. The study in [14] proposed an automated detection of COVID-19 cases using deep neural networks with X-ray images. This paper presented a new model for automatically detecting COVID-19 from raw chest X-ray images. The suggested approach is designed to deliver precise diagnostics for multi-class classification and binary classification. The DarkNet model was used as a classifier for the real-time You Only Look Once (YOLO) object identification system. Improving the performance of CNN to predict the likelihood of COVID-19 using chest X-ray images with preprocessing algorithms was proposed by Morteza Heidari et al. [15]. The purpose of this study is to create and evaluate a new computer-aided diagnostic method using chest X-ray images to identify pneumonia caused by the coronavirus. A histogram equalization technique and a bilateral low-pass filter are used to process the original image in the first two image preparation steps of the CAD method. Then, a pseudo-color image is created using the original image, two filtered images, and the original image. This image is fed into three input channels of a transfer learning-based convolutional neural network (CNN) model. Muhammad Ilyas et al. [16] discussed various methods used for Covid-19 detection using Artificial Intelligence. This paper outlines the difficulties we are now encountering as well as the various methods utilized to detect COVID-19. To stop the spread of the virus through contact, an automatic detection system must be created. For the detection of COVID-19, a number of deep learning architectures, including ResNet, Inception, Googlenet, etc., are being used. In [17], proposed an automatic Covid-19 detection method. To assess and contrast the created models, three distinct experiments are conducted in accordance with three preprocessing approaches. The objective is to assess the effects of data preprocessing on the outcomes and how well they can be explained. Similarly, a critical evaluation of various variability issues that could threaten the system and its impacts is carried out.

Shayan Hassantabar et al. [18] proposed a diagnosis and detection of infected tissue of COVID-19 patients based on lung X-ray image using convolutional neural network approaches. Three deep learning-based techniques were employed in this study to identify and diagnose COVID-19 patients using X-ray images of the lungs. A convolutional neural network (CNN) technique was introduced, which uses the lung images and deep neural network (DNN) methods based on the fractal characteristic of images, for the diagnosis of the condition. In study [19], an automatic detection of COVID-19 infection using chest X-Ray images through transfer learning was proposed. It employs various convolutional neural network (CNN) architectures that have been trained on ImageNet and modifies them to function as feature extractors for the X-ray images. Then, the CNNs are integrated with consolidated machine learning techniques, including support vector machine, k-Nearest Neighbor, Bayes, Random Forest, and multilayer perceptron (MLP). Govardhan Jain et al. [20] proposed a deep learning approach to detect Covid-19 coronavirus with X-Ray images. Using accessible resources and cutting-edge deep learning techniques, an alternative diagnostic tool to find COVID-19 patients is suggested in this work. The proposed approach is put into practice in four stages: data augmentation, preprocessing, creating stage-I and stage-II deep network models. In order to improve the generalization of the model and avoid the model from overfitting, this work used web resources of 1215 images that have been improved further by data augmentation techniques, bringing the total number of images in the dataset to 1832. Aras M. Ismael and Abdulkadir Şengür [21] introduced deep learning based covid-19 detection method. In order to categorize COVID-19 and normal (healthy) chest X-ray images, deep-learning-based approaches, including deep feature extraction, fine-tuning of pretrained convolutional neural networks (CNN), and end-to-end training of a constructed CNN model, have been used in this study. Pretrained deep CNN models (ResNet18, ResNet50, ResNet101, VGG16, and VGG19) were utilized for deep feature extraction. The Support Vector Machines (SVM) classifier was used to categorize the deep features using a variety of kernel functions, including linear, quadratic, cubic, and gaussian. The fine-tuning process also made use of the previously mentioned pre-trained deep CNN models. In [22], a novel CNN model called CoroDet for automatic detection of COVID-19 by using raw chest X-ray and CT scan images has been proposed. With the development of CoroDet, an accurate diagnostic tool for COVID and Normal, COVID, Normal, and Non-COVID Pneumonia, and 4 Class Classification was available (COVID, Normal, non-COVID viral pneumonia, and non-COVID bacterial pneumonia).

While deep learning methodologies and chest X-ray images have been widely employed in COVID-19 detection research, there remains a crucial requirement to evaluate the adaptability and resilience of these models across diverse imaging scenarios and population demographics. The absence of investigations into real-world variables, including demographic variances, imaging device fluctuations, and variations in data acquisition settings, raises legitimate concerns about the external reliability and validity of existing models. This underscores the urgency for more comprehensive and interdisciplinary research endeavors to enhance the practicality of these diagnostic tools.

The block diagram of the proposed method is given in Fig. 2. The proposed method is carried out using COVID-19 X-ray Dataset [23]. The dataset contains two folders: test and train. The dataset includes NORMAL and COVID-19 images with .jpg format. The models are trained and tested using the complete dataset. 30% of the dataset's data were used for testing, and the remaining 70% were used for training. The input images are preprocessed before applying to the pre-

trained model. In order to ensure numerical stability in CNN systems, normalization of data is a crucial step. Normalization increases the likelihood that a CNN model will learn more quickly and that the gradient descent will be stable. As a result, in this study, the input image pixel values have been normalized to fall between 0 and 1. The grayscale images used in the datasets under consideration were rescaled by multiplying the pixel values by 1/255. The CNN models have demonstrated to perform better on larger datasets and need a significant amount of data for optimal training. The dataset only contains a very small number of training X-ray images. Since it is difficult to gather medical data, this has been a major concern when doing analysis of medical images using DL algorithms. Data augmentation approaches, which enable to increase the number of images via a set of modifications while keeping class labels, have been frequently used to address this issue. Additionally, augmentation makes the images more variable and acts as a dataset. The preprocessing includes normalization and augmentation. The preprocessed images are used to train the modified VGG-16 model. Finally, the model classifies the chest X-ray images. The sample and augmented chest X-ray images are shown in Fig. 3 and Fig. 4 respectively.

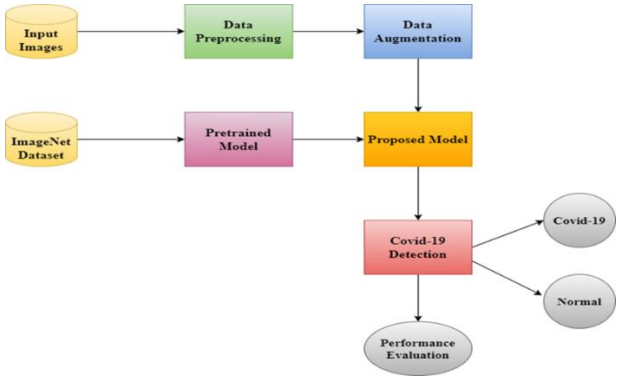

Fig. 2. Block diagram of the proposed method.

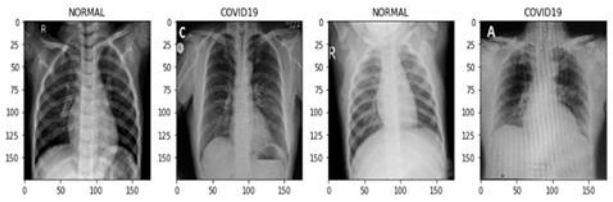

Fig. 3. Sample CXR images.

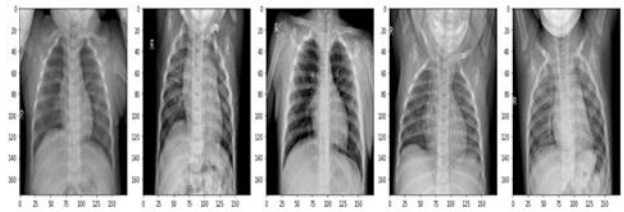

Fig. 4. Augmented CXR images.

III. METHODOLOGY

For the study of visual images, CNNs are the most widely used class of neural networks in deep learning. A multi-layered neural network that provides solutions, notably for the analysis, classification, and recognition of images and videos, is the fundamental aspect of CNN. CNN is made up of different layers. They are the convolution layer, the pooling layer and the fully connected layer. In essence, the convolutional and pooling layers provide the model's learning while the full connection layer handles categorization. The convolutional layer is the central part of CNN architectures. The feature map is created by applying high- and low-level filters to the input image. The pooling layer is often positioned between the convoluted layers. Its main objective is to reduce the size of the feature map in order to reduce the amount of computational resources required to construct the model. It also efficiently trains the model by removing its dominating and invariant characteristics. Although there are many different pooling methods, the maximum and average pooling layers are the most often used ones. Each neuron in the entire connection layer is connected to every neuron from the layer above. Depending on its topology, CNN architecture may have fewer or more complete connection layers. The output layer comes after the last full connection layer. It is now possible to create output distributions using SoftMax regression by obtaining probability distributions for the output classes in classification experiments.

Transfer learning is a machine learning method that applies knowledge that a CNN has learned from a batch of related data to a separate but related problem. The fundamental element of transfer learning is that knowledge can be acquired by transferring it from one related task to another. With pretrained models, the transfer learning design method is widely applied. These pretrained models are based on deep convolutional neural networks. Initial CNN training for a classification problem using sizable training datasets is required for this deep learning technique. Since a CNN model can learn to extract significant components of the image, the availability of data for initial training is a vital element of efficient training.

A. VGG-16

The Visual Geometric Group (VGG) Network is a simple model. Its integration with CNN models is common due to its deeper structure, which is followed by layers of associated double- or triple-convolution layers, which is the most noticeable difference between it and prior models. The model architecture is given in Fig. 5. It is possible to utilize the model to extract pertinent features from suitable new images. The ImageNet dataset has the ability to extract attributes from images, including brand-new ones that might not yet exist or that might be found in dataset categories that are completely unrelated to one another [24]. Therefore, it is advantageous to use pretrained models as effective feature removers.

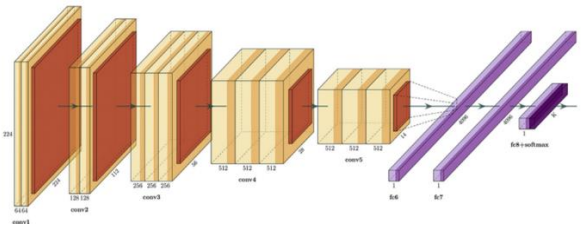

Fig. 5. VGG-16 architecture.

The VGG16 design uses three convolution filters with a total of 13 convolution layers for feature extraction. Each ReLU layer has a maximum pooling layer for sampling and is followed by a convolution layer. Its final classification layer is composed of 1000 units that are equivalent to the image categories in the ImageNet database, and it has three fully connected classification layers, two of which are hidden layers. This design simulates a larger filter while maintaining the benefits of smaller filter sizes. VggNet has been shown to perform better with fewer parameters. Furthermore, two ReLU layers rather than only one were used for the two convolution layers. The depth of the volumes increases as the number of filters increases since the convolution and partnering layers reduce the spatial size of the input volumes in each layer.

B. Modified VGG-16

The modified VGG-16 design reduces the number of parameters by decreasing the network depth in contrast to the original VGG-16 architecture in order to avoid problems with under and overfitting during training. The original architecture of the VGG16 convolutional network was preserved by doing feature extraction with two consecutive small convolutional kernels as opposed to a single large one. This expedites training while retaining the depth of the network by reducing the number of parameters while maintaining the VGG16 perceptual effects.

The input image size was altered initially, after which the hidden layer was divided into five blocks, each of which contained two convolutional layers and a pooling layer. Using 32 randomly generated 3x3 convolutional kernels, each convolutional layer extracted features, while the pooling layer compressed the image. Convolutional kernels in blocks 3 through 5 were all the same size (3x3), but there were, respectively, 64, 128, and 64 kernels in each block. When compared to VGG16, the number of parameters needed was decreased by decreasing the convolutional kernels. After that, the pooling layer reduced the size of the image, the flattened layer reduced feature mappings to one dimension, and three fully connected layers combined output features into two classes. Finally, the performance of the model is evaluated based on different metrics.

C. Performance Evaluation

Accuracy is one of the measures that is most frequently used while classifying data. Accuracy is a parameter measuring how well a model performs across all classes. When all classes are treated equally, it is advantageous. It is calculated by dividing the total number of predictions by the number of predictions that came true. The formula below can be used to assess a model's accuracy.

$$Accuracy = \frac{(TP+TN)}{(TP+TN+FP+FN)} \quad (1)$$

The ratio of Positive samples that were correctly identified is used to calculate precision. How precisely the model can classify a sample as positive depends on its precision. The capacity to correctly classify all positive samples as positive while avoiding incorrectly labeling a negative sample as positive is known as precision.

$$Precision = \frac{(TP)}{(TP+FP)} \quad (2)$$

By dividing the total number of Positive samples by the recall rate, the percentage of Positive samples that were correctly identified as Positive is obtained. Recall quantifies how well a model can find Positive samples. The recall increases as more positive samples are found.

$$Recall = \frac{(TP)}{(TP+FN)} \quad (3)$$

IV. Results and Discussion

A. Hardware and Software Setup

The system consists of a single NVIDIA GeForce GTX 1080 Ti GPU 2760 4MB, an Intel Core i7-6850K 12-core processor operating at 3.60 GHz, and additional parts. Google Collaboratory serves as the testing and training platform. The hyperparameters utilized for this study are tabulated in Table I.

TABLE I. Hyperparameters

Batch Size	32
Activation Function	ReLu
Optimizer	Adam
Loss Function	Binary Crossentropy

B. Experimrntal Results

In Table II, classification report for the modified VGG-16 model is tabulated. The model's precision, recall, and accuracy are 97.94%, 98.23%, and 95.58%, respectively.

Fig. 6 shows a plot of the modified VGG-16 model's accuracy. As the number of epochs increases, training and testing accuracy constantly improves.

Fig. 7 displays the modified VGG-16 model's loss. With more epochs, the training and testing loss always decreases.

TABLE II. Classification Report of Proposed Model

Parameters	Obtained Results
Accuracy	97.94 %
Precision	98.23 %
Recall	95.58 %

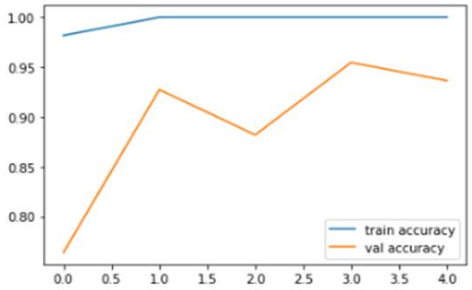

Fig. 6. Accuracy plot of proposed model.

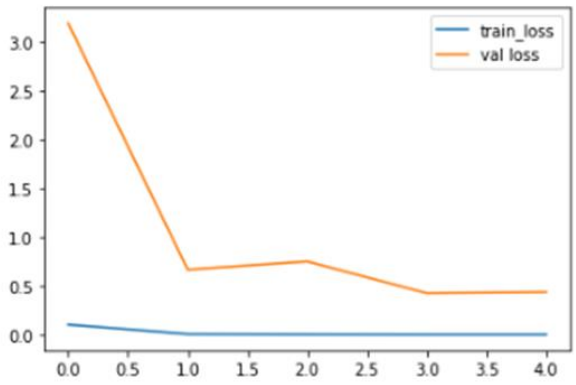

Fig. 7. Loss plot of proposed model.

A graph between numerous possible learning rates and the validation loss has been plotted in order to discover the learning rate for the model. The plot between learning rate and loss obtained for the model is shown below. The learning rate is a hyperparameter that determines how much to alter the model each time when model weights are updated in response to the predicted error. The plot between learning rate and loss of the model is illustrated in Fig. 8.

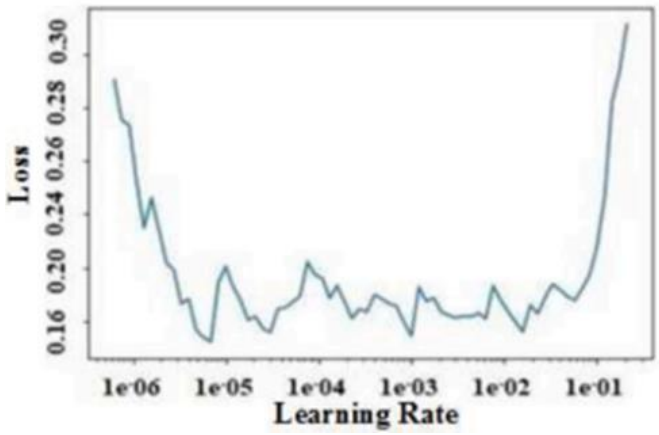

Fig. 8. Plot between learning rate and loss of the model.

It can be difficult to choose the learning rate since a number that is too little could lead to a lengthy training process that could become stuck, but a value that is too large could lead to learning a suboptimal set of weights too quickly or to an unstable training process. How quickly the model adapts to the situation is determined by the learning rate. Given the smaller changes to the weights made with each update, smaller learning rates necessitate more training epochs, whereas bigger learning rates produce quick changes and necessitate fewer training epochs.

The chest X-ray images were classified by the model as COVID-19 or NORMAL. Fig. 9 is an example of the image classification. The models can detect what category an image belongs to when given a randomly selected image as input.

The imaging similarities between normal and COVID-19 infection cases may have led to the misclassification, which is shown in Fig. 10.

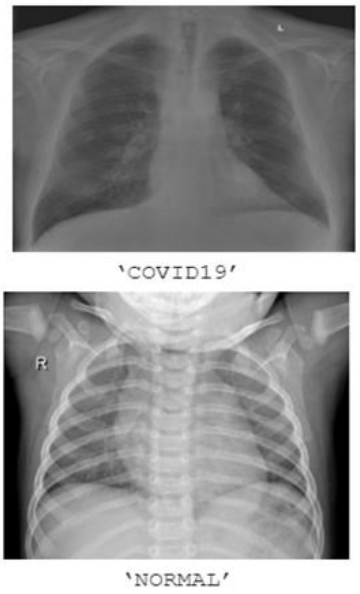

Fig. 9. Sample output of Covid-19 detection.

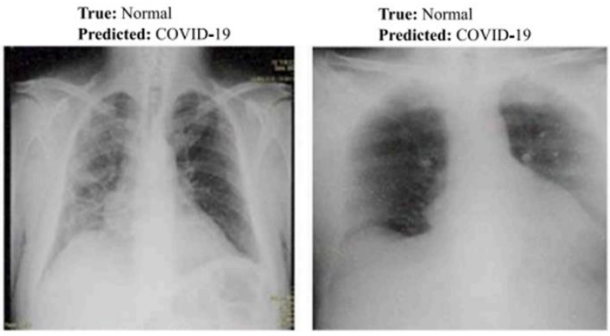

Fig. 10. Illustration of misclassification.

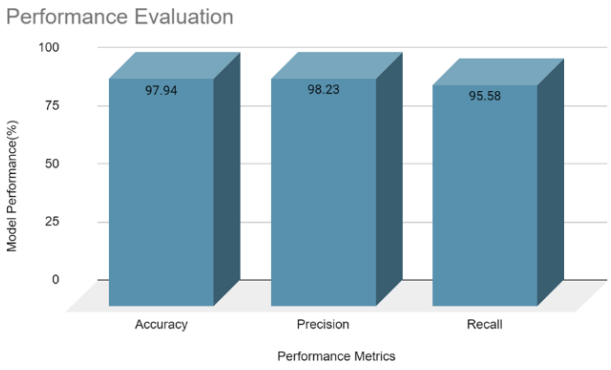

Fig. 11. Performance evaluation of proposed model.

The model's performance evaluation is graphically represented in Fig. 11. The x- axis and y- axis represent the performance metrics and model performance (%) respectively. The model obtained 97.94% accuracy, which outperforms other existing pre-trained models. The model also provides better precision and recall rate.

C. Discussions

The simulation results for the COVID-19 detection model using a modified VGG-16 architecture are promising, indicating a high overall accuracy of 97.94%. Precision, which measures the model's ability to correctly identify positive cases among the predicted positives, is notably high at 98.23%. The recall, representing the model's capability to identify all actual positive cases, is also strong at 95.58%. These metrics collectively suggest that the modified VGG-16 model exhibits a robust performance in distinguishing COVID-19 cases from normal cases.

In comparison with traditional detection methods, the high accuracy, precision, and recall values of the modified VGG-16 model underscore the potential of deep learning approaches in enhancing COVID-19 detection. Traditional methods often rely on manual interpretation or rule-based algorithms, which may lack the complexity and adaptability demonstrated by deep learning models. The precision and recall values above 95% indicate a low rate of false positives and false negatives, crucial for reliable COVID-19 diagnostics. The model's performance may be influenced by the diversity of the dataset, variations in image quality, and the representativeness of the COVID-19 cases. Moreover, the interpretability of deep learning models poses a challenge, making it crucial to ensure the clinical relevance and trustworthiness of the predictions.

In conclusion, the modified VGG-16 model exhibits a commendable performance in COVID-19 detection, outperforming traditional methods in terms of accuracy, precision, and recall. While these results are promising, further validation on diverse datasets and real-world clinical settings is necessary to establish the model's robustness and generalizability for practical implementation in the field of COVID-19 diagnostics. Additionally, efforts should be directed towards addressing interpretability concerns and ensuring seamless integration with existing healthcare practices.

V. Conclusion

According to the World Health Organization (WHO), more than five million people have been infected globally to date, and there have been about three lakh confirmed cases of death. Therefore, it is crucial to identify COVID-19 as soon as possible in order to stop its spread and lower its mortality. Currently, RT-PCR is the benchmark for diagnosing COVID-19. In this test, viral nucleic acid from sputum or a nasopharyngeal swab is found. This testing mechanism has a few drawbacks. The complicated and painful nature of this testing technique for the patients is another issue. As a result of these concerns, there is a huge need for alternative diagnostic techniques that deal with these issues. In this work a modified VGG-16 model was used for COVID-19 detection from chest X-ray images. This model classified the chest X-ray images into two categories: COVID-19 and NORMAL images. Finally, the performance of the proposed model is evaluated. The model has been validated on publicly available chest X-ray images. The best performance is obtained by the proposed model with an accuracy of 97.94%.

VI. Future Work

Therefore, in future work, the performance of the suggested methodology for multiclass classification issues will be established. In order to create a model that is more dependable, we also intend to investigate the application of optimization methods in conjunction with the DL models utilized in this study. In order to efficiently provide doctors with precise focal area detection during diagnosis and to facilitate early illness identification and prevention, the proposed model will be integrated with object detection.

Optimizing Crack Detection: The Integration of Coarse and Fine Networks in Image Segmentation

Hoanh Nguyen*, Tuan Anh Nguyen
Faculty of Electrical Engineering Technology, Industrial University of Ho Chi Minh City, Ho Chi Minh City, Vietnam

***Abstract*—In recent years, the automation of detecting structural deformities, particularly cracks, has become vital across a wide range of applications, spanning from infrastructure maintenance to quality assurance. While numerous methods, ranging from traditional image processing to advanced deep learning architectures, have been introduced for crack segmentation, reliable and precise segmentation remains challenging, especially when dealing with complex or low-resolution images. This paper introduces a novel method that adopts a dual-network model to optimize crack segmentation through a coarse-to-fine strategy. This model integrates both a coarse network, focusing on the global context of the entire image to identify probable crack areas, and a fine network that zooms in on these identified regions, processing them at higher resolutions to ensure detailed crack segmentation results. The foundation of this architecture lies in utilizing shared encoders throughout the networks, which highlights the extraction of uniform features, paired with the introduction of separate decoders for different segmentation levels. The efficiency of the proposed model is evaluated through experiments on two public datasets, highlighting its capability to deliver superior results in crack detection and segmentation.**

***Keywords*—Deep learning; crack segmentation; coarse-to-fine strategy; image segmentation**

I. Introduction

The structural integrity and safety of infrastructures, such as buildings, roads, dams, and bridges, are vital to the well-being of societies across the world. One of the earliest and most common indicators of deteriorating structural health is the appearance of cracks. Crack segmentation, an essential branch of computer vision and structural health monitoring, focuses on the accurate identification and tracking of cracks in various materials and surfaces. The primary objective is to detect cracks as early as possible, ensuring timely maintenance, prevention of potential catastrophic failures, and extension of the lifespan of structures. With the rapid development of deep learning [1], [2], [3], [4] and the emergence of segmentation models such as SegNet [5], UNet [6], FCNs [7], and the DeepLab series [8], [9], general semantic segmentation tasks and crack segmentation tasks, in particular, have achieved significant improvements [10], [11], [12]. However, crack segmentation still poses numerous challenges that need addressing [13], [14], [15]. First, cracks can appear in various shapes, ranging from fine lines to wide gaps, and may display in different depths, lengths, and orientations. This makes it challenging for models to generalize across all possible crack presentations. Second, the surface on which a crack appears often possesses its texture, which can resemble a crack, making it difficult to differentiate between actual defects and background patterns. Third, uneven and dynamic lighting conditions, as well as external factors such as dirt, moisture, or staining can either obscure cracks or create shadows that might be mistaken for cracks. In recent years, with the rapid advancement of convolutional neural networks (CNNs), many methods have been proposed to address these challenges. In study [16], the authors proposed a novel unsupervised multi-scale fusion crack detection algorithm for pavement images, which addresses challenges posed by intensity inhomogeneity, topology complexity, and other factors without the need for training data. This method integrates a windowed minimal intensity path-based technique for candidate crack extraction, cross-scale crack correspondence, and a multivariate statistical hypothesis test for crack evaluation. In study [17], the authors introduced a cutting-edge network architecture called feature pyramid and hierarchical boosting network tailored for pavement crack detection. This network integrates context information into low-level features through a feature pyramid approach, and introduces a unique nested sample reweighting process, along with a new measurement method, the average intersection over union for enhanced crack detection accuracy. Yue et al. [18] presented CrackNet-V, an enhanced deep network tailored for pixel-level crack detection in 3D asphalt pavement images. This advanced network, building upon the foundational principles of CrackNet, features a deeper structure with fewer parameters, thereby offering superior accuracy and computational efficiency, while also incorporating novel features like the leaky rectified tanh activation function for precise shallow crack detection. Zhengxin et al. [19] proposed a semantic segmentation neural network designed for road area extraction, seamlessly merging the capabilities of residual learning and the U-Net architecture. This model incorporates residual units for simplified deep network training while its rich skip connections streamline information propagation, resulting in a leaner yet more performative network. In study [20], the authors introduced the Crack Transformer network (CrackFormer), a specialized solution tailored for fine-grained crack detection, integrating innovative attention mechanisms within a SegNet-inspired encoder-decoder framework. CrackFormer features unique self-attention modules and efficient positional embedding, while also incorporating new scaling-attention modules, emphasizing semantic crack features and reducing non-semantic interferences.

Although the above methods have addressed many challenges of crack segmentation, some difficulties remain, especially with thin cracks. As illustrated in Fig. 1, thin cracks are often more difficult to detect, particularly in low-resolution images. Furthermore, thin cracks can easily be mistaken for the

natural texture of asphalt, especially when the asphalt surface is rough or granular. Thin cracks can also appear darker or fainter depending on the lighting conditions and the angle of image capture, posing challenges for consistent detection. To address these issues, this paper introduces a dual-network model that employs a coarse-to-fine strategy for enhanced crack segmentation. The model consists of two networks: the coarse network captures global image context to identify potential crack areas, followed by the fine network, which focuses on these identified regions at a high resolution to achieve precise segmentation. Both networks share an encoder, but use separate decoders to process images, ensuring high-quality crack detection results. The proposed model is evaluated on two public datasets, including CrackTree260 and DeepCrack537 datasets. Experimental results show that the proposed model delivers superior results in crack detection and segmentation.

Fig. 1. Some images illustrate the challenges faced when performing crack segmentation.

II. Proposed Model

Fig. 2 provides a detailed visualization of the multi-stage segmentation process implemented in the proposed method. The proposed pipeline consists of both a coarse and a fine network. While both networks use a shared encoder, denoted as E, they each have their own decoders: D_c for the coarse network and D_f for the fine network. The main objective of the coarse network is to capture global contextual information from the entire image and subsequently highlight regions potentially containing cracks. Based on the predictions from the coarse network, the fine network then zooms into these identified regions, focusing specifically on local patches considered to have cracks, to achieve high-resolution crack segmentation. An input image represented mathematically as $I \in R^{W \times H \times 3}$ undergoes a downsampling step first. This optimizes its size for an initial analysis without sacrificing key details. Following this, the coarse network processes the downsized image to identify regions that may have cracks, resulting in a coarse crack map. This map essentially serves as a probability output, given by $P = Sigmoid(D_c(E(I)))$, highlighting pixels with a higher probability of being part of a crack. To refine this output, a thresholding technique is applied, producing a more defined coarse crack mask. This mask is then employed as a guide for the subsequent fine network. The fine network delves deeper, cropping and zooming into the previously identified regions. Its primary task is to work on these local patches, operating at a higher resolution to accurately segment the cracks, leading to a precise segmentation result.

A. Shared Encoder

We use ResNet-101 architecture in [21] as the shared encoder of our model. ResNet-101, a variant of the Residual Network (ResNet) family, is a deep convolutional neural network architecture known for its excellent performance on a variety of computer vision tasks. At its core, the design philosophy behind ResNet-101 is the introduction of "residual blocks" which address the vanishing gradient problem encountered in very deep neural networks. The network begins with a single convolutional layer with a 7×7 kernel, stride of 2, followed by a max pooling layer. The majority of the network consists of sequences of residual blocks. These blocks allow the model to learn identity functions that ease the training of deeper networks by providing shortcut connections across layers. Specifically, a residual block contains a skip connection that bypasses one or more layers. ResNet-101 contains four main groups of residual blocks. The first group has 3 blocks, the second group has 4 blocks, the third group comprises a significant 23 blocks, and the fourth group has 3 blocks. Each block within these groups consists of 3 layers (i.e., a 1×1 convolution, a 3×3 convolution, and another 1×1 convolution), with the exception of the first block of each group, which adjusts the number of channels and downsamples using a stride of 2. For crack segmentation task, we remove fully connected layers at the end of the architecture to maintain spatial information throughout the network. In addition, to stabilize the activations and speed up training, batch normalization and ReLU (Rectified Linear Unit) activation functions are applied after each convolution within the blocks. The details of ResNet-101 structure used in this paper are shown in Table I. The deep nature of ResNet-101 enables it to capture a wide range of features at different scales, while its residual connections ensure that training remains stable and efficient even with its impressive depth.

B. Segmentation Decoders

For both coarse and fine segmentation decoders, this paper employs the Atrous Spatial Pyramid Pooling (ASPP) decoder in [22]. ASPP is a prominent module designed to capture multi-scale contextual information without the need for multiple input scales or exhaustive downsampling. Originally proposed for semantic image segmentation in the context of the DeepLab series of architectures, ASPP is specifically designed to handle the challenges posed by objects of varying scales in images. The core concept behind ASPP is to apply parallel dilated (or atrous) convolutions on the feature map, each having a different dilation rate. This results in capturing spatial information from different field-of-views without substantially increasing the number of parameters or the computational burden. The multi-scale feature maps resulting from these parallel operations are then concatenated. Specifically, the ASPP module comprises: A 1×1 convolution which captures the image's immediate context, three 3×3 convolutions but with varying dilation rates (e.g., 6, 12, and 18), which allow the network to capture spatial information from different ranges without downsampling, and a global average pooling layer to

process the feature map, capturing the holistic context of the image. The resulting features are then upsampled and concatenated with the other components. After concatenating the outputs from these parallel operations, the combined feature map passes through another convolution to produce the final enhanced feature map that fuses multi-scale contextual information. This feature map is then fed into the ASPP decoder for semantic segmentation, as shown in Fig. 3. In the ASPP decoder, the enhanced feature maps are first bilinearly upsampled by a factor of 4 and then concatenated with the corresponding low-level feature map from the backbone (i.e., Conv2 layer of ResNet-101). To implement the concatenation operation, a 1×1 convolution layer is applied to the low-level feature map to reduce the number of channels. After concatenation, two 3×3 convolution layers are used to refine the features, followed by another simple bilinear upsampling by a factor of 4. The refined feature map is finally fed into the segmentation head. The ASPP decoder enables the network to effectively segment objects of various sizes and scales in images, making it a powerful choice for many semantic segmentation tasks.

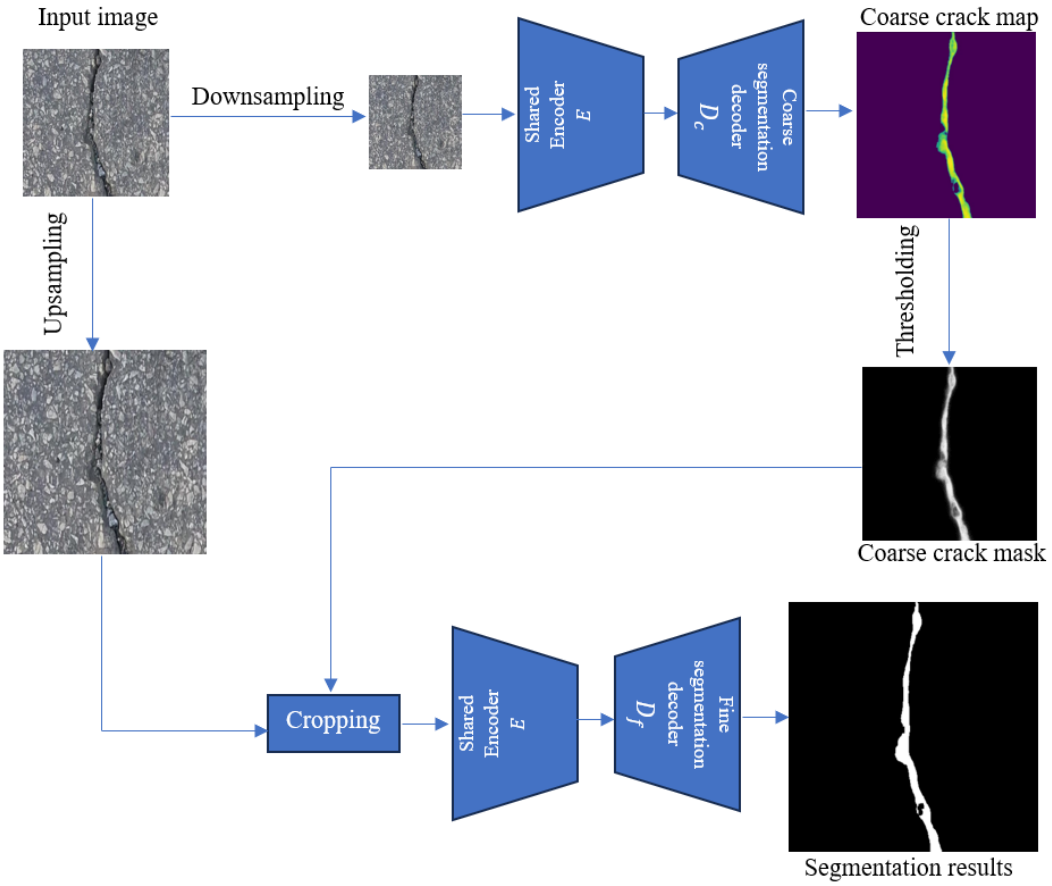

Fig. 2. The structure of the proposed model for crack segmentation.

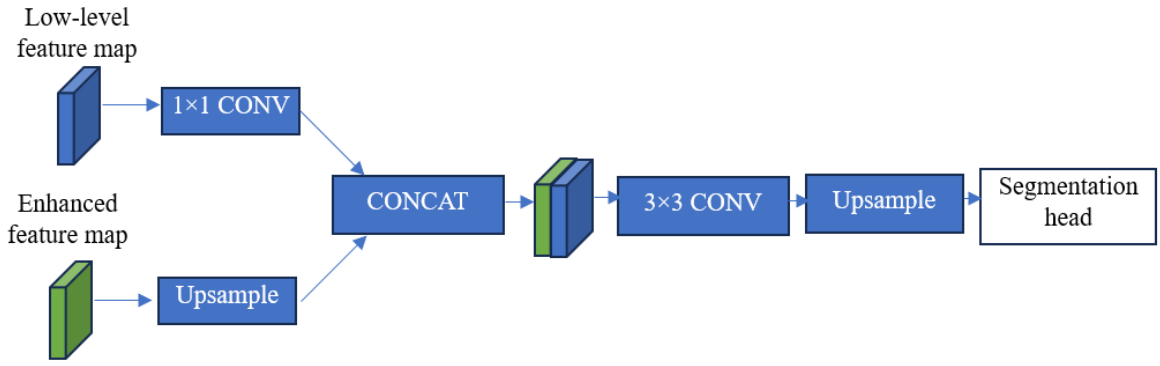

Fig. 3. The pipeline of the ASPP decoder.

C. Cropping

To extract high-resolution crack patches from the original image based on the coarse crack map, we first convert the coarse crack probabilities generated by the coarse network into a binary mask using a hard-thresholding method. This will produce a binary mask indicating the presence of cracks. To ensure that all potential details of the crack, even those that might have been slightly missed by the coarse network, are captured, we apply a dilation operation on the binary mask. This slightly enlarges the mask region. Next, we compute the bounding box for each contiguous region in the dilated binary mask. To generate these bounding boxes for crack regions, we select all the pixels with a corresponding density mask value of "1". We then merge the eight-neighbor connected pixels into a large candidate region. Finally, we use the circumscribed rectangle of the candidate region to crop the original image. This box encapsulates the region potentially containing the crack. Furthermore, we filter out crops with resolutions below the density threshold to eliminate noise and reject low-resolution patches. This step is crucial because crack segmentation doesn't perform well on low-resolution patches. After extracting the corresponding high-resolution patches from the original image, we feed each one into the fine network for detailed segmentation. As this network focuses only on smaller regions containing potential cracks, it can pay more attention to details, yielding better segmentation quality. Once the fine module processes the patches, it generates high-resolution segmentation for each patch. These segmented patches are then projected back to their original positions in the full-resolution image to obtain the final segmented result. By using this approach, the model benefit from both the global context provided by the coarse module and the local detail-centric approach of the fine module, ensuring accurate segmentation of cracks even in high-resolution images.

TABLE I. THE DETAILS OF RESNET-101 STRUCTURE USED AS THE SHARED ENCODER IN THIS PAPER

Layer type	Output size	Details
Input	H × W × 3	
Conv1	H/2 × W/2 × 64	7×7 convolution, stride 2
Max Pooling	H/4 × W/4 × 64	3×3 max pool, stride 2
Conv2_x (3 blocks)	H/4 × W/4 × 256	[1×1, 64], [3×3, 64], [1×1, 256] for each block
Conv3_x (4 blocks)	H/8 × W/8 × 512	[1×1, 128], [3×3, 128], [1×1, 512] for each block
Conv4_x (23 blocks)	H/16 × W/16 × 1024	[1×1, 256], [3×3, 256], [1×1, 1024] for each block
Conv5_x (3 blocks)	H/32 × W/32 × 2048	[1×1, 512], [3×3, 512], [1×1, 2048] for each block

D. Training Loss

In the domain of crack segmentation, the objective is to classify each pixel as either being part of a crack or not. This pixel-wise classification task can be effectively formulated and optimized using the Binary Cross Entropy (BCE) loss as follow:

$$L = \frac{1}{N}\sum_{ij} BCE(y_{ij}, \hat{y}_{ij}) \quad (1)$$

$$BCE(y, \hat{y}) = -ylog(\hat{y}) - (1-y)\log(1-\hat{y}) \quad (2)$$

where, y is the true label of the pixel, $\hat{y}$ is the predicted probability of the pixel belonging to the class labeled as foreground class.

The BCE loss quantifies the divergence between the predicted probability distribution and the actual distribution of the pixel labels. Specifically, for every pixel in the segmented image, the model predicts a probability score representing its confidence that the pixel belongs to the crack class. The BCE loss then computes the logarithmic difference between these predicted probabilities and the ground truth labels. When the model's prediction aligns closely with the actual label, the BCE loss approaches zero, indicating a perfect prediction. Conversely, if the model's prediction deviates significantly from the ground truth, the loss value increases. This property makes BCE loss particularly suitable for the crack segmentation task, as it penalizes misclassifications heavily, thereby driving the model to improve its pixel-wise classification accuracy. By minimizing the BCE loss during training, the segmentation model is guided to produce predictions that closely match the true crack structures in the images, leading to precise and reliable segmentation results. We use the BCE loss to both coarse and fine networks. The final loss L is the sum of the two:

$$L = \lambda_c L_c + \lambda_f L_f \quad (3)$$

where, λ_c and λ_f are coefficients for each loss, L_c is the BCE loss for the coarse network, L_f is the BCE loss for the fine network.

III. EXPERIMENTS

A. Dataset and Metrics

The proposed model is trained and evaluated on two public crack datasets: the CrackTree260 [23] and DeepCrack537 [24].

CrackTree260 is a dataset comprising 260 road pavement images, which is an extended version of the dataset from [23]. Images are captured using an area-array camera under visible-light illumination. This study utilized 200 of these images for training, 20 for validation, and 40 for testing. To enhance the training set, data augmentation techniques were employed. Specifically, each image was rotated at nine distinct angles ranging from 0 to 90 degrees in 10-degree increments. Following rotation, each image was then flipped both vertically and horizontally. From each flipped variant, five sub-images of 512×512 pixels were extracted – four from the corners and one from the center. As a result of this augmentation process, the training set accumulates a total of 35,100 images.

DeepCrack537 comprises 537 images, each having resolution of 544×384 pixels. These images depict a variety of cracks. Unlike other crack datasets, the diversity of cracks in DeepCrack537 is notable. Examples include top-down views, tilted views, cracks on both concrete and asphalt surfaces, variations in crack width from wide to thin, and instances where the cracks are partially occluded. For the purposes of this study, 300 images were utilized for training and 237 for testing.

For evaluation metrics, we use Precision (P), Recall (R), $F-measure$, mean intersection over union ($mIoU$) to evaluate the proposed model. Precision evaluates how many of the detected/segmented cracks (positive predictions) are actually real cracks.

$$P = \frac{TP}{TP+FP} \quad (4)$$

where, TP (True Positives) are the correctly detected cracks, FP (False Positives) are the wrongly detected cracks (i.e., detected cracks that are not real).

Recall measures how many of the actual cracks have been detected by the segmentation model.

$$R = \frac{TP}{TP+FN} \quad (5)$$

where, FN (False Negatives) are the actual cracks that the model failed to detect.

$F-measure$ is the harmonic mean of Precision and Recall. It provides a balance between the two. If either Precision or Recall is low, the $F-measure$ will also be low. It's especially useful when the class distribution is uneven.

$$F-measure = \frac{2\times P\times R}{P+R} \quad (6)$$

Mean intersection over union ($mIoU$) is a popular metric for segmentation tasks. It evaluates the overlap between the ground truth segmentation and the predicted segmentation.

$$mIoU = \frac{1}{2}\left(\frac{TP}{TP+FP+FN} + \frac{TN}{TN+FP+FN}\right) \quad (7)$$

B. Experimental Settings

The shared encoder based on ResNet-101 architecture is initialized with weights pre-trained on the ImageNet dataset [25] to take advantage of the extensive pretrained insights and rich feature representations it offers. The entire network was trained using the Adam optimizer [26] with a learning rate of 0.0001, which was reduced by a factor of 10 whenever the validation loss stabilized. Data augmentation techniques, including random rotations, zooms, and horizontal flips, were applied to prevent overfitting and enhance the model's generalization capabilities. The model is trained for 100k iterations with a batch size of 4. All experiments were conducted on a machine equipped with an NVIDIA RTX 4080 GPU, 64 GB RAM, and ran on the PyTorch framework.

C. Performance Evaluation

To demonstrate the effectiveness and superiority of the proposed method, we adopted eight existing and popular methods to compare to the proposed model, including Unet [6], TransUNet [27], FCNs [7], SegNet [5], and DeepCrack [28]. Table II shows results on the CrackTree260 dataset. From Table II, when examining the performance metrics of various models on the CrackTree260 dataset, the proposed model demonstrates superior performance across all metrics. With P of 0.892, R of 0.886, F-measure of 0.897, and mIoU of 0.894, the proposed model surpasses the other models in the ability to detect and segment cracks accurately. Notably, while DeepCrack comes closest to the proposed model with an F-measure of 0.852 and mIoU of 0.865, the proposed model still offers improvements, particularly in capturing the true positive rate as indicated by the highest recall. UNet and SegNet also demonstrate competitive results, with F-measures of 0.847 and 0.844 respectively. However, FCNs, with an F-measure of 0.463 and mIoU of 0.612, is the least effective among the mentioned models. TransUNet, despite being a transformer-based model, shows a relatively moderate performance with an F-measure of 0.771. Overall, the results suggest that the two-step approach of the proposed model is highly effective in detecting and segmenting cracks on the CrackTree260 dataset. For the DeepCrack537 dataset, the results are shown in Table III. From Table III, it's evident that the proposed model delivers the most impressive results in terms of crack detection and segmentation. With P of 0.891, R of 0.846, F-measure of 0.875, and mIoU of 0.878, the proposed model surpasses the other evaluated models. The DeepCrack model is the closest competitor with an F-measure of 0.847 and mIoU of 0.861, indicating a relatively high accuracy. SegNet also exhibits strong results with an F-measure of 0.840. In comparison, UNet and FCNs, while displaying reasonable performances, fall slightly behind with F-measures of 0.815 and 0.812, respectively. It is apparent from these results that the bi-level approach of the proposed model, involving a global context capture followed by focused high-resolution segmentation, is effective in the context of the DeepCrack537 dataset.

The visualization results of the model across datasets are depicted in Fig. 4. In this figure, the rows labeled "Input image" display images of various surfaces, each with distinct crack morphologies. The "Ground-truth labels" rows accurately depict the actual cracks present in the images. In contrast, the "Segmentation results" rows present the model's predictions. For most of the images, the segmentation results align closely with the ground-truth labels, indicating a high degree of accuracy in crack detection. This demonstrates the strength of our method in capturing both the global context through the coarse network and then refining the details through the fine network. Particularly in areas with intricate crack patterns or smaller fissures, the fine network provides superior results in segmenting these challenging features. However, there are instances, especially in the second set of images, where the segmentation results show a slightly broader crack outline than the ground-truth, suggesting a potential overestimation by the model in those cases. Overall, the visualization validates the effectiveness of our approach. While there are minor deviations in a few cases, the proposed pipeline demonstrates robust performance in segmenting cracks across diverse scenarios.

TABLE II. RESULTS ON THE CRACKTREE260 DATASET

Model	Metrics			
	P	R	F-measure	mIoU
UNet	0.860	0.834	0.847	0.861
TransUNet	0.797	0.746	0.771	0.803
FCNs	0.519	0.418	0.463	0.612
SegNet	0.851	0.837	0.844	0.858
DeepCrack	0.871	0.834	0.852	0.865
Proposed model	0.892	0.886	0.897	0.894

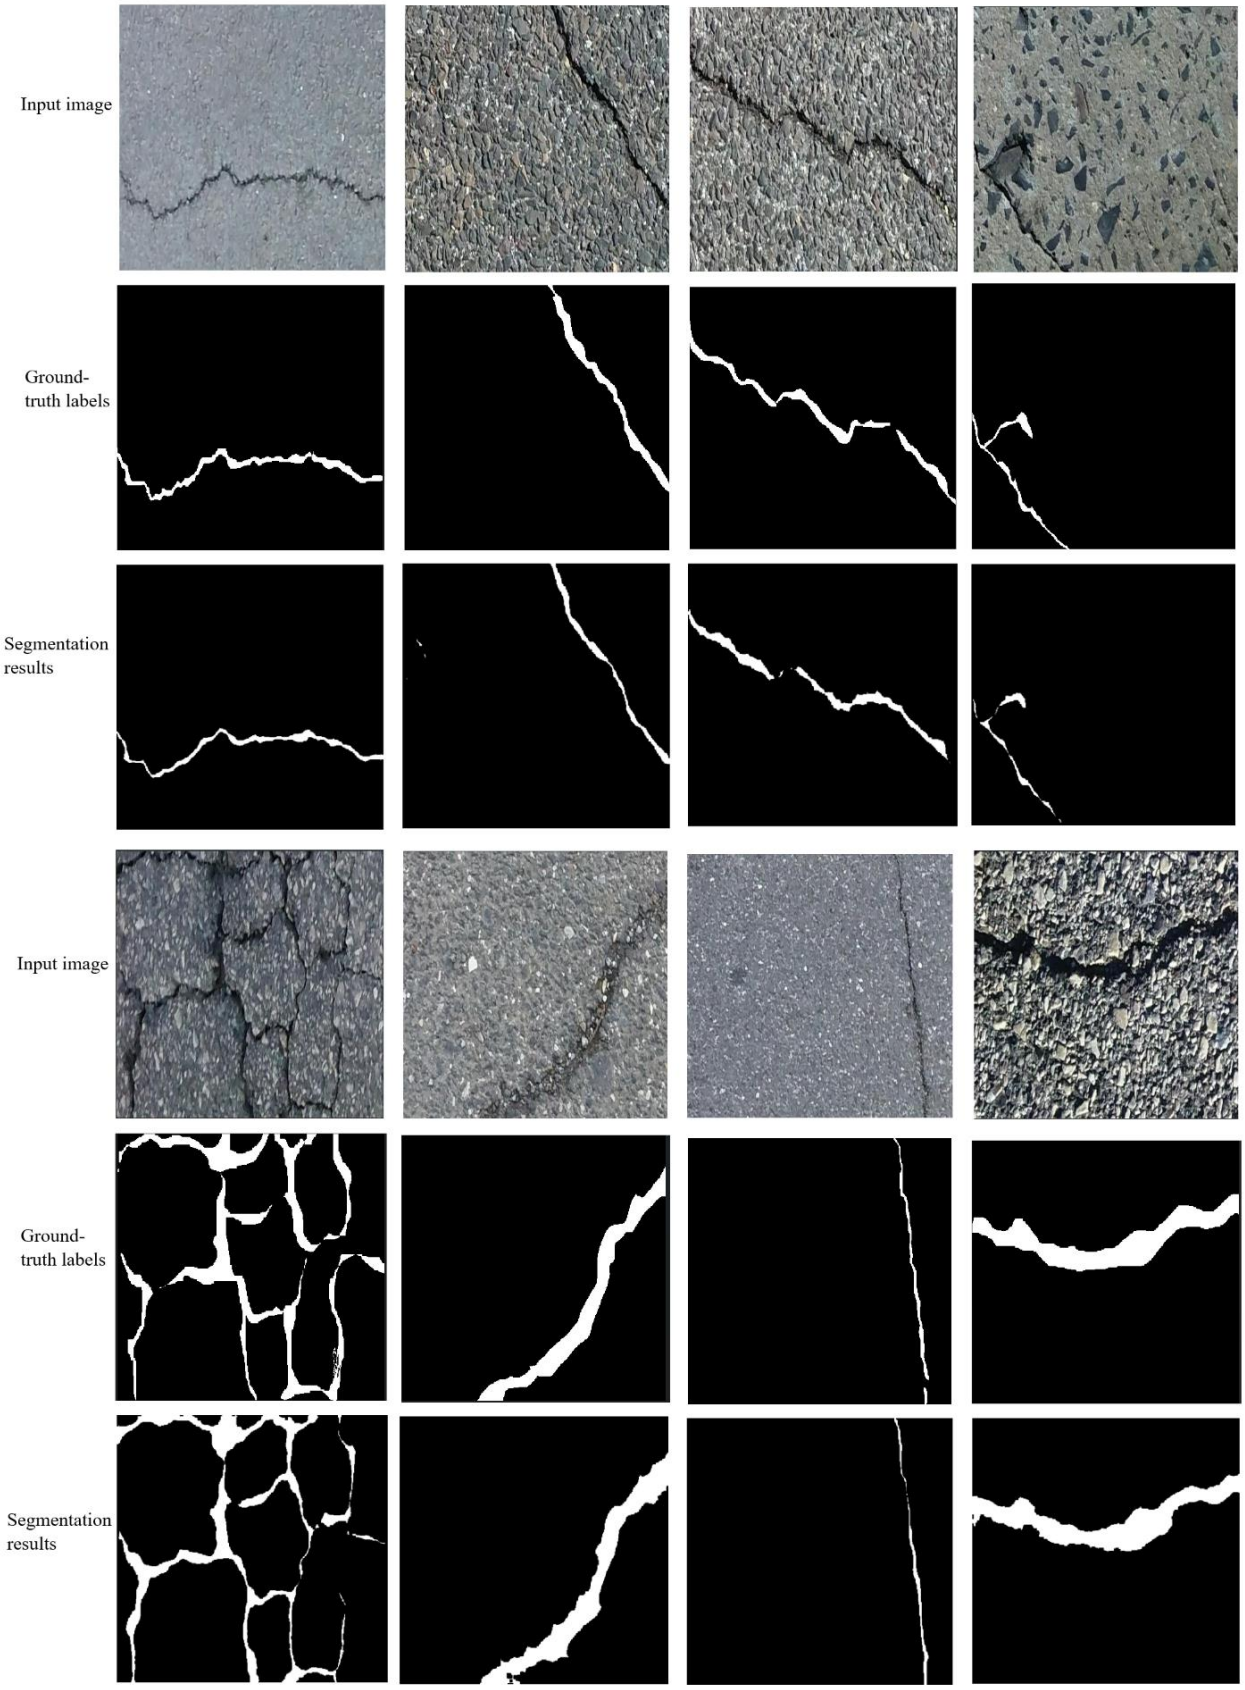

Fig. 4. Visualization results of the model on the datasets.

TABLE III. RESULTS ON THE DEEPCRACK537 DATASET

Model	Metrics			
	P	R	F-measure	mIoU
UNet	0.841	0.791	0.815	0.837
FCNs	0.829	0.796	0.812	0.833
SegNet	0.857	0.824	0.840	0.851
DeepCrack	0.876	0.819	0.847	0.861
Proposed model	0.891	0.846	0.875	0.878

IV. CONCLUSION

This study presents a dual-network model that optimally leverages the combined strengths of both a coarse and a fine network to enhance crack segmentation. Each network utilizes a shared encoder, with separate decoders tailored to their specific roles: the coarse network captures a holistic view of the image, emphasizing regions that potentially contain cracks, while the fine network focuses on these highlighted regions for precise high-resolution crack segmentation. The integration of the coarse network with the fine network was effective in addressing the challenges of crack detection. The experimental results on two public datasets underscore the robustness and effectiveness of the proposed approach in diverse scenarios. However, our model may struggle with extremely subtle cracks or those obscured by environmental factors, such as shadows or debris. Furthermore, the model's performance might vary depending on the quality and resolution of the input images. In future work, we plan to incorporate additional data augmentation techniques and explore the integration of advanced sensors for better crack detection in challenging conditions.

Abstract*—Reliable classification of Land Use and Land Cover (LULC) using satellite images is essential for disaster management, environmental monitoring, and urban planning. This paper introduces a unique method that combines a Convolutional Neural Network (CNN) with Human Group-based Particle Swarm Optimization (HPSO) and Ant Colony Optimization (ACO) algorithms to improve the accuracy of LULC classification. The suggested hybrid HPSO-ACO-CNN architecture effectively solves the issues with feature selection, parameter optimization, and model training that are present in conventional LULC classification techniques. During the initial phases, HPSO and ACO are crucial in identifying the best hyperparameters for the CNN model and fine-tuning the selection of critical spectral bands. ACO modifies the CNN's hyperparameters (learning rate, batch size, and convolutional layers), whereas HPSO finds the optimal selection of spectral bands. This optimization technique reduces the probability of overfitting while substantially enhancing the model's ability to generalize. Utilizing the selected spectral bands and optimum parameter configuration, the CNN algorithm is trained in the second phase. With Python implementation, this method uses both the spatial and spectral characteristics that the CNN detects to reach an outstanding 99.3% accuracy in LULC classification. The hybrid approach outperforms traditional methods like Deep Neural Network (DNN), Multiclass Support Vector Machine (MSVM), and Long Short-Term Memory (LSTM) in experiments using benchmark satellite image datasets, demonstrating a significant 10.5% increase in accuracy. This hybrid HPSO-ACO-CNN architecture transforms accurate and dependable LULC classification, offering an advantageous instrument for remote sensing applications. It enhances the area of satellite imagery evaluation by combining the advantages of deep learning techniques with optimization algorithms, enabling more accurate mapping of land use and cover for sustainable land management and environmental preservation.

Keywords*—Land use and land cover; human group-based particle swarm optimization; ant colony optimization; convolutional neural network; satellite image

I. Introduction

A crucial challenge that has significant implications across a range of regions is the accurate categorization of land cover and land use using satellite images. The primary focus of the position is the organized classification and labelling of the surface of the Earth, which serves as a fundamental perspective for understanding and managing the planet's changing landscapes. The designation of urban regions, the identification of infrastructural requirements, and the reinforcement of well-informed choices on land utilization allocation all have been made possible by the LULC categorization, which is crucial for urban planning [1]. This allows for the establishment of effective and environmentally responsible cities. It is a vital instrument in the field of management of the environment for determining how ecosystems are changing, detecting deforestation, and keeping track of the condition of ecosystems in their natural state. In addition, LULC categorization in agriculture provides farmers with knowledge about different crop categories, production, and farming methods, permitting targeted farming methods and boosting food security [2]. Accurate mapping of LULC can help with evaluating susceptibility, organizing for minimizing disaster risks, and adapting quickly to emergencies throughout disaster reconstruction and prevention operations. The capacity of satellite imaging to take wide-ranging images of the exterior of the planet from orbit is crucial for LULC categorization. These images provide us an unusual perspective from which can observe the intricate and constantly shifting topography of the earth [3]. The investigation has access to a variety of data on the Earth's surface, such as specifics about human behaviours, landscape

characteristics, and the surrounding environment, by using the camera's array of satellite sensors. A specific component of this categorization, known as land utilization, deals with the numerous ways individuals utilize and communicate with the land, including metropolitan regions, agricultural areas, transportation systems, manufacturing regions, and more. In contrast, land cover describes the physical properties of the Earth's surface independent of human activity, including forests, marshes, lakes and rivers, deserts, and arid areas. Together, the two distinct aspects related to land cover and land use provide an accurate representation of the Earth's surface and provide information regarding the complex interactions between the activities of humans and the surrounding ecosystem [4]. The level of accuracy of assessments made in a variety of disciplines is strongly impacted by how well LULC categorization is done. In urban planning, accurate regulatory control, infrastructure optimization, and support for ecologically friendly techniques are all aided by the definition of land utilization classifications. The capacity to distinguish between diverse kinds of land covers in management of the environment enables investigators to observe wildlife migratory patterns, follow habitat changes, and determine the effects of warming temperatures on ecosystems. In terms of agriculture, LULC categorization enables farmers to engage in decisions based on information, enabling them to select crops more effectively, manage irrigation more effectively, and lessen the impact of diseases and pests. Quick and precise LULC mapping is crucial for response to disasters in order to evaluate destruction, identifying impacted people, and efficiently arrange relief activities [5]. The key component for solving some of the most important issues confronting the global community, from development and deterioration of the environment to food availability and disaster resilience, is proper LULC categorization.

Satellite imagery is now more widely available and of higher quality than ever due to notable technological breakthroughs in the area of remote sensing in recent years. The latest phase of Earth observations has begun as a result of the growth in gathering information, providing an unusual viewpoint on the globe from orbit. Researchers have been able to collect data about the outermost layer of the planet and its changing operations at a degree of complexity never before possible due to the installation of innovative Earth-observing satellites with modern sensors. These satellites continually gather enormous volumes of information that cover a wide range of spectral data, temporal frequencies, and geographical resolutions [6]. Because of this, the field of remote sensing today is distinguished by an extensive collection of extensive and varied satellite imagery, which serves as a significant resource for a wide range of scientific, ecological, and social purposes. Even if the amount of available imagery from satellites is increasing exponentially, there are still many difficult problems it raises. For the information to be used effectively, it requires advanced approaches due to their enormous number and complexity. The fact that these images are multi-spectral and hyperspectral, indicating that they collect data from a broad variety of wavelengths, which include those outside the visible spectrum, presents one of the main obstacles [7]. This spectral variety adds a degree of complexity that necessitates sophisticated analytical methods capable of understanding the subtle differences in the information. Conventional LULC categorization methods suffer to handle this complexity because they are unable to capture the complicated patterns seen in multi-spectral and hyperspectral data. These methods are frequently founded upon manual characteristic engineering and rule-based systems. Traditional LULC categorization techniques frequently depend on hand-made characteristics and pre-established criteria, which may not be sufficient to capture the entire range of variability inherent in satellite images. These methods can be laborious and frequently need expertise in the area for extraction of features. Additionally, rule-based systems' low capacity for adapting to various and changing environments limits their usefulness. The immense prospective of deep learning methods, particularly CNNs, has, in comparison, emerged progressively more understood in the context of the analysis of satellite imagery [8]. CNNs are exceptionally effective at gathering pertinent characteristics from unprocessed information, which enables them to find complex spatial and spectral correlations that can resist manual characteristic engineering. They therefore provide a potential way to improve the accuracy and efficiency of LULC categorization using the vast amount of available satellite information.

The present article introduces a novel method that makes advantage of the interaction between algorithms for optimization and deep learning approaches to address the significant issues provided by the complexities of satellite images and the rising need for precise land use and land cover categorization. In particular, this innovative method combines Convolutional Neural Networks with two potent optimization algorithms—Human Group-based Particle Swarm Optimization and Ant Colony Optimization—to create a hybrid structure designed exclusively for the accurate and reliable categorization of LULC according to satellite imagery [9]. This integrative approach's primary driving force is to handle choosing characteristics and hyperparameter optimization, two crucial aspects of LULC categorization. The correct interpretation of satellite images depends heavily on identifying features, which involves choosing the most significant spectral bands or channels. Each of the categories are equally significant in the context of multi-spectral and hyperspectral imaging, and choosing a suitable combination of channels is essential for lowering distortion and redundancies while enhancing the approach capacity to discriminate between distinct land cover classifications. Human Group-based PSO intelligently selects the most relevant spectral bands to improve the standard of data given into the CNN using a collaborative procedure of optimization motivated by social group characteristics. The subsequent crucial issue the hybrid system addresses is hyperparameter optimization. A wide range of hyperparameters, including learning rates, batch sizes, and the number of convolutional layers, are included in CNNs as algorithms for deep learning. The effectiveness of the simulation is significantly impacted by these hyperparameters, therefore determining the optimum setup is extremely important [10]. ACO is used to adjust these hyperparameters, in order to ensure that the CNN performs at its highest level. It aims to minimize overfitting while

optimizing categorization accuracy by balancing model complexities and generalization. This combined strategy transcends the constraints of conventional approaches that depend on manual characteristic engineering and rule-based systems, signalling an important change in LULC categorization. This structure aims to enhance the accuracy and resilience of satellite based LULC categorization, permitting the efficient usage of the extensive and complicated information contained within satellite data. It does this by integrating the effectiveness of optimization methods into deep learning [11].

A crucial and fundamental stage in the field of satellite imagery evaluation, especially in the broader context of classifying land use and land cover, involves characteristic selection. The selection of the appropriate subset of spectral bands is crucial for a number of explanations, not the least of which is that not all spectral bands contributed similarly to the categorization process. Initially reducing data noise is accomplished by carefully choosing the spectral bands. Noise in imagery from satellites can come from a variety of places, such as air interference, sensor constraints, and changes in surface reflectance [12]. Feature selection eliminates or reduces the influence of noisy information by selecting the most pertinent bands, producing more accurate and precise categorization outcomes. This noise reduction improves the categorization model's general durability, making it less sensitive to incorrect classifications carried on by external influences. The process of categorization becomes quicker and more resource-efficient because to the reduction in redundancy, which also improves computing effectiveness. The present study uses Human Group-based Particle Swarm Optimization, a method informed by the combined intelligence of social networks, to carry out the process of characteristic selection effectively [13]. PSO replicates the cooperative behaviour of members of a group, where each member represents a possible mixture of spectral bands. These "particles" move around the spectral band subset search space, continuously modifying their placements in accordance with their individualized and shared understanding. Particles may successfully explore and utilize the search space thanks to PSO's cooperative characteristic by combining spectral bands in techniques that improve categorization accuracy while reducing noise and redundancies.

Convolutional Neural Network architecture tuning of hyperparameters is crucial for obtaining optimal results and strong adaptation as well as to characteristics selection. Hyperparameters include important factors that control whether deep-learning algorithms develop and are built, such as learning rates, size of batches, and the quantity of convolutional layers. These hyperparameters have a substantial impact on how well a CNN can recognize and understand complicated patterns in the information being processed. For example, during optimization, the learning rate determines the phase size and might affect the algorithm's convergence rate and quality. The batch size influences both computational effectiveness and generalization by affecting how the system procedures and modifies parameters during training [14]. Additionally, both the complexity and depth of the CNN is directly determined by the quantity of convolutional layers, with a greater number possibly permitting the collection of more complicated data. Therefore, it is essential to optimize these hyperparameters to ensure that the CNN performs at its optimal level while minimizing the danger of overfitting, which occurs when the algorithm develops excessively specific to the information used for training. This study presents a complete technique that integrates feature selection and hyperparameter optimization, two essential components of satellite image evaluation. The resultant hybrid method, which incorporates CNNs, ACO, and HPSO, has the possibility to transform satellite image processing. The combination of PSO for characteristic selection and ACO for hyperparameter optimization results in an integrated structure that makes use of both the representational strength of deep learning systems and the collective knowledge of optimization algorithms. This innovative method improves categorization accuracy while also strengthening resilience against complicated or noisy satellite imaging information. The hybrid PSO-ACO-CNN strategy that has been developed marks a substantial advancement in the effort to fully use satellite images for important applications in a variety of fields. Land cover and land use categorization skills, which are essential for environmental monitoring, urban planning, agriculture, and disaster management, are set to become more precise and dependable as a result of this technology. The study advances the latest developments in satellite image evaluation by demonstrating the efficacy and effectiveness of this framework via thorough investigations and findings. The potential significance of this study extends beyond the limits of research by providing real-world details that can enable experts to reach better decisions about how to manage the resources of the planet and deal with difficult problems. In short, the study represents a crucial step toward releasing satellite imagery's hidden potential for tackling pressing problems that the planet is currently and in future generations will be confronting.

The Key Contribution of the paper is given as follows:

- The study introduces the EuroSAT dataset, a sophisticated collection of satellite images created specifically for categorizing land cover and usage. This collection includes imagery from satellites with labeled data covering, different categories of land cover and usage across thirteen spectral bands. The massive dataset will be a valuable resource for the remote sensing and computer vision research as it allows for the investigation of deep learning and multimodal fusion techniques.
- The paper presents a unique hybrid optimization approach that combines Ant Colony Optimization for convolutional neural network hyperparameter optimization with Human Group-based Particle Swarm Optimization for feature selection. This technique addresses two important aspects of satellite image processing: selecting the appropriate spectral bands to employ and optimizing the CNN model for best results. The accuracy and robustness of the classification of land use and land cover are increased when these

optimization approaches are combined with deep learning.

- The research employs effective image pre-processing techniques, such normalization and histogram equalization, to enhance the quality of the acquired satellite images. These techniques reduce noise and improve system performance while ensuring that the input data to the classification model is of exceptionally high quality.
- By simultaneously optimizing numerous CNN model parameters, such as batch size and learning rate, the research expands on Ant Colony Optimization. The multi-parameter optimization technique ACO-DL enables the CNN to operate at peak efficiency, achieve ideal generalization, and avoid issues such as overfitting. It facilitates the training of the model more easily and leads to improved classification results.
- A comprehensive method that integrates data collection, picture pre-processing, feature selection, hyperparameter optimization, and CNN-based classification into a unified architecture is presented in the study. This comprehensive technique offers an effective way to accurately categorize land cover and use utilizing satellite data, and it has the possibility of revolutionizing the area of satellite image processing for a number of applications, such as urban planning and environmental monitoring.

The rest of the section is organised as shown below. Section II illustrates literature works on Land Use and Land Cover categorization. Section III gives the Problem Statement. Section IV covers the proposed technique for categorization of Land Use and Land Cover from satellite images. Section V illustrates the performance measures and summarises the findings and compares the method's performance to previous techniques. Section VI summarises the conclusion.

II. Related Works

The positive consequences of merging Sentinel-1 and Sentinel-2 imagery in the context of land use land cover categorization with U-Net and an evolving understanding of the combinatorial benefits of multi-sensor information fusion are highlighted. The benefits of using both Sentinel-1's radar data and Sentinel-2's optical information for improved LULC categorization have been studied in this field. Sentinel-1's radar information is useful for assessing land surfaces in a variety of environmental circumstances since it can operate in all weather conditions and can be observed through cloud cover. Contrarily, Sentinel-2's optical data offers high-resolution, multispectral data that specializes at catching specific spectral fingerprints, notably in differentiating between different plant varieties and urban characteristics. A potential method has evolved for combining these complementary information sources: U-Net, a deep learning architecture renowned for its capacity for semantic segmentation. In addition to increasing categorization accuracy, it also increases the resilience of LULC mapping by reducing the drawbacks of employing the various sensors separately, such as the sensitiveness of optical information to cloud cover and the sensitivity of radar information to specific varieties of land cover and roughness of the surfaces. Although this fusion strategy has a lot of potential, there are still difficulties in processing the volume of information, integrating multiple information modalities, and efficiently optimizing the deep learning algorithm's parameters [15].

A significant body of research highlighting the essential function of these technologies in evaluating environmental modifications in this important ecosystem has been revealed by the observation of land cover and land use modifications employing GIS and remote sensing methods in human-induced mangrove forest regions in Bangladesh. Investigations in previous years have demonstrated how well Geographic Information Systems technologies paired with remote sensing information, especially from satellites like Landsat and Sentinel, can capture and analyze alterations in mangrove forest cover, extent, and health. These methods have provided benefits including extensive coverage, recurrent gathering of information, and the capacity to distinguish between different land cover classes, that are crucial for tracking changes brought on by humans in mangrove ecosystems. Indicators like the Normalized Difference Vegetation Index and spectral characteristics have been used by researchers to recognize and categorize modifications, facilitating the discovery of elements like urbanization, aquaculture growth, and deforestation that have an impact on these ecosystems. However, issues with information quality, imagine interpretation, and the requirement for fine-scale observation to detect minor modifications still exist. Even yet, the combination of remote sensing and GIS offers a lot of potential for improving the comprehension of the dynamics and preservation of Bangladesh's human-induced mangrove forests [16].

Understanding the link between land cover and urban heat dynamics via remote sensing technologies is important, as demonstrated by the land-cover categorization and its effects on Peshawar's land surface temperature [17]. Previous studies have emphasized the benefits of using satellite imagery, especially Landsat and MODIS information, to map different types of land cover and measure how much that effect affects LST. Studies have shown how important land cover is in controlling urban microclimates, with permeable surfaces like buildings and roads causing higher LSTs that are frequently linked to the urban heat island effects. The influence of modifications to land cover on LST variations in Peshawar has been examined using a variety of categorization approaches, including supervised and unsupervised techniques, together with GIS tools. However, issues with information quality, geographical resolution, and the requirement for highly temporal-resolved statistics to record cyclical temperature fluctuations still exist. However, these studies contribute to the region's initiatives at development strategy and climate adaptation by offering significant understanding into the effects of urbanization-related modifications to land cover and their consequences for Peshawar's thermal environment.

A variety of research has been done on employing remote sensing technologies in order to track and understand the dynamic character of urban settings. This is evident in the study of urban land cover and land use changes employing

Random Forest categorization of Landsat time series information. With its constant and wide-ranging coverage, Landsat satellite information has proven to be a useful tool for tracking modifications to urban land cover over time. Random Forest, a machine learning algorithm, has been used in several research due to its efficacy in categorizing different types of land cover in metropolitan settings. The benefits of Random Forest, including its capacity to manage complicated spectral and temporal structures, account for noisy input, and produce reliable and accurate categorization outcomes, have been demonstrated by these researches. The investigations covered a variety of urban applications, such as detecting land use changes, assessing urban expansion, and characterizing urban heat islands, demonstrating the adaptability of this method. Due to their considerable effects on urban sustainability, management of resources, and quality of the environment, it also emphasizes the rising significance of monitoring modifications to urban land cover and land use. Urbanization, a global trend, has caused fast and occasionally uncontrolled expansion, changing the number of impermeable surfaces, deforestation, and urbanization, among other aspects of the land cover. Wide-ranging effects of these changes include higher energy use, changing microclimates, and ecological disturbances. In order to give statistical knowledge into these urban transitions, academics have increasingly resorted to remote sensing and machine learning approaches like Random Forest. Although the approach has many benefits, there are still some problems, such as the necessity for strong validation techniques, complicated information pre-processing, and modifying variables in the model. The substantial body of research in this area however emphasizes the crucial role that remote sensing and Random Forest categorization serve in dealing with the changing dynamics of urban land cover and land use transformations [8].

The evaluation of deep learning approaches to solve the challenges of satellite imagery evaluation highlights the rising interest in utilizing techniques based on deep learning for land use and land cover categorization in Southern New Caledonia [18]. Convolutional neural networks, in particular, have shown potential in automating LULC categorization activities. They have the capacity to gather features from unprocessed information, adjust to heterogeneous landscapes, and scale to multi-spectral and hyperspectral datasets, among other benefits. The complex and changing landscapes of Southern New Caledonia require effective methods for identifying spatial interdependence within images. The necessity for significant training data that is labeled, problems with the algorithm's interpretability, vulnerability to overfitting, computing resource requirements, and the requirement for balancing the collection of local and contextual data are still problematic. However, deep learning constitutes a substantial development in LULC categorization and has the possibility to enhance the knowledge of and ability to control the dynamics of land cover and land use in Southern New Caledonia.

Machine learning approaches were used to forecast land cover and land use from satellite photos, underscoring the increasing interest in utilizing cutting-edge technology for precise and effective land categorization. For tracking and comprehending modifications to land cover, imagery from satellites has evolved into a vital resource, and machine learning techniques have proven effective instruments in this field [19]. Several machine learning methods have been utilized in multiple studies to estimate the types of land cover and land use from satellite imagery. These methods have a number of benefits, including the capacity to handle big datasets, record complicated spatial patterns, and respond to various topographies. The breadth of research on machine learning-based land utilization forecasts has been demonstrated across a variety of applications, from urban planning and monitoring the environment to agricultural and disaster management. It also emphasizes the significance of precise land-use land-cover forecasts in tackling current issues like urbanization, deforestation, and environmental degradation. The capacity to observe and simulate modifications to land cover is essential for informed decision-making and effective utilization of resources as the global population keeps on growing urbanize and landscapes transform. By simplifying the categorization procedure and supplying accurate and fast data, machine learning approaches have been important in expanding our knowledge of these shifts. The necessity for high-quality information with labels, modelling generalization across diverse locations, and the understanding of complicated machine learning systems remained obstacles regardless their benefits. Nevertheless, the collection of research in this area highlights the possibilities of machine learning approaches in improving the ability to anticipate and efficiently react to modifications in land cover and land use.

An increasing number of researchers are interested in using advanced neural network topologies to improve the precision and effectiveness of land cover categorization operations, as shown by the examination of the deep learning framework for patch-based land cover categorization. Due to their ability to gather pertinent characteristics from image updates deep learning architectures, in particular Convolutional Neural Networks, have become increasingly popularity in recent years. It renders them ideal for classifying land cover from satellite or aerial images [20]. The benefits of CNNs have been demonstrated in research, particularly the capacity to deal with complicated land cover patterns, the capacity to concurrently record spatial and spectral data, and their adaptation to multi-spectral and high-resolution images. This research examined at a variety of deep learning architectures, including model topologies, hyperparameter tuning, and transfer learning, and have shown the way they may be used to achieve the highest possible accuracy in classifying land cover. The also highlights how important precise land cover categorization is for purposes in environmental evaluation, urban development, agriculture, and disaster prevention. For making decisions and policy creation, the capacity to autonomously and accurately classify different kinds of land cover at the patch levels is crucial. In this environment, deep learning architectures, which can handle massive datasets and provide real-time data, are emerging as an innovative technology. The necessity for large amounts of labeled information for training, the ability to interpret of models, and the computing resources necessary for deep network training are still issues. However, the large amount of research in this area shows the enormous potential of deep

learning architectures in enhancing the ability to categorizing land cover and addressing important problems with land cover and land use assessment.

The comprehensive extraction of multiscale timing dependency used in the land-cover categorization with time-series data remote sensing images emphasizes the growing significance of using temporal data in land cover assessment. Conventional land-cover categorization frequently employs images from a single date, which could not accurately represent how quickly land cover varies. On the other hand, time-series imagery from satellites, which are often collected over a long period of time, provide an extensive amount of information for comprehending land cover dynamics. Multiscale timing dependency, which takes into account not only the spectrum data but also time-dependent trends and relationships among observations, has been identified by investigators as having potential. Recurrent neural networks and machine learning methods have both been investigated to obtain thorough temporal information that will increase the reliability of land cover categorization. The results of these investigations show the benefits of using time-series information in land cover research, allowing for more accurate monitoring of modifications to land cover, urbanization, agricultural methods, and environmental alterations. The requirement for more study in this field is highlighted by the fact that there are still issues with data pre-processing, handling cloud cover, and dealing with the computing needs of analyzing large time-series datasets [21].

An integrated strategy that combines nature-inspired optimization approaches with modern deep learning methodologies to improve the accuracy of land cover categorization is reflected in the most effective orientation whale optimization algorithm and hybrid deep learning systems for land cover and use categorization. Due to the increasing accessibility of remote sensing information as well as computer resources, conventional land use land cover categorization methods have experienced substantial improvements. A potential optimization method for adjusting the hyperparameters of deep learning systems is the optimum guiding whale optimization algorithm, an extension of the whale optimization algorithm. This algorithm demonstrates increased convergence and optimization characteristics and is motivated by the social behaviour of humpback whales. This method uses spatial as well as temporal data from satellite images in combination with deep learning networks to accomplish accurate LULC categorization. The also highlights the significance of precise LULC categorization in several applications, such as urban planning, environmental surveillance, disaster preparation, and agriculture. Deep learning networks and the best guide whale optimization technique are used to solve the problem of improving complicated models while taking into account the special properties of remote sensing information. There continue to be issues with modelling interpretability, algorithm integration, and the requirement for a large amount of labeled training information. However, this method offers an innovative research area with the possibility of substantially enhance the accuracy and effectiveness of LULC categorization, which would be advantageous to many fields that depend on land cover data for making decisions and policy development [22].

The previously mentioned investigations pertaining to the classification of land use and cover highlight the growing need of using a wide range of remote sensing technologies and sophisticated methodologies to improve the ability to precisely and effectively evaluate the dynamics of land cover. These approaches have demonstrated an enormous amount of potential in terms of their ability to offer comprehensive data on alterations in land use and cover. The effectiveness of these methodologies in documenting changes in land cover and land use through time, for example, has been shown by studies undertaken in places like Peshawar, Southern New Caledonia, and human-induced mangrove forest areas in Bangladesh. Through the utilization of remote sensing technology, researchers have been able to get broad coverage, track alterations in land cover classes, and evaluate the effects of deforestation, urbanization, and aquaculture growth on diverse ecosystems. These methods have great potential to handle modern issues like catastrophe preparedness, urban planning, environmental protection, and agricultural management, where precise land cover data is essential. However, there are several difficulties and disadvantages with these intriguing approaches. The significant need for labeled training information which can be labour-intensive and time-consuming to obtain, particularly for extensive land cover mapping projects is one of the main obstacles. Furthermore, because they might affect the precision and dependability of classification results, the reliability and interpretability of information from remote sensing remain to be a cause for concern. Large time-series dataset management and analysis can provide logistical and technological difficulties. In order to fully realize the potential of these techniques and assure their successful implementation in real-world scenarios where accurate and timely land cover information is critical for well-informed decision-making and efficient resource management it must be essential that these obstacles be addressed.

III. PROBLEM STATEMENT

From the above literature review it is observed that the most important tasks in environmental monitoring, urban planning, and natural resource management is classifying land cover and land use utilizing satellite information. A critical component of decision-making processes is the correct categorization of land cover kinds, such as forests, urban areas, agricultural fields, and water bodies. The complexity and size of current satellite imaging information is frequently excessive for conventional strategies for land cover and land use categorization to manage [23]. This study suggests a unique method for addressing the issue by fusing the strength of hybrid HPSO and ACO with CNN for land use and land cover categorization. The goal is to create a categorization system that is accurate and effective, capable of autonomously analyzing satellite images and categorizing different types of land cover. By combining PSO and ACO with human input, the optimization procedure is regulated by human knowledge. By combining domain-specific expertise, this "human in the loop" method can produce superior outcomes.

IV. PROPOSED HPSO-ACO-CNN

Data gathering, pre-processing, feature selection utilizing a human group based PSO algorithm, and CNN hyper parameter optimization employing ACO constituted the approach used in this study. The process of gathering data includes building the EuroSAT dataset, which consists of 27,000 annotated Sentinel-2 satellite photos representing ten distinct land use and land cover classifications over 13 spectral bands. After data collection, normalization and histogram equalization were used in image pre-processing to improve the quality of the images. PSO was used in feature selection to intelligently identify pertinent spectral bands, while ACO was used to optimize CNN hyperparameters which includes batch size and learning rate. The CNN model, created for LULC categorization, completed training, and optimization was made possible by ACO-DL, a modification of ACO that allows for simultaneous optimization of several parameters. This hybrid approach provides a comprehensive approach integrating optimization approaches with deep learning for efficient satellite image processing. Its goal is to increase LULC categorization accuracy. Fig. 1 shows the overall structure of the proposed framework.

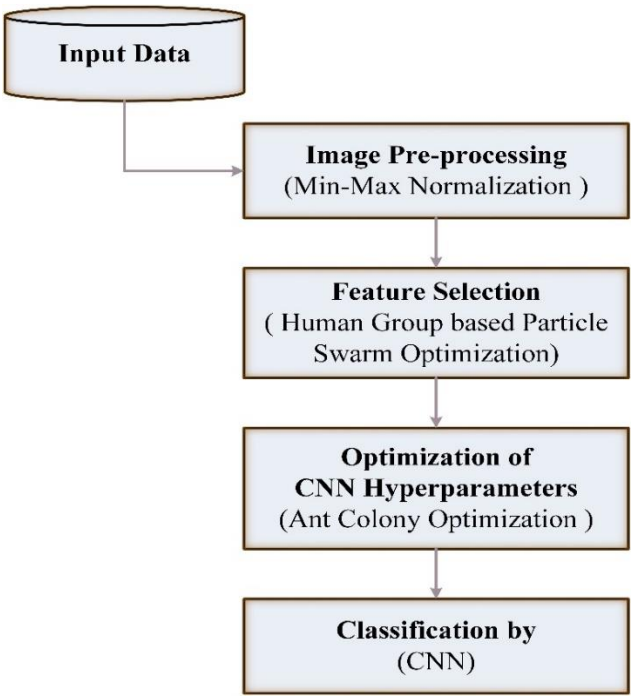

Fig. 1. Overall structure of the proposed framework.

A. Data Collection

The study presents an innovative set of satellite images for the categorization of land cover and land use. The Sentinel-2 satellite imagery that constitute up the 27,000 annotated images that constitute up the provided EuroSAT dataset depend on an overall of 10 distinct classifications. The patches are 64 by 64 pixels in size. The European Urban Atlas cities were chosen for the study's satellite images1. The given satellite image dataset, which includes thirteen spectral bands and has a significant amount of two thousand to three thousand image patches per class, differs significantly from earlier datasets in that it enables the investigation of multimodal fusion strategies in the overall setting of these bands. If deep neural networks need to be used for categorization, this is a particularly challenging problem. The offered dataset additionally depends on publicly available Earth observation information, opening up a variety of novel real-world applications. In accordance with the coverage in the European Urban Atlas, the areas included in the dataset were collected from cities distributed over thirty different European nations. Additionally, each individual picture patch's geoformation is made accessible to the public together with the labeled dataset EuroSAT. In order to obtain as much variation from the covered land cover and land use classifications as feasible, the study also extracted images taken throughout the year [24][1].

B. Image Pre-processing using Min-Max Normalization

To improve the quality of the satellite images, normalization and histogram equalization techniques are used after data collection. By altering the range of pixel values, a process known as image normalization, or contrast stretching, one may enhance the visually appealing qualities of satellite-image collection. (1) is a well-known simple formula that expresses the typical scenario of a min-max normalization to generate an additional image spanning from 0 to 1.

$$H_{out} = (H_{in} - Min)\frac{newMax - newMin}{Max - Min} + newMin \qquad (1)$$

Where the original satellite image is denoted as H_{in}, the minimum and maximum intensity values, which range from 0 to 255, are represented as Min and Max, respectively, the image after min-max normalization is denoted as H_{out}, and the new minimum and maximum values are denoted as $NewMin$ and $newMax$. The histogram equalization approach is then applied to enhance the image quality without eliminating any of the image's borders, patches, or points. The histogram equalization approach adjusts the normalized images' mean brightness to the allowable range's midpoint, while maintaining the original brightness prevents intrusive artifacts from appearing in the images.

C. Feature Selection using Human Group-based Particle Swarm Optimization

In this work, feature selection is done using Human Group-based Particle Swarm Optimization, which has the distinct benefit of simulating human cognitive capacities in optimization problems. By adding a human-guided component, HPSO improves upon the communal intelligence of particle swarm optimization, in which particles stand in for potential subsets of characteristics. The feature selection process is guided by heuristics and important domain experience provided by this human-in-the-loop technique, which increases its efficiency and context awareness. HPSO assures the selection of the most important characteristics while minimizing computational overhead by fusing human understanding with the computational power of PSO. This method is especially well-suited for difficult tasks like satellite image processing where domain knowledge is essential for precise feature selection. It improves the quality of selected

[1]https://ieeexplore.ieee.org/abstract/document/8736785/

characteristics, which in turn improves the efficiency of deep learning models like Convolutional Neural Networks. After generating the characteristic vectors, characteristics are chosen employing the human group-based PSO method. PSO is a population-based searching algorithm that usually simulates bird behaviour. In Eq. (2), is employed to modify the particle's position p_j and velocity v_j in order to produce new locations for each particle.

$$v_j(m+1) = w \times v_j(m) + h_1 \times d_1 \times \left(la_j(m) - p_j(m)\right) + h_2 \times d_2 \times \left(ga_j(m) - p_j(m)\right)$$

$$p_j(m+1) = p_j(m) + v_j(m+1) \quad (2)$$

where, m stands for the number of iterations, h_1 and h_2 are expressed as random real integers between [0, 1], w is a representation for the acceleration weight, a_j is a symbol for the best position, $la_j(m)$is a symbol for the local best position, and $ga_j(m)$ is a symbol for the global optimal position of the particle. In PSO, an adaptable uniform mutation is used to increase convergence and simplify implementation after the HGO method has been used to initially affect the particles.

A discrete multi-label is first converted into a continuous label using HGO. The employed approach locates the obtained feature vectors in accordance with decisionc_j, where the vectors of the particle's location are supplied as $p_j(m) = \left(p_j, 1, p_j, 2, p_j, C\right)$.

The feature selection algorithm's capacity for exploration is improved by the adaptive uniform mutation. The variety and choice of the mutation on each particle, p_j in this operator are controlled by a nonlinear functionp_n. Eq. (3) is used to update $p_n$at each cycle.

$$\mathrm{p_n} = 0.5 \times \mathrm{e}^{\left(-10 \times \frac{\mathrm{m}}{\mathrm{M}}\right)} + 0 \quad (3)$$

Where, m represents the number of iterations, M is designated as the maximum iteration, and the $p_n$value tends to fall as the number of iterations rises. If the $p_n$value is greater than the random number between [0, 1], the mutation selects the s elements at random from the particle. The mutation value of the items contained in the search space is then reset, with s serving as an integer value that limits the mutation range. Eq. (4) mathematically denotes the value of s as:

$$s = max\{1, |C \times p_n|\} \quad (4)$$

The following describes the human group-based PSO algorithm's step-by-step procedure.

Step 1: Establish the particle swarm's initial parameters, including (a) the number of iterations M, the swarm size T_k , and the archive size T_b. A non-dominated solution is saved into the archive after steps (b) initialize the particle locations, (c) estimate the aim of each particle, and do so.

Step 2: The particular best position of the particles is updated using the Pareto dominance relationship. The particular best position of the particles continues to remain unaltered if the new position $p_j(m+1)$ is superior to the previous personal best position$la_j(m)$, set$la_j(m+1) = p_j(m+1)$, where a_j is shown as the best position and $la_j(m)$ is shown as the local best position.

Step 3: Choose the global finest position from the archives according to the variety of solutions. To choose the particle's global optimal position$ga_j(m)$, a binary tournament is employed after initially calculating the crowding distance value.

Step 4: The decision value c_j is then initialized depending on$ga_j(m)$. The feature vector c's decision c_j is each a binary value$c_j = \pm 1, j = 1,2, \dots, T$. Each characteristic vector c is associated to the fitness value V(c), which is thought of as the weighted average of T stochastic contributions$W_i\left(c_i, c_1^i, \dots, c_k^i\right)$. However, the significance of decisions $c_j^i, j = 1,2, \dots, K$ and other K selections affects their contributions.

Eq. (5) mathematically illustrates the fitness function.

$$V(c) = \frac{1}{T}\sum_{i=1}^{T} W_i\left(c_i, c_1^i, c_2^i, \dots, c_k^i\right) \quad (5)$$

The total quantity of variables that interact decision values is denoted by the integer index$K = 0,1,2, \dots T-1$. The parameter$P \in [0,1]$, which represents the probability that each member has been informed of their contribution to the decision, determines the knowledge level of the $n^{th} n^{th}$ member. Each member n determines their individual estimated fitness utilizing (6) depending on their degree of knowledge.

$$V_n(c) = \frac{\sum_{i=1}^{T} \breve{c_{ni}} W_i\left(c_i, c_1^i, c_2^i, \dots, c_k^i\right)}{\sum_{i=1}^{T} \breve{c_{ni}}} \quad (6)$$

where, $\breve{c}$ is referred to as the matrix, whose generic member c_{ni} examines the numerical value one with probabilities (P and 0) with probabilities (1-P).

Step 5: Eq. (7) is employed to modify the particle's location $p_j$and velocity c_j in accordance with the decision valuec_j.

$$v_j(m+1) = w \times v_j(m) + h_1 \times d_1 \times \left(la_j(m) - p_j(m)\right) + h_2 \times d_2 \times \left(ga_j(m) - p_j(m)\right) \quad (7)$$

$$p_j(m+1) = p_j(m) + v_j(m+1) \quad (8)$$

Step 6: Apply Eq. (7) and Eq. (8) to uniform mutation.

Step 7: Utilizing the crowding distance approach, upgrade the external archives.

Step 8: Examine the termination circumstance: if the proposed algorithm completes the maximum number of iterations, the process should be terminated; otherwise, move back to phase 2. The HGO algorithm's fitness function $V_n(c)$ is used to remove the most deficient particles.

D. Optimizing CNN Hyperparameters using Ant Colony Optimization Strategy

The study utilizes Ant Colony Optimization to optimize numerous parameters simultaneously, which makes it a suitable method for fine-tuning Convolutional Neural Network hyperparameters. ACO is an optimization method that draws

inspiration from nature and is particularly efficient at navigating intricate search spaces. As such, it may be used to determine the best possible combination of hyperparameters for deep learning models. Its benefit is that it can investigate a large variety of hyperparameter values and adaptively modify them while optimizing. When working with hyperparameters, ACO's probabilistic method is extremely beneficial since it resembles how actual ants choose the shortest path in their natural environment. This method facilitates effective parameter space exploration and exploitation. This work uses the effectiveness of ACO to achieve optimal generalization, decreased overfitting risk, and enhanced CNN performance. As a result, it provides a reliable method for improving the model's accuracy in applications like satellite image categorization. ACO, developed by Marco Dorigo in 1992, is a standard heuristic swarm intelligence program that uses probabilistic calculations to identify the best planning pathway. ACO is a system based on positive feedback in which the ant finally chooses the path with the highest pheromone concentrations in order to obtain the best outcome possible in terms of the regulatory mechanisms.

The Convolutional Neural Network utilized in this study's Deep Learning framework was optimized using ACO. The study also altered the conventional ACO by using multitype ants to simultaneously improve different variables. The total quantity of ant varieties in ACO-DL is equal to the number of characteristics that need to be optimized. As a result, ACO-DL was able to optimize simultaneously a number of parameters related to the model in order to produce the best possible answer to the function of objective. The number of batches (A) in the network and the starting learning rate (L) in Adam were optimized for the CNN framework using ACO. The objective function (F (A, L)) selected was an accurate rate of predictions. Additionally, a given interval's values for A and L were determined in Eq. (9) and Eq. (10).

$$F_{max}(A, L) \tag{9}$$

$$k.t.\begin{cases} A \in [A_{min}, A_{max}] \\ L \in [L_{min}, L_{max}] \end{cases} \tag{10}$$

The fundamental concept is to iteratively discover the shortest path to the best solution of the goal function. In the meantime, the study established the subsequent two termination standards in order to ensure the efficiency of the optimization algorithm: 1) No apparent increase in accuracy; 2) the maximum number of repeats.

E. Classification Using Convolutional Neural Network

The CNN is the most efficient and productive approach network among deep learning techniques. Because CNNs can categorize intricate contextual images, they are widely used to categorize remote sensing data. Usually, these methods are not required for completing an output image prediction. CNNs are feed-forward neural structures that employ substantially local correlations to produce judgements by imposing an immediate interaction arrangement between neurons in neighbouring segments of the system. A maximal layer of pooling, the network layer, numerous convolutional layers, and fully linked layers constitute their architecture. Every stage of convolution calculates the weighted average of the prior characteristic using a channel before sending its findings via a stimulation functions to obtain the outcome. Using this method, the kernel measurement is computed to find neighbourhood correlations while preserving consistency for each region throughout the data clusters. The final characteristic pattern is created using constants at the lowest attainable unit level. The many levels of convolutional or layers of pooling are finally interfaced into a coherent unit using a fully coupled network of neurons. Eq. (11) and Eq. (12) gives the convolution operation.

$$fm_n^q(u, v) = UU_{\substack{id(x,y)e_n^q(w,t) \\ d \quad x,y}} \tag{11}$$

$$F_n^q = \left[fm_n^q(1,1), \ldots, fm_n^q(u, v), \ldots, fm_n^q(U, V)\right] \tag{12}$$

Following the extraction of the characteristics, a down sampling or pooling process is employed to gather the intersection of characteristics that are resistant to moderate transverse changes and deformation. It is given in Eq. (13).

$$R_n^q = s_r\left(F_n^q\right) \tag{13}$$

Similar to this, R_n^q stands for the Qth input feature-map's pooling characteristics-map of the mth layer, and s_r stands for the pooling operation. The maximum, average, L2, overlapping, and spatial pyramid pooling formulae are used in CNN. An activation function is used to speed up learning and offer a method of decision-making for a complicated feature-map. Both the non-linearity of the characteristics and the accelerated learning rate are provided by these activation functions. ReLu, sigmoid, tanh, maxout, and SWISH activation functions all have the same capability for supplying nonlinearity and resolving the vanishing gradient issue.

$$t_n^q = S_x\left(F_n^q\right) \tag{14}$$

S_x stands for the activation function in Eq. (14), F_n^q for the convolution output, and t_n^q for the converted output.

The two main decisions regarding design for CNN that offer superior efficiency and eliminate the overfitting issue are training and optimization. The number of extra problems for training the information generally grows along with the volume of information. The framework has difficulties when a novel or unfamiliar dataset is presented. Overfitting is a result of this issue, which dropout and batch normalization can solve. The dropout mechanism is employed to disable a large number of nodes at the conclusion of each cycle of the training phase. To enhance entire accuracy, strengthen the system's resistance to overfitting, and quicken the gradient descent process' convergence, batch normalization aims to impose a zero mean and a one standard deviation across every activation function in the established layer and for every single inadequate batch. The fully connected layer, the last component of the CNN framework as depicted in Fig. 2, combines every component with an additional layer to categorize. It gathers data from the characteristic extraction phase and analyses the output from every step before it. As a consequence, data categorization is accomplished by nonlinearly linking a set of chosen characteristics.

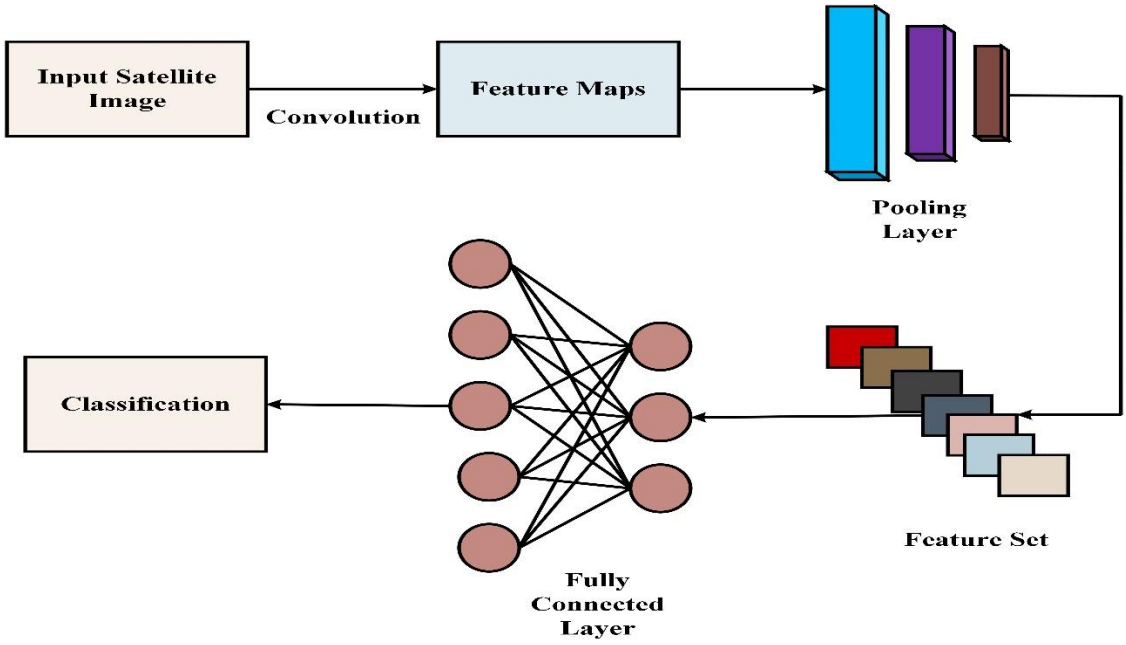

Fig. 2. CNN model.

V. Results and Discussion

The study first acquired a special EuroSAT dataset made up of twenty-seven thousand annotated satellite images from Sentinel-2 that included thirteen spectral bands and ten different land cover and land use classifications. To improve the quality and usability of these images for subsequent evaluation, necessary pre-processing techniques such as normalization and histogram equalization were used. The main contribution of this research is the combination of CNNs and PSO and ACO optimization approaches to enhance the accuracy of land cover and land use categorization. PSO was utilized to effectively choose the most pertinent spectral bands, decreasing data noise and redundancies. ACO significantly improved crucial CNN hyperparameters including batch size and learning rate, which improved the efficiency of the framework as a whole. On the EuroSAT dataset, the study assessed the hybrid PSO-ACO-CNN architecture and contrasted its performance with that of conventional categorization techniques and independent CNN models.

A. Performance Evaluation

To evaluate the success of categorization, assessment indicators are crucial. The method most frequently used for this objective is an estimation of precision. A classifier's accuracy for any particular set of data may be assessed by the proportion of test datasets that it properly classifies. Because making the optimal decisions will not be possible if the accuracy metric is used alone. To evaluate the performance of the classifier, researchers additionally employed other factors. Accuracy, recall, precision, and F1-score measures were used to evaluate the performance of the suggested technique. The following is a description of each measure's definitions:

T_{pos} (True Positive) refers to the amount of information that has been correctly categorized.

The term $Fpos$ (False Positive) represents the volume of reliable information that was incorrectly categorized.

False negatives (F_{neg}) are instances where incorrect information has been given an actual classification.

The categorization of incorrect information values is referred to as T_{neg} (True Negative).

The classifier's accuracy displays how frequently it makes the right assumption. The ratio of accurate forecasts to all other credible hypotheses is known as accuracy. It is demonstrated by Eq. (15).

$$Accuracy = \frac{T_{pos}+T_{neg}}{T_{pos}+T_{neg}+F_{pos}+F_{neg}} \quad (15)$$

The amount of correctly classified outcomes is determined by calculating the precision, or level of accuracy, of a classifier. Reduced false positives are the result of improved accuracy, whereas many more are the result of decreased precision. The percentage of instances that are correctly categorized compared to all occurrences is the definition of precision. It is defined by Eq. (16).

$$P = \frac{Tpos}{Tpos+Fpos} \quad (16)$$

The sensitivity of a categorization, or how much relevant information it produces, are determined by recall. The overall quantity of F_{neg} reduces with improved recall. Recall is the ratio of cases that have been correctly categorized to all of the predicted occurrences. This is demonstrable by Eq. (17).

$$R = \frac{Tpos}{Tpos+Fneg} \quad (17)$$

The combination of metrics known as F-measure, which reflects the weighted mean of recall and accuracy, are obtained by adding precision and recall. It is characterised by Eq. (18).

$$F1 - score = \frac{2 \times precision \times recall}{precision \times recall} \quad (18)$$

Area under the ROC Curve, or AUC, is a well-known evaluation metric for binary classification problems in deep learning and machine learning. The area under the receiver operating characteristic (ROC) curve, which is a graphic representation of the binary identification algorithm's efficacy, is evaluated by the area under the curve (AOC). The classifier in a binary classified problem tries to figure out whether the input information belongs to a positive or negative division. The $Tpos$ vs. the $F_{pos}$is shown on the ROC curve for various classification criteria. AOC values range from 0 to 1, with higher numbers denoting more efficiency. An absolutely randomized classifier has an AOC of 0.5, whereas an optimal classifier has an AOC of one. Because the method considers all possible degree of detection and provides a single number to compare the performance of different classifiers.

A deep learning model's training and testing accuracy score over a number of training epochs are summarized in Fig. 3. Every row displays the associated training accuracy and testing accuracy for an epoch number that ranges from 10 to 100. Testing accuracy assesses the model's effectiveness on new or validation information, whereas training accuracy shows how effectively the model is effective on the training information it was shown during training. Both training and testing accuracy often increase as the number of training epoch's rises, suggesting that the framework is learning from the information and getting more proficient in generating predictions. The model attains exceptionally accurate levels on both the training and testing datasets by the end of 100 epochs, indicating that it has acquired the ability to generalize to new, unanticipated information successfully. The graph shows the growth of the model's effectiveness as it goes through training.

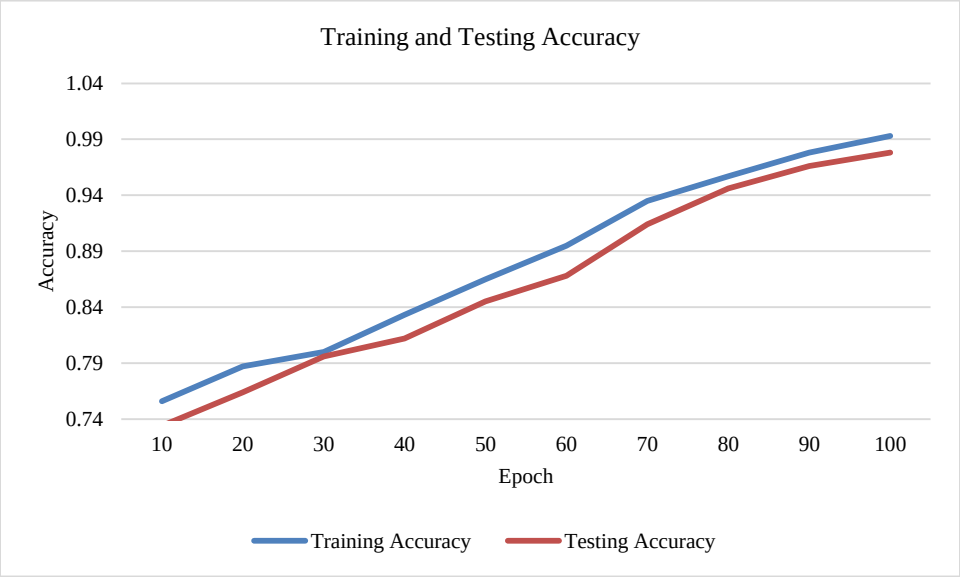

Fig. 3. Training and testing accuracy.

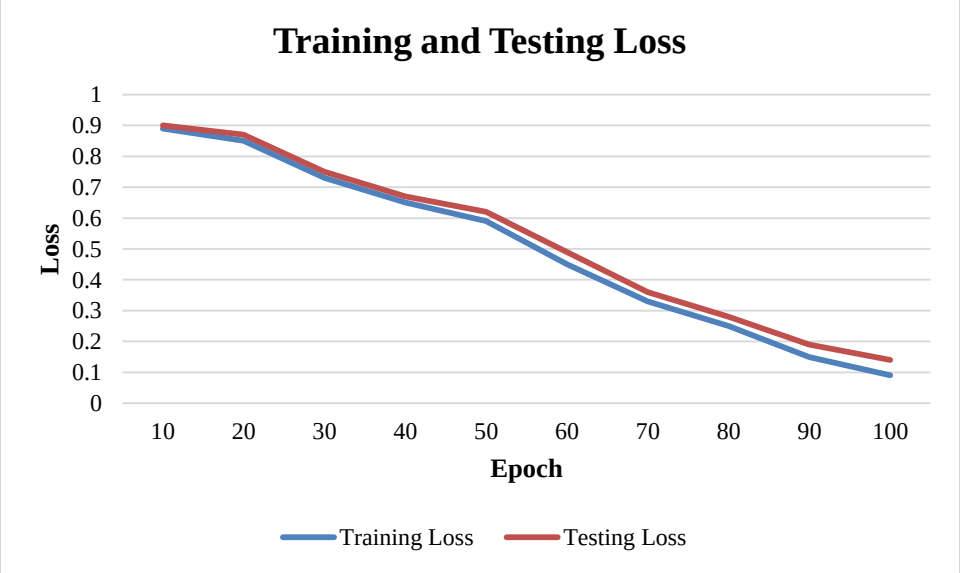

Fig. 4. Training and testing loss.

The testing and training loss values for a deep learning model throughout a variety of training epochs are shown in Fig. 4. The testing loss and the training loss are shown in each row, which is associated with an individual epoch number between 10 and 100. Testing loss evaluates the model's effectiveness on observed or validation information, where usually lower values indicate higher generalization. Training loss examines how well the model fits the training information, with lower values suggesting a better fit. This graph shows that both training and testing loss constantly reduce as the number of training epochs rises. The pattern indicates that if the model is trained, it becomes better at reducing errors and making predictions that are more accurate. The model's decreasing loss values show how it learns, and the lowest losses after 100 iterations show that the model has successfully converged and is capable of making accurate projections on both the training and testing datasets.

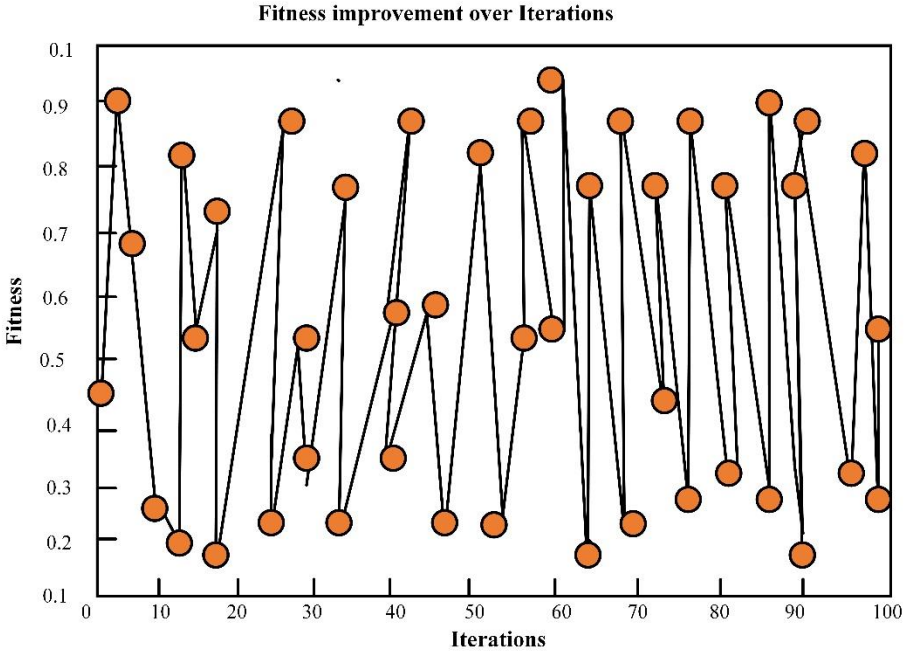

Fig. 5. Fitness improvement over iteration.

The development of an optimization algorithm—specifically, Ant Colony Optimization—over a number of iterations is seen in Fig. 5. The y-axis shows the fitness of the algorithm's created solutions, while the x-axis shows the quantity of iterations or generations. In ACO, fitness often refers to how well or effectively a solution addresses the issue at hand. The algorithm continually updates and improves its solutions to increase their fitness as it moves through iterations. As a result, the graph depicts how the solutions' fitness changes over time and, ideally, converges to an optimum or substantially optimal solution. Any levelling out or stability in the graph's later iterations denotes that the algorithm has probably achieved an optimal solution or a point of decreasing effectiveness. The sharp decrease or large loss in fitness towards the beginning of the graph's iterations signals rapid improvement. This illustration assists in evaluating the algorithm's rate of convergence and potency in locating superior solutions to the current optimization challenge.

The performance metrics of the HPSO-ACO-CNN hybrid deep learning model are summarized in Fig. 6. In order to evaluate the model's performance in a classification position, it offers important assessment metrics. The "Accuracy" statistic measures the model's overall accuracy in making predictions, and a high result of 99.3% shows that the model performs well in terms of categorization. "Recall" (98.7%) assesses the model's capability to properly recognize every single positive example, while "Precision" (99.2%) measures the model's capacity to correctly categorize positive cases. Precision and recall are combined into one score called the "F1-Score" (98.7%), which takes into account the trade-off between both. The HPSO-ACO-CNN model is very accurate and dependable in its categorization task, with an especially strong capacity to categorize positive situations properly while retaining a high overall accuracy level, according to these high values across all metrics.
