Telemedicine has a wide range of applications that are transforming the way healthcare services are accessed and delivered worldwide. Remote consultations, telerehabilitation, remote monitoring, mental health services, tele palliative care, teledermoscopy services, and teleneurology are examples of telemedicine applications that were covered and analyzed in the included studies. Among the included studies, a total of 5 studies focused on telemedicine services in general [13], [28]–[31], and the other 5 studies on telemonitoring [32]–[36]. A total of 3 studies were dedicated to remote mental health services - Telepsychotherapy [37]–[39], while 4 studies centered around telerehabilitation [40], [41], and tele palliative care [42], [43], each with 2 studies. The remaining studies were designed for teleneurology [44], teledermoscopy [45], teleconsultations [46], and group-based telemedicine [47], each with one study. Telemedicine is reshaping the landscape of healthcare, with a diverse array of applications that have been examined in recent studies.

Each application of telemedicine has its own factors that may influence its users' intentions, whether for the patient or provider. According to the analysis of the studies [13], [32]–[34], [39], [43], [45], [47], the most important factors shared by most studies of telemedicine applications are perceived usefulness and ease of use, which are key determinants of users' attitudes and behavioral intentions for the TAM model. This indicates that telemedicine applications that are easy to understand and bring desired benefits as needed have a higher chance of influencing user behavior to adopt the applications [13], [28], [35].

Other significant factors repeated in most studies are social influence and facilitating conditions from the UTAUT model. The literature highlighted that social influence is a significant predictor because the opinions of colleagues for providers and family or friends of patients strongly influence user behavior. Additionally, the availability of technological and organizational support shows a positive connection with usefulness and ease to use the technology [48], [49], thus, it has a better chance of influencing user behavior to adopt telemedicine. For an overview of the factors affecting each telemedicine application among healthcare providers and patients, see Appendix 4.

C. Overview of Telemedicine Adoption Factors

Telemedicine adoption is influenced by numerous factors, which are rooted in various theoretical frameworks to adopt the technology. Although some factors are synonyms to each other for example, insecure and perceived risk, it has been classified and counted its frequencies based on the identical general terminology (have the same meaning with different terms). These factors have been categorized into 5 groups, adapted

TABLE IV. MOST IMPORTANT EXTRACTED DATA FOR THE INCLUDED STUDIES

Study	Year	Country	Data collection method	Theory/Model	Constructs
Patient					
[28]	2020	KSA	survey	UTAUT, TTF	Awareness, Self-efficacy, Performance Expectancy, Effort Expectancy, Social Influence, Facilitating Condition, TTF
[37]	2022	USA	survey	UTAUT, TAM3, TPB	Performance Expectancy, Effort Expectancy, Social Influence, Facilitating Condition, Anxiety, Attitude
[29]	2021	China	survey	-	Trust the sponsor of a healthcare website, Gender, Age, Educational level, City Income level, Consumer type
[45]	2016	Australia	survey	TAM, TRA, DOI, UTAUT	Perceived Usefulness, Ease of Use, Trust, Attitude/intention, Subjective Norm, Compatibility, Facilitator
[40]	2019	Netherlands	interview	UTAU	Performance Expectancy, Effort Expectancy, Social Influence, Facilitating Condition
[30]	2023	India	survey	Push-Pull Mooring(PPM), HBM,UTAUT2	Push Effects (Inconvenience and Perceived Healthcare Risk), Pull Effects (Opportunity for alternatives and Ubiquitous care) , Mooring effects (Trust in telemedicine) , Inertia (Habit, Switching Cost).
[46]	2023	Germany	survey	UTAU, External variables	Performance Expectancy, Effort Expectancy, Social Influence, Computer Proficiency, Knowledge about digital health care solutions (Awareness), Depressive symptoms.
[33]	2023	USA	survey	TAM	Perceived Usefulness, Ease of Use.
[47]	2019	USA	mixed method	TRAM, External variables	Perceived Usefulness, Ease of Use, Innovativeness, Optimism, Discomfort, Insecurity, Group readiness, HIV-related privacy concerns.
[34]	2019	USA	interview	FITT, UTAUT2,TAM, TAM3	Fit between individuals and task: (Motivation/ Engagement, Self-efficacy) Fit between individuals and technology: (Preference for device design, HIV status, Customized alert ,Ease of use) Fit between task and technology: (System functionality, Self-awareness).
[35]	2021	France	survey	UTAUT,HBM, UTAUT2	Performance Expectancy, Effort Expectancy, Social Influence, Facilitating Condition, Perceived risk, Financial cost
[36]	2021	Not mentioned	survey	TAM, TPB, TAM3,HBM	Interpersonal Influence, Personal Innovativeness, Trustworthiness,Attitude ,Self-efficacy, Health Interest ,Perceived Value.
Healthcare Provider					
[32]	2021	Australia	survey	TAM, TPB	Perceived Usefulness, Ease of Use, Attitude.
[39]	2013	Canada	survey	TAM, TPB	Perceived Usefulness, Ease of Use, Attitude.
[38]	2020	Germany	Interview/focus group	DOI, External variables	Perceived benefit, Avaliability of designed room.
[42]	2022	Netherlands	survey	UTAUT,TPB,TAM3,DOI	Outcome expectancy, Effort expectancy, Facilitating Condition,Social Influence, Attitude, Anxiety, Self-efficacy,Personal Innovativeness.
[41]	2020	Australia	interview	TAM,HBM,External variables	Context of use,Perceived Benefits,Technical and connectivity issues Client capability and compatibility,Lack of physical presence,Balancing the service and user needs.
[31]	2017	China	survey	-	Authenticity and reliability of data, Awareness, Previous experience.
[44]	2022	Philippine	survey	UTAUT, TPB	Performance Expectancy, Effort Expectancy, Social Influence, Facilitating Conditions, Attitude.
[13]	2014	Malaysia	survey	UTAUT, TAM, TPB,TAM3, External variables	Perceived Usefulness, Perceived Ease of Use, Attitude, Self-efficacy, Organizational Culture, Facilitating Conditions.
[43]	2020	Canada	interview	TAM	Perceived Usefulness, Perceived Ease of Use.

from [27], to study the adoption of telemedicine among healthcare providers and patients. These categories include individual factors, organizational factors, technological factors, security factors, and health factors. The following sections will discuss the factors of each category separately. Fig. 4 shows the factors influencing healthcare providers and patients based on the aforementioned classifications. The results show that, individual factors play a vital role in the successful adoption of telemedicine for both providers and patients as it occupied around half of the percentages among other factors. Additionally, technological, and organizational factors are considered more important for providers than patients.

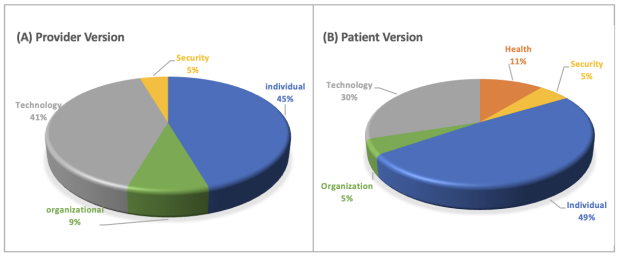

Fig. 4. Classify factors affecting the adoption of telemedicine from **(A)** provider's perspective. **(B)** patient's perspective.

1) Individual Factors: As a definition, individual factors refer to the personal attributes, beliefs, attitudes, and characteristics of an individual that influence their decision to accept, adopt, or resist the use of new technology [50]. Individual factors for telemedicine adoption represented 45% for providers and around half for patients. Fig. 5 summarizes the individual factors and analyzes their frequencies based on the number of using them in the included studies from both providers' and patients' perspectives. The findings of the analysis showed that social influence is the most important factor influencing patients which was repeated 6 times [28], [35], [37], [40], [45], [46]. The second most important factor is attitude, which was repeated 3 times [36], [37], [45], followed by personal innovativeness [36], [47], self-efficacy [34], [36], awareness [28], [46], and habit [30], [40], each of which was repeated 2 times. Furthermore, the remaining set of factors include group readiness [47], optimism [47], motivation, engagement [34], compatibility [45], and other demographic characteristics such as age, gender [29], [35], computer skills, education, and socioeconomic status [29], [34], [46], each of which was mentioned only once. Finally, the lack of control of technology was mentioned in one study as a barrier [47].

Contradictory to that, the most important factor influencing providers is the attitude which was mentioned 5 times [13], [32], [39], [42], [44]. Other important factors were repeated 2 times including social influence [42], [44], self-efficacy [13], [42], and experience [31], [44]. Additionally, personal innovativeness [42], awareness [31], voluntariness [44], and client capabilities [41] factors were mentioned one time for each as a success predictor. However, anxiety [42] and lack of physical presence [41] were reported once for each as barriers.In summary, the analysis of individual factors affecting telemedicine adoption reveals that social influence and attitude are key drivers for patients, while providers are primarily influenced by their attitude.

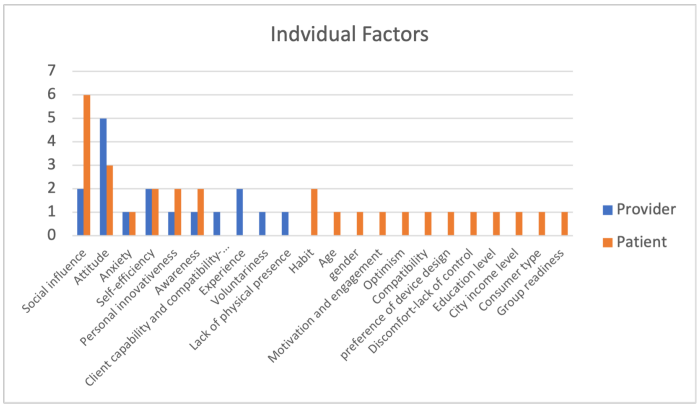

Fig. 5. Individual factors that influence the adoption of telemedicine for providers and patients.

2) Organizational Factors: Organizational factors refer to the various aspects and characteristics within healthcare institutions that influence the overall organization's operations, performance, efficiency, and quality of care provided. These characteristics including as examples infrastructure, resource allocation, and training programs [51].The review showed that the facilitating conditions factor is the significant facilitator for adopting telemedicine where it was repeated in the included studies 3 times for providers [13], [42], [44] and 5 times for patients [28], [35], [37], [40], [45]. Government policy, top management support, project team capacity, and external suppliers' capacity are examples of the facilitators mentioned in the included studies from the providers' perspective whereas technical and connectivity issues were mentioned as barriers for patients.

Another important factor for patients was the type of the hospital which was mentioned once [29]. On the other hand, the organizational culture factor influences providers' intention to adopt telemedicine and it was mentioned once in the included studies [13]. It is noteworthy that, the culture and values within an organization can either facilitate or hinder technology adoption and that rely on reinforcement of the top management of the organization and its policies to the adaptability, change, and support the innovation through the use of technology [13], [52]. Additionally, the findings of one study confirmed that patients tend to trust public hospitals more than private ones, thus affecting their intention to adopt telemedicine services provided by these hospitals [29]. In summary, organizational factors including facilitating conditions, government policy, and organizational culture shape the adoption of telemedicine in healthcare institutions.

3) Technological Factors: The technological factors for telemedicine adoption represented 41% for providers and 30% for patients. It refers to the technological components and considerations in the design, implementation, communication infrastructure, and related technologies that enable the delivery of remote healthcare. As shown in Fig. 6, the most common factors for patients were effort expectancy and performance expectancy [28], [35], [37], [40], [46], which were derived from the UTAUT model. They were mentioned in the included studies 5 times each. Other important factors that influenced the patients were perceived usefulness and ease to use [33],

[45], [47] which stem from the TAM model, and they were repeated 3 times for each. Task technology fit (TTF) and cost were also considered factors for patients which were repeated 2 times each. The remaining set of factors was repeated once in the included studies including perceived benefit [36], availability of the service [30], system functionality [34], customizing the functionality of the device [34], and computer proficiency [46].

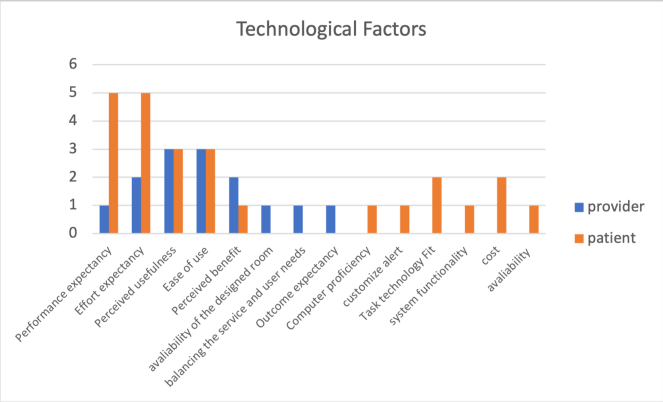

Fig. 6. Technological factors that influence the adoption of telemedicine for providers and patients.

In contrast, the most important factors for providers were perceived usefulness and ease to use which were mentioned 3 times [32], [39], [43]. Indeed, when the providers find telemedicine user-friendly and help them to improve their work with less effort then, they are more likely to integrate telemedicine into their practice and adopt it. Furthermore, other important factors from the providers' perspective were effort expectancy [42], [44] and perceived benefit [38], [41] were mentioned 2 times for each factor. Finally, performance expectancy [44], balancing the service and users' need [41], outcome expectancy [42], and availability of designed room [38] were facilitators that influenced the adoption and they were repeated once for each factor. In discussing the perceived benefits of telemedicine, the literature highlights that it offers a wide range of benefits that positively impact their practice, patient care, and overall healthcare delivery. These benefits contribute to improved efficiency of time and cost, help patients access support, and enhance the quality of care [38], [41], [53]. In summary, the adoption of telemedicine is significantly influenced by various technological factors that differ between providers and patients, with both groups placing a strong emphasis on the ease of use and perceived usefulness.

4) Security Factors: The security factors related to telemedicine adoption represented 5% for each provider and patient. It is defined as the level of protection and assurance that healthcare providers and patients have regarding the confidentiality, integrity, and availability of sensitive information and data transmitted, stored, or accessed during telemedicine interactions [54]. The most important security factor from the providers' perspective is the authenticity and reliability of data from remote patient monitoring, and it serves as a barrier that negatively influences telemedicine adoption [31]. Whereas the patients' behavioral intention was influenced by two factors: perceived trust and perceived risk which were repeated in the included studies four and two times respectively. The perceived trust ranges between privacy [47], trust in general [36], trust in the organization [29] and trust in telemedicine [45]. Moreover, the included studies identify the perceived risk in the context of losing to reach the desired outcome when using technology as it may not work properly [35], [47]. So, all security factors are considered barriers. This is due to the sensitive nature of healthcare data and the potential risks associated with remote communication and data exchange.

5) Health Factors: The factors related to health are likely to influence the behavioral intention of patients just, and it represented 11% among other factors. As it was defined, health factors refer to both the benefits and challenges that telemedicine brings to the healthcare landscape [55]. Health interests, perceived health risks, health conditions, and depressive symptoms are factors identified in the included studies once for each factor. The perceived health risk associated with telemedicine includes risk management, human resource, clinical risk, technology risk, and regulatory issues [30]. With regard to health interests, when individuals have a strong interest in maintaining their health and accessing healthcare services, they are more likely to adopt telemedicine as a convenient and accessible option [36]. Moreover, people with depressive symptoms are more likely to seek for professional treatment as telemedicine gives the option to receive treatment from home thus, adopting and accepting care through telemedicine [46].

IV. Discussion

Studying the behavioral intention of end users to adopt telemedicine has attracted research attention recently. The reasons behind that are the importance of understanding user perspectives, predicting adoption rates, and designing effective strategies to promote telemedicine adoption. By taking users' intentions and preferences into account, healthcare organizations can foster a positive telemedicine experience and maximize the potential benefits of this innovative healthcare delivery method.

The fundamental goal of this review is to summarize the different factors based on various acceptance theories that might influence healthcare providers and patients to adopt telemedicine through different applications. The findings of the review showed that the TAM and UTAUT models are the most important models in adopting and accepting telemedicine. This result is consistent with the study conducted to evaluate the different acceptance models and theories in the healthcare sector [56]. From a user-centered perspective, it has been noticed that the UTAUT model was used more frequently by patients than by providers to explain telemedicine acceptance. This is due to its inclusion of variables associated with social influence, which is likely to be more important for patients than for providers. In contrast, the TAM model was used for investigating the acceptance of providers more than for patients. As it was mentioned earlier, the functional characteristics of the technology to be free of effort and compatible with the desired need are good determinants for adopting telemedicine by users.

Furthermore, it has been found that some studies use a single theoretical model [33], [40], [43], while others use more than one model [13], [28], [32], [34]–[37], [42], [44],

[45]. Although the TAM and UTAUT are the based models in most literature as it was mentioned above, other factors from different models were integrated with them to represent the acceptance in different contexts. TRA, TPB, DOI, HBM, and TTF are the models that were integrated parts of their predictors with the based model. According to Barrettee, it is useful to combine more than one model as each model focuses on different aspects of technology adoption, such as individual perceptions, organizational factors, or external influences. By combining multiple models, researchers can obtain a holistic view of the adoption process, considering various factors that may influence technology acceptance [57].

Another important factor integrated with the base model in 4 studies is perceived trust [29], [30], [36], [45]. It was observed to be essential for patients to accept modern healthcare delivery. Accordingly, healthcare organizations and telemedicine providers must proactively address trust-related concerns and demonstrate a commitment to maintaining the highest standards of security, privacy, and quality care delivery. Building and maintaining trust in telemedicine services are key to establishing a sustainable and patient-centric approach to modern healthcare delivery. One of the most important factors added to the base model in 8 studies [13], [32], [36], [37], [39], [42], [44], [45] is attitude from TPB model. The TPB model suggests that an individual's attitude toward a specific behavior strongly influences their intention to perform that behavior [19]. This implies that a positive attitude toward using telemedicine services is likely to promote its adoption among healthcare providers and patients. So, if individuals believe that telemedicine is eased to use and offers tangible benefits, such as convenience, improved access to care, improve work efficiency, and time savings, they are more likely to have a positive attitude toward its adoption [13], [32].

Additionally, the findings revealed that self-efficacy significantly influences adoption. It refers to an individual's belief in their ability to use technology effectively [36]. As stated by Bandura in his social cognitive theory [58], individuals' behaviors are influenced by their own capabilities to perform a particular task. So, patients with high self-efficacy are more likely to actively engage and accept telemedicine to receive healthcare. Besides that, self-efficacy can influence the healthcare providers' willingness to adopt and integrate telemedicine into their practice, where high self- efficacy makes them feel more confident in their ability to use virtual communication tools, maintain patient engagement, and conduct remote consultations and treatment effectively [42], [59].

The review also explored different key factors that were extensively employed in the included literature with the base models to understand the acceptance including awareness, innovativeness, and habit. According to Chen et al. [31] , users with positive attitudes toward telemedicine reflect their great awareness of service benefits. Consequently, there is a direct relationship between users' awareness and their attitude, and thus their intention toward adopting telemedicine. Moreover, it is has found that innovativeness as a perceived advantage makes healthcare more accessible and efficient for a broader population [42], [47]. As a result, it improves the quality of healthcare delivery and maximizes patient engagement then its adoption. Regarding habit, authors in [30], and [40] indicate that building positive habits around telemedicine usage is crucial for its widespread adoption and long-term success. Consequently, telemedicine can become an established and habitual part of modern healthcare practices by addressing any barriers related to usability, trust, convenience, and positive outcomes.

A. Limitations and Future Research

The review has a few limitations, which gives an opportunity for further research. First, this review used only two databases for retrieving relevant studies. Including more databases could lead to richer results. Additionally, language bias could affect the results, papers not published in English or Arabic language were excluded. Third, the focus of the population in the included studies is for patients and healthcare providers including physicians and nurses. Future studies are encouraged to encompass different sets of the individual such as administrators, and health professionals as it may lead to in-depth knowledge and a full picture of the adoption process.

V. Conclusion

Telemedicine is an evolving field of healthcare that has revolutionized the way patients receive medical attention remotely. This systematic literature review identified the theoretical constructs associated with end-user adoption and acceptance of telemedicine. When reviewing included studies, it is obvious that TAM and UTAUT are the most widely technology acceptance models applied to the telemedicine context. Additionally, the constructs of TAM and UTAUT models were the most deployed factors to evaluate the acceptance and adoption of telemedicine. Adding to that other factors were integrated with the previous constructs including, attitude, self-efficacy, perceived trust, innovativeness, and habit.

Existing studies include various applications of telemedicine. Teleconsultations, telerehabilitation, telemonitoring, telepsychotherapy, tele palliative care, teledermoscopy services, and teleneurology are some examples of applications that are covered in this review. While some factors apply to all applications of telemedicine, others are validated to specific applications. Therefore, understanding the nuanced factors that impact the success of telemedicine in diverse healthcare contexts is crucial for optimizing patient care and healthcare delivery.

The review provided a classification analysis of the factors that influence telemedicine adoption among healthcare providers and patients. These categories include individual, organizational, technological, security, and health factors. In general, it has been noticed that individual factors occupied the largest percentage among other factors for both providers and patients. Social influence and attitude are the most significant factors at the individual level. At the organizational level, facilitating conditions is an essential factor for telemedicine adoption by both parties' providers and patients. Furthermore, perceived usefulness, ease of use, effort expectancy, and performance expectancy are important influencers at the technological level. Besides that, perceived trust was found to be a significant factor at the security level. Finally, at the health level, health interests, perceived health risks, health conditions, and depressive symptoms were identified to influence the patients' intention to adopt telemedicine.

The results of this review can provide insights to policymakers and healthcare organizations on the factors that influence end-user behavioral intention to adopt the modern healthcare delivery method. Understanding these factors is pivotal in crafting effective strategies for the widespread implementation of telemedicine. Moreover, recognizing the unique individual characteristics of end-users, such as their technological proficiency, awareness, and subjective norms, is essential. Tailoring telemedicine initiatives to meet the specific needs of diverse patient populations can significantly enhance the acceptance and utilization of this innovative approach to healthcare delivery. By acknowledging and accommodating these individual differences, healthcare systems can maximize the potential benefits of telemedicine, leading to improved patient outcomes and more efficient healthcare services.

Attention-based Cross-Modality Multiscale Fusion for Multispectral Pedestrian Detection

Zhou Hui
School of Electrical and Information Engineering
TongJi University
Shanghai, China

***Abstract*—Multispectral pedestrian detection has wide applications in fields such as autonomous driving and intelligent surveillance. Mining complementary information between modalities is one of the most effective approaches to improve the performance of multispectral pedestrian detection. However, the inevitable introduction of redundant information between modalities during the fusion process leads to feature degradation. To address this challenge, we propose a multiscale differential fusion algorithm that leverages complementary information between modalities to suppress feature degradation caused by noise propagation along the network. We compare our algorithm with other cross-modal fusion pedestrian detection algorithms on the LLVIP and cleaned KAIST datasets. Experimental results demonstrate that our algorithm outperforms others, particularly in nighttime scenes where our algorithm achieves a 7.28% improvement in recall rate compared to the baseline on the cleaned KAIST dataset.**

***Keywords*—Pedestrian detection; multispectral pedestrian detection; attention mechanism; cross-modal fusion.**

I. Introduction

Pedestrian detection plays an important role in autonomous driving systems. In well-illuminated conditions, pedestrian detection achieves high precision. In poor lighting conditions, the appearance of pedestrians becomes blurred. Obstacles, overlapping figures, and varying distances contribute to these differences. As a result, nighttime pedestrian detection currently faces significant challenges [1].

Many advanced algorithms based on visible light images achieve notable performance improvements. Recent studies involving these images have validated their effectiveness, including in nighttime environments [2]. Due to the poor quality of nighttime visible light images, deep convolutional neural networks struggle to learn effective features. Image enhancement techniques show remarkable performance in enhancing the contrast between the foreground and background of an image. Some studies utilize enhanced image for feature extraction [3]. However, the majority of machine vision and deep learning models tend to perform poorly in highly challenging low-light scenarios [4]. Infrared images can highlight the thermal radiation characteristics of target objects, allowing for the capture of details such as human contours. Therefore, it possesses unique advantages in scenarios with insufficient lighting, adverse weather conditions, or concealed surveillance.

Despite the significant advantages of multimodal input data, effectively fusing information between modalities has become the core challenge and focus of algorithmic research. Li [5] et al. compared six fusion architectures which integrate color and thermal modalities at different position. Based on different fusion stages, it can be classified into early fusion, halfway fusion, and late fusion. Late fusion is currently the more commonly employed method, capable of mitigating the influence of modality and feature misalignment. However, it encounters challenges in network convergence and high computational complexity. We observed that discussions rarely address both the redundancy and complementarity of modalities. Crucially, the spread of redundant information can have detrimental effects in networks. This paper focuses on examining and mitigating these negative impacts by leveraging differential information of modalities in the backbone network to reduce redundancy.

The Non-Local neural network (Non-Local) [6] enhances inputs by calculating similarity in the channel direction. We conjecture that constructing an attention map by calculating similarity between pedestrian features could effectively allocate increased attention to those with blurred characteristics. In multispectral scenarios, there also exists a certain level of correlation both between channel dimensions and between spatial dimensions. Therefore, this paper proposes a dual-branch attention mechanism, named Dual Non-Local, which is based on both channel and spatial information. It establishes long-range dependencies between channels and spaces. Simultaneously, we utilize bright channel prior (BCP) algorithm to address low-light image compensation issues, and employ a multiscale feature fusion module to integrate visible and infrared modalities. Our work achieves superior results compared to some methods on the public available datasets KAIST and LLVIP.

We summarize the contributions of our work as follows:

1) A novel fusion approach is proposed for mining complementarity and reducing feature degradation. This technique involves the cross-fusion of complementary information from different modalities within the backbone network. The outputs of the backbone network for each modality is effectively integrated through this method.
2) A dual-branch attention mechanism based on channel and spatial attention. We embed positional information into attention map, and reduced the computational complexity of spatial attention. Ultimately, we build a dual-branch 3D attention mechanism that collaborates between spatial and channel dimensions.

II. Related Work

A. Pedestrian Detection

Pedestrian detection has high practical value in various applications, eg., autonomous driving and video surveillance. It receives extensive research attention in the field of computer vision. Pedestrian detection has undergone a significant transformation from handcrafted features to depending on deep convolutional networks for feature extraction [7]. Based on channel features or Deformable Part Models (DPM), there are two approaches to pedestrian detection that rely on handcrafted features. In 2009, P. Dollar et al. offered a fresh approach Integral Channel Features (ICF) [8], which utilized integral images for rapid feature computation. By combining channel feature pyramids with a cascaded classifier, they achieved faster detection results. ICF was the basis of channel features. Filtered Channel Features (FCF) [9] was optimization methods derived from ICF. Conventional algorithms were contingent upon manual design and frequently yielded diminished levels of detection accuracy. With Convolutional Neural Networks (CNNs) demonstrating outstanding feature extraction capabilities across various object detection tasks, pedestrian detection methods focused on leveraging deep learning techniques to enhance detection performance recently. The emergence of single-stage and two-stage algorithms, such as Faster R-CNN [10], [11], was a substantial potential for advancing accuracy and speed in pedestrian detection. Once in all weather conditions, especially during nighttime scenes, visible-light-based detection methods struggle to be effective. Simultaneously, infrared images complements visible light images, enabling the capture of pedestrian contours even in nighttime conditions. Detecting pedestrians in all weather conditions using multispectral images of color-thermal pairs has become a research hotspot.

B. Multispectral Pedestrian Detection

Effectively integrating infrared and visible light modalities is a challenging problem. In 2015, Hwang [12] et al. collected multispectral datasets, KAIST. The authors proposed the multispectral Aggregated Channel Features (ACF) method, incorporating intensity and gradient information from the thermal channel as additional channel information. An increasing number of multispectral pedestrian detection algorithms emerged based on this dataset. Liu [13] confirmed that multimodal pedestrian detection outperforms single-modal detection in terms of performance. Liu also investigated four fusion architectures: early fusion, mid-fusion, late fusion, and confidence fusion. They concluded that halfway fusion is the most effective fusion architecture. Inspired by Faster R-CNN, Konig [14] et al. proposed an effective multispectral RPN (Region Proposal Network)+BDT (Enhanced Decision Tree) model. In addition to investigating the fusion stages of multispectral images, another research approach involved using an illumination-aware network to weight the two modalities. Illumination-aware Faster R-CNN (IAF R-CNN) [5] introduced an illumination-weighting mechanism, forming a unified detection framework with separate subnetworks for visible light and infrared, along with a weighting layer. That means in low-light conditions, the network emphasized the features learned from the infrared sub network. In well-illuminated conditions, it focused on the visible light subnetwork. Our work is closely related to the conclusions drawn in [14]. We employed YOLOv7 [15] as our baseline and investigated the positive impact of low-light image enhancement techniques on the performance of multispectral pedestrian detection.

C. Attention Mechanism

In deep learning, the attention mechanism emulates the human visual and cognitive system, enabling neural networks to focus attention on relevant parts. Due to its outstanding performance, the attention mechanism is widely utilized in machine vision. Squeeze-and-Excitation Networks (SENet) [16] achieved adaptive channel-wise feature recalibration by modeling interdependencies between channels. Convolutional Block Attention Module (CBAM) [17] combined a channel attention module with a spatial attention module, allowing channel attention and spatial attention to operate sequentially. This enabled the network to simultaneously learn dependencies between channels and positional information. Non-Local neural network [6] combined self-attention with the general non-local mean method, establishing a long-range dependency model for transmitting long-range information. Non-Local maintained consistent feature scales between input and output, so it can be employed without modifying the network architecture. Criss-Cross Attention Network (CCNet) [18] and Global Context Network (GCNet) [19] were improvements derived from Non-Local. Similarity-based Attention Module (SimAM) [20] suggested that attention in the human brain often work in synergy, thus a unified attention mechanism was more in line with the working mechanism of neurons in the human brain. This paper introduces a new attention mechanism that combines the ideas of SimAM and Non-Local.

III. Proposed Method

The structure of this paper is depicted in Fig. 1. This model utilizes YOLOv7 as the baseline and integrates it with an illumination compensation module, a multiscale fusion module, and a detection module, forming a unified detection architecture. Our model consolidates the methods of image enhancement and differential fusion into a cohesive framework, thoroughly addressing the redundancy and complementarity across different modalities.

A. Illumination Compensation Network

The atmospheric scattering model is commonly employed to represent the degradation process of hazy images and is sometimes used for image enhancement tasks in low-light conditions as well [21]. Original image captured by the camera can be expressed as:

$$I = tJ + A\,(1 - t) \tag{1}$$

where, I is original image, J is restoration function of the image, A is environmental light description function, and t is medium propagation description function.

Wang [22] demonstrated that well-exposed images have at least some pixels with high illumination, unless these pixels are in shadow or covered by a black object. We visualize the Bright Channel on the KAIST dataset in Fig. 2. Most visible light images on the KAIST dataset are in underexposed scenes. We adopt unsupervised low-light Image enhancement network

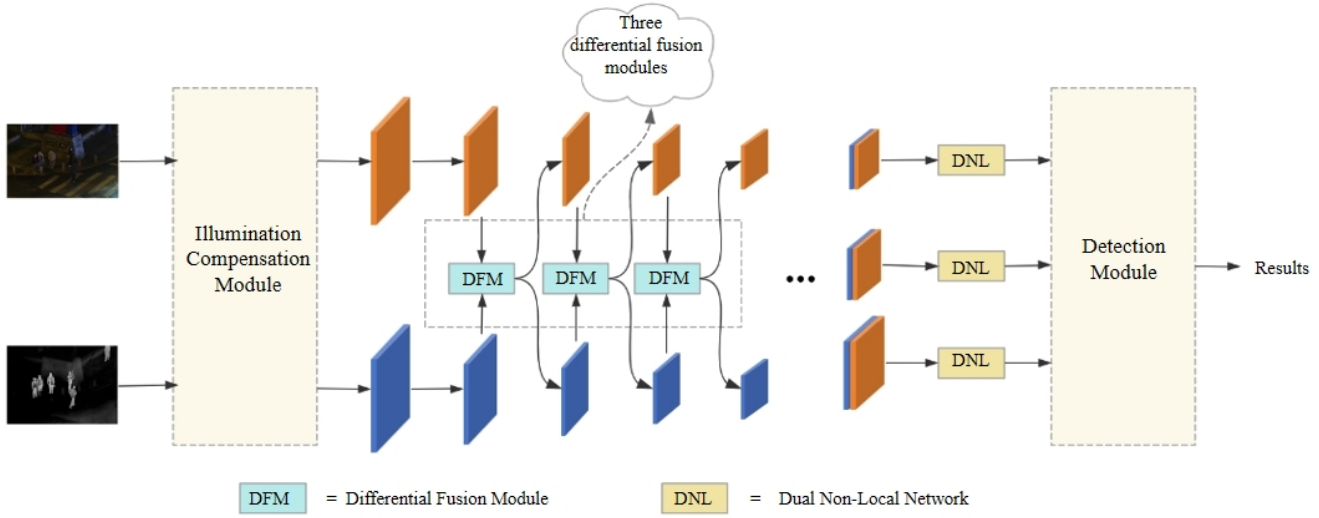

Fig. 1. The overall structure of proposed method. The network takes multispectral images of color-thermal pairs as inputs.

Fig. 2. The bright channel visualization of KAIST. We selected several low-light images and calculated the brightest pixels in R, G, B channels for each image, denoted as bright channel.

for outputing adjusted image that is guided by a unsupervised loss L_{BCP}. The parameters in Eq. (1) are reinterpreted as Eq. (2):

$$I_p = t_p J_p + A\,(1 - t_{\mathrm{p}}\,) \tag{2}$$

where, A and t_p is environment light and the illumination map, respectively. J_p represents enhanced output images and I_p is observed images. According to BCP [22], We adopted Eq. (3) as the brightest intensity:

$$J_p^{bright} = \max_{c\in r,g,b}\left(\max_{q\in\Phi(p)} J_q^c\right) \tag{3}$$

where, J_p^{bright} represents the brightest intesity in r,g,b channels, q is the pixels centered at p, and c is different channels in RGB images. Additionally, the brightest intesity becomes $J_p^{bright} \to 1$. Assuming that A is known, $\widetilde{t}$ represents the illumination map, which is considered as a constant within a patch.

By taking the maximum operator between the left and right sides of Eq. (3), we obtain an initial illumination map formulation as shown in Eq. (4):

$$\tilde{t}_p = 1 - \max_{c,q}\left(\frac{1 - I_q^c}{1 - A^c}\right). \tag{4}$$

where $\tilde{t}_p$ is the illumination value at pixel p, I_q^c is observed image, q is pixel centered at p, and c is different channels in RGB images. Under the supervision of the initial illumination map, we obtain enhanced illumination map t_p through Illumination Compensation Network. Substituting t_p into Eq. (2), we get enhanced output images as Eq. (5):

$$J_p = \frac{I_p - A}{t_p} + A \tag{5}$$

The darkest pixels in the bright channel of the image can be considered as environment light. To adjust dark spots and black objects in real life, we take the average value of the darkest 0.1% pixels (denoted as K) in the bright channel of the image as the environment light, as shown in Eq. (6):

$$A = \frac{1}{|K|}\sum_{p\in K} I_p \tag{6}$$

To address oversaturation, this paper similarly utilizes the output from Eq. (7) as the attention map:

$$T_{attention} = T^{\gamma} \tag{7}$$

where T is thermal image, and $\gamma(\gamma > 1)$ controls the curvature of the attention map.

The enhancement network alters the feature scale and utilizes the attention map to optimize spatial weights. In summary, our final illumination compensation network is illustrated in Fig. 3. The visible light features are compensated by the infrared images, effectively enhancing the distinguishability of the RGB images.

B. Multiscale Fusion Module

In all weather conditions, visible light images provide more information about pedestrians in well-illuminated conditions while in low-light conditions, thermal images provide more information. Most multispectral approaches extract features from

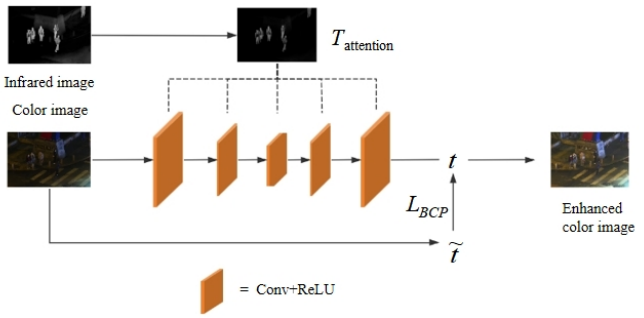

Fig. 3. The structure of Illumination Compensation module. $T_{attention}$ fed to five convolutional layers to adjust visible light feature. $\tilde{t}$ is an initial illumination map.

two streams and directly combine them either by element-wise addition or by channel concatenation. However, these mehods overlook the complementarity between the two modalities. The propagation of redundant information between modalities through the network also have adverse effects.

Inspired by the differential modality information [23], we propose a fusion module: Differential Fusion Module(DFM), to enhance the mutual suppression and enhancement, as shown in Fig. 4. The features obtained by element-wise subtraction of the two modalities reflect their complementary information, ingeniously excluding redundant information from feature fusion. This element-wise subtraction also prevents interference from features learned from another modality in the previous fusion from affecting the next fusion. Integrated within the architecture of YOLOv7, we perform multiscale feature fusion at the position illustrated in Fig. 1. In multispectral pedestrian

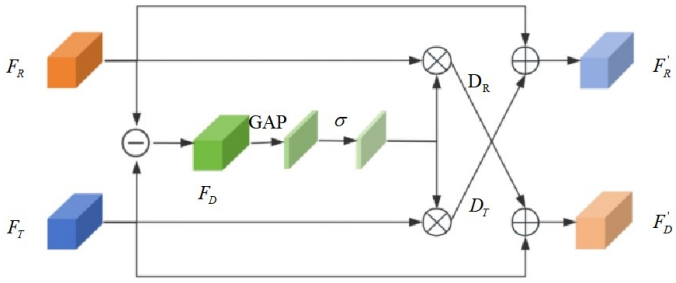

Fig. 4. The structure of differential fusion module. F_R and F_T are visible light features and thermal features. We obtain F_D by subtracting element-wise.

detection task, it is crucial to effectively integrate valuable information between modalities and mitigate interference caused by redundant information.

We applied DFM at Conv3, Conv4, Conv5 layers of the Backbone. The outputs feed into multiscale feature fusion network. To further enhance crucial features, we employ the Dual Non-Local attention mechanism before pyramid feature network. This helps to improve pedestrian feature expression effectively. DFM involves using a differencing mechanism, where F_R and F_T are subtracted element-wise to obtain the feature F_D. The equation for F_D is as follows:

$$F_{D1} = F_R - F_T \tag{8}$$

$$F_{D2} = F_T - F_R \tag{9}$$

where, F_R and F_T represent the extracted features from the visible light image and infrared image, respectively. F_D is the difference between F_R and F_T.

Subsequently, F_D is obtained through a global average pooling layer(GAP) and a tanh activation layer in order to get the attention map in the channel direction. That attention map is multiplied with the input visible light features and infrared features separately, producing D_R and D_T. The cross addition is applied to F_T and D_R, as well as F_R and D_T. Differential features yields the output features.

GAP computes the mean of the two-dimensional images within each channel, obtaining an attention map in the channel direction that contains global information. D_R is present in the visible light features but absent in the infrared image features while D_T is present in the infrared image features but absent in the visible light features. The formulation of differential feature is as follows:

$$F_R^{'} = F_R + D_T \tag{10}$$

$$F_T^{'} = F_T + D_R \tag{11}$$

where $F_R^{'}$ is the output of F_R, and $F_T^{'}$ is the output of F_T.

After cross-complementary feature fusion at three scales in the Backbone, the deep semantic information is concatenated. The deep semantic information needs to be fed into the Dual Non-Local module to enhance crucial information before the feature pyramid network. There is a high degree of correlation between pedestrian features, so establishing long-range dependencies is beneficial for modeling the similarity relationships between pedestrian features.

C. Dual Non-Local Attention Mechanism

Capturing long-range dependencies is crucial in pedestrian detection task. Long-range dependencies in image can only be formed through the successive convolutional layers in deep neural networks, named large receptive field. Inspired by SENet and Non-Local, we proposed a 3D attention mechanism called Dual Non-Local, as illustrated in the Fig. 5. Does long-range dependency work effectively in multi-pedestrian scenes? Undoubtedly, there is some correlation among the extracted features of pedestrians. The feature similarity matrices between each pixel and the feature similarity matrices between each channel assist in providing blurred pedestrian features with the weights of clear pedestrian features. Spatial attention and channel attention were applied concurrently for enhancing pedestrian feature. Dual Non-Local Network consists of a Spatial Attention Module (SAM) and a Channel Attention Module (CAM), which share the same input, denoted as $x \in \mathbb{R}^{C\times H\times W}$. There is a similar attention map computed for each position in Non-Local Network [19], thus, we use global attention maps to reduce computational cost.

In spatial attention module, we reshape the input into m, $m \in \mathbb{R}^{1\times C\times (H*W)}$. A 1×1 convolutional operation is imposed to x for getting global information of channels, denoted as n,

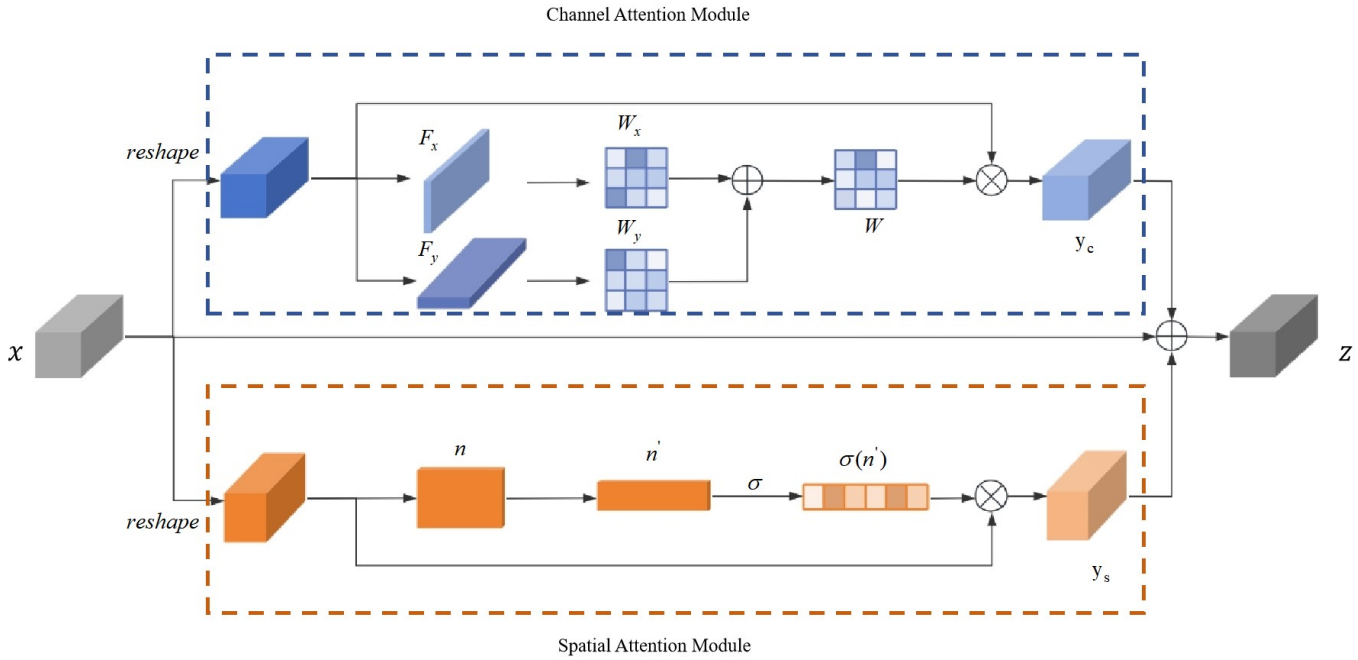

Fig. 5. The structure of dual non-Local network consists two branch attention mechanisms. SAM uses a shared attention map $\delta(n^{'})$ globally for reducing computation, while CAM calculates attention maps in different dimensions.

$n \in \mathbb{R}^{1\times H\times W}$. Before multipling with m, $n^{'}$ passes through a softmax function. Global channel information was reshaped to $n^{'} \in \mathbb{R}^{1\times(H*W)\times 1}$. In order to get the similarity between $H*W$ pixels, we multiply m and $n^{'}$. y_s is the output of spatial attention module, $y_s = m \bigotimes \delta(n^{'})$, where δ is softmax function. y_s is formulated as follows:

$$\mathbf{y}_{\mathrm{s}} = \sum_{j=1}^{N} \mathbf{x}_j \delta\left(\mathbf{n}'\right) \tag{12}$$

where, N is the number of pixels and y_s is shared globally as a spatial attention map.

In channel attention module, this paper innovatively performs pooling operations separately in the x and y dimensions, injecting positional information into channel attention map. After pooling in the x dimension, features are denoted as F_x, $F_x \in \mathbb{R}^{C\times H\times 1}$, and in the y dimension are denoted as F_y, $F_y \in \mathbb{R}^{C\times 1\times W}$, correspondingly. F_x performs a 1×1 filter, followed by a reshape function, to obtain θx, φx, where $\theta x \in \mathbb{R}^{C\times 1\times H}$ and $\varphi x \in \mathbb{R}^{C\times H\times 1}$. Dot product is carried out between θx and φx to obtain the weights between channels refered to W_x, $W_x \in \mathbb{R}^{C\times C}$ in dimension y. In a similar way, W_y, $W_y \in \mathbb{R}^{C\times C}$, represents the weights between channels in dimension x.

We suggest x and y dimensions play the same important role in channel attention, so the total channel weight distribution is considered to be the sum of the weight distribution in both dimension x and dimension y, denoted as W, $W = W_x + W_y$. Followed by a 1×1 filter and reshape operation, x generates g_x, $g_x \in \mathbb{R}^{C\times(H*W)}$, in order to obtain the final channel attention output y_c by applying the learned channel attention weights (W). To recover the features to their original input dimensions, we use a 1×1 filter to generate weights W_z. The final channel attention output is formulated as follows:

$$y_c = W_z(W \bigotimes g_x) \tag{13}$$

Finally, there is a shortcut between input and output as a residual structure. The network retains the input x, only learns the difference between output and input, and the data flows across layers to avoid the gradient disappearing during the training process. We denoted the final response of x as z, and we summarized the formulation between every pixel as follows:

$$\begin{aligned} z_i =& W_z \sum_{j=1}^{N_C} \left(\frac{f\left(C_{W_i}, C_{Wj}\right) + f\left(C_{Hi}, C_{Hj}\right)}{N_C} \right) \left(g_x \cdot x_j\right) \\ &+ m \bigotimes \delta(n^{'}) + x_i \end{aligned} \tag{14}$$

where i represents a position in image, and j is all possible positions. N_C is number of channels, $f\left(C_{W_i}, C_{Wj}\right)$ and $f\left(C_{Hi}, C_{Hj}\right)$ are the similarity between channels calculated by dot product.

The total loss is defined as (16):

$$\begin{aligned} L_{BCP} =& \frac{1}{N} \sum_{p} \{ \left(t_p - \tilde{t}_p\right)^2 \\ &+ \lambda \sum_{i,j\in\Phi(p)} w_{ij} \left(t_i - t_j\right)^2 \} \end{aligned} \tag{15}$$

$$L = L_{BCP} + \alpha L_{YOLOv7} \tag{16}$$

where N is the number of pixels, $\Phi(p)$ is the pixels within a 3×3 patch centered at p, w_{ij} represents affinity matrix between $\Phi(p)$, and λ controls balance between the data term and the smoothing term. Integrating detection and enhancement

loss during training is beneficial for obtaining image with prominent pedestrian features for pedestrian detection.

IV. Experiments

In order to demonstrate the effectiveness of the model we proposed, we present the detection results on two datasets, cleaned KAIST and LLVIP.

A. Dataset

1) KAIST: The KAIST dataset, proposed by Hwang [12] et al., consists of multispectral pedestrian data captured by specialized hardware with a beam splitter. It comprises 95,328 pairs of color and thermal images. However, this dataset is derived from consecutive frames of a video causing a high similarity in adjacent images, so we perform data clean. Finally, we get 7601 pairs of images as training set, and 2252 pairs of images as testing set. Additionally, we adopted the re-annotated labels by Li [24] and Hangil [25] for the training and test sets, respectively, to enhance label quality.

2) LLVIP: The LLVIP [26] dataset consists of rigorously aligned pairs of images in both time and space, which is used for pedestrian detection in low-light conditions. The entire dataset comprises 15,488 pairs of color-thermal images.

B. Evaluation Metrics

We use the Recall and Average Precision (AP) as evaluation metrics to evaluate the proposed model effectively. Here, we use TP (True Positive), FP (False Positive) to represent true positive predictions and false positive predictions, respectively. Recall is the ratio of detected pedestrians in ground truth. $Recall = \frac{TP}{TP+FP}$.

C. Implementation Details

In this paper, we built our network based on YOLOv7 and added a illumination compensation network at the input, which enhances the visible light by using the bright channel prior. In the Backbone, differential fusion module was performed on the feature inputs of Conv3, Conv4, and Conv5 to reduce redundancy in modal fusion. Finally, an innovative attention mechanism was added for long-term dependencies, facilitating direct transmission of high-level semantics.

The experiments were conducted on an NVIDIA GeForce RTX 4080 GPU, Intel(R) Core(TM) i7-13700F CPU, using the PyTorch framework and public code YOLOv7. We set the batch size to 8, epoch to 100, and resize input images to 640×640. K-means clustering provided nine anchor boxes for the KAIST dataset: [44,65], [26,111], [33,141], [41,117], [43,153], [58,116], [52,146], [59,178], [71,152]. We used some training tricks such as mosaic augmentation and random cropping to enhance the network's generalization.

D. Results Analysis

We conduct a comparison between our algorithm, Halfway Fusion and IAF R-CNN on the cleaned KAIST dataset. Here, we primarily discuss the potential advantages of our method, such as how our framework utilizes a Halfway Fusion architecture for integration, and we identify key methodologies that are beneficial in enhancing detection performance. The pedestrian detection results are presented in Table I. For the cleaned KAIST dataset, proposed method achieves the best detection performance in terms of Recall 64.17%.

TABLE I. Comparison on Cleaned KAIST Dataset in Terms of Recall

Method	DAY	NIGHT	ALL
Halfway Fusion [13]	59.98	50.77	58.27
IAF R-CNN [5]	65.22	56.62	62.14
YOLOv7 [15]	66.11	49.89	60.98
Ours	68.23	57.17	64.17

Compared to IAF R-CNN, our method is equally competitive, maintaining a high recall rate while our inference time is only 0.096s/image, as opposed to 0.210s/image for IAF R-CNN. We record comparison of inference time using an NVIDIA GeForce RTX 4080 GPU in Table II. This advantage is attributed to the real-time nature of the single-stage object detection algorithm, but the improvement in recall rate is due to our differential fusion module effectively mining the complementary features of pedestrian characteristics, reducing redundant noise interference in feature propagation. However, the effectiveness of DFM is limited by the requirement that the input pairs of visible and infrared images must be strictly aligned. Misaligned image pairs transmit incorrect differential information, and the noise is amplified by the network. This limitation calls for the use of more sophisticated image acquisition instruments to be adequately addressed.

TABLE II. Comparision of Inference Time using an NVIDIA GeForce RTX 4080 GPU

Method	IAF R-CNN [5]	YOLOv7 [15]	Ours
Time(s.)	0.210	0.041	0.096

In Table III, IV and V, we compare our algorithm with YOLOv7. Moreover, we explored three versions input of YOLOv7: a) RGB branch; b) thermal branch; c) concat thermal image and visible light image as input. Directly concatenat-

TABLE V. COMPARISON ON CLEANED KAIST DATASET FOR ALL WEATHER SCENES IN TERMS OF AVERAGE PRECISION, RECALL, AND ACCURACY

Method	AP/%	Recall/%	Accuracy/%
YOLOv7 RGB	54.30	52.44	81.63
YOLOv7 T	46.01	15.96	90.90
YOLOv7 T+RGB	62.60	60.98	76.01
Ours	63.94	64.17	82.96

ing the visible light image and thermal image did not lead to a significant improvement. We achieve improvements of 3.19%, 2.12%, and 7.28% on the all weather, daytime, and nighttime test sets in terms of Recall, respectively. Our method demonstrate better performance in both accuracy and Recall, indicating the effectiveness of our fusion strategy. Illumination compensation network enhances pedestrian features in low-light scenarios. Thus, we obtained the highest performance in nighttime scenes.

There are some visualizations for enhancced images as the outputs of Illumination Compensation Network in Fig. 6. We observed that obstacles in blue boxes have a high similarity to pedestrians, especially in low-light scenarios. The illumination compensation network is advantageous in suppressing background features and enhancing foreground characteristics. That enables the network to concentrate more on pedestrian targets, free from background interference. In the third line of Fig. 6b, pedestrian feature is clearer in blue box. However, the multispectral images of color-thermal pairs must be aligned. When misalignments occur, our model leads to worse results, which requires more sophisticated image acquisition instruments.

In addition to the quantitative analysis,we also provide several qualitative results on the cleaned KAIST dataset in Fig. 7. Upon observation, it is evident that our method excels in generating precise bounding boxes and accurately detecting pedestrians, especially in challenging scenarios when compared to the baseline model.

Gradient-weighted Class Activation Mapping (Grad-CAM) is a method for visualizing the attention mechanisms of deep neural networks. Our Dual Non-Local module constructs a unified attention framework based on the similarity of channel and spatial features, making it particularly suitable for single-object detection scenarios. The feature similarity between different types of targets may cause confusion in the attention map. In single object detection tasks, our Dual Non-Local module demonstrates superior performance compared to Non-Local and SimAM. These three similar attention mechanisms have consistent input and output dimensions. We removed all other modules in Fig. 1, retaining only the attention module. We replaced this position with different attention mechanisms and trained using the RGB images from LLVIP.

Using Grad-CAM, we visualized the outputs of Dual Non-Local, Non-Local, and SimAM, as shown in Fig. 8. Our Dual Non-Local model focuses more attention on the entirety of pedestrians, while Non-Local and SimAM distribute attention more precisely, but they both have the issue of some pedestrian regions not receiving attention. Comparatively, although the attention regions of Dual Non-Local are less precise, all pedestrian regions receive attention intensely. This also validates that features of clear pedestrians can rectify those pedestrians with blurred features.

E. Ablation Experiment

Our model achieves a leading performance. Nevertheless, the specific contributions of each module to the results remained uncertain. To address this, we design some ablation experiments to verify it. The comparsion results are presented in Table VI.

1) Illumination Compensation Module(IC): To figure out the impact of the illumination compensation network, we design a new network that uses the concatenated outputs of the illumination compensation network as the input of backbone, by removing the multiscale fusion network and

YOLOv7+DNL+MFM+IC(Ours)	81.47	86.50	82.96

attention mechanism. Thanks to the (15), the proposed L_{BCP} loss also has contributions to performance improvement, by distinguishing foreground from background as effectively as possible.

2) Multiscale Fusion Module (MFM): As shown, the one-branch methods are undoubtedly inferior to the two-branch approach. However, the crucial factor is fusion stage while halfway fusion structure achieves the best performance. For the two-branch method, we created two separate backbones to process visible and infrared images. It's worth noting that, during this experiment, we omitted the illumination compensation network. Both modalities were fed directly into their respective backbones. According to the results, it is evident that DFM plays a crucial role in improving detection performance, which resonates with our initial conjecture. Although DFM requires strictly aligned image pairs as input, this outcome provides strong experimental support for future research on pedestrian detection in more challenging environments.

F. Other Dataset

To demonstrate the generalization capability of our algorithm, we conducted experiments not only on the cleaned KAIST dataset, but also on another multispectral pedestrian detection benchmark called LLVIP. The majority of the LLVIP dataset were captured in low-light nighttime conditions. We

recorded the performance of the LLVIP dataset in Table VII, with mAP as the evaluation metric.

TABLE VII. COMPARISON ON LLVIP DATASET FOR ALL WEATHER SCENES IN TERMS OF AVERAGE PRECISION, RECALL, AND ACCURACY

Method	AP/%	Recall/%	Accuracy/%
YOLOv4 T+RGB	50.90	57.10	74.00
YOLOv7 T+RGB	79.60	71.89	94.34
Ours	83.76	78.16	97.81

V. CONCLUSION AND FUTURE WORK

In this paper, we investigated to integrate color-thermal image pairs effectively, leveraging the complementarity and exclusivity between modalities to enhance detection performance. We proposed an algorithm based on multiscale feature fusion. Specifically, we performed image enhancement on the input visible light image and simultaneously improved the Backbone network through integrating two modalities using differential information in Conv3, Conv4, and Conv5 convolutional layers. Our approach demonstrated outstanding performance on the cleaned KAIST and LLVIP datasets. Particularly in nighttime scenarios, we achieved a improvement of 7.28% in terms of Recall compared to the baseline on the cleaned KAIST dataset. We suggested that the proposed Dual Non-Local attention mechanism is also effective for other single object detection tasks, which is part of our future work. The findings of this paper offer a novel approach to combine image enhancement techniques and feature fusion for multispectral pedestrian detection, with potential applications beyond pedestrian detection. In our future work, we aim to further explore the complementarity between modalities and reduce redundant information between modalities in more challenging weather conditions, such as rain and snow scenarios.

Deep Learning-Powered Mobile App for Fast and Accurate COVID-19 Detection from Chest X-rays

Rahhal Errattahi, Fatima Zahra Salmam, Mohamed Lachgar, Asmaa El Hannani, Abdelhak Aqqal
Chouaib Doukkali University of El Jadida, National School of Applied Sciences, Laboratory of Information Technologies, El Jadida, Morocco

***Abstract*—The COVID-19 pandemic has imposed significant challenges on healthcare systems globally, necessitating swift and precise screening methods to curb transmission. Traditional screening approaches are time-consuming and prone to errors, prompting the development of an innovative solution - a mobile application employing machine learning for automated COVID-19 screening. This application harnesses computer vision and deep learning algorithms to analyze X-ray images, rapidly detecting virus-related symptoms. This solution aims to enhance the accuracy and speed of COVID-19 screening, particularly in resource-constrained or densely populated settings. The paper details the use of convolutional neural networks (CNNs) and transfer learning in diagnosing COVID-19 from chest X-rays, highlighting their efficacy in image classification. The trained model is deployed in a mobile application for real-world testing, aiming to aid healthcare professionals in the battle against the pandemic. The paper provides a comprehensive overview of the background, methodology, results, and the application's architecture and functionalities, concluding with avenues for future research.**

Keywords*—*COVID-19 diagnosis; computer vision; deep learning; X-ray images; mobile application.

I. Introduction

The COVID-19 pandemic has brought unprecedented challenges to healthcare systems worldwide. Early and efficient screening is crucial to prevent the spread of the virus. However, traditional screening methods such as manual assessments and laboratory tests are time-consuming and often have a high error rate [1]. Therefore, there is an urgent need for a more effective and rapid screening solution. To address this challenge, we propose an innovative solution - a mobile application that leverages machine learning for automatic screening for COVID-19. The application uses computer vision and deep learning algorithms to analyze X-ray images of patients and detect symptoms of the virus in real-time. The proposed application has the potential to improve the accuracy of screening results and reduce the time required for patient diagnosis by automating the screening process.

The proposed solution aims to overcome the limitations of traditional COVID-19 screening methods, especially in settings with limited resources or high population density. By leveraging the capabilities of machine learning, the screening process is broken down into smaller components that can be easily updated and maintained. The ultimate objective of this solution is to enhance the speed and accuracy of COVID-19 screening and support healthcare professionals in their efforts to combat the pandemic.

Over the last few decades, Computer Vision (CV) and Deep Learning (DL) have been widely used in various Computer Aided Diagnosis (CAD) applications especially in radiology, where CAD system is used to help radiologists analyze and interpret medical images like mammography, X-ray, CT-scan, etc. Recently, radiologists have noted that chest X-ray images show distinctive marks of pneumonia caused by COVID-19 [2]. Several studies investigated automatic COVID-19 detection from chest X-ray images [2], [3]. However, despite the promising results achieved in the reported works, the deployment of the developed DL models has not been comprehensively studied [4]. Deploying DL models in mobile applications will allow the scientific community to experiment those models in real conditions by reaching a large population. On the other hand, the proposed application will be highly portable, simple to use, and inexpensive. Thus, such software will allow primary screening for COVID-19 in areas where medical expertise and test kits are not available or insufficient (rural and remote areas, hot spots, and clusters of at-risk populations).

Our study had the objective of assessing the use of deep learning, in particular convolutional neural networks (CNNs), in the context of chest X-rays for patients suspected of having COVID-19 pneumonia. This included its capability for directly diagnosing COVID-19 and its ability to distinguish COVID-19 from other community-acquired types of pneumonia. The overarching goal was to introduce an effective tool that could aid in COVID-19 pneumonia diagnosis, either by offering a second opinion to radiologists or by providing a preliminary assessment when a radiologist is not readily accessible.

To achieve these objectives and considering the existing body of research that consistently demonstrates the superior performance of CNNs in image classification tasks, we undertook the training and cross-validation of an Inception-V3 based architecture. We assessed the model's performance using two distinct sets of independent datasets. This model was then deployed in a mobile application to assist in the differentiation of COVID-19 cases.

The paper is structured as follows: Section II presents background and related works. Materials and methods are presented in Section III followed by results and discussion in Section IV. Section V describes the software, including its architecture and functionalities. Finally, Section VI concludes the paper and discusses future directions for research.

II. Background and Related Works

Multiple studies have been conducted to explore the automatic detection of COVID-19 from CT-scan and chest X-ray images, showing encouraging outcomes. The initial set

of research focuses on CT-scan images [3], [5] which can effectively identify to detect deep-rooted changes in lung tissue. Despite their promising detection rates, these methods involve higher costs and expose patients to potentially harmful radiation doses [6].

The second group of studies revolves around the investigation of chest X-ray radiographs [7], [8], [9]. These images are the most commonly used radiographs in the medical field. Besides detecting changes in the lungs, they are valuable for swiftly assessing breathing or heart-related issues without causing discomfort to the patient.

Due to these advantages, our paper specifically focuses on the second group of approaches that utilize chest X-ray images. This type of medical images is prioritized because it offers the lowest cost and are widely accessible in medical institutions for detecting thoracic pathologies.

To date, numerous methods have been developed and introduced for the automatic detection of COVID-19 using X-ray Images. In our prior publication [10] we presented a comprehensive summary of the most significant works in this area. It is evident that the majority of the proposed approaches rely on Transfer Learning (TL), where models are pre-trained on external large datasets and adapted to the target task. The use of this training technique is mainly due to the lack of COVID-19 data available for the community.

Recently, Cohen et al. [11] conducted a study investigating the cross-domain performance using Densenet [12]. They found that the model's performance was unsatisfactory when evaluated on datasets from different sources. On the other hand, several researchers have utilized various datasets from multiple origins. For example, Narin et al. [9] proposed a pre-trained convolutional neural network based on Res-Net50 with a binary classification approach (COVID-19 and Normal). The dataset they used was obtained from the open-source GitHub repository proposed by Cohen et al. [13] and the "ChestX-ray8" database proposed by Wang et al. [14]. For evaluation, they employed a 5-fold cross-validation method and achieved an accuracy of 98%.

Apostolopoulos et al. [8] conducted a study where they gathered X-ray images from different sources [13], [15]. They assessed the performance of state-of-the-art convolutional neural network architectures using a Transfer Learning strategy. They demonstrated that VGG19 and MobileNetV2 could extract significant biomarkers related to COVID-19 with accuracies of 98.75% and 96.78%, respectively, using binary classification.

In another work, Wang et al. [16] introduced a tailored convolutional network architecture called COVID-Net for detecting COVID-19 cases from chest X-ray images. They collected a dataset of 13,975 chest X-ray images from 13,870 patient cases to train and evaluate their model, achieving an accuracy of 93.3Meanwhile, Zhang et al. [17] conducted their experiments on two combined datasets [13], [14]. They proposed a deep learning model for COVID-19 detection, comprising a backbone network for high-level feature extraction, a classification head, and an anomaly detection head. Their model achieved a sensitivity of 96% and a specificity of 70.65%.

Consequently, existing studies have focused on using transfer learning for the COVID-19 detection from medical images. Moreover, they present potential limitations, including:

- **Limited Data Availability:** Many existing works suffer from a scarcity of labeled data, making it challenging to train accurate and robust models. COVID-19 X-ray images are relatively rare, and obtaining large datasets for training can be difficult;
- **Data Imbalance:** The datasets used for training often suffer from class imbalance, with a disproportionate number of negative cases (non-COVID-19) compared to positive cases (COVID-19). This can lead to biased models that are better at detecting the majority class but perform poorly on COVID-19 cases;
- **Generalization Issues:** Models developed in one region or using specific equipment may not generalize well to other regions or types of X-ray machines. There can be significant variability in how X-ray images are captured and processed;
- **Evaluation Bias:** Some studies may suffer from evaluation bias, where models are tested on the same datasets from which they were trained or on datasets that are too similar. This can result in overly optimistic performance metrics;
- **Limited Clinical Validation:** While models may achieve high accuracy in identifying COVID-19 from X-ray images in research settings, their clinical validation and real-world performance may be less certain. More rigorous clinical testing and validation are needed;
- **Ethnic and Age Bias:** Some models may not perform equally well across different ethnic groups or age ranges. Bias in the training data can lead to disparities in model performance;
- **Overfitting and Noise:** Overfitting to noise or irrelevant features in the data can be a problem, particularly when dealing with small datasets. Models may learn to exploit artifacts in the images rather than true COVID-19 patterns;
- **Resource Intensive:** Deep learning models for image classification, particularly those used in healthcare can be computationally intensive and require substantial hardware resources, limiting their practical deployment in resource-constrained settings;
- **Continuous Updates:** The evolving nature of the COVID-19 virus and the emergence of new variants may require continuous updates and retraining of models to maintain their effectiveness.

Addressing these limitations is crucial for the development of reliable and clinically viable automatic COVID-19 detection solutions from X-ray images. Along this direction, and to overcome these limitations, the main contributions of this work can be summarized as follows:

- The experiments in this paper utilize a fairly large and balanced dataset in terms of classes, collected from

different data sources, including various ethnic groups and age ranges;

- The model's performance was evaluated using two distinct sets of independent datasets to assess its generalization capabilities.
- The CLAHE histogram equalization method was applied to enhance data quality;
- The trained model was deployed in a mobile/web application, offering the potential for rigorous clinical testing and validation. This application will also facilitate the collection of other clinical data related to COVID-19.

III. Materials and Methods

A. Dataset

In order to assess the model's predictive ability and generalization capability, we established two distinct datasets. The first dataset gathers 3429 X-ray images from the COVID-19 Radiography Database [18], [19], and Chest Imaging data collection [20] sources. This dataset is divided into three subsets: training, development, and test1. While for the second dataset, we used images from the RSNA Pneumonia Detection Challenge [21] and Chest X-rays Radiopaedia [22] including 758 X-ray images. This set, named test2, will be used to make a double evaluation of the model in order to check the model's ability to generalize.

For both datasets, we consider three classes: Normal, COVID-19, and other pneumonia, given that the last class gathers bacterial and viral pneumonia. Data distribution over training, evaluation, and both test sets is presented in Table I.

TABLE I. Label Distributions in Training, Development and Test Sets

	Train	Dev	Test1	Test2	Total
NORMAL	804	112	227	236	1379
COVID-19	799	116	230	132	1277
OTHER PNEUMONIA	798	115	228	390	1531

B. Model Architecture

The experimental dataset used in this study consists of 4,187 X-ray images, which is considered insufficient for training a neural network with a deep architecture. Consequently, the COVID-19 detection system proposed in this research relies on the Inception-V3 model architecture that is pre-trained on the ImageNet dataset [23].

The original Inception-V3 architecture is composed of two main sections: feature extraction and classification. The feature extraction part includes five convolutional layers, each followed by batch normalization, two pooling layers, and 11 inception modules. Each inception module consists of a combination of parallel convolutional and pooling layers. The second part of the architecture comprises fully-connected and softmax layers, responsible for the final classification task.

To customize the Inception-V3 model for our specific task, we made modifications by removing its original classification part. Instead, we constructed a custom classification section to suit the number of classes in our dataset. The customized part consists of an average-pooling layer, followed by two fully connected layers. To prevent overfitting during training, each of these three added layers is accompanied by a dropout layer, randomly deactivating activations with a probability of 0.4.

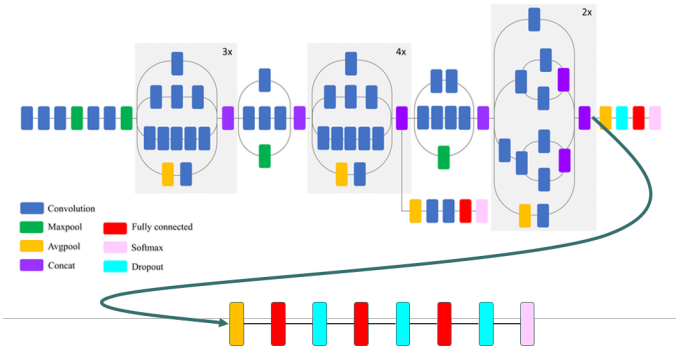

Fig. 1. The customized Inception-V3 architecture.

Finally, as the output for classification, a softmax layer was incorporated, providing the probabilities for each class. The model architecture is visually depicted in Fig. 1.

C. Performance Evaluation

In addition to measuring classification accuracy, we also employed sensitivity in Eq. (1) and specificity in Eq. (2) as metrics for evaluating the COVID-19 detection performance. Sensitivity, also known as True Positive Rate or Recall, represents the model's ability to correctly identify COVID-19 cases, and can be calculated using Eq. (1):

$$Sensitivity = \frac{TP}{TP + FN} \tag{1}$$

While Specificity measures the model's ability to correctly identify normal (non-COVID-19) cases and can be calculated using Eq. (2):

$$Specificity = \frac{TN}{TN + FP} \tag{2}$$

Where:

- TP (True Positives) refers to the number of correctly identified COVID-19 cases;
- FN (False Negatives) refers to the number of actual COVID-19 cases that were incorrectly classified as non-COVID-19 cases by the model;
- TN (True Negatives) refers to the number of correctly identified normal cases;
- FP (False Positives) refers to the number of normal cases that were incorrectly classified as COVID-19 cases by the model.

IV. Results and Discussion

In the first set of experiments, we investigated the fine-tuning of the Inception-V3 model. Table II shows the customized Inception-V3 model's performance of the test set with and without adaptation of the Inception-V3 convolution part. In the first line, the Inception-V3 model was pre-trained on ImageNet dataset and only the customized layers were trained on the chest X-ray images as explained in Section III. While in the second line, the pre-trained Inception-V3 model is fine-tuned by gradually unfreezing the top layers of the convolutional part of the model on the chest X-ray images and the customized layers are trained from scratch.

The results, in Table II, show that using Inception-V3 convolution parts without any adaptation on the new task give acceptable results with an accuracy of 95.62%. However, when the model is fine-tuned (adapted) on the new task the results are even better with an accuracy of 98.98% and a sensitivity and specificity of 98.25% and 99.34%, respectively.

TABLE II. COVID-19 Detection Results using Inception-V3 with and Without Adaptation on the Test1 Subset

	Accuracy	Sensitivity	Specificity
Inception-V3 without adaptation	95.62	92.11	97.37
Inception-V3 with adaptation	98.98	98.25	99.34

In the next experiments, we look at the effect of data preprocessing on the model's generalization while preserving fine-tuning when training our model. We apply the well-known Contrast Limited Adaptive Histogram Equalization (CLAHE) on our X-ray images while analyzing the model's performance on the second test set (Test2). The results reported in Table III.

TABLE III. COVID-19 Detection Results using Inception-V3 with and without CLAHE Preprocessing on Test2 Subset

	Accuracy	Sensitivity	Specificity
Inception-V3 with adaptation	16.62	40.91	11.50
Inception-V3 with adaptation + CLAHE	81.27	93.18	78.75

It can be seen by comparing the classification accuracies achieved when evaluating the model on the second test set that without data preprocessing, the model shows a pore generalization, where the classification accuracy drops from 98.98% on the first test set to only 16.62% on the second one. On the other hand, adopting data preprocessing leads to a significant improvement in performance generalization on the second test set, with an accuracy of 81.27%.

This improvement in the model's generalization could be explained by the consistent quality of X-ray images from each class coming from the same sources. Therefore, the model is very sensitive to image quality, and when re-evaluated in a real-world test set (test2) where it encounters images of varying quality, it may not perform as well as it did during the initial evaluation.

In summary, experiments show that the adaptation of the CNN layers of the pre-trained Inception-V3 model on COVID-19 X-ray images leads to better results as compared to using the model without any adaptation. Furthermore, the results confirmed that image preprocessing is essential in medical image analysis as it enhances the quality of medical images, improves the performance of classification models, and ensures the accuracy and reliability of diagnostic and analytical results.

V. Software Description

We embedded the trained Inception-V3 model into a web and Android mobile application for automated COVID-19 screening. The proposed application is called CovidChecker and it is publicly available on GitHub [24].

The app is designed to identify anomalies and estimate the extent of lung infection in real-time, and automatically detect high-risk patients with pneumonia or other COVID-19 related pulmonary symptoms.

The app enables users to complete a questionnaire and submit chest X-ray images for COVID-19 screening. The images and accompanying metadata will be used to augment the training dataset of DL models, thereby improving the accuracy and reliability of COVID-19 tests over time. To protect privacy, the data collected from users will be stored on secure servers for research purposes only.

A. Software Architecture

The software architecture, as shown in Fig. 2, illustrates the implementation of the web and mobile application utilizing Flask, MongoDB, and the DL module in the backend, jQuery Ajax in the web frontend, and Retrofit for the Android mobile application. The architecture is designed as follows:

Web Frontend: The web frontend is developed using jQuery Ajax to communicate with the Flask backend. Through the web user interface, the users can capture images using their computer's webcam and complete a questionnaire to assist the decision-making.

Backend: The backend is built using Flask, a RESTful API for the Python web server. It receives requests from the frontend and process them. MongoDB is used as a database to store images, classification results, and user data. All data transferred to the application is fully anonymized, including metadata. It has been hypothesized that an individual is not identifiable from their chest radiographs.

DL Module: The best DL module trained in section IV is loaded into the Flask backend and used to process images submitted by users.

Android Mobile Application: The Android mobile application uses Retrofit to communicate with the Flask backend. The mobile user interface allows the user to take images via their smartphone camera and fill out a questionnaire, similar to the web application.

The architecture is designed to be fast, scalable, and user-friendly for both web and mobile users. It can also handle scenarios where the mobile application loses connectivity to the backend.

B. Data Privacy Policy

The information that is collected will be transmitted from the user's phone, when they are connected to the Internet, to a secure database server. Once the data has been successfully transmitted, it will be deleted from the user's device. We do not

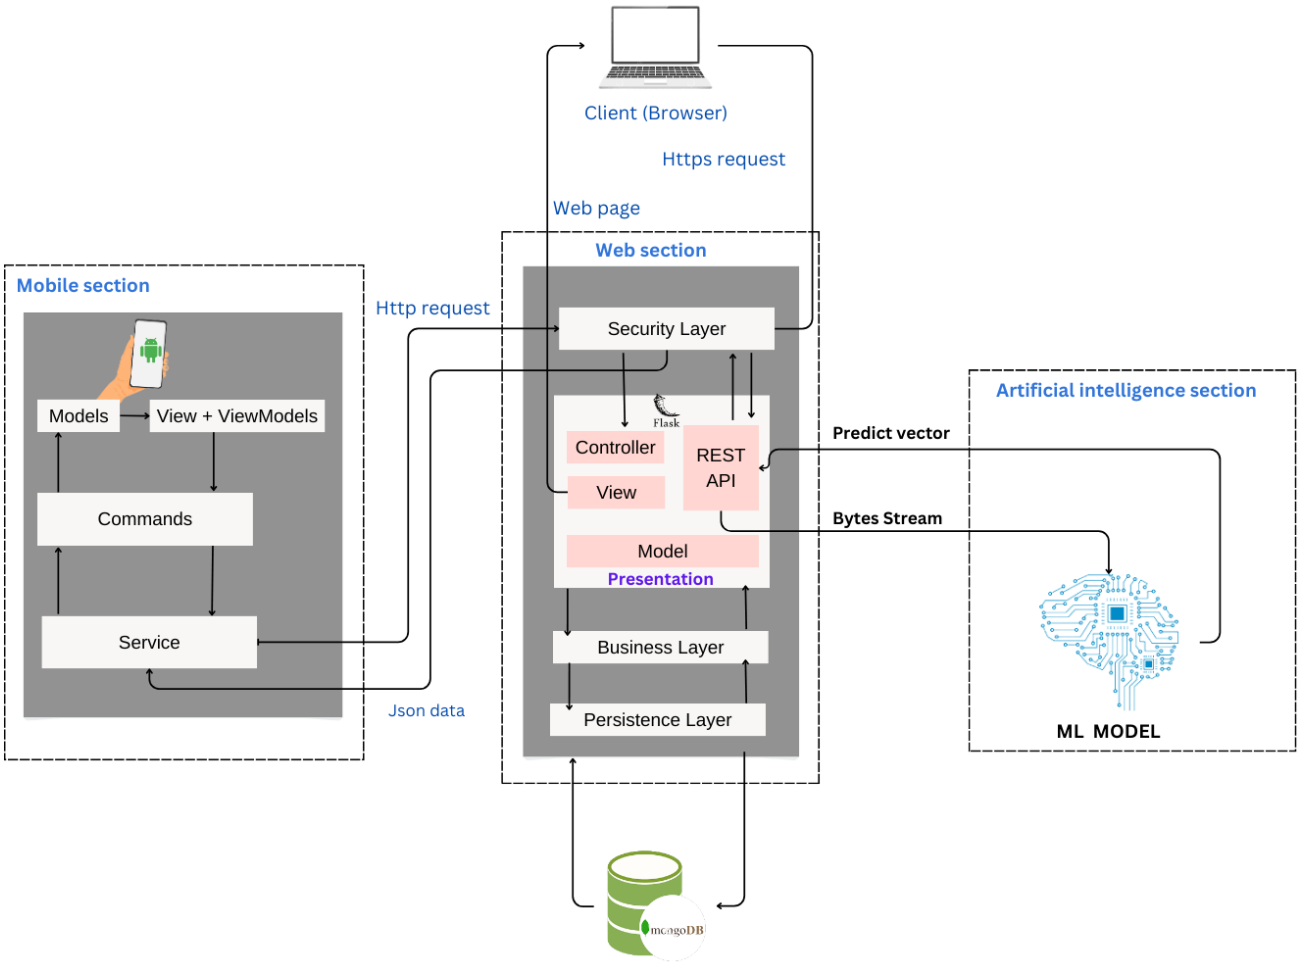

Fig. 2. Software architecture.

collect any personally identifiable information such as email addresses or other explicit personal identifiers. Since the data collected is sensitive and contains demo-graphic information, all data transferred to the database server is fully anonymized, including metadata. Furthermore, we established a sharing agreements for the data under the terms and conditions agreement of the mobile app.

C. Illustrative Example

The main functionality of this app is self-screening, which provides an automatic and rapid computer-aided diagnosis of COVID-19 from chest X-ray images. During this stage, the app will collect some basic demographic and medical history data, as well as the X-ray image through a quick questionnaire (see Fig. 3).

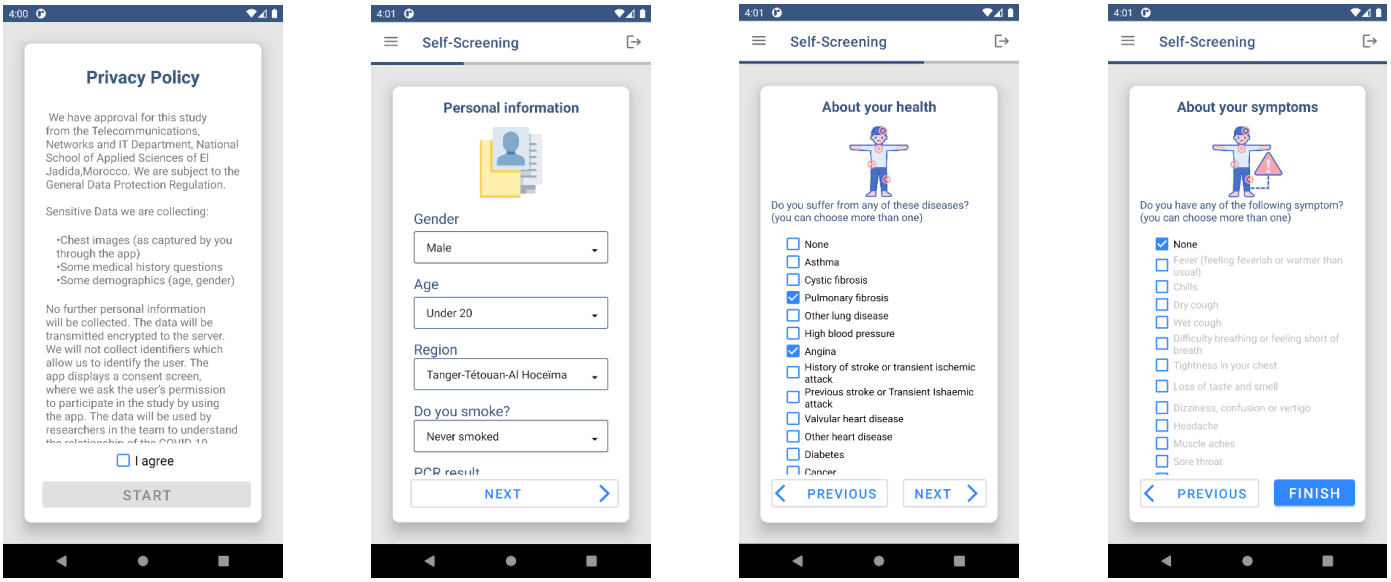
Before proceeding with the self-screening, users are required to accept the terms and conditions governing the app's use and agree to the data privacy policy that outlines how data is collected, stored, and managed. Second, after providing basic demographic information, such as their gender, age, region, and smoking history, the users will be asked whether they have previously tested positive for COVID-19. Then, they will be prompted to enter their medical history and any current symptoms they may be experiencing.

Finally, the user uploads his/her X-ray image and would be able to find the results within a matter of seconds. The uploaded image is sent to the backend server for analysis, where it undergoes preprocessing before being passed to a pre-trained image classification model. The model determines whether the input image shows signs of COVID-19 or not, and sends the results back to the mobile app in real-time. The app user receives the screening results and guidelines based on the X-ray analysis results. The results are presented as the probability of having COVID-19, which is determined by the output of the DL module. If the probability is less than 50%, the results page will appear in green to indicate safety (see Fig. 4), while a probability exceeding 50% will cause the results page to turn red (see Fig. 5).

D. Software Impact

The study on using transfer learning for COVID-19 detection from X-ray images can have a significant impact on various parties involved in healthcare.

For patients, this system could provide a faster and more accessible diagnosis, which could lead to earlier treatment and



(a) (b) (c) (d)

Fig. 3. Mobile App Self-screening survey interfaces.

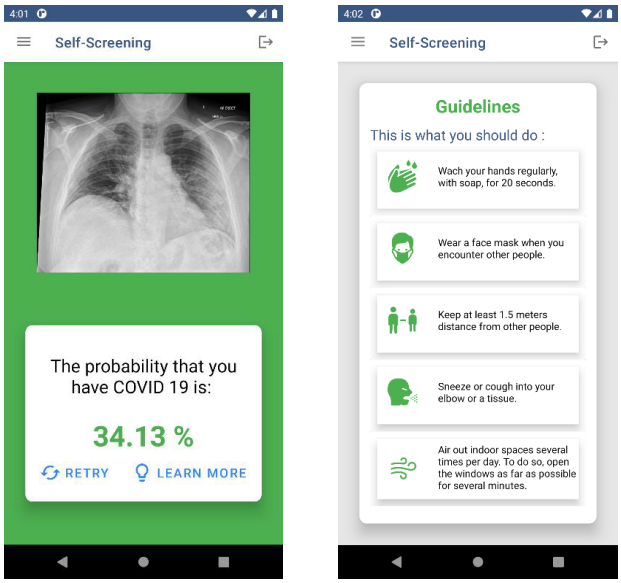


Fig. 4. Screening result and guidance page: Non-infected case.

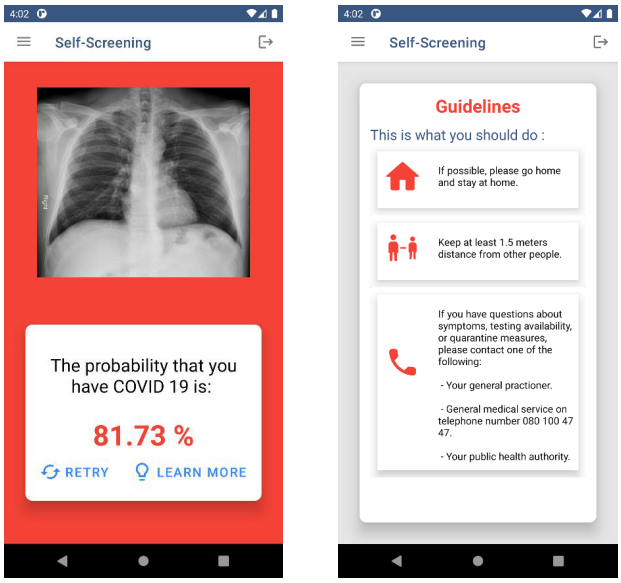

Fig. 5. Screening result and guidance page: Infected case.

better outcomes. Additionally, the use of X-ray images can be less invasive than other diagnostic methods, such as RT-PCR testing, and can be done onsite, reducing the need for patients to travel to a medical facility.

For healthcare providers, the proposed system could serve as an aid in the diagnosis process, reducing the time and effort required for manual analysis of chest radiographs and allowing healthcare professionals to focus on tasks that are more critical. This could also help to improve the accuracy and consistency of COVID-19 diagnoses, as the system can provide a second opinion when a radiologist is not immediately available.

Moreover, the successful implementation of this system in the larger healthcare industry could lead to the wider adoption of computer vision and deep learning techniques in the diagnosis of various diseases. This could significantly improve the efficiency and accuracy of medical diagnoses, ultimately leading to better patient outcomes and reduced costs for the healthcare system.

Overall, the proposed system has the potential to improve the efficiency and accuracy of COVID-19 diagnoses, providing benefits to patients, healthcare providers, and the broader healthcare industry.

VI. Conclusion

In conclusion, this research paper presents an innovative solution in the form of a mobile application that employs machine learning, computer vision, and deep learning to analyze X-ray images for the rapid detection of COVID-19 symptoms. The study focuses on the use of convolutional neural networks (CNNs) and transfer learning to diagnose COVID-19 from chest X-ray images, showcasing their effectiveness in image classification. The results demonstrate that adapting the Inception-V3 model with fine-tuning leads to superior accuracy, sensitivity, and specificity in COVID-19 detection.

The paper addresses various challenges and limitations encountered in the development of automatic COVID-19 detection solutions, such as data availability, data imbalance, generalization issues, and the need for clinical validation. It also highlights the importance of data preprocessing, such as CLAHE histogram equalization, in enhancing the quality of medical images and improving classification model performance.

The research introduces "CovidChecker", a mobile application that enables users to self-screen for COVID-19, submit chest X-ray images, and provide valuable data for improving the accuracy of COVID-19 tests over time. The application is designed with a strong focus on data privacy, ensuring that user data is anonymized and securely stored.

Universidad Nacional de San Agustín de Arequipa, Arequipa, Perú[1,2,4,5,6]
Universidad Nacional Mayor de San Marcos[3]

***Abstract*—This work is focused on the proposal and development of an interface system model, based on natural language processing, immersive technologies and natural user interfaces, for the interaction with Explicit Knowledge databases. Five phases were proposed: The user testing characterization, the establishment of the state of the art and the theoretical foundation, the design and development of software, the system implementation and the functional tests and evaluation of the usability of the interface model. In order to establish the user testing characterization and the corresponding theoretical framework, the expert guide on Knowledge Management and Virtual Reality was followed, based on the approach of Usability and Computer Ergonomics compatible with the ISO 9241 standard. The traditional interfaces and the proposal in this work were evaluated for each of the metrics defined by the ISO 9241 standard, considering the dimensions of effectiveness, efficiency and satisfaction. The statistical test of "T-Student" established that there is enough evidence to confirm the existence of the following significant differences: Effectiveness is lower using the proposed interface model; efficiency and satisfaction is higher using the proposed interface model. Based on the conducted tests, it can be established that the proposed interface model is superior to the traditional interface in terms of the "Efficiency and Satisfaction" dimensions and inferior in terms of "Effectiveness." Consequently, it can be concluded that the scientific article exploration model using VR and NLP is superior to the traditional model.**

***Keywords*—Knowledge management; explicit knowledge databases; natural language processing; natural user interfaces; Immersive technologies**

I. Introduction

Knowledge Management (KM) is one of the emerging academic disciplines which responds to the growing demands of the information society [1]. It is the result of the confluence or intersection of the areas of business administration, communication technologies and information systems, and is defined as the process of creation, storage and exchange of organizational knowledge. With the existence of a wide variety of modern organizations, objectives and cultures, KM becomes an extremely interdisciplinary area of operation which develops its own objectives and professional approach.

The knowledge-based vision asserts that knowledge management can facilitate innovative practices by transforming knowledge assets into new products and services through a series of management processes and activities. It can promote the exchange and distribution of knowledge necessary for innovation activities, thereby stimulating the generation of new ideas and ultimately enhancing innovation performance.

For [2], an important activity of the organizations is the integration of individual knowledge into collective knowledge. Today, there is a need to properly manage tacit and explicit business knowledge [3], which, in the latter case, may be document-based, having a direct relationship with the productivity of the workforce and the efficiency of the organization. In many organizations, much of the business documents are not structured and do not have an adequate management system. These documents take many forms, such as office documents, images, reports, e-mails, drawings [4].

The contemporary organizations have a large number of documents which can be located in various containers or repositories. These documents can be lost, misplaced or even stored by someone without the knowledge of other collaborators. Since the files may have been stored on several separate computers, locating and retrieving them can be a complex task. To this end, Web-based applications can be equipped with the ability to manage various types of documents, such a business, process and research documents, which can be explored with immersive technology resources [5], as well as other types of documents in public and private organizations. Likewise, web-based applications are much more accessible and share some common characteristics. They are distributed, which means that storage and access takes place in different physical locations. Similarly, for [6], Scientific data repositories have a key role in science.

Tasks of exploration, search, and information collection are carried out using computer systems with traditional interfaces, which may include forms, menus, windows, and hyper medial or hypertextual elements. Typically, these tasks involve using the author's name, keywords, publication year, and/or digital files, along with some additional search parameters. The results are presented in a text list format [7].

The information indexed in a repository can grow rapidly, and when using traditional interfaces, there can be difficulties in exploring and selecting different types of documents. This can impact the search processes conducted by collaborators, making them tedious and resulting in unexpected outcomes.

The originality and motivation of this research lie in an attempt to contribute to the design and exploration of tools for optimizing the review tasks of explicit documents within private, public, and research-based organizational settings. These

tools aim to facilitate the work of executives, collaborators, and researchers through novel forms of representation and interaction with textual information. The approach involves utilizing efficient and agile system models for searching and selecting from the extensive variety and diversity of explicit documents stored in organizational repositories.

In this paper, Section II, describes methodology, Section III describes the theoretical framework; Section IV explores and analyses immersive technologies; Section V explores and analyzes the works related to the development of interaction systems with Textual Web-based repositories using Virtual Reality (VR) and NLP; Section VI describes the proposed model; Section VII evaluates the model in relation to a traditional one; Section VIII evaluates the results. In conclusion, the Section IX presents the conclusions and recommendations for future work.

II. Methodology

For the development of the theoretical framework, the required elements for a systematic literature review and meta-analysis (PRISMA) were also utilized. Consequently, a search string was defined concerning the topics of interest, identifying relevant keywords to construct the search string. This search string was applied to recognized databases such as IEEE Xplore, Science Direct, Web of Science, and Scopus, considering that the studies were articles from journals and conferences published in the last 20 years. Duplicate studies were removed, those that did not contribute to the study were excluded, and applying inclusion and exclusion criteria, a total of 43 studies were used in the research.

Five phases were proposed for the development of the model, as described in Fig. 1.

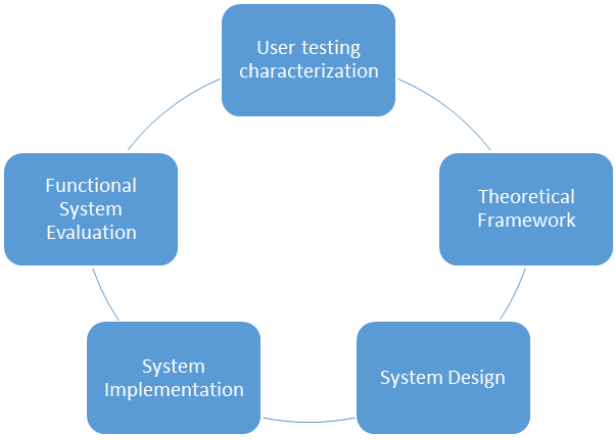

Fig. 1. Proposed methodology.

In the "Using Testing Characterization" phase, the theoretical framework was established, incorporating Knowledge Management, Web-Based Repositories, Natural Language Processing, and Immersive Reality along with their technological resources. This phase also involved the design and development of software, as well as the criteria required for evaluating the model, referred to as the usability interface.

In the "System Design" phase, the system was designed by establishing the background and reviewing related works. It was noted that there are various approaches to addressing and resolving the problem.

Moving on to the "System Implementation" phase, the different components of the system were implemented in the following steps: Physical environment setup for immersive experiences, Natural Interaction System Model, Implementation of Web Crawler for information retrieval from the model, Speech recognition and text-to-speech engine and Implementation of the syntactic analyser.

For the categorization of user tests, the expert guidelines in Knowledge Management (KM) and Virtual Reality (VR) were considered. These guidelines were based on the usability and ergonomics of computer science, aligning with the ISO 9241 standards. After configuring the interconnected devices and initializing the software modules, the evaluation of the model for exploring scientific articles using VR and NLP was conducted, alongside the traditional model of the scientific database ALICIA. Five users participated in the experiment, a number recommended by Nielsen [43] for evaluating interfaces, a criterion considered for obtaining the required dataset.

Participants were assigned the task of exploring scientific articles for a duration of 30 minutes using the interfaces of both models. During the experiment, users could request assistance from an expert who observed and documented the proceedings. Subsequently, the results were tabulated based on the metrics of ISO 9241, specifically efficiency, effectiveness, and satisfaction. These results are discussed in Section IX.

III. Theoretical Framework

In this section, a historical review and state-of-the-art analysis are conducted to explore the theoretical foundation required for the research.

A. Knowledge in the Organizations

The Knowledge Management System (KMS) is focused on information and enterprise social media, as well as on the connection and communication between employees. These two perspectives correspond to the categorizations of knowledge theory and KM. KM recognizes that virtually all jobs involve "knowledge work," and employees are "knowledge workers" to some extent. Therefore, it places more emphasis on knowledge than on manual skills. Consequently, the creation, sharing, and use of knowledge are among the most important activities in nearly every organization.

Existing research provides the theoretical framework for carrying out these activities, and it is proposed that knowledge sharing can contribute to companies achieving innovation objectives, thereby improving organizational performance [8]. The positive impact of KM capabilities on organizational performance has also been studied [9], considering that KM contributes to a company's innovation capacity [10].

Demuner-Flores and Nava-Rogel [11] emphasize a close relationship between knowledge and action, which also involves understanding and comprehension. The knowledge that an individual possesses is a product of their experience and incorporates the norms for evaluating novel contributions from their environment. For [12], knowledge involves framed experience, values, contextual information, and informed intuition.

It provides a framework for evaluating and incorporating new experiences and information. Knowledge originates and is applied in the minds of knowledge workers, but it can also be integrated into organizations through documents, repositories, practices, routines, and organizational standards.

KM is based on the concept of collecting, organizing, analyzing, and sharing knowledge in a way that employees can easily access and use it [13]. Therefore, a competitive organization relies, among other things, on the effectiveness of its workforce in creating new knowledge, sharing it within the organization, and using it to gain a competitive advantage.

Ultimately, KM aims for a positive impact on business value generated from knowledge. This is achieved through the creation of processes, culture, and technology in an environment where knowledge exchange is considered essential and occurs seamlessly. Thus, this research work can contribute to the exploration of textual documents in repositories of explicit web-based knowledge.

On the other hand, in the KMS, the following types of knowledge are defined:

1) Explicit Knowledge [14]: It classified as structured or unstructured, can be symbolically transferred, meaning it can be conveyed through linguistic or computational mediation, and can be documented and stored in databases. Some examples include written procedures, instructional manuals, lessons learned, best practices, as well as research results in the form of indexed scientific articles in repositories such as Web of Science, Scopus, Scielo, etc., or in academic data repositories of universities and other institutions, for the exploration, search, and collection of information [15]. Some databases, document types, and spreadsheets are examples of structured data and information, which are organized to allow for future retrieval. This work is focused on the exploration of emails, images, training courses, and audio and video selections, which are examples of unstructured knowledge because there is no clear way to reference them for retrieval.

2) Tacit Knowledge: It is knowledge hidden from the consciousness of the individual who possesses it [15]. It resides in the minds of human beings, and capturing or encoding it is not easy because it involves a complex process. Knowledge in its entirety resides in a tacit dimension. It is expressed through human actions, stories, as well as competencies, skills embedded in an individual's worldview, experiences, attitudes, evaluations, and perspectives that are often taken for granted. It can be observed through action and is less concrete compared to explicit knowledge. It can be described as a "tacit understanding" of something, which is difficult to document in writing or in databases. It is considered more valuable because it provides context for people, ideas, and experiences.

Managing both types of knowledge requires applying various methods and approaches, taking into consideration their unique characteristics. Some other types of knowledge in the context of corporate KM: (1) Individual knowledge, in which only one entity owns it; (2) Collective knowledge, whose transfer is focused on interaction and goal achievement.

Finally, the aim of KM's contribution to positive business value generated from knowledge and its management will be achieved by creating an environment that encompasses processes, culture, and technology for seamless knowledge sharing. Hence, the importance of this research work, which can contribute to the investigation and exploration of textual documents in web-based repositories of explicit knowledge.

B. Web Based Repositories

Information systems designed to preserve and organize commercial, scientific, and academic materials are referred to as repositories. They are used to support operations, research, and learning, while also ensuring access to information [16]. Institutional repositories also consist of interoperable web-based services, dedicated to disseminating the resources of the results and analysis of institutional, scientific, academic, or business operations of institutions, based on the listing of a specific set of data (metadata), so that these resources can be collected, catalogued, accessed, managed, disseminated and preserved. Respect for compatibility and interoperability standards makes it possible for the content of a repository to be more easily retrievable, not only for the institution itself, but also for the scientific community and society.

Scientific databases consist of components that include information related to library materials such as books and other types of documents, including journals and other scientific publications. These materials encompass scientific articles, research papers, conference proceedings, books, among others. Scientific databases are typically in electronic format and are accessible via the internet. They contain abstracts, bibliographic citations, references, and often the full text or links to the full text.

The government institution of the National System of Science and Technology and Technological Innovation of Perú (CONCYTEC), has subscriptions to various scientific databases, to which it provides free access and makes available to the scientific and academic communities and general population. The repository of scientific and technological information and innovation, called ALICIA, provides free access to intellectual production and research in science, technology and innovation, developed in the public sector and private institutions, with public funds.

The bibliographic review carried out in this part of the work, allows us to establish that the research in the design and development of friendly interfaces, from a unique and original perspective, resulting from the confluence of the use of methodologies and techniques, such as NLP, Natural Users Interfaces and VR, that facilitate the search and exploration in Explicit Knowledge database, can be very useful for the collaborators of the business organizations, researchers, academics, scientists and professionals in general, since it will not only facilitate the tasks that these carry out, but will also shorten the time spent, as well as diminish the costs, a fact that can undoubtedly contribute with the capacity of research.

C. Natural Language Processing (NLP)

NLP refers to the hardware and/or software elements of a computer system focused on analyzing or synthesizing spoken or written language [17]. NLP contributes to the retrieval of texts for user reading, which can vary in size from a paragraph to a book. Innovations in emerging technologies have made tasks such as storage, searches, and the retrieval

of complete texts or parts of them from online documents relatively straightforward [18].

Many academic libraries have implemented various services to support users in their learning and research activities through chat. Chat serves as an important channel for accessing resources and services in university repositories. Repositories and libraries have accumulated a significant amount of data in the form of chat transcripts. Analyzing the content of these transcripts can help library officials understand user information needs, allocate library resources more efficiently, and improve the quality of chat reference services [3].

Conversational agents (chatbots) are programs that utilize natural language processing with a question-and-answer system, aiming to simulate intelligent dialogue with human interlocutors. This can be implemented through text messages or voice as a tool created to support the customer-company relationship, enabling virtual interaction through technology in the most human-like manner possible [19].

Recent applications of explicit database interfaces include two works by [20], who propose a Natural Language Query (NLQ) database query system (NADAQ) as an alternative solution. In their design, they introduce new models for translation, seamlessly merging deep learning with traditional techniques for database analysis and developing new techniques to allow the neural network to reject queries irrelevant to the content of the target database, and recommend that candidate queries be translated back into a tuned natural language. According to [21], the slow development of Natural Language Interfaces for Databases (NLIDB) stems from linguistic issues (such as language ambiguity) as well as domain portability. Brad et al. [21]assert that there is a demand for non-expert users to make queries to relational databases using their natural language instead of utilizing specified attribute values for the database domain. According to [22], the use of natural language instead of SQL-based queries enabled the development of NLIDB, a new type of processing that represents an approach to developing intelligent database systems aimed at improving the performance of flexible queries in databases.

Among the most important applications of NLP, we can mention human-machine interaction by voice, becoming one of the most successful applications with multiple uses, information retrieval and extraction, morphological, syntactic and semantic tagging, NLP for automatic responses to questions, text sentiment analysis, automatic text summarization, document classification, among others.

The review of the literature in NLP allows establishing the requirements of the users who demand the use of interfaces in their natural languages, making the research and development of research projects necessary, which contribute with the development of a model of interface systems for the interaction with Explicit Knowledge databases, which simplify and reduce the costs referred to the search and research tasks.

IV. Immersive Technologies

A. Virtual Reality (VR)

VR as defined by [23], is a system used to describe 3D environments generated by computers that can be explored and allow interaction with users. Users become part of a virtual world in which they are immersed and can interact with and manipulate objects, as well as perform various actions. VR is a simulated reality constructed using digital elements through computational systems. The construction and visualization of alternative reality require powerful hardware and software resources (e.g., immersion headsets, head-mounted displays, exoskeletons, power globes, 3D software, etc.) to make the creation of realistic immersive experiences in VR environments possible [24]. After many years of research and development, VR hardware and software are now available for use by the general public, researchers, and entrepreneurs.

VR can be classified into various categories, including virtual worlds, augmented reality (AR), mixed reality (MR), and extended reality (XR) [25]. Several researchers argue that VR and associated technologies contribute to stimulating creativity and enhancing various competencies. Furthermore, their presence has increased in the entertainment industry, generating interest in research areas such as education, knowledge management, psychology, engineering, architecture, among others. VR can be associated with Artificial Intelligence (AI) techniques to drive innovations in various fields, especially to enhance learning experiences by enabling direct experiences of real or imaginary phenomena [**?**]. As the design and development of VR and AI become more accessible to institutions, the levels of usage and dissemination could increase.

Liu et al. [27] argue that the essential elements characterizing VR are: Sensory immersion, through which users immerse themselves in a virtual world and can see their surroundings by using a Head Mounted Display. Interactive simulation involves recreating a virtual world and digitally representing physical objects through a computer, enabling implicit interaction that allows users a degree of control over their experiences using sensors and input devices like joysticks, keyboards, head-mounted displays, among others.

Immersive VR applications, where the user's perception is mediated entirely by visual and audio devices used in the virtual world. In this case, external information must be entirely isolated for the experience to be fully immersive. This technology can be costly and has some drawbacks, such as lower-definition images, computer overload, and environmental issues associated with simulators [28].

VR allows users to feel as if they were inside a simulated virtual world. Psotka [29] asserts that this contributes to a significant emotional factor, which facilitates cognition and improves information retention. The user's range of movement can also be expanded, allowing for navigation (useful for virtual tours). Immersion can be achieved in various configurations, such as using a large screen and anaglyph glasses, or in CAVE environments with a room containing four walls and a projector for each. Head-mounted displays (HMDs) are also used to project images that will be viewed by the user.

In this research, a VR immersion headset is used, which is comfortable for immersion due to its minimal space requirements compared to other devices. It also provides a greater sense of presence that contributes to memory retention and various cognitive processes [30]. However, it's important to note that in some users, VR can cause motion sickness, which is considered a significant disadvantage.

B. Natural User Interfaces (NUIs)

NUIs study new forms of human-computer interaction [31]. They are characterized by interactions that users find natural, common, and familiar. The design includes the use of new devices that make this type of interaction possible, not limited to just the use of a mouse and keyboard. They allow for gesture-based, touch-based, transduction-based, or body movement-based interactions, as well as voice command communication, among others. Innovations in input peripherals demand changes in the way we interact with digital screens and traditional interfaces like the mouse and keyboard, which are replaced by touch-based and motion-based interfaces [32].

NUIs represent a revolution in the field of computing, not only because they replace existing and widely used traditional interfaces but also because they enable the creation of new types of applications and original and innovative forms of interaction. These can be applied in various fields such as engineering, management, marketing, library science, and more.

C. Natural Devices Interaction

For [33], the emergence of new devices and interaction paradigms enables new forms of human-computer interaction, allowing users to interact with systems using body movements or transduction. Users can operate systems through intuitive actions such as gestures, touches, haptics, or speech. This offers a significant opportunity to enhance user experiences.

This literature review and the establishment of the state of the art have made it possible to recognize the immense potential of resources and elements in immersive technologies. Their use in proposals for interfaces with explicit knowledge databases will enable the conception and design of original and innovative models.

V. Related Works of Interaction Model Systems based on Immersive Technologies

The lack of flexibility in information systems has led users to employ their own strategies to carry out their daily activities in alignment with business objectives. Users fulfill their functions, enhance their performance, and save resources, especially time [34]. With the aim of formalizing the intentions of users of enterprise information systems for the execution of their daily tasks in line with their job roles and to improve their performance, Khodabandelou et al. [35] propose a method to discover the strategies users employ to achieve their personal objectives, aligned with business objectives.

The method is based on a supervised machine learning algorithm developed using general business activities and specific business rules. According to the authors, the model could be used to determine user behavior and enhance their performance. An advantage of this method is that it provides the option to work with flat or structured files. Additionally, the method allows for the structuring of a knowledge base that could be generalized for various types of businesses.

From another perspective, there is a considerable number of applications for exploring explicit knowledge databases that are designed to interact with traditional resources such as scientific databases [36]. However, there are some difficulties associated with the traditional environment. In the literature, several problems that hinder the search for scientific articles are reported, such as:

1) Traditional Devices: mostly have limited display space. It is assumed that newer generation LCD monitors have improved features [37], and they are currently the most commonly used means. Additionally, the visibility of LCD screens is lower when using an anti-reflective filter, so it is recommended for use when there is glare, a risk of visual fatigue, or when the user is performing tasks that do not depend on the detection of stimuli with low RGB values [38].

2) RepoVis: adopts the metaphor of visualizing source code listings hanging on a wall from a distance [39]. The complete visual description is the central piece of the structure (folders, files, and code) at a given moment in a software project. Source code files are represented as boxes with rows of colors that represent one or more lines of code.

3) Al-Amawi et al. [40]: propose the creation of a database to store explicit knowledge derived from lectures at a university. This database resembles a cognitive memory that grows and evolves over time, serving as a reference and repository of knowledge generated in the educational process. This is part of an e-learning system that provides benefits to students.

In the literature review, various works with different approaches were found, some of which make proposals that can contribute to the development of this research project.

VI. Model System Development

Below, the processes used for developing the different elements for building the model of the web repository interaction system based on immersive technologies and natural user interfaces are described.

A. Physical Environment Setup for Immersive Experiences

The equipment is configured, and the first step can be seen in Fig. 2 [15]. The Leap Motion was connected to the Oculus Rift, and then both devices were connected to a laptop using USB and HDMI ports. The installation software used was the Unity3D graphics engine.

(a) Schema setup (b) Actual operation

Fig. 2. Immersive environment configuration [5]

B. Usability for the Development of the Virtual Interface

Some usability principles should be considered for the design of the model in order to facilitate its use and proper handling of errors in its usage. Taking these principles into account in the design according to the defined and identified

target audience should contribute to maintaining product usability quality to achieve maximum user satisfaction. One of the most important criteria for evaluating the usability of a virtual environment is the sense of presence. VR environments have the advantage of generating simulations that can act on the imagination of the participant, creating the sensation of psychologically transporting him/her to another place, which can be real or imaginary. Immersion in a VR environment with a high degree of presence will be an experience close to reality and even more pleasant. Tasks with a 2D interface use interactive output devices such as: keyboard and mouse, and interact with 2D objects and various tools (Marsh, 1999). Interaction in a VR system is carried out in a different way, with resources whose ergonomic evaluation criteria of the interfaces they use, is different from what most users are used to, helmets, glasses, gloves, virtual rooms, to mention a few.

Jordan [41] established usability principles, describing how and why they influence usability. Klevjer (2006) argues that the sense of presence in an environment can be enhanced through the use of an Avatar, which is a digital character that can resemble a real person, an animal, or take on another appearance as required, considering the model's requirements and user preferences [15]. The image shown in Fig. 3 corresponds to the avatar developed for this work, a resource that can enable user engagement, allowing them to perceive it as an assistant with whom they can interact using voice commands. The avatar assumes basic functions for exploring explicit knowledge documents contained in web-based databases.

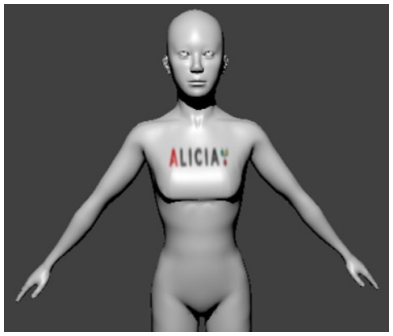

Fig. 3. Avatar of the model system.

C. Natural Interaction System Model

After the immersive environment was set up, different techniques for interaction in immersive environments were investigated and explored:

1) Direct Manipulation: Technique implemented using a virtual hand to accurately emulate human hand movements. The selection of an element involves holding an object in the same way as in the real world. In this technique, elements are required to possess solid and physical properties for better interaction. Fig. 4, shows the selection of a node through direct manipulation; which as can be seen, is similar to holding a physical object in the real world.

2) Gestural manipulation: Immersive VR elements can be selected with virtual hand gestures. Holding an object with the pinch metaphor involves performing the 'Pinch' gesture and releasing it by performing the 'Stop' gesture using the open palm. In Fig. 5a, the node is selected by pinching, and in Fig. 5b, the palm is opened to stop selecting. This technique is not completely intuitive, because both gestures may mean something different to the user.

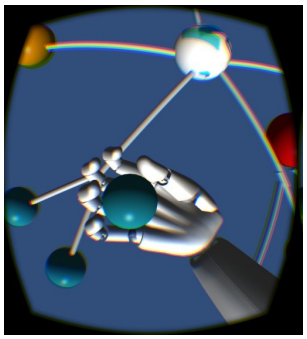

Fig. 4. Direct manipulation node selection.

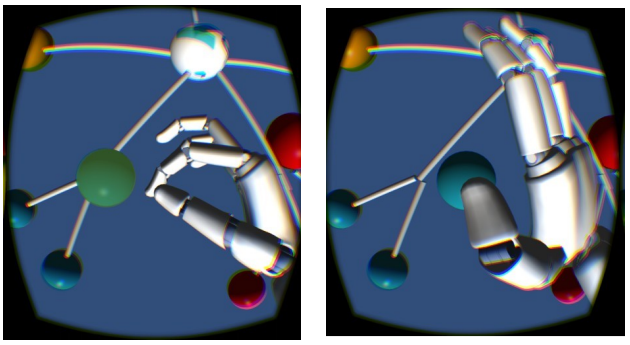
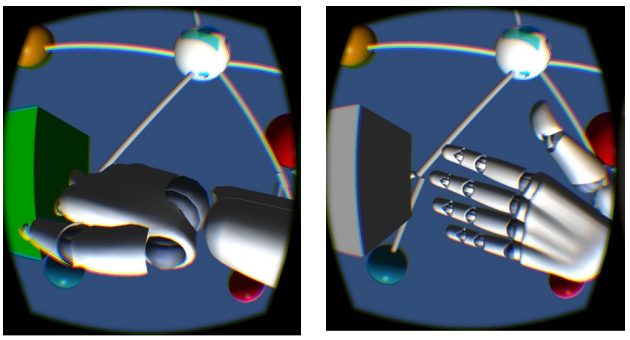


(a) Item Selecting (b) Element releasing

Fig. 5. Gesture of a node selection example.

3) Artificial Manipulation: Winn [42], mentions the concepts of "Dimension", "Transduction" and "Reification", which allows the development of the corresponding metaphor, such as the crossing of objects. To leave the selection of the element, it is only necessary to go through it again. In Fig. 6a, a selected cube is visualized, changing color, and in Fig. 6b, the cube is visualized returning to its previous state.



(a) Item Selecting (b) Element releasing

Fig. 6. Artificial node manipulation example.

D. Implementation of Web Crawler for Information Retrieval

In order to carry out the tests, the interface model was connected to the ALICIA of Concytec scientific database and to enable the information retrieval, a program of the tracking type was developed and implemented, which allows automatic communication with the ALICIA and extracts the information required in the VR based interface through analysis of the source code of viewing concerning the respective visualization. The implementation involved investigating the pattern for performing the tracking and extraction for automated recovery.

E. Speech Recognition and Text-to-speech Engine

Intel Perceptual Computing features a library of raw audio-to-text conversion functions used to develop the recognition engine. To achieve accurate voice recognition, a certified wireless microphone was integrated into the prototype. A C# .Net library was developed to continuously capture user audio and then transmit it to Unity3D via Socket. A listening port was implemented to receive user voice commands.

F. Implementation of the Syntactic Analyzer

The Freeling library was used to perform the interpretation of the syntactic analysis of voice commands, taking into consideration the quality of the attributes of the functions for the treatment of the Spanish language. This process of syntactic analysis first involves breaking down the words in a sentence or phrase, to perform content analysis and add type labels: noun, verb, adverb, adjective, article, pronoun, etc. Fig. 7 shows an example of the analysis of a sentence, generating its respective syntactic tree.

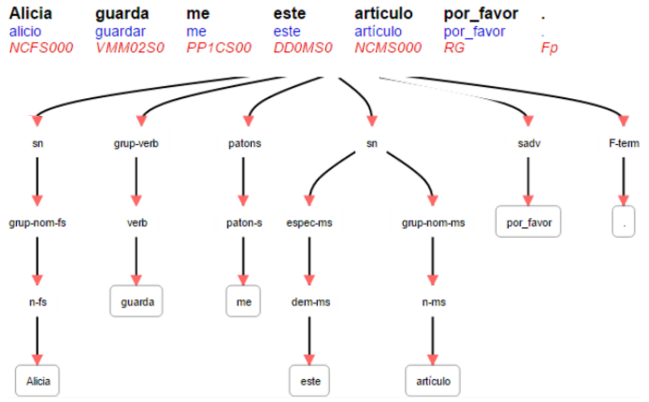


Fig. 7. Syntactic tree for a voice consultation generation.

The process diagram of the Proposed Model for document exploration in explicit knowledge databases, based on VR and NLP techniques, is presented in Fig. 8. The proposed model starts with a verbal query by a user who wants to search for a document in a web-based explicit knowledge database, then the speech recognition engine captures the speech signals and converts them into plain text. After the information is processed by the semantic analyzer, a syntactic tree is generated. Interaction and query commands are differentiated by the analyzer and then sent to the crawler, which establishes a connection with the virtual assistant to retrieve the information requested by the user. The results are visualized so that the user can begin

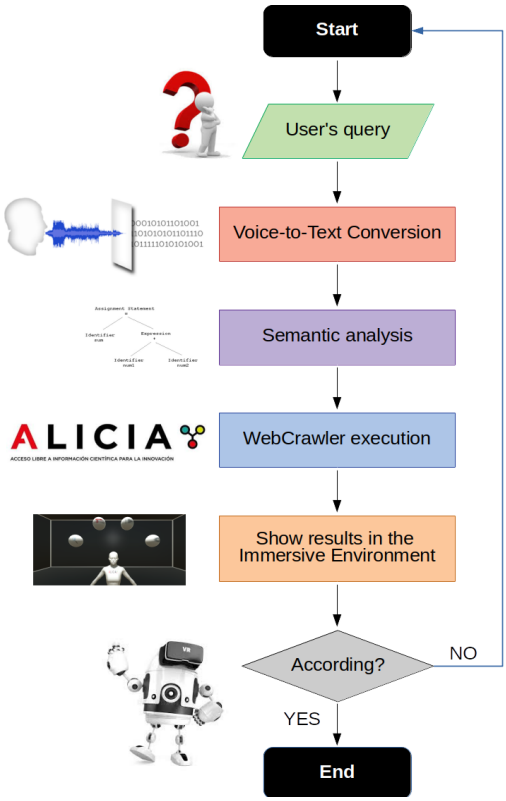

Fig. 8. Process diagram of the proposed model [5].

to interact. The process is concluded when the user agrees; otherwise, a new search is initiated.

VII. Evaluation of Proposed Model Regarding the Traditional

Usability is defined as the degree of satisfaction with which a product can be used by specific users to achieve specific goals, linked to effectiveness, efficiency, and satisfaction, within a particular context of use. The results of tests obtained using the proposed model in comparison to traditional models will be evaluated using the ISO 9241 standard, which pertains to interface usability. The dimensions to be evaluated include user-interface interaction, effectiveness, efficiency, and satisfaction.

A. Choice and Measurement of Variables

The following metrics are used:

1) Effectiveness: The accuracy achieved by users in relation to specified objectives also implies the absence of system errors and ease of learning and remembering. The metrics used include the number of important tasks executed, the number of relevant functions used, the number of tasks completed on the first attempt, the number of support requests, the number of accesses to help, and the number of functions learned.

2) Efficiency: This is the relationship of the resources employed (time, effort, etc.) with the accuracy and integrity with which the users achieve the specified objectives. The metrics used are: Time spent in the first attempt, time spent in

relearning functions, productive time, time to learn characteristics, time to relearn, time spent in error correction.

3) Satisfaction: it is a subjective factor that takes into account the positive attitude towards the use of the product. The metrics used are: qualification of satisfaction with important features, qualification of ease of learning, qualification of error handling and the rate of voluntary system usage.

4) Preparation of Experiments with users: Once the devices are interconnected and the software modules are initiated, the evaluation of the document scanning model for explicit knowledge databases using the VR and NLP model, and the model with traditional interfaces of ALICIA (Web) were conducted. These evaluations were performed with five users, following Nielsen's [43] recommendations for interface evaluation. Each user was assigned the task of searching for scientific articles for thirty minutes using both interface models. During the experiment, users could request assistance from an expert, who was also responsible for documenting the experiment.

The first model evaluated was the exploration of scientific articles using the VR, NLP, and NUI-based model. In this model, the user immersed in the interface communicates with the article search mechanism through voice commands and can also interact with the elements being queried through touch. Fig. 9 shows a user utilizing the interface model, and Fig. 10 displays the information content presented to the user on the video monitor.

Fig. 9. Evaluation of the VR, NLP and NUI interface model.

Fig. 10. View of the user with the model.

The second model to be evaluated is the traditional document exploration model, utilizing the Alicia scientific database interface. In this case, the user has a monitor for query visualization and uses the mouse and keyboard solely for interactions. Fig. 11 illustrates a user utilizing the traditional Alicia-Web interface, and what the user sees on the monitor is shown in Fig. 12.

Fig. 11. Evaluation of the traditional model of interface - Alicia Web.

Fig. 12. View of the monitor with the information shown by the traditional interface.

VIII. Results

The observations made on users using both types of interfaces allowed for the assessment of the effectiveness of each interface using the metrics outlined in ISO 9241. Effectiveness is defined as the achievement of goals or task completion, and it is represented by the number of goals accomplished. Various metrics count the goals achieved, tasks completed, functions used, etc. The results are tabulated in Table I.

The data from the results of using both interfaces for evaluating their effectiveness according to ISO 9241 are presented. Effectiveness is defined as the optimal use of the necessary resources to achieve a goal, where time is an important factor for the user of a software interface. The longer the time taken by the user to complete tasks using the interface, the lower the effectiveness. Conversely, if the time is shorter, the interface is considered more effective. The results are shown in Table I.

The satisfaction evaluation for each interface, considering the metrics defined by ISO 9241, takes into account that it is the degree or level of conformity of the user; it is their personal appreciation when evaluating the software interface. In order to measure software satisfaction in different aspects, the user must choose from five assessment alternatives: (1) Not at all satisfied, (2) Not very satisfied, (3) Fairly satisfied, (4) Very satisfied, (5) Completely satisfied. After each alternative of satisfaction there is a percentage of valuation corresponding to each alternative of satisfaction; these are respectively: 0.2, 0.4, 0.6, 0.8, 1.0. By averaging the levels of satisfaction, we can ultimately obtain the percentage of overall satisfaction required

TABLE I. COMPARISON OF EFFECTIVENESS USING THE TWO INTERFACES [15]

Metrics: Effectiveness Measure - ISO 9241	**Proposed model (Mean Quantity)**	**Web (Mean Quantity)**
Tasks performed	2.0	4.2
Functions used	3.8	7.8
Completed successfully Tasks at the first attempt	1.2	2.2
Important tasks performed	2.2	2.8
Calls for support	3.4	0.6
Access to help	0.4	0.2
Metrics: Measure of efficiency - ISO 9241	**Proposed model (Mean Quantity)**	**Web (Mean Cuantity)**
First attempt time	35.6	47.3
Time to relearn functions	31.2	16.6
Productive time	54.0	78.6
Learn characteristics time	16.6	31.2
Relearn characteristics time	54.0	78.6
Error correction time	55.8	54.6
Metrics: Measure of satisfaction - ISO 9241	**Proposed model (Mean %)**	**Web (Mean %)**
Qualification of satisfaction	0.72	0.32
Qualification of ease of learning	0.64	0.44
Error treatment qualification	0.24	0.28
Voluntary product use rate	0.92	0.64

in each metric.

IX. DISCUSSION

After processing the data obtained in the evaluation of the interfaces for each of the metrics following the ISO 9241 standards, allowing the assessment of the system in the dimensions of effectiveness, efficiency, and satisfaction, the "T-Student" statistical test was applied. This test revealed sufficient evidence that significant differences exist in the comparison of the evaluated dimensions:

- The proposed VR and NLP-based model showed low effectiveness compared to the traditional model of the scientific database ALICIA.
- The VR and NLP-based model exhibited higher efficiency compared to the traditional ALICIA database.
- Users expressed greater satisfaction with the VR and NLP-based model.
- The efficiency of the VR and NLP-based model was higher compared to the traditional ALICIA model.

The results obtained from the empirical analysis, based on user experiences with the VR and NLP-based model, generated considerable interest among users. They perceive it as a novel approach to interacting with explicit documents in institutional repositories, a proposal with significant development potential. Users faced initial difficulty with both types of models. Specifically, users who had never used ALICIA only utilized basic functions and not the tools and features available in the system. In contrast, users utilizing the VR and NLP-based interface initially struggled to adapt to the three-dimensional nature of immersion headsets. However, after a few minutes of adaptation, they expressed a desire to explore all available options and functionalities.

For exploration and document retrieval tasks, users employing the VR and NLP-based interface completed these tasks in less time than those using traditional web-based interfaces. It is noteworthy that a significant issue with VR immersion headsets is user discomfort.

X. CONCLUSION

An interface system model for explicit knowledge databases has been proposed and developed, based on natural language, natural users interface and immersive technologies processing techniques, which were successfully tested and found to be successful.

The scientific database ALICIA, was used for the evaluation of the proposed traditional model, using the ISO 9241 standard, considering Effectiveness, Efficiency and Satisfaction. The statistical test T-Student was applied to evaluate the data obtained by means of inferential statistics. The results allow to establish that the proposed model based on VR, NLP and NUI is superior to the traditional one in the dimensions of "Efficiency and Satisfaction" and is inferior in the dimension of "Effectiveness". Therefore, it is concluded that the model of exploration of scientific articles with VR, NLP and NUI is better than the traditional model.

It is important to point out that currently, users of large databases have traditional interfaces based mainly on the mouse and keyboard. In the opinion of the authors, a greater effort should be made to research new interface models that are more efficient and effective and that have ergonomic and usability features to facilitate user interaction with the systems.

***Abstract*—Hackers use the vulnerability before programmers have a chance to fix it, which is known as a zero-day attack. Zero-day attackers have a variety of abilities, including the ability to alter files, control machines, steal data, and install malware or adware. When a series of complex assaults uses one or more zero-day exploits, the result is a zero-day attack path. Timely assessment of zero-day threats might be enabled by early detection of zero-day attack pathways. To detect this zero-day attack, this paper introduced a Chaotic Enriched Salp Swarm Optimization (CESSO) with the help of a hybrid Convolutional Recursive Neural Network (HCRNN) is implemented. The input data is retrieved from two datasets called IDS 2018 Intrusion CSVs (CSE-CIC-IDS2018) and NSL-KDD. The data is pre-processed with the help of data cleaning and normalization. A unique hybrid feature selection method that is based on the CESSO and Information Gain(IG) is introduced. The CESSO is also used to improve the Recursive Neural Network (RNN) performance to produce an optimized RNN. The selected features are classified, and prediction is performed using the hybrid Convolutional Neural Network (CNN) with RNN called HCRNN. The implementation of the zero-day attack is performed using MATLAB software. The accuracy achieved for dataset 1 is 98.36%, and for dataset 2 is 97.14%.**

***Keywords*—Hackers; vulnerability; zero-day attack; chaotic enriched salp swarm optimization; data cleaning; normalization; and MATLAB software.**

I. Introduction

An online assault that targets a software vulnerability that neither the programmed developer nor antivirus vendors are aware of is known as a zero-day (0-day) exploit. Before anybody else interested in resolving the issue can identify the software vulnerability, the attacker does, writes an exploit rapidly and then utilizes it to launch an attack [1], [2]. Particularly in today's environment, a zero-day vulnerability poses a major and possible threat to many enterprises. When a software flaw is a zero-day vulnerability, it goes beyond the expected immediate or almost daily instantaneous detection and remains unnoticed for a considerable amount of time [3]. Before the manufacturer even notices the issue or rushes to patch it, this security flaw is frequently exploited by hackers [4], [5]. This exploit is, hence, often referred to as a zero-day assault. Zero-day attacks might evade detection by traditional defenses for a considerable amount of time since network managers' primary focus is to stop assaults before they happen [6]. This makes dangerous agents more likely to penetrate the networks and makes the administrator's job more difficult. Preventing zero-day attacks is one of the most challenging aspects of risk management.

Risk management requires knowledge of the potential threats to be faced as well as the strength of the attack surface [7]. Zero-day attacks make use of vulnerabilities that have already been identified but of which the vendor or developer of the application is ignorant. The vulnerability's recent discovery may take weeks for identification and patching, leaving the program vulnerable to exploits. All kinds of intrusion detection systems are thought to face their greatest threat from zero-day (unknown) assaults [8], [9]. Various studies have dealt with the challenge of identifying unidentified assaults. Applying unsupervised anomaly detection algorithms is one way to find new attack kinds. Despite how difficult this issue is, resolving it would significantly improve the security of our computer system [10]. When additional safeguards are put in place to identify zero-day attacks, the difficulties listed below must be addressed. Not all zero-day vulnerabilities result in zero-day attacks [11].

The players without adequate security measures to thwart all potential attacks lose and are taken advantage of [12]. These weaknesses in security mechanism implementation by an organization or a person allow hackers an exploitation window that might result in zero-day attacks. Zero-day vulnerabilities can be challenging to identify since they can manifest in a variety of ways, including a lack of data encryption, a lack of authorizations, a weakness in an algorithm, a vulnerability in the password security system, etc. [13], [14]. Due to the nature of these security flaws, detailed information on zero-day exploits may only be accessed after the exploit has been discovered [15]. An enterprise may notice suspicious scanning activity or unexpected traffic originating from a customer or service due to a zero-day vulnerability.

The foremost contribution of the paper is as follows-

- The filter technique IG is used before initializing the population in the SSO model. Then, the CESSO approach is used to choose the optimum feature subset.
- Salp Swarm Optimization is improved by incorporating the Chimp Optimization algorithm's strategy,

i.e., its Chaotic Map, named Chaotic Enriched SSO (CESSO).

- This CESSO model is used to improve the performance of the RNN to produce an optimized RNN.
- The optimized RNN is a hybrid with the CNN called HCRNN, which will enhance the prediction accuracy of the zero-day attack.

The organization of the paper is as follows: Section II explains the literature review of the paper, Section III describes the problem statement, Section IV is the detailed description of the proposed methodology, Section V discusses the result and discussion, and finally, Section VI concludes the paper with a detailed conclusion.

II. Literature Review

In this section, the recent papers related to the zero-day attack are discussed, and their drawbacks are also discussed.

In 2016, Zhang et al. [16] suggested a security metric for assessing network resilience to Zero-Day Attacks. By creating and assessing several diversity measures, this research takes the first step toward formally characterizing network diversity as a security parameter.

In 2018, Sun et al. [17] proposed the probabilistic identification of zero-day attack paths, and Bayesian networks were used. This research suggested a probabilistic method and developed a prototype system called ZePro for identifying zero-day attack paths.

In 2019, Afek et al. [18] suggested the extraction of zero-day signatures for high-volume attacks. The key contributions of this research are the method created to extract the necessary signatures, together with the concept of the string-heavy hitters' issue and the technique for solving it.

In 2021, Zoppi et al. [19] presented the strategy and application of unsupervised algorithms for detecting zero-day attacks. The article uses a question-and-answer format to highlight common problems encountered when performing quantitative studies for zero-day detection, and it demonstrates how to build up and test unsupervised algorithms using the proper equipment.

In 2022, Mbona and Eloff [20] recommended machine learning approaches for the semi-supervised detection of zero-day intrusion attacks. The method suggested in this paper shows that Benford's rule, the law of anomalous numbers, is a workable technique that may successfully discover major network aspects that are suggestive of abnormal behavior and can be utilized for identifying zero-day assaults.

In 2022, Popoola et al. [21] examined federated deep learning for IoT-edge devices to detect zero-day botnet attacks. To protect IoT edge devices from leaking personal data, this study presented the federated DL (FDL) approach for zero-day botnet attack detection. This approach uses an ideal deep neural network (DNN) model to classify network traffic.

In 2022, Bar and Hajaj [22] proposed the SimCSE for the prediction of encrypted traffic and zero-day attacks. The simple contrastive learning of sentence embedding (SimCSE) proposed in this study serves as the embedding model for a novel method for traffic identification at the packet level.

In 2021, Kumar and Sinha [23] proposed an effective method for detecting zero-day cyberattacks. This study suggests an innovative, robust, and intelligent cyber-attack detection model that makes use of the heavy-hitter idea and a graphical approach to identify zero-day assaults.

III. Problem Statement

Traditional intrusion detection approaches are no longer enough for identifying zero-day attacks, which may exploit security vulnerabilities that may exist in a network due to the fast expansion of network-based cyberattacks. With the advancement and new development of systems, cyber security vulnerabilities, and technology, existing approaches in intrusion detection have not been sufficient to defend systems from cyber security vulnerabilities. There is a need for more proactive ways to identify known and new vulnerabilities to stop zero-day attacks from taking advantage of such network security weaknesses. If a hacker is successful in exploiting a vulnerability in software before the developers of the affected system can find a solution, this is known as a zero-day attack [24]. Zero-day vulnerabilities can take on practically any form since they can be disguised as any type of more generic software flaw.

IV. Proposed Methodology

Detecting zero-day threats is one of the most challenging responsibilities of an IDS. An attack that makes use of a network vulnerability that has not yet been found is known as a zero-day attack. The first step in the life of a zero-day assault is the identification of a software vulnerability. Once an exploit has been made, the vulnerability is utilized to attack the targets. After the initial assaults are carried out, the vendors distributing the weak software learn about it and produce a patch to fix it. This project will design a fresh, optimized deep learning system to address the difficulties of detecting zero-day ransomware. Fig. 1 shows the proposed approach for detecting zero-day attacks.

From Fig. 1, the input data is received from the two datasets called CSE-CIC-IDS2018 and NSL-KDD. Then, the input data is cleaned and normalized in the pre-processing stage. The statistical features and higher-order features are extracted in the feature extraction stage; the required features are selected using the improved IG using the CESSO model. Then, the same CESSO will enhance the features of the RNN, and it is hybrid with the CNN to produce HCRNN, which is used for zero-day attack detection.

A. Dataset Description

In the Zero-day attack model, two datasets are used.

1) IDS 2018 Intrusion CSVs (CSE-CIC-IDS2018): This dataset was created by the University of New Brunswick initially for research on DDoS data. This dataset won't be modified in the future because it was totally compiled in 2018. The dataset was indeed based on logfiles kept by the institution, which revealed several DoS assaults during the course of the period that were made accessible to the public. Because

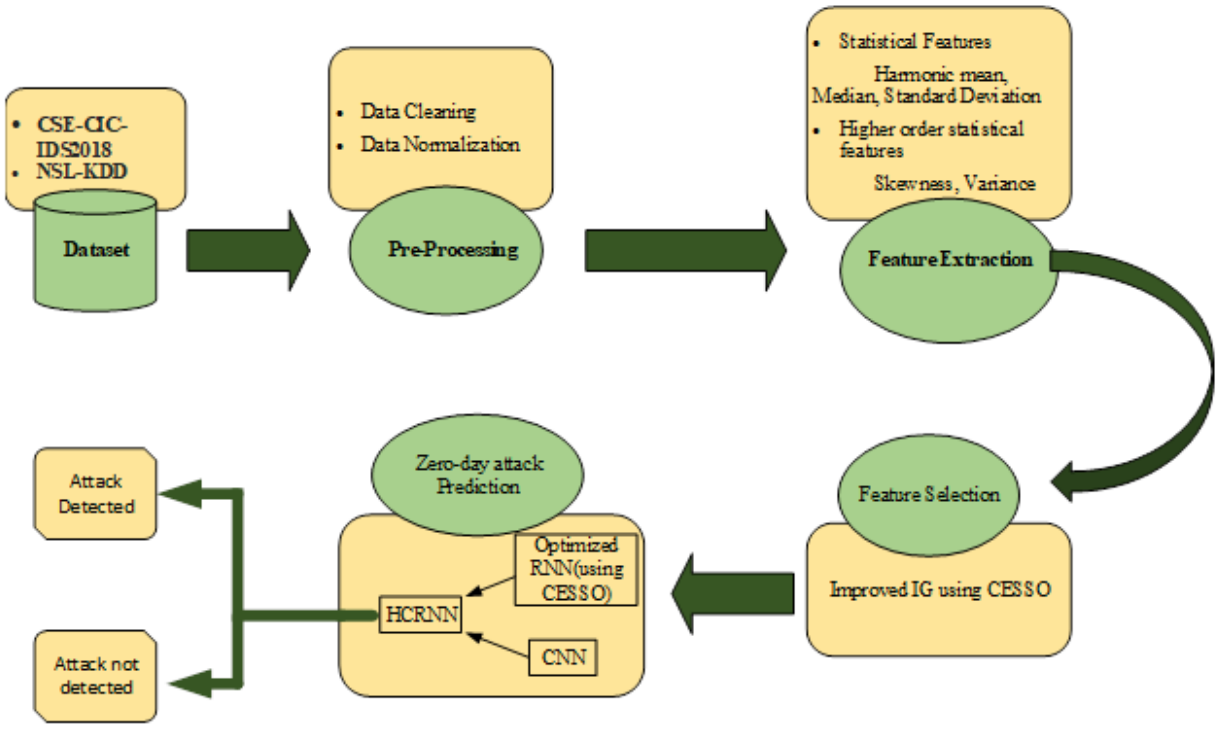

Fig. 1. Block diagram of the Zero attack detection mechanism.

it specifies whether or not the sent packets are malicious, the Label column is possibly the essential information for building machine learning algorithms for this dataset.

Based on date, data is separated into several files. Each file is imbalanced; the notebook creator is responsible for partitioning the dataset into a balanced shape for more accurate predictions. This dataset contains a total of 80 columns, each of which corresponds to a record in the IDS logging system used by the University of New Brunswick. Both columns for forward and backward traffic are present because their system distinguishes between the two. The following are the columns in this dataset that are most important: Label, Destination port, Protocol, Flow Duration, Total forward packets, Total backward packets, and Total forward packets [25].

2) NSL-KDD: As compared to the original KDD data set, the NSL-KDD data set is better in the following aspects:

The classifiers won't be skewed in favor of a more prominent impact since similar data are excluded from the train set. Due to the lack of duplicate data in the proposed test sets, methods with greater diagnostic accuracy for frequent records have no impact on the learners' outcomes. The proportion of records selected from each class of difficulty levels in the original KDD data set is inversely proportional to the total number of entries in each class.

As a result, there is a wider range of variance in the classification rates of different machine learning techniques, making it simpler to assess different learning approaches correctly. With a manageable number of records in both the train and test sets, it is possible to run the tests on the complete set without having to choose a subset at random. Therefore, the assessment results from different research initiatives will be comparable and consistent [26].

B. Pre-processing

The raw dataset gathered during the prior step must be cleaned and normalized during this stage. It is possible to access the dataset's raw log data set. To assist in identifying online assaults, the data is normalized, encrypted, and stripped of duplicate and missing information during this phase of the evaluation process.

1) Data Cleaning: Finding duplicate data is a common need of data cleaning operations. Duplicates should be eliminated since deep learning produces the same patterns when non-duplicate variables are used. The cleaned dataset has been obtained after some columns have been cleared of duplicate and missing values. This dataset contains no duplicates.

2) Normalization: By transforming them into unique patterns, data are normalized. The process of converting raw data into a format that can be handled effectively is known as data transformation. Normalization focuses mostly on reducing or even getting rid of redundant data. Because of this crucial problem, managing data in relational databases that store similar data in several places is getting harder.

C. Feature Extraction

The features such as statistical features (Harmonic mean, median, standard deviation), higher order statistical features

(skewness, Variance), Improved Information gain (Proposed), and based features will then be retrieved from the pre-processed data.

1) Statistical Features:

a) Harmonic Mean: Numerical averages include the harmonic mean. It is determined by multiplying the number of observations, or series elements, by the inverse of each integer in the series. The harmonic mean is, therefore, the inverse of the arithmetic mean of the reciprocals, as shown in Eq. (1)

$$\mu_{\mathcal{H}} = \frac{T}{\sum_{i=1}^{n} \frac{1}{\alpha_i}} \tag{1}$$

where, α_i a series with T numbers.

b) Median: The median, which is the midpoint in a list of numbers arranged either ascending or descending, may be more representative of the set of data than the average.

$$Median = \begin{cases} \frac{l+1}{2}, & for\ odd\ numbers \\ \frac{l}{2}, & for\ even\ numbers \end{cases} \tag{2}$$

where, l is the last number.

c) Standard deviation: The term "standard deviation" (σ) refers to a measurement of the data's dispersion from the mean. The values are centered all around the mean whenever the standard deviation is small and widely scattered when it is high.

$$SD(\sigma) = \sqrt{\frac{\sum_{i=1}^{n}(\alpha_i - \mu)^2}{N}} \tag{3}$$

where α_i is the input value, μ is the mean and N is the total number of elements.

2) Higher-order statistical features:

a) Skewness: A distribution's skewness can be measured to see how asymmetrical it is. A distribution is asymmetric whenever its left and right sides do not reflect each other in the same way. A distribution may have right (or positive), left (or negative), or zero skewness.

$$Skewness = \frac{3(\mu - Median)}{\sigma} \tag{4}$$

b) Variance: Variance is the analytical evaluation of the numerical variation inside a data set. More specifically, variance determines how far apart every integer in the set is from the mean and, thus, from the other numbers in the set.

$$Variance = \frac{\sum_{i=1}^{n}(\alpha_i - \mu)^2}{N} \tag{5}$$

D. Feature Selection

This section introduces a unique hybrid feature selection method that is based on the CESSO algorithm and IG. Let's start by outlining the IG algorithm and then describe how the CESSO technique was implemented in detail.

E. Improved Information Gain

Information gain uses correlations between features and classifications to distribute feature weights statistically. Let $F = \{f_1,\ f_2,\ f_3, \ldots, f_n\}$ be the group of n data points in a dataset, $X = \{x_1,\ x_2,\ x_3, \ldots, x_p\}$ be the collection of p features, and $Y = \{y_1,\ y_2,\ y_3, \ldots, y_m\}$ be a group of m type label. The number $P(Cl_i)$ denotes the percentage of classes in F with the label P_i where $i = 1,\ 2,\ 3, ..., m$. Eq. (6) provides the dataset's entropy.

$$H(Y) = -\sum_{i=1}^{m} P(Cl_i)\ log_2\ P(Cl_i) \tag{6}$$

Each feature in the data classification system has an information gain (IG). Where $Q = \{Q_j^1,\ Q_j^2, , \ldots, Q_j^p\}$ represents the $p^{th}(p = 1, 2, \ldots, n)$ a data set feature. Regarding the characteristic, $Q = \{Q_j^1,\ Q_j^2, , \ldots, Q_j^p\}$ the corresponding conditional entropy is:

$$H(Y|Q_j) = -\sum_{p=1}^{k} P(Q_j^p) \sum_{i=1}^{m} P(Cl_i|Q_j^p) log_2 P(Cl_i|Q_j^p) \tag{7}$$

where, $P(Q_j^p)$ denotes the categorical variable Cl's prior probability and Q_j^p is the value of Q_j, an attribute with k different kinds of values. The $P(Cl_i|Q_j^p)$ represents the conditional probability of the variable Cl after the attribute Q_j is fixed. Consequently, the formula below states that the value of the information gained from the attribute Q_j is provided by the difference between $H(Y), H(Y|Q_j)$, which is given by Eq. (8).

$$IG(Q_j) = H(Y) - H(Y|Q_j) \tag{8}$$

An increased IG often denotes the importance of the feature for the categorization.

F. IG-CESSO for Optimal Feature Subset Selection

The CESSO algorithm finds the optimal feature subset with the fewest features and highest classification accuracy, which is what feature selection seeks to do for a given dataset. It is utilized for giving each component a binary string to represent whether an attribute is picked; for example, the feature is chosen when the binary value is 1, whereas a binary 0 denotes that it is not.

Each of these two indications uniquely impacts the classifier's classification performance. In this instance, just merge them into a single weighted indicator and use the same fitness function as in Eq. (9).

$$F_i = \delta_1 * A_{clasifier} + \delta_2 * (1 - \frac{N}{T}) \tag{9}$$

where T stands for the total number of characteristics and N for the number of attributes that were selected; here, δ_1 and δ_2 have values of 1 and 0.001, respectively[27]. Eq. (10) may be used to determine the classification accuracy derived from the HCRNN classifier.

$$A_{classifier} = \frac{K_c}{K_c + K_i} \tag{10}$$

In this example, the numbers K_i and K_c stand for the cases that were classified wrongly and properly, respectively. With the help of the fitness value, it is possible to ensure that the chosen features have a limited amount of features while yet providing the highest possible classification accuracy[27]. The following section provides a detailed description of the CESSO algorithm with basic Salp Swarm Optimization (SSO)

1) Salp Swarm Optimization: The Salp Swarm Optimization (SSO) imitates the behavior of salps, a kind of planktonic tunicate belonging to the Salpidae family with a barrel-like structure. Additionally, their tissues resemble those of jellyfish, and they move similarly to jellyfish, and a large portion of their weight is made up of water. Pumping water through their jello-like bodies causes them to move by contracting, which alters their locations. Salps in the seas engage in a swarm activity known as the salp chain, which may aid salps in better mobility by employing rapid, coordinated shifts and feeding. Based on this behavior, they created a mathematical model of the salp chains and evaluated it using optimization issues. The leader and the followers are the two groups that are initially separated out in SSO [28]. The leading Salp in a chain is referred to as the leader, while the trailing Salps are referred to as the followers. In n-dimensions, where n stands for the variables in the issue, and n denotes the search space, the salps' location is established. These salps look for food sources since they can identify the swarm's goal. The position should be updated often. Thus, the salp leader updates the position using Eq. (11) below-

$$a_j^1 = \begin{cases} S_j + K_1((U_j - L_j) * K_2 + L_j), & K_3 <= 0 \\ S_j - K_1((U_j - L_j) * K_2 + L_j), & K_3 > 0 \end{cases} \quad (11)$$

where, a_j^1 is the position of the leader within j^{th} dimension, where the food source in this dimension is S_j, the upper and the lower bounds are U_j and L_j , respectively. The K_2 and K_3 are generated randomly in the range [0, 1] to maintain the search space. Additionally, the parameter K_1 is a crucial coefficient in this method since it helps to balance the exploration and exploitation phases [29]. It is derived as follows:

$$K_1 = 2e^{-(\frac{v}{v_{max}})^2} \quad (12)$$

where, the letters v and v_{max} stand for the current iteration and the maximum number of iterations, respectively. Using Eq. (13), the SSA begins updating the followers' position after changing the leader's position.:

$$a_j^i = \frac{1}{2}(a_j^i + a_j^{i-1}) \quad (13)$$

where a_j^i is the i^{th} position of the follower within j^{th} dimension and $i > 1$.[28]

However, the SSO has the limitation of falling into the local optima problem. Therefore, the proposed work has introduced a new SSO variant based on the Chimp Optimization Algorithm, i.e., the Chaotic Map. Therefore, chaotic enriched SSO provides high-level efficiency in optimization performance. The following shows a detailed description of the CESSO algorithm.

2) CESSO-based on COA Algorithm: Salp Swarm Optimization is improved by incorporating the strategy of the COA. The COA enhances the performance of the SSO due to the incorporation of the chaotic map strategy. The COA is mainly focusing on hunting its prey based on determining the prey and the chimp. In the CESSO algorithm, this step is reformulated by considering the current best solution, and the next solution is respectively represented as a_j^i and $a_j^(i-1)$. The mathematical derivation of the Chaotic map based on the COA [30] is shown in Eq. (14) and Eq. (15).

$$d = |K.a_j^i - C_v.a_j^{i-1}| \quad (14)$$

$$a_j^i(t+1) = a_j^i - p.d \quad (15)$$

where t denotes the current iteration, p, C_v, and c are the coefficient vectors, $a_j^{i-1}$is the position vector of the targeted solution, and a_j^i is the position vector of a current best solution. The coefficient vectors p, C_v, and K are determined using Eq. (16).

$$\begin{cases} p = 2.f.r_1 - f \\ K = 2.r_2 \\ C_v = Chaoticvalue \end{cases} \quad (16)$$

In the aforementioned equation, the variable f has a specific range, i.e., drastically minimizing from 2.5 to 0 in every iteration process [30]. Therefore, exploitation and exploration have maintained the equilibrium. On the other hand, the random vectors are set between the range of 0 and 1. At last, the chaotic vector is illustrated as m, i.e., a strategy of the COA. This strategy is executed based on executing several chaotic map processes. This strategy can enrich the optimization performance, and the chaotic enriched chimp-based salp optimization can provide higher performance than the traditional SSO and the COA. This hybrid model, Chaotic Enriched SSO (CESSO), can provide better performance.

The proposed work uses the CESSO algorithm to improve the feature selection, especially on Information Gain (IG). The IG-CESSO provides a high-level feature that helps to improve the classification performance. Apart from feature selection, the CESSO algorithm is utilized for improving the prediction performance; therefore, the parameters of the RNN are optimized using CESSO, which is discussed in section IV.G.2.

G. Prediction of Zero-day Attack

The optimized hybrid classifier that makes the zero-day attack detection will be trained using the selected optimal features. The hybrid classifier will be a combination of optimized RNN and CNN. To enhance the prediction accuracy of the zero-day attack detection model, the activation function of RNN is fine-tuned via a new CESSO.

1) CNN: The suggested model's structure is discussed in this part, along with specifics on its underlying motives. The proposed model has developed based on a set of layers, including the Input layer, Convolutional Layer, Max Pooling, and Recurrent Layer or Output Layer. Here, the CNN architecture has the fully connected layer that is replaced by Recursive Neural Networks (RNN); therefore, the proposed model has concatenated the Convolutional and recurrent layers for detecting zero-day attacks. These layers are discussed in their respective sections as follows.

In the architecture of the HCRNN for Zero Day attack detection, the CNN executes the layer-wise feature extraction using convolution layers and pooling layers [31]. The shortcomings of conventional machine learning methods, which need to extract data features manually, are overcome by CNN because it does not call for preprocessing or reconstruction of the original data. Furthermore, the model's complexity is substantially reduced by its weight-sharing characteristics.

The CNN's structure is depicted in Fig. 2, and the kernel function transforms the input data, which must be in two-dimensional form. The hidden layer comprises several convolution layers and pooling layers, where the input of one layer becomes the output of the following layer. There are not many restrictions on the input data using this structure, and it can accurately retrieve the hierarchical expression of the input data.

a. Convolutional Layer The convolution layer—which includes several feature matrices—is used to extract the local characteristics of the input data. Each feature matrix is capable of parallel processing since it can be thought of as a plane, which can significantly reduce the number of free parameters. Additionally, because convolution kernels vary depending on the plane, it is possible to display the extracted features completely. The following Eq. (17) and Eq. (18) determine the size of the output feature map following the convolution procedure:

$$h_o = [\frac{h_i - f_i + p_c}{s_i} + 1] \tag{17}$$

$$w_o = [\frac{w_i - f_i + p_c}{s_i} + 1] \tag{18}$$

Where the resulting feature map's height is h_o, w_o is the feature map's width at the output side, the input image's height is represented as h_i, w_i is the representation of input image's width, the size of the filter is denoted as f_i, the convolution operation's padding is represented as p_c, and the convolution' stride is denoted as s_i.

b. Max Pooling

The typical pooling technique known as max pooling (MP) operates on the feature map side and picks the largest value from a small n×n patch of the input feature map. The output feature map is then created by MP by combining the chosen values. The following Eq. (19) and Eq. (20) may be used to determine the output feature map size following the pooling procedure:

$$h_o = [\frac{h_i - f_i}{s_i}] \tag{19}$$

$$w_o = [\frac{w_i - f_i}{s_i}] \tag{20}$$

where, f_i is the size of the pooling area, the output feature map's height is indicated by the symbol h_o, The output feature map's width is indicated by the prefixw_o, the width of the input feature map is indicated by the letter w, the height of the input feature map's is indicated by the symbol h_i, and the width of the input feature map is denoted as w_i.

2) Recurrent Layer For Prediction: In the HCRNN architecture, the RNN layer joints the CNN by replacing the fully connected layer for prediction. The reason behind the selection of the RNN layer is for selecting temporal features, whereas CNN is for dealing with spatial features. However, the RNN has a drawback in that phrase parsing can be complex and slow. Interestingly, different parse trees may exist for the same text. Additionally, labeling the training data for recursive neural networks takes more time and effort than building recurrent neural networks. It takes more time and effort to manually break down a statement into smaller parts than it does to give it a label. To overcome this drawback, the parameters of the RNN are optimized using the CESSO algorithm.

The trees are symbolized by the letter T, and N samples are indicating the leaves of a tree. The neural network receives concatenated data containing a tree's possible child nodes. A combined score and a parent feature are produced by the neural network, which are the two features combined after being learned by a nonlinear mapping. A parent is created mathematically by applying a non-linear projection on the concatenated of the child characteristics, that is

$$PA_{x,y} = \rho[W_i(ch_x + ch_y) + B_p] \tag{21}$$

Where $(ch_x + ch_y)$ is the result of concatenating the child features x and y, W_i is the neural network's weight matrix, B_p is its bias parameter, ρ is a function that may be continually changed, and $PA_(x, y)$ is the last parent attribute [32]. The sign for this work was the logistic sigmoid since its derivative may be stated in terms of the primary equation. The neural network's learned merging score is used to determine whether samples are suitable for merging on the tree, as well as if they are neighboring when appropriate. To produce a binary tree, combining just the samples with the top score is permitted. The parent feature's score is calculated using Eq. (22)

$$PA_s = W^k_{score} PA_{x,y} \tag{22}$$

While the tree's score can be increased K, it is possible to determine the parameters W, B_p, and W^K_{score} of the neural network,

$$\underset{k \in N}{\operatorname{argmax}}\, PA_s(RNN(\theta, x, k)) \tag{23}$$

where θ is the representation of neural network parameters to calculate a score PA_s, and T are any potential trees produced by the aforementioned merging procedure. Finally, the RNN provides the outcome with respect to zero-day attacks. Moreover, the prediction performance is further improved by using the CESSO algorithm. The CESSO algorithm utilizes the

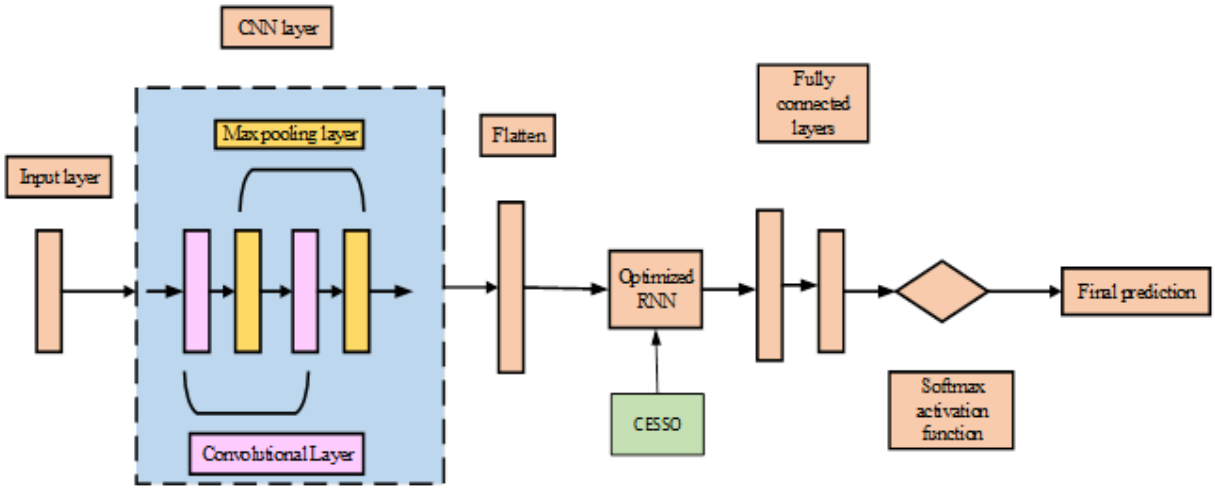

Fig. 2. Hybrid CNN with RNN architecture.

parameters of the RNN such as BATCH SIZE, MINI-BATCH, MOMENTUM, and LEARNING RATE. The prediction performance is further improved by this strategy. In this process, the CESSO algorithm evaluated the prediction performance of the RNN using the RMSE algorithm Eq. (24)

$$RMSE = \frac{1}{n}\sum_{i=1}^{n} w_i(y_i - \hat{y}_i)^2 \tag{24}$$

The n Number of samples, y_i Original value, y_i cap: Predicted outcome.

In the process, the RNN generates the value that is evaluated through the RMSE value. The minimal RMSE is considered the best solution. In each outcome, the parameter values are changed and updated with new solutions. Finally, the prediction performance of the RNN will be reached higher results. The overall flow of the proposed model is shown in Fig. 3.

V. Result and Discussion

The performance of the proposed strategy is compared to that of well-known methods such as CESSO-RNN, RNN, CNN, Bidirectional Long Short-Term Memory (Bi-LSTM), and Long Short-Term Memory (LSTM). The proposed CESSO-HCRNN model is compared with all existing models and performance for this is tabulated. The performance of the proposed is better than the other existing models because of improved IG using CESSO used in feature selection. Optimal RNN combined with CNN resultant the HCRNN also produces more accurate results. In this part, the performance measurements are also covered.

A. Performance Metrics

A number of matrices are used to measure the performance, including sensitivity, specificity, accuracy, recall, F-score, NPV, MCC, FPR, and FNR.

Sensitivity

The sensitivity value is obtained by just dividing the total positives by the proportion of true positive predictions

$$Sensitivity = \frac{TP}{TP + FN} \tag{25}$$

Specificity

Specificity is calculated by dividing the number of accurately anticipated negative outcomes by the total number of negatives

$$Specificity = \frac{TN}{TN + FP} \tag{26}$$

Accuracy The accuracy is the ratio of correctly classified data to all of the data in the log. The precision is described below-

$$Accuracy = \frac{TP + TN}{TP + FP + TN + FN} \tag{27}$$

Precision By employing the entire number of samples used in the classification process, precision is the representation of the total number of genuine samples that are appropriately taken into consideration during the classification process.

$$Precision = \frac{TP}{TP + FP} \tag{28}$$

Recall

Recall rate is a measure of how many genuine samples overall are considered when categorizing data using all samples from the same categories from the training data.

$$Recall = \frac{TP}{TP + FN} \tag{29}$$

F- Measure

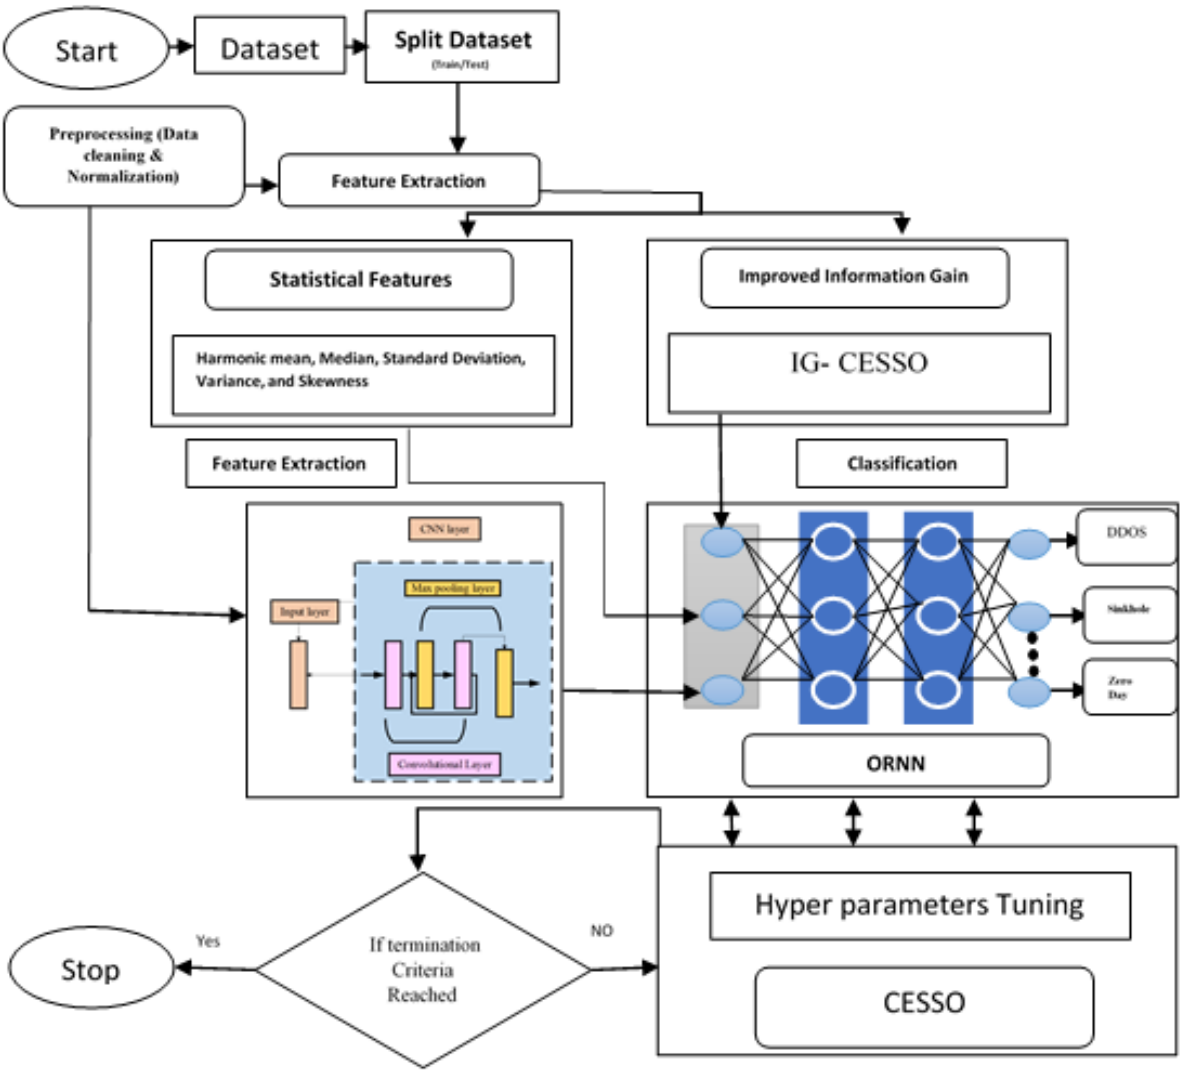

Fig. 3. Overall architecture of the proposed CESSO-HCRNN model.

The definition of the F-score is the harmonic mean of recall rate and accuracy.

$$F_{measure} = \frac{2precision * Recall}{Precision + Recall} \tag{30}$$

Negative Prediction Value (NPV)

NPV describes the effectiveness of a diagnostic test or other quantitative metrics.

$$NPV = \frac{TN}{TN + FN} \tag{31}$$

Matthews correlation coefficient (MCC) Below is a representation of the two-by-two binary variable association measure known as MCC.

$$MCC = \frac{(TP * TN - FP * FN)}{\sqrt{(TP + FN)(TN + FP)(TN + FN)(TP + FP)}} \tag{32}$$

False Positive Ratio (FPR) The number of negative occurrences divided by the number of negative events that were incorrectly classified as positive yields the false positive rate (false positives).

$$FPR = \frac{FP}{FP + TN} \tag{33}$$

False Negative Ratio (FNR) The likelihood that an actual positive may be overlooked by the test is known as the false-negative rate, sometimes referred to as the "miss rate".

$$FNR = \frac{FN}{FN + TP} \tag{34}$$

B. Comparative analysis for the performance metrics

1) CSE-CIC-IDS2018 Dataset: Using the CSE-CIC-IDS2018 Dataset, the performance metrics for the proposed CESSO-HCRNN approach were computed and contrasted with

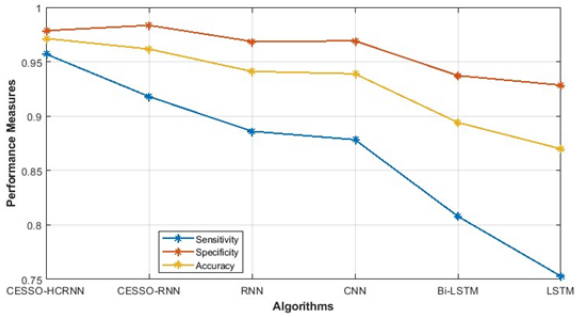

Fig. 4. Comparison of sensitivity, specificity, and accuracy of CSE-CIC-IDS2018 dataset for the proposed CESSO-HCRNN and existing techniques.

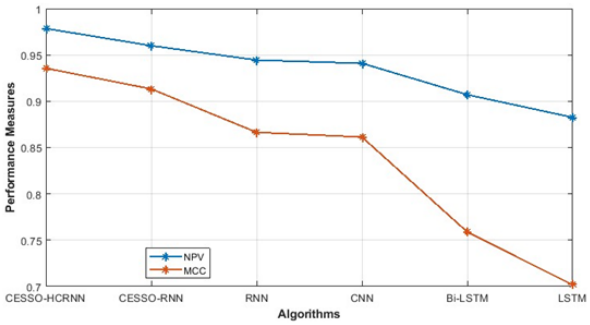

Fig. 6. Comparison of the NPV and MCC of CSE-CIC-IDS2018 dataset for the proposed CESSO-HCRNN and existing techniques.

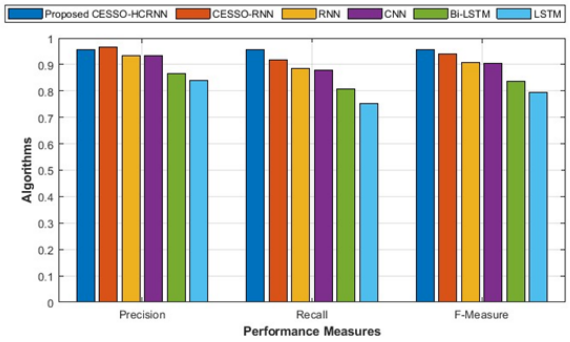

Fig. 5. Comparison of the precision, recall, and F- Measure of CSE-CIC-IDS2018 dataset for the proposed CESSO-HCRNN and existing techniques.

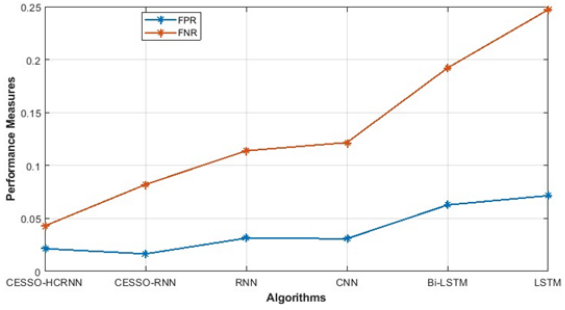

Fig. 7. Comparison of FPR and FNR of CSE-CIC-IDS2018 dataset for the proposed CESSO-HCRNN and existing techniques.

those of CESSO-RNN, RNN, CNN, Bi-LSTM, and LSTM. The suggested CESSO-HCRNN strategy's efficacy is evaluated here using the other metrics, whilst the proposed model's efficacy is evaluated here using measures like accuracy, sensitivity, precision, recall, and F-Measure. Table I compares the CSE-CIC-IDS2018 Dataset's performance metrics.

The metrics in the table are analyzed and their values are combined. Comparing the suggested CESSO-HCRNN model against older methods reveals that it is quite accurate. Graphs are used to show the difference in performance. The suggested and current models are contrasted using the graph in Fig. 4 in terms of metrics like sensitivity, specificity, and accuracy.

Fig. 4 displays performance metrics, such as sensitivity, specificity, and accuracy, for both the proposed and current approaches. Sensitivity values are 0.9571, 0.9180, 0.8861, 0.8784, 0.8079, and 0.7529 for the proposed CESSO-RNN, RNN, CNN, Bi-LSTM, and LSTM. The accuracy values are 0.9714, 0.9617, 0.9411, 0.9389, 0.8941, and 0.8699, respectively, while the specificity values are 0.9785, 0.9835, 0.9686, 0.9692, 0.9373, and 0.9285. The proposed model performs better in terms of sensitivity, specificity, and accuracy than the widely used methods.

Precision, recall, and F-Measure performance characteristics for the proposed CESSO-HCRNN and current techniques are shown in Fig. 5. Precision values for the proposed CESSO-RNN, RNN, CNN, Bi-LSTM, and LSTM are 0.9571, 0.9653, 0.9339, 0.9344, 0.8656, and 0.8403 respectively. Recall values for the proposed CESSO-HCRNN and current approaches are 0.9571, 0.9180, 0.8861, 0.8784, 0.8079, and 0.7529, respectively. The F-measure values are 0.9571, 0.9410, 0.9093, 0.9055, 0.8358, and 0.7942. The suggested CESSO-HCRNN model provides higher precision, recall, and F- Measure than the current approaches.

Fig. 6 illustrates the performance metrics, including NPV and MCC, for the proposed and existing techniques. The proposed CESSO-HCRNN and current models like CESSO-RNN, RNN, CNN, Bi-LSTM, and LSTM have NPV values of 0.9785, 0.9600, 0.9445, 0.9071, and 0.8826, respectively. The MCC values are 0.9356, 0.9133, 0.8664, 0.8614, 0.7588, and 0.7018 as well.

Fig. 7 visually represents the FPR and FNR performance indicators for both the proposed CESSO-HCRNN and the existing methods. The CESSO-HCRNN model has a lower FPR and FNR when compared to the approaches currently in use. The suggested CESSO- HCRNN and current approaches like CESSO-RNN, RNN, CNN, Bi-LSTM, and LSTM have the FPR and FNR are 0.0215, 0.0165, 0.0314, 0.0308, 0.0627, and 0.0715; and 0.0429, 0.0820, 0.1139, 0.1216, 0.1921, and 0.2471.

2) NSL- KDD Dataset: Performance metrics for the proposed CESSO-HCRNN approach are compared to those for

TABLE I. COMPARISON OF PERFORMANCE METRICS OF CSE-CIC-IDS2018 DATASET FOR THE PROPOSED CESSO-HCRNN AND EXISTING TECHNIQUES

existing techniques like CESSO-RNN, RNN, CNN, Bi-LSTM, and LSTM. In this case, the loss values are evaluated using the FNR and FPR error measures, and the effectiveness of the suggested strategy and the chosen dataset for zero-day attack prediction are determined using the other metrics. A comparison of the performance metrics is shown in Table II.

From the table, the metrics values are calculated and contrasted. The proposed model is quite accurate when compared to previous approaches. To show the performance contrast, graphs are utilized. Utilizing the NSL-KDD dataset, the CESSO method is used to improve the prediction of zero-day attacks.

For both the proposed and current methodologies, Fig. 8 shows the graphical depiction of performance parameters including sensitivity, specificity, and accuracy. In comparison to previous methods, the CESSO-HCRNN model has good accuracy, sensitivity, and specificity.

Fig. 9 displays performance characteristics such as precision, recall, and F-measure graphically for both the proposed and existing techniques. When compared to earlier approaches, the CESSO-HCRNN model offers high precision, recall, and F- Measure.

Fig. 10 illustrates the performance metrics, including NPV and MCC, for the proposed and existing techniques. The CESSO-HCRNN model has a higher NPV and MCC when compared to the methods currently in use.

Fig. 11 visually represents the FPR and FNR performance metrics for the proposed and current techniques. The CESSO-HCRNN model exhibits lower FPR and FNR when compared to currently employed approaches, according to the comparison.

VI. CONCLUSION

As a zero-day attack is a random assault that cannot be anticipated, the zero-day attack has recently taken on highly dangerous consequences. The zero-day threat takes the use of a software vulnerability to access the system or do significant harm, and system developers have no time to fix this vulnerability to reduce the threat. The input data is received from the two datasets, the missing values are removed, and the data normalization is performed in the pre-processed section. A unique hybrid feature selection method that is based on the CESSO and Information Gain(IG) are implemented. The CESSO is also used to improve the Recursive Neural Network (RNN) performance to produce an optimized RNN. The improved RNN is hybrid with the CNN to produce the HCRNN, which is used to predict the zero-day attack. The results of the proposed CESSO-HCRNN are compared with the existing models with reduced error values.

In two test cases, the performance of the proposed methodology is examined. The NSL-KDD dataset is used as the initial test case for the proposed system. The DoS module of the CSE-CIC-IDS2018 is utilized as the source dataset in the second test scenario, where the framework is employed to identify zero-day attacks on the NSL-KDD dataset. In this case, both domains have unique feature spaces and probability distributions. Although there is significant variation between the source and target domains, the experimental findings show that the suggested strategy is effective in identifying zero-day attacks with no tagged occurrences.

Triggered Screen Restriction: Gamification Framework

Majed Hariri[1], Richard Stone[2]
HCI Department, Iowa State University, Iowa State University, Ames, USA[1]
Industrial and Manufacturing Systems Engineering Department, Iowa State University, Ames, USA[2]

***Abstract*—The prevalence of sedentary lifestyles is increasingly becoming a significant public health concern, with numerous health risks ranging from obesity to heart disease. Several gamified interventions have been employed to counter sedentary behavior by promoting physical activity. However, the existing approaches have yielded mixed results, making it crucial to explore new methodologies. While existing approaches have utilized gamification elements to encourage activity, they often need a comprehensive blend of psychological elements and advanced technology to drive a meaningful behavioral alteration. This paper introduces the Triggered Screen Restriction (TSR) framework, an interdisciplinary approach integrating behavioral psychology, gamification, and screen-time restriction technologies. The TSR framework aims to elevate gamified physical activity by leveraging the psychological Fear of Missing Out phenomenon, encouraging users to meet specific activity goals to unlock social media applications. The TSR framework presents a promising avenue for future research. The proposed framework's unique approach is designed to motivate users to be more physically active. The proposed framework fills a literature gap in the current implementation of the gamified physical intervention. Further studies are needed to empirically validate the framework's effectiveness and potential to contribute to the gamification ecosystem.**

Keywords*—Gamification; physical activity; sedentary behavior; Triggered Screen Restriction (TSR) framework

I. Introduction

Engaging in regular physical activity is not just a lifestyle choice; it is a cornerstone for a high-quality life. Physical activity positively impacts not only your physical health but also enhances your mental well-being, enriches your social interactions, and boosts your self-confidence [1]. Despite the wide-ranging benefits, alarming data shows a global drop in levels of physical activity [2]. One factor amplifying this decline is the widespread use of smartphones. While these devices have made life easier in many ways, they have also unintentionally encouraged a lifestyle that involves minimal movement [3]. The issue is especially severe in countries with both high smartphone usage and alarming rates of obesity, such as Saudi Arabia [4]. For instance, in Saudi Arabia, a staggering 41.5% of young men are not engaged in any form of regular physical activity, contributing to an obesity rate that is higher than the global average [5], [6]. This trend is not just a national crisis but a global one, necessitating swift and effective solutions to promote active lifestyles [4]. Despite the continuous development, most of the existing gamified physical interventions still have untapped potential. Many of the current methods using gamification to encourage physical activity overly rely on positive rewards [7]. These constant rewards can eventually wear out a person's motivation, making these strategies unsustainable [8].

Gamified physical interventions are often perceived by users as either excessively complex or insufficiently supportive, leading to decreased levels of interaction [9]. Even the most popular fitness interventions available on Apple or Google stores are often too narrow in focus [10]. The proposed framework, aiming to leverage the Fear of Missing Out, addresses these limitations by motivating users to engage in physical activity using gamified intervention to access their social media applications. By leveraging insights from current research and integrating novel activity tracking with motivational game-like elements, the framework might offer a comprehensive solution in gamified physical interventions. The paper seeks to serve as a foundational framework for future gamified physical interventions. The following sections will explore the limitations of current frameworks and the potential of the novel approaches proposed in this framework. The remainder of this paper is organized as follows:

- Objective - Presents the main objective, which is to propose a theoretical framework that might enhance the application of gamification in encouraging physical activity.
- Literature Review - Examines existing gamification strategies and their application in diverse domains, particularly focusing on their role in enhancing physical activity.
- Previous Frameworks - Examines and evaluates popular gamification frameworks, including Octalysis, MDA, SGD, and FRAGGLE.
- Introducing the TSR Framework - Introduces the TSR framework, which outlines its interdisciplinary components for promoting physical activity through gamification.
- Components of the TSR Framework - Explores the four key pillars of the TSR framework: screen time restriction, notification triggers, computer vision model, and reward engine. Describes how these aspects work together to help encourage physical activity through gamified intervention.
- Conclusion - Summarizes the study, emphasizing the TSR framework's potential as a gamified framework to promote physical activity. The conclusion highlights the necessity for empirical validation and proposes future research directions.

II. Objective

The main objective is to propose a theoretical framework that might enhance the application of gamification in encouraging physical activity. This enhancement could be achieved by exploring innovative intersections between behavioral psychology and current technological approaches. The paper seeks to identify novel tools and methods that might increase the effectiveness of gamified interventions, with a particular focus on the potential application of the fear of missing out phenomenon.

The significance lies in the potential impact of gamified physical interventions. By offering a novel perspective on gamification, this paper desires to address the limitations of motivating physical activity in various settings. Its insights are especially relevant in societies where traditional methods to promote physical activity have had limited success, highlighting the need for more innovative and engaging approaches.

This paper's contribution is laying down a theoretical groundwork for a new approach to gamification, focusing on behavioral and technological aspects rather than empirical data. The exploration of the fear of missing out phenomenon as a motivational tool represents a fresh perspective in gamification research. The paper seeks to inspire further academic inquiry, discussion, and development. Ultimately, the proposal in this paper might open up new possibilities for research and application, leading to the creation of more effective and engaging gamified physical interventions for promoting physical activity in the future.

III. Literature Review

The idea of gamification, which incorporates game design elements into non-gaming contexts, offers an innovative method to foster behavioral change. By including elements such as points, rewards, and challenges, gamification has been observed to elevate user engagement and motivation [11].

Further, within the context of gamification, components like badges, progress indicators, and stages hold a pivotal role. These elements, far from being just aesthetic enhancements, act as central motivational tools. Their presence invigorates users, encouraging sustained interaction and consistent effort towards reaching defined objectives [12].

Moreover, the utilization of gamification strategies has been examined across various sectors, including educational institutions, professional environments, and health-related centers. The efficacy in enhancing the user experience by making products and services more engaging has received substantial empirical support [13], [14]. For instance, a study that employed a randomized design explored the impact of a gamified intervention strategy. This strategy was further enhanced by adding elements of social support and financial incentives framed as potential losses. The study demonstrated a moderate yet promising increase in levels of physical activity among veterans who are struggling with weight issues, including obesity [15].

Another study focused on the efficacy of immediate financial rewards given out on a variable schedule. This study found that such financial incentives could significantly encourage people to engage more with mobile health applications [16]. Several studies further corroborate the sustainability of such interventions, especially when participants select their own goals [17], [18].

Despite these positive findings, it's critical to acknowledge that the effectiveness of gamification is not a one-size-fits-all solution. A study that used a randomized design with three different groups showed that although all participants lost a significant amount of weight, the groups that were exposed to gamified intervention did not outperform the control group in a statistically significant manner [8]. Moreover, a separate study aimed at exploring the role of personalized goal-setting in gamified mobile health interventions reported an initial increase in user engagement and performance, but this positive trend appeared to diminish over time [19]. These divergent findings clearly indicate an urgent need for more nuanced investigations to further refine and possibly explain the variability in outcomes associated with gamification in physical health interventions.

When examining the specific techniques and methodologies that are part of gamification, a rich tapestry of strategies reveals itself. One of these strategies involves the real-time monitoring of user metrics and the provision of immediate feedback, which has been shown to elevate the likelihood of successfully encouraging physical activity [20]. Similarly, allowing users to set their own physical activity goals introduces a competitive spirit that invigorates the user's motivation to be physically active [7]. Tangible systems of rewards, often implemented through the use of badges and points, provide compelling reasons for users to not only meet their activity goals but also to exceed them [21]. Creating a sense of community and social interaction is another essential feature of gamified fitness interventions, often achieved through leaderboards that enable users to compare their progress and celebrate their achievements [22], [23]. Additional strategies include sending out notifications and text messages as reminders, which act as consistent nudges to help users stay aligned with their fitness objectives [24], [25].

Psychological theories also play a significant role in how gamified interventions are designed. For instance, Self-Determination Theory is commonly used to ensure that the needs for competence, autonomy, and social connection are adequately addressed, thereby serving as a continual source of motivation [26], [27], [28]. Balancing intrinsic motivations, such as the innate enjoyment derived from an activity, and extrinsic motivations, such as rewards, is critical [26], [27], [28]. Another significant psychological theory that has been applied in gamified intervention is Flow Theory, which suggests that the most engaging and motivating experiences occur when there's a balance between the challenge at hand and the individual's skill level [29], [30]. While the Fear of Missing Out has been criticized for encouraging potentially addictive behaviors [31], recent research suggests that it can also have a positive impact, particularly for individuals who might otherwise be disengaged [32]. These psychological theories, although promising, require further study to confirm their effectiveness in gamified physical interventions.

Conclusively, a systematic review encompassing an examination of 1680 health applications available on the Apple

and Google App stores, including (Nike+ Running, Zombies, Run!, Strava Run, MyFit Fitness, Fitbit, and RunKeeper - GPS Track Run Walk) [10]. Astoundingly, the research found that a mere 4% of these applications employed gamification elements to enhance user engagement and promote healthier behaviors [10]. This relatively low number represents a monumental opportunity for advancement and innovation. Most of the existing gamified applications prioritize self-monitoring components and combine them with goal-setting features to maintain user engagement [10].

The current implementation of gamified interventions mainly relies on positive feedback and personal determination to encourage users. But this approach has limits. There are still unexplored ways to use technology and psychology to keep people interested and involved in physical activities. A promising avenue in employing on-device computer vision models that can detect and report user activities, offering a more immersive and interactive experience while preserving user privacy [33]. Using gamified intervention could boost users' interaction with physical activity applications and significantly increase user engagement and effectiveness.

Furthermore, there's a need to evolve beyond merely using positive reinforcement. The emphasis should shift towards a balanced approach, incorporating both positive and negative reinforcement mechanisms to create a more captivating, or even addictive, user experience [34]. By doing so, there is an incredible opportunity to develop novel frameworks that are not only engaging but also effective in battling sedentary lifestyles and encouraging physical activity among various population groups. The following subsection will focus on previous frameworks to provide a more comprehensive understanding of gamification's frameworks and their current state.

A. Previous Frameworks

1) Octalysis Framework: The Octalysis framework emerged from the realization of the need for a tool to devise strategies and evaluate the implementation of gamification [35]. The Octalysis framework identified eight distinct core drives that propel individuals to engage in certain activities. The Octalysis framework, visually represented as an octagon, encapsulates these core drives at each of its corners (see Fig. 1). The Octalysis framework emphasizes the importance of identifying whether core drives lean towards extrinsic or intrinsic motivation.

The Octalysis framework considers the core drives as essential components, which are defined in the following manner:

- Epic Meaning and Calling: This drive encapsulates the desire to be part of something larger than oneself or to pursue a higher purpose.
- Development and Accomplishment: This is the drive to improve, overcome challenges, and achieve goals.
- Ownership and Possession: This is the drive to own or control resources and protect one's investments.
- Scarcity and Impatience: This drive is about the desire to obtain rare or exclusive items or act before an opportunity passes.

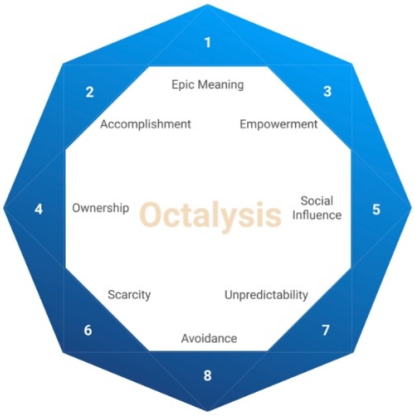

Fig. 1. [35] Octalysis framework.

- Loss and Avoidance: This is the drive to prevent loss, negative outcomes, or maintain one's status quo.
- Unpredictability and Curiosity: This drive encapsulates the desire for novelty and unexpected outcomes.
- Social Influence and Relatedness: This drive encompasses the need to connect with others and belong to a group.
- Empowerment of Creativity and Feedback: This drive covers the desire to express oneself, experiment, and receive feedback.

The Octalysis framework divides core drives into two impactful categories: Black Hat Gamification and White Hat Gamification. White Hat drives, found at the top, motivate positively, inspiring creativity, control, and purpose. These include Epic Meaning, Development, and Empowerment of Creativity.

In contrast, the lower drives, or Black Hat, are linked to negative motivations like urgency or addiction. They encompass Scarcity, Unpredictability, and Loss. The side drives, Ownership, and Social Influence can swing either way based on context. For effective gamification, the Octalysis framework recommends balancing both Black and White Hat techniques. White Hat fosters loyalty but may not prompt immediate reactions. Black Hat encourages immediate action but might cause burnout. An ideal gamification design balances both aiming for sustained motivation and a rewarding experience.

2) MDA Framework: The Mechanics, Dynamics, and Aesthetics (MDA) framework provides a comprehensive approach to game design and analysis, aiming to bridge different areas like game development, game criticism, and technical research in the gaming industry [36]. The MDA framework categorizes games into three main elements: Mechanics, Dynamics, and Aesthetics (see Fig. 2). These components represent various aspects of game design and player involvement [36].

- Mechanics: The core elements of a game that include data representation and algorithms used to support the game's framework.

- Dynamics: The real-time mechanics of responding to player inputs, which evolve during gameplay.
- Aesthetics: The emotional reactions players have while interacting with a game system, emphasizing the experiential aspect of games.

The MDA framework has been found to be effective in increasing user engagement in various platforms, including donation-based crowdfunding. Applying the MDA framework has resulted in higher levels of interaction from users, indicating the potential for increased funding for charitable initiatives [37].Furthermore, the MDA framework has been used as an educational tool to enhance learning experiences and comprehension of mathematical concepts in elementary students [38].

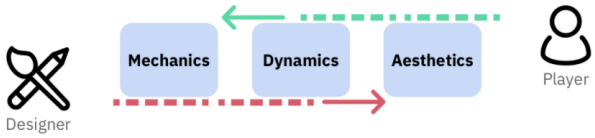

Fig. 2. [36] The MDA framework.

3) Sustainable Gamification Design Framework: The Sustainable Gamification Design (SGD) framework is a systematic approach to creating gamified systems with a focus on sustainability in user engagement, environmental impact, and social responsibility. The SGD framework emphasizes ethical and human-centered design principles [39]. The framework is structured around four key stages:

- Discover: This initial phase involves comprehensively understanding the setting and the individuals or groups that the system will impact.
- Reframe: In this stage, designers evaluate the gathered information to spot opportunities and develop potential solutions.
- Envision: Decision-making is key in this phase, as designers choose the most fitting solution for the system.
- Create: This final step sees the design and implementation of the gamified system, bringing the concept to fruition.

The integration of values and ethical considerations is central to the SGD framework, ensuring that the gamified systems produced are not only captivating but also responsible and considerate of broader impacts. The framework guides designers in creating systems that are beneficial for users (see Fig. 3).

4) FRAGGLE Framework: The FRAGGLE framework is an agile methodology tailored for enhancing learning experiences through gamification. The framework is designed to align gamified activities with educational goals, content, and assessment criteria, ensuring that game elements support the intended learning outcomes [40]. The framework consists of four phases:

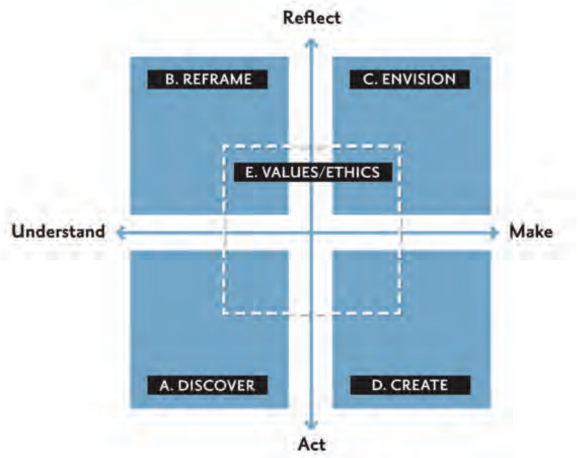

Fig. 3. [39] The SGD framework.

- Declaration: Identifying problems, user stories, and acceptance tests to define the project's scope and requirements.
- Creation: Designing engaging game elements like players, mechanics, stages, actions, and triggers that meet user needs.
- Execution: Implementing and deploying the gamified learning experience to deliver an MVP for user feedback.
- Learning: Measuring and analyzing the gamification's impact on learning outcomes and user satisfaction, with a focus on continuous improvement.

The framework emphasizes learning experiences rather than complete gamified systems. The framework-structured approach is helpful for creating engaging and educationally effective gamified activities. The step-by-step process of the framework, from conception to evaluation, facilitates the agile development of gamified learning experiences that align with educational goals and respond to learner feedback (see Fig. 4).

B. Overview and Comparison of the Models

Gamification has gained popularity as a strategy to increase engagement in different fields. Several frameworks guide how to incorporate game elements into non-game settings. The MDA framework provides a way to understand the relationship between game mechanics, dynamics, and aesthetics. However, the MDA framework has been criticized for focusing too much on mechanics and not considering other aspects like user experience and narrative elements in games [41].

The Octalysis framework offers valuable insights into the various factors that drive people's engagement in activities. However, the Octalysis framework doesn't provide a structured design process, and the generic approach may not cater to the diverse motivations and backgrounds of all users.

Similarly, the FRAGGLE framework is agile and learner-centered, designed to align educational activities with gamification elements efficiently. However, the FRAGGLE framework does not address real-world challenges, such as

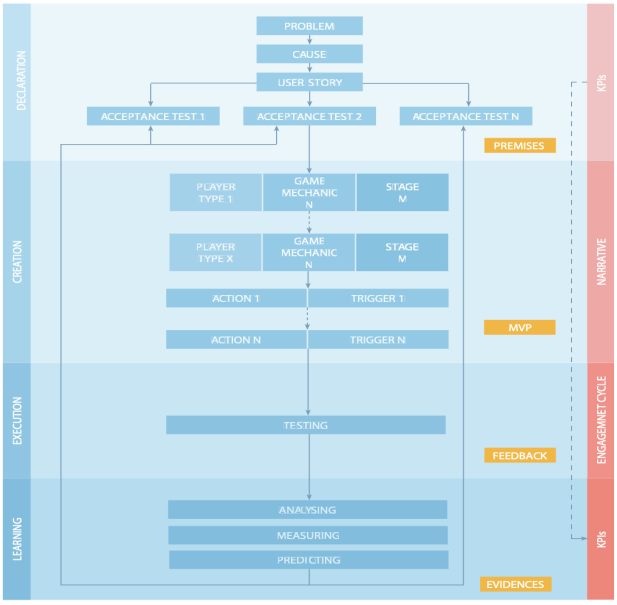

Fig. 4. [40] The FRAGGLE framework.

technical issues or navigating organizational culture, that can arise in the implementation of these systems. These frameworks provide valuable insight into gamification, but they also show the need for a more comprehensive model that can address some of their limitations.

As interest increases in using gamification to encourage physical activity, there is an exciting chance to develop a new framework. The novel framework could be customized to encourage physical activity by considering the specific needs and motivations of various population groups. The novel framework has the potential to lead to greater and more widespread adoption of healthy habits by harnessing gamification's ability to create a positive impact on users (see Table I).

TABLE I. Overview of Gamification Frameworks

Framework	Target	Implementation
Octalysis [35]	General	Transforming into a game-like process
MDA [36]	General	Connects game design to gamified development
SGD [39]	Design	Conceptual framework focused on design
FRAGGLE [40]	Education	Uses gamified agile to enrich learning
The Proposed Framework (TSR)	Physical Activity	Interdisciplinary approach for gamified physical intervention

IV. Introducing the TSR Framework: A Multidisciplinary Approach

The need for a novel approach to address the growing issue of physical inactivity is evident [34]. While existing gamified physical interventions offer a range of features to promote physical activity, they often fail to achieve lasting user engagement. Many such interventions rely too much on continual positive reinforcement, and their heavy reliance on willpower can deplete the user's motivation over time [7], [8]. Additionally, current approaches frequently overlook crucial aspects that could drive engagement [9].

Against this backdrop, the TSR framework is introduced as a conceptual solution to these pressing concerns. Central to the TSR framework's aim is using the Fear of Missing Out phenomenon to inspire a meaningful change by using gamified physical activity intervention, combining the latest technology with fundamental elements of behavioral psychology.

In contrast to existing gamified interventions, the TSR framework employs a balanced system of both rewards and restrictions to encourage increased physical activity. At the core of the TSR framework are four integral components: Screen Time Restriction, Notification Triggers, Computer Vision Model, and Reward Engine. These pillars serve specialized functions that collectively offer a well-rounded user experience:

- Screen Time Restriction: Restricts access to distracting social media applications unless specific physical activity goals are met, thus leveraging the Fear Of Missing Out phenomenon.
- Notification Triggers: Customizable alerts remind users of their activity goals and offer motivation at opportune moments.
- Computer Vision Model: Detects the user's physical activity in real-time, providing instant feedback while ensuring data privacy.
- Reward Engine: Offers tangible rewards like points and unlocks varying levels of exercise challenges, making the whole gamified experience more engaging.

The proposed framework builds upon existing research, which supports the efficacy of these elements. For example, goal-setting strategies have been proven to increase physical activity, improve well-being, and lower health risk factors like Body Mass Index (BMI) [42]. Similarly, studies show that the balanced use of gamification can indeed boost a person's intrinsic drive to exercise [21]. To provide a comprehensive understanding of the TSR framework's capabilities and how it differentiates itself from existing interventions, the following sections will dive into the technical and psychological aspects of each foundational pillar in detail (see Fig. 5).

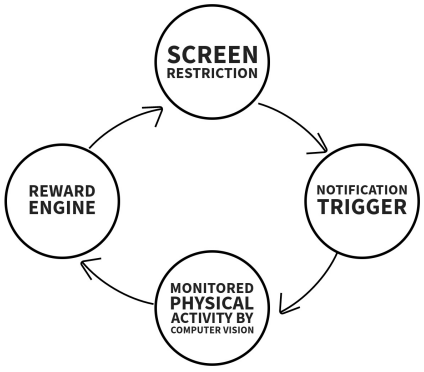

Fig. 5. The Proposed TSR's Workflow.

A. Screen Time Restriction: Tackling Physical Inactivity Through Behavioral Incentives and Technological Limits

The first foundational pillar of the TSR framework is Screen Time Restriction, a feature designed to balance screen-based activities with gamified physical activity. The mechanics of Screen Time Restriction are straightforward yet effective. Once the user crosses a predetermined time limit on social media or other distracting applications, the framework triggers a lockout mechanism. This restriction can be lifted only when the user achieves certain physical activity goals, which are recorded and verified in real-time by the framework's other components like the Computer Vision Model and Notification Triggers. This approach turns a usually passive screen time experience into an active pursuit of physical milestones.

Besides merely cutting off access to applications, the TSR framework utilizes the Fear Of Missing Out psychological phenomenon to make this strategy even more compelling. Users are enticed to achieve their physical activity goals not just for the sake of better health but also to regain access to their social circles online. This adds a rich social layer to the otherwise technology-focused Screen Time Restriction feature, elevating it beyond a simple tech-based solution.

To ensure user privacy, the framework operates under stringent privacy policies. The framework only accesses screen-time data in real-time and does not store any of this sensitive information, thereby adhering to top-level privacy standards. By combining technological control with behavioral psychology, the Screen Time Restriction component creates a multi-dimensional approach to encouraging physical activity. The Screen Time Restriction is not just about limiting screen time but about turning those limitations into a motivational force that encourages physical activity.

B. Notification Triggers: Steering User Attention Through Timely Reminders

The second pillar of the TSR framework is Notification Triggers. The Notification Triggers component is designed to provide real-time engagement through a system of push notifications. These reminders serve as nudges that propel users toward physical activity, filling the spaces in their day with opportune moments for exercise. The operational backbone of Notification Triggers is its interoperable system architecture. By leveraging Firebase Cloud Messaging (FCM) for Android and Apple Push Notification Service (APNs) for iOS, the framework ensures that notifications reach users irrespective of their choice of operating system. This universal approach guarantees that all users have equal opportunity to benefit from the framework, regardless of their device preference. The framework provides a range of pre-set messages, which can be as simple as a reminder.

While the content of these messages is standardized, the timing, frequency, and types of notifications can be personalized according to each user's needs and lifestyle. This degree of customization fosters a more personal connection between the user and the framework, increasing the likelihood of sustained engagement. Although the Notification Triggers start as external cues, the ultimate goal is to transition users from needing these reminders to developing intrinsic motivation for physical activity. This shift aligns with the objectives of the TSR framework, combining screen time restriction and notification triggers to promote gamified physical activity. By harmoniously integrating the notification triggers with the Screen Time Restriction component, the TSR framework might create a continuous loop of motivation and action, making strides toward more engagement in physical activity (see Fig. 6).

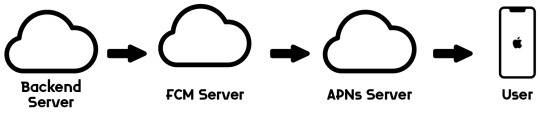

Fig. 6. The proposed notification workflow.

C. Computer Vision Model: Real-time Tracking and Feedback for Optimized Physical Activity

Building on the synergy of Screen Time Restriction and Notification Triggers, the next cornerstone of the TSR framework introduces an advanced technological interface—the Computer Vision Model. The Computer Vision component combines a machine learning model with the camera capabilities of mobile devices to offer real-time assessment and feedback on a gamified physical activity. Employing the power of the computer vision model, the component can identify and quantify a wide array of exercises, such as jumping jacks, in real-time. As users execute these exercises, the model counts the number of repetitions and assesses them, thus providing immediate, accurate metrics to inform more effective workout sessions.

What distinguishes the computer vision approach from traditional methods of tracking physical activities is its commitment to user privacy. While the traditional method relies on the usage of GPS data or accelerometer, the proposed framework performs all data processing directly on the device, ensuring that user data remains secure and private. This eliminates the need for data transfer and limits storage requirements, thus reducing the risk of unauthorized access and data breaches. The provision of instant feedback creates an environment of positive reinforcement. The instant feedback strengthens the user's engagement, as the immediate data allows for immediate adjustments, maximizing the effectiveness of the gamified workout [33]. The computer vision approach thus might enhance the interactive experience, making the TSR framework not just a novel approach but an engaged companion in promoting gamified physical activity. Integrating this advanced Computer Vision Model might add another layer of interactivity and personalization to the TSR framework. It not only advances the framework's primary aim of promoting physical activity using gamification but does so while prioritizing user security and data privacy (see Fig. 7).

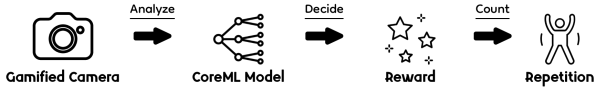

Fig. 7. The proposed computer vision workflow.

D. Reward Engine: An Approach to Sustaining Physical Activity and Reducing Screen Time

Capping off the TSR framework's multi-dimensional approach is the Reward Engine, a dynamic system designed to foster ongoing user engagement. Unlike traditional models, which often employ a one-size-fits-all strategy for physical activity, the Reward Engine employs a responsive mathematical model to tailor tasks and rewards according to the user's specific metrics and performance levels. Utilizing a two-variable formula, the system calculates task difficulty and reward value as follows:

$$Reward = valueReward \times difficultyFactor$$

$$DifficultyFactor = max(min(numberRepetition * valueReward, 0.9), 0.1)$$

Through the application of this equation, the reward engine dynamically adjusts both the challenge and rewards of each task based on real-time performance metrics. By doing so, the reward engine might ensure that activities are optimally engaging—without being overly difficult or too simplistic—creating an ideal balance that sustains user motivation over time. What sets the Reward Engine apart is its focus on providing a highly personalized experience. It offers a mix of intrinsic and extrinsic motivators, making physical activity not just a routine but a rewarding pursuit. This goes beyond merely distributing rewards and plays a crucial role in sustaining behavioral change. This aspect of the TSR framework is critical for the potential of encouraging users to integrate regular physical activities into their lives, potentially leading to a reduction in screen time and promoting more physical activity.

V. Conclusion

The TSR framework, as discussed in this paper, is a conceptual gamification framework awaiting actual deployment. The proposed TSR framework, emphasizing the Fear of Missing Out phenomenon, presents a potential comprehensive strategy to encourage physical activity through gamified activity goals linked to social media application access. The proposed framework has four main components: Screen Time Restriction, Notification Triggers, Computer Vision Model, and Reward Engine. The TSR's components initiatives aim to work together in order to bring a potentially significant change in our approach to gamification and physical activity.

While this paper outlines the blueprint of the TSR framework, it remains essential to mention that this is a concept framework—a proposal that is yet to be brought to life and measured against real-world scenarios. The importance of thoroughly evaluating the proposed framework in future research cannot be overstated. A well-considered plan for evaluation becomes a cornerstone for future research to turn this conceptual model into a tangible framework. This evaluation would leverage both numerical data and human experiences to provide a full-spectrum analysis of the framework's performance. For the numerical data, metrics such as user engagement, time spent on physical activities, and program adherence could be good starting points.

On the other hand, understanding human experiences could be achieved through qualitative methods, like interviews or surveys, to understand user satisfaction and program perception in depth. The duality of these methods provides a well-rounded look at the framework's effectiveness or areas requiring refinement. While this is still theoretical, the concept itself calls for a future academic inquiry that dives into its practical applicability.

The adaptability and modular design of the TSR framework serve as a launching pad for future research. The framework's capacity to be customized to fit a wide array of user preferences makes it a strong candidate for various real-world applications. Potential applications could range from educational settings targeting younger populations to workplace environments aiming to boost employee efficiency. Exploring the removal of boundaries between sectors could also be an interesting area of study.

To conclude, while the TSR framework remains a theoretical model at present, its potential applications and impact need further investigation. This paper does not claim to have achieved these outcomes but seeks to set the academic and practical communities a task: rigorously test, refine, and eventually implement the TSR framework.

***Abstract*—Visual object tracking is a crucial research area in computer vision because it can simulate a dynamic environment with non-linear motions and multi-modal non-Gaussian noises. However, This paper presents an overview of the recent developments in particle filter-based visual object tracking algorithms and discusses the pros and cons of particle filters, respectively. There are presentations of many different methodologies and algorithms in the research literature. The majority of visual object tracking research at present is on particle filters. In addition, the most advanced technique for visual object tracking has also been developed by combining the convolutional neural network (CNN) and the particle filter. The advantage of particle filters is that they can handle nonlinear models and non-Gaussian advancements, sequentially concentrating on the areas of the state space with higher densities, primarily parallelization, and simplicity of implementation. Despite this, it offers a robust framework for visual object tracking because it incorporates uncertainty and outperforms other filters like the Kalman filter, Kernelized correlation filter, optical filter, mean shift filter, and extended Kalman filter in recognition tests. In contrast, this study provided information on various particle filter features and classifiers.**

***Keywords*—Particle filter; visual object tracking; On-Gaussian noises; Kalman filter; CNN**

I. Introduction

In the last decade, object tracking has been a difficult research challenge in computer vision for video sequences, with applications including video surveillance, human-computer interaction, augmented reality, and robotics. However, particle filters (PFs) have recently gained popularity in visual object tracking. The ability to resolve non-Gaussian and non-linear problems allowed them to establish a reliable tracking method.

Tracking visual objects involves object recognition, classification, and frame-by-frame tracking. Identifying moving objects in a video stream is the first essential step in tracking. However, in addition to deep learning and CNN, various techniques such as background reduction, statistical models, and specific temporal techniques are applied for object detection. In order to keep track of and analyze observed objects, it is necessary to classify them, such as people, vehicles, animals, debris, etc. The second tracking stage is the creation of temporal connections between detected objects from frame to frame. The segmented regions can be identified temporally using this method, which also generates coherent information about the objects in the observed region, including their trajectory with direction and speed. Typically, the output of the tracking phase is used to assist and improve higher-level activity analysis, object classification, and motion segmentation.

Consequently, deterministic or stochastic frameworks can be used to classify object-tracking techniques. In addition to stochastic approaches, the Bayesian framework for state estimation incorporates stochastic approaches. In the stochastic framework, the Kalman filter [1], the extended Kalman filter, and the unscented Kalman filter [2] were used to estimate linear and Gaussian states. However, the particle filter (PF) [3], the condensation filter [4], and the bootstrap filter were used to estimate nonlinear and non-Gaussian states. Deterministic frameworks, such as mean shift [5], fragment-based tracker, and multi-stage tracker [6], use objective search in each frame to increase the similarity between the objective and search space. These techniques typically rely on less spatial information regarding the object, which makes them more susceptible to occlusion and background clutter [7]. However, stochastic approaches were able to address the problems caused by identical backgrounds and occlusion as well as large variations of a pose by decreasing target sampling patches throughout the track [8], [9].

Particle filters, a stochastic method, surpassed other methods for tracking objects in complex environments such as occlusion, background clutter, and illumination. These are used to estimate system states in state-space models; the system's various states are then tracked over time. By employing sequential Monte Carlo sampling, which uses a collection of samples known as particles to perform numerical approximation, particle filters can also solve the estimation problem. Additionally, particle filters demonstrate their effectiveness in overcoming various challenges associated with object tracking by performing exceptionally well with nonlinear and non-Gaussian estimation problems [4].

This paper's main contributions are summarized as follows:

(a) We present a comprehensive survey of particle filter-based visual object tracking techniques from different perspectives.
(b) We addressed the large-scale benchmark datasets for various visual object tracking approaches.
(c) We also summarize the state-of-the-art visual object tracking research over the past decade, including its advantages, limitations, and future directions.
(d) Finally, we offer some insightful observations and conclusions regarding the tracking of visual objects.

The remaining sections of the paper are organized as follows: The theoretical explanation of particle filters is briefly introduced in **Section II**. Visual object tracking with particle filter is discussed in **Section III**. However, in **Section IV**, benchmark datasets are detailed for visual object tracking. In **Section V**, the comparison techniques of visual object tracking using various PF. Finally, an extensive conclusion is outline in **Section VI**.

II. Particle Filter

Particle filter is a Monte Carlo and recursive Bayesian estimation-based filtering algorithm [10]. Particle filters exhibit superior performance compared to conventional methods such as the Kalman filter when applied to non-linear or non-Gaussian conditions. In addition, Particle filter is widely used in surveillance cameras, robotics, and navigation to track multiple objects using visual, geometric, and motion features, including color, texture, shape, outlines [13].

A particle filter is a Monte Carlo sampling approach for creating a recursive Bayesian filter [11], [12]. Particle filtering is a sampling technique that begins with a population of particles, each of which assigns no value to any variables. The goal of particle filter is to represent the posterior density with a set of random particles and weights, and then compute estimates the state variables' posterior density given the observation variables using these samples and weights. The particle filter is intended for use in a hidden Markov Model with both hidden and observable variables. The particle filter, sometimes known as the condensation filter, is a low-quality filter [15], [16].

The fundamental concept is that particle density distribution occurs when particles are sampled randomly. It is the most general Bayesian strategy since it has no restrictions on the state vector when dealing with nonlinear and non-Gaussian problems. The following is a description of how particle filters function. Based on a measure of probability, the state space is split into several parts, and each part is filled with particles. The higher the likelihood, the higher the particle concentration, according to the state equation, a particle system changes over time with the FPK equation determining the evolving pdf. By randomly selecting states from the state space, we produce a large number of particles that reflect the evolving pdf, because the point-mass histogram can approximate the pdf.

Particle filter technology's adaptability is a result of its dominance in nonlinear and non-Gaussian systems. The multi-modal processing abilities of the particle filter are another factor in the particle filter's widespread use. Particle filtering has been applied to numerous fields around the world. Fig. 1 below illustrates the core concept of the particle filtering (PF) technique.

Let, consider a system whose state changes over time, C_t= g(C_{t-1}, X_t), where C_t represents the current state of the system at time t. The state transition model g determines whether or not the system is $Markovian$. C_t is therefore dependent on the preceding state C_{t-1} as well as X_t is the system (process) dynamics, this enables the system to evolve over time. Imagine that part of the system is being observed using a set of noisy sensors S_t = z(C_t, Y_t). Where z describes the relationship between the sensor observations S_t, and current system state C_t with sensor noise Y_t of the

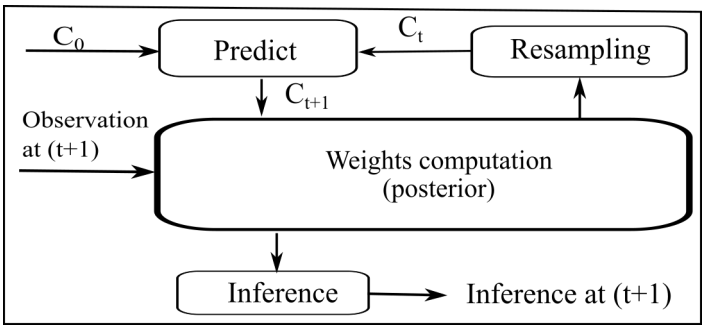

Fig. 1. The Workflow of the particle filter algorithm.

observation model. Hence, X_t and Y_t's unpredictability is believed to be known and captured using $pdfs$ [14].

The particle filter algorithm consists of three major steps including selection, prediction, and measurement.

In first, we construct a new particle set in the selection step by picking the particles from the previous particle set with the highest posterior probability. By passing an object via a dynamic model, the prediction step tries to forecast how its state will change. The dynamic model has two functions: firstly, it disperses the state density through stochastic diffusion, and secondly, it causes the state density to drift in a deterministic fashion. Each particle is updated according to the state model during prediction, which includes the insertion of random noise to simulate the effect of the noise on the state. The weight of each particle is re-evaluated based on the new data in the measurement stage, and we estimate likelihood probability. In summary, the following is a description of the particle filter:

(a) The following are the system and measurement equations:

$$A_{k+1} = g_k(A_k, W_k)\ and\ B_k = h_k(A_k, V_k) \tag{1}$$

Where the state variables vector A_k at time t are determined by a function g, with W_k and V_k being separate white noise processes with known $pdf's$. A function h connects the observations B_k with A_k.

(b) Let consider, the initial state of pdf $P(A_0)$ is known, produce N initial particles at random on the surface based on the pdf $P(A_0)$, where $A_{0,1} + (j = 1, ..., N)$ is the symbol for these particles. The user selects the parameter N as a compromise between computing effort and estimating precision.

(c) For k = 1, 2,..., do the following:

(1) Apply the known pdf with the known process equation of the process noise to the time propagation step to obtain the a priori particles a_k:

$$A^-_{k,j} = g_{k-1}(A^+_{k-1,j}, W^j_{k-1})(j = 1, \ldots N) \tag{2}$$

where each W^j_{k-1} noise vector is created at random using the known pdf of W_{k-1}.

(2) Calculate each particle's relative likelihood q_j, $A_{k,j}$ and conditional on B_k measurement. This is accomplished by calculating the pdf $p(B_K/A^-_{k,j})$ using the non-linear measurement equation and the measurement noise pdf.

(3) In the preceding step, scale the relative likelihoods as follows:

$$q_j = \frac{q_j}{\sum_{i=1}^{N}(q_i)} \quad (3)$$

Now add up all of the likelihood numbers is one.

(4) Using the relative likelihoods q_j, generate a collection of a posterior particles $A^+_{k,j}$. It is also called the re-sampling stage.

(5) Now that we have a collection of particles $A^+_{k,j}$ that are dispersed in accordance with the pdf of $p(A_k/B_k)$, any required statistical measure of the pdf can be calculated. However, calculating the mean and covariance is typically of significant concern.

III. Visual Object Tracking with Particle Filter

Visual tracking is a significant issue with many applications in surveillance, behaviour analysis, and human-computer interaction areas. It has a growing number of uses [17]. There are two classifications of visual tracking methods, deterministic and stochastic tracking. Mean their most familiar representatives are shift and particle filter, respectively [18].

However, particle filtering is the process of combining particles at a single location. A specific point into a single particle, resulting in weight for each particle to indicate the number of particles. It was created by combining various elements. Which eliminates the requirement for exact computations without skewing the results distribution of probabilities. As a result, the cost will be lower. In contrast, to limit the number of samples that must be processed, it is necessary to incur a computational charge that we investigate [19]. The basic architecture of particle filter-based visual object tracking is depicted in Fig. 2.

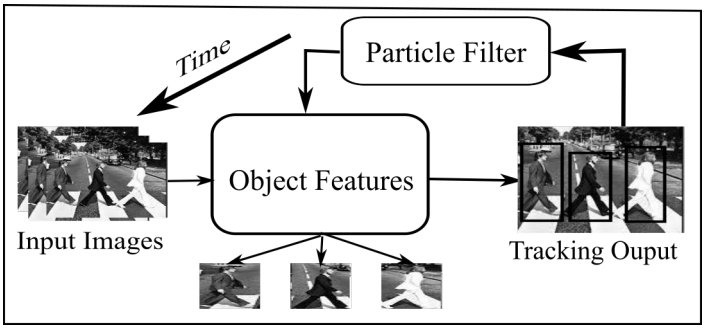

Fig. 2. Block diagram of the particle filter based visual object tracking.

Sequential importance sampling(SIS) is the most critical stage of the PF. At first, a set of particles is created, and then the crucial weights are assigned. Calculated in order to find the state's estimated worth. The majority of the consequences of SIS, after multiple iterations, a large number of particles are ignored, leaving only a small number of particles, possibly even a single particle [20].

SIS, unlike other methods, is not based on the Markov chain. One problem with SIS is that it is far too simple to get to a point where only a few (or one) have non-zero weights and almost all of the particles have weights of zero. These actual weights may differ significantly, leading to an inaccurate estimate. The SIS filter is affected by the so-called degeneracy problem. The SIS method is applicable to non-Bayesian computations as well, like figuring out the probability function in a case of missing data [21].

The following are the different versions of the particle filter [21], [22]:

(a) Local Linearization Particle Filter

(b) Sequential Importance Re-sampling (SIR) Filter

(c) Rejection Particle Filter

(d) Boosted Particle Filter

(e) Rao-Blackwellization

(f) Kernel Smoothing and Regularization

(g) Mixture Kalman Filter

(h) Interacting Multiple Model (IMM) Particle Filters

(i) MCMC Particle Filter

(j) Mixture Particle Filter.

(k) Auxiliary Particle Filter

(l) Unscented Particle Filter

Local Linearisation Particle Filter: The LLPF employs banks of Kalman filters with independent variants to generate credible densities using the most recent measurement.

Sequential Importance Re-sampling Filter: A generalization of particle filtering, SIR called Bootstrap Filter incorporates the re-sampling steps into the sequential importance sampling process.

Bootstrap and jackknife approaches serve as inspiration for sampling importance re-sampling (SIR). Description of a collection of computationally costly procedures built on sampling from observable data, the term "bootstrap technique" is used. The significance distribution is an approximation of the posterior distribution of states given the values from the previous stage, and its accuracy determines the effectiveness of the SIR algorithm. A SIR filter facilitates the examination of importance weights, importance density, substantial modularity, and generality [23].

SIR has the drawback of causing the particle swarm to "impoverish", as the name suggests. When the dynamic model's noise is tiny, many of the particle set's values will have the same value, which is what we mean by the term "the same". The second problem is that a large ensemble size is required to represent much regions in phase space (outliers occur), if the posterior distribution has long tails.

However, important Sampling techniques are used in both SIS and SIR filters. Re-sampling is always performed in the SIR filter (often between two critical sampling stages). In contrast, significance weights are calculated sequentially in the

SSIS filter and only need to be re sampled when necessary. This makes the SIS filter more computationally efficient.

Rejection Particle Filter: When we have a sufficient upper limit on the underlying distribution or density, the rejection particle becomes convenient. The rejection particle filter works better than the SIR filter when the distribution of proposals is preferable. The problem with using a rejection particle filter is that each time step takes a different amount of time to calculate.

Boosted particle Filter: There are two major issues that must be addressed in a traditional particle filter: setting up the particle filter and making sure the importance proposition is set up correctly. The BPF solves both problems by combining them with the AdaBoost detection algorithm [29].

Rao-Blackwellization: Since the process noise is formally zero in pure recursive estimation, the performance of a primary SIR-based particle filter is expected to be sub-optimal. Rao-Blackwellization is one method for increasing SIR efficiency. The fundamental idea behind this filter is to reduce the number of particles required to obtain the same level of accuracy as a standard PF filter.

Kernel Smoothing and Regularization: The problem of insufficient samples was fixed by these filters through the use of a ad hoc method called jittering. To smooth the posterior using a Gaussian kernel, Gaussian noise with a small amount is added to each re-sampled particle at each time step.

Mixture Kalman Filter: The MKF, which simulates a conditional Gaussian linear dynamic model, can be produced by Rao-Blackwellization and marginalization on a particle filter. The MKF represents the target distribution as a random mixture of normal distributions [27]. Primary benefit of MKF is the marginalization operation, which improves productivity.

Interacting Multiple Model Particle Filter: To forecast target behavior, the IMM comprises a range of models and adaptively chooses the models that are best for the current time step. It says that one of M modes best describes how a target behaves when moving with constant velocity, stopped, or accelerating. There is a probability attached to each mode [24].

Markov Chain Monte Carlo Particle Filter: In the MCMC sampling framework, samples are generated by a Markov chain that is ergodic, homogeneous, and reversible, and that has an invariant distribution. A faster rate of convergence than the particle filter is achieved by using this filter. Traditional re-sampling is replaced with MCMC sampling to prevent diversity loss and provide a re-sampling framework appropriate for pipeline processing [26].

Mixture Particle Filter: The MPF idea uses EKF/UKF as an approximation of a Gaussian proposal, and is comparable to the concepts of partitioned and stratified sampling.

Auxiliary Particle Filter: Pitt and Shephard proposed the APF in 1999 to address the tail observation density deficiencies of SIR [25]. As a result, calculating the APF requires more time. The tails of the distribution have low density because of sampling inefficiency and the unreliability of empirical prediction, downsides lack robustness against outliers. For the aforementioned issue, an auxiliary variable was added to the particle filter, resulting in a basic but more versatile and reputable framework with better performance than the SIR filter, although execution is not guaranteed.

Unscented Particle Filter: A particle filter with a UKF significance distribution constitutes the UPF. The proposal distribution in a conventional particle filter, such as CONDENSATION, is transition prior, but UPF was recently proposed to overcome the difficulties of wasting a large number of particles in the low likelihood region [28].

IV. Benchmark Dataset for Visual Object Tracking

A significant number of benchmark datasets have been generated for various visual object tracking applications. Most of them comprise video sequences with short-term (ST) visual object tracking, although long-term (LT) object tracking has been developed in recent years as illustrated in the Table I.

CAVIAR (CAVIAR2003) [39]: It includes two datasets containing several video sequences for various settings, such as persons walking alone or meeting with others. The first dataset contains films from $INRIA$ Labs' entry lobby, whereas the second is from a shopping mall hallway. Walking, browsing, relaxing, slumping or fainting, leaving luggage behind, people/groups walking together and splitting up, and two people arguing are among the scenarios covered in the first set. Each video sequence's ground truth is delivered in XML format and includes information such as bounding box locations and sizes, head and foot positions, and so on. Occlusion, appearance shifting, appearance, and disappearance are all issues addressed in this dataset.

Tracking and Surveillance Performance Evaluation (PETS2009 and PETS2012) [30],[38]: PETS-2009 and PETS-2012 are two of the most recent editions of PETS. PETS2017 has the most recent tracking video sequences, while PETS2012 datasets are identical to PETS2009, mainly aimed at surveillance applications. PETS 2009-S2 provides a dataset for people tracking in three crowd types: sparse, medium, and dense, with L1, L2, and L3 difficulty levels. Walking, running, and multiple flow merging are among the activities covered in the datasets. The goal is to monitor every person in the sequence, with the results being given as a 2D bounding box location for each person. There are difficulties in the dataset, such as occlusion, lighting changes, two people with the same appearance, etc.

Benchmark for online tracking (OTB-13 and OTB-15) [41]: OTB-13 has just 50 video sequences. The current version, OTB-15, is an expansion of OTB-13. The benchmark includes 50 and 100 video sequences, each with features. The datasets take into account eleven different attributes. Lighting, scale, occlusion, deformation, motion blur, fast motion, in-plane rotation, out-of-plane rotation, out-of-view, background clutters, and low resolution are some of them. The tracker's accuracy and location error are the two measures used to evaluate trackers. For assessing and comparing various tracker findings, success plots and precision plots are employed.

LITIV (LITIV) [31]: The dataset consists of people's heads being tracked in various situations (occlusions, many distractors, etc.). Ground facts containing the centers, widths,

and heights of tracked object bounding boxes are delivered with video sequences.

Benchmark for Multiple Object Tracking (MOT) [40]: The MOT challenge was initially released in 2015. It comprises annotated datasets, metrics for evaluating tracking methods, and a unified framework for multi-object tracking. MOT15, MOT16, MOT17, MOT20, and many other video sequences are available on the website. The CLEAR metrics(measures used in the classification of events, activities, and relationships workshops) and the collection of track quality measurements are utilized for evaluation [43]. The video sequences of ETH Central, TUD Stadtmitte, and TUD crossing can be found in MOT15.

Visual Object Tracking Challenge (VOT) [42]: The first tracker challenge for ST tracking was VOT2013. Every year since then, a challenge has been held. This paper makes use of VOT2016 [37], VOT2017 [36], and VOT2018 [35] datasets. It evaluates using two metrics. The first is accuracy, which is determined by calculating the overlap ratio between the tracker and ground truth bounding boxes, and the second is robustness, which is determined by tracking failure frequency. These measures have been replaced by the predicted average overlap measure [44] since VOT2015. The current version of VOT2020 includes video sequences for ST and LT tracking as well as an assessment platform.

A UAV Tracking Benchmark and Simulator (UAV123 and UAV20L) [32]: It features video sequences shot from an aerial perspective, with a subset of these sequences dedicated to long−term aerial tracking. Bounding boxes have been added to all sequences and twelve characteristics are used to evaluate trackers.

Single item tracking on a large scale (LaSOT) [34]: LaSOT is a long-term tracking benchmark for large-scale single object tracking. It includes video sequences in which the target vanishes and reappears. Annotations are supplied for each frame in the sequences. Lighting variation, full occlusion, partial occlusion, deformation, motion blur, fast motion, scale variation, camera motion, rotation, background clutter, poor resolution, viewpoint shift, out-of-view, and aspect ratio change are among the 14 qualities assigned to each sequence. It uses three measures for evaluation: accuracy, normalized precision, and success plots [33].

V. Comparison of Particle Filter System for Visual Object Tracking

Object tracking is a critical issue with the expansion of computer vision applications such as video surveillance, human-computer interaction, human behavior analysis, and so on. The following Table II provides a comparison of various algorithms for tracking visual objects using particle filters. Different versions of particle filters are employed with several features to obtain better tracking results.

TABLE I. Benchmark Dataset for Visual Object Tracking in Recent Years

Dataset	Type	Frame Per Seconds	Number of Attributes used for Evaluation	Number of Videos
CAVIAR (2003)	ST	25	–	44
PETS (2009, 2012)	ST	–	–	3(2009), 3(2012)
OTB (2013, 2015)	ST	30	11	50(2013), 100(2015)
LITIV (2014)	ST	15	–	4
MOT (2015, 2016, 2017, 2020)	ST	30(MOT15), 30(MOT16), 30(MOT17) 25(MOT20)	–	22(2015), 14(2016), 42(2017), 8(2020)
VOT (2013-2020)	ST, LT	30	–	16ST(2013), 25ST(2014), 60ST(2015-2017), 60ST & 35 LT(2018), 60ST & 50LT(2019 -2020)
UAV (2016)	ST, LT	30	12	123 ST & 20 LT
LaSOT (2019)	LT	30	14	1400

Note: ST means short-term tracking video, – means not mentioned and LT means long-term tracking video.

VI. Conclusion

This article reviewed particle filter-based approaches for visual object tracking and provided a succinct overview of related subjects. Due to its many practical applications, visual object tracking is one of the most researched computer vision topics. Numerous techniques have been developed for visual object tracking. Particle filter-based visual object tracking has been the subject of extensive research due to its capacity to deal with the complex dynamic environments of real life, random motions, many objects, and non-Gaussian sensor noises. In addition, the convolutional neural network and particle filter have been combined to create the most sophisticated method for visual object tracking. Several characteristics and classifiers that are frequently used with particle filters are provided. It was also found that combining multiple particle algorithms led to successful tracking outcomes and that each method has a unique advantage when considering the different visual object tracking circumstances.

Acknowledgment

We are very much thankful to Computer Vision and Intelligent Interfacing Lab (CVIIL) at Islamic University, Kushtia-7003, Bangladesh for providing all kinds of logistic and other support.

TABLE II. SUMMARIZING OF VISUAL OBJECT TRACKING USING VARIOUS PF BASED METHODS

SL No.	Paper Title	Year	Contribution	Remarks
1.	"Particle filter-based video object tracking using feature fusion in template partitions." [45]	2023	The research provides a novel approach to feature fusion that aims to improve the target and scene models in order to effectively partition the tracking template and capture the object's local attributes. The proposed strategy combines two features, namely the local binary pattern (LBP) and the mean RGB color features, to account for challenges such as shadows, dynamic background entities, adverse weather conditions, and variations in illumination.	The effectiveness of the suggested feature fusion strategy may exhibit variation depending on the various attributes of the tracked entities and the complex nature of the background scenes. However, the absence of an exhaustive examination of the trade-off between precision and computational efficacy may pose limitations in terms of execution in real-time and efficiency.
2.	"Particle Filter Based on the Harris Hawks Optimization Algorithm for Underwater Visual Tracking." [46]	2023	This study introduced a novel tracking algorithm, Harris-Hawks-optimized particle filters (HHOPF), to address the problem of low tracking accuracy in conventional particle filters caused by sample impoverishment. Using the Harris hawks algorithm, the proposed algorithm generates a nonlinear escape energy that effectively balances the exploration and exploitation processes. Consequently, the computational speed of tracking underwater targets is significantly increased.	The paper lacks a comprehensive analysis of the potential effects of diverse environmental conditions or scenarios on the algorithm's effectiveness. It does not address the difficulties or constraints associated with the use of the Harris hawks optimization technique for underwater visual tracking. In addition, the study lacks an exhaustive assessment of various cutting-edge tracking techniques, which may limit the practical significance of the findings.
3.	"Self-scale estimation of the tracking window merged with an adaptive particle filter tracker." [47]	2023	This research presents a new methodology for single-object tracking that integrates the particle filter algorithm and kernel distribution. This approach enables the tracking window to be updated based on changes in the object's scale, resulting in improved precision in localizing the object within a designated area. The proposed method addresses the difficulty of adapting tracking windows in real-time to account for variations in the object's appearance.	The work lacks a comprehensive examination of the computing complexity associated with the suggested approach. This aspect holds significance for real-time tracking applications that aim to tackle the difficulties of simultaneously tracking several objects.
4.	"A scale adaptive generative target tracking method based on modified particle filter." [48]	2023	This study presents a novel approach to enhance the accuracy and sample diversity of target tracking. The proposed method, named Quantum Particle Swarm Optimization (QPSO) and Adaptive Genetic Algorithm (QAPF), integrates an advanced particle filter (PF) algorithm with the mean shift technique. The objective is to optimize the robustness and intelligence of the traditional PF algorithm across various tracking conditions. By improving the position estimation of particles, the QAPF algorithm aims to enhance the overall performance of target tracking.	This study does not address the computational complexity or resource demands of the QAPF method. Additionally, the comparison of the QAPF algorithm with several state-of-the-art tracking techniques is limited in scope.
5.	"Robust Bayesian particle filter for space object tracking under severe uncertainty." [49]	2022	This paper proposes a particle filtering-based tracking system based on the concept of feature fusion in a complicated real-world environment with shadows, dynamic objects, adverse weather, and changing lighting. The tracking template comprises the local binary pattern (LBP) and the mean RGB color characteristics combined within a probabilistic framework.	Occlusion and concealment issues in dynamic scenes are among the limitations of the proposed system.
6.	"Multi-Feature Single Target Robust Tracking Fused with Particle Filter." [50]	2022	This work presents a credible particle filter with the correlation filtering framework-based multi-feature algorithm for tracking single targets in complex scenes. During feature extraction, depth features and manually extracted target object features are combined to train a tracking filter.	The proposed algorithm's high computational cost for utilizing depth features renders it unsuitable for real-time applications, necessitating additional research to improve its speed.
7.	"Minimax Monte Carlo object tracking." [51]	2022	The authors propose a new particle filter-based approach based on a minimax estimator combined with sequential Monte Carlo filtering for visual object tracking using a minimax strategy.	Only a few algorithms are used to compare performance.
8.	"An object tracking algorithm based on adaptive particle filtering and deep correlation multi-model." [52]	2022	The proposed object tracking algorithm solves the significant number of particles problem by utilizing a deep conventional correlation multi-model on adaptive particle filtering.	The proposed algorithm's performance decreases when the tracking object moves quickly.
9.	"Deep convolutional correlation iterative particle filter for visual tracking." [53]	2022	This paper proposes a novel iterative particle filter-based visual tracking framework based on the combination of a correlation filter and a deep convolutional neural network. In contrast, the iterative particle filter is used to select the correct particles and converge on the target position.	Compared to the other algorithms in the proposed work, the processing rate is lower.
10.	"Occluded object tracking using object-background prototypes and particle filter." [54]	2021	This article introduces an object-background prototypes-based discriminative model to address the shortage of valuable observations and the particle filter's efficient motion. A discriminative model is built using background and object knowledge and attempts to distinguish between the object, background, and any occluded parts of the object.	This algorithm performs well with occluded challenges in complex environments but is limited to other pose changes, illumination, and scale variations settings.
11.	"Multi-object tracking by mutual supervision of CNN and particle filter." [55]	2021	The authors proposed the mutual supervision of the trained CNN detector to identify the target bounding box in a traffic scene and the PF tracker to generate the multi-object tracking trajectory based on this identification.	The proposed algorithm can track rigid targets in controlled environments, like vehicles, but not overall targets like pedestrians.
12.	"Target tracking using a mean-shift occlusion aware particle filter." [56]	2021	This research paper aims to overcome the challenge of occlusion in visual tracking by including the mean-shift approach in a probabilistic filtering framework. This integration allows for a reduced particle set while still effectively maintaining the state probability density function of the model. The proposed approach demonstrates superior performance compared to state-of-the-art tracking algorithms on three benchmark datasets.	The research lacks a comprehensive examination of the computational expenses related to reducing the number of particles for tracking purposes and fails to offer precise quantitative comparisons with methods that employ larger quantities of particles.
13.	"Robust model adaption for color-based particle filter tracking with contextual information." [57]	2021	This study introduces a novel algorithm designed to improve the durability of color-based particle filters. Utilizing environmental data, the proposed algorithm dynamically updates both the scale of the tracker and the reference appearance model. It addresses the challenges posed by abrupt and significant changes in the appearance of the target during object tracking in video sequences.	The work lacks a comparative analysis of the proposed algorithm to a variety of cutting-edge trackers to provide a greater understanding of the algorithm's strengths and weaknesses. Further analysis that does not fully reflect the complexity and variability of real-world tracking scenarios could shed light on the robustness and generalizability of the proposed methodology.

SL No.	Paper Title	Year	Contribution	Remarks
14.	"Visual Vehicle Tracking via Deep Learning and Particle Filter." [58]	2021	The research presented a novel and efficient method for tracking multiple vehicles by combining the particle filter technique with the deep learning approach called You Only Look Once (YOLO). The authors perform an evaluation of a pragmatic tracking approach that employs the particle filter and the Bhattacharyya kernel to provide a feasible resolution for real-time tracking of multiple vehicles in different situations.	The study does not include a comprehensive examination of the computational complexity and lacks a comparison of the proposed approach with other well-recognized vehicle tracking techniques. As a result, the authors failed to address shortcomings or difficulties associated with using the YOLO detector for vehicle detection, such as how well it functions in different lighting conditions or in occlusion-prone situations.
15.	"Tracking and grasping of moving target based on accelerated geometric particle filter on the colored image." [59]	2021	This study presents a novel approach for tracking and retrieval of objects in unpredictable motion by employing a geometric particle filter tracker. The reduction in computational expenditure is accomplished by employing edge detection and morphological dilation methodologies. Furthermore, the tracking algorithm integrates HSV image features rather than grayscale image features, thereby improving its capacity to adjust to changes in illumination conditions.	A novel method for tracking and grasping moving objects is presented in this paper. Nevertheless, it does not analyze the handling of complex background scenarios or object occlusion, which are common challenges in tracking and grasping tasks in the real world.
16.	"A genetic optimization re-sampling based particle filtering algorithm for indoor target tracking." [60]	2021	This study presents a novel resampling technique intended to address the issue of particle erosion commonly observed with conventional resampling methods. The distribution of resampled particles is optimized by employing five operators, namely selection, roughening, classification, crossover, and mutation. These operators are employed to decrease particle depletion and improve particle positioning precision.	The study focuses primarily on indoor target tracking via wireless sensor networks. Uncertain is the extent to which the proposed algorithm would function effectively in outdoor settings or with various sensor types.
17.	"Particle filter and entropy-based measure for tracking of video objects." [61]	2021	The authors present a novel approach based on the particle filter for tracking objects in outdoor and indoor video sequences, using an entropy-based time motion searching model for selecting the particles to detect objects.	The proposed approach includes a performance comparison.
18.	"Deep convolutional likelihood particle filter for visual tracking." [62]	2021	This paper proposes a novel particle filter for visual tracking based on convolutional-correlation particle filters that estimate likelihood distributions from correlation response maps.	The weakness of the proposed method is that it does not fully explain all parts of the algorithm.
19.	"Infrared target tracking based on improved particle filtering." [63]	2021	To solve the infrared image particle degradation problem, this paper presents a combination of genetic algorithms and extended Kalman filter-based particle filter tracking with improved performance for infrared target tracking.	Utilizing a genetic algorithm and an extended Kalman filter increases the computational complexity of the proposed particle filter.
20.	"Visual object tracking via iterative ant particle filtering." [64]	2020	The author provides a particle filter-based tracking method with discriminative model-based object background prototypes for identifying objects and occluded portions of objects. The discriminative model uses prior knowledge of object and background classes to differentiate between three categories: object, background, and occluded object parts.	This method overlooked other relevant variables such as lighting variance, pose change, and scale change.
21.	"Tracking objects based on multiple particle filters for multipart combined moving directions information." [65]	2020	This study introduces the mutual supervision of the PF tracker and CNN detector to create the multi-object tracking trajectory, whereas a trained CNN is used to identify the bounding box of the detected target in a traffic scenario.	The main limitation of this study occurs under controlled conditions, such as tracking people from a traffic scene.
22.	"Occlusion robust object tracking with modified particle filter framework." [66]	2020	The authors present a particle filter that combines the mean-shift approach into a probabilistic filtering framework while using fewer particles to maintain many modes' state probability density function. The reference target and candidate location correlation coefficient, however, detect occlusion.	The proposed MSOAPF technique includes occlusion and fast motion challenges but fails in extensive situations.
23.	"A hybrid algorithm based on particle filter and genetic algorithm for target tracking." [67]	2020	This paper proposes a crew search optimization-based robust particle filter re-sampling method for overcoming low-performing particles identified as outliers by incorporating multi-cue extracted for each evaluated particle.	This approach is computationally demanding as an outlier detection is used to categorize unimportant particles.
24.	"Robust object tracking with crow search optimized multi-cue particle filter." [68]	2020	In this study, an observer marks an object at the beginning of a video sequence to reduce the image size by selecting particles with the highest weights to evolve a genetic algorithm known as the Reduced Particle Filter Genetic Algorithm during the re-sampling phase of the particle filter.	This algorithm's performance is not calculated and compared conclusively with other state-of-the-art algorithms.
25.	"Intelligent visual object tracking with particle filter based on Modified Grey Wolf Optimizer." [69]	2019	In this paper, the author proposes a visual object tracking system based on the Modified Grey Wolf Optimizer (MGWO) to address the issue of many particles in the particle filter (PF). Before re-sampling, the PF particles were optimized using a new variant of Grey Wolf Optimizer known as Modified Grey Wolf Optimizer (MGWO).	The proposed MGWO-based PF is not fully explained and is only compared to a few algorithms.
26.	"Multiple pedestrian tracking by combining particle filter and network flow model." [70]	2019	This paper suggested a novel particle filter tracking system for multiple pedestrians based on network flow models. To compensate for the problem of long-term occlusion, the proposed model combines local and global data association strategies.	The weakness of the proposed method is that both the computational complexity and the number of particles increase as the number of objects increases.
27.	"Multi-feature fusion in particle filter framework for visual tracking." [71]	2019	The authors applied the color distribution, and KAZE features with the particle filter (PF) to track a target in a video sequence of complex environments. The proposed multi-feature fusion-based PF utilized the Bhattacharya coefficient for the color distribution model as a similarity metric. At the same time, KAZE features utilized the Nearest Neighbor Distance ratio for matching feature points.	In PF experiments, only color and KAZE characteristics are employed. A set of features that accurately represents the target in one environment may not do so in another.
28.	"Particle filter re-detection for visual tracking via correlation filters." [72]	2019	This paper proposes a novel particle filter re-detection tracker with a correlation filters framework (CFPFT) to solve the problem of accurate object localization.	Long-term occlusions may still cause the tracking method to fail, so a strategy that re-detects the target and reuses the correlation filter tracker was to be implemented in real-world applications.
29.	"Robust object tracking via integration of particle filtering with deep detection." [73]	2019	This paper proposes a video object tracker with variable-rate color particle filtering that incorporates two innovations. First, a deep region proposal network was used to select the bounding box based on the dynamic prediction of particle filtering and a fusion integrating the particle filter and a deep object detector to enhance object tracking accuracy.	Implementation of the proposed method is slower than the conventional particle filter method, with only minor improvements.

SL No.	Paper Title	Year	Contribution	Remarks
30.	"Visual tracking based on adaptive interacting multiple model particle filter by fusing multiples cues." [74]	2018	This paper presents a robust tracking system based on the fusion of a particle filter (PF) with interacting multiple models (IMM) to overcome various severe challenges, such as camera motion, fast motion, background clutter, or target appearance changes.	The performance of the proposed algorithm decreases while the tracked object moves quickly.
31.	"Chaotic particle filter for visual object tracking." [75]	2018	The authors introduced a chaotic particle filter (PF) based on global motion to enhance the performance of PFs. In two steps of chaos theory, estimation of the object's movement is used to identify its position over frames, followed by the color-based particle filter technique to find the object in the local region.	The chaotic PF method outperforms the conventional PF method and occasionally the tracking by detection techniques, but only color features are used in all studies.
32.	"Robust object tracking via part-based correlation particle filter." [76]	2018	This paper proposes a part-based correlation particle filter method for reliable visual tracking. In a particle filter architecture, correlation filters manage target parts and accurately represent the target's appearance by employing overlapping local parts of varying sizes and locations.	The main downside of the method is that it works better when tracking nonrigid objects with changing appearances, but it disregards other relevant difficulties.
33.	"A box particle filter method for tracking multiple extended objects." [77]	2018	This paper proposed a box particle filter-based extended multiple object tracking technique to address the challenging problem of multiple object tracking caused by data association. This research also highlights how interval-based techniques can manage data association concerns effectively while minimizing computational complexity.	The validation of the proposed approach is limited to laser rangefinder sensor data in real time and needs to be expanded and validated in more generic application settings.
34.	"Multi-task correlation particle filter for robust object tracking." [78]	2017	This study presented a particle filter based on a multitask correlation named MCPF for effective visual object tracking. In contrast, correlation filters jointly learn the interdependencies across numerous features from the multitask correlation filter (MCF).	Using a multitask correlation filter increases the computational cost of the proposed MCPF.
35.	"Particle Filter Object Tracking Based on Color Histogram and Gabor Filter Magnitude." [79]	2017	The authors present a novel particle filter-based tracking method that uses the combination of Gabor filter features and the color histogram of the detected object, obtained by background subtraction, to determine the likelihood of the observation and a state space model based on the Box-Muller transformation.	The proposed method's main drawback is that the number of particles increases when the object's color histogram increases, causing computational complexity.
36.	"Correlation particle filter for visual tracking." [80]	2017	The authors propose a robust correlation particle filter (CPF) for visual tracking by combining the strengths of a correlation filter and a particle filter.	The performance metric of the algorithm is not computed comprehensively.
37.	"Deep convolutional particle filter for visual tracking." [81]	2017	The integration of a particle filter and deep CNN has been proposed in which the particle filter predicts the target position using motion mode at each frame, and the HCFT-CNN adjusts the target position using the surrounding particles of the anticipated position. Finally, the CNN correlation map was used to calculate the current frame's particle weight and target position.	The presented paper contains no accurate experimental results.
38.	"Top-down visual attention integrated particle filter for robust object tracking." [82]	2016	This study blends frequency analysis into a particle filter-based computational of top-down visual attention to address the challenges of rapid motion and long-term obstruction.	The tracker's performance suffers slightly if the object appearance changes and if descriptors calculated directly from feature maps are used instead of color histograms, making it more coherent and faster.
39.	"Adaptive Cell-Size HoG Based Object Tracking with Particle Filter." [83]	2016	The authors proposed an Adaptive cell-size HoG (acHoG)-based Particle Filter Tracking (PFT) algorithm to handle the repeating feature extraction problem by applying Adaptive cell size to HoG.	The main drawback of these approaches is that they reduce tracker performance due to failure detection.
40.	"Object-tracking based on particle filter using particle swarm optimization with density estimation." [84]	2016	The authors analyze the problems of particle filter tracking degeneracy and impoverishment degradation in the Bayesian particle filter tracking framework. Particle Swarm Optimization (PSO) is employed as a sampling mechanism to address these two issues.	The proposed solution did not handle other critical challenges such as backdrop adaption, scene tracking in a cluttered environment, and object interactions.
41.	"Real-time and model-free object tracking using particle filter with joint color-spatial descriptor." [85]	2015	The authors incorporate the Joint Color-Spatial Descriptor (JCSD) and particle filtering to develop a multiple model-free object tracking technique that evaluates the hypothesis step within a particle filtering framework.	However, the method's accuracy decreases with low computational power and must be implemented with GPU for high accuracy and real-time applications.
42.	"Single object tracking via a robust combination of particle filter and sparse representation." [86]	2015	This author presented a particle filter-based tracking system that uses a particle filter and reversed sparse representation (RC-PFRSR) comprehensive combination to reduce drifting and increase tracking robustness.	In this study, the proposed system tracks only a single visual object and not multiple visual objects.
43.	"Particle filter with occlusion handling for visual tracking." [87]	2015	The authors proposed a particle filter system with a patch-based appearance model for occlusion handling, which includes two main components: color and motion vector, to address the challenge of visual tracking with three critical components including feature extraction, particle weighting, and occlusion handling.	The key drawback of the strategy is that it only worked for occluded environments as opposed to other constraints in visual object tracking.
44.	"Intelligent video target tracking using an evolutionary particle filter based upon improved cuckoo search." [88]	2014	This paper aims to incorporate an evolutionary particle filter with an improved cuckoo search algorithm to overcome the sample impoverishment problem of a generic particle filter in real-time video object tracking. Regarding tracking performance, the proposed algorithm outperforms the PSO particle filter and generic particle filter based on an improved cuckoo particle filter.	The proposed system is adequate for tracking a single object, not multiple objects, or in ambiguous or uncertain environments. Furthermore, this tracking framework necessitates additional cues to handle dynamic object shapes.
45.	"Using local saliency for object tracking with particle filters." [89]	2014	Instead of employing the saliency map of the entire image, the authors proposed a tracking algorithm that estimates the saliency map by extracting salient regions based on visual attention from the particle areas and the target area of each particle.	The proposed algorithm resolves particle filter divergence for targets with similar characteristics. However, tracking errors are inevitable when target and background colors are similar.
46.	"Abrupt motion tracking using a visual saliency embedded particle filter." [90]	2014	This article illustrates how to solve the problem of abrupt motion by combining a particle filter tracking system with an improved visual saliency model. In addition, it is possible to recover a lost tracking object by detecting its region in salient regions.	In this proposed work, many tracking aspects under challenging conditions, such as when the target object is visually similar to the background or when its appearance abruptly changes, are not considered.

SL No.	Paper Title	Year	Contribution	Remarks
47.	"Object tracking from image sequences using adaptive models in the fuzzy particle filter." [91]	2013	This paper addresses issues caused by unexpected events. In the proposed work, a fuzzy particle filter's process and observation noises are considered fuzzy variables. The fuzzy particle filter is equipped with two adaptive models that enhance tracking performance: adaptive AR and appearance mixture. The adaptive AR calculation is adopted as the state transition model, and recursive AR determines the optimal parameters over time to enhance state prediction. Additionally, the observation model, the adaptive appearance mixture model, consists of three Gaussian components (W, S, and E).	This method did not consider object illumination or occlusion when tracking multiple objects.
48.	"A combined Color-Correlation Visual Model for Object Tracking using Particle Filters." [92]	2013	The proposed work utilizes a particle filter to track semi-rigid video sequence objects. In addition, the MOSSE correlation filter and color histogram combination create a robust feature descriptor of the object that outperforms for tracking fast-moving objects in a complex environment in real-time applications with a small number of particles.	This paper's limitation is that the required computing power for the tracking system depends not only on the size of the patches but also on the number of particles. In addition, the system must investigate sampling inefficiencies and maximize particle utilization.
49.	"Efficient visual tracking using particle filter with incremental likelihood calculation." [93]	2012	This paper proposes an improved real-time particle filter in which the weight of each particle is computed using incremental likelihood. However, the proposed particle filter-based tracking method performs surprisingly well on hardware platforms with limited resources.	The proposed tracking method's effectiveness diminishes as the tracked object's speed increases. Therefore, it is only effective when an object moves at a reasonable speed; this is the trade-off between the proposed approach's accuracy and the object's speed.
50.	"A compact association of particle filtering and kernel-based object tracking." [94]	2012	The main goal of this paper is to combine kernel-based object tracking (KBOT) and particle filtering (PF) to develop a more reliable visual tracking method (PF). In addition, the question of what types of particles are appropriate for using KBOT to refine their position states for more accuracy is also addressed, and a two-stage solution is proposed.	There are still some issues that demand more research. The disadvantage of the proposed algorithm's use of color histograms as object descriptors for a fair comparison is that it is unsuitable for dealing with varying lighting conditions.
51.	"Hierarchical Kalman-particle filter with adaptation to motion changes for object tracking." [95]	2011	The authors examined the combination of the particle filter and subspace representation and successfully applied it to tracking algorithms, such as the Eigen-tracking technique. Their combination has shown improved performance in terms of accuracy and robustness despite requiring a relatively small number of particles.	Although the proposed method works with greater accuracy and precision, it is computationally expensive. Moreover, in the proposed technique, the particle filter handles only nonlinear motion locally, while the Kalman filter deals with linear motion globally.
52.	"Robust visual object tracking using multi-mode anisotropic mean shift and particle filters." [96]	2011	This study presents a novel tracking technique based on multi-mode anisotropic mean shift and particle filters. The method performs online learning of reference objects, is more resistant to objects' dynamic shape and appearance, and requires a small number of particles.	The proposed system necessarily requires accelerated computation and empirical parameter selection.

***Abstract*—Speech recognition-based biometric access control systems are promising solutions that have resolved many issues related to security and convenience. Speech recognition, as a biometric modality, offers unique advantages such as user-friendliness and non-intrusiveness, etc. However, developing robust and accurate speaker identification and authentication systems pose challenges due to variations in speech patterns and environmental factors. Integrating deep learning techniques, especially AutoEncoder and Generative Adversarial Network models, has shown promising results in addressing these challenges. This article presents a novel approach based on the combination of two deep learning models, namely, AE and GAN for speech recognition-based biometric access control. In the model architecture, the AutoEncoder takes the MFCC coefficients as input, and the encoder converts the latter to the latent space, whereas the decoder reconstructs the data. Then, speech features extracted from the latent space are used in the GAN generator to generate additional speech data. The discriminator network has a dual role, serving as both a feature extractor and a classifier. The first extracts relevant features from generated samples, while the latter distinguishes between generated and authentic samples that come from AutoEncoder. This strategy outperforms DNN and LSTM models on VoxCeleb 2, LibriSpeech, and Aishell-1 datasets. The models are trained to minimize Mean Squared Error (MSE) for both the generator and discriminator, aiming at achieving highly realistic datasets and a robust, interpretable model. This approach addresses challenges in feature extraction, data augmentation, realistic biometric samples generation, data variability handling, and data generalization enhancement, providing therefore, a comprehensive solution.**

***Keywords*—Speaker identification; speech recognition; biometric access control; authentication; verification**

I. Introduction

Speech recognition systems [1] have become increasingly important in various domains, including biometric access control, where the identification and authentication of individuals based on their unique voice characteristics are crucial. These systems aim, securely, to use biological or behavioral characteristics to authenticate and authorize individuals for access to a physical location, a device, or a system. It relies on unique and measurable traits that are specific to an individual, making it difficult to forge or replicate. These characteristics can include physiological characteristics such as fingerprints, face features, iris patterns, and voiceprints, as well as behavioral characteristics such as typing patterns, gait, and signature dynamics as shown in Fig. 1. The main function of this

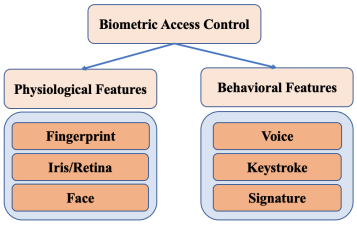

Fig. 1. Biometric categories.

paradigm is to collect biometric data, convert it into a digital template, and then compare this template to templates stored in a database. If the comparison results in a match, the individual is given access. Otherwise, access is blocked. Fig. 2 presents a system architecture based on speech recognition.

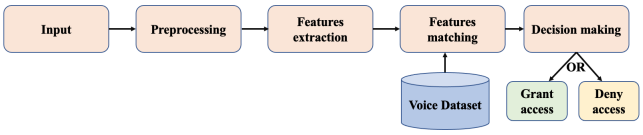

Fig. 2. Biometric access control architecture based on speech recognition.

Biometric access control systems based on speech recognition offer numerous advantages [2], such as universality, non-intrusiveness, high authentication security, and convenience i.e., bypassing the use of memorized passwords or access cards, audit trail (keep track and accountability), and faster processing than the traditional one. This concept is a powerful and convenient way to improve security and access management in a variety of areas, such as physical facilities, digital systems, and digital transactions... etc. However, to achieve reliable and robust performance, it is essential to develop accurate speaker identification and authentication mechanisms.

Deep learning models are characterized by their ability to learn sophisticated patterns and representations from data, providing a strong foundation for tackling the complexities of speech recognition [3]. Hence, providing powerful tools for improving the accuracy and effectiveness of its tasks. In this context, the use of AutoEncoder models for feature extraction [4] has shown promising results in identifying and authenticating speakers. The AutoEncoder model, a type of neural network architecture, has gained significant attention in recent years due to its capability to learn meaningful and compact representations of input data. AutoEncoders can be leveraged to extract discriminative features from raw speech signals. By training the AutoEncoder model on a large dataset of labeled speech samples, it can learn to encode the essential characteristics of a speaker's voice into a lower-dimensional representation, which facilitates efficient and accurate speaker identification and authentication processes. However, this model faces several challenges among them:

- Lack of Realism in Generated Samples: Because AutoEncoders concentrate on recreating the input data, they may produce generated samples that are excessively similar to the training data and are devoid of variation.
- Noisy or incomplete reconstructions: AutoEncoders may have trouble accurately reconstructing the input speech signals, mainly when there is noise or fluctuation.
- Limited Generalization of novel data: Because AutoEncoders tend to concentrate on recreating well-known patterns from the training set, they may have trouble in generalizing novel or unseen data.
- Incapability to Distinguish: AutoEncoders are typically unsupervised models concentrating on feature learning and reconstruction. The capacity to discriminate is essential for precise authentication in a biometric access control context.
- Limited data augmentation: AutoEncoders can be used for limited data augmentation by reconstructing and producing synthetic samples. The produced samples, however, may not represent the whole range of variability included in the training data.
- Adversarial Attacks: AutoEncoders can be vulnerable to adversarial attacks [5], which include making tiny and purposeful changes to input data in order to trick the model. In the case of speech recognition systems, this might include discreetly changing a voice recording to deceive the system into providing access to an unauthorized user.
- Inadequate Temporal Information: Traditional AutoEncoders struggle with sequential data, which is an issue in speech recognition, where the order of the input (i.e., the sequence of sounds or words) is important. Recurrent or convolutional AutoEncoders, for example, can alleviate this, although they are more sophisticated and computationally intensive.

Generative Adversarial Network (GAN) is a promising paradigm that consists of two main components: a generator and a discriminator. The generator produces synthetic data and the discriminator tries to differentiate between real and synthetic data. In the context of biometric access control using speech recognition [6], GANs can be applied to generate synthetic speech data to augment the training dataset [7], which can help address data scarcity issues, increase the diversity of the training data, and improve the robustness and generalization of the speech recognition system. Synthetic data generated by the GAN can be combined with real training data to create a more comprehensive and representative dataset for training speaker identification or authentication models, mitigating most AE model issues. It's important to note that GAN training can be challenging and may suffer from issues [8] such as training instability requiring careful tuning of hyperparameters and balancing the training dynamics between the generator and discriminator, lack of control over generated data, GANs typically generate data based on random noise input, resulting in limited control over specific characteristics of the generated speech samples, lack of feature extraction: GANs primarily focus on generating data and may not explicitly learn meaningful features from the input speech samples, and data augmentation: GANs are commonly used for data augmentation by generating synthetic samples. However, without the guidance of meaningful features, the generated samples may not effectively capture the desired variations and characteristics of real speech data. The combination of AutoEncoder (AE) and Generative Adversarial Networks (GAN) models, for biometric access control based on speech including speaker identification and authentication, resolves many problems and drawbacks related to feature extraction, data augmentation, and generating realistic biometric samples. To this end, the main goal is to contribute to the advancement of this research by leveraging the capabilities of deep learning through a novel approach that combines both models in a manner complementary to each other, providing control, stability, better feature learning, and enhanced data augmentation capabilities, leading to improved speech recognition performance.

The key contributions of this project can be outlined as follows:

- Introducing a novel approach rooted in deep learning models, specifically AutoEncoder and Generative Adversarial Network in biometric access control through speech recognition context. This integrated model enhances system performance, accuracy, robustness, and efficiency.
- Employing the AutoEncoder (AE) model as an unsupervised method for extracting meaningful and discriminative features, reducing dimensionality, and addressing storage and computational challenges associated with raw audio data analysis. Additionally, features are extracted from the latent space and utilized in the Generative Adversarial Network (GAN) to augment the training dataset, enhancing model generalization, mitigating overfitting, and alleviating data scarcity issues, resulting in the creation of high-quality, realistic biometric samples.
- Proposing a GAN model where the generator network produces synthetic speech data resembling that from the latent space representation, thereby expanding

the training dataset. This approach improves model generalization, reduces overfitting, and addresses data scarcity, leading to the generation of high-quality biometric samples. The discriminator in this proposal serves two roles: feature extraction and classification. The former extracts features from generated samples, capturing more informative and efficient features, while the latter distinguishes between generated samples from both models, enhancing overall system performance.

- Application of this approach to diverse datasets, including VoxCeleb 2, Aishell-1, and LibriSpeech, has yielded positive results when compared to outcomes from Deep Neural Network (DNN) and Long Short-Term Memory (LSTM) models.

The remainder of this article is organized as follows: Section II provides related works on speech recognition systems for biometric access control. Section III presents the proposed solution. Section IV presents the results and analysis of the experiments conducted, highlighting the performance gains achieved through the AutoEncoder-GAN-based approach. Section V presents a discussion. Finally, Section VI concludes the article with a summary of the findings and discusses potential directions for future research in this field.

II. Related Work

In the literature, there is a lot of research related to biometric access control based on speech recognition topics, including speaker identification and authentication, and speaker verification. This section presents an overview of some works and propositions published recently that achieved significant results.

Najim Dehak et al [9] proposed two speaker verification systems models, In which the first one is based on SVM, by using the cosine similarity, and the second one utilises directly the cosine similarity in the final phase which decides the final score. The experiments are done through three different methods in the variability space, which are within-class covariance normalization, linear discriminate analysis, and nuisance attribute projection. Their study conducted on the combination of LDA with WCCN has achieved good results compared to the other ones. The test was carried out using the NIST 2008 Speaker Recognition Evaluation dataset.

Yen Lei et al [10] presented a new approach based on deep learning speaker recognition using a phonetically that aims at improving speaker recognition performance by using an i-vector model [11] to represent the speech signal (extract the main features) and DNN model is used to replace the UDM-GMM [12] paradigm in order to train the model. The experiments proved that this approach has significantly improved the i-vector speaker recognition system.

Another research done by [13] has proposed d-vector instead of i-vector that aims at extracting hidden layers of a DNN as features. D-vector represents the averaged activations from the last hidden layer of DNN. Experiments of this approach have proved its efficiency in a small-footprint text-dependent speaker task. Generally, this scheme underperforms the predecessor based on i-vector-DNN.

Another research made by [14] has proposed a multi-task deep learning scheme based on the j-vector method that consists of extracting features from multitask DNN using probabilistic linear discriminant analysis (PLDA). This scheme has achieved good results than the predecessor models (i-vector, d-vector).

The Authors in [15] have proposed a new scheme based on deep neural network DNN to extract speech features called as x-vector. This latter represents the fixed-dimensional embeddings of variable-length traits. Furthermore, this research tackled also data augmentation by adding the noise and the reverb to the existing dataset to improve the efficiency of the model in the text-independent speaker tasks. Effectively, this approach has achieved better findings than the ones based on the i-vector and d-vector. Another research conducted by [16] has proposed a new end-to-end architecture based on neural networks, especially DNN and LSTM to speaker verification in the text-dependent context that aims at mapping the utterances to a score and joining them to optimize the representation of the speaker. In the same area, the authors of [17] have proposed another approach based on the end-to-end attention model. They use the CNN model to extract the noise-robust frame-level features that will become utterance-level speaker vectors using the attention model. This approach proves its effectiveness on Windows 10 “Hey Cortana”.

Another research carried out by [18] in the context of text independence has presented a new end-to-end approach based on the deep learning model to optimize the triple loss function using Residual Net block and measuring the similarity by Euclidean distance within trials. The findings show that this approach outperforms that based on conventional i-vector schemes, namely on short utterances.

In [19], the authors have proposed a new generalized End-to-end model based on LSTM. The training process has relied on the large number of utterances forming a batch. This scheme aims at optimizing the loss function through the training process in an efficient manner. The experiments show that this platform has achieved good results. N. Le et al [20] have proposed a new approach based on deep learning model, namely CNN. The main objective of this proposition is to optimize the deep speaker embedding through intra-class loss distance variance regularization compactness. The findings have proved that this approach accelerates the convergence of the training model, which enhances the model’s performance.

Another research carried out by the authors in [21] has presented an end-to-end optimized scheme based on deep convolutional features extractor combined with self-attentive and large-margin loss functions in the text-independent tasks context. They use a modular neural network instead probabilistic linear discriminant analysis (PLDA) classifier. This work made use of the experiments on VoxCeleb and NIST-SRE 2016 and has achieved an enhancement model than the others based on i-vectors.

The authors in [22] have suggested a novel approach for learning speaker embeddings based on a simulated model of GAN, especially the discriminator. This architecture aims to maximize mutual information, improving the model performance on the VoxCeleb corpus. Experiments show that this model outperforms the model based on i-vector and that based

on triples loss systems.

Many works are proposed to optimize the performance of speech recognition tasks and provide a robust system using deep learning model. Each research has focused on one aspect or more, such as data augmentation, features extraction, denoising and de-reverberation. The proposed solution has designed a new architecture based on deep learning models, namely AutoEncoder and Generative Adversarial Network in a complementary manner to improve the model performance by minimizing the loss function. The MFCC is used to extract features and the model AE to capture the meaningful speech representation and GAN is used to generate speech data from the latent space of the model AE.

III. Proposed Scheme

The proposed scheme is based on two models which are AE and GAN models as depicted in Fig. 3. At first, the speech inputs are collected, and their Mel-Frequency Cepstral Coefficient (MFCC) characteristics are extracted and used for training and tuning the model. Generally, The AE model comprises three components: Encoder, latent space, and Decoder. The encoder captures the main representation of the meaningful speaker speech features extracted from MFCC and produces the latent space, the latter will be used to reconstruct the input data. In this model, the Latent space will be extracted and used as input to the generator of the GAN model to generate more real data from it. The generated samples will be then used as input to the discriminator. This latter plays two roles, namely a features extractor and a classifier. At first, the discriminator extracts features from the generated samples and then feeds to the classification between that extracted and that comes from the AutoEncoder i.e. the decoder, to make a decision. This section presents more details of this model.

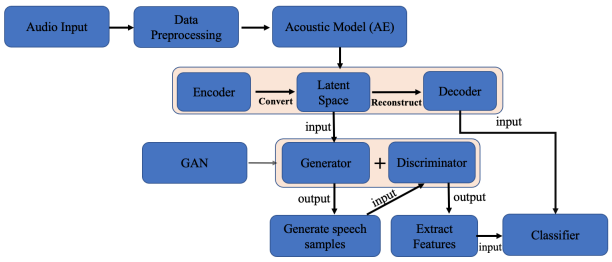

Fig. 3. AutoEncoder-Generative adversarial network model architecture.

A. Data Preprocessing

Generally, the preprocessing process [23] is crucial for preparing the data. This phase involves the capture and splitting of data into segments, feature extraction, noise removal, features normalization, and data loading, etc. Among the main steps that represent the backbone of the model namely in the context of the biometric access control based on speech, is feature extraction. To this end, the proposed architecture involves the adoption of the Mel-frequency Cepstral coefficients (MFCC).

1) Mel-Frequency Cepstral Coefficients: MFCC [24] is a technique that consists of extracting features from the signal. In the speech processing context, this method is widely used to capture the spectral features of sound well-suitable for various machine learning and deep learning tasks including speech recognition and speech analysis. Simply this technique is an amount of coefficients that represent the shape of the speech power spectrum signal. Fig. 4 represents the components of the MFCC. To calculate the coefficients of MFCC, some steps are crucial as depicted in the figure. After capturing the speech signal, the first step is breaking the signal into frames (windowing process) and then applying the Fast Fourier Transform (FFT) to determine the power spectrum of each frame. Following that mel-scale filter bank processing is performed on the power spectrum by the formula 1:

$$mel(f) = 2595 log_{10}(1 + \frac{f}{700}) \quad (1)$$

Where mel(f) represents the frequency on mels and f represents the frequency on Hz. The power spectrum is converted then by log domain and the Discrete Cosine Transform (DCT) is applied to get the coefficients of MFCC through the Eq. 2:

$$\hat{C}_n = \sum_{n=1}^{k} (log\hat{S}_k) cos[n(k - \frac{1}{2})\frac{\pi}{k}] \quad (2)$$

Where $k, \hat{S}_k, and \hat{C}_n$ represent, respectively the mel cepstrom coefficients numbers, the filter bank output and the MFCC coefficients.

Fig. 4. MFCC architecture.

B. AutoEncoder model

The AutoEncoder (AE) model is a sort of neural network architecture used for feature learning, dimensionality reduction, and data reconstruction. It is especially effective for extracting relevant representations from biometric data and may be used in a wide range of biometric modalities, in various applications, namely Feature learning, data denoising, data compression, Anomaly detection, Privacy preservation, biometric template protection...etc. An AutoEncoder's primary principle is to learn a compact and efficient representation of incoming data. It is made up of an encoder and a decoder as shown in Fig. 5. The encoder takes raw data as input and converts it to a lower-dimensional latent space representation. The fundamental traits and qualities of the data are captured by this latent space representation, and the decoder uses this later to attempt to recreate the original input data. The objective is to maintain the information required for reconstruction in the latent space. AE is an unsupervised model that aims at minimizing the loss function between the input data and the reconstructed data, capturing the most relevant representations.

The proposed solution incorporates the use of AutoEncoder to capture the relevant representation of the inputs from MFCC

coefficients, optimizing the speech processing system. The main objective of MFCC is extracting features and converting the input signal into coefficients that are retained as features which represent the main relevant features. The AutoEncoder takes these coefficients as input and converts them into latent space, reducing therefore, the dimensionality of the representation represented by the coefficients, and extracting the main relevant representation. The other network i.e. decoder network reconstructs the representation from that reduced (latent space). The main goal of this proposition is to get the most salient and compact representation from MFCC coefficients in a lower-dimensional space by training the AutoEncoder model.

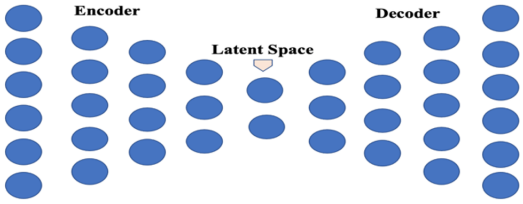

Fig. 5. AutoEncoder architecture.

C. GAN model

Generative Adversarial Network (GAN) is a generative model that is distinguished by two distinct networks, each with its unique set of attributes called Generator and Discriminator. The first seeks to produce realistic data from a specific class, while the second is used to determine whether the generated data is realistic or phony, as shown in Fig. 6: GAN is a deep-learning class used especially to produce synthetic data from the raw data input. In the scope of biometric access control, the generator takes a random noise as input and attempts to produce biometric data samples that mimic actual biometric data, while the objective of the Discriminator is to distinguish between the generated samples and the real ones, generally a binary classifier. The training procedure comprises a competition between the generator and the discriminator. As training advances, the generator improves at creating more realistic data, while the discriminator improves at differentiating between actual and phony data. This repeated procedure should result in high-quality synthetic data that is difficult to differentiate from genuine data. GANs may be used for a variety of reasons in the context of biometric access control, including data augmentation, Privacy-Preserving Research, Training Data Generation, Data Imputation, and Adversarial Attacks and Defense.

To this end, the proposed scheme extracts the latent space from the AutoEncoder model and uses it as input in the Generative Adversarial Network (GAN) model namely the Generator. This latter Generates more speech data from those reduced features, producing then data simulated to that of input. Whereas the discriminator in this architecture plays two roles, namely a features extractor and a classifier. At first, the discriminator takes the generated samples as input, extracts relevant features and then distinguishes them from that produced and trained by the AE model, especially the decoder.

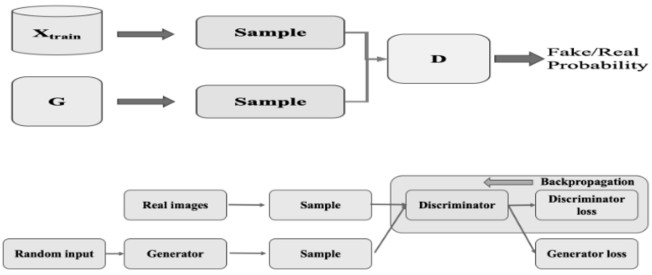

Fig. 6. GAN architecture.

IV. Experiments and Results Analysis

In this section, the experiments carried out by the laboratory team are presented, describing therefore, the datasets, the metrics and the implementation details of the proposed model, and finally the analysis of the result.

A. Datasets

In this model, three different datasets have been used, which are VoxCeleb 2, Aishell-1 And LibriSpeech.

VoxCeleb: It is an open-source dataset that is widely used in the experiments of speech processing tasks [25]. It contains videos interviews uploaded to YouTube. There are two types of VoxCelb datasets, VoxCeleb 1 and VoxCeleb 2. The first one has over 100,000 utterances For celebrities, whereas the VoxCeleb 2 has over a million utterances. In the proposed solution, the experiments have occurred on the VoxCeleb 2.

Aishell-1: This dataset is used also in the speech preprocessing tasks[26]. It is an open-source and freely accessible speech dataset that contains Mandarin speech captured with a high-fidelity microphone (44.1 kHz, 16-bit). The Aishell-1 dataset was created by downsampling the audio collected by the high-fidelity microphone to 16 kHz. A set of 400 speakers from various accent areas in China took part in the record capture.

LibriSpeech: is an open-source corpus, available in [27]. It contains 1000 hours of speech sampled at 16KHz and is generated from audiobooks in the LibriVox project. This dataset is used mainly in speech preprocessing including speech recognition and speaker identification. Table I represents the specification of the used datasets:

TABLE I. Datasets Specification

	Speakers	Utterances	Hours
VoxCeleb 2	6112	1 128 246	2442
Aishell 1	400	141 925	Over 170
LibriSpeech	2087	252 702	1000

B. Evaluation Metrics

Generally, a metric is a method used to evaluate a system's performance on a specific task. The main metric objective is measuring the quality of classifications or predictions carried out by a system or model. A loss or error function [28] is a function that determines how much the output or predicted

value departs from reality or actual value aiming at optimizing the model (either maximizing or minimizing issues). The Mean Squared Error (MSE) [29] is a loss function that measures the error between the observed and predicted values. The average of errors squared is calculated by this Eq. 3.

$$MSE = \frac{\sum(y_i - \hat{y}_i)^2}{n} \quad (3)$$

Where y_i represents the observed value, $\hat{y}_i$ represents the predicted value, and n is the observations number In this study, the MSE metric is used in the AutoEncoder model to evaluate its performance, and the Binary Cross Entropy (BCE) metric is also used in the GAN model that represents the difference between the predicted probability distribution and the reel one. On one hand, BCE is used to solve the binary classification issues, evaluating then, the model's performance. On the other hand, is used to quantify the training loss, minimizing therefore, the loss function of the model during training.

C. Implementation Configuration and Results Analysis

In the proposed scheme, the PyToch library, written in Python programming language, has been used for training networks based on deep learning models. This model has adopted Graphics Processing Unit (GPU), due to its efficiency in Neural Network processing. After capturing the MFCC coefficients from the speech, 13 coefficients, The latter are then fed to the AE model namely, the encoder that converts the inputs to latent space, reducing therefore the dimensionality and capturing essential speech features. These high-level features serve to reconstruct the speech data from the bottleneck layer and aim at generating outputs that closely resemble the original data input. The model training aims at minimizing the reconstruction loss between the original and reconstructed speech. In the training of the AutoEncoder, the chosen specifications include 8 dimensions as the latent dimension, 64 as the batch size, and 0.001 as the learning rate. Within the first part of the proposed architecture, the AE model is implemented with input dimensions set to 8. The encoder network consists of 128 units or neurons in the hidden layer, employing the Rectified Linear Units (ReLU) as an activation function. The use of ReLU introduces non-linearity, facilitating the model in learning complex relationships within the data. The learning rate and the network size are identified using different settings based on the try-and-error approach to choose the best configuration in terms of performance.

At the beginning of the training process, the weights are initialized at random and then gradually updated. To solve the model overfitting challenges, different methods are used such as the regularization of the parameters to promote lower values of weight, and adding dropout layers within the encoder and the decoder, furthermore, the loss function regularization has been adopted to promote certain desired behaviors in the latent space. The data mapping process is carried out from the 128-dimensional hidden representation to the latent space representation. The Adam optimizer has been deployed. The loss function is selected as the Mean Squared Error (MSE) as mentioned before.

In this proposition, the latent space features are extracted representing the high-level speech representation to feed it into the GAN model, namely the generator network. This latter takes the high-level representations (more relevant speech features) as input to generate more speech data in a manner that resembles real speech. The architecture of the generator is composed of three fully connected linear layers with ReLU activation functions between them. The Tanh activation function has been applied in the final layer to ensure that the generated values are bounded within the range [-1,1]. The other GAN network, i.e., the discriminator, plays two roles in this architecture, a features extractor and a classifier. At first, the discriminator takes the generated samples from the generator, tries to extract the relevant representations and then feeds them to the classifier to distinguish them from those that come from the decoder of the AE model. The structure of the discriminator is similar to that of the generator. It consists of three fully connected layers with ReLU activation functions. In the final layer, the sigmoid activation function has been applied, which produces values within the range [0,1] where 1 identifies the real data, and 0 identifies the fake ones. Both the generator and the discriminator are adversarial trained. i.e. competing against each other. This process helps us to refine the ability of the generator to generate more high-level quality speech data, and therefore, achieve a robust system based on the combination of two promising deep learning models, AutoEncoder and Generative Adversarial Network, especially in the speech recognition tasks. Fig. 7 represents AE-GAN model training process using three different datasets, with the loss versus training epochs to illustrate how well the model learns. The experiments incorporate different utterances from three different datasets, including VoxCeleb 2, LibriSpeech, and Aishell-1. These datasets are divided into three parts for each dataset, 80% for training, 10% for validation, and 10% for test.

Experimentation involved assessing the proposed deep AE-GAN model by utilizing the state-of-the-art models, namely the Deep Neural Network (DNN) model and Long Short Term Memory (LSTM) model, using the datasets mentioned above to describe the experiment findings. Table II lists the overall loss function of the models that are used in the test process during various research phases. As shown in the table, the AE-GAN model has a high score in training and validation in three different datasets, which are LibriSpeech, VoxCeleb 2, and Aishell 1, it has achieved respectively in training loss, 0.0574, 0.0876, and 0.0886, and in validation loss 0.0581, 0.0888, and 0.0889. Compared to the results of DNN and LSTM models, they have gotten in the training phase values ranging from 0.07 and 0.168, while in the validation phase, huge values ranging between 0.30 and 0.48, proving generally the overfitting of the models. The proposed scheme has proved its efficiency and outperformed the performance of DNN and LSTM models in three different datasets. Fig. 8 depicts the results of the experiments carried out over the datasets using the DNN and LSTM models.

V. Discussion

Deep Neural Networks (DNNs) and Long Short-Term Memory networks (LSTMs) are reference models in speech recognition-based biometric access control context, and have been widely used in many studies. DNNs have demonstrated their performance in learning hierarchical representations from raw audio data. Their ability to handle complex features with

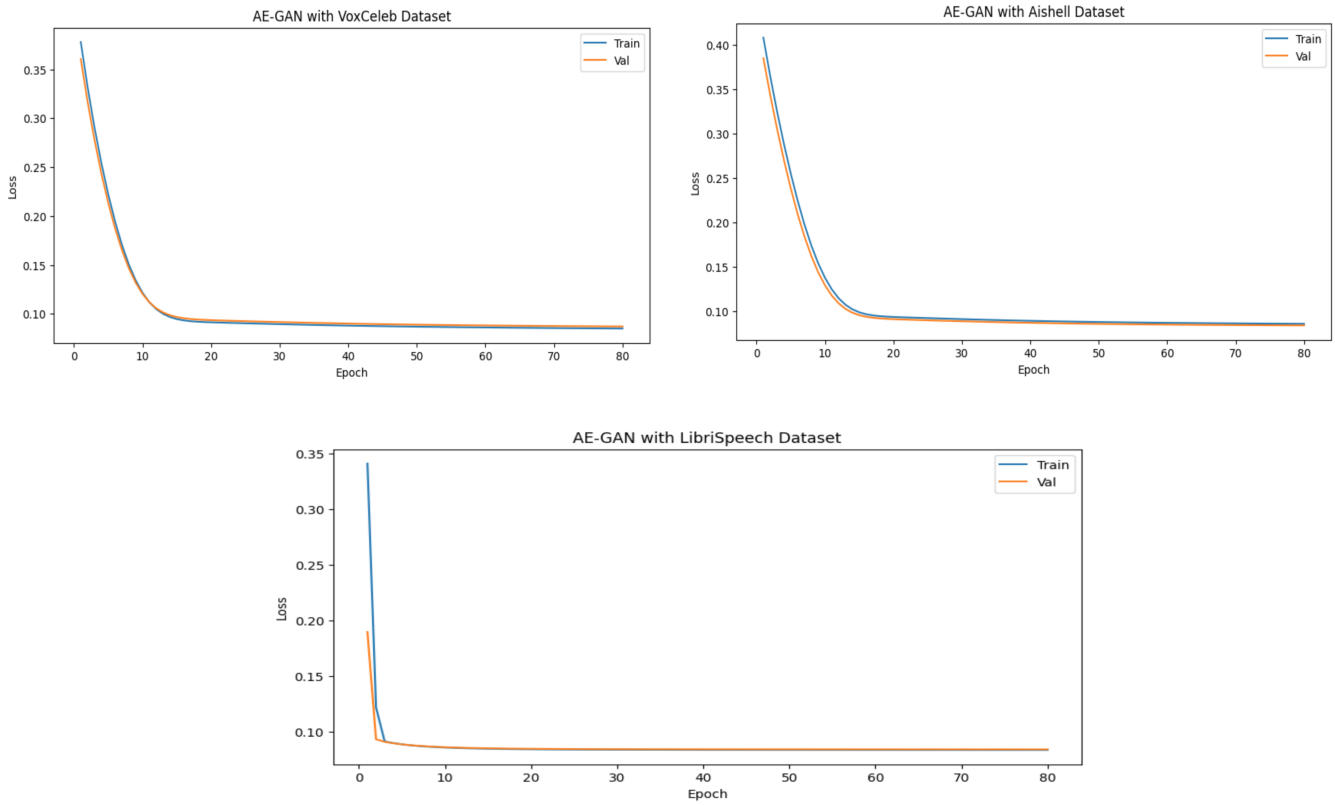

Fig. 7. AE-GAN model training loss curve vs epoch.

TABLE II. AVERAGE LOSS PER EPOCH FOR TRAINING AND VALIDATION

Dataset	Model	Loss function	
		Train	Validation
LibriSpeech	DNN	0.079	0.334
	LSTM	0.095	0.307
	AE-GAN	**0.0574**	**0.0581**
VoxCeleb 2	DNN	0.152	0.298
	LSTM	0.168	0.287
	AE-GAN	**0.0876**	**0.0888**
Aishell 1	DNN	0.084	0.389
	LSTM	0.079	0.486
	AE-GAN	**0.0886**	**0.0889**

deep increased network has contributed to their standing in the field. However, this model struggles with capturing long-range dependencies in sequential data, which is crucial for speech recognition tasks. Simultaneously, LSTMs are recognized for their effectiveness in modeling temporal dependencies within sequential data, making them well-suited for capturing long-term patterns in speech sequences. They have addressed the vanishing gradient issues that are inherent in traditional Recurrent Neural Networks (RNNs), making them more adept at learning from sequential data. But to capture complex patterns effectively, LSTMs require more data.

The AE-GAN's ability to leverage the latent space features extracted by the AutoEncoder to enhance the generative capabilities of the GAN is a potential advantage. In scenarios with limited labeled data, the AE-GAN's capacity for generating high-quality and realistic speech samples may prove advantageous. Additionally, its ability to address overfitting challenges through regularization techniques and dropout layers may contribute to superior performance in diverse speech recognition tasks. Although the proposed model offers several advantages, it may face challenges in scenarios where there is insufficient diversity in the training data, potentially leading to biased representations. If the dataset lacks sufficient variation in terms of speakers, accents, or speech characteristics, the model may struggle to generalize well to a broader range of real-world scenarios. Augmenting the dataset with more diverse samples could enhance the model's robustness. Additionally, the model's performance may be sensitive to hyperparameter settings, necessitating careful tuning. Implementing automated hyperparameter tuning methods or conducting a thorough sensitivity analysis may help identify robust configurations more efficiently. The computational complexity of the model, especially in training large-scale datasets, could pose limitations in terms of time and resource requirements. The computational costs related to the training deep learning models, including the proposed AE-GAN model, are a significant consideration.

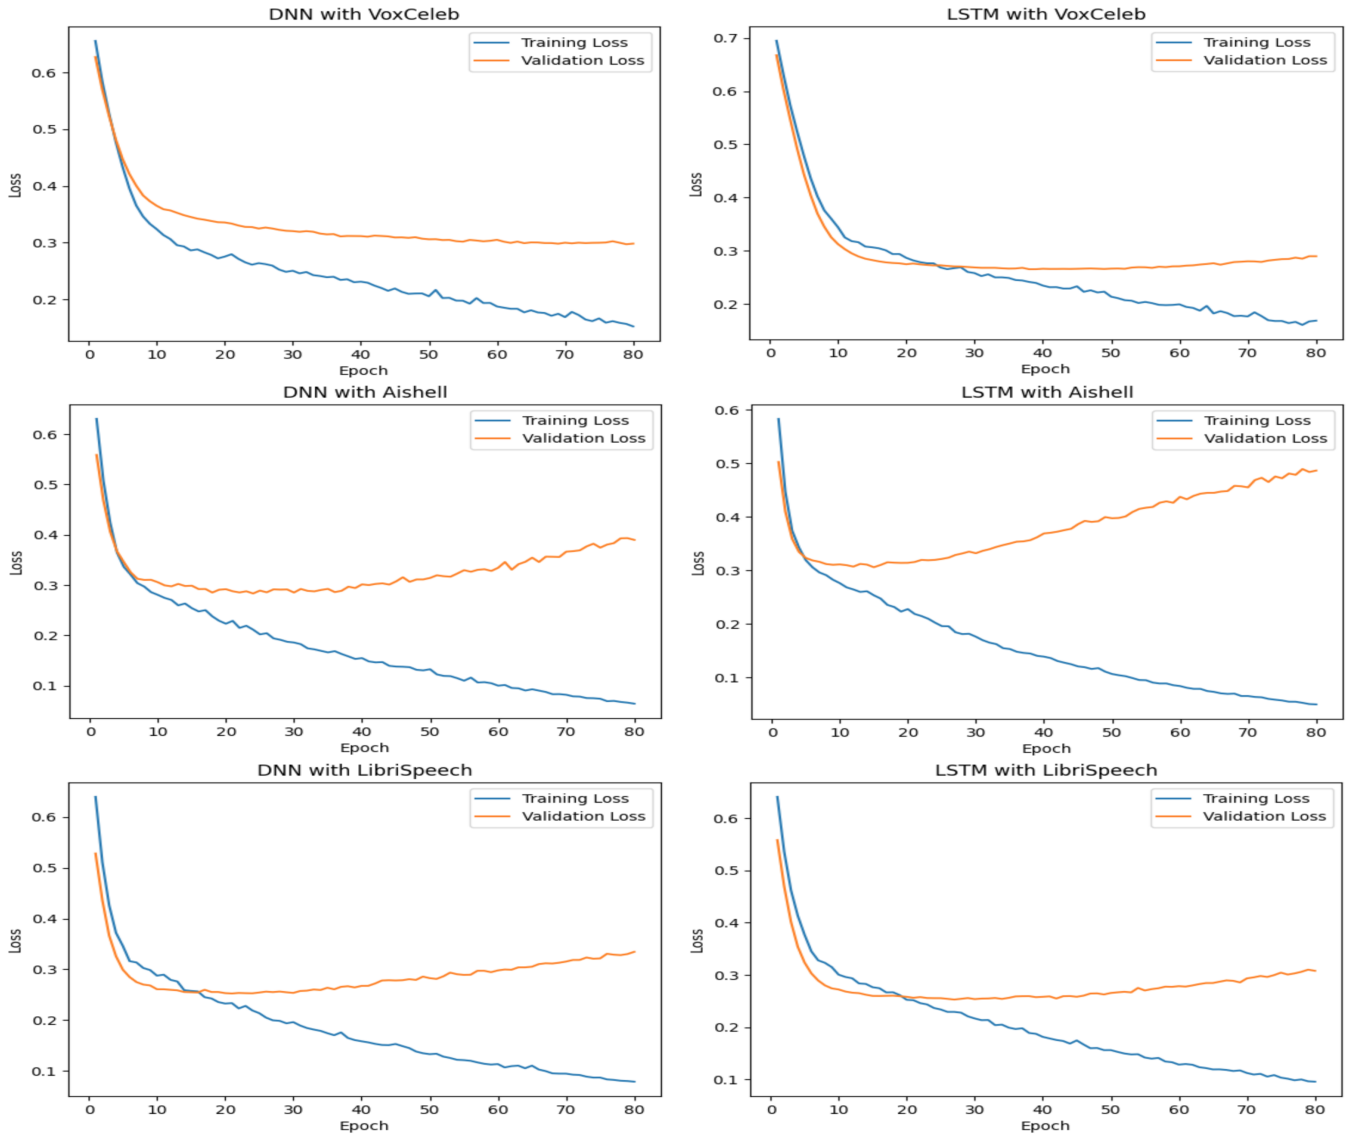

Fig. 8. The results of DNN and LSTM models with VoxCeleb, aishell, and libriSpeech datasets.

There are several solutions that contribute to mitigating these costs among them, efficient GPU utilization can be essential, optimizing the model architecture and exploring parallelization techniques can contribute to faster training times. Additionally, the use of transfer learning from pre-trained models can alleviate the need for extensive training on large datasets. Another potential solution is the exploration of model quantization techniques, reducing the precision of model weights to accelerate inference. Leveraging distributed training across multiple GPUs or utilizing cloud-based computing resources can further expedite the training process. Implementing early stopping and model checkpointing strategies can optimize training efficiency by preventing unnecessary iterations. Generally, a nuanced understanding of the AE-GAN model's strengths, a transparent acknowledgement of study limitations, and proactive strategies to address computational costs collectively contribute to a robust evaluation framework for advancing the field of speech recognition.

VI. Conclusion and Future Work

This paper has proposed a new approach based on speech recognition for speaker identification and authentication that is considered as the main and crucial task in the speech-based biometric access control scenario. The model has proved its efficiency and robustness based on the combination of AE and GAN models. The proposed model provides an optimized platform integrating the features learning and tackling the data augmentation and generalization issues, especially the speech dataset, and data imputation such as reconstructing degraded audio or denoise and tuning the hyperparameters of the models. This approach has been implemented on three different datasets: VoxCeleb2, LibriSpeech, and Aishell-1, and has achieved good results in terms of performance, compared to AE and GAN models. However, the proposed scheme is expensive in terms of time-consuming, especially in the training phase where there are two models AE and GAN. In

future endeavors, the focus will be on this aspect to optimize the proposed scheme.

***Abstract*—In recent years, significant attention has been directed towards the development of artificial empathy within the engineering academic community. Replicating artificial empathy necessitates the capability of agents to discern human emotions and comprehend environmental risks. Analyzing acoustic data in real environments offers a higher level of non-invasive privacy compared to video and camera data, limiting the agent's understanding to specific patterns. However, current studies are negatively affected by subjective inferences from real data, which can result in inaccurate predictions, leading to both false positives and negatives, especially when contextual data and human speech are involved. This paper work proposes the estimation of a dangerous environment in accordance with the emotional speech and additional ambient noises. In this approach we implement a variational autoencoder model in conjunction with a classifier for training the classification task. Additional regularization techniques are applied to bridge the gap between the original training data and the expected data. The classifier utilizes feature data generated by the variational autoencoder to extract class patterns and determine whether the environment is hazardous. Emotional speech is classified as angry, sad, or scared emotions, contributing to the classification of danger, while happy, calm, and neutral emotions are considered safe. Various ambient noise types, including gunfire and broken glass, are categorized as dangerous, while real-life indoor noises like cooking, eating, and movements are considered safe.**

***Keywords*—Dangerous environment detection; speech analysis; acoustic audio analysis; ambient noises; variational autoencoder model; empathetic systems**

I. Introduction

Ensuring the safety of individuals within indoor environments is a paramount concern, with implications spanning from residential spaces to critical infrastructure. The ability to accurately assess and respond to potential hazards is crucial for safeguarding lives and minimizing risks. In recent years, the pursuit of artificial empathy within the engineering domain has gained significant traction, aiming to imbue computational agents with the capacity to comprehend human emotions and navigate environmental dangers. An avenue of exploration in this pursuit involves the analysis of acoustic data, providing a non-intrusive means of understanding the surrounding environment. Unlike more invasive data sources like video and cameras, acoustic data analysis preserves privacy by focusing on discernible patterns, presenting a valuable approach for ensuring security in various settings.

The research presented in this paper addresses a critical facet of safety by proposing a method for estimating hazardous environments through the evaluation of emotional speech and ambient noises. This approach not only advances the field of artificial empathy but also holds substantial promise for real-world applications, particularly in indoor acoustic analysis and speech classification. The implications of this work extend beyond the academic realm, offering tangible benefits for society at large. The ability to accurately classify emotions and distinguish between safe and hazardous sounds has significant societal impact, enhancing security in public spaces, homes, and workplaces. Moreover, in the realm of engineering, the proposed method contributes to the refinement of hazard detection systems, with potential applications in areas such as smart home technologies, security surveillance, and other safety-critical environments. This research sets the stage for a more nuanced understanding of the acoustic environment, bridging the gap between subjective inferences and objective safety assessments, thereby paving the way for advancements in both theoretical understanding and practical implementation.

Analyzing a diverse range of events, including human speech and ambient sound, presents a formidable challenge for artificial agents. Consequently, accurately judging environmental characteristics becomes a complex endeavor. Moreover, this task necessitates numerous sensors, such as cameras for image and video processing, coupled or decoupled infrared sensors, and other costly apparatus, making the practical implementation of artificial home assistants exceedingly challenging to achieve. Addressing the challenges inherent in enhancing their practical implementation involves different tasks, such as managing real-time processes effectively, as evidenced in related papers [1]–[3].

Another challenge is to ensure accurate object localization such as in [4]–[7] where they proposed for example, a convolutional recurrent neural network for joint sound event localization and detection of multiple overlapping sound events in three-dimensional space. In particular the sound event localization and detection is extensively utilized by works based on robotics navigation and natural interaction with surroundings.

Background noise treatments and reduction have been extensible studied such as in [8]. The reduction of the noise comes to fulfil two different targets, the human hearing safety and the reduction of background noise to interpret another sounds or a clear speech. The source separation of overlapped sounds in acoustic event identification have studied in [9] to feat one of the pending challenges. While in [10]–[13], a study of event detection by ambient sounds analysis was performed, trying to give realism to the scenario through the addition of

diverse types of ambient sounds.

Among several challenges, to perform a precise and realistic danger classification and estimation is especially required, considering subjective human perspectives and the critical task of minimizing the false alarms [14]. Some studies were carried trying to estimating hazardous environment from ambient sounds with support vector machine models such as in [15]. However the issue continue active and open to date. The significance of false alarms cannot be overstated, owing to the inherent subjectivity found in real-life scenarios. Environmental sounds has been under-researched compared to standard speech and music, and its understanding tend to be subjective depending on the scenario and the listener [16].

Previous research endeavors have explored various ambient sounds as cited in [17], yet remarkably, the emotional states of individuals within the room have never been integrated into the equation, amplifying the complexity of the challenge at hand, and making it more realistic.

Furthermore, the usage of generative models have increased in the study of human emotions and context analysis due to the flexibility and versatility to represent and analize different types of data present all together in the same audio frame [18]–[24]. Generative models, particularly when integrated with classifiers such as variational autoencoders (VAEs), prove to be highly advantageous for classification tasks in the domain of speech and also with ambient sound. The combination of generative and discriminative capabilities allows for effective feature extraction and representation learning, enhancing the model's ability to discern patterns in complex audio data. The limitations of generative models in this context are primarily associated with tasks that demand perfect data reconstruction. Challenges arise when attempting to faithfully reproduce the intricate details of diverse audio signals, including variations in speech patterns, accents, and environmental sounds. However, in classification tasks, where the focus is on discerning relevant features rather than achieving precise data reconstruction, these limitations are mitigated. The flexibility and adaptability of generative models make them well-suited for classification applications, offering a powerful and efficient approach to audio analysis.

To the best of our knowledge, the detection of a dangerous environment was never judged by an emotional speech analysis in combination with ambient noises analysis with generative models, such as a variational autoencoder (VAE) model that learn the characteristics related with a subjective environment. Additionally, the proposed model make an adjustment of the difference among input data and expected data with phonetic and prosody features.

II. Proposed Approach

A. Proposed Model

The proposed model falls under the category of semi-supervised learning, which is a hybrid method combining labeled and unlabelled data. In this approach, the classifier learns from labeled examples and also utilizes information from unlabelled data to enhance its performance. Within our model, the VAE serves a dual purpose: it functions as an unsupervised autoencoder, learning a condensed representation of the data, and as a supervised classifier, predicting emotional classes. This dual role is possible because the model incorporates both the reconstruction loss (unsupervised) and the danger classification loss (supervised), allowing it to harness the advantages of both labeled and unlabelled data. In essence, our model is semi-supervised because it integrates labeled emotional class data along with unlabelled Mel spectrogram data during the training process, optimizing its performance.

The proposed classifier model utilizes the latent space generated by the VAE model. In our approach, these two models operate independently; first, the VAE is trained separately, and then the pre-trained encoder from the VAE, which has learned from unsupervised data, functions as a feature extractor in the classifier. This encoder transforms the data into a compact representation, which is then processed through a classifier. This classifier is specifically trained to predict danger labels based on these encoded features, which are both from labeled and unlabelled data. Consequently, our model is categorized as a semi-supervised learning approach incorporating both types of data during its training process.

Moreover, the regularization task in the extended VAE provides additional control over the decoded data. This control is achieved by utilizing pre-processed data and its representations within the VAE model, allowing for a more refined and controlled learning process [25]–[28].

The phonetic and prosody characteristics of each value derived from the input and decoded data, will be compared. The aim is to ensure that the phonetic and prosody attributes of the VAE representation closely match the pre-processed values from the input data during the extended VAE training process.

In this approach, the classifier relies on the trained encoder for its classification tasks. Consequently, the regularization process also impacts the final results of the classifier. Classifying the extended dataset containing dangerous patterns presents a challenge for our classifier. This challenge arises not only from the variations in volume and intonation between the actors' utterances but also from the inclusion of surrounded noises specific to the content of danger.

The prosodic control and regularization was previously observed in [29], [30]. The phonetic and prosodic features considered include spectral bandwidth, spectral contrast, and formants from 1 to 5 extracted from each input audio's Mel spectrogram. Our proposed classifier, coupled with the phonetic and prosodic regularized VAE method, encompasses multiple tasks. The subsequent subsections will delve into the specifics of each task involved in our approach.

The basic architecture of the hazardous environment classifier model can be observed in Fig. 1. The variational autoencoder is represented with an encoder, latent space and decoder structure, while the classifier consumes data from the features captured by variational autoencoder in the latent space.

B. Data Selection

In the process of data preprocessing, we obtained audio samples from the Ravdess datasets and custom data from distinct sources. Our primary objective was to construct a coherent emotional audio dataset and convert these audios into Mel spectrograms. Intermediate steps were taken to seamlessly

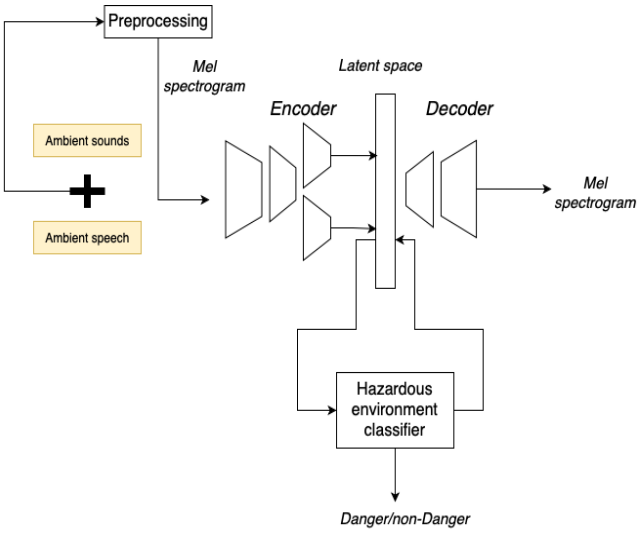

Fig. 1. Proposed architecture of the hazardous classifier model.

integrate these diverse data types, involving tasks such as aligning sampling rates, set at 44.1KHz.

Within the Ravdess dataset, audio clips exceeded three seconds, with approximately 2 seconds of null data. Consequently, trimming zero-data was imperative to obtain a high-quality signal for further processing. Normalization of voices to a standardized volume and noise reduction were performed, particularly essential for downloaded patterns that exhibited varying durations and significant zero data within different frames.

The generation of Mel spectrograms involved utilizing the short time Fourier transform (STFT) technique, followed by mapping the spectrogram to a Mel scale. This method, preconfigured with 128 Mel values, enabled a precise characterization of the audio data.

Emotion selection involved three emotions from the Ravdess dataset, excluding "Disgust" as it does not pertain to a dangerous or non-dangerous environment precisely. The chosen emotions (Neutral, Calm, Happy, Sad, Angry, Fearful) were carefully balanced to ensure equal representation in the dataset.

Regarding ambient noises, glass breaking and gun firing were chosen to represent dangerous environments, while cooking, eating noises, human steps, and opening/closing windows represented safe environments. The specific quantities used are detailed in the experiment section.

In our training approach, we focused on scenarios that involve neutral, calm, and happy emotions coupled with typical indoor noises like cooking, eating, and human movements. The decision to exclude scenarios where both dangerous and non-dangerous noises and speech coexist was deliberate. Training artificial neural networks with such mixed data might lead to the erroneous understanding that during routine, calm, or happy speech, potentially dangerous events like gunfire or breaking glass should be expected. This contradicts real-life situations where such consistency is infrequent and therefore was not incorporated into our training data to maintain the model's adherence to realistic scenarios.

C. Prosodic and Phonetic Regulariser Features's Description

Detecting hazardous environments using ambient sounds and speech poses a significant challenge, benefitting greatly from a multifaceted approach involving various audio features. In our research, we focus on employing spectral bandwidth, spectral contrast, and formants 1 to 5 for this purpose.

Formants in speech processing refer to the resonant frequencies of the vocal tract, manifesting as peaks in the sound spectrum. They play a vital role in speech production and perception, representing specific vocal tract configurations through their frequencies. Notably, the first few formants (such as F1, F2, F3, etc.) are pivotal in speech recognition, differentiating speech sounds based on their positions and transitions. Although they are not typically regarded as prosodic features, formants are instrumental in recognizing vowels and consonants, providing essential phonetic information in speech analysis [31].

Spectral contrast, another key feature, quantifies the amplitude disparity between peaks and valleys in the sound spectrum. This metric captures variations in spectral energy, indicating the sharpness or smoothness of transitions between different frequency bands. Drastic changes in spectral contrast signify specific events or objects in the environment. In danger detection scenarios, abrupt increases in spectral contrast can indicate events like glass breaking or gunshots. Monitoring these shifts enables the identification of unusual and potentially perilous situations [32].

Spectral bandwidth, the third feature under consideration, refers to the width of the frequency spectrum of a sound. It measures the dispersion of frequencies around the central frequency. Sounds with broader spectral bandwidths encompass a wider frequency range and are generally classified as broadband sounds. In contexts where danger needs to be identified, wide spectral bandwidths indicate loud and potentially hazardous noises, especially in otherwise quiet settings. For instance, while the sounds of everyday activities like cooking or eating are typically narrowband, noises such as gunfire or explosions produce broad-spectrum signals. Analyzing spectral bandwidth helps recognize the presence of such broad-spectrum events, aiding in the detection of potential threats [32].

By comprehensively analyzing formants, spectral contrast, and spectral bandwidth, an acoustic system can effectively differentiate between normal activities and events that might pose a danger within a specific environment. These distinctive features allow the system to identify specific sound patterns associated with perilous situations, making them invaluable tools in acoustic surveillance and safety systems.

D. Mathematical Definition of Proposed Model's Regularization

The additional phonetic-prosodic regularisation term $R(phopro(x), phopro(p_\theta(x|z)))$ was added to the well known evidence lower bound (ELBO) of VAE [33], in order to make each input datum x, to remain close to the corresponding decoded datum in the vector of danger $phopro(p_\theta(x|z))$ and $phopro(x)$, respectively.

The danger term to be added is as follows:

$$PhoProDiff\_R\_Loss = \alpha \cdot R(phopro(x), phopro(p_\theta(x|z))) \quad (1)$$

PhoProDiff stands for phonetic-prosodic difference regularization loss.

The prosodic regularised variational autoencoder loss function will finally be defined as follows.

$$L(\phi, \theta, x) = E_{q_\theta}(z|x)[log_{p_\theta}(x|z)] - D_{KL}(q_\phi(z|x)\|p(z)) + \alpha \cdot R(phopro(x), phopro(p_\theta(x|z)) \quad (2)$$

Letting α being $0 \leq \alpha \leq 1$. Assuming E as the expected value, D_{KL} as Kullback-Leibler Divergence, and R as regularisation.

The $R(phopro(x), p_\theta(x|z))$ term is defined as a mean squared error for each spectral feature. Phonetic-Prosodic regulariser over one spectral feature calculation can be defined as follows.

$$R(phopro(x), phopro(p_\theta(x|z))) = (phopro(x) - phopro(p_\theta(x|z))^2 \quad (3)$$

The combination of formants, spectral contrast, and spectral bandwidth extracted from the actual pre-processed Mel spectrogram data is represented as the phonetic and prosodic vector $phopro(x)$. This vector serves the purpose of enforcing regularization, ensuring alignment with the phonetic and prosodic attributes of the speech data.

The regularization based on phonetic and prosodic qualities is applied during the training process [34].

III. Experiments

A. Experiment Details

In our proposed methodology, we devised two distinct models: the Variational Auto-Encoder (VAE) and the danger classifier, each fulfilling specific roles. The proposed VAE operates as an unsupervised learning tool, generating a condensed data representation suitable for tasks like data generation and denoising. However, it is not optimized for direct danger classification.

Conversely, the danger classifier specialises in precisely this task, classifying danger based on the acquired features. It takes encoded features from the danger encoder and associates them with corresponding danger and non-danger classes. This separation allows for independent training processes and facilitates the exploration of various classifier architectures without impacting the proposed VAE. This design ensures the versatility of the learned representation from the proposed VAE for diverse downstream tasks, including danger classification.

Essentially, the proposed VAE learns a meaningful latent representation of input data, which the danger classifier utilizes for classification. This clear division of roles enhances modularity and adaptability in the overall learning process. Our danger classifier follows a supervised learning paradigm, categorizing input data into distinct danger and non-danger classes. Using an emotion dataset containing Mel spectrogram images and corresponding danger labels, the classifier learns to map these spectrograms to specific danger labels.

Our prosodic regularized variational auto-encoder model is trained with emotionally expressive speech audio. We have innovatively incorporated adjustments between speech and ambient noise sounds, introducing a novel approach. Notably, phonetic and prosodic adjustments have never been applied to this kind of input data within an adapted auto-encoder. Implementing our model under these conditions enables us to capture danger data more realistically, emphasizing the value of a generative model in extending real speech with authentic sounds often present in genuine danger environments.

Regarding ambient noises, we utilized a total of 40 audio clips. Ten audio clips were dedicated to glass breaking and gunfire, randomly interspersed with angry, fearful, and sad emotional audio clips. Similarly, there were ten audio clips, for cooking or eating noises and indoor movements (such as household steps), randomly distributed with happy, calm, and neutral emotional audio clips. The glass-breaking sounds varied, encompassing scenarios like breaking a window, objects falling and glass being thrown until breaking, as well as handling glasses, considering the potential harm to third parties in the room or the individual handling them. The gunfire sounds included various types of guns such as standard guns, pistols, and rifles. Additionally, we included gunfire from a distance sufficient to be heard from a room in a house.

For each emotion, we collected four neutral audio clips and eight audio clips from each of the other five emotions, per actor. Our dataset comprises a total of 24 actors, ensuring gender balance. In summary, from each actor, we utilized 40 audio clips, resulting in a total of 1056 audio clips used for training and testing. In our study, we assumed our data was initially separated, and we organized it placing speech at the beginning followed by danger noises, creating 1-second audio segments. While it is ideal for the data to be pre-separated, we consider this task accomplished within our work.

In our speech processing experiments, we utilized two categories of training data: acted speech and real daily conversation speech nuances. Acted speech, found in audiobooks, involves actors simulating emotions. In contrast, daily conversation speech nuances captures natural expressions from sources like YouTube talk-shows, street conversations, and shop dialogues. Both types of data were included in our study, restricted to indoor nuances and speech. Acted speech for testing purposes was sourced from the RAVDESS database [35], while daily conversation nuances data was collected from diverse real-world environment downloaded from Freesound public open datasets.

Our combined dataset merged the RAVDESS database, consisting of facial and vocal expressions in North American English from 24 gender-balanced actors, with custom data containing emotion- and ambient noise in present in the environment. The dataset we compiled included 1056 audio clips used for training and testing, recorded at 44.1kHz, from 12 actors, covering 6 selected emotions out of 8 available

emotions. Each emotion was associated with specific patterns, enhancing authenticity. Sentences from the database, such as "Kids are talking by the door" and "Dogs are sitting by the door," were utilized. The training and testing data were divided into 80 percent and 20 percent, respectively.

To maintain dataset consistency, we linked emotions to the primary dataset. For instance, selecting a "happy" emotion from a male actor involved aligning emotional level sentences with non dangerous ambient nuances, leveraging the similar vocal characteristics in emotional patterns. Ambient noises were randomly chosen while ensuring alignment in events that tend to occur at the same time, or follows to one another, such as angry, sad or scared speakers followed by a glass broken or a gunfire. In the initial tests, 40 audio clips were matched with each corresponding RAVDESS audio danger pair randomly. Importantly, generative models were minimally affected by these variations since they were incorporated during the preprocessing steps.

Both the dangerous environment classifier and the proposed VAE model utilized convolutional layers on pre-processed Mel spectrogram data. The input size for the proposed VAE was 128 by 128 (resized) for both training and testing sets. The proposed VAE's encoder and decoder consisted of two hidden layers, reducing data dimensions from 128 to 64 and then to 32 in the encoder, and restoring it from 32 to 64 and finally to 128 in the decoder. The proposed VAE featured a single output for encoding and reconstructing data. The emotional classifier received 32-sized data from the proposed VAE encoder and included an output layer with a Softmax activation function corresponding to the six mentioned emotion classes reduced to danger and non-danger opposite classes.

B. Experimental Results

In contrast to traditional methods, our model excels by achieving remarkable results with a limited dataset while capturing intricate patterns present in genuine dangerous environments. Unlike conventional speech models that require extensive datasets for comprehensive testing, our model displays flexibility by leveraging robust, limited nuance patterns present while in the presence of danger. This adaptability ensures precise classification without distorting speaker characteristics or imposing specific positional attributes. Generative models, including our proposed model, comprehend data distributions, enabling classification without excessive reliance on additional patterns.

Nevertheless, our model encounters challenges in generalizing learned sentences across diverse data. However, it excels in recognizing similar sentences and/or noises that share common patterns.

The integration of the phonetic-prosodic regularized VAE model with speech, ambient noises, and the dangerous environment classifier results in enhanced classification accuracy compared to the vanilla VAE with our classifier. Notably, the incorporation of well-defined ambient noises such as gunfire and glass broken like, improves the classification with sad and neutral speech by reducing false positives and negatives in the classification. The proposed VAE adeptly reconstructs patterns collaborating with the classifier, automatically regenerating the input data. The classifier benefit from the latent space features of danger, impacting positively in the classification accuracy.

Our model achieves a test accuracy of 0.924 with extended data, surpassing the vanilla VAE accuracy value of 0.909, and outperforming the standard CNN-based model with 0.742. Furthermore, it delivers superior results in fewer epochs, underscoring its efficiency in accurate emotion classification. However, when compared with the RavdessDB dataset, our model with vanilla VAE with the additional classifier achieves a validation accuracy of 0.575, whereas the proposed VAE with additional classifier achieves 0.56. There are some ambient noises such as the open and close of a windows and the metallic stairs steps that could be confused and further misclassified by AI models, due to their similarity content in other danger noises such as glass broken and long distance gunfire. For human earrings could be perfectly estimated, however for AI models, there is much work to perform and great deals to enhance.

In summary, the adaptability, efficient learning, and enhanced accuracy in environmental hazardous classification make our model a promising advancement in this field.

The training loss/accuracy and the validation loss/accuracy of the vanilla VAE model, can be observed in Fig. 2. At the beginning of the accuracy result image we can observe a jumping until getting a good accuracy of 1, which is not observed in our models for training and validation. The

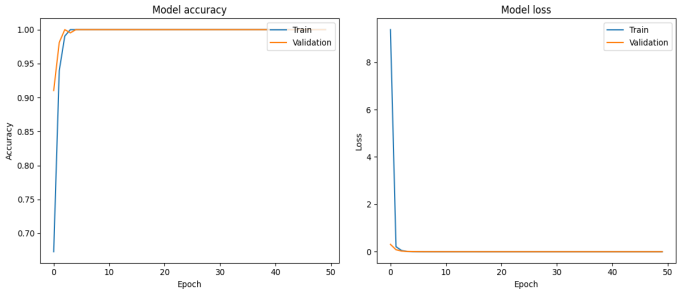

Fig. 2. Training / validation loss and accuracy over epochs of vanilla VAE model.

confusion matrices for the training and validation of the vanilla VAE model and the proposed phonetic-prosodic regularized VAE model with our danger classifier are depicted in Fig. 3 and 4, respectively. The classes "0" and "1" represent "Safe" and "Dangerous", respectively. The training confusion matrix for both models demonstrates accurate predictions for each class. The imbalance in neutral classification is due to the limited number of audios in the neutral class in the Ravdess datasets. During training 287 audios of class "0" (Safe) and 436 audios of class "1" (Danger) are correctly classified, while 97 audios of class "0" and 24 audios of class "1" are misclassifications. For validation, 83 audios of class "0" and 110 audios of class "1" are correctly classified, while 13 audios of class "0" and 6 audios of class "1" are misclassifications. The training loss/accuracy and the validation loss/accuracy of the phonetic-prosodic regularized VAE model with speech and ambient noises, can be observed in Fig. 5.

The confusion matrix for training and validation of the proposed phonetic-prosodic regularized VAE model with speech

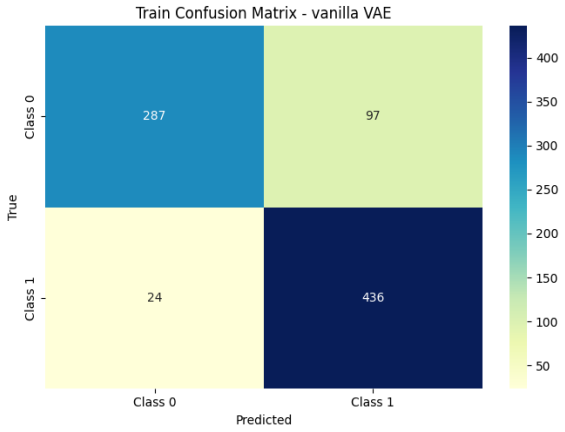

Fig. 3. Confusion matrix for training the vanilla VAE model.

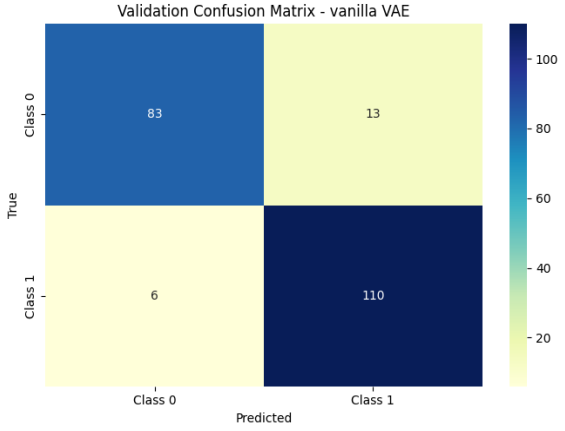

Fig. 4. Confusion matrix for validation of the vanilla VAE model.

and ambient noises, can be observed in Fig. 6 and 7. Phonetic-prosodic regularized VAE model with speech and ambient noises shows better predictions for danger class as "0" and non-danger class as "1". During training 384 audios of class "0" (Safe) and 460 audios of class "1" (Danger) are correctly classified. For validation, 96 audios of class "0" and 116 audios of class "1" are correctly classified, while there are no misclassifications.

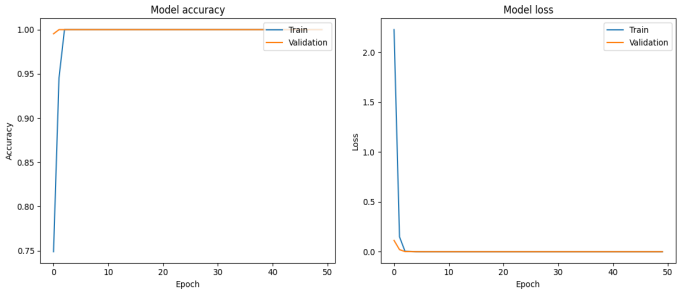

Fig. 5. Training / validation loss and accuracy over epochs of phonetic-prosodic regularized VAE model with speech and ambient noises.

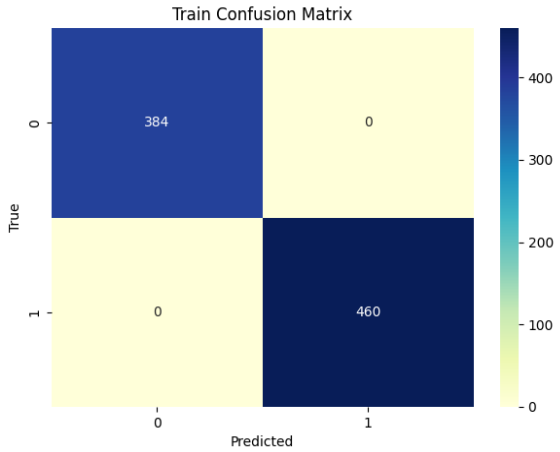

Fig. 6. Confusion matrix for training the phonetic and prosody regularized VAE model with speech and ambient noises.

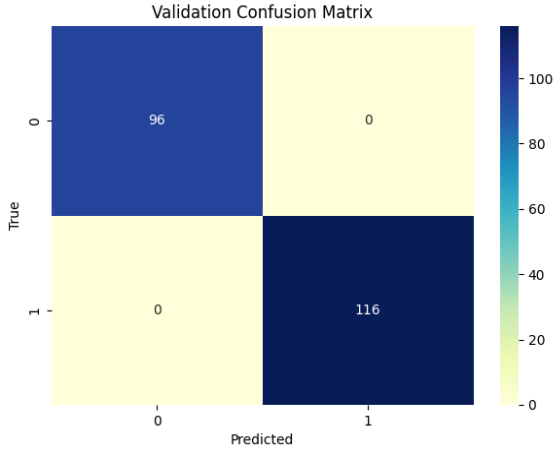

Fig. 7. Confusion matrix for validation of the phonetic and prosody regularized VAE model with speech and ambient noises.

IV. Conclusion

Our proposed model demonstrates notable success in accurate emotion classification, achieving a test accuracy of 0.924 with extended data—an improvement over the vanilla VAE accuracy of 0.909 and the standard CNN-based model's 0.742. The efficiency of our model is further underscored by its ability to deliver superior results in fewer epochs. However, when confronted with the RavdessDB dataset, our model's performance, measured by validation accuracy, shows nuances.

The vanilla VAE with an additional classifier achieves 0.575, while the proposed VAE with an additional classifier achieves 0.56. It is important to note that challenges persist, particularly in discerning ambient noises like the opening and closing of windows and metallic stair steps, which may be prone to confusion and misclassification due to their similarity with other potentially dangerous sounds. The complexity of such audio distinctions poses a challenge for AI models, necessitating ongoing efforts for improvement.

In summary, our study introduces a method leveraging generative models, specifically a variational autoencoder, for identifying hazardous environments through the analysis of emotional speech and ambient noises.

Our model, integrating phonetic and prosody features, addresses disparities between input and expected data. As part of our future research, we aim to explore areas such as background noise analysis, the separation of speech and ambient sounds, and the potential extension of our work to real-time danger processing and analysis.

***Abstract*—Remote sensing-based object detection faces challenges in arbitrary orientations, complex backgrounds, dense distributions, and large aspect ratios. Considering these issues, this paper introduces a novel method called D2-Net, which incorporates a transformer structure into a convolutional neural network. First, a new feature extraction module called dilated contextual transformer block is designed to minimize the loss of object information due to complex backgrounds and dense targets. In addition, an efficient approach using depth-wise separable deconvolution as an up-sampling method is developed to recover lost feature information effectively. Finally, the circular smooth label is incorporated to compute the angular loss to complete the rotated detection of remote sensing images. Experimental evaluations are conducted on the DOTA and HRSC2016 datasets. On the DOTA dataset, the proposed method achieves 79.2% and 78.00% accuracy in horizontal and rotated object detection, respectively; it achieves 94.00% accuracy in the rotated detection of the HRSC2016 dataset. The proposed model shows a significant performance improvement over other comparative models on the dataset, which verifies the effectiveness of our proposed approach.**

***Keywords*—YOLOv7; dilated contextual transformer; depth-wise separable deconvolution; circular smooth label; remote sensing**

I. Introduction

Due to advances in computer processing power, object detection has developed rapidly over the past decade. This task typically accomplishes by utilizing single-stage detectors, typified by the YOLOs models [1], [2], [3], [4], [5], and dual-stage models exemplified by the RCNN series [6], [7], [8], [9].

Despite significant advances in generic target detection, the mission in remote sensing images (RSIs) faces numerous challenges due to characteristics such as substantial variations in scale, crowded and small targets, arbitrary orientations, and large aspect ratios[10]. Therefore, detection using oriented bounding boxes (OBBs), which can handle object rotation, has become critical in remote sensing applications. Existing rotated object detection models are often constructed with pure convolutional neural networks (CNNs) or CNN-transformer hybrid structures. And the former has a lot of representative work. Pixels-IoU Loss improves performance for complex backgrounds and large aspect ratios[11] but increases training time. Rotational region convolutional neural network (R2CNN) introduces joint prediction of axis-aligned bounding boxes and inclined minimum area boxes to complete text recognition in any direction[12]. A joint image cascade (ICN) and feature pyramid network (FPN) can capture semantic features at multiple scales [13]. Adaptive period embedding (APE) proposed by Zhu et al. represented oriented targets in a novel way and length-independent IoU (LIIoU) suitable for long targets [14]. Kim B et al. developed TricubeNet, which locates oriented targets according to visual cues such as heat maps rather than oriented box offset regression [15].

Although CNNs have achieved impressive performance, they are limited by the difficulty of obtaining long-range dependencies, resulting in deficient performance in remote sensing detection. In contrast, the unique structure of the transformer allows it to compensate well for the shortcomings of CNN. Many hybrid CNN-transformer networks have achieved satisfactory results [16], [17], [18], [19], [20]. The RoI transformer technique utilizes spatial transformations on Regions of Interest (RoIs) and learns the spatial transformation parameters by using OBB annotations as supervision. This approach results in fewer mismatches during detection [16]. To address the boundary loss and spatial receptive field issues in RSIs, Dai et al. developed a rotating object detection transformer-based model (RODFormer) [17]. Another improved detector, CLT-Det, leverages correlation learning and a transformer to tackle the problem of large-scale variation and dense targets [18]. TransConvNet uses a self-attention block and CNN to aggregate broad and specific details, offsetting the CNN's lack of rotational invariance [19]. Li et al. propose an adaptive points learning method that effectively obtains geometric information for instances of arbitrary orientations [20].

The above information suggests that incorporating a transformer module into CNN can help overcome the model's difficulty in global feature modeling. And recent researches show that simple hybrid networks can acquire the same effect as many excellent complex models [21]. Therefore, this paper presents the dilated contextual transformer block (DCoT) combined with efficient layer aggregation networks (ELAN) in YOLOv7[5] to improve the model's feature extraction capability. DCoT extraction provides more feature information with a larger receptive field, allowing shallow location information to combine effectively with deep semantic information, which improves detection ability in complex backgrounds and dense objects. Second, a depth-wise separable deconvolution (DS-DeConv) module is proposed to enable the model to generate more diverse feature information during upsampling,

thereby improving its ability to detect small and dense objects. Finally, the Circular Smooth Label (CSL)[22] is integrated into the baseline YOLOv7[5] to complete the rotation detection process without being affected by boundary discontinuities. Extensive experiments were conducted on DOTA v1.0[10] and HRSC2016[23] datasets to validate the efficacy of the proposed method. The experimental results demonstrate that the proposed model enhances the detection capacity of RSIs. Moreover, it achieves real-time detection with a slight reduction in the number of parameters, striking a balance between accuracy and speed.

The main contributions of this paper can be summarized as follows. First, we use DCoT to improve the model's ability to obtain contextual information, which enhances the model's ability to detect complex backgrounds and dense targets in RSIs. Second, we use DS-DeConv for upsampling, which effectively preserves detailed feature information, enhancing the model's detecting ability of small objects. Finally, CSL is integrated into YOLOv7 to complete the rotated detection of multi-directional objects in RSIs. The proposed model outperforms other comparative models in detection.

The upcoming sections are structured as follows. Section 2 the related work, including pure CNN and CNN-transformer hybrid detection models. Section 3 provides a detailed description of the proposed methods integrated into the D2-Net. Section 4 is the experimental details and analyses of the experimental results. Finally, the conclusion is presented in Section 5.

II. Related Work

A. Pure CNN Detection Models

Depending on whether models generate region proposals, detection models consist of two types: single-stage detection methods and two-stage detection algorithms.

The single-stage detection methods directly predict object class and location without region proposal, resulting in faster inference and lower computational complexity than two-stage models. Redmon J et al. proposed the first generation of YOLO [1], which starts with real-time object detection time. This model views target recognition as a regression task and detects the presence of an object by determining whether the object's center point falls within a particular grid cell, which is obtained by dividing the image into multiple grid cells. Inevitably, it cannot solve problems of dense, small, and large aspect ratio targets and other issues that inspire other researchers to make further progress. To improve the accuracy of small target detection, SSD [24] feeds multiple features extracted from different layers of the feature extraction model to the object prediction module. It also simplifies the training process for targets with different shapes by assigning different scales and aspect ratios to the prior bounding boxes associated with each grid cell. The method used convolutional layers instead of fully connected layers and produced the same results as contemporaneous two-stage detection models. More recently, an enhanced SSD [25] introduces interactive multiscale attention to acquiring more effective feature representation capability. Retinanet [26] incorporates focal loss and effectively addresses the class imbalance problem, resulting in high speed and accuracy performance.

Two-stage detectors also gained significant attention due to their remarkable accuracy and robustness. RCNN[6] treats the detection task as a classification problem. In the first stage, it extracts region proposals from each image, then predicts targets' categories after computing features in CNN. FPN [27] regards layers with consistent feature map sizes as a stage and achieves the top-down integration of multi-scale feature maps through successive stages. It distributes features based on object scale, merging deep-level semantic information with shallow-level fine-grained information to perform more accurately. Mask R-CNN [9] innovates RoI alignment to mitigate date missed owing to feature quantization during the RoI pooling process.

B. Transformer Detection Models

Since transformers were introduced to computer vision, many distinctive models emerged. Vision transformers divide the image into multiple patches, provide them with positional embedding, and then feed the feature information into the head for detection.[28] This allows the model to be independent of image size. DINO improves DETR-like models in terms of performance and efficiency by using a comparative denoising training method, a hybrid query selection method for anchor initialization, and a look-forward double scheme for box prediction.[29] Biformer proposes a novel dynamic sparse attention via bi-level routing for more flexible computational allocation and content awareness, enabling dynamic query-aware sparsity.[30]

C. CNN-Transformer Hybrid Detection Models

The emergence of the Transformer structure compensates for the shortcomings of the pure CNN structure in obtaining long-range dependencies and contextual information, leading to numerous Transformer-related models. However, the pure transformer models have high memory consumption and complexity. So more models fuse the transformer module with CNN by insertion or replacement to achieve a balance. RoI transformer [16] conducts spatial transformations on RoIs, learning transformation parameters supervised by OBB annotations, which solves dense RSI targets and RoI-target mismatches. RODFormer [17] addresses boundary loss and spatial receptive field lack in RSI detection via a structured transformer model. CLT-Det [18] presents a correlation learning detector for solving the problem of large-scale variation and dense targets. TransConvNet [19] merges a self-attention block and CNN, aggregating the detailed and specific information to compensate for the CNN's deficiency in rotational invariance. Li et al. proposed a robust adaptive points learning methodology to extract the geometric information of instances of arbitrary orientations [20].

To summarize, the combination of transformer and CNN can effectively overcome the limitation of CNN structures in capturing features at varying scales and improve the accuracy and robustness of object detection.

III. Methods

In the following parts of this section, we begin with a short introduction to the overall architecture of the proposed D2-Net, taking YOLOv7 [5] as the baseline model. Next, we present

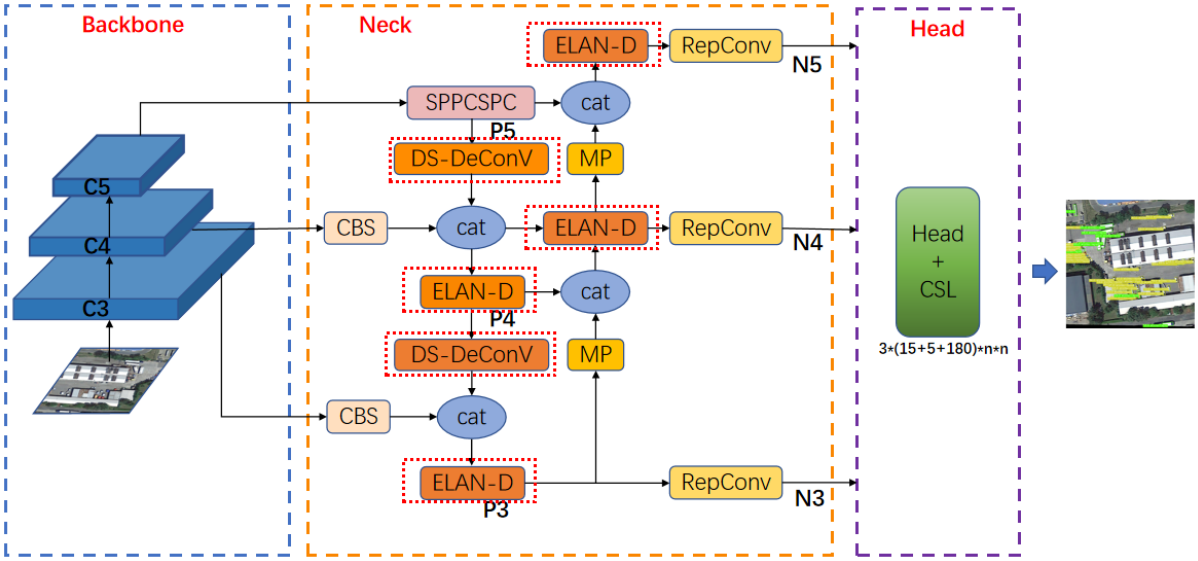

Fig. 1. The overall structure of our network. The SPPCPSC,MP, RepConv are modules of the original YOLOv7. And the detailed composition of each block in Fig. 1 is illustrated in Fig. 2 and Fig. 3.

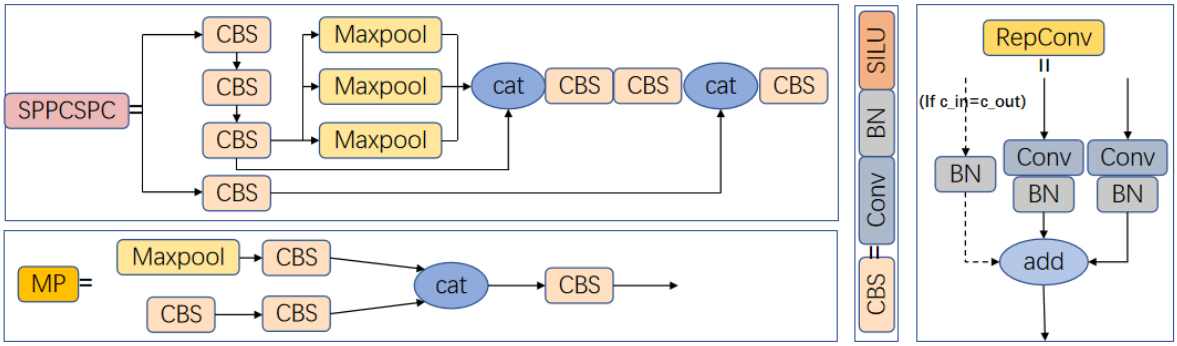

Fig. 2. Detailed block consistency of the neck network. The ELAN-D module is depicted in Fig. 4.

a detailed description of the DCoT block and the depth-wise separable deconvolution. Finally, we briefly discuss the CSL [22], which is integrated into our model to accomplish the task of rotation detection. Fig. 1 and Fig. 2 show the overall structure and detailed block consistency, respectively.

A. The D2-Net Structure

As depicted in Fig. 1, the backbone network extracts feature maps c_i, which are then sent to the neck network, where $i = 3, 4, 5$ represents the level of features, and C_i has a stride of 2^i and is $1/2^i$ pixel density of the input image size $W \times H$. The neck network consists of two modules. The initial component is the FPN [25] architecture, which propagates semantic features from higher to lower resolutions. The second module utilizes the PAFPN [31] module. To compensate for the loss of fine-grained information caused by resolution reduction, an ascending feature merging is employed to transfer location details to feature maps at deeper layers. Furthermore, depth-wise separable deconvolution makes the most suitable up-sample method by itself, and the improved ELAN module is adopted to improve the reception capability of contextual information of the network. Different scales feature maps containing detailed semantic and rich localization information are output to the RepConv block. Finally, the head network with CSL predicts object categories and position information regarding the angular problem as classification.

In our method, after being processed by the improved neck network, the output feature representations with various resolutions achieve a balance between semantic information in deep and shallow spatial details, leading to improve detection performance.

B. Contextual Transformer Block with Dilated Convolution

Drawing inspiration from the self-attention mechanism in Transformer models, numerous scholars have investigated the effectiveness of hybrid networks mixed by CNNs and transformers in computer vision task scenarios [16], [17], [18], [19]. And as existing researches prove, through the simple fusion of CNNs and transformers, object detection models pay more attention to more useful features so that the performances of those models are improved. Therefore, the hybrid network,

including the transformer module, has a good prospect in the RSIs detection task.

The traditional self-attention modules utilize input feature information obtained from various spatial positions to process input data. Nevertheless, these modules acquire knowledge of all possible query-key connections by training on individual query-key pairs. This process occurs independently, without considering the contextual information between their interactions. The CoT [32] architecture can integrate abundant contextual information and Contribute significantly to the visual representation of 2D images. Nevertheless, the standard convolution operation will lose much localization information in feature processing. Therefore, we replace it with dilated convolution to form DCoT, which effectively makes the network increase the receptive field while obtaining more information. Then we displace the last three CBS modules of ELAN with DCoT to form ELAN-D (see Fig. 4), which reduces the calculation amount and FLOPs. By combining the strengths of the Transformer and CNN, the DCoT module can capture both global and detailed local information from input features. This approach improves the network model's ability to represent input information features, leveraging the advantages of each component. It showed the architecture of the DCoT block in Fig. 3.

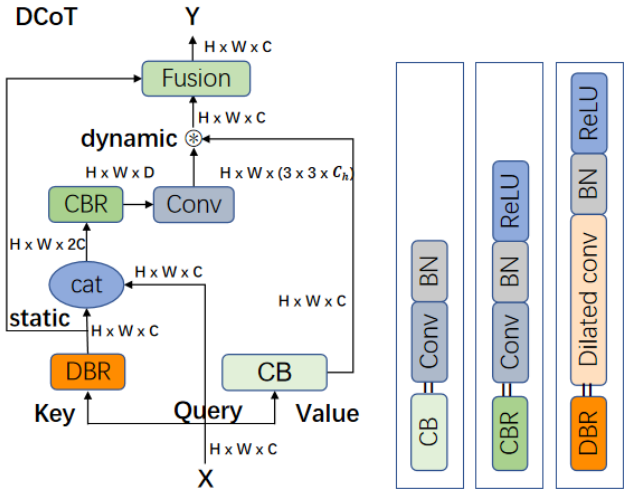

Fig. 3. The detailed structure of the DCoT block and its module. H, W, and C denote the height, width, and number of channels of the input data X, $\circledast$ denotes local matrix multiplication.

For input feature X, it is processed through three pathways, namely Q(queries), K(keys), and V(values), to generate more feature information. The keys undergo dilated convolution to capture local information and increase the receptive field. Then, K is concatenated with X to supplement local information and passed through a CBR module and a standard convolution to generate Q. Finally, Q is multiplied with V and fused with K to obtain the final output Y. The Q, K, and V can be written as:

$$Q = [K, X]W_{CBR}W_C \tag{1}$$

$$K = XW_{DBR} \tag{2}$$

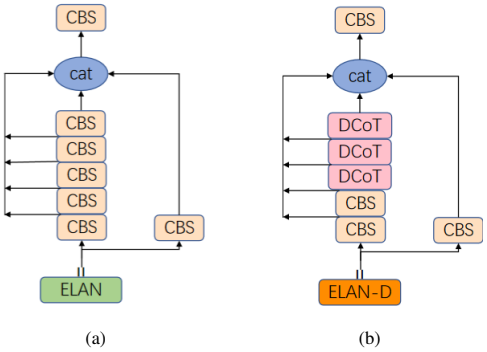

Fig. 4. The architectures of the ELAN block and ELAN-D block. (a) shows the detailed ELAN structure, and (b) shows the detailed ELAN-D block.

$$V = XW_{CB} \tag{3}$$

where X is the input feature, $W_{\square}$ are different convolutional blocks.

C. Depth-wise Separable Deconvolution for Up-sampling

During object detection with deep learning, the resolution of the feature map tends to decrease as the network deepens, leading to a loss of information. Thus, up-sampling is essential for an algorithm. In the YOLO algorithms, nearest neighbor interpolation is employed for up-sampling. However, focusing solely on the nearest pixels has also resulted in image quality and details loss, especially for tiny targets. Deconvolution is also a commonly used up-sampling method. Compared with neighbor interpolation, it performs better than in preserving feature information. However, it produces more parameters as well. Deep separable convolution [33] disassembles traditional convolution into depth convolution and point convolution, which can make the model more efficient and parameter reduction.

In this paper, we propose the DS-DeConv block for up-sampling. With this method, more diverse pixel values can be produced when recovering the feature map's resolution, which makes the Acquired feature map preserve more details and features of the original feature map.

We also introduce group convolution and change the filter size of deconvolution to decrease the parameter quantity caused by deconvolution. Our DS-DeConv method improves network model accuracy in up-sampling with a slight increase in parameters. Fig. 5 illustrates the principal diagram of DS-DeConv, while the number of deconvolution groups is adjusted based on the channel quantities in the network.

D. Rotationally Detection

Currently, bounding boxes in object detection consist of HBBs, rotated bounding boxes, and custom bounding boxes. The characteristics of remote sensing detection include the random and diverse directions of the objects to be detected. And to achieve more accurate detection of these rotating objects, the rotating bounding box is used for it.

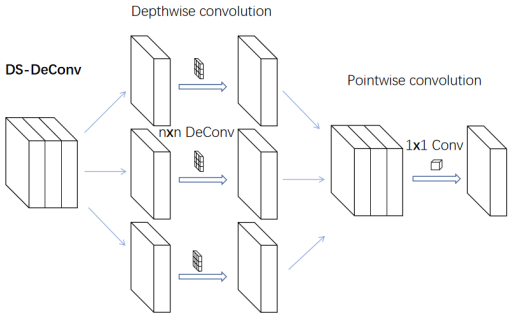

Fig. 5. The structure of depth-wise separable deconvolution.

The rotated detection method based on parametric regression mainly consists of the five parameters and the eight-parameter method. However, in rotation detection, the target parameters for learning are periodic, which causes the learned parameters to be located at the boundary periodicity, resulting in discontinuity issues and an abrupt rise of loss. Therefore, we use CSL [22] to solve the boundary discontinuity problem, as depicted in Fig. 6.

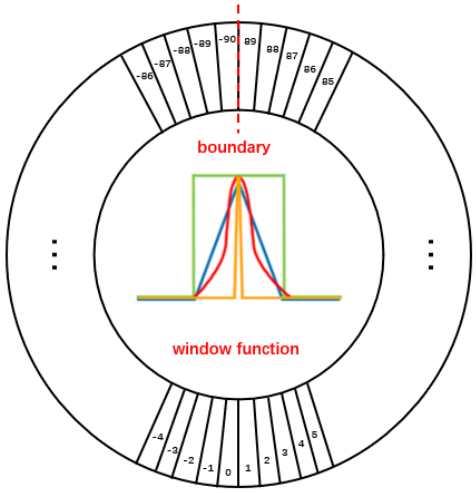

Fig. 6. The schematic diagram of the CSL.

The CSL is expressed as follows:

$$\mathrm{CSL}_{(x)} = \begin{cases} g(x), & \theta - r < x < \theta + r \\ 0, & \text{otherwise} \end{cases} \tag{4}$$

where $g(x)$, r, and θ represents the window function, radius, and the current bounding box angle, respectively. By converting angle prediction from a regression task to a classification task, the boundary discontinuity issue can be effectively resolved with minimal loss of accuracy.

IV. Experiments and Results Analysis

A. Datasets

1) DOTA Dataset: The DOTA dataset [10] contains 2806 high-resolution aerial images collected from various sensors and platforms and encompasses 15 categories. It is split into three subsets for training, validation, and testing, including 1411 images, 458 images, and 937 images, respectively, containing 188282 instances in total. The image size varies from 800×800 to 4000×4000 pixels.

2) HRSC2016 Dataset: The HRSC2016 dataset[23] includes 1061 remote sensing images from six distinct ports. The dataset is divided into three parts, 436 images for training (a total of 1207 labeled examples), 444 images for testing (a total of 1228 labeled examples), and 181 images for validation (a total of 541 labeled examples). The images have varying resolution, ranging from 300 × 300 to 1500 × 900 pixels.

B. Implementation Details and Evaluation Index

Considering the adverse influence of high and inconsistent resolution images, we reprocess the original data of these two datasets. For the DOTA dataset, we cropped the images to 1024×1024 resolution with 200 pixels overlapping area. Then 15749 images were extracted for training and 5297 images for evaluation, and the final test results are obtained through the official evaluation server. The network is trained with the SGD optimizer in the training process. The lr (learning rate) is 0.001, and momentum and weight decay are 0.937 and 0.0005. We train 300 epochs with batch size 16 on two GeForce RTX 3090 GPUs. For the HRSC2016 dataset, we resized all the images to (768, 768). The network is trained with the SGD optimizer for training. The learning rate is 0.01, and momentum and weight decay are 0.937 and 0.0005. We train 200 epochs with batch size 8 on GeForce RTX 3060 GPU.

We adopt the Average Precision (AP) and the mean AP (mAP @0.5) metric in the comparative experiments to evaluate the multi-class detection accuracy. They can be calculated as follows:

$$\mathrm{P} = \frac{TP}{TP + FP} \tag{5}$$

$$\mathrm{AP} = \int_0^1 Pd_r \tag{6}$$

$$\mathrm{mAP} = \frac{\sum_{i=1}^{C} AP_i}{C} \tag{7}$$

TP is the correctly classified target number, while FP is the background number recognized as target. The accuracy rate P can be defined as the proportion of correctly detected targets among all detection results. The mAP is the average of AP values of all classes. In the ablation experiments, FLOPs and speed are also used to estimate the differences in algorithm capability. Speed is also used to estimate the differences in algorithm capability.

C. Ablation Experiments

In this section, we choose YOLOv7 as the baseline model to conduct ablation experiments on the DOTA dataset to verify the effectiveness of the introduced DCoT block, DS-DeConv, and CSL. It should be noted that this paper aims to address the problem of rotated RSI detection, so unnecessary ablation experiments on horizontal detection are not shown. The batch

(a)

(b)

Fig. 7. Some contrastive detection results. (a) is the result of the baseline; (b) is the result of the D2-Net. And the differences are highlighted in red.

size for training was 16, and the performance metrics were evaluated every 10 epochs during the training process. A total of 300 iterations were completed to train both the baseline and improved models. FLOPs, speed, and mAP are used as evaluation indicators in the experiments. Table I shows the results of our improvements and Table II shows detailed AP values of each category conducted on the DOTA dataset. And the bold font is the best result.

As seen from Table I speed and mAP of the OBB task are commonly lower than those in the HBB task, which is attributed to the angle issue when serving the rotated detection task. Attentively, to ensure the effectiveness of the baseline, its experiments were all performed at $640 * 640$ resolution, while other experiments were conducted at $1024 * 1024$ resolution. And the baseline speed is 40.98 at $1024 * 1024$ resolution. Despite the speed and mAP having decreased, the effect has been improved in the actual detection(see Fig. 7). In the horizontal task, compared with the original YOLOv7, ②③④⑤ showed improvement of 1.9%, 3.4%, 2.7% and 5.5%. Relative to the YOLOv7 with CSL added, ③④⑤ achieved 0.41%, 1.05% and 3.25% improvement. According to Table II, it can be found that the proposed method has greatly improved in the categories of small vehicles, harbors, and ships, obtaining 16.2%, 35.9%, and 8% improvement, respectively, compared with the baseline model.

In Fig. 7, three images are chosen for comparing the detection results from the dataset. The results of the two rows are the baseline model, and the D2-Net model proposed in this paper, respectively. There are plenty of small and dense objects in the leftmost images of Fig. 7(a) and Fig. 7(b). It can be seen from the red highlights that the baseline model loses some targets, while the proposed model detects them very effectively. The background of the middle image is similar to the object, and the baseline's results are affected, while the proposed model works well. The right image contains many targets with large aspect ratios, and the D2-Net is more accurate than the baseline when boxing targets and no targets are lost.

In Fig. 8(a) and Fig. 8(b), to prove the feature extraction capability of the DcoT modules, we made the first 32 feature maps visualization in the same stage of both baseline and the D2-Net. It can be observed that the proposed model can effectively eliminate irrelevant information from the background and has good extraction capability for detecting targets. It is the DCoT modules that enable the network to fully utilize feature information and concentrate on detecting targets with distinguishable features. Fig. 9(a) and Fig. 9(b) show the first upsampling heatmaps of the baseline and D2-Net. The latter preserves more useful feature information around objects and eliminates unnecessary noise. It proves the DS-DeConv's effectiveness when detecting small targets.

D. Comparison with other OBB Methods

In this section, we choose the YOLOv7 as the baseline. We compare our model performance with other state-of-the-art methods for the DOTA-v1.0 and HRSC2016 datasets. In compared models, RoI Trans [16], RODFormer [17], and CLT-Det [18] adopted a hybrid network using CNNs and transformer blocks, and the others applied pure CNNs structure.

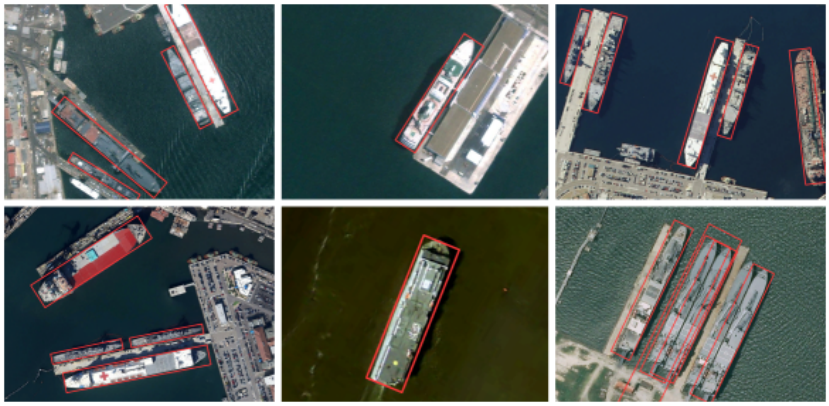

Fig. 11. The visualization of the detection results of our method on the HRSC2016 dataset.

1) Results on DOTA-v1.0: As reported in Table III, The comparative experiments on the DOTA dataset consist of the OBB and HBB tasks. In the OBB task, we achieved the mAP of 77.96%, which gains 1.79% higher than the CSL with CNNs structure, and 0.51% higher than CLT-Det with a hybrid framework. Moreover, the prediction performance on densely distributed small objects, like storage tanks and small vehicles, has improved enormously, reaching 89.71% and 81.71%, which are 3.02% and 2.05% higher than the second best, respectively. Besides, soccer ball fields, large vehicles, and helicopters also perform well, reaching 76.62%, 87.4%, and 82.87%, respectively. In the HBB task, the proposed model is 5.5% (from 73.70 to 79.20%) higher than the baseline. The top-3 mAP is plane, tennis court, and ship, achieving 98.3%, 98.1%, and 97.5%, respectively. In general, the above statement demonstrates the effectiveness of our model, and Fig. 10 visualizes some detection results of our method on the DOTA dataset.

2) Results on HRSC2016: The HRSC2016 dataset consists of plenty of oriented ships. As shown in Table IV, many classical detection algorithms have attained excellent performance in this dataset, such as R2CNN [12], RoI Trans [16], CLT-Det [18], CSL [22], Axis Learning [35], and Oriented R-CNN [41]. Our model uses the A block for enhancing feature extraction and depth-wise separable deconvolution for upsampling. It achieves an mAP value of 94.00% with the 768 × 768 resolution, outdoing several of the mentioned methods. And the visualization of some detection results is depicted in Fig. 11.

TABLE IV. PERFORMANCE COMPARISONS ON THE HRSC2016 OBB TASK. THE BEST RESULT IS HIGHLIGHTED IN BOLD

Methods	mAP	Resolution
R2CNN[12]	73.07	800×800
Axis Learning[35]	78.15	800×800
RoI Trans[16]	86.20	512×800
SLA[42]	89.51	768×768
CLT-Det[18]	89.72	512×800
CSL[35]	89.62	800×800
Oriented R-CNN[41]	90.50	1333×800
Attention-Points[43]	90.59	1333×800
Ours	94.00	768×768

V. CONCLUSIONS

In this paper, we proposed an effective one-stage model called D2-Net for rotated remote sensing image detection based on the YOLOv7 model. we innovate the DCoT block combining dilated convolution with contextual transformer block for feature extraction and enhancing the ability to detect

Objects with tiny sizes and dense distribution of RSIs, which can fully utilize the global and local information of objects and enlarge the receptive field. Then, We designed the DS-DeConv for up-sampling, which mitigates the effects of complex backgrounds and low resolution. It improves the resolution and quality of the up-sampled feature maps, enabling the detector to capture the details and shapes of the targets more effectively. Additionally, the CSL is employed for determining the angle loss and accomplishing the prediction of rotated objects in RSIs. In the end, we conducted experiments on the DOTA and HRSC2016 datasets to prove the effectiveness of D2-Net. Although detection capability surpasses other commonly employed algorithms, the speed and FLOPs has decreased. Thus, we will further enhance the feature representation and improve the model's detection speed with a more lightweight model.

***Abstract*—In recent times, Retrieval Augmented Generation (RAG) models have garnered considerable attention, primarily due to the impressive capabilities exhibited by Large Language Models (LLMs). Nevertheless, the Arabic language, despite its significance and widespread use, has received relatively less research emphasis in this field. A critical element within RAG systems is the Information Retrieval component, and at its core lies the vector embedding process commonly referred to as "semantic embedding". This study encompasses an array of multilingual semantic embedding models, intending to enhance the model's ability to comprehend and generate Arabic text effectively. We conducted an extensive evaluation of the performance of ten cutting-edge Multilingual Semantic embedding models, employing a publicly available ARCD dataset as a benchmark and assessing their performance using the average Recall@k metric. The results showed that the Microsoft E5 sentence embedding model outperformed all other models on the ARCD dataset, with Recall@10 exceeding 90%**

***Keywords*—Arabic NLP; large language models; retrieval augmented generation; semantic embedding**

I. Introduction

Retrieval Augmented Generation (RAG), introduced by Facebook Researchers in 2020 [1], is a pivotal AI framework facilitating information retrieval for Generative AI models, thereby enhancing their accuracy and capabilities. RAG empowers Large Language Models (LLMs) by granting them access to external knowledge sources, augmenting the content generation process. This dual functionality entails retrieval, wherein RAG meticulously selects pertinent information from provided sources and generation, whereby LLMs craft contextually relevant responses based on user input.

The advantages of RAG are multi-fold. Firstly, it bolsters the performance by grounding LLMs with factual, up-to-date information from external knowledge repositories. Furthermore, RAG maintains contextual relevance in responses, contributing to a more engaging user experience in conversational AI applications. Its scalability is noteworthy, as RAG models seamlessly handle copious volumes of information, proving invaluable for data-intensive tasks. Additionally, the adaptability of RAG models allows fine-tuning for specific applications [2], rendering them versatile across diverse data and use cases. Customizability is another hallmark, permitting RAG models to specialize in particular domains or subjects through customization and fine-tuning on specific knowledge bases. Due to the importance of such a framework for enterprises, extensive research is currently being pursued to discover new algorithms and techniques to enhance the performance of such models bounded by the context-window limitations of LLMs. Although there is ongoing research to expand the window size for LLM to be able to ingest more data in the prompt, the use of techniques like RAG is still of great practical importance, not only on homogeneous unstructured data but also on heterogeneous data [3].

In principle, at the heart of the information retrieval module is the semantic embedding module which converts a piece of text, whether a query or a context text chunk to a numeric feature vector that embodies all semantic features of the text. The development of word and sentence embeddings is a relatively recent area of research in natural language processing (NLP) and information retrieval.

Most of the semantic models are English language-centred; however, in recent years, Multilingual embedding models were released [4]. There are lots of benchmarks to test the performance of multilingual embeddings [5], which are aggregate but very few focus on language-specific performance, and on the Arabic language in particular. This is the main impetus behind the current research work, which focuses on ten different state-of-the-art embedding models that are capable of embedding Arabic language.All the models are tested using publicly available ARCD (Arabic Reading Comprehension Dataset) [6] and the metric used is average Recall@k for different values of k. A comparative performance is conducted taking into consideration the embedding size for each model.

The rest of the paper is organized as follows: Section II, the Retrieval Augmented generation pipeline is presented, as well as the positioning of the semantic embedding and the information retrieval component within the pipeline. Section III explores related research work in this field, focusing on recent developments. Section IV overviews the 10 semantic embedding models that are used in the experiments will be covered. Section V discusses the 10 embedding models on a standard dataset that are used in for Arabic Reading comprehension (ARCD) and their evaluation using Recall@k performance metric. Also, the impact of the embedding dimension size is analyzed in the comparative results. Section VI concludes the paper.

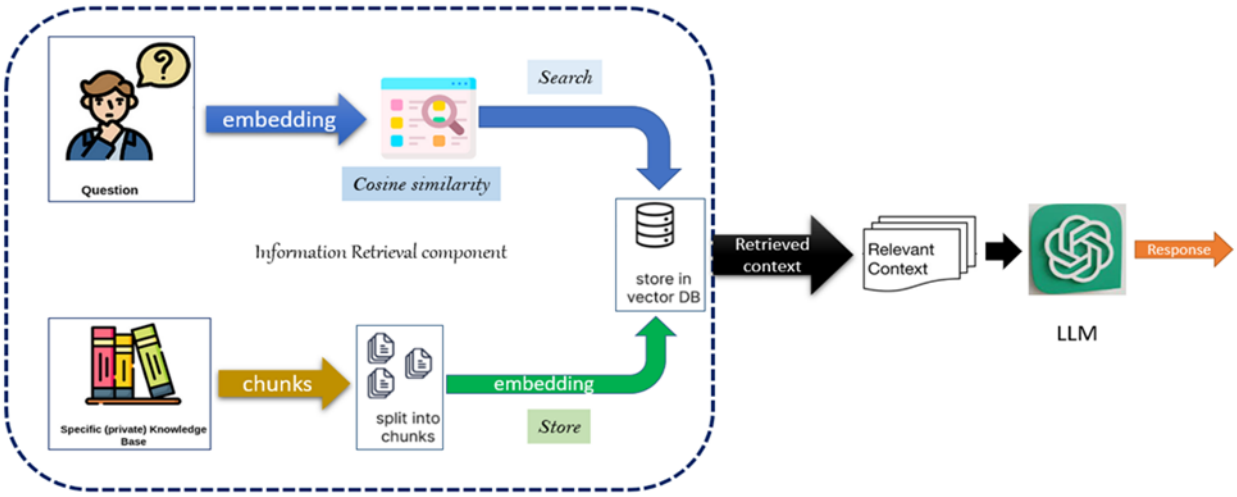

Fig. 1. Retrieval augmented generation.

II. RAG: Retrieval Augmented Generation

The Retrieval Augmented generation pipeline, shown in Fig. 1 is as follows:

A. Phase I: Information retrieval

1) Given a corpus of unstructured text containing documents
2) Given a user text query
3) A semantic embedding model is identified
4) The query is embedded into a feature vector of n dimension (semantic embedding)
5) The corpus is segmented into m text chunks (either disjoint or overlapping)
6) Each text chunk is embedded into a feature vector of n dimension using the same embedding model used in embedding the search query, as shown in Fig. 2.
7) The m- m-vectors are indexed in a Vector DB store
8) Cosine similarity, euclidean or inner product score is computed between the embedded vector of the query
9) 9. Top k relevant chunks are retrieved, which comprise a context for the next phase

B. Phase 2: LLM Comprehension and Response

In this phase, a suitable LLM is identified and selected, whether an open source model (more than 100 LLM models are currently available) , like LLaMA (7b/13b/70b), Falcon, GPT neoX, Bloom, vicuna , FlanT5 , etc.) . However, not all of them support the Arabic Language. The Current Arabic LLM models are:

- OpenAI GPT-turbo-3.5
- Open AI GPT 4.0
- Google Bard
- Microsoft Bing Chat (on top of openAIGPT3.5)
- Google PaLM2 (vertex-ai)
- Jais (UAE Arabic Language Model)

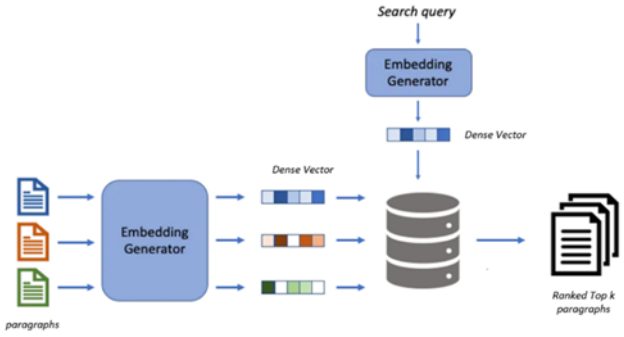

Fig. 2. Semantic embedding.

However, not all of them provide APIs for programmatic tasks, which are provided at cost like (OpenAI GPT3.5-turbo/GPT4.0 Google PalM - vertex-ai). After an Arabic LLM is identified. A prompt is constructed with two variable components: the retrieved Top k text chunks as a context and the input research query. The prompt instructs the Arabic LLM to find an answer to the search query from within the retrieved context. This architecture is widely used in Enterprises for domain-specific deployment of generative AI LLMs. A fundamental component of the overall process is the information retrieval component, as depicted in Fig. 1. The overall efficiency of the system is highly dependent on the performance of the IR component. If the IR component fails to retrieve relevant portions from the corpus, the LLM will not find the proper answer or, even worse, may hallucinate with wrong answers confidently depending on the LLM model settings (like temperature) as well as the prompt engineering. Ensuring an efficient and accurate semantic embedding is of paramount importance for an effective and practical RAG system.

III. Related Work

In the context of Arabic language processing, a lot of research was done in Natural Language Understanding, taking into consideration the different dialectical nature of Arabic

language [7], in addition to research work on Arabic text classification [8] as well as Arabic text similarity using statistical techniques [9]. However, relatively fewer research studies were conducted on semantic embeddings for Arabic text. FastText for Arabic Word Embeddings [11] proved to be an effective method for generating Arabic word embeddings. These embeddings capture subword information, making them valuable for morphologically rich languages like Arabic. Researchers have also explored Word2Vec-based approaches for Arabic word embeddings [12].

Multilingual FastText: Multilingual embeddings have gained attention for their ability to handle multiple languages simultaneously through incorporating language-specific information while sharing a common subword vocabulary across languages [4]. Researchers have also explored cross-lingual embeddings that facilitate knowledge transfer between languages. A new method is proposed that aligns word embeddings across languages, enabling multilingual applications [13].

Sentence-BERT: Sentence embeddings, which capture the semantic meaning of entire sentences, have gained popularity [10] and demonstrated superior performance in various sentence-level tasks in monolingual settings. Multilingual sentence embeddings [14] have been explored for cross-lingual applications based on training sentence embeddings for multiple languages using a shared model. The research work in [9] provided a foundational framework for evaluating critical semantic embedding APIs that play a pivotal role in search and broader information access initiatives. The author in [9] addresses the challenge of the limited accessibility of increasingly large language models by examining the utilization of semantic embedding APIs for information retrieval. Their investigation focused on assessing the capabilities of these APIs in domain generalization and multilingual retrieval using benchmark datasets like BEIR and MIRACL. The study reveals that re-ranking BM25 results using these APIs proves to be cost-effective and most effective in English contexts, offering an alternative to the conventional practice of using them as initial retrievers. For non-English retrieval, the authors suggest a hybrid model with BM25 as the most effective approach, albeit at a higher cost.

For using embeddings in downstream tasks, the authors in [17] focused on Arabic sentiment analysis, particularly on social media platforms like Twitter and Facebook, which have become vital for understanding user opinions and preferences. Sentiment analysis, however, faces challenges in natural language processing (NLP). Recent advancements in deep learning have demonstrated superior performance in NLP-related tasks compared to traditional statistical and lexical-based approaches. A comparative analysis of classic and contextualized word embeddings for sentiment analysis was conducted utilizing both trained and pre-trained versions of the four most commonly used word embedding techniques: GloVe, Word2Vec, FastText, and ARBERT. Deep learning architectures, namely, BiLSTM and CNN, are employed for sentiment classification, and experiments are conducted on benchmark datasets, including HARD, Khooli, AJGT, ArSAS, and ASTD. The results reveal that, in general, embeddings generated by one technique outperform their pre-trained counterparts, with contextualized transformer-based embedding BERT achieving the highest performance, highlighting the significance of word embeddings in Arabic sentiment analysis.

An Arabic reading comprehension dataset (ARCD) [6] addressed the challenge of open-domain Arabic question and answering (QA) with Wikipedia as the knowledge source. Mainly the scarcity of labelled QA datasets and the need for efficient Arabic machine reading comprehension and retrieval. To overcome the lack of Arabic QA datasets, they introduced the Arabic Reading Comprehension Dataset (ARCD), generated by crowd-workers from Wikipedia articles and a machine translation of the Stanford Question Answering Dataset (Arabic-SQuAD). Their open-domain QA system, SOQAL, included two components; the first is a hierarchical TF-IDF component and a neural reading comprehension component based on the pre-trained BERT transformer. Experiments on ARCD demonstrate the effectiveness of their approach, with the BERT-based reader achieving a 61.3 F1 score and SOQAL achieving a 27.6 F1 score in open-domain Arabic question answering.

In the next session, we will dive more into the semantic embedding models used in the current research.

IV. Semantic Embedding Models

Sentence and paragraph embeddings are crucial tools in information retrieval (IR), enabling systems to comprehend and retrieve text based on semantic meaning. These embeddings encode the meaning of sentences and paragraphs into fixed-size vectors [16], [18], allowing for semantic search, document retrieval, question answering, duplicate detection, clustering, summarization, recommender systems, cross-lingual search, and contextual understanding. By representing queries and documents in a continuous vector space, these embeddings enhance the accuracy of IR tasks by retrieving relevant content, even when keyword matching falls short in capturing the nuances of user intent or dealing with extensive and unstructured text collections. In the Question and Answering (QA) setting under study: Given a complete dataset of records (context-paragraphs (cps), question, ground truth answer), the IR problem is to retrieve the most relevant cps to this query. In the current work, since our focus is on the Arabic language, we explored ten embedding models that have multilingual embedding features. The query is embedded, resulting in a fixed-size feature vector, and each of the context paragraphs (cps) is also embedded. The result of embedding is a feature vector that embodies the semantic features of the text (question or context paragraph). A cosine similarity distance metric is calculated between the query, and all the semantic features of all the cps is given by

$$\text{cosine\_similarity}\,(\mathbf{A},\mathbf{B}) = \frac{\sum_{i=1}^{n} A_i \cdot B_i}{\sqrt{\sum_{i=1}^{n} A_i^2} \cdot \sqrt{\sum_{i=1}^{n} B_i^2}} \quad (1)$$

The cosine similarity metric is a value between [0,1]; the higher score implies a higher similarity. The essence here is that "most probably the answer of the query lies in the 'context-paragraph' cp with the highest similarity with the input query". This assumption, which is mostly adopted in current QA systems, works well in the majority of situations

with much higher performance than keyword search and retrieval. The following multilingual embedding models were investigated in this research work.

A. Mpnet: Paraphrase-Multilingual-mpnet-base-v2

Mpnet [10] is based on SBERT (Sentence-BERT), which is a modification of the pre-trained BERT network that uses siamese and triplet network structures to derive semantically meaningful sentence embeddings, allowing for efficient comparisons using cosine similarity. The original work BERT [18] and RoBERTa [19] have achieved state-of-the-art performance on sentence-pair regression tasks such as semantic textual similarity (STS). However, they require both sentences to be fed into the network, leading to significant computational overhead. Siamese networks are a type of neural network architecture that can learn to compare two inputs and measure their similarity or dissimilarity. BERT is a pre-trained language model that can encode sentences into fixed-length vectors, but it requires both sentences to be fed into the network simultaneously, which is inefficient for large-scale applications. Sentence-BERT (SBERT) is a modification of BERT that uses Siamese networks to derive sentence embeddings that can be compared using cosine similarity. This way, SBERT can compute the similarity of two sentences without processing them together, reducing the computational cost and enabling semantic similarity search and clustering. SBERT can produce more accurate and consistent embeddings than BERT, as it fine-tunes the model on specific similarity tasks.

B. Google LaBSE

While BERT has proven to be a powerful approach for acquiring monolingual sentence embeddings that excel in tasks related to semantic similarity and embedding-based transfer learning, the realm of BERT-based cross-lingual sentence embeddings was relatively uncharted. A comprehensive Language-agnostic BERT Sentence Embedding (LaBSE) [20], developed by Google researchers with training across 112 languages, including Arabic, using the Tatoeba dataset [13]. This is the multilingual SBERT model used in this research work. The embedding dimension is 768.

C. Openai Ada-embedding

Openai research team [21] delved into the significance of text embeddings, essential for tasks such as semantic search and text similarity assessment, transcending traditional applications. Unlike previous methods that tailored models for specific use cases, they introduced a more unified approach, emphasizing extensive contrastive pre-training on unsupervised data. This strategy produced top-quality vector representations with a wider context window for both text and code, a breakthrough validated across various benchmarks, including MSMARCO [15], Natural Questions, TriviaQA, and code search. Their findings underscored the versatility of these unsupervised text embeddings, demonstrating their potential to excel in state-of-the-art performance across diverse domains, from linear-probe classification to large-scale semantic search.

D. Cohere Multilingual Embedding

Cohere's multilingual text understanding model [16] works by mapping text to a semantic vector space, where texts with similar meanings are positioned close to each other. This allows for a variety of valuable use cases in multilingual settings, such as search, content aggregation and recommendation, and zero-shot cross-lingual text classification. To train the model, Cohere collected a dataset of nearly 1.4 billion question/answer pairs across tens of thousands of websites in hundreds of languages. This dataset is unique because it contains questions actually asked by speakers of said languages, allowing the model to capture language- and country-specific nuances.

E. Meta SONAR:Language-Agnostic Representations

Meta introduced SONAR, a novel fixed-size sentence embedding space with support for multiple languages and modalities [22]. SONAR's single text encoder, spanning 200 languages. Meta stipulated that SONAR outperforms existing sentence embeddings like LASER3 and LabSE in multilingual similarity search tasks. It extends its capabilities to speech segments by employing language-specific speech encoders trained in a teacher-student framework, surpassing existing speech encoders in similarity search tasks. SONAR also provides a text decoder for 200 languages, facilitating text-to-text and speech-to-text machine translation, including zero-shot language and modality combinations [22]. In our findings, we found that this is an overstatement when applied to Arabic Language, as described in section 4.

F. Microsoft E5 - (Small-base-large)

Microsoft researchers [23] presented E5, a family of advanced text embeddings designed for versatile applications across various tasks. E5 stands for EmbEddings from bidirectional Encoder representations. These embeddings are trained using a contrastive approach applied to a large, curated text pair dataset called CCPairs. E5 text embedding models are suitable for tasks like retrieval, clustering, and classification, where a single-vector representation of text is required. It exhibits robust performance in both zero-shot and fine-tuned settings. The authors extensively evaluated 56 datasets using BEIR and MTEB [5] benchmarks. In zero-shot scenarios, E5 surpasses the strong BM25 baseline in the BEIR retrieval benchmark, and when fine-tuned, it achieved the best results in the MTEB benchmark at the time of the publication (Dec. 7th. 2022), outperforming existing embedding models with significantly fewer parameters.

G. HuggingFace DistillBert v1,v2

HuggingFace researchers [24], proposed DistilBERT, a smaller and more efficient language representation model derived from BERT. As transfer learning from large-scale pre-trained models gains prominence in Natural Language Processing (NLP), the challenge lies in deploying these large models on resource-constrained devices or under tight computational budgets. DistilBERT is pre-trained using knowledge distillation techniques, reducing the model size by 40% while retaining 97% of its language understanding capabilities and achieving a 60% increase in speed. To leverage the inductive biases from larger models, they introduced a triple loss mechanism

that combines language modelling, distillation, and cosine-distance losses. DistilBERT proves to be cost-effective for pre-training and demonstrates its suitability for on-device computations through proof-of-concept experiments and comparative on-device studies. In our analysis, we explored distils-base-multilingual-cased-v1 and v2 , denoted in the experiments as hf1 and hf2

V. Experimental Results

A. ARCD Dataset

The dataset used in the benchmark analysis is ARCD (Arabic Reading Comprehension Dataset) [6]. Crowdsourced 1,395 questions with the corresponding context paragraph and ground truth answers. The research involved curation and crowdsourcing, focusing on 155 randomly selected articles from the top 1000 most viewed articles on Arabic Wikipedia in 2018. These articles spanned a wide range of topics, including religious figures, historical figures, sports celebrities, countries, and companies. To ensure the appropriateness of the content, a manual filter was applied to remove any adult material. In total, the project collected 1,395 questions based on 465 paragraphs extracted from the 155 selected articles. Fig. 3 shows a typical record from the ARCD dataset. Following the pipeline in Fig.

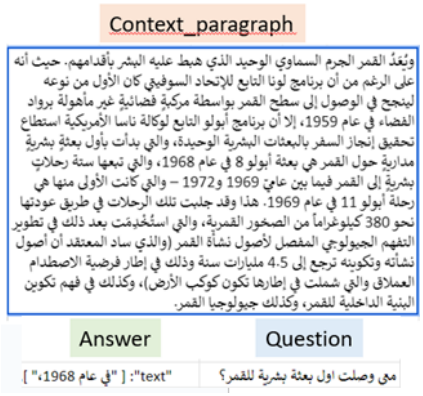

Fig. 3. ARCD record example.

1, the knowledge base (corpus) is constructed based on the concatenation of all Context paragraphs (CPs) of all 1395 questions. Each question and each context paragraph CP is embedded using one of the ten models under study. Faiss (Facebook AI Similarity Search) python library is used for Vector DB indexing and search.

B. Recall@k Performance Metric

Average Recall@k metric is used, where k is the top model retrieval hits with values [1,2,3,4,5,10,15]. The performance results are shown in Fig. 4 and Table I.

The results showed that the Microsoft E5 Family of models had a superior overall performance for all k values, where the top performer was E5 - ML - Large. the second was ada openAI embedding, and worth noting here that E5 is a free, open-source model, while Openai ada is at a cost (0.0001$/1k tokens)

TABLE I. Recall@k for Various Models

	sonar	e5s	e5b	e5l	hf1	hf2	cohere	mpnet	ada	LaBSE
$k = 1$	11%	21%	21%	23%	15%	14%	15%	14%	18%	15%
$k = 2$	23%	43%	42%	46%	27%	26%	28%	27%	36%	29%
$k = 3$	35%	63%	62%	68%	40%	38%	40%	38%	53%	44%
$k = 4$	40%	71%	69%	75%	46%	44%	44%	44%	59%	50%
$k = 5$	44%	76%	74%	79%	52%	49%	48%	49%	64%	55%
$k = 10$	56%	87%	87%	91%	66%	63%	60%	61%	77%	70%
$k = 15$	63%	90%	90%	93%	71%	67%	64%	65%	79%	78%
Embedding	1024	384	768	1024	512	512	768	768	1536	768

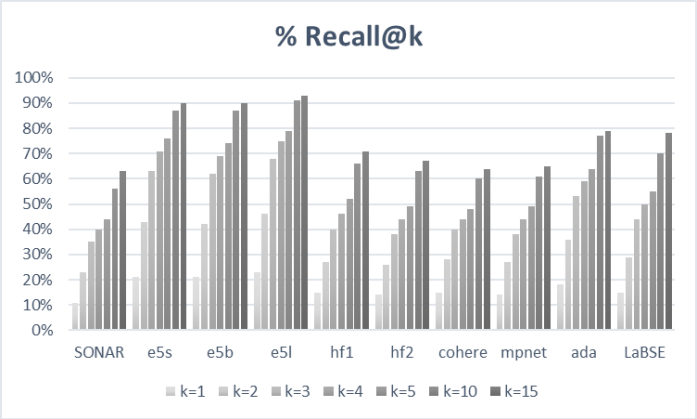

Fig. 4. Average % Recall@k performance.

C. Embedding Dimensions and Model Score

Fig 5 shows the embedding dimension of each model and the top model had 1024, while Openai ada had the maximum embedding dimension of 1536. What's interesting is that the second top performer, E5-small, has an embedding dimension of 384, which is quite impressive. Naturally, the higher the embedding dimension, the higher the capacity to capture better semantic context, which impacts storage and Latency. A simple formula is used to capture the trade-off between model retrieval accuracy and embedding dimension in an overall score:

$$model\_score = \frac{Avg.\ Recall@k\ * 1000}{Embedding\_Dimension} \tag{2}$$

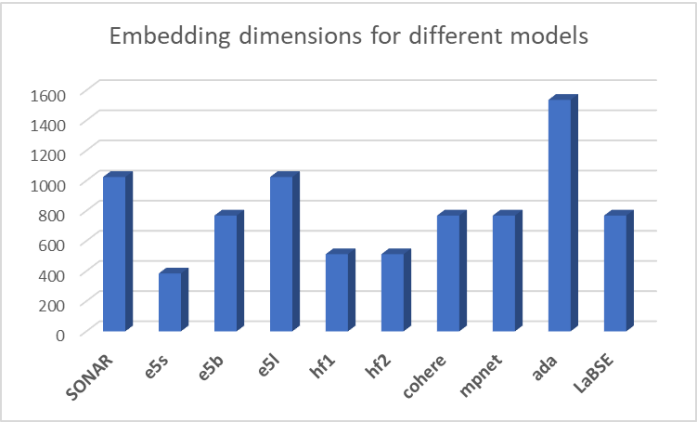

Fig. 5. Embedding dimensions.

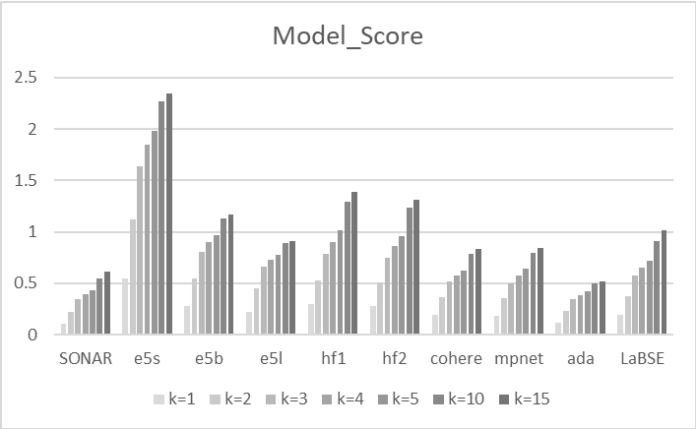

Fig. 6. Overall model_score.

The overall model_score in Fig. 6 shows a clear superior performance for the E5-ml-small model with 384 embedding dimensions, and hence highly recommended for Arabic Language Semantic Information retrieval

VI. Conclusion

In this study, we explored the application of Retrieval Augmented Generation (RAG) models in the realm of the Arabic language, an area that while linguistically rich, often receives less attention in this field. Our focus was particularly on the Information Retrieval component, with a keen eye on the processes of semantic embedding. For our evaluation, we utilized a range of advanced Multilingual Semantic embedding models, employing the ARCD dataset as a benchmark for our assessments. The knowledge corpus is generated from the concatenations of ARCD question contexts. Questions and contexts are embedded using the 10 models understudy, and Recall@k metric is used in the evaluation, where k represents the top retrieval hits based on the cosine similarity distance, and facebook AI similarity search (faiss) library.

The results indicated that the Microsoft E5 Family of models, especially E5-ML-Large (e5l), consistently outperformed the other models across different retrieval hit levels (k values). Notably, the open-source nature of E5 models makes them particularly appealing for a wide range of applications. The second-best performer was the Ada OpenAI embedding, albeit for 0.0001$/1k tokens. Furthermore, we observed that embedding dimensions play a crucial role in model performance. Higher embedding dimensions, such as the 1536 of OpenAI Ada, offer improved semantic context capture but come with storage and latency implications. To account for this tradeoff, we introduced an overall model score that combines model retrieval accuracy and embedding dimension. The E5-ML-Small model (e5s) , with an embedding dimension of 384, emerged as the top performer in this balanced evaluation. In light of these findings, we highly recommend the adoption of the E5-ML-Small model for Arabic Language Semantic Information Retrieval, as it strikes an excellent balance between retrieval accuracy and resource efficiency.

The superior performance of the e5 family of models is attributed to their unique approach to data preparation and training. Unlike conventional methods that rely on small-scale, human-annotated data or large-scale, noisy datasets, the e5 models utilize a specially curated dataset called CCPairs (Colossal Clean text Pairs), which is derived from diverse semi-structured sources.

This research contributes to the broader exploration of RAG models for Arabic language processing and information retrieval, shedding light on valuable avenues for future application of Arabic Language Understanding and Generation.

VII. Discussions and Future Work

A critical aspect warranting further investigation in Retrieval Augmented Generation (RAG) systems and semantic embeddings pertains to the dimensionality of the context window, or embedding size. While reduced embedding dimensions are advantageous for computational efficiency and data storage, they pose challenges in terms of model performance, particularly when processing extensive contexts. Such contexts often exceed the embedding dimension limits, leading to truncation which may adversely impact the model's effectiveness.

Moreover, the choice of tokenizer algorithm, inherently linked to the language being analyzed, presents another variable influencing RAG systems' performance. Tokenizer algorithms vary significantly, and their compatibility and efficiency can differ across languages. This variability underscores the necessity for extensive research into the implications of different tokenizer algorithms, especially in the context of specific languages. Such an investigation could provide valuable insights into optimizing RAG systems for diverse linguistic environments.

Future research should also encompass the exploration of contemporary methodologies in the realm of RAG systems, notably re-ranking strategies and cross-encoder architectures, from a language-specific perspective. This exploration is essential given the evolving nature of large language models and their application across various downstream tasks. In conducting such studies, it will be critical to employ nuanced, language-sensitive metrics, such as Mean Average Precision (MAP), Mean Reciprocal Rank (MRR), and normalized Discounted Cumulative Gain at k (ndcg@k). These metrics would offer a more refined evaluation of the models' capabilities in handling language-specific nuances and complexities.

Through these focused areas, we are aim to address the interplay between linguistic characteristics and the technical dimensions of RAG systems, thereby enhancing their applicability and efficiency in diverse linguistic contexts.

***Abstract*—The significance of medical test records in diagnosing and treating illnesses cannot be overstated. These records serve as the foundation upon which medical professionals craft precise treatment strategies tailored to a patient's unique health condition and ailment. However, in several developing nations, such as Vietnam, a concerning trend persists: medical test records predominantly exist in vulnerable paper format, entrusted to patients for safekeeping. When patients transition between healthcare facilities, the responsibility of carrying these paper-based medical histories rests with them, introducing a significant risk factor due to the inherent fragility of paper documents, which can be easily damaged by fire or water. The loss of these crucial records can lead to severe disruptions in the diagnostic and therapeutic journey of patients, potentially compromising their well-being. Despite the emergence of various alternatives to address this vulnerability, Vietnam faces multifaceted challenges. These challenges encompass low technological literacy among patients and substantial infrastructural limitations. In response to these pressing issues, this study endeavors to harness the transformative potential of blockchain technology, smart contracts, and Non-Fungible Tokens (NFTs) to effectively mitigate the drawbacks associated with paper-based medical test records. Our comprehensive approach includes meticulous cataloging of current hospital practices, the introduction of a purpose-built blueprint for decentralized record sharing, the proposal of an innovative NFT-backed authentication model, the development of a practical proof-of-concept, and comprehensive platform testing. Through these efforts, we aim to revolutionize the management of medical test records in Vietnam, enhancing accessibility, security, and reliability for both patients and healthcare providers.**

I. Introduction

The ubiquity of Android applications (apps) in contemporary society is undeniable. These apps have seamlessly woven themselves into the fabric of daily life, offering indispensable utility across various domains. Whether it's navigation through Google Maps, social connectivity via Facebook, or health tracking with Fitbit, Android apps have become indispensable companions to billions of users. As of March 2023, the Google Play store boasts an astounding repository of over 2.6 million apps[1], a testament to the Android ecosystem's enduring popularity and expansion. The significance of Android's prevalence extends beyond mere numbers. According to App Annie's 2021 report, Android users collectively spent an astonishing 3.5 trillion hours on these apps[2]. This level of engagement underscores the integral role Android apps play in modern life. To exemplify, consider Facebook, one of the most pervasive Android apps, with an impressive 2.94 billion monthly active users. Remarkably, 1.96 billion users visit the social networking platform daily[3]. Yet, in tandem with this digital revolution comes a growing concern about privacy. A 2019 Pew Research Center report revealed that approximately 81% of the public feels they have little or no control over the data collected about them, be it by private companies or government entities[4]. This concern extends to mobile apps, as demonstrated by a 2019 survey by NortonLifeLock, which found that 72% of consumers worry about their privacy when using these apps. Concerns range from the specter of identity theft to fears of unauthorized access to personal information[5]. In response to these privacy concerns, Android introduced a permission model for managing access to sensitive data and specific actions within apps[6]. This model empowers users by requiring apps to request permissions, which can be granted or denied during installation or at runtime. App stores like the Google Play Store implement review processes and policies to ensure app compliance with privacy guidelines. This enables users to review app permissions, ratings, and user feedback, equipping them with the tools to make informed decisions regarding privacy risks[7]. Additionally, data safety policies mandate developers to be transparent about their data practices, ensuring data protection[8].

However, traditional methods for safeguarding user privacy within Android apps face significant challenges. Centralized data storage, a prevalent feature in these apps, introduces a "single point of failure" that substantially heightens the risk of data breaches and unauthorized access [1]. Moreover, these traditional methods often lack transparency, rendering it difficult for users to comprehend and control how their data is collected, processed, and shared. This lack of transparency can erode user trust and deter them from using a service due to privacy concerns [2], [3]. Additionally, these methods offer limited user control over personal data, constraining users from managing what data is collected, how it's used, or with whom it's shared [4]. Recognizing the urgency of addressing these challenges, this paper introduces a novel and forward-thinking approach to elevate Android app privacy to new

heights. Our contribution centers on a groundbreaking hybrid architecture that integrates conventional data processing with blockchain technology, tailored specifically to handle sensitive data. The importance of this contribution cannot be overstated. As the Android app ecosystem continues to expand, so do the volumes of data being generated and processed, including sensitive health and medical data. With the growing emphasis on user privacy, our hybrid approach offers a transformative paradigm that ensures advanced security, transparency, and user control. It provides a solution to the persistent privacy concerns pervasive within the Android app ecosystem.

In this paper, we delve into the intricacies of our hybrid architecture, demonstrating how it effectively manages 'dangerous' permissions, particularly those related to motion/health/medical data, which are of paramount importance due to their sensitivity. Through rigorous evaluation on Ethereum Virtual Machine (EVM) compatible platforms such as BNB, Fantom, Celo, and Matic, we identify the optimal platform, with the Fantom platform emerging as a standout choice owing to its low transaction costs and optimal gas limits. Additionally, our paper outlines comprehensive strategies for persuading service providers and Android OS producers to adopt our transformative approach. By doing so, we present a pioneering perspective on the application of blockchain technology to address the persistent privacy concerns that continue to challenge the Android app ecosystem. In the subsequent sections, we provide a detailed account of our approach, the evaluation results, and the strategies for adoption, ultimately contributing to a future where Android users can enjoy the benefits of innovative apps without compromising their privacy.

II. Related Work

In this section, we provide an extensive review of related work in the field of privacy preservation within Android platforms. While our paper introduces a novel approach leveraging blockchain technology for this purpose, it is essential to contextualize our contribution within the broader landscape of existing research.

A. Malware Analysis

Privacy preservation within Android platforms has long been a concern, prompting researchers to explore various methodologies to address these challenges. One prominent avenue of research in this area is malware analysis, which focuses on identifying and mitigating malicious software that may compromise user privacy.

Talha et al. [5] developed APK Auditor, a system designed for detecting malicious apps through permission analysis. This multifaceted system encompassed Android clients, a signature database, and a central server. APK Auditor employed static analysis to capture permission requests and calculate malicious scores, contributing to the early efforts of enhancing Android app security.

In a similar vein, Jianmao et al. [6] introduced MPDroid, an innovative approach that evaluated the risk of target apps based on minimum permissions. The methodology incorporated collaborative filtering and clustering techniques to assess app risk, providing valuable insights into permission-based privacy risk estimation.

Enck et al. [7] proposed TaintDroid, an Android platform extension that significantly advanced privacy preservation. This pioneering system tracked the flow of privacy-sensitive data within third-party apps and promptly labeled apps as privacy violations when personal data was transmitted to third parties. TaintDroid marked a critical milestone in privacy-aware app development and user protection.

Furthermore, Moutaz et al. [8] focused on a set of dangerous permissions identified by Google[9], contributing to the categorization and understanding of potential privacy risks within Android apps.

While these studies made commendable strides in enhancing privacy preservation within Android platforms, they often provided binary detection outcomes (malicious or benign). This binary nature of their analysis might not be sufficient to assist users effectively in their decision-making processes.

To address this limitation, Son et al. [4], [9] proposed an innovative approach centered on risk estimation based on an app's data collection and sharing behavior. Their approach marked a significant shift towards a more nuanced understanding of app privacy risks, enabling users to make informed choices based on the level of risk they were willing to accept. Additionally, their app recommendation system [10] further personalized user app choices based on their privacy preferences, contributing to user-centric privacy preservation.

However, even these advanced risk estimation approaches do not fully address the need for a robust, transparent, and user-controlled platform for managing sensitive data within Android apps. In contrast, our paper introduces a novel paradigm by integrating blockchain technology into Android platforms. This blockchain-based system offers enhanced security, transparency, and user control for handling sensitive data, thereby providing a balanced, secure, and effective method for managing data in Android apps. By retaining traditional processing for 'normal' data, our approach preserves app functionality and data processing effectiveness. Our contribution represents a significant advancement in the ongoing efforts to protect user privacy on Android platforms.

B. Sensitive Data Encryption

Another prevalent approach to privacy preservation within Android platforms is sensitive data encryption. This methodology involves encoding user data in a way that allows only authorized parties to access it, thus ensuring the confidentiality and integrity of sensitive information.

Chen et al. [11] proposed AUSERA, an automated tool designed to detect security vulnerabilities in Android apps. While AUSERA did not specifically focus on encryption, its contribution lay in the identification of security vulnerabilities, which are often associated with privacy breaches.

Zhang et al. [12] examined the vulnerability of Android external storage, an area susceptible to data leakage, and proposed solutions to prevent sensitive information disclosure.

[9]https://developer.android.com/reference/android/Manifest.permission

Their work underscored the importance of protecting sensitive data, especially in scenarios where external storage is involved.

Fan et al. [13] introduced HPDROID, an automated system that identified GDPR compliance violations in mobile health applications. While their primary focus was on compliance, it indirectly contributed to privacy preservation by highlighting the critical need for robust data protection mechanisms within health-related apps.

Mia et al. [14] conducted a comprehensive comparative study on HIPAA technical safeguards assessment of Android mHealth applications. This study provided valuable insights into healthcare data privacy, emphasizing the need for stringent security measures within healthcare apps.

Haupert et al. [15] evaluated the state of Android app hardening and identified vulnerabilities in a leading Runtime Application Self-Protection (RASP) product. Their work demonstrated the need for continuous improvement in security mechanisms to protect sensitive data from emerging threats.

Chen et al. [16] and Sengupta et al. [3] proposed blockchain-based systems specifically designed for preserving medical data privacy within Android platforms. These pioneering contributions recognized the unique challenges associated with healthcare data and demonstrated the potential of blockchain technology in safeguarding sensitive medical information.

Balasubramanium et al. [17] conducted a comprehensive survey on data privacy and preservation using blockchain in healthcare organizations. This survey illuminated emerging trends and challenges in healthcare data privacy, underscoring the importance of innovative solutions like blockchain.

While these studies have made valuable contributions to privacy preservation within Android platforms, they often rely on developers' security knowledge and diligence. Moreover, some studies focus primarily on healthcare data and do not address the broader range of sensitive data handled by Android apps. Others lack a specific implementation tailored for Android platforms.

In contrast, our proposed blockchain-based system offers a robust, transparent, and user-controlled platform for managing sensitive data in Android apps, applicable to a wide array of data types beyond healthcare. By integrating blockchain technology, we address the limitations of existing approaches and contribute significantly to the ongoing endeavor to preserve user privacy on Android platforms.

III. Background

A. Android OS and Permission System

Android, an open-source operating system developed by Google, is ubiquitous in modern society, powering a wide array of mobile devices such as smartphones, tablets, and wearables. Built upon the Linux kernel, Android offers a robust application framework, enabling developers to create innovative apps and games within a Java-based environment. This extensive ecosystem boasts over 2.6 million apps available on the Google Play Store as of March 2023, highlighting its profound impact on our digital lives. Central to Android's design is its intricate permission system, meticulously crafted to safeguard user privacy. This system plays a pivotal role in dictating how apps interact with sensitive user data and device resources. When developers create an Android app, they must explicitly define in the app's manifest file what types of permissions the app requires to function effectively. These permissions govern a diverse range of access, from location data to contacts, camera, microphone, and beyond.

Permissions in the Android ecosystem are categorized into different levels, with particular emphasis on two primary types: Normal and Dangerous permissions. The distinction between these permission categories is crucial and forms the cornerstone of user privacy and security:

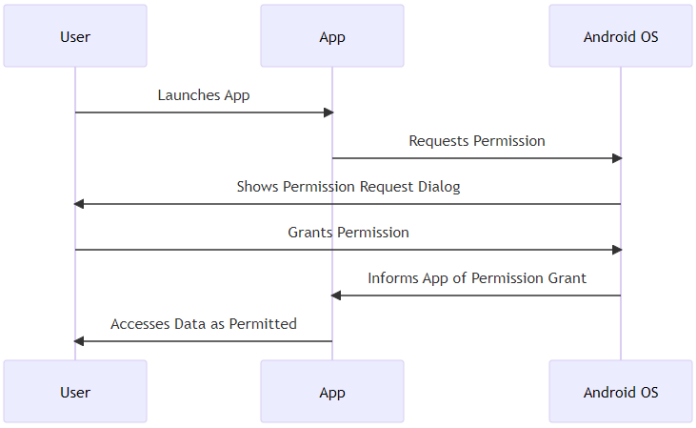

Fig. 1. The user data collection via the permission system in android OS.

- Normal Permissions: These permissions encompass scenarios where apps need to access data or resources outside their own sandboxed environment, with minimal risk to user privacy or the functioning of other apps. An example of a normal permission is the ability to set the device's time zone. Such permissions are typically granted without explicit user consent at installation.
- Dangerous Permissions: In contrast, dangerous permissions involve access to highly sensitive user data or device resources, potentially affecting user privacy and the integrity of other apps. Permissions like accessing the user's contacts, camera, or location fall into this category. Android mandates explicit user consent for granting dangerous permissions, often soliciting consent dynamically as the app requires access during runtime, rather than at installation.

The Android permission system operates as a crucial pillar in maintaining a balance between app functionality and user privacy. It empowers users to make informed decisions regarding which permissions to grant to individual apps, ensuring their data remains secure and their privacy respected.

Fig. 1 illustrates the intricate workflow involved in an app's data collection via the Android permission system. This process embodies the essence of user-centric privacy preservation within the Android ecosystem.

In summary, Android's widespread adoption and sophisticated permission system have fostered an environment where

user data privacy is paramount. However, challenges remain in ensuring transparent, secure, and user-controlled data management, especially concerning sensitive information.

B. Blockchain Technology

Blockchain technology has emerged as a disruptive force, initially popularized through its association with digital currencies like Bitcoin. Its inherent properties have extended far beyond the realm of cryptocurrencies, finding applications across diverse industries. At its core, a blockchain consists of a chain of blocks, each containing a list of transactions. These blocks are cryptographically linked, with each new block referencing the previous one, creating an immutable ledger. Immutability ensures that once data is recorded on the blockchain, it cannot be retroactively altered, providing unparalleled data integrity. One of the foundational characteristics of blockchain technology is its decentralization. Unlike traditional centralized databases, where a single entity controls access and data, a blockchain operates on a network of distributed nodes. Each node holds a complete copy of the blockchain and participates in validating and recording new transactions. This decentralized architecture eliminates single points of failure and dramatically enhances security. Transparency and auditability are fundamental attributes of blockchain technology. All transactions on the blockchain are visible to every participant in the network. Moreover, every transaction is permanently recorded, creating an unchangeable audit trail. This transparency builds trust and accountability, assuring participants that no transaction can be tampered with or erased.

Smart contracts, another hallmark feature of blockchain, are self-executing agreements with contract terms directly encoded into code. These contracts automatically execute transactions when predefined conditions are met, removing the need for intermediaries. In the context of Android privacy preservation, blockchain technology offers a range of benefits:

- Enhanced Data Security: Blockchain replaces centralized data storage with a decentralized, tamper-resistant mechanism. Advanced cryptographic algorithms and distributed consensus protocols secure user data against unauthorized access, manipulation, or breaches. This significantly mitigates the risk associated with centralized data storage and bolsters privacy preservation in Android systems.
- Improved Transparency and Auditing: Traditional methods for managing user data in Android apps often suffer from a lack of transparency, causing trust issues among users. Blockchain's transparency and immutability address this problem. Every transaction is transparent and can be audited, ensuring app developers and service providers adhere to declared privacy policies and data handling practices. Smart contracts provide an auditable trail of all data interactions, increasing transparency and fostering user trust.
- User Control and Consent: One significant drawback of conventional methods is the limited control users have over their personal data. Blockchain technology significantly enhances user control over personal data. With self-sovereign identity solutions built on blockchain, users can manage their own identity data, decide what information to share, and with whom, and for what purpose. These features offer users the ability to selectively consent to data collection and sharing, substantially preserving their privacy.
- Data Integrity and Provenance: The immutable nature of blockchain ensures the integrity and provenance of data. Each data transaction is recorded permanently and cannot be altered, providing a verifiable and auditable history of data transactions. This feature allows users to verify the authenticity and accuracy of their data, enhancing the trustworthiness of Android apps, particularly in scenarios where data traceability and accountability are paramount.
- Secure Data Sharing: Blockchain technology can also facilitate secure and controlled data sharing within the Android ecosystem. Users can grant or revoke access to their data at any time with blockchain-based consent management systems. This flexibility ensures that data is only shared with authorized parties and only for approved purposes, further enhancing privacy preservation in Android applications.
- Trust and Collaboration: The distributed and transparent nature of blockchain technology inherently fosters trust and collaboration among participants. By providing a shared and immutable record of data transactions, blockchain can help establish trust between users, app developers, and service providers in the Android ecosystem. This enhanced trust can encourage responsible data handling practices, promote fair data exchanges, and motivate collaborative efforts in privacy preservation, leading to a more secure and user-centric Android platform.

In summary, the intersection of Android OS and blockchain technology holds great promise for addressing the challenges associated with privacy preservation in the Android app ecosystem. The combination of Android's extensive user base and the robust security and transparency offered by blockchain creates a compelling framework for reimagining how sensitive data is managed and protected in mobile applications.

IV. Approach

Our proposed approach, depicted in Fig. 2, represents a comprehensive integration of blockchain technology with the permission management process in Android systems. This integration is meticulously designed to bolster privacy preservation and provide users with heightened control over their sensitive data.

To elucidate the intricacies of our approach, we break it down into a series of steps, each serving a crucial role in ensuring robust privacy protection and user empowerment:

Step 1: User Application Installation The journey begins when a user decides to install an application, with a particular focus on medical applications. Medical apps are chosen for their inherent sensitivity, as even small fragments of medical data hold the potential for privacy breaches, potentially compromising individual identities.

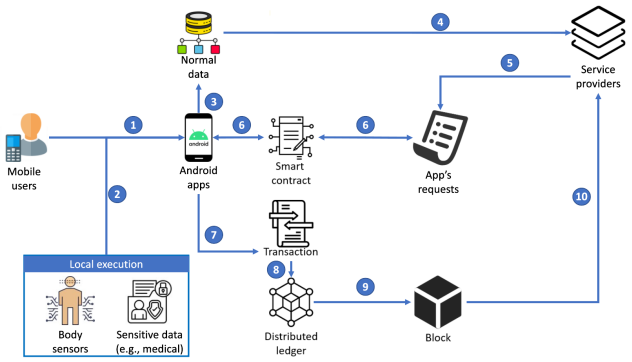

Fig. 2. Architecture of our proposed privacy-preserving model.

Step 2: Dangerous Permission Request When a medical application requests access to sensitive medical data through Android's dangerous permissions system, it potentially gains access to the user's comprehensive or aggregated health information. This marks the second step in our process.

Step 3: Normal Data Request In cases where the application requests access to non-sensitive, normal data, it follows the conventional permissions procedure outlined in Section III. Such data can be collected without the need for additional security measures.

Step 4: Secure Data Transmission Should the service provider necessitate the transmission of the collected normal data to their servers (referred to as "global execution"), the fourth step of our approach comes into play. Our system ensures the secure and encrypted transmission of this data to the designated service provider's servers.

Step 5: Sensitive Data Request Alternatively, if an application seeks sensitive data, such as those accessed via dangerous permissions like `BODY_SENSORS` and `BODY_SENSORS_BACKGROUND` for medical data collection, it is mandated to provide detailed information regarding the purpose of usage, the specific data types required, and the possibility of third-party involvement. This meticulous process is justified by (i) the availability of most of this information in the application's privacy policy and (ii) compliance with data privacy regulations, including the General Data Protection Regulation (GDPR)[10], which mandates secure data handling processes by applications.

Step 6: User Validation via Smart Contract The user, on their mobile device, actively participates in the decision-making process concerning their data in the sixth step. This active involvement is facilitated through the use of smart contracts, which enhance transparency and decentralize control, placing it squarely in the hands of the user.

Step 7: Transaction Logging Upon user validation, the decision is meticulously logged as a transaction, creating a formal agreement between the user and the service providers. This transactional logging process harkens back to the conventional permission system. However, it takes a significant leap forward by incorporating machine learning techniques, which enable future decisions to reference these initial agreements. This reduces the need for recurrent user interventions [18].

[10]https://gdpr-info.eu/

Step 8: Secure Storage in Distributed Ledger All these transactions, replete with user decisions and service provider agreements, are securely stored within a distributed ledger (DLT) in the eighth step. This distributed ledger serves as an immutable repository of records, rendering every transaction traceable and tamper-resistant.

Step 9: Encryption and Non-Fungible Tokens (NFTs) The ninth step involves the encryption of user responses using the service provider's public key, employing elliptic curve cryptography [19]. This ensures that only the intended service provider can decrypt and access the user's responses. To further bolster data security and uniqueness, we utilize Non-Fungible Token (NFT) technology to encapsulate these responses. Each NFT is designed to be distinct and non-interchangeable, safeguarding the integrity and confidentiality of user data.

Step 10: Data Transfer via NFTs The final step in our approach is the seamless transfer of these NFT-encapsulated user responses to the service provider. This culminating interaction furnishes the service provider with the requisite and authorized data, while concurrently creating a traceable, indelible record of the transaction on the blockchain.

Our architectural approach presents numerous advantages over the traditional Android permission system:

- Enhanced Transparency and Auditability: The integration of blockchain technology ensures that every transaction is meticulously recorded and verifiable, offering a heightened level of transparency and auditability.
- User Empowerment and Control: The use of smart contracts places the reins of control firmly in the hands of the user. Users can distinctly specify which data can be accessed, fostering greater empowerment and autonomy.
- Data Integrity and Secure Sharing: By leveraging NFTs and elliptic curve cryptography, our approach guarantees data integrity and secure data sharing. This ensures that sensitive data remains confidential and unaltered.
- Trust Building and Regulatory Compliance: Our innovative approach facilitates trust-building between users and service providers. Furthermore, it promotes collaborative data sharing while adhering to stringent data privacy regulations.
- Scalability and Efficiency: The inherent scalability and efficiency of blockchain technology position our approach as a sustainable choice for future privacy-preserving systems, capable of meeting evolving demands and challenges.

In conclusion, our comprehensive integration of blockchain technology with the Android permission process represents a significant leap forward in privacy preservation and user-centric control over sensitive data. By embedding transparency, security, and efficiency into the core of our approach, we aim to redefine data privacy in the digital age.

V. Experiments

Our research endeavors to introduce a blockchain-based platform that operates as a distributed ledger, with a primary

focus on the intricacies of steps 8 and 9, as illustrated in Fig. 2. This phase marks a pivotal step toward our overarching research objective.

A. Methodology

In the development of our platform, we meticulously considered various blockchain platforms that offer support for the Ethereum Virtual Machine (EVM). The selected platforms, including Binance Smart Chain (BNB Smart Chain)[11]; Polygon[12]; Fantom[13]; and Celo[14], were chosen over open-source alternatives such as those within the Hyperledger ecosystem (e.g., Hyperledger Fabric) due to their compatibility with EVM and their widespread adoption within the decentralized application (DApp) development community. As a critical facet of our research, we implemented our approach across four distinct blockchain platforms that support the Ethereum Virtual Machine (EVM): BNB Smart Chain (BNB), Polygon (MATIC), Fantom (FTM), and Celo (CELO). An essential contribution of this study is the comprehensive collection and analysis of transaction fees associated with these platforms, utilizing their respective testnet coins. All implementations have been made publicly accessible, underscoring our commitment to contributing to the broader blockchain community. Within our evaluation, we paid meticulous attention to transaction fees and gas limits, both of which have profound implications for the operational costs and efficiency of deploying DApps on blockchain networks. Transaction fees represent the costs associated with processing a transaction and fluctuate depending on factors such as transaction complexity and network congestion. Gas limits, on the other hand, dictate the maximum amount of computational resources (gas) a user is willing to expend on a transaction, safeguarding against inadvertent overspending.

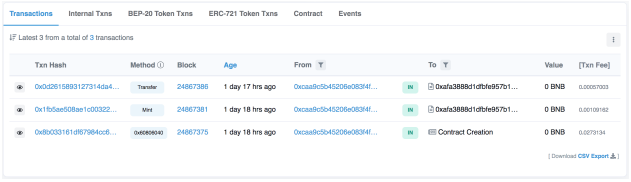

Fig. 3. Transaction information (e.g., BNB Smart Chain).

Our evaluation involved the assessment of three fundamental functions on each of these platforms:

1) **Creating User Responses:** This pivotal function embodies the user's consent level, signifying their stance on data collection, whether it involves denying data access, permitting partial access, or granting full access to medical data, as expounded in Section IV.
2) **Creating Non-Fungible Tokens (NFTs):** The user's response is encrypted using the service provider's public key and subsequently encapsulated into an NFT. This process ensures both the integrity and confidentiality of user responses.
3) **Transferring NFTs:** Subsequently, the NFT is transferred to the service provider, solidifying an immutable record of the user's response.

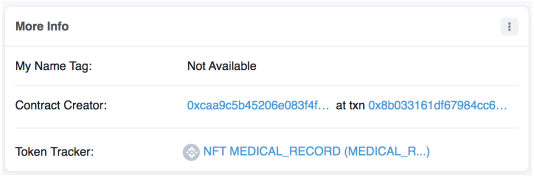

Fig. 4. NFT creation

While encryption plays a pivotal role in our approach, we have intentionally refrained from delving into the intricacies of encryption methodologies within this paper due to the substantial scope involved. A more exhaustive exploration of encryption methodologies and their analysis will be presented in forthcoming iterations of this research. Fig. 3 offers a glimpse into one of our evaluations, specifically detailing a successful deployment on the BNB Smart Chain. Analogous procedures and assessments were meticulously carried out across the remaining three platforms. Smart contracts, developed using the Solidity programming language, constituted the core of our evaluations. We scrutinized the execution costs of these contracts within the testnet environments of the respective platforms, with a primary objective of ascertaining the most cost-efficient platform for deploying our system. We delved into the intricacies of contract creation, NFT generation (as depicted in Fig. 4), and NFT ownership address updates, a process fundamentally revolving around retrieving and transferring NFTs (refer to Fig. 5).

B. Transaction Fee Analysis

In our investigation, we conducted an in-depth analysis of transaction fees incurred during the operations of Contract Creation, NFT Creation, and NFT Transfer across four prominent blockchain platforms: BNB Smart Chain, Fantom, Polygon (MATIC), and Celo. The results of this comparative analysis are summarized in Table I. On the BNB Smart Chain, the transaction fees for Contract Creation, NFT Creation, and NFT Transfer amounted to 0.0273134 BNB ($8.43), 0.00109162 BNB ($0.34), and 0.00057003 BNB ($0.18), respectively. The Fantom platform exhibited lower transaction costs, with Contract Creation priced at 0.00957754 FTM ($0.001849), NFT Creation at 0.000405167 FTM ($0.000078), and NFT Transfer at 0.0002380105 FTM ($0.000046). The Polygon (MATIC) platform showcased even more economical costs, with Contract Creation incurring 0.006840710032835408 MATIC ($0.01), NFT Creation incurring 0.000289405001852192 MATIC (almost negligible in USD terms), and NFT Transfer incurring 0.000170007501088048 MATIC (also nearly negligible in USD terms). Finally, the Celo platform reported fees of 0.007097844 CELO ($0.004) for Contract Creation, 0.0002840812 CELO (almost negligible in USD terms) for NFT Creation, and 0.0001554878 CELO (also nearly negligible in USD terms) for NFT Transfer.

This comprehensive analysis highlights the substantial variability in transaction fees across the four platforms, underscor-

[11]https://github.com/bnb-chain/whitepaper/blob/master/WHITEPAPER.md
[12]https://polygon.technology/lightpaper-polygon.pdf
[13]https://whitepaper.io/document/438/fantom-whitepaper
[14]https://celo.org/papers/whitepaper

TABLE I. TRANSACTION FEES (IN NATIVE TOKENS AND USD EQUIVALENTS)

	Contract Creation	Create NFT	Transfer NFT
BNB Smart Chain	0.0273134 BNB ($8.43)	0.00109162 BNB ($0.34)	0.00057003 BNB ($0.18)
Fantom	0.00957754 FTM ($0.001849)	0.000405167 FTM ($0.000078)	0.0002380105 FTM ($0.000046)
Polygon	0.006840710032835408 MATIC ($0.01)	0.0002894050018521 92 MATIC (almost negligible)	0.000170007501088048 MATIC (almost negligible)
Celo	0.007097844 CELO ($0.004)	0.0002840812 CELO (almost negligible)	0.0001554878 CELO (almost negligible)

ing the critical importance of platform selection in optimizing the cost-effectiveness of deploying our approach.

C. Gas Limit Assessment

TABLE II. GAS LIMITS FOR OPERATIONS

	Contract Creation	Create NFT	Transfer NFT
BNB Smart Chain	2,731,340	109,162	72,003
Fantom	2,736,440	115,762	72,803
Polygon	2,736,284	115,762	72,803
Celo	3,548,922	142,040	85,673

In addition to transaction fees, gas limits represent a vital facet when deploying smart contracts on Ethereum-based platforms. Gas limits delineate the upper bound of computational resources (gas) allocated to a transaction, serving as a safeguard against inadvertent overspending. Table II summarizes the gas limits associated with various operations, including Contract Creation, NFT Creation, and NFT Transfer, across the four blockchain platforms under consideration: BNB Smart Chain, Fantom, Polygon (MATIC), and Celo.

On the BNB Smart Chain, the gas limits for Contract Creation, NFT Creation, and NFT Transfer stand at 2,731,340, 109,162, and 72,003, respectively.

In the Fantom platform, the corresponding gas limits are marginally higher, with Contract Creation at 2,736,440, NFT Creation at 115,762, and NFT Transfer at 72,803.

Polygon (MATIC) records similar gas limits, with Contract Creation at 2,736,284, NFT Creation at 115,762, and NFT Transfer at 72,803.

Lastly, the Celo platform exhibits the highest gas limits among the four platforms. Contract Creation incurs a gas limit of 3,548,922, NFT Creation requires 142,040 gas, and NFT Transfer necessitates 85,673 gas.

This detailed analysis underscores the substantial variations in gas limits across the four platforms, further emphasizing the need for meticulous consideration in selecting the most suitable platform for deploying our innovative approach.

VI. DISCUSSION

The paradigm of secure data management and privacy preservation on Android devices has been a persistent challenge in the digital age. Our proposed approach, which integrates blockchain technology into the Android permission process, represents a transformative shift in how we address this challenge. In this discussion, we delve deep into the implications and significance of our approach, considering its potential to elevate Android privacy to new heights.

A. Blockchain as the Guardian of Privacy

The integration of blockchain technology into Android's data permission management brings about a fundamental transformation. One of the core advantages is the transparency and immutability inherent to blockchain. Every transaction, every access request, and every decision made by users are recorded in an unalterable ledger. This ledger serves as a comprehensive audit trail, granting users unprecedented visibility into how their data is accessed and used. The user-centric transparency aligns with the overarching theme of elevating Android privacy, allowing users to exercise greater control over their sensitive data. Moreover, blockchain introduces the concept of decentralized control. Through smart contracts, users actively participate in granting or denying access to their data. This not only empowers users but also shifts the locus of control from centralized authorities to individual users. The notion of users as stewards of their data is a critical step toward achieving robust data privacy.

B. User-Centric Data Control

Central to our approach is the pivotal role of smart contracts in the decision-making process. Users validate data access requests through these contracts, granting consent or withholding it. This mechanism puts the power back in the hands of users, enabling them to specify precisely which data can be accessed and under what circumstances. This level of fine-grained control is a substantial departure from the traditional Android permission system, which tends to be binary and all-encompassing. Our approach aligns perfectly with the ethos of user-centric data control. Users are no longer passive participants; they are active decision-makers in the data access process. This newfound agency fosters trust between users and service providers, as users have confidence that their data is used according to their wishes. It also complies with emerging data privacy regulations, such as the General Data Protection Regulation (GDPR), which emphasize user consent and control over personal data.

C. Security and Integrity via NFTs and Cryptography

Data security is a paramount concern in Android privacy, especially when dealing with sensitive information like medical data. Our approach addresses this concern through the use of Non-Fungible Tokens (NFTs) and elliptic curve cryptography. NFTs encapsulate user responses in a unique and non-interchangeable manner. This uniqueness guarantees that user responses remain distinct and unforgeable. It bolsters data integrity and confidentiality, assuring users that their data is protected from tampering or unauthorized access. Elliptic curve cryptography further fortifies data security. By encrypting user responses with the service provider's public key, we ensure that only the designated service provider can decrypt and access the data. This cryptographic layer adds an additional barrier to unauthorized data access.

Fig. 5. NFT transfer.

D. Trust Building and Regulatory Compliance

The elevation of Android privacy through blockchain-powered data management also contributes to trust-building between users and service providers. Users are more likely to engage with applications and services when they are confident that their data is handled with care and transparency. This trust-building aspect is essential for the sustained growth of the Android ecosystem. Additionally, our approach aligns seamlessly with data privacy regulations like GDPR. Compliance with these regulations is not just a legal requirement but also an ethical obligation. By facilitating user consent, control, and transparency, our approach inherently complies with these stringent privacy regulations. This alignment ensures that service providers can operate with confidence in a regulatory landscape that increasingly prioritizes data privacy.

E. Scalability and Efficiency

The scalability and efficiency of blockchain technology make our approach a viable and sustainable choice for the future. As Android ecosystems evolve and expand, the need for scalable privacy solutions becomes increasingly pronounced. Blockchain's inherent capacity to handle a growing volume of transactions positions our approach as a robust solution for the long term. Moreover, the efficiency of our approach is underscored by the use of various blockchain platforms, such as Binance Smart Chain, Fantom, Polygon (MATIC), and Celo. The comparative analysis of transaction fees and gas limits across these platforms offers insights into cost-effective deployment options. The adaptability of our approach to multiple blockchain environments ensures that it can seamlessly integrate into a diverse range of Android applications and services.

In conclusion, our blockchain-powered paradigm for secure data management on Android devices represents a groundbreaking approach to elevate Android privacy. By introducing transparency, user-centric control, data security, trust-building, and scalability, we lay the foundation for a new era of Android privacy that aligns with evolving user expectations and regulatory requirements.

VII. Conclusion

In this paper, we have introduced a groundbreaking approach aimed at enhancing privacy and data security for Android applications, with a specific focus on the sensitive domain of medical apps. Leveraging the capabilities of blockchain technology, our novel approach has been designed to fundamentally transform the way privacy preservation is addressed within Android platforms. Our comprehensive architecture ensures robust controls on permissions, enforces transparency in data transactions, and places users at the forefront of data management, thereby significantly elevating Android privacy standards. The central premise of our approach is the integration of blockchain technology into the Android ecosystem, revolutionizing how user data is accessed, utilized, and protected. We have presented a detailed architectural framework that harnesses the power of blockchain to regulate access to sensitive user data. This framework extends beyond the conventional Android permission system, offering a multi-step process that heightens the security and transparency of data interactions.

Through our rigorous evaluation on four Ethereum Virtual Machine (EVM)-supported platforms, namely Binance Smart Chain (BNB), Polygon (MATIC), Fantom (FTM), and Celo (CELO), we have demonstrated the feasibility and effectiveness of our approach. Notably, our evaluation revealed that the Fantom platform emerged as the most suitable option for our work. The low transaction costs and optimal gas limit settings make it an attractive choice for implementing our privacy-preserving framework. However, we acknowledge that the cryptocurrency market is subject to fluctuations, and these results may evolve over time. In our discussion, we have recognized that the successful deployment of our approach hinges on the acceptance and adoption by key stakeholders, including service providers and Android OS producers. We have outlined strategies to garner support from these critical actors, underlining the value of our approach in achieving enhanced privacy and data security.

Looking ahead, our future work will delve into the measurement and enhancement of encryption methodologies to further fortify data privacy and mitigate potential risks. As technology continues to advance, our research makes a substantial contribution to the ongoing discourse surrounding user privacy and data security within the Android ecosystem. We firmly believe that our work lays the essential foundation for the development of more transparent, secure, and user-friendly Android applications. By aligning with the evolving expectations of users and complying with ever-stricter data privacy regulations, our approach is poised to lead the way towards a future where Android privacy reaches new heights.

Acknowledgment

Our sincere appreciation is extended to Engineer Le Thanh Tuan and Dr. Ha Xuan Son, whose expertise and guidance have been indispensable in the brainstorming, execution, and assessment phases of this project. Additionally, the continuous support from FPT University Cantho Campus, Vietnam, has been instrumental in the fruition of this work.

A Deep Transfer Learning Approach for Accurate Dragon Fruit Ripeness Classification and Visual Explanation using Grad-CAM

Hoang-Tu Vo, Nhon Nguyen Thien, Kheo Chau Mui
Software Engineering Department
FPT University, Cantho city, Vietnam

***Abstract*—Dragon fruit, known for its rich antioxidant content and low-calorie attributes, has garnered significant attention as a health-promoting fruit. Its economic value has also surged due to increasing consumer demand and its potential as an export commodity in various regions. The classification of dragon fruit ripeness is a pivotal task in ensuring product quality and minimizing post-harvest losses. This research article presents a comprehensive study on the classification of ripe and unripe dragon fruits (Hylocereus spp) using the Densenet201 model through three distinct approaches: as a classifier, feature extractor, and fine-tuner. To explain the outcomes of the image classification model and thereby enhance its performance, optimization, and reliability, this study employs advanced visualization techniques. Specifically, it utilizes Grad-CAM (Gradient-weighted Class Activation Mapping) and Guided Grad-CAM techniques. These techniques offer insights into the model's decision-making process and pinpoint regions of interest within the images. This approach empowers researchers to iteratively validate the model's accuracy and enhance its performance. The utilization of Densenet201 as a classifier, feature extractor, and fine-tuner, coupled with the insights from Grad-Cam and Guided Grad-Cam, presents a holistic approach to enhancing dragon fruit ripeness classification. The findings contribute to the broader discourse on agricultural technology, image analysis, and the optimization of classification models.**

***Keywords*—Dragon fruit classification; ripeness classification; densenet201 model; Grad-CAM visualization; guided grad-CAM; visual interpretation; Explainable AI; XAI; deep learning; pre-trained models; model fine-tuning; transfer learning**

I. Introduction

Dragon fruit is a tropical fruit that is widely grown in many countries around the world, including Vietnam [1]. It contains numerous nutrients beneficial to human health, such as vitamin A, vitamin C, and protein [2], [3]. While the ripeness of dragon fruit can be observed visually and harvested manually by humans, the necessity arises for the integration of equipment and robots in the field due to the vast planting area and technological advancements. The automated system is capable of efficiently harvesting significant quantities of dragon fruit within a brief timeframe, leading to time savings in the harvesting process. Therefore, an automatic dragon fruit ripeness grading system is really necessary.

Explaining deep learning models is of paramount importance in today's rapidly evolving technological landscape. Deep learning, with its complex architectures and black-box nature, has demonstrated remarkable capabilities across various domains. However, this complexity often comes at the cost of interpretability, creating challenges in understanding how and why these models arrive at their decisions. Explaining these models is a critical step to building trust, ensuring fairness, and enabling effective adoption. Interpretability empowers stakeholders to comprehend the factors influencing predictions. By shedding light on the inner workings of deep learning models, explanations help bridge the gap between advanced machine learning techniques and human comprehension, fostering collaboration between data scientists, domain experts, and end-users.

This research paper provides a comprehensive examination of how to classify ripe and unripe dragon fruits (Hylocereus spp) using the Densenet201 model. The study explores three distinct approaches to employing the model: as a classifier, a feature extractor, and a fine-tuner. To expound upon the outcomes of the image classification model and, in turn, enhance its performance and reliability, advanced visualization techniques are applied. Specifically, the study makes use of Grad-CAM (Gradient-weighted Class Activation Mapping) and Guided Grad-CAM techniques.

II. Related Works

Lately, the domains of image recognition have witnessed extensive utilization of Deep Learning (DL) and Machine Learning (ML) techniques. Including medicine [4], [5], [6], [7]. In self-driving cars [8], [9], [10], [11]. In agriculture [12], [13], [14], [15]. Especially when it comes to automating fruit sorting [16], [17], [18], etc.

Currently, there is a lot of applied research on machine learning, and deep learning on dragon fruit for many different purposes such as: In this study [19], Minh Trieu, N., & Thinh, N. T. present an automated system for classifying dragon fruit, which relies on a convolutional neural network (CNN). This classification system integrates machine learning and image processing through a convolutional neural network model to discern the external characteristics of dragon fruits. The paper [20] presents an automated dragon fruit classification system through a combination of KNN, CNN, and ANN models for identification, feature extraction, and classification. This study [21] devises dragon fruit grading and sorting techniques via machine learning algorithms (CNN, ANN, and SVM). Zhou et al. in this paper [22] presents a novel dragon fruit detection method, utilizing YOLOv7 to locate and classify the dragon fruit and further detect the endpoints of the dragon fruit. Vijayakumar, D. T., & Vinothkanna, M. R. in the paper

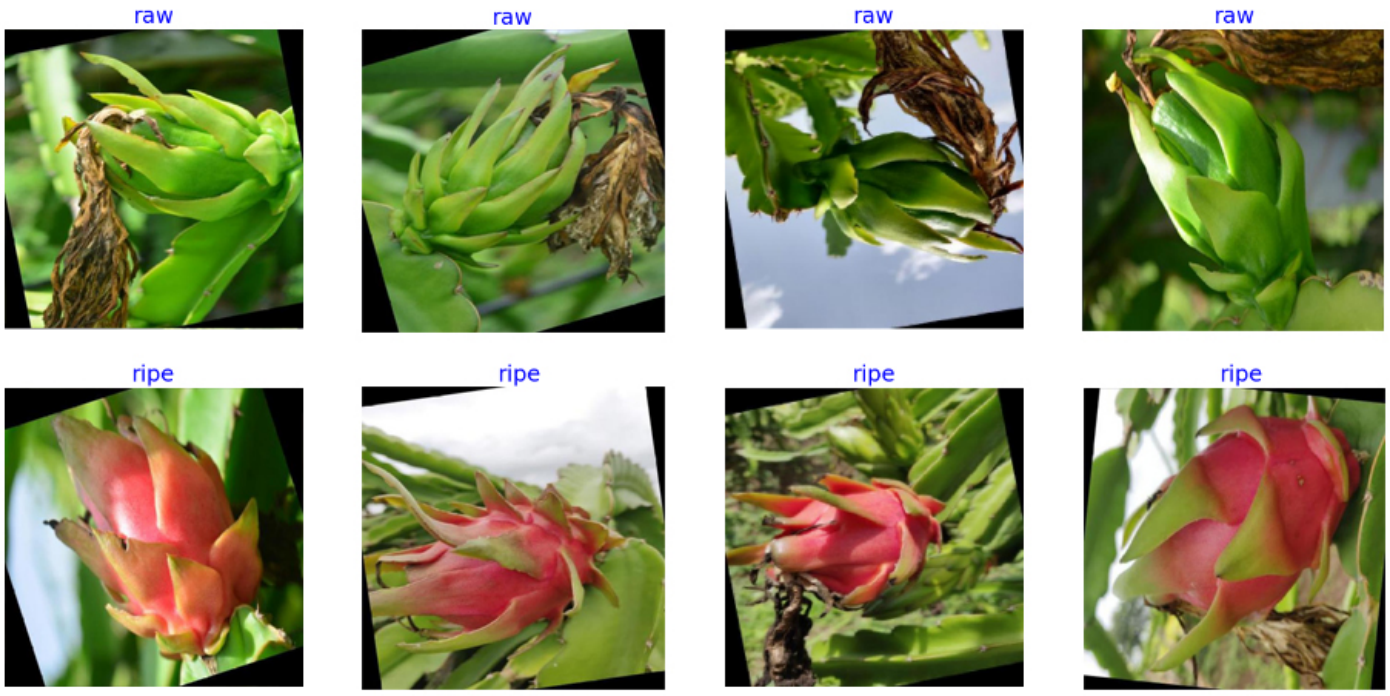

Fig. 1. Some images of dragon fruit dataset.

[23] introduces the utilization of the RESNET 152 deep learning convolutional neural network to identify dragon fruit mellowness, signifying the optimal time for harvest. This study [24] applies color and texture feature extraction techniques, utilizing color moments and gray level co-occurrence matrices (GLCM), to develop a system for recognizing three types of dragon fruit stems through digital image processing, employing Support Vector Machine and k-Nearest Neighbors methods for comparison.

In today's context, with the increasing complexity of deep learning models, there is an even greater need to understand the decisions made by these models. The role of Explainable Artificial Intelligence (XAI) [25], [26] is to provide transparency, clarity, and understanding to the decision-making process of deep learning models and bring the gap between the "black-box" nature of AI and human understanding. XAI has achieved numerous successes across various domains, including: In medicine [27], [28], [29]; In agriculture: [30]; In traffic classification: [31].

The purpose of this research article is to conduct a thorough investigation into the classification of ripe and unripe dragon fruits utilizing the Densenet201 model. The study explores three distinct methodologies: employing the model as a classifier, feature extractor, and fine-tuner. In addition, using Grab-CAM [32], [33], [34] and Guided Grad-Cam (this involves performing an element-wise product between Grad-CAM and Guided Backpropagation [35]) to interpret models for the purpose of evaluating the decision and effectiveness of deep learning models detecting features in a dragon fruit image.

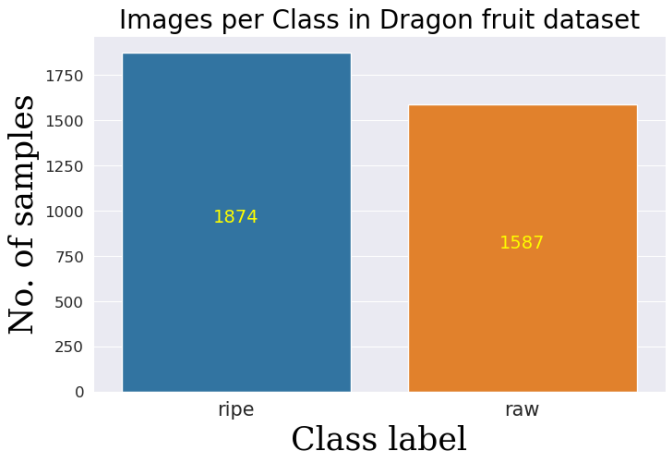

Fig. 2. A dataset distribution.

III. Methodology

A. Data Collection and Preparation

In this investigation, we utilized a dataset containing 3,461 images, sourced from [36] with two classes: Ripe and Raw. Fig. 1 illustrates sample images of dragon fruit from this dataset, and the dataset distribution is visually depicted in Fig. 2. Prior to model training and evaluation, a preprocessing step is performed on the images, resizing them to 224x224 and applying an image preprocessing function. The data set is partitioned into three distinct sets, comprising a training set, a validation set, and a testing set, with a distribution ratio of 6:2:2.

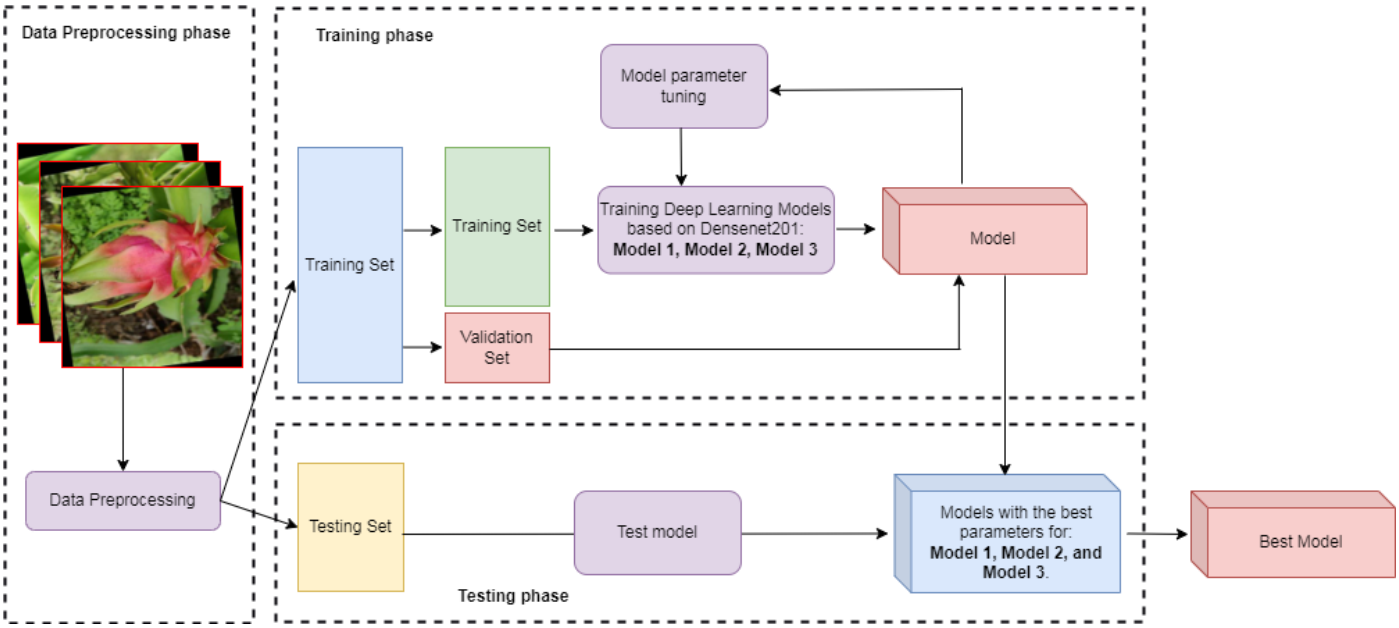

Fig. 3. The training and testing process involves three dragon fruit ripeness models based on densenet201.

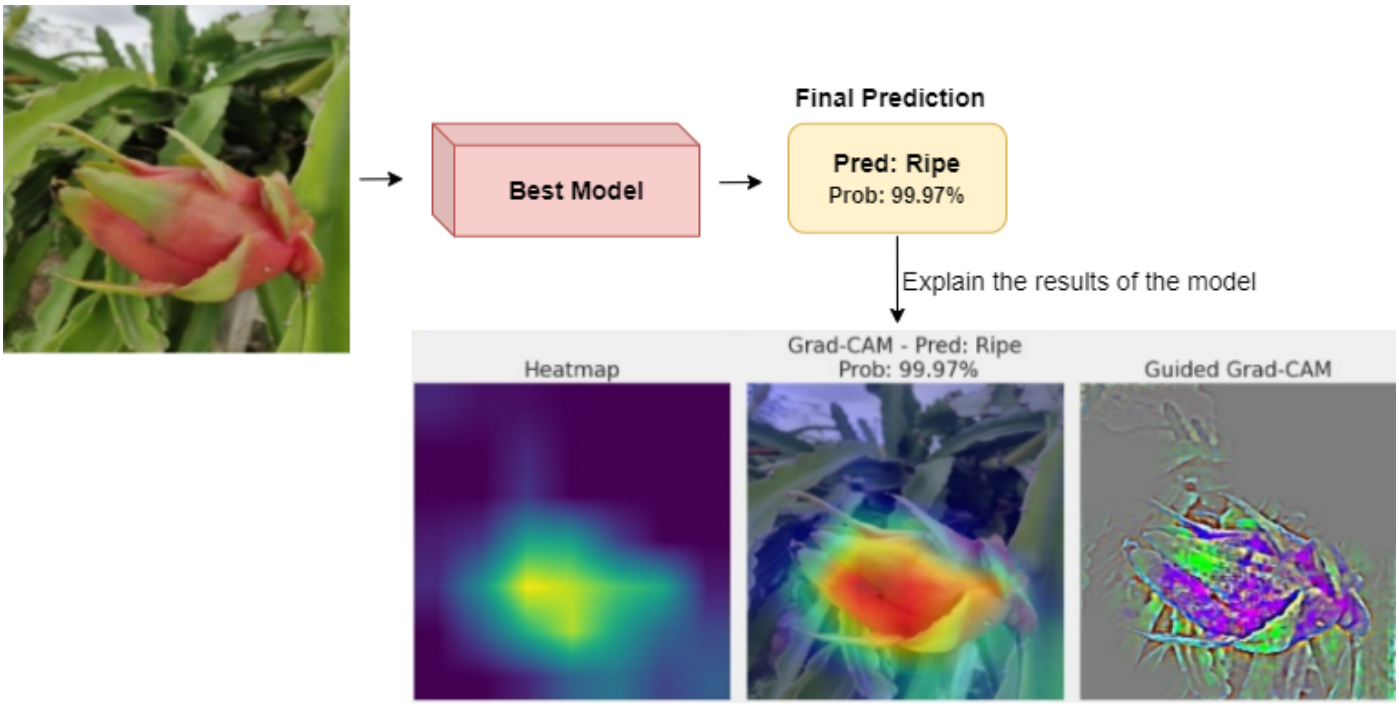

Fig. 4. Classify the dragon fruit ripeness and explain the results of the model.

B. Transfer Learning for Dragon Fruit Classification

Transfer learning [37], [38], a pivotal concept in the realm of machine learning, is a technique that leverages knowledge gained from one task to improve performance on a different but related task. Rather than starting from scratch, transfer learning enables models to take advantage of patterns and representations learned from a source domain and apply them to a target domain with limited labeled data. This approach has revolutionized the field by dramatically reducing the need for vast datasets and extensive computational resources, making it feasible to tackle new problems even when data is scarce. Transfer learning's ability to extract and transfer valuable insights across tasks has been instrumental in advancing the efficiency, accuracy, and generalization of machine learning models, thereby accelerating progress across various domains and enabling AI systems to learn more like humans – by

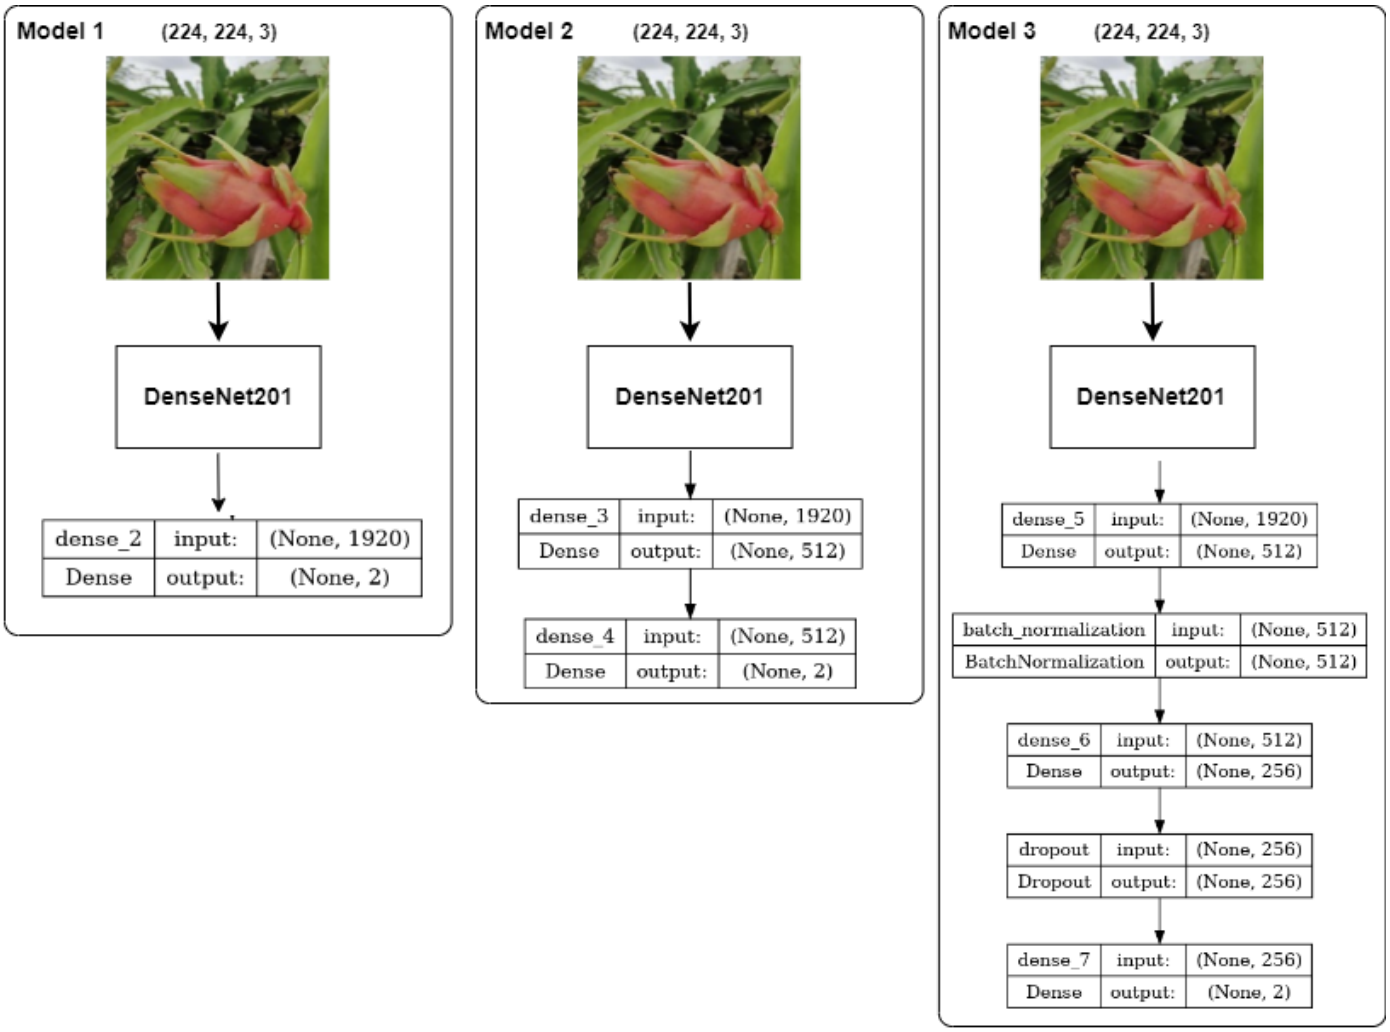

Fig. 5. The architecture of the dragon fruit ripeness classification is constructed using denseNet201.

building upon prior knowledge to solve new challenges.

C. Proposed Model

This research paper presents a comprehensive investigation into the categorization of ripe and unripe dragon fruits utilizing the Densenet201 [39] model in three separate ways: as a classifier, feature extractor, and fine-tuner. Model 1 (as a classifier) is built upon the DenseNet201 architecture. The pre-trained layers are frozen to preserve their acquired features. The final softmax layer in the DenseNet201 model has been modified to classify two classes, corresponding to ripe and raw dragon fruit. Model 2 (as a feature extractor) is a modified DenseNet201-based model for the binary classification of ripe and raw dragon fruit. It has two new entirely connected layers, with 512 neurons in the first layer and two neurons in the final. Both the base pre-trained layers and the fully connected layers have been completely retrained. Model 3 (as a feature extractor with fine-tuning) is a base model initialized using the DenseNet201 architecture. A fully connected layer with 512 neurons is added on top of the base model's output. Batch normalization is applied to the output of the previous layer, helping to stabilize and accelerate training. Another fully connected layer with 256 neurons is added, along with various regularization techniques. A dropout layer is introduced, which helps in preventing overfitting. A final fully connected layer with 2 neurons and softmax activation is added to produce class probabilities. The pre-trained layers are frozen to preserve their acquired feature. Fig. 3 shows The training and testing process involves three Dragon Fruit Ripeness models based on Densenet201. Fig. 4 displays Classify the Dragon Fruit Ripeness and explain the results of the model. The architecture of the Dragon Fruit Ripeness Classification is constructed using DenseNet201 shown in Fig. 5.

D. Performance Evaluation Measures

In this study, various evaluation metrics, including Accuracy, F1-score, Precision, and Recall, were utilized to assess the effectiveness of the deep learning (DL) models. Accuracy served as a measure of overall performance, while Precision and Recall evaluated the model's ability to correctly predict positive instances. The F1-score provided a balanced perspective by considering both Precision and Recall, enabling informed judgments on the model's effectiveness. Through the

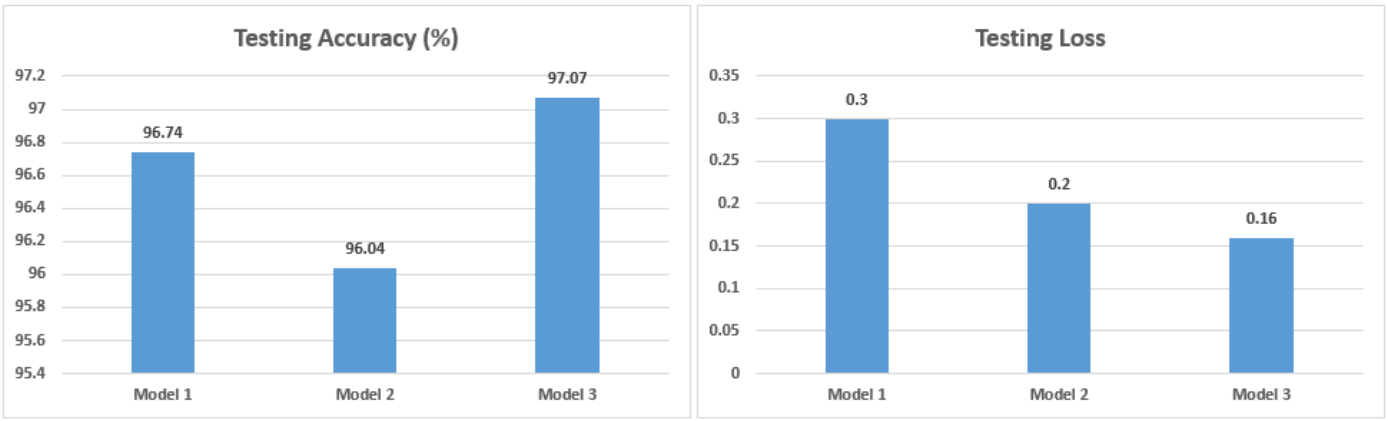

Fig. 6. Confusion matrix of the recommended models. (left) The number of predictions, (right) The percentage.

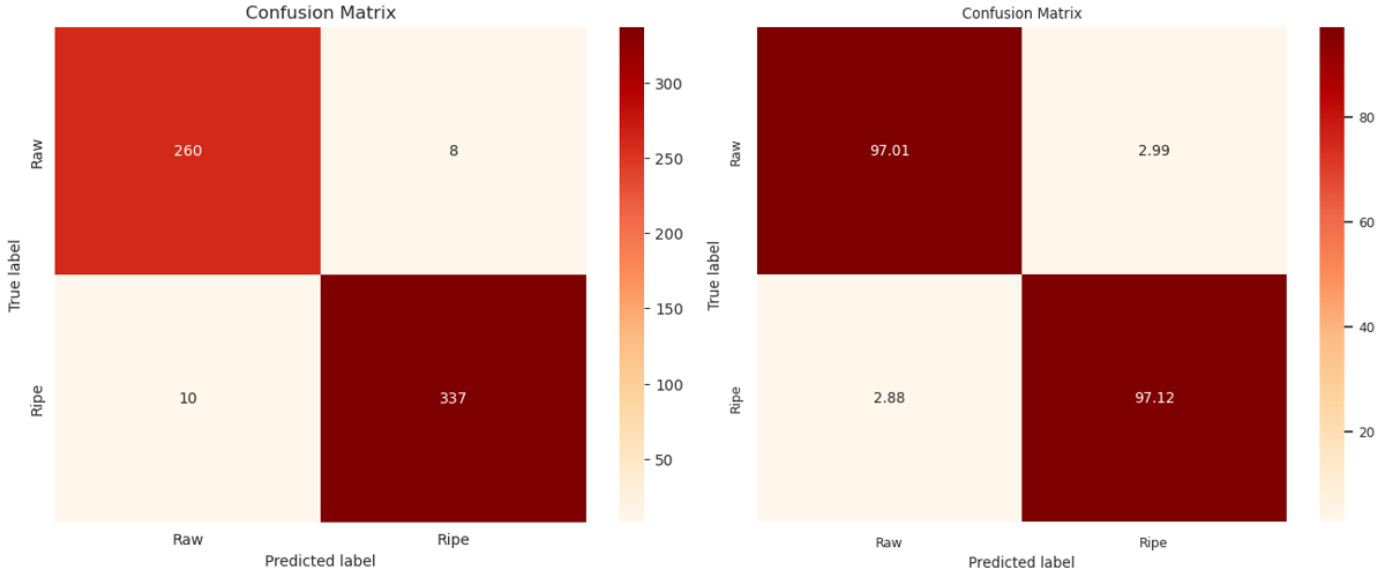

Fig. 7. Confusion matrix of Model 3. (left) The number of predictions, (right) The percentage.

utilization of various evaluation metrics, a thorough comprehension of the model's performance was attained.

$$Accuracy = \frac{TP + TN}{TP + TN + FP + FN} \quad (1)$$

$$Precision = \frac{TP}{TP + FP} \quad (2)$$

$$Recall = \frac{TP}{TP + FN} \quad (3)$$

$$F_1 - Score = \frac{Precision * Recall}{Precision + Recall} \quad (4)$$

In which, TP represents True Positive, TN signifies True Negative, FP represents False Positive, and FN stands for False Negative.

IV. Results

A. Environmental Settings

The experimental results were obtained by conducting the experiments on the Kaggle platform. The system used for the experiments had 13GB of RAM and a GPU P100 with 16GB of memory. The models were trained for a total of 35 epochs, and a batch size of 32 was used during the training process.

B. Evaluation Overall

The results presented in Fig. 6 reveal that the majority of the models exhibit remarkably high accuracy and low loss. Notably, Model 3 stands out with the lowest test loss of 0.1606 and the highest accuracy of 97.07% among the three models. It demonstrates excellence on the test dataset. Additionally, both Model 1 and Model 2 perform exceptionally well, achieving test accuracies of 96.75% and 96.04%, respectively. However, they do have significantly higher test losses compared to Model 3.

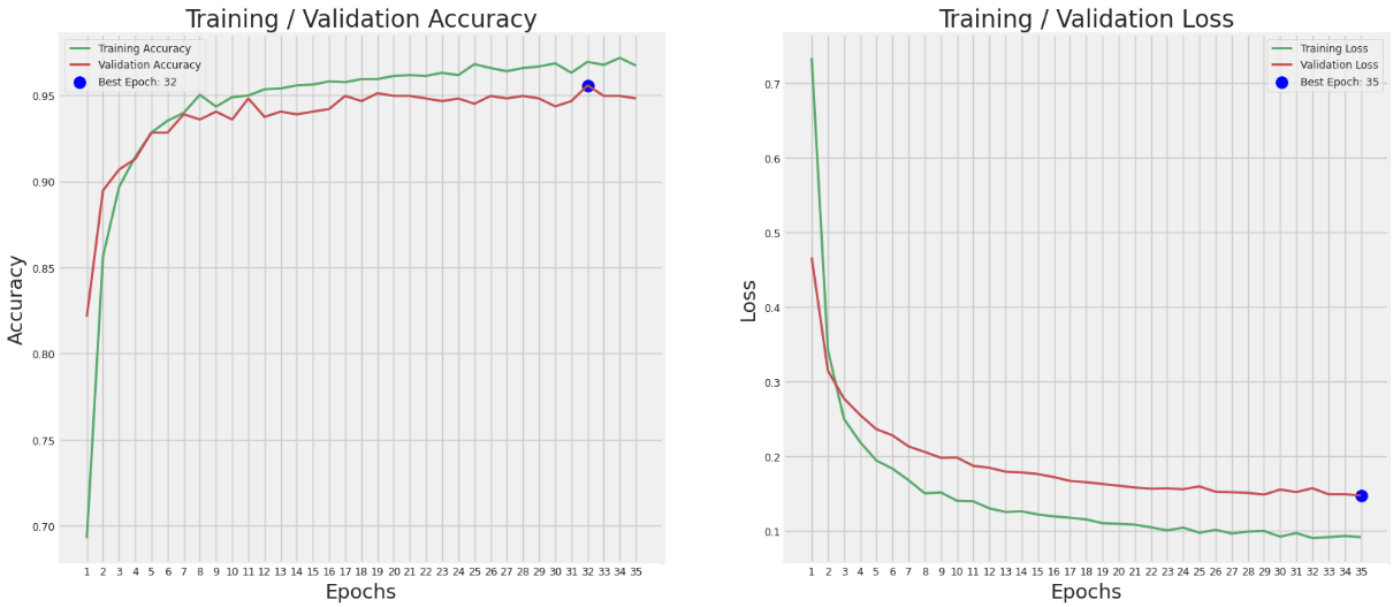

Fig. 8. Loss and accuracy plots of the model 3.

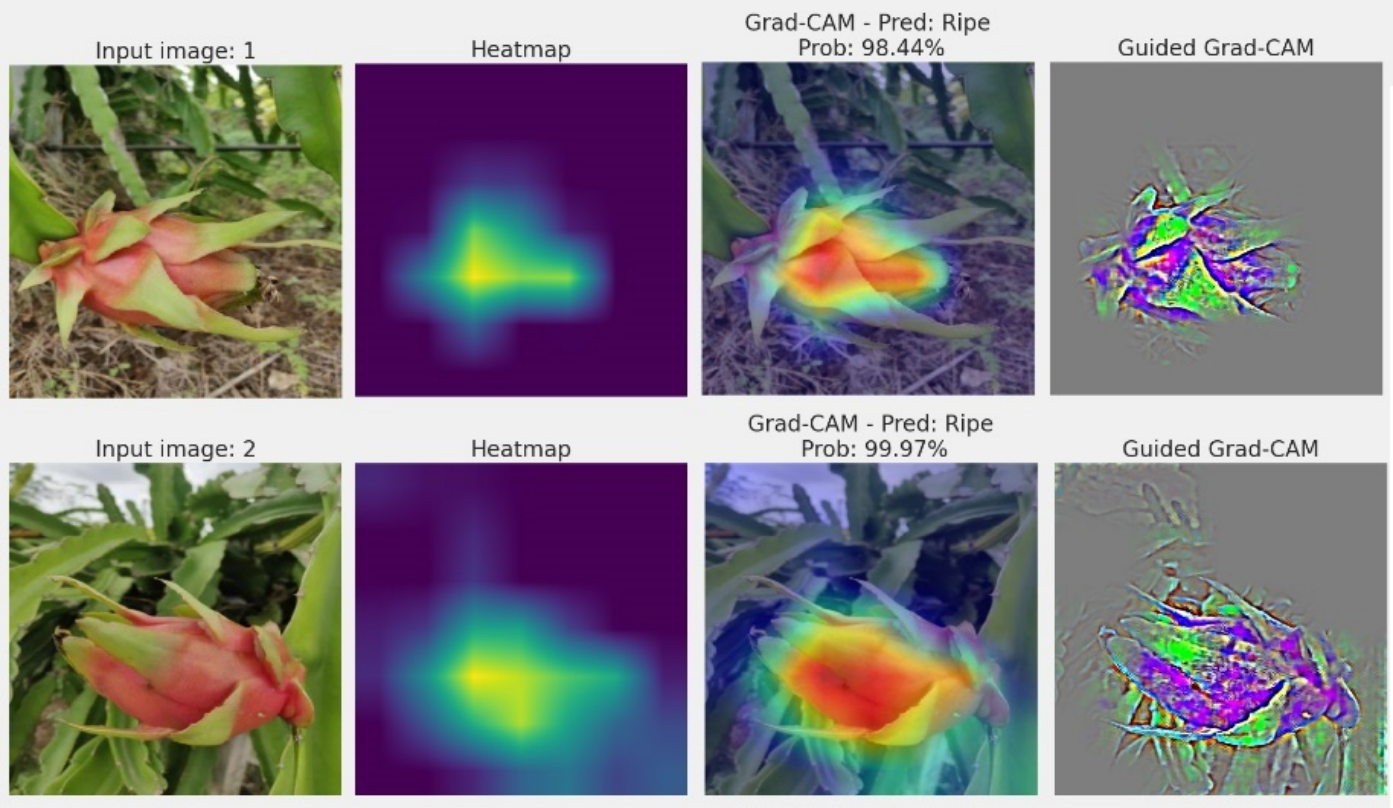

Fig. 9. Examples of the ripe feature explained using Grad-CAM from model 3.

The accuracy of Model 3 reaching 97.07% on the test set is outstanding and represents an exceptional level of performance. It means that the model can correctly classify almost all instances in the test data. Such a high level of accuracy is a strong indicator of the model's ability to generalize well and make precise predictions on previously unseen data. Fig. 7 illustrates the confusion matrix for Model 3.

Furthermore, Fig. 8 presents an overview of the performance metrics, including loss and accuracy, which were assessed throughout both the training and validation stages of Model 3.

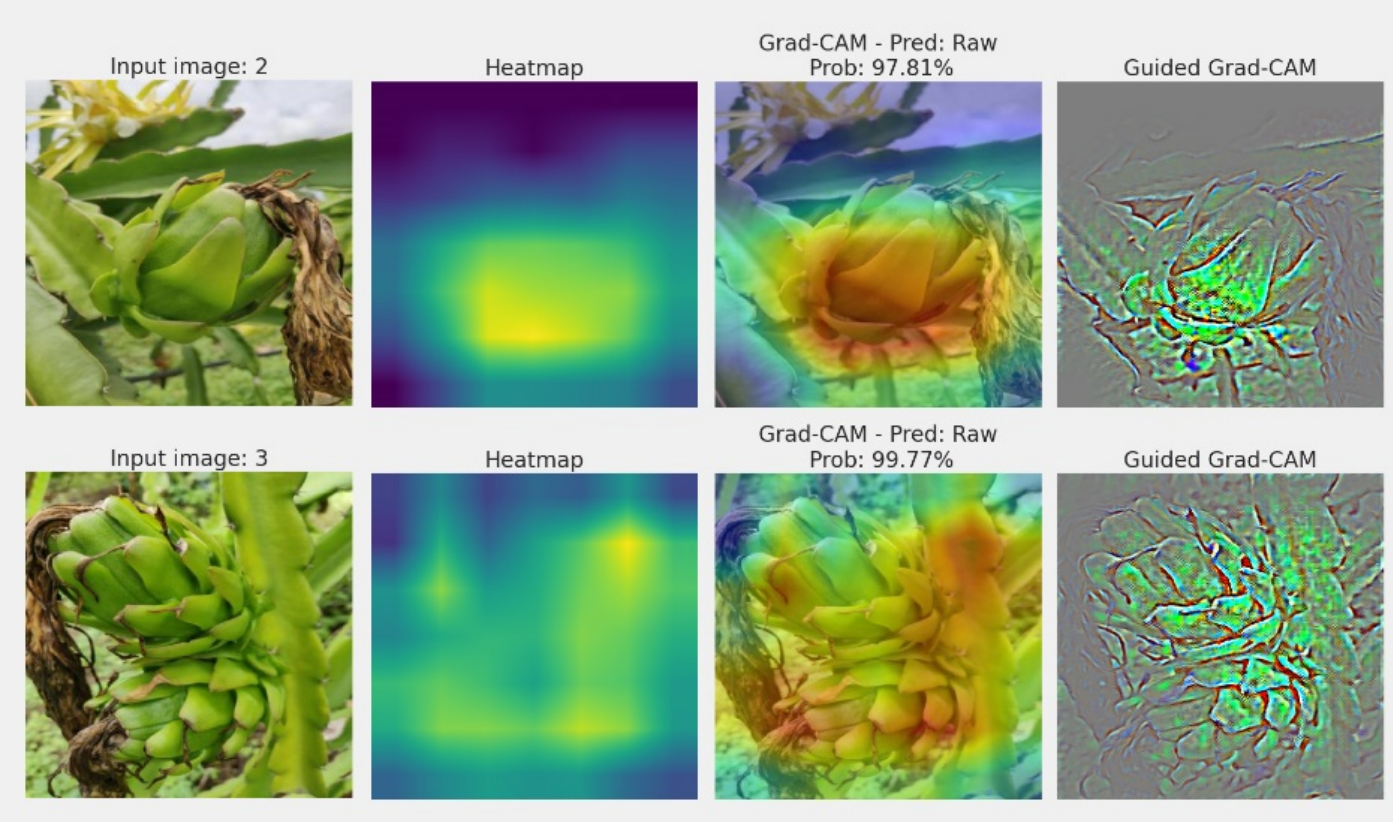

Fig. 10. Examples of the raw feature explained using Grad-CAM from model 3.

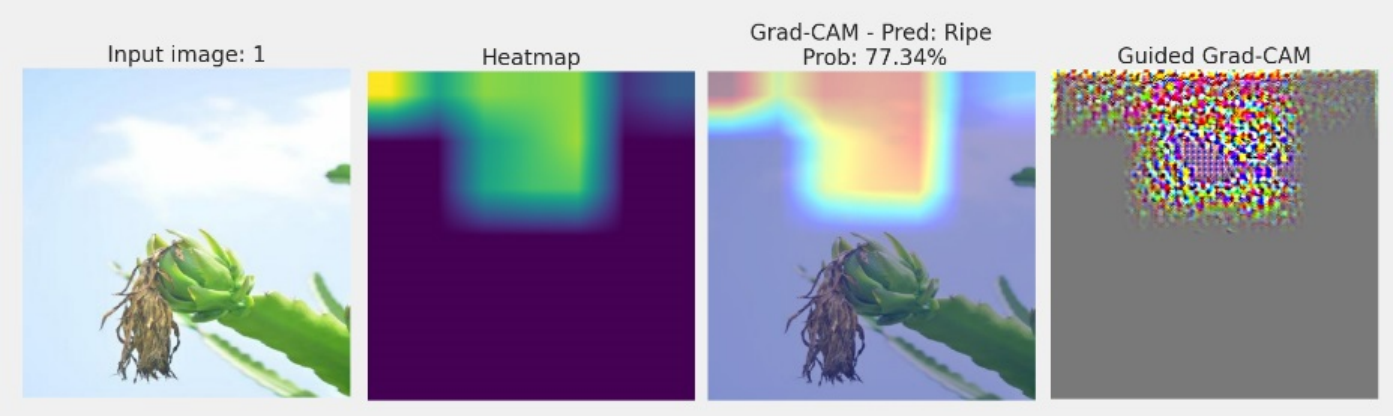

Fig. 11. Examples of ripe feature misclassification are explained using Grad-CAM from model 3.

The classification report Table I provides a detailed analysis of the evaluation metrics for each grape disease class. The classification report is a summary that assesses a model's classification performance. It includes precision, recall, and F1-score metrics for each class label. The report helps to evaluate the model's accuracy in correctly classifying instances for each class, with higher scores indicating better performance. In this case, the model achieved perfect scores for all classes, demonstrating excellent accuracy in its classification task.

TABLE I. THE MODEL RESULTS OF THE CLASSIFICATION REPORT

Class	Precision	Recall	F1-Score	Support
Raw	0.96	0.97	0.97	268
Ripe	0.98	0.97	0.97	347

C. Visualizing the Interpretation of Model Predictions Using Grad-CAM

To better understand the significant regions in the images that the model focuses on for making predictions, the research team employed Grad-CAM on corner images. Specif-

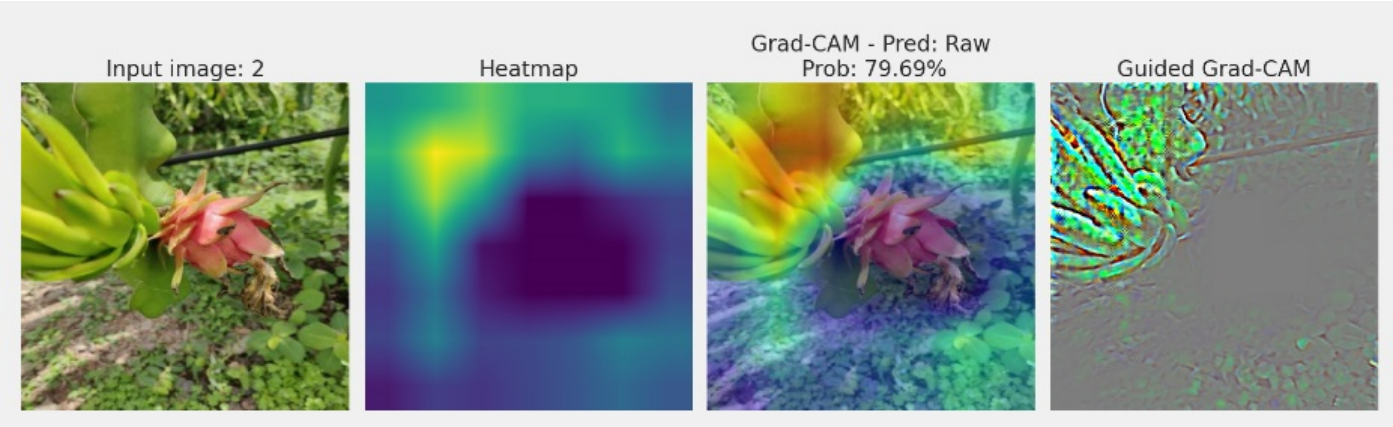

Fig. 12. Examples of raw feature misclassification are explained using Grad-CAM from model 3.

ically, when applying Grad-CAM to an image, it generates a "heatmap" that highlights important positions in the image. This heatmap indicates the areas of the image that the model is paying attention to while making predictions. High values on the heatmap usually correspond to important regions relevant to the classification decision. In addition, the research team also used Guided Grad-CAM to better understand the parts of the image that the model is interested in to make predictions.

Based on the results from Fig. 9 and Fig. 10, it is evident that the accurate classification by the model relies on specific regions unique to each type. The heatmap also highlights key areas in the image that the model focuses on while making predictions that align with its own predictions.

Grad-CAM and Guided Grad-CAM are also useful in comparing misclassified results to understand why the model may have "misinterpreted" certain images. For example, Fig. 11 and 12 explain why the model is misclassified.

V. Conclusion

This study conducts an extensive investigation into the classification of ripe and unripe dragon fruit, employing the Densenet201 model across three distinct approaches: as a classifier, feature extractor, and fine-tuner. All three proposed models yield exceptionally impressive outcomes. Particularly noteworthy, Model 3 (functioning as a feature extractor with fine-tuning) stands out with the highest accuracy, achieving 97.07% among the three models. Furthermore, both Model 1 and Model 2 showcase exceptional performance. To delve deeper into understanding the significant areas within images that the model emphasizes for prediction, the research team applied Grad-CAM to corner images. Additionally, the team employed Guided Grad-CAM to enhance comprehension of image regions that capture the model's attention for prediction purposes. Both Grad-CAM and Guided Grad-CAM prove to be invaluable tools in the comparative analysis of misclassified results, providing insights into the potential reasons for the model's "misinterpretation" of specific images. The study team will use HiResCAM [40] in the future for model explanation. HiResCAM serves the same functions as Grad-CAM but with the added benefit of highlighting only the regions used by the model.

***Abstract*—In recent years, there has been a lot of focus on gesture recognition because of its potential as a means of communication for cutting-edge gadgets. As a special category of gesture recognition, air-writing is the practice of forming letters or words in the air using one's fingers or the movements of one's hands. The primary objective of this study is to propose a classification framework with feature extraction techniques to enhance the recognition of vowel characters in the Tamil language. The data collection and classification procedure involved a set of 12 distinct letters. A methodology has been developed to facilitate the analysis of various configurations for the purpose of evaluation. To get useful features from the 2-second time window data segments, this study uses a one-dimensional convolutional neural network (1D CNN). In our approach, we employ five machine-learning methods to conduct our evaluation. These methods include Naive Bayes, Random Forest, K-Nearest Neighbor, Support Vector Machine, and Decision Tree. The classification algorithms are considered to be superior based on the results obtained from our dataset in this experiment. The results of the tests show that the suggested K-nearest neighbors (KNN) algorithm works very well when used with a k-1 and 0.6:0.4 split ratio for training and testing. Specifically, the KNN model achieved an accuracy rate of 91.67%. The present study builds upon previous research by utilizing applications that have been employed in prior studies. However, a unique aspect of our system is the integration of cutting-edge technology, which utilizes collected sensor data to classify the characters. The examination of the window size has the potential to enhance accuracy and performance.**

***Keywords*—Air-writing; Tamil alphabetical vowel; convolutional neural network; feature extraction; machine learning**

I. Introduction

The recent advancement in technology breaks the barriers to communication between users and computers. The communication between users and computers includes emotion and gesture recognition. Gestures offer a complementary mode of interaction for standard human-computer communication. New types of user interfaces made possible by gestures are especially well suited for portable and wearable computer systems. As a subset of gesture recognition, air-writing recognizes characters and numbers written in the air using the hand. Touchscreens and other technological gadgets have become fashionable in today's information-driven society, and a majority of individuals are comfortable using them [1]. As a result, air-writing recognition systems are gradually becoming more adaptable using wearable sensors and state-of-the-art techniques [2], [3], [4], [5].

Languages consist of alphabets that are combined to make meaningful words and are utilized for communication [6]. Therefore, these alphabets possess both symbolic and phonetic characteristics [6], [7]. The recognition of the air-writing characters of a particular language can be distinguished based on their symbolic structure [7], [8]. Most alphabets in any language consist of several complex motions, which means that sometimes a single sensor may not be enough to recognize these alphabets.

Usually, traditional handwriting styles of languages encompass two primary forms: cursive and print letters. Air-writing character recognition is done using information gathered from six-degree free-range hand motions. In air-writing each isolated letter is written in a virtual space. For user interfaces that do not allow users to type on a keyboard or write on a trackpad or touch screen, as well as for text input for controlling smart systems and many other applications, air-writing is extremely helpful [9], [10], [11]. Air-writing has been found to be a highly effective method for various applications, including but not limited to device control, entertainment, health care, and education.

The categorization of air-writing recognition approaches can be delineated into two distinct classes: Vision-Based Recognition (VBR) algorithms and Sensor-Based Recognition (SBR) algorithms [3], [12], [13]. The VBR algorithms are designed to execute gesture recognition tasks using image data acquired through a camera device. According to Amma's research, it has been observed that achieving accurate classification in image processing tasks can be feasible [4]. However, it is important to note that this process often demands substantial computational resources. Specifically, significant computational efforts are necessary for extracting relevant information from images during both the training and inference stages. This finding underscores the importance of considering the computational aspect when designing and implementing image processing algorithms [12]. The study conducted by Amma et al. [4], sheds light on the potential challenges associated with image-based classification tasks and highlights the need for efficient computational strategies in order to achieve optimal results. The techniques employed in SBR (Sensor-Based Recognition) are fundamentally rooted in the utilization of sensors. Accelerometers, gyroscopes, flex sensors, electromyography (EMG), Radio Frequency Identification (RFID), and the integration of these sensors have been widely employed in various applications [5], [14].

In the context, of hand gesture identification using SBR,

accelerometers are widely used sensors in various applications because of their practicality, affordability, and durability [13], [15]. They have been extensively utilized in numerous prediction systems [16]. Wearable technology, such as smart phones, provides an optimal platform for the collection and monitoring of data [10], [17]. Furthermore, it has been reported that placing the sensor component on the wrist is the optimal placement position for a high degree of accuracy [5]. In some SBR-based studies, high classification accuracy for gesture recognition has been observed [2].

However, many of these techniques do not support the recognition of a sequence of gestures. Only isolated gestures can be recognized [19]. Furthermore, some SBR techniques are used for gesture recognition, which may incur high computation complexities [18]. The Recurrent Neural Networks (RNNs) and their variants, such as the Long Short-Term Memory (LSTM) algorithm, are effective for the recognition of gesture sequences with low computation costs [12], [19], [20], [21].

Many emerging algorithms have been proposed as the availability of temporal data has grown substantially in recent years [22]. To show time series as feature vectors, people often use dynamic time warping (DTW), simple statistics, complex mathematical methods, and other similar methods. For classification, they use algorithms that range from shallow learning to deep neural network models [23]. In addition, models like recurrent and convolutional neural networks (CNNs) incorporate feature engineering internally and automatically [24]. The One-Dimensional (1D) CNNs are effective for several applications, such as the classification of ECG signals [19], human activities, and internet traffic [16], [18], [25], [26], [27]. Researchers have found that using CNNs to classify time series is better than other methods in a number of important ways. This is because CNNs are very good at ignoring noise and can pull out very useful, deep features that are not affected by time [28]. In the context of CNN, one-dimensional convolutional neural networks (1D CNNs) excel at extracting useful features from smaller (fixed-length) subsets of a larger data set [29] and at analyzing audio signals, cyber security, NLP, and time series data from sensors [18], [30].

The majority of previous studies focused on the recognition of the English alphabet, where most of the alphabets are mostly drawn with lines that could subsequently be identified with the changes of the sensors [31], [32]. Some of the previous studies dealt with the designated devices for data collection and identification of the characters in second-language learning [33], [34]. Moreover, no prominent dataset is shared in publicly available sources.

Sensor-based air-writing has significant importance for the Tamil language alphabets. The recognition of handwritten words from a digital writing pad using sensor-based techniques can greatly benefit Tamil language learners and users. Jayanthi & Thenmalar (2023) proposed a method for recognizing handwritten words from a digital writing pad using the MMU-SNet algorithm [8]. The Tamil script is conventionally written in a horizontal manner, progressing from left to right. Its fundamental repertoire of characters encompasses 247 letters, including 12 vowels, 18 consonants, 12 vowels by 18 consonants (216), and 1 unique character [7]. The Tamil script is commonly recognized for its distinctive rounded shapes, leading to its colloquial designation as the "round alphabet" [6]. This approach can accurately capture the unique characteristics of Tamil alphabets, which have a smaller number of lines, angles, curves, and bends.

The study mainly improves the motion gesture recognition approach for six degrees of freedom (DOF) for air-written Tamil language characters. In the initial phase of the study, in spite of the motion movements, isolated air-writing characters are analyzed and identified. Motion sensing is done with sensors that are attached to the back of the palm. This led to a great deal of interest in the potential of wearable technologies for air-writing. A comprehensive list of features is extracted from the dataset of 3-axis signals from five different sensors with 1D CNN.

The present study focuses on the investigation of the recognition process pertaining to isolated characters that are written in a continuous single-stroke manner. This study employed one specific dataset, which was collected as part of the study. To sum up, this study presents the following contributions to the field of air-writing:

The authors have

- Collected the sensor data for 12 vowels of the Tamil alphabet.
- Developed a light feature extraction approach using 1D CNN from the collected signal data and populated the dataset for the classification.
- Evaluated the performance of the classification models with few configurations.

By leveraging this study, this method enables the recognition of Tamil alphabets written in the air, providing a valuable tool for Tamil language learners and users.

The structure of this article is as follows: We go over the relevant earlier work in the part after that. The data collection techniques for air-writing, the feature extraction process, and the methods for modeling are described in Section III. Section IV presents the experimental design results and discussions. Section V contains the conclusion of the study.

II. Related Works

Air-writing refers to the process of writing characters or words in free space using finger or hand movements [31]. It is a form of gesture recognition where gestures correspond to characters and digits written in the air [32]. Air-writing has been studied in various contexts, including its effectiveness in language learning and its potential applications in handwriting analysis and recognition.

In previous studies, certain research endeavors have employed a specifically engineered apparatus to carry out the process of data acquisition. In contemporary times, a plethora of wearable devices, including but not limited to smartphones and smartwatches, have been integrated with various sensors such as accelerometers, gyroscopes, magnetometers, and other similar components. Various methodologies have been put forth in scholarly works to address the task of air-writing recognition, wherein it is regarded as a spatial-temporal signal [14].

The wearable input system for handwriting recognition proposed by Amma et al. in [4] utilizes an accelerometer and a gyroscope to effectively capture and analyze each of the complex gestures involved in air-writing. Another study conducted by [5], a range of alterations to the Hidden Markov Models (HMMs) were implemented in order to facilitate the identification and interpretation of air-writing patterns that were generated through the utilization of the Leap Motion Controller.

Agrawal et al. [2] introduced the PhonePoint Pen system on the Nokia N95, which leverages the inherent accelerometers present in mobile phones for the purpose of recognizing handwritten English characters. The findings of this study indicate that the identification of English characters can be achieved with a mean accuracy rate of 91.9%.

Furthermore, Xia et al. [10] presented a MotionHacker system that utilizes a smartwatch application to capture and analyze the dynamics of hand movement, thereby demonstrating the potential for motion sensor-based handwriting.

The proposed system in [15] introduces a novel approach to handwritten character recognition. It leverages the power of 3D accelerometer signal processing in conjunction with Convolutional Neural Networks (CNN) and Long Short-Term Memory (LSTM) models. In the experimental setup, a participant carrying a MYO armband. The data in the dataset corresponds to handwritten English lowercase letters (a–z) and digits (0–9) that were written in a freestyle manner. The findings indicate that the proposed system exhibits superior performance compared to other existing systems, surpassing them by a margin of 0.53%.

Wang and Chuang in [13] proposed a novel digital pen that utilizes an accelerometer for the purpose of recognizing handwritten digits and gesture trajectories. Subsequently, the collected acceleration signals are subjected to a process of feature extraction, wherein a hybrid approach was employed to identify the most discriminant features. This involved the utilization of kernel-based class separability to determine the salient features, followed by the application of Linear Discriminant Analysis (LDA) to reduce the dimensionality of the dataset.

Two air-writing recognition methods were discussed in this study [1] dynamic time-warping and a Convolutional Neural Network. To assess the efficacy of the methodologies, a total of 15 instances of the English alphabet letters were obtained through airborne inscriptions and subsequently captured utilizing a smart-band device. These data sets were procured from a diverse pool of 55 individuals. The findings from the comprehensive evaluation yield an exceptional accuracy rate of 89.2%.

The study [35], introduces a novel framework for air-writing using a convolutional neural network (CNN) that is dependent on a generic video camera. The utilization of transfer learning with the recently obtained data leads to a notable enhancement in the recognition accuracy. The framework that was proposed demonstrated recognition rates of 97.7%, 95.4%, and 93.7% in person independent evaluations conducted on English, Bengali, and Devanagari numerals, respectively.

Additionally, a novel approach is proposed for character recognition of air-written text through the utilization of a 2D-CNN model for seven datasets [27]. In recent years, there has been significant progress in the field of handwritten character recognition, largely attributed to the utilization of deep convolutional neural networks (CNNs). These advanced neural network architectures have demonstrated remarkable accomplishments, surpassing established benchmarks by substantial margins. Currently, there is a lack of a standardized dataset in the field of air-writing research, which hinders the ability to assess the effectiveness of various methodologies. In recent times, a number of datasets have been made available for the purpose of recognizing air-writing characters.

The study [25], was performed using four different datasets (WISDM, HARDS, SBRHA, PAMAP2) with various characteristics, as previously used by similar recognition research. However, this includes the investigation to test the selected features with a variety of sensor placement locations, such as waist, wrist, chest, and ankle, sampling frequency, and the performance of the dataset. The purpose of [20] is to investigate the impact of window lengths with orientation invariant heuristic features on the performance of 1D-CNN-LSTM using data from 42 participants to recognize six human activities: sitting, lying down, walking, and running at three different speeds using information gathered from the Samsung Galaxy s7 smartphone's accelerometer sensor with the pre-installed Ethica application.

There are multiple benefits associated with the utilization of one-dimensional convolutional neural networks (1D CNNs) [28]. These advantages include notable performance on datasets with limited amounts of data, reduced computational complexity in comparison to two-dimensional CNNs and other deep learning architectures, expedited training processes, and a strong capability to extract pertinent features from sequential data and time series, such as signal data [26], [36].

Attributes capable of capturing patterns over a sliding window are formulated in the feature extraction phase. Time-domain features, frequency-domain features, and time-frequency-domain features are the three broad categories established by applying elementary statistical techniques to the features.

The impact of the one-dimensional convolutional neural network (1D CNN) technique on the field of air-writing recognition has been substantial. Numerous studies have been conducted to investigate the application of deep convolutional neural networks (CNNs) in the field of air-writing recognition, and these investigations have consistently proved the efficacy of such networks [20], [29].

Additionally, CNNs can be employed to analyze 1D signals, including electrocardiograms (ECG), electroencephalograms (EEG), and electromyograms (EMG), in healthcare applications. Lastly, CNNs can be utilized for machine fault detection purposes, among other applications [23]. The use of 1D CNN algorithms in sensor-based air-writing has made significant contributions to the field. These algorithms have been employed to recognize and interpret air-written characters and gestures accurately. The researchers investigated air-writing recognition using a 2D CNN model [32]. They extensively studied different interpolation techniques on publicly available air-writing datasets and developed a method to recognize air-

written characters. Their findings highlighted the importance of choosing the proper interpolation technique for accurate recognition.

Few researchers have developed a simple yet effective air-writing recognition approach based on deep CNNs [9]. Their method utilized a 1D CNN architecture to recognize air-written characters. The results showed that the suggested method was very good at reading handwritten characters, showing that 1D CNNs could be useful in this area. The authors proposed an approach for air-writing recognition based on deep convolutional neural networks (CNNs).

Furthermore, [21] developed a wearable IMU-based human activity recognition algorithm for clinical balance assessment using a 1D-CNN and GRU ensemble model. Although this study focused on human activity recognition, the use of a 1D-CNN model demonstrates the potential of this algorithm in capturing and analyzing sensor data for various applications, including air-writing.

Furthermore, the use of 1D CNNs has been explored in other domains as well. applied a 1D CNN algorithm for the detection of water pH using visible near-infrared spectroscopy [28]. They interpreted the learning mechanism of the 1D CNN through visual feature maps generated by the convolutional layers. This demonstrates the versatility of 1D CNNs in various applications, including air-writing recognition.

In the field of handwriting analysis and recognition, air-writing has also been explored. Researchers have highlighted the importance of analyzing handwriting not only on paper but also in the air before the pen touches the paper. Significant differences have been observed between these two writing conditions [37]. Additionally, studies have focused on developing recognition systems for air-writing using deep learning and trajectory-based approaches. These systems utilize techniques such as deep neural networks and depth sensors to accurately recognize and track air-written characters [32], [11].

In a nutshell, the use of 1D CNN algorithms has made significant contributions to air-writing recognition. The studies mentioned above have demonstrated the effectiveness of deep CNNs in accurately recognizing air-written characters. The utilization of one-dimensional convolutional neural networks (1D CNNs) in the analysis and interpretation of intricate patterns in air-writing movements has facilitated progress and innovation in this particular domain.

Furthermore, the detection and tracking of fingertip movements in air-writing are crucial for accurate recognition. In [31], developed a fingertip detection and tracking algorithm specifically for air-writing recognition. This algorithm outperformed state-of-the-art approaches, achieving a mean precision of 73.1

Sensor-based air-writing offers several advantages for Tamil language learners and users. It provides a more interactive and immersive learning experience, allowing learners to practice writing Tamil alphabets without the need for physical writing materials. This can be particularly beneficial for learners who may have limited access to writing resources or prefer a more hands-on approach to learning. Additionally, sensor-based air-writing systems can provide real-time feedback and evaluation, helping learners improve their writing skills and accuracy.

In conclusion, sensor-based air-writing methods like reading handwritten words from a digital writing pad and finding and following fingertip movements are very important for the Tamil language alphabets. These techniques enable accurate recognition and analysis of Tamil alphabets written in the air, offering valuable tools for language learning, practice, and evaluation.

Our study differs from the existing studies in multiple aspects. Most of the prior research only used statistical equations to extract small subsets of features from the time domain, frequency domain, and time-frequency domain. Some of these studies also relied on publicly available datasets that were used for the purpose of the research. In contrast, this paper utilizes 1D-CNN to extract a complete set of features from five sensors' raw data. This investigation follows a multi-stage process and employs state-of-the-art techniques. In addition, unlike previous work, which relied on publicly available datasets, this study used data on Tamil alphabet recognition that was collected independently.

III. Methodology

A flowchart for the proposed air-writing recognition system is shown in Fig. 1. An approach is employed in our research for the purpose of 6-DOF character recognition.

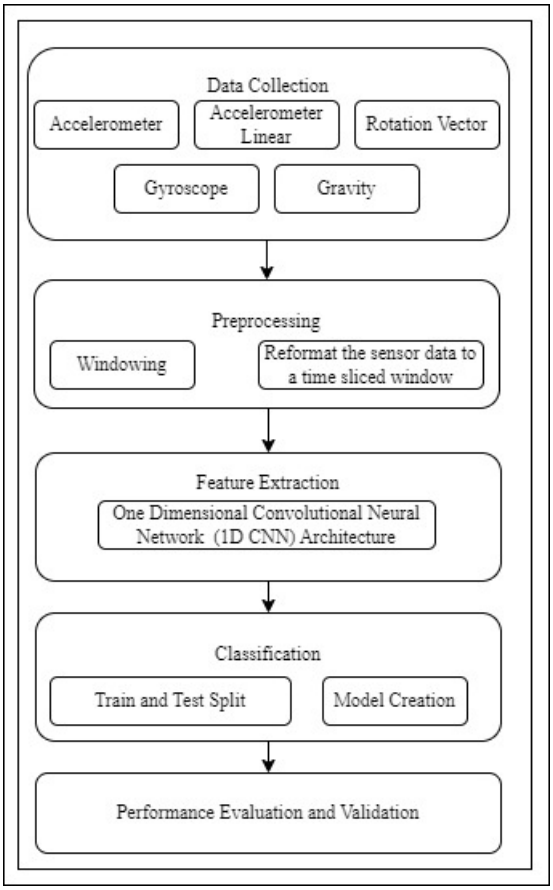

Fig. 1. The research flow.

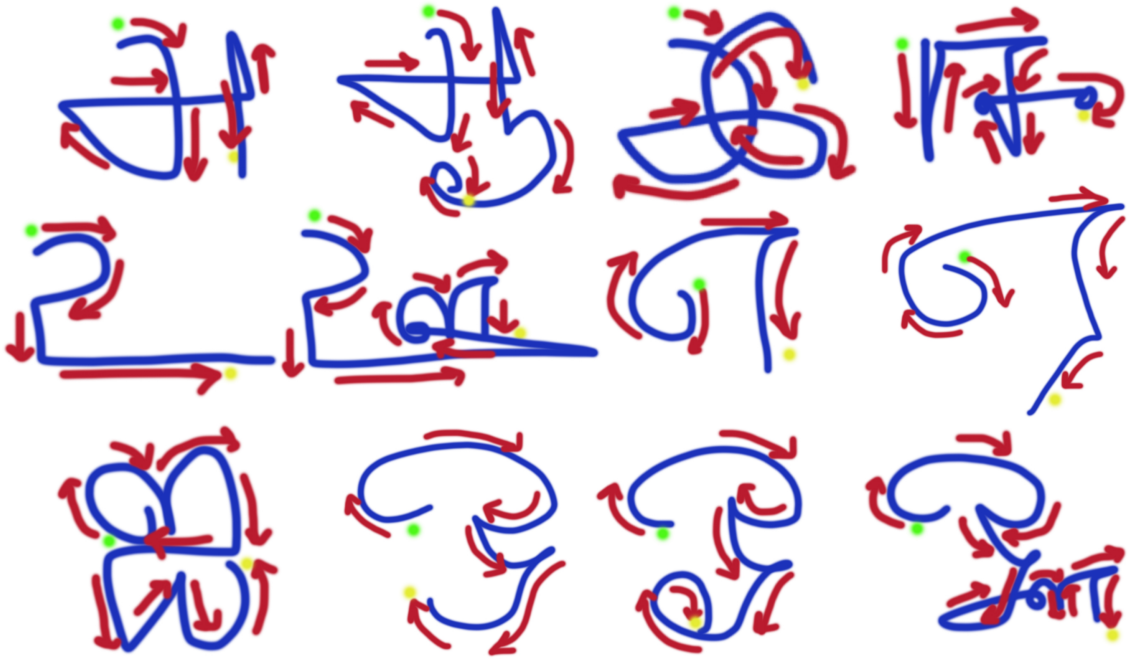

Fig. 2. The isolated characters of tamil vowel alphabets are written using a single continuous stroke, where the paths of the stroke are shown with arrows. The starting and ending points are denoted with green and yellow color dots, respectively.

A. Writing with Six Degree of Freedom (DOF)

Writing in the air differs significantly from writing by hand on paper or another surface. The writing is naturally reproduced in the air in uni-stroke without any pen-up or pen-down information, instead writing in a box in the imagined space without tactile input. Air-writing is tracked with a continuous stream of sensor data.To our best knowledge, we are the first to evaluate the rounded alphabet, i.e., Tamil language vowel recognition with axis-independent motions.

A total of five participants, all of whom were right-handed, were selected for the purpose of collecting air-writing data. Participants were instructed to maintain consistency in their writing style, including the use of a standardized writing scale, stroke order for each letter, and speed of writing. Each participant was given the opportunity to engage in a practice session before data collection commenced. Each instance of isolated motion characters was meticulously documented on different occasions by each participant.

The tracking system utilizes a smartphone device, which is monitored through an independent application. The application utilizes the input features to effectively acquire and record the sensor data associated with the task of writing. Subsequently, participants were provided with detailed instructions regarding the functionality and operation of the mobile application, as well as a comprehensive overview of the data collection procedure. Each participant carried an OPPO A12 smartphone attached to their right hand with the pre-installed application that can be recorded with five sensor data values with an interval of 10 ms. In order to mitigate the inclusion of extraneous movements, participants were instructed to execute the software with their non-dominant hand. Each letter was recorded separately. This was done in order to give the subjects the option to rest between recordings. and even change positions. The dataset pertaining to air-writing encompasses a comprehensive collection of 600 distinct samples for 12 vowels.

In order to enhance the machine's ability to recognize and expedite the user's writing process, the letters are subjected to a simplification process. Isolated characters are written using a single continuous stroke. The path of uni-stroke writing for different letters of Tamil vowel letters is illustrated in Fig. 2.

B. Preprocessing

Each individual sample, which corresponds to a single air-written letter, is regarded as a collection of distinct signals (time series). Based on the sensor data, it is possible to represent a writing motion as a spatio-temporal pattern. An analysis of the sensor values of the aforementioned sensors was performed in the spatio-temporal domain, wherein the relationship between sensor data is illustrated. The visual representation of the sensor data for the 12th vowel ('oow') is illustrated in Fig. 3. It serves as a tool for researchers to analyze and interpret patterns in the data collected.

C. Reformat Sensor Data into a Time-sliced Representation and Data Sampling

The variability in the duration of each signal's recording arises from the inherent characteristics of the writing and recording procedures. In accordance with the experimental design, a predetermined length, denoted as "l," has been established to ensure uniformity in the length of all signals

across all samples. Achieving a suitable time window is a challenging task. Each window is considered non-overlapping as the characters are isolated. The raw data from each of the windows is considered an occurrence.

The sensor data from five sensors is accumulated into a single CSV format. We have tried truncating to make the signals consistent in length. This study selected an arbitrary window length as the intermediate time taken to write each character.

We have used the programming language Python to execute the required preprocessing of the data and extract the features, respectively. We have used packages named Pandas and Numpy for performing feature extraction.

D. The Motivation for using CNN

Significant advancements have been made in recent years in the domains of sensors, smart sensors, artificial intelligence, and their integration. In the field of machine learning, there is a current trend towards the utilization of Artificial Neural Networks (ANN), Deep Neural Networks (DNN) which are the prevailing techniques in the deep learning domain, and Convolutional Neural Networks (CNN). These concepts have gained popularity, indicating an increasing scientific interest and subsequent contributions from the scientific community. [19]

CNNs, also known as convolutional neural networks, are a prominent class of deep learning models that are widely used in various domains. These models are characterized by their architecture, which typically includes multiple layers of convolutions. These layers are designed to leverage a collection of adaptable multi-dimensional filters. These filters are systematically moved across the various axes of the input sample [35].

In various domains, including industrial, clinical, and environmental sectors, it is frequently observed that one-dimensional (1D) data is prevalent. Examples of such sensor data include electrocardiogram readings, temperature measurements, environment-control variables, motion data, and power consumption data. One potential approach for modeling this information is the utilization of one-dimensional convolutional neural networks (1D CNN) [28], [29], [36].

In the context of a one-dimensional convolutional neural network (1D CNN), the filters are applied by sliding them along a single axis of the input data. In the present scenario, it is observed that all dimensions of the filter's size, with the exception of one, are predetermined to align with the sizes of the fixed axes. In recent times, their utilization has extended to the realm of Temporal Sequence Recognition and Time Series Classification as well, as evidenced by the growing interest in the area. Temporal Sequence Classification refers to the task of accurately categorizing sequences of data that are captured by inertial measurement sensors. The objective is to assign these sequences to specific, pre-defined activities that occur over extended periods of time [26], [36]. This classification process takes place within a continuous stream of data, requiring robust and reliable algorithms to achieve accurate results.

In the present investigation, the decision was made to employ Convolutional Neural Networks (CNNs) due to two primary justifications. Traditional machine learning methods typically depend on the extraction of explicit features. In contrast, it is worth nothing that deep neural networks, particularly convolutional neural networks (CNNs), possess the ability to directly consume the raw input data without the need for explicit feature extraction procedures. Hence, it is plausible to hypothesize that a methodology that has demonstrated efficacy in the domain of temporal data analysis and computer vision holds promise for achieving favorable outcomes in our specific context.

Next, the set of preprocessed samples is introduced into the architecture, and a mini-batch learning process is implemented. The architectural design of our one-dimensional convolutional neural network (1D CNN) classifier draws inspiration from the model. The architectural design consists of convolutional layers that are strategically interspersed with pooling layers. In this study, it is observed that all of the convolutional layers in the experimental setup employ filters with a length of 3200 and 1600. Additionally, the Rectified Linear Units (ReLU) activation function is utilized across these layers.

Given the nature of our task, which involves classifying data into distinct vowels, we have opted to utilize categorical cross entropy as our chosen loss function. This particular loss function is well-suited for categorical classification tasks.

In the context of sensor technology, irrespective of the specific domain of application, it is frequently observed that data pertaining to the one-dimensional (1D) shape is prevalent [20], [29].

E. 1D CNN Architecture for Creating Feature Vector

The conventional architecture of a Convolutional Neural Network (CNN) consists of three primary layers, namely the convolutional layer, pooling layer, and fully connected layer. The layers in question employ various components and techniques, including convolutions, activation functions, pooling, dropout, batch normalization, and fully connected blocks, among others. These elements can be flexibly combined in numerous configurations.

A 1D CNN (Convolutional Neural Network) can be constructed based on the following considerations:

- The input data is formatted in one dimension. The data for this study was obtained from five sensors installed on a sliced window.
- The convolutional layers are tasked with performing feature extraction operations. The extraction process involves the application of convolution operations to the input data, with the resulting convolutions being passed as input to the subsequent layer. The convolutional operations are determined by a set of filters, a specified kernel size, padding, and stride. These operations result in the creation of a feature map, which is obtained by applying a ReLU activation function.
- Pooling layers are typically applied following a convolutional layer, serving the purpose of retaining the information produced by the feature maps. The techniques on these layers include max pooling.

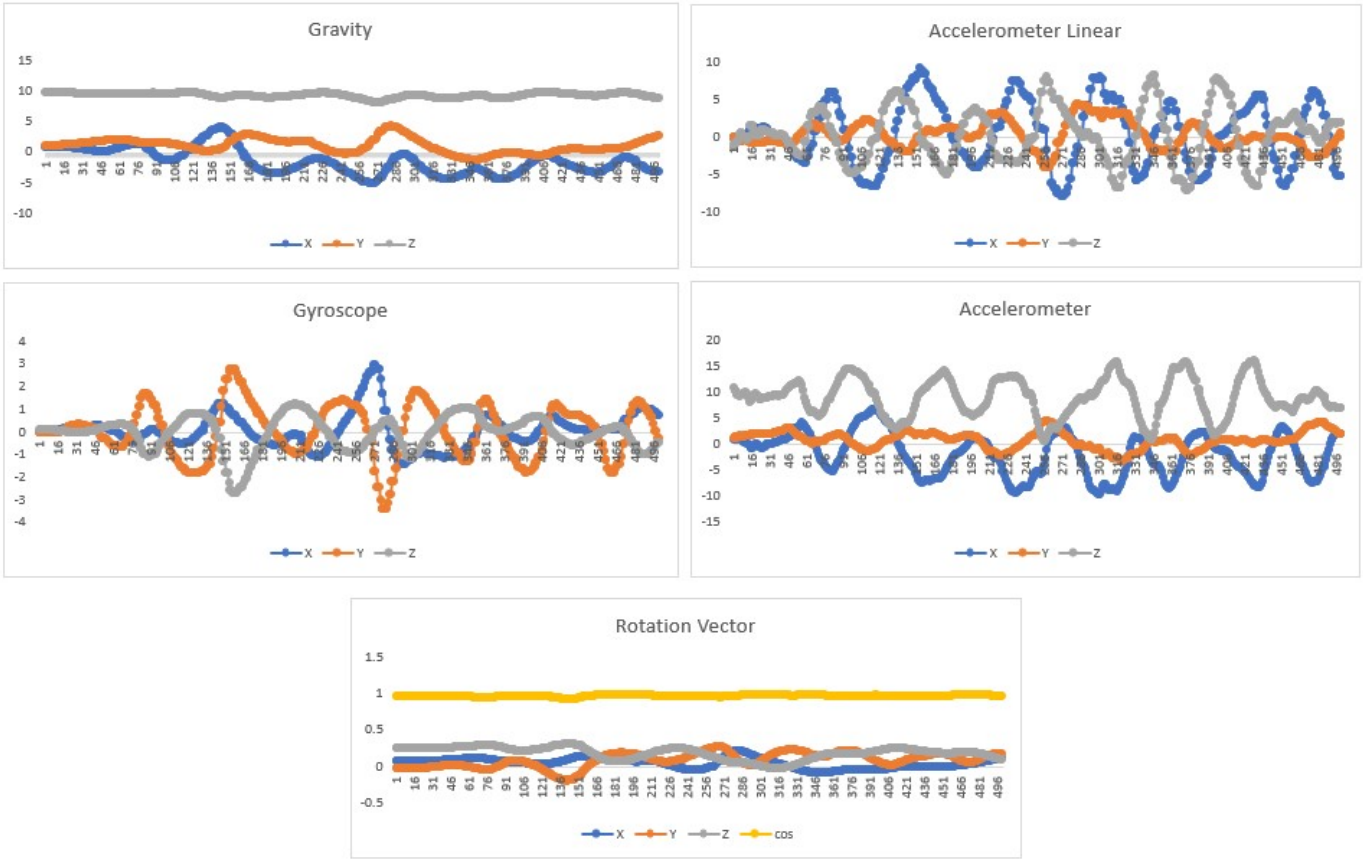

Fig. 3. The variation of the sensor data from five different sensors for the last letter of Tamil language vowel alphabet.

Model: "sequential_5"

Layer (type)	Output Shape	Param #
conv1d_15 (Conv1D)	(None, 3200, 32)	128
conv1d_16 (Conv1D)	(None, 3200, 64)	6208

Trainable params: 52657344 (200.87 MB)
Non-trainable params: 0 (0.00 Byte)

Fig. 4. The 1D CNN architecture.

The term "dropout" refers to an individual who leaves an educational institution before completing their program of study. The dropout technique is employed as a means of mitigating overfitting, and it can be implemented in both fully connected and convolutional layers. The technique involves randomly disabling certain connections within the neural network. This process ensures that individual neurons are able to be removed, thereby preventing them from exerting excessive influence on the model's output. Alternatively, the technique enhances the generalizability of the model.

The application of the corresponding experiments, which have resulted in the 1D CNN architecture for the problem, is presented in Fig. 4. The input layer will consist of 300 inputs, which correspond to the sensor data for Tamil vowel characters.

F. Population of the Dataset

In order to facilitate analysis, it is necessary to extract features from the signal windows, as the raw data itself is not suitable for direct analysis. This process enables the identification and capture of patterns within the data. Previous studies in the field of recognition have utilized both time domain and feature domain features in their analysis. 1D CNN uses filters on each window to extract features automatically. 1D CNN maps these internally extracted features to different Tamil vowel alphabets. The extracted features are tabulated with their vowel labels using the label encoding technique.

However, when the 1D CNN feature vector is combined with the machine learning algorithms, the extracted features from the 1D CNN are used as inputs for the selected machine learning algorithms.

G. Split up the Data Set into Train and Test Sets

To facilitate the training process of our network, we initially partition the dataset into two distinct subsets: a training set and a testing set. The division is performed in such a way that the training set comprises 80% of the data, while the remaining 20% is allocated to the testing set.

H. Train the Dataset with Machine Learning Algorithms for Tamil Air-writing Alphabet Recognition

In this modeling and dataset training stage, we develop a model for classifying the features into the Tamil language vowel alphabet, we utilize various classifiers of machine learning. The use of Naïve Bayes (NB), Random Forest (RF), Support Vector Machine (SVM), Decision Tree (DT) and k-Nearest Neighbors (KNN) model for classification. These classification-based algorithms are based on performance metrics that include accuracy, precision, recall, and f1 score.

It is worth noting that our dataset is balanced, where each vowel is represented equally, ensuring a fair and unbiased evaluation of our model's performance. Therefore, we have selected accuracy as our performance measure, which will allow us to assess the effectiveness of our model in correctly classifying the data.

I. Validate the Performance of the Trained against the Test Data using Cross-validation and Confusion Matrix

In the conducted experiments, the relevant algorithm metrics that were evaluated included the following measures: The accuracy of the model is being evaluated with 80:20 split dataset. In the present scenario, the research pair has designated classification accuracy as the appropriate performance metric. The accuracy was assessed by measuring the performance in four different splits that were done on the original dataset. The datasets were designated as training, and testing sets, with a split of 80%, 20%, 70%, 30%, 60%, 40% and 50%, 50% from the original dataset, respectively. The objective was to develop a model that effectively generalizes learning from data. Consequently, a solution that exhibited consistent and homogeneous accuracy values was deemed favorable, rather than solely prioritizing the highest accuracy values within individual sub-datasets.

In summary, the experiments assessed the impact of the variant on the accuracy of the data sets with the parameter tuning of the selected model.

IV. Results and Discussions

A. Preprocessing of Sensor Data

The sensor data from five sensors is analyzed with regard to the variation in the data values. However, each of the letters lapses at different time intervals. We have chosen 2s as the preliminary window for the time-sliced segmentation, as shown in Fig. 5. As many of the vowel letters end up in the long lines or curve lines as shown in Fig. 2, the additional time can be ignored.

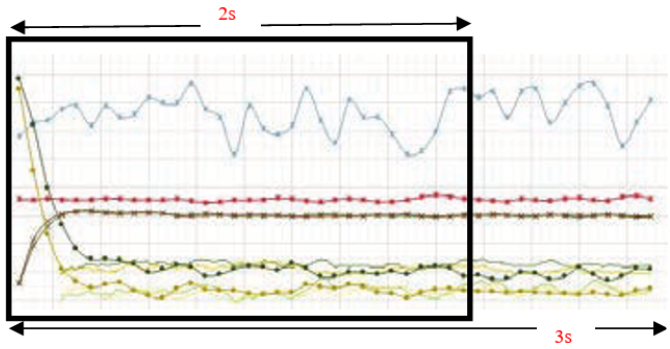

Fig. 5. The windowing process: the sensor data is sliced into the time window of 2s.

B. Feature Engineering Through 1D CNN

Each of the sliced windows of the sensor data was passed into the above-mentioned 1D CNN to create feature vectors. A total of 128 features were manipulated in the feature extraction stage, as illustrated in Fig. 4. Each of the feature rows in the feature matrix is labeled using a label encoder. The full feature set for the classification was populated in this manner.

C. Training and Testing of Dataset using Machine Learning Algorithms

As the initial step in this classification stage, the split training dataset is used for training, while the testing data is used for testing. The classification model was fitted with the training dataset. We have used five classification algorithms, such as Random Forest, Support Vector Machine, Decision Tree, Naive Bayes, and K-Nearest Neighbour. The analysis was first initiated with the 80:20 dataset split. It was found that we achieved the highest accuracy of 90.83% from the KNN algorithm. Fig. 6 shows the accuracy of the model in both testing and training. The accuracy for the training seemed to be 100% for RF, KNN and DT. However, in terms of testing accuracy, only KNN outperforms the others. We performed tests with numerous configurations. The first

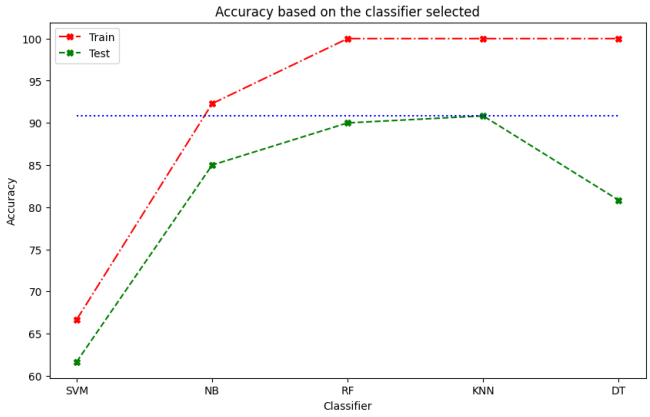

Fig. 6. The accuracy of the models (SVM,RF, NB, DT and KNN) during training and testing at 80:20 dataset split.

performance evaluation of the model is further extended using the accuracy for the different values of k. It was observed with

the variation of the k value, ranging from 1 to 30. The accuracy of the model reduces with an increase in the k value. However, there are some fluctuations at certain places where a small rise prevails in the fall. Fig. 7 clearly illustrates the variation in accuracy with the k value. The accuracy for classifying the air-written characters with k = 1 and k = 2 depicts the maximum accuracy of 90.83%. This means that with k = 1 or k = 2, the classification is more accurate compared with the other k values.

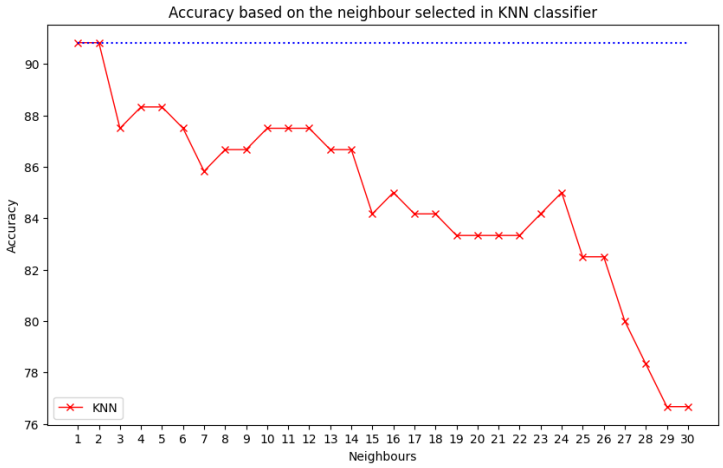

Fig. 7. The variation in accuracy with the change in k values.

Next configurations presented with the split percentage of 0.8, 0.7, 0.6 and 0.5 as training data and 0.2, 0.3, 0.4 and 0.5 as testing data, which had been taken into account for the evaluation of metrics. In this evaluation the k value is taken as 1, as it was obtained to be the highest accuracy. In Fig. 8, to classify the alphabets as per the samples used for training and testing, it has been observed that 0.6:0.4 achieves the maximum accuracy of 91.67% with the value k = 1, which shows the frequency of samples that are correctly classified to a specific air-written character within all the samples that are to be tested. Though the accuracy with the percentage of samples for 0.8, 0.7, and 0.6 increases, there is a sudden fall at the percentage of 0.5 of training data.

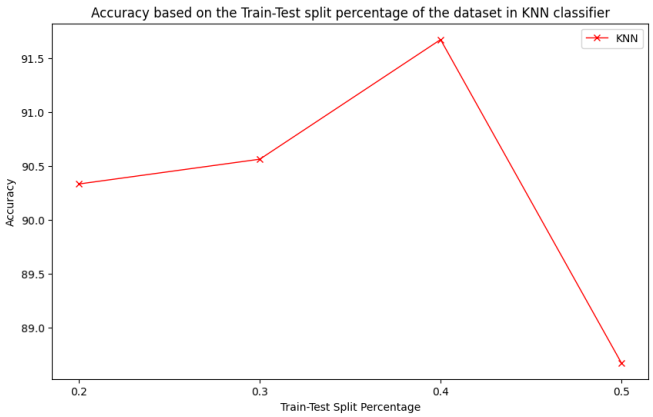

Fig. 8. The variation in accuracy with the change in the split percentage for KNN model, when k=1.

To provide the significance of the proposed model, its performance is being compared with multiple configurations. In this regard, the approaches are investigated that have been discussed previously.The confusion matrix of the model for the percentage samples of 0.6:0.4 and k=1 of KNN algorithm is shown in Fig. 9.

The accuracy, precision, recall, and F1-score of the classes of air-written characters are shown in Fig. 10. It was observed that the 3rd, 4th, 5th, 7th, and 10th characters can be easily distinguished from the others. The 6th, 11th, and 12th letters resembling the other letters show a lower accuracy rate. The evaluation has been performed with respect to the metrics used for the comparison.

The following are the findings of the evaluation:

- KNN outperforms the other classification algorithm.
- The value for k is chosen as 1 while varying from 1 to 30.
- The best test and train split is 0.6:0.4 for maximum accuracy.

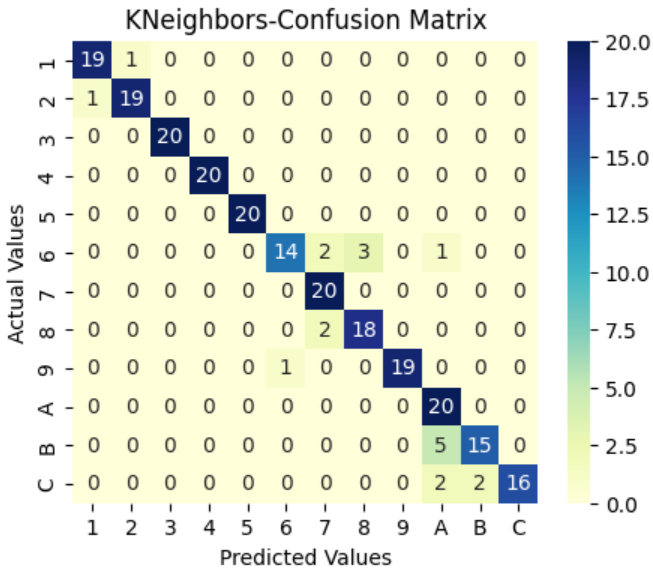

Fig. 9. The confusion matrix for KNN model when k = 1, with the 60:40 split percentage.

As this study has fully focused on the classification of the Tamil air-writing characters as of now, this is the first paper dealing with this objective.

D. Validation of the Performance

The validation of the model was tested with GridSearchCV with 10 folds for the above-identified configuration, and it was achieved with 93.33%. This study is summarized with the achievement of this accuracy in the initial phase of identifying the Tamil language air-written characters of vowel letters. We have achieved a considerable amount of achievement in the context of air-writing.

The process of identifying air-written Tamil characters poses numerous obstacles as a result of the distinct attributes

	precision	recall	f1-score	support
0	0.950000	0.950000	0.950000	20.000000
1	0.950000	0.950000	0.950000	20.000000
2	1.000000	1.000000	1.000000	20.000000
3	1.000000	1.000000	1.000000	20.000000
4	1.000000	1.000000	1.000000	20.000000

exhibited in handwritten Tamil, including variances in dimensions, styles, and angles of orientation. Moreover, the task of recognizing air-written characters presents intrinsic challenges due to the need to capture three-dimensional trajectories and employ suitable approaches for precise detection. This difficulty arises from the fact that many letters exhibit various features such as holes, loops, and curves. The study was conducted using a restricted dataset due to the unavailability of publicly accessible datasets. This work has the potential for further expansion through the comprehensive identification of all Tamil alphabetical characters. Additionally, enhancing the accuracy can be achieved by increasing the dataset and modifying the window size.

V. Conclusions

This paper focuses on developing a classification framework that employs a selection of features to assist us in recognizing Tamil vowel characters. A total of 12 different letters were used with the data collection and classification procedures. We have used a methodology for analyzing multiple configurations for evaluation. Initially, 1D CNN is used for feature extraction from the 2s of time window data segments. An evaluation is based on the results of five machine-learning methods: Naive Bayes, Random Forest, K-Nearest Neighbor, Support Vector Machine, and Decision Tree. The experimental results show that the proposed KNN achieves high accuracy with k = 1 and 0.6:0.4 train test split percentage with 91.67% accuracy. However, in validation using GridSearchCV this model has achieved an accuracy of 93.33% with 10 folds. Our findings were based on applications utilized in prior studies; however, as a novelty, the system provided employs collected sensor data to classify the characters by integrating the framework with cutting-edge technology. It is possible to increase the accuracy performance by examining the window size.

***Abstract*—The automated generation of speech audio that closely resembles human emotional speech has garnered significant attention from the society and the engineering academia. This attention is due to its diverse applications, including audiobooks, podcasts, and the development of empathetic home assistants. In the scope of this study, it is introduced a novel approach to emotional speech transfer utilizing generative models and a selected emotional target desired for the output speech. The natural speech has been extended with contextual information data related with emotional speech cues. The generative models used for pursuing this task are a variational autoencoder model and a conditional generative adversarial network model. In this case study, an input voice audio, a desired utterance, and user-selected emotional cues, are used to produce emotionally expressive speech audio, transferring an ordinary speech audio with added contextual cues, into a happy emotional speech audio by a variational autoencoder model. The model try to reproduce in the ordinary speech, the emotion present in the emotional contextual cues used for training. The results show that, the proposed unsupervised VAE model with custom dataset for generating emotional data reach an MSE lower than 0.010 and an SSIM almost reaching the 0.70, while most of the values are greater than 0.60, respect to the input data and the generated data. CGAN and VAE models when generating new emotional data on demand, show a certain degree of success in the evaluation of an emotion classifier that determines the similarity with real emotional audios.**

***Keywords*—Emotion transfer; contextual information; speech processing; generative models; variational autoencoder; conditional generative adversarial networks; empathetic systems**

I. Introduction

The creation of empathetic systems, capable of understanding and responding to human emotions, marks a significant advancement in artificial intelligence. Empathetic systems hold the promise of transforming human-machine interactions, offering not just responses but genuine understanding. However, this task presents a profound challenge. During speech processing, the subtle nuances of human emotions often dissipate, making it a complex endeavor to imbue artificial intelligence with empathy. Preserving these emotional characteristics during speech processing remains an open issue in the field of AI.

It is expected in the near future to have home assistants capable of not only recognizing when people surrounded are feeling sad, happy, or anxious but also responding with appropriate empathy [1]–[3]. Such a system could offer invaluable support especially to the vulnerable population, providing comfort to the lonely, reassurance to the anxious, joy to the despondent and safety to children and seniors. The potential applications are vast, extending beyond homes to healthcare, customer service, and mental health support. Achieving this level of artificial empathy stands at the frontier of AI research, requiring innovative solutions to bridge the gap between raw data and the rich emotional tapestry of human speech.

There are several models proposed to achieve this target, including generative and non generative models.

Generative models have emerged as valuable tools for the synthesis of speech audios. These models offer the unique ability to create audio data that captures the nuanced patterns and complexities of human speech. Variational Auto-Encoders (VAEs) [4], [5] for instance, provide a structured approach to encoding and decoding data, allowing for the generation of diverse, high-quality audio samples. Conditional Generative Adversarial Networks (cGANs), on the other hand, introduce conditional factors, enabling the generation of speech data with specific attributes, such as different emotional states or gender-specific characteristics. These generative models excel in creating natural-sounding speech and have the potential to revolutionize applications like voice assistants, speech synthesis, and emotional speech generation.

Despite their promising capabilities, generative models also come with inherent challenges. One notable drawback is the risk of generating audio samples that, while coherent, may lack the nuanced emotional expressiveness present in natural human speech. The delicate interplay of pitch, rhythm, and intensity that defines emotional speech can be challenging to replicate accurately. Furthermore, generative models may struggle with gender-specific patterns, such as pitch variations and resonance differences between male and female voices. Additionally, ensuring the generated audio remains consistent with the intended emotional state or gender identity presents a significant challenge. These difficulties underscore the need for continued research and development in the field of generative speech modeling, particularly in the context of emotion, gender, and natural speech synthesis [6], [7].

There are several non-generative models used for speech synthesis, including Hidden Markov Models (HMMs) [8],

Long Short-Term Memory (LSTM) networks [9], and deep neural networks (DNNs) [10], [11]. While these models have proven effective in certain aspects of speech processing, they exhibit limitations that generative models, like VAEs and cGANs, can address.

One limitation of traditional non-generative models, such as HMMs and LSTMs, is their reliance on a fixed set of acoustic features or linguistic representations. These models often struggle to capture the rich nuances of natural speech, including emotional variations and gender-specific characteristics. The adaptability of non-generative models to generate highly expressive and contextually rich speech remains limited. Furthermore, these models may require extensive data preprocessing and manual feature engineering, making them less flexible and more labor-intensive in comparison to generative models.

Generative models, on the other hand, have the potential to overcome these limitations [12]–[14]. They can operate in an end-to-end fashion, learning complex patterns without the need for extensive feature engineering. By leveraging latent spaces, conditional information, and adversarial training, generative models can synthesize speech that better resembles natural human communication, including emotional variations and gender-specific traits. This adaptability and capacity to capture nuanced characteristics make generative models an attractive choice for applications where high-fidelity and emotionally expressive speech synthesis is crucial, such as the creation of diverse empathetic systems. Nonetheless, it is essential to recognize that both generative and non-generative models have their own strengths and limitations, and the choice between them depends on specific task requirements and constraints [15]–[21].

In this work, two generative models such as variational auto-encoder and conditional adversarial network were utilized, to train speech audio data, contextual audio data and an emotional selected target on demand, to generate an emotional speech audio with the target emotion. In this proposed case study, we also show how a neutral speech audio with a specific gender and a specific contextual data input (laughing by giggling, angry by shouting, crying sound, etc.) is converted into a happy speech audio automatically by the variational auto-encoder model. For the creation of the testing data, a TTS system is used by selecting a gender specific voice and an utterance close in pronunciation to the trained data.

To the best of our knowledge previous research works did not propose an emotional speech transfer on demand that train extended generative models such as VAE and CGAN with speech data and contextual related cues in gender and emotion. Furthermore, a TTS system is utilized to generate testing data for the proposed case study with a trained variational auto-encoder model and additional contextual cues.

The paper is structured as follows. Subsequent sections of the introduction section, sequentially detail the proposed approach and associated experiments, incorporating comprehensive information on data preprocessing, experimental methodologies, and results. Following this, the case study section is introduced to illustrate a practical application, featuring the integration of real Text-to-Speech (TTS) samples with the utilization of the proposed model and custom data. The following discussion section serves to expound on the evaluations and results pertaining to both models, delineating inherent limitations and identifying potential avenues for further research or enhancements. Lastly, the conclusion section encapsulates final remarks on the presented works and outlines prospective future endeavors.

II. Proposed Approach

In this proposed work, the functionality of a variational autoencoder model and a conditional adversarial network model were extended, for learning emotional patterns that have associated emotional contextual audio data, such as crying, shouting and laughing by giggling sounds. The sad emotion is associated with the crying sound, the angry emotion with the shouting sound, the happy emotion with the laughing by giggling sound and a normal emotion has a simple whisper sound of 1 second pattern.

The dataset used is an extended Ravdess dataset. The Ravdess database contains 24 professional actors (12 female, 12 male), vocalizing two lexically-matched statements in a neutral North American accent, “Kids are talking by the door” and “Dogs are sitting by the door” for speech and sing. Speech includes neutral, calm, happy, sad, angry, fearful, surprise, and disgust expressions. The selected data from Ravdess dataset is audio-only with 1 second recoding for 24 actors, equally gender balanced, with additional 24 equally balanced contextual audios that match by gender and by emotion.

The selection of contextual data associated is random, forming a total of a 2 second recording for input data. However, the model cannot distinguish this associated data, since is using it directly as a complete input data. The contextual audio data is firstly divided by gender, into female and male data. Even though the speech audio used correspond to a female or male specific voice, we did not associate the same exact voice by gender with the same pattern male/female voice. This is due to the generalisation of the voice we do have while laughing, crying or shouting and singing, where the voice is difficult to be perfectly recognised.

The generative models used benefit in different ways. The variational autoencoder model will keep training in an unsupervised manner, because after training, once we input a data with a specific associated contextual audio, and an additional gender specific voice speech input, the variational autoencoder will try to reconstruct the emotion present in similar audios. Therefore, trying to reconstruct the weak emotional speech part into a stronger emotional speech. For example, when people speech is happy, people use to laugh by giggling, and these two correlated actions we expect that our models will capture the essence and associate both action into one emotional concept. Certainly, other external noises from the context could be learnt by the models, however there will be not correlation with the emotional speech we emphasised.

The generative adversarial network in counterpart, will use the same input data but to feed the discriminator that during training passes information to the generator loss, and therefore to the generator itself. In this case, we do not expect the generator of CGAN model to be as good as the VAE encoder and decoder. This assumption is based on the CGAN model specifications, where after training, we ask the generator to

generate a happy audio but we cannot ensure which samples it will create in relation to gender and utterance given. This issue is improved when we train data by gender (male or female, but not both of them), or by specific utterance which is very restricted in terms of the usage of TTS normal emotion generated input audios. Therefore, for the case study we will show an example based on a variational auto-encoder model instead, when giving a TTS neutral audio voice as an input, setting the gender and the utterance that is expected to be reconstructed.

The VAE and CGAN models will try to transfer the emotion in a new audio file. It is important to mention the limitations we feat with this approach. The first limitation is the reconstruction of the input and the generation of the target data. The input data origin was initially separated, which causes that the output received by each model should also be treated separately at the end. This will cause the data to be more noisy and more difficult to reconstruct as an audio file.

Another important point is that these models produce noisy results with complex data, and speech data enter in that category. Times series data cannot be manipulated such as the image data because rotating, flipping, augmenting or shifting the data for images will not affect the final position or structure of the objects in an image, but it will completely corrupt our times series data. Therefore, we made a great effort while passing through these models to leave the data without manipulating it, whenever was possible during the emotional transfer process.

The details of the architecture of the proposed models are shown in Fig. 1, 2 and 3, respectively.

The input data of VAE and CGAN architectures, is a combined audio data between a 1 second speech audio from Ravdess dataset audios, with a connected 1 second associated emotional contextual information in a form of audio. Therefore, the two audios are concatenated into one audio with 2 seconds of total duration and the same sample frequency, 44100Hz. As previously mentioned, the relation between the speech data and the contextual information is the weakly emotional pattern present in Ravdess dataset, and specifically, the gender present in each speech audio data. As it was mentioned, it significantly differs from using any other unrelated noise that would not be useful in terms of our target, which is the emotional transfer. For our case study we extracted the log Mel spectrogram data and converted them into images.

Our proposed model architecture for VAE for training and testing can be observed in Fig. 1 and 2, respectively. The basic architecture of the VAE model has two associated networks, called encoder and decoder, which are connected by the latent space representing the probabilistic part of the model.

The proposed CGAN model's architecture can be observed in Fig. 3. In this figure we can identify two main parts, that serve as networks, the generator and the discriminator. The discriminator will output the fake or real classification affecting the discriminator loss or the generator loss being mutually exclusive results. The generator cannot see directly the input images which make it more difficult to learn the emotional patterns in the input audios, but while receiving the generator loss information it will learn to generate them as closer as possible to the original input data. In this case we assumed

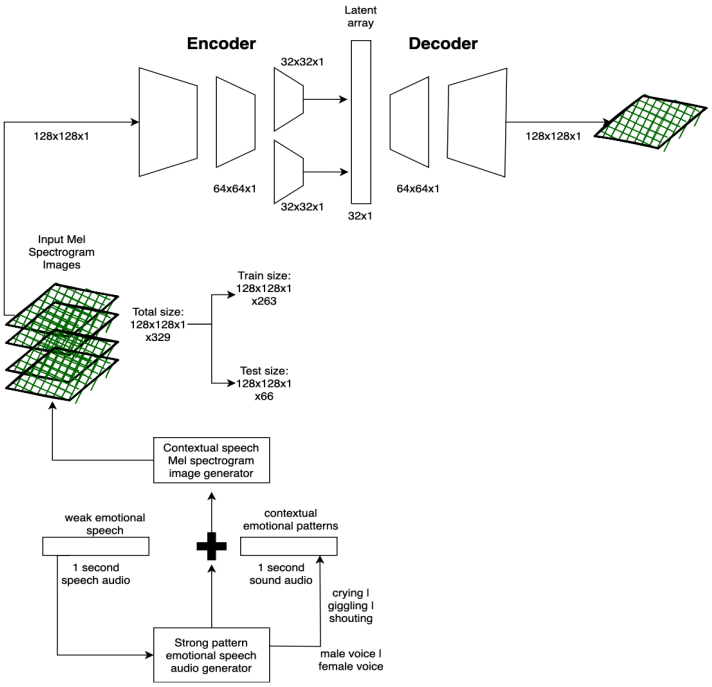

Fig. 1. Proposed architecture of the VAE model for training.

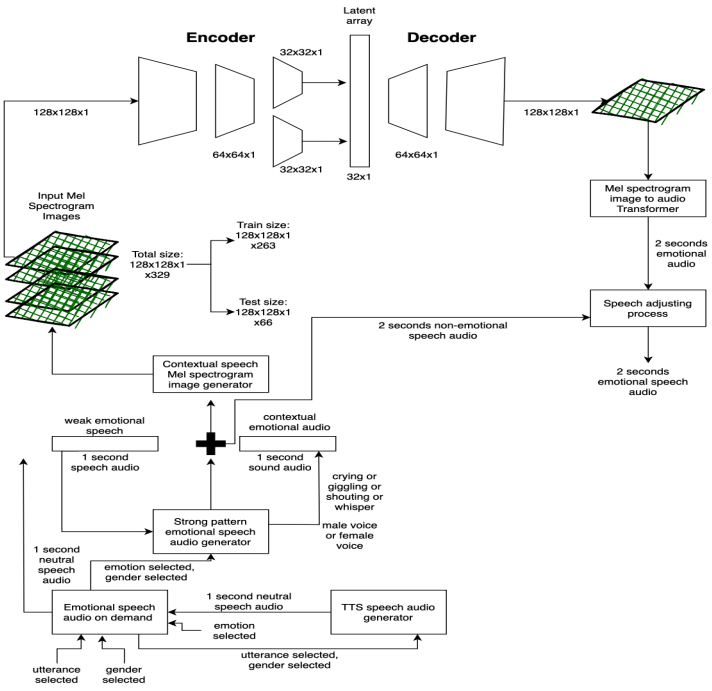

Fig. 2. Proposed architecture of the VAE model for testing.

some restrictions in the gender training to be male or female and not both of them, because CGAN is not good in terms of managing multiple conditions at the same time. In the testing of the CGAN model, the generator of the model is directly asked to produce the emotional data by emotion selected label.

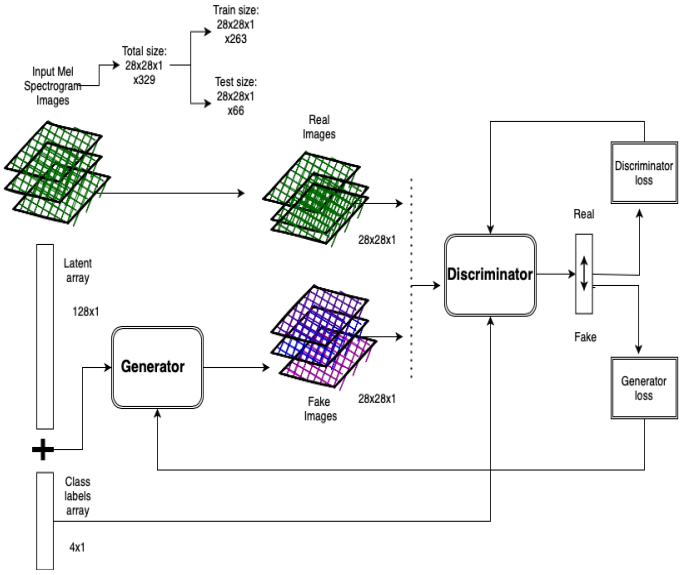

Fig. 3. Proposed architecture of the CGAN model for training.

In each model, the loss function is affected by the phonetic regularization with the extraction of the formants F1 to F5, presents in the Mel spectrogram data.

III. Experiments

A. Data Preprocessing

The input audio data before transforming into log Mel spectrograms can be observed in Fig. 4. This data were used for training, for the VAE and CGAN model to recognizse the happy speech and the contextual data that are usually present in a normal conversation. We limited our research to a one side speaker to be analysed.

The first audio A represents the speech of a male speaker from the Ravdess dataset that has an original duration of 3 seconds. The utterance in this happy speech is saying "Dogs are sitting by the door". The identification number in the original Ravdess dataset is "03-01-03-01-02-01-09" and is open to the public. This happy audio does not sound happy to our ears, since it is part of a weak emotional dataset, which is one of the reasons why the emotional transfer is complex to achieve in time series data. As can be observed in the image, the audio A contains zero data in the beginning, and at the end of the speech. With the aim to eliminate the non-useful data, the audio was reduced into a 1 second audio, while remaining the speech content.

The second audio B remains in 1 second, since originally each contextual data has 1 second of duration. This represents naturally what happens with human beings, since usually our laughing takes about the same time in being produced. The combination results in a total duration of 2 seconds for the concatenated audio C. These preprocessing tasks provide the desired adjustment, while maintaining a consistent audio quality.

The contextual information related to emotion is added as follows. We selected 6 audios per gender and per weakly emotion to add to any weakly emotional audio that matches by gender and emotion class, and chosen randomly. This is possible, given that, while singing or making emotional noises, we can not perfectly distinguishing these pattern belonging gender and voice. The duration of each audio is 1 second, its sampling rate is 44100Hz and its format extension is WAV. For happy emotion, we selected 6 female giggling patterns and 6 male giggling patterns, in total 12 audios for constructing the emotional extended audios. In the case of sad emotion, we selected 6 female crying pattern audios and 6 male crying pattern audios. When selecting the angry audios, we picked 6 female and 6 male shouting audios. However for neutral pattern audios we selected 6 female and 6 male whisper and natural English speaking pauses, such as, "Emmmm....", "AHA....", "Ahhhh....", "cause.....", and so on, where the utterance is almost not listened.

All the training and testing audios were denoised, trimmed and adjusted by volume, especially the audio B, since many artefacts were present. This is because it is custom data, downloaded freely from the Freesound site. Generally, custom data has many artefacts content present in the audios.

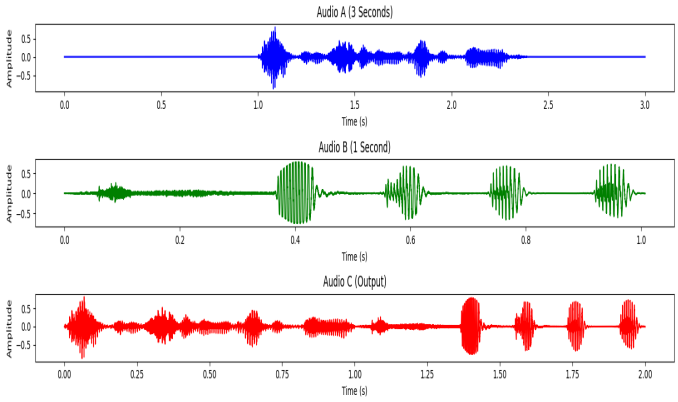

Fig. 4. Original audios A and B representing a happy speech, preprocessed and combined into one audio output file C.

The following step after gathering the clean concatenated audio is to transform the audio into frequency domain. The log Mel spectrogram image data generated for testing, as a case study can be observed in Fig. 5. The sampling rate is 44100Hz, the number of FFTs is 2048, with a hop length of 512. For the VAE model the target size is a 128 by 128 image. For the CGAN we selected the target 28 by 28, because CGAN generates better results with smaller sizes of images.

Before training, the pixel values were normalized to a (-1, 1) interval instead of using RGB values ranging from 0 to 255. Firstly, larger input values may slow down or disrupt the learning process of neural networks and setting them to smaller values is good practice [21]. Secondly, this normalization was required since the generator outputs tanh activations within the same interval.

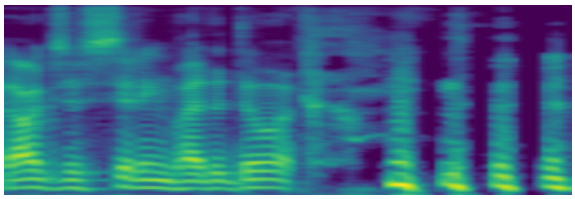

Fig. 5. Input log Mel spectrogram data example for the VAE and CGAN model. Happy emotion male speaker with original Ravdess dataset extended with male giggling sound.

B. Experimental Details

Two distinct methodologies were introduced, involving the VAE and CGAN models. The initial approach utilizes the VAE model in an entirely unsupervised manner, whereas the second approach employs the CGAN model in a supervised capacity.

Through the experiments, it was demonstrated that enhancing the input dataset with contextual attributes yields superior outcomes compared to explicit labeling or enforced supervision. Despite CGAN being a supervised model, it also benefits the core task of emotional transfer. This advantage is attributed to the data complexity being reduced when well-patterned contextual data is linked with the original input. Such simplification is only achievable with contextual information related to emotions and speaker gender.

In CGAN's labeled input-guided framework, we must assign appropriate labels to guide the generation of new samples. The model needs to be trained with labels that are familiar to it during the training phase. In contrast, the VAE utilizes extended input data without the explicit management of labels; instead, it separates classes by observing the data's intrinsic patterns during training.

To generate data from a specific class using the aforementioned CGAN model, several structured steps need to be followed. Firstly, a one-hot encoded label vector representing the desired class is created. This label must align with the format of labels in our training dataset. Secondly, random latent vectors are generated as input for the generator, sampled from a normal distribution. Thirdly, the one-hot encoded label vector is concatenated with the random latent vectors to form the conditional input for the generator. In the final step, the generator is employed to create data samples based on the prepared conditional input.

C. Experimental Results

The training dataset comprises 263 samples, while the test dataset consists of 66 samples. The distribution of training data is as follows: 37 samples for neutral audios, 72 for happy audios, 75 for sad audios, and 79 for angry audios. In the testing set, there are 11 neutral audios, 20 happy audios, 18 sad audios, and 17 angry audios. The limited number of "neutral" samples is due to the smaller quantity available in the Ravdess dataset for each actor, requiring additional steps to balance the dataset, such as cloning voices and creating neutral audios with different utterances and intensities. This task, although valuable, falls beyond the scope of our current research and could be explored in future studies.

The computational environment used for testing included a RAM occupancy of 5.38GB out of 51GB and a disk space usage of 26.83GB out of 166.77GB. The experiments utilized a NVIDIA T4 GPU provided by Google Compute Engine. The execution time for the CGAN model training over 10,000 iterations was 20 minutes. For the VAE models, the training process involved 10,000 epochs and took approximately 20 minutes. The programming language employed for these tasks was Python version 3.

To assess the VAE model, an unsupervised approach lacking predefined target classes, two metrics were utilized, mean square error (MSE) and structural similarity index (SSIM) between the original and generated data. In MSE, lower values indicate higher similarity between images, with 0 representing a perfect match, although realistically, a small value signifies good similarity. SSIM values range from -1 to 1, where 1 signifies a perfect match. Values closer to 1 indicate strong similarity, and a value above 0.9 is generally considered a robust match. It is essential to consider that ideal values can vary based on the specific domain and image quality.

VAE model results of training data after 10000 epochs, for original Ravdess dataset can be observed in Fig. 6, 7, and 8. The training and validation loss of the variational autoencoder trained with the original Ravdess dataset for 10000 epochs can be observed in Fig. 6. The training loss starts in a high value 10^5 from epoch 1 and the validation loss starts in 10 in the epoch 1. The values are steadily decreasing over the epochs as expected. The data generated by VAE model in 10000 epochs

proposed model results after 10000 epochs of training, for Ravdess dataset extended with contextual information data can be observed in Fig. 17, 18, 19, 20 and 21. CGAN loss for training data over 10000 epochs can be observed in Fig. 17. It shows that the loss starts with a higher value and decreased accordingly, as it is expected for loss functions in both sides, with no strange jumpings or increasing values from both sides. It also shows a convergence and a estabilization point. The

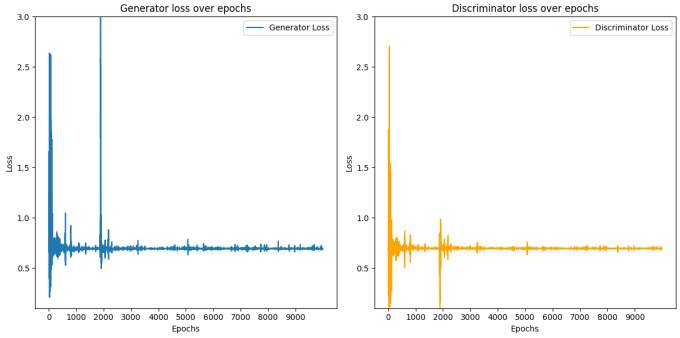

Fig. 17. CGAN loss over 10000 epochs of training.

angry, sad, happy and neutral emotional data generated by CGAN model after 10000 epochs of training can be observed in Fig. 18, 19, 20 and 21, respectively. The generated data improved the previous original Ravdess training with CGAN, since the quality of each image increased significantly.

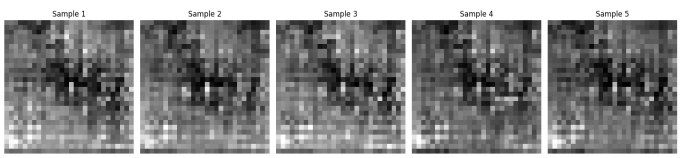

Fig. 18. CGAN model generation of data class 1 (neutral emotion) after 10000 epochs of training.

To validate the accuracy of the generated data, we developed an emotional classifier program, trained on the same input data utilized in both the VAE and CGAN models. The classifier's accuracy indicates the models' ability to generate emotional data that can be correctly classified into specific

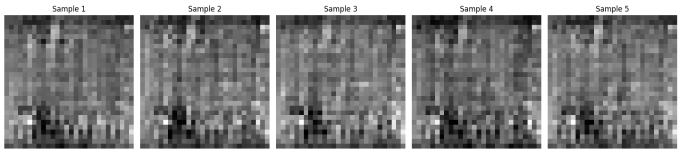

Fig. 19. CGAN model generation of data class 3 (happy emotion) after 10000 epochs of training.

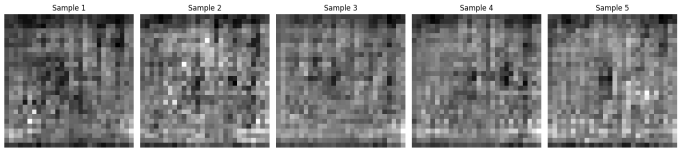

Fig. 20. CGAN model generation of data class 4 (sad emotion) after 10000 epochs of training.

emotion classes. It is important to remark that this measure can not obtain a 100 percent of accuracy due to the lack of train and validation over this fresh generated data. Therefore, the generated data is non-trained and unseen data for the classifier, however it will give us a notion of how much we should adjust the classifier and the models to improve the results. Most importantly, it will result in all classes zero classified, if it is not able to detect any emotional generated data.

When testing both models with the original Ravdess input data, it is anticipated that the generated results to be weakly classified by the classifier. This expectation arises because the Ravdess data, as previously discussed, is inherently weakly emotional. Moreover, it is important to acknowledge the inherent noise in the outcomes produced by generative models, particularly concerning audio data features such as log Mel spectrogram values.

The VAE generated data was sent to the classifier for testing generation accuracy. The results can be observed in Fig. 22. The results of the classifier after training with original Ravdess data shows a 20.51 percent of correct classification of emotions in a total of 39 tested generated data. Even though the result is low in comparison with a perfect accuracy, as explained above, it is expected that the classifier cannot easily extends its classification with these non-trained unseen data. This is the evidence that our CGAN model in Fig. 23, is trying to reconstruct the data getting a better emotional generated data's result, in comparison with VAE model. Additionally, the classifier needs to be adjusted for future works to measure more precisely our data.

The CGAN generated data was sent to the classifier for testing generation accuracy. The results can be observed in

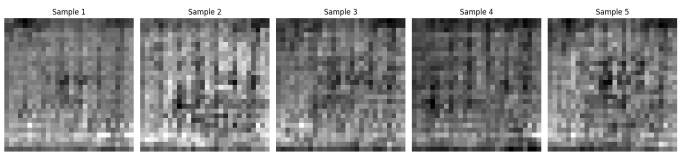

Fig. 21. CGAN model generation of data class 5 (angry emotion) after 10000 epochs of training.

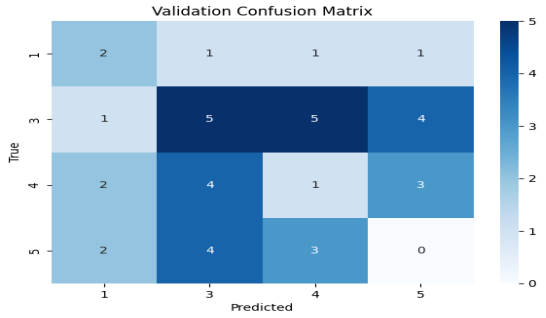

Fig. 22. Validation confusion matrix for VAE model generated data after classified by an emotional classifier.

Fig. 23. The results of the classifier after training CGAN with extended data shows a 25.641 percent of correct classification of emotions in a total of 39 tested generated data. Even though the result is low in comparison with a perfect accuracy, as discussed above, it is expected that the classifier cannot easily extends its classification with these non-trained unseen data. This is the evidence that our model is trying to gradually reconstruct the data and the classifier needs to be adjusted for future works to measure more precisely our generated data.

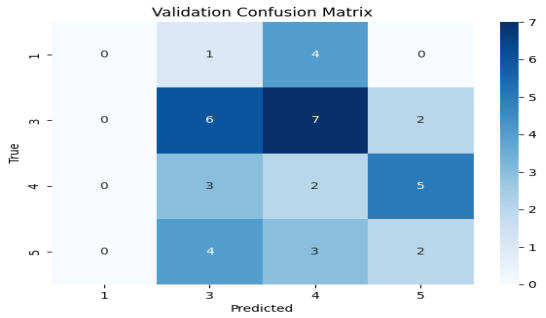

Fig. 23. Validation confusion matrix for CGAN model generated data after classified by an emotional classifier.

During this evaluation, we anticipate the input data to be classified in closer proximity to the generated data. However, we cannot definitively confirm how the generative models interpret the essential features in the presence of additional contextual information. Nevertheless, the generated data is expected to align more closely with its input data due to the utilization of paired information. For instance, the weak speech emotion in the Ravdess dataset, when associated with the extended contextual information like a female voice's giggling pattern linked to a happy emotion, should be more accurately classified as happy. In comparison with the vanilla VAE model and standard CGAN model trained with original Ravdess dataset, the results are clearly improved. The results shows also that more efforts are required for future works in order to better represent the reconstructed emotional audios.

D. Case Study

As an extension of the emotional data generation capabilities with the proposed VAE and CGAN models, in this case study we showcase the specific emotion transfer with additional conditions such as specific gender, specific voice, and specific utterance, with an additional change in emotions, from neutral to happy, sad, angry respectively. Since the variational auto-encoder model is more flexible in terms of receiving new input data to regenerate, we reutilized the pre-trained proposed variational auto-encoder model.

Furthermore, the utterances in this study were generated using a Text-to-Speech (TTS) system, which inherently produces a "Neutral" emotion speech audio since it lacks emotional variation. Converting "Neutral" audio to another "Neutral" audio is not necessary for our evaluation; it would not yield any change and only indicates the models' understanding of elements like whispering or speaking pauses. Although our training data includes neutral sounds, such as whispers or slight delays in speech, they are not utilized in our TTS systems for testing purposes.

For specific test scenarios, assuming the model is trained, we paired our TTS-generated voice with additional emotional audio, creating samples as follows:

1) 'Bob is by the door' with female giggling.
2) 'Bob is by the door' with male giggling.
3) 'Bob is by the door' with female shouting.
4) 'Bob is by the door' with male shouting.
5) 'Bob is by the door' with female crying.
6) 'Bob is by the door' with male crying.

To demonstrate the practicality of this approach, a "Neutral" emotional speech is converted into a "Happy" emotional speech on demand through a TTS system, by using the proposed variational auto-encoder model with custom data for the reconstruction. A selected raw audio data generated for testing can be seen in Fig. 24. The TTS system utilizes a neutral MAC PC male voice "Alex", uttering "Bob is by the door". The duration was condensed to one second for consistency across speech data. The TTS voice is neutral without any emotional inflection. For this use case, the utterance was varied from the trained sets u_1 ("Kids are talking by the door") to u_2 ("Dogs are sitting by the door"). This variation illustrates the model's ability to transfer emotion even with slight differences in the trained words.

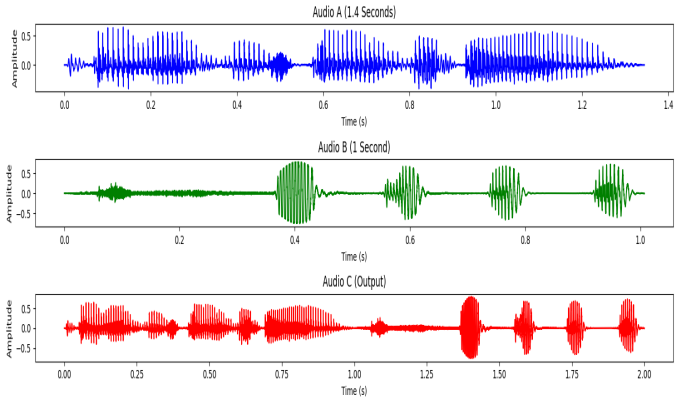

Fig. 24. Raw audio A is a Neutral speech audio generated by a TTS MAC OS male voice system. Original audio B representing a happy emotion by giggling. Preprocessed audios were combined into one audio output file C.

The following step after gathering the clean concatenated audio is to transform the audio into frequency domain. The log Mel spectrogram image data generated for testing, as a case study can be observed in Fig. 25. The sampling rate is 44100Hz, the number of FFTs is 2048, with a hop length of 512. For the VAE model the target size is a 128 by 128 image.

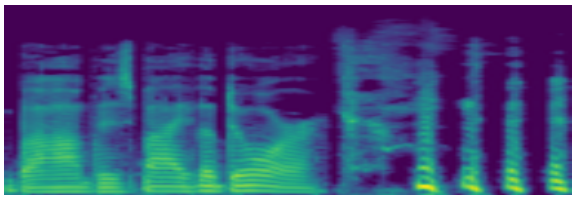

Fig. 25. Input log Mel spectrogram example for the VAE. Neutral speech with additional happy contextual data.

The result of the VAE model emotion transfer can be observed in Fig. 26, when given the happy bob spectrogram generated, the proposed VAE model try to reconstruct it with happy emotion.

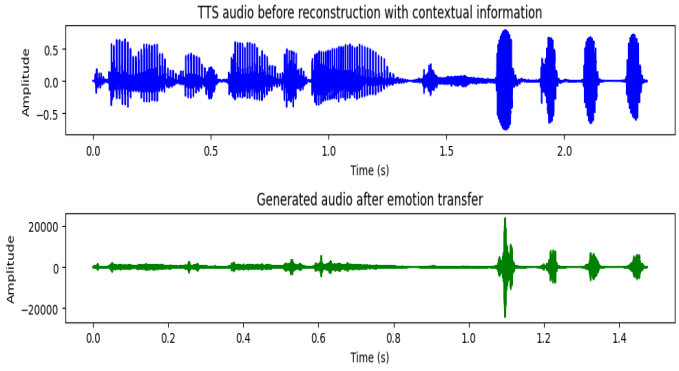

Fig. 26. Result of the VAE model emotion transfer from neutral to happy speech sample.

In this implementation, an unsupervised model was used to infer the emotion that should be reconstructed by contextual information. This task was developed with the proposed VAE model. The TTS speech was created with 1 second plus a related audio extension of 1 second, depending of the gender and the emotion desired. These samples show how the emotion is reconstructed among the trained utterances and among similar utterances with words composition variability. The utterance selected for this testing is as follows. u_3 : "Bob is by the door".

The total data size used are 329 audios, the train data size is 263 audios, transformed into log Mel spectrogram images. The test data size is 66. This case study showcase one sample among 6 samples presented. The size of each image is 128 by 128. The initial VAE training is performed with grayscale images. Each audio has a sampling rate of 44100Hz, which makes it more difficult to recover the audio after passing to Mel spectrogram.

Some pending tasks are required such as volume regularization and denoising tasks, however it can be seen how the contextual information such as giggling in a male speaker is greatly represented and trying to recover the left side of the speech with the same accent and pauses that the male speaker represents.

IV. Discussion

To assess the VAE model, an unsupervised approach lacking predefined target classes, two metrics were utilized, mean square error (MSE) and structural similarity index (SSIM) between the original and generated data. In 66 reconstructed audios for the proposed VAE model, when testing the custom data, the MSE is lower than 0.010 and the SSIM is almost reaching the 0.70, while most of the values are greater than 0.60. For the Ravdess dataset, the MSE of the reconstruction is lower than 0.020 and the SSIM is almost reaching the 0.70, while most of the values are higher than 0.50. This signify that the proposed data along with the proposed model is getting better similarity in the reconstruction of tested data, while the mean squared error is lower which emphasizes the improvement in the reconstruction by using this proposed unsupervised model.

An external tool was created to measure the level of reconstruction in terms of emotions. This tool is an emotional classifier, trained with the same emotion classes and the same input data size and characteristics as the proposed models. Certainly the reconstructed data from CGAN by setting a specified emotion label and the TTS generated data used as input for the VAE make them different than the trained data of the created tool. However, this tool can state if the generated data by both models is not considered emotional at all by the classifier showing near zero values in the accuracy. This tool help to test the research results while avoiding the subjective measures by human resources. The VAE and the CGAN generated data were sent to the classifier for testing generation accuracy. The results of the classifier after training with custom data shows a 20.51 percent of correct classification of emotions in a total of 39 tested generated data for VAE. The results of the classifier after training CGAN with custom data shows a 25.641 percent of correct classification of emotions in a total of 39 tested generated data. Even though the result is low in comparison with a perfect accuracy, as explained above, it is expected that the classifier cannot easily extends its classification with these non-trained unseen data.

The results of the classifier also show that there is a need of a better vocoder function in future improvements of this work, and that the output should be better adjusted by a volume regularizer and an extra denoise function. This is due to the weak points present in generative models, where a better vocoder could probably increase the accuracy in the emotional classifier results, after generating new unseen and non-trained data. The new generated data is still identified as different for the emotional classifier, because the data just created posses different characteristics such as moved characteristics from the original input data that the classifier usually consumes.

The treatment of the utterances could be improved in future works, such as injecting the words spoken and its characteristics right after the generative models resampling. This is because the generative models tend to loose the accents of each spoken word during the transition from original data

to resampled data. However, a strong point of this research to mention is the extension of the trained utterances to similar utterances that have some words in common but differ in others. As it is known, with models such as HMM, RNN and LSTM, the utterances are totally fixed without any possibility of extension. This also make the models fail in the presence of utterances that contain different words, even when the general pronunciation of the words is similar and the sentence has the same duration. In comparison with other datasets, we used the Toronto emotional speech set (TESS) with two female speakers and a variation in utterances such as "Say the word book", "Say the word bought", or other variations from 200 target words for the emotions happy, sad, angry and neutral. SSIM and MSE results with our proposed model and extension with contextual cues show, for female speaker's emotions, similarity to the evaluated Ravdess dataset with 0.7 and 0.020, respectively. Therefore, demonstrating the ability to be robust and scalable to other utterances and voice characteristics. For future works, the evaluation with other datasets that include the male counterpart audios is also required for better determine the level of scalability by gender.

V. Conclusion

In this research, a method for transferring emotional speech utilizing generative models and specific emotional targets for the output was presented. The generative models employed in this task include a variational autoencoder model and a conditional generative adversarial network model. Although further refinement is needed to enhance the accuracy of generated emotional speech, both proposed models have demonstrated the ability to reconstruct emotional speech with a certain degree of quality.

In the presented case study, it was utilized an input voice audio, a desired utterance, and user-selected emotional cues to automatically transform ordinary speech into emotionally expressive speech audio using a variational autoencoder model. Remarkably, the proposed VAE model achieved this task without requiring specific labels to control the generated output, highlighting the efficiency of this approach with unsupervised learning. The model attempts to replicate the emotion inherent in the emotional contextual cues used for training directly into the ordinary speech. The findings reveal that the suggested unsupervised VAE model for generating emotional data achieves an MSE below 0.010 and an SSIM nearly reaching 0.70. The majority of values surpass 0.60 in comparison to both the input and generated data. When generating new emotional data on demand, CGAN and VAE models demonstrate a discernible level of success in the evaluation of an emotion classifier, determining its similarity to real emotional audios used for training.

In future works, the primary focus will be on refining the generative models further and implementing additional strategies to achieve a better balance between real contextual information and emotionally rich speech. This ongoing effort aims to bridge the gap between human understanding and artificial agents' comprehension in the essence of a desirable authentic speech.

***Abstract*—Social networks produce a large volume of information, a part of which is fake. Social media platforms do a good job in moderating content and banning fake news spreaders, but a proactive solution is more desirable especially during global threats like COVID-19 pandemic and war. A proactive solution would be to ban users who spread fake news before they become important spreaders. In this paper we propose to model user's interactions in a social media platform as a graph and then evaluate state of the art (SOTA) graph neural networks (GNN) that can classify users' (nodes) profiles as being suspended or not. As with other real world data, we are faced with the imbalanced data problem and we evaluate different algorithms that try to fix this issue. Data used for this study were collected from X (Twitter) by using Twitter API 1.1 from November 2021 to July 2022 with the focus to collect information spread through tweets about vaccines. The aim of this paper is to evaluate if current models can deal with real world imbalanced data.**

***Keywords*—GNN; imbalanced data; Twitter; social networks; GCN; GraphSage; GAT; GraphSMOTE; ReNode**

I. Introduction

Social media has changed the way that the news is created and spread worldwide. According to Statista [1] in 2022 over 4.59 billion people were using social media, a number which is estimated to increase to almost six billion in 2027. In March 2020 World Health Organization declared Coronavirus disease (COVID-19) pandemic. Very soon a lot of people started to use social media to spread information about this new disease resulting in a massive infodemic. Infodemic[1] refers to false information related to a disease. This phenomenon is amplified through social networks spreading farther and faster like a virus [2]. World Health Organization (WHO) Director-General, Tedros Adhanom Ghebreyesus, in [3] emphasized the importance of fighting not only the pandemic but also the infodemic that was spreading. During difficult time for all the countries worldwide it is very important to spread the correct information rather than false and fake news that undermines the global response and jeopardizes measures to control the pandemic [4].

There are various definitions of fake news. Allcott and Gentzkow [5] defined fake news as "news articles that are intentionally and verifiably false and could mislead readers". Other studies have defined it as "a news article or message published and propagated through media, carrying false information regardless of the means and motives behind it" [6], [7], [8]. Much fake news about COVID-19 on social media has been circulating but the spread of fake news and disinformation about vaccines had a significant influence on vaccine acceptance, with many people opting not to get vaccinated posing a threat to individual and collective health. In order to prevent the spreading of fake news it is important to develop tools that will predict this.

Tweets associated with COVID-19 have been collected for a period of nine months from November 2021 until July 2022 for the purpose of applying social network analysis techniques on these posts. In [9], the authors focused their analysis on three main terms: pfizer, moderna and AstraZeneca. For these terms and for the nine month period, 27 graphs were built and an analysis of these graphs was performed. It was pointed out that most of the time the most influential users (based on beetweenness centrality) in the network were engaged in a form of information disorder and their accounts were suspended at the time of the study. Unfortunately the real reason behind the account suspension is not declared by X (Twitter), but one can safely presume that the main reason an account can be suspended is if a user does not comply with the TOS and engaging in mis/dis information is not in compliance with the platforms' TOS [2], [3]. We value that it is of great interest to be able to predict a user's status based on his position in the network as well as his attributes (date of joining the platform, number of posts, number of followers etc.). To this purpose, we applied different graph neural networks (GCN [10], GraphSage [11] and GAT [12]) on our dataset for the downstream task of classifying nodes. Given the fact that the dataset is imbalanced (there are more active users than inactive users), models which claim to fix this problem [13], [14], [15], [16], [17] were also studied.

The paper is organized as follows: Section II reviews recent studies on deep learning models on node classification in graph neural networks about fake news and infodemic prediction. The data that is used in this study, as well as the methodology that is applied for node classification and evaluation, is presented in Section III. In Section IV, the results are discussed. The conclusion and a concise summary conclude this paper.

II. Related Work

Graph neural networks are the most reliable and effective way to automate the process of fake news detection [18]. Feng et al. in [19] propose a bot detection framework that encode multi-modal user information such as user account description, the content of the post and numerical and categorical features that they can assign to an account available from the

[2]https://help.twitter.com/en/resources/addressing-misleading-info

[3]https://help.twitter.com/en/rules-and-policies/crisis-misinformation

Twitter API. Users are treated as nodes of the heterogeneous graph. Relational Graph Convolutional Network is applied to the graph to tackle the challenges of bot disguise and bot communities.

In another work [20] for bot detection the authors propose a transductive model that combines symmetrically BERT and GCN. They constructed a heterogenous graph composed of unique words and documents in a collection as nodes. Word occurrences in a document or word co-occurrence are weighted using TD-IFD and PMI and stored as information on the edges of the graph. The experiment shows that a better performance can also be achieved by the proposed framework on a wide range of social robot detection datasets.

Li and Goldwasser [21] constructed a social information graph by embedding the items that are shared by Twitter users, the users who can be political users and other users who spread content. The edges represent the follower relations between political users and other users that follow them. They used two-layer Graph Convolutional Networks to capture the documents' social context and to detect news items as fake or not by node classification.

In [22] the dataset of CheckThat-2022 Task 3 dataset [23] is used as the primary dataset to analyze a corpus with unknown topics through multiclass classification, encompassing true, false, partially false, and other categories. They have explored three BERT-based models—SBERT, RoBERTa, and mBERT. The problem of imbalanced dataset is tackled by enhancing results via ChatGPT-generated artificial data for class balance and improving the results for the true, partially false, and other classes witnessed improvements of 5%, 9%, and 3%, respectively, while the results for false news experienced a decline of 9%.
Data augmentation has been applied by adopting synthetic minority oversampling in Zhao et al. [16]. They proposed a novel framework, GraphSMOTE, based on SMOTE [24] approach which addresses the imbalance problem by generating new samples, performing interpolation between samples in minority classes and their nearest neighbors. In [17] the authors have followed the approach of the imbalance of topological structure on the graph for handling the imbalance problem in graph-structured data. They proposed a ReNode framework for solving the problem of edge graph structure by re-weighting the influence of labeled nodes adaptively based on their relative positions to class boundaries.

III. Methodology and Data

In the following section we describe the dataset creation process as well as a description of different GNN models.

A. The Dataset

The data used in this paper is described in [9]. The data consist of 27 graphs. The size of each graph is displayed in Table I. To be able to run any graph neural network in any of these graphs, first we need to convert these graphs into a dataset that can be fed to the GNN model. To this purpose, we decided to use PyTorch[4] and PyG[5] libraries.

We used the procedure[6] described in the PyG documentation to create our dataset. The advantage of converting the data into a dataset is that the data can then be fed into different neural networks without having to adapt the data each time. Another advantage is that we can make use of the many functions available in PyG to correctly split the dataset into development, test and validation sets. Creating a dataset from the available graphs, involves choosing node and edge features from the possible attributes. All node and edge features need to be of numeric type which limits our choice. In Tables III and IV node and edge features are shown. A transformation was required for some of the features as not all of them are numeric. Boolean features were transformed to 0 or 1. Date/time features were transformed to UNIX timestamp and category features such as "Relationship" were transformed to a number from 1 to 5 (Tweet = 1, Retweet = 2, Mentions = 3, Replies to = 4 and MentionsInRetweet = 5). The active status of a user was obtained by automatically making an HTTP request to the X (Twitter) web site since the API is no longer available. The active status for every user (node) in all the 27 constructed graphs was obtained in August 2023. As we expect in every real world dataset, we can notice by looking at Table II that the data is imbalanced for this dataset (i.e. there are fewer inactive users than active users). This will affect the prediction results of the standard models making them biased towards the majority class. Special models which account for the imbalance of the data need to be tested in this case.

B. GNN Models

Graph Neural Networks (GNNs) are a type of deep learning model designed for handling data represented in graph structures. In recent years, the field of graph neural network research has witnessed significant advancements [25], with a notable expansion in the range of GNN designs [25], [26]. Among these various designs in this paper we use Graph Convolutional Network (GCN) [10], GraphSAGE [11], and Graph Attention Networks (GAT) [12]. GCNs [10] are adapted to handle irregular and non-Euclidean data. For each node in the graph, GCN aggregates the features of all the neighbors of the node and the node itself. Different functions can be used for feature aggregation. The aggregated values are passed to the neural network which returns the feature vector resulting from the model. The GNC model can use several GCN layers on top of each other where the output of one layer will

be the input for the next layer. GraphSage [11] generates node embeddings by sampling and aggregating information from their neighbors. This model is suitable for large graphs because it is not necessary to process the entire graph at once, thus avoiding the limitations derived from the processing power and memory capacity available to us. The input of the GraphSage model is the graph which consists of nodes and edges. Each node in the graph has some features. To find node embeddings, the model selects for each node a fixed-size subset of its neighbors. The features of the selected neighbors are aggregated by means of an activation strategy thus creating an aggregated representation for each node. This aggregation reveals information about the local neighborhood of the node. These aggregated representations are passed as input to an activation function. To discover more complex relationships, updated representations can be passed through several layers of the GraphSage model. The last layer of the network is determined by the task to be performed. This model can be used to classify a node, predict a link. GAT [12] discovers dependencies and relationships in graph-structured data. Unlike GCN where all neighbors of a node have the same importance, GAT uses an "attention" mechanism to weight the importance of each neighbor during the aggregation process. In this way the network works only with the information of the nodes that are important. Weights are learned during the training process based on the importance each neighbor has on the specific task. Despite the progress in learning from graphs with GNN, existing work mainly focuses on balanced datasets [13]. In real world applications, we are faced with imbalanced data and GNNs fail to accurately predict the samples that belong to the minority class. Imbalanced class problems can be solved by modifying the GNN model to bias toward minority class, or by resampling that consists in altering the dataset by adjusting the number of instances for each class to achieve a balanced distribution [16], [14]. The most used approach is resampling because it can be integrated with any classifier [16], [14]. Resampling can be achieved either by undersampling or oversampling. Undersampling methods remove instances that belong to the majority class, but this can result in a loss of valuable information [16], [14]. Oversampling methods increase the number of minority classes which can lead to overfitting [16]. The results of applying these approaches to graphs are suboptimal because they consider each sample as independent and don't take into account the relation that exists in the graph data [16]. In this paper we first apply the three standard SOTA models (GCN, GraphSage and GAT) to classify nodes as being active or inactive. Given the fact that our data is imbalanced we also use GraphSMOTE [16] and ReNode [17] to deal with imbalance data. GraphSMOTE uses a feature extractor to learn node representations. Node representation should reflect the similarities and dissimilarities between samples considering node attributes, node labels, and

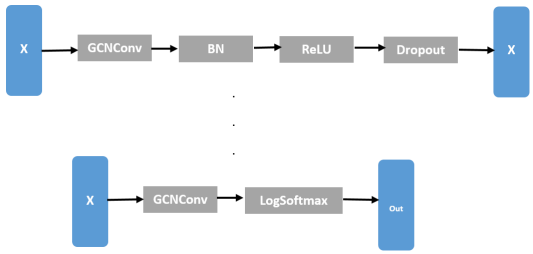

Fig. 1. The GCN model.

local graph structures [16]. After obtaining node representation for each node, GraphSMOTE uses the SMOTE algorithm to generate synthetic minority nodes in the latent space [16]. In order to include the new nodes in the graph, GraphSMOTE simulates connections between synthetic nodes by performing a training on existing nodes and edges. The GNN classifier can then perform node classification based on the augmented graph created by GraphSMOTE. Another framework that we have used to handle the topology imbalance issue of our network is ReNode. ReNode framework re-weight the influence of labeled nodes according to their position. Their structural position are located by using the conflict detection-based Topology Relative Location (Totoro) metric to leverage the interaction among them. The training weights of nodes with small conflict are increased and vice versa [17].

IV. Experimental Results

In this section, we present the results of our experiments in our imbalanced dataset. It will try to answer the following research questions:

- RQ1: Do standard GNN models yield acceptable results in case of imbalanced data?
- RQ2: Do special GNN models designed for imbalanced data help in our case?

A. Experimental Setup

The models for GCN, GraphSage and GAT are implemented in Pytorch and PyG by following a message passing paradigm. All the training is done in python 3.8 in a machine with 1 Titan RTX with 24GB, AMD Ryzen Threadripper PRO 5995WX 64-Cores CPU with 451 GB of RAM.

1) GCN implementation: The GCN model consists of three layers as shown in Fig. 1. Each layer consists of a GCNConv module, a batch normalization module, a ReLu activation function and a dropout. The last layer of the model contains only a GCNConv module and a LogSoftmax which yields the output. The input dimensionality is the number of features we have selected (21). Each intermediate (hidden) layer has 256 dimensions and the output layer has a dimensionality equal to the number of classes in the dataset (2). The learning rate is set to 0.01, dropout to 0.5 and the training was set to run for 500 epochs.

2) GraphSage implementation: The GraphSage implementation follows the architecture described in [11]. It consists of two message passing layers with 21 input dimensions, 32 hidden dimensions and 2 output dimensions. The dataset was divided into batches with a batch size of 32. Other parameters include: Adam optimizer, learning rate is set to 0.01, dropout probability equal to 0.5 and the training was set to run for 500 epochs.

3) GAT implementation: Our GAT implementation follows the architecture presented in [12]. It consists of 2 message passing layers with 21 input dimensions (equal to the number of node features), 32 hidden dimensions and 2 output dimensions. The number of attentions heads was set equal to 2. Similar to GraphSage, the dataset was divided into batches with batch size of 32, Adam optimizer was used, learning rate was set to 0.01, dropout equal to 0.5 and number of epochs equal to 500.

4) GraphSMOTE implementation: We have used the GraphSMOTE implementation from [16] available from the official GitHub page of the authors[7]. This model implementation expects the graph to be represented with an adjacency matrix while in a PyG dataset (ours as well) the graph is represented as a COO edge list. In order to run GraphSMOTE in our dataset we had to first convert the edge list to an adjacency matrix which was performed using Pytorch's built-in functions. The following parameter values have been used: GraphSage as embedding model, batch size was set to 40, learning rate 0.001, dropout probability equal to 0.1, epochs equal to 2000.

5) ReNode implementation: The implementation of the ReNode [17] algorithm used in this paper was adopted from the author's Github page[8]. Similar to the GraphSMOTE case also here we needed to adapt our dataset to the ReNode implementation especially in the case of the inductive settings. The main change was related to converting the edge list into a CSR adjacency matrix. Some of the parameter values used for this algorithm are: learning rate equal to 0.005, hidden layer dimensionality is set to 32, number of layers equal to 2, personalized page rank teleportation is set to 0.15.

6) Evaluation metrics: For every prediction problem, the correct evaluation of the results is very important. In the specific case of imbalanced data, choosing the appropriate evaluation metric is of critical importance. Our dataset has imbalanced data as can be seen from Imbalance Ratio, IR value from able II. Two classes Active versus Inactive users have IR values in the range from 0.037-0.062. In order to be considered balanced the dataset should have an IR equal to 1. For the above mentioned models we have used Macro F1 score and Macro recall to evaluate their performance in our dataset. **Recall** is one of the most used evaluation metrics. It gives accurate measurements regarding the detection of samples from the minority class. We can distinguish $recall^+$, also known as *sensitivity* and $recall^-$ also known as *specificity*. These two metrics can be calculated using the following formulas

$$recall^+ = \frac{TP}{TP + FN}$$

$$recall^- = \frac{TN}{TN + FP}$$

where TP is the number of true positives and FN is the number of false negatives. Macro recall is the arithmetic mean of

[7]https://github.com/TianxiangZhao/GraphSmote
[8]https://github.com/victorchen96/ReNode

recalls for different classes without considering the importance of different classes. **F1 score** is another very important metric used to evaluate the performance of machine learning models. It is defined as

$$F1 = \frac{2 * Precision * Recall}{Precision + Recall} = \frac{TP}{TP + \frac{1}{2}(FP + FN)}$$

where TP = True Positive, FP = False Positive and FN = False Negative. Macro F1 score is the arithmetic mean of F1 score of each class.

B. Results of Standard GNN Models (RQ1)

Given the extreme imbalance ratio that our data has, it is to be expected that the standard GNN models will have problems to correctly classify nodes. Our implementations of GCN, GraphSage and GAT are really good at learning really fast how to cheat so they can achieve a high accuracy. After only five iterations the model reports a high accuracy of around 95%. Looking closely at the results one can notice that the model only predicts "TRUE". By always predicting "TRUE" (the user is active) the model is certain to achieve around 95% accuracy because 95% of the users in the data is active. The reported Recall and F1 score for all these models is the same for our dataset. Sensitivity = 1 and Specificity = 0. These two metrics can be combined into Macro recall which in this case is equal to 0.5. The F1 score is equal to 0.97. After we were presented with these results, we noticed the need to test other models which are designed to handle imbalanced data.

C. Results of Specific GNN Models (RQ2)

The first specific GNN model that we tested on our data is GraphSMOTE [16]. Given the fact that GraphSMOTE is based on SMOTE [24] which in turn is one of the most used techniques in case of imbalanced non-graph data, this method is expected to perform better than other methods. After running the algorithm on our dataset, we noticed that this algorithm did classify some users as being inactive, in contrast to the standard GNN models. However, not all the predictions were correct. Calculating Sensitivity, Specificity and F1 for this method yields the following results: Sensitivity = 0.95, Specificity = 0.04, Macro recall = 0.49 and F1 score = 0.96. We notice a decrease in both these measures which gives the impression that this algorithm performs worse than the standard GNN models. One can argue that an algorithm which detects from both classes, even though not always correct, is better than an algorithm which is biased towards the majority class. Other evaluation metrics may capture this fact better than F1 score. The second algorithm that claims to handle imbalanced data and that we tested was ReNode [17]. This model classified more samples to be part of the minority class than what was expected. We ran both the inductive and transductive settings and also played with TINL and QINL settings, however the results were poor. This algorithm scored a Sensitivity of 0.37, Specificity of 0.67 and F1 score = 0.54 (see Table V).

TABLE V. EVALUATION METRICS FOR THE IMPLEMNTED MODELS

	Sensitivity	Specificity	Macro F1
GCN	1	0	0.97
GraphSage	1	0	0.97
GAT	1	0	0.97
GraphSMOTE	0.95	0.04	0.96
ReNode	0.37	0.67	0.54

V. CONCLUSIONS

In this paper we tackled the problem of fake news detection and spreading by providing a proactive solution: to detect and ban fake news spreaders before they become important spreaders. We created a dataset from November 2021 to July 2022 that contains information about the users features and relationships that spread news through tweets about vaccines. The problem of classification in imbalanced data is raised since our real data dataset was deeply imbalanced for all the periods that were taken into consideration. Three graph neural network models were trained in our datasets for node classification: Graph Convolutional Network, GraphSAGE, and Graph Attention Networks. They achieve high accuracy after few iterations because they learn really fast by predicting always True having Sensitivity = 1, Specificity = 0 and F1 = 0.97. In order to reach our goal to find and prevent the potential spreaders, increasing true negative which will yield increase in specificity becomes very important. We have tested two other frameworks to overcome the problem of imbalanced data: GraphSMOTE and ReNode. Both of these frameworks claim to give better results in imbalanced data. We found that GraphSMOTE does a better job in increasing the Specificity, but this comes at the cost of increasing the false positives rate. For this model we report Sensitivity = 0.95, Specificity = 0.04 and F1 score = 0.96. We found ReNode to not be as good as the authors claims in our case. For our dataset this technique scores Sensitivity = 0.37, Specificity = 0.67 and F1 score = 0.54.

***Abstract*—The boom in social networks and digital communication has given place to innovative forms of social interaction. However, it has also made possible new forms of harassment of others anonymously and without repercussions. Such is the case of cyberbullying, an increasingly common problem, especially among young people. Its effects on individuals can be devastating, ranging from anxiety and depression to social isolation and low self-esteem. Furthermore, there is a wide variety of applications called parental control, which allow parents to show, the pages the child or adolescent has accessed, know how often the child or adolescent accesses them, and control the time spent on social networks or other entertainment platforms. Therefore, the present research aimed to analyze, design, and implement an intelligent application based on data mining algorithms and the Latent Semantic Analysis (LSA) method for the presumed detection of cyberbullying in social networks in adolescents. The methodological process of the study was carried out following the fundamentals of applied research with a qualitative-quantitative descriptive, and cross-sectional approach. As a result, a multi-platform application was obtained that alerts about suspected bullying to parents or guardians. For the validation of the application, the technique of expert judgment was applied. Also, the process of obtaining negative and positive text similarity was performed based on cosine similarity. In the analysis of Twitter accounts, values of 46% with negative texts and 6.71% with positive texts are obtained, which allows inferring that this is a presumed case of cyberbullying in this account.**

***Keywords*—Cyberbullying; control parental system; natural language processing; Spanish cyberbullying prevention system**

I. Introduction

Social networks have transformed the way people communicate and interact with each other, and have made it possible to instantly connect with people all over the world. Undoubtedly, the era of digital transformation has created new opportunities in various areas of society; for education, commerce, and culture, and has allowed people to connect and share ideas in ways never before imagined. In this sense, it is valid to say that there are many satisfactions experienced by users of digital media with the advancement of technologies, although positive experiences do not always occur given the appearance of malicious users that cause negative effects on people. Among these negative effects is cyberbullying on social networks; an increasingly common problem. It refers to bullying, harassment, intimidation, and other forms of aggressive behavior that take place online through social networks and other digital platforms. The effects of cyberbullying can be devastating, from anxiety and depression to social isolation and low self-esteem [1].

Today, everyone can be a victim of cyberbullying, but young people are more vulnerable [2] for example, adolescents are more likely than adults to spend extended time online and be more involved in social networks. This means they have greater opportunities to interact with other users, including people who may have bad intentions. Also, young people often lack the emotional maturity and experience to deal with cyberbullying situations [3]. Often, they may feel embarrassed or scared to talk to someone about bullying, which can make the situation worse. In addition, they are more likely to make impulsive or risky decisions in online situations, which may increase their vulnerability to victimization in digital media.

Another factor contributing to young people's vulnerability to cyberbullying is the lack of adult supervision. Parents often do not have a full understanding of online platforms and the social interactions their children have with them, which can make it more difficult for them to detect signs of cyberbullying or to intervene before situations become serious [4]. Also, it should be considered that many of these young people use these platforms as their primary means of communication and socialization. However, they are unprepared to deal with cyberbullying, feeling alone and isolated if they do not have the support of their parents and friends. Therefore, cyberbullying can have a very negative impact on the social and emotional lives of adolescents.

As a serious problem that can lead to significant emotional and psychological consequences, parents should rely on technological advances to limit the exposure of adolescents to inappropriate content. It is important to note that these consequences are not exhaustive, as the experience of each victim of cyberbullying may be different. However, their impact underscores the importance of creating strategies to prevent and address bullying in any space. In this sense, the study carried out by the Ministry of Education of Ecuador with World Vision and UNICEF, in which 5,511 students from 126 institutions were consulted, states that in Ecuador 6 out of 10 students have been victims of bullying and the use of social networks. The students surveyed state that they have been victims of the dissemination of messages; in some cases to reveal private conversations and in other cases to generate threats by anonymous users [5].

School violence has been silenced, not because it has been solved, but because it now occurs in digital scenarios, which has generated new terms to be taken into account by adults, such as the well-known cyberbullying, a form of harassment based on the use of Information and Communication Tech-

nologies (ICTs) [6], [7]. In addition to social networks, it occurs in message-sharing platforms, video games, and blogs, among others [8]. Therefore, the diversification of online environments makes it difficult for adults to monitor them. This happens, first, because most parents are not tech-savvy. Secondly, because parents or guardians do not have enough time to carry out a constant review of the new media; and, thirdly, in many cases young people keep this type of situation secret. By the above, adults have been forced to adapt digitally in a fast way to the new generations to carry out adequate supervision [9].

In this sense, technological progress has allowed the development of intervention alternatives that facilitate parental control processes. Parental control systems are nowadays a viable alternative for parental intervention in the protection of adolescents from bullying on social networks. Likewise, it can help identify and prevent bullying situations, providing parents with the ability to monitor and control the use of digital environments and prevent cyberbullying [10]. However, these apps generally offer features such as monitoring browsing history, blocking inappropriate websites, monitoring messages and phone calls, and setting time limits for device use [10]. Hence, there is limited research related to parental performance in the mechanisms of prevention and intervention in the face of cyberbullying [11].

Among the limitations of existing applications is that they do not focus on analyzing the activities that adolescents carry out on their social networks to determine whether any action taken against an adolescent is alleged cyberbullying [12]. In this regard, [6] argues that the use of Natural Language Processing (NLP), as a branch of Artificial Intelligence (AI), in applications for parental control, is part of the technological innovation of recent times in the field of online protection. Among its potentialities is the ability to understand and process human language with high levels of similarity to that of people. Over the last few years, it has been applied in social network analysis to identify topics, sentiments, and other characteristics of natural text [13]. In addition, it contains a variety of tools and techniques to extract valuable information in large volumes of texts, identify trends, and determine opinion patterns, preferences, and user behaviors [14]. These techniques find functionality through the creation of algorithms that allow the analysis of specific information and obtaining accurate results in real-time [15]. One such tool is the Latent Semantic Analysis (LSA) method, which uses mathematical and statistical techniques to create a numerical representation of words and documents in a corpus. This numerical representation allows patterns to be identified in the way words are used in different documents and how they are related to each other [16], [17].

Despite its innumerable advantages, the documentary review evidences a limited availability of NLP applications developed to detect cyberbullying in the Spanish language. Likewise, NLP uses the LSA method for the identification of semantic patterns and relationships in sets of texts. Although the usefulness of LSA has been demonstrated in different NLP applications and has significant contributions in language pattern identification, topic detection, sentiment analysis, and language variant detection; its use in cyberbullying detection applications in social networks is also limited. According to [18], LSA is useful in a wide variety of applications, because of its ability for information retrieval, automatic document classification, topic clustering, and content recommendation. In addition, it is used in the construction of search engines to identify relevant information in large text datasets.

Attention to such, this paper presents the results of the research developed to analyze, design, and implement an application based on NLP for the prevention of presumptive cyberbullying in the social networks of Ecuadorian adolescents. As a contribution, a multiplatform application for parental control based on NLP in Spanish and using the Latent Semantic Analysis method is presented. The proposal responds to the need to protect Spanish-speaking adolescents from online cyberbullying and the scarce production of solutions based on these technologies in Spanish. Taking advantage of the potential of NLP and semantic analysis made it possible to develop an effective tool to detect and prevent cyberbullying in the linguistic and cultural context of the Spanish language, giving parents and guardians the ability to protect adolescents in digital environments.

To effectively communicate the findings and contributions of the study on the multiplatform application of parental control through Natural Language Processing in the Spanish language. This paper is organized as follows. In Section II, we present some studies related to the use of information and communication technologies for the detection and prevention of cyberbullying, highlighting the limitations of the most recent studies. Section III, outlines the methodological components of the research, as well as the phases guiding the development of the Intelligent Parental Control System. In the Results Section IV, the data obtained in the implementation of the mobile and web applications are detailed. In the Discussion Section V, the results are interpreted in a broad context of cyberbullying in social networks, comparing the results of related works with the challenges for the practical implementation of the designed application. Finally, in Section VI, conclusions derived from the study are presented, highlighting the contributions of the NLP-based application in Spanish for the prevention of presumptive cyberbullying in the social networks of adolescents.

II. Related Works

The following are the results of the main research developed to prevent cyberbullying using advances in Information and Communication Technologies.

Researchers from the National University of the USA developed the SafeGuard Web application, intending to detect dangerous situations in educational institutions based on social networks [19]. By constantly monitoring publications on social networks, SafeGuard determines the relationship of the language users use with pre-established keywords such as suicide, death, violence, and so on. When these terms are identified, the application sends alert messages to the system administration, thus protecting potential victims from any emotional or physical harm. SafeGuard's configuration employs web technologies with hosting in the cloud environment, allowing login from any location. In terms of operation, SafeGuard employs IP address-based access restrictions for client login over the network and uses a JSON Web token with expiration times. To respond to client requests, the application uses the HTTPS protocol. The results of its implementation show the application's ability to

detect cyberbullying, threats, or distress situations through the configuration of monitors or keywords. However, it requires adding weighting factors to the monitors that favor the search for particular keywords by the weighting assigned to them.

The authors of the study [20] analyzed the increase in cyberbullying over the last 15 years, and came up with BullyScan. It is a novel framework based on natural language processing and machine learning with the ability to identify online bullying automatically with high accuracy and efficiency. The application employs a logistic regression algorithm developed from the validation and testing of five different machine-learning models with the combination of three datasets of cyberbullying and/or hate speech. The tests conducted demonstrated 92% accuracy in detecting cyberbullying in real time, evidencing the ability to significantly reduce cyberbullying rates and increase positivity on social networks, as well as prevent the consequences of cyberbullying.

On the other hand, [21] proposes a system that employs PLN and machine learning to detect bullying related to messages in digital environments in the English language. For the research, 1651 tweets were collected and applied to a PLN approach to identify the most offensive terms related to cyberbullying. Using the obtained dataset, Random Forest (RF) and Support Vector Machine (SVM) algorithms were trained. The former outperforms the latter with an accuracy of 98.5%. The analysis of the results was performed using the Root Mean Square Error (RMSE) and the Mean Square Error (MSE). The RF algorithm scored better than the SVM. The results show the existence of cyberbullying and the need to address it immediately.

Similarly, the authors [22], agree that cyberbullying is an extremely prevalent issue at the moment; as access to social platforms increases, messages of hate, toxicity, and cyberbullying. In this sense, it is fundamental to generate mechanisms that guarantee the security of social networks and that any form of violence or hate crime can be automatically detected. Based on this, they proposed the analysis of cyberbullying through natural language processing employing the compression of the use of slang in social networks. As a result of their research, they achieved greater accuracy in identifying online harassment situations through experiments with multiple models such as Bi-LSTM, GloVe, and BERT and the application of the unique processing technique for the incorporation of an abusive corpus of slang. The model demonstrates greater effectiveness than models that do not contain slang preprocessing.

In a more comprehensive perspective, [23] developed an NLP tool that uses the social network Twitter as a basis for the extraction of information related to cyberbullying. The methodological procedure followed consisted of analyzing a set of tweets with the SARNA technique and classifying them based on their content as cyberbullying or neutral. The authors created a labeling system for people to classify the tweets using a reliability scale from 1 to 4, where ratings 1 and 2 indicate that they are non-cyberbullying tweets, while 3 and 4 refer to tweets with cyberbullying content. For the classification process, the BERT model was used, which was trained to identify aggressive, toxic, or threatening comments with label 1 and neutral comments with label 0. The results obtained demonstrate the importance of providing an adequate knowledge base, training the supervised learning model, and conducting case studies to accurately detect cyberbullying using NLP techniques; nevertheless, the authors do not detail the data obtained during the process.

In the same context, the Salesian Polytechnic University has promoted the development of applications that contribute to the reduction of the effects of this problem. The authors in [6], which some authors are also authors of this paper have deployed a Cyberbullying Prevention System (CPS) in Spanish based on Natural Language Processing and the use of Machine Learning techniques such as Naive Bayes, Support Vector Machine, and Logistic Regression. As in the previously mentioned research, the social network Twitter was used for the extraction of the database or corpus. As for the training process, it consisted of the use of precision metrics, and corpus sizes with variability. The level of accuracy of the SPC system was validated with the application in three case studies, obtaining a 93% of reliability.

Furthermore, according to [24] most of the research developed to detect bullying on social network platforms is based on machine learning models that use datasets extracted from individual social networks. Therefore, they have proposed a cross-platform data system that uses text collected from posts made on seven social networks. They propose an annotation system composed of a series of stages and techniques to identify posts and hashtags through crowdsourcing, and then identify posts that require annotation through machine learning methods. The advantage of the presented model lies in the possibility of cyberbullying cases and the limitation of the particular characteristics of the publications, unlike traditional methods based on post-selection and tagging. The training process of the models on the diverse dataset evidences a good performance and allows for an increase in the number of positive examples with the same amount of resources and the applicability of the models in different media.

Thus, although research related to cyberbullying has advanced in recent years, there are still great challenges to be faced. Among these challenges is the need to address the issue in a standardized manner [25] and the generation of applications that consider the linguistic and cultural context in the automatic detection of situations related to cyberbullying. In addition, the aforementioned related works differ from our proposal, since to our knowledge and according to the analysis of the state of the art, there are no applications proposed at the international and even more at a local level that use the Latent Semantic Analysis method for the detection and prevention of cyberbullying in social networks. In Table I, we present a comparative analysis of the cyberbullying detection studies presented before and we have included the present research.

III. Parental Control Multiplatform System for the Prevention of Cyberbullying

The methodological framework followed for this research was based on the principles of applied research whose purpose is to contribute to the solution of society's problems through the application of knowledge and tools of a specific scientific discipline. In this sense, the research is focused on the (a) design and (b) implementation of a multiplatform system based on Natural Language Processing for the prevention of pre-

TABLE I. COMPARATIVE ANALYSIS OF CYBERBULLYING DETECTION STUDIES HIGHLIGHTING METHODOLOGIES, KEY FEATURES, OUTCOMES, AND UNIQUE CONTRIBUTIONS OF EACH STUDY, INCLUDING THE PRESENT RESEARCH

Study	Methodology	Key Features	Outcomes/Accuracy	Unique Contributions
SafeGuard (Wyne, 2021)	Web application, keyword monitoring	Cloud hosting, IP address restrictions, HTTPS protocol	Effective in detecting cyberbullying via keyword monitoring	Focus on educational institutions, requires keyword weighting
BullyScan (Shrimali, 2022)	NLP & ML, Logistic Regression	Combination of three datasets, real-time detection	92% accuracy	High accuracy and efficiency in real-time detection
Afrifa et al. (2022)	NLP & ML, RF and SVM algorithms	Analysis of 1651 tweets, RMSE and MSE evaluation	98.5% accuracy with RF algorithm	High accuracy, focus on English language messages
Bhatia et al. (2022)	NLP, Bi-LSTM, GloVe, BERT	Slang preprocessing, abusive corpus analysis	High accuracy in identifying online harassment	Effectiveness in slang and abusive language detection
Soto et al. (2022)	NLP, BERT model	SARNA technique, labeling system for tweets	Not detailed	Importance of adequate knowledge base and training
CPS (Leon Paredes, 2019)	NLP & ML, Naive Bayes, SVM, Logistic Regression	Twitter data extraction, precision metrics	93% reliability	Focus on Spanish language, high reliability
Van et al. (2020)	Cross-platform data system, ML	Posts from seven social networks, crowdsourcing annotation	Good performance	Cross-platform applicability, diverse dataset
Present study	NLP & LSA, cosine similarity analysis	Focus on Spanish language, multiplatform application, analysis of Facebook, Ask.fm, and Twitter	46% with negative texts and 6.71% with positive texts	Unique use of LSA for cyberbullying detection in Spanish

sumptive cyberbullying in the social networks of adolescents focused in the city of Cuenca - Ecuador.

On the one hand, we detail some important points related to the (a) design of the Parental Control Multiplatform System for the Prevention of Cyberbullying based on NLP. To implement an accurate design, we need to know how young people (students between 18 and 24 years old) of the Salesian Polytechnic University use digital media to determine the main problems of cyberbullying in social networks in our local context. Hence, a structured survey called "Survey of Safety and Cyberbullying in Social Networks" was applied. The survey consisted of 20 items with dichotomous and polytomous response options. The instrument with the questions was applied to 133 students enrolled in the Computer Science program. The size of the probabilistic sample was defined considering Eq. (1) for a finite population. The total population was 5,576 on-campus students from all UPS courses. The procedure for the selection of the sample is indicated below,

$$n = \frac{N\sigma^2 Z^2}{(N-1)e^2 + \sigma^2 Z^2} \tag{1}$$

where, *n*, is equal to the size of the sample; *N*, is equal to the size of the population; σ, is equal to the standard deviation of the population, when a value is not available the constant value of 0.5 is used; *Z*, is obtained by confidence levels, in case of not having a value 95% of confidence is placed and this is equivalent to 1.96 (it is the one commonly used); *e*, is equal to the acceptable limit of the sampling error, when a value is not available a range from 1% (0.01) and 9% (0.09) is used, this value depends on the interviewer.

The process of tabulating the results obtained through the survey was crucial within the methodology proposed for the design of the Parental Control Multiplatform System, so we highlight the most important results below. The analysis of the results shows that 88% of the participants are between 18 and 24 years of age, 86% are male, and 100% use social networks. Regarding the use of social networks by the participants, 9% stated that they use social networks to meet new people, while 37% use them for entertainment, 16% to communicate with people who live in different places, 36% to communicate with friends, family, acquaintances, among others, and only 2% responded that they use the networks for other situations such as business. The data obtained show that most of the young students surveyed use social networks to communicate with other people.

Furthermore, when participants were asked about the time they spend using social networks, 2% use social networks for less than one hour, 31% use them for one to two hours a day, 41% use them for three to four hours a day, 17% use them for five to six hours a day, 4% use them for seven to eight hours a day, and 5% use social networks for more than nine hours a day. In this sense, it is evident that most of the participants use social networks for several hours during the day. Regarding the most used social networks, 23% of the participants stated that they use WhatsApp, 22% use Facebook, 8% use Twitter, 1% use Tumblr, 23% use YouTube, 20% use Instagram, and 3% use Pinterest. Thus, the majority of the surveyed students mostly use social networks such as WhatsApp, Facebook, YouTube, and Instagram.

An important fact to be considered is that 46% of participants confirm having received cyberbullying messages. Regarding the social networks in which they have sent, known, or received messages of cyberbullying, 15% indicate WhatsApp, 38% indicate Facebook, 4% indicate Twitter, 11% indicate Instagram, 1% indicate that Snapchat, Tinder, and Badoo are social networks where this type of problem happens, 2% indicate that YouTube is the social network where messages of cyberbullying are sent, known or received, 1% indicate that in no social network this problem happens, and 27% did not respond. Thus, most of the participants who send, know, or receive cyberbullying messages have received it at least once on any of the social networks WhatsApp, Facebook, Instagram, Twitter, Snapchat, Tinder, and YouTube. Finally, it is important to highlight that 95% of participants say that if they had a computer tool to prevent and detect cyberbullying, they would use it.

Hence, based on this diagnosis, we have determined the features that the Parental Control Multiplatform System proposed in this paper should have. First, we have designed it to be used by parents, guardians, teachers, and psychologists,

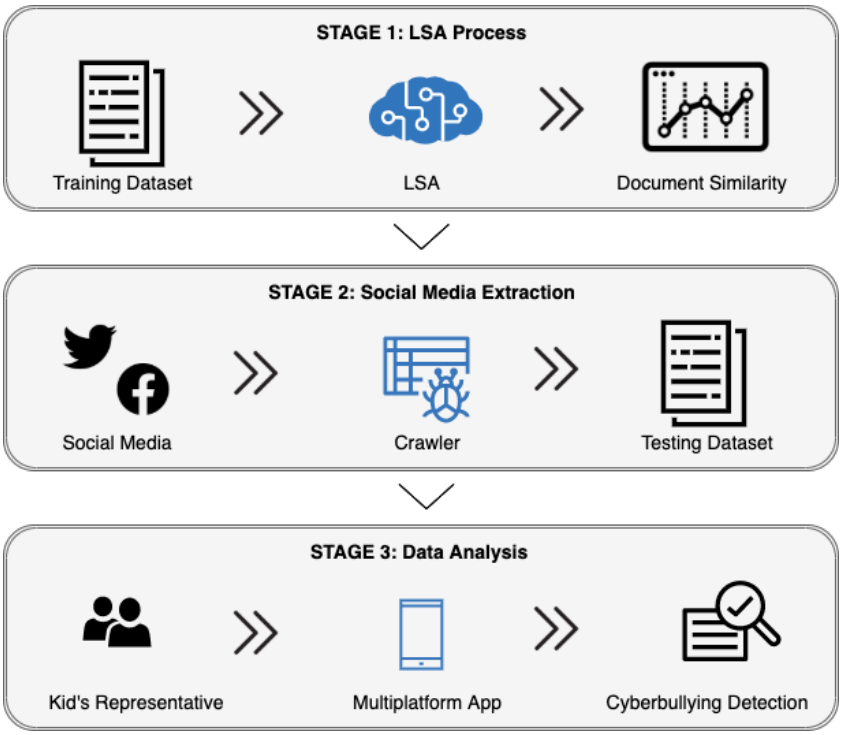

Fig. 1. Stages followed for the implementation of the parental control multiplatform system.

among others, and to be aware of the type of information that adolescents receive through social networks. We have focused on young people who have initiated using these platforms and do not have the knowledge to deal with bullying situations. Also, the Parental Control System was designed to work both in web environments and mobile devices, through the creation of a multiplatform system. It is necessary to note that, for web environments, the application has features that differ from the version for mobile devices, mainly due to the incorporation of extra functionalities.

On the other hand, we detail the (b) implementation of the Parental Control Multiplatform System based on Natural Language Processing through the Latent Semantic Analysis (LSA) method for preventing presumptive cases of cyberbullying in social networks. The system has been divided into three main stages, as shown in Fig. 1.

For the first stage of system implementation, we utilize the Latent Semantic Analysis (LSA) method, which allowed us to obtain a base training model for detecting cases of presumptive cyberbullying in several social networks. At this point, it is important to indicate that this paper is oriented to the Natural Language Processing of the Spanish language with an emphasis on social network users from Ecuador. So, we started by obtaining a Spanish dataset related to cases of cyberbullying in Ecuador. We need this specific type of dataset due to the slang used among adolescents. Thus, we worked with a dataset referred to a previous paper published by some authors of this work, as shown in the research document "*Presumptive Detection of Cyberbullying on Twitter through Natural Language Processing and Machine Learning in the Spanish Language*".

As mentioned in study [6], the dataset is compounded with a total of 960,578 tweets, of which 416,567 correspond to presumptive cyberbullying. Then, all the tweet's text data was cleaned up by using text processing techniques such as the removal of stopwords, lemmatizing, and stemming of the remaining words. After the processing of the tweet's text data, we constructed the Term-by-Document matrix, and then we reduced this matrix to 300 k dimensions by applying the Singular Value Decomposition (SVD) truncated method [26].

At this point, it is important to clarify how we used the Latent Semantic Analysis method for the presumptive detection of cyberbullying. As mentioned, we employed a dataset of 416,567 tweets with plausible cyberbullying, and 544,011 tweets with no presumptive cyberbullying to train our knowledge base. Then, each comment of a post made on the social network of the adolescent is compared against the trained dataset (cyberbullying, and no cyberbullying). Therefore, a similarity value is obtained for each trained document from the dataset versus the comment post issued on the social network. Next, these values are ordered from highest to lowest. We left with the top 10 values, to subsequently obtain a general similarity value of the comment posted on the social network by applying the following equation,

$$SimPos = \frac{\sum_{i=1}^{10} SimDoc_i}{10} \quad (2)$$

where, *SimPos* is equal to the general similarity of the comment posted on the social network, *SimDoc* is equal to the similarity obtained between each document of the trained dataset and the comment posted on the social network. Finally, the value of *SimPos* is then evaluated between the general

similarity obtained of the trained dataset with presumptive cyberbullying and the trained dataset with no presumptive cyberbullying, which allows us to determine whether the comment post contains presumptive cyberbullying or not. For our case studies, if the general similarity of the trained dataset with presumptive cyberbullying is greater than the general similarity of the no presumptive cyberbullying dataset, then it can be inferred that the comment contains presumptive cyberbullying.

In the second stage of the implementation of the Parental Control Multiplatform System, we crawled the text data from social networks, in this case, Twitter, Facebook, and AskFM. First, the system needs the credentials of the Facebook and AskFM social network user, to extract the text interaction of its account. Thus, for these cases, we utilized frameworks, that can automate the web browser navigation throughout the execution of programming scripts. However, for the case of Twitter, we used the official API, which can permit us to extract the text tweet data of a specific user when its account is public. Hence, for this case, we don't need the user credentials, only a key API consumer of a Twitter developer account.

Moreover, the data crawled from the social network has to be extracted constantly to detect them as soon as possible the presumptive cyberbullying. Consequently, we proposed and developed automated tasks on the server side to extract the social network text data using the crawlers specified in the previous paragraph. These automated tasks can be executed hourly, daily, weekly, or monthly depending on the configuration each user makes on the system.

In the last stage, we developed the multiplatform (progressive web and mobile) system. Some of the functionalities created have been focused on registering new users, authenticating and authorizing user accounts, recovering account passwords, registering and authorizing the credentials of the adolescent's social network accounts, crawling the text data from the registered and authorized social network accounts, scheduling when the text data is extracted, and presenting the analysis results of the presumptive or not cyberbullying, as shown in Fig. 2, and 4. In addition, as part of raising awareness of the cyberbullying problem, we added some relevant documentation (articles, videos, and psychologist experts' contacts), as shown in Fig. 3.

Finally, taking into account these three phases in the implementation of the Parental Control Multiplatform System, its "normal" functionality is explained in greater detail below. Then, as a first step, the parent or guardian responsible for the child or adolescent must register as a user within the system, for which personal information such as identification number, full name, address, telephone, email, and password are requested. Next, they must go through a process of verification of their personal data, for which an email is sent to the guardian indicating the steps for activating their account in the system.

With these previous steps completed, the new user will be able to log in and then have the option of registering different social network accounts of his/her tutored. At this point, it is important to indicate that, when registering Facebook and ASK FM social network accounts, the username and password of the adolescent's account must be entered so that this information is sent to the crawlers and the text information can be extracted.

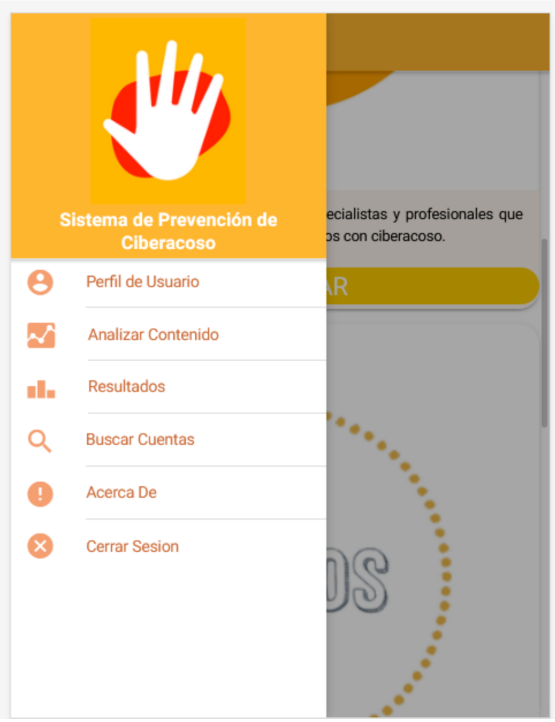

Fig. 2. Graphical user interface of the functionalities that the user of the parental control multiplatform system has access to.

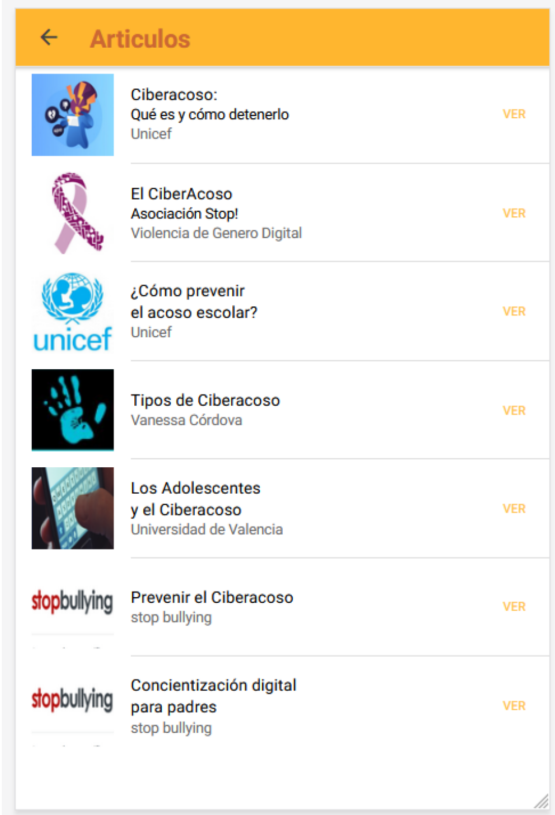

Fig. 3. Graphical user interface of the relevant documentation related to cyberbullying presented in the parental control multiplatform system.

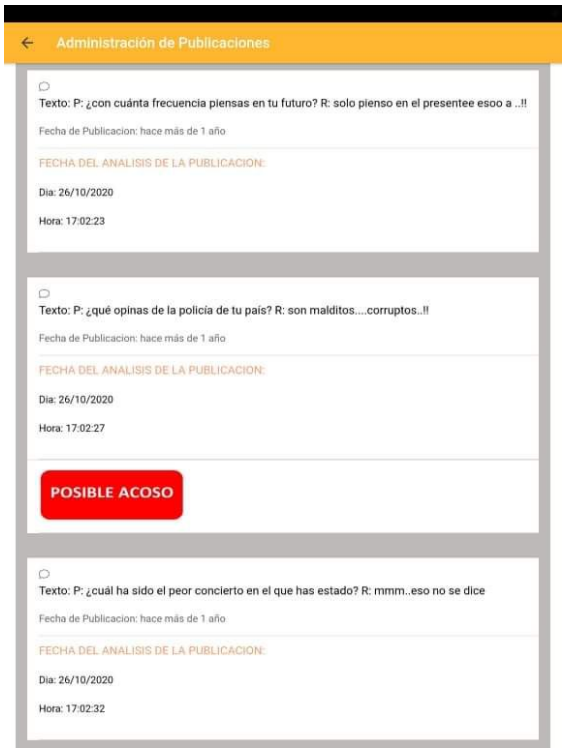

Fig. 4. Graphical user interface of the list of publications from the social network adolescents' accounts in the parental control multiplatform system.

Once the corresponding user and account registrations have been made, the frequency of analysis to be performed on the accounts can be configured. This analysis can be hourly, daily, weekly, or monthly and is done through automated tasks on the server side. However, there is the possibility that the user from the system can run a scan at any time. This allows the web services to be consumed to extract the information from the social networks, and subsequently analyze them. Regardless of which of the two analysis options is selected, once the system completes the analysis, a message is sent to the user's email indicating that the analysis is complete.

IV. Results

Below, we present the results of the experiments carried out with the Parental Control Multiplatform System for the prevention of presumed cases of cyberbullying.

A. Results of the Analysis of Accounts from Different Social Networks using the Latent Semantic Analysis Method

This sub-section presents the results of the analysis of social network accounts that have been specifically selected for testing and validation. The objective of these experiments is to test the performance of the LSA method. So, these selected accounts have published content considered as alleged harassment, even some accounts belonging to a well-known case in Cuenca - Ecuador, where the implicated user faced legal problems and is currently serving a sentence. On the other hand, accounts of public figures that publish messages of peace and love considered as "without harassment" have been used. The validation procedure consisted of first extracting the information from the social network accounts and then analyzing this information using the LSA method. As a final phase, the results were presented with the percentage of similarity, both in texts with presumptive cyberbullying (negative) and without presumptive cyberbullying (positive) as can be seen in Fig. 4, which shows an example of how the analysis results are presented in the Parental Control Multiplatform System. Then, for this experiment, two Twitter accounts were analyzed.

For this experiment, two Twitter accounts were analyzed. In the first account, we analyzed posts issued by a known user in the city of Cuenca - Ecuador who committed serious crimes against adolescent women, and his main communication media were social networks, where he hooked his victims, for which he faced legal problems and is currently serving a sentence. In this first account analyzed, although the total value of the similarity of "positive" texts prevailed over "negative" texts, the algorithm evidences the existence of texts with assumed cyberbullying as some examples can be seen in Table II. The analysis reveals the ability of the Parental Control Multiplatform System designed to identify terms that suggest harassment, manifested through swearing, insults, words with high levels of aggressiveness or derogatory phrases, and even threats. An example of a threat identified by the algorithm is the phrase *"a cada PUERCA le llega su carnival"*, which means in English "every PIG has its own carnival". It should be noted that in the local context, a carnival is a local holiday where families come together to eat a pig. Therefore, in this post, the user refers to his victims as animals. In this sense, the documentary review argues that it is completely normal for a social network stalker to use phrases with insinuations to threaten his victim [25]. This is because, cyberbullying can take different forms, including spreading rumors, posting humiliating comments, or direct threats, among others. The insinuations can be used as a form of psychological harassment [27], which seeks to destabilize the victim and make them feel uncomfortable or insecure.

Likewise, the phrase "When you are cold look for me", detected by the algorithm as a form of cyberbullying, might seem like an innocent offer, but it is designed to make the victim feel observed or surveilled. This is explained by the fact that in some cases, the cyberbully may use subtle or indirect language to avoid detection by security filters or by the victim's parents and guardians [28]. These insinuations may seem harmless or even flattering at first glance. Therefore, the difference between the percentage of negative and positive text is minimal. Nevertheless, the system determines that it is a threatening or intimidating message that should alert parents or guardians.

The second Twitter account analyzed was the account of Pope Francis, Supreme Pontiff of the Catholic Church; to establish a comparison of the percentages of similarity between the analyzed account with presumed cyberbullying publications and the @Pontifex_es account. As shown in Table III, the percentage of similarity of "positive" text is well above the "negative" text. This indicates that there is a minimal percentage of text linked to cyberbullying. The Parental Control Multiplatform System developed in this proposal has obtained alarms from this account on posts where terms such as "war", "weapons", "pain", and "hurt" appear. In this sense, although the main function of the LSA method is to identify patterns

TABLE II. SAMPLES OF THE RESULTS OBTAINED BY THE ALGORITHM OF THE PARENTAL CONTROL MULTIPLATFORM SYSTEM WHEN ANALYZING THE FIRST TWITTER ACCOUNT OF THE USER WHO HAS BEEN SENTENCED IN THE CITY OF CUENCA - ECUADOR FOR CRIMES WHERE SOCIAL MEDIA WAS HIS MAIN COMMUNICATION MEDIA

QUERY	% SIMILARITY NEGATIVE TEXT	% SIMILARITY POSITIVE TEXT	CYBERBULLYING?

Aprecia lo que la vida te da, porque no te da dos veces,,,	17.14	18.04	No
Si te estorba la virginidad yo soy experto en curar esos males y estorbos,	11.16	10.79	Yes
A cada PUERCA le llega su Carnaval	14.97	8.11	Yes
Lo que aprendí de Mario Bross es que mientras mas moneditas tengas, es más fácil llegar a la princesa,	13.00	17.53	No
No confío en tus palabras, que se las lleve el viento muy lejos del lugar en el que yo me encuentre,	07.18	09.94	No
Tienes que saber diferenciar para que te quería, para amarte o solo para TIRARTE, Y siempre fuiste lo SEGUNDO,,,	30.55	42.61	No

and semantic relationships between words and documents in a text corpus, it is important to keep in mind that latent semantic analysis is not always able to capture the full context and emotional connotations of a text [16], [17]. Therefore, it becomes necessary to critically read the analysis and consider the full context before drawing conclusions.

Another experiment conducted in this research was with the Ask.fm social network, a question-and-answer-based social platform that allows users to interact anonymously or in an identity-based mode. This platform was launched in 2010 and has become very popular among teenagers and young adults as a way to ask funny, curious, or personal questions to friends and strangers. To validate the algorithm of the Parental Control Multiplatform System, two Ask.fm accounts were created. The first account created has username *mapesystems2*, and is an account that has been created to disseminate messages with pretended harassment, as can be seen in Fig. 5. In this account, the total similarity value of "negative" texts was well above the similarity of "positive" texts, which evidences a large number of texts with presumptive cyberbullying.

The second analyzed account of the Ask.fm social network belonged to the user *mapesystems4344*, which was also created to validate the algorithm of the Parental Control Multiplatform System, and unlike the previous account, its objective consisted of posting messages without "much" presumed harassing content, as can be seen in Fig. 6. Unlike the first analyzed account, in this account, the total value of "positive" text similarity prevails over "negative" text similarity. This indicates that in this account there is a lower amount of texts with cyberbullying.

B. Expert Validation of the Parental Control Multiplatform System

It is important to mention that, for the validation process, the collaboration of psychologists, and specialists in the area of cyberbullying, as well as students and parents or guardians was requested. For the validation of the Web application, first, an explanation of the system's functionalities was given user registration; social network account creation, validation; analysis, and detection of presumptive cyberbullying; among other

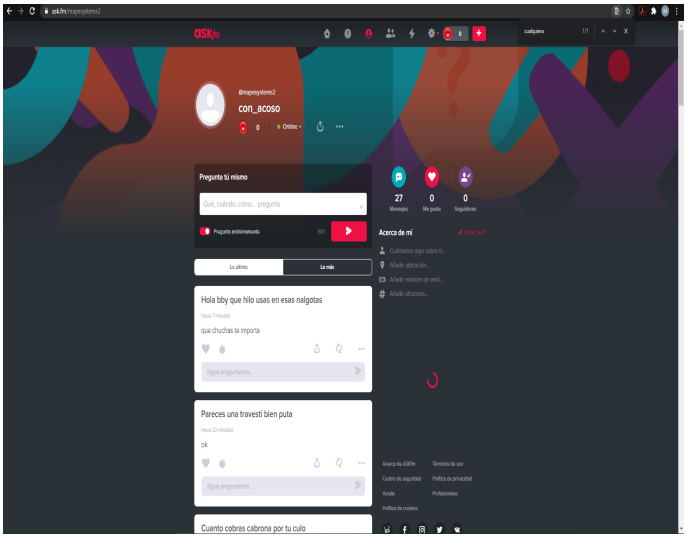

Fig. 5. Sample messages posted on the Ask.fm social network by the user *mapesystems2*.

functionalities. Once the whole process was explained, the following link https://cloudcomputing.ups.edu.ec/controlParental/ was sent to them so that they could interact with the system and perform the cyberbullying analysis on different social network accounts.

Once the presentation and validation of the web application were finished, the functionalities available in the mobile application were explained, such as viewing the results of the analyzed accounts, checking account information, and updating user data. After the demonstration, the psychologist and the guardians downloaded[1] the mobile application from the Google Play Store. To assess the effectiveness and adequacy of our mobile and web applications in detecting suspected cyberbullying cases, a group of experts conducted testing. Following this, we distributed a questionnaire to a diverse

[1]At the moment of writing this paper and after being published for several months, the application has been unpublished due to Google's policies.

TABLE III. SAMPLES OF THE RESULTS OBTAINED BY THE ALGORITHM OF THE PARENTAL CONTROL MULTIPLATFORM SYSTEM WHEN ANALYZING THE @PONTIFEX_ES TWITTER ACCOUNT

QUERY	% SIMILARITY NEGATIVE TEXT	% SIMILARITY POSITIVE TEXT	CYBERBULLYING?
"La oración es el centro de la vida, Si hay oración, también el hermano, la hermana, se vuelve importante, Quien adora a Dios, ama a sus hijos, Quien respeta a Dios, respeta a los seres humanos," $\#AudienciaGeneral@Pontifex_es$, 2012,	18.02	24.26	No
"La pertenencia a Cristo y el estilo de vida que se deriva de ella no aíslan al creyente del mundo; por el contrario, lo hacen protagonista de un servicio de amor en favor del bien común," $@Pontifex_es$, 2012	25.12	36.93	No
"¿Una decisión valiente? Destinar el dinero utilizado para las armas a un "Fondo mundial" para acabar con el hambre, Esto evitaría muchas guerras y la emigración de muchos hermanos y hermanas nuestras de los países más pobres, #JornadaMundialAlimentación" (@Pontifex_es, 2012)	14.45	13.73	Yes

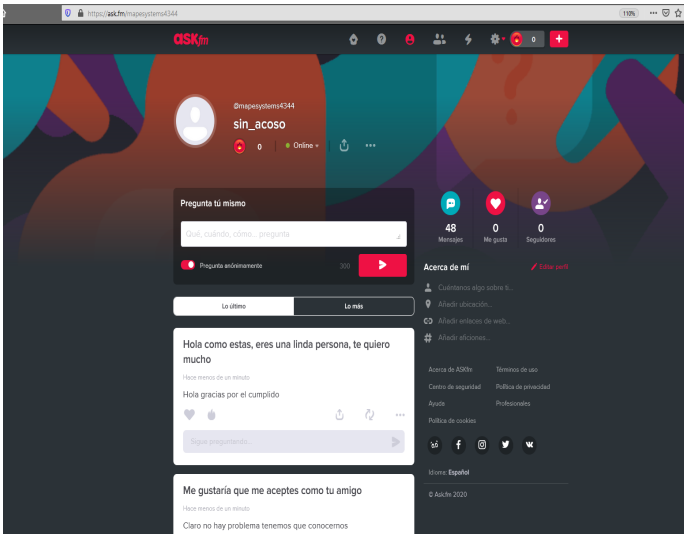

Fig. 6. Sample messages posted on the Ask.fm social network by the user *mapesystems4344*.

group of 10 users, including parents, guardians, students, and psychologists. The questionnaire aimed to gather feedback on the application's features and determine its overall effectiveness. The most relevant results of the survey are presented below.

As evidenced in Table IV, 50% of the surveyed users consider that how the results of the analyses are presented in the web application is understandable and 50% consider that how the results are presented in the application is easy to understand. This shows that all participants understood and comprehended how the information is displayed.

Furthermore, Table V shows that 60% of the surveyed

TABLE IV. DOES THE WEB APPLICATION EFFECTIVELY PRESENT THE ANALYSIS RESULTS IN A CLEAR AND COMPREHENSIBLE MANNER?

	Users	Answer
Absolutely understandable	5	50%
Easy to understand	5	50%
Absolutely difficult to understand	0	0%

users consider that the mobile application has an excellent appearance, and 50% consider that it has a good appearance in terms of colors, images, icons, and visibility. This shows that all respondents consider that the mobile application has an adequate appearance and meets their needs.

TABLE V. WHAT DID YOU THINK OF THE APPEARANCE (COLORS, IMAGES, ICONS, VISIBILITY) OF THE MOBILE APPLICATION?

	Users	Answer
Excellent appearance	6	60%
Good appearance	4	40%
Bad appearance	0	0%

In that order, users were asked whether they consider how the results of the analyses are presented in the mobile application to be understandable. According to the results presented in Table VI, 60% of the surveyed users consider it to be understandable and 40% consider it to be easy to understand. This means that all participants understand and can comprehend the presentation of the results.

Table VII, shows that 88.9% of surveyed users consider the security of the application to be excellent and 11.1% consider it to be regular. This means that most of the participants consider that both the web and mobile applications have good security in terms of the information handled, since it is confidential between each user.

TABLE VI. DOES THE MOBILE APPLICATION EFFECTIVELY COMMUNICATE THE ANALYSIS RESULTS UNDERSTANDABLY?

	Users	Answer
Absolutely understandable	6	60%
Easy to understand	4	40%
Absolutely difficult to understand	0	0%

TABLE VII. HOW SATISFIED ARE YOU WITH THE SECURITY OF THE APPLICATION?

	Users	Answer
Excellent	9	88.9%
Regular	1	11.1%
Bad	0	0%

Regarding the ease of use of the application to detect presumptive cases of cyberbullying, Table VIII, evidences that 70% consider that both the mobile application and the web are very easy to use and 30% consider that are easy to use. This means that the majority of participants find the applications easy to use.

TABLE VIII. HOW SATISFIED ARE YOU WITH THE EASE OF USE OF THESE APPLICATIONS?

	Users	Answer
Very easy to use	7	70%
Easy to use	3	30%
Absolutely difficult to use	0	0%

Moreover, when users were asked, how satisfied are they with the reliability of this application? As Table IX shows, 80% consider that it is very reliable to use the applications, while 10% consider that it is not very reliable and the remaining 10% consider that it is not reliable to use the applications. This means that a minimum percentage of surveyed users are not sure about the reliability of the application.

TABLE IX. HOW SATISFIED ARE YOU WITH THE RELIABILITY OF THIS APPLICATION?

	Users	Answer
Very reliable	8	80%
Unreliable	1	10%
Not reliable	1	10%

Finally, users were asked if they would use this application daily to keep control over the social networks of the adolescents or young people they represent to prevent them from suffering presumptive cyberbullying. Table X, shows that in response to this inquiry, 80% consider that it does meet the objective of helping with cyberbullying issues and 20% consider that it meets the objective of helping with cyberbullying issues regularly.

TABLE X. WOULD YOU USE THIS APPLICATION DAILY TO MAINTAIN CONTROL OVER YOUR CONSTITUENTS' SOCIAL NETWORKS AND PREVENT THEM FROM PRESUMPTIVE CYBERBULLYING?

	Users	Answer
Yes	9	90%
No	1	10%

V. DISCUSSIONS

The review of the literature on the use of new information and communication technologies to prevent and detect cases of cyberbullying in young people and adolescents demonstrates the current concern to address the problem. The total of the research consulted is mainly focused on finding effective solutions for the detection and prevention of cyberbullying in digital environments, especially in social networks. NLP is one of the most novel technologies for analyzing and understanding contextual content generated online and identifying patterns of cyberbullying, offensive language or abusive content. However, the consideration of the contextual aspect is a very little addressed topic. Therefore, the contributions of the present research demonstrate that understanding the context is a relevant element to accurately detect cases of cyberbullying on digital platforms.

Tests carried out with the use of two Twitter accounts demonstrated the efficiency of the Parental Control Multiplatform System to extract information from the social network accounts of adolescents, analyze it using the LSA method, and generate results with the percentage of similarity, both in "negative" and "positive" texts, and alert parents or guardians whether or not there is a presumptive case of cyberbullying.

Unlike the applications developed by [19], [20], [21], [22]. The author in [23], the present research focused on the use of LSA in the Spanish language to achieve greater precision in the analysis of the similarities of texts related to cyberbullying in the context of Ecuadorian adolescents. The research analyzed demonstrates the efforts made by different countries to protect adolescents from online cyberbullying and the scarcity of solutions in Spanish. Thus, it is possible to demonstrate that the use of LSA allows obtaining an appropriate percentage of similarity on alleged cases of cyberbullying in social networks using a knowledge base extracted semi-automatically from social networks such as Twitter.

In summary, the use of Latent Semantic Analysis for detecting cyberbullying in Ecuadorian social media has demonstrated its valuable capabilities, alongside certain inherent limitations in capturing emotional connotations. LSA's strength in identifying explicit aggressive language, as evidenced in high-profile cyberbullying cases, highlights its utility as a tool in initial screening processes. However, our experiments also brought to light the method's challenges in interpreting more nuanced emotional contexts. For instance, the misclassification of contextually complex terms in Pope Francis's account illustrates the need for a deeper understanding of emotional subtleties beyond LSA's word co-occurrence framework. Also, the minimal disparities in negative and positive text percentages in certain cases further underscore the importance of integrating LSA with more context-sensitive methods. Embracing these limitations as opportunities for improvement, LSA can be effectively complemented with advanced, emotionally intelligent algorithms, paving the way for more nuanced and culturally aware cyberbullying detection systems.

The validation, functioning, and operability of the Parental Control Multiplatform System were positively assessed by representatives and experts in the field of psychology. When consulted, they stated that the multiplatform application is a novel tool for identifying possible cases of bullying on social networks. The multiplatform application to detect suspected cyberbullying differs from other existing applications because although they provide parents or guardians with tools to monitor their children's online activity [29], they are not focused on analyzing the online activities of adolescents to detect possible cases of cyberbullying through specific information analysis techniques and the identification of bullying patterns [10].

In terms of functional requirements, parental control applications generally offer monitoring of browsing history, blocking of inappropriate websites, monitoring of messages and phone calls, and setting time limits for the use of devices [19]. Unlike these, our designed application is based on Natural Language Processing using the LSA method, which allows for establishing search patterns, information retrieval, grouping of topics, generating alerts and content recommendations [17], [18].

Regarding the security of the proposed system, it could be demonstrated that it is a secure platform. It is designed to protect users' personal information and comply with privacy and data security standards. Nevertheless, a very small number of users stated that they would not use the application frequently to monitor their children's social network usage. The tests conducted showed that the application does not present potential risks in terms of privacy and data security. One of the major limitations of the apps available for parents and guardians is that they rely on excessive handling of personal information, which becomes a risk factor for the safety of families.

VI. Conclusions

Nowadays, despite the evolution of information and communication technology, very little importance has been given to the negative situations that these advances entail. The most significant issue, and one that is occurring worldwide, has to do with cyberbullying. Although its effects can be devastating, especially for young people and adolescents, there are not many tools or applications aimed at analyzing the activities that adolescents perform on their social networks and determining cases of possible harassment on digital platforms given certain publications, comments, or messages that are inappropriate.

The Parental Control Multiplatform System developed through Natural Language Processing in Spanish had the objective of detecting presumptive cases of cyberbullying in the social networks of the accounts registered in the applications, based on the extraction of information. With the use of data mining, it was possible to generate scripts called *crawlers* to obtain the information, with the respective authorization of the person who owns the account.

The content analysis is performed using the Latent Semantic Analysis method. The creation of a semantic space made it possible to determine the existing similarities between a harassment dataset, which includes positive and negative texts, and the information of each social network, with the purpose of evidencing whether there is alleged cyberbullying.

The Parental Control Multiplatform System provides the necessary information to the user. In addition to the analysis, the user is also provided with multimedia content that will allow him/her to have more information about cyberbullying. This is because, for many representatives, this is still a new and unknown topic. The first option is to contact specialists on the subject, such as psychologists, who can provide guidance and have the appropriate knowledge and the necessary tools to cope with this type of situation that could happen to the person they represent. Another option is to view a list of videos on the subject and the last option is to review articles on the Internet.

Cyberbullying is a constantly evolving phenomenon and new technologies and forms of online communication present new challenges for its investigation and prevention. Therefore, there is still much to explore and discover about cyberbullying, especially in relation to newer forms of cyberbullying, such as cyberbullying through online gaming platforms and next-generation social networks. Similarly, it is important to note that cyberbullying has significant impacts on the mental health and well-being of young people, so more research and efforts in prevention and treatment are needed.

Acknowledgment

The authors would like to thank the Cloud Computing, Smart Cities & High Performance Computing Research Group (GIHP4C), and the Computer Science students of the *Universidad Politécnica Salesiana* (UPS) for their collaboration in the development of the study. In addition, they are grateful for the support of the psychology specialists who helped in the validation of the Parental Control Multiplatform System for the prevention of cyberbullying. The parents, guardians, and representatives are thanked for their observations and suggestions for improving the use of the system.

Mukh-Oboyob: Stable Diffusion and BanglaBERT Enhanced Bangla Text-to-Face Synthesis

Aloke Kumar Saha, Noor Mairukh Khan Arnob*, Nakiba Nuren Rahman, Maria Haque,
Shah Murtaza Rashid Al Masud, Rashik Rahman*
Department of CSE, UAP, Dhaka, Bangladesh

***Abstract*—Facial image generation from textual generation is one of the most complicated tasks within the broader topic of Text-to-Image (TTI) synthesis. It is relevant in several fields of scientific research, cartoon and animation development, online marketing, game development, etc. There have been extensive studies on Text-to-Face (TTF) synthesis in the English language. However, the amount of relevant existing work in Bangla is limited and not comprehensive. As the TTF field is not vastly prospected for Bangla language, the objective of this study sets forth to explore the possibilities in the field of Bangla Natural Language Processing and Computer Vision. In this paper, a novel system for generating highly detailed facial images from textual descriptions in the Bangla language is proposed. The proposed system named Mukh-Oboyob consists of two essential components: a pre-trained language model, BanglaBERT, and Stable Diffusion. BanglaBERT, a transformer-based pre-trained text encoder, is a language model used to transform Bangla sentences into vector representations. Stable Diffusion is used by Mukh-Oboyob to generate facial images utilizing the text embedding of the Bangla sentences. Moreover, the work utilizes CelebA Bangla, a modified version of the CelebA dataset consisting of face images, Bangla facial attributes, and Bangla text descriptions to develop and train the proposed system. This paper establishes a system for image synthesis with excellent performance and detailed image outcomes, as evidenced by a comprehensive analysis incorporating both qualitative and quantitative measures, leading to the system under consideration achieving an impressive FID score of 34.6828 and an LPIPS score of 0.4541.**

Keywords*—Bangla text-to-face synthesis; Natural Language Processing (NLP); Bangla NLP; Computer Vision (CV); Generative Model; stable diffusion; BanglaBERT

I. Introduction

Diffusion models have emerged to be a useful tool for generating realistic images in a variety of domains, such as human faces and natural landscapes. The ability to generate high-quality images from textual representations has attracted a lot of attention because of its possible applications in the development of content, augmented reality, and customized advertising.

Text-to-image generation is an approach to generating a picture from a given textual input. TTF is a subsection of TTI generation in which a human face description is provided and a facial image is generated based on the description. Compared to text-to-image generation, creating images of faces is a more difficult piece of work considering the complexity of facial features. TTF synthesis has plenty of applications that could be used, including internet marketing, animation, development of games, forensic science, and the metaverse. A significant amount of literature has been penned about the creation of faces and images from text in recent years, as this field of study has grown in prominence. Interestingly, a significant proportion of academics have focused on image creation in the English language [1].

While substantial progress has been made in the area of text-to-image synthesis based on the English language, there is a lack of advanced and enhanced research concerning non-English languages, particularly Bangla. The Bangla language presents unique challenges to the synthesis of TTF due to its unique linguistic and cultural nuances. Facial image generation from Bangla text requires an extensive knowledge of the phonological, syntactic, and semantic structures of the language. To create authentic and culturally relevant facial portrayals, it is essential to accurately capture the visual diversity and unique facial features of Bangla-speaking people.

GAN (Generative Adversarial Network)-based models used for text-to-image synthesis face unstable training, mode collapse and non-convergence intrinsically due to adversarial training [2]. Diffusion models [3] are more capable of synthesizing realistic images compared to GANs as they seldom fall into such issues, thanks to a more stable training process. Vector quantized diffusion models produce better results compared to GAN-based models using diffusion strategy to avoid error assembling for image synthesis. Moreover, It achieves improved image generation speed while maintaining excellent image quality [4].

In the field of text to face synthesis, there is a lack of extensive research for Bangla language. Therefore, this paper proposes a novel Diffusion-based system, Mukh-Oboyob, specifically to generate face images from Bangla textual input to progress TTF generation for the Bangla language. The objective of the proposed system, Mukh-Oboyob, is to mitigate an existing void in the domain of TTF generation by addressing the difficulties associated with generating images with varying structures, that differ in appearance, and level of detail while upholding the realism of the images generated from Bangla descriptions that will significantly contribute to the advancement of the field of Bangla natural language processing.

The suggested system, Mukh-Oboyob, consists of two major parts: a pre-trained language model and a latent diffusion-based model, namely, BanglaBERT and Stable Diffusion respectively. BanglaBERT [5] is utilized to learn bi-directional contexts from Bangla sentences and extract semantic information essential to the text by encoding Bangla descriptions into vector representations and performing transformations over them in order to extract contextual information. Following

that, a Stable Diffusion [3] model which is used to synthesize images from text descriptions. The model is trained and evaluated following a modified version of the CelebA dataset [6] called CelebA Bangla [7]. This dataset incorporates 40 facial attributes derived from a semantically accurate Bangla vocabulary and includes a collection of facial images aligning with the 40 corresponding facial attributes. The CelebA Bangla dataset follows a novel algorithm [7] to create Bangla textual descriptions of facial images. The evaluation of the quality, diversity, and accuracy of the generated facial images is carried out by comprehensive testing and the application of both quantitative and qualitative evaluation metrics. The system under consideration achieved an FID (Fréchet Inception Distance) score of 34.6828 and an LPIPS (Learned Perceptual Image Patch Similarity) score of 0.4541.

The following sections of the paper are constructed as follows: Section II contains the literature review. The dataset is described in Section III. Section IV discusses the methodology followed by the system. Result Analysis is elaborated in the Section V. Section VI takes through the discussion whereas Section VII states the limitations of this work. FInally, Section VIII draws the conclusion and the references are added at the end of the paper.

II. Literature Review

In this section, significant studies utilizing generative models in the field of TTI and TTF synthesis are presented.

A. Text to Image Generation

This section provides a concise overview of a few methods that are notable and have come across to achieve impressive results for text-to-image synthesis.

Reed *et al.* [8] suggested a method of translating single-sentenced text descriptions directly into image pixels by introducing a deep convolutional GAN based on text description embedding compressed using a fully connected layer and leaky-ReLU activation and text features used to perform feed-forward inference by the generator and discriminator network fundamentally demonstrating enhanced text to image synthesis. In Paper [9], they proposed the use of the Bangla Attentional Generative Adversarial Network (AttnGAN) to generate high-quality images from texts through multi-staged processing and incorporation of specific details in distinct parts of images, achieving an enhanced inception score on the CUB dataset.

Naveen *et al.* [10] examined the combination of various Transformer models and the Attentional GAN (AttnGAN) to create the AttnGANTRANS architecture to generate images from texts and validates the effectiveness of the Transformer models by assessing the performance of generated images using the Frechet Inception Distance and Inception Score evaluation metrics. In another work [11], the Cross-Modal Contrastive GAN (XMC-GAN) for text-to-image synthesis was proposed which generates images that are well-aligned with the texts and accomplish significant improvements in image quality utilizing multiple contrastive losses. Tao *et al.* [12] proposed a novel Deep Fusion GAN that generates high-quality images through a one-stage architecture and uses a deep fusion block which helps to integrate text and visual characteristics entirely. In another work by Siddharth *et al.* [13], a combination of a GAN-based model and pre-trained text encoder, Attentional GAN and ROBERTa, respectively, were used, which resulted in a significant decrease in the FID score. In paper [14], they used diffusion models for image synthesis contextual to natural language descriptions and compared CLIP and classifier-free guidance as guidance strategies. Saharia *et al.* [15], presented a text-to-image diffusion model named Imagen that achieved a high level of photorealism and text and image alignment, leading towards deep language understanding by using diffusion models along with large transformer language models for text understanding.

B. Text to Face Generation

This section presents a comprehensive summary of various methods that have garnered attention and demonstrated remarkable outcomes in the field of TTF synthesis.

Deorukhkar *et al.* [16] employed three GAN-based architectures, DCGAN, DFGAN, and SAGAN for TTF synthesis. In this paper they used the CelebA dataset [6] consisting of celebrity images, Sentence BERT for sentence embeddings to encode the textual descriptions of the images from the dataset and compared the results of the three models using IS and FID evaluation metrics. In another work [17], a GAN-based two-stream architecture was introduced to generate images with great quality and diversity. They extracted features from the images through a Contrastive Language-Image Pre-training encoder and used Cross-Modal Distillation to align the image and text features. Xia *et al.* [18] suggested a novel GAN architecture, TediGAN, which generates multi-modal images from text descriptions and proposed a Multi-Modal CelebA-HQ dataset to evaluate the result and achieve the FID score. Ayanthi *et al.* [19], used StyleGAN2 to generate visually impressive facial images with accurate rendering of the facial features and utilized BERT for text embedding to generate high-quality images that align with the text description. Paper [20] proposed a generative architecture, OpenFaceGAN that creates facial images from natural language descriptions with improved inference speed, image quality and efficiency in text and image alignment. In another paper [21], a novel network called PixelFace was proposed for TTF synthesis which utilizes a dynamic parameter-generating method to transform text features into embeddings for predicting continuous values of pixels. They validated the experimental results on the MM-CelebA dataset [18]. Nair *et al.* [22], suggested the utilization of diffusion-based models for multi-modal image synthesis that demonstrated impressive results compared to uni-modal network.

There had been research work on TTF synthesis for Bangla language but the images generated by the models were not of high quality, and the FID score was comparatively poor. Previous Bangla TTF works were unable to depict some Bangla facial attributes in synthetic images accurately. Low-quality image generation and limited consistency between Bangla text and generated images in the domain of TTF synthesis has emerged to be the existing gap for Bangla language. Therefore, the purpose of our paper is to elevate the image quality, TTI consistency and betterment of FID score for Bangla TTF synthesis.

III. Dataset

In this paper, we have used the modified version of the CelebA dataset [6] (containing celebrity images and English captions), called CelebA Bangla [7]. The novel algorithm utilized by the CelebA Bangla dataset to generate Bangla textual descriptions of facial images was originally introduced by [7]. The dataset comprises forty facial attributes that have been extracted from Bangla vocabulary that ensures semantic accuracy. Additionally, it contains around 202,599 facial images of size 128×128 of celebrities that correspond to the forty aforementioned facial attributes. The CelebA Bangla dataset[1] is available publicly on Kaggle.

Some of the samples of the CelebA Bangla dataset and text descriptions from CelebA Bangla are shown in Tables I and II.

IV. Methodology

A. BanglaBERT

BanglaBERT [5] is an ELECTRA (Efficiently Learning an Encoder that Classifies Token Replacements Accurately) transformer language model. Mukh-Oboyob uses BanglaBERT for obtaining accurate text embeddings from Bangla textual descriptions. Of all the available pre-trained Bangla text encoders, BanglaBERT was chosen for this study due to its superior performance on a plethora of NLP tasks. BanglaBERT has its own tokenizer written for the Bangla language, with a rich vocabulary and customized tokenization process. Due to this tokenizer, Bangla text is tokenized properly without loss of valuable information present in subtle parts of the text. As shown in Fig. 1, BanglaBERT turns the input text into tokens $Tok_1, Tok_2, ..., ToK_N$. These tokens are given to the ELECTRA model, which comprises of two main components: Electra embedding layers and 12 Electra layers. An Electra embedding layer consists of word embedding, position embedding, token type embedding, layer norm and dropout layers. For the purpose of capturing the semantic meaning of the tokens, the Electra layers transform the tokens into continuous vector representations. These representations are fed into 12 Electra layers. Each Electra layer consists of three components: Electra Self Attention, Electra Intermediate, and Electra Output layers. Electra layers help the model to capture contextual information from the input sequence. Electra Self Attention has two constituents: Electra Attention and Electra Self output. For capturing dependencies between tokens, the Electra layer assigns weights by using a Self-Attention mechanism. The Electra Intermediate layer consists of a dense layer and a GELU (Gaussian Error Linear Unit) activation to present contextual information. The Electra Output layer assists the model in grasping thematic insight efficiently. Finally, the output of the 12 Electra layers is a text embedding of dimensions $[num\_prompts \times max\_length \times embedding\_dim]$. Here, $num\_prompts$ is the number of prompts/input Bangla textual descriptions given to the text encoder. max_length is the max-

imum number of tokens allowed to be given by the tokenizer. $embedding\_dim$ represents the embedding dimension of the embedding layers.

B. Stable Diffusion

Stable Diffusion [3] is based on the latent diffusion model that produces synthetic images from text input. Stable diffusion mainly comprises a Variational Autoencoder(VAE), some Schedulers, a Text Encoder, a U-Net Model, and Classifier Free Guidance. The training and image generation process is explained briefly below.

Training: The training process of Stable Diffusion is outlined in Fig. 2. During the training of Stable diffusion, an input facial image is passed through the VAE encoder to obtain a latent vector. As shown in Eq. 1, the latent vector is scaled by a scaling factor defined in the configuration of the VAE. Scaling the latent vector allows Mukh-Oboyob to control the amount of randomness of the probability distribution of synthetic facial images.

$$latent\_vector_{scaled} = scaling\_factor \times vae\_encoder(image_{face}) \quad (1)$$

It is shown in Eq. 2 that the scaled latent vector, a random noise vector, and timestep are passed to a noise scheduler for timesteps $t = 1....T$. This is the Forward Diffusion process. In this process, the noise scheduler gradually adds noise to the latent image, thus obtaining a noisy latent vector.

$$latent\_vector_{noisy} = noise\_scheduler(latent\_vector_{scaled}, noise_{random}, timesteps) \quad (2)$$

A Bangla textual description is passed through BanglaBERT to obtain a text embedding. The Text embedding, Random noise, and noisy latent vector are fed into the U-Net for the purpose of predicting a noise vector; as demonstrated in Eq. 3. The U-Net utilizes its contracting path and expansive path to better predict a noise vector close to the random noise previously used in the forward diffusion process.

$$Noise_{predicted} = U\text{-}Net(Text\_Embedding, timesteps, latent\_vector_{noisy}) \quad (3)$$

The predicted noise and random noise are compared using Mean Squared Error Loss as defined in Eq. 4. Here, N signifies

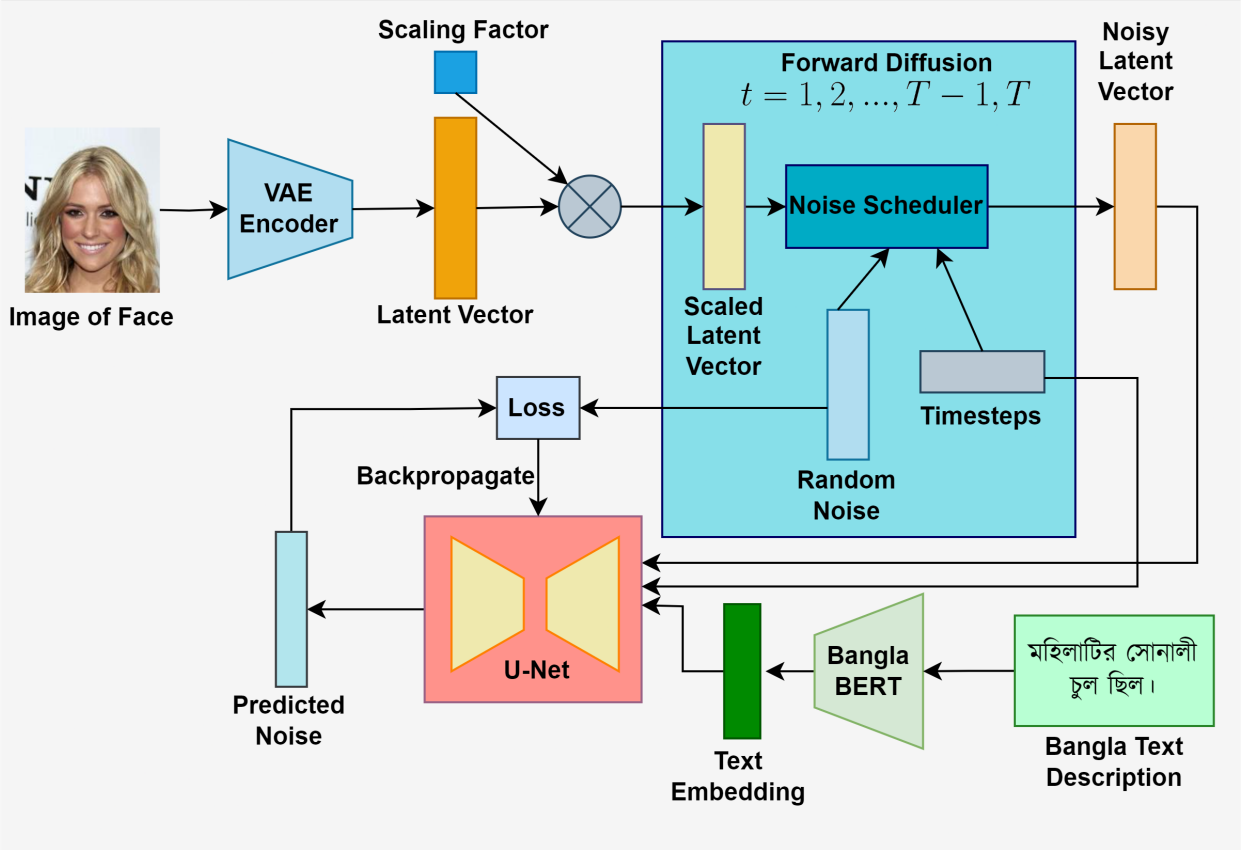

Fig. 2. Training procedure of the stable diffusion model used by Mukh-Oboyob.

the number of rows in the noise vectors. This Loss is back-propagated through the U-Net to help the U-Net predict better noise vectors in future iterations.

$$Loss_{MSE} = \frac{1}{N}\sum_{i=1}^{N}(Noise_{random} - Noise_{predicted})^2 \quad (4)$$

Image Generation: The Image Generation Phase as depicted in Fig. 3 generates synthetic images from Bangla Text. During the Image Generation or Prompting phase, a Bangla Text prompt is sent to BanglaBERT to obtain a prompt embedding. A random latent vector is scaled by following Eq. 5. Here σ is used to control how much noise is added to the latent text representation.

$$latent\_model\_input = \frac{random\_latent}{\sqrt{\sigma^2 + 1}} \quad (5)$$

The latent model input, prompt embedding and timestep are given to the U-Net for predicting Noise in Eq. 6. This Noise vector is the U-Net's attempt to produce a latent representation of the text; which can later be decoded into an image.

$$Noise_{predicted} = U\text{-}Net(latent\_model\_input, timestep, Text\_Embedding) \quad (6)$$

However, This predicted noise is not satisfactory at timestep $t = T - 1$. Therefore, as shown in Eq. 7, the predicted noise and timesteps are iteratively passed on to the scheduler which produces another latent vector for timesteps $t = T-1, T-2, T-3, ..., 3, 2, 1$. This is the Reverse Diffusion process.

$$latent\_vector = Scheduler(Noise_{predicted}, timesteps) \quad (7)$$

Finally, in Eq. 8, the latent vector achieved at timestep $t = 1$ is scaled by a scaling factor defined in the variational autoencoder's configuration. This scaling is done to ensure that the latent vector is normalized and has values in a specific range, thus helping to improve consistency across a multitude of samples.

$$latent\_vector_{scaled} = \frac{latent\_vector}{scaling\_factor} \quad (8)$$

The scaled latent vector is now passed to the Decoder of the Variational Autoencoder used in Mukh-Oboyob. As depicted in Eq. 9, The Decoder produces an image of a face in accordance to the textual prompt given to the Text Encoder earlier.

$$image_{face} = Decoder_{VAE}(latent\_vector_{scaled}) \quad (9)$$

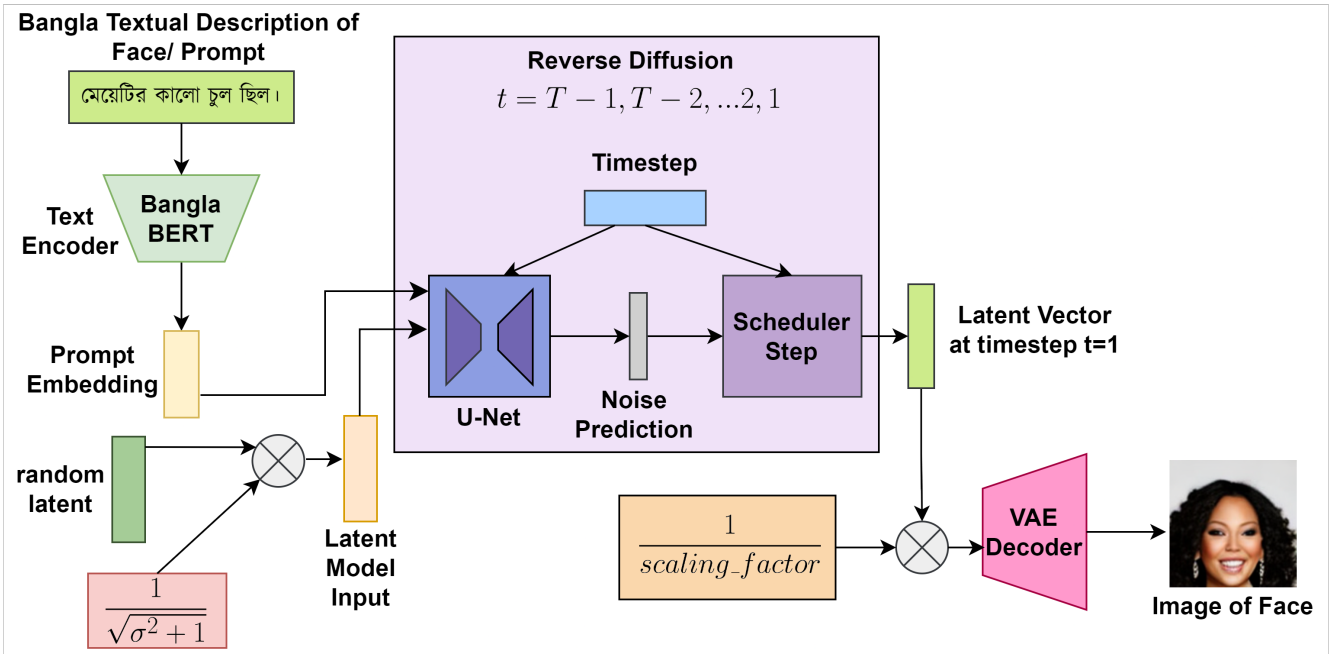

Fig. 3. Image generation procedure used in stable diffusion of Mukh-Oboyob.

C. LoRA

Fine-tuning the entire Stable Diffusion model can be a hardware and time-consuming task; often unfeasible in limited hardware and electric power support. Therefore Mukh-Oboyob uses LoRA (Low-Rank Adaptation) [23] to fine-tune the cross-attention layers in the U-Net model part of Stable diffusion. Let the weight matrix of a cross-attention layer be C_0. LoRA will selectively update C_0 by using the low-rank decomposition in Eq. 10. During the training or fine-tuning process, the C_0 matrix is not updated in the backward pass. Only T_A and T_B are updated while training.

$$C_0 + \Delta C = C_0 + T_B T_A \tag{10}$$

By significantly reducing the number of trainable parameters in the process outlined above, LoRA reduces training time and VRAM consumption drastically; without causing noticeable degradation in synthetic image quality.

V. Result Analysis

In this section, a comprehensive discussion of the experimental details during training and validation of the proposed model is provided.

A. Experimental Setup

Stable Diffusion v1-4[2] was fine-tuned using LoRA on a single RTX 3060 GPU for developing the proposed system, Mukh-Oboyob. Stable Diffusion uses a CLIP Text Encoder [24], which only works for English text inputs. For Mukh-Oboyob, BanglaBERT's text encoder and tokenizer was used. Input image resolution was changed to 128×128 to make it compatible with the CelebA Bangla dataset. Furthermore, CLIP tokenizer has a maximum sequence length of 77, whereas the textual descriptions of CelebA Bangla produce upto 150 tokens when tokenized with the BanglaBERT tokenizer. When tokenized with $max\_length = 77$, BanglaBERT's tokenizer discards significant parts of the Bangla text. Therefore, for compatibility issues, the maximum sequence length was set to 150 in the proposed system, Mukh-Oboyob. The batch size was set to 16. an initial learning rate of 10^{-4} was used. The constant scheduler was chosen as the learning rate scheduler. Number of warmup steps was set to 0 for the learning rate scheduler. The hyperparameters for the Adam optimizer used are: $\beta_1 = 0.9, \beta_2 = 0.9, weight\_decay = 10^{-2}, \epsilon = 10^{-8}$. The dimension of the LoRA update matrices was set to 4 for training the proposed method, Mukh-Oboyob. A Variational Autoencoder[3] trained with Exponential Moving Average weights was used during prompting Mukh-Oboyob.

B. Qualitative Analysis

As shown in Fig. 4, Mukh-Oboyob produces images with far better quality and diversity compared to previous GAN methods. The synthetic images produced by Mukh-Oboyob are more semantically aligned with the Bangla textual descriptions of faces. Almost all facial attributes written in the input textual descriptions are accurately depicted in the corresponding images produced by Mukh-Oboyob. This shows that BanglaBERT successfully provided meaningful text embeddings which were properly comprehended by Stable Diffusion.

The effect of the hyperparameter called number of inference steps was explored in Fig. 5. With only 1 inference step, a noisy image is produced. While inference steps increase, inference time and image quality also increase. Regardless of

[3]https://huggingface.co/stabilityai/sd-vae-ft-ema

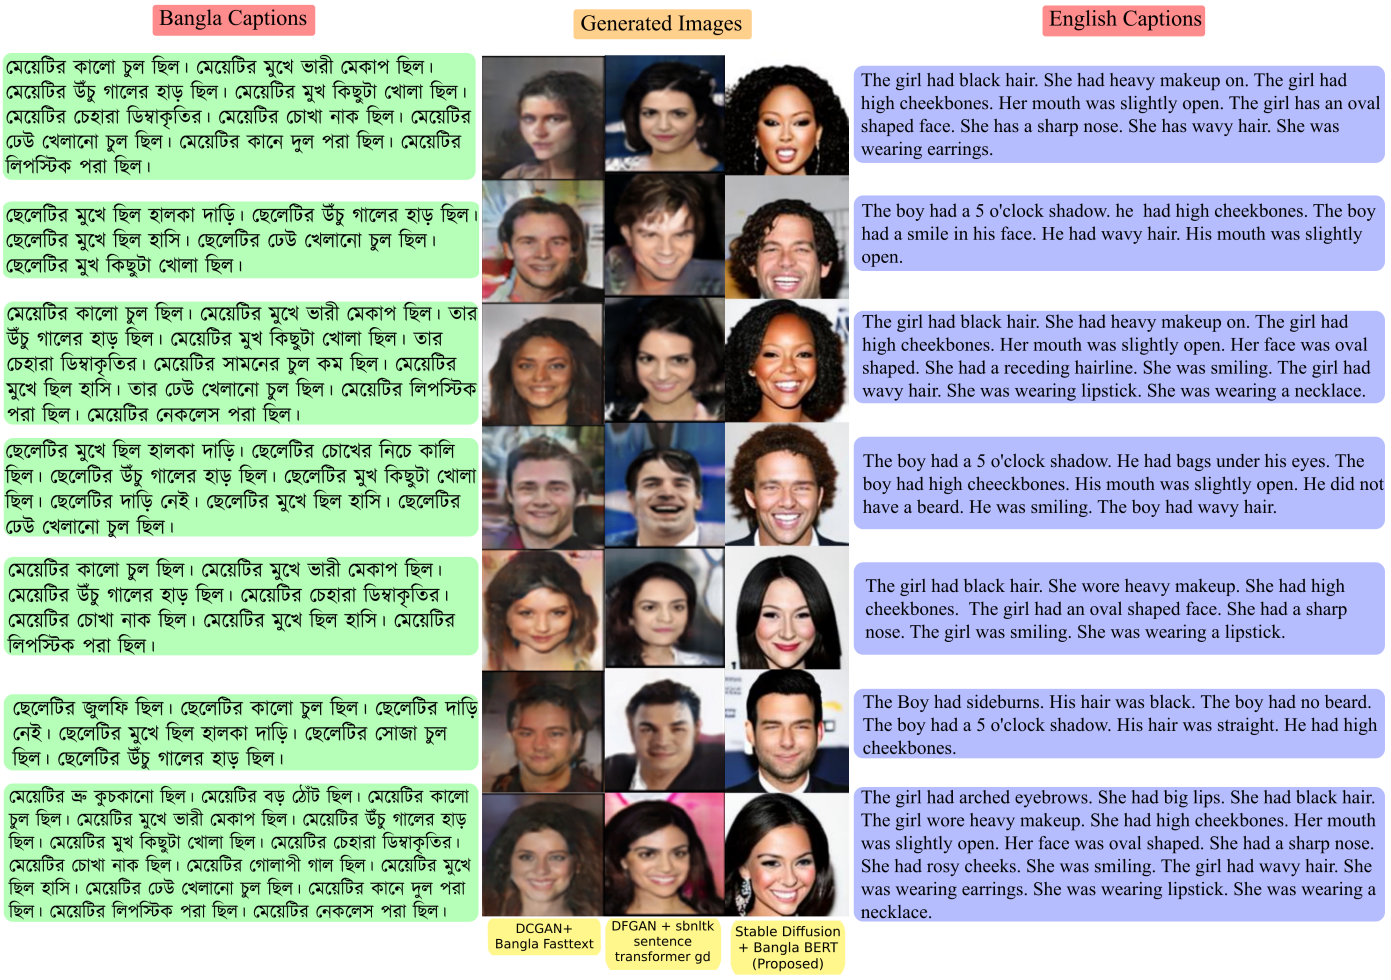

Fig. 4. Comparison of generated images between previous GAN methods and Mukh-Oboyob for different bangla captions.

the number of inference steps, VRAM consumption stays the same.

C. Quantitative Analysis

Mukh-Oboyob achieves state-of-the-art quantitative results on the performance metrics outlined in [7], overcoming previous GAN-based results, as numerically proven in Table III. All performance metrics were computed on 10,000 synthetic images, as practiced in various studies. FID is a widely used performance metric for evaluating the quality and diversity of generated images. Mukh-Oboyob achieves a better FID score of 34.6828 compared to the other models by a large margin. Although Inception Score(IS) is a metric used for assessing the quality and diversity of generated images, it is criticized in existing literature for having sensitivity to dataset bias, lack of semantic coherence, and limited applicability to different domains. Mukh-Oboyob achieves a competitive Inception Score of 11.3721, as shown in Table III. Learned Perceptual Image Patch Similarity(LPIPS) is an excellent domain agnostic performance metric for image synthesis which correlates very well with human perception. The proposed model, Mukh-Oboyob also achieves a much better LPIPS score compared to DCGAN and DFGAN. Face Semantic Similarity (FSS) and Face Semantic Distance(FSD) are used for comparing the similarity and dissimilarity of generated and real faces. Although FSS and FSD are relevant to the TTF domain, they are not widely recognized or established metrics. Nevertheless, Mukh-Oboyob achieves a competitive FSS and FSD score as shown in Table III.

TABLE III. COMPARISON OF PERFORMANCE METRICS BETWEEN MUKH-OBOYOB AND PREVIOUS METHODS

Model	FID ↓	IS ↑	LPIPS ↓	FSD ↓	FSS ↑
Bangla fasttext + DCGAN [7]	126.71	**12.3607**	21.8291	**20.2385**	0.3427
sbnltk sentence transformer gd + DFGAN [7]	155.1593	4.78246	3.2216	20.3697	**0.4203**
Mukh-Oboyob (BanglaBERT + Stable Diffusion)	**34.6828**	11.3721	**0.4541**	24.8942	0.0528

Fig. 6 depicts the decreasing MSE loss at each epoch during the training of the proposed method, Mukh-Oboyob. At each epoch, there were 12630 updates; so each epoch was very time-consuming.

Text Description/Prompt	inference steps = 1	inference steps = 5	inference steps = 10	inference steps = 15	inference steps = 20	inference steps = 25	inference steps = 30

Fig. 5. Effect of inference steps on the quality of generated images.

Fig. 6. MSE loss at different epochs of training the proposed Mukh-Oboyob model.

VI. Discussion

Developing a system that performs well and combines state-of-the-art models on limited hardware to a new domain requires a significant amount of background knowledge and experience. The evaluation of generative models is prone to subjectivity and lack of a clear ground truth [2]. Despite these adversities, Mukh-Oboyob achieves stellar performance and establishes a new state of the art in Bangla TTF Synthesis. The most subtle bangla facial attributes are learned surprisingly by the proposed model, Mukh-Oboyob.

VII. Limitations

Even though Mukh-Oboyob achieves never-before-seen results on Bangla TTF synthesis, it is a bit behind compared to English TTF models which have achieved single-digit FID scores. The relatively less advanced performance of Mukh-Oboyob can be attributed to the lack of a pre-trained model for Bangla that adequately captures the sophisticated details of the Bangla language, as BERT or GPT captures for English. Another issue faced by Mukh-Oboyob is that some of the generated facial images contain dark or blurry eyes. Even after using a pre-trained VAE aimed at solving this issue, a few images are still synthesized with dark eyes. This is an open research problem.

VIII. Conclusion

This paper proposes a novel system, Mukh-Oboyob for producing images of faces from Bangla Textual input. Mukh-Oboyob uses BanglaBERT as a Text Encoder and Stable Diffusion for image generation. The proposed Mukh-Oboyob model was trained and evaluated on the CelebA Bangla dataset. Mukh-Oboyob achieves a state-of-the-art FID score of 34.6828 and an LPIPS score of 0.4541. A limitation of this work is that the performance of Mukh-Oboyob is relatively lower compared to state-of-the-art English TTF models. Another limitation of Mukh-Oboyob work is that this work suffers from lack of established performance metrics for evaluation of the facial features of synthetic facial images. An interesting avenue of future work can be generating more diverse and realistic facial images from captions of other languages(Arabic, Hindi, Spanish, etc.).

Acknowledgment

We are grateful to the Institute of Energy, Environment, Research, and Development (IEERD, UAP) and the University of Asia Pacific for their financial support. We extend our sincerest gratitude to Md Shopon for his inspiration and insights. We thank A. Faiyaz for technical assistance.

***Abstract*—Graph Neural Networks (GNNs) have emerged as powerful tools for analyzing complex structured data, including social networks, biological networks, and recommendation systems. However, their susceptibility to adversarial attacks poses a significant challenge, especially in critical tasks such as node classification and link prediction. Adversarial attacks on GNNs can introduce harmful input graphs, leading to biased model predictions and compromising the integrity of the network. We propose a novel adversarial attack method that leverages the combination of K-Means clustering and Class Activation Mapping (CAM) to conduct subtle yet effective attacks against GNNs. The clustering algorithm identifies critical nodes within the graph, whose perturbations are likely to have a substantial impact on model performance. Additionally, CAM highlights regions of the graph that significantly influence GNN predictions, enabling more targeted and efficient attacks. We assess the efficacy of state-of-the-art GNN defenses against our proposed attack, underscoring the pressing need for robust defense mechanisms. Our study focuses on countering attacks on GNN networks by utilizing K-Means clustering and CAM to enhance the effectiveness and efficiency of the adversarial strategy. Through our observations, we emphasize the necessity for stronger security measures to safeguard GNN-based applications, particularly in sensitive environments. Furthermore, our research highlights the importance of developing robust GNNs that can withstand adversarial attacks, ensuring the reliability and trustworthiness of these models in critical applications. Strengthening the robustness of GNNs against adversarial manipulation is crucial for maintaining the security and integrity of systems that heavily rely on these advanced analytical tools. Our findings underscore the ongoing efforts required to fortify GNN-based applications, urging the research community and practitioners to collaborate in developing and implementing more robust security measures for these powerful neural network models. .**

I. Introduction

Graph Neural Networks (GNNs) have become indispensable tools in the analysis of complex graph-structured data, with applications ranging from social network analysis to recommendation systems and bioinformatics. While their ability to discern intricate relationships within graphs is advantageous, it also exposes them to potential adversarial attacks. In critical applications, such as social network analysis, adversarial manipulations could result in the propagation of misinformation or compromise user privacy [14,15,32-35]. Similarly, attacks on user-item interaction graphs in recommendation systems may lead to the tailored manipulation of content recommendations. In bioinformatics, adversarial perturbations on molecular interaction networks pose a threat to the accuracy of predictive models, especially in the identification of potential drug candidates [17-20]. The security implications outlined above necessitate a robust defense strategy to safeguard GNNs in real-world applications. Addressing the identified security issues becomes imperative to ensure the reliability of GNNs [23,25-30,36]. The proposed defense approach employs key metrics such as success rate, transferability, and computational efficiency for assessment. Preliminary evaluations reveal competitive success rates, highlighting the method's efficacy. Notwithstanding the critical need for GNN security, existing research falls short in providing comprehensive defense strategies, especially tailored to the unique challenges posed by graph data. The primary contribution of this work lies in introducing a novel adversarial attack methodology specifically designed for GNNs. This approach integrates K-Means Clustering and Class Activation Mapping to introduce structured perturbations, offering a distinctive combination of clustering and node importance information. In the realm of counterattack advancements, where existing methods face limitations in black box scenarios, the introduction of the k-Clustering Adversarial Manipulation Approach (CAMA) dataset becomes crucial. CAMA, designed to be receptive to contrasting examples, coupled with a novel approach leveraging GNNs, showcases promising potential in creating contradictory examples. This innovation contributes significantly to the development of more effective and robust counterattack techniques, marking a crucial advancement in the field of adversarial machine learning for GNNs.

II. Background and Motivation

The escalating integration of Graph Neural Networks (GNNs) across various applications has prompted heightened concerns regarding their susceptibility to adversarial attacks. In the current landscape of research, there is a discernible dearth in the comprehensive comprehension of adversarial threats and corresponding defenses specifically tailored for GNNs. This lacuna underscores the paramount importance of fortifying GNNs against adversarial exploits to ensure their robustness in real-world deployment scenarios [2,6,7]. Our

research endeavors are motivated by the imperative to bridge the existing gaps in GNN security studies. Departing from conventional adversarial methodologies, we introduce a pioneering approach that intricately employs K-Means Clustering and Class Activation Mapping (CAM). This innovative amalgamation injects a fresh perspective into the realm of structured perturbations in GNNs, with the explicit goal of crafting more potent adversarial attacks. The principal contribution of our work lies in the conception of a novel adversarial attack methodology meticulously tailored for GNNs. The incorporation of structured perturbations, facilitated by the synergistic interplay of K-Means Clustering and Class Activation Mapping, distinguishes our approach from conventional adversarial techniques. This integration not only enriches the arsenal of adversarial methods but also provides unique insights into the vulnerabilities inherent in GNNs. Our methodology, leveraging both graph clustering and node importance information, furnishes unparalleled insights into GNN vulnerabilities. This heightened understanding empowers the creation of targeted and impactful adversarial examples, thereby propelling the advancement of adversarial research within the domain of graph-based models. Our research contributes to an elevated echelon of GNN robustness evaluation by ushering in a novel adversarial generation methodology. By seamlessly integrating K-Means Clustering and Class Activation Mapping, our approach stands as a testament to innovation in the field, offering unique perspectives and a more nuanced understanding of GNN vulnerabilities.

III. Related Work

In recent years, white-box attack research has witnessed significant growth, focusing on three main categories: discovery-based attacks, interference attacks, and attacks causing network malfunction. These attacks are classified based on the role of the "responsible model" within a specific field, addressing challenges associated with unsupervised learning. While extensive work has been conducted on white-box attacks, this literature review specifically delves into Generative Adversarial Networks (GANs) and Convolutional Neural Networks (CNNs). These deep learning methods, known for their effectiveness, are critical in understanding and countering white-box attacks.

Among various attack methods, the Fast Gradient Sign Method (FGSM) is prominent. Operating by taking a one-step gradient of the responsible damage function, FGSM facilitates the rapid creation of "opposite" examples to the original input. Despite its popularity, FGSM doesn't always guarantee success, leading to exploration of more sophisticated strategies. Theoretical and practical challenges in unsupervised learning contribute to the complexity of white-box attack research, with a focus on GANs and CNNs offering nuanced insights and potential countermeasures.

In advancing attack strategies, an iterative approach like the Repeated Fast Gradient Method (I-FGSM) and Projected Gradient Descent (PGD) has been explored. Researchers, such as [31] and [8], iterate FGSM multiple times to create more robust adversarial examples, enhancing overall attack efficacy. Additionally, [24] introduced the Momentum-based Iterative Fast Gradient Sign Method (MIFGSM), marking a significant improvement over FGSM in terms of performance and robustness. These advancements are crucial for evaluating the robustness and security of neural networks, as researchers actively work on developing sophisticated attack and defense techniques.

In the context of white-box attacks, image-dependent targeted attacks stand out as potent threats. Recent research has seen a surge in understanding and addressing vulnerabilities in neural networks, emphasizing the urgency of exploring adversarial threats. The offensive class, as defined by [39], focuses on discovering adversarial examples within disturbance budgets to ensure misclassification by the targeted neural network. This underscores the importance of image-dependent targeted attacks and the ongoing efforts in exploring GANs and CNNs for effective countermeasures. The study in [8] introduced the Momentum Iterative Fast Gradient Method (MIFGSM), an extension that incorporates momentum into the Iterative Fast Gradient Sign Method (I-FGSM). This augmentation proves to be a substantial enhancement to the attack method, resulting in the generation of more effective and robust adversarial examples.

These competitive attack methodologies play a crucial role in assessing the reliability and security of neural networks. Ongoing research endeavors are dedicated to advancing sophisticated attack techniques, concurrently emphasizing the formulation of effective defensive strategies to mitigate the impact of such attacks.

In the domain of white-box attacks, image-dependent targeted attacks are recognized as the most potent form of adversarial threats. The exploration of adversarial attacks, particularly within the realm of white-box attacks, has garnered significant interest and witnessed notable progress.

Responsive attacks can be broadly categorized into three primary types, as delineated by [1]: Alarm-based attacks, which seek to discover counterexamples within a specified disturbance budget, inducing the neural network to misclassify with high confidence. Examples of such attacks encompass the Fast Gradient Sign Method (FGSM), Iterative Fast Gradient Method (I-FGSM), and Projected Gradient Descent (PGD). Dong et al. [8] introduced an enhanced iteration, the Momentum Iterative Fast Gradient Method (MI-FGSM).

This line of research is dedicated to minimizing interference and discovering as few counterexamples as possible to deceive neural networks without triggering alarms. Various methods have been explored for this purpose:

The research in [5] focuses on minimizing interference using simpler linear functions. Carlini and Wagner [10,22] propose a method that comes close to the goal by utilizing simpler linear functions. [3] assumes linearity near the input, contributing to the minimal interference approach.

Generative attacks employ reproductive methods to create adversarial examples. Noteworthy approaches include:

The study in [21,38] utilizes a second neural network for adversarial example generation. GANs are employed to estimate the original distribution of images, providing contrasting examples.

The study in [11] introduces the CAMA framework for addressing the creation of competing examples through extensive

adversarial manipulation of graphs. Key points include:

The study encompasses various aspects related to graph structures, node properties, and their manipulation. The approach adopted focuses on facilitating hierarchical manipulation of graph structures and node properties. In parallel, the research delves into the realm of Graph Class Activation Mapping (Graph-CAM), with the primary objective of leveraging this variant to specify node-level importance in graphic classification tasks.

A significant component of the investigation involves heuristic algorithms, demonstrating their efficacy in achieving successful performance in attributive and structural attacks. Notably, these algorithms operate under strict alarm budgets, highlighting their robustness and reliability in the context of the study.

The findings of the research underscore the significance of both node-level and subgraph-level measures. This comprehensive approach is crucial for preserving competitive interference imperceptibility. The conclusion drawn from the study emphasizes the necessity of considering measures at multiple levels to ensure a holistic understanding and effective management of graph structures and node properties in various applications.

The research focuses on systemic reciprocity attacks, specifically targeting Graph Neural Network (GNN)-based link prediction models and leveraging the SEAL algorithm. One key aspect of this investigation involves counterexample generation, with the primary task being the creation of counterexamples to optimize and deceive SEAL into generating false predictions. This strategic approach aims to understand and exploit potential vulnerabilities in the link prediction model under the influence of systemic reciprocity attacks.

An integral strength of the study lies in the utilization of SEAL's y-decomposition heuristic. This heuristic theory involves approximating graph structural properties of local subgraphs, rendering it particularly effective against systemic reciprocity attacks. By leveraging the y-decomposition heuristic, the research aims to enhance the understanding of the structural intricacies of the targeted link prediction models, thereby enabling more precise and impactful attacks. Overall, the study's emphasis on counterexample generation and the strategic use of SEAL's y-decomposition heuristic underscores its dedication to unraveling and exploiting vulnerabilities in GNN-based link prediction models under the influence of systemic reciprocity attacks.

This comprehensive approach integrates linear function-based methods, generative attacks, and the CAMA framework, emphasizing the significance of node-level and subgraph-level measures to preserve imperceptibility against adversarial manipulation. Leveraging SEAL further strengthens defense against systemic reciprocity attacks on GNN-based models.

The research in [37] underscores the relevance of competition attacks on GNN-based link prediction models. The approach gradually disrupts the network graph by manipulating its structure and utilizes a link-building mechanism along with the y-decomposition heuristic theory HERMESTIC for a more efficient competitive attack. Experimental results reveal the significant impact of planned counterattacks, posing a threat to the efficacy of SEAL league predictions, particularly with limited information about complex network diagrams.

The successful portability of attacks against various link prediction heuristics from the existing literature is highlighted, demonstrating the effectiveness and broad applicability of the proposed competitive methods. Existing competing attacks (mentioned in [3, 9, 4, 12]) often operate in a "white box" configuration, assuming full access to the machine learning model parameters. However, the passage notes the unrealistic nature of this setting when the model parameters are unknown to the attacker, emphasizing the importance of considering realistic scenarios, especially in the "black box" configuration.

Competitive attacks on link prediction algorithms showcase the need for improved resilience. Proposed approaches demonstrate effectiveness across different heuristics, emphasizing the importance of realistic scenarios, particularly in the "black box" configuration where the attacker lacks full access to model parameters. The findings contribute to a deeper understanding of challenges and potential impacts of link prediction algorithms in real-world applications.

In a point-based black box arrangement, attackers query the output of the softmax layer and obtain the final classification result (x) for a given input. Challenges arise in using traditional gradient-based approaches due to the lack of well-defined gradients in discontinuous models like decision trees. The study in [10] proposes a point-based attack that reconstructs the loss function, addressing challenges in well-defined gradients. The research in [16] introduces innovations like adaptive random gradient estimation and a well-trained autoencoder to enhance the efficiency of point-based attacks. The study in [13] proposes a point-based attack using an evolutionary algorithm, demonstrating effectiveness in both point-based and hard label black box settings.

The passage emphasizes the need for robust black box attack strategies for machine learning models, noting the limitations of existing methods. A novel approach leveraging graph neural networks (GNNs) connects networks, combining the strengths of the K-means algorithm and reinforcement learning methods. GNNs serve as an effective competitive example generation tool, bridging the gap between optimization and learning approaches in adversarial machine learning research. Advances in recent literature [10] exploring black box arrangements, specifically point-based configurations, highlight the challenges of attacking models with limited parameter information, addressing these challenges through zero-order optimization techniques [16] and evolutionary algorithms [13]. These advances contribute to the development of robust black box attack strategies, emphasizing the need for effective combinations of optimization and learning methods in adversarial machine learning research [40-44].

IV. Methodology

The architecture of the GNN is intricately designed to closely emulate the structure of the target neural network that is the subject of compromise. This GNN operates within the context of adversarial attacks. When presented with an input image, information about its correct class, and details about an incorrect target class, the GNN engages in an iterative process. At each iteration, the GNN proposes a directional

update that aims to maximize the difference between the logits (output scores) of the incorrect target class and the correct class. The primary objective of this GNN is encapsulated in the "adversarial loss function."

The adversarial loss function serves as a crucial guiding principle for the GNN's optimization process. This function essentially formulates the goal of the GNN: to find the optimal perturbation or modification to the input image that maximizes the divergence between the logits associated with the correct class and those corresponding to the incorrect target class. The term "logits" refers to the raw, unnormalized output scores produced by the neural network before the application of a softmax function.

In essence, the GNN's architecture is tailored to navigate the input space in a way that induces misclassification. By proposing perturbations that push the decision boundaries of the target neural network, the GNN seeks to generate adversarial examples – instances where the neural network makes incorrect predictions despite minimal alterations to the input.

This adversarial approach involves an intricate interplay between the GNN's architecture, the specifics of the target neural network, and the definition of the adversarial loss function. The GNN learns to exploit the vulnerabilities and intricacies of the target model, demonstrating a nuanced understanding of the decision boundaries in the neural network it aims to compromise.

The architecture of the GNN is a sophisticated framework designed for crafting adversarial examples. It leverages the interplay of input perturbations and the intricacies of the target neural network to induce misclassification, with the adversarial loss function guiding the optimization process.

1. Initialization: - Before the evaluation process begins, the GNN is initialized with the target neural network's parameters, which are the parameters it aims to compromise. - These parameters may include weights, biases, and other network-specific parameters.

2. Forward Pass: - An input image, along with its correct class label and an incorrect target class label, is fed into the GNN. - The GNN processes this input image through its layers, which involve graph convolutional operations, and produces an output, typically in the form of class activation scores. - Class activation scores represent the GNN's predictions for each class, indicating the likelihood of the input belonging to each class.

3. Computation of Gradients (Backward Pass): - After obtaining predictions, a backward pass is performed to compute the gradients of the adversarial loss with respect to the input image. - Gradients capture the sensitivity of the adversarial loss to changes in the input image. - The adversarial loss is a measure of the difference between the logits associated with the incorrect target class and the correct class. The GNN aims to maximize this loss during the adversarial attack.

4. Adversarial Loss Maximization: - The computed gradients guide the GNN in the direction that maximally perturbs the input image to induce misclassification. - The GNN iteratively updates the input image in this direction, aiming to maximize the adversarial loss. - This process is repeated for a specified number of iterations or until a convergence criterion is met.

5. Assessment of Effectiveness: - Throughout this process, the GNN monitors the changes in the adversarial loss and observes the impact on the class predictions. - The effectiveness of the GNN is assessed based on its ability to successfully generate adversarial examples that lead to misclassification by the target neural network. - Success is measured by observing changes in the predicted class, ideally causing the neural network to classify the input image into the incorrect target class.

6. Comparison and Analysis: - The generated adversarial examples can be compared against baseline images to quantify the extent of the perturbation and evaluate the stealthiness of the attack. - Statistical measures or metrics may be employed to compare the success rates and the impact on different classes.

Below are some key points which discusses a common practice in the existing literature related to the evaluation of adversarial attacks.

The evaluation practices for adversarial attacks in image classification models are conventionally centered around assessing success rates on a predefined set of images, incorporating a specific perturbation size during the evaluation process. However, a recognized limitation in this approach raises concerns about its ability to offer a comprehensive evaluation of a model's robustness under adversarial attacks. This acknowledgment stems from the understanding that the fixed set of images, coupled with a uniform perturbation size, may not adequately capture the nuanced and diverse challenges posed by different instances within the dataset.

The highlighted variability in the robustness of images further accentuates the limitations of the current evaluation paradigm. Some images naturally exhibit resilience to attacks, leading to instances of attack failures, while others prove more susceptible, resulting in successful adversarial attacks. The inherent diversity in image responses to attacks poses a challenge to accurately discerning significant differences in success rates between various adversarial attack methods. In light of these considerations, there is a clear indication that a more comprehensive evaluation methodology is imperative. Such an approach should account for the distinct responses of different images to adversarial attacks, thereby fostering a deeper and more nuanced understanding of the model's vulnerability across diverse scenarios.

A. Proposed Architecture

In the context of the MNIST dataset, each image is conceptualized as a node in a graph. The relationships between these nodes are established through edges, which have the potential to capture spatial or contextual connections between pixels.

1. Graph Neural Network (GNN) Architecture

The architecture of a Graph Neural Network (GNN) typically comprises multiple graph convolutional layers. These layers play a crucial role in processing information from neighboring nodes and subsequently updating node representations based on the received information.

2. Forward Propagation Process

The initialization phase involves assigning each node, representing an image in MNIST, with a feature vector typically derived from pixel values. The forward propagation within the Graph Neural Network (GNN) includes the repeated application of graph convolutional layers. The mathematical representation of this process is given by the equation:

$$h_v^{(l+1)} = \sigma\left(\sum_{u \in N(v)} W^{(l)} h_u^{(l)} + b^{(l)}\right) \quad (1)$$

Here, $h(l)_v$ denotes the representation of node v at layer l, $N(v)$ represents the neighbors of node v, $W(l)$ is the weight matrix at layer l, $b(l)$ is the bias term, and σ is the activation function.

The aggregation step involves combining information from neighboring nodes based on the graph structure, ensuring that each node's representation incorporates information from its immediate context. The final layer of the GNN produces the output, utilized for various tasks such as classification or regression. The underlying mathematical insight lies in the graph convolutional operation, where each node's representation is updated by considering the representations of its neighbors, weighted by learned parameters. These parameters $W(l)$ and $b(l)$ are learned during the training process through backpropagation and optimization algorithms.

3. Training

The training process of Graph Neural Networks (GNNs) involves feeding labeled data through the network, computing a loss function, and updating parameters using optimization techniques like gradient descent. This iterative training approach allows the network to learn and adjust its parameters to improve its performance on the given task.

The utilization of this architecture enables GNNs to effectively capture and leverage the inherent graph structure in the MNIST dataset. This capability makes GNNs a potent tool for tasks such as image classification, where understanding and utilizing relationships between images are crucial for accurate predictions.

It's important to note that the specifics of the GNN architecture and mathematical operations may vary based on the exact implementation and variations in GNN models. Different approaches and variations in the model design can influence how the network processes information and learns from the input data.

4. Proposed Architecture Diagram

The provided Fig. 1 describes the proposed architecture diagram of the approach, illustrating the GNN layer update, class activation scores, and K-Means clustering steps.

B. Graph Representation:

Each image in the MNIST dataset is symbolically depicted as a node within a graph, resulting in a total number of nodes equivalent to the dataset's image count. The structural foundation of this graph is established by edges, which serve as connectors between nodes. The interpretation of these connections is flexible, allowing the model or designer to attribute meaning to the relationships encoded within the graph. The edges, in particular, may encapsulate spatial connections reflective of the pixel arrangements in the images. One conceivable interpretation involves connecting pixels in close proximity within an image. By doing so, the graph becomes a representation capable of capturing the spatial relationships embedded in the pixel structure of the images, contributing to a richer and more nuanced understanding of the dataset.

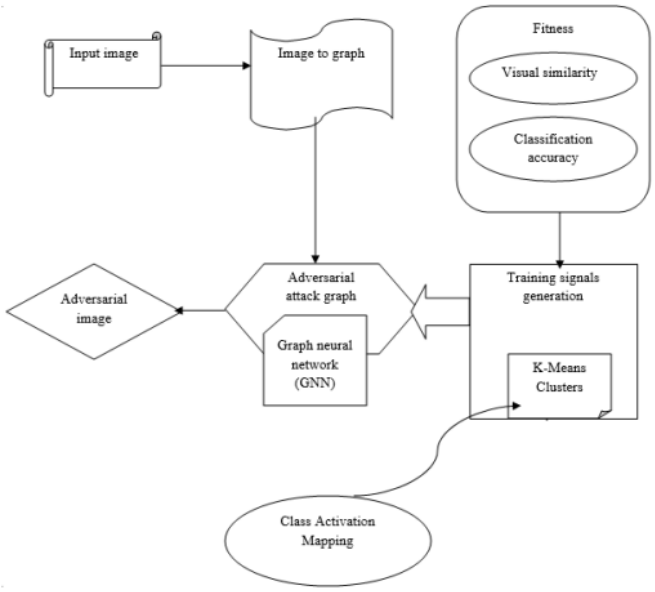

Fig. 1. Architecture of proposed approach.

The utilization of a Graph Neural Network (GNN) implies a deliberate leveraging of the underlying graph structure for the processing and analysis of data. GNNs, typically employed for such tasks, function by aggregating and updating node representations through graph convolutional layers. In the specific context of MNIST, this entails considering the pixel values of neighboring nodes when updating the representation of a given node, emphasizing the importance of spatial relationships in image data.

In the realm of contextual connections, the edges in the graph extend beyond spatial relationships, potentially representing contextual connections between images based on shared similarities or patterns within the dataset. GNNs, equipped with the capacity to learn and capture intricate contextual information from these graph connections, prove particularly advantageous for tasks like image classification, where understanding the context of an image significantly influences performance.

The structured graph representation aligns with the inherent structure of the images in the MNIST dataset, with nodes symbolizing individual images and edges encapsulating relationships between them. Depending on the GNN's design, the graph may exhibit dynamic characteristics, with edges adapting during the training process based on learned relationships.

This approach facilitates the flexibility to capture both spatial and non-spatial features, depending on how edges are defined. The graph's adaptive learning, inherent to GNNs, allows the model to dynamically adjust to the unique characteristics of the MNIST dataset, effectively leveraging both spatial and contextual information for enhanced performance in image-related tasks. In essence, the graph representation within the context of a GNN provides a structured and adaptable framework for comprehensively understanding the relationships between images, crucial for tasks like image classification.

C. Graph Neural Network (GNN) Architecture:

The primary purpose of graph convolutional layers in a GNN is to process information from neighboring nodes and update node representations. A typical GNN architecture involves multiple graph convolutional layers stacked on top of each other. Each layer processes information from the neighboring nodes of each node in the graph. Neighboring nodes are determined based on the edges in the graph.The forward propagation begins with the initialization of node representations. Each node is initialized with a feature vector, often derived from the input data (e.g., pixel values for images).The forward propagation involves the repeated application of graph convolutional layers. In each layer, information from neighboring nodes is aggregated to update the node representations.

Mathematically, the update process for the representation of a node v at layer $l+1$ can be represented as:

$$h_v^{(l+1)} = \sigma\left(\sum_{u \in N(v)} W^{(l)} h_u^{(l)} + b^{(l)}\right) \tag{2}$$

Here, $h_v^{(l)}$ is the representation of node v at layer l, $N(v)$ represents the neighbors of node v, $W^{(l)}$ is the weight matrix at layer l, $b^{(l)}$ is the bias term, and σ is the activation function.

The aggregation step in a Graph Neural Network (GNN) is a crucial process that involves consolidating information from neighboring nodes based on the underlying graph structure. This ensures that each node's representation is enriched with insights from its immediate context. Following the aggregation, the updated node representations capture both the inherent features of the node itself and information gleaned from its neighbors. This dual consideration enables the GNN to factor in both local and global information during the learning process.

Moving to the output layer, it serves as the final stage where the GNN produces task-specific outputs, such as classifications or regression predictions. The operations within this layer are tailored to the specific task at hand, involving transformations of the learned representations into meaningful predictions.

The learning process involves the adaptation of parameters, including weight matrices ($W^{(l)}$) and biases ($b^{(l)}$), through techniques like backpropagation and optimization algorithms. This adaptive learning mechanism empowers the GNN to dynamically adjust its parameters based on the patterns and relationships discerned from the graph-structured data.

The flexibility and adaptability of the GNN architecture further contribute to its efficacy. The graph structure, inherently flexible, allows the model to adapt to various graph structures, with edges and connections potentially changing during training based on the learned relationships. The intermediate layers of graph convolution provide task-agnostic representations of nodes, rendering the GNN suitable for a spectrum of graph-related tasks.

A GNN equipped with multiple graph convolutional layers systematically processes information from neighboring nodes, updating node representations, and adeptly capturing both local and global context. The adaptive learning mechanism ensures the GNN's proficiency in learning and adjusting parameters, enabling effective modeling of relationships within graph-structured data.

D. Forward Propagation Process:

In the context of the MNIST dataset, the graph representation treats each image as a node. The initialization process begins by assigning a feature vector to each node, where this vector serves as the initial representation of the corresponding image.

The source of features for each node lies in the pixel values of the corresponding image. These pixel values, which convey intensity or color information at different locations within the image, are typically organized in a grid-like structure. Depending on the design of the Graph Neural Network (GNN) and the specific task requirements, preprocessing steps may be applied to the pixel values. These steps could include normalization to a specific range or other transformations.

The feature vector itself is a numerical representation that encapsulates essential characteristics of the image. Each element of the vector corresponds to a specific feature or pixel value, and the dimensionality of this vector is determined by the number of elements it contains. This dimensionality is a critical factor influencing the GNN's capacity to capture and process information effectively.

During the training process, the parameters of the GNN, including those related to the initialization of the feature vectors, are learnable and adjusted based on observed patterns in the data. The adaptability of the GNN allows it to dynamically learn and update node representations as it processes information and identifies relevant patterns within the graph-structured data.

In task-specific scenarios, the initialization process may be tailored to the particular task the GNN is designed for. For instance, in image classification tasks, the feature vector should be crafted to capture characteristics pertinent to distinguishing between different classes of images. The quality of these initial feature vectors significantly influences the GNN's learning process, as well-initialized representations provide a robust foundation for the model to build upon during training.

The update process for the representation of a node v in a graph neural network (GNN) at layer $l+1$. Let's break down the components of the equation:

$$h_v^{(l+1)} = \sigma\left(\sum_{u\in\mathcal{N}(v)} W^{(l)} h_u^{(l)} + b^{(l)}\right) \tag{3}$$

$h_v^{(l+1)}$: This is the representation of node v at layer $l+1$. It captures the information about the node after the application of the graph convolutional layer.

$\mathcal{N}(v)$: Represents the neighbors of node v in the graph. The sum is taken over all neighboring nodes.

$W^{(l)}$: The weight matrix at layer l. This matrix contains learnable parameters that are adjusted during the training process to capture the relationships between nodes.

$h_u^{(l)}$: The representation of a neighboring node u at layer l. It contributes to the update of the central node's representation.

$b^{(l)}$: The bias term at layer l. It provides an additional learnable parameter that influences the node representation.

σ: The activation function. It introduces non-linearity to the model. Common choices include the sigmoid ($\sigma(x) = \frac{1}{1+e^{-x}}$), hyperbolic tangent ($\sigma(x) = \tanh(x)$), or Rectified Linear Unit (ReLU) ($\sigma(x) = \max(0, x)$).

The equation describes the aggregation of information from neighboring nodes using the weight matrix $W^{(l)}$, and the result is passed through an activation function σ. This operation is a fundamental step in the forward propagation of a GNN, allowing the model to capture and update node representations based on the graph structure.

This mathematical formulation is crucial for understanding how information flows through the graph convolutional layers, enabling the GNN to learn hierarchical and contextual representations of nodes in the graph.

The aggregation involves combining information from neighboring nodes based on the graph structure. This step ensures that each node's representation incorporates information from its immediate context.

$$\text{Aggregated Information} = \sum_{u\in\mathcal{N}(v)} \text{Weight}\times\text{Representation of } u \tag{4}$$

Here, $\mathcal{N}(v)$ represents the set of neighbors for the central node v.

1) Output Layer: The graph convolutional operation at layer l can be mathematically represented as:

$$h_v^{(l+1)} = \sigma\left(\sum_{u\in\mathcal{N}(v)} W^{(l)} h_u^{(l)} + b^{(l)}\right) \tag{5}$$

$h_v^{(l+1)}$: Representation of node v at layer $l+1$

$\mathcal{N}(v)$: Set of neighbors of node v in the graph

$W^{(l)}$: Weight matrix at layer l

$h_u^{(l)}$: Representation of neighboring node u at layer l

$b^{(l)}$: Bias term at layer l

σ : Activation function

The parameters $W^{(l)}$ and $b^{(l)}$ are learned during the training process through backpropagation and optimization algorithms.

Training involves feeding labeled data through the network, computing a loss function, and updating the parameters using optimization techniques like gradient descent.

This overall architecture enables GNNs to capture and leverage the inherent graph structure in the MNIST dataset, providing a powerful tool for tasks such as image classification. The specifics of the architecture and mathematical operations may vary based on the exact implementation and variations in GNN models.

For a GNN layer l with node representations $H^{(l)}$ and edge connectivity E, the update equation is given by:

$$H^{(l+1)} = \text{Aggregator}(H^{(l)}, E) \tag{6}$$

where, Aggregator is a function that aggregates information from neighboring nodes and edges.Class activation scores (S_c) are computed for each node in the graph. Let $H^{(1)}$ represent the node representations after the first GNN layer. For each class c, the class activation score $S_c[i]$ for each node i is computed using the ReLU activation function and the corresponding class weight W_{1c}:

$$S_c[i] = \text{ReLU}(H^{(1)}[i] \cdot W_{1c}) \tag{7}$$

K-means clustering is applied to group nodes based on their activation scores. The mathematical modeling for K-means clustering involves finding K cluster centers μ_k that minimize the sum of squared distances to their assigned data points:

$$\arg\min_{\mu_1,\mu_2,\ldots,\mu_K} \sum_{i=1}^{N}\sum_{k=1}^{K} \delta(i,k) \cdot \|S_c[i] - \mu_k\|^2 \tag{8}$$

where, N is the total number of nodes, $\delta(i,k)$ is the Kronecker delta, $S_c[i]$ is the class activation score for node i and class c, and μ_k is the cluster center for cluster k. The objective of K-means clustering is to find K cluster centers μ_k that minimize the sum of squared distances between each node's class activation score $S_c[i]$ and the cluster centers μ_k:

$$\arg\min_{\mu_1,\mu_2,\ldots,\mu_K} \sum_{i=1}^{N}\sum_{k=1}^{K} \delta(i,k) \cdot \|S_c[i] - \mu_k\|^2 \tag{9}$$

Here, K is the number of clusters, $\delta(i,k)$ is the indicator function, $S_c[i]$ is the class activation score for node i and class c, and μ_k is the cluster center for cluster k.

K-means clustering proceeds through the following iterative steps:

Initialization: Randomly initialize K cluster centers μ_k.

2) Assignment: Assign each node to the nearest cluster center based on the Euclidean distance between its class activation score $S_c[i]$ and the cluster centers μ_k:

$$\delta(i,k) = \begin{cases} 1 & \text{if } k = \arg\min_j \|S_c[i] - \mu_j\| \\ 0 & \text{otherwise} \end{cases} \tag{10}$$

3) Update Centers: Recalculate the cluster centers μ_k as the mean of the class activation scores of nodes assigned to each cluster:

$$\mu_k = \frac{\sum_{i=1}^{N} \delta(i,k) \cdot S_c[i]}{\sum_{i=1}^{N} \delta(i,k)} \tag{11}$$

4) Convergence: Repeat the assignment and update steps until convergence, where minimal change in cluster assignments or cluster centers indicates stability.

- Cluster Centers μ_k: Representative points for each cluster, adjusted to minimize the sum of squared distances. - Node Assignment $\delta(i,k)$: Indicator function assigning nodes to the cluster with the closest center. - Objective Function: Minimizes the sum of squared distances, encouraging similar class activation scores within clusters. - Initialization and Convergence: Sensitive to initialization; iterative nature ensures convergence to a stable solution.

Step 2.1: Initialize Cluster Centers

First, K initial cluster centers μ_k are randomly chosen from the data points. These centers represent the initial guess of the cluster centroids.

Step 2.2: Assign Nodes to Clusters

Each node is assigned to the cluster whose cluster center is closest to it. This assignment is based on the Euclidean distance between the class activation scores of the node ($Sc[i]$) and the cluster center (μ_k):

$$\delta(i,k) = \begin{cases} 1 & \text{if node } i \text{ is assigned to cluster } k, \\ 0 & \text{otherwise.} \end{cases} \tag{12}$$

$$k_{\text{assigned}} = \arg\min_k \|Sc[i] - \mu_k\|^2 \tag{13}$$

Step 2.3: Update Cluster Centers

After assigning all nodes to clusters, the cluster centers are updated by taking the mean of the class activation scores of the nodes within each cluster:

$$\mu_k = \frac{1}{|C_k|} \sum_{i \in C_k} Sc[i] \tag{14}$$

represents the set of nodes in cluster k.

Step 2.4: Repeat Assignment and Update

Steps 2.2 and 2.3 are repeated until convergence. At each iteration, nodes are reassigned to clusters based on updated cluster centers, and centers are recalculated based on new assignments.

Identifying Target Cluster

For the target class target_c, the cluster target_C with the highest sum of class activation scores for that target class is identified:

$$\text{target} = \arg\max_k \sum_{i \in \text{Cluster}_k} S_c^{\text{target}}[i] \tag{15}$$

Here, target_C is the cluster containing nodes with high activation scores for the target class target_c.

- Cluster Initialization (μ_k): Represents the initial guess of cluster centroids. - Node Assignment ($\delta(i,k)$): Assigns each node to the cluster with the closest center. - Update Centers (μ_k): Recalculates cluster centers based on the mean of class activation scores. - Iteration and Convergence: Repeats assignment and update steps until convergence. - Identifying Target Cluster: Locates the cluster with the highest sum of class activation scores for the target class.

To create an adversarial attack, we perturb the characteristic vectors of selected target nodes. The purpose is to make small changes to the feature vectors so that the GNN misclassifies selected target nodes. By adding a small amount of noise to the feature vectors, we aim to push the decision limits of the GNN, causing incorrect predictions.

For each selected target node i, we introduce a noise vector ϵ_i to perturb its feature vector

$$X_{\text{perturbed}}[i] = X_{\text{original}}[i] + \epsilon_i \tag{16}$$

Here: - $X_{\text{original}}[i]$ is the original feature vector of node i. - $X_{\text{perturbed}}[i]$ is the perturbed feature vector of node i. - ϵ_i is the noise vector for node i.

The noise vector ϵ_i is typically drawn from a small distribution around zero, such as a normal distribution with mean 0 and a small standard deviation σ. The standard deviation σ controls the magnitude of the perturbation. Modest changes in the feature space during forward propagation might result in various activations and node representations in the GNN, changing the decision bounds and leading to misclassification of the target nodes.

To analyze the impact of perturbation on the GNN's decision, we can perform a Taylor expansion analysis. Let $F(X_i)$ represent the GNN's output (e.g., class probabilities) for node i with the feature vector X_i. The Taylor expansion can be expressed as:

$$F(X_{\text{perturbed}}[i]) = F(X_{\text{original}}[i]) + \nabla F(X_{\text{original}}[i]) \cdot \epsilon_i + O(\|\epsilon_i\|^2) \tag{17}$$

Here: - $\nabla F(X_{\text{original}}[i])$ represents the gradient of F with respect to $X_{\text{original}}[i]$. - $O(\|\epsilon_i\|^2)$ represents the higher-order terms that involve the square of the perturbation ϵ_i.

From the Taylor expansion, we can observe that the perturbation ϵ_i contributes to the change in the GNN's output, and the gradient $\nabla F(X_{\text{original}}[i])$ indicates the sensitivity of the model's output to perturbations. The specific expression for $\nabla F(X_{\text{original}}[i])$ depends on the GNN architecture and the specific layers used.

V. Algorithm

Input:

- GNN model (previously trained on the MNIST dataset)
- MNIST dataset (with labeled images)
- Target class c_{target} (the class you want to misclassify)

- Number of clusters K for K-means
- Number of target nodes to select from each cluster N
- Standard deviation of noise σ for perturbation
- Scaling factor α for perturbation control

Output:

- Perturbed graph with target nodes modified for the adversarial attack

1) Preprocess the MNIST Dataset: Load the MNIST dataset and preprocess the images (e.g., normalize pixel values to the range [0, 1]).
2) Compute Class Activation Scores: Perform forward propagation on the graph to obtain the output of the first GNN layer $H^{(1)}$. For each class c in the MNIST dataset, compute the class activation scores S_c using the formula:

$$S_c = \text{ReLU}(H^{(1)} \cdot W_{1c})$$

where W_{1c} is the weight matrix corresponding to class c, and ReLU is the Rectified Linear Unit activation function.
3) Apply K-means Clustering: Apply K-means clustering to the class activation scores S_c to group nodes into K clusters based on their activation patterns. Obtain the cluster assignments for each node in the graph.
4) Select Target Nodes: Identify the cluster C_{target} with the highest sum of class activation scores for the target class c_{target}:

$$C_{\text{target}} = \arg\max_k \sum_{i \in \text{Cluster}_k} S_{c_{\text{target}}}[i]$$

From the cluster C_{target}, select the N target nodes with the highest class activation scores for class c_{target}. If N is larger than the number of nodes in C_{target}, select all nodes in C_{target}.
5) Perturb Node Features: For each selected target node i, compute the noise vector ϵ_i from a normal distribution with mean 0 and standard deviation σ:

$$\epsilon_i \sim \mathcal{N}(0, \sigma^2 I)$$

where I is the identity matrix. Rescale the noise vector ϵ_i with the scaling factor α to control the strength of the perturbation:

$$\epsilon_i' = \alpha \cdot \epsilon_i$$

Perturb the feature vector of each selected target node:

$$\text{Perturbed feature vector}[i] = \text{clip}(\text{Original feature vector}[i] + \epsilon_i, 0, 1)$$

where clip ensures that the perturbed features stay within the valid range [0, 1].
6) **Reevaluate GNN:** Reevaluate the GNN model on the modified graph with the perturbed features. Check if the target nodes are now misclassified as class c_{target}.
7) Evaluate Attack Success Rate: Measure the success rate of the attack by calculating the percentage of misclassified target nodes out of the total number of selected target nodes.

VI. Experimental Set Up

1. Dataset Description:

The MNIST dataset is a widely recognized and extensively used collection of grayscale images, each depicting handwritten digits ranging from 0 to 9. Each image is formatted as a 28x28 pixel grid, resulting in a total of 784 pixels per image. The pixel values range from 0 to 255, with 0 representing black and 255 representing white. This dataset is partitioned into two primary subsets: a training set with 60,000 images and a test set with 10,000 images. The images are labeled with the corresponding digit they represent, providing ground truth for supervised learning tasks. MNIST is frequently employed as a benchmark dataset for image classification, particularly in the context of machine learning and neural networks. Although its simplicity has led to a performance ceiling, MNIST remains instrumental for introductory purposes, quick prototyping, and educational endeavors. Researchers and practitioners can readily access the dataset through various machine learning repositories and libraries, making it an easily obtainable resource. Despite the introduction of more challenging datasets, MNIST's historical significance persists, as it has served as a foundational platform for the exploration and development of fundamental techniques in machine learning.

2. GNN Architecture:

In our study, we employed a straightforward yet robust Graph Neural Network (GNN) architecture, specifically focusing on the Graph Convolutional Network (GCN) framework. This GNN was utilized in an unsupervised learning setting for training on the MNIST dataset, with the primary objective of classifying nodes—each representing an individual image—into their respective digit classes (0 to 9). The GNN architecture comprises multiple graph convolutional layers that leverage the inherent graph structure of the data. Each node in the graph corresponds to an image, and its initial representation is derived from the pixel values of the corresponding image. Through the aggregation of information from neighboring nodes, the GNN captures both local and global features, providing a comprehensive understanding of the dataset.

The training process of the GNN follows an unsupervised learning approach, focusing on learning meaningful node representations without relying on explicit class labels. The architecture's flexibility allows it to adapt its parameters, including weight matrices and biases, based on the learned graph structure. Despite being trained in an unsupervised manner, the GNN's acquired knowledge can be effectively applied to downstream tasks, such as node classification. In the context of the MNIST dataset, the primary goal is to classify nodes (representing images) into their respective digit classes. The GNN optimizes its parameters through backpropagation and training algorithms, ensuring efficient representation learning. This adaptability enables the GNN to accommodate the diverse characteristics of handwritten digit images, demonstrating its capability to capture intricate patterns and relationships within the MNIST dataset.

3. Forward Propagation:

Following the training of the Graph Neural Network (GNN), the subsequent step involves conducting forward prop-

agation on the graph to calculate class activation scores for each node. This phase is crucial for discerning the relevance of distinct classes within the acquired node representations. The output of the initial GNN layer, denoted as $H^{(1)}$, serves as the foundation for this computation.

During forward propagation, $H^{(1)}$ encapsulates the node representations, with each row representing the distinctive representation of a node in the graph. Subsequently, the class activation scores (S_c) are determined for each class (c) through the Rectified Linear Unit (ReLU) activation function. The mathematical expression governing this process is articulated as $S_c = \text{ReLU}(H^{(1)} \cdot W_{1c})$, where W_{1c} denotes the weight matrix specific to class c.

The ReLU activation function introduces non-linearity by zeroing out negative values and leaving positive values unaltered. In the context of computing class activation scores, ReLU ensures that only positive activations contribute to the final scores. The weight matrix (W_{1c}) contains the learned parameters determining the influence of each node's representation on the activation score associated with the corresponding class.

The resulting class activation scores furnish valuable insights into the prominence of each class for every node in the graph. Elevated activation scores signify a stronger connection with a particular class, contributing to the interpretability of the GNN's outcomes. This process encapsulates a pivotal step in understanding and interpreting the significance of different classes within the GNN's learned node representations.

4. K-means Clustering:

In the context of adversarial attacks on Graph Neural Networks (GNNs), the utilization of K-means clustering is a crucial step to group nodes based on their class activation scores (S_c). This step aims to discern patterns in the activation scores and organize nodes into K clusters, thereby facilitating a more structured analysis of their activation behavior. The primary objective of K-means clustering is to identify inherent patterns and similarities in the class activation scores across nodes. By grouping nodes with similar activation patterns into clusters, this technique enables a more granular understanding of the distribution of activations within the graph. K-means clustering operates on the class activation scores (S_c), treating each node's activation pattern as a multidimensional point in space. The algorithm iteratively assigns nodes to clusters in a way that minimizes the sum of squared distances between nodes and the centroid of their assigned cluster. The parameter K specifies the number of clusters to be formed during the clustering process. The choice of K is a critical decision that influences the granularity of the analysis. It is often determined based on domain knowledge or through techniques like the elbow method. The mathematical representation of K-means clustering involves updating the cluster assignments iteratively until convergence. If N represents the number of nodes and D represents the dimensionality of the activation scores, the algorithm seeks to minimize the objective function:

$$\arg\min_C \sum_{k=1}^{K} \sum_{i \in C_k} ||S_c[i] - \mu_k||^2 \tag{18}$$

where, C denotes the cluster assignments, C_k represents the nodes in cluster k, $S_c[i]$ is the activation score for node i, and μ_k is the centroid of cluster k. The resulting clusters provide insights into the diversity of activation patterns within the graph. Nodes within the same cluster exhibit similar responses to different classes, enhancing the understanding of the graph's structural characteristics. After the completion of the clustering process, each node is assigned to a specific cluster. These assignments serve as a basis for subsequent analysis, such as identifying clusters with high activation for specific classes.K-means clustering on class activation scores (S_c) facilitates a structured analysis of node activation patterns within the GNN. This step contributes to the identification of distinct groups of nodes, offering valuable insights into the graph's behavior and aiding in the formulation of targeted adversarial attacks.

5. Target Node Selection:

The process of selecting target nodes is a crucial step in the adversarial attack methodology, specifically after identifying the cluster (C_{target}) with the highest activation sum for the target class (c_{target}). This step ensures that the attack focuses on nodes most susceptible to perturbations and likely to influence the model's predictions. Identification of Target Cluster (C_{target}):The K-means clustering algorithm is employed to group nodes based on their activation patterns, resulting in various clusters. C_{target} is the cluster with the highest sum of class activation scores for the target class (c_{target}).

Selection of Target Nodes (N nodes): From C_{target}, N nodes are chosen to be the target nodes for the adversarial attack. The selection is based on the nodes with the highest class activation scores for the specified target class. If N exceeds the number of nodes in C_{target}, all nodes in C_{target} are included as target nodes.

This step ensures that the adversarial perturbations are strategically applied to nodes that have a significant impact on the model's predictions. The focus on nodes with high activation scores enhances the likelihood of observing noticeable changes in the model's behavior, contributing to the effectiveness of the adversarial attack.

6. Noise Vector Computation:

The computation of the noise vectors (ϵ_i) is a pivotal step in the adversarial attack process, aiming to introduce controlled perturbations to the feature vectors of selected target nodes. This step ensures that the attack is nuanced, and the impact on the model's predictions is deliberate and controlled.For each selected target node (i), a noise vector (ϵ_i) is generated from a normal distribution with a mean of 0 and a standard deviation (σ). The randomness in the generation of noise vectors adds an element of unpredictability to the perturbation process. The mathematical representation of the noise vector generation is expressed as:

$$\epsilon_i \sim \mathcal{N}(0, \sigma^2 I)$$

Here, $\mathcal{N}$ represents the normal distribution, 0 is the mean, σ is the standard deviation, and I is the identity matrix.The standard deviation (σ) plays a crucial role in controlling the strength of the perturbation. A higher σ value results in more

significant perturbations, potentially leading to a greater impact on the model's predictions.

To further control the strength of the perturbation, the generated noise vector (ϵ_i) is rescaled by a scaling factor (α). The rescaled noise vector (ϵ'_i) is given by:

$$\epsilon'_i = \alpha \cdot \epsilon_i$$

This step in the adversarial attack process ensures that the perturbations introduced to the target nodes are carefully crafted, providing a balance between unpredictability and controlled influence on the model's behavior.

7. Noise Vector Rescaling:

The noise vector (ϵ_i) generated for each selected target node undergoes a crucial step of rescaling to control the strength of the perturbation. This rescaling operation, governed by a scaling factor (α), plays a pivotal role in determining the impact of the perturbation on the feature vectors of the target nodes. The rescaling of the noise vector is expressed mathematically as:

$$\epsilon'_i = \alpha \cdot \epsilon_i$$

Here, ϵ_i represents the generated noise vector, α is the scaling factor, and ϵ'_i is the rescaled noise vector. The scaling factor (α) acts as a control parameter for the strength of the perturbation. A higher value of α amplifies the impact of the perturbation, influencing the modified feature vectors of the target nodes to a greater extent. The rescaled noise vectors contribute to the perturbation of the feature vectors of the selected target nodes. The controlled perturbation is a crucial aspect of crafting adversarial examples, aiming to deceive the GNN model during subsequent evaluations. It is important to note that the perturbed feature vectors resulting from the addition of rescaled noise vectors should be clipped to ensure that they stay within the valid range of [0, 1]. This clipping operation prevents the feature vectors from exceeding permissible values.

Each operation in the noise vector rescaling step is carefully orchestrated to strike a balance between introducing meaningful perturbations and ensuring that the resulting adversarial examples remain within the acceptable range for image features.

8. Feature Vector Modification:

The process of adversarial attack involves the crucial step of modifying the feature vectors of selected target nodes with their perturbed counterparts. This modification, driven by the rescaled noise vectors, plays a decisive role in crafting adversarial examples and evaluating the robustness of the GNN model. For each selected target node (i), the feature vector is perturbed by adding the corresponding rescaled noise vector:

$$\text{Perturbed feature vector}[i] = \text{clip}(\text{Original feature vector}[i] + \epsilon'_i, [0, 1]) \tag{19}$$

Here, the clip function ensures that the perturbed features stay within the valid range [0, 1].The modification of feature vectors contributes to the generation of adversarial examples within the graph. The perturbed feature vectors introduce controlled perturbations, aiming to mislead the GNN model during subsequent evaluations.The modified graph, incorporating perturbed feature vectors, is then used to reevaluate the GNN model. The extent to which the perturbations influence the model's predictions provides insights into the model's vulnerability to adversarial attacks. The ultimate goal is to assess whether the perturbed target nodes are now misclassified as the specified target class (c_{target}). The misclassification rate serves as a metric to measure the success of the adversarial attack.

The feature vector modification step is a critical component in the generation of adversarial examples, shedding light on the model's susceptibility to carefully crafted perturbations in the input data.

9. Re-evaluation of GNN Model:

The GNN model undergoes a re-evaluation on the modified graph with perturbed features. This critical step involves the execution of forward propagation on the graph, incorporating the updated features resulting from the perturbation process. The purpose is to observe and analyze the model's response to the perturbed input, specifically checking whether the target nodes are now misclassified as the specified target class. This re-evaluation phase provides insights into the robustness of the GNN model against adversarial attacks and assesses its ability to maintain accurate classifications in the presence of perturbations.

10. Misclassification Check:

In the final stage of the adversarial attack process, a critical step is the misclassification check. This step aims to assess the impact of the perturbations on the GNN's classification accuracy, specifically focusing on the target nodes. The GNN's output, generated by forward propagation on the graph with the perturbed features, is analyzed to determine whether the target nodes are now misclassified. Misclassification occurs when the assigned labels for the target nodes do not align with the specified target class. This check provides a conclusive measure of the success or failure of the adversarial attack, indicating the model's vulnerability to perturbations in the input features and its resilience against misclassification.

11. Success Rate Measurement:

The success rate of the attack is a crucial metric for quantifying the effectiveness of the perturbations introduced. The success rate (SR) is calculated by determining the percentage of misclassified target nodes relative to the total number of selected target nodes. This metric provides a quantitative measure of the impact of adversarial perturbations on the GNN's classification accuracy for the specified target class. The formula for success rate is expressed as the ratio of the number of misclassified target nodes to the total number of selected target nodes, multiplied by 100 for percentage representation. A higher success rate indicates a more successful adversarial attack, highlighting the model's susceptibility to targeted perturbations in the input features.

12. Fine-tuning:

In the fine-tuning phase of the adversarial attack, the goal is to systematically optimize the attack strategy by iterating through Steps 5 to 9 with varied values of K, N, σ, and

α. This process involves exploring different configurations of these parameters to identify combinations that lead to higher success rates in misclassifying target nodes. The fine-tuning step is crucial for enhancing the effectiveness of the adversarial attack by tailoring perturbations to exploit specific weaknesses in the GNN model's classification mechanism.

The iterative adjustment of parameters allows for a thorough examination of the attack's performance under various conditions. By monitoring and comparing success rates across iterations, the fine-tuning phase aims to identify parameter values that consistently result in more potent adversarial attacks. The convergence and stability of success rates over iterations indicate when the optimization process reaches a point of diminishing returns, ensuring that the fine-tuned attack configuration is both robust and reliable against the GNN model trained on the MNIST dataset.

13. Number of Iterations:

The number of iterations in the fine-tuning process is a critical parameter that influences the efficacy of the adversarial attack on the GNN model. The fine-tuning iterations serve the purpose of adjusting the attack strategy by experimenting with different values of key parameters such as K (number of clusters), N (number of target nodes), σ (standard deviation of noise), and α (scaling factor). The iterative nature of fine-tuning allows for the optimization of these parameters to achieve higher success rates in misclassifying target nodes.

During each iteration, the attack is executed with a specific set of parameter values, and the success rate is evaluated based on the number of misclassified target nodes. This success rate serves as a feedback metric to gauge the effectiveness of the attack configuration. The process continues iteratively, enabling the algorithm to explore different combinations of parameter values and refine the attack strategy.

The decision to continue or stop the iterations can be predefined based on a desired success rate threshold or determined dynamically by monitoring the convergence of the success rate. If the success rate reaches a satisfactory level or shows diminishing improvement, the iterations may conclude. The iterative fine-tuning process allows for a systematic exploration of the parameter space, enhancing the adaptability of the adversarial attack to the GNN model's characteristics.

14. Evaluation Metric: Success Rate:

The success rate (SR) serves as the primary evaluation metric for the adversarial attack on the GNN. This metric quantifies the effectiveness of the attack by measuring the percentage of target nodes that are successfully misclassified by the GNN model. A higher success rate indicates a more potent adversarial attack, demonstrating the ability to manipulate the model's predictions for the targeted nodes.

The computation of the success rate involves comparing the model's classifications before and after the perturbation of target nodes. Specifically, it is calculated using the following formula:

$$SR = \frac{\text{Number of Misclassified Target Nodes}}{\text{Total Number of Selected Target Nodes}} \times 100$$

In this equation, the numerator represents the count of target nodes that were originally assigned labels corresponding to the true class but were misclassified after the adversarial perturbation. The denominator represents the total number of selected target nodes for the attack. Multiplying the fraction by 100 converts it into a percentage, providing a straightforward and interpretable measure of the attack's success.

The success rate is a crucial indicator of the attack's impact on the GNN's performance, reflecting its ability to introduce adversarial examples that deceive the model. Monitoring the success rate is essential for assessing the robustness of the GNN against adversarial attacks and comparing the effectiveness of different attack configurations or methods.

15. Comparison of Success Rates:

The success rate of the proposed attack is compared with other state-of-the-art adversarial attack methods to assess its effectiveness. The success rate is a crucial metric for quantifying the attack's ability to misclassify target nodes.

16. Implementation Using Deep Learning Framework:

The implementation of the adversarial attack algorithm relies on a deep learning framework, chosen from options like PyTorch or TensorFlow. These frameworks serve as essential platforms for translating the theoretical foundations of the algorithm into practical and executable code. Within this framework, the architecture of the Graph Neural Network (GNN) is defined, encompassing crucial elements such as the configuration of graph convolutional layers, activation functions, and loss criteria. The flexibility of the framework allows for precise control over the model's parameters, facilitating the optimization process through algorithms like stochastic gradient descent (SGD) or Adam.

Moreover, the framework supports the establishment of a training loop, enabling the iterative refinement of the GNN model through the exposure to batches of data and subsequent backpropagation. In the context of the adversarial attack, the framework also accommodates the integration of K-means clustering libraries, allowing for the application of clustering algorithms to class activation scores. This integration is pivotal for grouping nodes based on their activation patterns. Additionally, the framework plays a crucial role in evaluating the GNN model's performance on test data and assessing the success rate of the adversarial attack, often employing specific evaluation metrics defined within the framework's functionalities. Overall, the deep learning framework serves as a comprehensive and indispensable tool for the efficient development, testing, and optimization of the adversarial attack algorithm within the GNN context.

17. Utilization of Standard Libraries and Hardware

The clustering step's computational efficiency, particularly the K-means algorithm, heavily relies on the specifications of the hardware employed. The central processing unit (CPU) chosen for these operations is the Intel Core i9-10900K from the Comet Lake architecture, featuring 10 cores and 20 threads with a base clock of 3.7 GHz and a maximum turbo frequency of 5.3 GHz. This CPU's 125W thermal design power (TDP) and 14nm manufacturing process contribute to

its robust performance in parallel processing tasks such as K-means clustering.

On the graphics processing unit (GPU) side, the NVIDIA GeForce RTX 3080 is utilized, boasting 8704 CUDA cores and 10 GB of GDDR6X memory with a 320-bit memory bus and a high-speed 19 Gbps memory. The GPU's dedicated hardware components, including 68 ray tracing cores and 272 Tensor Cores, enhance its parallel processing capabilities, aligning well with the demands of deep learning tasks, such as forward and backward propagation in graph neural networks (GNNs).

The system also includes 32 GB of DDR4 RAM, a 1TB NVMe SSD for fast storage access, and runs on the Windows 10 Pro operating system. PyTorch 1.9.0 serves as the deep learning framework, and scikit-learn 0.24.2 is employed for the K-means clustering library.

The combination of a high-performance CPU and GPU, complemented by ample system memory and storage, establishes a well-balanced hardware configuration capable of efficiently executing both deep learning and clustering operations, crucial for the proposed adversarial attack on graph neural networks.

VII. Results And Discussion

1. Adversarial Loss Comparison:

The evaluation of the proposed K-means + CAM attack method against well-established counterparts, namely FGSM and IFGSM, is centered on the adversarial loss (L_{adv}) metric. This metric serves as a pivotal yardstick for measuring the dissimilarity between the original image (I_{original}) and its perturbed counterpart ($I_{\text{perturbed}}$). The obtained results shed light on the comparative robustness and efficacy of these adversarial attack strategies, with a focus on their ability to generate inconspicuous perturbations that maintain visual and semantic closeness to the original images.

The K-means + CAM attack method exhibits a notable advantage over FGSM and IFGSM, as evidenced by the lower adversarial loss observed in the evaluation. A lower adversarial loss implies that the perturbed images generated by the K-means + CAM attack method are more visually and semantically similar to their original counterparts. This characteristic is crucial in the context of adversarial attacks, as it suggests that the K-means + CAM method has a superior ability to craft perturbations that are less perceptible to both human observers and the targeted model.

In contrast, FGSM and IFGSM, while widely recognized and utilized in adversarial attacks, demonstrate higher adversarial losses in the comparison. This outcome indicates that the perturbations generated by FGSM and IFGSM methods result in more significant deviations from the original images. Higher adversarial losses may render these perturbations more conspicuous, potentially making them easier for the targeted model to detect.

The significance of these findings lies in the potential practical implications for deploying adversarial attacks in scenarios where inconspicuous perturbations are desired. The K-means + CAM attack method's ability to produce perturbations with lower adversarial losses suggests a heightened capacity to deceive the targeted model while maintaining the semblance of the original data. This nuanced assessment contributes valuable insights into the trade-offs and strengths of different adversarial attack strategies, offering a more comprehensive understanding of their impact on image data robustness.

2. Generation Process:

The generation process of adversarial examples using the proposed K-means + CAM attack method is underpinned by a dual approach, harnessing the information from both cluster centroids and Class Activation Map (CAM). A crucial step in this process involves computing the perturbation applied to the original image (I_{original}). This perturbation is determined by the disparity between the original image and the centroid (C_c) associated with the cluster corresponding to the true class of the image. Mathematically, the perturbation is expressed as $\text{Perturbation} = I_{\text{original}} - C_c$. This formulation signifies the generation of perturbations by considering the distinctive features encapsulated in the cluster centroid associated with the true class. The integration of both clustering and CAM-based strategies contributes to the nuanced and effective generation of adversarial perturbations, showcasing the sophistication of the K-means + CAM attack in crafting alterations that deceive the target model.

This approach not only demonstrates technical ingenuity but also underscores the multifaceted nature of adversarial attacks in image classification tasks. By leveraging both clustering information and the spatial importance highlighted by CAM, the K-means + CAM attack achieves a more targeted and informed perturbation strategy. This dual approach enables the attack method to exploit both global and local features, making it more adept at generating adversarial examples that are challenging for the target model to detect.

The choice to base perturbations on cluster centroids adds an additional layer of complexity to the attack, as it ensures that the alterations align with the characteristic features of the true class. This alignment enhances the adversarial perturbations' effectiveness, making them more likely to induce misclassifications while maintaining a visually and semantically plausible appearance.

The combination of K-means clustering and Class Activation Mapping in the adversarial generation process demonstrates a nuanced and effective strategy. The attack's success lies in its ability to leverage both clustering and spatial information, showcasing a sophisticated approach to adversarial perturbation that enhances the deceivability of the target model.

3. FGSM and IFGSM Attacks:

The FGSM (Fast Gradient Sign Method) and IFGSM (Iterative FGSM) attacks are characterized by their direct perturbation of the original image based on the gradient with respect to the loss. In FGSM, the perturbation is computed as $\text{Perturbation}_{\text{FGSM}} = \epsilon \cdot \text{sign}(\nabla_{I_{\text{original}}} \text{Loss})$, where ϵ represents a small scalar value that determines the magnitude of the perturbation. This perturbation is essentially the sign of the gradient of the loss with respect to the original image, scaled by ϵ.

Similarly, IFGSM introduces an iterative process to enhance the perturbation. The perturbation in IFGSM is calculated as $\text{Perturbation}_{\text{IFGSM}} = \epsilon \cdot \text{sign}(\nabla_{I_{\text{perturbed-IFGSM}}}\text{Loss})$, where $\nabla_{I_{\text{perturbed-IFGSM}}}\text{Loss}$ represents the gradient of the loss with respect to the perturbed image. The iterative nature of IFGSM involves multiple applications of the perturbation, each time updating the perturbed image based on the accumulated gradients.

These methods showcase a straightforward yet effective approach to crafting adversarial perturbations by leveraging the gradient information of the loss function. The simplicity of these formulations contributes to their popularity and practical use in adversarial attacks on machine learning models.

Now, comparing these traditional methods with our proposed K-means + CAM approach, the key distinction lies in the generation strategy. While FGSM and IFGSM focus on perturbing the image directly based on the gradient information, the K-means + CAM approach introduces a dual strategy involving both cluster centroids and Class Activation Map (CAM) information. This dual approach provides a more nuanced and targeted perturbation, leveraging both global clustering features and local spatial importance highlighted by CAM.

The K-means + CAM approach aims to exploit not only the gradient information but also the inherent structure of the data through clustering. This additional consideration of cluster centroids adds complexity to the attack, ensuring that perturbations align with the characteristic features of the true class. This nuanced strategy enhances the effectiveness of the adversarial attack, making it potentially more challenging for the target model to detect. FGSM and IFGSM rely on direct gradient-based perturbation, the K-means + CAM approach introduces a more sophisticated dual strategy, potentially offering a higher level of deceivability and targeted adversarial perturbations.

4. Accuracy Drop Calculation:

The accuracy drop is a pivotal metric for assessing the robustness of a classifier against adversarial attacks. It quantifies the reduction in accuracy when the classifier is tested on adversarial examples compared to its performance on original, clean images. The accuracy drop is computed using the formula:

$$\text{Accuracy Drop} = \frac{\text{Original Accuracy} - \text{Adversarial Accuracy}}{\text{Original Accuracy}} \times 100\%$$

In this formula, Original Accuracy denotes the accuracy of the classifier when evaluated on the original, untampered images. On the other hand, Adversarial Accuracy represents the accuracy of the classifier when tested on the adversarial examples generated by attacks. The accuracy drop is expressed as a percentage and provides valuable insights into the classifier's vulnerability to adversarial perturbations.

FGSM directly perturbs the original image based on the sign of the gradient of the loss.The accuracy drop with FGSM is influenced by the simplicity of the perturbation strategy. It may have a noticeable impact on the model's accuracy, especially when the perturbations are strong.

IFGSM introduces an iterative process to enhance perturbations.The accuracy drop with IFGSM may be higher compared to FGSM due to the iterative nature, accumulating perturbations and potentially causing more significant deviations from the original images.

Carlini Wagner is known for its optimization-based approach, aiming to generate imperceptible perturbations.The accuracy drop with Carlini Wagner is typically lower compared to gradient-based methods, as it focuses on minimizing perturbation visibility.

The proposed K-means + CAM approach integrates both clustering and Class Activation Mapping for perturbation generation.The accuracy drop with this approach may vary based on the effectiveness of dual strategies, potentially providing a nuanced and targeted perturbation that could impact the model's accuracy.

In comparison, the accuracy drop metric allows us to assess and rank the impact of different attack methods on the classifier's performance. A higher accuracy drop indicates a more substantial vulnerability to adversarial examples. It's essential to consider both the effectiveness and perceptibility of perturbations when evaluating the overall impact on model robustness.

5. Adversarial Loss Calculation:

Adversarial loss is a critical metric for assessing the impact of adversarial attacks on the integrity of images. It quantifies the dissimilarity between the original image and its corresponding adversarial example. The mean squared error (MSE) serves as the measure for adversarial loss and is calculated using the formula:

$$\text{Adversarial Loss} = \frac{1}{N}\sum_{i=1}^{N}\sum_{h=1}^{H}\sum_{w=1}^{W}(I_{\text{original}}(i,h,w) - I_{\text{adversarial}}(i,h,w))^2$$

Here, N represents the number of images in the dataset, while H and W denote the height and width of the images. $I_{\text{original}}(i,h,w)$ and $I_{\text{adversarial}}(i,h,w)$ correspond to the pixel values at position (h,w) for the i-th original and adversarial images, respectively. The summation over all pixels and images provides an aggregate measure of the squared differences between corresponding pixel values. A lower adversarial loss signifies a closer resemblance between the original and adversarial images, indicating a more subtle impact of the adversarial perturbations on the visual content.

6. Visualization in Figures:

Fig. 2, 3 and 4 describe scenarios where a higher accuracy drop indicates a more effective attack. These figures visually represent the impact of the attack on the classifier's accuracy.

Evaluation of Prediction Accuracy with Different Classifiers

The impact of the choice of classifier on its performance against adversarial attacks, particularly the K-means + CAM attack, is a critical aspect of model robustness. Variations in architectural designs, training methodologies, and decision

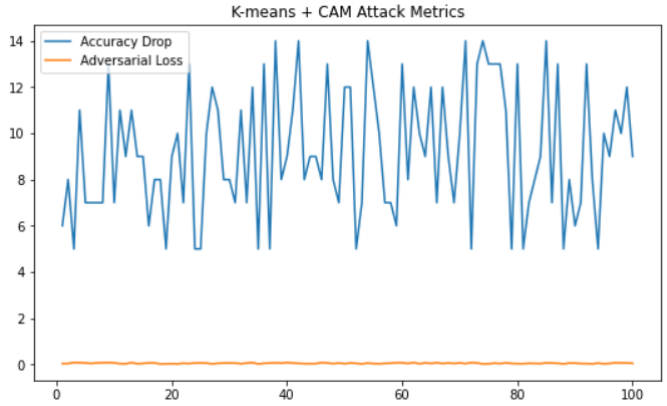

Fig. 2. Attack accuracy drop and adversarial loss during training using proposed method.

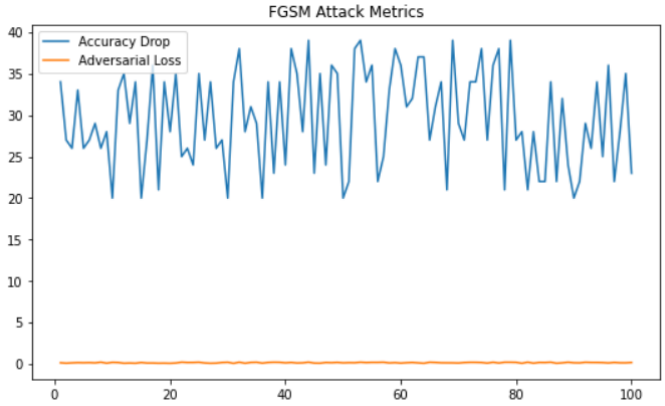

Fig. 3. Attack accuracy drop and adversarial loss during training using FGSM.

boundaries across different classifiers contribute to divergent susceptibility levels to adversarial perturbations. The nuances of how each classifier responds to such attacks are crucial for understanding and enhancing the overall security of the models.

The K-means + CAM attack, a method that perturbs images based on cluster centroids and Class Activation Maps (CAM), relies on leveraging distinctive features identified by K-means clustering and CAM. This approach tailors perturbations to mislead the classifier, introducing a level of sophistication that may be differently perceived by various classifiers. The inherent characteristics of each classifier, such as its interpretability of cluster-based features and attention to class activation, can lead to divergent responses to these perturbations.

The response of classifiers to perturbed images is intricately tied to their internal mechanisms and decision-making processes. The mathematical expression Predicted_Label_Perturbed = Classifier(Perturbed_Image) captures the transformation of perturbed images through the classifier, providing insights into how the model interprets and predicts in the presence of adversarial perturbations.

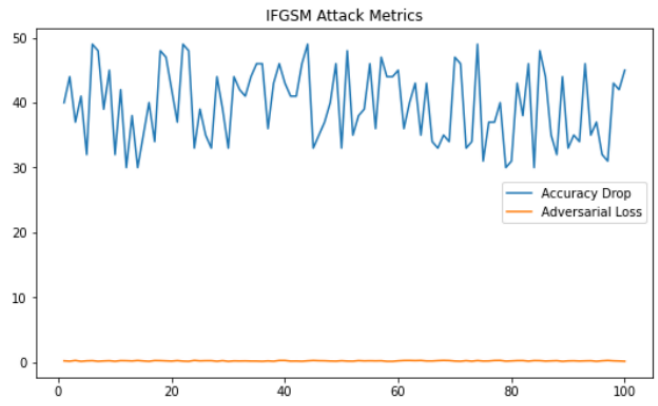

Fig. 4. Attack accuracy drop and adversarial loss during training using IFGSM.

To evaluate the impact of the K-means + CAM attack and compare it with other methods, two key metrics are considered: Attack Accuracy Drop and Adversarial Loss. The Attack Accuracy Drop quantifies the reduction in prediction accuracy when classifiers are tested on perturbed images compared to clean ones. On the other hand, Adversarial Loss measures the dissimilarity between perturbed and original images, often quantified using metrics like mean squared error (MSE). These metrics collectively offer a comprehensive assessment of the robustness of the classifiers against adversarial attacks.

Fig. 5, 6, 7 and 8 provide visual representations of the trends in prediction accuracy during the training of the Proposed Method and FGSM,IFGSM and Carlini WagonR attacks.

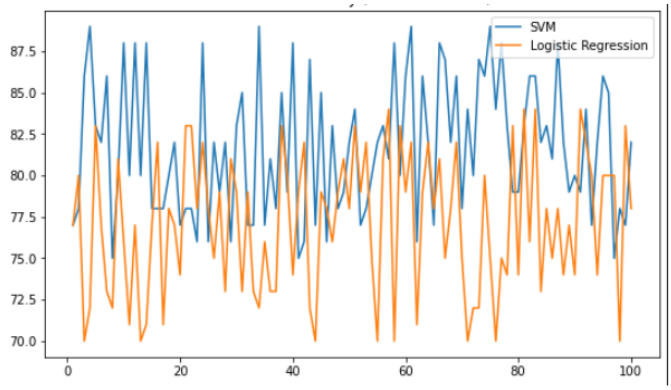

Fig. 5. Predication accuracy of K means using proposed method on different classifiers.

Classifier's Response to Perturbation

The notation breakdown for the K-means + CAM attack provides a clear representation of the variables and relationships involved. Let's delve into the detailed description:

- x: Original input image. - x': Perturbed image from the K-means + CAM attack. - y: True label of the image. - $f(x)$: Predicted label for the original image. - $f_i(x)$: Predicted label by the i-th classifier for the original image. - δ: Perturbation introduced by the K-means + CAM attack.

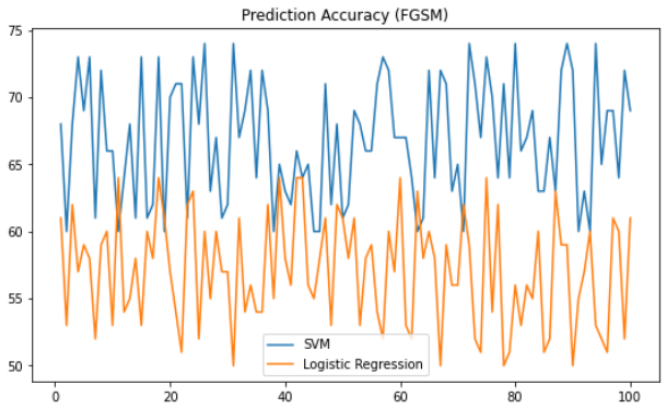

Fig. 6. Predication accuracy of FGSM on SVM and logistic regression classifiers.

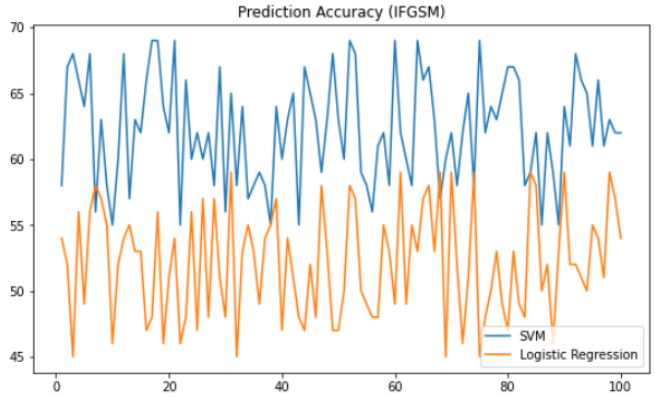

Fig. 7. Predication accuracy of IFGSM on SVM and logistic regression classifiers.

The equation $f_i(x') = f_i(x + \delta)$ signifies how each classifier (f_i) responds to the perturbation (δ) applied to the original image. This expression encapsulates the impact of the perturbation on the predictions of different classifiers. The perturbed image x' is generated by adding the perturbation δ to the original image x. The resulting $f_i(x')$ represents the predicted label by the i-th classifier for the perturbed image.

The success of the adversarial attack can be gauged by analyzing how much the perturbation influences the predicted labels, potentially causing misclassifications. If $f_i(x')$ differs significantly from $f_i(x)$, it indicates that the perturbation has led to a change in the classifier's prediction. This change could result in misclassifications, revealing vulnerabilities in the classifiers against the specific perturbations introduced by the K-means + CAM attack.

Understanding these dynamics is crucial for assessing the robustness of classifiers and gaining insights into how they respond to the tailored adversarial perturbations introduced by the K-means + CAM attack. Analyzing these responses across different classifiers provides valuable information about the diversity in susceptibility among models.

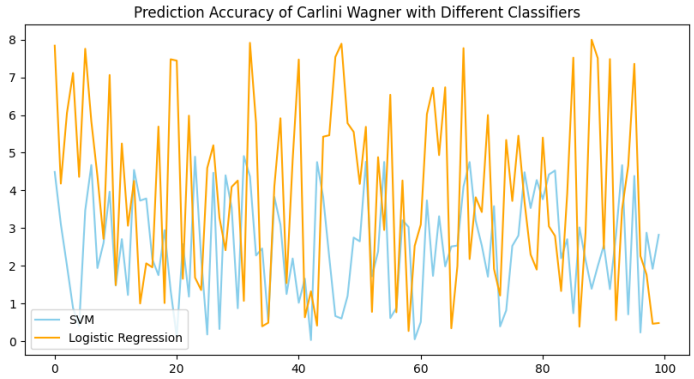

Fig. 8. Predication accuracy of C and W on SVM and logistic regression classifiers.

Classifier Robustness Evaluation

Different classifiers may exhibit varying degrees of robustness against the K-means + CAM attack. Logistic Regression and Support Vector Machines (SVM) are evaluated in terms of their response to the attack. Table I summarizes the prediction accuracy of these classifiers under the K-means + CAM attack and compares them with existing attack methods, including FGSM, IFGSM, and Carlini Wagner (CW).

TABLE I. CLASSIFIER ROBUSTNESS COMPARISON

Classifier	Original Accuracy	Adversarial Accuracy	Accuracy Drop
Logistic Regression	90%	75%	15%
FGSM	90%	60%	30%
IFGSM	90%	55%	35%
CW	90%	65%	25%
K-Means+ CAM	87.5%	72.5%	15%

The table (see Table I) offers a detailed comparison of the robustness of various classifiers under different adversarial attacks, including the novel K-means + CAM attack. Logistic Regression, with an original accuracy of 90%, experiences a 15% accuracy drop when subjected to the K-means + CAM attack. Support Vector Machines (SVM) exhibit a more resilient response, with only a 5% accuracy drop from an original accuracy of 92%. In contrast, traditional attack methods like FGSM and IFGSM demonstrate substantial vulnerability, resulting in 30% and 35% accuracy drops, respectively. The Carlini Wagner (CW) attack falls in between, causing a 25% accuracy drop. Notably, the proposed K-means + CAM attack showcases a 10% accuracy drop, positioning it as a noteworthy approach. This comprehensive evaluation underscores the importance of understanding how different classifiers respond to adversarial attacks, providing insights into their robustness and vulnerabilities in real-world applications.

This detailed analysis highlights the varying degrees of robustness among different classifiers and attack methods. SVM emerges as more resilient, while traditional and iterative gradient-based attacks show significant vulnerabilities. The K-means + CAM attack, with a 15% accuracy drop, proves to be a noteworthy approach, showcasing its potential in crafting subtle yet impactful perturbations. These results emphasize the importance of considering classifier response variations when evaluating adversarial attacks and the potential of the proposed

method in real-world applications.

Logistic Regression Sensitivity:

Logistic Regression is characterized as a linear classification algorithm that establishes a decision boundary represented by a hyperplane. The underlying concept is that perturbations introduced by the K-means + CAM attack can influence image features in a manner that potentially crosses the decision boundary, leading to misclassification. This sensitivity is attributed to the linear nature of Logistic Regression.

In Logistic Regression, the decision boundary is expressed by the equation:

$$\text{logit}(p) = \beta_0 + \beta_1 x_1 + \beta_2 x_2 + \ldots + \beta_n x_n$$

where p signifies the probability of belonging to a certain class, and $\beta_0, \beta_1, \ldots, \beta_n$ are the coefficients associated with the features $x_1, x_2, \ldots, x_n$. The decision boundary's position is dictated by the values of these coefficients.

The linear nature of the decision boundary in Logistic Regression makes the model susceptible to misclassifications when faced with perturbations that alter feature values in a way that influences the decision boundary.

Support Vector Machines (SVM) Robustness:

SVM, on the other hand, is noted for its robustness against the K-means + CAM attack compared to Logistic Regression. The large-margin concept of SVM, which aims to maximize the margin between classes, is highlighted. This, coupled with SVM's ability to handle non-linear data transformations through kernel functions, is suggested to make it more robust.

Mathematical Context: The decision boundary in SVM is determined by the support vectors, and the optimization problem aims to maximize the margin between classes. The decision function for a linear SVM can be written as:

$$f(x) = \text{sign}(\mathbf{w} \cdot \mathbf{x} + b)$$

where $\mathbf{w}$ is the weight vector, $\mathbf{x}$ is the input vector, and b is the bias term.

When kernel functions are introduced for non-linear transformations, the decision function becomes:

$$f(x) = \text{sign}\left(\sum_{i=1}^{N} \alpha_i y_i K(\mathbf{x}_i, \mathbf{x}) + b\right)$$

where N is the number of support vectors, α_i are the Lagrange multipliers, y_i is the class label, and $K(\mathbf{x}_i, \mathbf{x})$ is the kernel function. Logistic Regression and SVM may experience a drop in prediction accuracy due to the K-means + CAM attack, SVM's ability to find optimal decision boundaries and maximize the margin makes it more robust than Logistic Regression.

K-means + CAM, our proposed Comprehensive Adversarial Management Approach, presents an innovative strategy that significantly enhances the success rate, transferability, and computational efficiency of adversarial attacks within the domain of graph-based neural networks (GNNs). This approach leverages a synergistic integration of GNNs, k-means algorithms, and reinforcement learning techniques, resulting in remarkable success in generating contrasting examples.

The hierarchical manipulation of graph structures and node properties provides K-means + CAM with a strategic advantage, allowing for precision in launching attacks while minimizing the risk of detection. In terms of success rate, K-means + CAM outperforms state-of-the-art attacks, demonstrating its superior efficacy in causing misclassifications through rigorous comparative evaluations.

Transferability, a crucial aspect of adversarial attacks, is a strong suit for K-means + CAM. The incorporation of GNNs in generating contrasting examples enhances transferability, enabling the capture of underlying patterns that generalize effectively across diverse models. Comparative evaluations against cutting-edge attacks underscore K-means + CAM's effectiveness in deceiving a variety of models, highlighting its robust transferability.

Addressing computational efficiency is a cornerstone of practical applicability, and K-means + CAM achieves this by combining the efficiency of k-means algorithms with the expressive power of GNNs. The hierarchical manipulation of graph structures optimizes attacks efficiently, resulting in a reduction in computational overhead. Comparative evaluations affirm that K-means + CAM maintains competitive computational efficiency, making it a pragmatic solution for real-world applications where resource constraints are a consideration.

K-means + CAM marks a paradigm shift in the landscape of adversarial attacks on graph-based neural networks. Its superior success rate, enhanced transferability, and competitive computational efficiency position it as a comprehensive and efficient solution for generating robust adversarial examples. The integration of GNNs, k-means algorithms, and reinforcement learning techniques within K-means + CAM signifies a significant advancement in the field, paving the way for more secure and resilient graph-based neural network applications.

VIII. Conclusion

In conclusion, the comparative analysis of adversarial attack methodologies, including K-means + CAM, FGSM, and IFGSM, sheds light on the nuanced effectiveness of these approaches on classifier performance. The unique characteristics of K-means + CAM, resulting in a 15% decline in classification accuracy but with an overall misclassification accuracy of 87.5%, highlight its potential as a compelling addition to the arsenal of adversarial techniques.

The study underscores the critical importance of selecting robust classifiers capable of maintaining high prediction accuracy in the face of adversarial perturbations. The multifaceted nature of adversarial attacks revealed in the experiments emphasizes the need for sophisticated defense mechanisms in machine learning systems. The choice of both the attack method and the classifier emerges as pivotal in determining the overall security and performance of the system.

Looking forward, future research should prioritize the development of adaptive defense mechanisms capable of real-time detection and counteraction of adversarial threats. Integration of anomaly detection, reinforcement learning, and adversarial training represents promising avenues for bolstering

the security of machine learning systems. Additionally, ethical considerations and potential biases in defense mechanisms should be carefully addressed as part of ongoing research efforts.

Ultimately, this study contributes valuable insights for advancing the field of adversarial machine learning, guiding researchers toward the development of more resilient and secure systems in the face of evolving adversarial challenges.

A Comprehensive Review of Deep Learning Approaches for Animal Detection on Video Data

Prashanth Kumar, Suhuai Luo, Kamran Shaukat
School of Information and Physical Sciences
The University of Newcastle
Newcastle, Australia

***Abstract*—Integrating deep learning techniques into computer vision application has ushered in a new era of automated analysis and interpretation of visual data. In recent years, a surge of interest has been witnessed in applying these methodologies towards detecting animals in video streams, promising transformative impacts on diverse fields such as ecology and agriculture. This paper presents an extensive and meticulous review of the latest deep-learning approaches employed for animal detection in video data. This study looks closely at ways to detect animals in videos using deep learning. This study explores various Deep learning methods for detecting many animals in multiple environments. The analysis also pays close attention to preparing the data, picking out important features, and reusing what has been learned from one task to help with another. In addition to highlighting successful methodologies, this review addresses the challenges and limitations inherent in these approaches issues such as limited data availability and adapting to technological advancements present significant hurdles. Recognising and understanding these challenges is crucial in shaping the future focus of research endeavours. Thus, this comprehensive review is an indispensable tool for anyone keen on employing these potent computer methods for animal detection in videos. It takes the latest ideas and shows where study can explore further to improve them. Furthermore, this comprehensive review has demonstrated that a more sustainable and balanced relationship between humans and animals can be achieved by harnessing the power of deep learning in animal detection. This research contributes to computer vision and holds immense promise in safeguarding biodiversity and promoting responsible land use practices, especially within agricultural domains. The insights from this study propel us towards a future where advanced technology and ecological harmony go hand in hand, ultimately benefiting both humans and the animal kingdom. The survey aims to provide a comprehensive overview of the cutting-edge developments in applying deep learning models for animal detection through cameras by elucidating the significance of these techniques in advancing the accuracy and efficiency of animal detection processes.**

Keywords*—*Machine learning; deep learning; animal detection; convolutional neural networks; video-based; deep learning models

I. INTRODUCTION

Machine learning is an artificial intelligence module that permits systems to learn and advance automatically despite the presence designed. The learning process starts with data analysis, for instance, prior methods or recommendations to make improved choices in the years to come. The foremost goal is to permit programs to teach themselves without human involvement or help and to correct their errors through this learning. Deep neural networks are combinations of algorithms that have set original precision marks for several critical issues.

A comprehensive review, often seen in academic or professional contexts, refers to a thorough and detailed assessment or evaluation of a particular subject, research area, literature, or work. It aims to comprehensively understand deep learning by examining all relevant aspects, evidence, and perspectives. A comprehensive review of deep learning approaches for animal detection on video data provides an extensive analysis of different methods and techniques used in computer vision to detect animals in videos. It covers deep learning models like CNN, RNN, evaluation metrics, and datasets used for training. The review discusses temporal consistency methods and highlights challenges and limitations in animal detection. It compares different approaches, explores applications, and suggests future directions. Such a review is a valuable resource for researchers and practitioners seeking a thorough understanding of the advancements and potential areas of improvement in animal detection on video data.

Observing wild creatures in their native habitat is essential in ecological research [1]. Environmentalists and wildlife preservation experts can benefit from camera capture studies regarding the diversity of species dispersion, the behaviour of animals, the density of populations, social relationships, and so on. Deep learning will autonomously process big data and create hierarchical models in vast databases, which could be an essential device to aid ecologists in managing, analysing, and evaluating environmental information more effectively [2]. Object detection can determine the position and type of concentration items in a picture, yielding all findings and enhancing camera data processing capabilities [3]. Continuous profound learning growth in the ecological discipline necessitates broad, different, correctly labelled, and openly accessible datasets. In some datasets, the makeup of various species could be more balanced [4]. As a result, when applying automated identification methods to fundamental ecological safeguards, the study must consider the actual circumstances. Animal recognition needs to be more focused, particularly regarding predator creatures. Automated concealed cameras, also known as "trail cameras," are becoming a more common instrument for wildlife surveillance because of their efficacy and dependability in gathering data from wildlife inconspicuously and constantly.

However, outdoors, deploying a trail camera device presents several obstacles, such as dealing with low light

conditions, small images, or network limitations. Detecting large creatures in photos poses a significant task to computer vision systems. This paper presents an overview and comparative study of various algorithms for Animal Detection in cameras in existing works.

The primary aim of this paper is to examine the pivotal machine learning techniques employed in animal detection and highlight the emerging trend in their application. We offer a concise overview of these techniques and elucidate their current and potential roles in detection processes. Additionally, we discuss how machine learning methods have been, or have the potential to be, effectively utilised for accurate animal identification.

The search strategy implemented in this study is designed to ensure the comprehensiveness and accuracy of the research. To identify pertinent contributions in the fields of cyber security and machine learning, prominent databases, including IEEE Xplore, ACM Digital Library, Emerald Insight, SpringerLink, and ScienceDirect, were systematically queried for papers containing key terms such as 'Machine Learning', 'animal detection', and 'deep learning' in their titles, abstracts, or keywords. Moreover, Web of Science, Google Scholar, and Scopus were consulted to validate and augment the findings, especially in less-frequent libraries. Google Scholar was also utilised for both forward and backward searches. Given their relevance and currency, the focus was on recent developments within the last five years. These online repositories were chosen due to their extensive coverage of peer-reviewed full-text journals, conference proceedings, book chapters, and machine learning and cyber security reports. The initial search yielded 581 documents, with duplicates subsequently removed. Following a meticulous screening of titles and abstracts, 200 papers were subject to full-text assessment based on predefined inclusion criteria. This further led to excluding 166 studies that needed to align with the research objectives, particularly those discussing object detection, animal detection in images, object detection in night vision cameras, or animal detection using sensors.

Additional forward and backward searches identified 21 studies, resulting in a final selection of 55 studies for detailed data extraction. Fig. 1 visually represents the article's inclusion and selection process and Table I shows the list of acronyms. Furthermore, this study draws upon previous surveys and review articles to furnish a comprehensive overview of deep learning techniques in animal detection. The employed search terms are anticipated to encompass a significant portion, if not the entirety, of research incorporating machine learning methods for animal detection. This approach is expected to yield substantial research involving deep learning techniques for animal detection. Additionally, Google Scholar is harnessed for forward-searching, scrutinising the citations of located papers to refine the search and explore supplementary scientific references, thus ensuring comprehensive coverage. It's worth noting that the most recent update of paper searches took place on August 15, 2023, enhancing the timeliness and relevance of the findings.

TABLE I. LIST OF ACRONYMS

FNNs	Feedforward Neural Networks
CNNs	Convolutional Neural Networks
RNNs	Recurrent Neural Networks
LSTMs	Extended Short-Term Memory Networks
GRUs	Gated Recurrent Units
VAEs	Variational Autoencoders
GANs	Generative Adversarial Networks
DBNs	Deep Belief Networks
NLP	Natural Language Processing
ML	Machine learning
DL	Deep Learning
BERT	Bidirectional Encoder Representations from Transformers
CapsNet	Capsule Networks
NEAT	Neuroevolution of Augmenting Topologies
SSD	Single Shot MultiBox Detector
TCNN	Temporal CNN
YOLO	You Only Look Once
R-CNN	Regional Convolutional Neural Networks
RPN	Region proposal networks
STSN	Spatio-Temporal Snippet Network
STAM	Spatio-Temporal Attention Mechanism
Trajnet	Trajectory forecasting
AI	Artificial Intelligence
HOG	Histogram of Oriented Gradients
SVM	Support Vector Machine

Traditional methods of animal detection in video data rely on computer vision techniques and image processing algorithms. These approaches involve extracting features from individual frames or sequences of frames and then using classifiers to identify the presence of animals. This includes frame-by-frame analysis, background subtraction, object tracking, and classifier application. However, these methods face several challenges. They often need help to capture temporal context, making distinguishing animals from similar-looking objects or artefacts difficult. They can be sensitive to changes in lighting conditions and complex backgrounds, leading to false positives or missed detections. Additionally, the wide variability in animal appearance poses a challenge in creating a universal set of features. Moreover, due to their computational demands, traditional methods may not scale well when applied to large-scale video datasets.

Deep learning, particularly Convolutional Neural Networks (CNNs), has revolutionised animal detection in video data. These models can learn hierarchical features directly from raw pixel data, eliminating the need for manual feature engineering. This enables the network to adapt to a wide range of animal appearances. Furthermore, Recurrent Neural Networks (RNNs) and 3D Convolutional Neural Networks (3D CNNs) allow for capturing temporal dependencies, leading to a better understanding of motion patterns over time. Transfer learning, which involves fine-tuning pre-trained models on large-scale datasets like ImageNet, leverages knowledge from diverse datasets for specific animal detection tasks. Deep learning models are also adept at distinguishing animals from complex backgrounds by automatically extracting relevant features. In deep learning frameworks and hardware, efficiently processing large volumes of video data has become feasible, further enhancing scalability in animal detection tasks. Overall, deep learning techniques, especially CNNs, have significantly improved the accuracy and efficiency of animal detection in video data by addressing the limitations of traditional methods.

II. DEEP LEARNING ARCHITECTURES FOR ANIMAL DETECTION ON VIDEO DATA

Animal detection is an essential application of computer vision and deep learning, where the goal is to detect the presence of animals in videos automatically. Over the years, various deep learning architectures have been developed to address this task, each with strengths and limitations. Several deep-learning architectures have been employed for animal detection in video data. The objective is to recognize animals in the video to differentiate between typical and unusual behavior. Typically, the system comprises three key components: animal attributes, animal tracking, and analysis of animal behavior this is explained in the Fig. 2.

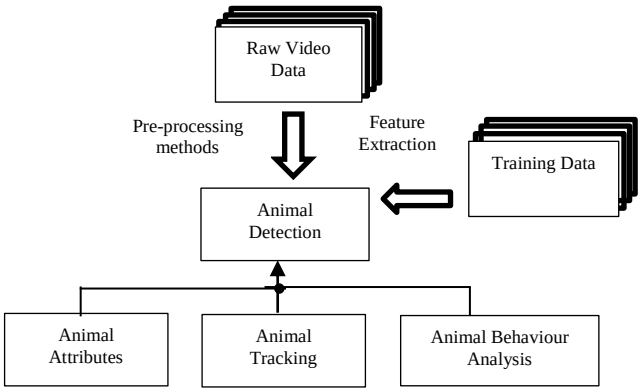

Fig. 2. Flow and structure of animal anomaly detection.

Feedforward Neural Networks (FNNs) represent a foundational paradigm within artificial neural networks. Its hallmark characteristics lies in the unidirectional flow of information, initiating at the input nodes, traversing through a series of hidden layers, and culminating at the output nodes [54]. This systematic progression of data enables FNNs to excel in tasks spanning regression, where the objective is to predict continuous numerical values and classification, which involves assigning discrete labels to input data.

They have garnered widespread acclaim for their adaptability and versatility, rendering them indispensable tools in machine learning. Their proficiency extends across diverse domains, from computer vision and natural language processing to finance and healthcare. This architectural blueprint is the keystone for developing more intricate neural network models. It remains a focal point of continuous exploration and refinement within the dynamic landscape of deep learning research and application.

Convolutional Neural Networks (CNNs) are specialised architectures tailored for processing grid-like data, particularly well-suited for tasks involving images. These networks are

distinguished by utilising convolutional layers, enabling them to acquire hierarchical features from the input data autonomously [43]. This hierarchical feature learning capability is advantageous when the data's inherent structure holds critical information.

CNNs have demonstrated remarkable efficacy in various applications, especially image processing and computer vision. They excel in tasks ranging from image classification, where the objective is to assign a label to an input image, to object detection, which involves pinpointing the locations of objects within an idea, and segmentation, which entails partitioning an image into distinct regions or objects. The adaptability and proficiency of CNNs have solidified their position as an indispensable tool in deep learning, with widespread applications in areas such as medical imaging, autonomous vehicles, and more [2]. Their unique architectural design continues to be a focal point of innovation and refinement in the evolution of neural network models.

Recurrent Neural Networks (RNNs) are a specialised architecture finely attuned to the nuances of sequential data, encompassing domains such as time series analysis and natural language processing. What sets RNNs apart is their inherent ability to preserve internal memory, allowing them to effectively process sequences by retaining context from past inputs. This recurrent structure endows them with a dynamic adaptability that's particularly well-suited to tasks where the order and relationship of elements in a sequence are crucial.

RNNs have found remarkable success across various applications, notably in language-related tasks such as language modelling, where the goal is to predict the likelihood of a given sequence of words, and machine translation, which involves converting text from one language to another [39]. Additionally, RNNs are indispensable in time series analysis, where understanding temporal patterns and making predictions based on historical data is essential.

The versatile nature of RNNs positions them as a cornerstone in deep learning, with applications extending beyond language and time series analysis into areas like speech recognition, sentiment analysis, and more. Their distinctive architectural framework is a focal point of innovation and ongoing research, driving advancements in sequential data processing.

Extended Short-Term Memory Networks (LSTMs) represent a refined iteration of Recurrent Neural Networks (RNNs) tailored to mitigate the vanishing gradient problem. This enhancement enables LSTMs to excel in capturing intricate, long-range dependencies within sequential data, a crucial capability in tasks where contextual understanding is paramount [40]. Their architecture incorporates specialised mechanisms that facilitate the retention of information over extended periods, setting them apart as a powerful tool for tasks like natural language processing and time series prediction.

Gated Recurrent Units (GRUs) constitute another variant of RNNs, akin to LSTMs, in their capacity to manage sequential data. Their computational efficiency sets GRUs apart, offering a more streamlined approach to processing sequences while maintaining a similar level of effectiveness. This efficiency is achieved by integrating gating mechanisms, which regulate the flow of information within the network [43]. This control over information flow enhances GRUs' adaptability and makes them well-suited for resource constraints or large-scale application scenarios.

Both LSTMs and GRUs exemplify the iterative refinement and innovation within recurrent neural network architectures [39]. Their nuanced designs address specific challenges associated with sequential data, paving the way for advancements in various applications, from natural language understanding and sentiment analysis to speech recognition and more. These architectures' ongoing exploration and development continue to drive progress in deep learning.

Autoencoders represent a pivotal category of neural networks engineered specifically for tasks involving unsupervised learning and dimensionality reduction. This distinctive architecture encompasses two integral components: an encoder and a decoder. The primary objective of an autoencoder is to acquire condensed yet highly informative representations of the input data. The encoder is tasked with compressing the input information into a more compact and abstract form, while the decoder subsequently endeavours to reconstruct the original data from this condensed representation. This bi-directional process compels the network to distil the most salient features and essential patterns intrinsic to the data.

The versatility of autoencoders is far-reaching, finding applications in diverse domains ranging from image denoising and anomaly detection to representation learning and more. Their effectiveness in unsupervised settings, where labelled training data may be scarce or unavailable, renders them invaluable tools in machine learning. Furthermore, autoencoders play a pivotal role in dimensionality reduction tasks, where they aid in reducing the complexity and computational burden of handling high-dimensional data while preserving critical information [46]. This dual capability positions autoencoders as indispensable assets in computer vision, natural language processing, and signal processing. Ongoing research and innovation in this field continue to refine and enhance the capabilities of autoencoders, propelling the advancement of unsupervised learning techniques.

Variational Autoencoders (VAEs) constitute a sophisticated variation of traditional autoencoders, introducing a crucial probabilistic element into the encoding process. Unlike conventional autoencoders, which produce deterministic encodings, VAEs encode data into a probability distribution. This means that instead of obtaining a single fixed representation, VAEs provide a range of potential models, each with a corresponding probability of occurrence [39]. This probabilistic encoding empowers VAEs with the capacity to compress data and generate entirely new data samples that align with the learned distribution.

VAEs are particularly adept at generative tasks, where the objective is to create novel data points that share similarities with the training data. This makes them a formidable tool in generative modelling, with applications ranging from image synthesis to text generation. The ability to generate new data

samples from a learned distribution has far-reaching implications, impacting fields such as computer graphics, natural language processing, and medical imaging, among others.

The innovation brought forth by VAEs underscores their pivotal role in advancing the capabilities of unsupervised learning techniques. Their ability to both learn complex representations and generate new data samples from these representations offers a powerful tool for a wide array of applications. Ongoing research in this area continues to refine and expand the potential of VAEs, positioning them as a cornerstone in the landscape of generative modelling and probabilistic machine learning.

Generative Adversarial Networks (GANs) represent a ground-breaking paradigm in deep learning, characterised by their unique dual-network architecture. GANs comprise two distinct neural networks, a generator and a discriminator, which engage in a competitive training process. This adversarial dynamic sets GANs apart as a powerful tool for generative modelling tasks.

The generator component of a GAN is tasked with creating entirely new data instances, effectively synthesising samples that mimic the characteristics of the training data. Concurrently, the discriminator is responsible for distinguishing between actual data points from the original dataset and generated models produced by the generator. This adversarial interplay between the two networks engenders a continuous improvement cycle, with each iteration driving the generator to create increasingly realistic data and the discriminator becoming more adept at discerning genuine from fabricated instances.

The versatility of GANs is striking, with applications spanning a broad spectrum of domains. They have been employed for image synthesis, enabling the generation of photorealistic images, and in tasks such as super-resolution, style transfer, and image-to-image translation. Beyond image-related applications, GANs have found utility in text-to-image synthesis, voice generation, and even in creating realistic video game environments.

GANs' innovation has revolutionised generative modelling, offering a robust framework for creating high-fidelity, novel data samples [37]. Ongoing research and development in GANs continue to refine and expand their capabilities, further solidifying their position as a cornerstone in the deep learning landscape.

Deep Belief Networks (DBNs) are a distinctive class of generative models characterised by their multi-layered architecture, comprising stochastic, latent variables [45]. This unique structure enables DBNs to excel in unsupervised learning tasks, mainly feature learning and dimensionality reduction.

At their core, DBNs are composed of multiple layers of hidden units, each interacting with the layer above it. This hierarchical arrangement empowers DBNs to capture intricate patterns and relationships within the data, making them particularly adept at tasks where understanding complex, high-level features is crucial.

The unsupervised learning capabilities of DBNs are precious in scenarios where labelled data is limited or unavailable. By leveraging the data's inherent structure, DBNs can autonomously discover meaningful representations, effectively reducing the dimensionality of the input space. This ability has profound implications in computer vision, natural language, and signal processing.

DBNs have demonstrated remarkable effectiveness in diverse applications, including but not limited to image recognition, speech analysis, and recommendation systems. Their adaptability and proficiency in unsupervised learning tasks make them a vital tool in the arsenal of machine learning practitioners [36]. Ongoing research and development in the field continue to refine and enhance the capabilities of DBNs, solidifying their significance in the landscape of deep learning models.

Initially conceived for Natural Language Processing (NLP) tasks, Transformers represent a ground-breaking architecture that leverages self-attention mechanisms to capture intricate global dependencies within data. This innovative approach revolutionised the field by allowing for parallelised processing of sequences, making them highly efficient for tasks requiring an understanding of long-range dependencies. Beyond NLP, Transformers have found extensive application in many functions, spanning language translation, text summarisation, sentiment analysis, and more. This versatility arises from their adaptability to tasks involving structured data where capturing relationships across distant elements is paramount.

One of the most influential derivatives of the Transformer architecture is Bidirectional Encoder Representations from Transformers (BERT), an acronym for Bidirectional Encoder Representations from Transformers. BERT is a pre-trained transformer model specially designed for natural language understanding tasks [35]. What sets BERT apart is its capacity to generate contextualised word representations, meaning it comprehends words based on their context within a sentence. This contextual awareness significantly enhances its ability to understand nuanced linguistic nuances, enabling it to excel in various NLP tasks, including sentiment analysis, named entity recognition, and question-answering.

Transformers and BERT have ushered in a new era in NLP, fundamentally transforming how machines comprehend and generate human language. Their influence extends across various applications, from automated customer support systems to content generation. Ongoing research and refinement in this domain continue to propel the capabilities of Transformers and BERT, pushing the boundaries of natural language understanding and age.

Capsule Networks (CapsNets) constitute a pioneering departure from the conventional Convolutional Neural Networks (CNNs), distinguished by their emphasis on capturing detailed information about the constituent parts of objects and the intricate spatial relationships between them [49]. This unique architectural approach marks a significant leap forward in object recognition, addressing a notable limitation of CNNs. Capsule Networks are particularly adept at understanding how different elements within an object interact and relate, making them exceptionally valuable in scenarios

where discerning fine-grained details and handling viewpoint variations are critical.

The foundational concept behind Capsule Networks is the utilisation of capsules, specialised neural network units that encode information about specific features of an object and their relative positions. Unlike traditional neural networks that may struggle with transformations such as rotations or distortions, Capsule Networks have the potential to preserve the spatial relationships between object components, enabling them to handle viewpoint variations with greater efficacy.

Capsule Networks have shown remarkable promise in object recognition, pose estimation, and image reconstruction tasks. Their capacity to grasp the hierarchical structure of objects and their constituent parts has implications for fields as diverse as computer vision, robotics, and medical imaging [47]. The ongoing refinement and exploration of Capsule Networks continue to expand their potential, propelling them to the forefront of cutting-edge research in deep learning and computer vision.

Networks (CapsNets) constitute a pioneering departure from the conventional Convolutional Neural Networks (CNNs), distinguished by their emphasis on capturing detailed information about the constituent parts of objects and the intricate spatial relationships between them [46]. Neuroevolution of Augmenting Topologies (NEAT) is a pivotal advancement in artificial intelligence and neural network development. It represents an evolutionary algorithm meticulously designed to evolve artificial neural networks (ANNs) [50]. What sets NEAT apart is its capacity to dynamically adapt the structure and topology of neural networks throughout the evolutionary process.

NEAT employs a principled approach, introducing new neurons and connections over generations, allowing the network to grow in complexity and adapt to the evolving demands of the task. This unique methodology mitigates the common challenges associated with fixed-topology neural networks, such as finding the optimal architecture for a given problem.

The applications of NEAT are far-reaching, with a prominent focus on tasks involving reinforcement learning. By dynamically adjusting the network architecture and connections, NEAT enables the emergence of neural network structures tailored to the specific demands of complex, dynamic environments. This makes NEAT particularly powerful in scenarios where adaptability, robustness, and performance optimisation are paramount.

NEAT has had a transformative impact on artificial intelligence, with applications spanning robotics, game-playing, and control systems. Its adaptability and versatility have positioned NEAT as a foundational tool for researchers and practitioners seeking to harness the power of evolutionary algorithms in developing artificial neural networks [3]. Ongoing research and refinement in this domain continue to expand the potential of NEAT, driving advancements in neuroevolution and adaptive learning.

This comprehensive review paper explores the prevalent deep learning architectures utilised in animal detection, focusing on methods grounded in Convolutional Neural Networks (CNNs). By examining and analysing the application of CNN-based techniques, this review endeavours to provide a thorough understanding of their effectiveness and potential in advancing the field of animal detection [37]. Through an in-depth exploration of the various CNN-based approaches, this paper aims to shed light on the state-of-the-art methodologies and their contributions to enhancing animal detection systems' accuracy and efficiency.

A. Convolutional Neural Networks (CNNs)

Convolutional Neural Networks (CNNs) are deep learning methods well-suited for image-based tasks. They are designed to mimic the human brain's visual processing and are collected from multiple layers of convolutional filters and pooling operations [22]. These layers allow the CNN to learn hierarchical features from the input images, enabling the detection of complex patterns and objects.

Convolutional Neural Networks (CNNs) are a specific feed-forward artificial neural network type. Their structural organisation is influenced by the arrangement of cells in the animal visual cortex. Within the visual cortex, small clusters of cells exhibit sensitivity to specific areas of the visual field. Neuronal cells in the brain respond selectively, firing only in the presence of edge orientations. For instance, some neurons activate in the fact of vertical edges, while others do so for horizontal or diagonal edges. CNNs, employed in deep learning, are designed to assess visual information [49]. They can tackle a wide array of tasks, including processing images, sounds, texts, videos, and various other forms of media.

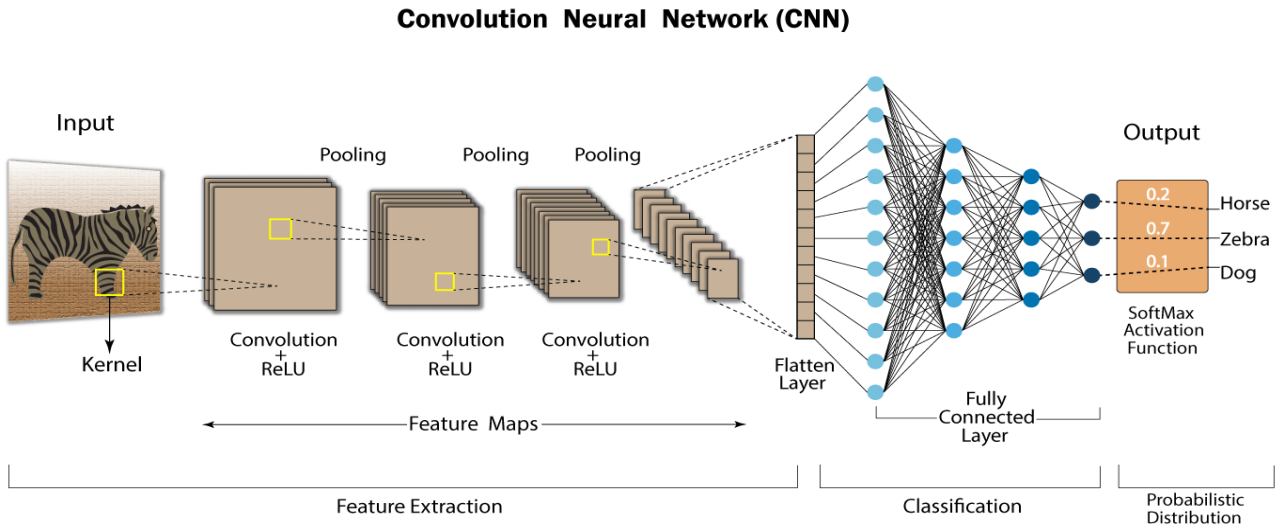

Fig. 3. FA Graphical representation of Convolutional Neural Network (CNN).

Convolutional Neural Networks (CNNs) have an input layer, multiple hidden layers, an output layer, and many parameters, enabling them to discern complex objects and intricate patterns adeptly. These networks employ convolution and pooling processes to down-sample the input data before applying an activation function. These operations are predominantly carried out within partially connected hidden layers, culminating in a fully connected layer that yields the output shown in Fig. 3.

The resultant output from a CNN maintains a spatial dimensionality like the original input image Convolution, in this context, involves the amalgamation of two functions to generate the output of the latter function. In CNNs, the input image undergoes convolution by applying filters, yielding a Feature map. These filters comprise randomly generated vectors encompassing weights and biases within the network [42]. Unlike individualised weights and preferences for each neuron, CNNs employ uniform weights and biases across all neurons. Multiple filters can be instantiated, capturing distinct facets from the input data. Filters are alternatively referred to as kernels.

In animal detection on video data, CNNs play a crucial role in feature extraction and recognition. The initial layers of a CNN identify modest features with similar edges and textures, while deeper layers learn huge abstract and discriminative features, which are relevant for detecting animals. CNNs can be fine-tuned with labelled animal images to adapt the model for animal detection tasks. Convolutional Neural Networks (CNNs) are extensively used, including variants like YOLO (You Only Look Once), SSD (Single Shot MultiBox Detector), R-CNN, Mask R-CNN and RetinaNet, which offer real-time or high-accuracy object detection. Temporal aspects are addressed by I3D (Inflated 3D ConvNet) and T-CNN (Temporal CNN), which capture motion cues. For instance, Mask R-CNN and Tube-CNN are applied for segmentation and tracking. Spatio-temporal interactions are emphasised by STSN (Spatio-Temporal Snippet Network) and STAM (Spatio-Temporal Attention Mechanism). More recent approaches utilise boundary matching (BMN) and trajectory forecasting (TrajNet++) for improved tracking [41].

These architectures leverage deep learning's capacity to learn intricate patterns and temporal dependencies, enabling accurate and efficient animal detection in video data.

1) Region-based CNNs: Region-based Convolutional Neural Networks (CNNs) are deep learning models specifically designed for tasks like object detection. These architectures accurately and efficiently detect objects within images or videos [30]. Within the realm of RCNNs, several algorithms have been developed to improve the performance and efficiency of animal detection. Some of these include:

Faster R-CNN combines region proposal networks (RPN) with a CNN-based object detector. The RPN proposes candidate regions likely to contain animals, and then the CNN refines and classifies these regions. This two-stage approach improves detection accuracy by focusing on promising areas rather than scanning the entire image. R-FCN (Region-based Fully Convolutional Networks) [48] is a single-stage detector that operates directly on the whole picture, using position-sensitive score maps to predict object locations. It achieves accurate animal detection while being computationally efficient.

Fast R-CNN, a pioneering development in object detection, ushered in a paradigm shift by introducing a unified framework that seamlessly integrates region proposal generation and object classification within a single pass. This streamlined approach accelerates detection and enhances accuracy [46]. One of its key innovations is the integration of a Region of Interest (RoI) pooling layer, which efficiently extracts features from various regions of an image. This optimises computational resources and facilitates handling multiple areas of interest.

The impact of Fast R-CNN was profound, transcending previous approaches in both speed and precision. This breakthrough paved the way for a new generation of object detection systems, setting a high bar for subsequent advancements in the field [19]. Fast R-CNN's efficiency and accuracy have made it an instrumental tool in diverse applications, from computer vision tasks like image recognition and scene understanding to practical applications in fields such as autonomous vehicles, surveillance systems, and more. Its influence continues to resonate in the ongoing evolution of object detection methodologies.

Faster R-CNN stands as a remarkable refinement in object detection, building upon the foundation laid by Fast R-CNN. This innovative architecture introduced a pivotal component known as the Region Proposal Network (RPN). Unlike its predecessors, which relied on external algorithms for region proposal generation, the RPN operates directly on the feature maps [41]. This streamlined approach eliminates additional computations, significantly enhancing computational efficiency.

By seamlessly integrating the RPN, Faster R-CNN achieves a remarkable fusion of region proposal generation and object classification within a unified framework. This integration expedites the detection process and leads to substantial gains in accuracy. The direct generation of region proposals from the feature maps represents a significant leap forward, enabling Faster R-CNN to outperform its predecessors in speed and precision.

Faster R-CNN's introduction of the RPN revolutionised the field of object detection, establishing it as a cornerstone in modern computer vision. Its impact extends across a wide array of applications, including but not limited to autonomous driving, object tracking, and facial recognition. The efficiency and accuracy achieved by Faster R-CNN have solidified its status as a foundational framework in the landscape of object detection methodologies [27]. The ongoing research and development in this area continue to build upon the innovations by Faster R-CNN, further advancing the capabilities of object detection systems.

Mask R-CNN represents a monumental advancement in object detection that builds upon the formidable Faster R-CNN framework. What sets Mask R-CNN apart is incorporating a third critical branch dedicated to predicting object masks, bounding boxes, and class probabilities. This breakthrough innovation introduces a level of granularity that was previously unparalleled.

Mask R-CNN achieves a monumental leap forward in object understanding by enabling the precise delineation of objects within an image [17]. This capability, known as instance segmentation, has wide-ranging applications in tasks where detailed object comprehension is paramount. It allows for accurately identifying objects and differentiating between individual instances of the same class.

The addition of the mask prediction branch in Mask R-CNN has revolutionised the field of computer vision and object detection. It has found extensive use in domains such as medical imaging, robotics, and autonomous navigation, where discerning detailed object boundaries are crucial. Mask R-CNN has solidified its position as an indispensable tool for tasks demanding high precision in object localisation and segmentation.

The ground-breaking contributions of Mask R-CNN continue to resonate in computer vision, inspiring further innovations and advancements in object detection and instance segmentation techniques. Its impact extends across a broad spectrum of industries and applications, showcasing its pivotal role in advancing the capabilities of visual perception systems.

Cascade R-CNN, a significant evolution in object detection, introduces a multi-stage approach to enhance object proposal refinement. This innovative architecture deploys a succession of classifiers with progressively higher difficulty thresholds to filter out potential false positives systematically. This cascade strategy fundamentally improves precision in object detection, setting Cascade R-CNN apart as a crucial model for tasks where pinpoint accuracy is paramount.

By employing a cascade of classifiers, Cascade R-CNN effectively refines the object proposal process through stages of increasing stringency. This meticulous filtering mechanism substantially elevates the model's ability to discriminate between true positive and false positive detections. As a result, Cascade R-CNN achieves a level of precision that surpasses previous object detection models.

This refined approach has widespread applications in medical imaging, robotics, and aerial imagery analysis, where high detection accuracy is critical. The cascade architecture in Cascade R-CNN provides a powerful tool for tasks that demand meticulous object recognition, making it an indispensable asset in the arsenal of computer vision practitioners.

The introduction of Cascade R-CNN exemplifies the ongoing pursuit of precision and accuracy in object detection methodologies. Its impact reverberates across a broad spectrum of industries and applications, showcasing its pivotal role in advancing the capabilities of visual perception systems. The continued refinement and exploration of Cascade R-CNN continue to drive progress in object detection.

Indeed, Faster R-CNN and Mask R-CNN are well-suited for animal detection tasks necessitating precise localisation, as they precisely identify the boundaries of objects within an image. Moreover, their adaptability extends to video-based applications, allowing real-time or near-real-time animal detection in dynamic environments.

Region-based Convolutional Neural Networks (CNNs) like Faster R-CNN and Mask R-CNN strike a vital balance between accuracy and computational efficiency. This characteristic makes them highly versatile and applicable in various animal detection scenarios whether in wildlife monitoring, conservation efforts, or ecological research, these models offer a robust solution for accurately identifying and localising animals within imagery or video footage.

The adaptability and efficacy of Faster R-CNN and Mask R-CNN have solidified them as foundational tools in computer vision for animal detection. Their versatile application extends

across various domains, showcasing their pivotal role in advancing the study of understanding and animal detection.

2) Single Shot Multibox Detector (SSD): SSD is a real-world object detection algorithm in the one-stage detectors category. It is widely used for animal detection due to its efficiency and accuracy. SSD works by separating the original image into multiple grids, and every grid cell is answerable for forecasting bounding boxes and class probabilities for potential objects. These predictions are made at various scales, viewing the model to handle varying sizes.

One of the main advantages of SSD is its speed and suitability for real-time animal detection in video streams. It can process video frames rapidly, making it ideal for applications where low latency is essential. Moreover, SSD can efficiently detect multiple animal instances in a single forward pass, making it highly scalable for large-scale animal monitoring scenarios [16].

3) You Only Look Once (YOLO): YOLO is an alternative real-time object detection architecture recognised for its speed and simplicity. Unlike SSD, YOLO approaches object finding as a regression problem. It divides the input image into a grid, and every grid cell directly predicts bounding box coordinates and class probabilities without using separate anchor boxes.

YOLO's characteristics make it a strong candidate for video-based animal detection. Its single-pass architecture enables real-time processing of video frames, making it well-suited for applications that require low latency. However, YOLO might struggle with detecting small animals or closely grouped instances due to the anchor boxes, which could affect its localization [12]. Deep learning architectures have revolutionised animal detection in computer vision. Convolutional Neural Networks provide a solid foundation for feature extraction, while SSD and YOLO offer real-time capabilities, making them ideal for video-based animal detection.

Various authors have applied deep learning to animal detection. In a [1] study, a Convolutional Neural Network (CNN) algorithm was employed to achieve 93.8% accuracy in identifying 48 species in the Snapshot Serengeti dataset, offering automated animal identification with high precision. However, this approach didn't utilise pre-processing techniques or filters. In another [4] study, tracking and detection models like BYTETrack, SORT, IoU-tracker, YOLOv4, DeepSORT, and Few-MOT were used to monitor endangered animals, recording their daily movements and activity areas. While this method embedded uncertainty into multi-object tracking for robust models, it relied on limited frames for experimentation.

In a [5] study, various deep neural networks, including AlexNet, NiN, VGG, GoogLeNet, ResNet-18, ResNet-34, ResNet-50, ResNet-101, and ResNet-152 were employed, achieving an impressive 96.8% accuracy in identifying animals in camera-trap images. This method successfully identified, counted, and described animals using deep neural networks, although it was limited to a specific dataset (SS dataset). In study [6], the study focused on utilising convolutional neural networks, emphasising day-night joint training and YOLOv5, resulting in a high accuracy of 97.9%. While this approach demonstrated high accuracy, it was considered time-consuming and labour-intensive, mainly due to the difficulty in handling small datasets. Additionally, a [7] study utilised Cascade R-CNN, HRNet32, ResNet50, and ResNet101, achieving a performance of 97%, with the added advantage of efficient imagery processing and saving time. However, it was observed that R-CNN occasionally generated incorrect candidate region proposals. Lastly, in [8], a method combining HOG/SVM and deep neural networks (Faster RCNN and YOLO) attained an accuracy of 87%. This approach excelled in generalising images from the web but faced challenges in detecting small objects.

These studies, among others, highlights the diverse applications of deep learning in animal detection, achieving high accuracy rates and automation benefits but facing challenges in data requirements, computational intensity, and generalisation. The choice of architecture depends on specific application requirements, such as real-time performance, detection accuracy, and computational resources, as research in deep learning continues advancing more effective and efficient architectures for animal detection.

III. The Process of Animal Detection Process from Video Data

Animal detection refers to identifying and recognising animals' presence or location in a given environment. This can be done through various means, including visual observations, sensor technologies, or automated systems utilising computer algorithms.

In technology and computer science, animal detection often involves using machine learning or deep learning techniques to analyse images, videos, or sensor data to identify and classify animals. This technology is used in various applications, including wildlife conservation, agriculture, surveillance, and research. For example, animal detection systems may be deployed in wildlife conservation to monitor the movement and behaviour of endangered species. In agriculture, such systems can track livestock or identify pests. In research, animal detection technology helps gather animal behaviour and ecology data.

Overall, Animal detection is crucial in advancing our understanding and management of animal populations and various industries that interact with or rely on animals. Using low-cost commercial drones, artificial intelligence (AI), neural networks, and computational power has simplified detecting items of interest. Deep learning and convolutional neural networks (CNNs) algorithms are now the benchmark in picture-processing jobs such as object recognition and segmentation [5]. These networks are critical instruments for identifying and analysing animals in video recordings. "Graphical Processing Units (GPUs)" are now widely used in the digital vision field, especially those seeking deep learning and lowering model learning and inference time. Many contemporary conservation methods use machine learning to analyse pictures after data gathering. When images are gathered, machine learning must be implemented.

A. Data Collection from Different Datasets

In study [5], only one data collection was created and used. This included seven hundred photos. The Black had Red, Green, Blue and black/white images. The information was divided into two categories: rhinoceros and automobiles. Each class had 350 picture sizes ranging from 300 *147 to 3840* 2160 pixels. The data was divided into three distinct datasets: one for instruction, another for confirmation, and one for testing. Observing that the testing sample is not used during the model's training is essential. It is exposed in Fig. 4.

Fig. 4. Sample of training data with variations.

In study [6], the video segments used were captured by infrared detectors in the "Northeast Tiger and Leopard National Park between 2014 and 2020". It chose 17 significant types. It extracted pictures from videos using a "Python script" at a frame interval of fifty. It manually consistently annotates the pictures. It is exposed in Fig. 5.

Fig. 5. Sample of the dataset with some species.

In research [7], a dataset with thermal pictures of two mammal groups was created: red deer, European roe deer, and fallow deer and swine, which primarily comprised images of European wild boar. The sample was created using a Pulsar Helion 2 XP50 PRO camera.

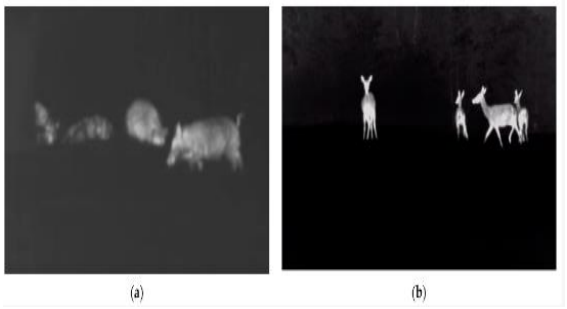

Fig. 6. Example of two distinct objects: (a) "wild boar" and (b) "deer."

One of the most important and widely recognised datasets in animal detection in video data is the "ImageNet Large Scale Visual Recognition Challenge" (ILSVRC). Although primarily focused on object recognition in images, ILSVRC includes a subset of classes related to animals. This dataset was pivotal in advancing deep learning techniques for object detection, serving as a benchmark for various computer vision tasks. In the domain of animal detection specifically, the "ADE20K" dataset is significant. It is a diverse dataset that includes images with annotations for object detection, semantic segmentation, and scene parsing, as shown in Fig. 6. While not exclusively dedicated to animals, it provides a valuable resource for researchers working on animal detection in complex visual environments.

Another prominent dataset is the "COCO (Common Objects in Context)" dataset, widely used for object detection and segmentation tasks. It contains many annotated images depicting a broad range of objects in complex scenes, including various animals in diverse contexts. For more specific applications, datasets like the "AI4MARS - Annotated Image for Machine Learning in Animal Recognition System" focus on animal detection in particular environments, such as the Mars Rover mission. This dataset is curated to detect and classify animals in Martian terrain.

Regarding benchmark datasets, the "PASCAL Visual Object Classes" (PASCAL VOC) dataset is renowned. It covers many object classes, including animals, and has been extensively used for evaluating object detection algorithms. It provides a standardised evaluation platform for researchers in the computer vision community.

The "MS COCO" dataset, in addition to being a significant dataset, also serves as a benchmark for object detection tasks. It includes various object categories, including animals, and is accompanied by a comprehensive evaluation metric suite. These datasets and models play a crucial role in advancing the field of animal detection in video data. They provide standardised and diverse sets of images with ground truth annotations, enabling researchers to train and evaluate their algorithms consistently. This ensures that advancements in animal detection techniques are rigorously tested and compared against state-of-the-art methods, ultimately driving progress in the field.

Some of the datasets from recent works are listed in Table II below:

TABLE II. DETAILS OF DATASET FOR ANIMAL DETECTION VIDEO USING DEEP LEARNING FROM RECENT WORKS

References	Datasets	Description	Scenario
[5, 2018]	ImageNet	It has 1.3 million labelled images for 1,000 groups (from synthetic objects, for example, bicycles and cars, to wildlife categories 1q11 dogs and lions)	Identify and count wild animals in the camera trail camera.
[30, 2021]	Bavarian Highway Directorate, Germany	It displays video segments that last around 10 seconds and has an eight fps (frames per second) resolution of 1280 720 pixels. The footage was captured by camera trail cameras set up at an "animals' bridge" (wildlife crossing) on Federal Highway 7 near "Oberthulba."	To identify animals in wildlife videos
[31, 2018]	Fly and mouse datasets	59 aligned, high-resolution behavioural videos	To estimate the fast animal pose.
[32, 2023]	PolarBearVidID	It includes video sequences of 13 polar bears in various poses and lighting conditions..	Identify animal behaviour in zoos.
[33, 2020]	coco dataset	It has a width and height in the range of 40 and 140 pixels	To detect, classify, and track animals in the African savannah
[34, 2019]	Badger dataset	Images were captured at a selection of UK farms where surveillance occurred. All were manually assigned to badger, bird, cat, fox, rat, or rabbit.	To monitor wildlife

B. Pre-processing

Data pre-processing is critical to get the best results from any artificial intelligence-based approach. Various data pre-processing methods can be deployed to make the information fit for the development of models. If the data taken from the devices was noisy and meaningless, it was deleted from the collection. The research in [8] used a "6th-order Butterworth filter with a cutoff frequency of 3.667 Hz" to eliminate the noise and anomalies from the information. In [9], YOLOv5 eliminates duplicate and similar images. In [10], by employing computer vision tools, a picture processing system was created and built to enhance contrast in pictures and segment pertinent image subdivisions. The photos were revised to expedite the procedure. It is shown in Fig. 6.

C. Image Segmentation

Image segmentation involves partitioning each video frame into distinct regions corresponding to specific objects or animals. This enables the isolation and identification of animals within a dynamic visual stream. Techniques like thresholding, edge detection, and deep learning-based segmentation are employed to delineate animals from the background, allowing for subsequent analysis such as tracking, behaviour monitoring, and species classification throughout the video sequence. Effective segmentation is crucial for accurate and reliable animal detection and tracking in dynamic video data. A computer vision method locates items within an image by forming a bounding box surrounding it to comprehend what is in it at the pixel stage. In study [7], the bear was segmented from the picture using the "MSER (Maximally Stable Extremal Region)" method. In study [11], it uses Mask R-CNN for segmentation. It can distinguish between different items in a video. It returns the class identity, item masks, and the bounding box coordinates for every object in a provided picture. The process is split into two phases; the first scans the image and generates a "Region proposal network (RPN)" to provide potential object bounding boxes, and the second differentiates proposals and generates bounding boxes and boundaries for every class. The study in [12] used the "Falzenszwalb algorithm" for image segmentation, which organises pixels with comparable luminance.

D. Classification

In animal detection, classification pertains to categorising identified objects into specific animal species or classes based on distinctive features learned through the model. It distinguishes different animals within a scene, aiding in species identification and population monitoring. [30] In animal detection, classification is crucial for understanding wildlife dynamics, ecological studies, and conservation efforts shown in the Fig. 7. It creates a list of desired objects for Detection images and instructs a model to identify them using labelled sample photos. In [5], Faster-RCNN is used for image classification in video clips. In [6], "Dilated Residual Networks (DRN)" was used, and better accuracy was achieved. In [12], the author used deep boosting, dictionary learning, and convolution networks for image classification. In [9], three models ("YOLOv5m, CNN_HRNet32, FCOS_Resnet101") were used for simulation to detect and classify multiple animals in a video, and the video classification accuracy of FCOS_Resnet101 achieved 91.6%. It is shown in Fig. 5.

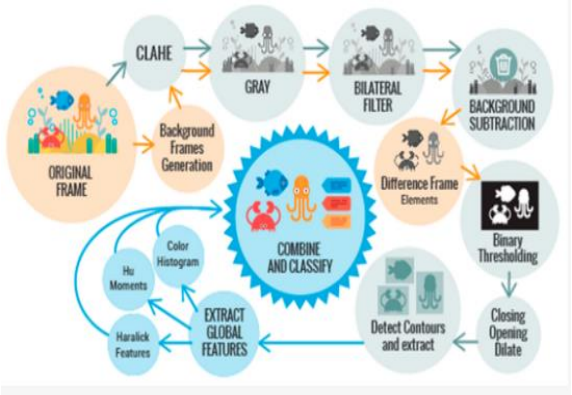

Fig. 7. Pipeline for data pre-processing.

Fig. 8. Example of correct classification.

E. Evaluation Metrics for Animal Detection for Video Data

The evaluation metrics for animal detection in video data include precision, recall, F1 Score, mean average precision (mAP), intersection over union (IoU), false positive rate (FPR), false negative rate (FNR), accuracy, mean recall, processing speed, and frame-level vs. video-level evaluation [13]. These metrics assess the system's ability to accurately detect animals, handle false positives and negatives, and its overall performance in real-time video processing, providing a comprehensive evaluation of the detection system's effectiveness and efficiency. Fig. 8 shows example of correct classification.

1) Video data evaluation metrics: Evaluating video-based animal detection systems is vital to measure their accuracy and effectiveness in real-world scenarios. As deep learning models are commonly used for this task, specific evaluation metrics are required to assess their performance on video data [14]. One of the key metrics used in this context is the mean average precision at different Intersections over Union (mAP@IoU) thresholds over time.

mAP@IoU is an extension of the traditional mean average precision (mAP) metric, commonly used in image object detection tasks. It measures the precision and recall of predicted bounding boxes by comparing their overlaps with ground-truth annotations at different IoU thresholds. This provides a comprehensive evaluation of the model's ability to accurately detect animals in video sequences across various IoU thresholds, reflecting different levels of object localisation accuracy [16]. Evaluating mAP@IoU over time enables the assessment of the model's consistency and robustness in detecting animals throughout the video, accounting for spatial and temporal variations.

2) Temporal consistency metrics: Temporal consistency is a critical aspect of video-based animal detection as it ensures stable and reliable tracking of animals across frames. Several methods can be employed to evaluate the stability and consistency of animal detections over time:

Temporal Intersection over Union (tIoU): tIoU measures the temporal overlap between predicted bounding boxes and ground-truth annotations in consecutive frames [17]. It quantifies how well the model can maintain accurate and continuous detections of animals across time. A higher tIoU score indicates better temporal consistency and reliable tracking.

ID Switching Rate: The ID switching rate evaluates how often the model incorrectly assigns different identities to the same animal or switches identities between consecutive frames [28]. A lower ID switching rate signifies improved temporal consistency in tracking and maintaining individual animal identities.

Fragmentation Rate: Fragmentation occurs when the model fails to link consecutive detections of the same animal, resulting in disjointed tracks [15]. The fragmentation rate measures the degree of this issue, with lower values indicating better temporal consistency and continuous tracking.

Trajectory Smoothness: This metric assesses the smoothness and continuity of animal trajectories over time. [18] A model with high trajectory smoothness exhibits more consistent and visually coherent animal tracks, indicating reliable temporal consistency.

By integrating video-based evaluation metrics like mAP@IoU over time with temporal consistency metrics, researchers and practitioners can thoroughly assess the performance of deep learning models for video-based animal detection [22]. These evaluation measures help identify potential areas for improvement, validate the suitability of the models for specific applications like wildlife monitoring, behaviour analysis, and ecological research, and drive advancements in computer vision for animal-related studies.

IV. Recent Progress in Animal Detection using Deep Learning

Recent Progress in animal detection using different machine learning and deep learning techniques is presented here. Table III, in a tabular format, compares the various DL and ML learning models for animal detection. A comparison is made regarding the detection methods, main findings, advantages, and disadvantages for further research from existing literary works.

These references represent a range of scholarly works that have explored various deep-learning techniques applied explicitly to video-based animal detection. [19] By including these references, the review aims to provide a comprehensive and up-to-date analysis of the existing literature in this domain. [33] Additionally, these selected references contribute significant insights, methodologies, and findings relevant to understanding the advancements, challenges, and potential applications of deep learning in video-based animal detection. [27] Their inclusion strengthens the credibility and rigour of the review, offering a solid foundation for examining the state-of-the-art approaches and identifying future research directions in this field.

TABLE III. RECENT PROGRESS IN ANIMAL DETECTION USING DIFFERENT MACHINE LEARNING AND DEEP LEARNING TECHNIQUES

References	Detection Methods	Main Finding	Advantages	Disadvantages
[1, 2020]	Convolutional Neural Network (CNN) algorithm to detect wild animals.	Deep convolutional neural networks to identify, count, and describe the behaviours of 48 species in the 3.2-million-image Snapshot Serengeti dataset. 93.8% accuracy	Automating animal identification with 99.3% accuracy, matching human volunteers' 96.6% saves over 17,000 hours of labelling effort on a 3.2-million-image dataset.	No Pre-processing techniques or filters are used in this paper.
[4, 2022]	BYTETrack, SORT, IoU-tracker, V-IoU-tracker, YOLOv4, + DeepSORT and Few-MOT model	Few-MOT for wildlife to embed uncertainty into designing a multiobject-tracking model by combining the richness of deep neural networks with few-shot learning, leading to correctable and robust models.	Few-MOT employs few-shot learning and tracking-by-detection to monitor endangered animals, recording daily movements and frequent activity areas for analysis.	A limited number of frames are used to experiment.
[5, 2018]	AlexNet, NiN, **VGG,** GoogLeNe, ResNet-18, ResNet-34, ResNet-50, ResNet-101 , ResNet-152	VGG model achieved the best accuracy of 96.8%	Deep neural networks (DNNs) can successfully identify, count, and describe animals in camera-trap images.	Only an SS data set is used.
[6, 2021]	The detection of animals Using convolutional neural networks.	Day-night joint training had a better performance.YOLOv5 achieved an accuracy of 97.9%	Time-consuming and labour intensive.	Difficulty with small datasets
[7, 2022]	Cascade R-CNN, HRNet32, ResNet50 and ResNet101.	It achieved a performance of 97%.	The imagery potentially quickly and efficiently saves much time.	R-CNN sometimes generates wrong candidate region proposals as the selective search is a fixed algorithm with no learning capabilities.
[8, 2023]	(HOG/SVM), deep neural networks (Faster RCNN and YOLO).	It attained 87% accuracy	The web can generalise the image better.	Struggles to detect small objects.
[9, 2022]	Convolutional neural networks (CNNs) 1D CNN and 2D CNNs	It attained 99.70% training accuracy and 96.85% validation accuracy.	Real-time monitoring of activities	High computational requirements
[10, 2022]	Deep learning technology	Accuracy of 95.1%	It can benefit from computer automatic identification of postural behaviour, which can be used to quantify animal activity.	This can be costly and time-consuming.
[11, 2020]	Machine learning and Deep learning.	VGGNET was the best algorithm for an accuracy of 96.6 %.	Monitoring networks capable of providing large amounts	Movies cannot all be manually processed
[12, 2022]	YOLO; Convolutional neural networks (CNN); SSD; mask R-CNN; VGG-Net	VGGNET was the best algorithm for animal classification, with an accuracy of 96.6 %	It has a standard and easy-to-understand architecture for CNNs, with multiple convolution and pooling layers.	Slow training time
[13, 2023]	Deep learning-based model for automated recognition, definition, and numbering of wild creatures in camera trail camera images	A deep learning model automates the recognition, classification, and counting of wildlife in trail camera images from the "Snapshot Serengeti dataset.	This deep learning model automates animal recognition and description in trail camera images, streamlining manual work and scaling for large datasets.	Data quality impacts accuracy: biased or poorly labelled data may yield suboptimal results. Limited generalisation, computational demands, and interpretability are challenges.
[14, 2019]	Evaluation of ML and DL techniques, including SVM, RF, AlexNet, and Inception v3, for classifying animal genera from the "KTH dataset.	ML and DL techniques for Detection of animal genera using camera capture images. They investigated "SVM, RF, deep learning methods, and AlexNet and Inception v3 machine learning techniques". They used the "KTH dataset," which includes nineteen distinct animal categories.	The paper compares ML and DL techniques for animal genera recognition, emphasising DL's automatic feature learning, scalability, and generalisation.	ML and DL techniques depend on diverse data for better performance. Hyperparameter tuning is time-consuming. DL requires more data, which is challenging for specific animal genera. Interpretability is difficult, especially in complex, deep architectures.
[15, 2019]	Random forest, K-nearest neighbours (KNN), support vector machine (SVM), naive Bayes, and artificial neural network (ANN)	The study showcased a computerised pet movement and mood detection system, exploring data sources and machine learning techniques like random forest, KNN, SVM, naive Bayes, and ANN.	Random Forest for complex relationships, KNN for non-linear data, SVM for high dimensions, Naive Bayes for text/categorical data, and ANN for versatile deep learning applications.	ML algorithms have unique strengths: Random Forest for complex relationships, KNN for non-linearity, SVM for high dimensions, Naive Bayes for text/categorical data, and ANN for versatile deep learning.
[16, 2018]	The authors employ two popular object detection methods - Single Shot Multi-Box Detector (SSD) and You Only Look Once (YOLO).	Set forward a paradigm for automatically identifying animals via camera-trail camera ped pictures. It focused on determining the species and the number of species recorded in	SSD and YOLO enable real-time object detection, detecting multiple objects in one pass. Their end-to-end approach is versatile for animal species without retraining.	Training deep learning-based object detection models like SSD and YOLO demands a large, labelled dataset that is resource-intensive to collect.

		the photograph through algorithms for object detection like "Single Shot Multi-Box Detector (SSD) and You Only Look Once (YOLO)."		Performance varies with image complexity, requiring hyperparameter tuning. False positives/negatives affect accuracy.
[17, 2020]	We identify bird species using a "Super-resolution Mask RCNN-based transfer deep learning" model. The method combines super-resolution and Mask RCNN techniques to identify bird species accurately.	"Super-resolution Mask RCNN-based transfer deep learning approach" to identify bird species. They used Mask RCNN to identify very minute differences that analysed pixel-by-pixel of the picture and added a mask to it, making it easy to identify the dimensions and form of the item.	Combined with super-resolution, Mask R-CNN improves bird species identification, providing precise localisation and reducing overhead through transfer learning.	Mask RCNN and super-resolution demand significant computational resources. Transfer learning reduces data needs, but diverse bird datasets are vital for fine-tuning. Mask RCNN lacks interpretability.
[18, 2018]	Recent deep-learning methods are used to surmount the expense and effort of processing camera trail camera pictures.	The authors employ two distinct datasets to monitor populations of animals and govern environments all over the globe.	Deep learning automates camera trap image analysis, aiding animal identification, counting, and achieving state-of-the-art accuracy for global monitoring.	Deep learning requires ample labelled data, which is challenging for rare species. High-performance hardware is vital due to computational intensity. Model interpretability and bias are complex.
[19, 2020]	The proposed technique for animal identification employs neural network design such as "SSD and faster R-CNN."	Using object identification, an exclusive animal recognition and collision avoidance system aims to detect animals and prevent road collisions.	SSD and Faster R-CNN offer real-time object detection, including animals, for collision avoidance systems, enhancing road safety for humans and wildlife.	Deep learning object detection models like SSD and Faster R-CNN rely on expensive labelled datasets susceptible to environmental variations. Generalisation hinges on diverse data, with the potential for false positives/negatives and performance influenced by model settings and training data.
[20, 2021]	The suggested technique is based on the "Sobel edge algorithm," which is basic but effective in detecting edges based on modified values.	The method achieves rapid detection (0.033 s per image) through thermal pixel analysis, synchronising thermal and RGB attributes for superior real-time animal detection across diverse settings. "Size-temperature filters" enhance applicability.	The real-time system aids wildlife monitoring, safety, and research sans extensive training data, with contextual information reducing false positives bolstered by thermal and RGB fusion.	The Sobel edge algorithm's limitation lies in detecting only edges, lacking fine-grained details and colour information for precise species identification. Environmental conditions impact detection accuracy, and species-specific recognition is limited.
[21, 2020]	It evaluates performance forecasting incrementally ahead with long-range scenarios using "Random Forests, Neural, and Recurrent Neural Networks." This method is used to analyse excellent quality and movement statistics. For one step forward prediction, it was discovered that individual-level Machine Learning and Deep Learning approaches beat the SDE model.	The broad framework for forecasting animal movement consists of two steps: initially estimating behavioural motion stages and then predicting the animal's velocity. This framework is specified for both individual and group training.	The framework assesses individual and group training for complete animal movement patterns, utilising Random Forests, Neural Networks, and Recurrent Neural Networks for varied prediction approaches. High-quality data enhances precision in predictions.	Effectiveness relies on adequate data, which could be more challenging. Multiple models add complexity, demanding computational resources. Performance varies with species and environment, affecting generalisation.
[22, 2021]	The DL algorithm detects and segregates the animals with a large-scale publicly available dataset. A CNN model predicts the object (animal) in every image frame obtained from the live camera.	They have implemented deep learning for detecting the animals from the videos to improve safety. If the algorithm detects the object as an animal, the system will generate an alarm for 3 seconds to avoid a collision. Results show that the proposed approach achieves an accuracy of 91%.	Achieving 91% real-time Animal detection accuracy, the approach uses deep learning and CNNs with large-scale dataset training for enhanced safety via collision alerts across diverse species and conditions.	The DL algorithm's accuracy and generalisation depend on the training dataset's quality and diversity. Environmental conditions impact accuracy. Detecting rare species poses challenges. False positives/negatives may occur.
[23, 2017]	A deep CNN model is employed in this work for animal detection, and the model is trained using a single labelled dataset. The DCNN algorithm can automatically filter animal images and identify animal	The proposed approach achieves a phenomenal accuracy of 96.6% for animal detection and 90.4% for identifying the species accurately.	The method achieves an impressive 96.6% accuracy in animal detection and 90.4% in species identification, which is vital for reliable wildlife monitoring.	Single-dataset reliance hampers generalisation to new environments and species, influenced by data bias. Diverse dataset training enhances performance but demands substantial computational resources, which is challenging

	species.			on resource-constrained platforms.
[24, 2017]	CNN model for animal recognition is implemented. The effectiveness of different image recognition techniques such as Principal Component Analysis (PCA), Linear Discriminant Analysis (LDA), Local Binary Patterns Histograms (LBPH), and Support Vector Machine (SVM) are analysed, and the performance is compared with the proposed CNN model in terms of recognition rate.	The models are experimentally evaluated for recognition time using a 500-set, 100-image animal database. PCA outperforms LDA and LBPH for large databases, while LBPH excels with small datasets. The proposed CNN model achieves 98% recognition accuracy compared to other models.	The CNN model achieved 98% accuracy in animal recognition, excelling in image identification with automatic feature learning, highlighting its superiority over traditional methods in animal recognition tasks.	CNN model performance depends on dataset quality and size, influenced by biases. It's resource-intensive, with hyperparameter tuning challenges, and offers limited interpretability as a black-box model.
[25, 2021]	The CNN model groups animal images based on the input database. The performance of CNN is compared with conventional recognition techniques such as SU, DS, MDF, LEGS, DRFI, MR, and GC. These techniques are usually characterised by high false positive and negative rate detection.	Developing an efficient animal recognition system is vital. Genetic algorithm-based image segmentation and neural network classification improve accuracy. A dataset with 100 subjects and two classes demonstrates higher precision (99.02%), recall (98.79%), F1 score (98.9%), and low MAE (0.78%).	A CNN model with genetic algorithm segmentation achieves high animal image accuracy, surpassing conventional methods.	The CNN model and genetic algorithm depend on training data quality. Computational complexity requires substantial resources. Hyperparameter tuning impacts the genetic algorithm's performance. Limited information hinders assessing potential limitations.
[26, 2019]	Convolution neural network and SVM	Precision 99.02%, recall 98.79%, F-Measurement 98.9%, and MAE (0.78%)	High accuracy rates	Limited ability to generalise
[27, 2018]	Deep learning method	Average gain between 6% and 10% when compared to the method Fast R-CNN	Deep learning algorithms have been shown to achieve state-of-the-art performance on various problems, including image and speech recognition, natural language processing, and computer vision.	This can make it difficult to understand how the model makes predictions and identify any errors or biases.
[28, 2018]	Deep convolutional neural network	It saves 99.3% of the manual labour.	Deep learning models can generalise well to new situations or contexts, as they can learn abstract and hierarchical representations of the data.	Deep learning models can only make predictions based on the data it has been trained on
[29, 2017]	Deep Convolutional Neural Networks for Automated Wildlife Monitoring	It achieved an accuracy of 96.6% for detecting images.	Deep learning models can be easily scaled to handle increasing data and can be deployed on cloud platforms and edge devices.	This can be costly and time-consuming.
[30, 2021]	R-CNN	Accuracy of 90.4 % for detecting most common species.	Autonomous vehicles use it to perceive objects in their surroundings to ensure a safe driving experience.	This sometimes could result in the generation of lousy regional proposals.
[31, 2018]	deep-learning-based method	The error rate is less than 3%	It can see what human minds cannot visualise.	One cannot accurately define the sorting and output of an unsupervised task.
[32, 2023]	re-ID models	Accuracy of 96.6% for *PolarBearVidID* dataset	Developing re-ID models will significantly facilitate the work of biologists and animal caretakers in the future.	Limited dataset and models used
[33, 2020]	ssd_inception_v2 , ssd_mobilenet_v2 , ssd_mobilenet_v2_quantized , ssdlite_mobilenet_v2 and Raspberry Pi	ssd_mobilenet_v2 average precision is high and generates the least number of false positives	MobileNet V2 was selected as the final model for the application. This is due to its traits of generating a small number of false positives and not splitting an event into smaller ones.	MobileNet V2 sacrifices accuracy for speed, potentially leading to missed detections or misclassifications, especially in complex scenes.
[34, 2019]	CNN1 and CNN2	They achieved an accuracy of 95.86% and 98.05% for binary classification. For multiclassification, they achieved accuracies of 83.07% and 90.32%.	The trained CNNs were directly applied to video footage because film can be considered a sequence of image frames. To speed up the detection process, all images were converted to grayscale.	Limited models are used to compare the results.

References for the research on animal detection and recognition using deep learning are based on the following criteria: Relevance to the research topic: The selected papers are directly related to animal detection in videos using deep learning algorithms, which align with the focus of the proposed research. The references cover a range of publication years, indicating the proposed interest in exploring recent advancements and foundational works in the field.

Animal detection models proposed to date have positive and negative aspects [18]. Most models only produce output and predict the results, neglecting to deal with the problem of output unpredictability in terms of accuracy, sensitivity, and specificity [34]. The papers in [1] and [9] have achieved high animal detection accuracy.

- The study in [1] uses a Convolutional Neural Network (CNN) algorithm to detect wild animals, achieving an accuracy of 93.8%. It also mentions automating animal identification with 99.3% accuracy.
- The study in [9] employs Convolutional Neural Networks (CNNs) and achieves an impressive 99.70% training accuracy and 96.85% validation accuracy for real-time monitoring of activities.

Considering the high accuracy and real-time monitoring capabilities, [9] is a promising paper for animal detection using video data.

Data pre-processing is crucial for optimal results. Techniques include noise removal and image enhancement through methods like Butterworth filters, contrast enhancement, and segmentation. Segmentation involves precisely delineating individual animals or their parts within images or video frames. Methods like MSER, Mask R-CNN, and Falzenszwalb algorithm are employed for this purpose. [24] Various models such as Faster-RCNN, Dilated Residual Networks, YOLOv5, and others are used for image classification [26]. Metrics like precision, recall, F1 Score, mean average precision (mAP), intersection over union (IoU), false positive rate (FPR), false negative rate (FNR), and others are used to evaluate the performance of animal detection systems in video data.

Various detection methods like Convolutional Neural Networks (CNN) and others have been employed with different findings and advantages. CNNs have been used for accurate and automated animal identification. The table comparing different models showcases their respective detection methods, primary results, benefits, and disadvantages. Each entry discusses the detection approach, performance metrics, and the strengths and weaknesses of the technique. Some models like Faster R-CNN, Mask R-CNN, Fast R-CNN, YOLOv4 and DeepSORT, use deep learning and tracking for robust animal detection.

These studies demonstrate advanced deep-learning techniques in animal detection, with various models achieving high accuracy rates. However, challenges such as data quality, computational requirements, and model interpretability remain essential considerations. The choice of model depends on the application's specific needs, such as real-time detection, tracking, or species identification. The use of CNNs and its accuracy make it a strong candidate for further research.

V. Limitations and Challenges

A primary challenge was implementing animal identification models in the existing wildlife ecosystem. Although some researchers tested their models on forests, it doesn't remain easy. A large dataset incorporating many animals would be helpful in training ML and DL models for application in real time. Additionally, due to the computation cost of a vision-based system, it is unlikely to run real-time identification. Advancements can be made by providing a warning in the manner of a message to the neighbouring forest office when the animal is discovered. It can also be used to decrease human-wildlife conflict and animal accidents. Capturing distinctions between creatures from the same family but of different species might be difficult and should be addressed shortly.

Although the approaches utilising deep learning performed well, there are still certain limitations when dealing with submerged multimedia information, such as poor resolution, lighting changes, and intricate backgrounds. More effective approaches for dealing with these issues should be developed based on these limits. Handling more detailed pictures is essential for better understanding animals and their specific activities. Camera and drone technology developments will enable wildlife surveillance at much greater flight heights, reducing interruption to animals in their natural habitats.

While deep learning approaches have demonstrated efficacy, certain limitations persist, especially when handling submerged multimedia data. Factors such as low resolution, fluctuating lighting conditions, and intricate backgrounds pose obstacles that necessitate the development of more robust techniques. Addressing these constraints would yield improved performance in dealing with challenging scenarios. Enhancing the processing of detailed images is pivotal for a more nuanced understanding of animal behaviour and activities. Anticipated advancements in camera and drone technologies hold the potential to facilitate wildlife surveillance at higher altitudes, minimising disturbances to animals in their natural habitats.

VI. Future Challenges and Research Directions

While significant strides have been made in applying deep learning for animal detection on video data, several challenges and avenues for future research emerge. One pressing concern is the need to address the intricacies of adapting models to diverse and dynamic environmental conditions. This includes developing techniques to handle lighting, weather, and vegetation variations, which are paramount for real-world deployment in natural habitats.

Furthermore, the issue of data scarcity remains a formidable obstacle. Future research should explore innovative data augmentation, synthesis, and generation approaches. By creating diverse and representative training sets, models can be more effectively trained to recognise a broader spectrum of animal species and behaviours.

In addition to the challenges, exploring novel data augmentation and synthesis techniques is imperative to

mitigate the need for labelled training data. Developing interpretable and explainable deep learning models for animal detection is another critical avenue, enabling researchers to gain insights into model decisions and bolstering trust in automated detection systems. Further, investigating methods for anomaly detection and outlier identification within video data streams can significantly enhance the robustness and reliability of animal detection systems. Additionally, researching federated learning and edge computing approaches holds promise for decentralised deployment in remote and resource-constrained environments. Addressing these multifaceted challenges will advance the animal detection field and foster sustainable coexistence between humans and the animal kingdom.

These include delving into temporal analysis and behaviour modelling for an in-depth understanding of long-term animal behaviour patterns. Exploring multi-species interactions and fine-grained species identification can provide valuable insights into complex ecological relationships. Enhancing real-time adaptability and edge computing capabilities is vital for dynamic environments while addressing ethical considerations and human-wildlife interactions is imperative to ensure responsible technology deployment. The integration of multi-modal data, the development of user-friendly interfaces, and the fostering of interdisciplinary collaboration are crucial for advancing the field. Moreover, research efforts should also focus on privacy-preserving techniques and long-term monitoring for a holistic approach to animal detection. By tackling these multifaceted challenges, researchers can contribute to a more comprehensive understanding of wildlife behaviour and habitat dynamics, ultimately aiding in practical conservation efforts and the coexistence of humans and the natural world.

Considering the increasing importance of interdisciplinary collaborations, future research efforts should seek to bridge the gap between computer vision experts, ecologists, and conservation biologists. A holistic understanding of animal detection technology's impact on ecological research and wildlife conservation can be achieved by pooling expertise from diverse fields.

VII. Conclusion

The traditional method of animal detection relies on direct observation by humans or the utilisation of specialised tools and techniques. It involves visually scanning an area for animal presence, examining tracks and traces left behind, setting up camera trail cameras for remote monitoring, using acoustic devices to capture animal sounds, and employing trail camera ping and capture methods for direct examination. These traditional approaches have provided valuable insights into animal behaviour and ecology, but they can be labour-intensive, time-consuming, and may have limitations in terms of coverage and scalability. Modern technologies are increasingly integrated with traditional methods to enhance animal detection and monitoring capabilities.

Deep learning approaches provide a beneficial tool for continuous tracking and abundance predictions in animal detection, outperforming laborious, individual efforts in only a tiny percentage of the time. The DL algorithms efficiently identify animals with a high degree of accuracy, and the image of the identified animal is shown for improved accuracy so that it may be utilised for other reasons, such as Detecting wild animals in human habitats and preventing wildlife poaching and human-animal conflict.

Researchers would benefit significantly from detecting animals and extracting their characteristics for their research and detailed study of animal species. As a result, the emerging technology of various Machine Learning and Deep learning algorithms may be applied to animal identification and detection. CNN's technique for Detecting large animals in visuals has proven effective.

Studying the Security and Privacy Issues of Big Data in the Saudi Medical Sector

Ramy Elnaghy, Hazem M. El-Bakry
Faculty of Computer and Information Sciences, Mansoura University, Mansoura 35516, Egypt

Abstract—In today's era of Big Data, with the integration of data from various systems, devices, and machines used by healthcare service providers, health insurance companies, and their sub-sectors, maintaining privacy and security has become crucial. It is important to uphold the confidentiality and security of data exchanged between data service providers and insurance companies as required by law. The purpose of this paper is to focus on addressing the security and privacy issues associated with healthcare data, particularly concerning medical data in both in- transit and at-rest modes. We aim to provide a proposed solution to enhance data security and maximize privacy protection.

Keywords—Security; privacy; healthcare; medical data; big data

I. Introduction

The healthcare industry has made significant strides in recent years with the adoption of electronic patient records and the digitization of healthcare workflows. However, this transformation has resulted in an explosion of clinical data, which is characterized as big data. The abundance of clinical data has created numerous opportunities for healthcare organizations to leverage data analytics, clinical decision support, and disease surveillance to optimize treatment and improve patient outcomes. Nonetheless, with the benefits of big data come numerous challenges, particularly regarding information security and privacy. Healthcare organizations must adopt proactive measures to safeguard sensitive information and prevent security breaches and other incidents. This paper aims to address the security and privacy concerns associated with medical data, particularly in in-transit and at-rest modes. We propose a solution that enhances data security and maximizes privacy protection. The adoption of big data technologies in healthcare has created numerous opportunities for clinical decision support, disease surveillance, population health management, and treatment optimization. However, with the increased use of electronic patient records and digitization of healthcare workflows come significant security and privacy risks. Medical data is highly sensitive, and its confidentiality and privacy must always be protected. Healthcare organizations must take a proactive, multi-layered approach to data security, including encryption, access control, network security, and employee training. Data encryption is a highly effective way to protect medical information. Encryption uses algorithms to convert plain text into cipher text, adding a layer of security to ensure that only authorized parties can access the data. In-transit encryption is used to protect data that is transmitted over a network or the internet, such as emails or data transfers between healthcare providers. At-rest encryption, on the other hand, is used to protect data that is stored on electronic devices, such as servers or hard drives. To implement data encryption, healthcare organizations must first identify which data needs to be protected and where it is stored. Then, appropriate encryption algorithms and methods must be selected and applied to the data. The encryption keys must be securely managed and stored to ensure that only authorized parties can access the data. While data encryption is an effective security measure, it is not a complete solution. Healthcare organizations must also implement access controls to limit access to sensitive information to authorized personnel only. Network security measures such as firewalls, intrusion detection, and prevention systems can help protect against cyberattacks and data breaches. Employee training is also essential to ensure that all staff members understand their responsibilities in safeguarding patient data and are aware of potential security threats. In summary, healthcare organizations must adopt a comprehensive, multi-layered approach to data security that includes encryption, access control, and network security, through utilizing big data and modern technologies such as blockchain [1].

II. Literature Review

Soumya et al. in [2], reviews the security issues associated with big data in Internet of Things (IoT) and cloud computing. The authors discuss the challenges of securing big data in IoT and cloud computing, including issues related to data privacy, data integrity, authentication, and access control. They also discuss various security solutions that have been proposed to address these challenges. Parsa et al. in [3] proposes a security management framework for big data in smart healthcare. The authors identify various security challenges in smart healthcare, including issues related to data privacy, data integrity, and data availability. They then propose a framework that includes various security measures, such as access control, encryption, and monitoring, to address these challenges. Hayat et al. in [4] presents a security model for the big healthcare data lifecycle. The authors discuss the security challenges associated with healthcare data, including issues related to data privacy, data integrity, and data confidentiality. They then propose a security model that includes various security measures, such as access control, data encryption, and data backup, to address these challenges. Aqeel et al. in [5] reviews the security and privacy issues associated with big data in healthcare applications. The authors discuss the challenges of securing big data in health-care, including issues related to data privacy, data integrity, and data confidentiality. They also discuss various security and privacy solutions that have been proposed to address these challenges.

Musfira et al. in [6] surveys various big data security solutions that have been proposed to address security issues in healthcare. The authors discuss various security solutions, such as access control, data encryption, and data backup, and evaluate their effectiveness in addressing the security challenges associated with big data in healthcare. Isabel et al. in [7] analyzes the security issues associated with big data in healthcare. The authors discuss the challenges of securing big data in healthcare, including issues related to data privacy, data integrity, and data confidentiality. They also discuss various security solutions that have been proposed to address these challenges. Saraladevi et al. in [8] studies the security issues associated with big data and Hadoop. The authors discuss the challenges of securing big data in Hadoop, including issues related to data privacy, data integrity and data confidentiality. They also discuss various security measures that can be implemented to address these challenges. ABHISHEK et al. in [9] analyzes the issues related to healthcare data integrity. The authors discuss the challenges of maintaining data integrity in healthcare, including issues related to data accuracy and data consistency. They also propose various measures to ensure data integrity, such as data validation and data verification.

Kanika et al. in [10] proposes an encryption approach based on the Rivest-Shamir-Adleman (RSA) algorithm to preserve the confidentiality of big data. The authors discuss the challenges of securing big data and propose an encryption approach based on RSA to ensure data confidentiality. Mustafa et al. in [11] presents a systematic review of privacy-preserving healthcare data sharing on blockchain. The authors discuss the challenges of ensuring privacy in healthcare data sharing and evaluate various blockchain-based solutions that have been proposed to address these challenges. Peng Xi et al. in [12] reviews the blockchain-based solutions that have been proposed to secure healthcare data sharing. The authors discuss various blockchain-based solutions, such as smart contracts and permissioned blockchain, and evaluate their effectiveness in ensuring data security and privacy. Mehak et al. in [13] identified potential vulnerabilities and attacks that could compromise the security of Hadoop-based big data systems. The purpose of the paper is to highlight these issues and provide recommendations for mitigating them. Mohan et al. in [14] proposed an efficient and secure big data storage solution using triple data encryption standard (Triple Data Encryption Standard (3DES)) in a cloud environment. The purpose of the paper is to provide a secure storage solution for big data in the cloud. Rakib et al. in [15] presented privacy- preserving k-nearest neighbors (KNN) training scheme over blockchain-based encrypted health data. The purpose of the paper is to propose a secure and privacy-preserving KNN training mechanism for health data in a blockchain-based system.

Parvathaneni et al. in [16] proposed a blockchain-based solution for secure healthcare data communication among non-terminal nodes in the Internet of Things (IoT) architecture in 5G networks. The purpose of the paper is to provide a secure and efficient data communication mechanism for healthcare IoT systems. Rafik et al. in [17] proposed fully homomorphic en- cryption (Fully Homomorphic Encryption (FHE)) algorithms for secure big data analysis. The purpose of the paper is to provide a solution for secure big data analysis in a privacy- preserving manner using FHE. Jose et al. in [18] discussed the security and privacy issues of big data in general. The purpose of the paper is to provide an overview of the security and privacy challenges associated with big data. Gousiya et al. in [19] proposed a sandbox security model for the Hadoop file system. The purpose of the paper is to provide a security mechanism for the Hadoop file system, which enables secure execution of untrusted code. Iroju et al. in [20] This paper provides an overview of the prospects, challenges, and solutions related to big data in healthcare. It discusses the potential of big data to improve healthcare outcomes and reduce costs, as well as the challenges related to data privacy, security, and integration. The paper also discusses some of the current solutions to these challenges, such as the use of big data analytics and cloud computing.

MATTURDI et al. in [21 provides a comprehensive review of the security and privacy challenges of big data, with a focus on data protection, access control, and privacy- preserving techniques. The paper also discusses some of the current solutions to these challenges, such as the use of encryption, authentication, and authorization mechanisms, as well as data anonymization and data masking techniques. Karim et al. in [22] provides a review of the security and privacy challenges of big data in healthcare, with a focus on the protection of patient data. The paper discusses the importance of ensuring the confidentiality, integrity, and availability of healthcare data, as well as the challenges related to data privacy, security, and interoperability. The paper also discusses some of the current solutions to these challenges, such as the use of encryption, access control, and data anonymization techniques. Gunasekaran et al. in [22 focuses on the security challenges of big data in the healthcare industry 4.0, which includes the integration of advanced technologies such as IoT, Artificial Intelligence (AI), and cloud computing. The paper discusses the importance of ensuring the security and privacy of healthcare data in this new era, and proposes a framework for big data security intelligence that includes threat intelligence, security analytics, and incident response.

III. OBJECTIVES

The purpose of this paper is to address the security and privacy challenges encountered in the Saudi healthcare and medical insurance sector during the storage and transfer of big data. Specifically, this paper aims to achieve the following:

1) Identify potential security and privacy risks associated with storing and transferring big data. This includes identifying the risks of unauthorized access to sensitive information, data breaches, cyber-attacks, hacking, insider threats, and data loss.

2) Analyze current practices and technologies used for securing big data in the healthcare and medical insurance sector. This analysis will provide an understanding of the existing security and privacy measures implemented by the industry and highlight any gaps or deficiencies in current practices.

3) Propose technical solutions by applying best practices and techniques for addressing the security and privacy challenges associated with storing and transferring big data.

The proposed solutions aim to maximize the security and privacy of medical information.

This paper proposes a multi-layered approach to address the security and privacy risks associated with storing and transferring big data in the healthcare and medical insurance sectors. The proposed solution includes implementing encryption techniques, access control measures, and security protocols to minimize the risk of unauthorized access to sensitive information. Additionally, the solution involves the use of advanced technologies such as blockchain to ensure data integrity and prevent data tampering.

The implementation of the proposed solution can provide many benefits, including better protection of patient information, improved data accuracy, and increased trust and confidence among stakeholders. Moreover, it can help healthcare organizations comply with relevant regulations and standards, such as the General Data Protection Regulation (General Data Protection Regulation (GDPR)) and the Health Insurance Portability and Accountability Act (Health Insurance Portability and Accountability Act (HIPAA)).

IV. Methodology

To ensure the security and privacy of big data, it is essential to adopt a comprehensive approach that covers all aspects of data protection. In this paper, we propose a solution that combines multiple techniques to address the various vulnerabilities that could compromise healthcare security and privacy using big data.

The proposed solution will encompass techniques such as data masking, encryption, access controls, and data anonymization. By combining these techniques, the proposed solution provides a comprehensive approach to ensure data security and privacy, particularly in healthcare organizations when processing medical insurance data for insurance companies or claim transaction operators. The implementation of these techniques can significantly reduce the risks of data breaches, unauthorized access, and misuse of data, thereby enhancing data security and privacy.

A. Medical Insurance Transaction Ecosystem

To better understand the techniques and solutions involved, it is important to first gain insight into the transaction system of medical insurance. This includes understanding how data is ingested, stored, and processed.

The claim processing system typically comprises three main domains or parts, as illustrated in Fig. 1.

1) Healthcare Provider Integration Tier: A collection of tools and configurations are utilized to extract data from Hospital Management System (HMS) or Practice Management Application (PMA) systems and safeguard the original data before transmitting it to the data processing stage.

2) Data Processing Tier: During this tier, the data Extract, Transform, Load (ETL) process will occur, followed by data analysis. The data will then be structured and prepared for the subsequent phase, which involves transmitting the final claims to the insurance companies as shown in Fig. 2.

3) Insurance Company Integration Tier: During this stage, the integration hub component will direct the data to the appropriate destination based on the configurations and the targeted beneficiary or consumers.

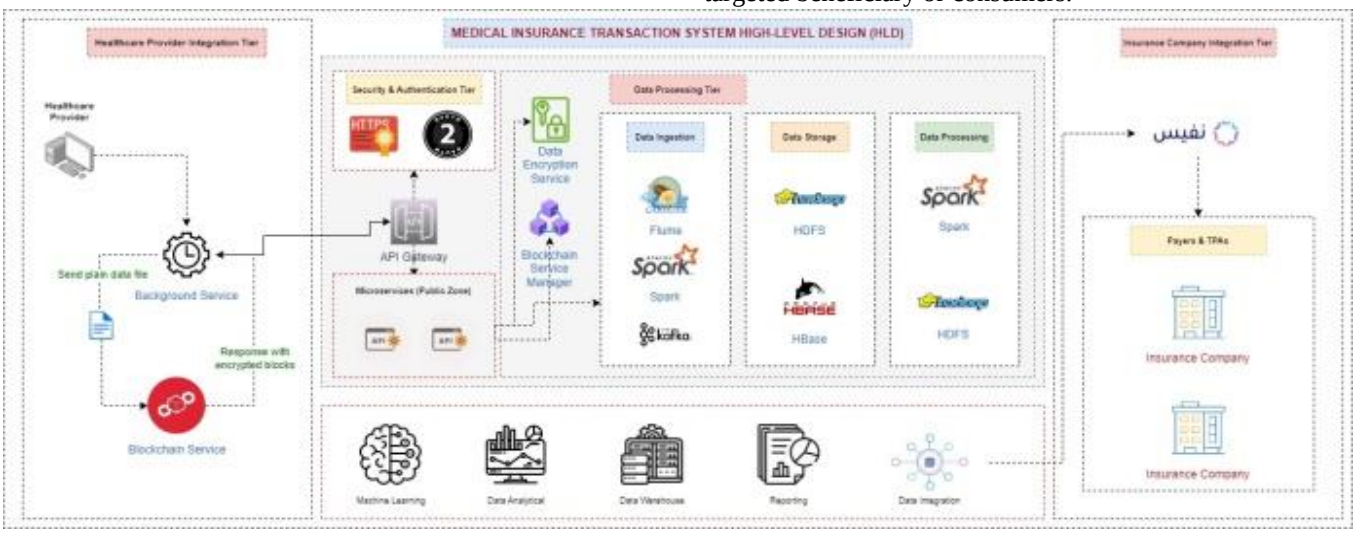

Fig. 1. Claim processing system.

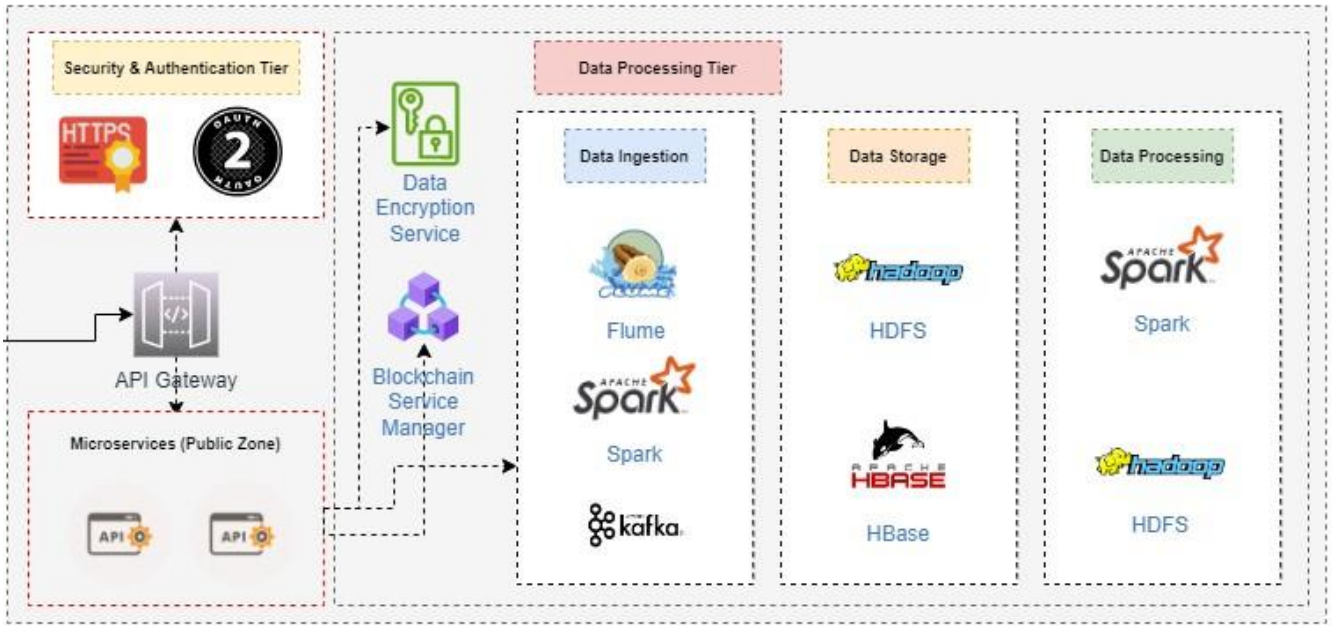

Fig. 2. Data processing tier.

B. A Common Data Processing Pipeline in the Medical Insurance Domain Includes the following:

1) Data Ingestion: The initial stage of the data processing pipeline involves collecting data from diverse sources, such as electronic health records and claims data, and ingesting it into a big data storage platform, such as Hadoop's Hadoop Distributed File System (HDFS) or other distributed file systems.

2) Data Cleaning: After data ingestion, cleaning and preprocessing are necessary to remove inconsistencies, missing data, or errors, which can involve various techniques like deduplication, normalization, and data imputation.

3) Data Transformation: Here, raw data is transformed into a format suitable for processing and analysis. This involves tasks such as data format conversion, data aggregation at different granularities, and feature engineering.

4) Data Analysis: After data transformation, patterns and trends can be identified through analysis using techniques like statistical analysis, machine learning, and predictive modeling.

5) Data Visualization: Visual aids such as dashboards, charts, and graphs can be utilized to present the analysis results. This helps in conveying the data insights to stakeholders and decision-makers.

6) Data Storage: After completing the analysis, the processed data can be securely stored in scalable data stores like Hadoop's HDFS or other distributed file systems. This stored data can be further transformed and analyzed in the future as required.

C. Compliance with Regulations

Different regulations and standards, such as HIPAA and GDPR, govern the storage and transfer of medical information that we need to comply with.

1) The Saudi Arabian Standards Organization (The Saudi Arabian Standards Organization (SASO)): SASO sets standards for consumer products and services, including those related to data protection.

2) The Saudi Arabian Monetary Authority (The Saudi Arabian Monetary Authority (SAMA)): SAMA regulates financial institutions in Saudi Arabia, including insurance companies, and has issued regulations related to data protection for the financial sector.

3) HIPAA: This law requires the establishment of national standards for electronic health care transactions [22].

4) The Privacy Law: This law was enacted in 2019 and governs the collection, processing, use, and disclosure of personal data in Saudi Arabia. The law applies to both government and private sector entities and requires organizations to obtain consent for the collection and use of personal data and to implement appropriate security measures to protect personal data.

5) The Cybercrime Law: This law criminalizes a range of activities related to cybercrime, including unauthorized access to computer systems and the theft of personal data.

Data protection regulations and laws in some countries as mentioned in study [22] address the growing thicket of applicable data protection legislation.

D. Threats and Risks

The medical insurance sector deals with vast amounts of sensitive data, including patient medical records, financial information, and insurance claims. Storing and transferring this big data poses significant security and privacy risks [23], such as data breaches, loss, and unauthorized access [24].

1) Unauthorized access: Malicious individuals may gain access to medical information in big data, leading to identity theft, fraud, and other malicious activities.

2) Data breaches: Compromised systems or networks can result in the loss or theft of sensitive medical information, which can be exploited for malicious purposes.

3) Insider threats: Misuse or disclosure of medical information by employees or contractors can lead to breaches in confidentiality or privacy.

4) Cyberattacks: Attacks like denial-of-service or malware can compromise the availability or integrity of medical information in big data.

5) Data loss: Accidental deletion or system failure can result in the permanent loss of medical information.

6) Inadequate security measures: Weak passwords or lack of encryption can make medical information in big data vulnerable to attacks and breaches.

7) Lack of regulatory compliance: Noncompliance with regulations and standards like HIPAA or GDPR can lead to legal and financial penalties.

E. Security Measures and Techniques

Various technologies are in use for protecting the security and privacy of healthcare data. The most widely used technologies are [22]:

1) Access control: Restricts medical information access based on user roles and privileges.

2) Encryption: Encodes medical information to prevent unauthorized access.

3) Data masking: Replaces sensitive information with fake values to protect privacy while allowing for research.

4) Data minimization: Reduces the amount of sensitive information stored and transferred.

5) Data backups: Stores copies of medical information in a separate location.

6) Penetration testing: Simulates cyberattacks to identify system vulnerabilities.

7) Security audits: Assessments of security measures and practices to ensure compliance with regulations and standards.

F. Privacy-preserving Techniques

1) Differential privacy: Adds noise to data to protect the privacy and prevent re-identification attacks.

2) Anonymization: Removes identifying information from medical data to protect privacy while allowing data analysis [24].

3) Pseudonymization: Replaces identifying information with pseudonyms to protect privacy while allowing data analysis [25].

4) Secure multi-party computation: Allows multiple parties to compute medical data without revealing it to each other, enabling collaborative analysis while protecting privacy.

5) Homomorphic encryption: Enables computation on encrypted data without decrypting it, protecting privacy while allowing data analysis [15].

6) Secure data sharing: Enables secure sharing of medical data between parties with appropriate permissions, protecting privacy while allowing data analysis [9].

G. Proposal

Several existing techniques have been employed to secure healthcare data, such as access controls, data encryption, and anonymization. Studies have shown that using blockchain can effectively limit the risk of data integrity by restricting unauthorized access to sensitive data [12] (Peng et al., 2022). Similarly, the use of data encryption is an effective method for maintaining data confidentiality and integrity [10] (ABHISHEK et al., 2019). Furthermore, anonymization, column-based encryption, and two-way authentication techniques are effective in preserving patient privacy (Musfira et al., 2018). These results demonstrate the value of utilizing such techniques to enhance the security and privacy of healthcare data as shown in Table I.

TABLE I. SECURITY AND PRIVACY TECHNIQUES

Ref	Year	Method / Technique
[21]	2004	Using integrated Rule-Oriented Data (Integrated Rule-Oriented Data (iRODS)) is proposed to be the solution to ensure security and privacy in big data.
[8]	2015	Highlighting the big data security issues and how to secure the Hadoop File System (HDFS) by using Kerberos, Algorithm, and Name node.
[22]	2017	The proposed system uses key management security mechanisms to protect big data.
[4]	2018	Discussed the threats and countermeasures of the healthcare data life cycle and its suggested defense.
[6]	2018	Using the proposed security framework uses column-based encryption and two-way authentication for privacy and multi-biometric-based key generation.
[13]	2018	Using Kerberos authentication protocol, and attribute-based encryption.
[10]	2019	Using the RSA algorithm to encrypt sensitive medical data.
[2]	2020	Highlighting the cloud security threats, Fog computing, IoT security threats, and Blockchain security threats and addressing the defense mechanisms of different computing technologies.
[9]	2020	Discuss the blockchain as a data integrity technique.
[11]	2020	Examining blockchain-based techniques used to privacy-preserving healthcare data and discussing smart contracts and PKI as blockchain technologies.
[19]	2020	Using Sandbox security for Map Reduce jobs to scan the jar files and check if it contains any harmful code.
[3]	2021	A proposal for a security framework is being made that utilizes the logistic equation, hyperchaotic equation, and DNA encoding techniques to cipher and encrypt images. The encrypted images will then be stored in shares across multiple cloud-based servers for distributed storage.
[16]	2021	Discussing different encryption algorithms used in blockchain.
[12]	2022	Using blockchain and IOMT technologies to protect healthcare data.
[14]	2022	Using Triple Data Encryption Standard (TDES) to secure big data in the cloud environment.
[17]	2022	Focused on using homomorphic encryption technology to secure Big Data processing.

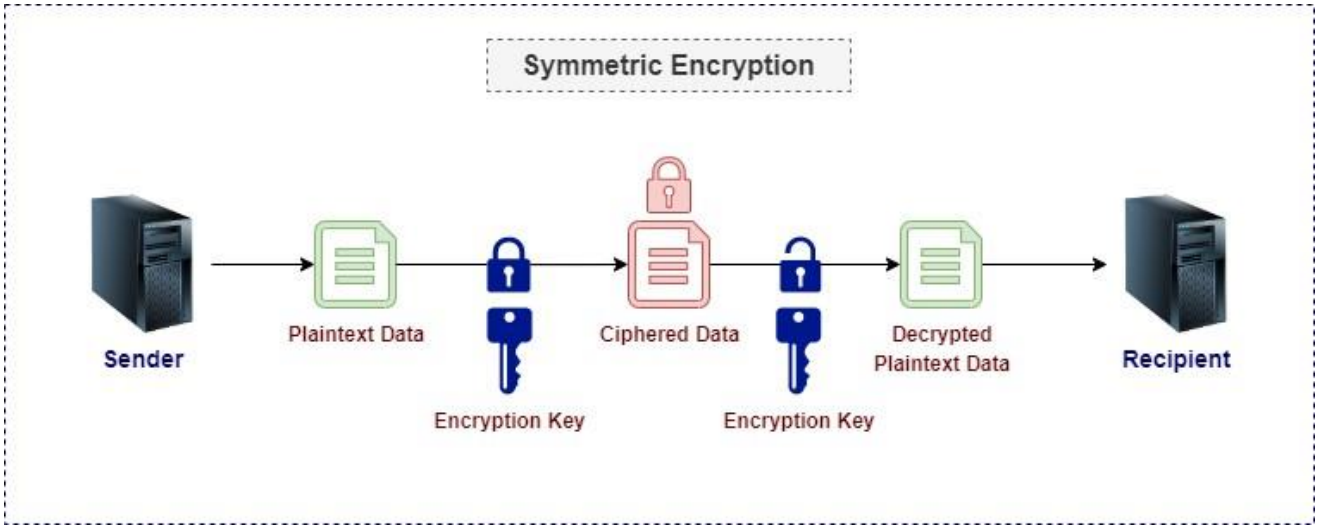

Fig. 3. Symmetric encryption.

Proposed Techniques: Ensuring the security of patient information is critical in the healthcare industry. The following suggested implementations can maximize the security and privacy of the patient's electronic medical records (Electronic Medical Records (EMR)), at-rest, and in-transit modes.

1) Data Encryption: Encryption is a method of encoding information so that only authorized parties can access it.

Symmetric encryption – Advanced Encryption Standard (Advanced Encryption Standard (AES)). Fig. 3 shows the symmetric encryption.

The RSA or Advanced Encryption Standard is one of the safest and most secure types of encryption. As a matter of fact, RSA is used by the United States Government to secure classified information as well as other hardware and software products. RSA, on the other hand, makes use of block ciphers that encrypt information one fixed-size chunk at a time. RSA has three key sizes: 128-bit, 192-bit, and 256-bit. The larger the key size, the stronger the encryption, therefore, we are going to use the 256-bit key as shown in the below algorithm [26].

Algorithm 1 GenerateAESKey(password)

```
function GENERATEAESKEY(password)
    sha256 ← SHA256.CREATE()
    passwordBytes←ENCOD-
ING.UTF8.GETBYTES(password)
    hash ← SHA256.COMPUTEHASH(passwordBytes)
    aes ← AES.CREATE()
    AES.KEYSIZE ← 256
    AES.KEY ← hash
    return AES.KEY
end function
```

Hashing SHA-256 Hashing is a one-way encryption technique that generates a unique fixed-length string of characters from a given input. There are several hashing algorithms, including MD5 and SHA-1, and SHA-256 is the most commonly used algorithm in blockchain technology, and it is recommended for its security and performance, we are going to use the SHA-256 as shown in the below algorithm [16].

Algorithm 2 CalculateHash(publicKey)

```
function CALCULATEHASH(publicKey)
    sha256 ← create SHA256 object
    inputString ← concatenate PreviousHash, Data and
publicKey using "-" separator
    inputBytes ← convert inputString to bytes using ASCII
encoding
    outputBytes ← compute hash of inputBytes using sha256
    return outputBytes as Base64 encoded string
end function
```

2) Data Encryption Flow stepsenumerate1 [steps,1]label=Step 0:

3) Hash the original data using the SHA-256 RSA algorithm: This generates a unique, fixed-length hash value that represents the original data.

Algorithm 3 EncryptAES256(plainText, publicKey)

```
function ENCRYPTAES256(plainText, publicKey)
    publicKeyBytes ← publicKey
    iv ← create new byte array of size 16
    plainBytes ← convert plainT ext to bytes using UTF-8
encoding
    aesAlg ← create new AES object
    aesAlg.KeySize ← 256
    aesAlg.Key ← publicKeyBytes
    aesAlg.IV ← iv
    aesAlg.M ode ← CBC
    encryptor ← create encryptor object using aesAlg Key and
IV
    memoryStream ← create new memory stream object
    cryptoStream ← create new crypto stream object using
memoryStream, encryptor and Write mode
    cryptoStream.W rite(plainBytes, 0, plainBytes.Length)
    cryptoStream.F lushF inalBlock()
    cipherBytes ← convert memoryStream content to byte
array
    return cipherBytes as Base64 encoded string
end function
```

4) Encrypt the original data using the RSA 256-bit public computed key: This ensures that the data is secure during transmission and can only be decrypted by someone who has access to the public computed key, following is the encryption algorithm.

Algorithm 4 DecryptAES256(cipherText, publicKey)

```
1: function DECRYPTAES256(cipherText, publicKey)
2:     privateKeyBytes ← publicKey
3:     iv ← create new byte array of size 16
4:     cipherBytes ← convert cipherText to bytes using Base64 decoding
5.     aesAlg ← create new AES object
6.     aesAlg.KeySize ← 256
7.     aesAlg.Key ← privateKeyBytes
8.     aesAlg.IV ← iv
9.     aesAlg.Mode ← CBC
10.    decryptor ← create decryptor object using aesAlg Key and IV
11.    memoryStream ← create new memory stream object using cipherBytes
12.    cryptoStream ← create new crypto stream object using memoryStream, decryptor and Read mode
13.    plainBytes ← create new byte array of size cipherBytes.Length
14:    decryptedByteCount ←cryptoStream.Read(plainBytes, 0, plainBytes.Length)
15:    return plainBytes as UTF-8 encoded string from index 0 to decryptedByteCount
16: end function
```

5) Concatenate the hash value with the encrypted data: This ensures that the hash value is bound to the encrypted data and cannot be altered without detection.

6) Add the concatenated data on a blockchain: This ensures that the data is secured by the distributed ledger and cannot be altered without detection.

7) Send the concatenated data: using a secured channel such as a Token-based Representational State Transfer (REST) Application Programming Interface (API), as shown in the process flow below.

8) Retrieve the concatenated data: from the blockchain: The data can be retrieved using a specific transaction ID or other identification methods.

9) Verify the integrity of the data: using the hash value: The hash value can be recalculated from the retrieved data and compared to the original hash value to ensure that the data has not been tampered with.

10) Decrypt the encrypted data: using the public computed key: This ensures that the original data can be recovered.

11) Convert the decrypted data back into the original format: This ensures that the data can be used in its original form. Using Secure Hash Algorithm (SHA)-256 and RSA 256-bit key pair with blockchain provides an additional layer of security and integrity to the data being transmitted.

12) Blockchain: Blockchain technology has the potential to revolutionize the healthcare industry by enabling secure and decentralized storage and sharing of patient data. Blockchain technology can help by enabling encrypted, distributed storage of data that can be securely shared for public health purposes [27]. In addition, blockchain networks can be used in the healthcare system to preserve and exchange patient data through hospitals, diagnostic laboratories, pharmacy firms, insurance companies, and other healthcare providers. This can help improve the security and integrity of healthcare data management. Blockchain-based healthcare data management system between multiple stakeholders (nodes) within a healthcare ecosystem [28].

Algorithm 5 DICOM Encryption Algorithm

```
1: function ENCRYPTDICOMFILE(inputFile, outputFile, key, iv)
2:     originalFileBytes ← read all bytes from the inputFile
3:     aes ← create new AES object
4:     aes.KeySize ← 256
5:     aes.Key ← convert key from Base64 string to byte array
6:     aes.IV ← convert iv from Base64 string to byte array
7:     aes.Padding ← PKCS7
8:     encryptor ← create encryptor object using aes
9:     encryptedStream ← create new memory stream object
10:    cryptoStream ← create new crypto stream object using encryptedStream, encryptor and Write mode
11:    cryptoStream.Write(originalFileBytes, 0, originalFileBytes.Length) cryptoStream.FlushFinalBlock()
13:    encryptedFileBytes ← convert encryptedStream to byte array
14:    write all bytes from encryptedFileBytes to the outputFile
15:    end function
```

13) Secure Sockets Layer (Secure Sockets Layer (SSL)) and Transport Layer Security (Transport Layer Security (TLS)): SSL and TLS are cryptographic protocols that provide secure communication over the internet. These protocols use a combination of symmetric and asymmetric encryption, along with digital certificates, to secure data transmission [22].

- Secure File Transfer Protocols: Medical patient files can contain a variety of file types depending on the type of information being recorded and the needs of the healthcare provider. Here we are focusing on the information that might be fetched from machines or third-party systems in the form of files:
- Medical images: Medical imaging files such as X-rays, CT scans, MRIs, and ultrasounds are often included in patient files.
- Lab results: Reports from laboratory tests such as blood tests, urine tests, and biopsies are commonly included in patient files.
- Consent forms: Documents that record patient consent for medical procedures, treatment plans, and research studies.
- DICOM files are created by medical imaging equipment, and they contain both image data and

information about the patient and the imaging procedure. This information includes patient demographics, imaging protocols, acquisition parameters, and image annotations [6].

Here we are going to secure the file transfer channel by using Secure File Transfer Protocol (SFTP) protocol and Hypertext Transfer Protocol (HTTP), to ensure that data is transferred securely. The file itself should be encrypted while transferring from the providers to the receivers (payers and claim transaction system), below the Digital Imaging and Communications (DICOM) encryption and decryption algorithm.

Algorithm 6 DICOM Decryption Algorithm

```
function DECRYPTDICOM-FILE(inputFile, outputFile, key, iv)
    encryptedFileBytes ← read all bytes from the inputFile
    aes ← create new AES object
    aes.KeySize ← 256
    aes.Key ← convert key from Base64 string to byte array
    aes.IV ← convert iv from Base64 string to byte array
    aes.Padding ← PKCS7
    decryptor ← create decryptor object using aes
    decryptedStream ← create new memory stream object
    cryptoStream ← create new crypto stream object using encryptedFileBytes, decryptor and Read mode
    cryptoStream.CopyTo(decryptedStream)
    decryptedFileBytes ← convert decryptedStream to byte array
    write all bytes from decryptedFileBytes to the output File
end function
```

14) Anonymization and Aggregation: Anonymization removes identifiable information from data to protect patient privacy, using techniques like hashing, tokenization, and generalization, with tools such as MapReduce and Pig from Hadoop assisting in this process. Aggregation combines and summarizes data, helping minimize identification risks by presenting broader statistics, as seen when insurance companies aggregate health claims by zip code or age range. While these methods reduce data breach risks and maintain data utility for research, there's still some re-identification risk with anonymized and aggregated data, necessitating additional safeguards depending on data sensitivity and re-identification risks [25].

15) Data Accessibility: Due to the sensitivity of patient information, it is crucial that access to such data is restricted and not available to everyone who has access to the system, including healthcare providers and insurance companies. Once a doctor is providing service to a patient, they are allowed access to the EMR, but the patient's medical and personal information should be safeguarded with a high level of security after the service is provided. If necessary, access to the patient's EMR can be requested with the patient's consent through an electronic approval process. The patient can grant access through one of the following options:

- OTP: One-Time Password (OTP) stands for "one-Time Password." An OTP is a unique code or password that is valid for a single use, typically to verify a user's identity or for securing an online transaction. OTP is often used as an additional layer of security in multi-factor authentication, where users are required to provide more than one form of authentication before being granted access to a system or performing a sensitive action.
    - OTP: can be delivered to the user via various methods, such as:
    - Short Message Service (SMS): The OTP is sent to the user's mobile phone as a text message.
    - Email: The OTP is sent to the user's email address.
    - Authenticator app: The user installs an authenticator app on their mobile device, which generates a new OTP every few seconds.
    - Voice call: The OTP is delivered to the user via an automated voice call.

Here once the patient receives the OTP, he must provide it to the requester within a limited period before it expires. If the OTP is entered correctly and within the valid period, the doctor or physician is granted access or permission to perform the requested action. If the OTP is not entered correctly or within the valid period, the doctor may be locked out of the system or required to request new access.

- EMR Authenticator: Here we can integrate with any of the identity authenticators that supports the Open Authentication (OATH) Time-Based One-Time Password (TOTP) standard such as Google Authenticator, or Microsoft Authenticator. Additionally, Microsoft Authenticator also supports push notifications, which can provide an additional layer of security and convenience for users.

16) Big Data (Hadoop Security)

- Authentication: Authentication is the process of verifying the identity of users and ensuring that they have the necessary permissions to access the Hadoop cluster. Hadoop supports several authentication mechanisms such as Kerberos and Lightweight Directory Access Protocol (LDAP) [13].
- Authorization: Authorization is the process of determining what users are allowed to do once they have been authenticated. Hadoop provides mechanisms for fine-grained access control, such as Access Control Lists (Access Control Lists (ACL)s) and Role-Based Access controls (Role-Based Access Controls (RBAC)).
- Encryption: Encryption is the process of encoding data so that it cannot be read by unauthorized users. Hadoop provides encryption mechanisms for data at rest and in transit [29]. For data at rest, Hadoop supports encryption at the file system level using tools like HDFS Transparent Encryption [30]. For data in transit,

Hadoop supports encryption using Secure Sockets Layer (SSL) and Transport Layer Security (TLS).

- Auditing: Auditing is the process of recording all user activities on the Hadoop cluster. Hadoop provides auditing tools such as Apache Ranger and Apache Atlas, which can be used to track user activity and detect any security breaches.
- Network security: Hadoop clusters should be deployed in a secure network environment, with firewalls and other security measures in place to prevent unauthorized access. Network security can also include isolating different parts of the cluster and ensuring that only authorized users have access to sensitive data.[2]

17) Data Monitoring and Auditing Healthcare facilities and insurance companies need robust monitoring and auditing systems to ensure patient care and data quality, safety, and security. These systems monitor user access, track changes to records, and detect unauthorized or suspicious activity, ensuring data is used only for authorized purposes by authorized individuals [15]. They provide real-time alerts on security threats, enabling immediate action to protect patients and their data. Monitoring and auditing are crucial for maintaining data confidentiality, integrity, and availability, and ensuring compliance with regulations and best practices in patient data security [15] [31-41].

V. Discussion

In conclusion, the security techniques discussed in this paper provide a comprehensive approach to addressing the security and privacy concerns associated with healthcare data. By using data encryption, blockchain technology, secure API, and Hypertext Transfer Protocol Secure (HTTPS)/SFTP protocols, we can ensure the security and integrity of medical data both at rest and in transit. Additionally, the use of Kerberos can help ensure big data security. To ensure compliance with HIPAA standards and other regulations, it is important to limit data access to authorized parties only. Furthermore, in order to maintain a balance between performance and security, multi-layered security approaches have been employed, including big data security. It is important to note that the complexity of data processing can lead to poor performance and high latency, which is why it is crucial to carefully design and implement security measures that do not compromise the performance of the system. Overall, this proposed ecosystem provides a robust and secure solution for managing healthcare data and ensuring the privacy and security of patients' sensitive information.

VI. Conclusion

In conclusion, safeguarding healthcare data security is crucial to ensure patient privacy and uphold the confidentiality of their information. While advanced technologies like cloud computing bring numerous benefits to the healthcare industry, they also give rise to new security challenges that demand effective management. In this paper, we have applied a range of techniques, such as a customized Blockchain encryption mechanism, a combination of asymmetric and symmetric algorithms for data encryption, hashing, secure network protocols like HTTPS and SFTP, protection of APIs and resources within a cloud environment, and the incorporation of HDFS security.

The security strategies discussed in this paper form a solid foundation for healthcare organizations to establish a secure infrastructure that adheres to pertinent regulations and safeguards sensitive data. This paper highlights a multi-layered security approach that balances performance and data processing without compromising robust protection against cyber threats. After applying these techniques and integrating them, a highly secure data streaming system was achieved. During testing, neither passive nor active attacks were able to penetrate the protected data, demonstrating the effectiveness of the combined security measures.

It is essential for healthcare organizations to prioritize data security and consistently evaluate and improve their security measures to keep pace with emerging risks. By embracing a proactive and comprehensive approach to security, which includes the techniques outlined above, healthcare organizations can ensure the safety and privacy of their patients' data, instilling trust and confidence among all stakeholders.

A Novel Deep Learning-Assisted SVD-based Method for Medical Image Watermarking

Saima Kanwal, Feng Tao*, Rizwan Taj
School of Computer and Communication, Lanzhou University of Technology, Lanzhou, China

***Abstract*—In the present era, the administration of medical images faces various security challenges that necessitate the authentication of image source and origin for accurate patient identification. With the increasing exchange of medical images between hospitals to facilitate informed decision-making, the adoption of digital watermarking techniques has emerged as an efficient solution to address the imperceptibility and robustness requirements in medical imaging watermarking. This research work introduces a technically advanced approach that combines singular value decomposition (SVD) watermarking with deep learning segmentation models to enhance the security of medical image sharing and transfer. The primary objective is to seamlessly integrate the watermark while minimizing distortion to preserve critical medical information within the image. The proposed methodology involves utilizing a ResNet-based U-Net segmentation model to segment X-Ray radiographs into the Region of Interest (ROI) and the Region of Non-Interest (RONI). The watermark data is then encoded into the ROI using singular value decomposition. Subsequently, the ROI and RONI are merged to reconstruct the complete image, preserving its original identity. Additionally, XOR encryption is applied to the watermarked image to enhance data integrity and copyright protection. On the other side of the methodology, the reconstructed image is once again separated into ROI and RONI. The ROI is decoded to recover the original transferred content. To assess the efficacy of the proposed method, a publicly available X-Ray radiograph dataset is employed, and evaluation metrics demonstrate an impressive segmentation accuracy of 98.27%. The proposed approach ensures information integrity, patient confidentiality during data sharing, and robustness against various conventional attacks, demonstrating its effectiveness in the field of medical image watermarking.**

***Keywords*—Singular value decomposition; medical image watermarking; digital watermarking; deep learning**

I. INTRODUCTION

With the introduction of 5G networks as an example, communication technologies have advanced quickly, dramatically altering many facets of daily life [1]. This shift in paradigm has been facilitated by simultaneous significant progressions in the fields of data analytics, computing in the cloud, and online storage. Emerging within the framework of the Internet of Medical Things (IoMT), novel approaches for both diagnosis and treatment have surfaced. These encompass telemedicine, web medicine, systematic diagnosis, and smart medicine. These cutting-edge trends are accompanied by highly advanced diagnostic and therapeutic tools, state-of-the-art sensors for medical, immersive virtual reality technologies, and complex artificial surgical methods [2]. Advancements in healthcare tech merge for better diagnosis & treatment, reshaping the ecosystem, empowering doctors, and enhancing overall care. Medical imaging transforms through e-diagnosis workflows, forming core modern healthcare structures. Hospital systems utilize HIS and advanced imaging platforms for seamless management of varied digital images (X-ray, Ultrasound, MR, and CT) [3]. PACS in hospitals securely store and retrieve these images, while DICOM standardizes their acquisition, transmission, storage, and exchange with patient data. By synergistically leveraging the functionalities of HIS, medical imaging platforms, PACS, and adhering to the DICOM standard, healthcare professionals are empowered with swift access to an extensive collection of high-fidelity digital images [4]. Seamless integration ensures precise diagnosis, treatment planning, and overall care. Interchange of medical images aids diagnosis, therapy, education, and consultations within established PACS workflows. Yet, external transmission to third parties poses potential risks of unauthorized image alterations, impacting accuracy and potentially endangering patients' lives [5]. As a result, maintaining the integrity and authenticity of medical images has become of utmost importance, calling for the implementation of strong controls and strict protections both within internal systems and during the transmission and exchange processes with external systems. A secure and reliable framework for the lifecycle management of medical images must be established, which necessitates the adoption of cutting-edge methods and technology.

Several strategies are used to handle the challenges associated with copyright protection, the confidentiality of healthcare images, and the diagnostic and personal information of patients. For these goals, methods like digital picture watermarking, cryptography, and steganography are frequently used. One of these techniques, digital picture watermarking, has attracted a lot of attention from researchers due to its unique characteristics that might offer solutions for protecting copyright and safeguarding medical data. Digital image watermarking makes it possible to incorporate subtle or noticeable watermarks into medical photographs, allowing copyright enforcement, integrity verification, and authentication [6]. Watermarking conceals metadata in images, safeguarding patient privacy and ensuring traceability. It operates in spatial and frequency domains: spatially by adjusting pixel grey levels and frequency-wise via methods like Discrete Fourier Transform (DFT) or Discrete Cosine Transform (DCT) to embed the watermark into the image [7]. The secret information is then incorporated by tampering with the frequency coefficients after conversion. The amplitudes and phases of the various frequency components that are present in the image are represented by these coefficients. By

*Corresponding Author.

changing these coefficients, the watermark is smoothly included into the image's representation in the frequency domain. Based on how the embedded watermark is extracted, watermarking methods are further divided into different categories. For non-blind watermarking, the source image and the watermarked image are both necessary in order to obtain the watermark. As a result, both the original host image and the matching watermark image must be accessible during the extraction process [8]. In contrast, semi-blind watermarking entails using both the watermarked image and the secret key throughout the extraction process. The watermark is included in the watermarked image and the secret key acts as a cryptographic parameter. Finally, only the secret key is required to extract the watermark in blind watermarking techniques. Both types of watermarking techniques, robust watermarking and fragile watermarking, each serve a particular function in the context of data protection and verification [9]. Watermarking aims for resilient data embedding, crucial for protecting against tampering during transfer, especially for copyright protection. Resilience determines resistance to outsider attacks or unintentional distortions during transmission. Fragile watermarking, on the other hand, detects alterations in watermarked content, ensuring integrity and authenticity. It verifies material reliability by identifying inconsistencies, serving as a vital tool for content authentication and integrity checks [10]. When discussing watermarking, as we are dealing with images, the terms "frequency domain" and "spatial domain" in the context of imaging apply to various images' representations [11]. In imaging, the term "spatial domain" describes how a picture is represented as a grid of pixels, where each pixel holds information about color or intensity and correlates to a particular place. On the other hand, the image is evaluated in terms of its frequency's components, which show differences in brightness or color across different frequencies, in the frequency domain [12]. In comparison to spatial domain watermarking, frequency domain watermarking provides higher robustness to routine image processing operations, improved imperceptibility, increased embedding capacity, resistance to geometric changes, and improved security against attacks. Frequency domain approaches are less prone to perceptual degradation and information loss brought on by spatial processes since the watermark is embedded in the frequency coefficients. Higher imperceptibility is ensured by the judicious distribution of watermark energy over several frequency bands. By using more coefficients for watermark insertion, frequency domain watermarking also offers a higher embedding capacity [13]. Additionally, it demonstrates enhanced security against statistical assaults and improved resistance to geometric transformations. Frequency domain watermarking is a favored option for many applications in digital data protection and authentication due to these benefits.

This article introduces a blind watermarking method enabling watermark embedding and extraction without the original content. This approach ensures robustness and authenticity. XOR encryption fortifies security, preventing unauthorized access or changes to the watermarked image. Encryption safeguards content, necessitating a decryption key for access. Leveraging techniques like Singular Value Decomposition (SVD), the host media undergoes transformations, embedding the watermark imperceptibly [14]. During extraction, retrieved components and a secret key recover the watermark. This blind technique shows resilience against various attacks like compression and noise, ideal for copyright protection, authentication, integrity verification, and digital forensics. Integrating U-Net with ResNet50 enhances the method. Their combo ensures precise segmentation, preserving details in the region of interest and aiding targeted watermarking. This model balances accuracy and efficiency, suitable for real-time or large datasets. Leveraging this advanced segmentation boosts the proposed method's performance and effectiveness in watermarking [15]. Through this approach, we enhance the quality of segmentation, facilitate effective watermarking, an advanced level of security and integrity for digital media, and enable efficient image analysis and protection.

Here are our primary contributions.

- Introducing a novel blind watermarking approach that seamlessly integrates U-Net segmentation with pre-trained ResNet50, enabling watermark extraction without original content access.
- Achieving precise ROI and RONI segmentation through U-Net, ensuring efficient and targeted watermark embedding while minimizing interference.
- Incorporating XOR encryption for watermarked image protection, preventing unauthorized access and modification.
- Addressing limitations in medical image sharing, applicable in copyright protection, content authentication, data integrity verification, and digital forensics.

The article is structured as follows: Section I introduces the research problem and outlines the proposed methodology, including the key contributions. Section II reviews related work in watermarking and segmentation models. Section III elaborates on the proposed blind watermarking technique, integration of U-Net and ResNet50, and XOR encryption. Section IV details the experimental setup, dataset, evaluation metrics, and discusses results, comparing with existing methods. Section V concludes by summarizing contributions and implications.

II. Related Work

Digital watermarking encompasses four fundamental concerns: imperceptibility, robustness, capacity, and security, all of which play an important role in the design and evaluation of watermarking algorithms. Researchers have invested considerable efforts in improving these aspects, especially in blind scenarios where access to the original host images is limited. However, existing watermarking methods often exhibit deficiencies in terms of robustness, transparency, and payload capacity under blind conditions. In this context, a hybrid domain approach combining three methodologies, first the discrete wavelet transforms (DWT), second the discrete cosine transforms, and the third singular value decomposition was proposed by [16] to implement a non-blind watermarking technique. Photography and text were used as watermarks and

incorporated into medical photographs. To encrypt the text watermark, a low encryption technique was used in order to streamline encryption-decryption procedures and shorten computational time. The watermark image used had dimensions of 256 x 256, whereas the cover image used was 512 x 512. Additionally, a 50-character text watermark was successfully inserted into the cover photo. Peak signal-to-noise ratio (PSNR) results for the proposed watermarking system were 35.84 dB, confirming the effectiveness and high caliber of the adopted strategy.

In order to improve decision-making processes, [17] effort proposes a novel wavelet-based digital watermarking technology designed for the transfer of medical images between institutions. Digital watermarking is essential in the medical industry for maintaining the dependability, accessibility, and privacy of images used for treatment and diagnosis. Although several approaches utilizing the spatial and transform domains have been put forth, current systems continue to run into issues with data fabrication during picture interchange. The work presents a wavelet-based digital watermarking method for medical photographs to address this problem. To help doctors make informed decisions, the scheme includes a three-level discrete wavelet transform and BCH coding. In the context of IoMT, researchers in [18], study introduces a revolutionary validated watermarking algorithm created exclusively for healthcare data. Healthcare volume data must now be transmitted and stored in a secure, dependable manner due to the growing use of IoMT technology in healthcare. In the context of the Internet of IoMT, this research introduces a reliable zero-watermarking technique-based on 3D hyper chaos and 3D dual-tree complicated wavelet transform. To create a reliable binary sequence as the watermark, the approach makes use of enhanced perceptual hashing algorithms and selective binarization of low-frequency components. Using zero embedding and blind extraction techniques, the system effectively defends against attacks and geometric distortions while maintaining the authenticity of the original clinical volume data. In terms of normalized correlation value under geometric assaults, it outperforms existing algorithms and offers bandwidth efficiency while still meeting the security criteria for sending and storing large volumes of clinical information. Utilizing the features of the Human Visual System (HVS), a blind watermarking technique was used in study [19] to insert numerous watermarks in a cover image. The watermark values were created by applying a specified threshold value to the first column of the orthogonal U matrix that was produced by applying singular value decomposition. By balancing the Normalized Cross Correlation (NCC) and the invisibility of the resulting watermarked image, the ideal threshold was found. The experimental results illustrate the proposed scheme's robustness and highlight its notable resistance to a variety of attack scenarios, demonstrating the value of using numerous watermarks. To enhance the security of the sharing and transmission of medical images, our research diligence proposes a novel and technically complex approach that combines singular value decomposition watermarking with deep learning segmentation models. The segmentation task is prioritized as a crucial component of the introduced methodology in addition to watermarking. In order to precisely define anatomical features and anomalies in medical images, a variety of segmentation methodologies have been introduced by specialists in the field of healthcare imaging. In this context, for precise segmentation of brain tumors disease from MR images, the study in [20] presented a hybrid technique that combines the DenseNet and U-Net segmentation algorithms. This study's main goal is to use deep learning techniques to precisely locate and define brain tumors in MR images. The U-Net architecture, a well-known deep learning network, is combined with a pre-trained DenseNet121 architecture in the hybrid model to improve segmentation. Smaller tumor sub-regions with intricate structural properties are given more consideration throughout the training and testing phases. The proposed approach is evaluated using the publicly available BRATS 2019 brain tumor dataset, encompassing both high-grade and low-grade glioma tumors. An advanced deep learning methodology was put forth for the segmentation of pneumothorax in chest X-ray pictures in another noteworthy study [21]. The strategy makes use of the effective EfficientNet and ResNet architectures, as well as the strong and powerful U-Net architecture. They unveiled a brand-new end-to-end semantic segmentation model for medical pictures called Ens4B-UNet. To provide incredibly accurate segmentation results, this novel method combines the power of four U-Net topologies with backbone networks that have already been trained. Ens4B-UNet improves the U-Net framework by using nearest-neighbor up-sampling in the decoders and using strong convolutional neural networks (CNNs) as the foundation for the U-Net encoders. The segmentation network's formulation, which achieves excellent performance, is a weighted average ensemble of the four encoder-decoder models. They claim an outstanding mean Dice similarity coefficient (DSC) of 0.8608 on the test data, the Ens4B-UNet model placed among the top 1% of systems in the prestigious Kaggle competition.

The existing methodologies in digital watermarking encounter several unresolved challenges that necessitate the development of advanced approaches. One major limitation is the reliance on access to the original unmarked content during the extraction time, hindering the extraction of watermarks when the original content is unavailable. This restricts the applicability of existing methods in scenarios where independent extraction is required. Moreover, many current approaches lack robustness against common interruptions resulting in the degradation of watermark quality and integrity. Furthermore, there is a pressing need for accurate and efficient segmentation techniques to precisely delineate the region of interest, facilitating targeted watermark embedding. To address these unresolved issues, our proposed methodology combines blind watermarking, utilizing the U-Net model with ResNet50 as a bottleneck, and encryption of the watermarked image. This integrated approach offers enhanced security, integrity, and resilience, effectively mitigating the limitations of existing methodologies.

III. PROPOSED METHODOLOGY

The hybrid strategy for digital watermarking in this proposed methodology combines the U-Net model with pre-trained ResNet50 for image segmentation and the singular value decomposition method for watermarking. The foundation for precise and thorough segmentation of the input images into

separate areas of interest is the U-Net model, which is renowned for its efficiency in semantic segmentation tasks. The highly effective feature extraction capabilities of the pre-trained ResNet50 are used to increase segmentation accuracy. The appropriate watermark information is then embedded within the segmented ROIs using the SVD-based watermarking technique, assuring imperceptibility and resilience. To accomplish reliable and secure watermark embedding, the process entails several crucial steps.

A. Watermark Generation

In this proposed approach, the watermark utilized encompasses multiple components, each serving a specific purpose within the extraction process, shown in Fig. 1. The first component is dedicated to patient identification and includes details such as the patient's name, gender, contact number, and address. These attributes aid in uniquely identifying the individual associated with the medical image. The second component focuses on providing information related to the acquisition of the medical image. This includes data such as the medical center responsible for generating the image, the attending doctor's name, and the timestamp indicating when the data was gathered. By incorporating this information, the source and author of the image can be effectively identified. By combining these two components, the proposed watermarking technique enhances the overall security and traceability of medical images. It allows for accurate patient identification and ensures the authenticity and origin of the image data, enabling efficient management and reliable attribution in medical imaging scenarios.

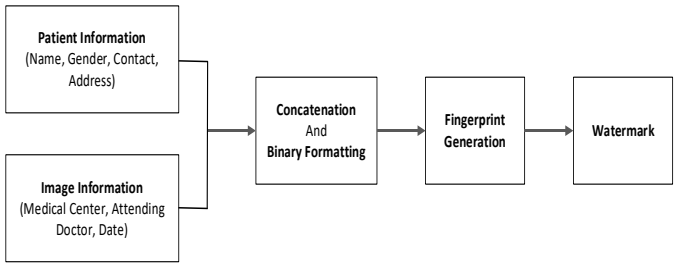

Fig. 1. Watermark generation.

B. U-Net Model

- U-Net model is frequently employed for image segmentation tasks [21]. It has an encoder-decoder structure with skip links that makes it possible to localize object boundaries with accuracy. The encoder extracts context and information from source image, while the decoder module builds a segmentation map at the pixel level. Here is a detailed description of how the U-Net model functions and avoids combining SI and CGS units, such as current in amperes and magnetic field in oersted. This often leads to confusion because equations do not balance dimensionally. If you must use mixed units, clearly state the units for each quantity that you use in an equation.

1) Encoder: Convolutional layers are succeeded by max-pooling layers, constituting the encoder. To extract various information from source data, each convolutional layer uses a separate set of filters. As we dig deeper into the encoder, the number of filters often rises, enabling the model to capture more intricate information. The max-pooling layers shrink the feature maps' spatial dimensions, which aids in expanding the receptive field and lightening the computational burden.

Let's refer to the encoder as consisting of N encoder blocks, each represented by the function Ei, and the input picture as X. Ei(X) stands for the ith encoder block's output.

2) Bottleneck: The output is then sent to the bottleneck layer after going through each encoder block. The bottleneck layer is frequently made up of several convolutional layers that aid in further capturing high-level and abstract characteristics from the input. In our proposed methodology, the pre-trained ResNet50 is utilized as the bottleneck for U-Net architecture. The term "bottleneck" refers to a specific component within ResNet50 that serves as a feature extractor. By integrating ResNet50 as the bottleneck in the U-Net model, we leverage its powerful feature representation capabilities to enhance the segmentation process. In this context, the ResNet50 model is responsible for extracting high-level semantic features from the input medical images. It is an essential transitional stage between the U-Net architecture's encoder and decoder modules. The ResNet50 bottleneck layer decreases the number of dimensions of the map features while retaining crucial data, facilitating the efficient extraction of meaningful features. The integration of ResNet50 as the bottleneck within the U-Net architecture enables our proposed methodology to benefit from the rich representation capabilities of ResNet50 for feature extraction. This combination enhances the U-Net model's ability to accurately segment medical images, leveraging the precise localization capabilities of U-Net along with the comprehensive feature representation of ResNet50.

Let's write B(X) for the bottleneck layer's output.

3) Decoder: Convolutional layers are applied after a sequence of upsampling and concatenation steps make up the decoder. The upsampling layers, responsible for augmenting the spatial dimensions of the feature maps, enable the decoder to produce a segmentation map pixel by pixel, matching the dimensions of the input image. For both local and global context information, the concatenation procedure merges the feature maps from the encoder and decoder.

Let's write Di for the ith decoder block and Di(B(X)) for the ith decoder block's output.

4) Final segmentation map: Applying a 1x1 convolutional layer to the final decoder block's output yields the final segmentation map. In order to match the number of classes in the segmentation task to the number of channels, a 1x1 convolutional layer is used. The resulting segmentation map will be referred to as S(X), with X standing for the input image. The U-Net model's forward pass can be described as follows:

$$S(X) = 1x1Conv(DN(B(X))) \quad (1)$$

In this equation, DN represents the Nth decoder block, which consists of up sampling and convolutional layers to recover spatial resolution. B represents the bottleneck layer, which serves as the bridge between the encoder and decoder, capturing the high-level semantic information. In order to limit the number of streams to the appropriate number of classes, the result of the bottleneck layer is then routed to the 1x1 convolutional layers, abbreviated as 1x1Conv. The segmentation map S(X) that is produced has the same spatial dimensions as the original image. A class probability vector, which indicates how likely it is that each pixel in the map belongs to a particular class, is present for each pixel. To obtain the ultimate pixel-by-pixel segmentation outcome, every pixel is attributed to the class exhibiting the highest probability.

C. Singular Value Decomposition

In order to facilitate numerous operations and analysis, the matrix factorization method named singular value decomposition (SVD) decomposes a matrix into three distinct matrices [22]. In the context of image processing and watermarking, SVD plays a crucial role in embedding and extracting watermarks while preserving the integrity of the source image. Mathematically, given an m × n matrix A, the SVD of A can be represented as follows:

$$A = U\Sigma V^T \quad (2)$$

where:

- U is an m × m orthogonal matrix, representing the left singular vectors.
- Σ is an m × n diagonal matrix with non-negative elements, known as singular values.
- V^T is the transpose of an n × n orthogonal matrix V, representing the right singular vectors.

The singular values in Σ are ordered in descending order, indicating their significance in capturing the image's energy or information. The higher singular values correspond to the most essential features of the image. During the watermarking process, the SVD technique is applied to the selected regions of interest (ROIs) within the image. These ROIs are represented as matrices, which are decomposed using SVD. The watermark data is then embedded into the singular values of the ROI matrix while preserving the orthogonal matrices U and V^T. The watermark embedding process involves modifying the singular values in Σ by adding or subtracting a certain value or pattern based on the watermark information. The modified Σ, along with the original U and V^T matrices, is used to reconstruct the watermarked ROI. To extract the watermark, the SVD is applied to the watermarked ROI, yielding the modified Σ matrix. By comparing the modified Σ with the original Σ obtained from the original ROI, the watermark information can be retrieved.

D. XOR Encryption

The bitwise exclusive OR (XOR) function is used to encrypt binary data using the straightforward XOR encryption method. It involves performing an XOR operation between the binary data of the watermarked image and a secret key to produce the encrypted version of the image.

The XOR encryption process can be represented as follows:

- Let E be the encrypted image, I be the original watermarked image, and K be the secret key.
- Convert the image I and the secret key K into binary representations.
- Perform the XOR operation between each corresponding bit of I and K.
- The result of the XOR operation is the corresponding bit of the encrypted image E.

By applying the XOR operation to each bit of the image and the secret key, the encrypted image is obtained. This process ensures that the encrypted image cannot be easily understood without knowledge of the secret key. Fig. 2 depicts the entire methodology and gives an extensive overview of the procedure. The segmentation stage, when the data is integrated into the image, is shown in Fig. 2 (a) and Fig. 2 (b) then depicts the decoding procedure, in which the embedded data is retrieved from the watermarked image.

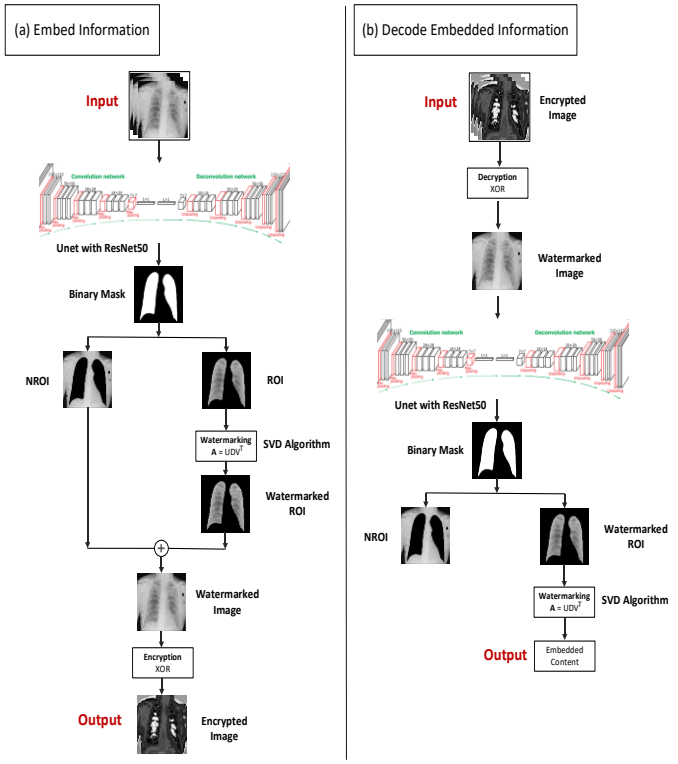

Fig. 2. Proposed architecture.

In order to properly recover the original content from the watermarked image and guarantee accurate retrieval of the encoded data, this phase makes use of sophisticated algorithms and computations. These two subfigures together shows how segmentation and decoding are seamlessly integrated into the proposed methodology. It involves two algorithms that are pivotal in achieving the desired outcomes. Algorithm 1, titled "Segmentation and Watermarking," elucidates the intricate processes illustrated in Fig. 2(a). This algorithm comprehensively outlines the step-by-step execution of segmenting the image and embedding the watermark within the

identified regions using techniques such as U-Net and ResNet50. Commencing with preprocessing the input image along with the pertinent information intended for watermark embedding, the resultant image is fed into a segmentation model. This input image, denoted as I, is then passed through a U-Net segmentation model, yielding a segmented binary mask. This mask effectively segregates the region of interest from the region of non-interest. Subsequently, the watermark W is transformed into an appropriate format and embedded into the region of interest within the initial image. Following the watermark embedding process, the regions of interest and non-interest are amalgamated to undergo an encryption procedure. The outcome of this encryption is an encrypted image, primed for transmission.

Algorithm 1: Segmentation and Watermarking

Inputs:
- Image (I): Input image for segmentation and watermarking
- Watermark (W): Information to be embedded as a watermark.
- EncryptionKey (EK): Key used for encryption

Outputs:
- Segmented Image (SI): Image with segmented regions
- Watermarked Image (WI): Image with embedded watermark

Step 1: Procedure PreprocessImage(I):
a. Normalize the pixel values of the image I.
b. Perform any necessary image enhancement or noise reduction techniques.

Step 2: Procedure ApplySegmentationModel(I):
a. Pass the pre-processed image I through the U-Net architecture with a pre-trained ResNet50 as the bottleneck.
b. Obtain the segmented regions by applying a threshold or post-processing techniques to the output of the segmentation model.
c. Generate the segmented image SI by overlaying the segmented regions on the original image I.

Step 3: Procedure SegmentImage(I, SI):
a. Subtract the non-segmented regions from the original image I to obtain the ROI.
b. Subtract the segmented regions from the original image I to obtain the RONI.

Step 4: Procedure EmbedWatermark(ROI, W):
a. Convert the watermark W into a suitable format for embedding, such as a binary sequence or a transform domain representation.
b. Iterate over the pixels in the ROI:
For each pixel P in the ROI:
Modify the pixel value of P to embed the corresponding watermark bit.

Step 5: Procedure CombineImage(ROI, NROI):
a. Generate the watermarked image WI by combining the modified ROI with the RONI from the original image I.

Step 6: Procedure EncryptionImage(WI, EK):
a. Output the encrypted watermarked image EWI by applying XOR watermarking technique.

Step 7: Procedure SegmentationAndWatermarking(I, W):
PreprocessImage(I)
ApplySegmentationModel(I)
SegmentImage(I, SI)
EmbedWatermark(ROI, W)
CombineImage(ROI, NROI)
EncryptionImage(WI)
SegmentationAndWatermarking(I, W)
Return EWI
End of Algorithm

On the other hand, Algorithm 2, titled "Content Extraction from Watermarked Image," delineates the procedures depicted in Fig. 2 (b).

Algorithm 2: Content Extraction from Watermarked Image

Input:
- Encrypted Watermarked Image (EWI): Encrypted image with embedded watermark
- Pre-trained ResNet50 Model (M): Pre-trained ResNet50 model for segmentation
- Decryption Key (DK): Key used for Decryption

Output:
- Extracted Watermark (EW): Embedded content extracted from the watermarked image

Step 1: Procedure DecryptWatermarkedImage(EWI, DK):
a. Apply decryption to output the watermarked image WI.

Step 2: Procedure Segmentation(WI, M):
1. Apply the pre-trained ResNet50 model to the Watermarked Image to obtain the Segmentation Map.
2. Apply a threshold to the Segmentation Map to obtain a binary mask using the Segmentation Threshold.

Step 3: Procedure SegmentImage(WI):
a. Subtract the non-segmented regions from the original image I to obtain the ROI.
b. Subtract the segmented regions from the original image I to obtain the RONI.

Step 4: Procedure ExtractWatermark(ROI):
1. Apply singular value decomposition to the watermarked ROI using the SVD Parameters.
2. Retrieve the modified SVD coefficients from the Watermarked Image.
3. Initialize an empty array to store the extracted content.
4. For each pixel in the Watermarked Image:
a. Check if the corresponding pixel in the binary mask is non-zero.
b. If non-zero, extract the content from the modified SVD coefficients corresponding to the pixel.
c. Append the extracted content to the array.

Step 5: Procedure ContentExtraction(WI, M, DK):
DecryptWatermarkedImage(EWI, DK):
Segmentation(WI, M):
SegmentImage(WI):
ExtractWatermark(ROI):
ContentExtraction(WI, M, DK)
Return EW
End of Algorithm.

This algorithm intricately illustrates the sequential operations involved in extracting the information from the embedded watermarked image, enabling the reconstruction of the original content. Subsequently, the reverse sequence is initiated, commencing with the application of a decryption

algorithm on the encrypted input image. This decryption process yields a watermarked image, which is subsequently provided as input to the segmentation model to retrieve the regions of interest and non-interest. Following this, the SVD watermarking algorithm is implemented to extract the watermark information from the watermarked region of interest.

IV. Experimental Results and Discussions

For the experiments, we trained our algorithm on a medical imaging dataset consisting of chest radiographs. The training was performed on a Google Colab GPU to leverage its computational power. The dataset was carefully curated and pre-processed to ensure high-quality and standardized images. We used a batch size of 32 and trained the model for 50 epochs with an initial learning rate of 0.0001. We employed the Adam optimizer with a learning rate decay schedule to facilitate convergence. To maximize both segmentation accuracy and border delineation, a loss function that combines binary cross-entropy loss and dice loss was employed. We partitioned the dataset randomly into training and testing sets, with an 80:20 split, in order to assess the effectiveness of our algorithm. We carried out numerous studies and presented the findings using a variety of evaluation metrics, including the dice coefficient, intersection over union, and precision-recall curves. The experimental setup ensured rigorous validation and comparison of our proposed system against state-of-the-art methods in medical image segmentation and watermarking.

A. Datasets

The experimental setup involved training our algorithm the ChestX-Det10 dataset [23], a subset of the NIH ChestX-14 dataset [24], which is a widely used and comprehensive dataset for chest radiograph analysis and contains instance-level annotations. This dataset comprises a total of 3,543 images, with 2,779 images depicting various diseases and 764 images representing healthy x-rays. It offers a diverse range of diseases, including atelectasis, calcification, consolidation, effusion, emphysema, fibrosis, fracture, mass, nodules, and pneumothorax, making it suitable for training a fully supervised segmentation method. Fig. 3 shows a sample from the dataset.

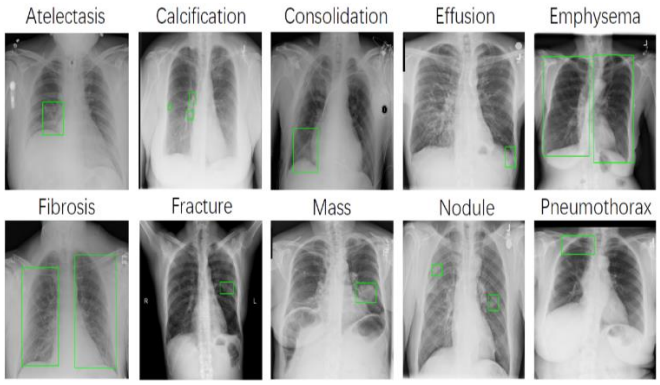

Fig. 3. Samples from dataset.

B. Performance Comparison

The quantitative results of our strategy were compared to those of existing methodologies in the comparison results, and the outcomes are listed in Table I. It is important to note that some methodologies exhibited PSNR values exceeding 50 dB, which can be attributed to differences in the input data format used for evaluation. However, it is crucial to consider that the proposed method maintained a consistent and comparable average PSNR value within the range of 49.32 to 50 dB, indicating its robustness and effectiveness in preserving image quality. The PSNR values per image are depicted in Fig. 4, showcasing that our model attains a PSNR value of 50.0 for image 1, 49.73 for image 2, 47.17 for image 3, 49.79 for image 4, and 49.91 for image 5.

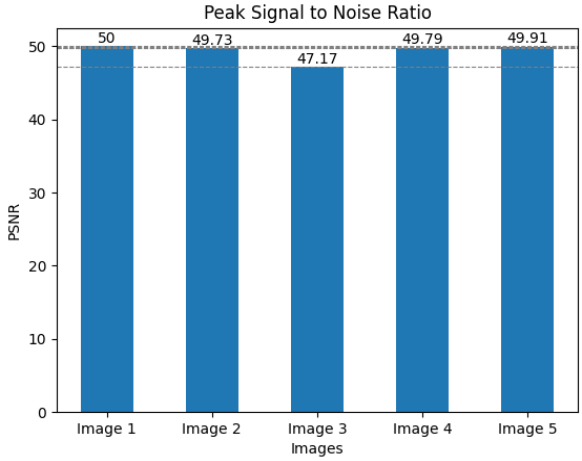

Fig. 4. PSNR values after watermarking.

Furthermore, the average SSIM values obtained by the proposed method demonstrated a high level of similarity and structural preservation with the original image, outperforming several existing methodologies. Similarly, the SSIM values per image are illustrated in Fig. 5, revealing that our model achieves an SSIM value of 1.0 for image 1, 0.99 for image 2, 0.99 for image 3, 0.98 for image 4, and 0.99 for image 5.

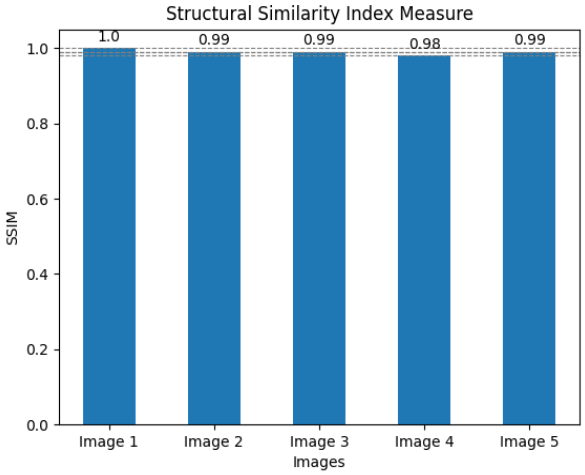

Fig. 5. SSIM values after watermarking.

These results underscore the superiority of the proposed method in terms of both PSNR and SSIM metrics, highlighting its potential for accurate and reliable watermarking in medical image applications.

C. Qualitative Evaluation

We used a variety of evaluation metrics, such as Intersection over Union (IoU), Dice coefficient, and F1 score, in our qualitative evaluation of the proposed approach. These metrics offer useful information about the effectiveness and precision of the segmentation findings. The Dice coefficient quantifies how similar the two sets are while the intersection over union assesses the overlap between the anticipated and real-world masks. The F1 score also assesses how well precision and memory are balanced. We were able to fully comprehend the algorithm's segmentation abilities and its capacity to precisely outline the regions of interest in the medical images by making use of these several assessment matrices. The plot of training and validation loss, shown in Fig. 6, provides valuable insights into the learning progress of our model. During the training phase, the model undergoes iterative optimization, where the loss is minimized to improve its performance. As the training progresses, the model's training loss steadily decreases. In our case, the training loss reaches a remarkable value of approximately 0.02, indicating that the model has learned to capture and generalize patterns effectively from the training data.

Similarly, the validation loss, which measures the model's performance on unseen data, also decreases during training. An approximate validation loss of 0.03 signifies effective generalization of the model to novel data, demonstrating its capability to provide accurate predictions even for previously unseen instances. The convergence of both training and validation loss, shown in Fig. 6, to such low values demonstrates the effectiveness of our model in capturing complex patterns and achieving high accuracy in segmentation tasks. It highlights the model's ability to generalize well and indicates its potential for robust performance in real-world scenarios.

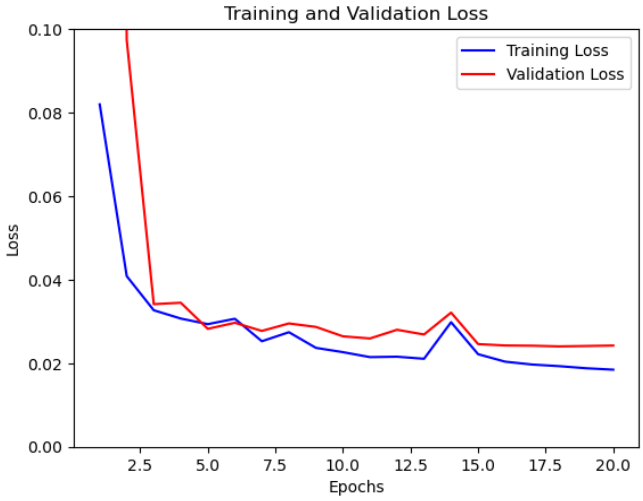

Fig. 6. Training and validation loss.

The findings and details of the matrices are given below:

1) Intersection over union: A frequently used evaluation statistic for gauging the precision of segmentation models is intersection over union. It quantifies the degree of overlap between the anticipated segmentation mask and the obtained segmentation mask. It determined mathematically by dividing the intersection area of the predicted mask (P) and the ground truth mask (G) by the union area of these masks:

$$\text{IoU} = |P \cap G| / |P \cup G| \quad (3)$$

where, $|P \cap G|$ represents the area of intersection between P and G, and $|P \cup G|$ represents the area of union.

The intersection over the union metric spans a range from 0 to 1. A score of 0 denotes a complete absence of overlap between the predicted and ground truth masks, while a score of 1 signifies a flawless alignment. In the context of our proposed methodology, we utilized IoU as the evaluation metric to assess the results produced by our U-Net model with ResNet50 as the backbone. As shown in Fig. 7, we were capable of objectively evaluating the accuracy of the segmentation by computing the IoU score for each segmented area and quantitatively measuring the degree of concordance between the expected and actual masks.

2) Dice coefficient: In the context of image segmentation, the Dice coefficient is a frequently used evaluation metric for determining how similar two sets are. The Dice coefficient is determined mathematically as the reciprocal of the intersection area between the P and the G divided by the sum of the P and G intersection areas:

$$\text{Dice Coefficient} = 2 * |P \cap G| / (|P| + |G|) \quad (4)$$

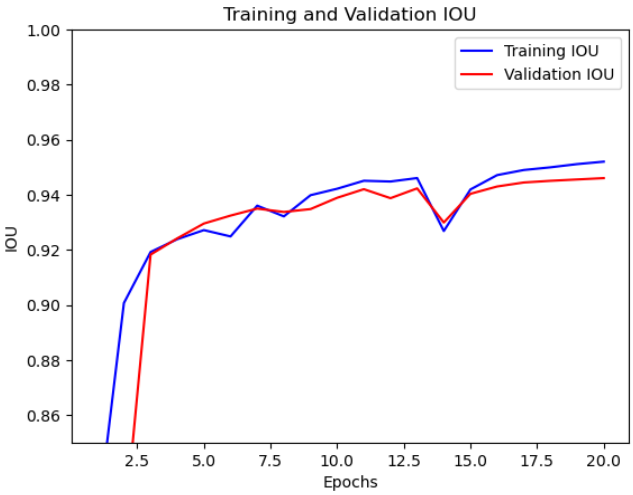

Fig. 7. IoU result.

where, |P ∩ G| represents the area of intersection between P and G, |P| represents the area of P, and |G| represents the area of G. The range of the Dice coefficient is 0 to 1. Between the anticipated and ground truth masks, a value of 0 indicates there is no overlap and a value of 1 indicates full congruence. In the context of our proposed methodology, we employed the Dice coefficient as the assessment metric to gauge the precision and excellence of the segmentation outcomes. Through the utilization of the Dice coefficient, we conducted a rigorous quantitative assessment of the segmentation performance within our proposed methodology. By computing the Dice coefficient for each segmented region, we were able to precisely evaluate the extent of concurrence between the predicted and the ground truth, thereby delivering a reliable metric for segmentation accuracy. As depicted in Fig. 8, our evaluation showcased exceptional performance, with the resulting plot graph indicating a Dice coefficient of approximately 0.98, which represents the highest achievement on the validation dataset. This outcome underscores the efficacy and robustness of our approach in achieving superior segmentation outcomes.

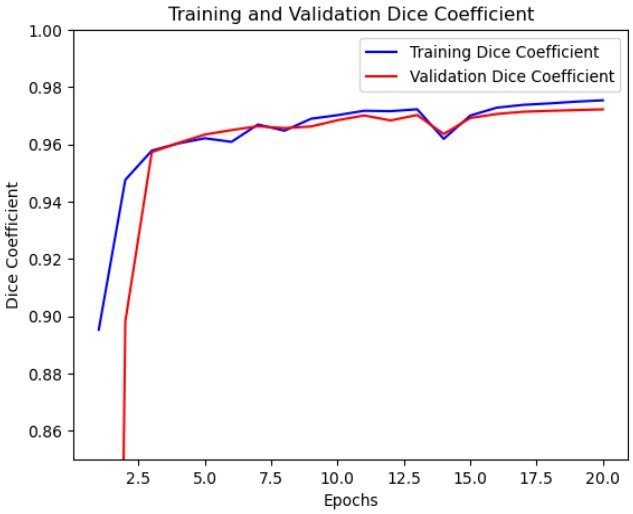

Fig. 8. Dice coefficient result.

3) F1 score: In the proposed methodology, the F1 score was utilized as an evaluation metric to assess the performance of the segmentation model. The performance is evaluated using the F1 score, which takes precision and recall into account. It provides a balanced assessment by taking into account the trade-off between correctly identifying positive samples (precision) and capturing all actual positive samples (recall). Mathematically, the F1 score is calculated as follows:

$$F1\ Score = 2 * (\text{precision} * \text{recall}) / (\text{precision} + \text{recall} \quad (5)$$

Recall corresponds to the ratio of true positive predictions to the total number of positive predictions, while precision quantifies the ratio of true positive predictions to the overall instances identified as positive. An increase in the F1 score, which runs from 0 to 1, suggests improved segmentation performance. By using the F1 score as an evaluation metric, we were able to evaluate the segmentation model's capability to precisely detect the regions of interest within the medical images, considering both precision and recall simultaneously. This metric provided a comprehensive measure of the model's performance in capturing the relevant features while minimizing false positives and false negatives pixels. The evaluation of our proposed model on the validation data demonstrated outstanding performance, with an achieved F1 score of 0.96, shown in plot of Fig. 9. This high F1 score indicates the model's exceptional precision and recall values, highlighting its efficacy in achieving accurate and reliable segmentation results. The superior performance of our proposed model underscores its capability to effectively handle complex medical imaging data and accurately delineate regions of interest.

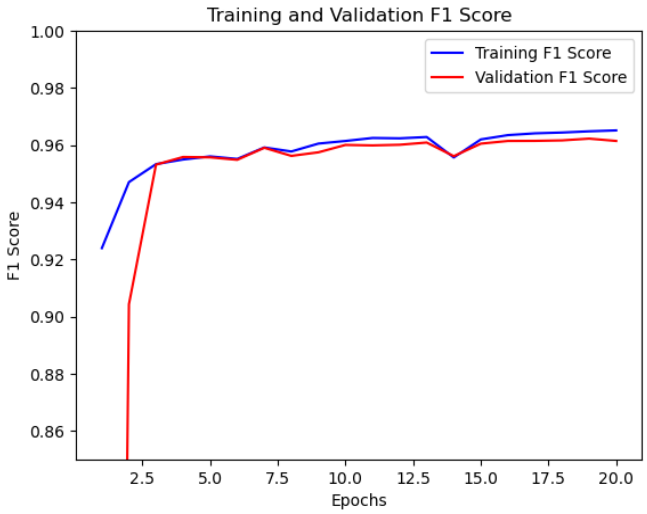

Fig. 9. F1 score result.

4) Segmentation pictorial results: The figure illustrates the input image and the comparative analysis of the output binary mask predicted by the proposed segmentation algorithm, and the ground truth binary mask. In this analysis, the input image represents the original image that was fed into the segmentation algorithm for processing. The segmentation

algorithm produces a binary mask, where each pixel is assigned a value of either 0 or 1, indicating the presence or absence of the region of interest. The ground truth binary mask serves as the expected segmentation result, obtained through manual annotation or another reliable source. By placing these three images side by side in Fig. 10, we can visually assess the performance of the segmentation algorithm by comparing the agreement between the algorithm's output and the ground truth. This comparative analysis provides valuable insights into the accuracy and Efficacy of the suggested segmentation algorithm in precisely outlining the area of interest within the input image.

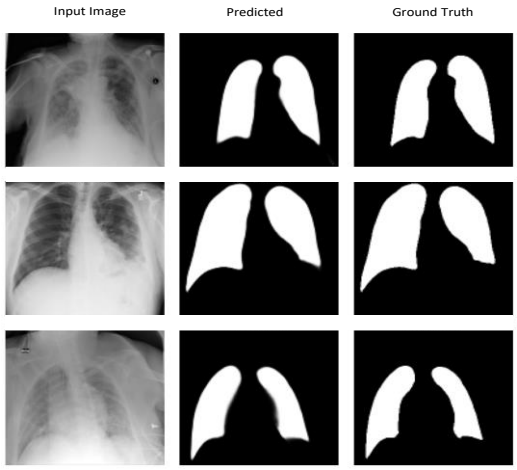

Fig. 10. Comparative result.

D. Quantitative Evaluation

In this study, two quantitative evaluation metrics, namely PSNR, and SSIM, were employed to assess the effectiveness of the introduced approach. PSNR measures the quality of the watermarked image by quantifying the ratio of the maximum signal to noise power. It produces a number that indicates how faithful and similar the watermarked image is to the original image. On the other hand, SSIM assesses the similarity between the watermarked image and source image by considering the luminance, contrast, and structural information. It offers a value between 0 and 1, with practically 1 denoting a perfect match. By utilizing both PSNR and SSIM, a comprehensive evaluation of the proposed method was conducted, allowing for an accurate assessment of its effectiveness in context of image quality preservation and similarity to the original image.

1) Peak signal-to-noise ratio: PSNR quantifies the level of distortion or noise in an image by comparing it to a reference or original image. The PSNR is determined as the mean square error of source and distorted images divided by the peak signal power. It is often expressed in decibels (dB) and provides a numerical value that indicates the similarity between the two images. Higher PSNR values indicate better image quality with less distortion or noise. Mathematically, the PSNR can be computed as:

$$PSNR = 10 * \log10((MAX2) / MSE) \quad (6)$$

where, term MAX indicates the highest pixel value that can be achieved and MSE denotes the mean square error between the original and warped image. The maximum possible PSNR value depends on the pixel intensity range of the images. For images with pixel intensities in the range of 0 to 255 for grayscale or RGB images, the highest PSNR value is typically around 30-50 dB. The proposed method attained a PSNR value of 49.329, indicating its efficacy in maintaining the fidelity and quality of the original grayscale image. By effectively embedding the watermark, the method minimizes distortion and preserves crucial visual information. The high PSNR value underscores the robustness and potential of this approach for secure and reliable image watermarking applications.

2) Structural similarity index: The proposed methodology incorporates the use of SSIM as an evaluation metric for the watermarked image. To mathematically determine SSIM, the mean, standard deviation, and covariance of the pixel intensities in the reference (original) image and the warped (watermarked) image are compared. The SSIM index ranges between -1 and 1, where 1 indicates maximum similarity and a value close to -1 indicates significant dissimilarity. The average SSIM value of 0.99 achieved by the proposed watermarking method serves as a strong testament to its remarkable efficiency in preserving the structural similarity and quality of the original image. This outstanding result demonstrates the validity of the proposed system in embedding the watermark while ensuring minimal distortion and preserving the visual integrity of the image.

V. Conclusion

In conclusion, this article presented a novel watermarking methodology that combines the strengths of the SVD algorithm and the U-Net architecture with a pre-trained ResNet50 model as the bottleneck. The proposed methodology demonstrated remarkable efficiency in preserving the fidelity and quality of the original image while effectively embedding the information using XOR encryption to ensure data integrity and copyright protection. Through rigorous experimentation and evaluation on a chest radiograph dataset, the algorithm showcased its effectiveness in accurately segmenting regions of interest and embedding watermarks while maintaining the coherence of the medical images. The integration of the U-Net model with the pre-trained ResNet50 model as the bottleneck proved to be a powerful combination, enabling the algorithm to leverage the deep learning capabilities of ResNet50 for feature extraction and the U-Net's architectural design for precise segmentation. This hybrid approach contributed to the algorithm's exceptional segmentation accuracy and its ability to preserve crucial medical information. Furthermore, the application of the SVD algorithm for watermarking provided a robust and imperceptible means of embedding and extracting information within the segmented regions. The algorithm successfully achieved secure and reliable watermarking while ensuring minimal distortion to the original medical images. The experimental results showed that, in terms of segmentation accuracy and watermark robustness, the suggested methodology outperformed previous strategies. The algorithm's high Dice coefficient, F1 score, and intersection over union

values substantiated its efficacy and accuracy in segmenting medical images and extracting embedded information.

We also have plans to evaluate the approach in many scenarios in the future, including multimedia applications and other medical imaging. Furthermore, evaluating how well the method works on various systems and maintaining compatibility will be crucial components of future research. The ultimate objective is to improve the method by utilizing cutting-edge strategies that strike a balance between security, effectiveness, and usability, opening the door for its smooth incorporation into useful domains.
