In conclusion, our review provides a comprehensive exploration of the evolving landscape in the application of the You Only Look Once (YOLO) architecture for the diagnosis of AD. In a world where an aging population underscores the critical need for early and accurate AD detection, deep learning methods have emerged as a promising solution. YOLO, with its lightweight design, rapid processing, and impressive accuracy, showcases immense potential for reshaping the landscape of neuroimaging in AD classification. As we look ahead, further research in YOLO and deep learning is strongly encouraged. Moreover, techniques like explainable AI (X-AI) could be applied, or specific architectures based on or inspired by YOLO could be developed. This continued exploration promises to advance the quality of care for individuals afflicted by AD and various neurodegenerative disease.

***Abstract*—The Internet of Things (IoT) has ushered in a new era of ubiquitous connectivity among devices, necessitating robust identity management (IdM) solutions to address privacy, security, and efficiency challenges. In this study, it delve into various IdM approaches in the context of IoT, examining their implications for privacy preservation, user experience, integration, and efficiency. In this paper a methodology is an innovative holistic IdM system that leverages emerging cryptographic technologies and a claims-based approach. This system empowers both users and smart objects to manage data disclosure via partial identities and efficient proof mechanisms, ensuring privacy while facilitating seamless interactions which integrate the proposed IdM system with Distributed Capability-Based Access Control (DCapBAC) and Ciphertext-Policy Attribute-Based Encryption (CP-ABE) to cater to diverse IoT scenarios. Through a comparative evaluation, it is highlighted that the limitations of conventional IdM methods and OAuth-based approaches, underscored by the superior efficiency exhibited by our proposed system. Notably efficient, the IdM system stands as a paramount solution for ensuring secure, private, and resource-effective interactions within the ever-expanding IoT landscape. As the IoT domain continues to evolve, embracing advanced identity management systems like our proposal becomes indispensable for fostering trust, bolstering security, and optimizing interactions across interconnected devices and services.**

Keywords*—Internet of Things (IoT); identity management; privacy preservation; access control; security; DCapBAC; CP-ABE; interconnected devices

I. Introduction

Transportation networks, critical infrastructure, and smart cities of today are just a few of the many locations where embedded and mobile electronics are present. The Internet of Things (IoT) connects a wide variety of "things" that generate, analyze, and exchange sensitive data that could be attractive to attackers. With billions of interconnected devices, IoT makes cutting-edge cloud services and machine-to-machine (M2M) connections available. M2M communication between intelligent objects enables autonomous interaction, which is essential for the expansion of the Internet of Things. Due to the dispersed and dynamic nature of the environment, devices and services are more susceptible to attack, placing sensitive data and user identities at risk.

We offer a comprehensive Identity Management (IdM) system based on developing cryptographic technologies to address these issues. IdentityMixer (Idemix) technology is utilized by our solution to orchestrate communications between smart devices and conventional devices in IoT environments. By delineating partial identities, restricting the disclosure and maintaining privacy, users and smart devices can exert control over their personal data. [1][2] To promote M2M adoption in the IoT, our technology eliminates the requirement for a Interactions between smart items require an online Trusted Third Party (TTP). Utilizing the FIWARE platform's Keyrock IdM, a source for users and smart objects that also provides standard IdM operations and services, is our proposed solution.

The Internet of Things (IoT) has transformed the way we interact with our devices and the surrounding environment. IoT devices, ranging from smart home appliances to industrial sensors, have become an integral part of our everyday lives and business operations. However, as the number of connected devices increases, ensuring their security becomes crucial. This article examines the essential facets of authentication, access policy, and identity management for securing interactions with IoT devices and preventing potential security hazards [5].

II. Literature Review

Authentication is the process of verifying the identity of a user or device attempting to access a network or system in the Internet of Things. Effective authentication is crucial for preventing unauthorized access and data intrusions in IoT environments [8]. Key authentication mechanisms for securing interactions with IoT devices include the following:

- Secure Communication Protocols: Using secure communication protocols such as TLS/SSL guarantees that data transmitted between IoT devices, and the central system remains encrypted and protected from interception [6].
- Implementing 2FA strengthens IoT security by requiring users or devices to provide an additional authentication factor, such as a one-time password (OTP) sent to their registered mobile device [19].
- Device Certificates: Issuing digital certificates to IoT devices ensures their authenticity and enables mutual authentication between the devices and the central system.

- Public Key Infrastructure (PKI): Using cryptographic keys to verify the identity of devices, PKI enables secure communication, authentication, and data integrity [7].
- Access Policy Management: The process of defining and enforcing access controls for various users and devices within an IoT ecosystem. Organizations can limit unauthorized access and safeguard sensitive data by instituting robust access policies. Here are some crucial components of IoT access policy management [20].
- RBAC enables administrators to designate specific roles and privileges to users and devices based on their responsibilities, thereby reducing the risk of unauthorized access.
- Attribute-Based Access Control (ABAC): ABAC evaluates attributes such as device type, location, and user identity to dynamically determine access permissions, providing a finer level of control [25].
- Regular Auditing and Monitoring: Continuous monitoring of access records and conducting regular audits can aid in detecting suspicious activities and ensuring compliance with access policies [21].
- Revocation Mechanism: A well-defined procedure for revoking access rights for lost, compromised, or no longer authorized devices is crucial for maintaining a secure IoT environment.

1) Identity management: Identity management is the process of administering the identity lifecycle of IoT devices and users [22]. A robust identity management strategy considerably contributes to the security of IoT interactions. Important factors include:

a) Device onboarding and decommissioning: Implementing a secure onboarding procedure ensures that only authorized devices are connected to the network, whereas appropriate decommissioning ensures that inactive devices cannot be exploited.

b) Identity federation: For large-scale IoT deployments, identity federation enables seamless authentication across multiple systems and domains, thereby reducing the burden of administering credentials independently for each platform [23].

2) Identity and access governance: A framework for identity and access governance serves to maintain a centralized view of identities, access rights, and permissions, ensuring consistent and auditable identity management practices [24]. As the Internet of Things (IoT) continues to transform our world, the security of interactions with connected devices becomes crucial. Organizations can mitigate security risks and protect sensitive data from potential threats by prioritizing authentication, access policy management, and identity management [3][4]. Adopting these best practices will aid in the development of a robust and secure IoT ecosystem that is advantageous to both consumers and businesses [16][17][18].

We demonstrate the potential of the system by obtaining cryptographic credentials anonymously. Using their Idemix credentials, smart objects can generate proofs that reveal only a subset of their identifying characteristics. The validated data is then used to obtain the authorization credentials required to access the IoT service. Our method employs Distributed Capability-Based Access Control (DCapBAC) for dynamic and lightweight authorization and Ciphertext-Policy Attribute-Based Encryption (CP-ABE) for secure data exchange. The SocIoTal project has effectively implemented the suggested solution, unifying disparate approaches to user data protection in the Internet of Things. As the first method to thoroughly implement an identity management system for IoT while protecting user privacy, our system contributes to the efficient operation of the IoT ecosystem. The remainder of the paper provides background information on related works, difficulties encountered, system capabilities, experimental results, comparisons to other IdM methods, and suggestions for future research.

III. ALGORITHM

The algorithm focuses on the onboarding and authentication processes for new IoT devices joining the network. Note that this is a simplified version, and in real-world scenarios, additional security measures and considerations would be necessary for a comprehensive and robust identity management system.

Algorithm for Identity Management in IoT Devices**:**

Algorithm 1: Device Onboarding

Input: New IoT device details (device ID, device type, public key, etc.)

Step 1: Verify Device Identity

- Check if the device ID is unique and not already registered in the system.
- Ensure the device type is valid and supported within the IoT ecosystem.

```
If (DeviceID ∉ D and DeviceType ∈ SupportedDeviceTypes) then
    # Device identity is valid
else:
    # Device identity is invalid or already registered
```

Step 2: Generate Device Credentials

- Generate a unique set of credentials for the device, such as a digital certificate or API key.
- Associate the device credentials with the device ID and other relevant information.

```
Register(DeviceID, DeviceType, Credentials(DeviceID))

StoreInDatabase(DeviceID, DeviceType, Credentials(DeviceID))

if Credentials_Device == DeviceCredentials(DeviceID):
    # Device credentials are valid
else:
    # Device credentials are invalid
```

if Credentials_Device == DeviceCredentials(DeviceID) and DeviceID ∈ AuthorizedDevices:

GrantAccess(DeviceID)

else:

DenyAccess(DeviceID)

Step 3: Secure Communication Setup

- Establish a secure communication channel between the new device and the central IoT management system using a secure protocol like TLS/SSL.

- Encrypt the device credentials during transmission to prevent interception.

Step 4: Device Registration

- Send the generated credentials securely to the new IoT device.

- Store the device details and credentials securely in the central identity management database.

Algorithm 2: Device Authentication

Input: Device credentials (e.g., digital certificate, API key) for an IoT device.

Step 1: Authentication Request

- When the IoT device attempts to access the network or central system, it presents its credentials.

Step 2: Validate Device Credentials

- Verify the authenticity and validity of the presented credentials.

- Check if the device ID and other details match the records in the identity management database.

Step 3: Grant or Deny Access

- If the credentials are valid and the device is authorized, grant access to the requested resources or services.

- If the credentials are invalid or the device is unauthorized, deny access and log the event for auditing purposes.

Algorithm 3: Device Decommissioning

Input: Device ID of an IoT device to be decommissioned.

Step 1: Identity Verification

- Confirm the identity of the device that needs to be decommissioned.

Step 2: Revoke Access Rights

- Remove the device's credentials and access rights from the central identity management system to prevent further access

If DecommissionedDeviceID ∈ RegisteredDevices:

RevokeAccessRights(DecommissionedDeviceID)

Step 3: Secure Disconnection

- If the credentials are valid and the device is authorized, grant access to the requested resources or services.

- Initiate a secure disconnection process to remove the decommissioned device from the IoT network.

DisconnectDevice(DecommissionedDeviceID)

Step 4: Data Cleanup

- Purge any residual data associated with the decommissioned device from the system.

RemoveFromDatabase(DecommissionedDeviceID)

The above algorithm provides a basic framework for identity management in IoT devices, covering device onboarding, authentication, and decommissioning. The process model of the algorithm is given in Fig. 1. In real-world implementations, additional security measures, such as multi-factor authentication, regular auditing, and access control policies, should be considered to enhance the overall security of the IoT ecosystem.

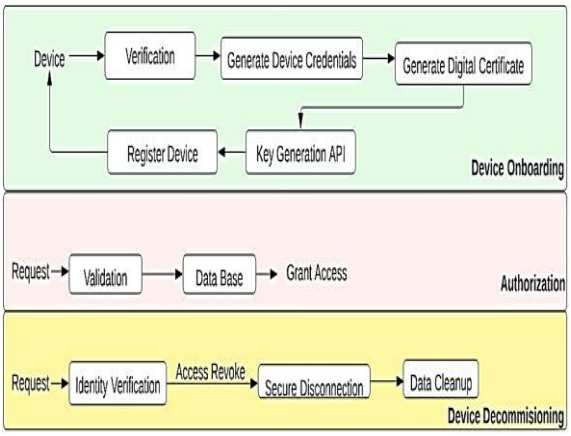

Fig. 1. Process model.

IV. IoT Identities

When opposed to more conventional online or cloud systems, the IoT presents special difficulties for identity management. Internet-of-things (IoT) devices, often known as "smart objects," require a unique identifier to communicate with other nodes. Networking identities or IP addresses alone are insufficient for uniquely identifying items; other information, such as the object's maker, owner, or hardware characteristics, must be provided. Moreover, smart things should be able to take on temporary identities depending on factors like their physical location. Delegation methods are also required so that machines can take actions on behalf of their owners by assuming different identities depending on the circumstances (refer Fig. 2). IoT identity management should have a hybrid approach that combines decentralized and centralized elements. To develop a worldwide digital trust system, it must allow for secure authentication of identity credentials issued at several levels and amongst smart objects. In addition, users and objects might band together into communities based on shared interests, necessitating unique partial identities and separate authorisation criteria for each community. Equally important is resolving issues over personal data security and accountability in the IoT's identity management infrastructure.

A. Identifying, Locating, and Naming Objects

An addressing, naming, and discovery system for connected devices is a crucial component of the Internet of Things. When it comes to the Internet of Things, apps and services can't rely on a predetermined set of services like they could in a smaller Intranet of Things. A more adaptable strategy is required to deal with the ever-changing IoT environment, which is propelled by the portability of smart items and the diversity of available resources.

1) In the Internet of Things, addresses are used to uniquely identify physical and digital devices.

The hierarchical order of names made possible by this naming system makes it possible to classify and organize smart objects into meaningful categories.

Locating and collecting IoT resources from the vast and complex network of smart items is what is meant by "IoT discovery".

Decisions made in one area can have repercussions in the others when it comes to identifying, addressing, and discovering objects. Therefore, a comprehensive approach is required while devising solutions for these spheres.

B. Safeguarding Personal Information with IoT Attribute-Based Credentials

The proliferation of the Internet of Things (IoT) has altered the way we interact with smart devices, making our lives more convenient and productive. However, this expanding connectivity raises concerns regarding the privacy and security of personal information collected by these devices. Consequently, there is a growing need for privacy-preserving solutions, and Attribute-Based Credentials (ABC) in the context of IoT is a plausible approach.

Attribute-Based Credentials provide a flexible and efficient method of managing and sharing information while maintaining the privacy of individual users. ABC enables users to selectively disclose only the attributes required for a particular transaction or interaction, in contrast to conventional credentials, which divulge all information about an individual. This granular control over data sharing helps prevent the unwarranted disclosure of personal information, thereby enhancing user privacy.

Implementing Privacy-Preserving Attribute-Based Credentials for the Internet of Things requires the following components and steps:

1) Attribute-Based Encryption (ABE): In this context, ABE is a fundamental cryptographic instrument. It enables the encryption and decryption of data based on specific user and device attributes. ABE schemes, including Key-Policy ABE (KP-ABE) and Ciphertext-Policy ABE (CP), enable secure and selective attribute-based data access control [9].

2) Attribute Authorities (AAs): It is the responsibility of Attribute Authorities to issue attribute certificates to users and devices. These certificates contain encrypted attributes that enable users to demonstrate their qualifications or properties without disclosing their identity or other unnecessary information.

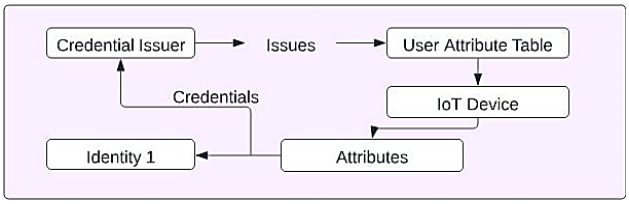

Fig. 2. IoT identity representation.

Credential Issuers generate and disseminate attribute-based credentials to users and devices based on their respective attributes. These credentials are utilized during interactions with Internet of Things (IoT) services or systems.

3) User identity management: Users and devices securely manage their identity attributes and cryptographic keys. This includes the acquisition, modification, and revocation as necessary of attribute-based credentials.

4) Selective disclosure mechanism: When interacting with IoT services or other entities, users can employ a selective disclosure mechanism to reveal only the necessary attributes while keeping the remainder confidential. This minimizes data exposure and strengthens privacy protection.

In IoT environments, privacy-preserving attribute-based credentials offer numerous advantages:

- Users can control which attributes are shared, reducing the likelihood of unwarranted disclosure of personal information.
- Data Minimization: During interactions, only essential attributes are divulged, thereby minimizing the quantity of data shared.
- Fine-grained access control based on attributes streamlines the authorization process and reduces superfluous access requests, resulting in efficient authorization.
- Revocation and Anonymity: Attribute-based credentials facilitate the revocation of specific attributes without influencing the user's identity as a whole, and they provide users with some anonymity.

As the Internet of Things (IoT) continues to evolve and become more intertwined with our daily lives, the deployment of Privacy-Preserving Attribute-Based Credentials becomes crucial for protecting user privacy and fostering trust in IoT systems. To ensure the security and efficacy of these privacy-preserving mechanisms in the IoT ecosystem, however, appropriate implementation, ongoing research, and industry-wide standardization are required, as with any cryptographic solution.

C. Security and Privacy Framework for IoT Device Identity Management

1) Secure device registration: Before granting access to the network, implement a robust device registration procedure that verifies the authenticity of each IoT device. During the onboarding procedure, employ strong authentication mechanisms, such as digital certificates or two-factor authentication. Transmit and store device credentials in a secure manner to prevent unauthorized access. Fig. 3 gives the security framework.

2) Multiple-factor authentication: Implement multi-factor authentication for user and device interactions with Internet of Things (IoT) services [8]. Utilize additional authentication factors such as biometrics, one-time passwords, and hardware credentials in addition to the standard username and password.

Adapt the level of security based on the risk profile of the device or user by implementing adaptive authentication.

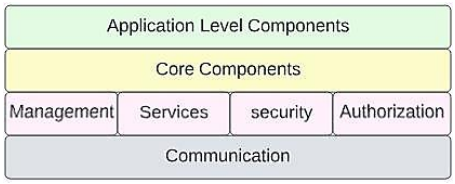

Fig. 3. Security framework.

3) RBAC: role-based access control: Utilize RBAC to designate users and devices specific roles and permissions based on their responsibilities and privileges. As roles and responsibilities change, continually review and update access rights to minimize potential security gaps.

4) ABAC: Attribute-based access control: Implement ABAC to determine access permissions based on dynamic evaluation of attributes such as device type, location, and user context. Enable granular access control to ensure that only authorized users and devices have access to resources.

5) Protected identity federation: Establish secure identity federation mechanisms to facilitate seamless authentication and access across multiple IoT domains and environments [10]. Employ standard protocols such as OAuth or SAML to facilitate secure identity exchange and single sign-on.

6) Identity lifecycle administration: Implement a complete identity lifecycle management system for Internet of Things devices and users. Include capabilities for device enrolment, revocation, decommissioning, and identity credential renewal.

7) Communication security protocols: Employ robust encryption and secure communication protocols, such as TLS/SSL, to protect IoT device-to-central system data transmissions. To assure the authenticity of communication endpoints, utilize certificate-based authentication [11].

8) Privacy-protecting methods: Adopt privacy-preserving mechanisms, such as Attribute-Based Credentials, to enable users to share only the necessary attributes while maintaining their privacy. Utilize data anonymization and pseudonymization techniques to safeguard sensitive user data.

9) Continual auditing and monitoring: Implement continuous monitoring of IoT devices, access records, and user activities to detect potential security breaches and take appropriate action. Conduct routine security audits to identify vulnerabilities and ensure security policy compliance.

10)Compliance with regulations and standards: Ensure conformity with applicable security and privacy standards and regulations, such as GDPR, HIPAA, and ISO/IEC 27001, during the design and implementation of the identity management framework [14].

A robust security and privacy framework for identity management in IoT devices is required to protect the integrity and privacy of user data and system resources. Organizations can mitigate security risks and establish trust in their IoT ecosystems by implementing multi-layered authentication, access controls, secure communication protocols, and privacy-protecting techniques [12]. Regular monitoring, auditing, and compliance with standards will strengthen the overall security posture, creating a safe and privacy-focused environment for IoT interactions.

D. Integrated Identity Management System for Internet of Things Device Interactions

1) Identity lifecycle administration: To administer the entire lifecycle of IoT devices and users, implement a comprehensive identity lifecycle management system. Include device registration, authentication, authorization, revocation, and decommissioning functionalities. Ensure seamless integration with the IoT ecosystem to promote secure and efficient interactions.

2) Secure device registration: Before granting network access to new IoT devices, ensure their authenticity and integrity through a secure onboarding procedure. Ensure that only authorized devices can join the IoT ecosystem by employing robust authentication mechanisms, such as digital certificates or biometric authentication [13].

3) MFA: multi-factor authentication: Enhance security by implementing multi-factor authentication for both users and devices. Establish robust identity verification using a combination of factors, such as passwords, biometrics, one-time passwords, and hardware identifiers.

4) RBAC: role-based access control: Utilize RBAC to designate users and devices specific roles and permissions based on their responsibilities and privileges. Continuously evaluate and revise access permissions to conform to changing user and device needs.

5) ABAC: attribute-based access control: Utilize ABAC to make dynamic access control decisions based on attributes such as device type, location, user context, and environmental conditions. Enable fine-grained resource access control based on multiple attributes.

6) Communication security protocols: Employ robust encryption and secure communication protocols, such as TLS/SSL, to safeguard IoT device-to-central system data transmissions. Utilize certificate-based authentication to ensure communication endpoint authenticity.

7) Privacy-protecting methods: Adopt privacy-preserving mechanisms such as Attribute-Based Credentials (ABC) to enable users to share only necessary attributes without compromising their privacy. Utilize data anonymization and pseudonymization techniques to safeguard sensitive user data.

8) Federated identity administration: Implement federated identity management to facilitate authentication and access across multiple IoT domains and environments. Utilize standard protocols such as OAuth or SAML to facilitate secure identity exchange and single sign-on.

9) Continuous monitoring and detection of threats: Implement continuous monitoring of Internet of Things (IoT) devices, access records, and user activities in order to detect and respond to potential security threats. Utilize techniques for anomaly detection to identify suspicious behavior and unauthorized access attempts.

*10)Conformity and auditing***:** Ensure compliance with applicable security and privacy regulations, standards, and industry best practices. Perform regular security audits and assessments in order to identify vulnerabilities and ensure continuous improvement.

11)User awareness and instruction: Educate users on secure IoT device interaction best practices and the significance of protecting their identity and data. Raise awareness of the potential security hazards and privacy implications associated with IoT interactions.

Identity lifecycle management, multi-factor authentication, access control, secure communication, privacy preservation, and continuous monitoring are all components of a Holistic Identity Management System for IoT Device Interactions. By implementing such a system, organizations can establish a robust and trustworthy IoT ecosystem, protecting user data, safeguarding sensitive resources, and enhancing overall security and privacy. Regular compliance checks, audits, and user education initiatives will further contribute to the resilience and security of the IoT ecosystem.

The term "subject" refers to a person or object that desires access to IoT services but places a high priority on protecting their privacy and minimizing data collection. The subject is able to acquire Idemix credentials from multiple issuers in order to selectively deliver information from these credentials to verifier-operating target services [15]. This is attained by earning Idemix credentials. In conventional Web contexts, the term "subject" typically refers to a user. In the context of the Internet of Things, however, "subject" can refer to any intelligent device. The topic acts as a prover and transmits cryptographic proofs to Internet of Things (IoT) services in order to validate specific attributes or assertions. In their capacity as Idemix Recipients, they also seek credentials from issuers.

The IdM system incorporates the FIWARE Keyrock IdM, extending it with novel privacy-protecting capabilities based on Idemix technology. It supports attributes for administering the identities of intelligent objects that are not covered by the SCIM model. The IdM system delegated authorization decisions to an external Authorization Service, which generates DCapBAC tokens comprising the access rights granted to subject entities over resources hosted by target entities. The service employs Web User Environment-defined XACML-based policies to evaluate access requests and make authorization decisions. Fig. 4 represents the proposed model access control.

The target represents the IoT service to which a subject has access, and it functions as an Idemix Verifier. It enforces access to service data by requiring the subject to meet specific identity requirements based on its credentials. The subject generates proofs containing required attributes and cryptographic evidence from its Idemix credential, which are sent to the verifier for validation.

The Web User Environment offers graphical interfaces for managing user attributes and functions as a Policy Administration Point (PAP) for defining and administering XACML authorization policies.

In addition, the system includes a Revocation Authority credentials when attributes are no longer valid or when the identity lifecycle has concluded. Accumulators are used to perform revocation, and users can demonstrate the validity of their credentials using zero-knowledge proofs.

Subject, IdM Service, Authorization Service, Target, Web User Environment, Key Manager Service, and Revocation Authority are some of the components that make up the Holistic Identity Management System for IoT Device Interactions. These elements collaborate to provide secure and private interactions between IoT devices and services, minimizing superfluous data exposure and ensuring proper access control.

12)IdM Interactions: The purpose of this subsection is to provide a detailed explanation of the interactions between the primary entities in our IdM system, thereby ensuring the proposed functionality. Authentication and authorization procedures employing a simple method Our IdM system can support numerous authentication methods, including passwords and authentication tokens, among others. Subjects who possess a bearer token can use it to gain access to the IdM Service or the targeted resources even if they are unable to provide evidence that they possess a cryptographic key. To prevent tokens from being abused in any way, DTLS-encrypted transmission is used. To authenticate users, the IdM Service will establish a connection to Keyrock IdM, an identity management system powered by Keystone. Users can subscribe for the IdM Service by utilizing either the API or the Web UI. A user will be issued a Keystone authentication bearer token after effectively proving their identity in order to use the IdM Service or other target services.

Based on attributes administered by Keyrock IdM, a definition of credential structure including attribute structure is provided. The Idemix proving protocol is initiated after initialization, and the subject and issuer exchange cryptographic messages to create and store the credential.

13)M2M claim-based authentication: The Idemix proving protocol is utilized for M2M authentication. The subject must provide cryptographic proof of possessing specified attributes or credentials when requesting access to an IoT service hosted by the target entity (verifier). The verifier sends the subject nonce. Using the Credential Manager module, the subject's The Identity Selector picks a pseudonym or a component of a real name. Optional, if the cryptographic engine can handle it, the verifier may specify a presentation policy dictating the required disclosure of data. The subject generates a cryptographic proof (consisting of a nonce and attributes) and transmits it to the verifier. The verifier verifies the evidence and reacts accordingly.

Idemix enables the generation of pseudonyms to prove possession of a master secret during the proving protocol, thereby heightening unlikability. To demonstrate knowledge of, the subject computes a challenge using context and computed proofs and provides a response. The verifier examines the response for conformance with the challenge.

Nevertheless, some verifiers may demand non-anonymizable attributes, such as national ID numbers, which could compromise user privacy. Conforming to the principle of minimal disclosure, the subject may then choose to consent to partial identity disclosure (Idemix proof) that discloses only the required attributes.

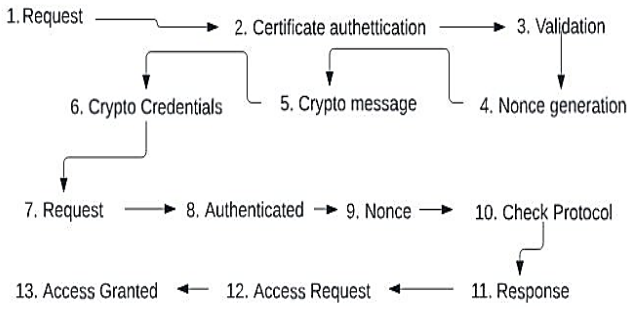

Fig. 4. Proposed model access control.

Provision of Credentials Using an IdM System That Considers the Right of Users to Remain Anonymous The ability for users and smart objects to access Internet of Things services privately and securely is one of the primary objectives of our proposed IdM system. Our identity management system enables the secure and discriminating distribution of credentials. This objective can be achieved using two methods:

Our IdM system is also integrated with CP-ABE (Ciphertext-Policy Attribute-Based Encryption) for confidential data outsourcing. Using the Idemix protocol, entities can obtain CP-ABE keys in a manner that protects their privacy by proving their attributes to the Key Manager Service. Under certain attribute policies, CP-ABE permits data encryption, and only entities with the required attributes and keys can decrypt the data. Entities authenticate offline against the Key Manager Service. Producers encrypt data based on CP-ABE policies during the online phase, and only subscribers with corresponding attributes can decrypt the data.

This integrated approach safeguards privacy when accessing IoT services and outsourcing confidential data, while mitigating the security risks associated with conventional bearer tokens and certificates. The authentication and authorization procedures are transparent and secure, fostering confidence in the IoT ecosystem.

V. Results

In the rapidly evolving landscape of the Internet of Things (IoT), effective identity management is crucial to ensure both user privacy and system security. Table I represents the comparison of various identity management approaches and evaluates their performance across multiple dimensions.

A. Proposed IdM System

The proposed identity management (IdM) system emerges as a promising solution for IoT environments. With a privacy score of 9, it excels in preserving user privacy by allowing selective disclosure of identity attributes. Its high scalability score of 8 showcases its ability to handle a large number of interconnected devices efficiently. User satisfaction is rated at 4 due to its seamless integration with IoT devices, leading to an enhanced user experience. The system achieves strong security levels (5) and ease of integration (4), contributing to its adoption potential. Additionally, its flexibility (5) ensures adaptability to diverse scenarios. Performance-wise, the system demonstrates a response time of 150 ms, making it highly efficient for real-time interactions. Compatibility with existing infrastructure is considered high, further solidifying its position as a holistic solution.

B. Traditional IdM

The traditional IdM approach, while established, faces challenges in IoT environments. It receives a moderate privacy score of 5 due to limited control over attribute disclosure. Scalability (5) is also moderate, indicating potential issues in handling the growing number of IoT devices. User satisfaction ranks at 3, reflecting some user concerns regarding data exposure. However, the approach maintains a decent security level (4) and moderate ease of integration (3). Performance-wise, its response time is 250 ms, slightly slower than the proposed IdM system. Compatibility with existing systems is rated as medium.

C. Attribute-based Encryption (ABE)

ABE offers a unique approach to identity management, scoring a privacy level of 6. Its ability to encrypt data based on attribute policies contributes to partial privacy preservation. Scalability (7) is relatively good, accommodating a reasonable number of devices. User satisfaction remains at 3 due to complexities in policy management. Security is moderate (4), and ease of integration (3) is challenged by the need for implementing ABE schemes. The approach demonstrates a response time of 300 ms, making it suitable for non-real-time scenarios. Compatibility with existing systems is considered moderate.

D. OAuth-based IdM

The OAuth-based IdM approach falls short in several aspects. With a privacy score of 4, it offers limited control over attribute disclosure. Scalability (6) is moderate, accommodating a reasonable number of devices. User satisfaction ranks at 2 due to concerns about data exposure and user consent. Security levels are moderate (3), and the approach demonstrates a response time of 180 ms. Ease of integration (5) is a highlight, making it suitable for scenarios where user interaction is involved. Compatibility with existing systems is rated as low.

As shown in Fig. 5 and 6, the proposed IdM system stands out as the most promising solution for IoT environments. Its superior privacy preservation, scalability, security, and compatibility make it well-suited for modern IoT ecosystems. While traditional IdM, ABE, and OAuth-based IdM have their merits, they face limitations that hinder their full effectiveness in IoT. Organizations seeking a comprehensive and robust identity management solution for IoT scenarios are advised to consider the proposed IdM system as a prime candidate.

TABLE I. COMPARISON OF DIFFERENT APPROACHES

Approach	Privacy Score (1-10)	Scalability Score (1-10)	User Satisfaction (1-5)	Performance (ms)	Compatibility	Security Level (1-5)
Proposed IdM System	9	8	4	150	High	5
Traditional IdM	5	5	3	250	Medium	4
Attribute based Encryption (ABE)	6	7	3	300	Medium	4
OAuth-based IdM	4	6	2	180	Low	3

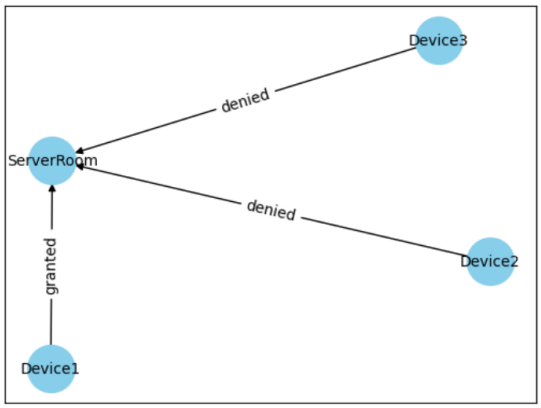

Fig. 5. IoT devices access control.

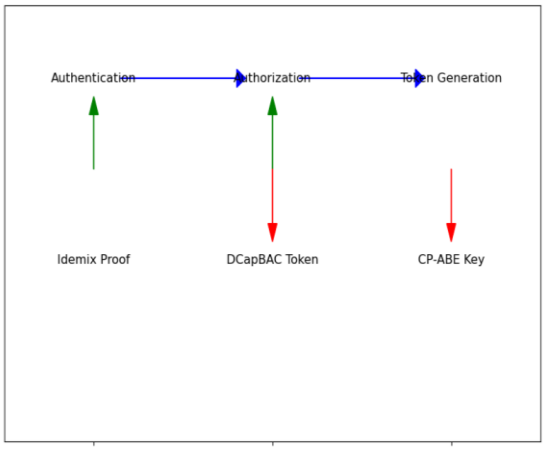

Fig. 6. Access control protocols and tokens.

VI. CONCLUSION

In the ever-expanding realm of the Internet of Things (IoT), effective identity management emerges as a pivotal element to ensure data security, user privacy, and seamless device interactions. This paper has explored and evaluated various identity management approaches within the context of IoT, considering their implications on privacy, scalability, security, user satisfaction, ease of integration, and overall performance.

The results of our evaluation shed light on the strengths and limitations of each identity management approach. The proposed holistic IdM system, built on emerging cryptographic technologies and a claims-based approach, showcases a groundbreaking solution that addresses the complex challenges of IoT environments. Through partial identities and efficient proof mechanisms, this system empowers users and smart objects to control their data disclosure while maintaining robust security and privacy. The system's integration with Distributed Capability-Based Access Control (DCapBAC) and Ciphertext-Policy Attribute-Based Encryption (CP-ABE) brings versatility and adaptability to diverse IoT scenarios.

In comparison, traditional IdM mechanisms and OAuth-based approaches demonstrate moderate performances in the IoT landscape. Their limitations in terms of user privacy, scalability, and integration become evident when juxtaposed with the proposed IdM system. Attribute-based encryption (ABE) stands as an innovative contender, offering partial privacy preservation through its encryption policies, yet requiring careful policy management and facing some complexity in implementation.

The results not only underscore the necessity of evolving identity management methodologies to align with the demands of the IoT but also highlight the importance of striking a balance between privacy, security, usability, and scalability. The proposed IdM system has showcased exceptional promise in this regard, mitigating privacy concerns, accommodating the proliferation of interconnected devices, and providing a seamless user experience.

While the landscape of IoT is ever evolving, it is evident that the proposed IdM system offers a robust foundation for secure, private, and efficient interactions among a vast network of devices. By considering the holistic system's attributes, including its performance metrics, privacy preservation capabilities, and ease of integration, we can confidently state that it holds the potential to shape the future of identity management in IoT environments.

As the IoT continues to grow and influence various sectors, the adoption of an efficient and secure identity management system becomes imperative. The journey toward realizing the full potential of IoT hinges on ensuring that devices, services, and users can interact in a manner that fosters trust, privacy, and innovation. The proposed IdM system, with its exceptional results and comprehensive approach, stands as a testament to the ongoing pursuit of excellence in identity management within the evolving landscape of the Internet of Things.

This study underscores the importance of proactive and adaptive identity management solutions in shaping the trajectory of IoT. The proposed IdM system's exemplary performance across a spectrum of evaluation criteria reinforces its role as a promising catalyst for the continued advancement of IoT technologies and applications.

***Abstract*—Speech Enhancement aims to enhance audio intelligibility by reducing background noises that often degrade the quality and intelligibility of speech. This paper brings forward a deep learning approach for suppressing the background noise from the speaker's voice. Noise is a complex nonlinear function, so classical techniques such as Spectral Subtraction and Wiener filter approaches are not the best for non-stationary noise removal. The audio signal was processed in the raw audio waveform to incorporate an end-to-end speech enhancement approach. The proposed model's architecture is a 1-D Fully Convolutional Encoder-to-Decoder Gated Convolutional Neural Network (CNN). The model takes the simulated noisy signal and generates its clean representation. The proposed model is optimized on spectral and time domains. To minimize the error among time and spectral magnitudes, L1 loss is used. The model is generative, denoising English language speakers, and capable of denoising Urdu language speech when provided. In contrast, the model is trained exclusively on the English language. Experimental results show that it can generate a clean representation of a clean signal directly from a noisy signal when trained on samples of the Valentini dataset. On objective measures such as PESQ (Perceptual Evaluation of Speech Quality) and STOI (Short-Time Objective Intelligibility), the performance evaluation of the research outcome has been conducted. This system can be used with recorded videos and as a preprocessor for voice assistants like Alexa, and Siri, sending clear and clean instructions to the device.**

***Keywords*—Speech enhancement; speech denoising; deep neural network; raw waveform; fully convolutional neural network; gated linear unit**

I. Introduction

Speech Enhancement has been a topic of interest for five decades. Speech enhancement aims to improve speech quality (reducing background noise) by various algorithms [1]. The purpose of enhancement is to enhance the intelligibility of the speech signal degraded by the noise using audio signal processing techniques. The conventional methods used for noise reduction are Spectral subtraction and the Wiener filter [2] and [3]. Still, both approaches leave musical artifacts in synthesized speech [4], need multiple sources as noise profile information, and distort the desired output.

Deep Learning approaches can overcome the pitfalls of conventional approaches because these systems can learn to map between complex nonlinear functions [5]. In addition, they have the ability to produce desirable outputs that can be used to decrease the Word Error Rate (WER) of automatic speech recognition (ASR) systems [6], boost the performance of speech-to-text systems [7], and in general, increase the intelligibility of speech which can be beneficial for any system whose performance is dependent on the intelligibility of speech. In Deep Learning, the classical approach to suppress noise through the signal is mask-based signal denoising [8], in which DNN models produce a TF mask that filters out the noise and leaves the speech. Mask-based approaches are mostly done on magnitude spectrograms of audio [9], [10]; this creates a challenge of reconstructing the audio again to the time domain once it is filtered using the predicted spectrogram mask and reconstruction of audio is heavily dependent on the phase of noisy input audio.

Another investigated approach is a mapping-based approach where a representation of a complex nonlinear noisy signal is directly mapped onto a clean signal [11], [12] and [13]. Mapping-based approaches directly map noisy signals to their clean representations. Due to the fast variation of amplitudes in raw audio waveforms, mapping-based approaches are based on STFT (short-time Fourier Transform) of audio.

A. Proposed Approach

Our proposed approach is a mapping-based approach in raw audio waveform (time-domain). The loss function is optimized for time and STFT of audio. This approach eliminates the requirement of reconstruction of the audio from the spectrogram output into raw audible audio waveform as in [11] and [12], rather it generates the audible enhanced speech output directly. The magnitude spectrogram of audio is incorporated inside of the loss function rather than as input to the model as in [9] and [13], which gives us leverage to do speech enhancement on raw audio waveform directly. Given an audio, our system directly generates its clean representation without any additional post-processing on the output of the model. The proposed approach focuses on enhancing the speech and suppressing the noise in audio sampled at 22.05 KHz. To achieve this U-Net architecture is used. The choice of this architecture is due to the fact that it takes audio as raw waveform without any manual feature extraction and provides output also in the raw audio waveform, which can be converted to mp3 file and can be saved on disk directly. It consists of convolutional layers and a middle layer which is a

bottleneck. The middle layer (bottleneck layer) represents the data in encoded representation which is then decoded by the Decoder architecture connected to the bottleneck layer.

The objectives of this research are two-fold:

1) Discusses the common approach in deep learning, specifically mask-based signal denoising, where deep neural network (DNN) models generate a time-frequency (TF) mask to filter out noise from the audio signal.

2) Reviews mapping-based approaches that directly map complex nonlinear noisy signals onto clean representations. It distinguishes these approaches from mask-based methods and notes that mapping-based methods typically rely on the short-time Fourier transform (STFT) of audio due to the fast variation of amplitudes in raw audio waveforms.

3) Introduces a novel mapping-based approach specifically applied to raw audio waveforms in the time domain

B. Research Distribution

Section II of this paper covers related work in speech enhancement, followed by Section III, which discusses the dataset used for this research. Section III also consists of discussion on the U-Net Architecture. Section IV covers model training, and Section V, the last section discusses results and concludes the paper.

II. Related Work

Speech enhancement research has been ongoing for the last half-century. Earlier, classical linear noise filtering approaches were used for reducing noise. Two notable examples are spectral subtraction and wiener filter approaches [2] & [3]. The former needed multiple sources and works average with static noise and below the bar with non-stationary noises. The latter had its pitfalls, such as it required two sources; one of them is a mixed signal, and the other is the background sound signal. With the rise of deep learning, these pitfalls were eliminated as deep learning made it easier to notably reduce the noise in the noisy speech samples. This approach made no assumptions regarding the statistical attributes of the signals and used a wide variety of noise types to provide a variety of noisy speech samples for training [14]. Moreover, these systems can learn to map between complex nonlinear functions. They can produce desirable outputs that can be used to decrease the Word error rate (WER) of automatic speech recognition systems (ASR). In general, it can increase intelligibility, which can benefit any system whose performance depends on speech intelligibility.

In a notable work [15], a causal model was proposed based on auto-encoder architecture. They also proposed effective data augmentation techniques, frequency band masking, and reverberation. Their results suggest that the proposed system is comparable to the SOTA (State-Of-TheArt) model across all performance measures while working directly on the raw waveform. It also discovered that up-sampling the audio before feeding it into the encoder improves accuracy, and then they downsampled the outputs by the same amount.

Another innovative approach, presented in [16] proposed a new deep learning-based framework for real-time speech enhancement on dual-microphone mobiles for close-talk scenarios. They used a masking-based approach using a computationally efficient CRN (Convolutional Recurrent Neural Network), which was trained for intra-channels and inter-channels. Their experimental results showed that their proposed approach outmatched the DNN-based and other traditional methods.

Alternatively, authors in [17] used a hybrid approach using DSP techniques and deep learning for noise suppression. The deep recurrent neural network with four hidden layers was used. The resulting lower complexity made it practical to be used in video-conferencing systems. Their results showed a significant improvement in quality from deep learning, especially for non-stationary noise types.

The authors of [7] also used a hybrid approach consisting of noise estimation and speech-to-text block. This paper's focus was on spontaneous speech in the medical domain. As the medical terms used in the area are complex, and speech recognition systems often fail to recognize those words, the idea here was to propose an algorithm that resolves this issue. Non-linear spectral subtraction for noise reduction and the Hidden Markov Model (HMM) were incorporated for converting the speech to text to reduce the word error rate.

This paper [18] discussed the classical approaches for noise reduction by using filters. It also discusses stationary and non-stationary noise and its subtypes. This approach [19] combined a short-time Fourier transform (STFT) and a learned analysis and synthesis basis in a stacked-network method with less than one million parameters for real-time noise suppression. [20] an improved approach to their previous research was proposed, where the Deep Denoising Autoencoder (DAE) is trained on only clean speeches. In this paper, they trained DAE on pairs of noisy signals and clean output using a mapping-based approach stack AE approach where AE is stacked to form DAE to estimate the noise from the noisy signal. This paper [21] explores a greedy layer-wise pretraining strategy to train a DAE for speech restoration and then applies that restored speech for noisy robust speech recognition.

III. Methodology

A. Dataset

Datasets consist of pairs of corresponding audios sampled at 22.05 KHz stored in WAV format in a Linux environment. The dataset is created using two publicly available datasets. From one dataset noisy environment audio samples are obtained and from another dataset, clean human speech audio samples are obtained later these two samples of datasets are mixed together using simple arithmetic addition in order to create noisy simulated environments and their corresponding clean speech pairs.

Noise samples are from the DEMAND dataset to generate simulated noisy environments [22]. The DEMAND dataset is recorded with an array of sixteen microphones with an original sampling rate of 48kHz. It is publicly available in 48kHz or a downsampled version of 16kHz. In this paper, the

48khz version is downsampled to 22.05kHz utilizing the librosa module of Python and later used in the dataset. Three noise profiles (noise environments) are chosen from the DEMAND dataset namely DKITCHEN, PRESTO, and OMEETING. DKITCHEN includes recordings of kitchen noises while cooking. At the same time, PRESTO consists of a set of noise recordings taken from the university restaurant during lunchtime, and OMEETING, consisting of meeting room sounds during discussions from the microphone array. At first, all 16 channels of DKITCHEN, PRESTO, and OMEETING are mixed together respectively in order to create a single noise profile for each environment.

Next, the first eight channels of PRESTO and OMEETING are mixed together. This was done because it is observed that in the case of PRESTO and OMEETING with all sixteen channels added together, the noise profile was overruling the speech components in raw audio and also in spectrograms. Our proposed model takes 2.97sec windows of inputs, so eight sections of length equal to 2.97sec are used from each noise profile. Eight sections are used because for each speaker eight utterances are chosen. Later these noise sections are mixed with each speaker.

For clean speech representations, eight unique utterances of 47 notable speakers from the Valentini dataset are used [23]. Then mixed the noisy environment samples and the clean samples from the Valentini dataset, to create simulated noisy environment signals, and their correspondence clean speech representation. These pairs of audio are converted to pickle format and saved on the disk.

There are a total of five batches of data, each with 376 utterances of 47 unique speakers. Batch-1 represents the DKITCHEN (sixteen channels mixed) noise condition, Batch-2 represents the PRESTO (sixteen channels mixed) noise condition, Batch-3 represents the OMEETING (sixteen channels mixed) noise condition, Batch-4 represents PRESTO (eight channels mixed) noise condition and Batch-5 represents OMEETING (eight channels mixed) noise condition.

B. Notations and Problem Settings

Targeting speech enhancement in mono-aural signals, where $x \in R^T$ is the given signal composed of additive background noise as $n \in R^T$ and clean speech $y \in R^T$. so that $x = y + n$. The length T is of a fixed duration, which equals *65536* samples when audio is sampled at 22.05 KHz. Our main objective is to find a function *f* through the non-linear architecture of the neural network that reduces the enhancement function to $f(x) \approx y$.

In this problem set, the function *f* is the neural network architecture, producing the clean speech *y* at its output layer.

C. UNET Architecture

As presented in Fig. 1, the adopted neural network architecture is a one-dimensional UNET encoder-to-decoder architecture with skip connections [24] and gated linear units. The input shape of the model is equal to the number of 65536 samples when audio is sampled at 22.05 KHz; the output shape is also the same as this is an end-to-end approach.

Gated Linear Units [25] are incorporated in the encoding and decoding blocks of the model; there are no GLU in the bottleneck section of the model; convolution layers throughout the model are one-dimensional.

A detailed overview of the proposed Fully Convolutional Gated Encoder-to-Decoder architecture is shown in Fig. 2. The proposed model has three sections Encoder Section, Bottleneck section, and Decoder section, which is in the end is connected to the output layer producing clean speech output. Each section of the model and their connection with each other is discussed as follows.

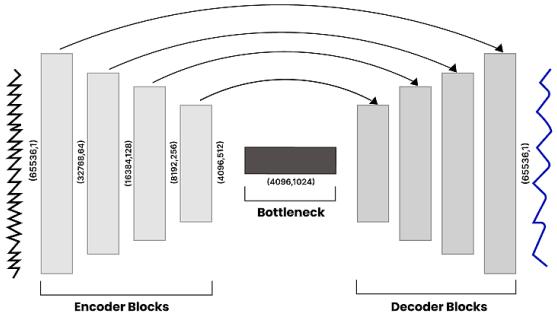

Fig. 1. Proposed fully convolutional gated encoder-to-decoder architecture with bottleneck for speech enhancement. Input and output shapes are the same.

1) Encoder section: The encoder section compresses the data of the input from a higher dimension to a lower dimension while reducing the noise from the data. The input of the encoder is the raw audio, and its output is a compressed data format that represents the input raw audio. Leaky ReLU is used as an activation function so that the model can learn to flow the gradient from most neurons. Most of the input data consists of negative values and the range of input data is [-1,1]. ReLU was also used as an activation function in order to obtain a sparse network but with ReLU, a dead ReLU problem was observed as input data is in the range of [-1, 1]. One-dimensional convolutional layers are used with batch normalization, Leaky Relu activation, and Gated linear Units are applied. The encoder section contains two layers of convolution than the max pooling layer.

2) Bottleneck section: The tanh activation function is used in the bottleneck section to apply a non-linear transformation on the signal at the most encoded layer. The input of the bottleneck section is the output of the encoder section, there are no Gated linear units applied at the bottleneck section, and it is also fully convolutive as the encoder section. In the bottleneck section, the one-dimensional convolutive layer is used with batch normalization, and the tanh activation function is applied. The bottleneck section contains two convolution layers only.

3) Decoder section: Transpose one-dimensional convolution is applied to convert back the original shape of the data. The decode section consists of one-dimensional convolution transpose along with gated linear units and

concatenation layers which serve as skip connections so that the model uses the features learned in the encoder section of the model.

4) Output layer: The output layer consists of a single channel focusing on mono-aural speech enhancement; Tanh activation is applied at the output layer, which provides the final denoised signal. In the output layer, a single one-dimensional convolutional layer is used which acts as a dense layer with a shape of (65536,1). The output layer is connected to the decoder layer. And it gives the same data shape as the input layer.

D. Objective

Mean Absolute Error (L1 Loss) is used as a loss function to minimize the error between the predicted signal $\boldsymbol{y'}$ and the clean signal $\boldsymbol{y}$. L1 loss is incorporated over the time domain of signals to reduce the loss over the sequential time domain and to minimize the loss over the spectral domain, L1 loss is used over on STFT (short-time Fourier transform) of the signals.

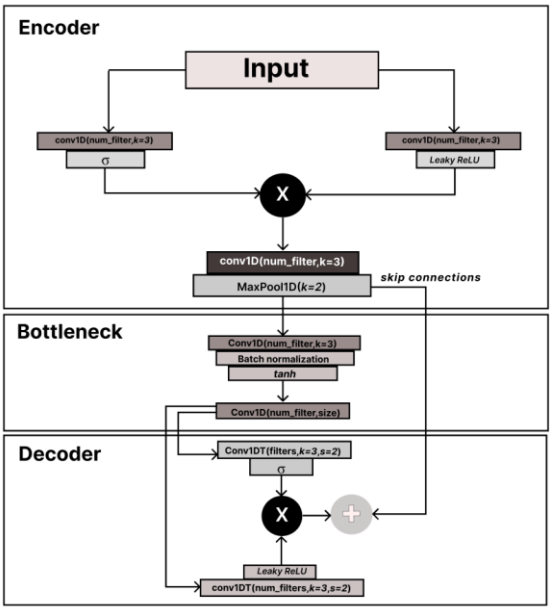

Fig. 2. Detailed overview of each separate block of the model and their connections with each other. The input and output shapes are the same.

Lastly, these L1 losses are added together to optimize the model in both the time domain (on amplitude vectors) and the spectral domain (on STFT).

A minimal epsilon value = $1e^{-10}$ is used to omit the undefined log error.

$$L_{stft}\,(y, y') = L_{mag}\,(y, y')$$

$$L_{mag}\,(y, y') \Rightarrow \frac{1}{T}|| \, log\,|STFT(y)| + \varepsilon - log|STFT(y')| + \varepsilon||_1$$

And,

$$L_{time}\,(y, y') = ||y - y'||_1$$

Overall, we wish to minimize the following:

$$L_1 \Rightarrow L_{mag}\,(y, y') + L_{time}\,(y, y')$$

IV. Training

Proposed model is trained on our custom dataset, 100 epochs for each of the three batches. The best model is saved for each of the three batches while monitoring the lowest L1 loss over the spectral domain, as discussed in Section 3.3.

Table I reports the training parameters, using the Adam optimizer, which has a learning rate of 1^{e-4}, with a momentum of β1=0.9 and a denominator momentum of β2=0.999.

TABLE I. Tuning Hyper-Parameters of Adam Optimizer Used for Training the UNET Model

Optimizer Tuning hyper-parameters	
optimizer	Adam
lr (learning rate)	1^{e-4}
β1 (momentum)	0.9
β2 (denominator)	0.999

The audio samples used for training are sampled at 22.05 KHz. The first 282 samples are used for the training set and the remaining 94 samples are used for the validation set. A batch size of 4 is used, dividing the data into 71 batches, each consisting of four unique utterances of the same speaker and the next batch containing the. The model optimizes the loss function and adjusts the weights. The next batch includes four different unique utterances of the previous speaker. After that, the next batch focuses on different speakers. The random order of data was not utilized. In each training session with varying noise conditions, the utterances' order remains consistent with their corresponding pairs in the noisy environment.

Gated linear units are used in order to control the information flow inside the model. It is observed that Gated liner units act as voice activity detection layers. Where clean speech is present, the neurons have greater weight and lower weight where noise is present. The output layer acts as a normalization layer for the denoised output.

V. Result

The performance of the model is calculated over cumulative loss of Mean Absolute Error of predicted and actual audio samples in both the time domain which is WAV MAE and also is spectral domain which is STFT MAE.

It is observed that the addition of STFT MAE in loss function improved the audible quality of speech in noisy environments and preserved the speech components of audio by making them sound less distorted.

Firstly, performance is evaluated over sixteen channels of respective noise environments that were present in the DEMAND dataset [22], this is reported in Table II. Then performance is evaluated over only eight channels of respective noise environments. It is observed that in the case of 16 channels of PRESTO and OMEETING audile quality of

audio was distorted, the reason behind this is that in the case of PRESTO and OMEETING noise environment babble noise is present and when it gets mixed with human speech it is hard for model to differentiate between noise and speech. We reported the performance of PRESTO and OMEETING with eight channels mixed together in Table III and a significant drop in Loss is observed while preserving the speech quality with less distortion.

TABLE II. PERFORMANCE OVER SIXTEEN CHANNEL MIX

Noise Environment All Sixteen Channel Mixed	Train			Test		
	LOSS	***WAV MAE***	***STFT MAE***	***LOSS***	***WAV MAE***	***STFT MAE***
DKITCHEN	0.755	0.011	0.744	0.777	0.012	**0.764**
PRESTO	0.734	0.017	0.716	0.811	0.018	**0.792**
OMEETING	0.537	0.010	0.527	0.573	0.010	**0.563**

This table represents the cumulative loss, the wav loss over signals, and the STFT loss of the signals. This metric represents the performance of the model where the lowest STFT MAE is observed in each noise condition. All sixteen channels of noise are added together in all of three noise profile cases.

TABLE III. PERFORMANCE OVER EIGHT CHANNEL MIX

Noise Environment First Eight Channel Mixed	Train			Test		
	LOSS	***WAV MAE***	***STFT MAE***	***LOSS***	***WAV MAE***	***STFT MAE***
PRESTO	0.665	0.012	0.653	0.744	0.013	**0.730**
OMEETING	0.494	0.008	0.486	0.510	0.009	**0.500**

This table represents the cumulative loss, the wav loss over signals, and the STFT loss of the signals. This metric represents the performance of the model where the lowest STFT MAE is observed in each noise condition. Eight channels of noise are added together in all of the two noise profile cases.

A significant drop in STFT Loss is observed in Table III. When the first eight channels are mixed, and the output audio quality is better than the previous setting in the case of PRESTO and OMEETING. Reducing the number of channels in DKITCHEN is not tested because the audible intelligibility of the clean speeches was satisfactory, this shows that the model is giving better results on the DKITCHEN environment despite higher STFT MAE as reported in Table II.

On Objective measures, intelligibility, and speech quality is measured as reported in Tables IV and V. The metrics used are PESQ [26] and STOI [27]. Baseline PESQ and STOI are calculated over denoised signals by using the noisereduce library of Python. Then it is compared with PESQ and STOI of denoised signals of the model.

TABLE IV. PERFORMANCE ON OBJECTIVE MEASURES USING PESQ AND STOI (SIXTEEN CHANNELS MIXED)

Noise Environment All Sixteen Channel Mixed	Test Set	
	PESQ wb	***STOI***
Baseline_DKITCHEN	1.16	0.83
DKITCHEN	**1.60**	**0.85**
Baseline_PRESTO	1.30	0.66
PRESTO	**1.31**	**0.73**
Baseline_OMEETING	1.30	0.82
OMEETING	**2.46**	**0.88**

Objective measures of enhanced speech on PESQ and STOI. Sixteen channels of noise are added together in all three noise profile cases.

TABLE V. PERFORMANCE ON OBJECTIVE MEASURES USING PESQ AND STOI (EIGHT CHANNELS MIXED)

Noise Environment First Eight Channel Mixed	Test Set	
	PESQ wb	***STOI***
Baseline_PRESTO	1.24	0.74
PRESTO	**1.38**	**0.81**
Baseline_OMEETING	1.35	0.85
OMEETING	**3.24**	**0.90**

Objective measures of enhanced speech on PESQ and STOI. Eight channels of noise are added together in all of the two noise profile cases.

In Tables IV and V, our performance of the model in objective measures using PESQ and STOI is reported. Improvement in the audible quality of denoised speech is observed when the human voice is more prominent (audible) in signal than in the noise environment. There is a significant improvement in both objective measures over the baseline model, baseline measurement is carried with PESQ and STOI on our test set using spectral gating.

VI. DISCUSSION

In summary, this research addresses the challenges in speech enhancement by examining a mapping-based approach on raw audio waveforms using the U-Net architecture. The study identifies limitations in conventional methods like Spectral subtraction and the Wiener filter, prompting an exploration of deep learning solutions.

The proposed approach optimizes the loss function for both time and short-time Fourier transform (STFT) of audio, enabling the direct generation of clean audio representations without additional post-processing. The research systematically evaluates mask-based and mapping-based deep learning approaches, revealing the effectiveness of the latter in various noise environments through a comprehensive metric.

Objective measures, including PESQ and STOI, indicate notable improvements in audible quality and intelligibility of denoised speech compared to baseline models. The research findings have practical implications for applications such as automatic speech recognition and speech-to-text systems. The mapping-based approach on raw audio waveform emerges as a viable strategy for addressing the inherent challenges in speech enhancement, offering tangible advancements in audio quality assessment.

VII. CONCLUSION

The proposed approach can be scaled by incorporating all the noise profiles into one single dataset and training a model in a single pass over the entire dataset, the hypothesis is that the model may generalize better to each noise condition, and a reduction in Loss is observed. It is observed that the intelligibility of output speech samples is improved when STFT is included with the Loss Function, as discussed in the objective of this paper. In the future, the proposed approach can be scaled with the use of multiple-resolution STFT loss as used in [28, 29].

Hotspot Identification Through Pick-Up and Drop-Off Analysis of Ride-Hailing Transport Service

Ragil Saputra[1], Suprapto[2*], Agus Sihabudin[3]
Department of Computer Science, Universitas Diponegoro, Jl. Prof. Soedarto SH Tembalang Semarang Indonesia[1]
Department of Computer Science and Electronics, Universitas Gadjah Mada, Bulaksumur Yogyakarta Indonesia[1, 2, 3]

***Abstract*—It is important to extract hotspots in urban traffic networks to improve driver route efficiency. This research aims to identify hotspot pick-up and drop-off (PUDO) areas in ride-hailing transportation services using a clustering approach. However, there are challenges in applying clustering algorithms to trajectory data in the coordinates of the Global Positioning System (GPS). So this research proposes modifications to the Density-Based Spatial Clustering of Applications with Noise (DBSCAN) algorithm by considering the radius from the center of the cluster to determine the presence of amenities around the cluster. We used a dataset containing 55,988 trip trajectories of Grab drivers over a two-week period in Jakarta. A preliminary statistical analysis was carried out to understand the distribution of trips. Next, we identify the PUDO point of each trip for use in the clustering analysis. The research explores the various parameters and settings of the clustering method and their impact on the results. The study found that the results obtained from the clustering method are sensitive to parameter selection, including epsilon radius and minimum number of points needed to form a cluster. The optimal cluster with the best parameters (eps: 0.25, minpts: 100) in the pick-up (PU) location analysis produced 17 clusters with the silhouette coefficient of 0.752, while in the drop-off (DO) location there are 18 clusters with a silhouette coefficient of 0.694. Overall, the research highlights the potential of the clustering analysis method for ride-hailing transportation.**

***Keywords*—Hotspot identification; ride-hailing; transportation; PUDO location; clustering analysis**

I. Introduction

A. Background

The rise of application-based transportation services, such as ride-hailing has revolutionized the way people move around in modern cities [1]. In the context of transportation services, "pick-up" often denotes the time when a vehicle (such as a taxi, or ride-hailing service) arrives at a designated location to collect passengers or packages. While “drop off” can refer to the time when a vehicle arrives at the destination location, and passengers or packages are left at that location.

The exponential growth in the use of these services has created enormous opportunities to analyze and understand urban mobility patterns [2]. In the study of Zhang et al [3], mobility-based data analysis has become the main focus in uncovering complex urban movement patterns. There have been many studies that use taxi data to examine urban mobility, such as Veloso et al [4] use of taxi trajectory data from Lisbon to discuss the spatiotemporal variation of taxi services, correlations between pick-up and drop-off (PUDO) sites, and driver behavior, and Liu et al [5] use of taxi trajectory data from Shanghai to explore human movement patterns. The taxi traces were also mined for characteristics and behaviors of the vehicular network, including anomalous and driver behavior, dynamics of mobility patterns, interactions between vehicles, and the relationship between gender and mobility [6]. Additionally, Keler et al [7] examined where automobile routes connect at specific rush hours in urban locations.

By identifying origin and destination (OD) flow clusters in urban travel data, it is possible to determine prospective routes for public transportation service settings [8]. In order to locate the taxi OD hotspot, the available OD pairs from empirical mobility traces are first grouped [9]. A deep understanding of hotspots, namely areas with heavy travel activity, has great potential for shaping more efficient transportation planning and better traffic management [10]. Although there have been previous studies exploring hotspot analysis in urban mobility, Dutta et al [11], use of more sophisticated and comprehensive clustering methods is still an important area of exploration.

Exploring urban mobility patterns has become a main focus in recent years, with previous research analyzing trajectory data [12]. Therefore, in this context, it is essential to define several key terms and assumptions that will form the basis of this study before presenting the main theorem. We define a hotspot as a location with a high concentration of PUDO points are adapted from [13]. We assume that the dataset used in this study is representative of the overall ride-hailing transportation system in the study area. Additionally, we assume that variables like the time of day, day of the week, and the location of well-known destinations have an impact on drivers' PUDO patterns.

B. Motivation

The majority of previous research on ride-hailing has been on the routing method, with little emphasis paid to optimizing PUDO locations that are sensitive to the spatial and temporal need distribution [14]. When taking a shared trip with multiple riders, the PUDO optimization is vital to prevent pointless detours. Whereas in the conventional system, the vehicle is frequently obliged to pick up passengers at certain locations [15]. Detours are made in order to pick up additional riders frequently result in longer travel times and higher costs. The PUDO position, where all potential PUDO points must therefore be optimized urgently.

Shen et al [2], suggests a cluster analysis approach for identifying various metropolitan online ride-hailing operation trends. Based on the suggested intensity and stability indicators

of ride-hailing vehicle operational characteristics, k-means++ clustering technique is applied. The results show that there are three distinct operating patterns for online ride-hailing services. In the study of Zhang et al [3], the goal is to identify the distribution of areas with high travel demand as well as the relationship between travel demand and Point of Interest (POIs). Tang [16], utilizes taxi GPS trajectory data to analyze urban human activity and mobility in Harbin city. The researchers employ the DBSCAN algorithm for PUDO location clustering and develop four spatial interaction models to understand pick-up location searching behavior.

However, with the rise of ride-hailing services, there is a need to develop new methods for analyzing PUDO patterns of drivers. Gunawan and Susilawati [17], addresses limitations in current ride-hailing PUDO location selection practices, which often prioritize spatial distribution and company interests over passenger needs. Research using neural networks was carried out by [18], seeks to examine the integration of clustering models and deep learning techniques. The model, which can concurrently capture the spatial and temporal fluctuations of taxi hotspots, was proposed for taxi hotspot prediction.

There have been several studies interested in discussing the applications for the clustering analysis method in transportation systems. Zhang et al [19], used DBSCAN to cluster PUDO data from a ride-hailing service in China. A pick-up points recommendation model (PPRM) is introduced, utilizing DBSCAN to cluster historical orders. This clustering enables finding contextually relevant candidate PU points. The other research by Wang and Ren [20], introduces a two-level divide approach and enhances the K-means++ algorithm to refine the clustering of taxi passenger hot spots based on GPS location data. The method is validated using a week of New York City's green taxi data, demonstrating superior accuracy and comparable time efficiency when compared to traditional K-means and DBSCAN methods.

Based on previous research, clustering analysis method has become an increasingly popular approach in the field of data mining and machine learning. Rafiq and McNally [21], use clustering these data points, ride-hailing companies can gain insights into traffic patterns and usage trends of their customers, which can help them optimize their operations and improve their overall service quality.

To build on prior research that examined trajectory data to investigate urban mobility patterns, this study employs a clustering approach to identify hotspot PUDO areas for ride-hailing transportation services. The DBSCAN algorithm was chosen due to its ability to identify clusters of varying shapes and sizes. However, it has limitations in handling spatial datasets, therefore, this study proposes modifying the DBSCAN algorithm to take into account the radius from the cluster's center to determine the presence of facilities in the cluster's vicinity. Our method identifies concentrations of PUDO locations that can be used to determine potential hotspots. While this study does not provide a direct comparison with previous methods, the proposed method is superior to previous approaches because it considers the radius from the center of the cluster to determine the presence of amenities around the cluster, uses a large dataset of ride-hailing trajectories.

The paper is structured as follows. Section II describes data processing, and proposed method. The findings and results gleaned from the methodology are discussed in Section III. Section IV concludes by summarizing the work and offering recommendations for the future.

II. METHODOLOGY

A. Data Collection

The dataset is derived from Grab's food delivery and logistics in Jakarta, and it includes 4,000 daily trajectories collected from 2019-04-08 to 2019-04-21 (inclusive, UTC/ Universal Time Coordinated). The trajectories were gathered from drivers' phones while they were on the road. The total number of GPS pings in the collection is 61.549.964; each GPS ping has values for its trajectory ID, latitude, longitude, timestamp, accuracy level, bearing, and speed [22]. The raw data sample is shown in Table I.

The names of the fields in Table I are covered below.

1) Trajectory ID: A number used to identify different GPS mobility trajectories.

2) Latitude: A GPS location's latitude coordinate.

3) Longitude: A GPS location's longitude coordinate.

4) Timestamp: Time the GPS locations were recorded is shown by the timestamp. The UTC standard is used in the format. One second is the quickest sample interval for each GPS point.

5) Accuracy level: Shows the radius of the circle that, with a certain probability, contains the real location.

6) Bearing: The degrees relative to true north.

7) Speed: The immediate speed is expressed in meters per second.

TABLE I. TEST RAW DATA

Trajectory ID	Latitude	Longitude	Timestamp	Accuracy Level	Bearing	Speed
4820	-6.591032	106.834468	09/04/19 10.33	4	194	20.42
46324	-6.247526	106.977663	10/04/19 05.22	10.72	101	4.22
15007	-6.267404	107.036016	19/04/19 02.57	3.149	108	1.99
4239	-6.293342	106.820029	10/04/19 01.31	10	288	1.01

B. Data Preprocessing

The next step is to pre-process the data to create trajectory, the data includes the point of trajectory of captured trips. The trips were divided based on the trajectory ID, and the minimum and maximum trajectory times recorded for each trip were used to determine the PUDO information. The result of dataset contains in total 55,988 trajectories with the distribution of number of trips is show in Fig. 1.

The daily distribution of trips is depicted in Fig. 1. We simply display the relative frequency of travel requests discussed in this article in order to maintain data confidentiality. As seen in Fig. 1(a) pick-up (PU) time, the temporal travel demand is typically distributed over the normal working day. Between 6 P.M and 12 noon, it is relatively high, but after that, the tendency begins to decline until 9 P.M. The trend then went upward once more until 10 P.M. The same trend also occurs in drop-off (DO) time, presented in Fig. 2(b).

C. Proposed Method

The main analysis involves applying the Density-Based Spatial Clustering of Applications with Noise (DBSCAN) method to the preprocessed data to identify clusters of PUDO locations. DBSCAN was introduced by Ester et al [23], which is a clustering algorithm commonly used in data analysis to identify clusters of data points based on their spatial density.

It's particularly useful when dealing with data where clusters might have irregular shapes and varying densities. The algorithm categorizes data points into three main types [24]: core points, border points, and noise points. A core point is a data point that has at least a specified number of neighbor points (*minpts*) within a certain distance (ε). These points are at the heart of a cluster. A border point is a point that is within the ε distance of a core point but doesn't have enough neighbors to be considered a core point itself. And finally, noise points are any points that are neither core nor boundary points.

The following steps make up the algorithm [25]:

1) Identify the core points or points visited by more than minpts neighbors by locating all neighbor points within ε.

2) Make a new cluster for each core point if it hasn't already been done so.

3) Find all points connected to it by density recursively, then group them with the core point in the same cluster.

4) Points a and b are said to be density connected if point c has a significant number of points in its neighbors and both of those points are close to the ε. Chains are used in this process. Inferring that b is a neighbor of a, if b is a neighbor of c, c is a neighbor of d, and d is a neighbor of e, then b is a neighbor of a.

5) Iteratively go over the remaining unexplored points in the dataset. All points that do not form a cluster are considered noise.

In this paper, we modified the DBSCAN algorithm from Kambe and Pe [25] to better suit the ride-hailing context by creating a function called DBSCAN_FIT that takes three parameters: x (dataset), ε (epsilon, the maximum distance between two points to be considered in the same cluster), and *minpts* (the minimum number of samples in a cluster). This function utilizes the DBSCAN algorithm to cluster the data and produces visualizations of the clusters, including those labeled as noise (points not belonging to any cluster). Additionally, the function calculates centroids for each cluster and assesses the amenity around each centroid. The pseudocode for the DBSCAN_FIT is shown in Algorithm 1.

To obtain the amenity information with function `get_amenity`, we used OpenStreetMap (OSM) data to identify the facilities or points of interest around each centroid. Specifically, we used the OSM API to query the database for the amenities within a certain radius of each centroid. We then used the OSM tags to extract the names of the amenities and assigned them as labels to the corresponding clusters. At a given average latitude on Earth, we use the number 111,320 as a conversion factor to translate differences in degrees of latitude or longitude into distances in kilometers.

Algorithm 1. DBSCAN_FIT

Input : x (dataset), eps, minpts
Output : labels, centroid, amenity

```
Funnction DBSCAN_FIT(x, eps, minpts){
        dbs = DBSCAN(eps,minpts)
        dbs.fit(X)
        labels = dbs.labels_
        label_unique = pd.Series(labels).value_counts()
        if label_unique.shape[0]>2 {
                cent = []
        amen = []
        for i in range(max(labels)+1){
        centroid = (X[labels==i].mean().values/111.320) + np.array([min_lat,min_lon])
        centroid += [centroid]
        amenity = get_amenity(centroid[0], centroid[1], eps*4*1000)
        amenity += [amenity]
                }
        }
        else
                return 0
return labels, centroid, amenity
}
```

D. Cluster Performance Measure

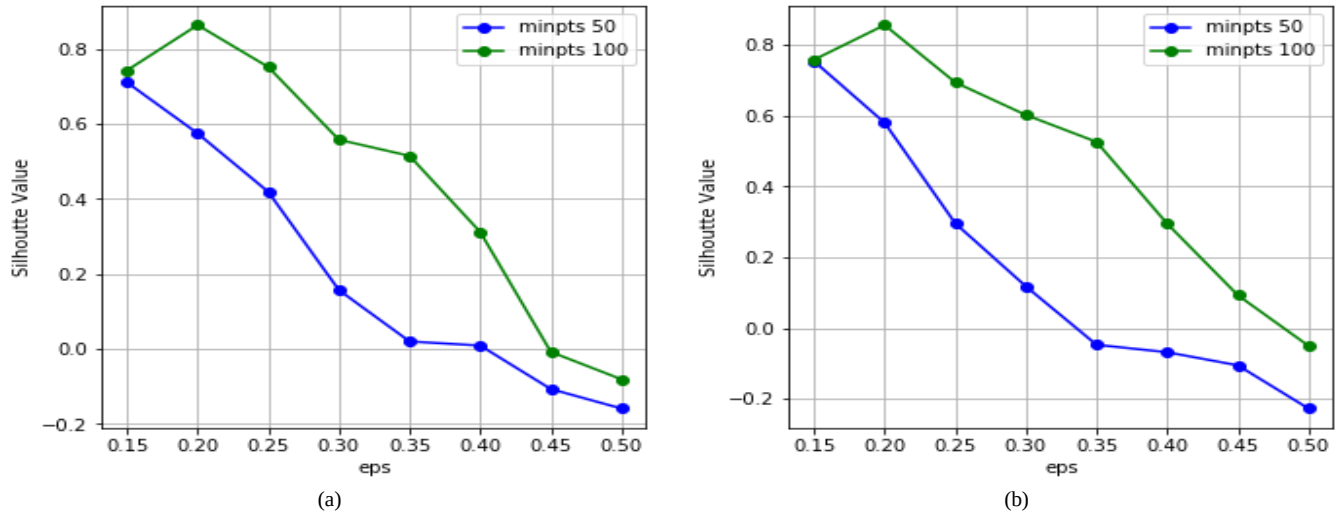
To evaluate the quality and coherence of clusters obtained through clustering algorithms, the Silhouette Coefficient (SC) was used. It quantifies the cohesion and separation between clusters. Ranging from -1 to 1, a higher SC indicates well-defined clusters where data points are closer to their own cluster members than to others. A score close to 0 suggests data points on cluster boundaries, while negative scores indicate potential misassignments [26].

A higher SC would indicate well-defined clusters of PUDO points, highlighting their coherence and separation from other clusters. This metric becomes essential in assessing the accuracy of clustering results and validating the effectiveness of algorithms. The silhouette score guides the determination of how accurately identified hotspots represent distinct patterns, thereby enhancing the credibility of the hotspot identification approach in ride-hailing transport services.

III. Result and Discussion

A. Experimental Result

Our research focuses on the complex interaction of epsilon (ε) values in the DBSCAN_FIT algorithm in order to do a thorough study of clustering results. To achieve this goal, we conducted a preliminary analysis of the data and found that *minpts* values below 50 did not produce enough clusters to be useful for hotspot identification, while values above 100 resulted in too many clusters, making it difficult to identify meaningful patterns. Therefore, we chose to focus on *minpts* values of 50 and 100 in our analysis and visualization, as these values produced the most meaningful results for hotspot identification. In Fig. 2, the outcomes of this investigation are graphically summarized. Fig. 2(a) shows the silhouette value for pick up and Fig. 2(b) shows the silhouette value for drop-off.



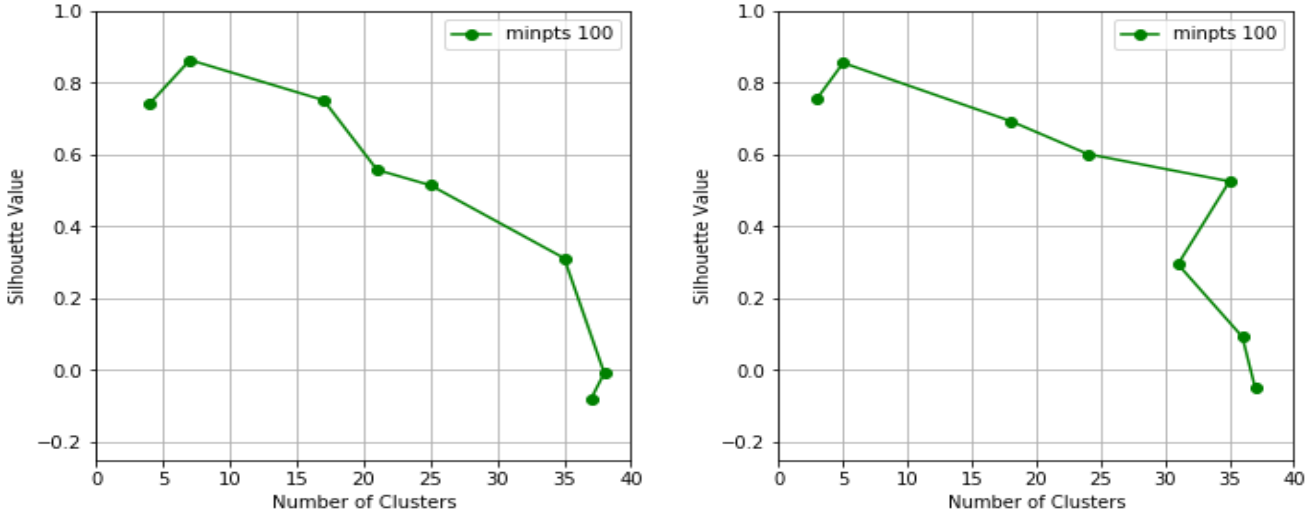
(a) (b)

Fig. 2. Variation epsilon (ε) value for the (a) pick up and (b) drop off.

The graph on Fig. 2, the graph illustrates the variation in the silhouette coefficient with changing values of ε. Two curves are depicted, one for a minimum number of points (*minpts*) set at 50, and the other for *minpts* set at 100. The results indicate that, for *minpts* 50, the silhouette coefficient (SC) tends to decrease as ε increases, suggesting a negative impact on clustering quality. In contrast, for *minpts* 100, the SC exhibits fluctuations, with some ε values resulting in higher coefficients. From the graph, it can be inferred that for *minpts* 100, the SC is more stable and potentially yields better clustering results compared to *minpts* 50 within a specific range of ε values.

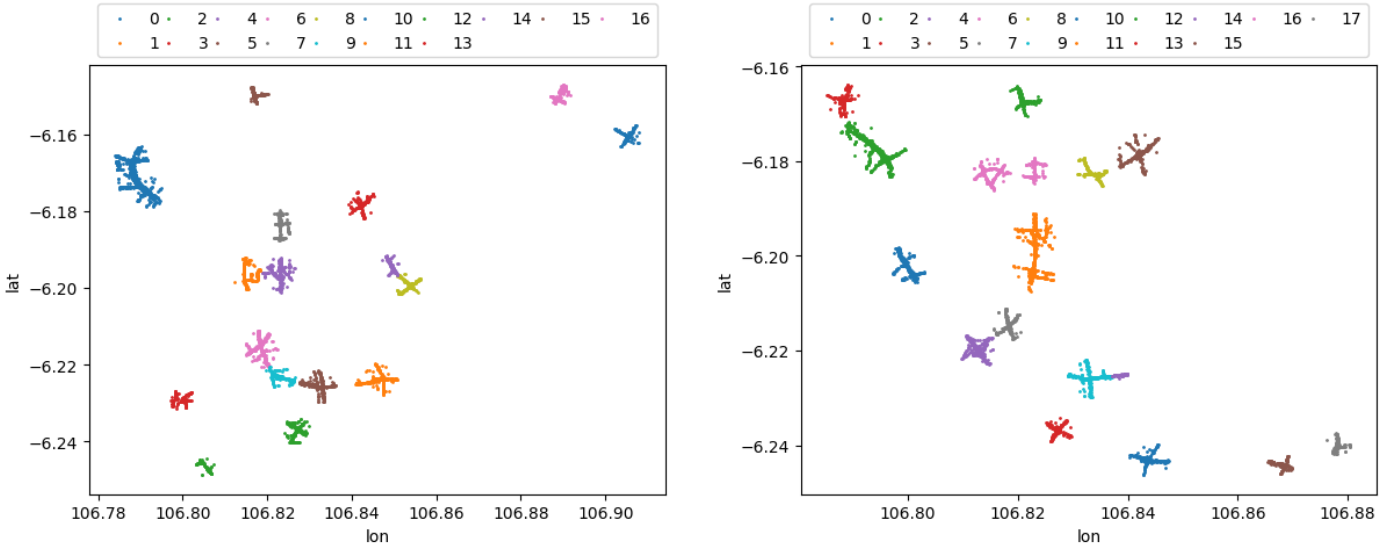
Furthermore, it is evident that the *minpts* value plays a pivotal role. The *minpts* 100 configuration consistently outperforms *minpts* 50, yielding higher SC values. So in this study *minpts* 100 is used as a reference to find the optimal number of clusters. Compare the value of the SC with the number of clusters formed presented in the Fig. 3.

The number of clusters formed ranging from 3 to 37 presented by Fig. 3. In the context of hotspot identification, a higher number of clusters can provide a more detailed picture of variations in the distribution of hotspots. However, on the other hand, the SC value is also important because it determines the quality and coherence between clusters. So the optimal number of clusters was chosen as 17 clusters for the PU location and 18 clusters for the DO location. So that the map distribution of PUDO locations is illustrated in Fig. 4.



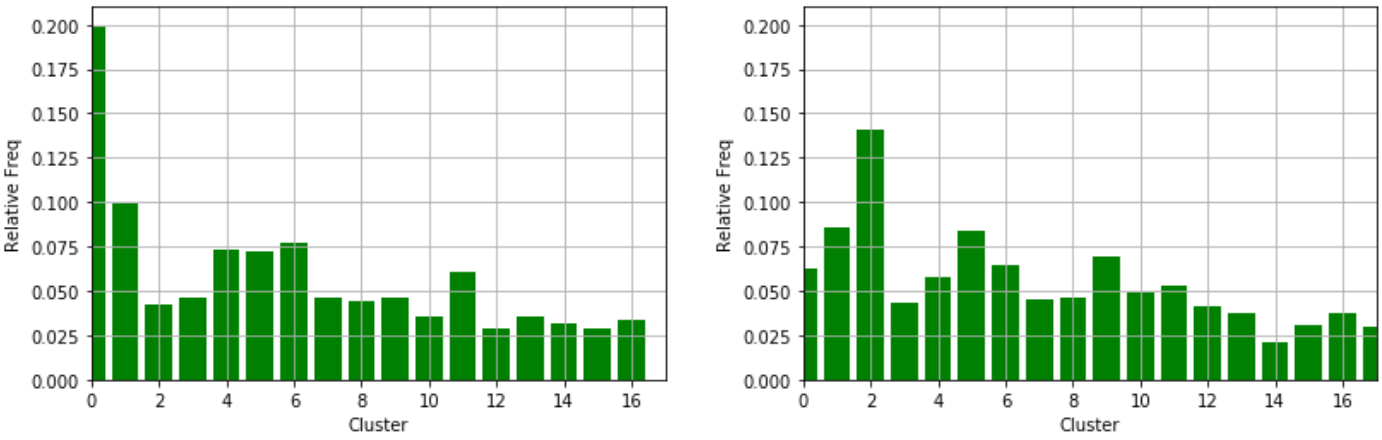
(a) (b)

Fig. 3. Silhouette coefficient and number of clusters of (a) pick up and (b) drop off.



(a) (b)

Fig. 4. The map distribution of (a) pick up location and (b) drop off location.



(a) (b)

Fig. 5. Number of trips (relative frequency) in cluster (a) pick up and (b) drop off.

The distribution of PUDO locations inside each cluster is shown in the Fig. 5. The cluster number is represented on the x-axis, while the number of trips inside each cluster is represented on the y-axis, in relative frequency. This information is crucial in our effort to locate hotspots for application-based transportation services. These findings are directly related to our study's primary objective, which was to develop a special technique for identifying hotspots by closely analysing PUDO patterns. We have learned a lot from the clustering analysis. With the parameters $\boldsymbol{\varepsilon}$: 0.25 and *minpts*: 100, the ideal cluster structure specifically produced 17 clusters for the PU localization analysis, showing an outstanding SC of 0.752. On the other hand, the DO location analysis revealed 18 clusters with a silhouette coefficient of 0.694. These clusters have varied levels of activity, as seen by the bar chart in Fig. 5, indicating the existence of distinct hotspots throughout the transportation network.

Based on Fig. 4 and Fig. 5 show that the highest hotspots for both pick-up and drop-off sites. It follows that these places represent prospective areas that could be used to enhance driver trips. Using the methods we propose, most potential hotspots are presented in Table II along with their amenity labels.

B. Discussion

To assess the performance of clustering, we conducted a comparative analysis with two distinct inpuvts values: 50 and 100, while exploring the influence of the $\boldsymbol{\varepsilon}$ parameter across a range from 0.15 to 0.5. The Silhouette Coefficient (SC) served as our evaluation metric [26]. Our findings are consistent with previous studies that have examined the impact of the $\boldsymbol{\varepsilon}$ parameter on DBSCAN clustering [23] [24]. For example, [23] found that larger values of $\boldsymbol{\varepsilon}$ can lead to the formation of overly large clusters, which can reduce the effectiveness of the clustering algorithm. Similarly, [24] found that larger values of $\boldsymbol{\varepsilon}$ can lead to a decrease in the quality of the clustering results. Our study builds on these findings by examining the impact of both the $\boldsymbol{\varepsilon}$ parameter and the *minpts* value on the performance of clustering in the context of ride-hailing services.

One important aspect of the study is the influence of algorithm parameters on the clustering results. The study found that the results obtained from the clustering method are sensitive to parameter selection, including epsilon radius and minimum number of points needed to form a cluster. The study explored the influence of the $\boldsymbol{\varepsilon}$ parameter across a range from 0.15 to 0.5 and found that for *minpts* 50, the SC tends to decrease as $\boldsymbol{\varepsilon}$ increases, suggesting a negative impact on clustering quality. In contrast, for *minpts* 100, the SC exhibits fluctuations, with some eps values resulting in higher coefficients.

Although our study does not explicitly mention the most surprising results, we found that our approach of analyzing pick-up and drop-off (PUDO) patterns was effective in identifying hotspots in ride-hailing transport services. Our analysis revealed commuting patterns of users and different hotspots in the transportation network. In this study, several limitations were identified that require careful consideration. Firstly, the dataset utilized in this research was limited to a single ride-hailing service, which may limit the generalizability of the analysis results to other services. Secondly, this study only accounted for factors such as time and location in the PUDO analysis, while other factors such as weather or special events in certain areas may influence PUDO patterns and were not considered in this study.

TABLE II. THE POTENTIAL HOTSPOT

Cluster	Type	Center Latitude	Center Longitude	Amenity
0	PU	-6.2210668	106.824997	restaurant: Planet Hollywood Jakarta / cinema: Setiabudi 21 / fuel: SPBU / restaurant: Loewy / restaurant: Bakso Solo
2	DO	-6.1999132	106.824234	nightclub; restaurant: DanceSignal Spot - Immigrant / parking_entrance: restaurant: Lanna Thai / cafe: nan / restaurant: Skye

IV. CONCLUSIONS

Our study reveals that DBSCAN_FIT clustering with ε: 0.25 *minpts*: 100 and yields 17 clusters for PU locations and 18 clusters for DO locations, demonstrating their potential as

hotspots in ride-hailing services. However, the limitation lies in the trade-off between cluster quantity and quality. A more comprehensive understanding of ride-hailing hotspots is achieved, emphasizing the need for a balance between cluster granularity and silhouette coefficients. Other researchers can use our method of analyzing hotspots through PUDO patterns to find hotspots in other transportation networks. This approach can help improve efficiency and help drivers optimize the routing of transportation services.

Future studies should consider utilizing datasets from multiple ride-hailing services to enhance the generalizability of the analysis results. And, additional factors such as weather or special events in certain areas should be taken into account in the PUDO analysis to provide a more comprehensive understanding of the factors that influence PUDO patterns.

***Abstract*—This paper presents the evaluation of a mobile application employing Tangible User Interface (TUI) technology to enhance the educational involvement of children experiencing dyslexia. The primary objective of this application is to assist these children in overcoming challenges related to reading, spelling, pronunciation, and writing, issues often associated with lower self-esteem and dissatisfaction in an academic setting. The study adopts a User-Centered Design (UCD) approach, focusing on the specific needs and preferences of children with dyslexia during development. The evaluation involved 30 children with dyslexia, divided into two groups: a control group utilizing the non-tangible DisleksiaBelajar mobile app (DB) and a treatment group utilizing the DisleksiaBelajar 3D Tangible (DB3dT) app, which incorporates tangible elements. Results indicated that the DB3dT app achieved significantly higher usability scores (79.5%) compared to the DisleksiaBelajar app (51%). Furthermore, the treatment group utilizing the DB3dT app surpassed the control group in learning performance. In summary, the evaluation demonstrated that integrating tangible elements into the DB3dT app notably enhanced the learning experience for children with dyslexia when compared to the non-tangible DisleksiaBelajar app. The children exhibited increased engagement and a willingness to repeat activities, suggesting potential advancements in learning outcomes and performance.**

I. INTRODUCTION

Dyslexia is a learning disorder which is commonly found to have difficulty explicitly in language. Children with dyslexia tend to have language difficulty that leads them to be incompetent in reading skills, word recognition, differentiate the sound of letters, recognize mirror letters, and create the syllables in the sentences. Besides, dyslexic students also may face difficulty with spelling, writing, and speaking. In current teaching method, dyslexic students have limitation as the study material unable to offer feedback in learning and multisensory technique is not being embraced appropriately [1].

Multisensory techniques are required to allow dyslexic students to use all senses such as touch, see, hear, and kinesthetic movements in learning to read, make sound of the letters correctly and recognize, and distinguish the mirror letters. Besides, the current teaching module has constraints in terms of delivery to the students while learning. For instance, teachers are required to teach single sound values or letter sounds, word recognition and phonological awareness module such as rhyming and blending the words to the students which relying heavily on the teachers as well as required to teach one- to -one to students which lead to extremely labor intensive, and prolonged in performing the teaching procedure. This teaching module can be a real challenge to deliver and difficult to produce the sound of the letters correctly to students.

An appropriate tangible interaction learning model is developed to promote interactive and engaging learning experiences for dyslexic students to improve the current teaching approach [32]. One technique that has extremely beneficial in learning for dyslexic students is incorporating Tangible User Interface (TUI). TUI provides numerous advantages such as fun learning, collaboration, and support for children with dyslexia in learning mostly in language [2, 3]. TUI allows users to interact with physical objects in the real world, connecting to the digital information in the virtual world and including spatial and embodied facilitation. The advancement of interactive systems has been propelled by the increasing availability of novel devices and methods of interaction. Users now have access to a range of innovative interactive technologies across various application domains, including natural user interfaces, multi-touch displays, cameras, and sensor-based interactions [28].

TUI has been applied with success to children with special education needs. The works in [12, 13, 14, 15, 16, 17, 31] collectively demonstrate the benefits of tangible interaction for children with Dyslexia and Attention Deficit Hyperactivity Disorder (ADHD). TUI provides a suitable method for engaging children in playful learning and has been shown to facilitate improvements in reading, spelling, writing, and letter sound correspondence skills, as well as higher retention abilities in learning environments. The incorporation of tactile and multisensory elements enhances the learning experience, promoting exploratory activities and offering a playful learning environment that supports the unique needs of children with dyslexia. Overall, TUI has proven to be an effective approach in supporting the learning and development of children with dyslexia.

In research [29] discussed systematic mapping of toy user interfaces which focus on physical tangible toys and revealed the opportunities of TUI in education domain. As an example, in [30], the authors furnish a comprehensive examination of the TUI. They delve into its functional characteristics, present various application cases, and explore the design and application considerations related to TUI in the context of

education. This paper presents the evaluation of TUI system using experiment for children with dyslexia in improving learning engagement.

The structure of the study is based on the following: Section II will present the literature review, Section III will present the methodology used in the research, Section IV and Section V will present the results and discussion, Section VI will present the conclusion and future work.

II. Literature Review

A. Tangible User Interface (TUI)

Over the years the benefits of TUI have been rapidly expanded to build embedded and cooperating user experiences. TUI allows the interaction of physical items known as tangibles with computer applications. TUI has several inherent benefits compared to traditional user interfaces (e.g., keyboard or mouse interfaces), with a natural environment and rapid haptic feedback when users get both digital and physical feedback. Research demonstrates TUI enables students to participate in learning activities cognitively, emotionally, physically, and socially. TUI is also recognizable to students who have difficulty with learning such as dyslexics. Dyslexia is an impairment in the language that affects reading, writing, speaking, and listening. The conventional dyslexia learning using multi-sensory procedure has proven to be effective in assisting individuals to learn. However, owing to its rigorous, extended, and one-on-one teaching procedure, this method is highly demanding.

For children with dyslexia, who benefit from multisensory learning, TUI offers advantages through tactile and kinesthetic modalities that are absent in GUI. These modalities enhance the learning experience for these children, providing them with a more engaging and effective learning environment. For children with dyslexia, it is crucial to incorporate tactile and kinesthetic senses when designing TUI systems for teaching them to read and write. By considering their specific needs, the design space must include necessary guidelines that highlight not only the interface but also the learning styles, learning activities, dyslexia learning methods, student's level, and feedback.

TUI in children's learning has garnered significant interest due to its benefits. One such benefit is that tangible interaction, which utilizes embodiment and various forms of feedback (e.g., audio, visual, and haptic), supports different learning styles of children [4]. TUI in learning is commonly incorporated into play activities, which have the potential to promote the cognitive, motor, and physical development of children. When children play, they engage their cognition to think, explore, and enjoy the learning process. However, ensuring children's engagement in learning poses significant challenges [5, 6].

B. Engagement

One of the most important aspects in learning performance is student engagement. This is because level of engagement leads to improved retention, which improves learning performance [7]. In the teaching and learning of children with dyslexia, engagement functions as a nonverbal behavior that necessitates attention. In the context of children with dyslexia, learning engagement is often a big struggle due to the difficulties they face such as They may feel frustration and anxiety due to their difficulties in reading and writing, leading to negative attitudes toward learning, emotional outbursts, or withdrawal from academic tasks [8]. These struggles can impact self-esteem, giving rise to feelings of inadequacy and reluctance to participate in school activities [9]. As a coping mechanism, children with dyslexia may exhibit avoidance behaviors, such as avoiding reading or writing tasks, resisting class participation, or hiding their difficulties from others [10]. Consequently, they may struggle to maintain focus during reading or writing tasks, leading to distractibility and difficulty staying on task. This can significantly affect their overall academic performance and hinder their ability to engage in learning activities and follow instructions [11].

C. Related Works

TUI has been utilized as an assistive technology in educational settings for children with learning difficulties. In this context, six TUI learning systems related to language learning for children with special needs are discussed. The first system, Character Alive [12] a TUI system to support children with dyslexia aged between 5-7 years old in reading and writing skill was developed. The system emphasized on the learning Chinese literacy acquisitions for Mandarin language and provides multisensory approach to allow children in reading and writing of the Chinese characters and words. The system incorporates tangible objects which use dynamic color cues, 2D tangible cards and provide intuitive feedback such as audio, tactile and visual using animations representations. The function of using color cues in the system to inform children on the common patterns of similar characters. Besides, children can arrange and organize the 2D tangible cards which allow them on the tactile feedback and kinesthetic learning environment. Moreover, the use of animation in the system can capture children attention and enable them to memorize the Chinese characters effectively. Though, the work is still in progress which the researcher has not conducted any usability testing to evaluate in terms of the effectiveness of the system.

The second system PhonoBlocks [13] a TUI system developed for reading that uses dynamic colour cues embedded in 3D tangible letters to provide additional decoding information and modalities for children aged 5-8 years old, who are having difficulty learning to decode English letter-sound pairs. The work has addressed several TUI design guidelines in assisting dyslexic to read such as spatiality, various types of interaction modalities, and multiple ways of letter representation as well as structured procedures. PhonoBlocks allows simultaneous use of visual, auditory as well as kinesthetic or tactile approach in both physical and digital representations. It also focuses on the 3D design of tangible letters which facilitates dyslexic children to learn letter as a basis rather than words because they often struggle with letter-sound correspondences and mirror-letter such as b and d.

Third, Block Talks [14] is a system that combines TUI and augmented reality (AR) to support children aged 8-10 in learning English sentence construction. The system utilizes

tangible blocks that represent different elements of a sentence, such as subjects, verbs, and objects. Children can physically manipulate and arrange these blocks to create meaningful sentences. This hands-on approach provides a structured and scaffolded learning experience that fosters language development and helps children grasp grammar rules and sentence formation. The engagement and fine motor skills involved in the tangible interaction promote a deeper understanding of sentence structure. Additionally, AR technology enhances the learning experience by providing visual and auditory feedback, contextual information, and interactive storytelling elements. For example, through the AR display on the screen, children can better comprehend sentence construction concepts and see their constructed sentences come to life. Evaluation results show that Block Talks effectively engages children and promotes their understanding of sentence structure. The use of TUI with the blocks stimulates hands-on learning and facilitates the development of language skills, including grammar and syntax.

Fourth, Interactive Fruit Panel (IFP) [15] is a TUI serious game developed to support children with special needs in learning an alternative communication system. IFP offers three key advantages in facilitating communication skills for children with special needs. Firstly, it utilizes a tangible interface in the form of a fruit panel, allowing children to physically interact with the panel. This hands-on approach promotes engagement, fine motor skills, and a multisensory learning experience. Secondly, IFP incorporates a serious game element, making the learning process enjoyable and motivating for children. Finally, IFP is specifically designed to address the unique needs of children with special needs in learning alternative communication. It provides a structured and intuitive interface that supports language and communication development, enabling children to express themselves effectively. Evaluation findings indicate that when children played with IFP, they showed increased concentration compared to using traditional games. Moreover, the use of IFP resulted in less distraction for the children.

Fifth, Tactile Letters is a multimodal TUI tabletop system developed to teach English alphabet sounds to children with dyslexia aged five to six years old [16]. The system utilizes texture cues in the form of two sets of tangible letters, each consisting of 24 letter cards. Children can choose to interact with the 3D tangible letters or use the letter cards on the interactive tabletop. When children connect the tangible letters correctly, audio feedback is provided to reinforce their learning. The design guidelines of this work emphasize spatiality, allowing children with dyslexia to decode and arrange the letters in their environment. Additionally, multiple senses, including audio, visual, and tactile, are incorporated into the prototype. By providing a hands-on and multisensory learning experience, Tactile Letters aims to improve letter recognition and enhance visual processing for children with dyslexia. The evaluation results indicate that the incorporation of texture cues successfully captures the participants' attention and increases their engagement with the program. The inclusion of frequent kinesthetic movement promotes brain activity and aids in word retention, surpassing the effectiveness of traditional flashcards. Participants expressed interest in the program and gained knowledge from the phonics-based reading program. Tactile Letters serves as a potential reading tool for children with dyslexia, assisting them in independent reading practice and learning, complementing their regular classroom instruction.

Six, TraceIt is another tool designed to support children with dyslexia in reading through a hands-on and interactive learning activity [17]. TraceIt utilizes air tracing interaction to improve letter formation and enhance visual processing. The program incorporates color-based physical objects and offers a multisensory learning experience. The evaluation results reveal that the air tracing interaction technique successfully captures the participants' attention and increases their engagement with the program. The inclusion of frequent kinesthetic movement promotes brain activity and aids in word retention, surpassing the effectiveness of traditional flashcards. Participants not only expressed interest in the program but also gained knowledge from the phonics-based reading program. TraceIt demonstrates good potential as a reading tool for children with dyslexia, providing a playful and interactive learning environment that complements their regular classroom instruction.

The works by [12, 14, 15, 16, 17] collectively demonstrate the benefits of TUI for children with dyslexia. TUI provides a suitable method for engaging children in playful learning and has been shown to facilitate improvements in reading, spelling, writing, and letter sound correspondence skills, as well as higher retention abilities in learning environments. Overall, TUI has proven to be an effective approach in supporting the learning and development of children with dyslexia.

III. METHODOLOGY

User-Centered Design (UCD) was adopted in this study, which involves understanding the user and their needs and context throughout the entire process from user requirements to evaluation stages. UCD consists of four phases: understanding the context, specifying user requirements, designing solutions, and evaluating against the requirements [18]. In this research, UCD was incorporated to develop a prototype and gain a deep understanding of users by involving them in the design process and product development. The focus was on meeting users' needs and improving their experience with the proposed solutions.

A. The Experiment

A quasi experiment was conducted in DAM centers in Ampang and Bandar Baru Bangi that aimed to evaluate the effectiveness of the DB3dT app in engaging students with dyslexia. Due to the limited number of participants available for randomization, a quasi-experiment was chosen. The participants in this study were children with dyslexia who were already attending predetermined classes in the DAM centers and were assigned to an eight-week intervention conducted within their school setting. These children were classified based on their level of study, which included beginner, intermediate, and advanced levels. The experiment consisted of two groups: the control group and the treatment group. The control group comprised 15 children with dyslexia who did not receive any stimulus. In their case, a non-tangible

approach using the DisleksiaBelajar mobile app was provided. On the other hand, the treatment group consisted of 15 children with dyslexia who received stimulus in the form of the DB3dT app. For this group, tangible objects such as tangible cards and toys were prepared to enhance their interaction with the app (see Fig. 1). The children in the treatment group engaged with the DB3dT app through task activities specifically prepared for them.

Fig. 1. The tangible objects- flashcards, 3D alphabet and toy.

B. The Procedure

The experiment was conducted on school property, utilizing a private space provided by the school principal. The location for the evaluation activity was assigned by the teacher and chosen based on its convenience, accessibility, and suitability for video recording purposes [19]. The decision to conduct the experiment in a school setting was aimed at providing the participants with a familiar and comfortable environment throughout the procedure [20]. Creating a comfortable atmosphere was important to promote a sense of ease for the participants [21] and ensure their comfort during the session [22].

Fig. 2. Experiment with children.

The session began with an introduction between the student, facilitator, and observer to help the student become acquainted with the setting and the session. The facilitator then explained the instructions regarding the instruments and the tasks required. In the control group, fifteen children were instructed to use the non-tangible approach using the DisleksiaBelajar mobile app. On the other hand, the treatment group, comprised of another fifteen children, were asked to use the tangible approach with the DB3dT app. Throughout the experiment, a facilitator was present near the students to assist them in using the application. An observer was also seated in front of the students to observe their engagement through facial expressions and behavior. Considering the vulnerability factors associated with the participants, such as their age and disabilities, maintaining a high-quality relationship between the facilitator and students was crucial [23] (see Fig. 2). Additionally, the facilitator communicated instructions in the Malay language to ensure clarity and understanding for the children.

During the session, whenever a student required assistance, such as when they needed help with spelling specific terms or when they were unfamiliar with the vocabulary of an object in Malay, support was provided and recorded. If a student struggled significantly with the exercises and remained inactive for a prolonged period, the question was skipped to save time and minimize demotivation. Two mobile tablets were utilized during the experiment, specifically for the DisleksiaBelajar mobile app and the DB3dT app. The DisleksiaBelajar mobile app was developed specifically for children aged between 6 to 12 years old with dyslexia, aiming to enhance their Malay language skills. Both instruments were introduced in this quasi-experiment as entirely new approaches. This was done to ensure that neither group of dyslexic children had any prior knowledge or bias when using these apps. The DB3dT app employed a tangible approach, while the DisleksiaBelajar mobile app utilized a non-tangible approach. These two apps had similar activity modules focusing on phonology, spelling, and reading skills. Prior to the start of the experiment, the children with dyslexia were introduced to and familiarized with the mobile tablets, including learning how to use the camera, and understanding the functions and settings of the devices. For the experiment setup, materials such as a mobile tablet, a video recorder, and a mobile phone were used. The session lasted for 45 minutes and was recorded using a video camera for further analysis.

C. The Instruments

Several data collection instruments were used in this experiment: Tangible approach using DB3dT application, non-tangible approach using DisleksiaBelajar application, System Usability Scale (SUS), Again-Again Table and Observation Form. The SUS serves the purpose of evaluating the system's usability from the perspective of dyslexic children. In addition, the use of a five-point Smileyometer scale, as shown in Fig. 3, allows students to rate their experience with the SUS ranging from 1 to 5, with a rating of 5 representing the most positive response. Fig. 4 displays the ten items that are evaluated in this scale. To ensure comprehension among children, the items were translated into Malay language without altering their original meaning. This

instrument has been validated and previously used in the study conducted by [24]. As some children may not be able to read fluently, facilitators assist in reading the items. The Again-Again table was utilized to evaluate enjoyment, engagement and confirm acceptance of the DB3dT app by children with dyslexia that using 3-point Likert scale of 'Yes, Maybe, No' (*Ya, Mungkin, Tidak*) as shown in Fig. 5. As described by [25], human emotion should be considered when validating user acceptance for assessing user experience. The Again-Again table from the Fun Toolkit [26] was utilized as a self-reporting approach for children. According to [24, 27], the Again-Again table was utilized because students are highly likely to experience enjoyment when an activity is engaging, making them willing to do it again.

D. The Application

The DisleksiaBelajar 3d Tangible (DB3dT) application was developed based on the proposed learning model [32]. The DB3dT app enables children to interact with digital information using tangible objects such as tangible letter cards, alphabet blocks, and toys in the physical environment. In study [12], the author developed a reading augmented reality using 2D and 3D cards to compose a character within a word and sentences in supporting children Chinese reading and writing skills.

This DB3dT facilitates phonology, spelling, and reading skill development specifically tailored to dyslexic learning patterns. Through intuitive interaction with tangible objects, children can construct words from syllables and view augmented reality 3D overlay content on a screen during the learning activity. The application incorporates various sensory experiences, including tactile, auditory, visual, and kinesthetic elements, to strengthen literacy skills. There are five learning activity modules in DB3dT app as depicted in Fig. 6.

Fig. 3. Smileyometer.

	Soalan	Skala
1	Saya akan sentiasa menggunakan aplikasi DB3dT ini.	
2	Aplikasi DB3dT ini mudah digunakan.	
3	Saya berjaya menggunakan aplikasi DB3dT ini tanpa bantuan orang lain.	
4	Aplikasi DB3dT ini berfungsi dengan baik.	
5	Saya suka menggunakan aplikasi DB3dT ini.	
6	Saya faham arahan yang digunakan dalam aplikasi DB3dT ini.	
7	Saya seronok apabila menggunakan aplikasi DB3dT ini.	
8	Aplikasi DB3dT ini membantu saya dalam mempelajari Bahasa Melayu dengan baik.	
9	Saya berjaya menggunakan aplikasi DB3dT ini tanpa sebarang masalah.	
10	Saya yakin menggunakan aplikasi DB3dT ini.	

Fig. 4. The 10-items for system usability scale.

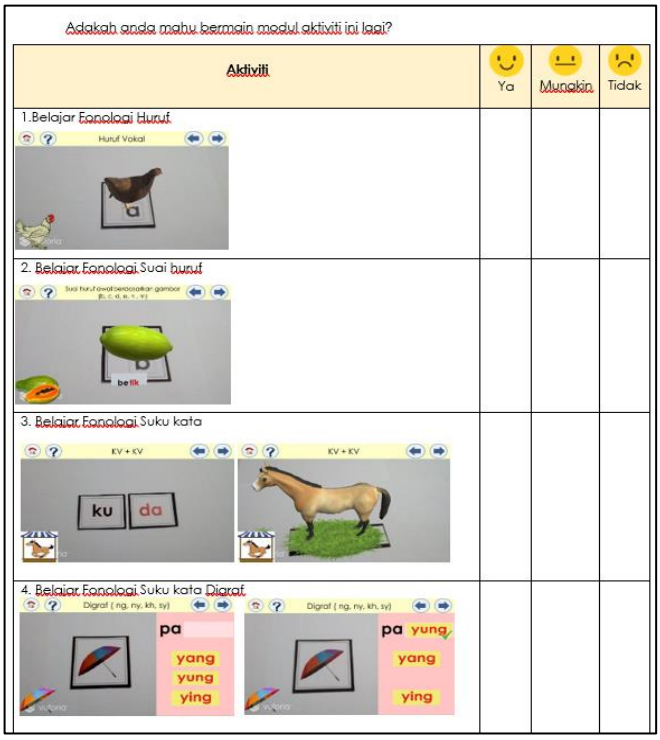

Fig. 5. Again-Again table.

Fig. 6. Five learning activity modules in DB3dT app.

1) Huruf, Suai Huruf and Suku Kata modules: This module focuses on phonology skills, specifically vowels, consonants, and syllable exercises. The vowel activity evaluates the student's knowledge of vowels, requiring them to differentiate vowel sounds and match the world's first letter in the Huruf module. Pictures are provided alongside the words to assist students in selecting the correct vowel. On the other hand, the consonant practice addresses five common consonant mistakes in the Malay language, as shown in Fig. 7. This task assesses a learner's ability to identify consonant sounds and match them correctly. The syllables exercise consists of two types: Vowel + Consonant Vowel (V+CV) and three-syllable combinations (CV+CV+CV), among others. This activity evaluates the learner's ability to recognize pictures, choose the correct syllable, and drag it into the appropriate word. To provide a challenge, similar syllables are also presented as distractors. In the Suai Huruf module, students match initial letters with corresponding pictures. This module introduces six letters: b, d, c, e, n, and m, which are

known to cause confusion among dyslexic children. The objective is to help dyslexic students understand and recognize these letters, as shown in Fig. 8. The Suku Kata module focuses on sorting and recognizing CV and CVCV syllables using picture hints, as depicted in Fig. 9.

Fig. 7. Vowel and consonant activity in the *Huruf* module.

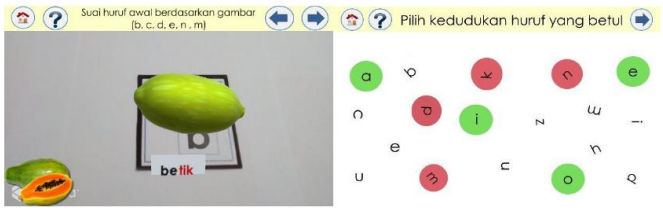

Fig. 8. Matching initial letters with picture and identify correct letter position in the *Suai Huruf* module.

Fig. 9. Sorting syllables using CVC and CVCV in the *Suku Kata* module.

2) Ejaan (Spelling) module: The Ejaan module is designed to assist dyslexic children in identifying spelling based on picture hints provided at the bottom left of the screen. The students are asked to manipulate tangible letters to construct the correct spelling. Each letter is accompanied by its corresponding sound. An example of the activity involves spelling the word "kuda" using CVCV words, as shown in Fig. 10. Additionally, dyslexic students learn to spell digraphs (ny, ng, kh, sy) and diphthongs (ai, au, oi), as depicted in Fig. 11. Finally, the module includes an activity where dyslexic students need to identify the correct spelling of colors, helping them practice spelling words correctly, as depicted in Fig. 12.

Fig. 10. Spell and divide the CVCV in the *Ejaan* module.

Fig. 11. Spell and divide the CVCV in the *Ejaan* module.

Fig. 12. Choosing correct colors spelling in the *Ejaan* module.

3) Bacaan (Reading) module: This module provides children with short passages themed around animals in the zoo. Students have the option to read the passages on their own or listen to the system narrator by pressing the audio icon. They can then select and interact with tangible animal figurines displayed on the screen. Four animal figurine toys are available for selection: Tiger (Harimau), Rhinoceros (Badak sumbu), Turtle (Penyu), and Orang Utan. Students can scan the tangible animals, triggering an augmented video of the animal along with accompanying sounds and a narration of its story. Following the Bacaan module, dyslexic children can engage in comprehension exercises by clicking on the Latihan icon at the top of the screen. These exercises require them to answer questions based on the animal stories they previously learned, with three exercises provided for each animal, as shown in Fig. 13.

Fig. 13. Reading a short passage and learning comprehension modules.

IV. Results

In this study the primary objective is to examine the effectiveness of the DB3dT app to enhance student engagement in learning for children with dyslexia through a

quasi-experiment. We presented descriptive statistics to determine the average on-task behavior of the students as a measure of the effectiveness of the DB3dT app. The experiment results were analyzed for usability testing using the System Usability Scale (SUS), usability observations, user experience using the Again-Again Table, and a checklist of children's performance in learning activities.

A. Descriptive Statistic

According to the results presented in Table I, the average on-task time for beginner students in the control group, who used the non-tangible approach (DisleksiaBelajar mobile app), was recorded as 14 minutes and 93 seconds (SD= 2.72). In comparison, for the treatment group that used the tangible approach (DB3dT app), the average on-task time was recorded as 33 minutes and 58 seconds (SD= 6.18). This indicates that students in the treatment group were more engaged with the activity modules, even at the beginner level. Furthermore, among students at the intermediate level, those in the control group exhibited an average on-task time of 12 minutes and 49 seconds (SD= 1.37), while the treatment group recorded an average of 31 minutes and 30 seconds (SD= 7.74). This translates to a twofold increase in on-task time for the treatment group indicating that students using the DB3dT app retained their engagement for a longer period compared to those using the DisleksiaBelajar mobile app. Some students mentioned that the DisleksiaBelajar mobile app was too easy for them, leading them to complete tasks quickly. Finally, the analysis of average on-task time between the control group and treatment group for advanced students was conducted.

The results showed that students in the control group were engaged with the activity modules for approximately 11 minutes and 39 seconds (SD= 2.72) using the DisleksiaBelajar mobile app, whereas the treatment group recorded an average of 22 minutes and 54 seconds (SD= 3.73) using the DB3dT app. These values indicate that there was a twofold difference in on-task time between the two activity modules due to the higher mastery level of the advanced students. Since advanced students were more proficient in performing the activity modules, their engagement time was shorter compared to beginner and intermediate levels. Nonetheless, the treatment group still retained twice the engagement time compared to the control group. This suggests that using the tangible approach (DB3dT app) in the treatment group resulted in higher engagement levels with the activity modules compared to the non-tangible approach used in the DisleksiaBelajar mobile app. In general, the adoption of a tangible approach in learning activity modules plays a crucial role in measuring student engagement based on on-task time. The results clearly indicate that students using the DB3dT app spend more time engaged compared to students using the DisleksiaBelajar mobile app.

B. System Usability Scale

Based on these scoring rules, the average score for the DB3dT app (tangible approach application) is 79.5%, whereas the average score for the DisleksiaBelajar app (non-tangible application) is 51%. In conclusion, the DB3dT app with its integration of tangible elements like augmented models, animations, videos, and text, was found to be more usable for students with dyslexia compared to the DisleksiaBelajar mobile app. This can be seen in the analysis of each questionnaire item, which showed more positive responses (odd numbered items) for the DB3dT app versus the DisleksiaBelajar app (see Fig. 14). The DB3dT app also had fewer negative responses (even numbered items) than the DisleksiaBelajar app for most items. For item 5, which asked about system function integration, the treatment group scored 4.3 and the control group scored 4.1, a minor 0.2-point difference. This small difference is likely because students felt the functions were good in both apps. Overall, the tangible elements incorporated in the DB3dT app made it more engaging and usable than the non-tangible DisleksiaBelajar mobile app for children with dyslexia.

TABLE I. RESULT FOR ON-TASK TIME FOR BOTH GROUPS

	Control Group					Treatment Group				
Beginner	18.00	17.17	15.17	12.24	12.1	37.37	24.83	30.19	40.54	34.99
Average	14.93					33.58				
SD	2.72					6.18				
Intermediate	11.87	14.34	13.51	11.74	11.03	27.31	26.3	43.99	33.4	25.51
Average	12.49					31.30				
SD	1.37					7.74				
Advanced	10.37	14.89	13.52	9.89	8.3	27.74	18.63	21.12	20.21	25.02
Average	11.39					22.54				
SD	2.72					3.73				

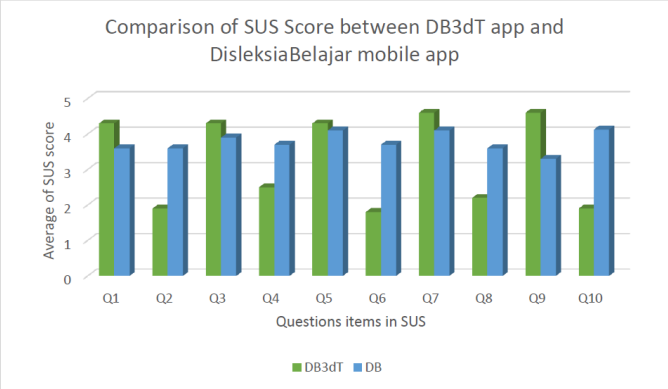

Fig. 14. Comparison of SUS score for DB3dT app and DisleksiaBelajar mobile app.

C. Usability from the Observation

In this study, observational notes were utilized to capture the students' signs, expressions, and behavior while interacting with both tangible and non-tangible applications. These notes were used to make a comparison between the DB3dT app as a tangible application and the DisleksiaBelajar mobile app as a non-tangible application as shown in Table II. During the experiment, it was observed that each student had different abilities in responding to the applications. Students at the beginner level encountered challenges in answering comprehension questions and struggled with reading lengthy passages. On the other hand, students at the intermediate and advanced levels demonstrated confidence in engaging with the activities and were able to answer comprehension questions effectively. Based on the observations, two distinct types of students emerged: those who were on-task (engaged) and those who were off-task (disengaged). Engaged students exhibited dynamic concentration and active interaction with the application. They required less supervision and demonstrated independent participation. In contrast, disengaged students displayed various behavioral issues such as excessive talking, difficulty sitting still, hyperactivity, fear of making mistakes, easy distractibility, and a tendency to give up quickly during the activities. The results indicated that the tangible approach offered additional advantages for both engaged and disengaged students. Using the DB3dT app, both types of students remained engaged for longer periods. The DB3dT app's activities allowed students to interact with the learning materials based on their level of engagement, encompassing cognitive, behavioral, and emotional aspects.

D. User Experience using Again-Again Table

The Again-Again table was also used to evaluate enjoyment and engagement for children with dyslexia. The children scored each DB3dT app activity interface that they wanted to play again using a 3-point Likert scale of 'Yes, Maybe, No'. Thirty children completed the scoring. Frequencies of the scales were calculated to analyze the activities. This study relates to the work of [27], which used enjoyment as a metric to quantify students' emotions while interacting with a mobile app for those with speech delays. The result in Table III indicates that most children highly enjoyed certain DB3dT activities, such as *Fonologi Suku Kata* and *Ejaan*, with all students willing to play them again. They found these activities easy and engaging, attributing their enjoyment to the fun tangible letter cards they could arrange on the board, interesting 3D visuals on screen, and letter sound feedback. Additionally, the children needed minimal assistance during these tasks, displaying genuine enjoyment and enthusiasm while using the app. In contrast, activities like *Fonologi Huruf*, *Fonologi Suku Kata Digraf*, and *Latihan Pemahaman* had only 73% agreement among students to play again. Some students found these activities more challenging due to reading difficulties, needing more facilitator support to identify sentences.

TABLE II. COMPARISON OF STUDENT'S RESPONSE FROM OBSERVATIONAL NOTES

Study Level	DisleksiaBelajar mobile app (DB) (non-tangible)	DB3dT app (tangible)
Beginner	• Displayed no reaction when they were asked about the letters. • Kept on trying and making mistakes of each letter.	• Amazed with the tangible objects. • Kept playing with the tangible cards and figurine toys.
	• Unable to sit still and were restless.	• Got distracted with the tangible objects/ cards.
	• Confused by some letters, especially 'b' and 'd', and were unable to read long passages	• Unable to sit still and restless.
	• Asked for help from the facilitator when doing the activity.	• Followed the words and letters when learning letters.
	• Bored and wanted to quit the activity.	• Abled to engage with the learning activity even when facing technical issue.
Intermediate	• Showed excitement when answering the questions.	• Displayed astonishment as soon they saw 3D objects appearing on the screen.
	• Confidently saying 'yes' and finding it easy after completing the activity.	• Clapped their hands when scanning tangible objects.
	• Confused by some letters, especially 'b' and 'd', and were unable to read long passages	• Smiled while doing the activity.
Advanced	• Showed no expression and were bored because the activity was deemed easy.	• Abled to read the passages of the animal story.
	• Felt shy but still wanted to do the activity.	• Excited to use the black board to arrange letters.
	• Displayed no expression when they answered the questions correctly.	• Smiled when they were able to answer the learning comprehension questions.

Additionally, 80% of children agreed to play the *Fonologi Suai Huruf* activity again, while only 53% agreed for the *Bacaan* activity. Feedback showed these activities were more difficult, with some struggling to read fluently, blend syllables, and comprehend long sentences and passages. Overall, the findings indicate children prefer activities with tangible objects like cards and letters, as these elements greatly influence their interest in learning. To enhance the learning experience, incorporating visual, audio, and kinesthetic

components is crucial. In conclusion, the Again-Again table demonstrates the DB3dT app is enjoyable to use. This confirms that the children's experiences and feelings while engaging with the DB3dT app, as revealed in Table III, align with the Again-Again table results. The tangibility elements made activities more engaging and fun for children with dyslexia.

E. Performance Checklist

In this experiment, student engagements were evaluated using a performance checklist that consisted of various questions related to their learning activities. The purpose of utilizing this checklist was to assess their progress in the learning tasks and obtain a comprehensive understanding of their learning outcomes. The questions covered different aspects of phonology learning, including identifying vowel and consonant letters, matching letters, learning syllable patterns (CVCV, CVC), spelling, and reading short paragraphs with 4, 5, and 6 sentences. The total possible score for these questions was 40. Both groups were given this performance checklist as an exercise based on the learning modules they had previously completed.

TABLE III. FREQUENCY RESPONSE TO AGAIN-AGAIN TABLE FOR DB3DT APP

Activity	Would you like to play again?	Frequency
Fonologi Huruf (Letter Phonology)	Yes	**11**
	Maybe	**4**
	No	-
Fonologi Suai Huruf (Letters Matching Phonology)	Yes	**11**
	Maybe	**3**
	No	**1**
Fonologi Suku Kata (Syllables Phonology)	Yes	**15**
	Maybe	-
	No	-
Fonologi Suku Kata Digraf (Digraph Syllables Phonology)	Yes	**11**
	Maybe	**4**
	No	-
Fonologi Suku Kata Diftong (Diphthong Syllables Phonology)	Yes	**12**
	Maybe	-
	No	**3**
Ejaan (Spelling)	Yes	**15**
	Maybe	-
	No	-
Bacaan (Reading)	Yes	**8**
	Maybe	**6**
	No	**1**
Latihan Pemahaman (Comprehension Exercise)	Yes	**11**
	Maybe	**2**
	No	**2**

The average total score of all 15 participants was 67.5%. It is worth noting that the control group scored slightly lower, at 60%, while the treatment group achieved a score of 65% at the beginner level, as depicted in Fig. 15. At the intermediate level, the control group attained an average score of 72%, whereas the treatment group scored 77% (see Fig. 16). Lastly, at the advanced level, the control group obtained an average score of 69.5%, whereas the treatment group excelled with an average score of 89.5% (see Fig. 17). These results suggest that the children with dyslexia in the treatment group displayed higher levels of engagement in the learning activities across all three proficiency levels compared to the control group.

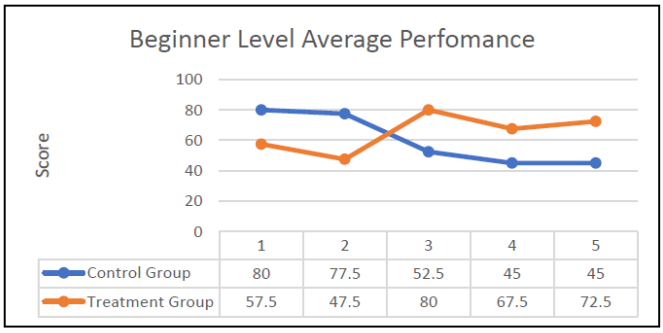

Fig. 15. Beginner level average performance.

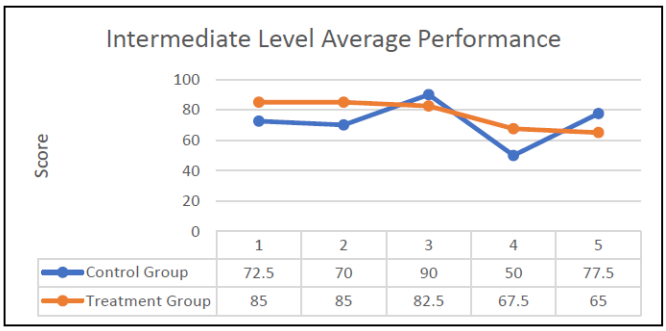

Fig. 16. Intermediate level average performance.

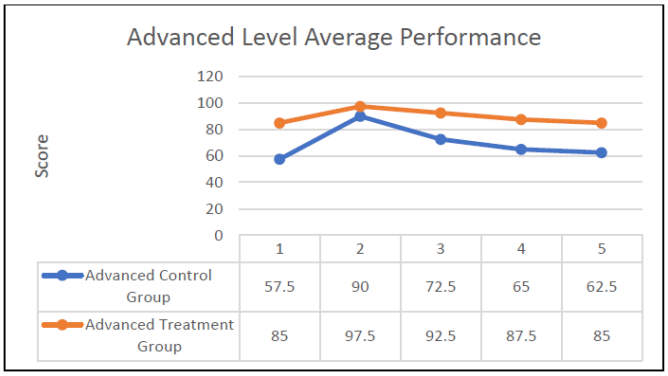

Fig. 17. Advanced level average performance.

V. DISCUSSION

This section discusses on evaluating the usability aspects and engagements of the DB3dT app. The evaluation encompasses the main aspect which is the effectiveness of the DB3dT app in promoting children's engagement. To evaluate the effectiveness of the DB3dT app in promoting student engagement, a quasi-experiment was conducted involving dyslexic students. The students were divided into control and treatment groups to compare the results based on their on-task time when using the non-tangible approach using the

DisleksiaBelajar app (control group) and the tangible approach using the DB3dT app (treatment group). The on-task time was utilized as a measure of student engagement. The results indicated that the treatment group, which used the DB3dT app, exhibited better and longer engagement compared to the control group using the DisleksiaBelajar mobile app, additionally, the hypothesis testing revealed a significant effect, indicating that the DB3dT app had a significant impact on improving engagement for children with dyslexia in the learning process.

Additionally, the SUS and Again-Again table were used to measure DB3dT app usability. Results showed the DB3dT app (tangible approach) had higher average usability at 79.5% versus 51% for the DisleksiaBelajar app (non-tangible). The Again-Again table also measured enjoyment and engagement. Most DB3dT activities were found to be fun and enjoyable, with children willing to play them again, indicating higher engagement. This aligns with research showing increased performance from sustained learning engagement [33].

The learning performance checklist and exercises also showed the treatment group had higher engagement, with average total marks of 77.5% compared to 67.5% for the control group. The higher scores for the DB3dT app group indicate its effectiveness at retaining engagement. In summary, usability and engagement metrics showed tangibility elements in the DB3dT app enhanced the learning experience for children with dyslexia versus the non-tangible DisleksiaBelajar app. The children were more engaged and willing to replay activities, suggesting potential learning and performance improvements.

VI. Conclusion and Future Work

Overall, the effectiveness of the DB3dT app in promoting student engagement was evaluated by conducting a quasi-experiment that involved children with dyslexia. In conclusion, the DB3dT app demonstrated positive outcomes in supporting children with dyslexia learning the Malay language. The tangible elements incorporated in the DB3dT app increased engagement and understanding compared to the non-tangible mobile app. Based on the findings of this research, it is evident that the DB3dT app enhances learning activity and improves engagement among children with dyslexia. It also provides a usable approach for children in the learning process. Considering the constraints of limited time and funds, there are several recommendations for future research that can further enhance the understanding and application of the DB3dT app. For future work, we will replicate this research using students with diverse learning disabilities, such as dysgraphia or dyscalculia, would allow for an examination of how different types of learning disabilities impact the behavioral intention to use the DB3dT app accurately. This broader applicability of the results would provide valuable insights into its effectiveness across various learning disabilities.

Acknowledgment

We extend our sincere appreciation to the Dyslexia Association of Malaysia (DAM), Dyslexia Genius Malaysia (DGM), and the expert panels, including educational experts and dyslexia teachers, for their invaluable support in this research. A special acknowledgment goes to all the children with dyslexia who actively participated in this study. We are grateful to the university's ethics committee (JKEUPM) for approving our research application and express our thanks to the Ministry of Higher Education (MOHE) under FRGS/1/2019/ICT01/UPM/02/4 (vot. 5540289) for providing the necessary research funding.

FOREX Prices Prediction Using Deep Neural Network and FNF

Asmaa M. Moustafa[1]*, Mohamed Waleed Fakhr[2], Fahima A. Maghraby[3]
Arab Academy for Science Technology & Maritime Transport-College of Computing and Information Technology,
Heliopolis, Cairo Governorate, Egypt

***Abstract*—One of the largest financial markets on the planet is the foreign exchange (FOREX) market. Banks, retail traders, businesses, and individuals trade more than $5.1 trillion in FOREX daily. It is very challenging to predict prices in advance due to the market's complex, volatile, and highly fluctuating nature. In this study, the new FOREX Normalization Function (FNF) is proposed and used with different models to predict the prices of the AUD/USD, EUR/USD, USD/JPY, CHF/INR, USD/CHF, AUD/JPY, USD/CAD, and GBP/USD. Two models are proposed in this study. The first model contains FNF as a normalization and feature extractor, followed by a Convolutional Neural Network (CNN). The second model utilizes FNF and a Support Vector Regressor(SVR). The forecasts are set for a one-day timeframe, with predictions made for 1, 3, 7, and 15 days ahead. The efficient ability of the proposed method to solve the FOREX prediction problem is proven by performing experiments on nine real-world datasets from different currencies. Additionally, the models are evaluated using Mean Absolute Error (MAE) and Mean Squared Error (MSE). Applying the presented models to 9 different datasets improved the results by an average between 0.5% and 58% of MAE.**

***Keywords*—FOREX prediction; CNN; normalization function; SVR**

I. Introduction

FOREX, also known as "foreign exchange" involves changing one currency into another. Every day, traders trade trillions of dollars [1]. Due to significant currency rate fluctuations, this market is unpredictable, complicated, and subject to frequent changes [2]. The market is always open, although trading takes place in the four main time zones: European, Asian, Australian, and North American [3]. The opening and closing hours of each of these zones differ. The market is protected from scammers since it takes significant money to impact exchange rates. Over the past few decades, scholars have become increasingly interested in forecasting foreign exchange. Unlike the stock market, the foreign exchange market doesn't require large amounts of cash. Leverage is one of the most critical tools related to the market. Leverage is the process of increasing the future return on investment by using borrowed funds[4]. Traders, individuals, professionals making expensive purchases, entrepreneurs, and investors employ leverage. This approach is beneficial for those with little finances and is also a vital element of the FOREX market that attracts private and small investors.

Both technical analysis and fundamental analysis can be used to forecast FOREX prices. While technical analysis only uses historical time series data to make FOREX market predictions, the fundamental analysis considers various variables, including the company's and the nation's economic and industrial conditions [5]. Algorithmic trading refers to trading in which automated programmed algorithms implement orders instead of human traders. Algorithmic trading is utilized by hedge funds, pension funds, and other financial institutions [6], [7]. A lot of work has been put in by both academics and trading companies to find possible factors that could lead to much higher profits[8]. Numerous studies have attempted to forecast the movement of the FOREX market. The most crucial decision in FOREX is predicting the direction of currency price movement. Accurately forecasting currency prices can yield several advantages for traders and vice versa. In recent years, the academic community has made a lot of effort to develop machine learning models for FOREX market prediction.

On the other hand, numerous verifiable study types have been undertaken to understand and anticipate currency patterns in the FOREX market using machine learning algorithms. Generally, many methods are categorized into three categories: machine learning models, deep learning models, and hybrid forms.

Machine learning algorithms include Random Forest, Support Vector Machine, XGBoost, etc. Deep learning-based methods demonstrate how advanced neural models can significantly enhance prediction results. Like statistical methods, these methods require knowledge of effective signals to be utilized as input. The researcher utilized deep learning methods such as RNN, LSTM, CNN, GRU, and Transformers [2]. Long short-term memory (LSTM), a recurrent neural network (RNN), excels at modeling temporal patterns and is commonly employed in various tasks involving time series problems. CNNs are used to analyze price patterns by utilizing images of financial data as input [9]. This study attempts to answer the following questions: What normalization method improves FOREX prediction accuracy? What is the percentage of improvement on different dataset results? Which model, when used with the FOREX normalization function, gives the best results? Therefore, the objectives of this study are to utilize the FNF method with various machine and deep learning models and to compare the proposed model with two baseline models. Then, show the percentage of error reduction made by FNF.

This paper’s primary contributions are summed up as follows:

- FOREX Normalization Function FNF is proposed to predict FOREX prices.FNF generates 84 different normalized features.
- FNF and Convolutional Neural Networks FNF-CNN are used in the first model 1 dimension convolution layer applied on FNF features to predict the close price of the next 1,3,7,15 days.
- FNF and Support Vector Machine FNF-SVR are used in the second model. Four kernels are applied on FNF features to predict the close price of the next 1,3,7,15 days. The forecasts are set for a one-day timeframe. Applying the previous models to 9 different datasets improved the results by an average between 0.5% and 58% of MAE.

The rest of this research is organized in the following manner: Section II reviews the related work, Section III provides an overview of the key scientific concepts, and Section IV describes the proposed models and their architectures, used datasets, evaluation metrics, and training configuration. Section V contains the results of the proposed models compared to baselines, discussion and ablation study. Finally, the paper concludes in Section VI.

II. Related Work

Various methods have been used in previous years to forecast the FOREX market. Numerous approaches have been attempted, mostly based on Artificial Intelligence principles. Some methods contain just one processing technique, while others combine two or more techniques. Researchers have used a variety of linear and nonlinear models for FOREX forecasting. Naive models such as Exponential smoothing, Autoregressive Moving Average model (ARMA), and Autoregressive Conditional Heteroskedasticity models (ARCH) and their variants (GARCH, EGARCH, etc.) are some of the most often used strategies for modeling volatility in time series [10]. Using machine learning methods like artificial neural networks (ANN) has been the subject of extensive study in recent years. The outstanding quality of ANNs used for time series forecasting problems is their innate capacity for nonlinear modeling without any assumption regarding the statistical distribution being invalid based on the observations. The most popular is the multi-layer perceptron (MLP), which has one hidden layer. Support vector machines (SVM), initially designed to address classification issues, are currently used for time series forecasting. Least-square SVM (LS-SVM) and Dynamic Least-square SVM are two common SVM models for forecasting time series [11]. Some researchers have applied deep learning models to predict FOREX prices. Hee Kueh and Leonard have proposed a comprehensive intelligent system for automated FOREX trading. The algorithm utilizes an ensemble methodology to make decisions; each strategy preprocesses technical data in order to produce a distinct buy or sell signal. The ensemble model takes all the signals from the different strategies and uses majority voting logic to decide what to do next [12] .The problem with this system is its low accuracy, and it was tested only on the EUR/USD dataset. Pornwattanavichai and Maneeroj [13] proposed a cascading model for the FOREX market. They made forecasts using Fundamental Data and Technical indications based on BERT. They used the EUR/USD dataset from February 3, 2003, through February 28, 2020, which included 4,455 days. However, this system has limitations; it has not been tested on many datasets. Junior and Appiahene [14] developed a conceptual framework centered on a FOREX forecasting module that uses the Hurst test to determine whether a time series is predictable. They then applied a two-layer stacked LSTM architecture and correlation analysis to multiple currency datasets, including EUR/AUD, AUD/JPY, and AUD/USD. However, the problem with this framework is that it is not generalized to many currency pairs or window times. Dash S. and Sahu [15] employed a Deep Predictive Coding Network Optimized with a Reptile Search Algorithm for short-term forecasting over three days to forecast exchange rates of the CHF/INR, USD/EUR, and AUD/JPY currency pairs. However, this system produces a high mean absolute error value and does not support long-horizon forecasting.

Salman and Saeed U proposed the FLF-LSTM model to predict EUR/USD prices. They enhanced prediction using a custom loss function named FLF with a single LSTM and different activation functions [16]. Areej and Mohamed [17] used RBF, MLP, and SVM algorithms as classifiers to predict the direction of the price and compared them based on percentage classification performance. Ikhagvadorj and Tsendsuren [18] proposed a framework consisting of seven neural networks with different activation functions. The outputs of these neural networks are concatenated and then fed into the softmax layer to produce probabilities or importance weights for each neural network. This model uses extended Min-Max normalization for financial time series data. Haixu and Jiehui [19] used the Autoformer for long-term FOREX price prediction at different time steps (96, 192, 336, 720). Autoformer is a variation of the transformer that uses Auto-Correlation instead of self-attention. Auto-correlation focuses on the connections of sub-series among underlying periods, while self-attention focuses on the connection between time points.

In conclusion, previous research indicates low results, and the impact of preprocessing has not been researched in detail. Also, the datasets used were not diverse and did not contain a large number of values for the time horizon. This paper addresses the impact of data preprocessing and scaling to enhance price prediction by using FNF. Nine datasets are used in this research, and the horizon values are 1, 3, 7, and 15. FNF is used in this paper with different models. The proposed models outperform the baselines.

III. Background

In this section, the necessary context for introducing our method is presented. First, CNN, SVM, LSTM, and XGBoost are examined.

A. CNN

The Convolutional Neural Network (CNN) has demonstrated remarkable advances in several domains associated with pattern recognition and image processing throughout the previous decade. One of the primary advantages

of CNNs is their ability to effectively decrease the parameter count within Artificial Neural Networks (ANNs) [20].

1) Convolutional Neural Network Element: To develop a comprehensive understanding of (CNNs), it is necessary to examine their fundamental components. The input layer receives input and transfers it to the convolution layer[21]. The parameters of a convolutional neural network are arranged into an array of three-dimensional structural units called kernels or filters. Let us assume that the filter's dimensions in the qth layer are Fq × Fq × dq and L_q height of layer q, B_q width of layer q. The following equation defines the convolutional process from the q-th layer to the (q + 1)th layer [22].

$$h_{ijp}^{(q+1)}=\Sigma_{r=1}^{F_q}\Sigma_{s=1}^{F_q}\Sigma_{k=1}^{d_q} w_{rsk}^{(p,q)} h_{i+r-1,j+s-1,k}^{(q)} \quad (1)$$

$$\forall i \in \{1 \dots, L_q - F_q + 1\}$$

$$\forall j \in \{1 \dots, B_q - F_q + 1\}, \forall p \in \{1 \dots, d_{q+1}\}$$

The 3-dimensional tensor $W(p,q) = w_{ijk}^{(p,q)}$ represents the parameters of the pth filter in the qth layer. The indices i, j, and k represent the positions along the filter's height, width, and depth. The qth layer's feature maps are represented by the three-dimensional tensor $H(q) = h_{i,j,k}^{(q)}$ [22]

The pooling layer will then perform downsampling along the provided input's spatial dimension. Researchers use either max pooling or average pooling [23]. The fully-connected layer will perform the same functions observed in conventional artificial neural networks. It is also recommended that the Rectified Linear Unit (ReLU) activation function be employed between these layers to enhance performance [23]. The output layer generates the final prediction value [21]. A common CNN is shown in Fig. 1 [24].

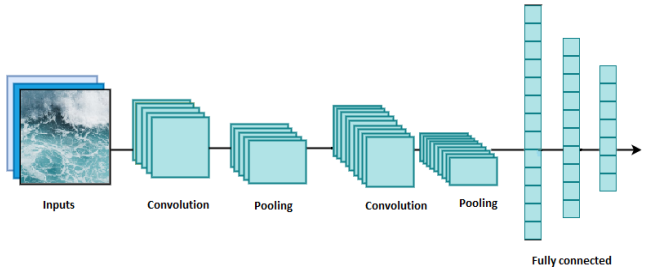

Fig. 1. Convolutional neural network architecture [24].

B. SVM

Support Vector Machines (SVM)can be used for prediction when the outcome is binary, multinomial, or continuous. Classification is a common term for regression with Bernoulli outcomes in statistical learning. Multinomial regression is also known as multiclass classification. The procedure is called regression when the results are continuous [25].

1) Support Vector Regression (SVR): In SVR, the ∈-insensitive loss function is minimized. If the loss is smaller than ∈, then the loss equals zero. The following equation (2) is utilized, known as the simple linear loss function:

$$L_\epsilon = \begin{cases} 0 & \text{, if } |y_i - f(x_i)| < \epsilon \\ |y_i - f(x_i)| - \epsilon, & \text{otherwise} \end{cases} \quad (2)$$

In support vector machines, kernels can achieve nonlinear regressions, such as radial basis function (RBF) and polynomial kernel [26]. The SVR can also be used with a linear kernel. The linear kernel equation is presented in (3), but nonlinear kernels are more flexible.

$$K(x_i, x_{i'}) = \sum_{j=1}^{p} x_{ij}\, x_{i'j} \quad (3)$$

$i \in \{1, \dots, n\}$ and $i' \in \{1, \dots, n\}$. We will call this inner product K . P is the number of x variables, and j=1,...,p. The variables p and x are mapped into a higher-dimensional space by nonlinear kernels [25], [26].

RBF, a radial basis function, is the most common option for a nonlinear kernel. Equation 4 presents it[25].

$$K(x_i, x_{i'}) = \exp\{-\gamma \sum_{j=1}^{p} (x_{ij} - x_{i'j})^2\} \quad (4)$$

where $\gamma > 0$ is an additional parameter for adaptability. When a test observation is quite far from a training observation, the exponent becomes strongly negative, and $K(xi, xi')$ reaches zero. Sometimes, more variables, such as polynomials, must be added as a function of the original variables. Polynomial variables expand the number of regression variables. The following equation shows the polynomial equation [25] [26].

$$K(x_i, x_{i'}) = (\beta_0 + \gamma \sum_{j=1}^{p} x_{ij}\, x_{i'j})^d \quad (5)$$

Where $\gamma > 0$ and $\beta 0$ are additional parameters for adaptability, $\beta 0$ "biases" the similarity metric for all samples. Applying this kernel implies adding polynomial powers of the x variables [25].

C. LSTM

The Long Short-Term Memory (LSTM) is an architectural design of recurrent neural networks (RNNs) that aims to provide a more precise characterization of temporal sequences and their long-range dependencies in comparison to traditional RNNs [27]. In this section, LSTM architectures will be explored.

1) LSTM architectures: The Long Short-Term Memory (LSTM) model has specialized memory blocks within its recurrent hidden layer. The memory blocks in the network consist of memory cells that possess self-connections, enabling them to retain the temporal state of the network. These memory cells are accompanied by specialized multiplicative units known as gates, which regulate the information flow within the network. In the original architecture, each memory block comprised an input and output gate. The input gate regulates the influx of input activations into the memory cell, while the output gate regulates the transmission of cell activations from the current cell to the remaining components of the network [28] [29]. Subsequently, the forget gate was incorporated into the

memory block. Furthermore, the current Long Short-Term Memory architecture incorporates peephole connections that link the internal cells to the gates inside the same cell. This design allows the LSTM to acquire accurate output timing information [30].

An LSTM network calculates a mapping from an input sequence x = (x_1, ..., x_t) to an output sequence y = (y_1, ..., y_t) by calculating the network unit activations using the following equations iteratively from t = 1 to T:

$$i_t = \sigma(W_{ix}\, x_t + W_{im}\, m_{t-1} + W_{ic} ct\text{-}1 + b_i) \quad (6)$$

$$f_t = \sigma(W_{fx}\, x_t + W_{fm}\, m_{t-1} + W_{fc}\, ct\text{-}1 + b_f) \quad (7)$$

$$c_t = ft \odot ct\text{-}1 + it \odot g(W_{cx}\, x_t + W_{cm}\, m_{t-1} + b_c) \quad (8)$$

$$o_t = \sigma(W_{ox}\, x_t + W_{om}\, m_{t-1} + W_{oc}\, ct + b_o) \quad (9)$$

$$m_t = o_t \odot h(c_t) \quad (10)$$

$$y_t = \varphi(W_{ym}\ m_t + b_y) \quad (11)$$

The weight matrices W terms denote weight matrices, W_{ic} , W_{fc} , W_{oc} are represent diagonal weight matrices corresponding to peephole connections. σ represents the logistic sigmoid function, while b represents bias vectors (bi represents the input gate bias vector). The input gate, forget gate, output gate, and cell activation vectors i, f, o, and c are identical in magnitude to the cell output activation vector m. ⊙ represents the element-wise product of the vectors g and h, where g and h represent the cell input and cell output activation functions, respectively [31].

D. XGBoost

XGBoost, an abbreviation for extreme gradient boosting, is well recognized as a common, robust, and efficient implementation of gradient boosting [32]. XGBoost is an ensemble model that efficiently implements decision trees to create a composite model with superior prediction performance compared to individual techniques employed alone. The output of XGBoost is calculated using the following equation:

$$\hat{Y}_i^T = \sum_{k=1}^{T} f_k(x_i) = \hat{y}_i^{T-1} + f_T(x_i) \quad (12)$$

where $\hat{\boldsymbol{y}}_{\boldsymbol{i}}^{\boldsymbol{T-1}}$ i is the generated tree, $\boldsymbol{f}_{\mathbf{T}}(\boldsymbol{x}_{\mathbf{i}})$ is the newly created tree model, and T is the total number of tree models [33].

IV. Research Methodology

In this section, two models are proposed: FNF-CNN and FNF-SVR. The first model uses FNF to normalize data and extract new features; those features become input for CNN. The second model also uses FNF and then a Support Vector Machine. Finally, four different kernels are used. The architecture of the models is explained in this section.

A. Proposed Approach

1) Model I: FNF-CNN: Multiple models and preprocessing methods are used in this paper to enhance results and present the impact of FNF. For example, the Moving Average and normalization of the close price are calculated using the following equation:

$$FNFc = MAw(close) - close \quad (13)$$

Here, FNFc represents the normalized close price, and MAw is the Moving Average of window size w. The first proposed model calculates the FNF equation for open, high, low, and close. The time windows range from 1 to 21 days. Then, all moving average features are normalized (FNF) and fed to a 1-dimensional convolutional neural network (CNN). MSE is the loss function, and ReLU is the activation function, as shown in Fig. 2.

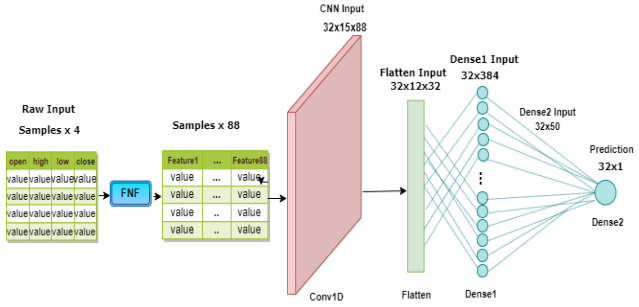

Fig. 2. The architecture of FNF-CNN to predict one day ahead.

A deep learning framework is used with extended Min-Max normalization [18] as the first baseline model. The raw data consists of open, high, low, and close prices from the previous time step, and the target is to predict close prices for the next day. The second baseline model is the Deep Predictive Coding Network Optimized with Reptile Search Algorithm (RSA-DPCN) [15]. RSA-DPCN is used to predict the future price of currency pairs for short-term time frames, such as three, seven, and 15 days ahead of the closing price of EURUSD, AUDJPY, and CHFINR [15]. Fig. 3 shows the proposed model to predict three days ahead of the closing price.

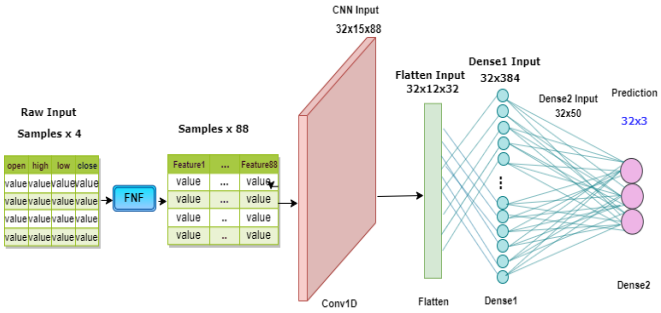

Fig. 3. This model is similar to the previous model in Fig. 2, but it is used to predict the price for the next three days.

2) Model II: FNF-SVR: The Moving Average from Windows 1 to 21 is calculated for all features in the second model. Then, all moving average features are scaled and fed to the Support Vector Regressor (SVR), as shown in Fig. 4. Different kernels are used to obtain the best results.

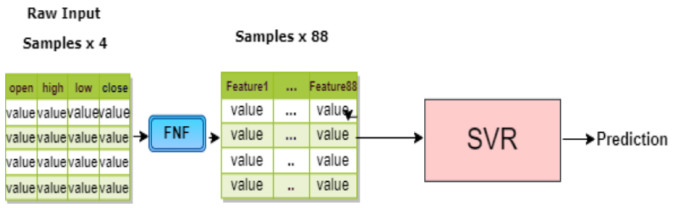

Fig. 4. Architecture of FNF-SVR.

XGBoost and LSTM with FNF are used to compare the results of different machine and deep learning models. For all models, MSE is used as a loss function. TensorFlow 2, Keras, Pandas, and XGBoost frameworks are used in the experiments.

B. Dataset

All models in this paper have been applied to the following datasets: The datasets in group 1 contain daily prices of (GBP/USD, EUR/USD, USD/CHF, USD/JPY, AUD/USD, USD/CAD) from 2000 to 2019. The datasets are partitioned into three parts: training (80%), validation (20%), and testing (the last 365 days)[18]. The dataset group 2 contains daily prices of AUD/JPY, CHF/INR, and EUR/USD from 2015 to 2020 [15].

C. Evaluation Metrics

Mean Absolute Error (MAE) is used to assess the model's performance and is expressed by Eq. (14) [34].

$$MAE = \frac{\sum_{t=1}^{T} |y_t - \hat{y_t}|}{T} \quad (14)$$

Here, y_t denotes the actual value of the price at period t, $\hat{y_t}$ Denotes the forecasted price value at period t, and T denotes the sample size. In other words, the MAE is the mean of the absolute difference between the predicted and actual prices throughout the test set. The actual price and the predicted price differ significantly when the MAE is high [34].

Mean Squared Error (MSE) is another method used to evaluate model performance. MSE is the average squared difference between the actual currency price and the values predicted by the model. Eq. (15) presents MSE [16].

$$MSE = \frac{\sum_{t=1}^{T} (y_t - \hat{y_t})^2}{T} \quad (15)$$

D. Training Configuration

In the first group of datasets, when the FNF-CNN model is used, the time windows range from 1 to 21 days. This range is used because increasing it above 21 leads to increased preprocessing without improving results and reducing the number below 22 reduces the accuracy of the results. The inputs to the first layer are (15x88), with nine previous time steps and 88 features.The number of previous steps was chosen as 9 because increasing it leads to increasing prediction error. The number of filters is 32, the kernel size is 4, and the next layer is flattened these hyperparaemeters chosen after many trails . These parameters were chosen after experimenting with the number of filters: 64 and 128. The experiments showed that using 32 filters leads to better results. Filter sizes of 8 and 16 were also tested, but they did not affect the improvement of the results. The last two layers are dense, and ReLU is used as the activation function..The FNF-LSTM model is a combination of FNF to extract features and LSTM to predict closing prices, and Adam is used as an optimizer. The learning rate and epochs of FNF-CNN and FNF-LSTM are 0.001 and 250, respectively. When we use a large number of epochs, overfitting occurs. Therefore, the appropriate value was equal to 250.The number of layers used is 5 and 3 in FNF-CNN and FNF-LSTM, respectively. The FNF- XGBoost model, which includes FNF and XGBoost Regressor, is used with 80 estimators and max depth=70, and the results look promising. All of these hyperparameters were selected based on many trials.

V. Results and Discussion

A. Results

This section shows the results compared to the results of baseline one and baseline two. FNF-SVR-RBF refers to the FNF-Support Vector Regressor model with a radial basis function. The FNF-SVR-p2 and p3 refer to the FNF-Support Vector Regression model with a polynomial degree 2 and 3 kernels, respectively. Table I shows the MAE results of baseline 1 compared to the proposed models. Table II is the same as Table I but for MSE.

Using FNF generates 84 features, and this variety of features affects results by reducing error.CNN supports efficient feature learning. This resulted in the proposed models performing better than the baseline 1. Additionally, it is worth noting that the SVR model with FNF yielded the best results among all the models in the tables. Fig. 5 shows the price compared to the FNF-SVR, FNF-CNN, and FNF-LSTM prediction for EUR/USD and USD/JPY from dataset group 1. These graphs show that the model has learned the market trend and predicts the prices based on the actual trend.

TABLE I. MAE Results of Baseline1 compared with Proposed Models

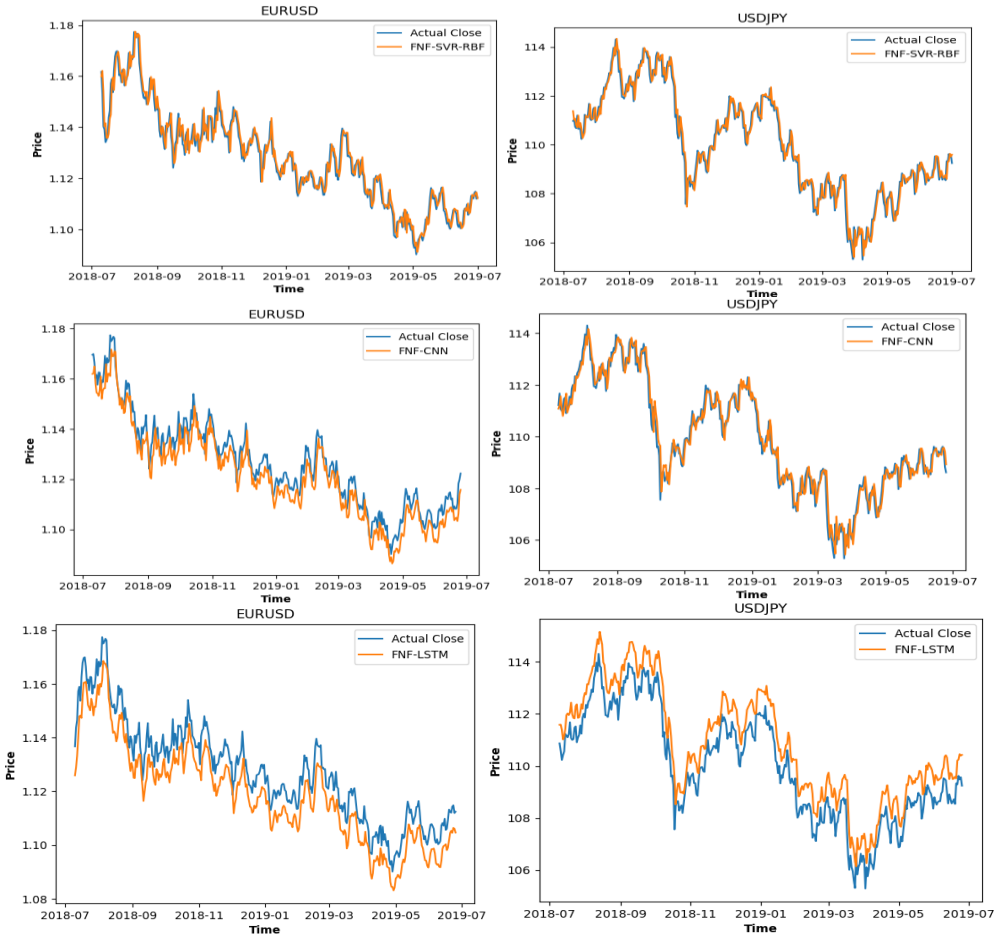

Fig. 5. On the left, the Actual closing price of EUR/USD compared to FNF-SVR-RBF, FNF-CNN, and FNF-LSTM predictions, and the right shows USD/JPY dataset results.

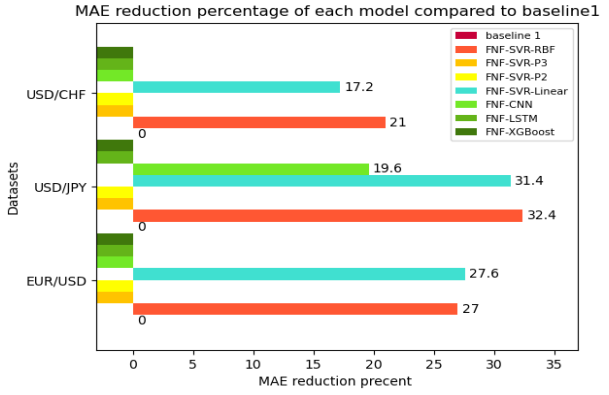

Fig. 6. The MAE reduction percentage of each model compared to baseline 1 applied on USD/CHF, USD/JPY, and EUR/USD datasets

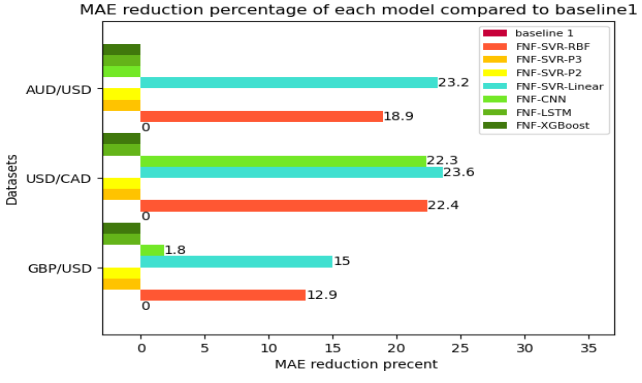

Fig. 7. The percentage reduction in MAE for each model, compared to baseline 1, applied to the AUD/USD, USD/CAD, and GBP/USD datasets.

In the previous results, using FNF with SVR and CNN outperformed baseline 1 in most datasets. Fig. 6 and 7 show the percentage reduction in MAE for each model compared to baseline 1. The preprocessing and feature extraction stages are the main reasons for error reduction.

Table III shows the results for the AUD/JPY dataset of baseline 2 compared to the proposed models. Table IV and Table V are the same as Table III but for the CHF/INR and EUR/USD datasets. The 84 features extracted using FNF also enhance the result of multistep prediction, like 3, 7, and 15 days. From the results, the FNF-SVR and FNF-CNN models outperform baseline two on the AUD/JPY and CHF/INR datasets. Based on CHF/INR and AUD/JPY datasets, we find that the results of the FNF-SVR model are close to the results of the FNF-CNN model.FNF-LSTM also outperforms baseline 2 in most datasets because LSTM learns temporal dependency.

The following section shows the percentage of error reduction by many models compared to baseline2. There is a significant reduction in errors in the AUD/JPY and CHF/INR datasets. The improvement is observed for the 3, 7, and 15 horizons, as shown in Fig. 8. However, using the proposed models on the EUR/USD dataset does not enhance the results because the strength of trend and seasonality in the EUR/USD time series is low.

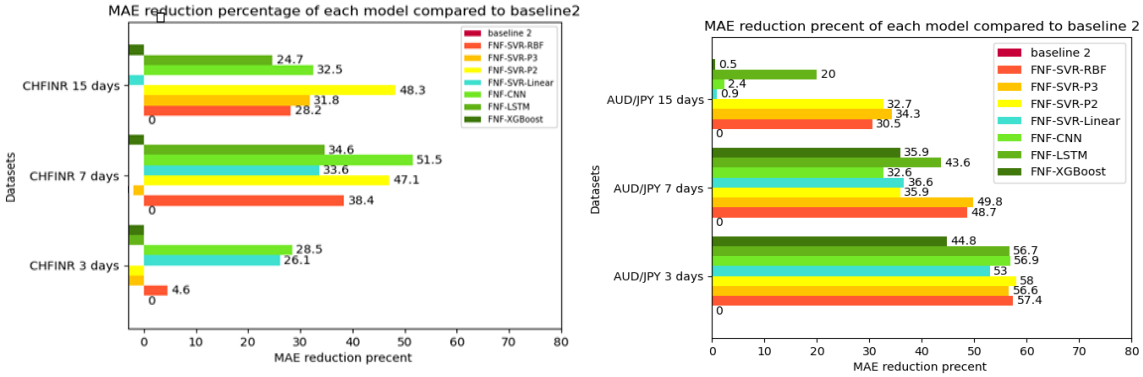

Fig. 8. The MAE reduction percentage of each model, compared to baseline 2, was applied to the AUD/JPY and CHF/INR datasets.

The results appear to vary between different datasets because each dataset has different statistical properties, and the strength of trend and seasonality differs from one time series to another.

B. Discussion and Ablation Study

This section presents an ablation study for the proposed models, FNF-SVR and FNF-CNN, and compares their results with and without FNF. Additionally, this section includes an ablation study applied to the FNF-LSTM model.

1) FNF-CNN: This study examines the impact of using FNF with CNN and the effect of each layer in CNN. The following tables demonstrate the impact of each layer in CNN. In the first baseline, the objective is to predict the next closing price of the next day. The USD/JPY Dataset from group 1, which was used in the first baseline, is shown in Table VI. Table VI illustrates the impact of removing specific layers and FNF on the USD/JPY dataset from group 1. Numbers in the header of the table refer to different model element combinations. The Conv1D refers to the one-dimensional convolution layer, and MaxPooling1D refers to the one-dimensional max pooling layer. The results of the proposed model outperform all other compared components of the models. Tables VII and VIII present the results of USD/CHF and AUD/USD datasets. In most datasets of the first baseline, the FNF-CNN model outperforms other candidate CNN components. If we look at the results of the second column (FNF-CNN) and fifth column (model element combinations 3), which shows the results of the model with FNF and without it, the impact of scaling and feature extraction enhances results in most datasets. Using FNF with the CNN model improved the results by 12.3% and 26.0% in terms of MAE for the datasets USD/JPY and AUD/USD, respectively. These tables also confirm that the layers used in FNF-CNN are the ones that generally produce the best results on different datasets.

The second baseline target predicts the closing price of 3, 7, and 15 days ahead. Tables IX, X, and XI show the results of the CNN ablation study on the CHF/INR dataset from group 2. The target is to predict the closing price for the next 3, 7, and 15 days. The results show that using FNF improves performance compared to not using it because FNF generates many features that enhance prediction accuracy. Additionally, these tables validate that the FNF-CNN layers are those that typically yield the best results across a variety of horizons.Using FNF with the CNN model improved the results by 51.1%, 16.0%, and 17.0% MAE for the datasets CHF/INR when horizons equal 3, 7, and 15, respectively.

2) Impact of Kernels and FNF on the SVR model: This section presents the impact of FNF with different SVR kernels. The USD/CHF and AUD/USD datasets from group 1 are used to predict the next day's closing price. The FNF results outperform those without it, as shown in Fig. 9. In the second baseline, the target is to predict the closing price in the next 3, 7, and 15 days; the MultiOutputRegressor from the Keras library was used to do this.

To discuss the previous results in detail, we will explain the percentage of improvement in the results for each time series separately. Applying FNF-SVR on the USD/JPY dataset from group 1 enhances the results by 0.2%, 0.7%, 0.5%, and 2.6% of MAE when using RBF, Poly degree 3, Poly degree 2, and linear kernels, respectively. Using FNF and SVR on the AUD/USD dataset from group 1 enhances the results by 4.2%, 76.1%, and 32.2% of MAE when using RBF, Poly degree 3, and Poly degree 2 kernels, respectively. When we apply the SVR-FNF model on the CHF/INR dataset from group 2 to predict the next three days, the results enhance by 6.7%, 99.7%, and 29.5% of MAE when using RBF, Poly degree 3, and Poly degree 2 kernels, respectively. When we applied the previous experiment on the same dataset but with a horizon equal to 7 days, the results enhanced by 86.7%, 99.7%, and 52.0% of MAE. However, when the horizon is equal to 15 days, the results enhanced by 84.3%, 99.8%, and 34.6%, respectively.

3) FNF-LSTM: In this section, the FNF-LSTM ablation study is presented. The following Datasets, USD/JPY, USD/CHF, and AUD/USD from group 1, are used and displayed in Fig. 10. This figure shows MAE is reduced when FNF is used. Fig. 11 shows the results of the same experiment on the CHF/INR and AUD/JPY datasets from group 2. The results demonstrate that the use of FNF enhances prediction in most datasets.

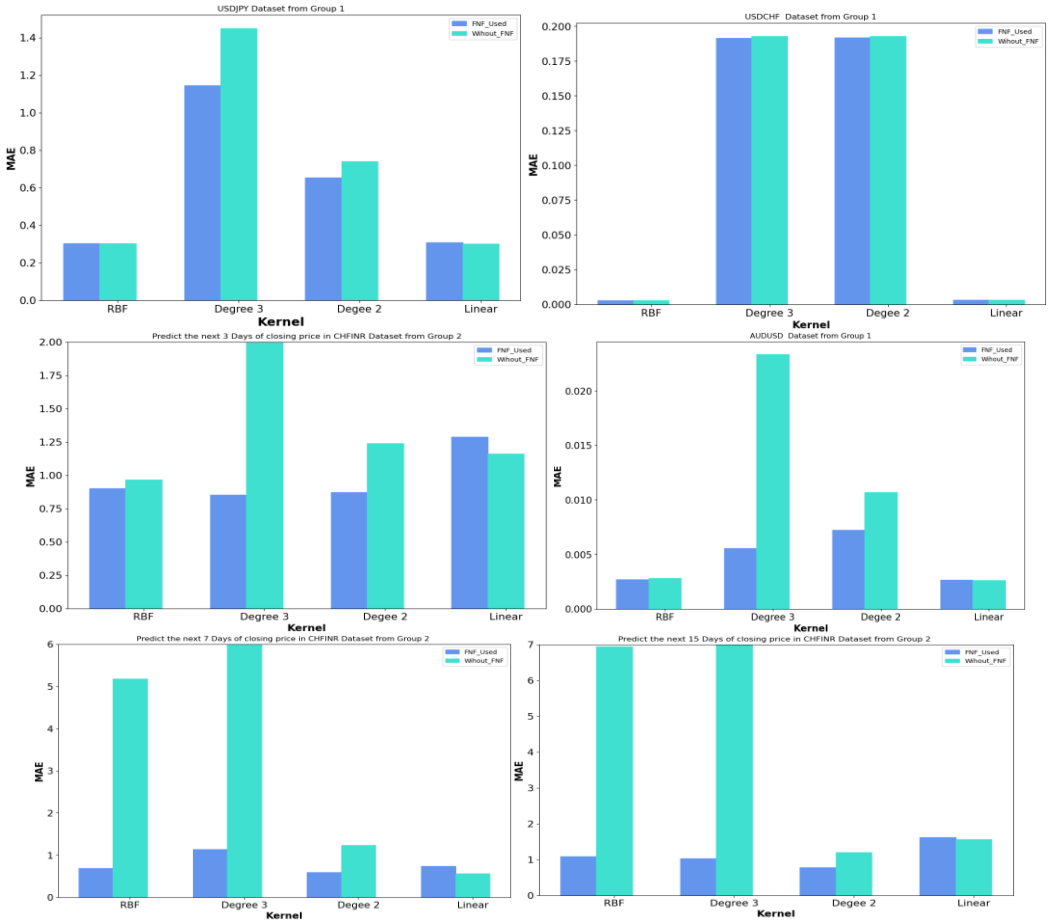

Fig. 9. (a) Impact of FNF and SVR kernels applied on USDJ/PY, USD/CHF, and AUD/USD datasets from group 1 at the top and middle left of this figure. (b) The last three charts show the effect of FNF and Kernels on the CHF/INR dataset from Group 2 to predict the next 3, 7, and 15 days.

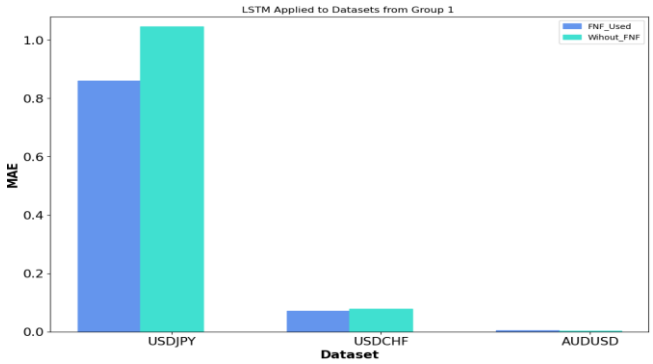

Fig. 10. Impact of FNN with LSTM applied to the USD/JPY, USD/CHF, and AUD/USD datasets from Group 1 to predict the next-day closing price.

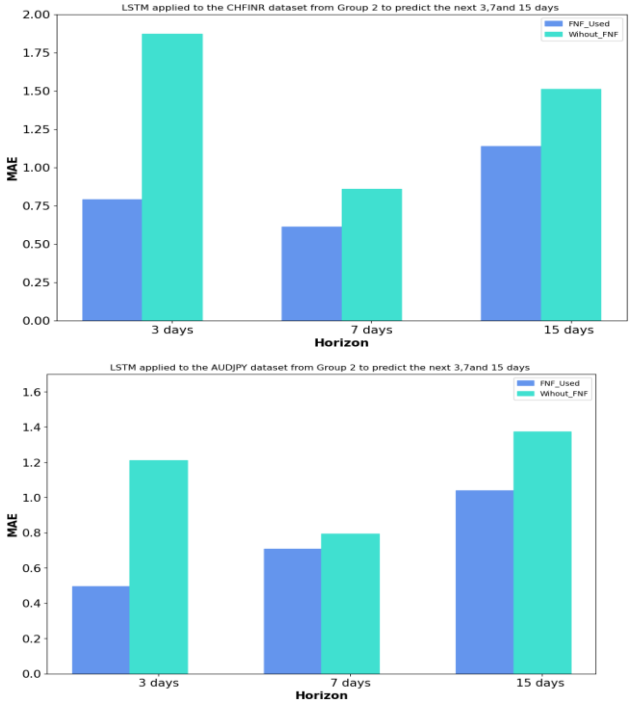

Fig. 11. FNF-LSTM Ablation Study applied to CHF/INR and AUD/JPY Datasets from Group 2 to predict the next 3, 7, and 15 days.

Because every dataset has unique statistical characteristics, and each time series has a variable strength of trend and seasonality, the results appear to differ between them. LSTM can learn temporal dependencies, but when we use FNF-LSTM on the USD/JPY and USD/CHF datasets from group 1, the results are enhanced by 17.8% and 9.5%, respectively, while the results of AUD/USD are not enhanced. Applying FNF-LSTM on the CHF/INR dataset from group 2 to predict the next 3, 7, and 15 days enhances results by 57.8%, 28.7%, and 24.6% of MAE, respectively. Applying FNF-LSTM on the AU/DJPY dataset from group 2 to predict the next 3, 7, and 15 days enhances results by 58.9%, 10.6%, and 24.4% of MAE, respectively.

VI. Conclusion

This paper proposed a FOREX normalization function used as a preprocessing method. This function is used with a machine learning model (SVR) and deep learning model(CNN) to enhance FOREX price prediction. Moving Averages and Scaling on raw data are essential steps to minimize error. Nine FOREX datasets are used in different horizons (1, 3, 7, and 15 days). Mean Absolute Error and Mean Squared Error are used to evaluate all models. The best performance results come from FNF-SVR and FNF-CNN. In this research, we compare different models with FNF and without it. The comparison between the proposed models and the two baseline models shows that our proposed models outperform the baseline models. The development of these proposed models is still in its early stages. Since the models present an exciting and potentially successful research topic, many enhancements must be investigated. The importance of this study is that it reduced the prediction error, which researchers can use this study to build decision support systems used in automated trading. Traders can also use its results to help make decisions to buy and sell currencies.

The limitation of this study is that we did not test the presented models on long-term prediction and did not test them on more datasets. In future work, the same proposed models will be used with different activation functions to find enhanced activation functions for FOREX and train the model using more datasets with varying time frames.

***Abstract*—Now-a-days, the network has significant roles in transferring data and knowledge quickly and accurately from sender to receiver. However, the data is still not secure enough to transfer quite confidentially. Data protection is considered as one of the principal challenges in information sharing over communication. So, steganography techniques were proposed which are the art of hiding information that prevents secret text message detection from intruders. Nevertheless, most steganography methods use low bits number of secret messages. Moreover, these methods applied a single logic gate for encrypting the secret message. Therefore, this paper proposes a new method for the encryption of secret messages based on the Huffman technique to reduce the secret message dimensions. In addition, the proposed method uses two different logic gates namely XOR and XNOR for increasing the message security. The RGB Lena image is used as the cover image of the secret message. There are six different experiments conducted with respect to various lengths of the secret messages in bits. The experimental results show that when using the highest number of bits (i.e., 66288), the proposed method achieved 0.0233 MSE, 64.4589 PSNR, 0.9999998 SSIM, and 8.2383 encryption time. The proposed method has the ability to encrypt the secret message with a high number of bits.**

Keywords*—Steganography techniques; color images; XOR gate; NOR gate; huffman technique

I. INTRODUCTION

Nowadays, communication is quite necessary for transmitting information quickly and accurately from the sender to the receiver [1]. Meanwhile, the internet in this modern era provides high convenience in transferring big amounts of data in several parts of the world. Everyone needs safety and secrecy in communicating data [2]. In our daily life, there are many secure pathways that we use such as internet or telephone for sharing and transmitting the information. But unfortunately, these pathways still not safe at a particular level [3]. Consequently, there are two common techniques which are widely used in hiding information and then sharing it safety. These techniques are cryptography and steganography [4, 5]. In the cryptography technique, the message or the text is adjusted in an encrypted form and the encryption key is known only to both sender and receiver. However, the transmission of an encrypted message in such a type of technique may lead to easily excite the attacker's suspicion, and hence this encrypted message will be intercepted, attacked and then decrypted [6]. Therefore, steganography techniques have been proposed and developed in order to overcome the insufficiencies of the cryptographic technique [7].

Steganography is the science of communicating in such a method that it covers and hides the presence of the communication [8]. Thus, there is no one that can detect the existence of a message because the steganography technique hides its presence. On other words, the steganography technique is hiding the message inside multimedia content such as video, audio and image files, where the message will be embedded with one of these multimedia contents [9]. Steganography technique is consisting of two main terms which are the data or the message and cover image [10]. The message is the secret information that needs to be hidden. While the cover image is referred to the carrier that hides or covers the message. Fig. 1 shows the steganography diagram. Steganography's word has been taken from Greek words, where "stegos" indicates to "cover" and "grafia" indicates to "writing" and these two words are defining together as "covered writing" [11]. There are many different techniques of steganography such as spatial domain methods, spread spectrum technique, statistical technique, transform domain technique, and distortion technique [12]. Also, there are different measurements which determine the performance efficiency of steganography techniques such as Peak Signal to Noise Ratio (PSNR), Mean Square Error (MSE), Structural Similarity Index Measure (SSIM) and Signal to Noise Ratio (SNR) [13, 14]. Steganography technique is quite valuable and it can be applied in many domains such as communication and secret data storing, e-commerce, database systems, data alteration protection, and media [15]. As we mentioned previously that the steganography technique has different

categories for hiding information which are embedding the information in text, images, audios, videos, or protocol. The images are considered the most common cover objects which have used for steganography technique [16]. Due to the digital images are broadly proliferated on the Internet and also due to provide a large number of excessive bits in the digital image. The picture steganography is considered as a method for secret and ambiguity correspondence that intends to transfer many of mystery information. Generally, to the cover picture extent among conveying parties. Besides, it aims to avoid the suspicion for non-conveying gatherings in such type of correspondence [17].

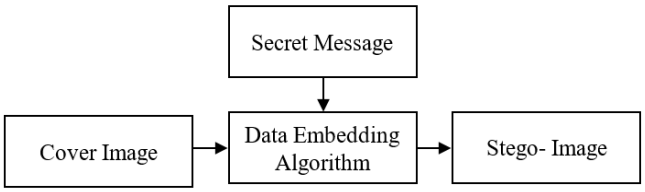

Fig. 1. The steganography diagram.

The image in the computer is a set of numbers that form various light intensities in different image areas. This numeric representation is constituted individual points and a grid which are referred to as pixels [18]. On the Internet, most images are consisting of a rectangular map for the image's pixels which are represented as bits. These pixels are presented horizontally and displayed row by row. The bits number in a color image named the bit depth that belongs to the bits number utilized for every pixel. In present color images, the smallest bit depth is 8 (i.e., there are 8 bits used for representing each pixel color) [19]. Grayscale and monochrome images use 8 bits for every pixel and these pixels are able to present 256 various colors or grey shades.

The digital color images are usually stored in files of 24-bit and use the pattern of RGB color that is known as true color as well. All colors for pixels with 24-bit picture are derived from three essential colors which are Red, Green and Blue (RGB). Each color is produced with 8 bits. Hence, in every pixel, there are 256 different amount of RGB colors as well as to more than 16-million combinations that lead to producing more than 16-million colors in the image [20]. With regards to images, hiding the message in the image is performed by taking the cover object as an image that is indicated as image steganography. The pixel intensities in image steganography are used in order to hide the message [21]. In steganographic images, the Least Significant Bit (LSB) is considered a widely known technique due to its high advantages in encrypting texts in images [22-24]. However, the conventional LSB technique still needs more enhancements in the steganographic technology [25, 26].

Moreover, recent steganography techniques used in the image are yet suffering from the small amount of data that required to be hidden in the cover image. Also, these techniques are showing some negative effects and wasting some of the hidden data. Moreover, there is an urgent need to find a method that is able to hide data without distinguishing between the hidden data and the original covering data. Therefore, the aims of this paper are as follow:

- In this work, we propose the Huffman technique in order to reduce the dimensionality of the secret message.
- Propose two different logic gates called XOR and XNOR for increasing the encryption security of the secret message.
- The proposed method is performed based on six different experiments with respect to various lengths of the secret messages in bits.
- The performance of the proposed method is evaluated in terms of MSE, PSNR, and execution time.

The remainder of this paper is organized as follows: Sections II shows the related works in the steganography technique for hiding information in images. Section III presents the proposed method in terms of the Huffman technique and two logic gates. Section IV discusses the experimental results. Finally, Section V presents the conclusion of this paper.

II. Related Work

Recently, the steganography techniques for hiding text in images have beheld a huge significance by researchers and developers due to the importance such these techniques in terms of hiding data. Furthermore, recent steganography methods of hiding data such as XOR and XNOR logic gates worked on providing a high level of security, where the intended user can only access to the secret data. In other words, the unauthorized user has no ability to detect hidden data, where this is an extremely critical issue in order to protect the sensitivity and confidentiality of information and messages being sent. Here, we will review the up-to-date techniques used in the steganography field. Besides, Table I summarizes the related works used for the encryption of secret messages in images. A steganography technique is proposed in [27] to protect information transported from attackers. This method is worked on the encryption of secret information by using the XNOR gate and the encryption key. The information that required to be encrypted is hidden in a color image by applying Least Significant Bit (LSB) algorithm. Furthermore, this method relies on chromatic channels extraction of 3 RGB channels for every pixel and 2 bits of LSB bits and then determining the channel that will hide the encryption message bit. The second LSB bit is used as an indicator that determines the channel. Meantime, the first LSB bit is replaced with the encrypted message bit, where all the encrypted message bits will be hidden in the cover image. Four different types of images have used as a carrier file which are Airplane, Peppers, Lena, and Baboon. The dimension of all these images is 512x512. Also, different amounts of information were used as secret messages to analyze and evaluate the method, where the smallest amount was 4700 bits and the largest amount was 24250 bits. The performance of this method is evaluated in terms of two measurements which are namely Peak Signal to Noise Ratio (PSNR) and Mean Square Error (MSE). According to the best-achieved results of the largest amount of secret information are shown that the highest PSNR and lowest MSE are 53.65 and 0.0339 respectively which have obtained from Lina image. However, the amount of hidden information is still not encouraging and a bit small.

The authors in [28] have presented a method to hide text in a color images in order for keeping the information from intruders. This method has two main stages. In the first stage, the steganography technique is used to hide the information in the transmission, where it has used the XOR operation gate for hiding the text bit in the image bit and specifies the position of the image bits according to a random key (the random key has the same length of the secret text). While in the second stage, it has used Triple data encryption standard (3DES) algorithm. This algorithm is used to encrypt the resulting image and the key. Subsequently, the key and image are sent to the receiver. In this method, two types of images have used which are Lena image (256x256 pixels) and Tree image (250x360 pixels). The results of this method have shown that Lena image has 52.0235 PSNR and 0.10024 MSE, while tree image has better performance with 55.0016 PSNR and 0.03602 MSE. However, this method has ignored the length of the confidential text in bit, where it has not taken into account. Furthermore, the steganography technique is applied in [29] to hide the text messages in 24-bit color images. In this method, two schemes have proposed which are embedding data scheme and extraction scheme. In embedding data, the text messages will be hidden in the cover image by using the LSB algorithm. In the extraction scheme, it has used XOR operation to Most Significant Bits (MSB) to recover the secret text from a stego-image. The MSB bits identify the object shape in the image. These two schemes are requiring a key that is created randomly. The experiments have carried out on six different types of images which are Toy (3264 x 2448), Mosque (767x619), Cat (645x533), Flower (551x451), View (32644x2448), and Sunset (1632x1224). The statistical analysis of this method is show that the highest value of PSNR is 63.738 that has obtained by View image, and its MSE value was 0.0026. In this regard, the LSB algorithm is used also in [30] for hiding and protecting secret text message in Image. In this work, the LSB algorithm is combined with XOR encryption techniques in order to increase the security of the text message. Four images have used to embed text messages, these images are Barbara, F16, Lena, and Soccer. All these images have a size of 256x256 pixels and it has used three different sizes (i.e., 1 KB, 2 KB, and 4 KB) of the text messages which are needed to be hidden. The experimental results have shown that the highest achieved PSNR for 1 KB, 2 KB, and 4 KB is 63.5195 (Lena image), 60.3883 (Soccer image), and 57.3182 (Soccer image), respectively. Besides, the lowest MSE for 1 KB, 2 KB, and 4 KB is 0.0289 (Lena image), 0.0595 (Soccer image), and 0.1206 (Soccer image), respectively. Also, the extracted text messages have tested by Character Error Rate (CER) and the value was 0, which proves that text messages have extracted totally. However, the embedded text messages in the cover image are small and limited. A secure model that has embedded text messages for reliable communication was proposed in [31]. Furthermore, this model has used the LSB algorithm for embedding text message bits. In this model, the LSB is based on the secret key and logistic map, this is a spatial domain technique to embed more information in color image without deteriorating the quality of the image. The logistic map method is used for embedding the message bits randomly in the image. The image type used in this work is the Lena image. According to the results, the maximum capacity text messages stored in the cover image is 29127 bytes (233016 bits) and PSNR has been achieved 55.91. A secure method for embedding secret text messages in color images is proposed in [32]. This method is used Integer Wavelet Transform (IWT) technique that is based on the LSB algorithm. The secret text messages are hidden in the LSB algorithm, and the inverse IWT is used to form the stego-image. The secret information is hidden in the approximation coefficient in the components of blue and green colors. While the actual length of the secret data and the sender signature are embedded in the LSB algorithm in the component of the red color of the cover image. In this method, six different types of images have used which are Lena, Baboon, Pepper, Airplane, House, and Tiffany. The size of each image of all these color images is 512×512 pixels. The experimental results are shown that the hybrid IWT-LSB can be embedded secret data with a size of 24 576 bits, where the highest PSNR was 55.5622 that achieved by Baboon image, and the MSE was 0.1807. However, from the studies mentioned above, we can observe some limitations that can be summarized as follow:

- Most models and methods which are used steganography techniques for embedding text messages are yet suffering from a low amount of embedding text messages.
- Majority of these methods are worked on one logic gate in the encryption of secret messages in which results in a low-security level.
- Finally, the execution time of experiments is mostly ignored.

TABLE I. THE SUMMARY OF RELATED WORKS

Years	Techniques	Images	Secret Message Size	PSNR	MSE	Ref.
2020	XNOR and LSB	Airplane, Peppers, Lena, and Baboon	24250 bits	53.65	0.0339	[27]
2020	XOR and 3DES	Lena and Tree	-	55.0016	0.03602	[28]
2019	XOR and MSB	Toy, Mosque, Cat, Flower, View, and Sunset	24 bits	63.738	0.0026	[29]
2019	XOR and LSB	Barbara, F16, Lena, and Soccer	1 KB, 2 KB, and 4 KB	63.5195, 60.3883, and 57.3182	0.0289, 0.0595, and 0.1206	[30]
2018	LSB and logistic map	Lena	29127 bytes	55.91	-	[31]
2018	IWT and LSB	Lena, Baboon, Pepper, Airplane, House, and Tiffany	24 576 bits	55.5622	0.1807	[32]

III. PROPOSED METHOD

A. Encryption Algorithm

In the proposed method, there are three main phases. Fig. 2 shows the steps of these three phases. The first phase includes four steps which are read the secret message, convert the secret message from text to decimal, implement the Huffman to compress the data (reduce the dimensionality), and convert the data from decimal to binary. While in the second phase, the secret message will be encrypted by using the following steps:

- Enter the encryption key value in binary with 8 bits.
- Implement the XNOR logic gate on every other 4 bits (i.e., first 4, third 4, fifth 4 and so on) of the secret message with the first 4 bits of the encryption key.
- Implement the XOR logic gate on every other 4 bits (i.e., second 4, fourth 4, sixth 4 and so on) of the secret message with the second 4 bits of the encryption key.

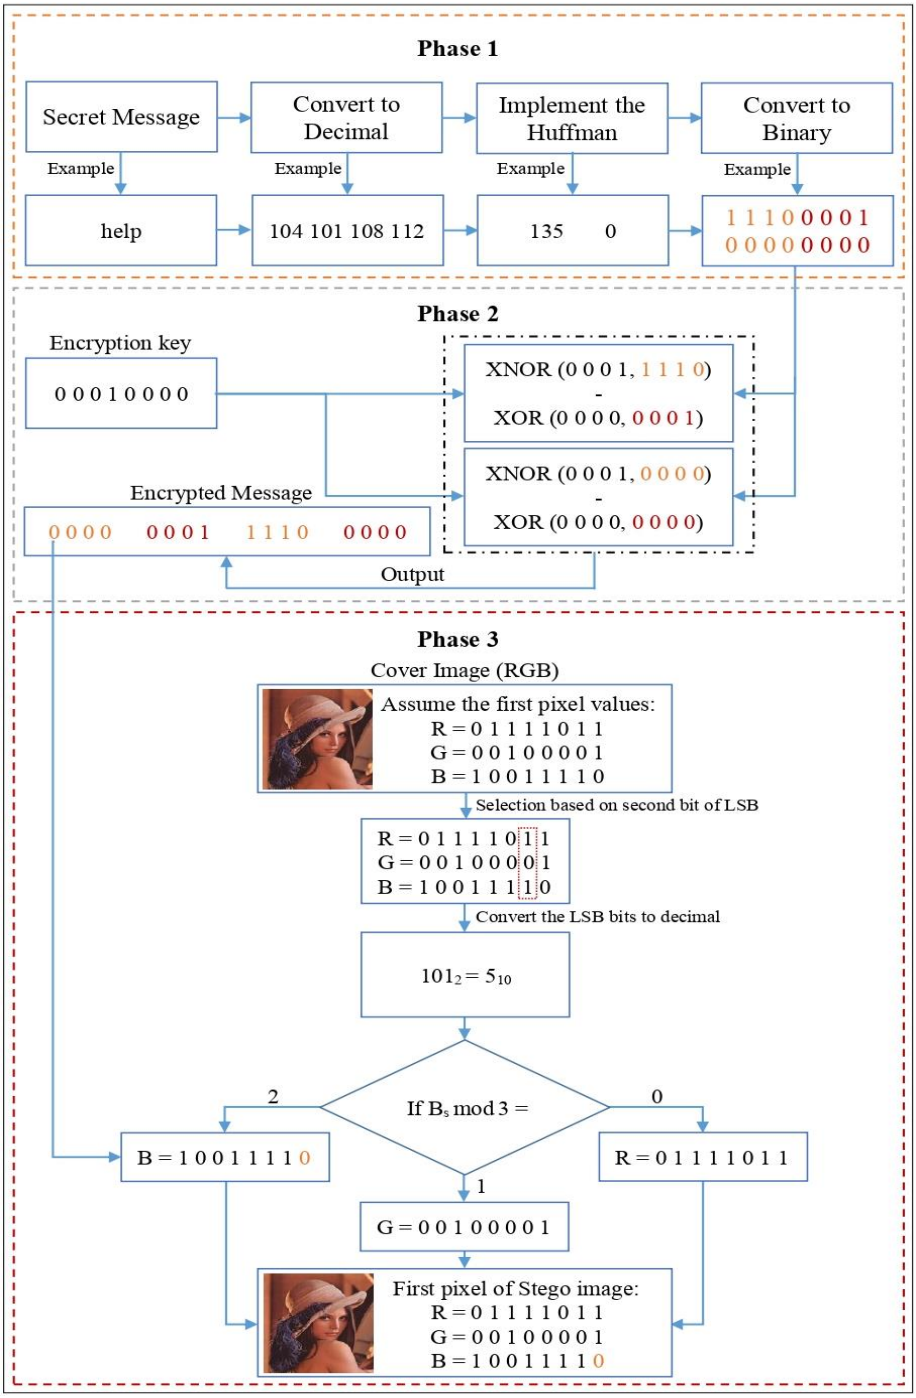

Fig. 2. The three phases of the proposed method.

Furthermore, the third phase includes the following steps:

1. Read the cover image.
2. Selection of one of three RGB channels based on second bit of LSB bits of three channels in decimal and return in B_s.

a. If (B_s mod 3) = 0

Then Red channel is selected.

b. If (Bs mod 3) = 1

Then Green channel is selected.

c. If (Bs mod 3) = 2

Then Blue channel is selected.

3. Apply the LSB algorithm to the selected channel and coding by storing the encrypted bit instead of the first bit of LSB bits.
4. Stego image is achieved.

An example is provided below to encrypt the word "help" as a secret message into the cover image. The steps of this example as follow:

1. Secret message = help.
2. Secret message in decimal = 104 101 108 112.
3. Huffman of the secret message = 135 0.
4. Huffman of the secret message in binary with 8 bits = 1 1 1 0 0 0 0 1 0 0 0 0 0 0 0 0.
5. Encryption key = 0 0 0 1 0 0 0 0.
6. First 4 bits of the Huffman's secret message in binary = 1 1 1 0.
7. Second 4 bits of the Huffman's secret message in binary = 0 0 0 1.
8. Third 4 bits of the Huffman's secret message in binary = 0 0 0 0.
9. Fourth 4 bits of the Huffman's secret message in binary = 0 0 0 0.
10. First 4 bits of the encryption key = 0 0 0 1.
11. Last 4 bits of the encryption key = 0 0 0 0.
12. The first 4 bits of the encrypted message = XNOR (Step 6, Step 10) = 0 0 0 0.
13. The second 4 bits of the encrypted message = XOR (Step 7, Step 11) = 0 0 0 1.
14. The third 4 bits of the encrypted message = XNOR (Step 8, Step 10) = 1 1 1 0.
15. The fourth 4 bits of the encrypted message = XOR (Step 9, Step 11) = 0 0 0 0.
16. The encrypted message bits = 0 0 0 0 0 0 0 1 1 1 1 0 0 0 0 0.
17. Read the cover image. Table II shows the selection and encryption processes to create four pixels of the stego image.

TABLE II. THE SELECTION AND ENCRYPTION PROCESSES OF FOUR PIXELS IN THE STEGO IMAGE

Pixel	Channel	Value of the channels in binary (cover image)	Second LSB of the three channels	Selected channel	Message bit	Value of the channels in binary (stego image)
1st	R	01111011	$101_2 = 5_{10}$	2 B	0	01111011
	G	00100001				00100001
	B	10011110				10011110
2nd	R	01111011	$101_2 = 5_{10}$	2 B	0	01111011
	G	10100001				10100001
	B	10011111				10011110
3rd	R	01000111	$100_2 = 1_{10}$	1 G	0	01000111
	G	10010001				10010000
	B	10000001				10000001
4th	R	01111011	$110_2 = 3_{10}$	0 R	0	01111010
	G	00111110				00111110
	B	10001100				10001100

B. Decryption Algorithm

This section will present the processes for extracting the secret message from stego image. These processes are summarized below. In addition, Table III shows the determination of RGB channel based on second bit of LSB.

1. Get stego image.
2. Selection of one of three RGB channels based on second bit of LSB bits of three channels in decimal and return in Bs.
   a. If (B_s mod 3) = 0

   Then Red channel is selected.

   b. If (Bs mod 3) = 1

   Then Green channel is selected.

   c. If (Bs mod 3) = 2

   Then Blue channel is selected.
3. Apply the LSB algorithm on the selected channel to get the encrypted message bits (0 0 0 0 0 0 0 1 1 1 1 0 0 0 0 0).
4. Input the encryption key = (0 0 0 1 0 0 0 0) and apply the following steps:
   a. XNOR decoding on the first 4 bits of the encrypted message and the first 4 bits of the encryption key. Therefore, XNOR (0 0 0 0, 0 0 0 1) = 1 1 1 0.
   b. XOR decoding on the second 4 bits of the encrypted message and the last 4 bits of the encryption key. Therefore, XOR (0 0 0 1, 0 0 0 0) = 0 0 0 1.
   c. XNOR decoding on the third 4 bits of the encrypted message and the first 4 bits of the encryption key. Therefore, XNOR (1 1 1 0, 0 0 0 1) = 0 0 0 0.
   d. XOR decoding on the fourth 4 bits of the encrypted message and the last 4 bits of the encryption key. Therefore, XOR (0 0 0 0, 0 0 0 0) = 0 0 0 0.
5. The Huffman's secret message in binary is obtained = 1 1 1 0 0 0 0 1 0 0 0 0 0 0 0 0.
6. Convert each 8 bits of the Huffman's secret message to decimal = 135 0.
7. Apply the Huffman to normal which decodes the Huffman's secret message in decimal to get the normal secret message in decimal = 104 101 108 112.
8. Convert the secret message from decimal to character to get the secret message = help.

TABLE III. THE DETERMINATION OF RGB CHANNEL BASED ON SECOND BIT OF LSB

Pixel	Channel	Value of the channels in binary (stego image)	Second LSB of the three channels	Selected channel	Message bit
1st	R	01111011	$101_2 = 5_{10}$	2 B	0
	G	00100001			
	B	10011110			
2nd	R	01111011	$101_2 = 5_{10}$	2 B	0
	G	10100001			
	B	10011110			
3rd	R	01000111	$100_2 = 1_{10}$	1 G	0
	G	10010000			
	B	10000001			
4th	R	01111010	$110_2 = 3_{10}$	0 R	0
	G	00111110			
	B	10001100			

IV. EXPERIMENTAL RESULTS AND DISCUSSION

In this study, the Lena color image (RGB) with (512 × 512 × 3) dimensionality was used in order to conduct six different experiments. The six different experiments were implemented based on various lengths of the secret message in bits (i.e., 3640, 6872, 26224, 33128, 40032, and 66288 bits). In this proposed method, we have used Huffman method in order to reduce the dimensionality of the data (i.e., secret message). Furthermore, there are two logic gates which are XNOR and XOR have been used for the purpose of encrypting the Huffman of the secret message with the encryption key. It is worth mention that all experiments have been implemented in MATLAB R2019a programming language over a PC Core i7 of 3.20 GHz with 16 GB RAM and SSD 1 TB (Windows 10).

The proposed method has been evaluated in terms of the most common performance measurements used in the steganography techniques which are Mean Square Error (MSE), Structural Similarity Index Measure (SSIM), and Peak Signal-to-Noise Ratio (PSNR). Besides, the proposed method has been evaluated in terms of the execution time. The MSE, PSNR and the execution time can be calculated as the following equations:

$$MSE = \sum_{m=0}^{M-1} \sum_{f=0}^{F-1} \|A(m,f) - T(m,f)\|^2 \quad (1)$$

$$PSNR = 10log\,10\left(\frac{255^2}{MSE}\right) \quad (2)$$

$$Execution\ Time\ (T) = T_{End} - T_{Start} \quad (3)$$

where, $A(m, f)$ refers to the pixel value of the cover image, $T(m, f)$ refers to the pixel value of the stego image, and M and F refer to the height and width of the images, respectively. In the six different experiments, the minimum and maximum numbers of the secret message bits are 3640 and 66288, respectively. Based on the experiments results, when the minimum number of the secret message bits is used, the proposed method is achieved 0.0013 MSE, 77.1531 PSNR, and it has taken 0.9543 sec for the execution time. Meanwhile, the proposed method has been obtained 0.0140 MSE, 64.4589 PSNR, and 8.2383 sec by using the maximum number of the secret message bits.

Furthermore, Table IV illustrates the full results of the six different experiments in terms of MSE, PSNR, SSIM, and encryption time in seconds. Fig. 3 shows the histograms of the three colors (red, green, and blue) separately for the original image (cover image) and the stgo images with different lengths of secret messages in bits. Moreover, Fig. 4 demonstrates all the color histograms (red, green, and blue) for the original image (cover image) and the stgo images with different lengths of secret messages in bits. Based on Fig. 3 and Fig. 4, the proposed method has not been influenced the three channels of the original image colors (red, green, and blue). In other words, the proposed method has the ability to encrypt high numbers of secret message bits without affecting the quality of the image.

Moreover, the proposed method has been compared with other methods using Lena image [30, 33-37] as shown in Table V. The experimental results showed that the proposed method has been outperformed the other methods in terms of number of bits, MSE, SSIM and PSNR. Although the proposed method has been shown the high ability to encrypt a high number of bits in RGB image, there are some limitations in the proposed method which can be summarized as follow:

- All experiments of the proposed method have been conducted using one image only. In other words, the proposed method is evaluated using the Lena image only.
- The proposed method has been evaluated based on the standard image size (512 × 512 × 3). Whilst other evaluations based on varying the image sizes may lead to obtaining different results.

TABLE IV. THE RESULTS OF THE SIX DIFFERENT EXPERIMENTS

Image	Number of bits	MSE	PSNR	SSIM	Encryption Time (s)
Lena (512 × 512 × 3)	3640	0.0013	77.1531	0.9999998	0.9543
	6872	0.0023	74.4227	0.9999996	1.0754
	26224	0.0091	68.5274	0.9999983	3.2982
	33128	0.0116	67.480	0.9999976	4.4995
	40032	0.0140	66.6573	0.9999969	4.8424
	66288	0.0233	64.4589	0.9999934	8.2383

TABLE V. COMPARISON RESULTS BETWEEN METHODS USING LENA IMAGE

Method	Number of bits	MSE	SSIM	PSNR
[33]	24500	-	0.997242	52.9817
[34]	960	5.73706	0.99374	40.54391
[35]	22248	0.042486	0.999919	57.079979
[36]	1200	0.0038	-	72.242
[37]	14357	-	-	41.72
[30]	32000	0.1290	-	57.0260
Proposed Method	**3640**	**0.0013**	**0.9999998**	**77.1531**
	66288	**0.0233**	**0.9999934**	**64.4589**

V. CONCLUSION

In this paper, we have presented a new method in the encryption of secret messages in the RGB image. The proposed method is used the Huffman technique in order to reduce the secret message dimensionality. In addition, there are two logic gates (i.e., XNOR and XOR) have been used in order to encrypt the Huffman of the secret message with the encryption key. The proposed method has been implemented based on six different experiments with respect to various lengths of the secret messages in bits (i.e., 3640, 6872, 26224, 33128, 40032, and 66288 bits). All experiments have been performed using the RGB Lena image with the size of (512 × 512 × 3). The experimental results are showed that the proposed method has been achieved 0.0013 MSE, 0.9999998 SSIM, 77.1531 PSNR, and it has taken 0.9543 sec when the number of the secret message was 3640 bits. Meanwhile, the proposed method achieved 0.0233 MSE, 0.9999934 SSIM, 64.4589 PSNR, and 8.2383 sec when the number of the secret message was 66288 bits. Based on the results, the proposed method is able to encrypt the secret message with a high number of bits efficiently. Future work can include using different RGB images such as Airplane, Peppers, and Baboon with varying sizes and other measurements such as Bits Per Pixel (BPP).

***Abstract*—One of the initiatives adopted by the Indonesian government to combat the development of COVID-19 in Indonesia is Community Activities Restrictions Enforcement. Many public opinions emerged, both for and against this policy. There are so many comments every second that it is certainly not easy to analyze them by reading each one by one. This task necessitates computer applications. Therefore, this study was conducted to produce an application that can help analyze public sentiment on the policy through social media, namely Twitter, into three classes: positive, neutral, and negative. The method used in this research is bidirectional long short-term memory (BiLSTM), one of the algorithms of deep learning. This study trains the model using the dataset, which consists of 10,486 tweets. The model receives an f1-score of 76.67 %. Thus, the model can be used to analyze public sentiment when the same policy is enforced. It can determine public acceptance of this policy. Thus, the system created in this research can be used as evaluation material for the government to review the policy when it is implemented in the future. However, this study concentrates on how to develop the sentiment analysis system and does not examine how the community responds to government policy.**

***Keywords*—Sentiment analysis; COVID-19; BiLSTM; deep learning; government policy**

I. INTRODUCTION

There are several obstacles that must be overcome in order for Indonesia's political system to function effectively given the country's status as a growing democracy with a sizable population [1, 2]. The political choices that are made by the government have significant repercussions, both directly and indirectly, on the daily lives of the people who live in Indonesia. This encompasses fundamental concerns like as the distribution of wealth, economic equality, human rights, the maintenance of a healthy environment, and the satisfaction of fundamental needs like education and health care. As a result, the leaders and policymakers in Indonesia have a significant challenge in terms of preserving political stability and developing appropriate policies.

The public mood regarding these policies is a reflection of the sentiments, opinions, and perspectives of many individuals and groups [3]. The vast majority of these sensations may be freely communicated through social media, online news platforms, or online discussion forums, which are increasingly reflecting people's emotions in real-time [4]. This point of view should not be ignored by the government, which is the organization that is responsible for formulating and enforcing policies. They should, rather, view this sentiment data as a useful source of knowledge that may assist them in better directing their policies and should do so by capitalizing on it.

The political discourse and polarization that exists in Indonesia have a significant impact on the decision-making processes there as well [5, 6]. Analysis of public sentiment can assist in detecting recurring patterns of support for or opposition to a certain program or leader. It gives an overview of the extent to which diverse political and social ideas exist in society, which is vital for establishing an effective communication strategy and defusing political tensions.

The influence of sentiment analysis can also have an effect on how the public perceives the government in today's digital and social media-driven environment, which links the public at large [7,8]. It is much easier for governments to earn the support and trust of their constituents when they react rapidly to the sentiments and viewpoints expressed by the populace. On the other hand, apathy for public feelings or a refusal to respond to them might result in demonstrations.

As a result, sentiment analysis is not only a tool for analyzing public mood, but it is also a critical factor in the effective crafting of policies and sustaining the political stability that is required in Indonesia's ever-shifting process of democratization. The use of technology such as machine learning in sentiment analysis provides governments with more powerful and efficient tools to analyze large amounts of data and respond in a timely way. This can have a beneficial influence on the government's ability to be effective and responsive. As a result, having a grasp of and making use of sentiment analysis in the context of political policy in Indonesia is an absolute must in order to successfully navigate the political and social dynamics that will continue to emerge in the years to come.

In order to address this issue, the present study used sentiment analysis to evaluate the political strategies of the Indonesian government in response to the COVID-19 pandemic. The Indonesian government published the implementation of restrictions for community activities (PPKM) policy on July 3, 202. It is one of the government's measures to regulate community activities in order to combat the rise in COVID-19 cases in Indonesia. From July 3 until July 20, this policy—originally known as the PPKM Java-Bali emergency—was formally in effect. Then, on July 20, the president announced the extension of PPKM until the 25th and modified the designation of PPKM to level 4 during a virtual press conference. It was used to stop the spread of COVID-19 and minimize the requirement for inpatient care. The 44 areas and cities that made up the Java and Bali regions at first were the only ones to which it was applied. On July 12, however, the administration decided that it would also apply to non-Java and non-Bali areas after deliberating for more than a week. 15 cities and regencies in regions with the highest COVID-19 spread rates were covered by it outside of Java and Bali. The government set restrictions on people's mobility during the era. Residents, for example, must bring a minimum vaccination letter and the results of a PCR swab test or an antigen test indicating a negative result for COVID-19 when traveling by any mode of transportation [9].

The enactment of this policy caused controversy among the people of Indonesia. Some people supported this policy, but not a few people opposed it for certain reasons. Of course, the government issued this policy for the welfare of society. If it is discovered that the policy causes social unrest, the government must respond. The public's opinion of a policy can be seen through the comments that appear in the mass media [10]. One of them is Twitter, a social media site. There are so many comments every second that it is certainly not easy to analyze them by reading each one by one. This task necessitates computer applications. This application can facilitate the analysis of the sentiment that appears in all Twitter comments on this policy automatically and quickly. The computer analysis of textual opinions, attitudes, and emotions is known as sentiment analysis, also referred to as opinion mining [11]. Natural language processing, text analysis, computational linguistics, and biometrics are used to systematically identify, extract, quantify, and study emotional states and subjective information [12]. It is widely used for textual data to help businesses or organizations understand customers' needs based on their opinions of a product or service. The government needs this study's sentiment analysis to help it understand how the general public feels about PPKM policies.

Different techniques can be used to analyze sentiment [13]. One of the deep learning algorithms that are most frequently used is long short-term memory (LSTM) [14]. It is more accurate than the recurrent neural network (RNN) approach for problems involving long texts. It was developed to solve the long-term memory issue brought on by fading gradients while using RNNs to process massive sequential data [15]. When a gradient has a very low value or is extremely close to zero, the network weight remains constant, indicating that the training process cannot be sustained. However, the LSTM algorithm still has some drawbacks. The standard LSTM only considers the previous context. Despite the fact that text identification is seen not only in one direction from the previous context but also in the next context [16]. To address this issue, this work employs the bidirectional long short-term memory (BiLSTM) method. Based on the foregoing, it develops the BiLSTM model to automatically categorize the public sentiment toward PPKM policies during the COVID-19 pandemic. The data came from social media users' tweets on PPKM. This model is a fundamental component of computer algorithms that automatically categorize data tweets into three groups. Thus, there is no need to read each remark individually. Since every second there are so many comments. This categorization is reliant on language hence the success of an application cannot be directly applied if a different language is used. This application's outcomes are supposed to let the government observe the response of the Indonesian people to policies created more quickly and readily, so that they may be examined and utilized as material to consider when establishing a policy in the future. This study concentrates on how to develop the system and does not examine how the community responds to government policy. A second contribution of this study is the generation of a novel dataset that is unique to the Indonesian language for the PPKM topic.

II. Related Works

Sentiments are the underlying feelings, attitudes, assessments, or emotions underpinning an individual's viewpoint. Sentiment orientation might be positive, negative, or neutral. A sentiment target sometimes referred to as an opinion target, is the entity or feature of the entity about which the feeling is conveyed. The computational study of attitudes, opinions, judgments, and feelings concerning things and their features that are expressed in text is known as sentiment analysis. In general, sentiment analysis commonly uses two approaches: the rule-based/lexicon-based approach [17] and the machine learning/supervised learning approach [18]. By concentrating on the structure and features of the social network, sentiment analysis, and dangers including spam, bots, false news, and hate speech, Antonakaki et al. provide an effort to map the current study themes in Twitter [19]. Best practices for data sampling and access are also presented, in addition to Twitter's fundamental data model. This overview provides a foundation for the application of computational methods like Graph Sampling, Natural Language Processing, and Machine Learning in various fields.

COVID-19-related sentiment analysis research has also been extensively explored in recent years. Ridwan et al. collected English tweets that talked about COVID-19 and were geolocated as "Singapore." [20]. The system is based on the VADER lexicon-based classifier and the emotions from the pre-trained recurrent neural networks to find correlations between real-world events and changes in sentiment over the whole time period. The results of the sentiment analysis showed that about half of the tweets in the dataset were positive, and about a quarter of the tweets were negative or neutral. Topic modeling also showed that most of the talk about COVID-19 on Twitter was about staying home and that these conversations were mostly positive, which contributed to the overall positive mood during the study period. Overall, the results showed that the community supported the steps taken

by the Singapore government during COVID-19. This was clear from the positive comments on Twitter.

Sattar et al. use Twitter data to figure out how people feel about different COVID-19 vaccines [21]. It used the Twitter API and the Python library Tweepy to get about 1.2 million tweets. The tweets were collected from April 10 to May 17, 2021. It only got English tweets, and we used NLTK to do more data analysis. It builds the forecasting model classifier with well-known machine learning regression algorithms: Support Vector Machine (SVM) for regression, k-Nearest Neighbor (KNN), Linear Regression (LR), Random Forest (RF), M5 model tree, Gaussian process for regression, and Multi-layer Perceptron (MLP). Even though some of the vaccines have side effects, we find that the general public is more positive than negative about them. The model for predicting vaccinations says that by the end of July 2021, 62.44% of the population will have had at least one dose of vaccine and 48% will be fully vaccinated. The prediction model says that 73.53% of adults will be partially vaccinated on Independence Day (4 July 2021). The findings give a way to measure how the public talks about the COVID-19 vaccination and how to live a healthy life during the pandemic. It classifies tweets into different emotions like inspired, happy, annoyed, sad, angry, afraid, etc.

Many other studies related to sentiment analysis in English have been carried out, such as in English [22], Arabic [23], Italian [24], and Hindi [25]. Moreover, Intan NY et al. did COVID-19-related research in Indonesia. The research addresses the COVID-19 problem in Indonesia, for policies related to vacations [26]. Government initiatives regarding this vacation program have resulted in a diversity of societal perspectives. Using a bidirectional encoder representation from transformers (BERT) technique, they apply sentiment analysis to this government policy. This research produced a new dataset on this subject. The data was taken from the YouTube comments area and classified into three categories: favorable, neutral, and negative. This study generated an F-score of 84.33 percent. Using Twitter data, more COVID-related studies conducted in Indonesia have been conducted [27, 28].

III. METHODOLOGY

Our case study deals with the implementation of government regulations to address the increase in COVID-19 cases in Indonesia. PPKM has gained support from a range of segments of Indonesian society. Twitter is a social media platform where the general public may express their ideas. This research was conducted through stages that included data collection from Twitter social media, data labeling, text preprocessing, data splitting, feature selection, feature extraction, modeling, and evaluation of the model that has been built. The proposed framework is illustrated in Fig. 1.

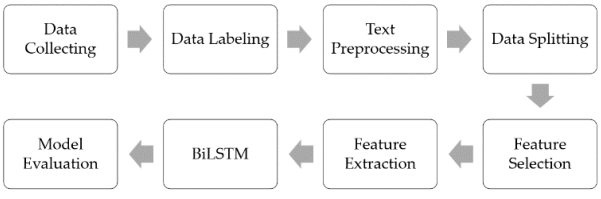

Fig. 1. Proposed framework.

A. Data Collecting

Data obtained from Twitter about the PPKM policy served as the study's subject. The unstructured, heterogeneous input is then categorized into attitudes that are positive, negative, or neutral. The procedure of data collection involved tweets posted by Twitter users between July 1 and August 19, 2021. 10,486 tweets, or 200 tweets each day for 50 days in this period make up the research data. Nevertheless, the obtained data for this study were only collected in Indonesian. Using the Python module snscrape, the scraping operation is carried out to retrieve the data. Government socialization of this policy began on July 1 and was completed on July 3, 2021. Fig. 2 depicts the peak of the topic discussion trend in Indonesia from July 4 through 10, which was the first week that this policy was put into effect.

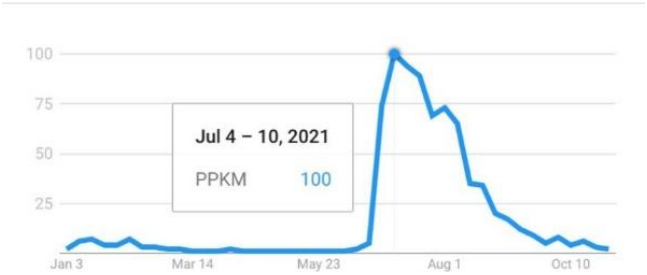

Fig. 2. Trends in PPKM policy tweets in Indonesia.

B. Data Labeling

The labeling of the collected tweet data was done manually, one tweet at a time. Several members of the Faculty of Cultural Sciences of Universitas Padjadjaran were implicated. The findings served as the foundation for this study. Negative tweets comprise profanity, expressions of hostility, criticism, wrath, fear, and despair, as well as expressions of disagreement with government-issued PPKM policies. In the meanwhile, tweets can be classified as positive if they contain terms with positive connotations, give support, demonstrate delight, encourage compliance, and comply with other PPKM criteria. If a tweet does not fall into the good or negative categories, it is labeled as neutral. In this phase, tweets that were deemed to be noise or unrelated to the opinions of Indonesians were also deleted. Its process involved manually deleting tweet data obtained from news accounts, government entities, nonprofits, and businesses. Additionally, tweets with promotions, ads, and tweets in regional languages were removed.

C. Text Preprocessing

Before the text data was processed to the next step, this stage cleaned the data of noise or modified the data's format to make the data processing easier [29]. Each language has its own characteristics hence the procedures and methodologies might differ between languages. The actions taken in this study, i.e.

- Case folding: This step transforms a word's individual letters into a single, consistent shape that may take the form of lowercase or uppercase letters [30].
- Noise reduction: During this step, the text was cleared of distracting elements including mentions, hashtags, links, numbers, symbols, punctuation, and emoticons.

- Tokenizing: This method divided the text into tokens, which were utilized to create practical features. Words in their entirety serve as the stage's tokens.
- Normalizing: In this step, the tokens were normalized to a standardized form. The Indonesian dictionary updated them with standard forms that replaced abbreviations, slang, and other non-standard forms.
- Stemming: By locating and eliminating any affixes present, this step reduced the word to its most basic form.
- Stop-word removal: In this phase, terms that were used excessively or whose definitions were irrelevant to learning are eliminated.

D. Data Splitting

This study used a 7:3 ratio to divide the dataset into training and testing data. 7,340 tweets were used for the training data, whereas 3,146 were used for the testing data. A 10 k-fold cross-validation procedure was then used to separate the training data from the validation data.

E. Feature Selection

Experiments on the minimum count threshold value were conducted during the feature selection step. The limit utilized to filter the existing characteristics based on a word's frequency of occurrence across the entire corpus was the min count value. The characteristics in question in sentiment analysis are the tokens or words that make up a phrase. At this point, irrelevant tokens were eliminated, namely those with too few occurrences

F. Feature Extraction

The process of feature extraction involves numerous initial feature changes that result in the production of new, more important features. It can be used in this situation to simplify the data representation and minimize complexity by treating each variable as a linear combination of the original input variables. The process of obtaining word lists from text data and turning them into a collection of features that the classifier may use is known as feature extraction on text [31]. Word2Vec is a method for feature extraction that appears to be an improvement over the drawbacks of the bag of words (BOW) method, which can create inaccurate models because it doesn't take into account word order or context. To create the appropriate context, it is important to take into account the arrangement of words in a document. When the same type and number of words are used in a document, the word order might yield distinct interpretations, which will impact the sentiment. Another strategy, word embedding, can be applied to get around this. It is a method of representing text in which similar-sounding words are represented similarly in a vector space [32]. In other words, it displays similar terms based on how closely connected the corpus is. It can often be divided into two categories: pre-diction-based embedding and frequency-based embedding. The count vector, TF-IDF, and co-occurrence vector techniques are the ones most frequently employed in frequency-based embedding. As for the frequently employed prediction-based approach, it is Word2Vec. It uses the context of the words around it to quantitatively identify word similarities. It makes vectors whose numerical representations are based on things about words, like how they are used in a sentence. Also, it trains a corpus of text as input data and generates a vector list of words (embedding) as output from a model. The resulting word meanings and word embedding relationships have beneficial properties like vector arithmetic and are spatially represented [33]. It is a self-supervised learning system that gains knowledge from unlabeled input, like a group of texts. The learning technique makes use of conditional probabilities to anticipate certain phrases using some of the words they are surrounded by in a corpus of text. Word pairs that are close in proximity to one another in the text and were one-hot encoded (input, label) make up the training set.

Skip-gram architecture was used in this study since, according to research; it performs better [34]. During training, the skip-gram algorithm could be used to predict the word context of the input word by examining the words nearby. The size of the dimensions and the size of the window serve as the Word2vec hyperparameters that would be optimized. 50, 150, and 300 are the study's test dimensions, whereas 2, 5, 10, and 14 are the study's test window sizes.

G. BiLSTM

The RNN technique, which is utilized in the field of deep learning, has undergone development in the form of LSTM. It was intended to alleviate the vanishing and exploding gradient problems that occur when RNNs are employed to handle extensive sequential input. The cells can learn to recognize substantial input with the aid of the input gate, store it for a long time with the aid of the forget gate, learn to hold onto it for however long is necessary with the assistance of the forget gate, and then learn to delete it when needed. This explains why the algorithm is capable of picking up persistent patterns in time series, lengthy texts, and other data [35].

A memory cell with three gates requires the following gates to control the flow of information:

- Forget gate to decide what data should be removed from the memory cell or not,
- Input gate, which decides what data should be entered into the memory cell,
- Output gates are used to decide the output based on the input and memory cell.

LSTM's first step is to decide what data will be eliminated from the cell state. The choice is made by the sigmoid activation function that takes place in the forget gate layer. The forget gate will take input from ht-1 and xt and output a value between 0 and 1. While 0 indicates that the information will be stored from Ct-1, and 1 indicates that it will be removed.

The information that will be kept in the cell state must then be decided. It is split into two sections. The input gate layer, also known as the sigmoid activation function, first decides what data will be updated. Following that, the vector Ct of new candidate values that can be added to the state is created by the tanh activation function. The outcomes of the sigmoid and tanh activation functions will be merged in the following step, and their values will be utilized to update the state. The subsequent step is to transform the prior cell state, Ct-1, into the new cell

state, Ct. At this point, the value of the new candidate will be added to the prior state after being multiplied by the output from the input gate, and the output from the forget gate. At this stage, processes such as the removal of unimportant information and the addition of significant actual information into the cell state, as defined in the preceding step, occur [36]. The filtered cell state determines the output outcomes. The sigmoid activation function will initially mix input and data from the preceding hidden layer to determine which portion of the cell state should be created. The output from the sigmoid is then multiplied by the output from the tanh activation function (to obtain a value between -1 and 1), yielding only the preset information. Each time step of the LSTM cell's overall process provides two outputs: Ot, which serves as the time step's output and is used as a hidden state, and Ct, which creates a new cell state and is passed on to the following time step.

BiLSTM, a variant of the LSTM algorithm, tries to observe a certain sequence from front to back or back to front. The network creates a context for each character in the text by utilizing their past and future. The goal is to maximize the utilization of an input sequence by stepping through the input step time both forward and backward. In order to create two layers side by side using this design, the first layer is duplicated repeatedly. The input sequence is then fed into the first layer, and the second layer receives a reverse copy of the input sequence. This strategy was created a while back as a general strategy to enhance the functionality of recurrent neural networks [37]. the forward layer and backward layer's information flow. It is typically employed when the order of the data is a factor. It is justified in the context of voice recognition since research suggests that rather than a one-way linear interpretation, humans perceive what is spoken in the context of complete speech. Although it was initially designed for speech recognition, the bidirectional is now a crucial component of LSTM sequence prediction as a method to enhance model performance.

The BiLSTM model neural network layer in this study can be illustrated in Fig. 3. This study's BiLSTM model was developed using the Keras module, which may be obtained at https://keras.io (accessed on 18 February 2020). The first layer was the embedding layer whose embedding matrix values were obtained from the Word2vec model. The embedding matrix resulting from Word2vec was used as the initialization value of the embedding layer's weight which was then updated during the training process. Input on this layer was in the form of tweets which were represented in word index sequences. The sequence had a maximum length of 65 words. Tweet data consisting of less than 65 words was a padded 0 in front of it, while data tweets that were more than 65 words will be truncated so that the length of each tweet sequence is the same. When a shape tuple has a none dimension, it indicates that the network is open to inputs of any dimension.

A 65 x 150-pixel matrix representing each piece of data was the embedding layer's output which is from the feature extraction stage. The maximum length for each data point was 65, and the maximum length for each word's vector representation was 150. The matrix served as the BiLSTM layer's input. The forward LSTM layer and the back-ward LSTM layer are the two LSTM layers that make up the BiLSTM layer, which is made up of one layer altogether. The output of the BiLSTM layer has a size of 65 32 thanks to the combination of the 16 units from each of these LSTM layers with a dropout of 0.5. The GlobalMaxPool1D layer was then given the output from the BiLSTM layer. By taking the largest value in the temporal dimension, this layer was able to down-sample two-dimensional data into one dimension, producing an output with 32 dimensions. It then moves on to the layer for batch normalization. It altered the input to make it uniform. Each input variable's statistics were tracked by the layer during training and utilized to normalize the data. Through a straightforward regularization effect, it can expedite the training process and, in some situations, improve model performance.

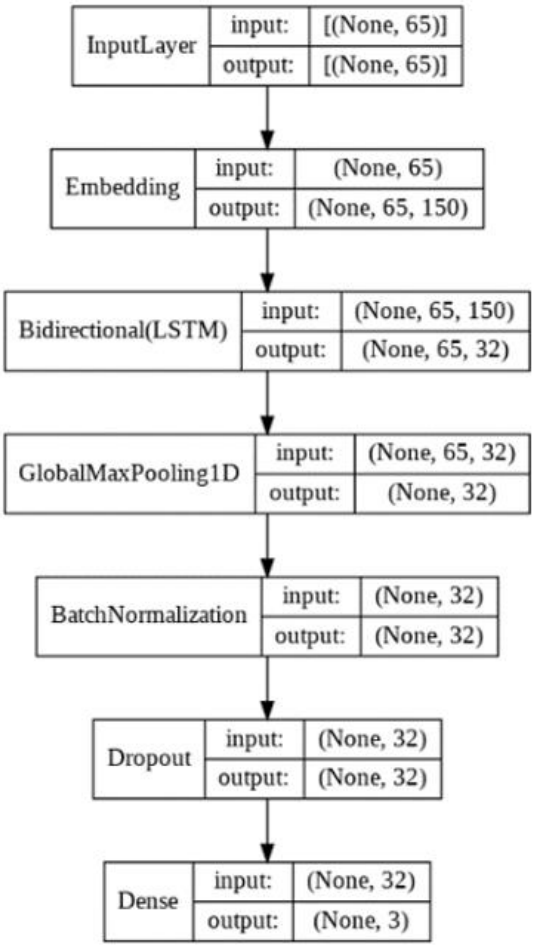

Fig. 3. BiLSTM model architecture.

TABLE I. HYPERPARAMETER VALUES

Hyperparameter	Value
Optimizer	Adam
Merge mode	Concat
Dimension size	150
Activation	Softmax
Max sequence length	65
Max epoch	50

Thus, the layer based on the dropout was a safeguard against overfitting [38], and the resulting layer was dense, fully connected, and had three units. The layer served as the output layer for the Softmax activation function, which created class probabilities from the input with values ranging from 0 419 to 1 for each class. The prediction of input data had the three classes' greatest value making the following step reasonable. It trained the model's trainable parameters defined and assembled earlier. Early stopping was used to avoid overfitting during the model training process using data by assessing the hyperparameter batch size with epoch 50. Table I displays the hyperparameter values used in this investigation. The grid search method in finding optimal hyperparameters was used, in which every combination of predetermined hyperparameters was tried to select the combination that produced the best f1-score value.

H. Model Evaluation

After the BiLSTM model had been successfully created, the next step was to evaluate the model using the confusion matrix values. The metric in this study was the f1-score. It is one of the assessment measures that is often used in sentiment analysis scores. This metric is used to quantify how well a model is able to categorize comments into various sentiment categories, such as positive, negative, or neutral. The F1-score is a metric that offers an overall view of the quality of the model classification since it combines both precision and recall into a single value. Because it strikes a good balance between precision and recall, it is an appropriate tool for use in situations in which the ratio of false positives to false negatives is a significant consideration in sentiment analysis. When identifying sentiment, a high F1 score shows that the model has a high level of precision as well as recall.

IV. Results

The hyperparameters that were analyzed to create the optimal BiLSTM model were the number of BiLSTM layers, the number of BiLSTM units, batch size, dropout rate, and learning rate.

A. Analysis of the Number of Layers

With dropout rate=0.1, batch size=16, and learning rate=0.01, one and BiLSTM layers one and two were stacked against one another and evaluated in this study. Table II shows that using one BiLSTM layer as opposed to two leads in a higher f1-score. The findings of this experiment demonstrate that employing one layer of BiLSTM instead of two layers led to a higher f1-score. It is clear that the model with two layers of BiLSTM could not ensure that the model's performance would be enhanced. Because it yielded improved f1-scores, utilizing just a BiLSTM layer was sufficient for this study. The capacity of the model to learn can theoretically be increased by adding layers to the neural network. However, the model can extract more intricate patterns from the supplied data because of its expanded learning capacity. In general, this is advantageous because the model learns more and becomes better at properly predicting data. On the other side, there is a chance that the created model will be overfitted as a result. According to this criterion, the model performed well when predicting data that has been thoroughly researched but poorly when predicting data that has never been observed.

TABLE II. Analysis of the Number of Layers

Number of layer	LSTM Unit	F1 score
1	16	74.49%
1	64	74.27%
2	16	72.72%
2	64	73.40%

B. Analysis of BiLSTM Unit

Table III demonstrates that an f1-score with a declining trend was obtained by in-creasing the hidden units in the LSTM layer. The model with 16 hidden units generated the model with the highest f1-score, 74.49 %. In this study, 16, 64, and 128 BiLSTM units were examined. Table III gives an overview of the test outcomes that have been evaluated. The test results demonstrate that an f1-score value with a falling trend will be produced by increasing the number of hidden units in the BiLSTM layer. The model with 16 hidden units yields the model with the highest f1-score, or 74.49 %, compared to the other models. It demonstrated that utilizing 16 hidden units in each BiLSTM layer—or 32 units in the BiLSTM layer—was sufficient for the model to extract patterns from the supplied dataset. A higher hidden unit count also did not result in a higher f1-score. It is due to the fact that a model with an excessively large number of hidden units may get overfitted, have a low f1-score in the validation data, and be overly complex.

TABLE III. Results of The BiLSTM Unit

Number of layers	BiLSTM Unit	F1 score
1	16	74.49%
1	64	74.27%
1	128	73.46%

C. Analysis of Dropout

The best outcomes are displayed in Table IV when a dropout of 0.5 was used. It suggests that the optimal model would consist of a BiLSTM layer, 16 LSTM units, and a dropout of 0.5, which would effectively reduce overfitting, raise the average f1-score value, and offer the best model. The model's ability to handle overfitting was less ideal due to the dropout value being too small. Because too many neurons were eliminated during the training phase due to an excessively high dropout number, the final model was subpar.

TABLE IV. Analysis of the Dropout Rate

Dropout rate	LSTM Unit	F1 score
0.1	16	74.49%
0.3	16	74.08%
0.5	16	74.57%

D. Analysis of Batch Size

According to Table V, batch size 32 produced the highest f1-score when compared to the other sizes. The batch size value was about right—it wasn't either too big or too tiny. Larger data sets result in faster model convergence, but since there are so many of them, the model finds it challenging to

identify patterns in the data. Otherwise, if it is too little, the algorithm might not take into account the true level of variance in the sampled distribution, which could lead to a noisy training process.

TABLE V. ANALYSIS OF THE BATCH SIZE

Dropout rate	Batch size	F1 score
0.5	16	74.57%
0.5	32	75.37%
0.5	64	75.08%

E. Analysis of Learning Rate

Table VI shows that when the learning rate was set to 0.001, the model performed at its best. If the learning rate was excessively sluggish and required more repetitions, convergence happened more slowly. If the learning rate was too high, the convergence would occur quickly but the step size would be enormous and the optimal point would be exceeded. The table shows that a model with a learning rate of 0.0001 has a substantially lower f1-score.

TABLE VI. ANALYSIS OF THE LEARNING RATE

Batch size	Learning rate	F1 score
32	0,01	75.37%
32	0,001	76.34%
32	0,0001	70.40%

F. Model Evaluation

The tests with a 10-fold cross-validation technique is presented in Sub-chapters 4.1 to 4.5. The model was then applied to the test data that had been previously separated. 3,146 data points total—including 1,510 negative class data, 1,236 neutral class data, and 400 positive class data—were utilized to evaluate the final model. Fig. 4 demonstrates that in epoch 8, the model obtained the best f1-score. The overfitting that caused the early termination mechanism to end the training process automatically in epoch 9 can be seen. It also demonstrates that there are not many differences in the curves between the training and validation sets of data, indicating that the developed model performs reasonably well. The results of the final model test on the test data shown in the confusion matrix are shown in Fig. 5.

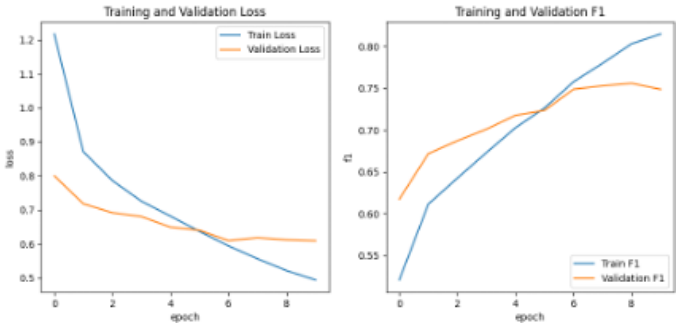

Fig. 4. Graph of F1-Score and loss.

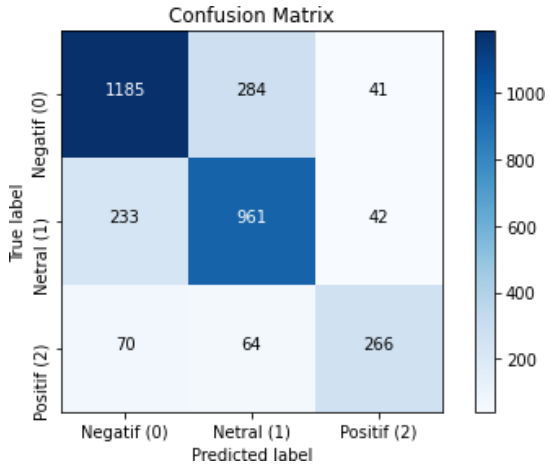

Fig. 5. Confusion matrix.

Also, Table VII displays the precision, recall, and f1-score for each class. The classification result shows metrics for each negative, neutral, and positive class. It is clear that negative classes frequently have metrics that are superior to those of other classes. The built-in model's performance receives a f1-score of 76.67 %.

TABLE VII. MODEL EVALUATION RESULTS

Metric	Negative	Neutral	Positive
Precision	79.64%	73.41%	76.22%
Recall	78.48%	77.75%	66.50%
F1-score	79.05%	75.52%	71.03%

Fig. 6. PPKM trends in November 2021.

G. Sentiment Prediction

This research focuses on the development of computer applications for PPKM-related sentiment analysis in Indonesia. The BiLSTM model was derived from the collected ground truth data in this study. By this model, various sentiment analysis-related data, specifically PPKM-related data, may be automatically classified. An example of test data is PPKM comments data collected in November 2021. In order to avoid an upsurge in COVID-19 cases in Indonesia before the year-end holidays, the government raised the PPKM level once again at the end of 2021. As a result, some Indonesians became quite interested in the PPKM subject. Fig. 6 displays a Google Trends graph of the PPKM keyword's search volume in November 2021. The graph demonstrates that on November 18, the PPKM again declared a peak. On November 17, 2021, the government declared that PPKM level 3 would once again be implemented. 31,788 tweets in total were collected. Based

on this research, there are 10,370, 13,836, and 7.58, respectively, fell into the negative, neutral, and positive categories. In November 2021, a neutral class of 43.5 percent dominated the public's opinion on the PPKM policy. It was followed by a negative class of 32.6 percent, while a small percentage of 23.9 percent expressed a favorable attitude. The majority of tweets that were categorized as neutral provide news or information about PPKM policy. The tweet content that was labeled as unfavorable typically reflects the public's dissatisfaction and frustration with the effects of PPKM's implementation. It demonstrates that the majority of Indonesians disapprove of the PPKM policy, which the government can utilize as evaluation information for reviewing current and future policies.

V. CONCLUSION

The topic of the study was data acquired from Twitter on the PPKM policy. The input is then classified as positive, negative, or neutral. The technique for collecting data involves tweets written by Twitter users between July 1 and August 19, 2021. The research data consists of 10,486 tweets, or 200 tweets every day over 50 days. This is the study's contribution. It is the creation of a new dataset that is unique to the Indonesian language in relation to the PPKM issue.

Also, this study creates the BiLSTM model to automatically classify public opinion on PPKM policies during the COVID-19 epidemic. The best model, with a final f1-score of 76.67 %. Reading each comment individually is unnecessary. Since every second, so many comments are posted. This categorization is dependent on language; hence, the success of an application cannot be directly applied when a different language is utilized. The results of this application are intended to allow the government to monitor the response of the Indonesian people to newly formed policies more quickly and easily, so that they may be analyzed and used as future policy-making material. This research focuses on developing the system and does not investigate how the community reacts to government policies. Last, this article only discusses one of the deep learning algorithms, specifically the BiLSTM method. With the rapid growth of deep learning, however, research may be conducted on the most recent algorithms with the goal of improving performance.

The focus of future work will be on developing more sophisticated pre-processing methods to improve the accuracy of public opinion sentiment on government policy during the COVID-19 pandemic, as well as exploring the application of transfer learning techniques to strengthen understanding of complex patterns in Indonesian language text data.

ACKNOWLEDGMENT

The funding for this project was provided by the Library and Online Data Research Grant from Universitas Padjadjaran, under contract number 1959/UN6.3.1/PT.00/2021.

Faculty of Computer Science and Engineering, Universitas Multi Data Palembang, Palembang, Indonesia[1]

***Abstract*—Rank Reversal in Multi-Criteria Decision Making (MCDM) is a phenomenon that occurs when an alternative is added or deleted because of a change in the order in which the result is ranked. The evaluation of the weight of criteria, which are established based on whether a decision maker considers them important, impacts the alternative ranking result in MCDM. Changes in decision result ranking called rank reversal cannot be acceptable. Many researchers have done lots of research and created new methods for eliminating rank reversal, but until now there is still research that denies these new methods are free from rank reversal. The Analytical Hierarchy Process Method (AHP), the oldest Decision support Method has an advantage in the decision according to the Decision Maker's (DM's) preference. Still, it is vulnerable to the rank reversal phenomenon. While Characteristic Object Method (COMET) is a method claimed to be free of rank reversal phenomenon. This paper will discuss how the integration of COMET to AHP especially in the phase of generating characteristic value and characteristic objects is added to the AHP phase, which will have an impact on digital marketing strategy decision-making for private Universities in Indonesia, especially the city of Palembang. The combination of COMET and AHP in this paper is tested with several testing tools; they are case study testing, accuracy testing, and sensitivity analysis testing. The result of the combination of COMET and AHP will be named C-AHP, which is a consideration of DM's preference for the criteria weight, and the generation of alternative comparison based on criteria, or any other attributes makes AHP free from rank reversal.**

***Keywords*—Method; combination; C-AHP; rank reversal; elimination**

I. INTRODUCTION

Multi-Criteria Decision Making (MCDM) Alternative ranking is affected by the weight given by the DMs (Decision Makers) to the criteria. The main methods of MCDM such as TOPSIS (Technique for Order Preference by Similarity to Ideal Solution), ELECTRE (Elimination Et Choix Tradusiant la REalite), PROMETHEE (Preference Ranking Organization Method for Enrichment Evaluation), AHP (Analytical Hierarchy Process), and their combination, have been criticized in accordance with the occurrence of a problem called Rank Reversal Phenomenon (RRP) [1]. Rank reversal is a phenomenon where the alternative's order of preference is altered when a new alternative is added, or an existing alternative is deleted from a decision problem. A rank reversal occurs when a new alternative has been added or an old alternative eliminated from decisions, and the order of preference for other options is changed. In 1980 Belton and Gear first observed a change in ranking in the AHP [2]. One of the most important criteria for selecting the MCDM method is the phenomenon of rank reversal. There has been no answer to the question of a shift in rank as far as MCDM is concerned. Therefore, to obtain genuine results, a DMM (Decision-Making Method) using MCD (Multi-Criteria Decision) methods must know the problems that arise because of rank reversal. The rank reversal issue has not been solved yet in the MCDM context. Consequently, to obtain a valid result, DMs using MCDM methods should be familiar with rank reversal phenomenon challenges. Although a lot of researchers declare that RRP is a natural feature of the decision-making process, RRP is undesirable and unwanted because it indicates unreliability in the MCDM approach, in the research about sustainable material selection, the research result showed that there was no way to confirm whether the number of options and criteria had any effect on rank reversal [3].

There have been many studies regarding RRP, which tried to eliminate rank reversal using various methods for the past 10 years. In 2014, a framework for the experiments to determine the cause of rank reversal in an MCDM Method was done, the result is a modification of a method with a robust combination in it [4]. In addition to the RRP research carried out in 2017 with a reciprocal fuzzy preference relationship based on additive consistency for addressing RRP, there were also new methods that use proximity-indexed values and have demonstrated their accuracy compared to existing MCDM methods [1] [2]. An RRP investigation into potential causes of rank reversal was carried out in 2018, which indicates that preference followed by ranking score aggregation is the primary cause of RRP because of a lack of information in other research papers. A method for aggregation of scores has been proposed in some research to describe and illustrate the phenomenon of rank reversal using numerical examples. Compared to other tested methods, the results are better. According to the literature on decision-making, several methods suffer from this phenomenon, and one of them is AHP [5]. From 2020 era until 2023 the RRP research focused on the new method and/or the enhancement of the old method in MCDM with the additional Fuzzy to eliminate RRP such as AHP and TOPSIS method [6][7][8].

AHP as the method that applied for the last 25 years in many MCDM decision-making, has been used in lots of decisions in various fields. The pairwise comparison is the basic way of breaking down the problem into a hierarchy of subproblems making AHP a method with its advantages [9][10]. The numeric value assigned to each variable in AHP helps decision-makers defend a cohesive paradigm by deriving the relative weight of each component of the hierarchy, criteria, and alternatives [11]. For the management of qualitative and quantitative multicriteria elements in decisions, as a powerful and efficient tool, For the following criteria and benchmarks, AHP is capable of applying sensitivity analysis. Because of combined comparisons, judgment and calculation are easy in AHP. Moreover, AHP provides proof of compatibility and incompatibility decisions which is the compensation for the multicriteria decision making. With the combination of mathematics and expert judgment, AHP helps decision makers to make better choices both about tangible criteria and intangible criteria [12][13][14]. Besides its advantages, AHP also has disadvantages; RRP is neither a fatal flaw of the AHP nor a desirable property of it. It is a symptom of inherent problems with the AHP [15]. [16] When a decision problem is broken down into smaller problems, ranking irregularities occur in AHP each comprising two alternative solutions and a set of identical criteria as the first problem, which is called the Rank Reversal Phenomenon (RRP) in AHP.

Continuing the first version of the AHP method affected by RRP which was founded by Saaty & Vargas in 1984, Belton and Gear in 1983-1985, and Schoner & Wedley in 1989 who brought out a new version of AHP called the 'ReferenceAHP', to avoid RRP. This means that the weighting of the criteria is changed on each occasion when a different criterion is introduced or deleted. The underlying mathematical justification for this phenomenon is rank reversal local preferences are normalized, in the relative measurement mode, with a reduced level of hierarchy so that they add up to 1. As new alternatives are inserted or removed, Changes in local preferences will be influenced by other alternatives the result may therefore be a change in the end ranking of alternatives. Belton & Gear agrees with this statement as well [17]. In 2012, scholarly papers from an assessment of 61 scholarly papers on AHP methodologies and ranking reversals were carried out in 18 journals [18]. [19]A few studies conclude that the findings do not cover all the areas, the establishment of a new hybrid method for implementing and evaluating the results of studies will be proposed in future work, together with its proposal to evaluate every completed study. By using different methods that will be used in future work, a hybrid method will be integrated and used.

By using different methods that will be used in future work, a hybrid method will be integrated and used. Unlike conventional methods, COMET (Characteristic Object Method) uses a different approach, during initial investigations the phenomena of rank reversal have not been observed. To determine the measurement standard with a fuzzy reference model, a constant set of specially selected characteristic objects distinguishes the COMET model which is independent of the alternatives. The ability of COMET to detect multiple criteria models for the decision-makers, including a nonlinear multicriteria model, is its greatest advantage. [20] The COMET method was primarily designed to deal with actual value data in the first place. In several cases, it has proved difficult to define precisely the exact attributes of decision criteria. Therefore, in complicated decisions with data uncertainties, the use of intervals or fuzzy numbers should be substituted for numerical values.

In this research, as the solution to the AHP in the RRP problem, the advantage of COMET in analyzing characteristics through the categorization of characteristics objects with characteristic value and the classification of criteria and the consistent criteria will be added to AHP and combined with the pairwise comparison in AHP. The purpose of this research is to avoid and eliminate RRP in AHP and the impact on the case of digital marketing strategy decisions in private higher education in Palembang City, Indonesia.

II. Literature Review

A. The Correlation COMET and AHP

COMET and AHP have similarities in the pairwise comparison step. The unstable solution obtained in AHP is caused by the only discrete value of priority for all alternatives from the space of problem which COMET can provide the solution for it [21]. AHP is the best way to prioritize as it delivers highly accurate results for decisions that need to be made. Conventional AHP has scalability problems that can be solved with the modification of the AHP method structure [22]. AHP is also the method to have a coherent result, where to calculate the weights of the criteria, first, we need to establish the criteria' weight by comparing them in pairs [23]. With this strength of AHP combined with the advantage of COMET, AHP can be more powerful in avoiding and eliminating the RRP.

B. COMET and AHP Combination

To create a free RRP, the COMET method needs to be done step by step, the following Fig. 1 is the step of the COMET method [24][25].

Meanwhile, two main steps are carried out in the AHP method, Setting up the problem's hierarchy structure is an initial step, The next step is to give each grade of the hierarchy a nominal value, then set up a pairwise comparison matrix [12][26] The AHP hierarchy structure, and the form of the structure is as presented in Fig. 2.

From the COMET framework steps, and AHP, can be stated that COMET has the biggest contribution in the criteria modification which the adding of a characteristic value and characteristic object to the Criteria is the main key to eliminate the rank reversal. Before adding the numerical example, let's look at the combination of COMET and AHP named the C-AHP method which is depicted in the following Fig. 3.

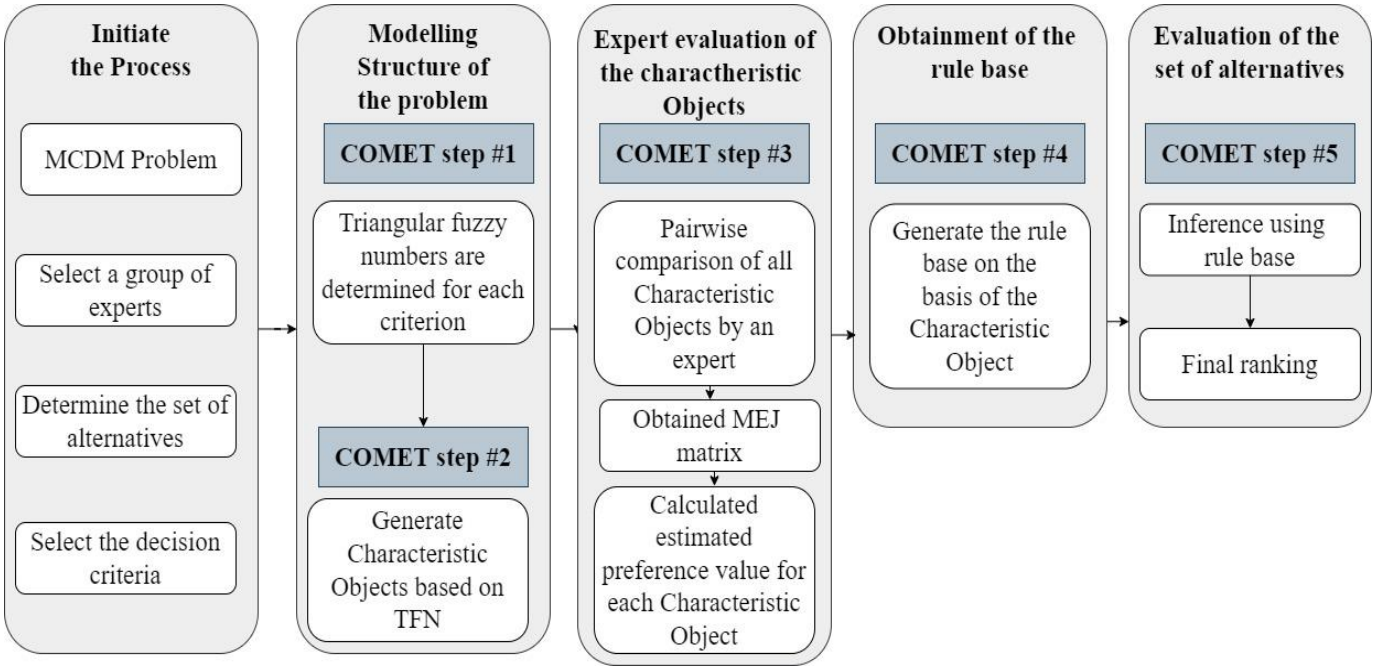

Fig. 1. COMET method model.

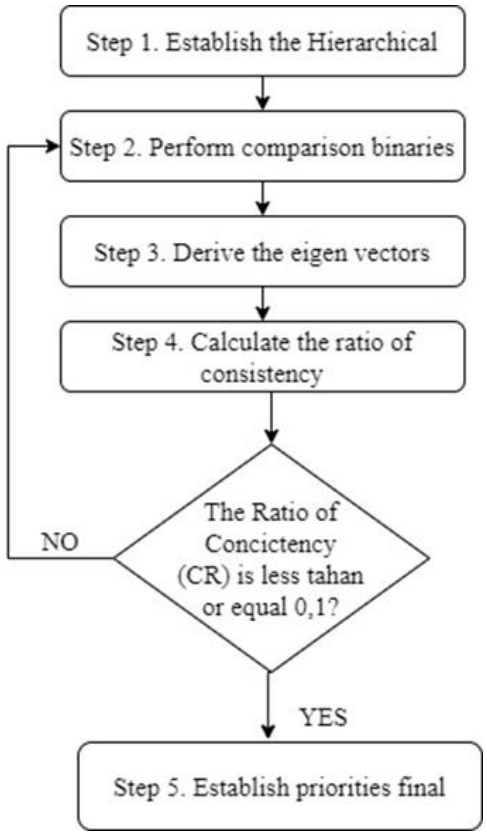

Fig. 2. The AHP method model.

C. Characteristic Object and Value

The characteristic object method (COMET) is based on the idea that a characteristic object is obtained as a combination of values characteristic to individual criteria, points that are regularly distributed in the problem state. By combining fuzzy theory set elements to define a decision model in the area of a problem, which is mainly designed for dealing with real-valued data [23][27]. In COMET, it is the first step to determine how many variants are associated with certain linguistic values that describe criteria, then, a characteristic variable is generated from values of vertices with particular fuzzy numbers [28]. Before the pairwise comparison is conducted, based on the distance from the nearest characteristic objects and their values, preference is given to each alternative [29][30]. For all these criteria, the domains and fuzzy numbers are determined. As a combination of the crisp values of all the fuzzy numbers, the characteristic objects are obtained.

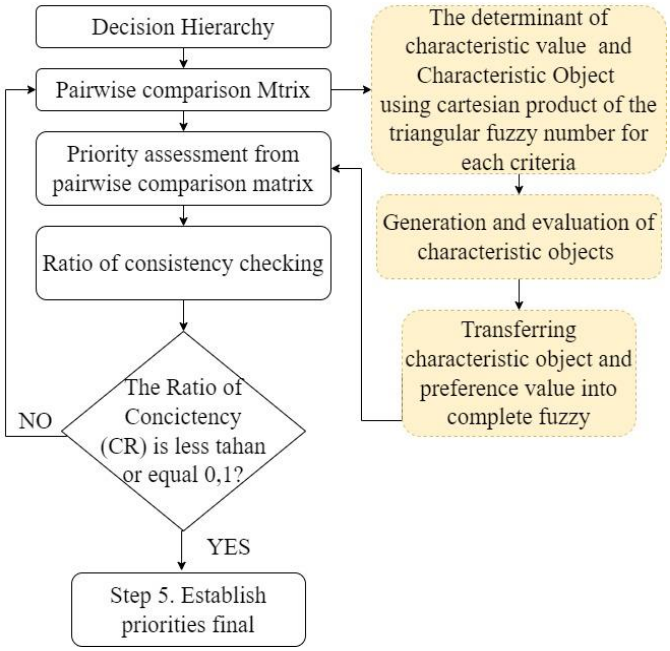

Fig. 3. The C-AHP method framework combination.

III. RESEARCH METHODOLOGY

The methodology of this research as shown in Fig. 4, started with the COMET method component analysis that gives the biggest part to reduce or remove rank reversal in decision-making. Formulation of COMET and AHP focusing on the characteristic value and characteristic object exist in the COMET method, and how its triangular fuzzy number affects the weight of the criteria in AHP. The combination of COMET and AHP is then generated into one framework combination form of those two methods which is later called C-AHP. The new framework, C-AHP, will be implemented in the numeric case, it is digital marketing for private higher education.

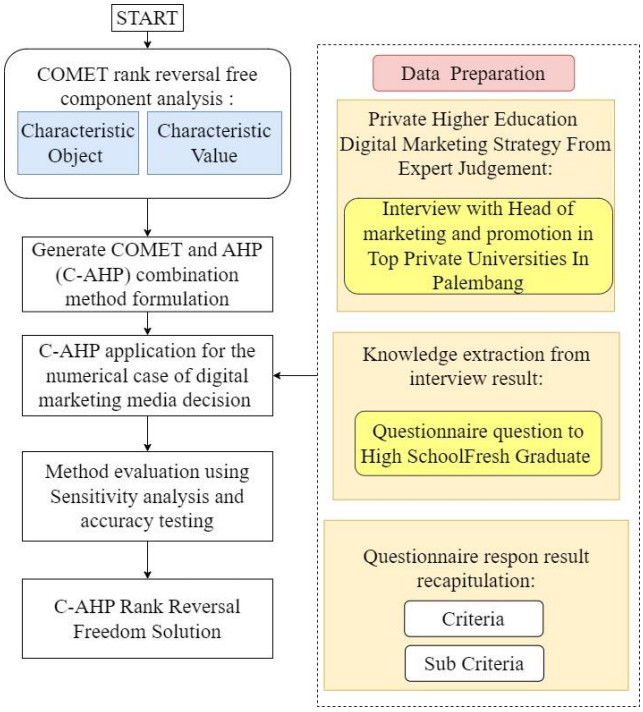

Fig. 4. Framework for C-AHP combination.

Data preparation for the higher educational marketing strategy started with interviewing the head of marketing and public relations in a private University, to collect the digital marketing strategy and criteria according to their wants and needs. After the interview result is a recap and the resulting knowledge about the digital marketing strategy and criteria, the next step is the question questionnaire will be made, which refers to the interview result and will be given to newly graduated high school student, to check whether the criteria is the same between those two parties. After the questionnaire is given to high school graduate students, the result will be a recap and the final criteria and sub-criteria for digital marketing will be established. To prove the rank reversal paradox avoidance in the C-AHP Method, the data from the questionnaire and interview results will be integrated and used in the C-AHP method for the numerical calculation. An additional step is added at the beginning of the C-AHP step after the criteria are determined, then will be building the characteristic value for each criterion. After defining the characteristic value, a characteristic object is created according to its characteristic value, using the formula as follows:

A. Characteristic Value of Criteria

In this concept, by using the number r of criteria to define the size of the problem and establish its dimensionality,

B. $C_1\ C_2\ ,...,C_r$.

The selection of the triangular fuzzy numbers for each criterion is made.

C_i, as example $C_{i1}\ C_{i2}\ ,...C_{ic}$

The result of this is as follows::

$$C_1\{C_{11},C_{12}\ ,...,C_{1c1}\}$$

$$C_2\{C_{11},C_{12}\ ,...,C_{1c1}\}$$

$$\ldots\ldots\ldots\ldots\ldots\ldots..$$

$$C_r\{Cr_1,Cr_2\ ,...,C_{rcr}\}$$

C1, C2,..., Cr for all criteria, are numbers of fuzzy numbers. After obtaining the triangular fuzzy number, and then a linguistic model has been created.

C. Generating Characteristic Object (CO)

CO $C(C_1)$ x $C(C_2)$ x...x$C(C_r)$

The next step is to define all of the set values for a given characteristic object as a result.

$$CO_1 = \{C(C_{11}),C(C_{21}),\ldots,C(C_{r1})\}$$

$$CO_2 = \{C(C_{11}),C(C_{21}),\ldots,C(C_{r2})\}$$

$$\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots$$

$$CO_t = \{C(C_{1c1}),C(C_{2C2}),\ldots,C(C_{rcr})\}$$

t is a number of CO [31]

$$t = \prod_{i=1}^{r} c_i$$

D. Pairwise Comparison of Characteristic Objects

Before we carry out an evaluation and a final ranking, a comparison of characteristic Objects between Characteristic Object (CO) for each criterion will be implemented. With the scale of:

$$\alpha \text{ is } = f(COi, COj) = \begin{cases} 0{,}0,\ f_{exp}(COi) < f_{exp}(COj) \\ 0{,}5,\ f_{exp}(COi) = f_{exp}(COj) \\ 1{,}0,\ f_{exp}(COi) > f_{exp}(COj) \end{cases}$$

This step is the normalization step that will make sure that each alternative and criteria have the same consistent numeric calculation even though there is a new alternative added or deleted.

E. Previous Related COMET and AHP Research

The previous works regarding to COMET and AHP, or one of the method, which related to the combination of those method, analyzed in this paper. The result of latest work related to this research is started in 2016 in the research about the rank reversal paradox in management decisions: the comparison of the AHP and COMET methods, the result is COMET is free of

rank reversal in compare to AHP on the Problem of Selecting Providers. COMET method is very easy to use, and the simplest models given reliable results. in 2020, intuitionistic fuzzy sets in multi-criteria group decision making problems using the characteristic objects method, resulting the case is academic problem of selection of the best mobile company using fuzzy set. In this research, on 2023, the case in digital marketing strategy decision for private higher education in South Sumatra, Palembang, Indonesia, combining COMET and AHP for the Rank Reversal Phenomenon free.

IV. C-AHP Implementation in Digital Marketing Private Higher Education Decision

A. Digital Marketing Private Higher Education Decision

Data sample for digital marketing private higher education is taken in two ways; first interview with the head of marketing and/or public relations in private higher education, University in Palembang City is done. The interview questions about digital marketing strategy are Table I:

TABLE I. Interview Questions

Question	Answers
Is there a specific target or niche targeted at the prospective student market segment?	SMA & SMK
Is the marketing strategy model used the same for all study programs/faculties?	All the same
How big is the comparison between the amount of conventional/offline marketing compared to digital / online at your university?	50% offline - 50% Online
Is there a strategy for when to use conventional marketing media and when to use digital marketing at your university?	No
What are the criteria or conditions to be considered when determining which digital marketing media to use? In meaning, what are the criteria for choosing marketing media at your university?	No
What are the strategies and/or media used for digital marketing strategies at your current university? is one of these lists - SEO - Content marketing - Paid search - Social media - Marketplaces - Paid advertising media, banner ads - Media chat - Emails - Influencer - Affiliate marketing	SEO FB IG TIKTOcK WA Blast Marketplace Paid Advertising
Which do you use most of all the digital marketing media mentioned earlier?	
Which digital marketing media has an impact in terms of: - Easily measurable results - Increasing customer loyalty, which ensures the most retention of customers - Cost-effectiveness - Conversion rate: the percentage of your website's visitors who do business on your company's page, actions they take during their visit and steps that lead them to make transactions	All the same
You agree that the needs and benefits of digital marketing in the field of education should be summarised as follows: t's measurable IEasy to Access impactful Instant Feedback System Brand awareness reach	Yes
Demographics, age or other characteristics are usually the criteria which you will be considering when it comes to a particular Digital Marketing.?	No we come to every school which accept us

As shown in the methodology, from the interview results, knowledge about the targeted and planned digital marketing strategy of a private higher education institution's Marketing Director or Public Relations and promotion Department is created. The next step is to collect data from the questionnaire with the question using the Likert scale, where the data of the questionnaire is taken from 325 respondents, who are high school graduate students in Palembang city. Using the Slovin formula, this research uses a population of 420 with the error of tolerance e=0,05 and using the Slovin formula:

$$n = \frac{N}{1+Ne^2} \quad (1)$$

The sample from the formula is 204 respondents, but from the questionnaire responses, 325 respondents fill and answer the questionnaire. So minimum sample is n=325. From this sample result, the validity and reliability test are conducted, and the result for validity with the tolerance of error is 0,05, resulting in the r count being bigger than the r table for every aspect of the question which means all the value is valid. The reliability test for the graduated high school student is shown in Table II and Table III:

TABLE II. Reliability Test Result

		N	%
Cases	Valid	325	100,0
	Excluded[a]	0	0,0
	Total	325	100,0

TABLE III. Reliability Cronbach Result

Cronbach's Alpha	N of Items
0,732	39

To the answers of the interviewed person, it is concluded that the criteria and sub-criteria for the digital marketing strategy in the decision of which media to choose, is as shown in Table IV:

TABLE IV. Criteria and Sub Criteria

Criteria	Name	Sub Criteria
C1	Advertising Type	Video, Photo, short video
C2	Advertising content	Program explanation, campus facilities, tuition fee and scholarship, campus performance
C3	Marketing Period	Anytime, April-june, October-December, Januari-March, July-September

From the questionnaire and interview result comparison, the alternatives for this research are Google ads, Instagram, WhatsApp blast, and YouTube.

The C-AHP method will be used to avoid rank reversal paradox in this digital marketing for private higher education decision, following the C-AHP method framework combination in Fig. 4, with these steps:

1) Problem and decision hierarchy: As the first step in C-AHP still follows the AHP stages, the problem domain definition starts with the hierarchical structure format, as shown in Fig. 8.

2) Determination of characteristic value: To generate a characteristic object, characteristic value is the first thing to settle. Characteristic value is different for each criterion it depends on the data and assumption. In the agreed and very agreed choice, use the triangular fuzzy number and the number of answers chosen by the respondent, The characteristic value of the criteria is set out in this case as presented in Table V:

TABLE V. CHARACTERISTIC VALUE

Criteria	Sub Criteria	Value
C_1 (Advertising type)	Video	65
	Photo	92
	Short Video	193
C_2(Advertising content)	Campus Performance	47
	Scholarship	48
	Tuition Fee	61
	Campus Facilities	67
	Program Explanation	70
C_3 (Marketing Period)	July-September	11
	October-December	17
	Januari-March	18
	April-june	21
	Anytime	32

There is a minimum possible value and a maximum possible value for each characteristic value. For instance, video 65 is the minimum possible value for advertising type and the highest possible value can be the shortest video 193, and a medium value is photo 92. After the characteristic value Triangular Fuzzy number for each criterion is conducted next step is to result in the linguistic model of the characteristic value which shown in Fig. 5, Fig. 6, and Fig. 7.

C_1 Advertising type, linguistic model

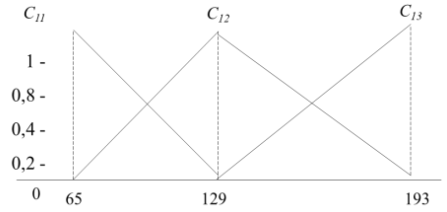

Fig. 5. Characteristic value type.

C_2 Advertising content, linguistic model

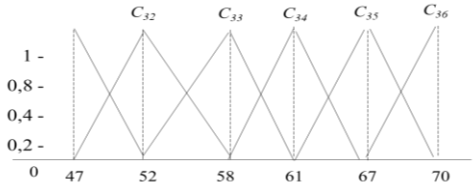

Fig. 6. Characteristic value advertising content.

C_3 Period, linguistic model

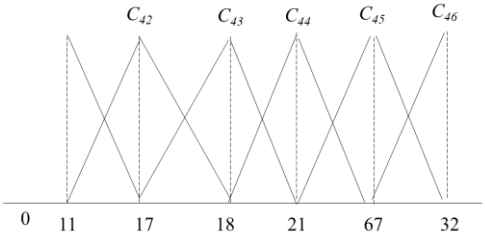

Fig. 7. Characteristic value period.

B. Generate Characteristic Object Value

From the characteristic value, the characteristic object can be generated using the formula to generate, and then from the characteristic object, with the limitations of maximum possible and minimum possible it will limit the additional aspect of criteria, and when a ranking result of digital marketing is obtaining, and another alternative in example TikTok occurred, the rank result difference will not be too far because the limitations of the character of the criteria are works in C-AHP model since the comparison of the criteria in pairs with another criterion. After the Criterion value is determined, the pairwise comparison with the generated score 0, 0,5, and 1 is entered in the criteria and sub-criteria value and the result of the final ranking is obtained.

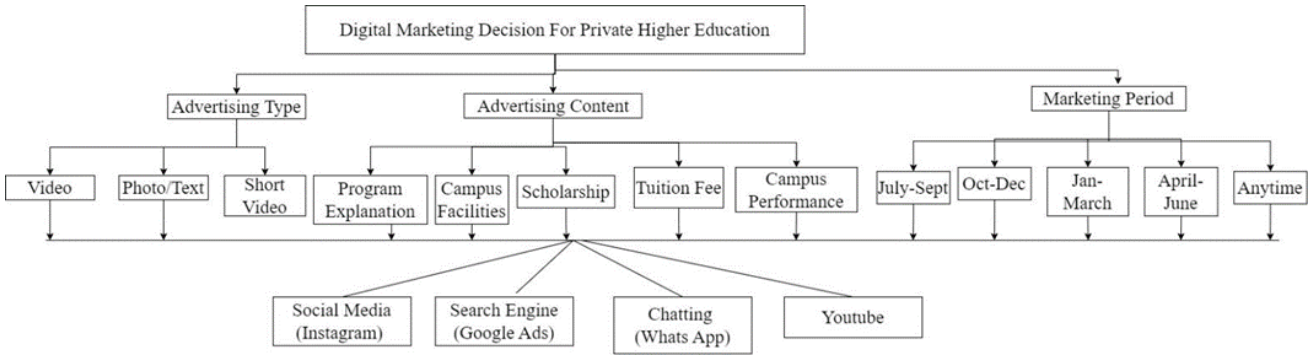

Fig. 8. Decision hierarchy digital marketing strategy.

V. Result and Discussion

From the C-AHP numeric calculation, with additional characteristic value and object in the criteria formulation, in the digital marketing for higher education case study, the Consistency Ratio (CR) results for criteria and sub-criteria is consistent with the score of Criteria is -0,66 and sub-criteria is -1,00 for C1, -0,50 for C2, and -0,67 for C3. This CR result shows because the result is under 1,00 shows that it is acceptable to implement. After all, it is stable and reliable. This research result has shown that C-AHP is reliable in keeping the criteria value stable even when the changes of alternatives are done. The addition of the same alternative and the reducing alternatives is done, and the result is the rank not changing for A1, A2, A3 and A4 as the alternative for the digital marketing higher education strategy case. The rank of the alternative remains the same. The case study has proven that C-AHP in the digital marketing strategy is affected by the characteristic object and value generation. This statement is proven by the accuracy and sensitivity analysis conducted on the variable chosen as the characteristic object in the criteria and sub-criteria, which changed with the adding of one point, and deduction of one point and the result is the sensitivity analysis acceptable. Adding a point to this research in the future will be the implementation of C-AHP in another case outside digital marketing for higher education strategy. As the same with the previous research conducted, the Rank Reversal phenomenon is eliminated for the comparison with other free rank reversal methods already conducted but there is no test to the result in the previous research using accuracy and sensitivity analysis.

VI. Conclusion

The rank reversal paradox in AHP with the combination of COMET and C-AHP was able to reduce the RRP in the decision to the digital marketing strategy for private higher education in Palembang city. The key combination for C-AHP is characteristic value and characteristic object which brought new weight to the criteria and sub-criteria in decision making, and also when generated it brings limitations to any addition or changes of the alternatives in the digital marketing strategy for private higher education.

Future studies can be conducted for the specific possibility of C-AHP implementation in another case study and can also be conducted for the same case with changes in the weight of the criteria from characteristic objects and values. The decision in this research is conducted by an individual; the future research can use C-AHP for the group decision support system in the group decision maker.

***Abstract*—In the last two decades, many technologies have been deployed and utilized in Soccer games (Football) as a result to the huge investment of Federation of International Football Association (FIFA). These technologies aim to monitor and track all soccer match objects including players and the ball itself in order to measure the player performance, and tracking the players' positions and movements at the field. Latest emerging artificial intelligence and computer vision techniques are being used recently in many systems and deployed in different scenarios. Identifying all field objects automatically has to be the first step in the monitoring process of soccer games. In this paper, we are proposing an automated system that has the ability to detect and track the ball and to detect and classify players and referees on the soccer field. The proposed system implements a detection model using a real-time object detection model YOLOv7 to detect the ball and all humans on the field after building a labeled dataset of 1300 different soccer game frames. It also deploys Improved Color Coherence Vector (ICCV) features to classify all humans on the field to five classes (Team1, Team2, Goalkeeper1, Goalkeeper2, and Referee) using K-Nearest Neighbor algorithm. The proposed system has achieved high accuracy in both the detection and classification modules.**

***Keywords*—Soccer game; football; YOLOv7; human detection and classification; ball detection; improved color coherence vector**

I. INTRODUCTION

In the realm of sports, where every moment carries significance, the automated computer vision detection and recognition of soccer match field objects has emerged as a pivotal technological advancement [1]. Soccer, often referred to as football in many parts of the world, stands as one of the most globally celebrated and passionately played sports. Over the years, it has not only evolved in terms of gameplay but has also embraced technology to analyze and elevate the sport to new heights. The integration of automated computer vision has ushered in a transformative era, fundamentally reshaping how we perceive and comprehend soccer matches.

The soccer field itself serves as a dynamic canvas, where players, the ball, and various other elements such as goalposts, corner flags, and boundary lines converge to create a complex and fast-paced spectacle. Traditionally, the task of monitoring and dissecting these elements fell to human operators, a process fraught with potential errors and subjectivity. However, with the advent of automated computer vision, we have witnessed a profound shift in our ability to capture, process, and leverage data from soccer matches [2]. This technology empowers us to identify and track field objects in real-time, providing invaluable insights to coaches, players, analysts, and fervent fans.

In this context, this paper delves into the profound significance of automated computer vision in the detection and recognition of soccer match field objects. We explore the tangible applications of this technology, its impact on game analysis, player performance evaluation, automatic offside detection, and fan engagement. Furthermore, we delve into how it is poised to redefine the future of soccer as we know it. Through this exploration, it becomes increasingly evident that automated computer vision is not just a tool but a transformative force that is redefining the very essence of soccer analysis and appreciation.

In the past two decades, the world of soccer (or football) has witnessed a profound transformation, fueled by substantial investments from organizations like the Federation of International Football Association (FIFA) [3]. These investments have ushered in a new era of technology-driven enhancements within soccer games, aimed at monitoring and tracking various aspects of the game, including player performance and positional data [4]. Recent advancements in artificial intelligence and computer vision techniques have played a pivotal role in this transformation.

The initial step towards automating the monitoring process of soccer matches involves the automatic detection and classification of all relevant objects on the field. In this context, several Convolutional Neural Network (CNN) architectures were suggested and deployed to detect the ball and the players on the soccer field [5, 6]. In addition, several research works have addressed the detection of soccer events, ball events, actions on the soccer game, and team tactics estimations [7, 8].

In general, several researchers have addressed the detection process of soccer field objects for various applications but, it is also important to classify these objects to ease the monitoring process of each soccer team player. In this context, the class of each human on the soccer field should be determined to enable tracking of individual players and team movements.

In this paper, we present an automated system designed to detect and track the soccer ball and classify players and

referees on the field using state-of-the-art techniques. In this work, we aim to: 1) construct an annotated detection dataset that consists of 1300 soccer game matches' images; 2) detect soccer field objects, ball and humans using YOLOv7; 3) classify every human on the soccer field to Team1, Team2, Goalkeeper1, Goalkeeper2, and Referee using Color Coherence Vector and k-NN classifier; and 4) improve the detection precision and the classification accuracy by implementing a cascaded detection and classification systems. Overall, this system aims to provide an accurate and efficient method for detecting and classifying soccer game objects, which can be beneficial for coaches, broadcasters, and analysts in different computer vision applications such as team performance monitoring, automated offside detection and tactics estimation.

This paper is organized as follows. Section II provides a theoretical background of the techniques being used. Section III demonstrates the architecture of the proposed system. Section IV presents the experimental results and discussion. Finally, conclusions are drawn in Section V.

II. THEORETICAL BACKGROUND

A. YOLO

You Only Look Once (YOLO) is convolutional neural network architecture for object detection in one shot [9, 10]. YOLO partitions the input image into N grids, each with equal dimensions. Each grid is responsible for the detection and localization of the object that it contains. In general, YOLO networks extract features through a backbone. The extracted features are combined and mixed in the neck, and then they are passed along to the head of the network to predict the locations and classes of objects around which bounding boxes should be drawn [11, 12].

The YOLOv7 algorithm, an upgraded version of YOLO object detectors, surpasses all known object detectors in both speed and accuracy [13]. YOLOv7 was trained only on MS COCO dataset from scratch without using any other datasets or pre-trained weights. It improved real time object detection accuracy without increasing the inference cost.

YOLOv7 has extended efficient layer aggregation networks (E-ELAN). It also has model scaling for concatenation-based models. The YOLOv7 algorithm also uses a technique called anchor boxes to improve the accuracy of object detection. Anchor boxes are pre-defined shapes that the algorithm uses to predict the location of objects in an image. By using anchor boxes, the algorithm is able to detect objects of different sizes and shapes with greater accuracy.

B. Improved Color Coherence Vector

Color Coherence Vector (CCV) is a color feature extractor that encodes information about color spatial distribution. It classifies each pixel in the image as either coherent or incoherent. Coherent pixels belong to a big connected component (CC) while incoherent pixels belong to a small connected component. CCV aims to build a low dimensional representation of the image through the following steps [14]:

1) Blur the image by averaging.

2) Quantize the image colors into n distinct colors.

3) Classify each pixel either as coherent or incoherent by:

a) Finding the connected components for each quantized color.

b) Determining the Tau's value which is typically about 1% of image size. Pixels are considered coherent if they belong to any connected component with number of pixels are more than or equal to tau.

4) For each color compute two values: α which is the number of coherent pixels, and β which is the number of incoherent pixels.

Improved Color Coherence Vector (ICCV) has more spatial information with respect to CCV and thus; it is more efficient in comparing image contents [15]. In addition to (α, β) pairs that were computed by CCV, the mean of position coordinates (rows and columns) for the maximum connected region in the coherent pixels (γ) is computed using ICCV. Each quantized color would be described accordingly by four values in the form of (α, β, γ_x, γ_y). The size of feature vector would be the number of quantized colors multiplied by 4.

C. K-Nearest Neighbor Algorithm

The k-nearest neighbor algorithm (k-NN) is one of the simplest machine learning algorithms. Any test object is assigned to its nearest neighbors' class by adopting majority voting. Nearest neighbors are determined by measuring a distance metric which could be the Euclidean distance, the hamming distance, or the correlation. Number of nearest neighbors is defined by K which is a problem dependent parameter [16, 17]. k-NN has two stages; determining the nearest k neighbors and determining the class by majority voting.

III. THE PROPOSED SYSTEM

The proposed system shown in Fig. 1 is composed of three modules:

- Dataset Preparation: in which soccer game field images of on-going games are collected, pre-processed, annotated, and augmented to build the dataset for training, evaluating, and testing the YOLO detection model.
- Human and Ball Detection: in which a YOLOv7 deep learning model is selected and trained on both the training and validation datasets and then, evaluated on the test dataset. The detection model has the capability of detecting the ball and all humans on the soccer field
- Humans' Classification: in which k-NN classifier is being used to classify detected humans to team1, team2, goal keeper, and referee using Color features of detected human. Human templates of team1, team2, goal keeper, and referee are used in the classification based on Color Coherence Vector (CCV).

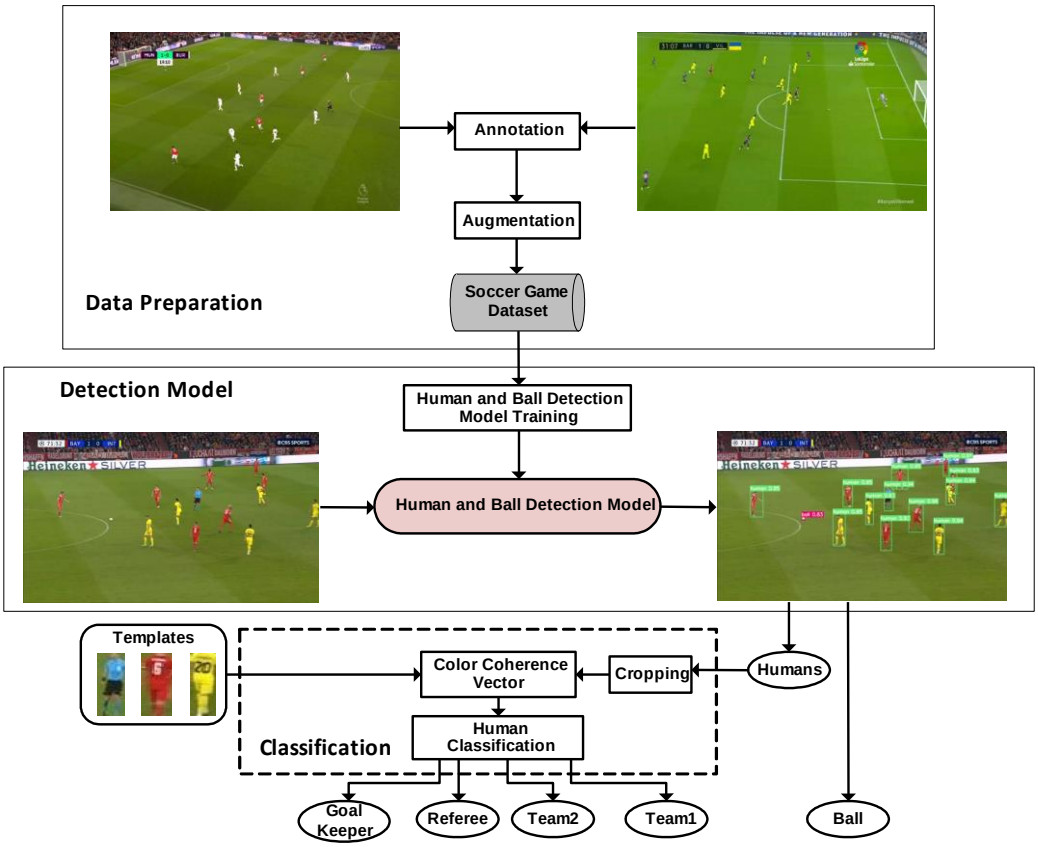

Fig. 1. The proposed system.

A. Dataset Preparation

In this module, a labeled dataset of 1300 different soccer match images was constructed. This dataset will be used for training, validation, and testing the Human and Ball detection model.

1) Image collection: A set of 1300 different images of different soccer matches was constructed. 810 images were obtained from multiple videos of soccer game matches and 490 images were obtained from the online dataset at [18]. All images were captured from a single camera position covering one half of the field. Several images were selected for each soccer game. Fig. 2 shows samples of soccer matches' images.

2) Annotation, preprocessing and augmentation: In this step, the collected images were uploaded to Roboflow platform, where it was labeled into two classes: human and ball using Roboflow's annotation tool. Fig. 3 shows some annotations of ball and humans on the original images.

The annotation task of the original 1300 images has resulted into 25636 different labels of both ball and human labels as shown in Table I.

TABLE I. SUMMARY OF ANNOTATED IMAGES

Number of Images	Annotations	Ball Annotation	Human Annotation
1300	25636	1174	24462

Fig. 2. Sample images of soccer game matches.

Fig. 3. Sample images of soccer game matches

After labelling, some preprocessing and augmentation tasks of the images were applied as follows:

- Preprocessing:
  - Auto Orient: Applied
  - Resize: Fit within 640x640
- Augmentations:
  - Grayscale: Apply to 25% of images
  - Saturation: Between -25% and +25%
  - Brightness: Between -30% and +30%

After Augmentations, a set of 2203 images were obtained. These images were splitted into 83% (1826), 12% (273), and 5% (104) for training, validation, and testing, respectively.

B. Human and Ball Detection Model

In this module, YOLOv7 algorithm is used for human and object detection. Model training was achieved on Google Colab notebook. Once the model was trained, it was tested on a separate set of validation images to evaluate its performance.

1) Model training and evaluation: The model was trained using YOLOv7. This model is evaluated for detecting two classes: human and ball. Two epoch choices were used to train the model; 100 and 180.

The model detection performance was evaluated using mean average precision (mAP), recall and precision. The evaluation metrics that were used to evaluate the model are explained as follows:

Precision is a measure of a network's ability to accurately identify targets at a single threshold, calculated by:

$$\text{Precision} = \frac{\text{Tp}}{\text{Tp+Fp}} \quad (1)$$

Recall is a measure of the network's ability to detect its target, calculated by:

$$\text{Recall} = \frac{\text{Tp}}{\text{Tp+Fn}} \quad (2)$$

Where:

- Tp: are the Bounding Boxes (BB) that the intersection over union (IoU) with the ground truth (GT) is above 0.5.
- Fp: two cases (a) BB that the IoU with GT is below 0.5 (b) the BB that have IoU with a GT that has already been detected.
- Tn: there are not true negative, the image is expected to contain at least one object.

Fn: images containing an object were the method failed to produce a BB.

Intersection over Union (IoU) is a method used to compare two arbitrary shapes, i.e., object widths, heights, and location of two boxes into the original region. This will evaluate the precision of the object detector on particular dataset [19] as in (3). Fig. 4 shows how IoU is calculated diagrammatically.

$$\text{IoU} = \frac{\text{Area of Overlap}}{\text{Area of Union}} \quad (3)$$

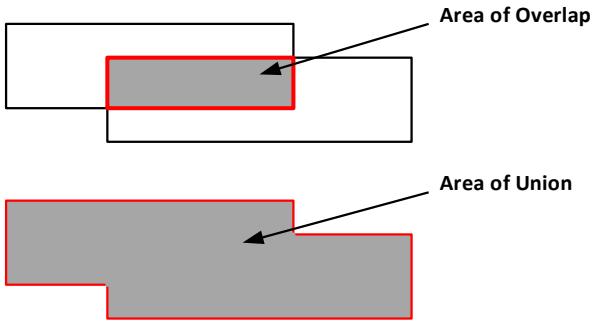

Fig. 4. Diagrammatic example intersection over union (IoU) calculation.

Average precision is a method combining recall and precision for the entire ranking. It is the average of precision in a single ranking [20].

$$AP = \frac{1}{|Class|}\sum_{c \in class} \frac{TP(c)}{TP(c)+FP(c)} \quad (4)$$

Mean average precision (mAP) is the average of precision values at the rank where there is a relevant document [21]. It is calculated from precision, recall and interception over union IOU.

$$mAP = \frac{AP}{Total\ number\ of\ class} \quad (5)$$

C. Humans' Classification

This module classifies the detected humans in the previous module to team1, team2, goal keeper, and referee using shirt

colors of detected human. Color Coherence Vector (CCV) is used to describe the color features and k-NN is deployed for classification. The classification has been achieved by comparing each detected human with stored templates of humans from the same soccer match.

1) Template preparation and preprocessing: Template Preparation and Preprocessing have been done prior to features extraction and classification. At first, manual cropping of humans on the soccer match images was achieved for image group of each distinct soccer match. Five suitable templates of team1, team2, goalkeeper1, goalkeeper2 and referee were selected. Each five templates were obtained from different image frames of the same soccer match to choose the best body orientation of each class. Each single template represents the body area of the human excluding the head and lower part of leg to concentrate on distinct color features for classification. All templates were resized to 25x50. Fig. 5 shows the five templates of humans selected from different images of the same soccer match.

Next, each detected human in the detection module is cropped automatically to exclude most of the soccer field background and body parts that haven't distinct color features. This process has been done by cropping 15% from each side of the detected humans' area as shown in Fig. 6.

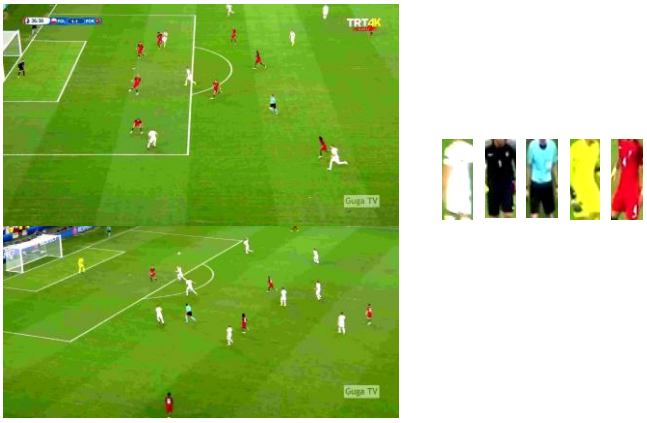

Fig. 5. Example of template preparation.

Fig. 6. Examples of cropping detected humans' images.

2) Color feature extraction using ICCV: Color features of human templates and all cropped images of all detected humans are extracted using Improved Color Coherence Vector (ICCV). The output of this stage is a feature vector of size 64x1 based on the following steps:

- Quantize the color-space into 16 distinct colors.
- Classify each pixel either as coherent or incoherent by finding the connected components for each quantized color and determining the tau's value to be 5% of image's size. Any connected component with number of pixels more than or equal to tau then its pixels are considered coherent otherwise they are incoherent.
- For each color, compute the number of coherent pixels (α), the number of incoherent pixels (β), and the mean of position coordinates (rows and columns) for the maximum connected region in the coherent pixels (γ).

Each quantized color would be described accordingly by four values in the form of (α, β, γx, γy). For the 16 colors, we would gain a feature vector of size 64x1.

3) Classification using k-NN: Each detected human would be classified to team1, team2, goalkeeper1, goalkeeper2 or referee based on 3-NN classifier. Nearest neighbors are determined by measuring the Euclidean distance and determining the class by majority voting.

Classification accuracy can be calculated according to the following formula:

$$\text{Accuracy} = \frac{\text{Tp+Tn}}{\text{All Elements}} \quad (6)$$

Where Tp and Tn are the elements correctly classified by the model.

IV. Results and Discussion

In this section, we demonstrate the experimental results of both the detection and classification modules. We have tested the detection model on 104 images that were picked randomly from various soccer matches. In the classification module, we have achieved the testing on five different matches because we use color features which are different on each single match. A total number of 51 different images have been selected to validate the classification results.

A. Detection Results

In this section, we evaluate the performance of the YOLOv7 detection model, which plays a crucial role in automatically identifying and tracking soccer field objects such as the ball and players. The results provide insights into the model's accuracy and effectiveness in object detection.

Fig. 7 serves as a comprehensive illustration of the YOLOv7 model's performance in identifying and localizing objects of interest, including both players and the ball. This figure utilizes three distinct metrics—Accuracy, Precision, and mAP@0.5—to evaluate the model's precision in object localization and its proficiency in correctly classifying objects.

Fig. 8 presents a valuable snapshot of the quantitative metrics used to evaluate the performance of the detection model throughout the training process. These metrics include precision, recall, and mean average precision (mAP@0.5), which provide insights into the model's effectiveness in detecting objects of interest in soccer matches.

Precision measures the accuracy of positive predictions made by the model. It is a crucial metric for object detection, as it assesses the model's ability to correctly identify objects without generating too many false positives. Recall evaluates the model's ability to detect all relevant objects in the dataset, minimizing false negatives. It is particularly important in ensuring that no objects of interest are missed. mAP@0.5 is a comprehensive metric that combines precision and recall across different object classes. It considers precision-recall trade-offs and provides an aggregate assessment of the model's performance.

The confusion matrix, as shown in Fig. 9, provides a detailed breakdown of the model's performance, including true positives (TP), false positives (FP), true negatives (TN), and false negatives (FN) for each object class (e.g., ball, humans and background).

Fig. 10 offers an insightful comparison between different models' training using varying numbers of training epochs (specifically, 100 and 180). The key takeaway from this figure is that it underscores the importance of training the model beyond 100 epochs for achieving optimal performance.

To perform model testing, we loaded the saved weights of the trained model and passed the test dataset through it. Fig. 11 shows some examples of detection model Inference.

The results of the model testing showed very good accuracy and performance in detecting objects of interest in the images. Overall, the model testing was successful in demonstrating the accuracy and effectiveness of the trained model in detecting objects of interest in the images.

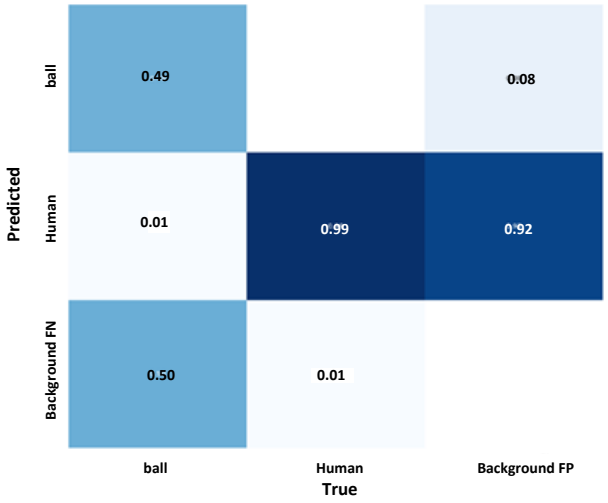

Fig. 9. Confusion Matrix of the detection model.

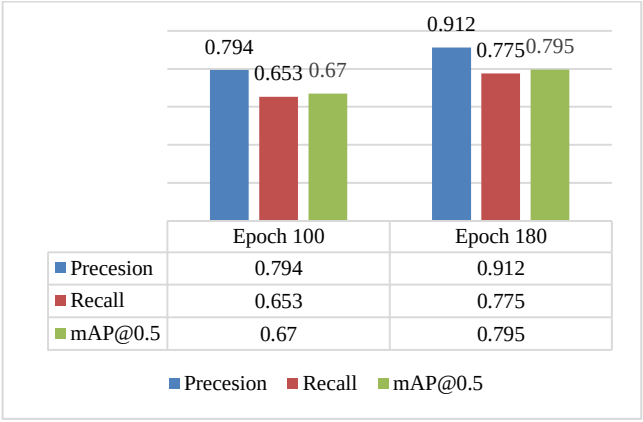

Fig. 10. Comparison between two different models using different epochs.

Fig. 11. Model Inference examples

B. Classification Results

The proposed human classification module has been tested on 5 different soccer matches to validate its performance for different color variances among humans' shirts on each single match. Fig. 12 shows cropped human images for each one of the five matches. These images are used in the discussions of the classification results. For each match, 11 to 14 frames have been selected to obtain 2 human templates for each one of the five human categories (team1, team2, goalkeeper1, goalkeeper2, and referee) and the rest detected humans are used to test the classification accuracy. A total number of 827 humans is existed among all selected soccer matches' frames. Table II shows the exact division of these images cross the five matches. Table III shows the division of the five tested human classes cross the five matches.

Fig. 13(a) to (e) shows the confusion matrices of the five matches. The classification accuracy for each human classes cross the five soccer matches is presented in Table IV.

In Match 1, the classification results exhibit strong accuracy with 94.8%. The model fails to predict correctly some players from Team2. This happens because of the similarity between the shirt color (green) and the background. The prediction of the referee fails in two cases because of the similarity between the Referee colors (black) and both Team1 and Goalkeeper2 colors.

Match 2 demonstrates consistent performance in classification, with an accuracy of 95.5%. The model succeeds in all cases where color variance between the five classes is high. It misclassifies some instances in Team2 and Goalkeeper2 because of the existence of black and dark colors in these different classes.

Fig. 12. Cropped images of all human classes in each Match.

TABLE II. HUMAN DATASET IMAGES' DIVISION CROSS THE FIVE SOCCER MATCHES

Soccer Match	No. of image frames	No. of human templates	No. of tested humans	No. of all existed humans
Match 1	11	10	135	145
Match 2	12	10	154	164
Match 3	11	10	141	151
Match 4	13	10	168	178
Match 5	14	10	179	189
	61	**50**	**777**	**827**

TABLE III. THE NUMBERS OF TESTED IMAGES FOR EACH HUMAN CLASS CROSS THE FIVE SOCCER MATCHES

	humans	Team1 (T1)	Team2 (T2)	Goalkeeper1 (GK1)	Goalkeeper2 (GK2)	Referee (Ref)
Match 1	135	47	55	3	4	26
Match 2	154	64	59	2	5	24
Match 3	141	54	58	2	4	23
Match 4	168	71	63	5	4	25
Match 5	179	77	61	4	5	32

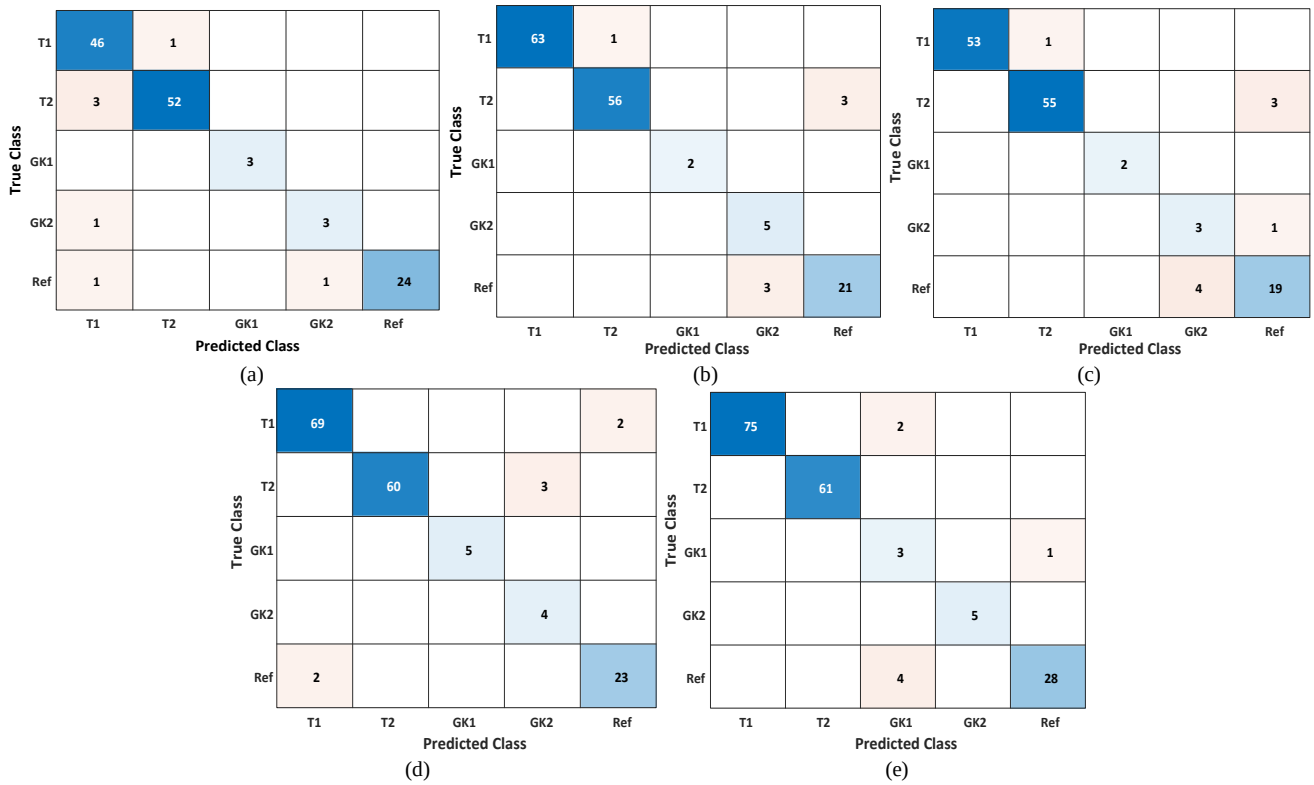

Fig. 13. Confusion matrices of the classification module for: a) Match 1, b) Match 2, c) Match 3, d) Match 4, e) Match 5.

TABLE IV. THE CLASSIFICATION ACCURACY FOR EACH HUMAN CLASSES CROSS THE FIVE SOCCER MATCHES

Soccer Match	Team1 (T1)	Team2 (T2)	Goalkeeper1 (GK1)	Goalkeeper2 (GK2)	Referee (Ref)	**Overall Accuracy**
Match 1	97.9%	94.5%	100%	75.0%	92.3%	**94.8%**
Match 2	98.4%	94.9%	100%	100%	87.5%	**95.5%**
Match 3	98.1%	94.8%	100%	75.0%	82.6%	**93.6%**
Match 4	97.2%	95.2%	100%	100%	92.0%	**95.8%**
Match 5	97.4%	100%	75.0%	100%	87.5%	**96.1%**
	97.8%	**95.9%**	**95.0%**	**90.0%**	**88.4%**	

In Match 3, classification accuracy is slightly lower at 93.6%, but the model still maintains robust performance. Team2 and Referee classes have some misclassifications based on the color similarity. Referee classification is challenging.

Match 4 demonstrates outstanding classification accuracy at 95.8%. Goalkeeper1 and Goalkeeper2 classes perform exceptionally well while Team1 and Team2 show some misclassification due to the background of the cropped images.

In the final match, the model maintains high classification accuracy at 95.4%. The model has some misclassification results especially between Referee and Goalkeeper1 because of the similarity of colors between these two classes.

In general, the classification module performs exceptionally and has excellent classification accuracy with an overall accuracy of 95.2%. The model succeeds to classify 740 different instances from a total of 777 cross the five matches. For some instances, misclassification arises because of color similarities between shirt colors or the effect of background color (soccer field color). Low color variance may lower the classification performance since we use color feature descriptors (ICCV) in this module.

V. CONCLUSIONS

In this paper, we have proposed an automated system that has the ability to detect the soccer ball and classify players and referees on the soccer field using computer vision techniques. The proposed system implements a detection model using YOLOv7 to detect the ball and all humans on the field after building a labeled dataset of 1300 different soccer game frames. It also deploys Improved Color Coherence Vector (ICCV) features to classify all humans on the field to five classes (Team1, Team2, Goalkeeper1, Goalkeeper2, and Referee) using K-Nearest Neighbor algorithm. The proposed system has achieved high efficiency in both the detection and classification modules.

The proposed system can be considered the first phase of any computer vision application in soccer game matches. It can be deployed on game analysis, player performance evaluation, automatic offside detection and fan engagement. Furthermore,

we delve into how it is poised to redefine the future of soccer as we know it. Through this exploration, it becomes increasingly evident that automated computer vision is not just a tool but a transformative force that is redefining the very essence of soccer analysis and appreciation.

Mohammed VI Polytechnic University[2]

***Abstract*—Mobile Geographic Information Systems (GIS) plays a vital role in data collection, offering diverse functionalities for spatial data handling. Despite advancements, accurately determining the usage environment during development remains challenging. This study uses machine learning and natural language processing to automatically classify user reviews based on the ISO 25010 quality-in-use model. Motivated by the challenge of gauging user experience during development, stakeholders analyze user reviews for insights. An experimental study compares Support Vector Machine (SVM), Random Forest, Logistic Regression, and Naive Bayes classifiers, revealing superior performance by SVM and Random Forest, particularly in efficiency evaluation. Findings underscore the efficacy of SVM in classifying user reviews, emphasizing its effectiveness in evaluating efficiency within mobile GIS applications. Moreover, it provides valuable insights for stakeholders, contributing to the enhancement of software quality of mobile GIS apps.**

***Keywords*—Mobile GIS for data collection; machine learning; software product quality; ISO/IEC 25010; natural language processing; user experience**

I. Introduction

Mobile GIS has known a significant rise in recent years as a method for data acquisition across diverse disciplines including, but not limited to, environmental monitoring [1], urban planning [2], and emergency management [3]. These GISs allow users to efficiently capture, analyze, and store spatial data related to space, resulting in an increase in productivity compared to traditional methods [4]. The implementation of Mobile GISs can provide significant benefits in terms of cost-effectiveness and real-time data acquisition [5]. In fact, mobile GIS is widely considered for data collection purpose, primarily due to the set of sensors supported by mobile devices that enable capturing positions especially Global Positioning System (GPS) and the Global Navigation Satellite System GNSS. In addition, mobile GIS enable orientation measure through the compass sensor [6]. Moreover, from a data quality point of view, mobile GISs functionalities allow controlling data quality during collection activities [7]; thereby aspect of data quality can be ensured. For instance; the accuracy of data is verified by implementing data validation rules that prevent users from inputting data when the positioning system provides values out of tolerance. Another aspect of data quality is the completeness of data which can be achieved by ensuring that all required items are collected. Finally, the verification of data consistency is achieved through the application of spatial constraints. These constraints serve to alert the user when collected data conflicts with information from other data sources. For instance, an area may be collected as a building, whereas in another data source, it is classified as a farm. These functionalities and features have the potential to influence the attractiveness of the application by partially or fully meeting user's needs. In fact, multiple mobile GIS apps, specifically designed for data collection, are currently available for public use in app repositories [8]. These repositories allow users to provide their feedbacks in the form of ratings and reviews, which are crucial for app developers and designers to improve their services and tailor the applications to meet user needs. However, due to the large number of feed backs and the diversity of wording used, reading and analyzing all reviews and ratings is time consuming manually, thus the need for the automation of this process. Moreover, the quality-in-use evaluation of these apps from the user point of view with respect to (International Standardization Organization) ISO 25010 standard [9] can be a tedious and a difficult task.

Besides, recent technological advancements have resulted in the proliferation of frameworks and libraries for natural language processing (NLP) [10], a specific area within the field of computer science and artificial intelligence that focuses on the comprehension, interpretation, and generation of human language by computers. One widely employed technique in NLP is the Term Frequency-Inverse Document Frequency (TF-IDF) vectorization, which represents text as numerical vectors [11]. When combined with machine learning (ML) classification methods, this technique enables the automated categorization of natural language into predefined classes.

For software quality, the ISO 25010 model provides two distinct models: The first is a software product quality model, which outlines eight characteristics pertaining to the static and dynamic properties of a given specific system or software product. The second is a quality-in-use model which defines the quality in use as the extent to which a product or system can be used by specific users to meet their needs and achieve specific goals with effectiveness, efficiency, freedom from risk, and satisfaction in specific contexts of use. In addition, the quality in use model defines five quality characteristics: (1) effectiveness, which refers to the accuracy and completeness with which users achieve their specified goals; (2) efficiency, which refers to the resources expended in relation to the accuracy and completeness with which users achieve their goals; (3) satisfaction, which refers to the degree to which user needs are satisfied when a product or system is used in a specified context of use; (4) freedom from risk, which refers to the degree to which a product or system mitigates potential

risks to economic status, human life, health, or the environment; and (5) context coverage, which refers to the degree to which a product or system can be used with effectiveness, efficiency, freedom from risk, and satisfaction in both specified contexts of use and in contexts beyond those initially identified.

This study assesses the quality-in-use of mobile GIS for data collection by employing manual labeling, NLP techniques, and term frequency-inverse TF-IDF as pre-processing steps on collected reviews and ratings. Subsequently, ML classification techniques are applied to the pre-processed reviews through an experimental process to identify the most suitable classifier for the specific domain of mobile GIS data collection. The classification of reviews aligns with the quality-in-use model of the ISO 25010 standard.

The study's novel contributions in the field of mobile GIS for data collection can be summarized as follows:

1) Proposing a novel application of natural language processing techniques, specifically IF-IDF, for analyzing user reviews in the context of mobile GIS. This approach enables the extraction of valuable insights from a large volume of user-generated data.

2) Evaluating the performance of four machine learning techniques - Logistic Regression, Support Vector Machine, Random Forest, and naïve bayes - in classifying user reviews based on the ISO 25010 quality characteristics, with a particular focus on the "efficiency" class (characteristic).

3) Comparing the performance metrics of SVM and Random Forest in identifying reviews belonging to the "efficiency" class, showcasing the superior performance of SVM.

4) Underlining the significance of SVM as a suitable classifier for classifying mobile GIS user reviews according to ISO 25010, offering better performance in accurately categorizing reviews related to "efficiency."

The paper is organized as follow: Section II provides an overview of the related works. Section III presents the method. Section IV outlines the experimental process, and Section V presents the results of the study. Section VI discusses the findings, and Section VII addresses potential threats to validity. Finally, Section VIII encompasses Conclusion and potential future works.

II. Related Work

In order to identify the used approaches for analyzing and classifying user reviews and ratings in mobile GISs for data collection, an analysis of previous relevant studies was conducted, with a focus on the type of study (i.e., review or empirical study, etc.), the scope (i.e., the mobile applications of GIS for data collection, or mobile applications in general, etc.), the quality aspects (i.e., quality attributes from ISO 25010 or others), NLP techniques, and ML techniques.

The aforementioned relevant studies are presented in Table I, which indicates that there have been diverse approaches employed to tackle the issue of software quality for both mobile apps in general and mobile GIS specifically for data collection purposes. For instance, Lew et al. [12] employed a modeling framework, 2Q2U (Internal/External Quality, Quality in Use, Actual Usability, and User Experience), to evaluate the quality of a desktop GIS application. This framework adopts a flexible approach to integrate and establish connections between the usability and user experience in order to evaluate software applications. Rahman et al. [13] conducted a study to validate the reliability and validity of an instrument aimed at assessing the influence of GIS quality and user satisfaction on individual work performance. The researchers drew upon an extensive analysis of existing literature and sought input from experts to develop a comprehensive questionnaire consisting of 68 items specifically related to GIS quality, user satisfaction, and individual work performance. In addition, Moumane et al. [14] conducted an empirical study with the objective of assessing the usability of mobile applications on different mobile operating systems. The study aimed to evaluate a framework specifically designed for mobile environments, based on the usability characteristic outlined in the ISO 9126 Software Quality Standard. Meng et al. [15] conducted an assessment of the usability of a Web-based Public Participatory GIS (Web-PPGIS) in a practical application setting. The researchers administered a questionnaire to participants and discovered notable disparities in system usability. These variations were observed based on the users' levels of experience and education. Other related studies have focused on the quality of data in mobile GIS as part of the system. Wang et al. [7] outlined the open architecture of field-based Mobile GIS and emphasized the importance of spatial data quality considerations. The study further elucidated how spatial data quality issues were tackled within the Mobile GIS context, in accordance with internationally recognized geoinformatics standards like ISO and Open Geospatial Consortium (OGC) standards. Furthermore, in another study by Song et al. a linear evaluation model utilizing Geographical Weighted Regression (GWR) and a nonlinear evaluation model based on random forest (RF) were developed [16]. These models were employed to quantitatively assess the relationship between geographical factors and the positioning bias of mobile phone locations.

With respect to the application of ML classification and NLP, Oyebode et al. [17] used ML classification, NLP, and TF-IDF techniques to evaluate and classify 88,125 user reviews in 104 mental health apps based on predefined classes. Five techniques were involved in this study and they are RF, Multinomial Naïve Bayes (MNB), Support Vector Machine (SVM), Logistic Regression (LR), and Stochastic Gradient Descent (SGD). Dos et al. [18] conducted a user feedback classifier based on ML of Decision Tree (DT), Naïve Bayes (NB), LR, RF, and SVM for the classification of reviews on mobile apps across various domains. The classification was performed in accordance with software quality characteristics defined by the ISO 25010 standard. In addition, Dias et al. [19] applied ML techniques and NLP in the context of software requirements classification. The study employed four algorithms: LR, SVM, MNB, and kNN. The results indicated that the use of TF-IDF in conjunction with LR produced the best classification results in differentiating requirements.

The authors in [20] has presented a measure of the external quality of mobile GIS for data collection by assessing the degree of impact of requirements related to mobile GIS for data collection on each external quality characteristic, aligned with ISO/IEC 25010. In a separate study, the authors in [21] presented a catalog of requirements for mobile GIS data collection, and demonstrated how it can be used to evaluate such applications.

This study diverges from the aforementioned related work by integrating various dimensions. Notably, while prior studies have explored diverse aspects such as Mobile GIS for data collection, algorithm development, and evaluation, the current study uniquely incorporates and merges these facets. Specifically, the investigation delves into the intersection of Mobile GIS for data collection and the application of both machine learning and natural language processing techniques. In contrast to certain previous studies that addressed the scope of Mobile GIS for data collection but refrained from employing machine learning techniques, this study bridges the gap by incorporating advanced methodologies to automatically classify user reviews based on the ISO 25010 quality-in-use model. This integration enables a more comprehensive understanding of the user experience, contributing a novel perspective to the existing body of literature in this domain. Through the integration of the Mobile GIS scope for data collection with the refined application of machine learning techniques, this study presents a distinctive and valuable contribution to the field, laying the foundation for more refined insights and progress in the evaluation of software quality for mobile GIS applications.

To the best of our knowledge, there have been no prior assessments conducted on the quality in use of mobile GIS for data collection using the ISO 25010 standard, natural language processing (NLP), and machine learning (ML) techniques.

III. METHOD

The methodology employed in this study comprises five stages, as illustrated in Fig. 1: data collection, data preprocessing, data labeling, data vectorization, automated classification, and evaluation. The subsequent subsections offer a detailed overview of each step in the methodology:

A. Data Collection

During the data collection step, a two-fold approach is used to gather users' reviews on mobile GIS applications for data collection.

- First, a pre-existing list of apps obtained from [8] was utilized, and specific inclusion criteria were applied to determine their selection. Each app needed to satisfy the following inclusion criteria: (1) relevance to mobile GIS for data collection, (2) an update date of 2020 or later, and (3) a minimum of five user reviews.
- Second, a combination of the Google Play API [22] and a Java program, developed by the research team, was utilized to gather user reviews from the selected applications.

As a result, a set of 19 apps were selected in the data collection step with a total of 8,793 reviews collected from these apps (see Table II) for comprehensive list of the selected applications and detailed of collected reviews).

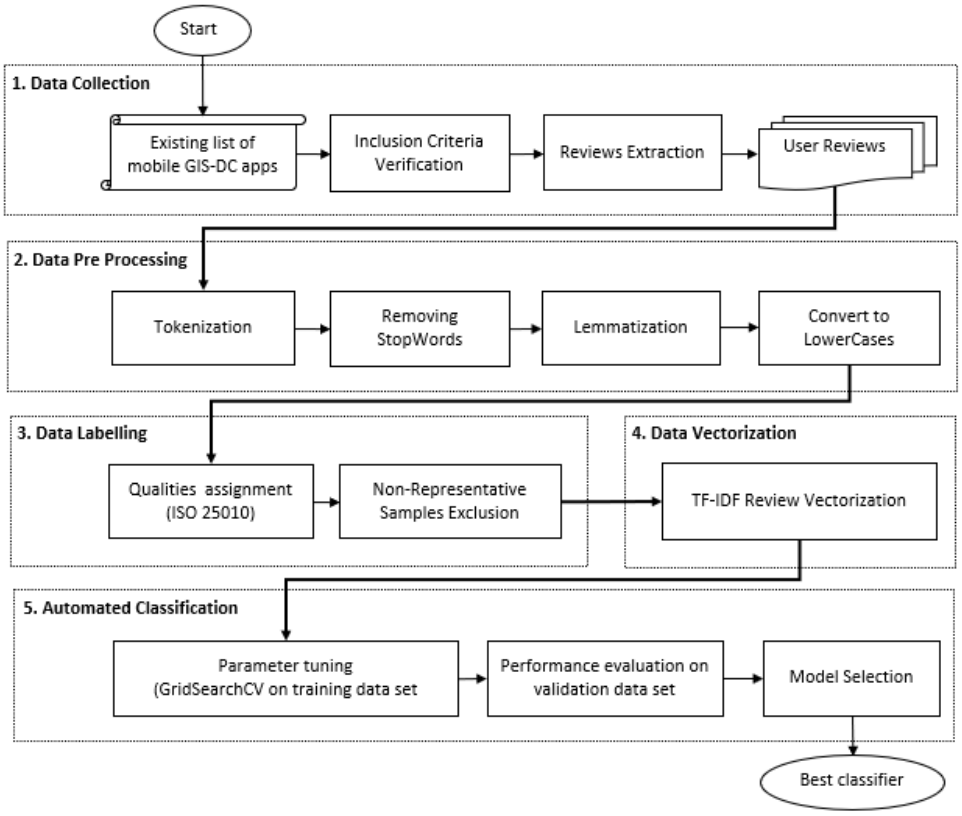

Fig. 1. User reviews classification pipeline.

TABLE II. MOBILE GIS APPS SELECTED

Application Name & Link	Number of Reviews
Mappt: GIS Data Collection	57
QField for QGIS	467
Mobile Topographer GIS	148
My GPS Coordinates	1570
Mobile Data Collection	64
GIS Mapper - Surveying App for	5

MapPad GPS Land Surveys	286
Save Location GPS	1056
Locus GIS offline land survey	179
SW Maps - GIS & Data Collector	388
Epicollect5 Data Collection	102

B. Data Preprocessing

Data preparation is a crucial step in natural language processing (NLP), involving the cleaning and preprocessing of raw text data to eliminate irrelevant information. In order to achieve this, the following well-known steps were followed [23]:

- Tokenization: In NPL, tokenization involves segmenting words into units called tokens based on certain rules such as removing punctuation or capitalization. The resulting tokens are intended to convey a semantic meaning. The tokenization of the collected reviews was achieved by removing punctuation marks, digits, and foreign characters (non-Latin) from the text data.
- Removing stop words: Stop words are commonly occurring words within text data that have little semantic value, such as "the" or "is", and are removed during preprocessing for NLP. The Natural Language Tool Kit (NLTK) package contains a pre-built list of stop words that can be downloaded and used [24]. However, to ensure the inclusion of domain-specific terms in the data analysis, the authors of this study have compiled a list of words related to mobile GIS to prevent them from being removed during preprocessing. This list included for instance "GPS" - a widely-known sensor used for positioning that facilitates data collection via mobile GIS. Other term of “Accuracy" was included in the list as it relates to the precision of positioning, and consequently, the quality of data collected through mobile GIS. Additionally, “Map” was involved in the list as it’s an important component in GIS that allow data presentation.

- Lemmatization in order to reduce words to their base form. For instance, words of "running," "ran," and "run" will be reduced to their base form "run".
- Convert words to lowercase.

The aforementioned steps of data preprocessing were achieved using a python program developed by the authors of this study. For each review in the data set, the program executes successively the operations of Tokenization, removing stop words, Lemmatization and converting to lowercase. The output of these steps is then stored into new column of 'pre-processed-review'.

C. Data Labelling

The data labelling step consists on the classification of the user reviews (resulted from step 2) through a manual process, which was carried out by the primary author, with respect to the quality characteristics specified in the ISO 25010 model for quality-in-use. For each review, the corresponding predefined quality characteristics are affected by the primary author and then validated by the others authors for relevance and consistency. In cases of disagreement, a consensus was achieved through collective discussion among all authors. The manual process was conducted through a web application that was specifically developed by the research team for this purpose. Fig. 2 depicts the interface of this application, which enables users to navigate through reviews and manually assign quality characteristics to each review by clicking the button related to the corresponding quality. At the end of the data labelling, a comma-separated values (CSV) file that contains the pre-processed-review with the corresponding label is generated using the button CSV. It is noteworthy that during the data labeling process, certain reviews were deemed ambiguous due to their unclear meanings or the presence of non-Latin characters that remained from the data preparation stage. As a result, these reviews were excluded from the data set, resulting in a reduction in the total number of reviews from 7322 to 6904. Table III shows the detailed results in term of reviews and quality characteristics.

D. Data Vectorization

This step consists of transforming text reviews into numerical values which can then be utilized as input for machine learning classification algorithms. TF-IDF [25] an extensively utilized technique in natural language processing, facilitates the transformation of text data into numerical vectors with a focus on classifying user reviews. This method computes multiplication of the term frequency (TF) with the inverse document frequency (IDF) for each term present in the review, yielding a numerical representation of the significance and rarity of the terms. This numerical representation enables the detection of patterns and trends within user reviews and the subsequent categorization of these reviews according to specific quality characteristics.

TABLE III. DISTRIBUTION OF REVIEWS ACROSS QUALITY CHARACTERISTICS

Quality Characteristic	Number of reviews
Context Completeness	78
Flexibility	6
Effectiveness	2236
Efficiency	952
Economic Risk Mitigation	25
Environmental Risk Mitigation	2
Health and Safety Risk Mitigation	6
Comfort	1128
Pleasure	1653
Trust	190
Usefulness	628

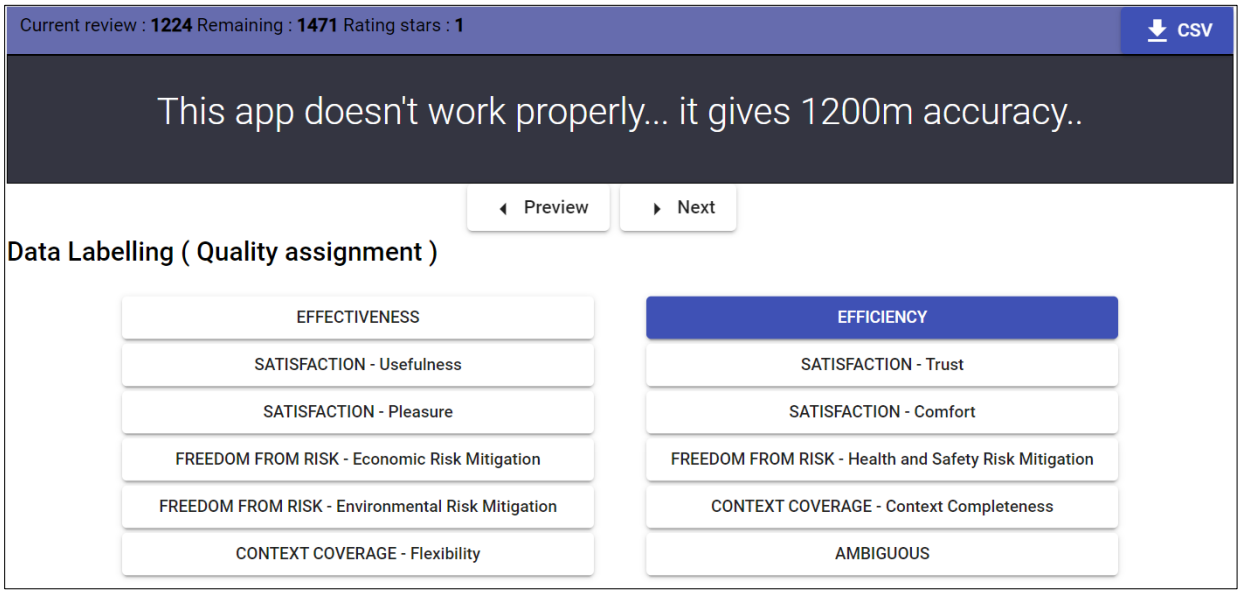

Fig. 2. Screenshot of the data labelling web interface.

In order to apply the TF-IDF vectorization technique on the user reviews, the authors developed a Python script that makes uses of the Scikit-learn [26]. This script reads the CSV file generated during the preceding data labeling phase and computes the frequency of each term in the reviews along with their respective importance scores. The resulting TF-IDF matrix comprises the user reviews in the rows and the overall terms in the columns. Moreover, the script stores the quality characteristic of each review, obtained from the data labeling step, in an additional column labeled "labels". Finally, the output of the script is produced in a new CSV file named "TF-IDF.csv".

E. Automated Classification and Evaluation

The objective of this step is to identify the most suitable machine learning algorithm for classifying user reviews related to mobile GIS for data collection based on quality-in-use characteristics of ISO. To achieve this, the datasets generated through steps 1 to 3 were used as input for the classification methods. Given the impracticality of testing all potential combinations of classification techniques, an experimental study was conducted to automate the testing and evaluation process for each machine learning algorithm's performance.

To summarize, in this study, a dataset of user reviews related to a set of mobile GIS for data collection was obtained. These reviews were subjected to preprocessing utilizing natural language processing methodologies, followed by vectorization utilizing the TF-IDF vectorization technique. A manual labelling process was carried out to classify reviews based on the quality-in-use model of ISO. A dataset with 6904 reviews was obtained and will be used in the experimental study performed in the next section.

IV. Experimental Study

In this section, an experimental study is conducted to explore the application of machine learning (ML) classification techniques on the pre-processed reviews (obtained from steps 1 to 3 in the previous section). The objective is to identify the best classifier for mobile GIS data collection.

A. Dataset Preprocessing

As shown in Table III, A few quality characteristics within the quality-in-use model have limited or insignificant representation due to the small number of available samples. These qualities are: Context Coverage – Flexibility with only six reviews, Freedom from Risk quality with 2, 6, and 25 reviews respectively to Environmental, Health and Safety, and Economic Risk Mitigation. To maintain the validity and reliability of the model, reviews associated with these particular qualities were subsequently excluded from further analysis. Thus, the dataset has undergone a reduction in the total number of samples from 6904 to 6815.

Furthermore, Fig. 3 presents a statistical analysis of the data related to this study, revealing a notable discrepancy in the sample distribution across different quality characteristics. This discrepancy gives rise to an imbalanced data challenge. To mitigate the issue of imbalanced data, the Synthetic Minority Over-sampling Technique (SMOTE) [27] was utilized to generate synthetic samples.

B. Experimental Process

The experimental process steps used is summarized as the following:

- Four ML techniques are used, namely: (1) Support Vector Machine was introduced by (Vapnik and coworkers) as “a training algorithm that maximizes the margin between the training patterns and the decision boundary” [28]. The SVM classifiers can be improved by modifying the kernel functions (Linear, Polynomial…) and its parameters (C: regulation, gamma: kernel coefficient …) [29]. (2) Logistic Regression is a statistical method applied for classification tasks by analyzing the relationship between a binary variable and one or more independent variables using a logistic function. [30]. (3) Naive Bayes is defined as a simple probabilistic model for classification that assumes that the features are conditionally independent given the class label [31]. The method models the probability of each class given the observed features using Bayes' theorem, and selects the class with the highest probability as the predicted class for a given input. (4) Finally, Random Forest is defined as an ensemble learning method that perform classification by aggregating the predictions of multiple decision trees [32].
- A Grid Search [33] tuning parameter method with five-fold cross-validation was employed to identify the optimal set of hyper-parameters for each technique (see Table IV for the values for GS parameters).

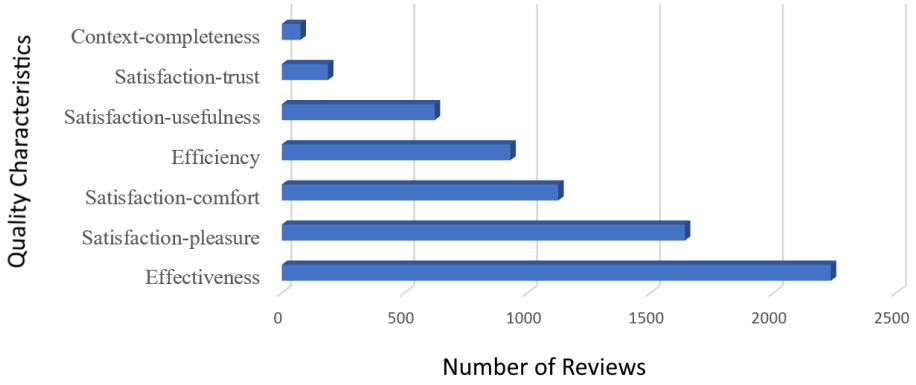

Fig. 3. Distribution of the dataset into quality classes.

TABLE IV. VALUES OF GRID SEARCH PARAMETERS

Model	Parameter	Values
Logistic Regression	Regularization Parameter C	0.1, 1, 10
	Optimization Algorithm	liblinear, lbfgs, saga
Support Vector Machine	Regularization Parameter C	0.1, 1, 10
	Kernel Function	linear, rbf, sigmoid
	Gamma	scale, auto
	Degree	2, 3
Random Forest	Number Of Decision Trees	50, 100, 200
	Criterion	gini, entropy
	Max Depth	None, 10, 20
	Min Samples Split	2, 5
	Min Samples Leaf	1, 2
	Max Features	sqrt, log2
	Bootstrap	True, False
naïve bayes	Alpha	0.1, 0.5, 1.0
	Algorithm	Multinomial Naïve Bayes

- A Python script was developed using the Scikit library to achieve optimal classifier performance. The script implements the algorithm depicted in Algorithm 1 and is available upon email request to the author.

Algorithm 1: Grid Search for ML Algorithms

Initialize a model-params dictionary of the four ML algorithms and their parameters

Create an empty report array

Compute

For each model in model-params

  Create gvv instance of GridSearchCV with model params and five-fols cross-validation

  Fit gcv with the training set to find the best hyper parameters

  Test the fitted model on the test dataset

  Compute the confusion matrix

  Compute the evaluation metrics

  Add the confusion matrix and the evaluation metrics to the report

  End

Display report

- The performance of the four-classifier experimented in this study was evaluated using four commonly used accuracy criteria [34]: (1) Precision, which quantifies the proportion of true positive predictions among all positive predictions made by the classifier. (2) Recall, which quantifies the proportion of true positive predictions among all actual positive instances. (3) Accuracy, which quantifies the proportion of correct predictions made by the classifier among all instances. (4) F-score, which combines precision and recall into a single score.

V. RESULTS ANALYSIS

Table V displays the performance of each classifier with respect to all the utilized performance metrics, along with the corresponding optimal values for the hyperparameters.

The results indicated that:

- The Random Forest classifier achieved a precision of 0.81, indicating that, out of all instances that were predicted as positive, 81% were actually positive. The classifier also achieved a recall of 0.79, indicating that, out of all true positive instances, 79% were correctly identified by the classifier. The overall accuracy of the classifier was found to be 0.79, indicating that 79% of the predictions made by the classifier were correct. The F1-score, which is a harmonic mean of precision and recall, was found to be 0.80, indicating that the precision and recall of the classifier was balanced.
- The SVM classifier obtained scores that were slightly different from those of the Random Forest classifier, with a precision score of 0.79, an accuracy score of 0.80, a recall score of 0.80, and an F1-score of 0.79.
- The Logistic Regression classifier performed slightly worse in terms of accuracy and recall, but obtained 0.81 in precision and 0.79 in F1-score.
- The Naive Bayes classifier had the lowest scores across all accuracy criteria, indicating that it performed less well than the other three classifiers.

Moreover, the confusion matrices scores related to SVM and Random Forest were calculated and presented respectively in Table VI and Table VII. As depicted in the confusion matrices, both models demonstrate strong performance. This is evidenced by the majority of entries being located along the diagonal of the matrices.

TABLE V. GLOBAL CLASSIFICATION SCORES AND HYPER PARAMETERS

Model	Performance scores				Hyper Parameters	
	Precision	*Accuracy*	*Recall*	*F1-score*	*Parameter*	*Value*
Random Forest	0.81	0.79	0.79	0.8	Number Of Decision Trees	200
					Criterion	entropy
					Max Depth	None
					Min Samples Split	2
					Min Samples Leaf	1
					Max Features	log2
					Bootstrap	False
Support Vector Machine	0.79	0.8	0.8	0.79	Regularization Parameter C	10
					Kernel Function	rbf
					Gamma	scale
					Degree	2
Logistic Regression	0.81	0.77	0.77	0.79	Regularization Parameter C	10
					Optimization Algorithm	saga
naïve bayes	0.77	0.73	0.73	0.75	Alpha	0.1
					Algorithm	Multinomial Naïve Bayes

TABLE VI. SVM CONFUSION MATRIX

TABLE VIII. SVM AND RANDOM FOREST QUALITY CLASS SCORES

Classifier	Quality Class	precision	recall	F1_score
SVM	Context Completeness	0.67	0.14	0.24
	Effectiveness	0.9	0.9	0.9
	Efficiency	0.74	0.8	0.77
	Comfort	0.69	0.76	0.73
	Pleasure	0.87	0.89	0.88
	Trust	0.44	0.18	0.25
	Usefulness	0.64	0.56	0.6
Random Forest	Context Completeness	0.33	0.14	0.2
	Effectiveness	0.93	0.89	0.91
	Efficiency	0.73	0.78	0.75
	Comfort	0.76	0.73	0.74
	Pleasure	0.9	0.85	0.87
	Trust	0.2	0.46	0.28
	Usefulness	0.62	0.57	0.59

Furthermore, the performance scores related to SVM and Random Forest were calculated for each quality class and the results are presented in Table VIII. As demonstrated, the precision, recall, and F1-score demonstrate heterogeneity across various categories, providing valuable insights into the classification performance of each algorithm. Subsequently, in the following section, these outcomes will be discussed in the context of the criteria for mobile GIS for data collection to select the best classifier from SVM and RF.

VI. Discussion

Table V illustrates that the accuracy metric for SVM and RF classifiers achieved high values of 0.80 and 0.79, respectively. These results suggest that both classifiers were successful in correctly classifying a high proportion of instances, indicating that the vectorization process utilizing TF-IDF was successful in identifying relevant terms within the corpus of user reviews. Note that TF-IDF was previously identified in research as a strong vectorization method among user reviews [17, 18].

The effectiveness of TF-IDF in mobile GIS for data collection reviews can be explained by its adeptness at capturing term significance through frequency calculations. Within this domain, where reviews frequently incorporate specialized terminology and jargon pertaining to geographic information, mobile devices, and associated technologies, TF-IDF stands out by recognizing and assigning importance to these specific terms based on their frequency. This emphasis on the frequency of domain-specific terms contributes to a more precise representation of the data, aligning with the high accuracy metrics observed in the classifiers' performance as highlighted in Table V.

The SVM classifier and Random Forest classifier were evaluated using precision, accuracy, recall, and F1-score metrics. The results revealed that the Random Forest classifier obtained scores of 0.81, 0.79, 0.79, and 0.80, respectively, while the SVM classifier obtained scores of 0.79, 0.80, 0.80, and 0.79, respectively. These results indicate that the Random Forest classifier performed slightly better in terms of precision and F1-score, while the SVM classifier performed better in terms of accuracy and recall.

The SMOTE technique has been employed to mitigate the issue of class imbalance. however, a detailed analysis of class scores is still necessary to reveal any performance variations of classifiers on specific classes and provide a more comprehensive understanding of their capabilities. Although no significant differences were observed in the four performance scores of the two classifiers, Random Forest and SVM, an exhaustive evaluation of their performance was conducted, taking into account the specific domain of mobile GIS for data collection. In fact, the requirements of mobile GIS for data collection regarding the positioning accuracy is crucial, as it affects directly the quality of collected data [21], which subsequently impacts the overall data collection process. Moreover, a real challenge is associated with GPS positioning accuracy in smartphones [35] and extensive investigations were conducted to identify factors that influence the accuracy of mobile GIS positioning [36-38]. In this light, various solutions have been adopted to enhance the positioning accuracy in mobile mode [39, 40]. Therefore, comparing the performance of Random Forest and SVM classifiers on the class of efficiency can aid in selecting the best classifier for mobile GIS data collection purposes.

Based on the evaluation of the classifiers scores presented in Table VIII, the SVM classifier appears to be a more suitable option for identifying a maximum number of user reviews belonging to the "Efficiency" class in mobile GIS data collection. The SVM classifier exhibits a higher F1-score (0.77), recall score (0.80), and precision (0.74) as compared to the Random Forest classifier (F1-score: 0.75, recall: 0.78, precision: 0.73) for this class. These findings suggest that the SVM classifier has a greater ability to detect positive samples of the "Efficiency" class while maintaining a good balance between precision and recall. Furthermore, the SVM classifier has a higher precision score (0.74) than the Random Forest classifier (0.73) for this class, indicating that the SVM classifier generates fewer false positive predictions. Thus, the SVM classifier may be the optimal choice for this classification task in the mobile GIS data collection domain.

In addition, the complexities inherent in user reviews within the mobile GIS for data collection domain introduce a level of intricacy marked by complex and nonlinear relationships between linguistic expressions and corresponding sentiments. These reviews serve as reflections of nuanced discussions prevailing in this specialized technical domain. Leveraging their unique capacity to define optimal hyperplanes within high-dimensional spaces, SVM exhibit notable proficiency in capturing the nuanced patterns embedded in these reviews. The algorithm's adeptness in recognizing subtle differences and correlations within the technical language of user reviews establishes SVMs as a resilient and effective choice for classifying user-generated content within the intricate realm of mobile GIS for data collection. This underscores their efficacy in addressing the inherent complexities specific to mobile GIS for data collection.

VII. Threats to Validity

Although objectivity was applied during the research process, there may still be limitations to this study:

- In the natural language processing phase, certain terms may have been erroneously categorized as stop words and consequently eliminated from the dataset. This could impact the construct validity of the study. To address this issue, a specialized GIS term dictionary was constructed to ensure that relevant terms are not automatically removed during the data preprocessing stage, thus improving construct validity.
- The automated classification in this study concerned mobile GIS user reviews, which could pose potential challenges to external validity. To address this concern, the set of studied reviews was carefully chosen to ensure a representative sample. This limitation may have slightly affected the performance metrics, but optimism exists that the results may be utilized in forthcoming studies related to mobile GIS.

- User reviews were assigned manual classifications based on the quality-in-use model. However, there is a possibility that a review may belong to more than one class which impact the internal validity. To address this issue, only the clearest classification was considered.

VIII. Conclusion and Future Work

This study involved an experiment aimed at identifying the best classifier for analyzing user reviews of mobile GIS applications in the context of data collection. The process involved five steps: data collection, data preprocessing, data labeling, data vectorization, automated classification, and evaluation.

The evaluation of classifiers unveiled notable performance metrics. The Random Forest classifier showcased balanced performance, exhibiting a precision of 0.81, a recall of 0.79, an accuracy of 0.79, and an F1-score of 0.80. The SVM classifier, with slightly differing yet competitive scores, achieved a precision of 0.79, accuracy of 0.80, recall of 0.80, and an F1-score of 0.79. Likewise, the Logistic Regression classifier demonstrated a precision of 0.81, accuracy of 0.79, recall of 0.79, and an F1-score of 0.79, while the Naive Bayes classifier showed lower scores across accuracy criteria. Notably, when honing in on the "efficiency" class, the SVM classifier outperformed the Random Forest classifier, displaying superior precision (0.74), recall (0.80), and F1-score (0.77) compared to the Random Forest classifier (precision: 0.73, recall: 0.78, F1-score: 0.75). These results underscore the effectiveness of the TF-IDF vectorizer and SVM classifier combination within the specific domain of mobile GIS for data collection, emphasizing the significance of efficiency requirements in this context. The implications of this study extend to developers and designers of mobile GIS applications, providing insights for automatic quality evaluation using the ISO 25010 quality-in-use model.

In future investigations, the aim is to expand the scope of the study by increasing the number of experiments conducted. This expansion will enable a more extensive gathering of relevant and accurate results. Additionally, we intend to investigate the correlation between external quality and the quality-in-use of mobile GIS applications specifically designed for data collection purposes, with the ultimate goal of developing a predictive model for quality-in-use. This may have practical implications for enhancing the user experience and satisfaction of mobile GIS applications for data collection by ensuring that external quality meets the requirements of quality-in-use.

***Abstract*—Bitcoin is the first and most famous cryptocurrency. It is a virtual currency that is operated in a decentralized form using cryptographic strategies called blockchains. Although it has experienced significant market acceptance by traders and investors in recent years, it also suffers from volatility and riskiness. Technical analysis is one of the most powerful tools used for trading signals' allocation using some algorithmic strategies called technical indicators. In this research, a newly proposed multi-objectives decomposition-based particle swarm optimization algorithm is used to find the best parameter values for some technical indicators, which in turn generates the best trading signals for Bitcoin trading. In this context, three conflicting objectives have been used, i.e., the return on investment, the Sortino-ratio, and the number of trades. The proposed algorithm is compared to the original MOEA/D algorithm as well as the indicators using their original parameters. Results showed the superiority of the proposed algorithm during the training and testing periods over the other benchmarks.**

***Keywords*—Bitcoin; technical analysis; decomposition; particle swarm optimization; MOEA/D**

I. Introduction

Unlike the well-known physical currencies such as dollars or euros, bitcoin is a sort of digital currency backed by cryptographic protocols called blockchains [1]. These cryptographic protocols facilitate secure online payment with no need for intermediaries. There exist significant fluctuations in the bitcoin prices every day which increases its volatility and raises the level of risk [2]. This volatility enormously affects the traders' outcomes. So, powerful algorithms are always needed to help the traders and investors get the best returns with the minimum level of risk.

The algorithmic trading strategies for cryptocurrencies can be classified into three different models, i.e., models based on machine learning, Portfolio Optimization (PO) models, and trading-strategies optimization models.

Machine learning and deep learning are used in the literature as predictive models to forecast the future price patterns based on the analysis of historical market data [3], [4], [5], and [6].

PO in the context of cryptocurrencies entails selecting a combination of cryptocurrencies and determining the appropriate weights for each asset in order to achieve the desired portfolio characteristics. Depending on the preferences of the investor, the objective may be to maximize returns, minimize risk, or achieve a specific risk-return trade-off [7]. Portfolio optimization researches can be categorized into statistical models such as Modern Portfolio Theory (MPT) as found in [8], [7], and [9] and Multi-Objective Evolutionary Algorithms (MOEA) models such as [10], and [11].

The trading strategies optimization models mainly aim to allocate the optimal trading signals that enhance the trading outcomes. In study [12] a signal herding model is proposed in order to enhance the decision-making process. In study [13] the trading signals are generated based on the market tweets sentiments whereas in study [14], both time series analysis and social signals are used to produce tractable trading strategies.

Trading signals generation or allocation can be achieved using Technical Analysis (TA) based indicators. Although the optimization of the TA based trading-strategies was found in the literature for other types of markets such as physical currencies and stock markets, it was not found for cryptocurrencies. So, this research tries to cover the lack of this research point by proposing new optimized algorithmic trading-strategies for some Technical Indicators (TI).

As can be seen previously, cryptocurrency trading can be considered as a Multi-objective Optimization (MO) problem. As it involves handling a set of conflicting objectives simultaneously such as maximizing the returns and the percentage of the profitable trades to the non-profitable ones, minimizing risks, the transaction costs, and the number of trades, etc. [15].

The MO problem is described as in Eq. (1) [16]:

$$\text{Maximize } F(x) = (f_1(x), \dots \dots f_m(x))^T \quad (1)$$

subject to $x \in \Omega$

Such that: Ω is the variable or decision space, F: $\Omega \rightarrow R^m$ is the objective space, where m is the total number of objectives. As there are multiple contradictions between the different objectives, there can never be a unique solution that satisfies all the objectives simultaneously but rather a set containing the whole non-dominated solutions referred to as Pareto Set (PS). Let $x_1, x_2 \in R^m$, it can be said that x_1 dominates x_2 only if $x_1^i \geq x_2^i$ for each $i \in \{1, 2, \dots, m\}$ and $x_1^j > x_2^j$ at least once for $j \in \{1,2, \dots, m\}$. The set of the objective vectors corresponding to the points in the PS is called the Pareto Front (PF).

MOEA based on Decomposition (MOEA/D) is one of the most simple and efficient techniques to solve MO problems. It

can efficiently find the best set of non-dominated solutions regardless of the increasing number of objectives [17], [18]. On the contrary, MOEA based on Pareto dominance can efficiently handle problems with lower number of objectives, however by increasing the number of objectives it can hardly cover the entire (PF) [18].

MOEA/D transforms the MO problem into a simple set of scalar sub-problems then, it solves each of them simultaneously and independently. This transformation is achieved with the help of two basic factors, i.e., aggregation or also called Scalarization Functions (SF) and a set of well-selected weight vectors. These are the basic factors that control the performance of MOEA/D algorithms.

New decomposition strategies were found in the literature either by proposing new SFs as in [19], and [20] or by using a combination of different SFs [21], and [22].

Some changes to the original weight generation mechanism that was originally proposed by Zhang [17] were also found in the literature such as MOEA/D-URAW [23], AWD-MOEA/D [24] and MOEA/D-AWG [25].

The MOEA/D algorithms were successfully applied to different application areas such as PO [11], [26], image segmentation [27], and network routing [28].

In this paper a new MO Particle Swarm Optimization Algorithm using Decomposition (MOPSO/D) is proposed for BTC trading signals' allocation. The algorithm optimizes the original parameters of three of the most used TIs. A new weight generation strategy was also presented and used in order to further improve the performance of the algorithm. The proposed algorithm is compared to the original MOEA/D and the TIs with their original parameters based on three objectives, i.e., the return, the risk, and the number of trades.

The rest of this paper will be organized as follows: In Section II, the trading signals allocation mechanisms are described. Section III shows the proposed algorithm, whereas Section IV presents the results and the conclusion in Section V.

II. Trading Signals Allocation Mechanisms

Cryptocurrencies are well-known for their extreme volatility, which refers to the huge and sudden price changes they encounter over short periods of time. This nature raises the riskiness level of such markets, making them hardly predictable. So, for the investors to get the benefits from crypto-market trading, there should be powerful algorithms that ensure the profitability and safety of their trading. As seen in Fig. 1, the Bitcoin value started in 2017 at about 1,000 USD and has risen to 20,000 USD. Then, it dropped back again, up to 4,000 USD by 2019.

TA tools (specifically the Technical Indicators TA) are frequently used by investors for their simplicity. They are used either as the basic trading strategies or as confirmation tools to generate and allocate the trading signals, i.e., buy and sell. For example, most PO tools basically depend on them in order to get their final trading decisions [29] and [30].

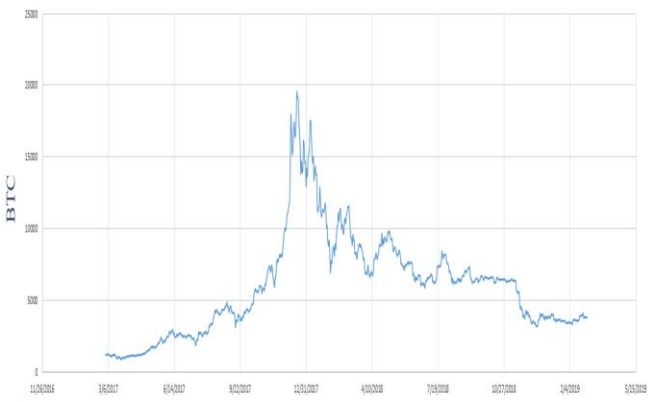

Fig. 1. The value of Bitcoin (BTC) in USD from 2017 to 2019.

A. Technical Indicators (TIs)

The TIs are mathematical formulations (equations) that are operated in an algorithmic manner. Each of these indicators has its own parameter combinations that controls its final performance [31]. The original values of these parameters are generated by their creators, however with more challenging markets such as the crypto market it could not always provide the required performance . The main objective of this study is to find the optimal set of parameters that helps allocating the best trading signals (buy and sell).

Three TIs are considered in this study, i.e., Double Weighted Moving-Average (DWMA), Exponentially Smoothed Rate of Change (ES-RoC) and Stochastic Relative Strength Index (S-RSI).

The DWMA indicator in [32] is one of the versions of Moving Average indicators (MAs). This type of indicators is used to generate an updated price average based on the selected time frame. The term double here means that the signals are generated based on the crossovers between two WMAs with different time frames.

A buy signal is provided when the shorter WMA crosses from below to above the longer WMA and vice versa for the sell signal. The WMA is calculated as seen in Eq. (2), such that n is the number of days used for calculations and P refers to the daily prices. For example, P_1 is the closing price for the first day of calculations and P_n.is the most recent price value at day n. The DWMA has two parameters n_1 and n_2 for the short and long WMAs consequently, such that the original parameters values are {20,50}.

$$WMA = \frac{(P_1 * n) + (P_2 * n-1) + \cdots + (P_{n-1} * 2) + \square(P_n)}{\frac{[n*(n+1)]}{2}} \quad (2)$$

The ES-RoC [31] indicator calculates the rate of change for the values of the Exponential MA (EMA) values over the past n days. The EMA is a type of MAs where the weighting for the days of calculations grows exponentially rather than the linear weighting as in WMA. The range of the outputs of this indicator is always in the range ±100.

The signals are generated by crossing above or below the center line (which is zero in this case) for buy and sell signals in sequence without considering a definite overbought or

oversold level. This indicator is mainly used to evaluate the strength of the upcoming trends. The ES-RoC is calculated as shown in Eq. (3), where $EMA_{current}$ is the value of the EMA on the last day of calculation and EMA_n is the value of the EMA *n*-days ago.

In this study, two extra parameters, i.e., overbought and oversold levels are produced for trading signals generation. Rather than crossing above or below zero line, the buy and sell signals are generated by crossing through the oversold and overbought levels for buy and sell signals consequently. The original parameter values for ES-RoC are 14 and 20 days for the RoC and the EMA sequentially.

$$ES_{RoC} = \frac{EMA_{current} - EMA_n}{EMA_n} \times 100 \quad (3)$$

S-RSI [31] is a mixed indicator that applies the Stochastic-Oscillator (SO) indicator to the RSI value. RSI is another indicator that analyses current price levels against those of the recent past. The output values lie in the range from 0 and 100 that is used to identify the oversold and overbought levels.

The signals are generated by the crossovers with these levels the same way as the ES-RoC. The value of S-RSI [31] is calculated as shown in Eq. (4). Such that *n* and *t* are the timespans for RSI and S-RSI in sequence. The original parameters of the S-RSI are 14 days for both *n* and *t* with an overbought level of 70 and oversold level of 30.

$$S\_RSI = \frac{RSI_{current} - min(RSI_t)}{max(RSI_t) - min(RSI_t)} \quad (4)$$

$$RSI_{current} = 100 - \frac{100}{1 + \frac{avg\_gain(n)}{avg\_loss(n)}} \quad (5)$$

B. Objective functions

For the optimization process at hand, three conflicting objectives are selected.

- The percentage Return on Investments (RoI): it evaluates the profitability of the investment strategy by comparing the investment net gain to the total investment costs as shown in Eq. (6). This is a maximization objective as the investors always aim to maximize their profits.

$$RoI = \frac{Net\_gains}{Investment\_costs} * 100 \quad (6)$$

- Sortino Ratio (SR): is a measure of the risk of investment. It is calculated as in Eq. (7), where σ_{down} is the Standard Deviation (SD) of the returns that are below the average (the downward SD). The target here is to maximize the SR in order to minimize the risk.

$$SR = \frac{aggregated\_return}{\sigma_d} \quad (7)$$

- The number of trades: The target here is to get the minimum number of trades.

III. The Proposed Algorithm

As mentioned before, the idea behind the decomposition-based algorithms is to simplify the MO problem and convert it into a group of single objective SPs. This simplification is accomplished using the SF or aggregation function. Different scalarization approaches were found in the literature. Among the most recommended SFs due to its simplicity and adaptability to different types of problems is the Chebyshev approach [33]. As a result, a number of variants were proposed in the literature to enhance its performances.

The Augmented Chebyshev (ACh) is one of the variants with an additional augmentation term that was proposed in order to improve the quality of the PF solutions and to discard the weak optimal solutions [34]. This is the one which is adopted in this research.

The approximated PF of the MO problem represented in Eq. (1) can be obtained by simplifying it into simpler scalar SP. The objective function of the j^{th} SP is given as in Eq. (8).

minimize

$$g^{ACh}(x \mid w^j, z^*) = max_{1 \le i \le N}\{ w_i^j \left| \frac{f_i(x) - z_i^{nad}}{z^* - z_i^{nad}} \right| \} + \rho \sum_{i=1}^{N} |f_i(x) - z_i^*| \quad (8)$$

Such that: $z^* = (z_1^*, z_2^*, \dots \dots z_m^*)^T$ is the reference point, i.e., $z_i^* = \max\{f_i(x) | x \in \Omega\}$ for $i = 1 \rightarrow m$ objectives and z_i^{nad} is the nadir point, where $z_i^{nad} = \min\{f_i(x) | x \in \Omega\}$.

The second part of the previous equation is the augmentation term, where ρ is the augmentation parameter which is a very small value such that $\rho \in [0.001, 0.1]$ [35].

Each SP is assigned a separate weight vector, such that each vector has m elements one for each objective $w = \{w_1, w_2, \dots . w_m\}$, where each element value ≥ 0 and the summation of all elements equals 1.

A neighborhood technique is utilized to optimize each SP based on its neighboring SPs. The j^{th} SP neighborhood comprises the set of SPs that are with T distance from j, such that T represents the neighborhood size. The steps of the original MOEA/D can be found in [18].

The proposed algorithm (algorithm 1) aims to optimize the parameters of three algorithmic trading approaches over three challenging objective functions. In this research, a new MOPSO/D algorithm is implemented, where the algorithm starts by randomly generating the initial particles' positions, velocities, such that, $P^j(t)$ and $v^j(t)$ are the current position and velocity of particle j at time t in sequence. In our application, the particles' positions represent the indicators' parameters.

The PSO considers the interactions and movements of particles as a swarm to locate the optimal points in the search space. Over different iterations, the particles cluster into an ideal position in the search space by employing both exploration and exploitation. The particles attempt to improve their position in the known beneficial regions by exploitation, while also exploring undiscovered regions of the feasible space.

Both exploitation and exploration processes can be managed during the velocity update step. Such that the accelerators c_1 and c_2 are used for the exploitation purposes, whereas. The inertia component ω is needed for exploration.

Algorithm 1: The proposed MOPSO/D algorithm for BTC trading

Inputs:

'C historical prices.

: The number of SPs.

The number of objectives.

: An initial set of weight vectors.

The size of the neighborhood.

ıpty External Archive (EA).

Steps:

1. Initialization:

- Generate a swarm of particles $x^1 \rightarrow x^N$ at random.
- For each particle j, initiate the current position P^j. The personal and global best positions, i.e., P^j_{Pbest}, and P^j_{Gbest} are initially set as P^j.
- For each particle j, initialize the velocity v^j=0.
- Initialize the reference point z^* and nadir point z^{nad}
- Calculate the Euclidean distances for each couple of weight vectors.
- Define the neighborhood of each particle j as, $B(j) = \{j_1, \cdots, j_T\}$, where $w^{j_1}, \cdots, w^{j_T}$ are the T closest weight vector to w^j.

2. Update

For (each iteration i = 1→ $iter$), do

For (each particle j = 1→ N), do

Calculate: g^{ACh}.

According to the g^{ACh} *value*, update P^i_{Pbest} and P^i_{Gbest}.

Update the reference and nadir points.

Update the velocity as:

$$v^j(t+1) = \omega\, v^j(t) + c_1 r_1 \left(P^j_{Pbest} - P^j(t)\right) + c_2 r_2 \left(P^j_{Gbest} - P^j(t)\right)$$

where, ω is the inertia component, c_1 and c_2 are two predefined constant accelerators, r_1, and r_2 are two random variables ∈ [0,1].

Update the current position as:

$$P^j(t+1) = P^j(t) + v^j(t+1)$$

Apply mutation operator.

Update the EA.

End

Update weight vectors W (algorithm 2).

Update neighborhood $B(j)$.

End

3. Return EA.

For further exploration of the search space, a uniform mutation is added to the algorithm to enhance the diversity of the current algorithm; however the resultant particles after mutation are subjected to a repair process that ensures that the new particles positions are never worse than the previous ones. Finally, the nondominant solutions are returned in a final External Archive (EA).

A. Weight Assignment

As mentioned before, the weight assignment method plays a crucial role in influencing the search process of MOEA/D algorithms. The diversity or the distribution of the weight vectors affects the quality of the final solutions to a high degree. Similar or identical vectors generate poor solutions that could not efficiently cover the whole PF.

The methods for generating weight vectors can be categorized as either uniform or random weight creation. Uniform weight creation involves constructing weights in repetitive patterns to guarantee the equitable distribution of vectors over the PF.

In [17], Zhang introduced a structured or uniform weight distribution architecture, such that each weight vector ∈ $\left\{0, \frac{1}{H}, \frac{2}{H}, \ldots, \frac{H}{H}\right\}$, with H being a positive integer parameter used for regulation. The number of SPs or weight vectors $N = C^{m-1}_{H+m-1}$ (C refers to the mathematical combinations).

The uniform distribution is effective in problems with continuous PFs. Nevertheless, it is not suitable for problems with complicated or scattered PFs [36]. A further problem with uniform distribution is that it occasionally generates vectors that are similar or extremely near to each other, resulting in duplicate solutions.

On the contrary, the random distribution of weights allows for a more comprehensive investigation of the search space, as it produces vectors that are not necessarily evenly distributed throughout the PF [18]. This, in turn, yields a range of distinctive and varied solutions since it generates vectors that are dissimilar from each other. The drawback with randomly distributed weights is that there is no assurance that the resulting vectors can accurately represent the whole PF [18].

Since the shape of the (PF) for real world problems is scattered and cannot be easily covered, finding the Pareto optimal points cannot be obtained by simple search strategies. To overcome this problem, an alternative scenario suggesting a Dual Weight assignment mechanism has been implemented denoted as (MOPSO/D-DW).

As seen, both uniform and random assignments have their benefits and drawbacks. In this study, a new weight assignment method is developed to combine the benefits of both strategies into a single algorithm (Algorithm 2).

The proposed strategy is a simple yet efficient. The main idea is to switch between the uniform and random generations over the different iterations.

This process ensures keeping the whole PF covered through the uniform distribution iterations while hitting other random areas during the random iterations. In this case, the particles neighbors are recalculated during each iteration which

improves the particles experience through the search process improving both the diversity and convergence.

Algorithm 2: Dual weight assignment algorithm

Inputs:

- *H:* A regulating integer parameter greater than zero.
- *m:* The number of objectives.
- *iter:* The number of iterations.

Steps:

1. Calculate the number of weight vectors $= C_{H+m-1}^{m-1}$.
2. Let U be a set of values in the range [0,1] with an increment of $1/\mathrm{H}$. U = $\{0, 1/\mathrm{H}, 2/\mathrm{H}, \ldots \ldots 1\}$.
3. Evaluate

For (*j*=1→*N),* do

  For (*i*=1→*m),* do

    - Generate a new non repeated weight vector w_i^j, such that $w_i \in U$ and $\sum_{i=1}^{m} w_i = 1$.
    - Append w_i^j to $\mathrm{W_U}$, such that $\mathrm{W_U}$ is the set of all uniformly generated vectors.

  End

End

For (*i*=1→ *iter*), do

If (*i* % 2== 0*)*, then

For (*j*=1→*N),* do

    - Generate a weight vector w_i^j, with w_i randomly selected from [0,1] and $\sum_{i=1}^{\mathcal{N}} w_i = 1$.
    - Append w_i^j to W.

  End

Else W← W_U

End

End

4. Return W

To summarize the optimization process in a more understandable way, the algorithmic trader first generates a set of random indicators' parameters (particles positions) along with a collection of a uniformly generated weight vectors one for each particle. The particles positions are then assessed by applying the indicators parameters to the training data set and calculating the resultant values for each of the objectives.

Moreover, a fitness aggregation technique in Eq. (8) is then employed to aggregate the three objectives. Based on the aggregated fitness value, the personal and global best positions are updated which in turn are used for updating both the velocities and positions of the particles. The algorithm continues till the maximum iterations and the final results (the best parameters) are obtained from the EA. These parameters are then tested on the testing data set.

IV. Experimental Results

The proposed algorithm is used to find the optimal trading signals for (BTC versus USD) trading during the interval from 3/1/2017 till 3/1/2019 which is considered as the training interval. The optimal set of parameters found during the search are tested upon the closing prices during the testing interval 3/1/2019 till 3/1/2021.

A. Evaluation Metrics

An evaluation metric serves as an indicator or assessment of the quality of the solutions that have been developed. Multiple measures exist for evaluating MO algorithms, each designed to assess distinct characteristics [37]. The convergence, diversity, and statistical measures are crucial assessment factors. Various metrics have been discovered that assess either a single criterion or multiple criteria concurrently. The study included three distinct indicators: the Generational-Distance (GD), the Hypervolume (HV), and the Average Fitness (AF).

- The GD serves as a metric to quantify the distance between the produced non-dominated solutions (the estimated PF) and the actual or true PF [38]. In real-world problems, it is possible to utilize a reference set derived from the collection of estimated PFs produced from all the search techniques under consideration. The lowest GD value indicates the proximity of the derived solution set to the true PF or reference set, and conversely, the higher the GD value, the more away the solution set is from the true Pareto Front [38].
- The HV indicator quantifies both the diversity and the convergence. It measures the *m*-dimensional volume of the objective space region, which is defined by the estimated PF and a reference point that is dominated by all solutions in the front [37].
- The AF is the average of the fitness values of the PF solutions found along a set of independent runs.

B. Parameter Settings

The parameter settings are as follows: the swarm size N = 351, the uniform weight regulating parameter H = 25. The total number of iterations is 150. The augmentation variable ρ = 0.05. The mutation rate=0.15. A neighborhood size (T) = 20. For PSO parameters, the inertia component ω =0.8, both constant accelerators c_1 and c_2 are set as 0.5. For the original MOEA/D, the crossover rate =0.8 and the other parameters are kept as before.

The indicators parameters are as follows: the time spans for all the indicators ∈ [3, 120] days. The ES-RoC over bought and sold levels range within ±10% from the center line. The S-RSI overbought level ∈ [60, 90], while the oversold level ∈ [10, 40].

C. Results

To evaluate convergence and diversity of the solutions generated by the proposed algorithm (MOPSO/D-DW) against the original MOEA/D, each algorithm is evaluated over 10 independent runs. The reported results in the following tables are the best and average values for each algorithm over these runs.

Table I shows a comparison between the values of the best and average GDs obtained by both algorithms. The best results among the two alternatives are displayed in bold. Again, the best GDs are the lowest values.

Table II shows a comparison between the best and average HVs obtained by the algorithms, where the best values (the higher values) are also shown in bold as before.

As seen from the tables, the proposed MOPSO/D-DW algorithm showed the best values in terms of both metrics, i.e., GD and HV. The proposed strategy always showed lower GDs and higher HVs which ensures closer solutions to the true PF with the best distribution of solutions.

To evaluate the efficiency of trading signals generated by the proposed algorithm, the AF of the obtained solutions over 10 independent runs are compared against both the MOEA/D and the TIs using their original parameters.

Due to the conflicts among the different objectives, the evaluation of the counterpart strategies is performed through a ranking methodology, such that each objective is ranked as compared to the same objective over the three counterpart strategies. The best rank is given a value of one, while the worst is given a rank of three. Finally, the total ranks obtained by each strategy are summed in order to evaluate its overall performance.

Table III shows a comparison of the three trading strategies, i.e., the TIs using their original parameters, the MOEA/D and the proposed MOPSO/D-DW during training.

TABLE I. A COMPARISON OF THE BEST AND AVERAGE GD OBTAINED BY EACH ALGORITHM

		MOEA/D	MOPSO/D-DW
DWMA	Best	1.40E-03	**0.00E+00**
	Average	2.53E-02	**0.00E+00**
ES-RoC	Best	5.91E-02	**3.20E-03**
	Average	7.83E-02	**4.34E-03**
S-RSI	Best	4.32E-01	**1.73E-01**
	Average	8.74E-01	**2.95E-01**

TABLE II. A COMPARISON OF THE BEST AND AVERAGE HV OBTAINED BY EACH ALGORITHM

		MOEA/D	MOPSO/D-DW
DWMA	Best	9.09E-02	**9.72E-02**
	Average	5.98E-02	**9.72E-02**
ES-RoC	Best	2.00E-03	**2.19E-02**
	Average	1.54E-03	**1.14E-02**
S-RSI	Best	5.06E-02	**2.91E-01**
	Average	2.97E-02	**2.64E-01**

TABLE III. THE AF OBTAINED BY THE THREE TRADING STRATRGIES FOR EACH INDICATOR OVER 10 INDEPENDENT RUNS DURING TRAINING

		Original parameters			MOEA/D			MOPSO/D-DW		
		RoI%	**SR**	**Trades**	**RoI%**	**SR**	**Trades**	**RoI%**	**SR**	**Trades**
DWMA	AF	518.49	0.87	10	559.91	0.88	5.92	704.18	1.08	7.41
	Rank	3	3	3	2	2	1	1	1	2
ES-RoC	AF	-29.85	-0.07	7	102.19	5.03	1.46	264.27	7.3	2.44
	Rank	3	3	3	2	2	1	1	1	2
S-RSI	AF	-75.6	-0.34	59	216.3	0.37	17.97	437.97	0.57	16.98
	Rank	3	3	3	2	2	2	1	1	1
Total ranking			27			16			11	

TABLE IV. THE AF OBTAINED BY THE THREE TRADING STRATRGIES FOR EACH INDICATOR OVER 10 INDEPENDENT RUNS DURING TESTING

		Original parameters			MOEA/D			MOPSO/D-DW		
		RoI%	**SR**	**Trades**	**RoI%**	**SR**	**Trades**	**RoI%**	**SR**	**Trades**
DWMA	AF	**983.77**	**1.03**	7	627.34	1.1	**6.26**	804.8	1.01	7.94
	Rank	1	1	2	3	3	1	2	2	3
ES-RoC	AF	-4.29	0.02	50	72.76	0.16	**20.06**	**76.63**	**0.28**	22.65
	Rank	3	3	3	2	2	1	1	1	2
S-RSI	AF	25.17	0.42	50	87.58	1.68	0.63	**203.11**	**2.05**	**1.01**
	Rank	3	3	3	2	2	2	1	1	1
Total ranking			22			18			14	

As seen from the table, the proposed MOPSO/D-DW algorithm could provide the best ranking followed by the MOEA/D with the TI's original parameters are given the worst ranking.

The same process is repeated in order to evaluate the benchmark methodologies during testing. As seen from Table IV, the proposed algorithm again provided the best ranking followed by MOEA/D.

Fig. 2 shows the summation of the ranks obtained by the last tables during both training and testing for each of the algorithms. Again, the algorithm assigned the lowest sum of ranks is the best. As can be seen, the proposed algorithm could achieve the best ranking during both the periods under study.

For further analysis, the best and median values obtained by the proposed algorithm are examined during both training and testing periods, such that the comparison is performed based on the average performance of each objective independently. In this case, the best obtainable RoI values for each indicator (i.e., DWMA, S-RoC, S-RSI) are averaged during both training and testing, and so on for the rest of the objectives. This process is repeated for the median value for each objective during both training and testing. The best and median values are compared to the original TIs in order to check the overall performance of the generated trading strategies in different ways, especially during the testing period, which is the main challenge.

Fig. 3 shows the best and median RoI values obtained by the proposed algorithm MOPSO/D-DW over 10 runs during both training and testing compared to the original TI's. As seen, during training, the best and median RoI values extremely exceed the indicators' original parameters RoI. During testing, it can be noted that both the median and the original indicators' parameters provide returns (RoI) that are close to each other, however, the median RoI of the proposed algorithm is still higher than the original parameters.

Fig. 4 shows the best and median SR obtained by the proposed algorithm versus the original indicators during both training and testing. Again, SR is a measure of the risk with higher values indicate lower risk. It can be seen that, the proposed algorithm provides better SR in all cases.

To figure out the effect of the selected parameters on the final trading signals in more detail, an example showing the difference between the effect of trading using the DWMA original parameters, i.e., 20-50 days and one of the generated solutions by the proposed algorithm, i.e., 18-38 days during the testing period for BTC, is clarified through Fig. 6 and Fig. 7 consequently.

Fig. 5 shows the best and median number of trades obtained during the two periods. In this case each buy-sell pair is considered as a single trade. As previously mentioned, lower values are always required as this in turn reduces the trading commissions. The proposed algorithm could also maintain the best number of trades in all the cases.

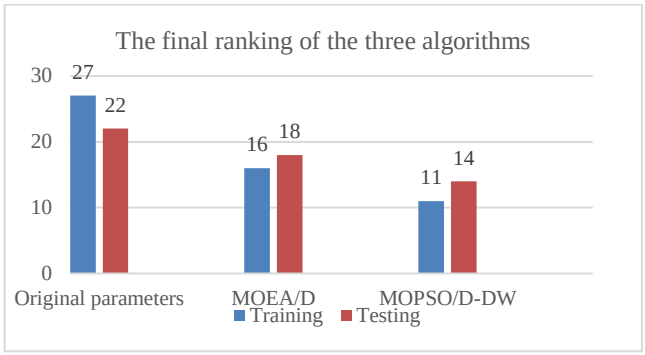

Fig. 2. The final summation of the ranks generated by the three trading strategies.

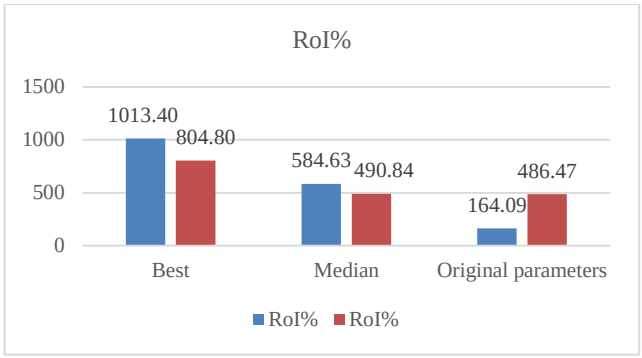

Fig. 3. The best and median RoI values obtained by the MOPSO/D-DW compared against the original TIs during both training and testing.

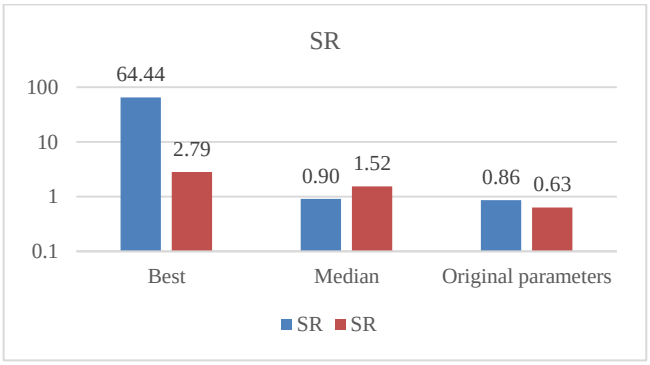

Fig. 4. The best and median SR values obtained by the MOPSO/D-DW compared against the original TIs during both training and testing.

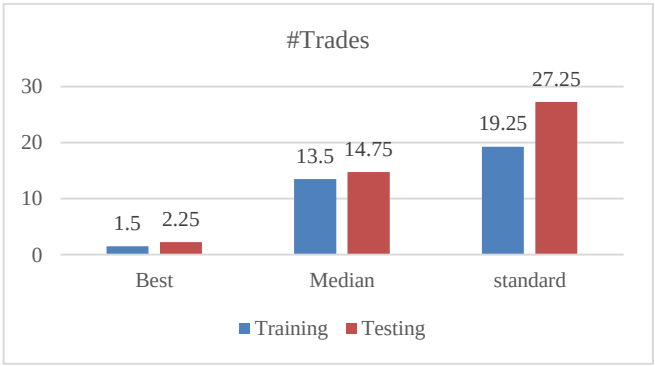

Fig. 5. The best and median number of trades obtained by the MOPSO/D-DW compared against the original TIs during both training and testing.

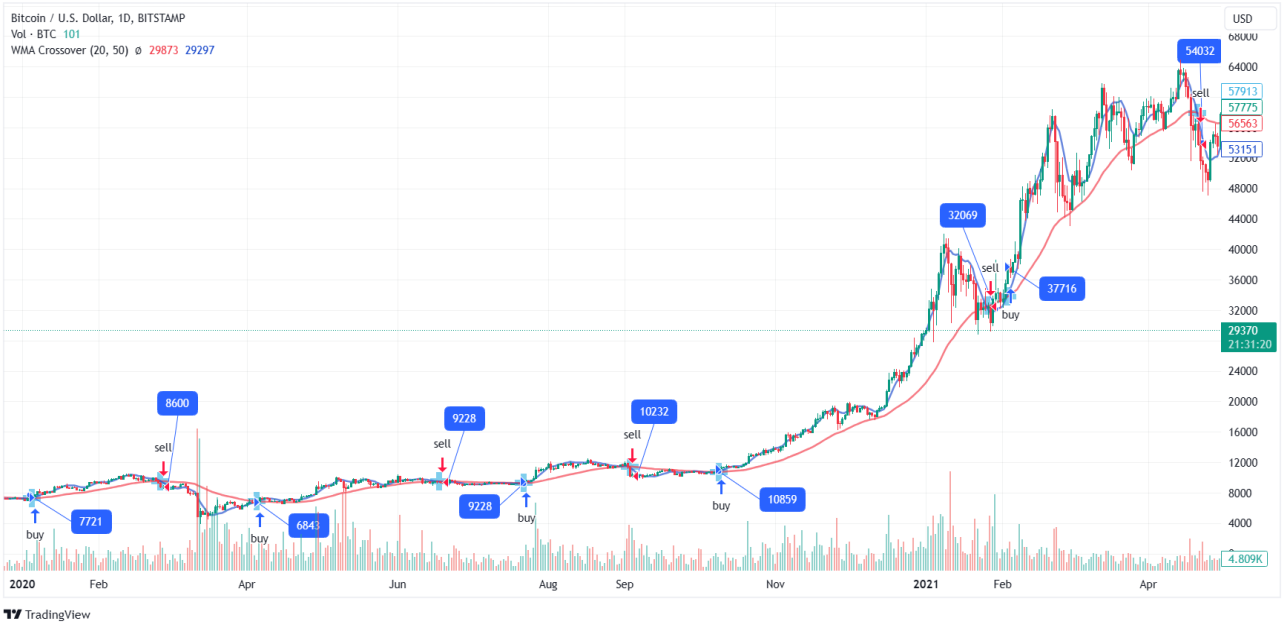

Fig. 6. The Crossovers between an 20-50-days DWMA indicator (the red line for the short WMA, whereas the blue line is for the long WMA) for BTC / USD trading (The buying and selling prices are highlighted in blue in each case).

Fig. 7. The Crossovers between an 18-38-days DWMA indicator (the red line for the short WMA, whereas the blue line is for the long WMA) for BTC / USD trading (The buying and selling prices are highlighted in blue in each case).

The figures show the set of generated signals, i.e., buy and sell, by each parameter combination, showing the buying and selling price in each case. As seen, both of the parameter sets provide a set of profitable trades during the period under study; however, the generated parameter combination in this case is more sensitive to market changes, providing more profitable trades.

V. Conclusion

Cryptocurrency, specifically Bitcoin (BTC), is a decentralized digital payment system that takes its name from the encryption mechanism used for verifying their digital transactions. As there is no need for traditional banking strategies, it attracted millions of traders all over the world. Crypto markets always suffer from instability or volatility which either yields to high returns or extremely harmful losses.

So, the study and analysis of the market is a major demand for investors to get the best returns with the least possible risks.

In this research, a new algorithm is proposed to optimize the trading signals' allocation strategies found in the literature named TIs. The algorithm proposes a new MOPSO/D that is based on a new dual weight assignment methodology MOPSO/D-DW. The algorithm is used to optimize three of the most famous and widely used TIs named DWMA, ES-RoC, and S-RSI.

The algorithm is compared to the MOEA/D and the TIs with their original parameters based on three objectives. The RoI is used for the evaluation of the investment returns, the SR is used for risk evaluation and the third objective is a calculation of the total number of trades. Results showed that the proposed algorithm showed promising results in terms of all the evaluation metrics during the training and testing intervals.

The problem with this optimization process is that the parameters that provide the best returns during the training period are not always the best during testing, but they still maintain good performance with high returns or at least no general losses. This is due to the extreme volatility found during both training and testing, such that the market shows a sideway performance during the testing period, with an extreme jump at the end of the period. For future research, a more complex normalization process could be tested instead of the linear normalization used in this research. The optimization process can be extended to more indicators and a large number of cryptocurrencies. The proposed dual weight-generation strategy could also be tested under different conditions.

A New Method for Revealing Traffic Patterns in Video Surveillance using a Topic Model

Yao Wang*
Henan Industry and Trade, Vocational College, Zhengzhou Henan, 450053, China

***Abstract*—Research on video surveillance systems, for instance, in intelligent transportation systems, has advanced due to the growing requirement for monitoring, control, and intelligent management. One of the next issues is extracting patterns and automatically classifying them, given the volume of data produced by these systems. In this study, a theme approach was utilized to translate visual patterns into visual words in order to reveal and extract traffic patterns at crossings. The supplied video is first cut up into segments. The optical flux technique is then used to determine the clips' optical flux characteristics, which are based on a lot of local motion vector data, and translate them into visual words. The thin-group thematic coding method is then used to teach traffic patterns to the proposed system using a non-probable thematic model. By responding to a behavioral query like "Where is a vehicle going?" these patterns convey observable motion that can be utilized to characterize a scene. The results of applying the suggested method to the QM_UL video database demonstrated that the suggested method can accurately identify and depict significant traffic patterns such as left turns, right turns, and intersection crossings.**

Keywords*—Group thin topic coding; QM_UL video; optical flux; traffic patterns

I. Introduction

The deployment of surveillance cameras is one of the most common strategies for boosting security and managing public spaces better. The majority of public spaces and intelligent transportation networks virtually always have these cameras in situ [1]. These cameras are crucial in video surveillance because they may give decision-makers access to all the details and activities occurring in the monitored area [2]. For instance, in smart transportation systems, these binoculars can be used to monitor and control the volume and kind of traffic, vehicle offenses, and traffic patterns at crossings. On the one hand, the use of these video surveillance cameras has become quite widespread [3]. On the other hand, as their use has increased, a vast amount of multimedia data has been produced, making it virtually impossible for people to monitor these cameras, necessitating the need for a system. Intelligent monitoring, automatic pattern detection, and pattern extraction are all clearly audible [4]. There are two sorts of studies that are accessible for the examination of traffic scenes: a) studies based on the route. A training dataset for machine learning is created using paths that have been observed over a lengthy period of time [5] and [6]. In fact, such a study is still unreliable in challenging circumstances because of the lack of steady and dependable multipurpose tracking algorithms [7]. Rapid response to unexpected shifts in traffic [8] also commonly causes analysis problems. b) Analysis that does not involve tracking and is based solely on the low-level motion vector Optical flux [9] is the most commonly used technique and contains a lot of data about local movement. Using this simple motion feature, more complex models, like thematic ones, might be built for evaluating complex traffic scenarios [10]. Some examples of probabilistic topic models are the Probabilistic Latent Structure Analysis [11], the Probabilistic Conceptual Latent Analysis [12], the Dirichlet Latent Allocation LDA [13], and the Hierarchical Dirichlet Process HDP [14]. were originally developed to unearth concealed headers in a massive corpus of text documents before they were adopted by academics for video analysis. In [15], a fully sparse topic model (TM) (FSTM) is proposed as a simple variant of LDA and PLSA. According to research [16], thin topic coding (STC) using a non-probabilistic topic model (NPTM) can be used to learn hierarchical hidden representations of enormous data sets. Group Thin Topic Coding (GS-TC), a brand-new non-probabilistic topic model, is suggested in [17] for learning thin hidden representations of big text document sets. An effort has been made in [18] to highlight odd and uncommon actions, such as the fire engine stopping the regular flow of traffic. Thin group thematic coding has been enhanced for this purpose, and the thin light flux method has also been applied to extract movement patterns. When compared to previous similar works, the key distinction between our work and others is the utilization of dense light flux in this article to extract movement pattern features and the thematic coding of the primary thin group. Even though using dense light flux requires a larger computation area than using thin light flux, more movement patterns are still recovered. The approaches used to convert the prevalent visual traffic movement patterns into descriptive phrases allowed us to zero down on eight key traffic patterns within the dataset. These eight traffic patterns are: a) Crossing the intersection from the eastern side to the western side; b) Crossing the intersection from the southern side to the northern side; c) Turning right from the eastern side to the northern side; d) Turning left from the western side to the northern side; d) Turning left from the west to the northern side; e) Crossing the intersection from west to east; f) Turning right from south to east; g) Crossing the intersection from north to south; and h) Finding traffic patterns directly results in a useful scene model and streamlines scene analysis. Despite the fact that there have been numerous studies in this area, machine vision systems still struggle with this problem. The automatic detection of traffic patterns in this paper is accomplished using the group thin thematic coding framework (GS-TC). First, a series of separate, non-overlapping clips are created from the surveillance camera video. Then, the discrete

visual stream words are translated into discrete light flux characteristics for each pair of subsequent frames in the clips. The words in the visual stream are then translated into words contained in each video clip, which is then treated as a document. To put it another way, visual elements become visual words. In order to find hidden patterns that reveal the distribution of common motion in the scene, the GS-TC approach is then used. The results demonstrate that useful traffic patterns, such as left turn, right turn, and crossing the intersection, can be retrieved from intersections using the proposed method when applied to real footage. The reasons for choosing the "proposed method" that we consider suitable for dealing with such problems are the following:

1) Growth in video surveillance data: This study confirms the increasing use of surveillance cameras in various applications, leading to significant growth in video data. This increasing amount of data makes manual monitoring impractical and necessitates the development of automatic pattern recognition methods. The proposed method offers a solution to this problem by automatically identifying and classifying traffic patterns.

2) Communication with intelligent transportation systems: surveillance cameras are important in intelligent transportation systems. These systems need to monitor and control traffic patterns at intersections, which makes the proposed method particularly relevant to this field.

3) Using optical flux features: This method uses optical flux features extracted from video frames. Optical flux data contains information about local movement, which is very important for analyzing traffic scenarios. This research discusses the use of optical flux and its potential to build more complex models, such as thematic models, to assess traffic patterns.

4) Thematic coding approach: In this work, a thematic coding approach is chosen, which is usually used in natural language and text processing. Applying this approach to video data, they aim to transform visual traffic movement patterns into descriptive expressions that enable the identification and classification of traffic patterns.

5) Identifying common traffic behaviors: This article also emphasizes the importance of recognizing common traffic behaviors such as turning left, turning right, and moving straight through intersections. These behaviors are considered significant traffic patterns and the proposed method is designed to identify them. The authors' overall contributions to this paper can be summarized as follows:

- Providing a non-surveillance way for video surveillance to identify traffic trends.
- Using the thematic paradigm, drivers at crossings are instructed on traffic patterns.

The overview of related studies follows in Section II. Section III provides background information on the theory behind flow detection and traffic patterns. The traffic dataset, the execution strategy, and the useful outcomes are all covered in Section IV. Section V concludes with recommendations for additional research.

II. BACKGROUND

In Europe, road traffic noise is a big problem, exposing almost 20% of the population to dangerously high noise levels. In order to facilitate decision-making techniques aimed at controlling or reducing noise exposure, effective monitoring and measurement of sound levels in sensitive regions is essential [31]. However, expensive equipment and maintenance duties are needed for spatiotemporal measurements with continuous range and lengthy duration. Thus, the goal of the research [32] is to create an intelligent mobility approach that is affordable and can be used to estimate traffic noise levels using roadside video images. The created method consists of an algorithm that uses dynamic microscopic models to evaluate noise and extract traffic volume, identify vehicle classes, and estimate each vehicle's speed from video records. These later models are based on the already available noise emission models (NEMs) for estimating source sound power levels and a sound emission model that can estimate the corresponding A-weighted sound pressure levels given any road vehicle speed as input slow. The created method is distinguished by its modular structure, which makes it simple to add new variables to the sound propagation model and/or replace the NEM. The process is put to the test under various service levels on a medium-sized city's rural roads. The findings reveal that the noise estimation errors are less than 1 dBA, indicating great accuracy. The issue of traffic congestion in large cities is getting worse due to the swift growth in both the population living in metropolitan areas and the quantity of motor vehicles. The paper aims to perform cluster analysis for daily traffic congestion index curves in order to discover patterns of traffic congestion and examine their spatial-temporal changes. Initially, the coefficient of variation is used to apply weights in order to improve the K-means clustering method because the significance of sample points varies slightly over different time segments. A better K-means clustering algorithm is suggested to find patterns of traffic congestion. Second, changes in traffic congestion patterns over time and space are analyzed using the paired t-test method.

A. Exposing Traffic Patterns

Fig. 1 displays an example of traffic monitoring scenarios at an intersection using a surveillance camera positioned above the intersection. Traffic movement patterns are regular and circular traffic situations, such as "straight passage" and "right turn". The technologies and algorithms for detection, identification, tracking, and categorization of items suffer substantially as a result of the complexity of many of these settings. In these situations, topic models can be utilized to locate and highlight patterns in order to map words, documents, and subjects to certain pattern recognition ideas.

B. Coding of Thin Group Topic

Consider a collection of documents $D = \{w_1, \dots, w_D\}$ that includes N terms from the vocabulary collection V. A document is only a vector | I| after which $D = \{w_1, \dots, w_{|I|}\}$, appears, where I is a set of m word indices. The nth entry (n $\in$I) in w_n indicates the number of occurrences of the desired

word in a particular document. We consider the parameter $\beta \in R^{K*N}$ as a unitary 2 distribution in V is used to describe a dictionary with K bases, each of which is taken to be the foundation of the subject [19].

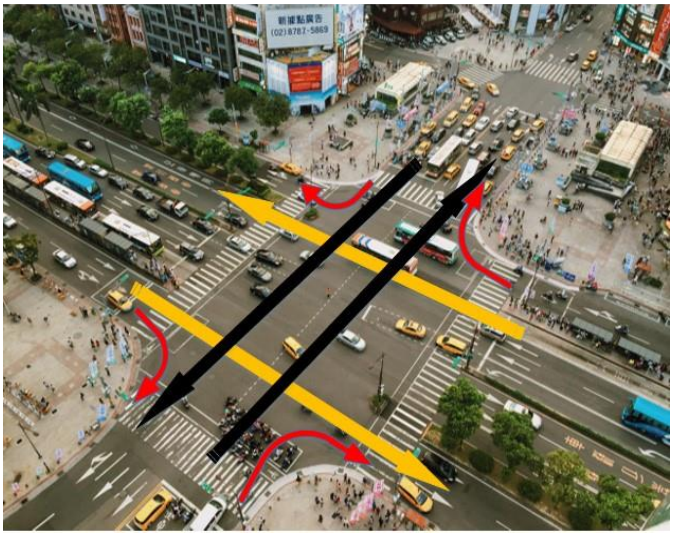

Fig. 1. An intersection traffic scene includes typical traffic movements including left turns, right turns, and crossing the intersection.

For the dth document (w_d), the GS-TC method maps it to a semantic space assigned by a set of auto-learned β addresses and directly encodes the non-normal word $s_{d,.m} \in R^K$ determines for each specific word in the document w_d.

Then the mixture ratio of the whole document w can be derived from the code word $s = \{s_{.1}, \ldots, s_{|I|}\}$ and the headings β. The optimization issue is resolved by the GS-TC approach in accordance with (1). The first part (1) is the non-normal difference KL between the observed words $w_{d,.n}$ and their reconstruction $\beta_{.n}\ s_{d,.m.}^T$.

$$\min \sum_{d=1}^{D} \sum_{m=1}^{|I_d|} \left(\sum_{k=1}^{K} S_{d,kn}\ \beta_{kn} - w_{d,m} \ln \left(\sum_{k=1}^{K} S_{d,km}\ \beta_{km} \right) \right) + \lambda \sum_{d=1}^{D} \sum_{k=1}^{K} \left\| S_{d,k.} \right\|_2 + C \quad (1)$$

$$\text{s.t}\ s_{d,.n} \geq 0\ \forall d, m$$

$$\sum_{k=1}^{K} \beta_{km} = 1, \forall k$$

$$\theta_k = \frac{\sum_{m=1}^{|I|} S_{km}\ \beta_{km}}{\sum_{m=1}^{|I|} \sum_{l=1}^{K} S_{\mathrm{Im}}\ \beta_{\mathrm{Im}}} \quad (2)$$

The second step involves using the LASSO approach to apply a variety of norms for the reconstruction coefficients matrix, which results in proportionate thin coding at the document level. The symbols used in (1) are defined in Table I. It should be noted that the word codes can be used to determine the mixture ratio of the document surface. The variable θ_k is used in (2) [20] to indicate the contribution vector of the k_{th} title in the document w.

TABLE I. THE DEFINITION OF THE SYMPTOMS AND VARIABLES UTILIZED IN (1) AND OPTIMIZATION OF THE GS-TC TECHNIQUE

Signs	Description
$\boldsymbol{m = 1, \ldots, N}$	Index_of words
$\boldsymbol{\theta_d}$	Percentage_of titles in the dth _document
$\boldsymbol{d = 1, \ldots, D}$	Document_index
β	Titles_Dictionary
$\boldsymbol{S_{d,m}}$	mth-word representation in dth-document
$\boldsymbol{w_{d,m}}$	How many times the word n appears_in the given document
$\boldsymbol{k = 1, \ldots, K}$	Index of _titles
$\boldsymbol{I_d}$	Set of index words _that appear in document dth

C. Related Works

Most methods for analyzing traffic can be classified into two broad categories. In the first category, the target object, such as a car or a person, is first recognized, followed by tracking, and the paths gleaned are then used for additional analysis. Undoubtedly, the grouping of traces is a straightforward technique that makes it possible to identify anomalies [21]. Regardless, the accuracy and dependability of these approaches heavily rely on the detection and tracking techniques, which are susceptible to errors brought on by obstruction, noise, shifting lighting conditions, and changing weather. Additionally, the grouping of routes necessitates a comparison of all samples' similarity, which can be computationally taxing [22]. In the second type, information about motion and appearance is gleaned from video frames without the aid of detection and tracking methods. The strategy utilized in these articles [7] and [23] is to directly develop a model of movements and activities using these extracted attributes. A sizable number of research projects have recently concentrated on the use of topic models (TM). For instance, utilizing probabilistic conceptual latent analysis (PLSA), anomaly detection and motion-based scene segmentation have been carried out in [24]. Using the two-level Dirichlet process (dp), normal and aberrant activity were distinguished in [25]. In [26], a two-level LDA topic model was applied to extracting rules and recognizing anomalies after it was utilized to identify anomalies and learn behavior for the efficient display of clips with a dispersed set of motion patterns. The author in [19] presents an unsupervised method for anomaly detection that uses the thin thematic group coding (GS-TC) framework to learn movement patterns. In [27], it is planned to use license plate number data obtained from video surveillance cameras to determine urban road vehicle density, city-wide regional vehicle density, and hot routes. To improve the precision of the visualization's impact, this article used a method for detecting outliers based on Dixon's detection approach and Internet crawling technologies during data analysis and processing. This study developed an urban road vehicle traffic index for the visualization map design in order to visually and

numerically depict the region's traffic operating state. An experiment was carried out in Guiyang using the information from the road video surveillance camera system to confirm the method's viability. From three visualization maps, a number of geographical and temporal characteristics of urban traffic are clearly and effectively identified. The outcomes demonstrate the suggested framework's satisfactory performance in terms of visual analysis, which helps with traffic management and operations. The author in [28] introduces DeWiCam, a smartphone-based detection system that is small and powerful. Utilizing the natural traffic patterns of wireless camera streams is the core concept behind DeWiCam. DeWiCam is more difficult to utilize than conventional traffic pattern analysis because it cannot access data that has been packed in data packets. DeWiCam, on the other hand, circumvents this issue and can accurately find neighboring Wi-Fi cameras. A human-assisted recognition approach is suggested to further determine whether a camera is interested in a certain room. Image resolution and audio channel inference are two additional DeWiCam add-on functions that are available to enhance further security. DeWiCam is put to use on the Android operating system and assessed using in-depth tests on 20 cameras. DeWiCam can identify cameras with 99% accuracy in 7:2 seconds, according to test data.

III. Proposed Method for Detecting Traffic Patterns

A. Process of the Proposed Method

Fig. 2 and 3 depict the general and specific steps of the suggested strategy that makes use of the topic model. When considering an input video, the video is first momentarily split into *D* non-overlapping clips, with each clip being treated as a separate w_d document. The scene is initially divided into $C_x * C_y$ square cells, each of which covers $p*p$ pixels, in order to construct stream words. After that, using the optical flux technique, motion vectors are extracted for each pair of subsequent frames. In order to eliminate noise and preserve dependable flows, a motion vectors are subjected to a threshold value, t. The other motion vectors $s_i = (x, y, u, v)$, whose positions (x and y) are fixed in a grid with a distance of p pixels, are sampled to create flow words. The examples of motion vectors include then split into an O-number of directions based on their displacement (u, v). Finally, a group of fixed words is generated, $N = C_X \times C_y \times O$ and $V = \{1, \dots N\}$, each of which has two content aspects: "position information" and "direction information" of movement. The frames include a collection of the video clips' stream words. Then, a video clip is shown as a vector with the form $w = (\omega_1, \dots, \omega_N)$, where ω_n denotes how many times the n_{th} word appears in the clip. The symptoms are depicted in Table II along with the video's counterparts.

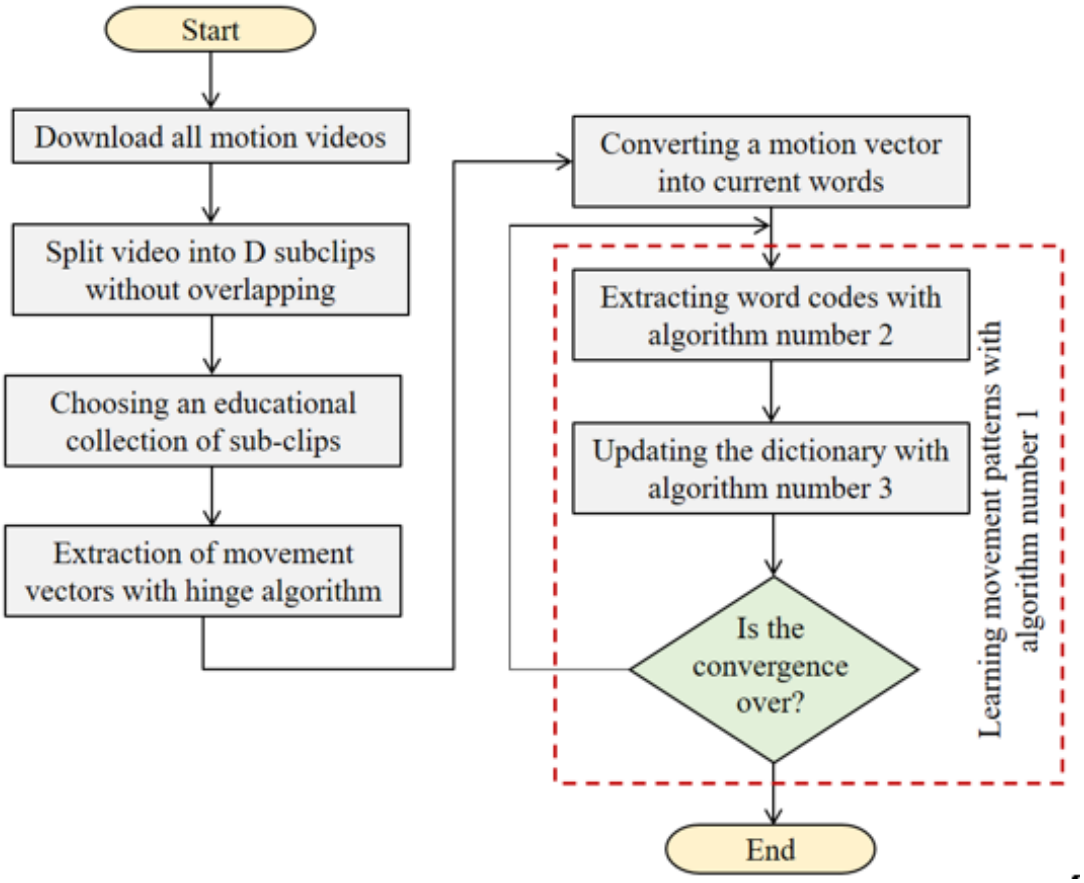

Fig. 2. The general process of the proposed method of detecting normal traffic patterns of vehicles.

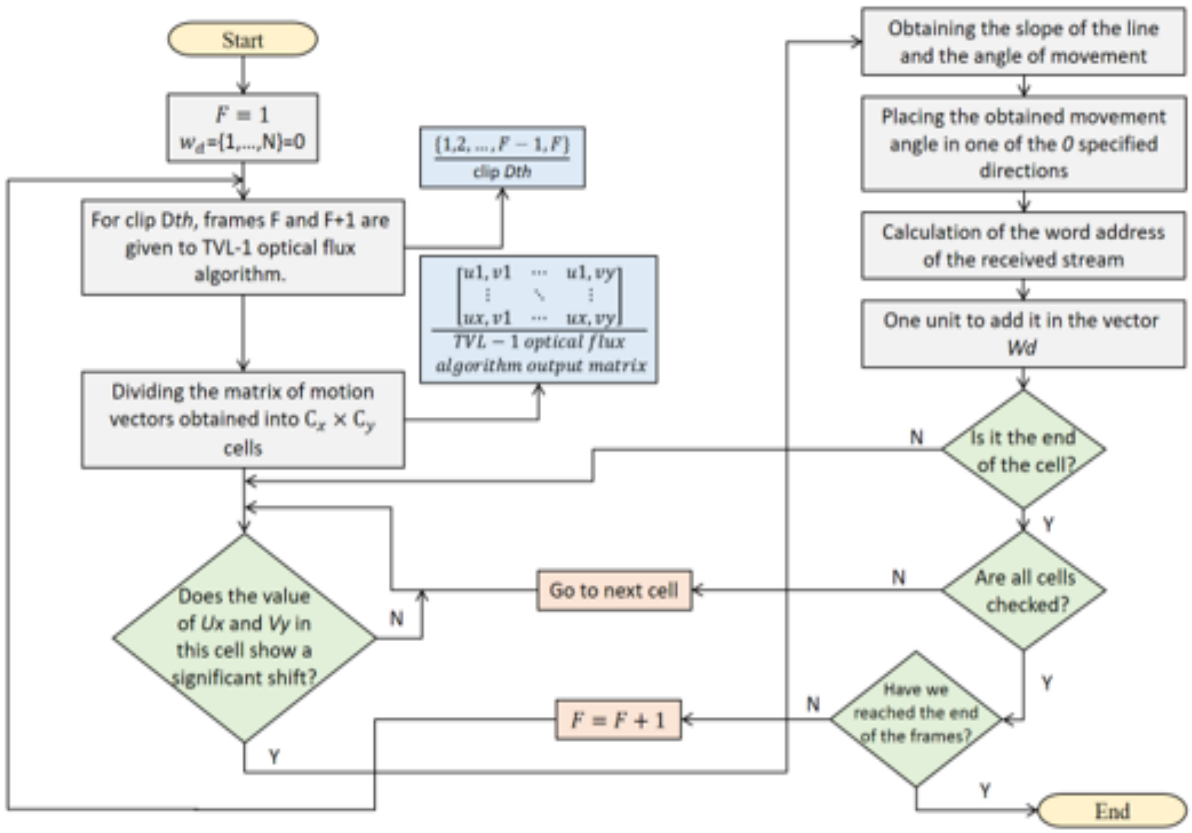

Fig. 3. Partial flowchart of the proposed method, video display with the subject model in detecting normal traffic patterns of vehicles at intersections. Identifying normal traffic patterns of vehicles.

TABLE II. SYMBOLS AND VARIABLES USED IN THE VIDEO, ALONG WITH THEIR EQUIVALENTS

Signs	Description
$\boldsymbol{d = 1, \dots, D}$	Index of clips
$\boldsymbol{k = 1, \dots, K}$	Index of movement patterns
$\boldsymbol{n = 1, \dots, N}$	A Word-Flow Index
$\boldsymbol{I_d}$	Index set of flow words that happened in clip dth
$\boldsymbol{w_{d,n}}$	number of occurrences _ word nth clip dth
β	A Movement Pattern Dictionary
$\boldsymbol{\theta_d}$	Clip share dth of templates
$\boldsymbol{S_{d,n}}$	How significant the nth stream word was in the dth clip

B. Learning Traffic Patterns using GS-TC

Eq. (3) provides a summary of the general GS-TC formula. The GS-TC formula in [18], which is based on reducing the variance of KL, does not apply to this equation because the 2 soft reduces reconstruction errors to a minimum. The optimization problem can be solved more easily by using soft minimization 2□ [21]. The objective function in (3) is convex, which means that while one of the two is constant, it is convex around $\{S_d\}_{d=1}^{D}$ and β. The CDA algorithm [29], which alternately optimizes on $\{S_d\}_{d=1}^{D}$ and β and is depicted in Algorithm 1, is a common solution.

Algorithm 1: Intelligent transportation systems' learning algorithms for understanding typical vehicle traffic patterns

Input: training video clips$\{w_d\}_{d=1}^{D}$, hyper parameter λ, and topic count
Output: dictionary β, word codes s
$\beta \in R^{K \times N}$ a positive-definite random matrix.
Initialize $\{S_d\}_{d=1}^{D} \in R^{D \times K \times N}$ to random matrices with positive elements
l^{old} = Using Eq. (3), figure out the cost function.
repeat
for $d = 1$: D
calculate S_d with Algorithm 2
end for
Apply Algorithm 3 to Dictionary β
l = A cost function can be calculated using formula (3).
If $(\boldsymbol{l - l^{old} < \varepsilon})$**then**
Break
Else
$l = l^{old}$ until the conditions for termination are met, usually convergence.

$$\min_{\{S_d\}_{d=1}^{D},\beta} \sum_{d=1}^{D} \left(\left| \left| w_d - diag(S_d^T \beta) \right| \right|_2^2 + \lambda \left| \left| S_d \right| \right|_{2,1} \right) \quad (3)$$

$$\text{s.t. } s_d \geq .0 \; \forall d, \beta_k \geq ., \left| \left| \beta_{k.} \right| \right|_1 \geq 1, \forall k$$

where $S_d \in R^{K\times N}$ and parameter λ is a non-negative parameter for thin control.

C. Extracting Word Codes using Thin Coding Algorithm

In the following, the word codes $\{S_d\}_{d=1}^{D}$ will be obtained by optimization according to Eq. (4) with the assumption of constant β dictionary.

Due to conditional independence, this step can be carried out separately for each document by addressing the optimization problem. Since the word codes are organized into titles and each title is unique, this optimization makes use of the BCD technique by solving the issue for each S_{kn}.

The difficulty of locating the roots of a complex quadratic equation is the end result of this approach. By expressing the optimization problem in accordance with Eq. (5) and (6), it is possible to acquire the entire matrix s without having to calculate each S_{kn} individually.

Algorithm 2: Thin coding algorithm

$P = diag(w_{d,1}, \dots, w_{d,N})$
l^{old} = Cost function calculation per formula (5)
Repeat
$R = diag(\frac{1}{\left\|S_{d,1.}\right\|_2 + \varepsilon}, \dots, \frac{1}{\left\|S_{d,k.}\right\|_2 + \varepsilon})$
$S_d = (\beta\beta^T + \lambda R)^{-1}\beta P$
l = Cost function calculation per formula (5)
If $(l - l^{old} < \varepsilon)$then
Break
Else
$l = l^{old}$
Until the convergence occurs or the end point is reached.

$$\min_{\{S_d\}_{d=1}^{D},\beta} \sum_{d=1}^{D}\left(\left||w_d - diag(S_d^T\beta)\right||_2^2 + \lambda\left||S_d|\right|_{2,1}\right) = \sum_{d=1}^{D}\left(\sum_{n=1}^{N}(W_{d,n} - S_{d,n}^T\beta_{.n})^2 + \lambda\sum_{k=1}^{K}\left\|S_{d,k.}\right\|_2\right) \quad (4)$$

$$\text{s.t. } s_d \geq .0, \forall d$$

$$\min_s \left||w_d - diag(s_d^T\beta)\right||_2^2 + \lambda\left||S_d|\right|_{2,1} \quad (5)$$

$$\text{s.t. } s > 0$$

$$\min_s trace(PP + s^T\beta\beta^T s - 2Ps^T\beta) + \lambda\, trace(s^T Rs) \quad (6)$$

$$\text{s.t. } s > 0$$

that in (6), $R = diag(\frac{1}{\left||s_{10}|\right|_2} + \varepsilon, \dots, 1/||S_{k.}||_2)$ and $P = diag(w_1, \dots, w_N)$ is. We consider the value of ε much smaller than the non-zero values of s and add it to the denominator to prevent division by zero. Since the norms of l_p for $p \geq 1$ are convex functions, according to (5) and its equivalent, Eq. (6), the problem is the optimization of convex functions with respect to the matrix s. Therefore, assuming zero slope can be a closed-form solution for calculating the ss matrix according to Eq. (7). Algorithm 2 shows the thin coding algorithm.

$$\beta\beta^T s - \beta P + \lambda Rs = 0$$
$$s = (\beta\beta^T + \lambda R)^{-1}\beta P \quad (7)$$

D. Dictionary Update Using Dictionary Learning Algorithm

After discovering each of the set's hidden word codes, the optimization problem (8) is solved to update the β dictionary. By locating the slope's root, Eq. (8)'s convex optimization problem can be successfully solved. Instead of calculating each β_{kn} separately to solve the dictionary learning problem, a general solution can be suggested to acquire the full β matrix by altering (8) to (9).

$$\min_\beta \sum_{d=1}^{D}\left(\left||w_d - diag(s_d^T\beta)\right||_2^2\right) = \sum_{d=1}^{D}\sum_{n=1}^{N}(w_{d,n} - s_{d,n.}^T\beta_{.n})^2 \quad (8)$$

$$\text{s.t. } \beta \geq 0, \sum_{n=1}^{N}\beta_{kn} = 1, \forall k$$

$$\min_\beta \sum_{d=1}^{D}\left(\left||w_d - diag(s_d^T\beta)\right||_2^2\right) = \sum_{d=1}^{D} trace(P^T P + s_d^T\beta\beta^T s_d - 2P^T s_d^T\beta) \quad (9)$$

which is $P = diag(w_{d,1}, \dots, w_{d,N})$. Setting the slope to zero yields the value of β per Eq. (10).

Algorithm 3: Dictionary learning algorithm

$P = diag(w_{d,1}, \dots, w_{d,N})$
$\beta = (\sum_{d=1}^{D} s_d\, s_d^T)^{-1}(\sum_{d=1}^{D} s_d\, P)$
for $k = 1 : K$
for $n = 1 : N$
$\beta_{kn} = \max(\beta_{kn}, 0)$
end
end
for $k = 1 : K$
$\beta_{k.} = \frac{\beta_{k.}}{\left||\beta_{k.}|\right|_1}$
End

$$\sum_{d=1}^{D}(S_d\, S_d^T\beta - s_d\, P) = 0$$
$$\beta = (\sum_{d=1}^{D} S_d\, S_d^T)^{-1}(\sum_{d=1}^{D} s_d\, P) \quad (10)$$

The proposed method is depicted in detail in Algorithm 3 of the dictionary learning process in Fig. 2.

E. Discussion

In this article, a new method for revealing traffic patterns in video surveillance using the topic model is presented. This method focuses on extracting and classifying traffic patterns from video footage, with specific application in intelligent transportation systems. The proposed method involves segmenting video clips, extracting optical flux features, and using a topic coding approach to train the system about traffic patterns. The results of applying this method in the video data set are promising to identify and depict different traffic patterns. The importance of the article begins by emphasizing the increasing use of surveillance cameras in various applications, including intelligent transportation systems. The growth of video data is a challenge for manual monitoring and necessitates the development of automatic pattern recognition methods. This research deals with a practical problem and the identification of traffic patterns is very important for traffic management and analysis. It briefly discusses the available approaches for analyzing traffic scenes. It mentions the challenges associated with tracking-based methods and the potential of optical flux data to create more complex models. The introduction provides valuable background to the proposed method and provides context for its importance. This paper also discusses the identification of eight key traffic patterns in the dataset and provides a list of these patterns. However, it would be useful to include more information on how these patterns are determined and how they relate to real-world traffic scenarios. In addition, the paper notes that two traffic patterns were indistinguishable due to camera positioning, which raises questions about the method's limitations and potential improvements. In summary, the paper introduces an attractive approach to traffic pattern detection in video surveillance, but could benefit from a more detailed description of the method, a deeper analysis of the results, and a discussion of its broader significance and potential limitations.

IV. Implementation of the Proposed Method and Results

A. Implementation Environment

To acquire the optical flux of the clips, the proposed method was implemented in the C++ programming environment using open_CV functions. The methods were implemented using the C++ linear algebra package Armadillo [27], and the software was run on a computer with an Intel Core i4790 7 processor and 8 GB of memory.

B. Total Data and their Characteristics

The video images used in this article are from the QMUL1 dataset, which is shown in Fig. 4 as an example.

The activity analysis and behavior comprehension applications of this traffic data collection are particularly beneficial [28]. The tough video images in this bank have a resolution of 288 x 360, a frame rate of 25 frames per second, and a total of one hour (90,000 frames). It should be noted that the topic model has swiftly adopted this image bank as a go-to resource. Fig. 5 displays the eleven typical traffic patterns from the QMUL dataset, and Table III lists each one's description. They are as follows: Turning left from the south side to the west is traffic pattern number one. Crossing the intersection from the east to the west is traffic pattern number two. Turning right from the north side to the west is traffic pattern number four. Turning left from the west to the north is traffic pattern number five. Turning right from the east side to the north is traffic pattern number six. Turning left from the north side to the east is traffic pattern number seven. It should be noted that the camera's angle and height off the ground have a significant impact on how accurately the optical flux algorithm detects motion vectors. Also, Fig. 6 shows examples of traffic patterns in this collection.

Fig. 4. QMUL dataset containing one hour (90,000 frames) of high-volume traffic video collected at the intersection.

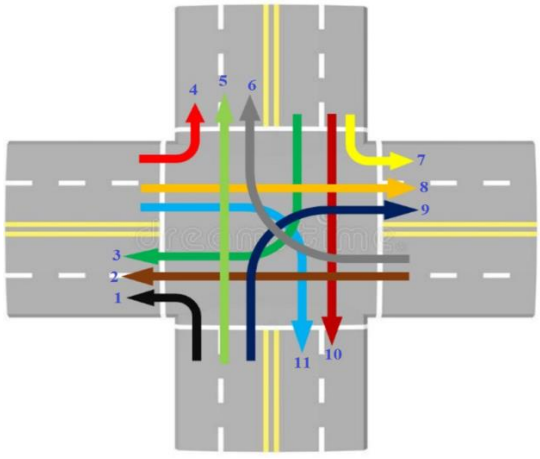

Fig. 5. Common traffic patterns in the QMUL data set (the description and numbering of the patterns are given in Table III).

TABLE III. TRAFFIC PATTERNS THAT ARE TYPICAL AND FREQUENT IN THE QUML DATASET

Traffic pattern number	name of the movement pattern	Recognizability
1	From the south side, turn left and head west.	□
2	moving from the east side of the intersection to the west side	□
3	From the north side, turn right to reach the west side.	□
4	From the west side, make a left turn to the north side.	□
5	moving from the south side of the crossroads to the north side	□
6	From the east side, make a right turn to the north side.	□
7	From the north side, make a left turn to the east side.	□
8	moving from the west to the east across the intersection	□
9	On the south side, turn right toward the east.	□
10	from the north side to the south side of the intersection	□
11	From the west side, turn right to go to the south side.	□

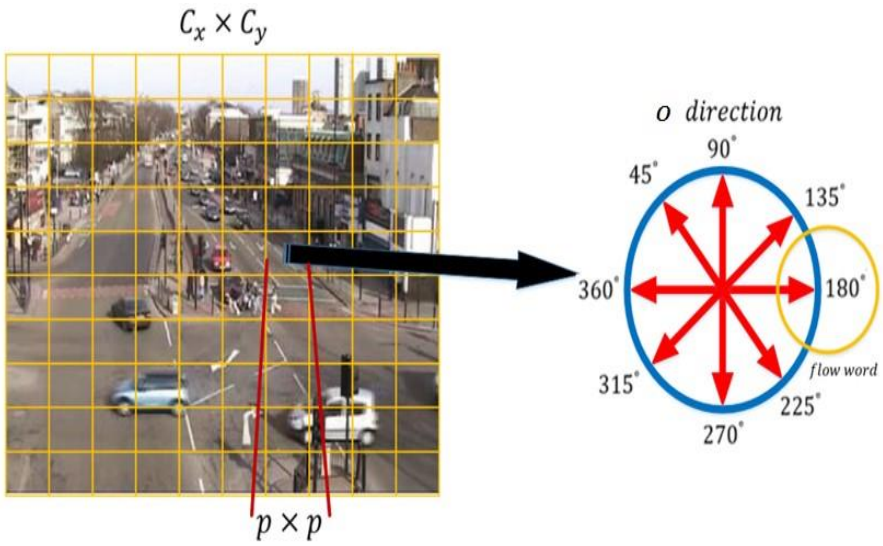

Fig. 7. How to make stream words.

C. Implementation Processes of the Proposed Method

In implementing the proposed method, the input video was first divided into three-second sub-clips. Then the optical flux characteristics were extracted for each pair of consecutive frames in each clip using the TVL-1 optical flux algorithm [29]. After that, as shown in Fig. 7, the output of the optical flux algorithm was divided into 10 x 10 cells. According to the resolution of each frame, there are 29 x 36 cells, and each of the motion vector values in each cell is one of 8 directions: 45º, 90º, 135º, 180º, 225º, 270º, 315º, and 360º. Then this process is repeated for each clip, and finally each clip is displayed with a vector length of $N = 8 \times 36 \times 29 = 8352$. Each member of the vector represents the number of occurrences of the current word. We experimentally set the λ parameter equal to 0.1 and the K value equal to 25. We considered the maximum number of repetitions of the program to be 20, and the value of ε for the convergence of the algorithms was 0.01. In this experiment, 200 clips were used for training.

D. Implementation Results

After running the proposed algorithm on the QMUL bank, traffic patterns were extracted. As can be seen in Fig. 8, three common movement behaviors—turning left [Fig. 8(a)], turning right [Fig. 8(b)], and crossing the intersection [Fig. 8(c)]—have been extracted. Also, in Fig. 8(d) to 8(i), two traffic patterns have been extracted simultaneously. As mentioned before, due to the importance of the location of the camera in the detection of traffic patterns, traffic patterns one and seven are undetectable in the QMUL bank and are not observed in the detected traffic patterns. Finally, according to the number and timing of red lights and traffic routines of cars in this data set, the proposed method has been able to correctly extract eight meaningful flows and patterns from the nine existing traffic patterns (accuracy 88.8%). The use of local movements, which is the movement of pixels between two frames, as features of "direction of flow detection" and "motion patterns", increases the possibility of misdiagnosis. For example, the presence of pedestrians or other moving objects increases the possibility of detecting meaningless patterns.

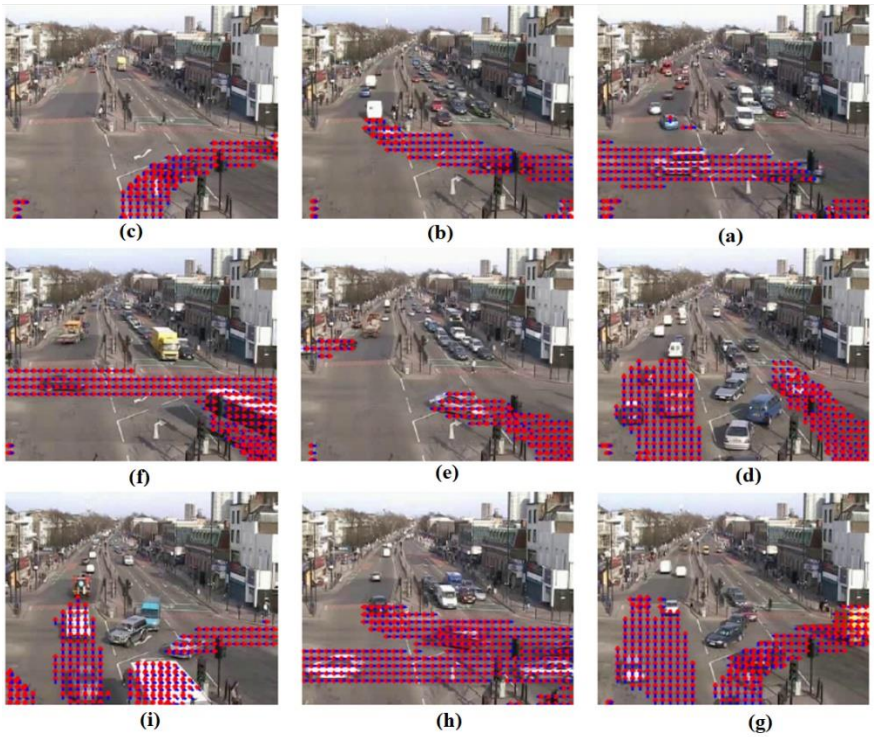

Fig. 8. Traffic flows and patterns obtained by the proposed method, (a) going left (b) turning north (c) a right turn from south to east, (d) crossing the intersection (e)) a right turn from west to south (f) going right from the west side to the south side (g) crossing the intersection from the south side to the north side (h) turning right from the east side to the north (i) turning to Right from south to east.

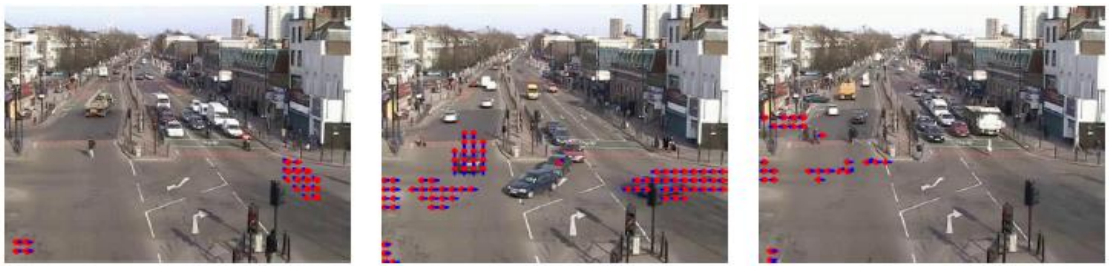

Fig. 9. Traffic patterns extracted from QMUL bank that do not have a specific meaning.

Naturally, scientists have employed these patterns to identify anomalies and peculiar movements [1]. There are other traffic patterns in the bank, as seen in Fig. 9 taken from QMUL, that have no clear significance. Therefore, it will be challenging to analyze the scenario, uncover the rules, and apply them using the patterns gleaned from the thematic model. Some traffic flows and patterns recovered have no particular significance because of the topic model's nature, which was primarily created and utilized for processing natural language and text and does not account for difficulties such as abrupt changes in illumination, image size, or camera viewing angle.

This paper has several significant contributions in the field of traffic pattern detection in video surveillance, which can be summarized as follows:

1) Unsupervised Traffic Pattern Recognition: The main contribution of this work is the development of an unsupervised method to identify and classify traffic patterns in video surveillance data. Traditional approaches often rely on predefined training datasets or tracking techniques, which may be limited by the need for extensive manual labeling or tracking accuracy issues. The proposed method takes a different approach by using a topic coding model to automatically extract traffic patterns without the need for a previous training dataset. This non-supervised nature of the method makes it adaptable to a wide range of traffic scenarios, including scenarios with diverse and evolving patterns.

2) Topic coding with optical flux features: This paper introduces the use of topic coding, a technique commonly used in natural language processing, in the context of video analysis. This method transforms visual traffic movement patterns into descriptive expressions that enable the identification and categorization of significant traffic patterns. To achieve this goal, the authors use optical flux features extracted from video frames that contain detailed information about local motion. This combination of thematic coding and optical flux features provides a new and promising approach for traffic pattern recognition. The contributions of this work extend to the development of an automated system to recognize common traffic behaviors at intersections, such as left turns, right turns, and crossing intersections. These contributions have significant relevance for applications in intelligent transportation systems, traffic management, and public safety, where accurate and automatic traffic pattern detection is essential for efficient monitoring and decision-making.

V. Conclusion

In urban traffic, crossroads play a significant role, and surveillance cameras are frequently utilized to regulate and control public spaces. The traditional method of video surveillance does not function well due to the vast volume of video data and the unreliability of humans; therefore, a system that automatically collects traffic flows and patterns is necessary. A non-supervisory strategy to identify traffic patterns in video surveillance was put forth in this paper. First, the optical flux algorithm is used to determine the traffic flow in each frame. The Car was taught using the theme model of these traffic patterns because behaviors like turning left, turning right, and traveling straight through an intersection are considered to be common significant traffic patterns in the images observed by the camera. According to the position of the camera in the QMUL bank, the implementation results revealed that the suggested method was able to accurately calculate eight significant motion patterns out of a total of nine conceivable patterns. Turning left, turning right, and passing straight are frequent and permitted in areas where traffic is controlled, such as junctions, according to traffic regulations and driving laws. Now, if there are movements that deviate from these authorized and typical patterns, they can first be identified as unexpected events before suitable choices, like recording a violation, can be taken into account. In other words, future studies may focus on the identification of violations in terms of atypical movement. A future study might examine how well the suggested algorithm holds up to environmental elements in the image, such as changes in light intensity, camera position, and difficulties similar to those seen in image processing. Some limitations and potential challenges in this study are as follows:

Reliability of tracking-based methods, one class of which involves first tracking objects (e.g. cars or people) and then using the tracked trajectories for further analysis: This indicates that these methods may suffer from challenges related to the accuracy and reliability of object detection and tracking.

Inadequate anomaly detection, where some existing methods may not effectively detect anomalies or unusual traffic behavior: This shows that the proposed approach can potentially detect unexpected events or violations by identifying patterns that deviate from the permitted and normal traffic behaviors. This indicates that existing methods may have limitations in detecting and classifying anomalies in traffic patterns.

Environmental variability, where the location and angle of surveillance cameras can significantly affect the accuracy of optical flux-based motion vector detection: This suggests that existing methods may be limited by environmental factors, such as changes in lighting conditions, changes in camera positions, and other challenges commonly encountered in video surveillance.

Improving Deep Reinforcement Learning Training Convergence using Fuzzy Logic for Autonomous Mobile Robot Navigation

Abdurrahman bin Kamarulariffin, Azhar bin Mohd Ibrahim*, Alala Bahamid
Department of Mechatronics Engineering, International Islamic University Malaysia, Kuala Lumpur, Malaysia

***Abstract*—Autonomous robotic navigation has become hotspot research, particularly in complex environments, where inefficient exploration can lead to inefficient navigation. Previous approaches often had a wide range of assumptions and prior knowledge. Adaptations of machine learning (ML) approaches, especially deep learning, play a vital role in the applications of navigation, detection, and prediction about robotic analysis. Further development is needed due to the fast growth of urban megacities. The main problem of training convergence time in deep reinforcement learning (DRL) for mobile robot navigation refers to the amount of time it takes for the agent to learn an optimal policy through trial and error and is caused by the need to collect a large amount of data and computational demands of training deep neural networks. Meanwhile, the assumption of reward in DRL for navigation is problematic as it can be difficult or impossible to define a clear reward function in real-world scenarios, making it challenging to train the agent to navigate effectively. This paper proposes a neuro-symbolic approach that combine the strengths of deep reinforcement learning and fuzzy logic to address the challenges of deep reinforcement learning for mobile robot navigation in terms of training time and the assumption of reward by incorporating symbolic representations to guide the learning process, and inferring the underlying objectives of the task which is expected to reduce the training convergence time.**

Keywords*—Autonomous navigation; deep reinforcement learning; mobile robots; neuro-symbolic; Fuzzy Logic

I. INTRODUCTION

Advancements in robot navigation have spurred the development of algorithms that leverage basic rules and environmental mapping to optimize path planning. Rule-based methods, such as Fuzzy logic and Neuro-fuzzy techniques, have been extensively explored to enhance navigation decisions and tracking performance under uncertain conditions [1], [2]. While these methods offer valuable insights, they often require extensive justification and may not fully meet the demands for efficient and accurate path planning.

To address this challenge, researchers have turned to bio-inspired approaches, such as genetic algorithms and swarm optimization, which draw inspiration from biological behavior and incorporate prior knowledge to simulate human cognitive processes [3], [4]. One particularly promising area in navigation research is reinforcement learning (RL), which enables autonomous agents to learn and make sequential decisions in complex environments. Machine learning models, including supervised, unsupervised, and reinforcement learning, have played a pivotal role in robotics research, enabling learning, adaptation, and effective detection and classification. Deep reinforcement learning (DRL), a fusion of RL and deep neural networks, has emerged as a powerful approach for decision-making tasks involving high-dimensional inputs [5], [6].This article aims to delve into the application of RL techniques, specifically Q-learning and deep Q-networks, for mobile robot path planning. By seamlessly integrating these techniques with widely used frameworks such as ROS, Gazebo, and OpenAI, a robust and autonomous navigation system can be developed, leading to improved performance, optimized routes, and efficient obstacle avoidance in complex environments. The evaluation of this system will undoubtedly contribute to the advancement of autonomous robotics. The trial-and-error learning process inherent in RL offers immense potential for building human-level agents and has been extensively explored in various domains [7] [8]. Deep learning (DL), characterized by its ability to extract meaningful patterns and classifications from raw sensory data through deep neural networks, has revolutionized the field of machine learning. When combined with RL, in the form of DRL, this integration has shown remarkable success in tackling challenges associated with sequential decision-making [9], [10]. Notably, DRL excels in scenarios involving a vast number of states, making it an ideal candidate for addressing navigation complexities. Nevertheless, achieving optimal navigation remains an ongoing challenge, necessitating further optimization and effective handling of high-dimensional data. Reinforcement learning methods offer valuable approaches for learning and planning navigation, empowering agents to interact with their environment and make autonomous decisions. Various studies have proposed agent-based DRL approaches for navigation, successfully simulating diverse scenarios without the need for intricate rule-based systems or laborious parameter tuning. However, there is still room for improvement in terms of achieving the shortest and fastest routes. To enhance navigation performance and optimize evacuation paths, researchers have explored techniques such as look-ahead crowded estimation and Q-learning, which have demonstrated superior results compared to other RL algorithms [6]. Additionally, CNN-based robot-assisted evacuation systems have been developed to maximize pedestrian outflow by extracting specific features from high-dimensional images. Furthermore, iterative, and incremental learning strategies,

like vector quantization with Q learning (VQQL), have been proposed to expedite the learning process and optimize navigation by gradually improving interactions among agents [11], [12]. These advancements in DRL continue to show great promise in addressing the speed of agent learning and optimizing navigation processes. In the realm of task planning, the ability to find a series of steps that transform initial conditions into desired states is crucial. Task planning becomes especially important when atomic actions alone cannot accomplish a task. Neuro-symbolic task planning has emerged as an effective approach, allowing for the incorporation of restrictions, guidelines, and requirements in each activity. However, traditional task planners often rely on detailed hand-coded explanations, limiting their scalability. To overcome this limitation, a combination of deep learning and symbolic planning, known as a neuro-symbolic approach, has shown potential by leveraging visual information instead of hand-coded explanations [3], [13], [14]. However, collecting image data for neuro-symbolic models in robotic applications is a labor-intensive process that involves steps such as creating problem instances, defining initial and goal states, operating robots, and capturing scene images. The challenges associated with data collection have hindered the widespread adoption of neuro-symbolic models in robot task planning. Neuro-symbolic models excel in reasoning, providing explanations and manipulating complex data structures. Conversely, numerical models, such as neuronal models, are preferred for pattern recognition due to their generalization and learning abilities. A unified strategy proposes that the characteristic properties of symbolic artificial intelligence can emerge from distributed local computations performed by neuronal models, spanning cognitive functions from the neuron level to the structural level of the nervous system. By integrating neuro-symbolic and numerical models, a comprehensive framework can be established to leverage the strengths of both approaches in robotics. This integrated approach holds the potential to enable efficient task planning, grounding symbols in perceptual information, and enhancing pattern recognition capabilities. Ultimately, this integration could advance cognitive functions and pave the way for the creation of more sophisticated robotic systems.

This paper is organized as follows. Section II presents the proposed method which integrates the reinforcement learning (RL) and fuzzy logic for mobile robot path planning, aiming to create a robust autonomous navigation system that optimizes routes and efficiently avoids obstacles in complex environments. Section III illustrates the simulation set-up, while Section IV provides an evaluation of the training process of the policy optimization. Finally, Section V presents the evaluation and verification of the developed policy based on the proposed method, followed by the conclusion.

II. METHODS

The methodology for this project involves the utilization of simulation tools, namely Gazebo, ROS (Robot Operating System), and OpenAI Gym. Gazebo provides a realistic environment for simulating the mobile robot path planning system, while ROS serves as a comprehensive framework for controlling the robot and interfacing with its sensors and actuators. OpenAI Gym is used to train and evaluate the reinforcement learning algorithms. The main focus of this project is to apply reinforcement learning techniques to mobile robot path planning. Unlike traditional approaches that rely on SLAM or mapping techniques, the project aims to enable the robot to learn the optimal path through a reward and punishment system. By using reinforcement learning algorithms such as Q-learning, SARSA, and DQN, the robot can learn to navigate its environment efficiently and safely. To facilitate communication between the simulation and the robot, ROS integration is implemented. This integration allows the robot to receive sensor data, send control commands, and interact with the simulation environment seamlessly. By leveraging the capabilities of ROS, the reinforcement learning algorithms can effectively interface with the robot's actions and observations [15]–[17].The reinforcement learning algorithms receive feedback through a reward and punishment system based on the robot's performance in reaching the goal while avoiding collisions and obstacles. The training aims to optimize the robot's decision-making and path planning abilities. Performance analysis is conducted to assess the effectiveness of the trained reinforcement learning models. Metrics such as the time taken to reach the goal, collision occurrences with static and dynamic obstacles, and the number of pathing alterations are measured and analyzed. These metrics provide insights into the path planning efficiency, collision avoidance capabilities, and adaptability of the reinforcement learning approach. In conclusion, the methodology of this project involves using simulation tools (Gazebo, ROS, and OpenAI Gym) to evaluate the application of reinforcement learning algorithms (Q-learning, SARSA, and DQN) in mobile robot path planning. The integration of ROS ensures seamless communication between the simulation environment and the robot, while the OpenAI Gym environment provides a standardized framework for training and evaluating the algorithms. The methodology enables rigorous testing and analysis of the robot's performance in terms of path planning, collision avoidance, and adaptability to dynamic environments. This following subsection discusses the mathematical model of Q-learning with fuzzy logic approach theory towards navigation problems, and experimentation setup that is used in this work.

In the context of agents utilizing visual SLAM, traditional algorithms are still employed for final path planning on the map. However, RL offers numerous applications, and in mobile robot navigation, it can replace the path planning part. The RL model, after training, can effectively make decisions, enabling the agent to select its path from one location to another based on interactions with the environment [18], [19]. The environment is abstracted into a grid map representation, with each position on the map corresponding to an agent's state. Transitioning from one state to another reflects the actual movement of the entity, while the agent's behavioral decision-making is represented by its state choice at each step in the RL model. The reward value plays a pivotal role in guiding path selection. Early Q-learning recorded reward values between position states in a table, guiding the next state selection. As depth-enhanced learning emerges, the DL model is integrated, replacing the table with a neural network, which provides corresponding decision results by inputting the state [20], [21]. The weighting parameters in the neural network

influence the choice of the next state. On the other hand, when incorporating fuzzy logic into the RL model, the decision-making process becomes more nuanced and interpretable. Fuzzy logic allows for handling uncertainties and imprecise information, enabling the agent to reason with vague input and output values. By combining RL and fuzzy logic, the agent can make more human-like decisions, considering both the environment's precise measurements and the agent's subjective understanding of the surroundings. This fusion can enhance path planning in complex and dynamic environments by considering various factors and optimizing the decision-making process.

A. Q-Learning Algorithm

RL defines any decision maker as an agent and everything outside the agent as the environment. The agent aims to maximize the accumulated reward and obtains a reward value as a feedback signal for training through interaction with the environment. Beyond the agent (who perform actions) and the environment (which made of states), there are three major elements of a reinforcement learning system:

- Policy $\boldsymbol{\pi}$: It is to formalize an agent's decision and determine the agent's behaviour at a given time. A policy π is a function that maps between the perceived state and the action is taken from that state.
- Reward $\boldsymbol{r}$: The agent receives feedback known as rewards, r_{t+1} for each action at time step t, indicating the inherent desirability of that state. The main goal of the agent is to maximize the cumulative reward over time. The total sum of the rewards (return) is:

$$R_t = r_{t+1} + r_{t+2} + r_{t+3} + \ldots r_T,\ T\text{: final time step}$$

The agent-environment interaction breaks into episodes where each episode ends in a state called the terminal state, followed by a reset to a standard starting state. In some cases, the episodes continue where final time step would be $T = \infty$, and the return become infinite. So, a discount factor γ is introduced. The discounted return is defined as:

$$R_t = r_{t+1} + \gamma\, r_{t+2} + \gamma^2\, r_{t+3} + \ldots = \sum_{k=0}^{\infty} \gamma^k r_{t+k+1}$$

$$0 < \gamma < 1$$

Rewards can be sparse (after a long sequence of actions), every time step, or at the end of the episodes.

- Value function: Most of the RL algorithms are based on estimating value functions (states or state action). Value function is used to estimate how good a certain state is for the agent to be in (state value function), or how good a certain action is to perform in a specific state (state-action value function). The state value functions under the policy π, denoted $V\pi(s)$, is the expected return,

$$V^{\pi}(s) = E_{\pi}\{R_t | s_t = s\} = E_{\pi}\left\{\sum_{k=0}^{\infty} \gamma^k r_{t+1+k} | s_t = s\right\}$$

The state-action value function under policy π, denoted $Q^{\pi}(s, a)$, as the expected accumulated return from state s and action a. Q^{π} is also known as action value function or Q-Learning algorithm.

$$Q^{\pi}(s,a) = E_{\pi}\{ R_t | s_t = s, a_t = a\} = E_{\pi}\{\sum_{k=0}^{\infty} \gamma^k r_{t+1+k} | s_t = s, a_t = a\}$$

$$Q^{\pi}(s,a) = E\,[r_{t+1} + \gamma r_{t+2} + \gamma^2 r_{t+3} + \cdots | s, a\,]$$

Reinforcement learning is about finding an optimal policy that achieves a lot of reward over the long-term. A policy π is defined to be better than or equal to a policy π' if its expected return is greater than or equal to that of π' for all states.

$$\pi \geq \pi' \text{ if and only if } v^{\pi}(s) \geq V^{\pi'}(s), \text{for all states}$$

Optimal Value Functions must satisfy the below conditions:

$$V^*(s) = max\ V.(s), \text{ for all states}$$

$$Q^*(s, a) = maxQ.(s, a), \text{ for all states and actions}$$

We get the optimal policy by solving $Q*(s, a)$ to find the action that gives the most optimal state-action value function,

$$\pi^*(s) = arg \max_a Q^*(s,a)$$

Q-Learning algorithm is an off-policy value-based RL algorithm and very effective under unknown environment [6], [21], [22]. The value of a state-action can be decomposed into immediate reward plus the value of successor state-action $Q^{\pi}(s', a')$ with a discount factor (γ).

$$Q^{\pi}(s,a) = E_{s'a'}[r + \gamma Q^{\pi}(s', a') | s, a]$$

And according to the Bellman optimality, the optimal value function can be expressed as:

$$Q^*(s,a) = E_{s'a'}[r + \gamma \max_a Q^*(s', a') | s, a]$$

Update the value function iteratively to obtain optimal value function,

$$Q(s,a) \leftarrow Q(s,a) + \alpha.\,[r + \gamma \max a'\ Q(s', a') - Q(s,a)],$$

α: learning rate

$Q(s, a)$ converges to $Q^*(s, a)$ as $t \rightarrow \infty$.

Algorithm 1 illustrates the overall framework of the proposed Q-learning to generate the shortest route for navigation mapping.

Algorithm 1. Overall framework of the Q-Learning

```
Initialize Q (s, a) arbitrarily
repeat for each episode.
Initialize s.
  for each step of the episode do
    Choose a from s using € greedy policy.
    Do action a and observer r and s'
    Q(s, a) ← Q(s, a) + α. [r + γ max a'  Q (s', a') - Q (s, a)]
    s ← s'
  until s is terminal
```

B. Fuzzified Reward Function

The fuzzy logic-based approach has been adopted to enhance the decision-making [23], [24] process of the autonomous agent navigating through a maze. This work incorporated symbolic representation by adopting fuzzy logic into the reward function to guide the learning process and address the challenge of the computational demands of training. The proposed fuzzy reward function has three input variables and one output. The input variables are distance to obstacle (near, medium, far), distance to target (near, medium, far), and visual range (off target, medium, on target). The output variable is the reward points (see Fig. 4).

By employing three membership levels for each input variable (See Fig. 1, 2 and 3), a comprehensive set of 27 fuzzy rules has been devised (see Table I), effectively covering all possible combinations of the environment states. These rules dictate the agent's rewards, which are categorized as punishment (least), medium, and reward (most). By leveraging the flexibility and adaptability of fuzzy logic, the agent is guided through its learning process with a more nuanced and context-aware reward system, allowing it to make more informed decisions in a variety of maze scenarios and significantly improving its learning efficiency.

Table I presents a comprehensive and systematic overview of the fuzzy logic rules governing the agent's decision-making process in the maze navigation task. The table showcases the various combinations of input possibilities, encompassing distance with obstacles, distance with target location, and visual range, each categorized into appropriate linguistic variables (e.g., near, medium, far; off target, medium, on target). For every unique combination, the corresponding fuzzy logic "If/Then" rules are defined, determining the agent's rewards as punish, medium, or reward. Table I highlights the agent's adaptability and versatility through the vast array of rules, capturing the intricacies of different maze scenarios. With 27 distinct rules, the fuzzy logic system can precisely respond to the agent's real-time observations, guiding it towards optimal actions that lead to successful navigation. This rich and nuanced reward system empowers the agent to effectively learn from its experiences, enabling it to avoid obstacles, approach the target, and dynamically adjust its behavior based on varying visual cues. Consequently, the "If/Then Analysis Fuzzy Logic Rules Possibilities" table serves as a powerful tool in understanding and implementing the complex decision-making process of the agent, fostering efficient learning and successful maze navigation.

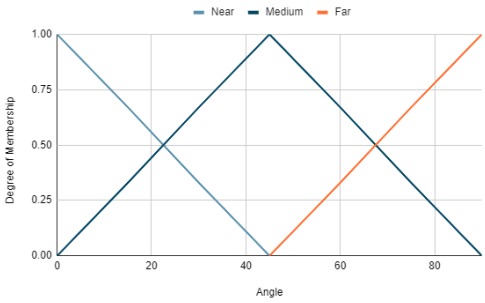

Fig. 1. Visual range.

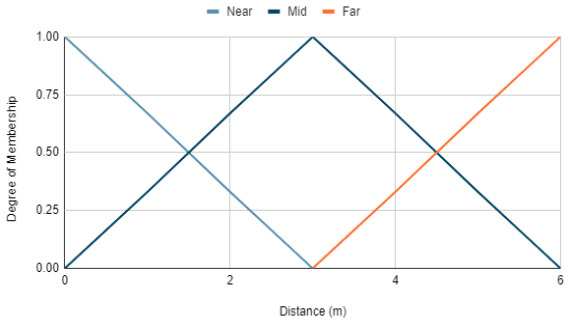

Fig. 2. Distance to target.

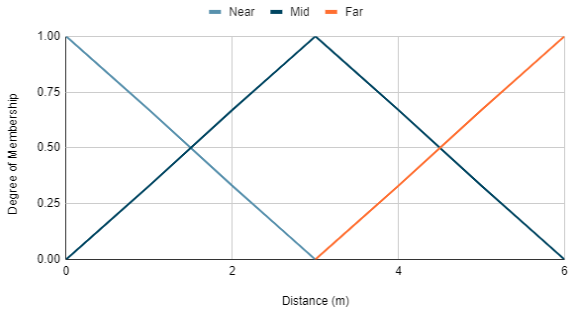

Fig. 3. Distance to obstacle.

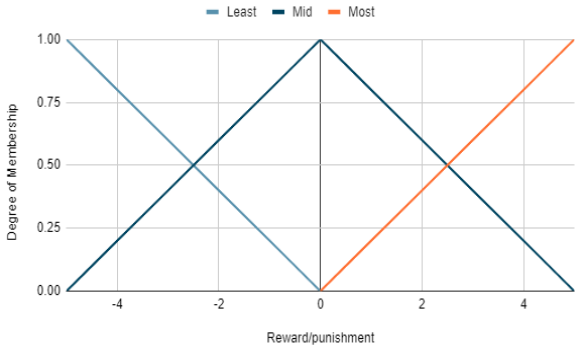

Fig. 4. Output fuzzy: reward points.

TABLE I. IF/THEN FUZZY LOGIC RULES FOR REWARDS

Distance	Visual Range	Obstacle (Near)	Obstacle (Medium)	Obstacle (Far)
Target (Near)	Near	High Positive	High Positive	High Positive
	Medium	Mid Positive	Mid Positive	Mid Positive
	Far	Low Positive	Low Positive	Low Positive
Target (Medium)	Near	High Middle	High Middle	High Middle
	Medium	Low Middle	Middle	Low Middle
	Far	Low Middle	Low Middle	Low Middle
Target (Far)	Near	Low Negative	Low Negative	Low Negative
	Medium	Mid Negative	Mid Negative	Mid Negative
	Far	High Negative	High Negative	High Negative

III. SIMULATION SETUP

To thoroughly evaluate the enhanced performance of the proposed method, this study embarked on constructing a detailed 3-D raster map model and crafting two distinct simulation maps, meticulously illustrated in Fig. 5(a) and Fig. 5(b). In this simulated environment, dynamic obstacles, symbolized by white cylinders, were strategically placed, posing challenges to a TurtleBot simulation machine car, visually presented in black. The machine car's laser range, portrayed in blue, scanned the surroundings as it navigated through the intricate maze. The red square pinpointed a target training point, emphasizing the complexity of the assigned tasks.

Fig. 5(a) specifically delves into a scenario where the TurtleBot is tasked with locating a singular target location represented by the red square amid a set of four cylindrical obstacles. This intricate setting simulates real-world challenges where the robot must efficiently identify and navigate towards a specific point among various hindrances.

Fig. 5(b) presents a more intricate scenario where the TurtleBot is assigned the mission of identifying two specific cylinders as target locations within a maze of block obstacles. This heightened complexity mirrors scenarios where the robot must discern and navigate through a maze-like environment to pinpoint multiple objectives. This detailed simulation environment allows for a comprehensive assessment of the proposed method's effectiveness in handling diverse and intricate navigation tasks.

The computer used for the simulations was equipped with a 4-core Intel i5 7400 CPU running at 3.00 GHz, 8 GB of RAM, running on the Ubuntu 16.04 operating system, and utilizing the ROS kinetic system. The article leveraged certain parameters for the 3-D environment model, which were sourced from the ROS open-source community. The corresponding parameter settings are as follows:

$$r_{goal} = 100,\ r_{obstacle} = -100,\ \varepsilon = -100,\ \sigma_x = \sigma_y = 1$$

$$\gamma_{goal} = 0.9,\ r_{obstacle} = 0.9,\ r_{critical} = 0.8,\ r_{otherwise} = 0.75$$

In the context of this work:

- " *r* " signifies a single reward.
- σ_x and σ_y represent the obstacle center coordinates.
- γ (gamma) serves as the discount factor, influencing the importance of future rewards.

In this context, *r* represents a reward, with r_{goal} and $r_{obstacle}$ being specific awards assigned to reaching the goal and encountering obstacles, respectively. The term γ serves as the discount factor, influencing the importance of future rewards in the context of reinforcement learning. The parameters ε, σ_x, and *and* σ_y represent the grid center coordinates, contributing to the spatial representation of the environment and the localization of obstacles.

IV. TRAINING PERFORMANCE OF THE PROPOSED METHOD

The visual representations in Fig. 5(a) and Fig. 5(b) aimed to illustrate the improved method's performance across different simulation maps. While these figures may not directly demonstrate capabilities, they serve as visual aids to showcase the distinct scenarios and complexities encountered by the agent in each environment. It's essential to acknowledge that the term "validation" in the context of comparing results from Reinforcement Learning (RL) and Fuzzy Logic (FL) approaches refers to a qualitative assessment rather than a formal validation process.

In Fig. 5(a), the experiment showcased the performance of the improved method on the first simulation map, providing insights into how the agent navigates a specific environment. On the other hand, Fig. 5(b) illustrated the capabilities of the improved method on the second simulation map, highlighting its adaptability to different scenarios. By comparing the results from RL and FL approaches, the article qualitatively validated the effectiveness of the enhanced technique in the complex 3-D environment. These visual representations offered a valuable qualitative assessment, helping to understand the

nuanced behaviors of the agent, its path planning strategies, and obstacle avoidance mechanisms in diverse settings. The improved method consistently demonstrated superior performance, efficiently finding optimal routes to reach the target point while navigating around obstacles effectively. The simulations offered valuable insights into the agent's behavior, path planning, and obstacle avoidance, elucidating fundamental aspects of autonomous robot navigation. The superior performance of the enhanced method was evident in its ability to navigate efficiently, choosing optimal routes while circumventing obstacles effectively.

Furthermore, the deliberate choice of Fig. 5(b) as a test run was made to rigorously assess the proposed method's robustness in scenarios with increased complexity and multiple target points. This strategic selection adds an additional layer of validation, demonstrating the algorithm's efficacy in handling intricate navigation tasks.

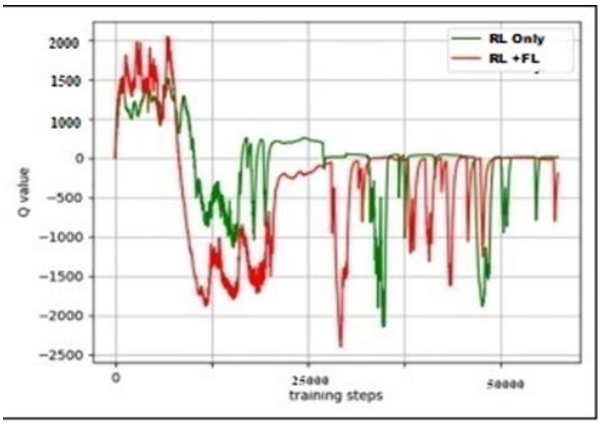

Fig. 7. Q-value comparison.

As shown in Fig. 7, in the Q-value map, the Fuzzy Logic (FL) example has a faster convergence speed, especially in 50 K training sessions, and after approximating 25 K trainings, the Q value of the FL algorithm is still richly transformed, showing the FL is less likely to fall into local optimum. This segment of our analysis offers a glimpse into the noteworthy performance attributes of the FL local search approach. As depicted in Fig. 8, which illustrates the bonus map, the FL example stands out due to its utilization of a multiple reward mechanism and a loop memory network. This distinction is most evident in the greater reward values attributed to the FL path, which correspondingly signify a reduced occurrence of repeated errors. In essence, a higher reward value in this context indicates a superior capacity to identify and follow an optimal path with fewer deviations. Turning our attention to Fig. 9, we delve into the loss diagram. Here, we observe a compelling trend: the loss associated with the FL example is consistently lower compared to that of the RL example. This finding is particularly significant, as it underscores the model's proficiency in minimizing error during the learning process. A lower loss value reflects a more accurate prediction and action selection by the model, emphasizing the effectiveness of the FL approach in optimizing path planning. To provide a closer examination of this phenomenon, Fig. 10 offers a magnified view of the loss diagram from Fig. 9. This detailed perspective reaffirms the rationality and effectiveness of the loss function employed in our model. The stability in parameter learning, particularly evident in the FL example, facilitates faster convergence to the optimal values. This not only enhances the efficiency of path planning but also showcases the model's robustness in navigating complex environments.

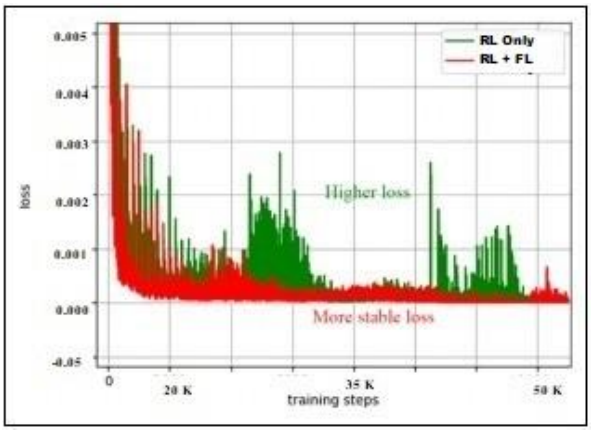

Fig. 10. Loss comparative enlarged view.

V. Evaluation and Verification of the Developed Policy

This work conducted three comprehensive tests to rigorously evaluate the performance of the proposed method. Each simulation aimed to assess the effectiveness of the respective algorithm in enabling the mobile robot to learn and navigate its environment autonomously.

To verify the practical performance of the model, physical tests were conducted on the robotic machine based on the robot operating system (ROS). The TurtleBot machine car was employed for these experiments to ensure consistency and reliability. The test environment comprised an obstacle zone constructed in the laboratory terrain, with the ideal distance from the starting point to the target point set at 8.3 meters. Fig. 5(a) and Fig. 5(b) depict the laser environment after its construction. It's important to note that the use of TurtleBot in these experiments is not meant to directly reduce errors in the algorithm. Instead, TurtleBot provides a standardized platform for testing, ensuring consistency and reliability across multiple trials. The choice of TurtleBot contributes to the creation of a controlled and reproducible testing environment, minimizing potential errors arising from variations in hardware and environmental conditions. This emphasis on error reduction pertains to the establishment of a robust and reliable basis for evaluating the proposed method's performance in real-world scenarios rather than directly mitigating errors in the algorithm or system. Following the integration of the trained model into the navigation function package, a meticulous series of verification tests was carried out to assess its performance. Each testing round consisted of five restarts, with three experiments conducted within each round to ensure the robustness of the evaluation process. For instance, in the first round of experiments, the robot's performance was tested through three individual trials: the first trial covered a distance of 8.8 meters in 77 seconds; the second trial covered 9.0 meters in 78 seconds, and the third trial spanned 8.6 meters in 73 seconds. By calculating the mean of these results, we obtained an average performance of 8.8 meters covered in 76 seconds.

Table III presents the detailed results of the first round, where the robot covered distances of 8.8 meters in 65 seconds, 8.6 meters in 53 seconds, and 8.7 meters in 56 seconds during the three tests. The calculated mean for Table II was 8.7 meters covered in 58 seconds. Notably, Table II exhibited a higher learning rate compared to Table II, indicating improved efficiency in path planning and execution.

TABLE II. The Example of RL Algorithm

Examples	**length/time**			
	Test 1	Test 2	Test 3	Mean
First Round	8.8 m/77 s	9.0 m/78 s	8.6 m/73 s	8.8 m/76 s
Second Round	9.3 m/86 s	9.1 m/83 s	8.9 m/74 s	9.1 m/81 s
Third Round	8.9 m/68 s	8.6 m/63 s	9.2 m/70 s	8.9 m/67 s
Fourth Round	9.1 m/78 s	8.9 m/73 s	8.7 m/71 s	8.9 m/74 s
Fifth Round	9.2 m/80 s	9.2 m/77 s	8.6 m/77 s	9.0 m/78 s

TABLE III. The Example of Reinforcement Learning with Fuzzy Logic Algorithm

Examples	**Length/Time**			
	Test 1	**Test 2**	**Test 3**	**Mean**
First Round	8.8 m/65 s	8.6 m/53 s	8.7 m/56 s	8.7 m/58 s
Second Round	8.8 m/63 s	8.9 m/69 s	8.7 m/60 s	8.8 m/64 s
Third Round	8.7 m/66 s	8.7 m/70 s	8.5 m/68 s	8.6 m/68 s
Fourth Round	8.7 m/73 s	8.8 m/65 s	8.6 m/66 s	8.7 m/68 s
Fifth Round	8.4 m/71 s	8.7 m/73 s	8.4 m/69 s	8.5 m/69 s

The overarching analysis of these comprehensive tests reveals that the Fuzzy Logic approach consistently outperforms other methods in terms of both time consumption and path length, particularly in the scenario represented in Fig. 5(b). It consistently finds shorter paths in less time, highlighting its superior efficiency. Additionally, the Fuzzy Logic method demonstrates remarkable stability in locating multiple paths, underscoring its prowess in complex environment path-finding.

However, it's important to acknowledge certain limitations associated with the Fuzzy Logic-based approach. While it excels in various aspects of path planning, it may face challenges when confronted with highly dynamic and rapidly changing environments. Fuzzy Logic, being rule-based and reliant on predetermined membership functions, might struggle to adapt swiftly to unpredictable obstacles or situations. Additionally, its performance could be impacted by the complexity and size of the environment, as processing a vast amount of data can introduce computational overhead.

Therefore, while the Fuzzy Logic approach proves highly effective in many scenarios, it may not be the optimal choice for applications demanding real-time adaptability in extremely dynamic settings. Exploring its boundaries and considering alternative approaches for such specific scenarios remains a valuable avenue for future research and development.

VI. Conclusion

This research introduced a novel navigation method based on Q- learning and fuzzy logic for efficient path planning of agents in diverse environments. The proposed approach combines the strengths of deep learning with symbolic reasoning, specifically Fuzzy Logic, to overcome the challenges faced by traditional DRL methods in mobile robot navigation, reducing the global path search time by 6-9% and shortening the average path search length by 4-10% compared to pure Q-learning. The incorporation of symbolic representations in the learning process leads to reduced training convergence time and more practical path planning results. The experimental results demonstrate its efficiency and effectiveness in complex environments, making it a promising solution for autonomous robotic navigation in urban megacities. As future work, the effectiveness of new RL algorithms will be explored in even more challenging environments, further advancing the field of autonomous robotic navigation.

***Abstract*—To address the challenges of insufficient multimodal information fusion and insufficient long-range dependencies features extraction for brain tumor segmentation, this paper propose a novel network based on asymmetric encoder and multimodal cross-collaboration. The network employs an asymmetric encoder-decoder architecture. Firstly, the invert ConvNext split convolution (ICSC) block is used in the local refinement encoder and improved SwinTransformer with DscMLP enhancements (DscSwinTransformer) module is used in global associative encoder. The local and long-range dependencies of each stage of two parallel encoders can be well extracted by hybrid fusion. Moreover, this paper adds a multimodal cross-collaboration (MCC) module at the beginning of the two encoders to fully exploit the complementary information between modalities and reduce the reliance on a single modality during model training. Coordinate Attention (CA) is used in the bridge part of the encoder and decoder to capture important spatial location information. Then, the depthwise separable convolution (DscConv) module is used in the decoder branch to reduce the computation while maintaining good feature extraction ability. Finally, this paper uses a hybrid loss function of BCE, Dice and L2 loss to mitigate the problem of class datas imbalance. Experimental results show that our model achieves Dice coefficients of 0.897, 0.905 and 0.824 in the whole, core and enhanced tumor regions, respectively. These results show that the performance of our proposed method outperforms in comparison with several existing methods in core and enhanced tumor regions.**

***Keywords*—Brain tumor; multimodal cross-collaboration; asymmetric encoder; coordinate attention**

I. Introduction

A brain tumor is a mass or cluster of aberrant cells in the brain that impairs brain tissue function. Brain tumors are primarily classified as malignant or benign [1]. Malignant brain tumors are one of the most severe cancers at present, posing an increasing threat to human health. Brain tumors are classified as I-IV by the World Health Organization. Because the higher the grade of the brain tumor, the shorter the patient's survival time [2-3], early detection and treatment of brain tumors is critical. However, because the shape, size, location, and border of MRI images from various brain tumor patients vary, it is difficult to properly segment the brain tumor area. Manual segmentation of brain tumors by doctors is very time-consuming and inconsistent among different doctors for the same patient, while automatic segmentation techniques based on brain tumor MRI images can automatically locate and segment the shape, position and boundary of the brain tumor area, thus assisting doctors in diagnosing patients' conditions and alleviating their workload. Therefore, the research of brain tumor segmentation algorithm has significant scientific value and clinical relevance for efficient diagnosis of brain tumors.

At present, most segmentation networks do not properly use multi-modal complementary information. This study proposes a multi-modal cross-coordination feature fusion module, which reduces the feature dependence on a single mode and obtains rich context information of different modal complementary information. In order to obtain long-range dependencies information while extracting local feature information, this paper uses dual encoders to obtain spatial and coordinate attention information at different stages. In this paper, the mixed loss function is further designed to alleviate the problem of class imbalance in brain tumor data sets, so that the model can effectively segment different types of brain tumor regions.

II. Related Work

With the advancement of deep learning technologies, convoluted neural networks have emerged as the primary way for diagnosing brain tumor locations. U-net [4] is a typical segmentation network based on the encoder-decoder structure. Later, the Unet-type structure was further developed, such as Unet++ [5] with nested and densely connected structures, DenseUnet [7] that combines DenseNet [6] network and U-net, and Vnet [8] structure for volumetric segmentation. Convolutional neural networks can capture local features, but they have difficulty in modeling explicit long-range dependencies from the global feature space.

However, Local and global features are essential for dense prediction tasks. Vision Transformer [9] leverages self-attention mechanism to model long-range information, enabling CNN hybrid Transformer to fuse and extract local and distant features effectively. In this regard, TransBTS [10] network is proposed, which incorporates Transformer into the 3D CNN encoder-decoder architecture for the first time, enhancing global feature extraction. TransBTSV2 [11] further improves TransBTS by redesigning the Transformer module

and introducing deformable bottleneck module to capture shape-sensitive local features. SwinBTS [12] structure employs 3D SwinTransformer as both encoder and decoder of the network to extract global information from feature maps efficiently, using convolution operation for upsampling and downsampling. Unetr [13] network connects the Transformer encoder to the decoder with different resolutions through skip connections, capturing global multi-scale information more effectively.

Moreover, different brain tumor regions have large scale differences, and the receptive field of ordinary convolution is not enough to extract rich contextual feature information. In this regard, Liu et al. [14] proposes a lightweight ADHDC-Net network that combines hierarchical convolution with different dilation rates and tumor region relation-guided attention; Chang et al. [15] proposes a dual-path and multi-scale attention fusion module that merges feature maps with different receptive fields for dense pixel prediction; Rehman et al. [16] designs SDS-MSA-Net, which extracts features from 3D and 2D inputs separately, and uses selective depth supervision to assist the output, accelerating the model convergence speed, but at the same time processing 3D and 2D resources increases the computational cost. The above improved structures enhance the extraction ability of global features and multi-scale attention features respectively, but most of the current networks are limited to simple concatenation fusion of multi-modal brain tumor data input level, which cannot fully utilize the complementary fusion information between different modalities. Therefore, Liu et al. [17] designs a two-stage network that performs pixel-level fusion and feature-level fusion of multi-modal images to achieve more fine-grained utilization of multi-modal information; Zhou et al. [18] proposes an attention feature fusion module that can fuse different modalities and selectively extract useful feature information, but the core of the above networks still needs to improve the segmentation accuracy of the enhanced tumor region.

To solve the aforementioned challenges, our study offers an asymmetric encoder and multimodal cross-collaboration brain tumor segmentation network (AEMCCNet). This paper's primary contributions are summarized as follows:

1) This paper proposes an asymmetric encoder-decoder structure, where parallel local refinement encoder and global associative encoder use redesigned invert ConvNext split convolution (ICSC) block and improved SwinTransformer [19] with DscMLP enhancements (DscSwinTransformer) module respectively, which can effectively capture the fusion information of local details and long-range dependencies features in three stages of the encoder.

2) To reduce the model's dependence on a single brain tumor modality during training, this paper proposes a multimodal cross-collaboration (MCC) module, which can fully utilize the complementary information between modalities.

3) To obtain more accurate segmentation results, this paper uses coordinate attention (CA) Module [20] in AEMCCNet, which encodes the channels along horizontal and vertical directions. This transformation can capture remote features along one spatial direction and preserve precise location information along another direction, which is very important for generating spatial detail selective information.

4) To tackle the class imbalance issue, this paper employs a hybrid loss function composed of binary cross entropy, Dice, and L_2, which enhances brain tumor segmentation accuracy even further.

III. Methodology

A. AEMCCNet Network

The overall architecture of the brain tumor segmentation network based on asymmetric encoder and multimodal cross-collaboration proposed within this study is seen in Fig. 1.

The network model is an asymmetric encoder-decoder structure, where T1 and T1ce modalities are the inputs of the local refinement encoder; T2 and Flair modalities are the inputs of the global associative encoder. Both the local refinement encoder and the global associative encoder first use MCC module designed in this paper to fully learn the cross-modal features and reduce the model's dependence on a single modality [21]. Then this paper uses the ICSC Block and DscSwinTransformer module designed in this paper respectively, and the parallel dual-stream encoders fuse with each other at each stage, increasing the link throughout low-level detail features and high-level semantic features. Moreover, CA module is applied to the fused feature maps along two dimensions of MRI images to aggregate features, model long-range dependencies and channel transformation, and enhances the extraction of useful information while suppressing the influence of invalid information on tumor segmentation performance. Finally, depthwise separable convolution (DsConv) [22] is used in the decoder module to acquire the semantic details of the fusion information obtained from asymmetric dual-stream encoder and low-level decoder modalities.

B. MCC Module

To reduce the dependence on a single brain tumor modality during the model training process, and to better utilize the complementarity between T1, T1ce modalities and T2, Flair modalities to cross-extract features, this paper designs a MCC module, as shown in Fig. 2.

First, modality A and modality B separately go through 7×7 channel-by-channel convolution (DwConv) to obtain rich context information of a single modality, and then cross-multiply with the features of another modality after 1×1 convolution to obtain y_{11} and y_{21}, respectively, as shown in Eq. (1) and Eq. (2), to extract recognizable features from one modality to assist in correcting another modality;

$$y_{11} = \mathrm{Dw7\times7}(B) \otimes \mathrm{Conv1\times1}(A) \tag{1}$$

$$y_{21} = \mathrm{Dw7\times7}(A) \otimes \mathrm{Conv1\times1}(B) \tag{2}$$

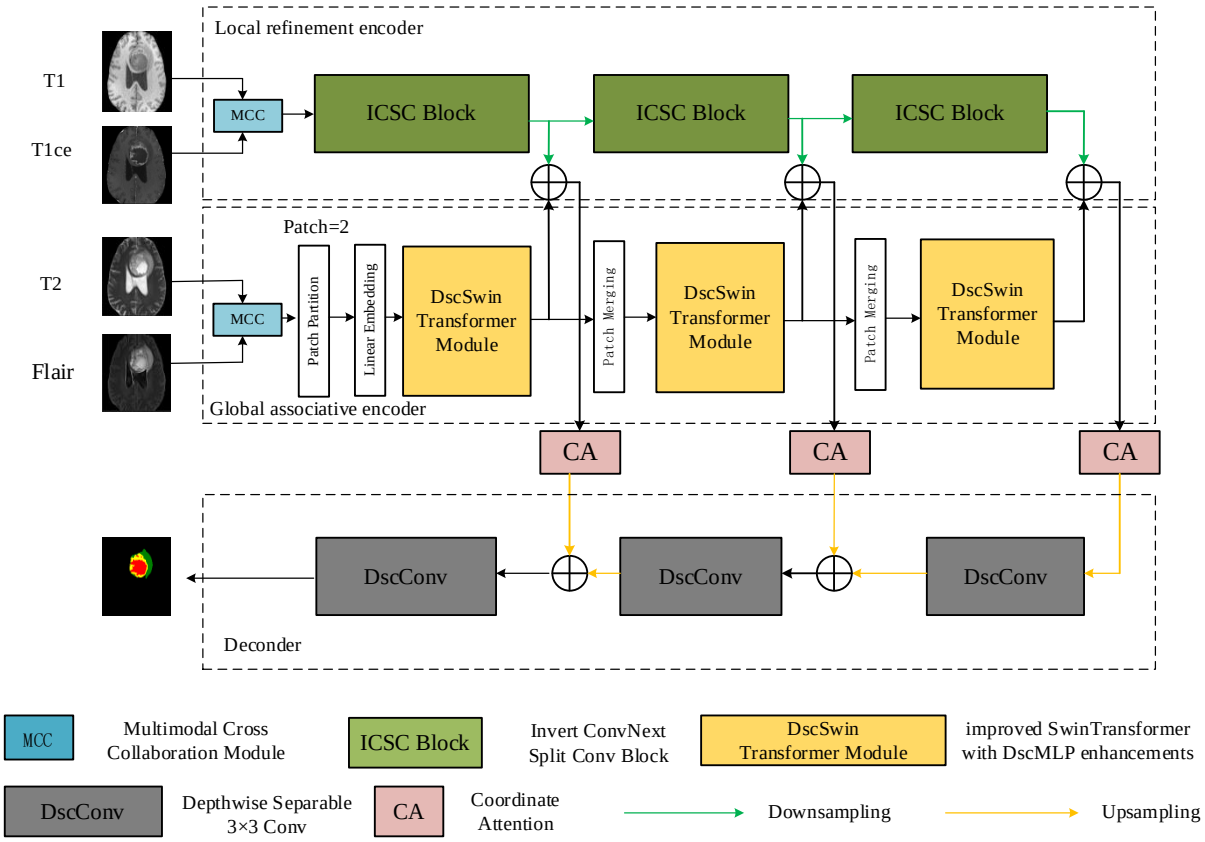

Fig. 1. Overall architecture of proposed AEMCCNet.

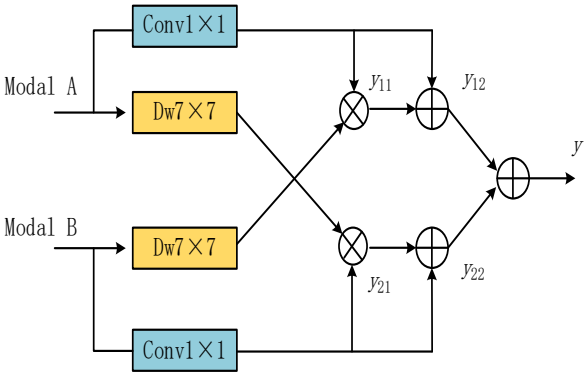

Fig. 2. Structure of a MCC module.

Then, the features of the same modality after 1×1 convolution are added and fused with the cross-fused features to generate the feature maps y_{12} and y_{22}, as stated in Eq. (3) and Eq. (4).

$$y_{12} = y_{11} + \text{Conv1}\times1(A) \tag{3}$$

$$y_{22} = y_{21} + \text{Conv1}\times1(B) \tag{4}$$

Finally, the branch modality features $y_{12}$and y_{22} are element-wise added and fused to generate the output feature map y of the module, as illustrated in Eq. (5).

$$y = y_{12} + y_{22} \tag{5}$$

C. ICSC Block

As shown in Fig. 3(a), MobileNetV2 [23] swaps the order of convolutional dimensionality increase and decrease in the Inverted Residuals structure, uses depthwise separable convolution to reduce the computational cost, and enhances the nonlinear expression ability of the network. As shown in Fig. 3(b), ConvNext Block [24] inherits the feature of wide convolutional dimension in the middle layer of Inverted Residul, and sets the depthwise separable convolution kernel size to 7×7, Padding=3. This paper draws on the advantages of these two modules and redesigns the ICSC Block of channel-split, as shown in Fig. 3 (c).

The input feature map of this module is $X \in R^{C\times H\times W}$,, where C is the number of channels. First, X is split into two $C/2$ branches X_{11} and X_{21} along the channel dimension. The left branch X_{11} uses 7×7 depthwise separable convolution to extract rich spatial context information, and then uses two 1×1 convolutions to increase and decrease the dimension respectively, obtaining the feature map X_1. The right branch X_{21} first uses 1×1 convolution to reduce the dimension, then uses 3×3 depthwise separable convolution to extract spatial rich information and increase the dimension, and then uses 1×1 convolution to reduce the dimension again, obtaining the feature map X_2. Then, the outputs of the two branches are concatenated and fused along the channel direction. Finally, the fused feature map is added with the original input feature map by identity connection to obtain the output feature map y of this module as shown in Eq. (6) to Eq. (8).

$$X_1 = Conv1(g(Conv1[L(Dw7(X_{11}))])) \quad (6)$$

$$X_2 = Conv1(Relu6(Dw3[B(Conv1(X_{21}))])) \quad (7)$$

$$Y = X + [X_1, X_2] \quad (8)$$

where, *DW7*() is a channel-wise convolution with a kernel size of 7×7, *Conv1*() is a convolution with a kernel size of 1×1, *L* is LN normalization operation, *B* is BN normalization operation, *g*() is gelu() activation function, *Relu6* is activation function, [·] is channel-wise concatenation and fusion.

D. DscSwinTransformer Module

Encoder-decoder structure based on CNN lacks the ability to capture long-range dependencies features, while lightweight SwinTransformer Block uses sliding window self-attention mechanism to capture global dependencies features information. In SwinTransformer Block [19], the multilayer perception (MLP) uses two fully connected layers for dimension transformation, but using fully connected layers in image segmentation causes partial segmentation information loss.

Inspired by the above content, this paper replaces the multilayer perception (MLP) in DscSwinTransformer Module with the designed depthwise separable perception (DscMLP), which can further refine the context information and improve the nonlinear transformation of features. As shown in Fig. 4, DscMLP takes the feature X after self-attention W-MSA, sliding window self-attention mechanism SW-MSA, and reshapes the shape of the feature map *X* first from [B, H×W, C] to X_1 in [B, C, H, W] dimensions, where B, C, H, and W are the batch size, the number of channels, the height, and the width, respectively, of the model training settings; Then it applies depthwise separable convolution and identity connection on X_1 in parallel respectively, and performs element-wise multiplication on the two-branch results; finally it reshapes the feature dimension to [B, H×W, C] dimension output feature map *Y*.

The DscSwinTransformer Module is used in the three stages of the global associative encoder, and the repetition number of SwinTransformer in each stage is 1; before the first stage the output feature map $y \in R^{C\times H\times W}$ of the multimodal cross-collaboration module is partitioned into *M* patches of size *P*×*P*,*P*=2 in the Patch Partition module, and each patch is reshaped into a one-dimensional vector $y_p \in R^{M\times(P\times P\times C)}$, then these patches are flattened along the channel direction and mapped to *D* dimensions by the Linear Projection module $E \in R^{(P\times P\times C)\times D}$, while adding a learnable position variable $E_{pos} \in R^{(P\times P\times C)\times D}$ to obtain the feature *z*, as shown in Eq. (9):

$$z = y_p E + E_{pos} \quad (9)$$

In the DscSwinTransformer Module, layer normalization (LN) is first used and residual connection is performed on W-MSA, SW-MSA, DscMLP, as shown in Fig. 4, the above process can be expressed as.

$$\hat{Z}^k = W - MSA(LN(Z^{k-1})) + Z^{k-1} \quad (10)$$

$$Z^k = DscMLP(LN(\hat{Z}^k)) + \hat{Z}^k \quad (11)$$

$$\hat{Z}^{k+1} = SW - MSA(LN(Z^k)) + Z^k \quad (12)$$

$$Z^{k+1} = DscMLP(LN(\hat{Z}^{k+1})) + \hat{Z}^{k+1} \quad (13)$$

To generate 2x downsampling, between the DscSwinTransformer modules use patch merging to increase dimensionality and decrease token numbers.

Fig. 3. Comparison of Convolutional Blocks from left to right as (a) InvertedResidual Block, (b) ConvNeXt Block, (c) ICSC Block.

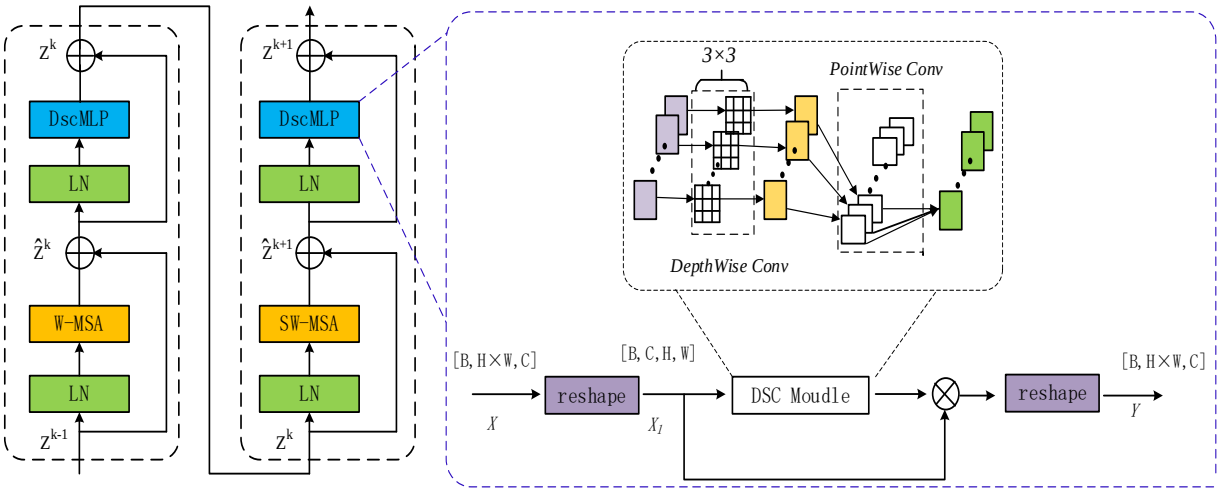

Fig. 4. Structure of DscSwinTransformer module.

E. CA Module

In deep network segmentation models, such as SE attention and CBAM attention, it has been proven that they can significantly enhance channel attention and spatial attention weights, and promote the model's segmentation performance, but they typically ignore positional details, which is vital for creating selective spatial features. Therefore, this paper introduces CA module [20], which embeds positional information into channel attention, as shown in Fig. 5.

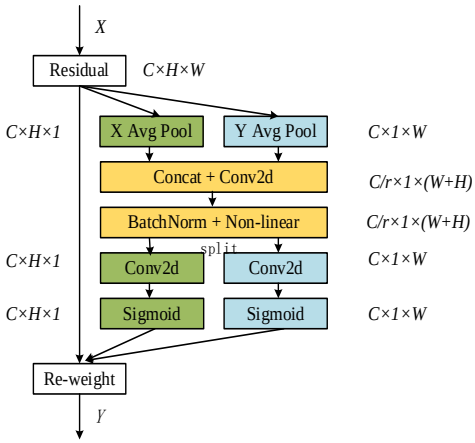

Fig. 5. Structure of CA module.

Coordinate information embedding alongside coordinated attention generation make up the two sections of the CA module. The coordinate details embedding implies encoding the input feature map *X* along both vertical and horizontal axes, respectively, using pooling kernels of shapes (H, 1) and (1, W) within the channels, to create two-dimensional feature maps that can capture distant features through one spatial direction and retain accurate positioning data along the other. Eq. (14) and Eq. (15) illustrate this:

$$Z_c^h(h)=\frac{1}{W}\sum_{0\le i\le W}X_c(h,i) \tag{14}$$

$$Z_c^w(w)=\frac{1}{H}\sum_{0\le j\le H}X_c(j,w) \tag{15}$$

where, $Z_c^h(h)$ is a result of the *C*th channel with height *h*, and $Z_c^w(w)$ is similarly.

The second transformation is the generation of CA module. First, $Z_c^h(h)$ and $Z_c^w(w)$ are concatenated, and then a 1×1 convolution function *F* and the feature mapping *f* of spatial data within multiple directions was extracted using an activation function that is nonlinear, as shown in Eq. (16).

$$f=\delta(F([Z^h,Z^w])) \tag{16}$$

Then *f* is decomposed into a pair of distinct tensors $f^h\in R^{C/r\times H}$ and $f^w\in R^{C/r\times W}$, and the convolution function F is used to transform them into tensors with the identical number of channels just like the input *X*, and the function of Sigmoid activating is utilizing to derive the attention weights g^h and g^w on two directions respectively. Ultimately, the module's initial feature map multiplies element by element with the two separate attention weights to yield the module's output *Y*, as indicated in Eq. (17) to Eq. (19).

$$g^h=\sigma(F(f^h)) \tag{17}$$

$$g^w=\sigma(F(f^w)) \tag{18}$$

$$Y(i,j)=X(i,j)\cdot g^h(i,j)\cdot g^w(i,j) \tag{19}$$

IV. Experimental Settings

A. Dataset

This paper uses the dataset from the Brain Tumor Segmentation (BraTS) competition in 2019, which contains 76 cases of low-grade glioma and 259 cases of high-grade glioma. This paper divides the training and testing data of the BraTS2019 dataset according to a ratio of 8:2. The

segmentation results are evaluated by the performance indicators of the whole tumor region (core tumor region and edema region), core tumor region (enhanced tumor region and necrosis region) and enhanced tumor region.

B. Data Preprocessing

Since training with 3D format images takes a long time and requires better GPU and more memory, this paper chooses to use 2D slices to train the proposed network. The size of the 3D data for each modality is 240×240×155. Since there is a lot of useless background information on the outer edge of the brain tumor data, which causes the problem of data class imbalance, this paper first crops the spatial size of the 3D data to 160×160×155 to eliminate the useless spatial background information, and then slices the data along the channel direction, transforming the 3D data into 155 slices of 160×160 2D slices to meet the needs of the model training in this paper.

Due to different imaging mechanisms, different modalities have different image contrast, so normalization is used to make the data intensity of different modalities balanced, which is conducive to the model using complementary information between different modalities. The normalization operation is shown in Eq. (20):

$$z = \frac{x - \bar{x}}{\lambda} \tag{20}$$

In the above equation, x is the cropped 2D sliced image, $\bar{x}$ is the mean value of the input image, λ is the standard deviation of the input image, and z is the normalized image.

As shown in Fig. 6, the images of four modalities and the ground truth label of a slice of a case after preprocessing in this paper are shown from left to right as (a) T1, (b) T1ce, (c)T2, (d) Flair and (e) Ground truth (GT) label. In the network model prediction image and the ground truth label, green represents edema tumor region, yellow represents enhanced tumor region and red represents necrosis and non-enhanced tumor region.

C. Experimental Environment Configuration

The software version is PyTorch 1.11.0 with Cuda 11.3, and the hardware environment consists of a 32 core CPU processor, 30GB RAM, and a GPU with NVIDIA RTX A5000, 24GB video memory. To update the model weights, this paper utilizes the Adaptive Moment Estimation (Adam) algorithm [25] as the optimizer; the detailed training experiment configuration is shown in Table I.

D. Evaluation Metrics

Four distinct assessment standards are employed to assess the segmentation accuracy of the model in this study to evaluate the how effective the suggested model algorithm. As described in Eq. (21), the Dice similarity coefficient is a value between 0 and 1. The closer to 1, the more similar the brain tumor segmentation result is to the manual label result, and the better the segmentation effect.

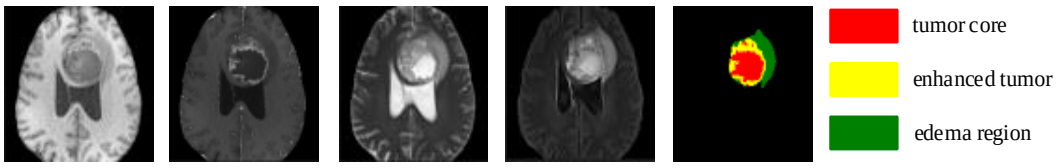
$$Dice = \frac{2TP}{2TP + FP + FN} \tag{21}$$

Sensitivity is a measure of the model's ability to predict positive pixels. Precision is used to measure the ability of the model to correctly predict pixels. As shown in Eq. (22) and Eq. (23).

$$Precision = \frac{TP}{TP + FP} \tag{22}$$

Where TP stands for true positive pixels, FN represents for false negative pixels, FP means for false positive pixels, and TN indicates for true negative pixels.

$$Sensitivity = \frac{TP}{TP + FN} \tag{23}$$



(a) T1 (b) T1ce (c) T2 (d) Flair (e) GT

Fig. 6. Images after data preprocessing. from left to right as (a) T1, (b)T1ce, (c) T2, (d) Flair and (e) GT label.

TABLE I. EXPERIMENTAL CONFIGURATION

Configurations	Values
Software version	PyTorch11.0
GPU	NVIDIA RTX A5000
Optimizer	Adam
Initial learning rate	0.003
Momentum	0.09
Weight decay coefficient	0.00001
Batch szie	24
Tranning Epoches	300

To calculate the distance between the model segmentation border and the real label boundary, the Hausdorff distance (HD) has utilized, the higher the segmentation precision, the lower the Hausdorff distance. Eq. (24) shows the calculation formula.

$$Hausdorff = \max\left\{\max_{x\in X}\min_{y\in Y} d(x,y), \max_{y\in Y}\min_{x\in X} d(x,y)\right\} \quad (24)$$

Here y represents GT and x represents the predicted segmentation result, $d(x,y)$ is the Euclidean distance between x and y. In this paper, HD95 is used in the evaluation, which means taking the 95th percentile result.

E. Hybrid Loss Function

As indicated in Eq. (25), binary cross entropy (*BCE*) is often utilized as a loss function for performing segmentation operations for various medical data sets.

$$L_{BCE} = -\frac{1}{N}\sum_{i=1}^{N}\left[y_i \log(p_i) + (1-y_i)\log(1-p_i)\right] \quad (25)$$

Where N denotes the overall amount of output pixels, y_i means the la-bel value for the ith pixel, and p_i defines the model prediction value for the ith pixel. Since the BCE loss function assigns equal weights to foreground and background pixels, but there is a large difference in the proportion of foreground and background pixels in multimodal brain tumors, and foreground pixels account for only a minority, there is a problem of data class imbalance. This study applies the *Dice* loss function to the *BCE* loss function to overcome the problem of data class imbalance, as seen in Eq. (26):

$$L_{\text{Dice}} = 1 - \frac{2\sum_{i}^{N} p_i y_i + \varepsilon}{\sum_{i}^{N} p_i + \sum_{i}^{N} y_i + \varepsilon} \quad (26)$$

The value given by the parameter has been set to 10^{-6} to ensure data stability. In addition, overfitting is prone to occur during the training of the model, so based on this L_2 loss is introduced to alleviate the overfitting problem during the training of the model, which is advantageous to network convergence. The L_2 loss function is shown in Eq. (27):

$$L_2 = \frac{1}{N}\Sigma_i^N \left(y_i - p_i\right)^2 \quad (27)$$

In summary, the hybrid loss function in this paper is shown in Eq. (28):

$$L = L_{\text{Dice}} + \alpha L_{\text{BCE}} + \beta L_2 \quad (28)$$

The approach of controlling hyperparameters is applied in this paper to evaluate the most effective settings. The variation range of hyperparameters α and β values is shown in Table II

First, β is set to 0 to test the best hyperparameter α. As shown in Fig. 7, the fluctuation range of α is between 0 and 1. When α is 0.5, the model in this work hits the peak point in the whole tumor (WT), core tumor (TC), and enhanced tumor (ET) regions, implying that its predictive ability is best at this time.

On this basis, the experimentation of the optimal superparameter β was continued, as shown in Fig. 8, where the fluctuation of β ranges from 0 to 0.1 spacing. The Dice coefficient of this paper's model on WT, TC and ET regions reaches 0.897, 0.905 & 0.824 when the finalized parameter α is 0.5 and β is 0.05, and the prediction performance of this paper reaches the best.

The best hyperparameters α=0.5 and β=0.05 are substituted into the hybrid loss function. When the model training iteration number is 295 rounds, as illustrated in Fig. 9, the model's training and validation loss values tend to be optimum.

F. Ablation Experiment

To evaluate the efficacy of the design along with addition of modules in this study, under the same experimental conditions of using the same loss function and parameters, this paper replaces the original 3×3 convolution module of the encoder-decoder structure with depthwise separable convolution, which serves as the Baseline structure of our model. This paper adds different modules to the Baseline structure, and Table III displays the outcomes. Where MCC stands MCC module, ICSC represents ICSC block CA indicates CA module and DscSwinT represents DscSwinTransformer Module. By incorporating the MCC module to the first layer of the encoder before entering the Baseline, the Dice values of the whole tumor, core tumor and enhanced tumor regions in the model increase by 0.6%, 0.9% and 1.5%, respectively. Based on Baseline, using the ICSC block, the performance of the model in the WT, TC and ET regions is further improved. Similarly, based on Baseline, using the DscSwinTransformer to obtain the accuracy indicators of the ET and TC regions are significantly improved. Based on Baseline, adding CA module, the Dice indicators of the WT and TC are significantly improved.

TABLE II. VARIATION RANGE OF HYPERPARAMETERS

Hyperparameters	Variation Range
α	Between 0 and 1
β	Between 0 and 0.1

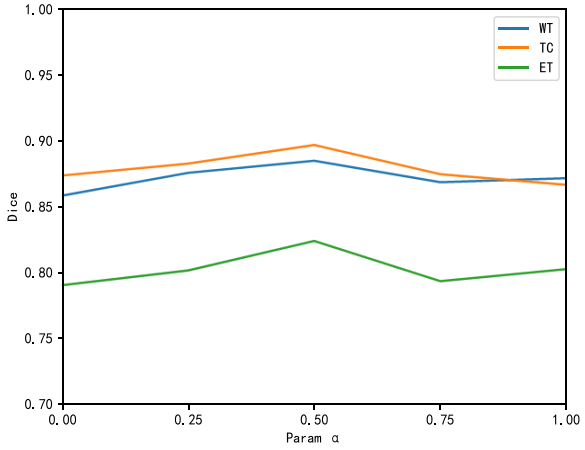


Fig. 7. Effect of hyperparameter α on model performance.

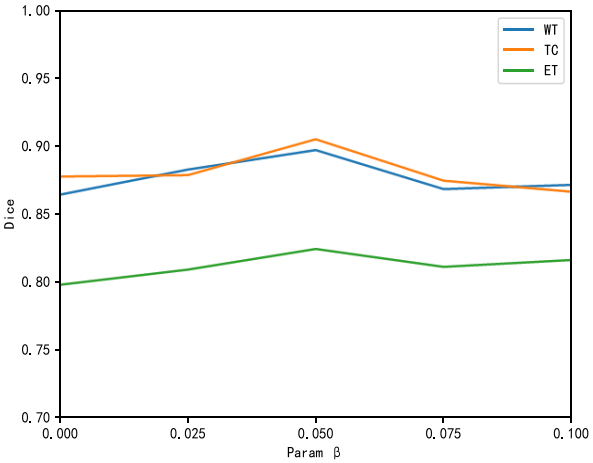

Fig. 8. Effect of hyperparameter β on model performance.

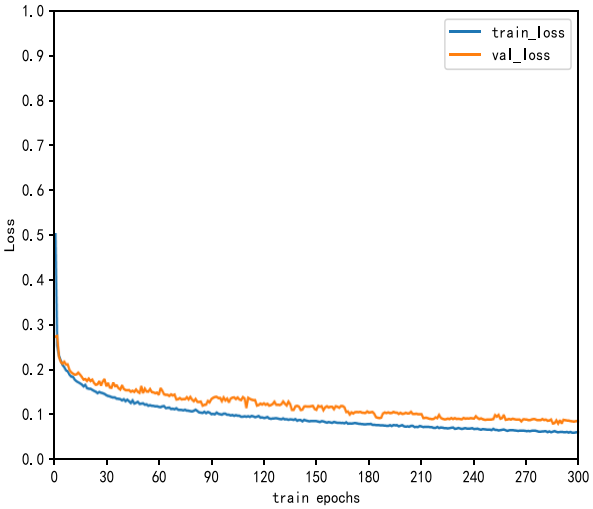

Fig. 9. Model training Loss variation.

Finally, this paper integrates the modules designed and used above into our structure. Compared with the Baseline structure, the Dice values of the WT, TC and ET increase by 5.1%, 5.3%, 6%, respectively. The hausdorff distance values of the three types of tumors are also the lowest values for ablation comparison experiments, proving the effectiveness of this method.

To test the effectiveness of adding different attentions to the bridging part between the asymmetric dual-stream encoder and decoder, this paper compares the CA module mechanism with SE [26] channel attention, CBAM [27] channel spatial attention, and ECA [28] efficient channel attention, respectively, as shown in Fig. 10 (a) and Fig. 10(b). After using the improved CA module in the decoder branch, the Dice similarity coefficient and HD95 of the model reach the best.

G. Experimental Results

To further verify the effectiveness of our method for multimodal brain tumor MR image segmentation, this paper uses part of the BraTS2019 dataset as the test set to compare with other advanced methods, and the results are shown in Table IV.

Compared with the classic 2D U-net and Unet++ networks, our model has a significant performance improvement in the whole, core and enhanced tumor regions. When compared with the advanced 3D models TransBTSV2, SwinBTS and MBANet, the 3D models have an advantage in segmenting the whole tumor due to their spatial continuity, but our 2D model uses DscSwinTransformer Module to strengthen the extraction of long-range dependencies features, making the Dice value of the whole tumor region close to the advanced 3D segmentation methods, and having the most optimal values in the overall evaluation indicators.

Finally, this paper segments some samples from the BraTS2019 test dataset and compare them with the input images and segmentation results as shown in Fig.11, where each row represents a patient case. U-net has over-segmentation phenomenon in the edema region of the second case, and also over-segments the core and enhanced tumor regions of the third case; The current advanced SwinBTS and TransBTSv2 networks have good segmentation effects on the edema region due to their spatial continuity, but they mis-segment part of the enhanced tumor region as necrotic tumor region in the second and third cases. Our proposed segmentation model improves by 5.7% and 2.2% respectively on the TC and ET tumor regions compared to the advanced TransBTSV2 network, showing that our method has better segmentation effects on the tumor core and enhanced regions.

H. Complexity Comparative Analysis

To better evaluate the performance of the model, we compare the number of parameters (Params) and the amount of computation (FLOPs) of the network model under the same input size, as shown in Table V. The quantity of parameters of our modelis reduced by about 75.45% compared to the CNN hybrid SwinTransformer structure SwinUnet, and the amount of computation is reduced by about 44.66%. Moreover, compared with the advanced 3D model SwinBTS, the number of parameters of our model is reduced by about 14.68%, and the amount of computation is reduced by about 70.09%. In summary, our model embeds depthwise separable convolution in each proposed module, and only uses one DscSwinTransformer Module in each stage of the global associative encoder. This substantially minimizes the number of parameters and the amount of computation required by the model, resulting in excellent segmentation performance for TC and ET regions.

TABLE V. COMPARATIVE ANALYSIS OF COMPLEXITY

Method	Params/M	FLOPs/G
U-net [4]	69.71	28.46
TransUnet [30]	96.07	48.34
TransBTS [10]	32.99	333.00
SwinBTS [12]	27.64	89.46
Unetr [13]	92.58	41.19
Ours	23.58	26.75

V. DISCUSSION

Due to insufficient hardware resources, this article only changed the number of rounds of model training on the basis of the same training parameters. The results showed that in the 295th round of model training, Dice, Precision, and HD95 in the model validation set were optimal. The sensitivity values in the TC and ET regions still had a gap compared to the optimal values of the network. This may be related to the removal of slices without lesion information during the process of slicing 3D images into 2D images in data preprocessing. Considering the segmentation performance presented by the four evaluation indicators, this article retains the 295th training model as the optimal model for the network to test the test set. If the GPU computing resources are sufficient, further increasing the training rounds can be considered to find the optimal value of the comprehensive evaluation indicators during the training process as the optimal model.

A lightweight AEMCCNet network model is proposed in this paper. It can be seen from subsections F and G of Section IV that compared with other network models, the proposed model has better segmentation effect in the core and enhanced tumor regions. In addition, the AEMCCNet network in Section IV, subsection H, reaches the optimal values of the number of parameters and the amount of computation. For the whole tumor area, 2D network cannot capture the information of adjacent sections of 3D brain tumor cases, but AEMCCNet is close to the segmentation effect of 3D network, and multiple adjacent sections can be combined for segmentation in the future.

VI. CONCLUSION

To address the problems of insufficient fusion of multimodal brain tumor information and inadequate extraction of long-range dependencies features, this paper adopts an asymmetric encoder-decoder structure, which incorporates the MCC module, ICSC block, DscSwinTransformer module, and CA module designed in this paper into the architecture, and offers an asymmetric encoder-based brain tumor segmentation algorithm with multimodal cross-collaboration. The MCC module can reduce the model's dependence on a single brain tumor modality during training and fully utilize the complementary information between modalities; the local refinement encoder branch uses the ICSC module to split channels and extract local detail features, enhancing the network's non-linear expression ability; the global associative encoder uses DscSwinTransformer module to strengthen the capture ability of long-range dependencies features; the bridge part between the asymmetric encoder and decoder uses the CA module to enhance the location weight of spatial detail

selective information; the decoder branch uses DscConv to maintain good feature extraction ability while reducing computation; During network training, a hybrid loss function is redesigned to handle the class imbalance and overfitting issues. The findings from the experiments reveal that the model's accurate segmentation of WT region is comparable to that of advanced 3D segmentation algorithms., while the Dice coefficient of TC and ET regions is better than other advanced models. At the same time, in the comparative experiment, it has the best values of other evaluation indicators, and uses DscConv throughout the model to minimize model parameters and calculations, but the extraction of edge detail information of enhanced tumor is still insufficient. Therefore, in future work, we will explore using an efficient encoder-decoder structure enhanced by edge operator attention or a low-parameter 2.5D network to further improve the segmentation accuracy of enhanced tumor region.

DATA AVAILABILITY

The datasets for this study can be found in the BraTS 2019 da taset available at: https://www.med.upenn. edu/cbica/brats2019/data.html.

***Abstract*—Brain tumors originating from uncontrolled growth of abnormal cells in the brain, presents a significant challenge in healthcare due to their various symptoms and infrequency. While Magnetic Resonance Imaging (MRI) is essential for accurately identifying and diagnosing malignant tumors, manual interpretation is often complex and sensitive to mistakes. To address this, we introduce BrainTumorNet, a specialized convolutional neural network (CNN) created for MRI-based brain tumor diagnosis. We ensure improved image quality and a robust dataset for model training by including preprocessing approaches involving CLAHE and data augmentation. Additionally, we integrated a blockchain-based data retrieval technology to enhance the security, traceability, and collaboration in MRI data management across several medical institutions. This blockchain framework ensures that MRI data, once input from hospitals, stays immutable and can be safely retrieved based on unique hospital IDs, promoting a trustable environment for data exchange. Performance assessments conducted on multiple MRI datasets showcased BrainTumorNet's commendable proficiency, with accuracy rates of 98.66%, 97.17% and 94.24% on the dataset 1, dataset 2, and dataset 3, respectively. The model's performance was evaluated using a comprehensive set of metrics, including accuracy, specificity, recall, precision, f1-score, and confusion matrix. These measures are essential for evaluating a model's strengths and limits, emphasizing BrainTumorNet's ability to generate accurate and relevant predictions and its effectiveness in determining negative classification. BrainTumorNet's performance was compared with six renowned deep learning architectures: VGG16, ResNet50, AlexNet, MobileNetV2, InceptionV3, and DenseNet121. Our work highlights BrainTumorNet's potential capabilities in simplifying and boosting the accuracy of MRI-based brain tumor diagnosis while ensuring data integrity and collaboration through blockchain.**

I. Introduction

Brain tumors develop from abnormal cell growth in the brain [1]. While cells normally follow a regular development and death cycle, sometimes they expand uncontrolled, resulting to harm in the brain. There are around 120 distinct forms of brain tumors and central nervous system (CNS) exist. In 2021, the American Cancer Society anticipated that brain and CNS cancers will cause 18,600 adult and 3,460 child deaths. The probability of surviving five years after being diagnosed is roughly 36%, and 10 years is 31% [2]. In 2019, the National Cancer Institute recorded 86,010 new cases of brain and CNS cancers in the U.S. It's believed that roughly 700,000 Americans live with a brain tumor, with 60,800 of them being non-malignant and 26,170 being cancerous [3]. Globally, the World Health Organization recorded roughly 9.6 million new cancer diagnoses in 2018 [4].

Early diagnosis of brain tumors is vital for patient survival. Analyzing brain tumor images effectively is vital to determining a patient's health state. Physicians and radiologists traditionally scan magnetic resonance (MR) images to discover abnormalities. However, this strategy depends greatly on the medical skill of the practitioner [5]. Differences in experience and the complexity of the imagery may make diagnosis with the human eye challenging. Doctors may struggle to rapidly analyze MR images because they often include several abnormalities or unnecessary data. The difficulty of accessing this large quantity of information increases as the number of data increases, making manual tumor identification time-consuming and costly. There's a rising demand for an autonomous computer-aided diagnostics (CAD) system to solve these issues. Such technologies may help doctors and radiologists by enabling fast and precise identification of cancers, thereby contributing to preserving human lives.

Artificial intelligence (AI) provides automation with capacities following human brain functions, such as learning and problem-solving. In the field of brain tumor identification and diagnosis, AI's accuracy provides crucial help, particularly considering the sensitive nature of the task. There are several initiatives to improve brain tumor categorization. However, the variation in tumor properties, such as their form, texture, and contrast variations across people, continues to be a problem. Machine learning (ML) and deep learning (DL), two branches of AI, have brought in a new era for the practice of neurosurgery. These cutting-edge methods include data preparation, feature extraction, selection, reduction, and classification as their final steps. Recent research [6] reveals that AI permits neurosurgeons to perform surgeries with unsurpassed confidence, enabling more precise brain tumor diagnosis.

Deep learning (DL) is an advanced version of machine learning that dives into data using multi-layered representations. By establishing a feature hierarchy, DL ensures fundamental features aid in developing advanced ones. This technique strengthens classic neural networks by incorporating several hidden layers between input and output, allowing them to capture complicated, non-linear relationships. Because of its excellent performance in recent years, DL has become the frontrunner in many medical image analysis difficulties, including tasks like image denoising, segmentation, authentication, and classification.

Brain tumors, due to their various appearances and sporadic frequency, have long been a main topic of worry in the medical community. Though useful, traditional diagnostic approaches often depend on human mistakes, particularly given the delicate nuances of MRI imaging. Recognizing these problems, we designed BrainTumorNet. Designed to overcome current diagnostic inadequacies, BrainTumorNet employs the ability of deep learning to negotiate the difficulties of MRI-based tumor identification. Our objectives for BrainTumorNet are not simply confined to enhanced diagnostic capabilities; we also emphasize a smooth, transparent, and most crucially, a secure data flow. This is where the integration of blockchain technology plays a key role, bringing in an approach where data integrity and trustworthiness become the standard rather than the exception. As our study develops a comprehensive strategy, blending cutting-edge AI with the resilience of blockchain, we intend to redefine the standards in brain tumor detection. The key findings of this research are:

- BrainTumorNet, a novel proposed model, demonstrated significant proficiency in identifying brain tumors using multiple MRI datasets.
- The addition of the CLAHE preprocessing approach significantly improved the image quality, leading to better model performance.
- Utilized a rigorous data augmentation method to increase the dataset's size and prevent the model from overfitting and improve its generalizability across various MRI images.
- We implemented a blockchain-based system for MRI data retrieval in recognition of the essential requirement for data security and traceability in medical diagnostics. This integration promises a clear, dependable, and immutable data handling procedure.
- Using six thorough performance indicators on three different datasets, we systematically evaluated BrainTumorNet's effectiveness. This comprehensive assessment confirmed the model's consistently good performance, proving its durability and dependability.

II. Literature Review

CNN has been extensively employed to address various issues, but its performance in health-related image processing applications is outstanding. Several techniques have been developed based on DL to identify brain tumors on MRI images in recent years. Most of them focused on binary segmentation to identify brain tumors.

Zhao et al. [7] developed an inventive method for brain tumor segmentation by integrating a complete Convolutional Neural Network (CNN) with Conditional Random Fields (CRFs). This unified framework assured visual excellence and spatial coherence in the segmentation outcomes. They employed three segmentation models trained on 2D image segments and slices from axial, coronal, and sagittal views. These models were combined using a voting-based fusion approach for precise tumor segmentation. On the other hand, Mohsen et al. [8] utilized a Deep Neural Network (DNN) classifier to differentiate an MRI dataset into four categories: normal tissue, glioblastoma, sarcoma, and metastatic bronchogenic carcinoma tumors. They incorporated Principal Component Analysis (PCA), an effective feature extraction technique, with the discrete wavelet transform (DWT) before classification. The ensuing evaluations showcased remarkable performance across all metrics.

Paul et al. [9] focused on 989 axial images, intending to simplify the neural network procedure by omitting the incorporation of three distinct axes with redundant diagnostic information. Both fully connected networks and CNNs were utilized for classification. When trained with axial data, the neural network achieved an impressive accuracy of 91.43% employing five-fold cross-validation, indicating its classification precision. On the other hand, Ari et al. [10] presented a three-step method. The initial phase contained preprocessing, where nonlocal means and local smoothing techniques decreased noise. In the subsequent step, the extreme learning machine with local receptive fields (ELM-LRF) was employed to classify cranial MR images as benign or malignant. Finally, image processing techniques segmented tumor areas in the third phase.

In this research, Abiwinanda et al. [11] aimed to train a CNN model to identify the three most prevalent forms of brain malignancies: gliomas, meningiomas, and pituitary tumors. They developed the simplest conceivable CNN architecture, consisting of one layer each of convolution, max-pooling, and flattening, followed by a complete connection from a single hidden layer. Using the basic architecture and no previous region-based segmentation, the study attains a maximum validation accuracy of 84.19%. Afshar et al. [12] have recently included newly generated CapsNets to alleviate the problem with CNNs that fail to properly exploit spatial interactions. Since the relationship between the tumor and the neighboring tissue is a crucial sign of tumor kind. Because of this, a specialized version of the CapsNet architecture for classifying brain tumors is proposed, including the tumor's coarse borders as additional inputs inside its pipeline to sharpen its attention.

However, Khan et al. [13] proposed a method comprising three critical phases: preprocessing, brain tumor segmentation applying k-means clustering, and benign/malignant tumor identification via a fine-tuned VGG19 model. This method has been assessed employing the BraTS 2015 benchmark dataset. Furthermore, they proposed synthetic data augmentation to expand the training dataset size, which consequently enhanced the classification accuracy. Yahyaoui et al. [14] offer a new semantic approach by fusing 2D and 3D MRI data in this study. Preprocessing, categorization, and fusion are the three stages that make up the whole system. To classify 2D brain data, the DenseNet model is used, and the 3D-CNN model was created specifically for 3D brain scans. Authors relied on a domain-specific ontology to accomplish the fusion of the output classes.

Furthermore, Murthy et al. [15] deployed the Optimized Convolutional Neural Network with Ensemble Classification (OCNN-EC) for tumor image classification. This deep learning approach encompasses an ensemble classifier containing a Deep Neural Network (DNN), an autoencoder, and a Support

Vector Machine (SVM). This ensemble replaces the completely connected layer once the ACV-DHOA has optimized the count of convolutional layers and hidden neurons. In this study, Latif et al. [16] argue that features from the MR images are extracted using a deep CNN network and then input into a support vector machine classifier. This research uses the BraTS dataset to categorize Gliomas into many classes. The suggested method attained a remarkable 96.19% accuracy.

Several recognized limitations in MRI-based brain tumor diagnosis were clear in light of available studies. Notably, many existing models struggle with accuracy problems, the difficulties of adding data to MRI datasets, and the complexity of managing various MRI data sources. We established BrainTumorNet to close these gaps and improve the diagnostic capability. The purpose of our proposed model is to achieve higher performance in the detection of brain tumors from MRI images. BrainTumorNet aims to establish a new standard in both accuracy and reliability in the field of brain tumor diagnosis, further enhanced by blockchain technology for secure and transparent data administration.

III. METHODOLOGY

This section highlights the main methods we employed during our research, including image preprocessing, deep feature extraction, blockchain integrity, and deep learning algorithms. The process of tumor detection is presented in Fig. 1.

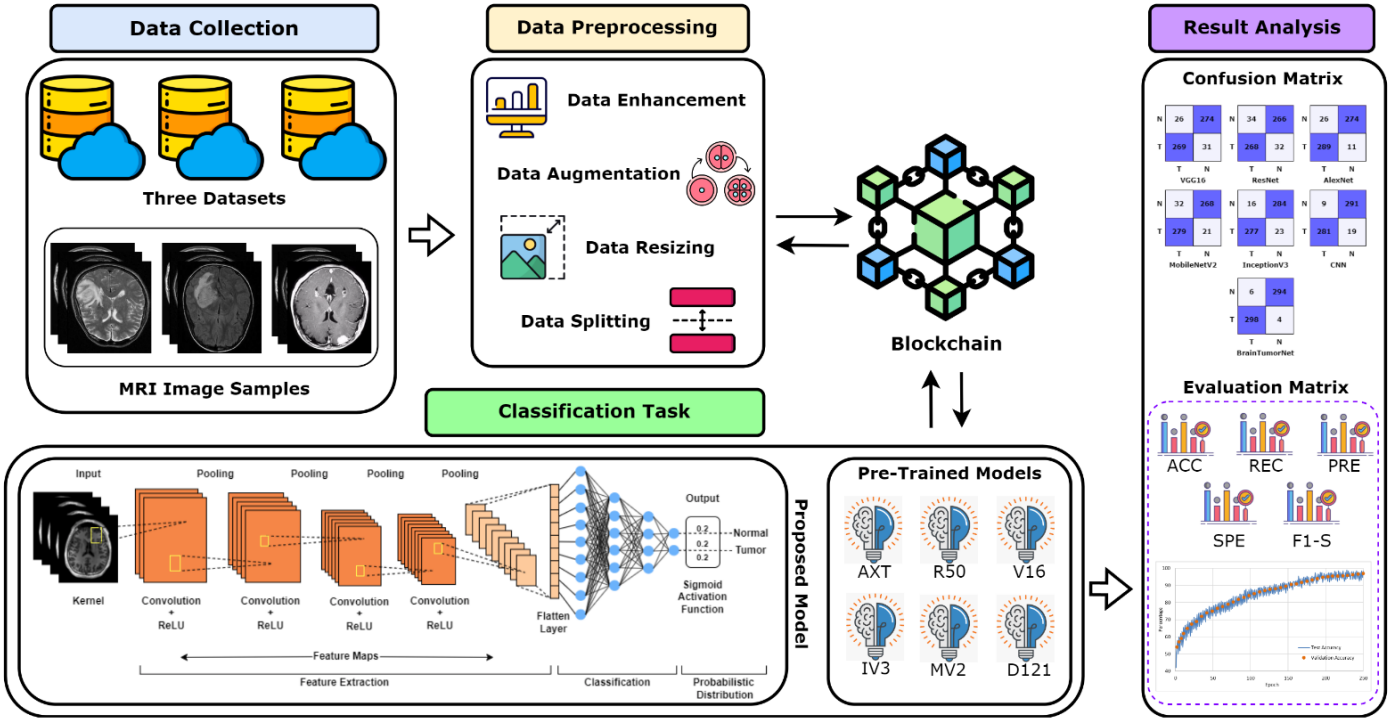

Fig. 1. The entire system of the proposed model BrainTumorNet.

A. Data Collection:

For the study, three publicly available datasets are used. The datasets are image datasets that contain MRI images of the brain. The detailed description of the employed dataset is stated below:

1) Dataset 1 (DT1): Br35H: Brain Tumor Detection 2020 [17] is the first dataset used in the study. It is an MRI image dataset. The dataset consists of 1500 images positive for brain tumors and 1500 images of normal brains. The normal and tumor class dataset samples are shown in Fig. 2(a).

2) Dataset 2 (DT2): The BraTS 2019 [18] is the second dataset used in this study. The dataset contains 1500 MRI images of the brain with tumor and 1500 MRI images of the normal brain. The sample images of this dataset are presented in Fig. 2(b).

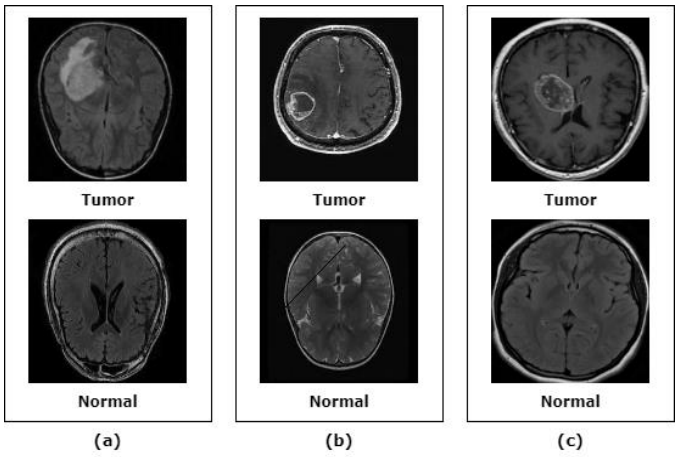

Fig. 2. Data sample of the three datasets (a) DT1 (b) DT2 (c) DT3.

3) Dataset 3 (DT3): The third dataset used in the study is available in the Kaggle data repository [19]. This is an unbalanced image dataset. It contains 170 MRI images of normal brain and 230 images of brain with tumor. The sample images of the normal and tumor class of DT3 are presented in Fig. 2(c).

B. Data-preprocessing:

1) Clache: Contrast limited adoptive histogram equalization (CLAHE) is used to enrich the image quality. CLAHE improves the contrast of the MRI image. Images are normalized using this technique, which also highlights finer information for Machine Learning (ML) classifiers to pick up on. By boosting contrast locally, the CLAHE method gets beyond the limitations of traditional, global approaches. Critical hyper-parameters for this technique are the tile size and clip limit. Multiple permutations of all these settings are examined before the ideal values of tileGridSize (8, 8), and the clip limit is settled on (3.7). Algorithm 1 displays the process of CLAHE.

Algorithm 1: CLAHE Working Process

Procedure CLAHE (Image I, ClipLimit c, GridSize g)
- $I_{gray} \leftarrow$ Convert I to grayscale
- $CLAHE_{object} \leftarrow$ Initialize CLAHE with c and g
- $I_{processed} \leftarrow$ Apply $CLAHE_{object}$ on I_{gray}
- Save $I_{processed}$ as 'clahe_output.jpg'
- **Return** $I_{processed}$

End

2) Data augmentation: The datasets, DT1 and DT2 are well balanced datasets. However, DT3 is a highly imbalanced dataset and consists of a small amount of data. Since ML models require a fairly large dataset to train and produce efficient performance result. To do this, we leverage the ImageDataGenerator class in the Keras library to generate high-quality images for the expansion of our training data. Table I has the image-making parameters. After augmentation, the final count of the DT3 is 500 images of normal brain and 500 images of brain tumor. Algorithm 2 represents the procedure of augmentation.

TABLE I. ATTRIBUTES OF IMAGEDATAGENERATOR

Attributes	Values
Shear_range	0.3
Zoom_range	0.2
Vertical flip	True
Horizontal flip	True
Rescale	1/255

Algorithm 2: Augmentation for Balancing Image

Procedure AugmentData
- Define ImageDataGenerator attributes
- Function LOAD_IMAGES (directory)
  - **Return** images from *directory*
  - End
- *NormalImages* ← LOAD_IMAGES (normal_dir)
- *TumorImages* ← LOAD_IMAGES (tumor_dir)
- **While** count of normal_images ! 500 **do**
  - Augment 'normal' images
- End
- **While** count of tumor_images ! 500 **do**
  - Augment 'tumor' images
- End
- Return Count

End

3) Resize image: For uniformity's sake, we resize every picture in the collection to 128×128 pixel, since the original dimensions of images in the three datasets (DT1, DT2, and DT3) vary substantially.

4) Dataset splitting: The datasets are divided into training and validation subsets. The division is done at a ratio of 80:20, where 80% of each data belongs to the training set and the remaining 20% to the test set. Table II shows the data division of each set.

TABLE II. DATA DISTRIBUTION OF THE DATASETS

Dataset	Training set	Test set	Total
DT1	2400	600	3000
DT2	2400	600	3000
DT3	800	200	1000

C. Blockchain Framework for Secure Data Management in BrainNet

Our proposed system incorporates blockchain architecture to ensure effective and secure data retrieval and sharing procedure designed for managing medical MRI data. Many institutions may cooperatively exchange and store MRI information to improve the BrainTumorNet model's detection abilities without compromising patient data integrity. Our work emphasizes the MRI data retrieval and sharing procedures inside our method, based upon the multi-organization blockchain designs mentioned by [20], [21].

1) Blockchain-based MRI data retrieval process: In the framework of our study, every participating data source/hospital provides MRI data, storing it as a unique transaction inside the blockchain network. Before this data is placed into the blockchain, it undergoes a preprocessing stage. Initially, the MRI images are improved using the CLAHE approach, which increases the contrast and overall visibility of tumor locations in the images. Following this, Data Augmentation methods are applied to extend the dataset intentionally. This assures increased variety and assists in training the BrainTumorNet model more robustly.

Retrieving this data from the blockchain nodes hinges on two key parameters: the distance between the nodes (d) and the unique ID of the hospital (ID). Each hospital denoted as x_i, is assigned a unique ID, determined in part by its distance d_{ij} from another hospital x_j. This can be represented as,

$$ID_i = f(x_i, d_{ij}) \quad (1)$$

where, f is a function computing the ID based on the hospital's attributes and its distance from other hospitals.

The blockchain system maintains log tables that register these unique IDs, ensuring that data integrity is maintained at all times. When BrainTumorNet needs to access specific MRI datasets for its diagnostic tasks, it retrieves the relevant data from the corresponding hospitals using the retrieval function $R(ID_i)$. This function returns the data x_i if ID_i exists in the log table, otherwise it returns to error.

Moreover, the neighborhood distance between two sources, x_i and x_j, plays a critical role in efficient data access. The distance d_{ij}, can be determined by,

$$d_{ij} = g(l(x_i), l(x_j)) \quad (2)$$

where, g is the distance function and $l(x)$ represents the location of source x.

This research effort aims to establish a new benchmark in secure, transparent, and collaborative medical diagnostics, laying the foundation for further advancements in this interdisciplinary field by combining the robustness of blockchain technology with the diagnostic prowess of BrainTumorNet and rigorous preprocessing steps.

D. Deep Learning Models for Classification

Our proposed model's major objective is to automatically identify people who have brain tumors while decreasing classification time and increasing accuracy. For the purpose of finding brain tumors utilizing multiples MRI datasets, we proposed a novel, reliable and robust CNN model BrainTumorNet. To establish the most effective transfer learning strategy for the classification assignment, six pre-trained models including VGG16, ResNet50, AlexNet, MobileNetV2, InceptionV3, and DenseNet121 are tested. The significant characteristics and some essential properties of the selected deep CNN models are compiled in Table III The next section includes an entire discussion of the model utilized in this study.

1) AlexNet: This model is consisting of five convolution layers and three fully linked layers. certain number of convolution layers are succeeded by the max-pooling layer (1, 2, and 5 layers). The ReLU nonlinearity is applied to the output of every fully connected and convolutional layer. Each of the connected layers has 4096 neurons [22]. During training, neurons are "turned off" with a predefined probability to prevent data over-adjustment using a regularization technique known as dropout [23].

TABLE III. PROPERTIES OF THE DEEP LEARNING MODELS EMPLOYED IN THIS RESEARCH

Model	Input Shape	Custom Input Shape	Parameters	Size (MB)
VGG16	224×224	224×224	138×10^6	552
ResNet50	224×224	224×224	25.6×10^6	102
AlexNet	227×227	224×224	60×10^6	240
MobileNetV2	224×224	224×224	3.5×10^6	14
InceptionV3	229×229	224×224	23.8×10^6	95
DenseNet121	224×224	224×224	8×10^6	32
BrainTumorNet	222×222	-	2.16×10^6	10

2) ResNet50: ResNet50 [24] is a 50-layer Convolutional Neural Network (CNN) composed of 48 fully connected layers, one max pooling layer, and one average pooling layer. It's capable of performing up to 3.8×10^9 floating-point computations. To resolve the vanishing gradient issue prevalent in traditional CNNs and expedite the training process, ResNet50 employs a spectrum of convolutional filters of varying sizes [25]. With fewer filters, ResNet's operates more promptly. This architecture is trained using approximately 23 million parameters. The network is designed to receive images where the height, breadth, and channel dimensions are multiples of 32.

3) VGG16: The Visual Geometric Group is referred to as VGG [26]. Simonay and Zimmerman [27] created the VGG model. VGG employs 3×3 convolutional layers that are layered on top of one another and become deeper over time. Max pooling layer is responsible for reducing the volume size. Afterwards, a softmax classifier is followed by two completely connected layers with a total of 4096 nodes each [27].

4) InceptionV3: At the ImageNet Recognition Challenge, Google introduced Inception version 3 [28]. The Auxillary Classifiers contain a label smoothing classifier, a factorized 7×7 convolution classifier, a batch norm classifier, an RMSProp optimizer, and a downscaling classifier for extracting and augmenting data from label sequences. The InceptionV3 model's training time is shortened by substituting bigger convolutions for smaller ones. Several optimization methods may be used to remove constraints and make an InceptionV3 model more flexible. The model is designed employing max pooling, convolutions, concatenations, dropouts, and fully-connected layers.

5) MobileNetV2: MobileNetV2 [38] is built upon an inverted residual structure, with residual connections

interconnecting its bottleneck layers. The intermediate expansion layer utilizes lightweight depth-wise convolutions to provide non-linear feature filtering. Following the initial convolutional layer with 32 filters, MobileNetV2 incorporates 19 residual bottleneck layers, resulting in a total of 53 layers for the network. The model has been pre-trained using over a million images from the ImageNet database, classified into 100 distinct categories. As a result, the network has gathered an enormous number of features from a diverse multitude of images.

6) DenseNet121: The Dense Convolution Network is a deep learning model that employs feedforward to link each layer to all subsequent layers [29]. DenseNet has (L(L+1))/2 direct lines compared to L connections for conventional L-layer CNNs. A feature map may be found in every layer of the model. Each layer's feature map serves as the following layer's input. It allows for the most information to be sent throughout the network by linking all levels directly to one another. DenseNet's primary benefits are a large reduction in parameter count, prevention of gradient runaway, improvement of feature diffusion, and encouragement of feature reuse. DenseNet needs fewer parameters than conventional CNN since the feature map is not repeatedly trained. Additionally, DenseNet uses regularization to lessen the possibility of overfitting. Each of the four dense blocks in DenseNet121 has six, twelve, twenty-four, and sixteen convolution blocks.

7) BrainTumorNet (Proposed Model): BrainTumorNet model is both small in size and computationally effective, improving performance across various datasets. This model is precisely designed for CNN that processes grayscale images with dimensions of 222×222×1 to identify brain tumors from MRI scans. The network is designed with four distinct blocks that have been optimized for feature extraction. Each of these blocks begins with a Conv2D layer, which is statistically stated by,

$$I'_{x,y,k} = \sum_{i=-\infty}^{\infty} \sum_{j=-\infty}^{\infty} I_{x-i,y-j,k} . K_{i,j,k} \qquad (3)$$

where, $I_{x,y,k}$ is the input feature map at position (x, y) for the k[th] channel. $K_{i,j,k}$ represents the kernel or filter at position (i, j) for the k[th] channel and $I'_{x,y,k}$ is the output of feature map after convolution at position (x, y) for the k[th] channel.

Following the convolutional transformation, there is a MaxPooling layer, which is presented as,

$$P_{x,y,k} = max_{i=0}^{s-1} \, max_{j=0}^{s-1} \, I_{sx+i,sy+j,k} \qquad (4)$$

Here, $P_{x,y,k}$ is the pooled output at position (x, y) for the k[th] channel, and s denotes the pooling window size.

Each block ends with a batch normalization layer, stabilizing the activations and ensuring the features remain standardized. As the depth of the network increases, the spatial dimensions are progressively reduced, encapsulating more complex and sensitive patterns essential to tumor identification. Once the entire spatial panorama has been thoroughly evaluated, the extracted features are flattened into a 1D tensor, covering a size of 10816. This tensor then runs across two dense layers, described by,

$$y = Wx + b \qquad (5)$$

Here, y is the output of the dense layer, W symbolizes the weight matrix, x represents the input to the dense layer, and b is the bias term.

The end of BrainTumorNet's activities is encapsulated in its last output layer, which is equipped with a sigmoid activation function. This design option provides binary classification capabilities, properly denoting whether the input MRI shows the existence or absence of a tumor. Table IV demonstrates the architecture of the proposed model BrainTumorNet. Fig. 3 illustrates a visual output of the proposed model.

This proposed model for detecting brain tumors using MRI images surpasses prior approaches through feature extraction and processing efficiency improvements. Increasing filters on convolutional layers are utilized to identify detailed features, which are essential for identifying brain tumor characteristics. Convolutional layers employ a balanced layout of 1×1 stride and 3×3 kernel size to optimize image processing, followed by max pooling. This arrangement minimizes the loss of information while preserving computational efficiency. Integrating BatchNormalization enhances learning stability, facilitating fast and consistent training. The model reaches the highest point with a binary classification output layer that is designed to ensure precise tumor detection. This architectural design signifies an important improvement in the accurate detection of brain tumors by addressing the distinct difficulties associated with MRI image analysis.

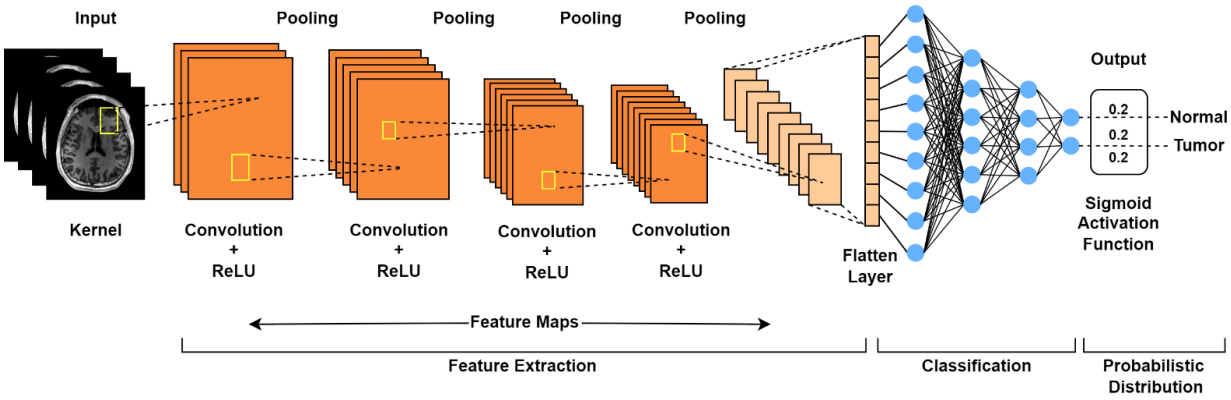

Fig. 3. The architecture of the proposed model BrainTumorNet.

TABLE IV. DESCRIPTION OF BRAINTUMORNET ARCHITECTURE LAYERS USED FOR BRAIN TUMOR DETECTION

Operation	Layer Name	No. of Filters	Stride Size	Kernel Size	Padding Size	No. of Channels	Input Shape	Output Shape
Input Image	Input Layer	-	-	-	-	3	222 × 222 × 1	-
Convolution	Convolution 2D	32	1×1	3×3	Same	32	222 × 222 × 1	222 × 222 × 32
Pooling	Maxpooling	-	2×2	2×2	Valid	32	222 × 222 × 32	111 × 111 × 32
Normalization	BatchNormalization	-	-	-	-	32	111 × 111 × 32	111 × 111 × 32
Convolution	Convolution 2D	32	1×1	3×3	Same	32	111 × 111 × 32	111 × 111 × 32
Pooling	Maxpooling	-	2×2	2×2	Valid	32	111 × 111 × 32	55 × 55 × 32
Normalization	BatchNormalization	-	-	-	-	32	55 × 55 × 32	55 × 55 × 32
Convolution	Convolution 2D	64	1×1	3×3	Same	64	55 × 55 × 32	55 × 55 × 64
Pooling	Maxpooling	-	2×2	2×2	Valid	64	55 × 55 × 64	27 × 27 × 64
Normalization	BatchNormalization	-	-	-	-	64	27 × 27 × 64	27 × 27 × 64

Normalization	BatchNormalization	-	-	-	-	64	13 × 13 × 64	13 × 13 × 64
Flattening	Flatten	-	-	-	-	-	13 × 13 × 64	10816
Fully Connected	Dense	128	-	-	-	-	10816	128
Fully Connected	Dense	64	-	-	-	-	128	64
Output	Dense	2	-	-	-	-	64	2

E. Hyperparameters Tuning:

The principal objective of this research is to develop the most efficient model BrainTumorNet for classifying brain MRI data. Hyperparameters are a group of factors that have the ability to impact the model's training process and provide the best outcomes [30-32]. These parameters include the volume of epochs, batch size, image size, optimizers, activation function, learning rate, decay rate, dropout rate and regularizer. During the experiment, we conducted several trials before settling on batch size, learning rate, regularization factor, etc. Different pre-trained models, including VGG16, ResNet50, AlexNet, MobileNetV2, InceptionV3, and DenseNet121, are used to execute the proposed brain tumor detection. Using a variety of optimizers, each model was assessed for 250 epochs. Each model is first tuned using Keras-tune to obtain the appropriate hyperparameter ranges. We employ the widely utilized grid search strategy for parameter tuning. Table V displays the parameters after tuning used during model training.

F. Evaluation Matrix

Accuracy, Specificity, Recall, Precision, and F1-score are some of the performance metrics calculated to assess the models' efficacy. Accuracy measures the rate of a model produce accurate predictions. The relevant predictions of positive classes are determined by calculating precision. Efficiency in predicting the negative class from the whole set of classes is measured by specificity. Contrarily, recall is the proportion of true positive classes that were anticipated. The F1-score measures how well specificity and recall are combined. Eq. (6) through Eq. (10) below express the parameters.

$$Accuracy = \frac{TP+TN}{TP+FP+TN+FN} \quad (6)$$

$$Precision = \frac{TP}{TP+FP} \quad (7)$$

$$Recall = \frac{TP}{TP+FN} \quad (8)$$

$$Specificty = \frac{TN}{TN+FP} \quad (9)$$

$$F1-score = 2 \times \frac{Precision \times Recall}{Precision+Recall} \quad (10)$$

Here, True Positive (TP) is the proportion of positive predictions that turned out to be accurate. True Negative (TN) is the accurately anticipated negative images. False Negative (FN) represents the count of positive photos that were incorrectly labeled as negative. Similarly, False Positive (FP) represents the count of negative data that were incorrectly labeled as positive.

TABLE V. THE FINAL HYPERPARAMETERS USED TO TRAIN THE MODELS

Model	No. of Epochs	Batch Size	Image Size	Optimizers	Activation Function	Learning Rate	Decay Rate	Dropout Rate	Regularizer
VGG16	250	64	224×224	Adam	Softmax	0.000001	1e-3	0.2	1e-4
ResNet50	250	64	224×224	SGD	ReLU	0.0001	1e-4	0.2	1e-4
AlexNet	250	64	224×224	Adagrad	ReLU	0.00001	1e-2	0.2	1e-4
MobileNetV2	250	64	224×224	SGD	Softmax	0.1	1e-4	0.2	1e-4
InceptionV3	250	64	224×224	Adam	Sigmoid	0.001	1e-3	0.2	1e-4
DenseNet121	250	64	224×224	Adam	ReLU	0.0000001	1e-2	0.2	1e-4
BrainTumorNet	250	128	222×222	RMSProp	Sigmoid	0.01	1e-5	0.2	1e-4

IV. Experimental Results

A. Experimental Setup

We utilized the Keras 2.10.0, TensorFlow 2.0, and Python 3.7 programming languages to execute the proposed models and produce results. Visualization was done using the Seaborn and Matplotlib packages. System specifications include AMD Ryzen 7 running at 3.90 GHz, 32 GB of RAM, a MD Radeon RX 580 series GPU, and a Windows 10 setup.

B. Result Analysis

Six different transfer learning models and novel BrainTumorNet model were employed in the study to detect brain tumor from MRI data. Furthermore, the seven models are employed on the three datasets containing MRI images of the brain. The purpose of the study is to identify a robust model that can classify MRI data to diagnose brain tumor. The models were run for 250 epoch and the outcome of each epoch are recorded for all three datasets. Using Eq. (6) through Eq. (10), we can calculate the performance parameters of each model and so assess how well each model performs.

In Fig. 4 we can see the results of the performance indicators for DT1. Among the transfer learning models, it is seen, the model CNN consistently displays high performance, with an accuracy of 95.34%. A precision of 96.14% was attained, along with 95.78% recall, 96.32% specificity, and 95.95% f1-score. It is followed by InceptionV3 with specificity of 92.55%, similarly the model falls well short of perfection in accuracy (93.5%), precision (92.17%), recall (95.78%) and f1-score (93.13%). Likewise, the other models, including VGG16, AlexNet, MobileNetV2, and ResNet50, all have subpar accuracy (90.47%, 93.75%, 91.24% and 89.02%, respectively). Contrary to the transfer learning models, the proposed model performs with exceptionally high measures. The accuracy of the proposed model BrainTumorNet is 98.66%. Similarly, the specificity is 98.59% and the f1-score is 97.69%.

Fig. 5 displays the outcomes of DT2's key performance metrics. The CNN model shows the highest classification efficiency among the transfer learning models with an accuracy of 94.76% and an f1-score of 94.98%. The accuracy score of VGG16, ResNet50, AlexNet, MobileNetV2 and InceptionV3 are 85.78%, 91.45%, 92.01%, 89.71% and 90.83% respectively. Performance-wise, the proposed BrainTumorNet model is much superior to transfer learning methods with an accuracy of 97.17%.

The results of DT3 are recorded and presented in Fig. 6. Similar to the other datasets, the CNN model has the best classification efficiency among the transfer learning models in DT3 with an accuracy of 92.5% and an f1-score of 92.79%. Similar to the previous datasets, in DT3, the BrainTumorNet shows the highest efficiency. The classification accuracy of the model is 94.24%. The precision, recall, specificity, and f1scores are 96.34%, 95.06%, 94.59%, and 95.69%, respectively.

The performance matrix shows that the proposed fine-tuned model performs consistently with the highest accuracy over the three datasets. However, the classification accuracy of the three datasets varies. The datasets DT1 and DT2 achieve accuracy of 98.66% and 97.17%, respectively. These accuracies are quite similar to the accuracy achieved from DT3, which is 94.24%.

The datasets DT1 and DT2 have higher counts of data compared to DT3. When employed on DT3, the models have less data to train on, so their performance suffers. On the contrary, when the BrainTumorNet model is trained and validated on DT1, it achieves the highest performance efficiency.

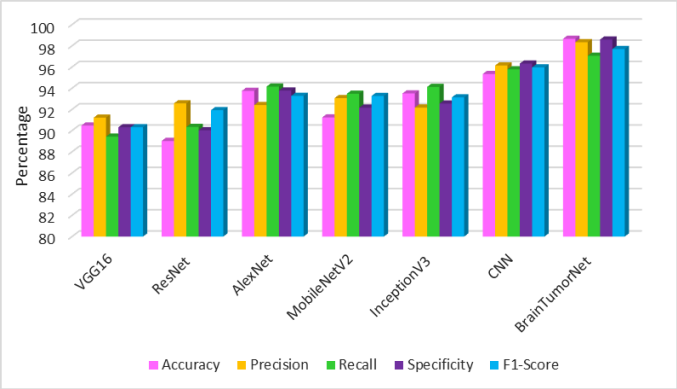

Fig. 4. Perfromance of the models for DT1.

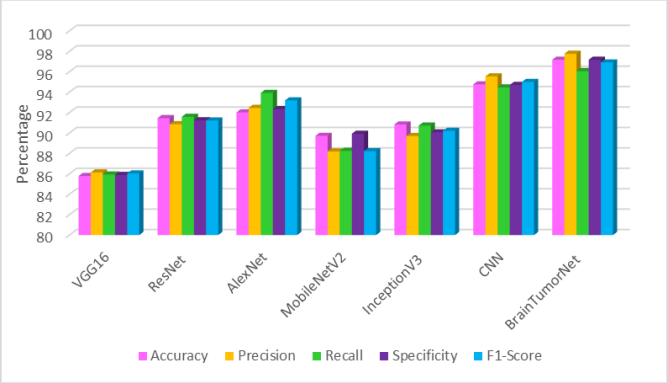

Fig. 5. Performance of the models for DT2.

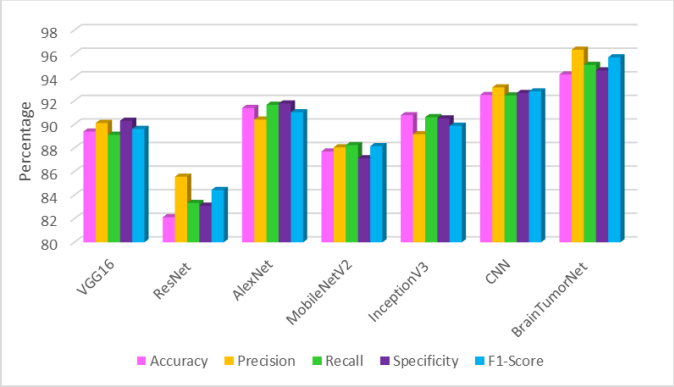

Fig. 6. Perfromance of the models for DT3.

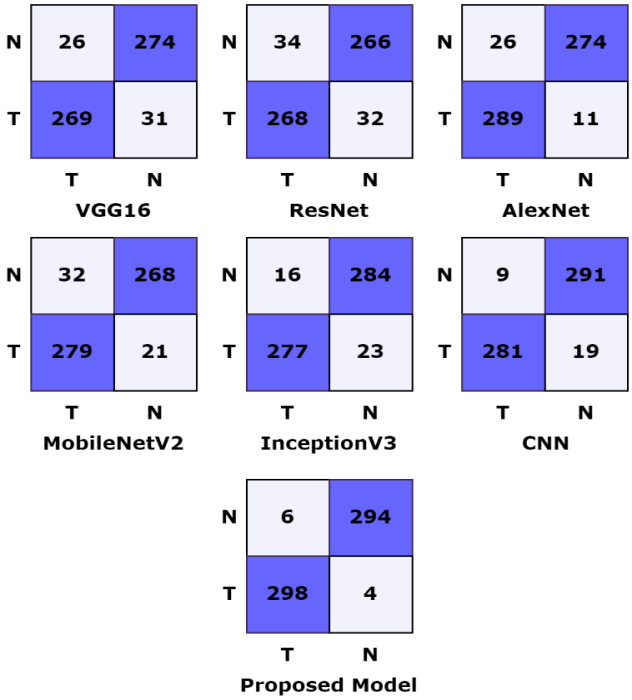

Fig. 7. Confusion Matrix of DT1 for the employed models.

In Fig. 7, we present the confusion matrix created by the seven models on the dataset DT1. In the confusion matrix, T refers to data with brain tumors, and N refers to data from normal brains. The confusion matrix was built from the validation set of DT1 consisting of 600 data. It can be observed from the confusion matrix that the proposed model BrainTumorNet correctly predicts the most data and has the lowest incorrect predictions.

In Fig. 8(a), the progress of the performance accuracy of the proposed model (BrainTumorNet) on DT1 is illustrated. The performance of the model on 250 epochs is presented during both training and validation of the model. It can be observed that in the 1st epoch, the model starts with a very low training accuracy of 42% and validation accuracy of 54%. However, with each progressing epoch, the model's accuracy increases rapidly. On the final epoch, the model provides the highest training accuracy of 97.83% and validation accuracy of 98.66%.

Likewise, in Fig. 8(b), the progress of the loss of the proposed model (BrainTumorNet) over 250 epochs is presented. On the 1st epoch, the model demonstrates a high training loss of 4.75% and a validation loss of 4.33%. Over the increased epoch, the loss rate gradually decreases with consistency. On the final epoch, the model achieves the lowest training loss of 0.207% and validation loss of 0.135%.

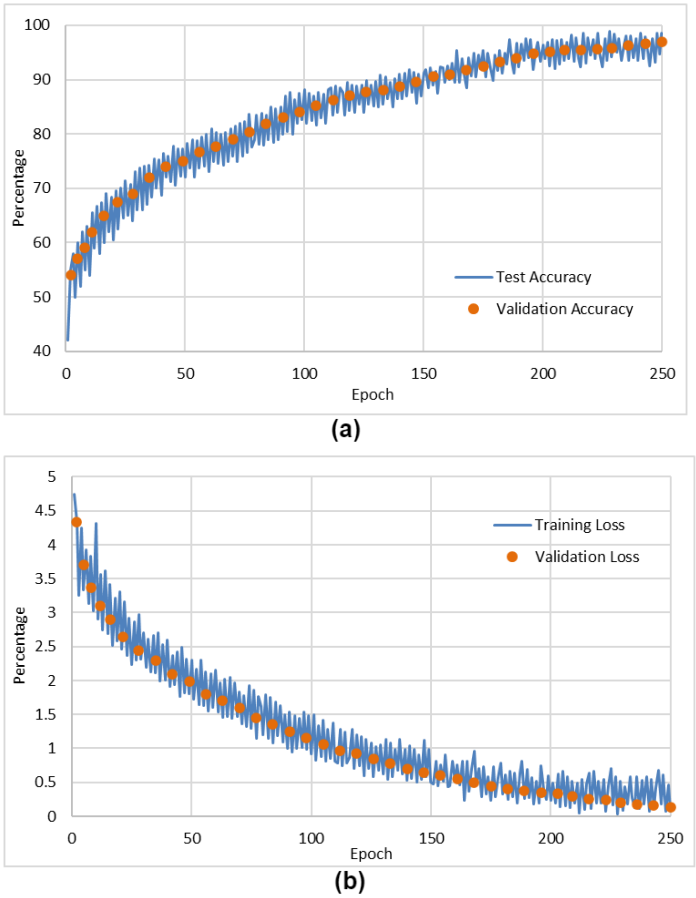

Fig. 8. (a) Accuracy and (b) Loss of proposed model on DT1 per epoch.

V. State-of-the-Art Comparison

This paper introduces BrainTumorNet, a complex convolutional neural network (CNN) specifically designed for classifying images of brain tumors, to address the crucial difficulty of reliably identifying brain tumors using Magnetic Resonance Imaging (MRI). Advanced preparation techniques were used to ensure the highest level of data quality, including CLAHE for image improvement, data augmentation for assuring dataset variety, and blockchain integration for secure and traceable data administration. By recording accuracy scores of 98.66%, 97.17%, and 94.24% across three datasets during testing, BrainTumorNet demonstrated its outstanding abilities and established a new standard when compared to other pre-trained models. This study raises the standard for MRI-based brain tumor identification and gives professionals a crucial diagnostic tool. Table VI thoroughly evaluates BrainTumorNet's performance in relation to other existing models.

TABLE VI. STATE-OF-THE-ART COMPARISON OF PROPOSED MODEL

Authors	Data Type	Methods	Accuracy
Khan et al. [13]	MRI	Fine-tune VGG19	90.03%
Yahyaoui et al. [14]	MRI	DenseNet	92.06%
Febrianto et al. [33]	MRI	CNN	93%
Afshar et al. [34]	MRI	CapsNet	90.89
Anaraki et al. [35]	MRI	Shallow CNN	94.20
Rehman et al. [36]	MRI	3D CNN	92.67%
Sajjad et al. [37]	MRI	VGG19	90.67%
Banik et al.	MRI	BrainTumorNet	98.66%
			97.17%
			94.24%.

VI. CONCLUSION

BrainTumorNet, a CNN model developed to detect brain tumors from MRI images, was demonstrated in this research article. Its performance was improved through a rigorous data preparation process that included CLAHE and data augmentation. Brain TumorNet's unique incorporation of blockchain technology assures MRI data management that is highly secure and identifiable, thereby developing confidence and facilitating collaborations focused on data integrity. Assessed through the utilization of a wide variety of metrics such as accuracy, specificity, recall, precision, f1-score, and confusion matrix, BrainTumorNet demonstrated its ability to perform by attaining accuracy rates of 98.66%, 97.17%, and 94.24% on three separate datasets. Furthermore, it outperformed six pre-trained deep learning models. Despite infrequent misclassifications, its overall efficacy represents a significant development in the field of medical imaging. It is believed that integrating deep learning with blockchain will bring about an important change in perspective in healthcare management and brain tumor detection in the future.

Proposal of a Machine Learning-based Model to Optimize the Detection of Cyber-attacks in the Internet of Things

Cheikhane Seyed, Jeanne roux BILONG NGO, Mbaye KEBE
Laboratory LIRT- Polytechnic Superior School, University Cheikh Anta DIOP (UCAD), Dakar, 10200, Senegal

***Abstract*—In this article, we propose a model to optimize the detection of attacks in IoT. IoT network is a promising technology that connects living and non-living things around the world. Despite the increased development of these technologies, cyber-attacks remains a weakness, making it vulnerable to numerous cyber-attacks. Of course, automatic computer intrusion detection systems are deployed. However, it does not make it possible to mobilize the full potential of Machine Learning. Our approach in this maneuver consists of offering a means to select the least expensive ML method in terms of learning in order to optimize the prediction of threats to introduce IoT objects. To do this, we make modular design based on two layers. The first module is a canvas containing the different methods most used in ML such as supervised learning method, unsupervised learning method and reinforcement learning method. The second module introduces a mechanism to measure the learning cost linked to each of these methods in order to choose the least expensive one in order to quickly and efficiently detect intrusions in IoT objects. To prove the validity of the proposed model, we simulated it using the Weka tool. The results obtained illustrate the following behaviors: The classification quality rate is 93.66%. This last result is supported by a classification consistency rate of 0.882 (close to unity 1) demonstrating a trend towards convergence between observation and prediction.**

***Keywords*—IoT; Machine learning; cyber-security; detection of attacks; weka tool; classification quality and consistency**

I. INTRODUCTION

IoT refers to a network of smart objects around the world via the Internet, allowing them to collect and exchange data without any human interference [1]. However, security in the Internet of Things (IoT) is a major concern because it is susceptible to cyber-attacks like any other network given the proliferation of connected devices and the massive data collection they perform [2].

Intrusion Detection System (IDS) is an effective technique for detecting cyber-attacks in any network. IDS detects cyber-attacks efficiently and quickly at fog nodes compared to the cloud [3]. The IoT network consists of connections between different types of smart objects, ranging from supercomputers to tiny devices that may have very little computing power. It is therefore difficult to secure this type of network and cyber security is therefore a major challenge.

Faced with this new mode of operation of the strike chain, traditional network security is no longer suitable. Certainly, computer systems for automatic intrusion detection are deployed [4, 5]. Most of the latest IDS are based on machine learning algorithm for training and detection of cyber-attacks on the network. However, their conceptual deficiency does not make it possible to mobilize the full potential of Machine Learning.

The problem that arises is that these IDS do not emphasize the impact linked to the learning cost for the ML method used. This can slow down the attack prediction process by choosing an ML method that is inappropriate for the context and environment of IoT objects.

In this context, we propose an approach to boost the detection of attacks by choosing the optimal method in terms of learning cost to provide a prediction of attacks that is fast, efficient and reflects reality.

The contribution consists of proposing a new process framework for integrating ML techniques. This process is based on three pillars. The first is the dynamic dimension of the cyber-attacks chain. This problem is addressed by proposing an updatable dataset in terms of sampling and scoring of variables. The second is the competition process of different existing ML methods. The third is the introduction of cost-sensitive learning using a risk-based cost matrix.

The remainder of this article is organized as follows: Related work is given in Section II, Section III delves into Approach and method, then Section III deals with the proposed modeling, then Section V deals with the methods and materials. Section VI dedicated to the results and discussions and finally we present the conclusion and the perspectives of our work in Section VII.

II. RELATED WORK

Intrusion detection systems are built based on data collected and trained using supervised, semi-supervised and unsupervised learning methods [6]. This article proposes to evaluate the performance of intrusion detection systems over the long term. The objective is to be able to detect still unknown zero-day attacks.

On the other hand, a summary on the analysis of security threats, issues and solutions for Cloud computing uses machine learning algorithms [7]. They are used to overcome security issues of cloud computing in supervised, unsupervised, semi-supervised and hardened modes.

The Internet of Connected Things in the industrial domain (I-IoT) is also an active area of research and is the subject of several studies. The problem of low detection rates and high proportions of false alarms is addressed in this article [7]. The sole objective of this work is to detect and stop cyber-attacks. Concerns about the costs and impact of this detection are not the focus.

The article in [8] makes an important contribution to solving the problem of security of connected objects. An in-depth analysis of the literature is assigned to them. The articles cited in this study certainly differ in their aims and objectives. Some of them approach the question from the reasonable angle of the technical constraints intrinsic to the IoT, notably storage, memory and energy.

Other authors in [9, 10] introduce the notions of layered architecture with or without integration of techniques such as machine learning, artificial intelligence and cryptography. The contextualization of the security issue of connected objects remains reactive and corrective. However, the proposed solutions do not seem to be part of an innovative and proactive methodology.

In the article [11], the authors have access to a review of the typology of anomalies, detection layers, context and methodology. What emerges is an overly simplistic view of anomaly classification. All attacks are classified into a single anomaly category, resulting in only four anomaly types. This represents more than half of the population. In addition, the type of attack is not well specified. More than 90% of articles do not consider context. This further weakens the robustness of the proposed solutions.

The articles in [12,13] shows the need to focus on learning methods for Cyber security in IoT Networks, the quality of the data used and the importance of security issues in free decision-making. This last point is crucial with regard to the cognitive dimension of the proposed solution.

In the paper [14], the authors proposed a cyber-attack detection framework for IoT using the voting-based ensemble learning approach. This idea of ensemble learning like Random Forest (RF) is good, but the process does not include risk-based thinking although it achieves over 97% accuracy.

The authors in [15] proposed several approaches based on recurrent neural networks (RNN) using long short-term memory (LSTM), auto encoders and multi-layer perceptron. For the authors [16], deep learning LSTM is applied with the resampling of an imbalanced dataset. Here again, no risk prioritization or cost discrimination was applied. The overall accuracy rate of 99% did not resolve the impact of individual cyber-attacks.

In the work [17], it is recognized that the IoT cyberspace is like an “unsecured Internet of Things” and that emerging technologies (machine learning, block chain) are key solutions. This survey reveals that there are many problems associated with the use of machine learning techniques. Topics include dataset accuracy and versioning.

However, these articles do not seem to draw attention to the innovative approach of modular analysis and security segregation based on learning costs which prompted us to focus in this research study on the impact of learning cost of ML methods thus influencing the effectiveness of attack predication in IoT.

III. Approach and Methodology

The majority of detection systems are based on classical linear structure learning models (see Fig. 1). That is, we draw a dataset S from an operational IoT network. This data set and the underlying variables describe a particular state of a functional system. Critical security factors may constantly change over time horizon t, with respect to the dynamics of cyber threats. The resulting M-model becomes inappropriate for tracking cyber-attacks due to short-term mutations in the threat process called block chain.

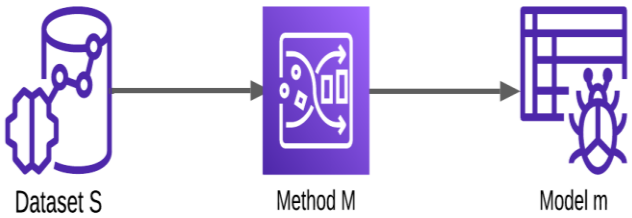

Fig. 1. Classic intrusion detection model.

Viable, reliable and agile machine learning that streamlines operations and strengthens businesses is a very serious and time-consuming task [18]. Indeed, this approach to cyber security modeling does not call into question the improvement in algorithmic performance delivered by a one-way learning method. As a result, we will not be able to capitalize on the differential advantage offered by a range of different learning methods. Additionally, it should be noted that omitting the impact of the learning process and attack detection would reduce the quality of the model. The reason is that cyber-attacks differ in terms of their impact on the entire company and in terms of the resources used to neutralize them. These conceptual cognitions constitute the very foundation of our motivation to propose a new type of approach to modeling cyber security issues. We seek to achieve essentially the following objectives.

On the one hand, the goal of our approach is to define what represents an acceptable algorithmic methodology. It allows the learning engine to have access to a set of machine learning methods to increase the algorithmic space. The reason is to match the most salient issues that need to be resolved. This will increase the quality of intrusion detection and the cyber security of connected objects. Additionally, the outcome of this expected performance depends on the raw data sampling process. The quality criteria for this sampling include not only the size of the data set but also the relationship between the descriptive variables called inter-correlation. This last parameter should ideally be reduced to zero. In addition, the delay in capturing network data has a great advantage. This will keep the dataset up to date and consistent with threat level and complexity.

On the other hand, the objective is to follow a risk-based approach when analyzing the cyber-security attack chain or kill chain. This means that cyber risk must be identified first. Then,

the assessment of this risk is based on its probability and its total impact on the system. The end goal of this process is to prioritize each risk category in terms of cost weighting. This will lead to a framework enabling the integration of security objectives, taking into account the risk tolerance level of security councils, and at the same time reduce the costs induced by security and insecurity related to the Internet of Things.

The ultimate goal of this approach is to develop an optimized model that recovers all the drawbacks linked to the state of the art of cyber-security and ensures enhanced cyber-security of connected objects. This model should compensate for the shortcomings of the approaches discussed in the state of the art.

IV. Proposed Modeling

The motivation for proposing a new intrusion detector optimization model lies in the fact that NIDS attempts to apply the same intrusion filters regardless of the risk policies in place. Since zero risk is unrealistic, it is essential to control its assessment and level of acceptance.

The ultimate goal of this approach is to develop a model allowing you to choose among Machine Learning methods (supervised, unsupervised and reinforcement), the optimal method to effectively detect intrusions in IoT objects. This choice is essentially based on the cost-sensitive technique thus minimizing the learning impact of attacks and intrusions in IoT objects.

Upgrading the generic classification and detection model involves redefining the methodology. To do this, we imagined the creation of two functional layers at the conceptual level (see Fig. 2). This brings us to modular programming of the detection engine. On the one hand, the first module serves to design the algorithmic component of the methodology in order to integrate a wide range of learning methods. On the other hand, the second module models the security-cost component of the methodology. This allows the security manager to control the acceptable level of risk in relation to the typology of cyber-attacks. In this way, the most optimal classification method will be chosen. This is the least expensive method in terms of negative impact.

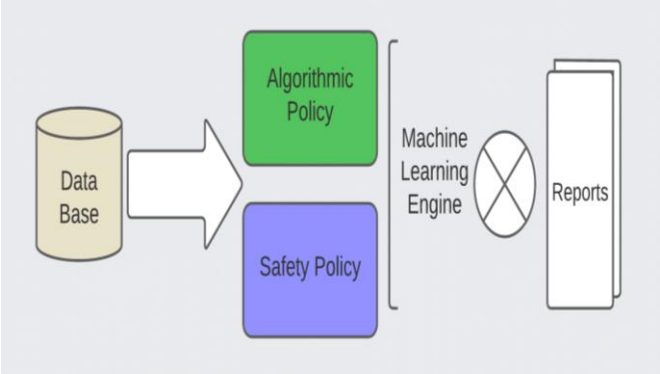

Fig. 2. Macro-learning optimization method for cyber-attacks.

We find ourselves in an optimization automation process with the possibility of acting on the algorithmic parameters and the security cost.

Achieving the previously set optimization goals will be a prerequisite for achieving the optimized cyber security logic model (see Fig. 3).

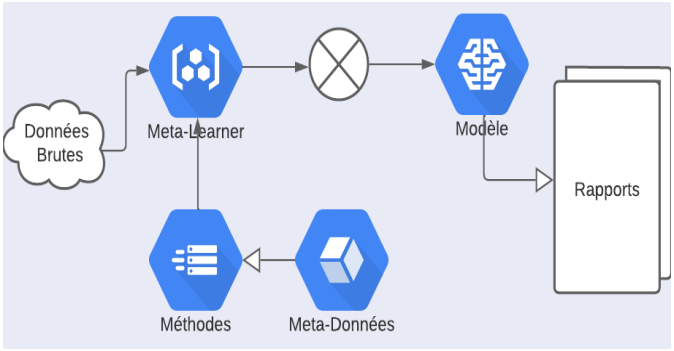

Fig. 3. Optimized cyber-security logic model (olm).

This process takes place in two successive phases. First, we introduce the concept of Meta-Learning on which algorithmic policy is based. Next, we present the cost-aware learning technique. This will make it possible to implement the entity's security policy in terms of intrusion detection and cost control.

Meta-learning corresponds to what we could call macro learning. This involves understanding the behavior of multiple learning methods. The objective is to collect metadata consisting of performance values and algorithmic parameters associated with the methods.

This approach makes it possible to nest or encompass several learning methods within a single Canvas. We know that the quality of an algorithm includes not only how well it predicts reality, but also how quickly it is executed. This is the basic principle of the meta-learning process.

In the second block dedicated to security policy, we propose to introduce the notion of learning costs (impacts). The goal of classical learning is to minimize the errors generated by the difference between prediction and observation. Since not all errors have the same cost or impact, we will use the cost-sensitive learning technique. The fundamental principle of cost-aware learning is that the learning engine is informed about the cost or impact of intrusion detection scenarios.

At the formal level of the description of the proposed model, we are faced with an operational research problem. On the one hand, it involves defining an objective function, which takes into account the resource constraint and aims to maintain a level of algorithmic performance and to reduce the expression of costs.

Let n be the bisquare dimension matrix, the confusion matrix M (Mij) and the cost matrix C (Cij). The objective function F should be the aggregation of all effects that trigger resource consumption. This includes the cost of detection training and the cost of missed detection of an intrusion. F will be the scalar product of M and C:

$$F = (M * C) = \sum_{\substack{i=1 \\ j=1}}^{n} \left((M_{i,j} * C_{i,j}) \right)$$

Since the first diagonal corresponds to well-classified items, their cost is identical and can be normalized to Cij=1:

$$F = \sum (\mathrm{M_{i,j}} * \mathrm{C_{i,j}}) + \sum (M_{i,i}) \ , \qquad i \neq j$$

The cost of well-classified elements related to correct detection is $\sum(\mathrm{M_{i,i}})$. This is simply a computational cost. Thus, the remaining quantity $\sum(\mathrm{M_{i,j}} * \mathrm{C_{i,j}})$ of F corresponds to the cost linked to the impact of cyber-security. The linear optimization of the objective function is obtained by:

$$min \sum (M_{i,j} * C_{i,j}), \qquad i \neq j$$

V. Methods and Materials

A. Dataset

To conduct the proposed work, we used the latest DDoS attack dataset CICIDS2018 [19]. Most DDoS attack datasets have many limitations, such as missing relevant data and redundancy, which are unreliable. The CICIDS2018 datasets contain up-to-date real-world working network like data. This dataset was collected for five consecutive days with many different cyber-attacks as well as normal data. This dataset contains the latest network data with and without attack, very close to real network data. This dataset is unbalanced, so we balanced it using a duplication method because it seriously affects the training of the deep learning method and therefore testing. This work is applied in an environment containing a 32-bit Intel Core-i5 processor with 8 GB of RAM in a Windows 10 environment.

B. Confusion Matrix

The confusion matrix is a predictive analysis tool in machine learning. It is also known as an error matrix, and is used to evaluate the performance of a machine-learning model based on classification, which aim to predict a categorical label for each input instance [20].

We can also say that the confusion matrix is a summer table of the number of correct and incorrect predictions produced by a classifier for binary classification tasks.

The matrix displays the number of true positives (TP), true negatives (TN), false positives (FP), and false negatives (FN) produced by the model on the test data (see Table I).

- True Positive (TP): when the actual value is Positive and predicted is positive.
- True Negative (TN): when the actual value is Negative and prediction is Negative.
- False Positive (FP): When the actual is negative but prediction is Positive. Also known as the Type 1 error
- False Negative (FN): When the actual is Positive but the prediction is Negative. Also known as the Type two errors.

TABLE I. Confusion Matrix Basic Metrics

Techniques	Observation	
Learning (Predicted Class)	(True Positives) TP	(False Positive) FP
	(False Negative) FN	(True Negative) TN

C. Performance Metrics

The performance of proposed deep learning models for the detection of DDoS attack is measured by standard matrices as Accuracy, Recall and Precision. The definition and the equation for the same is given below:

Accuracy: An indicator makes it possible to measure the proportion of well-classified individuals relative to the entire population examined. It is obtained using the following equation:

$$Accuracy = \frac{\mathrm{TP} + \mathrm{TN}}{\mathrm{TP} + \mathrm{FN} + \mathrm{TN} + \mathrm{FP}}$$

Precision: An indicator of false alarms. It allows us to answer the following question. What proportions of positive identifications were actually correct? It is obtained using the following equation:

$$Precision = \frac{\mathrm{TP}}{\mathrm{TP} + \mathrm{FP}}$$

Recall: A metric that characterizes detection failures. This failure results in the presence of false negatives. It is obtained using the following equation:

$$Recall = \frac{\mathrm{TP}}{\mathrm{TP} + \mathrm{FN}}$$

D. Weka Tool

The physical implementation of the IoT cyber-security model requires the use of hardware and software resources. In order to produce an Optimized Physical Cyber-security Model (OPCM), we opted for open source software that is well known in the scientific research community. This is Weka and its applications.

WEKA provides implementations of learning algorithms that you can easily apply to your database. It also includes a variety of tools for transforming datasets. These include algorithms for discretization and sampling. It can also be used to pre-process a dataset, integrate it into a learning scheme, and analyze the resulting classifier and its performance [21].

In this article, we use the tool for apply learning methods to a dataset and analyze its output to learn more about the data. The objective is to verify the performance of our cyber security mechanism in effectively predicting attacks hitting the IoT.

VI. Results and Discussions

The evaluation study of the proposed model is based on a set of tests obtained after simulating the model in the Weka tool. These data will be provided as input values to the prediction function. The results of this operation will be compared with the corresponding observation values.

Fig. 4. Prediction (star series) of cyberattacks using confusion matrix.

As these results show in Fig. 4, we notice that almost 2863 packets are denial of service (see DINAIL*). This prediction is confirmed by the observations of the test set. In addition there are 1928 packets recognized as benevolent (see Normal*) both in prediction and in observation. We find the errors made by the model for a column of observations outside the first diagonal. There were 1628 predictions ARP spoofing (see SPOOF*). The curves show that the prediction (star series) of cyber-attacks is very close to the values from observation.

To assess the validity of the model, several indicators can measure these objectives at the same time. We have the holistic statistical estimates, which evaluate the overall performance of the model. These indicators reflect the quality, shortcomings and consistency of the learning process.

Correctly Classified Instances	29306	93.6623 %
Incorrectly Classified Instances	1983	6.3377 %
Kappa statistic	0.882	
Mean absolute error	0.0254	
Root mean squared error	0.1592	
Relative absolute error	12.0258 %	
Root relative squared error	49.0447 %	
Total Number of Instances	31289	

Fig. 5. Performance statistics.

In Fig. 5, the results obtained illustrate the following behaviors: The classification quality rate is 93.66%. This rate shows a high level of conformity between predictions and observations. This result is supported by a classification consistency rate of 0.882 (close to unity 1), demonstrating a trend towards convergence between observation and prediction. This deduces the accuracy and performance of the model evaluated.

We then proceed to deepen our assessment of the model's validity using other metrics such as the model's sensitivity, specificity and precision.

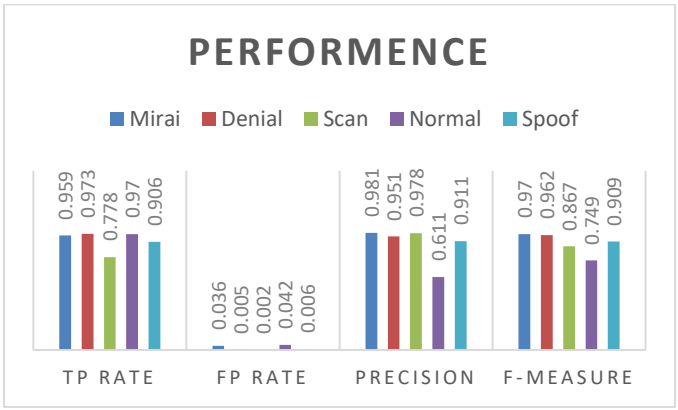

Fig. 6. Learning assessment metrics.

From these test results (see Fig. 6), we deduce that the sensitivity varies between 74% and 97%, while the specificity of the model is between 95.8% and 99.8%. The false alarm rate (false positives) is therefore between 0.2% and 4.2%.

VII. Conclusion

Our exploration has revealed major IoT security risks. The physical security of IoT is challenged in remote sites. Hardware and software upgrades and updates are critical. This is a major constraint to the scale of the threat.

This threat is accentuated by the availability of tools for researching and exploiting vulnerabilities in the IoT system. This represents obvious cyber security challenges.

In this design, special attention is paid to the cybernetic strike chain. To adapt to this, we opted for an optimized detection model. This optimization is based on algorithmic and security policies.

This integrates the potential of algorithmic methods and the reduction of learning costs. To implement it, macro-learning (Meta learning) and discriminated cost methods are used. The programming is carried out on the Weka of the machine-learning platform.

Construction of an Intelligent Evaluation Model of Yield Risk Based on Empirical Probability Distribution

Zhou Yanru[1], Yang Jing[2]
Chaohu University, School of Mathematics and Big Data, Chaohu 238000, China[1]
Hefei Technology College, School of Architectural Engineering, Chaohu 238000, China[2]

***Abstract*—In order to improve the accuracy of yield risk evaluation, an intelligent evaluation model of yield risk based on empirical probability distribution is constructed. The dimensionality reduction method of risk factor based on principal component analysis is adopted. After adjusting the multiple data dimensions of risk factors that affect the rate of return to a unified dimension, the cluster-based evaluation index screening method is used to build the evaluation index set that best reflects the risk of the rate of return; The index weight vector equation method based on entropy weight and information entropy is used to set the evaluation index weight. Through the comprehensive evaluation model based on the empirical probability distribution of risk indicators, the empirical probability distribution information of risk indicators at all levels is analyzed, and the risk level of yield is intelligently evaluated. The research structure shows that the model can effectively evaluate the level of return risk and provide an effective reference for preventing and controlling investment return risk.**

Keywords*—Empirical probability distribution; yield; risk intelligence evaluation; principal component analysis; clustering; weight

I. INTRODUCTION

The characteristics of the investment itself, the complexity of the market environment and the risk management ability of investors will greatly affect the project's return on investment [1]–[3]. In order to obtain the highest return, investors should evaluate the investment risk of the product in the early stage. Because the risk always accompanies the return, and the high return must be accompanied by the high risk, so once the risk occurs, it may give investors a devastating blow [4], [5] The greater the risk of the activity is, the greater the loss of the final result if the decision is wrong, and vice versa. Risk cannot be completely avoided, but rational choice can minimize risk [6]. When conducting risk evaluation, investors should consider the source and use of funds. When examining the use of funds, that is, the investment of projects, they should also comprehensively consider the risks of financing and the overall market environment [7].

According to the analysis of the existing risk evaluation models, Authors used the NPV analysis model and @ risk software to assess the economic benefits and risks of China's carbon capture, utilization and storage projects in the context of carbon neutrality. Although the evaluation effect is effective, it is limited by the completeness of software functions. If the software is abnormal, whether the evaluation accuracy meets the standards remains to be tested [8]. Researchers built a risk evaluation model for overseas mining investment based on the structural power theory. Firstly, they built an evaluation index system of mining investment risk with the safety structure, production structure, financial structure and knowledge structure as the criterion level; then, the Topsis method and grey correlation analysis method were used to build a grey correlation risk evaluation model to complete the effective evaluation of overseas mining investment risk. However, this model does not analyze the problem of data dimension and indicator overlap, and the evaluation ability needs to be optimized [9]. Authors used the case analysis method to identify the investment risk of overseas railway construction projects and built a risk index system. Relevant methods establish the risk assessment model of overseas railway construction project investment. But the evaluation accuracy of this model is limited by the training effect of the neural network [10].

Although the above methods have made some progress, the accuracy of rate of return risk evaluation is low, and there are problems in evaluating the risk level of rate of return. Therefore this study focuses on the intelligent evaluation of yield risk. After reducing the dimension of risk factors, the clustering algorithm is introduced to cluster risk factors and build the optimal yield risk index system. On the basis of determining the weight of each index, empirical probability distribution theory is introduced to build an intelligent evaluation model of yield risk based on empirical probability distribution. In this model, the dimension reduction method of risk factors based on principal component analysis is adopted. After adjusting the data dimensions of various risk factors that affect the rate of return to a unified dimension, the evaluation index set that best reflects the rate of return risk is constructed by the evaluation index screening method based on clustering. The index weight vector formulation method based on entropy weight and information entropy is used to set the evaluation index weight. Through the comprehensive evaluation model based on the empirical probability distribution of risk indicators, the empirical probability distribution information of risk indicators at all levels is analyzed, and the risk level of return rate is intelligently evaluated. After the experimental test, the conclusions are as follows: (1) After reducing the dimension of the data of the influencing factors of yield risk,

the data dimension is obviously controlled in a unified range, which ensures the regularity of the data; The test results of cross-correlation coefficient of yield risk assessment results show that the cross-correlation coefficient is 1, and there is a significant correlation between the yield risk assessment results and the actual yield risk level; Compared with other models, the evaluation effect is the best, which can accurately evaluate the risk level of return, and the evaluation results are in line with the reality.

II. Intelligent Evaluation Model of Yield Risk

According to the classification of systematic risk and non-systematic risk, the classification of risk types of return on investment is shown in Fig. 1.

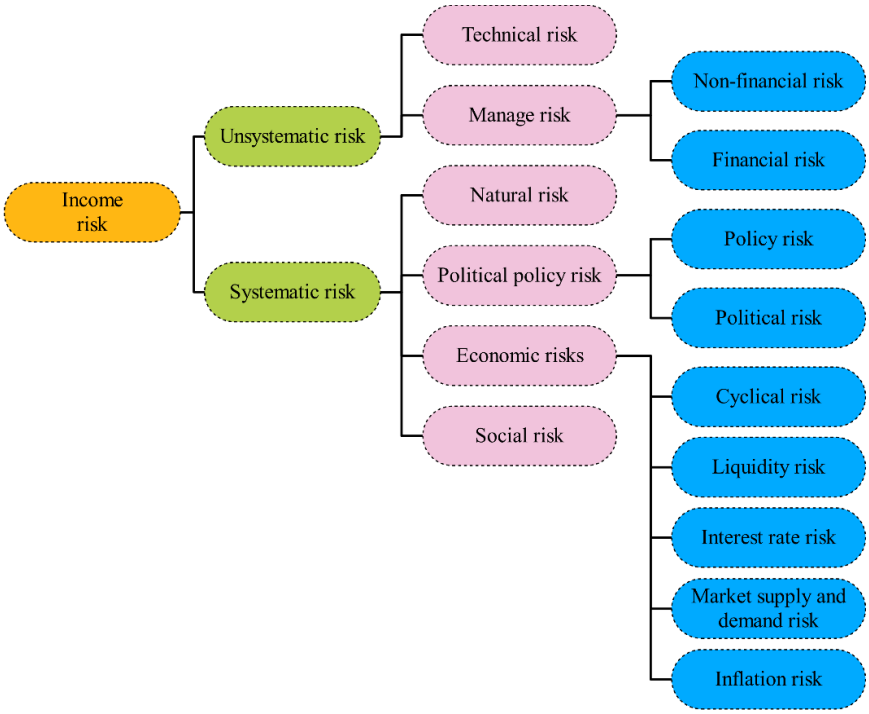

Fig. 1. Classification of risk categories of return on investment.

A. The Dimensionality Reduction Method of Risk Factor Based on Principal Component Analysis

According to the risk types described in Section II, many risk factors affect the rate of return. These risk factors are highly related to economic data, and the data dimensions are inevitably different [11], [12]. If such factors are directly used in the rate of return risk evaluation, it will increase the number of evaluation tasks. As a statistical analysis method for data dimensionality reduction, the principal component analysis method can transform multiple dimensions of the rate of return risk factors into a unified dimension on the premise of retaining most of the original information so as to improve the efficiency of data analysis [13], [14].

Principal component analysis (PCA) is a statistical analysis method with the main method of reducing data dimensions. On the premise of losing little original information, it transforms multiple influencing factors into several comprehensive factors (principal components) by calculating covariance, explains the internal structure of multiple influencing factors through a few principal components, catches the main contradictions and reduces the number of variables, and achieves the purpose of data compression and improving the efficiency of analysis [15], [16]. The main steps of the dimensionality reduction method for risk factors based on principal component analysis are as follows:

1) Standardize the data of yield risk factors. The risk factor data of the original yield is standardized to eliminate the impact of the yield risk factor data dimension and order of magnitude [17]. The standardization equation is:

$$a'_{ij} = \frac{a_{ij}-\beta_j}{R_j} \quad (1)$$

In the formula, a'_{ij} is the risk factor data of the standardized rate of return; a_{ij} is the original factor data; β_j and R_j are the sample mean and standard deviation of the jth yield risk factor; i=1,2,3,...,n, j=1,2,3,...,m, and are the number of samples and the number of factors.

2) Calculate the correlation coefficient matrix of standardized factor data [18]. The correlation coefficient matrix $S = (s_{ij})_{m\times m}$ is the m -order symmetric matrix, and the correlation coefficient s_{ij} represents the degree of correlation between the i -th factor and the j -th factor. The calculation equation of s_{ij} is:

$$s_{ij} = \frac{\sum_{h=1}^{n}(a_{hi}-\beta_i)(a_{hj}-\beta_j)}{\sqrt{\sum_{h=1}^{n}(a_{hi}-\beta_i)^2}\sqrt{\sum_{h=1}^{n}(a_{hj}-\beta_j)^2}} \quad (2)$$

In the formula, a_{hi} and a_{hj} are the h standardized data of the i -th and j -th risk factors respectively. β_i is the mean value of the second risk factor sample.

3) For the characteristic vector v_i of the yield risk factor, $\sum_{j=1}^{m} v_{ij}^2 = 1$ is required, where v_{ij} represents the j -th component of the characteristic vector v_i[19], [20].

4) Calculate the variance contribution rate and determine the principal component. Variance contribution rate F_i represents the proportion of variance of principal component G_i in the total variance, and its calculation equation is:

$$G_i = \frac{\varepsilon_i}{\sum_{i=1}^{m} \varepsilon_i} \times S_{ij} \tag{3}$$

Generally, the first h principal components of the cumulative contribution rate $\sum_{i=1}^{h} G_i \geq 85\%$ can contain most of the original factor information [21].

5) Calculate the principal component load (principal component coefficient matrix). The relationship between the principal component load value z_{ij} and the eigenvector v_i is:

$$\Omega_{ij} = \frac{v_{ij}}{\sqrt{\varepsilon_i}} \times G_i \tag{4}$$

6) Determine the dimension of risk evaluation factors of return rate [22]. Principal component load value Ω_{ij} and variance contribution rate F_i of the principal component jointly determine the final dimension of yield rate risk assessment factors. Then:

$$\Psi_j = \frac{\sum_{i=1}^{h} |\Omega_{ij}| G_i}{\sum_{j=1}^{h} \sum_{i=1}^{h} |\Omega_{ij}| G_i} \tag{5}$$

In the formula, Ψ_j is the dimension of the j -th yield risk factor.

B. Cluster-based Evaluation Index Screening Method

There is usually "coverage" and "overlap" of information between evaluation indicators. In order to obtain more accurate and objective evaluation results, this paper first determines and eliminates the indicators whose information is covered and then adjusts the weight of evaluation indicators according to the amount of information overlap.

Determining the evaluation index set usually includes two stages: rough selection and simplification of the evaluation index. The rough selection indicator set mainly considers the comprehensiveness of the evaluation indicators and is determined by the experts in the field and the evaluators through consultation; the selected indicator set mainly considers the representativeness of the evaluation indicators, which can be determined by statistical analysis methods such as correlation analysis based on the evaluation indicator value. There is no relevant quantitative method for the rough selection of evaluation indicators. Here, only a few main principles to be followed are given:

1) Purpose principle. To select evaluation indicators, it must first clarify the purpose of the evaluation. The evaluation indicators concerned vary with different purposes.

2) The principle of comprehensiveness. This principle needs to be followed in the rough selection stage of evaluation to ensure that the information contained in the evaluation index set reflects the effectiveness of weapons and equipment as fully and comprehensively as possible. As a result, there is also a phenomenon of coverage and overlap between evaluation indicators.

3) Principle of independence. This is a slightly conflicting principle with the principle of comprehensiveness. In the process of rough selection of evaluation indicators, it is necessary to compromise with the principle of comprehensiveness. It is to avoid the coverage and overlap of evaluation indicators as much as possible and ensure that certain characteristics of weapon equipment effectiveness will not be repeatedly reflected in multiple evaluation indicators.

4) Feasibility principle. The selected evaluation index must have a clear meaning, which can not only be understood and recognized by most people but also determines the evaluation index value based on sufficient and reliable data.

In this section, in the risk factor set after dimension reduction in Section II(A), the "very close" risk indicator factors can be determined through cluster analysis. At this time, these indicators can be considered to cover each other. Here, the distance between the yields risk evaluation indicators A_i and A_j is given as follows:

$$D_{ij} = 1 - \frac{\sum_{h=1}^{m} \left(A_i^h - \bar{A}_i\right)\left(A_j^h - \bar{A}_j\right)}{\sqrt{\left[\sum_{h=1}^{m} \left(A_i^h - \bar{A}_i\right)\left(A_j^h - \bar{A}_j\right)\right]^2}} \tag{6}$$

In the formula, D_{ij} represents the distance between indicators A_i and A_j; $\bar{A}_i = \sum_{h=1}^{m} A_i^h / m$, $\bar{A}_j = \sum_{h=1}^{m} A_j^h / m$; m is the number of indicators.

It is assumed that the risk evaluation index of return rate, class O_N, is obtained by combining class O_H and class O_Z, and the distance between it and class O_I is defined by the middle distance method as follows:

$$d_{nI} = \sqrt{\frac{1}{2} d_{HI}^2 + \frac{1}{2} d_{ZI}^2 - \frac{1}{4} d_{HZ}^2} \times D_{ij} \tag{7}$$

where, d_{nI} represents the distance between the class O_N and O_I; d_{HZ} represents the distance between classes O_H and O_I; d_{ZI} represents the distance between classes O_Z and O_I; d_{HI} represents the distance between classes O_H and O_Z.

If O_N and O_I only contain one yield risk evaluation index A_i and A_j, there are:

$$d_{nI} = D_{ij} \tag{8}$$

Further, the evaluation index screening method based on clustering is as follows:

1) Set the distance threshold σ between the evaluation indicators, and treat the yield risk evaluation indicator $A_1, A_2, \ldots, A_m$ as m different categories;

2) Calculate the distance between classes according to Eq. (6) to Eq. (8);

3) Determine whether the minimum distance $d_{nI} = d_{min}$ is less than σ;

4) If yes, merge classes O_H and O_Z into a new class O_N, and skip to step (2), otherwise execute step (5);

5) Output evaluation index class O_N.

Assume that O_N contains the set of yield risk evaluation indicators $\{l_1, l_2, \ldots, l_z\} \subseteq \{A_1, A_2, \ldots, A_m\}$, and z is the number of yield risk evaluation indicators included in O_N. At this point, it can be considered that $\{l_1, l_2, \ldots, l_z\}$ has basically covered each other, and it is further necessary to select the most representative yield risk evaluation index from them. Since the complex correlation number S_i reflects the degree of correlation between l_i and other indicators, the larger the value is, the higher the degree of coverage between l_i and other indicators is; that is, the more representative $l_i$is. The complex correlation coefficient between l_i and other indicators are as follows:

$$S_i = \sqrt{\frac{1}{z-1}\left(\sum_{j=1}^{1} s_{ij}^2 - 1\right)}, i \in z \tag{9}$$

where, s_{ij} is the correlation coefficient between indicators.

Further, the complex correlation coefficient corresponding to the representative index l_s of O_N is $S_s = \underset{1 \le i \le z}{max} S_i$.

After the reduction of yield risk indicators, the set of yield risk evaluation indicators obtained is $\{\hat{A}_1, \hat{A}_2, \ldots, \hat{A}_u\} \in \{A_1, A_2, \ldots, A_m\}$, u is the number of yield risk evaluation indicators after the reduction, and the set of indicators $\{\hat{A}_1, \hat{A}_2, \ldots, \hat{A}_u\}$ is the evaluation indicator system that best reflects the yield risk after the reduction.

C. Index Weight Vector Equation Method based on Entropy Weight and Information Entropy

1) Equation ion of weight vector in index layer considering data entropy weight: Entropy weight is an indicator to measure the degree of information provided by indicator data. By evaluating the degree of variation of data, we can measure the impact of the indicator data on the final rate of return risk evaluation results [23].

Firstly, the following steps are adopted to equation the weight vector between indicators within each indicator layer:

a) Through the expert scoring method, it can get the importance matrix $B(t) = \left(b_{ij}\right)_{m \times m}$ between the indicators in the k -th index layer of $\{\hat{A}_1, \hat{A}_2, \ldots, \hat{A}_u\}$, where $k = 1,2, \ldots, u$, b_{ij} is the importance between the i -th index and the j -th index. The maximum eigenvalue and eigenvector of $B(t)$ are calculated as shown in Eq. (10).

$$\gamma(k) \frac{1}{\hat{A}_u} \sum_{1}^{\hat{A}_u} \frac{(B(t) \cdot \varpi(k))}{b_i}_{max} \tag{10}$$

In the formula, $\varpi(k) = (\varpi_1, \varpi_2, \ldots, \varpi_u)^T$ is the approximate eigenvector of the k -th index layer, which is the initial weight. A consistency check is performed on $\gamma(k)_{max}$, and if it is satisfied, it can proceed to the next step; otherwise, return to step (1) to re-evaluate $B(t)$ [24].

b) The information entropy evaluation is carried out for the jth index of the k -th index layer in $\{\hat{A}_1, \hat{A}_2, \ldots, \hat{A}_u\}$. The evaluation method is as follows (11):

$$f(k,j) = \frac{-\sum_{z=1}^{Q(k,j)} q(k,j,z) \ln\left(2, q(k,j,z)\right)}{ln\left(Q(k,j)\right)} \tag{11}$$

In the formula, $f(k,j)$ is the information entropy of the j -th index in the k -th index layer; $Q(k,j)$ is the number of factor data of the j -th index of the k -th index layer; $q(k,j,z)$ is the satisfaction index of the z -th index factor data in the k -th index layer.

c) The improvement of $\varpi(k)$ taking into account information entropy is shown in Eq. (12):

$$\bar{\varpi}(k) = \varpi(k)^{T} f(k) \tag{12}$$

In the formula, $\bar{\varpi}(k)$ is the weight vector of the k -th index layer taking into account the information entropy; $f(k)$ is the information entropy vector of the k -th index layer; It can normalize the above equation:

$$\bar{\varpi}(k,j) = \frac{\bar{\varpi}(k,j)}{\sum_{j=1}^{m} \bar{\varpi}(k,j)} \tag{13}$$

In the formula, $\bar{\varpi}(k,j)$ is the weight of the j -th index in the k -th index layer after normalization.

2) Formulation of weight vector of criterion layer considering weight information entropy

However, the impact of different criteria levels on the final rate of return risk evaluation results is different, which cannot be reflected by the traditional expert scoring method and needs to be improved by using weight information entropy [25].

The formulation steps of the weight vector of the criterion layer considering the weight information entropy are as follows:

a) Based on the expert scoring method and the feature vector method [26], the weight vector between the criteria layers is obtained as $\varpi_{m \times m}$, and the specific method is the same as the weight vector between the indicators within the specified criteria layers.

b) The entropy weight is reflected in the criterion layer as follows: the weight information entropy of different evaluation indicators in the criterion layer, and the weight information entropy of the k -th criterion layer is calculated as shown in Eq. (14):

$$f'(k) = \frac{-\sum_{j=1}^{m(k)} \bar{\varpi}(k,j) \ln\left(2, \bar{\varpi}(k,j)\right)}{ln\left(m(k)\right)} \tag{14}$$

where, $f^{'}(k)$ is the weight information entropy of the k -th criterion layer; $m(k)$ is the number of indicators in the k -th criterion layer.

c) The weight vector $\varpi_{m \times m}$ between the criteria layers is improved by using the weight information entropy, as shown in equation (15).

$$\bar{\varpi}(k) = \varpi(k)^{T} f'(k) \tag{15}$$

where, $\bar{\varpi}(k)$ is the improved weight vector of the criterion layer. To sum up, the k -th criterion layer can be obtained, and the comprehensive weight of the j -th index is shown in Eq. (16):

$$\varpi(k,j) = \bar{\varpi}(k)f'(k) \quad (16)$$

D. Comprehensive Evaluation Model Based on the Empirical Probability Distribution of Risk Indicators

In order to comprehensively evaluate the return risk of each proposed investment project, we adopted an expert scoring method based on questionnaire. Considering that the rate of return risk index system consists of multiple groups of indicators, and each group of indicators contains different numbers of factors, a questionnaire scoring table is tailored for each project.

The design of the questionnaire carefully considered various risk indicators to ensure that quantitative and qualitative data were covered, so that experts could comprehensively and accurately assess risks. Specially invited 20 experts from the industry to participate in the grading. These experts have profound academic background and rich practical experience in related fields, and their grading has high authority and reference value. In the questionnaire, experts need to tick the corresponding level according to the data collected by the index system and their cognition of the project risk level. This process ensures that every expert can score according to a unified standard, thus increasing the objectivity and accuracy of scoring.

After this process, 20 answers from different experts will be obtained for each project. These answers provide valuable data to construct the empirical probability distribution of risk indicators. Through statistical analysis, we can understand the distribution of various risk indicators and the overall risk assessment of the project by experts. In order to ensure the validity and reliability of the questionnaire, a strict validity test is carried out. The content validity test is used to ensure that the questions and options in the questionnaire can fully reflect the rate of return risk index system. Secondly, the structural validity test is carried out, and the factor structure of the questionnaire data is analyzed to ensure that the measured results of the questionnaire are consistent with the expected risk factor structure.

1) Calculate the empirical probability distribution of risk indicators at each level:

$$q_{1ij}(Y_h) = \frac{1}{20}\varpi(k,j) \quad (17)$$

In the formula, $q_{1ij}(Y_h)$ refers to the probability distribution column of the risk indicators at the criterion level among the risk indicators at each level; Y_h is the risk level. Similarly, there are similar expressions for risk indicators at the indicator level, namely:

$$q_{2ij}(Y_h) = \frac{1}{20}\bar{\varpi}(k,j) \quad (18)$$

In the formula, $q_{2ij}(Y_h)$ represents the probability distribution column of the risk indicators at the indicator level among the risk indicators at each level.

Among the risk indicators at all levels, the empirical probability distribution of the j -th risk factor of the i -th risk indicator at the criterion level is:

$$G_{1ij}(y) = \sum_{h=1}^{5} q_{1ij}(Y_h) \quad (19)$$

At this time, the total empirical probability distribution of risk indicators at the indicator level can be expressed as:

$$G_{1i}(y) = \sum_{j=1}^{\bar{\varpi}(k,j)} G_{1ij}(y) \quad (21)$$

In the formula, $\bar{\varpi}(k,j)$ is the comprehensive weight of risk indicators at the indicator level.

2) Based on the empirical probability distribution of risk indicators at all levels, the risk level of the rate of return is evaluated:

$$Q^{(1)} = \left(q_{ij}(Y_1), q_{ij}(Y_2), q_{ij}(Y_3), q_{ij}(Y_4), q_{ij}(Y_5)\right) \quad (22)$$

In the formula, $q_{ij}(Y_1)$ is the empirical probability distribution column data of indicators in risk level 1. The total value of empirical probability distribution is 1. It is mainly used to judge the degree of risk level based on the proportion of empirical probability distribution of risk indicators in each risk level. In the issue of income risk evaluation, the risk level is mainly divided into five levels, namely, lower risk, low risk, medium risk, high risk and higher risk.

III. Experimental Analysis

In order to analyze the use effect of the model in this paper, the risk level of the return rate of two enterprises invested by a private equity fund is evaluated. A comprehensive data set is needed to train and verify the model, and the data set of yield risk is selected as the experimental data set, which is collected from publicly available financial databases, including historical yield data of financial markets such as stocks, bonds and futures. Collect GDP growth rate, inflation rate, interest rate, etc. from economic databases or official institutions, and collect income, profits, assets, etc. from company financial reports or public databases.

Data preprocessing is an important step to build the model. Firstly, data cleaning is carried out to remove the repeated, abnormal and wrong data points in the data set to ensure the accuracy and reliability of the data. Secondly, in order to eliminate the influence of dimension and range in feature data, feature normalization is carried out, so that different features can be compared and calculated fairly. Finally, the missing values are filled by interpolation or regression to ensure the integrity and continuity of the data. These pretreatment measures can improve the efficiency and accuracy of model training, and provide a solid data foundation for building an intelligent evaluation model of return risk based on empirical probability distribution. Table I is the information on yield risk indicators constructed by this model.

Table II shows the setting details of the weight of the yield risk evaluation indicators in this model:

The model in this paper analyzes the investment risk of two enterprise projects using the risk evaluation of the rate of return. Table III is the empirical probability distribution column of risk indicators of Enterprise 1 and Enterprise 2.

TABLE I. INFORMATION ON YIELD RISK INDICATORS

Criterion layer	Indicator layer	Factor
Financial risk	Solvency	Current ratio
		Quick ratio
		Asset-liability ratio
		Liabilities/EBIT
	Profitability	Net interest rate of equity
		Profit margin of main business
		Net asset interest rate
	Operational capacity	Total asset turnover
		Inventory cycle rate
		Accounts receivable turnover rate
	Cash payment ability	Free cash flow
		Cash flow debt ratio
		Sales cash ratio
	Growth ability	Sales growth rate
		Profit growth rate in the past two years
Non-financial risk	Industry risk	Political and economic fluctuation risk
		Policy and regulatory risks
		Industry life cycle risk
	Market risk	Sales risk
		Supply chain risk
		Market competition risk
		Market development risk
	Product risk	Property right risk
		Product substitution risk
		Technical environmental risk
		Product technical risk
		Product economic risk

TABLE II. WEIGHT SETTING DETAILS OF YIELD RISK EVALUATION INDICATORS

Criterion layer	Indicator layer	Weight	Factor	Weight
Financial risk	Solvency	0.140	Current ratio	0.273
			Quick ratio	0.296
			Asset-liability ratio	0.176
			Liabilities/EBIT	0.255
	Profitability	0.312	Net interest rate of equity	0.487
			Profit margin of main business	0.315
			Net asset interest rate	0.198
	Operational capacity	0.179	Total asset turnover	0.312
			Inventory cycle rate	0.302
			Accounts receivable turnover rate	0.386
	Cash payment ability	0.114	Free cash flow	0.4
			Cash flow debt ratio	0.302
			Sales cash ratio	0.298
	Growth ability	0.255	Sales growth rate	0.491
			Profit growth rate in the past two years	0.509
Non-financial risk	Industry risk	0.258	Political and economic fluctuation risk	0.322
			Policy and regulatory risks	0.24
			Industry life cycle risk	0.438
	Market risk	0.271	Sales risk	0.288
			Supply chain risk	0.227
			Market competition risk	0.251
			Market development risk	0.234
	Product risk	0.471	Property right risk	0.204
			Product substitution risk	0.194
			Technical environmental risk	0.154
			Product technical risk	0.253
			Product economic risk	0.195

TABLE III. THE EMPIRICAL PROBABILITY DISTRIBUTION OF RISK INDICATORS OF TWO ENTERPRISE PROJECTS

Risk level	Item 1	Item 2
1	0.450	0.173
2	0.347	0.290
3	0.151	0.263
4	0.052	0.143
5	0.000	0.131

As shown in Table III, the empirical probability distribution column value of Project 1 accounts for the largest proportion in risk level 1, followed by risk level 2, and 0.00 in risk level 1, while the empirical probability distribution column value of Project 2 accounts for the largest proportion in risk level 2, followed by risk level 3. There are empirical probability distribution columns in five risk levels, indicating that the risk is greater than Project 1.

Fig. 2 and Fig. 3 show the details of the data distribution dimensions before and after the dimensionality reduction of the data of the factors influencing the yield risk.

As shown in Fig. 2 and Fig. 3, the data dimension of the model in this paper is significantly different before the dimensionality reduction of the data of the factors influencing the yield risk. If such data is directly used in the intelligent risk evaluation, it will increase the difficulty. However, after reducing the dimension of the data of the factors influencing the yield risk in this model, the data dimension is obviously controlled in a unified range, ensuring the regularity of the data.

Whether the risk evaluation results are credible when the model is used to assess the project yield risk of two enterprises is tested, and the cross-correlation coefficient reflects the test results. The analysis method of correlation number Γ_{ij} is:

$$\Gamma_{ij} = \frac{cov\left(Q_i^{(1)}, Q_j^{(1)}\right)}{Q_i^{(1)} Q_j^{(1)}} \tag{22}$$

In the formula, $Q_i^{(1)}$ and $Q_j^{(1)}$ are the standard deviation between the risk level of the i -th and j -th project rate of return and the risk level of the actual rate of return. The value of Γ_{ij} is 0, indicating that there is an error in the yield risk evaluation result; If the value of Γ_{ij} is close to 1, it indicates that there is a significant correlation between the yield risk evaluation result and the actual yield risk level. Then the cross-correlation coefficient of the yield risk evaluation results of the model in this paper is shown in Fig. 4.

As shown in Fig. 4, the cross-correlation coefficient test results of the yield risk evaluation results of the model in this paper show that the cross-correlation number Γ_{ij} is 1, indicating that the yield risk evaluation results are significantly correlated with the actual yield risk level, and the evaluation results are reliable.

In order to highlight the mining effect of the model in this paper, it compares the model in reference [8], model in reference [9] and model in reference [10] to determine whether the model in this paper has application advantages. Fig. 5 shows the comparison test results of the four models.

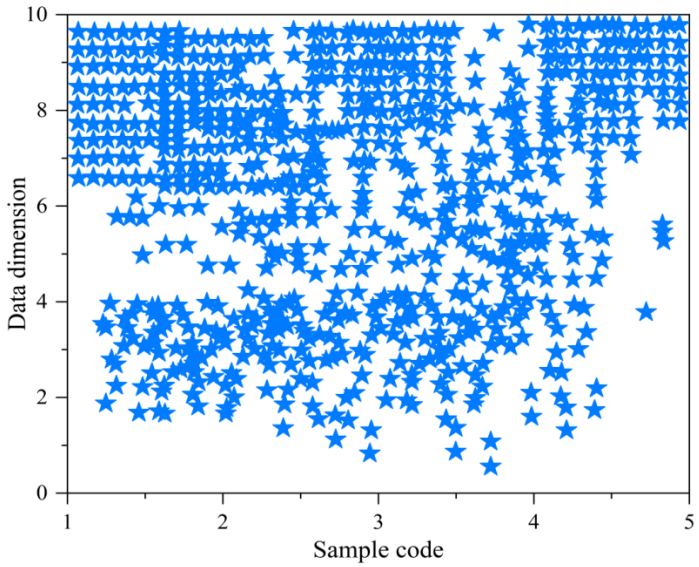

Fig. 2. Before dimensionality reduction of the data of yield risk influencing factors.

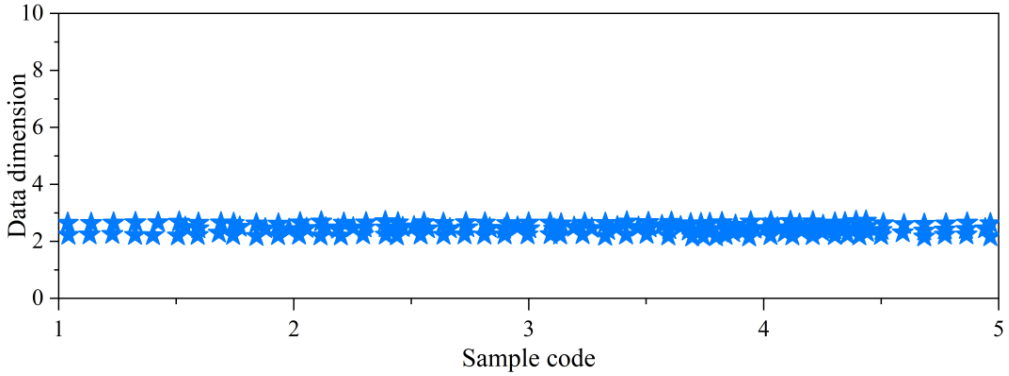

Fig. 3. After the dimensionality reduction of the data on the influencing factors of yield risk.

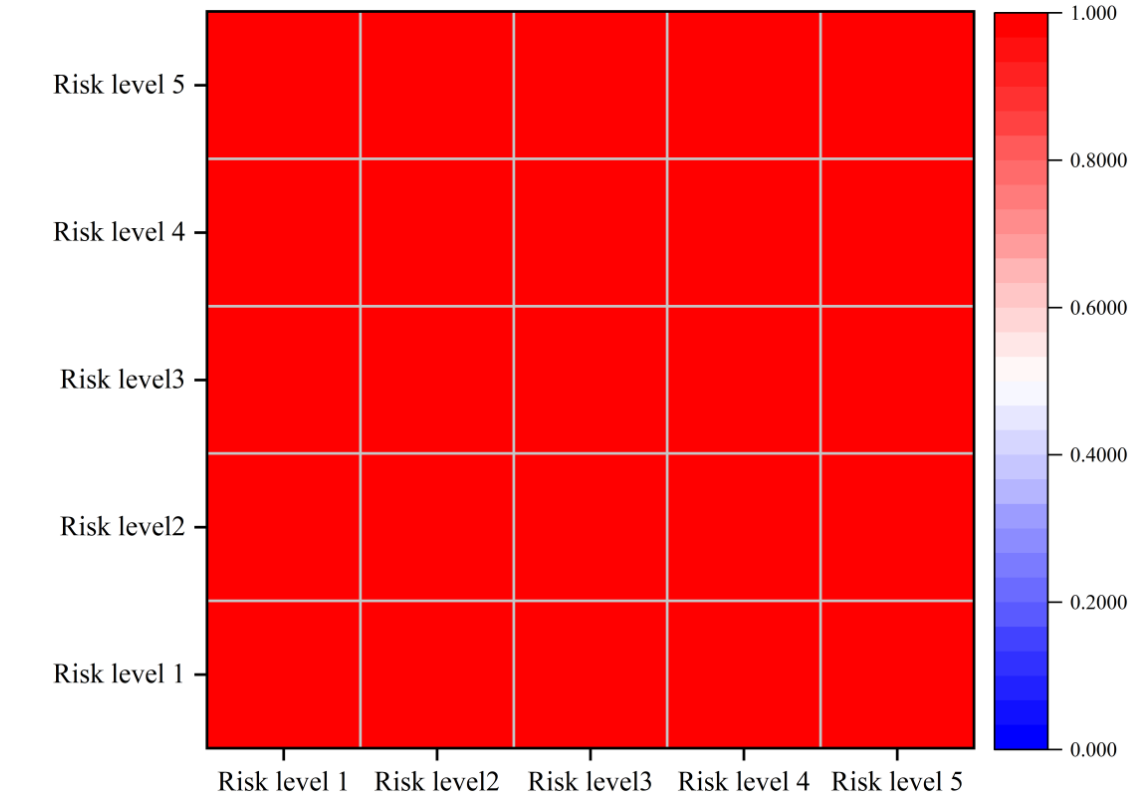
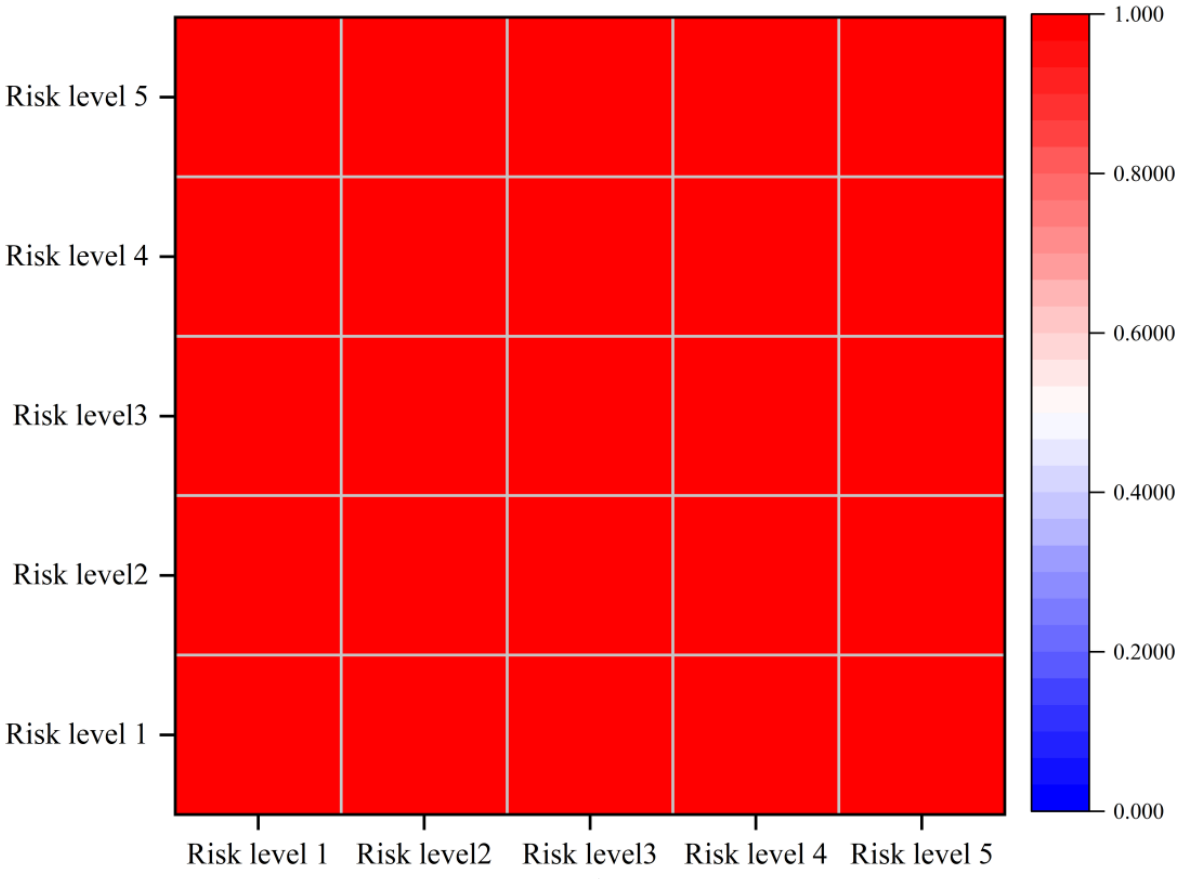


(a) Project of enterprise 1



(b) Project of enterprise 2

Fig. 4. The test results of the cross-correlation coefficient of the yield risk evaluation results of this model.

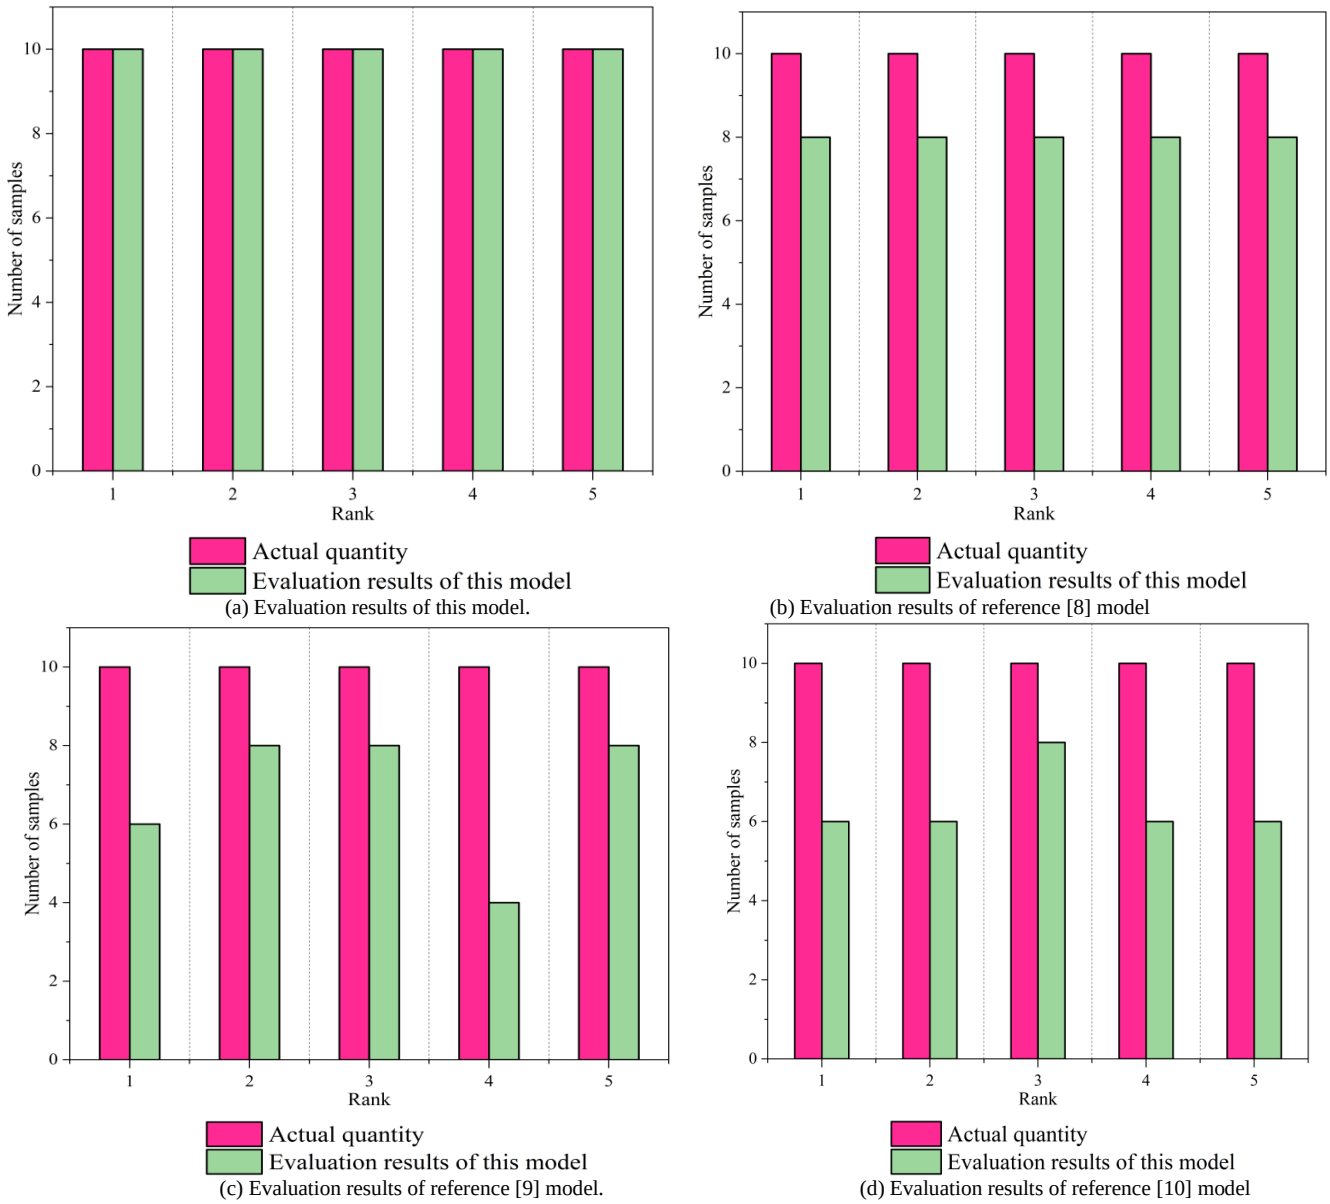


Fig. 5. Comparative test results of four models.

As shown in Fig. 5, after the model in this paper, the model in reference [8], the model in reference [9] and the model in reference [10] evaluate the same yield risk target, the evaluation effect of the model in this paper is the best, which can accurately evaluate the yield risk level, and the evaluation results are in line with the reality. However, the evaluation results of the model in reference [8], the model in reference [9], and the model in reference [10]are biased. The reason is that the model in this paper can reduce the dimension of risk indicators and screen indicators before evaluation so as to ensure the rationality of indicators.

IV. Conclusion

This paper constructs an intelligent evaluation model of yield risk based on empirical probability distribution, comprehensively analyzes the yield risk from multiple perspectives, analyzes it from financial and non-financial perspectives, constructs an intelligent evaluation index of yield risk, and designs a comprehensive evaluation model based on the empirical probability distribution of risk indicators. After in-depth performance testing in the experiment, the test conclusions are as follows:

1) After the dimensionality reduction of the data of the factors influencing the yield risk in the model of this paper, the data dimension is obviously controlled in a unified range, ensuring data regularity.

2) The cross-correlation coefficient test results of the yield risk evaluation results of the model in this paper show that the correlation number is 1, the yield risk evaluation results have a significant correlation with the actual yield risk level, and the evaluation results are reliable.

3) Compared with other models, the model in this paper has the best evaluation effect and can accurately evaluate the

risk level of the rate of return. The evaluation results are in line with reality.

For the future research work of the intelligent evaluation model of return risk based on empirical probability distribution, the following are some prospects:

1) Establish a more accurate model: Future research can explore a more accurate model and introduce market sentiment and macroeconomic indicators to improve the prediction accuracy of the model.

2) Consider the nonlinear relationship: In fact, there may be a nonlinear relationship between stock returns, and future research can explore how to consider the nonlinear relationship to better describe and predict the return risk.

3) Consider the change of market conditions: The change of market conditions is one of the important factors affecting the rate of return. Future research can explore how to adjust model parameters according to different market conditions and provide corresponding risk assessment.

***Abstract*—The effectiveness of machine learning (ML) and deep learning (DL) models on the Quora question pairs dataset is investigated in this study. ML models, including AdaBoost, reached 73.44% test accuracy, while ensemble learning approaches enhanced outcomes even further, with the Hard-Voting Ensemble achieving 76.13%. DL models, such as FCN, demonstrated test accuracy of 81% with cross validation. These findings contribute to natural language processing by demonstrating the potential of ensemble learning for ML models and the DL models' detailed pattern-capturing capacity.**

***Keywords*—Ensemble learning; natural language processing; deep learning; machine learning**

I. INTRODUCTION

Ensemble learning has grown increasingly popular as an efficient machine learning technique to increase accuracy and predictability in predictions. At its core, ensemble learning entails merging multiple models into a more accurate predictor [1]. There are various techniques for producing multiple models simultaneously. Bagging is one such approach [2], where multiple models are trained on random subsets of training data for multiple models to share a set of results. Another technique, called boosting [3], allows models to be trained sequentially to address errors from prior models. A third technique called stacking [4] uses multiple models trained on identical data and employs a meta-model as a bridge to integrate their outputs. Stacking is a method by which multiple models are trained to find an ideal way of combining their predictions. Predictions from base models serve as input into an intermediate-level model which then learns how to weigh and combine them to produce a final prediction.

Ensemble learning offers numerous advantages over single models. It reduces the risk that an overfitted model becomes too complex and learns noise instead of patterns in data; and captures more patterns. Ensemble learning can also enhance the predictability and stability of predictions by creating a model less sensitive to small fluctuations in data. Furthermore, ensemble learning combines all models' strengths for improved accuracy in forecasts. Ensemble learning in machine learning refers to the practice of combining multiple models into one to increase accuracy and robustness. This involves training multiple models on one dataset using different initializations or hyperparameters for their training sessions. Ensemble learning's central concept is that combined models will outperform individual ones due to being better at capturing more patterns while avoiding overfitting. Ensemble learning in natural language processing has yielded excellent results for a range of tasks such as text classification and sentiment analysis. Ensemble learning can easily manage various data types - textual as well as structured data - making it applicable to many NLP tasks. Selecting the optimal ensemble method and configuration can be a complex process that involves extensive experimentation and evaluation. Furthermore, training multiple models may prove too expensive a prospect; hence ensemble learning has proven an indispensable asset to NLP applications. Recent machine learning studies have demonstrated the power of ensemble learning over individual classifiers when it comes to improving performance. Ensemble learning has had a considerable effect on machine learning applications, leading to its widespread usage across various domains such as text classification. [5- 8]. Deep neural networks (DNN), one of the cornerstones of machine learning, have emerged as a formidable force over recent years. DNNs have contributed to advancing natural language processing and text classification techniques. Speech recognition, object detection, visual object recognition, and object identification all benefit. [9]. Deep learning techniques differ from classical machine learning in that they automatically identify and extract complex features without manually creating them [10]. Deep learning employs multiple network architectures to address problems, including feed-forward neural nets, convolutional networks, and recurrent networks [11]. Recently, many attempts have been made to combine DNNs and ensemble methods to enhance prediction performance. To develop ensemble deep learning, one of the easiest and simplest approaches is integrating deep learning directly into existing ensemble learning methods. Most attempts focus on creating weighted-average models of deep learning models; studies have demonstrated that ensembles incorporating DNNs outperform individual DNNs for classification tasks [12].

The Quora Question-Pairs dataset is one of the most frequently utilized resources for identifying question pairs. With over 400,000 questions identified as either duplicates or not duplicates, this dataset offers an excellent way to pinpoint question pairings. Duplicate questions must be identified to reduce redundancy on search engines, forums, and question-answering software. Unfortunately, due to its wide range of languages and question structures, this task is no easy feat. This

study investigates the efficacy of ensemble learning methods in recognizing question pairs from the Quora Question Pairs data set. Various ensemble methods were compared to improve the accuracy of machine learning models as well as deep learning models. Current experiments demonstrate how ensemble learning can be accomplished by combining models such as logistic regression, random forests, and XGBoost with deep learning models like convolutional neural networks or long-short-term memory networks. This study will conduct further investigations of hyperparameters and assess the interpretability of ensemble models, contributing to an expanding body of research in ensemble learning and natural language processing (NLP), providing insight into optimal ensemble methods and configurations to identify question pairs; these results may also have applications in search engines, online forums and question answering software systems.

This research performs comparative experiments on the dataset using the most popular ensemble techniques; weighted and vote ensemble methods, which contribute to and encompass the development of ensemble learning algorithm, extensive experimentation with various machine learning models, performance evaluation, comparative analysis against existing methods, and an exploration of prediction strategies within the context of ensemble learning for semantic similarity. To that purpose, the following are the primary contributions of the paper:

In current study, comprehensive trials were carried out by cross-validating training several machine learning models, followed by precise evaluations. This strategy demonstrates the ensemble methods underlying potential for assessment the performance of models on the dataset of Quora question pairings. Ensemble learning approaches using a varied variety of machine learning models had not been investigated on the Quora question pairs dataset.

This analysis using Current Ensemble Techniques is expanded to evaluate the effectiveness of ensemble approach with a number of well utilized ensemble techniques. The competitiveness and benefits in the context of semantic similarity are shown in this comparative analysis.

This research covers a comparison by applying deep learning to the Quora question pairs dataset which enables us to illustrate deep learning's performance and natural benefits in dealing with the issues given by question pair classification tasks that providing a complete evaluation of model performance and emphasizing the practical value of these gains in tackling real-world situations.

This paper is organized as follows. Section II presents the related works. Data preparation is shown in Section III. Section IV discusses the proposed model. While the results and discussion are given in Section V. Finally, Section VI concludes the current research.

II. Related Work

Several studies as shown in Table I, have investigated the effectiveness of different ensemble methods, such as bagging, boosting, and stacking, in improving the performance. Study by Dhakal et al. [13] focused on used Natural Language Processing to address the issue of question duplication in Q&A forums by using Deep Learning to determine whether question pairings are duplicates. Sharma et al. research [14] investigated the task of Natural Language Understanding (NLU) through the analysis of duplicate questions in the Quora dataset. They explored the dataset extensively and applied a variety of machine learning models, including linear and tree-based models. To overcome the duplicate question problem provided by the Quora dataset, they tried an enormous number and variety of machine learning models. A basic Continuous Bag of Words neural network performed the best, they also performed error analysis and discovered some subjectivity in the dataset's labelling.

Chandra and Stefanus [15] modelled the Quora question pairings dataset to find a related question; The assignment is a binary categorization. They attempted several methodologies and algorithms, as well as a distinct approach from earlier efforts. For XGBoost and CatBoost, they employed Bag of Words with Count Vectorizer and Term Frequency-Inverse Document Frequency with Unigram for feature extraction. Furthermore, they tested the WordPiece tokenizer, which considerably increases model performance, and they were able to get up to 97 percent accuracy. They tested Bag of Words with two boosting algorithms: Catboost and XGBoost. They also used simple LSTM and BERT to evaluate Quora Question Pairs. The results reveal that BERT outperformed the other models.

The goal of research done by Sharma et al. [16] was to determine whether a question pair is similar; they used a dataset provided by Quora on Kaggle to accomplish this. That dataset had four lakh records, which assisted us in training their models and obtaining the necessary outcomes. They employed Natural Language Processing knowledge and different classification and boosting techniques to determine which is more useful, then they examined the accuracy of various models to determine which method is best suited for the task. The same has been done with the aid of multiple graphs and tables to highlight the differences in the accuracy of various algorithms. It was critical to clean and pre-process the data before applying any algorithm. After that, they used techniques such as the Count Vectorizer with XG Gradient Boosting, the TF-IDF Vectorizer with XG Gradient Boosting, Logistic Regression, and Random Forest.

Anishaa et al. [17] proposed a novel approach by filtration of the Quora datasets using SQLite which takes one-quarter the time it takes to pre-process the same dataset using existing methodologies such as python functions. It concluded that XGBoost outperformed the other machine learning approaches discussed, it has also been discovered that pre-processing with SQLite has improved response time. To analyses and find the best model, they employed machine learning techniques such as Random Forest, Logistic Regression, Linear SVM (Support Vector Machine), and XGBoost. The error log loss functions (0.887, 0.521, 0.654, and 0.357) of the machine learning algorithms were analyzed and compared. XGBoost has the best performance among the other models.

Chandra and his colleagues [18] provided a technique for detecting duplicate question pairs in their study by dividing the

selected dataset in a 70:30 ratio. A technique known as random splitting was employed. It was discovered that if a feature timestamp for each question was given, then a time-based splitting might be utilized to partition the dataset, because the questions asked earlier differed greatly from the questions answered recently. Enabling this feature increases accuracy. The model uses the Glove pre-embedding to classify the questions. Features such as fuzzywuzzy help to achieve very minimal log loss. The log loss for the XGBoost model was 0.35, while the log loss for the Siamese LSTM model was 0.21.

Furthermore, Gontumukkala et al. [19] proposed a method to overcome two drawbacks of Quora as the occurrence of duplicate questions that cause ambiguity and insincere questions that lessen the value of the site by suggesting a strategy to address these two issues using Deep Learning (DL) and Natural Language Processing (NLP) approaches. Bi-directional Long Short-Term Memory (BiLSTM) and Bi-Gated Recurrent Unit (BiGRU) architectures with attention mechanisms were used for both problems, and Siamese Manhattan Long Short-Term Memory (MaLSTM) architectures were used for question pair identification. Five different word embeddings were used for each problem. When it comes to accuracy, precision, recall, and F1 Score, the models that have been used are performing well. For the classification of sincere questions, their model achieved the highest accuracy of 95% and the highest F1 score of 0.82 using FastText + BiLSTM + BiGRU. For the identification of Quora question pairs, their research work achieved the highest accuracy of 90% and the highest F1 score of 0.89 using Paraphrase-MiniLM-L6-v2 + Siamese MaLSTM.

Sendi et al. [20] introduced a transparent, deep ensemble classification method based on multiagent arguments. This approach leverages deep learning algorithms combined with argumentation to outperform traditional ensemble methods, providing explain-ability while meeting Explainable AI needs. Furthermore, Mohammed and Kora [21] proposed a novel ensemble meta-learning strategy which combines multiple classifiers was proposed.

Karlos and his colleagues [22] presented the proposed ensemble method outshone other ensemble methods on benchmark datasets in terms of performance. Furthermore, its meta-learner's performance was further improved by taking advantage of probability distributions for class labels. This paper describes an ensemble-based training scheme for binary classifying using random feature splitting.

Gonçalves et al. [23] assessed the effectiveness of a multi-view ensemble for full-text classification using different document sections as views. Results demonstrate its accuracy in classification accuracy and F1-score calculations. C4.5 serves as their meta-learner to implement support vector machine algorithms for stacking. For views creation, they utilized the OHSUMED full-text biomedical dataset; results from experiments demonstrate that multi-view techniques significantly improve text classification within biomedical text mining. Findings indicate that adding text from certain sections to datasets outperforms simply using titles and abstracts alone.

Haghighi and Omranpour [24] offered an ensemble classifier stacking model to recognize handwritten digits. Addressing different writing styles and structural similarities among digits, this model uses a convolutional network (CNN) paired with bidirectional long-short-term memory (BLSTM) to unify both methods. It utilizes the innovative use of image class probability vectors as input to the meta-classifier, further increasing accuracy with its deep-learning model through BLSTM's ability to learn vectors and arrays. Stacking ensemble classification helps reduce recognition errors by considering similarities between Persian/Arabic numbers and writing style variations. The model was tested on a large dataset consisting of 102.352 points from 102.352 classes of Persian/Arabic data. It achieved high accuracy rates of 99.98% for the training set and 99.39% for the test set. These results demonstrate enhanced performance compared with convolutional neural network experiments and previous research.

Araque et al. [25] investigated ways of improving performance using both deep learning techniques and traditional surface approaches for Sentiment Analysis. Deep learning offers advantages over surface approaches in terms of automatic feature extraction and richer representation abilities. This paper features six contributions; as an initial task, a deep-learning-based sentiment classifier using word embedding is constructed as a baseline solution. Second, two ensemble techniques combine the baseline with other surface classifications commonly employed for Sentiment Analysis. Thirdly, they introduce two models that leverage data from multiple sources by combining surface and deep features. Fifthly, a taxonomy that classifies all proposed models is presented. Seven datasets from microblogging and movie reviews domains are utilized to conduct various experiments that compare performance between proposed models and baseline deep learning systems. An F1-Score analysis verifies the performance of their proposed models.

A study done by Onan et al. [26] implemented a multi objective voting scheme for sentiment analysis that uses optimization. The ensemble method incorporates a static classifier, majority voting errors, forward search, and multi objective differentiation evolution algorithm. Base learners include Bayesian log regression, naive Bayes (linear discriminant analysis), logistic regression, and support vector machine while the current method outshone ensemble learning techniques in various classification tasks. Ankit and Saleena [27] offered a Twitter Sentiment Analysis which detects sentiments and opinions within tweets. To achieve accurate classification of tweets they selected an accurate classifier. They consider common base classifiers such as Naive Bayes and Random Forest, SVMs, and Logistic Regression as base classifiers. An ensemble classifier combining all these classifiers is then proposed to improve performance and accuracy.

Convolutional Neural Networks (CNN) [28] used to identify the semantic similarity of questions using the Quora question pairs dataset. Glove pre-trained word embedding applied to identify the semantic similarity between queries. This word embedding vector is fed into CNN, and the results are compared to Siamese Neural Networks. The model achieved an accuracy of 79%. Wang et al. [29] used the Stack Overflow dataset to investigate three deep learning algorithms

to identify duplicate questions: DQ-CNN, DQ-RNN, and DQ-LSTM, which are based on CNN, RNN, and LSTM, respectively. Six distinct question groups are used to evaluate the effectiveness of DQ-CNN, DQ-RNN, and DQ-LSTM. Except for the Ruby question group, their experimental results reveal that DQ-LSTM outperforms DupPredictor, Dupe, DupePredictorRepT, and DupeRep in terms of recall-rate@5, recall-rate@10, and recall-rate@20.

III. DATASET

In this study, experiments were conducted on the Quora Question Pairs dataset, which is widely used for question pairs identification tasks. The dataset consists of 404,290 question pairs, each identified by a unique ID. For each question pair, the dataset provides the question IDs (qid1 and qid2), the actual text of the first question (question1), the actual text of the second question (question2), and a binary label indicating whether the questions are duplicates (1) or not duplicates (0).

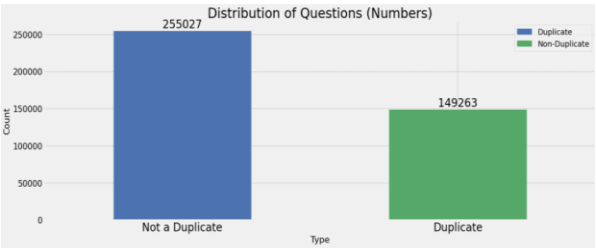

Fig. 1. The distribution of questions in the QQP dataset.

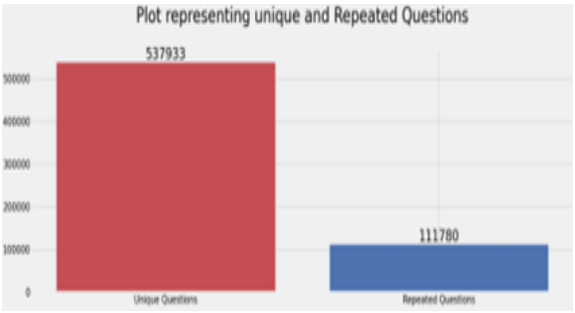

Fig. 2. Unique and repeated questions in the QQP dataset.

Fig. 1 shows a notable aspect of the dataset is the distribution of question pairs. Approximately 63.08% of the pairs are labeled as not similar or non-duplicates, while 36.92% are labeled as similar or duplicates. This class imbalance should be taken into consideration during the data preprocessing and model training stages.

One interesting idea were explored during the data preparation stage is the identification of unique and repeated questions as shown in Fig. 2. By analyzing the dataset, discovered that 98% of the questions occur only once, implying that most questions do not repeat themselves. The dataset also revealed that the maximum number of times a question is repeated is fifty.

Understanding the distribution and uniqueness of questions provides valuable insights into a dataset, aiding in designing appropriate preprocessing techniques and sampling strategies.

Cross-validation was used to assess the performance of models on the Quora Question Pairs dataset. The code snippet illustrates how to select and initialize various machine learning algorithms, such as Gaussian Naive Bayes (GNB), Logistic Regression (LR), Stochastic Gradient Descendant, Decision Tree (DT), Random Forest AdaBoost Extra Trees. Deep Learning classifiers included Fully Connected Networks (FCN), LSTM Bidirectional LSTM.

As part of models' assessment, stratified 10-fold cross-validation were used to compare models. This technique ensures each fold maintains an equal distribution of classes to that found in the original dataset and minimizes potential bias. Accuracy scores were used to judge each classifier's performance; files containing this information allow for thorough comparisons among them.

Cross-validation provides us with a powerful way to evaluate the performance of simple models for question pair identification using the Quora dataset. Reliable estimates of each model's accuracy allow us to make informed choices about suitability for ensemble learning; the results of which will inform future hyperparameter tuning and model selection steps leading to an ideal ensemble model to identify question pairs.

IV. PROPOSED MODEL

This paper proposes a model of a schematic representation architecture that uses ensemble approaches on the QQP dataset to improve the accuracy and reliability of question pair similarity prediction as provided in Fig. 3. This architecture integrates their predictions to provide strong and comprehensive similarity evaluations, with the goal of capitalizing on the strengths of varied base models. The ensemble technique tries to increase predictive accuracy while also establishing a more robust foundation for question pair analysis by synthesizing multiple perspectives on question relatedness. This architecture advances the subject of question similarity assessment within the context of the Quora dataset by integrating several modelling strategies and evaluating their combined efficacy.

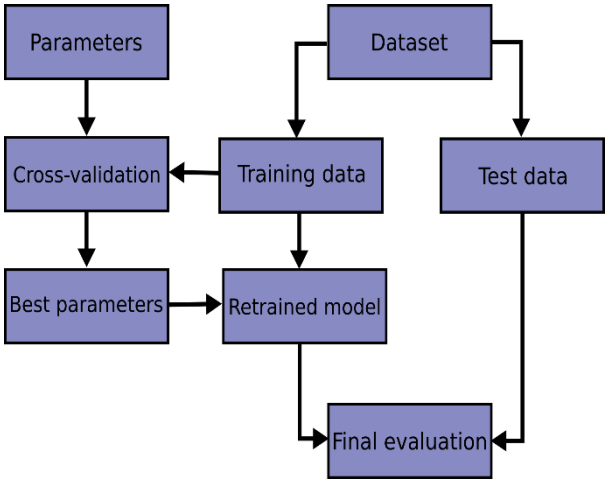

Fig. 3. Proposed general model architecture.

At this stage, text data was processed in various ways to extract features that would aid in the modeling process. The text was initially tokenized using the Tokenizer module of TensorFlow Keras preprocessing modules. This process converted sentences to integer sequences according to word indexes; tokenized sequences were then either extended or reduced until reaching 25 words long. Pre-trained GloVe word embeddings were employed to capture semantic information present in text documents, using word-to-vector maps provided. By iterating over the word index, a matrix of word

embeddings was produced, initially initialized with zeroes before gradually being filled up by GloVe embeddings' word vectors. This word embedding matrix was employed to transform text data, using tokenized and padded question data to fit neural network input requirements for model training. These features were denoted q1_data (original data) and q2_data (transformed version of data), then stored for training use.

Ensemble Learning with Machine Learning Classifiers Approach

Ensemble learning techniques are powerful tools that can increase model performance by combining predictions from different base models into one cohesive prediction. In this research study [36], voting ensemble and weighted average were employed as ensemble techniques.

The Voting Ensemble Technique involves aggregating individual model predictions to produce a final result. A hard voting technique was employed, in which the model with the highest number of votes was selected to predict class. This collective decision-making enabled more effective performances compared to any one model within an ensemble.

Soft voting was utilized, taking into account the probabilities associated with each class prediction and adding up each label's predicted probabilities to determine which class had the highest predicted probability. This method also factored in confidence levels associated with each model prediction to enhance ensemble predictive abilities.

Simple averaging the ensemble techniques was used as a simple averaging approach or weighted averaging. This approach averages the predicted values across different base models using element-wise averages and was utilized in both classification and regression tasks to provide more accurate prediction models from diverse models.

This section presents an in-depth overview of the machine learning (ML) classifiers utilized in this ensemble framework to identify question pairs. These algorithms include Gaussian Naive Bayes (GNB), Logistic Regression (LR), Stochastic Gradient descent, Decision Tree Random Forest, and Gradient Boosting Machine.

Gaussian Naive Bayes, a probabilistic classification method that utilizes Bayes' theorem and assumes independence of features, is derived from Bayesian Naive Bayes. Logistic Regression, on the other hand, is a linear model widely used to estimate probabilities associated with binary outcomes using logarithmic functions. Stochastic Gradient Descent optimizer model parameters iteratively using random subsets from the training data, while Decision Tree creates an interwoven tree-like structure by recursively partitioning features into feature splits. Random Forest employs ensemble averaging to combine multiple decision trees into an ensemble for improved prediction performance, while AdaBoost trains weak learners iteratively by assigning greater weights to instances that have been misclassified, and Extra Trees creates a group of random decision trees to improve generalization. Gradient Boosting Machine creates an ensemble by continuously adding models that correct previous errors.

The dataset was examined using an ensemble learning approach, employing various machine learning models. The dataset was divided into two sets for analysis - X_train (training) and X_test (testing), with target variables created as copies of these two groups Y_train and Y_test, respectively.

For evaluation purposes, widely popular classifiers were trained such as Gaussian Naive Bayes, Logistic Regression, Stochastic Gradient descent, Decision Tree, and Random Forest classifiers as well as AdaBoost Extra Trees Gradient Boosting Machine and Random Forest to compare models' performances against each other. Each of the classifiers employed its respective hyperparameters and training algorithms to train on training data before being deployed on testing data to predict target variables.

An ensemble prediction was created by combining predictions from each model using a simple average technique and then comparing these predictions against labels to calculate accuracy scores. Furthermore, performance metrics such as precision, recall, and F1 scores; specificity loss logs; ROC scores; Cohen's Kappa coefficient of correlation values were calculated and recorded.

Voting Classifier was used to implement a voting-based ensemble. Two variations, hard and soft voting ensembles were explored; hard voting uses majority voting to combine individual classifier predictions; while soft voting used probabilities weighted according to each classifier's confidence in its prediction. Both ensembles were evaluated on the accuracy, classification reports, and confusion matrices for evaluation. A data frame (score) was produced to summarize the results, detailing each model and ensemble's performance metrics.

A. Deep Learning Approach

The current approach also integrates Deep learning (DL) classifiers such as Fully Connected Networks, Long Short-Term Memory, and Bidirectional LSTM into its repertoire. FCN is an architecture of neural networks with fully connected layers; typically used for classification tasks. LSTM is a recurrent neural network type capable of modeling long-term dependencies within sequential data, while Bidirectional LSTM adds context information from past and future inputs by processing sequences both forwards and backward simultaneously. This ensemble framework harnessed their complementary properties and strengths in combination with each other to increase accuracy and robustness for question pair identification tasks. Finally, experimental results were presented as well as evaluating their performance.

As part of the current experimental setup, this study analyzed this dataset using deep learning methods, demonstrating several neural network models including Fully Connected Network, Long Short-Term Memory network (LSTM), and Bidirectional LSTM models. a Time Distributed Layer was used, which employs deep learning architecture to classify questions as duplicates or not. Below is an outline of its implementation and evaluation process.

Initializing all variables and data structures. Next, the dataset was split into two sets - training and testing. Within the training set there can also be further subdivided into five folds

to facilitate cross-validation. The current model was then built using Keras' functional API for flexible architecture consisting of two input layers for every pair of questions posed to it.

The embedding layer transforms words into dense vectors of fixed size for every question, using pre-trained embeddings of words to capture semantic data. Output from this embedding is fed into a Time Distributed Layer followed by a Max Pooling operation to produce fixed-length representations of each question, before being concatenated together and passed through several dense layers such as batch normalization and dropout regularization to reach completion.

The final layer is a dense layer with a sigmoid activation function. This layer produces a score that indicates the likelihood of two questions being identical.

A 5-fold cross-validation approach is used to evaluate the model. Once trained using a set number of epochs and callbacks are implemented to save weights based on validation accuracy, then tested against a test set to evaluate accuracy and loss of prediction.

The algorithm incorporates visual elements like confusion matrices and learning curves to get a general sense of how well its model is performing. Other metrics, such as precision, recall, F1 scores and specificity metrics were used to evaluate the classification performance of the models.

FCN model architecture features dense layers with different activation functions and dropout layers to prevent overfitting, created using an Adam optimizer with binary cross-entropy function and dropout layers as dropout layers to avoid overfitting. The LSTM architecture employed a recurrent network with LSTM cells. Data was reshaped according to input requirements for an LSTM model and dense layers were added similar to an FCN; dropout layers were also implemented to enhance generalization. Finally, this model was constructed and trained using an optimization algorithm, loss function, and FCN model as its training environment. Implementing the Bidirectional-LSTM Model An additional bidirectional layer was added to an LSTM architectural model for training of Bidirectional-LSTM model, enabling it to capture data from past and future timesteps while increasing understanding of temporal dependencies. Finally, an LSTM was used as the training medium.

V. RESULTS

A. Evaluation Metrics

- Accuracy, which stands as one of the most fundamental, and intuitive evaluation metrics as it measures the ratio of correctly predicted instances over the total number of evaluated instances as shown in formula (1). It signifies the overall correctness of a model's predictions. While accuracy serves as a valuable initial assessment, it may not be the sole determinant of a model's performance, particularly when dealing with imbalanced datasets where one class predominates over others [37].

$$\boldsymbol{Accuracy} = \frac{TP+TN}{TP+TN+FP+FN} \quad (1)$$

- Error Rate, which quantifies the proportion of incorrectly predicted instances within the dataset and provides a clear picture of misclassifications which is the ratio of incorrectly predicted instances over the total number of evaluated instances as shown in formula (2) and is particularly relevant in scenarios where false positives or false negatives bear substantial consequences [37].

$$\boldsymbol{Error\ Rate} = \frac{FP+FN}{TP+TN+FP+FN} \quad (2)$$

- Precision [37], which accentuates the accuracy of positive predictions and quantifies the proportion of true positive predictions (correctly identified positive instances) relative to the total number of positive predictions (comprising true positives and false positives) as shown in formula (3).

$$\boldsymbol{Precision} = \frac{\boldsymbol{TP}}{\boldsymbol{TP+FP}} \quad (3)$$

- Recall (sensitivity or the true positive rate) assesses a model's capability to correctly identify all relevant instances from a dataset [37]. From the proportion of true positive predictions in relation to the total number of actual positive instances (encompassing true positives and false negatives) as shown in formula (4).

$$\boldsymbol{Recall} = \frac{\boldsymbol{TP}}{\boldsymbol{TP+FN}} \quad (4)$$

TABLE IV. COMPARISON TABLE OF ML BASED MODELS

- F1-score, as shown in formula (5) represents the harmonic mean of precision and recall. This metric strikes a balance between precision and recall, offering a consolidated score that accounts for both false positives and false negatives [37].

$$\boldsymbol{F1-score} = \frac{\boldsymbol{2\times Precision\times Recall}}{\boldsymbol{Precision-Recall}} \quad (5)$$

B. Ensemble Learning on ML Results

At this research facility, an in-depth evaluation was conducted to select the ideal model. To do so, several classifiers were used such as Gaussian Naive Bayes (GNB), Logistic Regression (LR), Stochastic Gradient descent Decision Tree Random Forest AdaBoost Extra Trees to select an effective one.

As part of this evaluation of each classifier's performance, first conducted a stratified cross-validation with 10-folds to assess their performance and select the most accurate models for further study, cross-validation scores for each fold were then computed as illustrated in Table II which offers a side-by-side comparison of the variability and average performance of several machine learning methods. The best mean accuracy is demonstrated by Random Forest and Extra Trees, although numerous other algorithms, including Logistic Regression and Decision Tree, also perform consistently.

Calculation and summarizing the mean and standard deviation of cross-validation results for each model as provided in Table III.

After selecting classifiers, an in-depth analysis was conducted using grid search to fine-tune their hyperparameters. This involved optimizing each model's parameters using cross-validation with the GridSearchCV feature; hyperparameters were chosen carefully based on empirical evidence and prior knowledge for each classifier.

After optimizing hyperparameters, every classifier was trained using the entire training dataset. Standard scaling was applied both during training and testing to ensure unbiased evaluation, predictions were made using training data, predictions were made from both sources simultaneously while accuracy and computational time were recorded.

Reports were prepared on the optimal settings and scores for each classifier, along with grid scores from parameter tuning processes, to give an insight into performance variations between hyperparameter combinations. After using independent test data to assess the generalization abilities of classifiers, their generalization abilities were evaluated using various performance metrics. The results of the performance metrics of machine learning models as presented in Table IV reveal that Naive Bayes obtained moderate accuracy but demonstrated a trade-off between precision and recall.

Table V illustrated the additional results presents the performance metrics of ensemble learning techniques applied to the previously mentioned machine learning models. The two ensemble methods used are Simple Average and Voting (both Hard-Voting and Soft-Voting).

Simple Average, Hard-Voting Ensemble, and Soft-Voting Ensemble were among the ensemble approaches used to enhance overall prediction accuracy. The results of applying ensemble learning techniques to the previous machine learning models show improved performance compared to individual models. The Simple Average ensemble achieved good accuracy and precision, but its recall rate was relatively low. The Hard-Voting Ensemble achieved the highest train accuracy and a balanced performance between precision and recall. The

Soft-Voting Ensemble showed a good overall performance, with higher recall but slightly lower precision compared to the Hard-Voting Ensemble. Both ensemble methods demonstrated better performance metrics compared to the individual models, suggesting the effectiveness of combining multiple models in improving predictions.

By leveraging the strengths of individual models and combining their predictions, ensemble learning techniques have the potential to enhance the performance of machine learning models.

TABLE V. ENSEMBLE ON SIMPLE BASE MODELS

	Train Accuracy	Test Accuracy	Precision	Recall	F1 Score	Specificity	Matthew Correlation Coefficient	Cohen Kappa	ROC Score
Simple Average	0.74303	0.69804	0.73163	0.28782	0.41312	0.93819	0.30955	0.25852	0.61301
Hard-Voting Ensemble	0.79982	0.76133	0.67724	0.67563	0.67643	0.81150	0.48737	0.48737	0.74357
Soft-Voting Ensemble	0.78274	0.75000	0.63556	0.75703	0.69100	0.74588	0.48896	0.48374	0.75145

In order to optimize these ensemble methods and determine their applicability to other datasets, additional analysis and experimentation are required. The Hard-Voting Ensemble outperformed the individual models in terms of accuracy, precision, memory, and discriminating ability. The Soft-Voting Ensemble exhibited good accuracy and recall as well, but with somewhat lower precision than the Hard-Voting Ensemble. Individual models were outperformed by both ensemble techniques, with the Soft-Voting Ensemble having the greatest ROC score, suggesting higher discriminating abilities.

C. Deep Learning Results

The provided results present the performance metrics of deep learning models applied to the Quora question pairs dataset. The evaluated models consist of Fully Connected Network (FCN), Long Short-Term Memory (LSTM), and Bidirectional LSTM (Bi-LSTM).

The results in Table VI show how three deep learning models, FCN, LSTM, and Bi-LSTM, performed in a classification test. The FCN model obtained 68.47% train accuracy and 68.54% test accuracy, suggesting consistent performance across training and testing periods.

Moreover, through the application of cross-validation, the initial test accuracy of the FCN model, which stood at 68.54%, was significantly improved to 0.81 % as demonstrated in Table VII.

1) Deep learning using cross validation: The results given in Table VIII showed the performance metrics of the FCN model when cross validation was done for a binary classification task. The evaluation of the model was carried out in two classes, which were labeled as 0 and 1. Precision, recall and F1 score were computed for each class.

Results from a binary classification model that was applied to a dataset with two separate classes labelled as 0 and 1. The outcomes are performance measures for a binary classification model for the classes labelled 0 and 1. The model obtains 86% accuracy, 84% recall, and an F1 score of 85% for class 0. It achieves 73% accuracy, 77% recall, and a 75% F1 score for class 1. Collectively, these measures show that the model performs very well at categorizing cases into class 0, while also achieving better for class 1 examples, even though with significantly lower precision.

VI. DISCUSSION

The outcomes and performance metrics of different machine learning and deep learning classifiers in the current study are analyzed to evaluate their effectiveness in predicting target classes.

The results of the performance metrics of machine learning models reveal that Naive Bayes obtained moderate accuracy but demonstrated a trade-off between precision and recall. These results are in consistence with [13] where they proposed to use of ANN's minimal cost architecture and the selection of highly dominating attributes from the questions make it an excellent model for detecting duplicate questions and subsequently finding high-quality replies to queries in Q&A forum. They obtained 0.673 % of accuracy from Multinomial Naive Bayes model.

Logistic Regression performed poorly; however Stochastic Gradient Descent displayed balanced precision and recall in agreement with [16] study article adopted by Sharma et al. who employed Natural Language Processing knowledge and different classification and boosting techniques to determine which is more useful. Then they examined the accuracy of various models to determine which method is best suited for the task. The same has been done with the aid of multiple graphs and tables to highlight the differences in the accuracy of various algorithms. By comparing the two questions, Sharma et al. were able to determine whether they were identical. They used a dataset provided by Quora to solve this hard challenge and trained multiple machine learning algorithms on four entries to determine whether two questions are identical or not. They used multiple techniques after cleaning and preparing the data as needed. First, they used logistic regression, which produced unsatisfactory results. Therefore, they attempted xG boosting with Count Vectorizer and TF-IDF Vectorizer, and they got an accuracy of more than 80%. With 125 trees, Random Forest produced the best results, yielding an accuracy of 83%, which is quite impressive. The performance of the Decision Tree and Random Forest models was comparable, with the latter obtaining slightly greater accuracy and specificity in consistence with results obtained by [13] and [14], which showed percent of specificity of 0.683% and 73.2% respectively. AdaBoost worked admirably, displaying strong accuracy, precision, recall, and discriminating abilities. Extra Trees and Gradient Boosting Machine performed rather well, with a trade-off between various models to determine which method is best suited for the task. The same has been done with the aid of multiple graphs and tables to highlight the differences in the accuracy of various algorithms. By comparing the two questions, Sharma et al. were able to determine whether they were identical. They used a dataset provided by Quora to solve this hard challenge and trained multiple machine learning algorithms on four entries to determine whether two questions are identical or not. They used multiple techniques after cleaning and preparing the data as needed. First, they used logistic regression, which produced unsatisfactory results. Therefore, they attempted XG boosting with Count Vectorizer and TF-IDF Vectorizer, and they got an accuracy of more than 80%. With 125 trees, Random Forest

produced the best results, yielding an accuracy of 83%, which is quite impressive. The performance of the Decision Tree and Random Forest models was comparable, with the latter obtaining slightly greater accuracy and specificity in consistence with results obtained by [13] and [14], which showed percent of specificity of 0.683% and 73.2% respectively. AdaBoost worked admirably, displaying strong accuracy, precision, recall, and discriminating abilities. Extra Trees and Gradient Boosting Machine performed rather well, with a trade-off between precision and recall. These results are in accordance with [14] and [15] where they investigated the task of Natural Language Understanding (NLU) by examining duplicate question identification in the Quora dataset. They conducted extensive investigation of the dataset and employed various machine-learning models, including linear and tree-based models. The researchers discovered that a simple Continuous Bag of Words neural network model outperformed more complex recurrent and attention-based models with accuracy of 83.4 %.

1	0.73	0.77	0.75

The machine learning models' performance on the Quora question pairs dataset produced diverse results as the Logistic Regression model had a challenging time classifying positive instances, showing limited success along with the Naive Bayes and Stochastic Gradient Descent models. The Gradient Boosting Machine and AdaBoost models achieved the highest train accuracies, outperforming the Decision Tree, Random Forest, and Extra Trees models. These results are in agreement with authors of [17] research, where their goal was to find the best machine learning technique for removing all duplicate questions and increasing user satisfaction. Using a real-time dataset, this work trained and tested four machine learning models to recognize duplicate inquiries. The raw dataset was discovered to be 7GB in size. PL/SQL was used to pre-process data before it was stored in the database. PL/SQL loads the full dataset only once, and data is acquired directly from the database whenever a query is conducted, making this procedure quick and efficient. In one hour, the complete dataset was cleaned and pre-processed effectively. While existing solutions use python methods available in python libraries to pre-process massive datasets, it takes four times as long as PL/SQL. Four distinct machine learning models were applied, and their results were evaluated to determine which model performed the best. Following execution, the error parameters referred from the log loss function for the random model, logistic regression model, linear SVM, and XGBoost are 0.887, 0.521, 0.654, and 0.357, respectively. Because efficiency is inversely related to error function, it can be concluded that XGBoost is the optimal model, delivering highest accuracy in the shortest amount of time, which is supplemented by the unique pre-processing procedures performed using PL/SQL, hence improving overall response time.

The results of the Simple Average ensemble had a middling accuracy but a better specificity, suggesting its ability to recognize negative events in agreements with [22], which offered the use of base ensemble consists of two participants in soft voting mode, but multiple classifiers combined into an ensemble method to improve predictive performance. In addition, the experimental results demonstrated by [26] and [27] showed that ensemble classifiers perform significantly better than standalone classifications or majority voting ensembles for sentiment classification purposes. Furthermore, that research explored how feature representation and preprocessing affect sentiment classification performance in consistent with current data results.

The Deep Learning model has a comparatively high accuracy of 79.29%, indicating its ability to categorize positive events reliably. The reduced recall of 20.02%, on the other hand, indicates that the model struggled to catch many positive events. When compared to the FCN model, the LSTM model performed better in terms of accuracy, precision, and recall. It obtained 70.53% train accuracy and 70.49% test accuracy, with a precision of 78.14% and a recall of 27.89% in consistency with [18] study, which used a Siamese LSTM to assess the semantic similarity of two queries in order to improve prediction. The Siamese network is an architecture composed of parallel neural networks, namely LSTM units, for the parallel processing of two questions, with each question passing through an Embedding Layer, an LSTM unit, and then a dense layer. Following that, the outputs of two networks were integrated and compared, yielding a similarity score reflecting

how similar two queries are. The log loss metric was used as the major statistic in this study to evaluate alternative models. The main addition is that the Siamese network is utilized to process two questions in parallel and find vector representations for each. The vectors produced by this technology enable more effective similarity detection than existing models. The GloVe word embedding method was used to determine the semantic similarity of two queries. As the basis model, a random classifier was developed, then logistic regression, linear SVM, and the XGBoost model were utilized to reduce log loss. Finally, a Siamese LSTM was proposed, which significantly minimizes the loss. The XGBoost model accurately identified 69% of question pairings as duplicate, resulting in a recall rate of 0.69. The precision rate was 0.79, and the F1- score was 0.73. Finally, as compared to individual models, ensemble techniques performed better in the classification challenge. The Hard-Voting Ensemble and Soft-Voting Ensemble performed better in terms of accuracy, precision, memory, and discrimination, highlighting the value of mixing various models. These findings extend machine learning approaches for categorization problems by emphasizing the potential benefits of ensemble methods in improving prediction performance. Furthermore, current results are in agreement with [26] study which proposed a model that identifies duplicate question pairs by integrating three word embedding feature extraction techniques (Google News Vector, FastText Crawl, and FastText Crawl Subword), which results in significantly higher accuracy than these embeddings independently. Furthermore, this study developed a novel Siamese MaLSTM model that uses the Manhattan distance to determine semantic similarity among questions with 95% accuracy, far outperforming previous studies. Looking closely at the manhattan values, the manhattan score classifies the question pairings more accurately than any other embedding in a blend of different word embedding predictions; the duplicate question score is nearly one, while the non-duplicate pair values are nearly zero.

VII. Conclusion

In this study, a thorough investigation of deep learning (DL) and machine learning (ML) models using the dataset of Quora question pairings. To ensure a reliable analysis, the dataset was put through ten folds of cross-validation. A variety of machine learning (ML) models were trained, such as Naive Bayes, Logistic Regression, Stochastic Gradient Descent, Decision Tree, Random Forest, AdaBoost, Extra Trees, and Gradient Boosting Machine, and evaluated the performance of each model using a variety of evaluation criteria.

These findings showed that the ML models performed at various levels. While models like Decision Tree, Random Forest, AdaBoost, Extra Trees, and Gradient Boosting Machine performed better, models like Naive Bayes and Logistic Regression had little success. Following that, ensemble learning strategies like Simple Average, Hard Voting, and Soft Voting were used to improve the performance of the ML models. These ensemble approaches significantly increased F1 scores, accuracy, and precision, demonstrating their efficacy in combining predictions from many models.

In addition, this study investigated how well DL models like the Fully Connected Network (FCN), Long Short-Term Memory (LSTM), and Bidirectional LSTM (Bi-LSTM) performed. The DL models' performance was assessed using precision, recall, and F1 scores after they were trained on the identical dataset of Quora question pairs. Cross-validation was used to evaluate the FCN model with two classes, and the results showed precision, recall, and F1 scores of 0.81 for both classes. These results show that the FCN model has performed well overall.

This study discovered that the ensemble learning techniques applied to the ML models produced competitive results when comparing their performance to that of the DL models. The DL models, on the other hand, showed off their capacity to identify intricate patterns and connections in the dataset. With high precision, recall, and F1 scores for both classes, the FCN model showed promise.

In summary, the current study emphasizes the effectiveness of using ensemble learning techniques to improve the performance of machine learning models. Moreover, this study has observed that deep learning models, the FCN model demonstrate great potential in accurately categorizing pairs of questions. These discoveries contribute to the progress of natural language processing. Offer valuable insights for enhancing question pair classification tasks. Moving forward, it would be beneficial to concentrate on refining these models exploring different architectures and examining their applicability to diverse datasets and real-world scenarios.

VIII. Future Work

In light of current study's results in employing ensemble learning techniques to enhance deep learning models, several avenues for future work emerge, broaden this ensemble learning approach to include a broader range of deep learning architectures, improve computational efficiency, and improve interpretability. Will also examine applications in domains with limited labelled data, assess generalization skills further, and develop adaptive ensemble weight techniques for dynamic data distributions.

The Fusion Method of Virtual Reality Technology and 3D Movie Animation Design

Xiang Yuan, He Huixuan
Shijiazhuang University of Applied Technology, Animation Academy, Shijiazhuang City Hebei Province, 050031, China

***Abstract*—To further improve the design effect of 3D film and television animation, integrating virtual reality technology with 3D film and television animation design is studied. This method uses 3Ds Max software in virtual reality technology to build 3D film and television animation scenes by manual modeling. Based on the established 3D film and television animation scene, texture mapping is performed on it, and then the 3D film and television animation character model is established and simulated. After optimizing the established 3D scene and character model using the improved quadratic error measurement algorithm, the roaming interaction of 3D film and television animation scene is realized through Unity3D software, and the integration of virtual reality technology and 3D film and television animation design is realized. The experimental results indicate that the 3D film and television animation scene created using virtual reality technology is very realistic, which can effectively optimize the 3D film and television animation model. The number of path nodes is the least when the 3D film and television animation scene roams and interacts, which has a relatively significant application effect.**

Keywords*—Virtual reality technology; 3D film and television; Animation design; model optimization; roaming interaction

I. INTRODUCTION

3D animation technology is also known as 3D animation technology. 3D animation technology has recently advanced functions such as animation character modeling, material design adjustment, scene environment building, etc. [1]–[3]. It can use various visual communication techniques to reconstruct and simulate more complex spatial scenes, logical thinking, character representation, and other external forms and realize the scheme on the 3D software platform [4]–[6]. At present, virtual reality technology can be applied more and more widely [7], especially in the direction of virtual simulation modeling in 3D space. VR and 3D animation technology can be integrated through 3D integrated model reconstruction and virtual scene creation [8], [9]. In the next stage of the development of 3D modeling technology [10], virtual reality technology is bound to bring innovations and breakthroughs to 3D animation production technology. Therefore, integrating virtual reality technology and 3D film and television animation design will encourage researchers to move towards more in-depth technology integration products [11] and then break through the outdated 3D animation-producing technology to make 3D animation more authentic through virtual scene reproduction.

Abas A et al. [12] suggested a multi-scale transformation multi-focus image fusion method, which fused virtual reality technology and 3D images through a meta-heuristic optimization algorithm to achieve the integration of virtual reality technology and 3D film and television animation design. Mila B et al. [13] proposed an experimental method for social aspects of game virtual reality, which applies virtual reality technology to establish game virtual scenes and characters and realizes the integration of virtual reality technology and 3D film and television animation design. Tastan H et al. [14] proposed the method of building modeling using the handheld user interface and direct operation in immersive virtual reality. This method combines holistic virtual reality technology, portable user interface, and direct operation modeling technology to obtain 3D film and television animation scenes, realizing the integration of virtual reality technology and 3D film and television animation design. Jo, H et al. [15] proposed different visual environment reproduction methods and used this method to integrate virtual reality technology with 3D film and television animation design to obtain urban soundscape and landscape. Karagiannis P. et al. [16] proposed a fusion method using simulation and virtual reality technology. This method utilizes virtual reality technology to build scene and character models and then uses the simulation technology of 3D film and television animation to integrate the scene and characters to integrate virtual reality technology and 3D film and television animation design.

Virtual reality technology is an important direction of simulation technology, which is a combination of simulation technology, computer graphics, human-machine interface technology, multimedia technology, sensing technology, network technology, and other technologies. It is a challenging interdisciplinary and research field with cutting-edge technologies. 3D animation, also known as 3D animation, is not limited by time, space, location, conditions, or objects. It uses various forms of expression to present complex and abstract program content, scientific principles, abstract concepts, etc. in a concentrated, simplified, vivid, and vivid form. Based on the above analysis, it can be concluded that the current research question is how to further improve the effectiveness of 3D film and television animation design, as well as how to integrate virtual reality technology with 3D film and television animation design. Therefore, this paper proposes a fusion method of virtual reality technology and 3D film and television animation design. Through manual modeling, texture mapping, character simulation, and optimization processing, achieve more realistic, interactive, and optimized 3D film and television animation scenes. In order to provide more efficient, realistic, and interactive solutions for 3D film and television animation design, promote the development of virtual reality technology, and bring more diverse and immersive virtual

experiences to entertainment, education, cultural and artistic fields.

II. Comparative Analysis

Compared with similar works mentioned in the introduction, this paper aims to further enhance the design effect of 3D film and television animation, and explore the integration method of virtual reality technology and 3D film and television animation design. Below, a fair comparison will be made between this work and similar previous works, highlighting the advantages of this work:

1) Method innovation: This paper uses 3D Max software from virtual reality technology to manually model 3D film and television animation scenes. Unlike the multi-scale transformation and multi focus image fusion method proposed by Abas et al. [12], this method applies virtual reality technology to the modeling process in a more direct way, thereby improving the realism and detail representation of the scene.

2) Texture mapping processing: In this work, texture mapping processing was applied to the established 3D film and television animation scene. This step makes the scene more realistic and visually appealing. In contrast, Mila et al. [13] did not extensively explore the application of texture mapping processing in the experimental methods of social aspects in game virtual reality.

3) Simulation processing: This paper establishes a 3D film and television animation character model and performs simulation processing on the model. By simulating the actions and behaviors of characters, the authenticity and realism of the characters are enhanced. In contrast, the method proposed by Karagiannis et al. [16] combines simulation and virtual reality technology to establish scene and character models, but does not explicitly mention the simulation processing of character models.

4) Improved optimization algorithm: This paper uses an improved quadratic error measurement algorithm to optimize the established 3D scene and character models. This algorithm helps to improve the accuracy of the scene and the appearance of the characters, thereby enhancing the quality of 3D film and television animation. In contrast, the method proposed by Tastan et al. [14] used handheld user interfaces and direct operations for building modeling, but did not provide a detailed description of the optimization algorithms used.

In summary, compared with previous similar works, this work has innovation in exploring the integration process of virtual reality technology and 3D film and television animation design. By using 3Ds Max software for modeling, texture mapping, simulation, and improved optimization algorithms, this work successfully enhances the realism and visual effects of 3D film and television animation, bringing new possibilities for the integration of virtual reality technology and 3D film and television animation design.

III. Integration Design of 3D Film, Television, and Animation

A. Integrated Technical Architecture

The realization of virtual reality technology is a foundation for 3D film and television animation designs [17]. The essence of 3D animation is a sense of stereo vision generated by the continuous projection of graphics and images. Experiments can transform the imagination in their minds into 3D animation models and realize model creation and visual optimization through the 3D modeling software platform. Virtual reality technology is gradually extended and developed based on three-dimensional animation technology. Its advanced scene reconstruction ability initially needs three-dimensional models to build. The prerequisite for the final realization of virtual reality space scenes is the adaptive transformation ability of three-dimensional images. Experiments can conduct interactive feedback of virtual reality scenes by upgrading 3D animation technology. Therefore, virtual reality technology and 3D animation technology come from a school of thought design [18]. After the development of 3D animation technology, it is called virtual reality technology. However, the interactivity of 3D animation technology stays in the passive information acceptance of the experimenter. The interactivity of virtual reality technology can make the system cooperate and deepen the scene according to the behavior logic of the experimenter and convey the space scene simulated by computer data artistically. 3D animation technology is the fundament of producing virtual reality technology data. Here, the technical architecture for integrating virtual reality technology and 3D film animation has been designed and shown in Fig. 1.

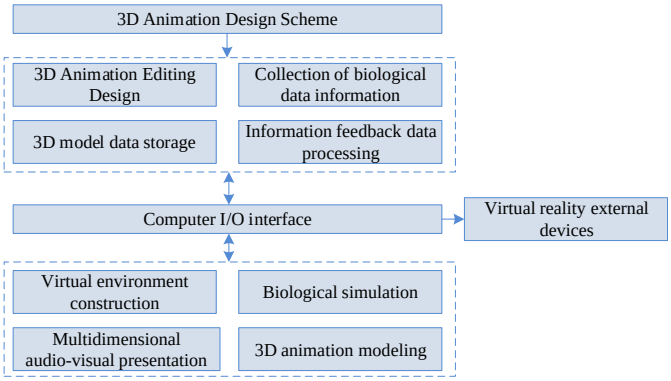

Fig. 1. Architecture of virtual reality technology and 3d film and television animation design integration technology.

The integration technology of virtual reality technology and 3D film and television animation design gets 3D animation pictures of virtual reality through virtual environment construction, multi-dimensional audio-visual presentation, biological simulation, and 3D animation modeling, and then connects 3D animation editing design, biological data information collection, 3D model data storage and information data feedback processing through computer I/O interface, realize the integration of virtual reality technology and 3D film and television animation according to 3D animation design scheme and virtual reality external equipment.

B. Manual Modeling Method of Animation Scene Based on 3Ds Max

The first step of basic 3D animation production is 3D scene modeling, and a 3D model scene is the golden key to open animation production. As a model designer, it is necessary to determine various modeling data of 3D scenes. For some indoor scenes with small space areas, it is relatively easy to obtain basic measurement data. Obtaining more reliable scene data is impossible for virtual scenes with large space and unlimited space. Now, it is essential to collect virtualization information data according to the previously simulated spatial scene data samples [19], reconstruct the scene model with the help of powerful computer data model processing ability, and complete this spatial scene modeling work with the highest efficiency through this virtual scene simulation method. This method enlarges and outputs the scene information through virtual reality, efficiently completes the reconstruction of a 3D model scene, and improves the accuracy of scene model data through virtual reality assistance to create a more realistic virtual world.

1) Construction of 3D film and television animation scene model: This section will introduce the processes of producing complex 3D film and television animation scene models in 3Ds Max [20] and final 3D film and television animation scene models. The technical process of 3D animation 3D Max model construction is illustrated in Fig. 2.

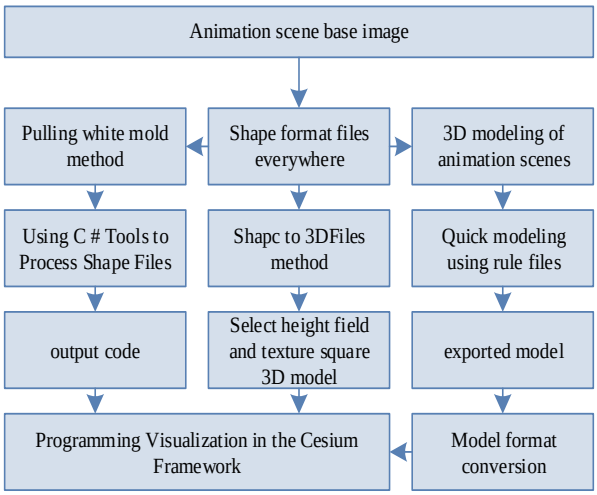

Fig. 2. 3D animation 3D max model construction technology process.

The production of 3D film and television animation scenes is the most difficult part of 3D software. The concept of time dimension is added in the production process, and almost any object or parameter can be animated in 3Ds Max [21]. Import the designed virtual scene base map or real image scene base map into the 3Ds Max software, and export the shape format file through 3Ds Max. Based on the cut file, you can quickly create 3D film and television animation scenes using rule files, export 3D film and television animation scenes and convert the model format, convert the shape format file into 3D Tiles method, select the elevation to generate 3D film and television animation scene, use the pull white mold method, process the shape format file through C # tool and output the code, and then program the code, animation scene model and format converted animation scene model in the Cesium framework to achieve 3D animation 3Ds Max model construction.

2) Realization of 3D film and television animation scene; After the 3Ds Max model is established, 3D Exploration, Wcvt2pov, and other software can convert the 3Ds Max model into the corresponding OpenGL C C++ format file, or the program can directly load the 3Ds Max model. The software format conversion method can preserve the model's color, texture, and other information [22]. However, some limitations are that software support and manual interaction are required for model transformation, and only one model can be transformed at a time. Therefore, the efficiency could be higher. The method of program direct loading can freely control the model to be loaded and promote the efficacy of program operation. After the 3DS model is loaded into the OpenGL program, the corresponding scaling, rotation, movement, and other controls are also required. The detailed process is as follows:

a) Read 3Ds Max models. 3Ds Max files are organized in a block structure, and there is a nesting relationship between blocks. Therefore, the 3D model data in the 3Ds Max file is read from a block in the model file, and the functional information of the block is judged according to the block ID, and then the corresponding processing is performed according to the block ID. A sub-block is read in the block processing process, such as the main editing block; block information is judged, and the corresponding data is extracted and stored.

b) Build model display list. When writing OpenGL programs, if you encounter repeated work, you can create a display list, load the repeated work, and call the display list where necessary. There are generally four steps to using the display list: assigning the display list number, creating the display list, calling the display list, and destroying the display list.

c) Minimum and maximum according to 3Ds Max model x, y the coordinates and the actual required width and height of the 3D scene are used to calculate their scaling ratio and scale the model. The functions used are: $glScalef(GLfloat\ x, GLfloat\ y, GLfloat\ z)$. Multiply the current matrix by a matrix indicating the scaled object. x, y and z refer to the scaling in corresponding directions, respectively.

d) Rotate the model according to the direction angle of the model in the 3D film and television animation scene. The functions used are: $glRotatef(GLfloat\ x, GLfloat\ y, GLfloat\ z)$. Multiply the current matrix by a matrix indicating a rotating object. The object will reach around (0,0,0) reach (x, y, z) the line of rotates counterclockwise, parameter $angle$ represents the rotation angle.

e) Calculate the model according to the position of the 3D movie animation scene model in the 3D scene x, y, and z

translate the 3D movie animation scene model. The functions used are:

$glTranslatef(GLfloat\ x, GLfloat\ y, GLfloat\ z)$ Multi ply the current matrix and a matrix indicating moving objects. These three parameters indicate the displacement values in three coordinates, respectively.

f) Realize the placement of 3Ds Max models in the 3D scene according to the corresponding size, direction, and position, call the display list, and complete the drawing of 3D movie animation scene models.

C. Texture Mapping Processing

After the establishment of 3D film and television animation scene models, to make the scene more realistic, it is necessary to conduct texture mapping processing on it. Before texture mapping, select the contour of a 3D film and television animation scene [23]. Here, a cubic uniform B-spline curve extracts the contour of 3D film and television animation scenes. The expression formula of the curve parameter equation is as follows:

$$C(u,v) = [x(u), y(u), z(u)] \quad (1)$$

In the above formula, $C(u,v)$ represent cubic uniform B-spline curve equation; u and v are parameters; $x(u)$, $y(u)$, $z(u)$ all are cubic B-spline basis functions.

The cubic uniform B-spline curve and expression formula are as follows:

$$r_i(u) = C(u,v)\sum_{j=0}^{3} N_{j,3}(u) \quad (2)$$

In Eq. (2), $r_i(u)$ represents the i th sum of three cubic uniform B-spline curves; $N_{j,3}$ represents the total number of cubic uniform B-spline curves.

After the contour line is drawn, rotate the selected rotational axis to build the model [24]. The right-hand coordinate system is used in texture mapping, x the positive direction of the shaft is to the right and y the positive direction of the axis is upward, so the rotation axis is selected as y shaft. Therefore, the parametric equation of the surface after rotation is:

$$\begin{cases} x = x(u) * sin(v) \\ y = y(u) \\ z = x(u) * cos(v) \end{cases} \quad (3)$$

For the gridding of 3D film and television animation scene models, the unit length of the grid will be intercepted according to the curvature of each point of the drawn contour line, and the grid will be further subdivided where the curvature is large. The curvature solution formula is as follows:

$$k = \frac{r_i(u)|\ddot{r}(s)|}{x^2+y^2+z^2} \quad (4)$$

In the above formula s indicates the arc length parameter; t represents a non-arc length parameter; $\ddot{r}(s)$ means right $r(s)$ perform a second derivative.

After the above steps, the mesh of the 3D movie and television animation scene model is more reasonable, and the resulting mesh quadrilateral tends to be the non-planar area of the original model, which is more conducive to rendering in the texture mapping phase.

Texture mapping technology can simulate the fine and irregular color texture on the surface of people (objects). The texture mapping technology can cover any planar figure (image) on the 3D animation model's surface [25] so that the model surface can produce a more realistic color texture, enhance the authenticity of 3D animation, and facilitate the modeling processes. There are two steps in texture mapping technology. The first step is to determine the texture attribute, determining which part of the person (object) surface parameters must be set as the texture shape. The second step is to create a mapping relation between the texture space and the person (object) space and a mapping relation between the person (object) space and the screen space. Fig. 3 shows the mapping definition.

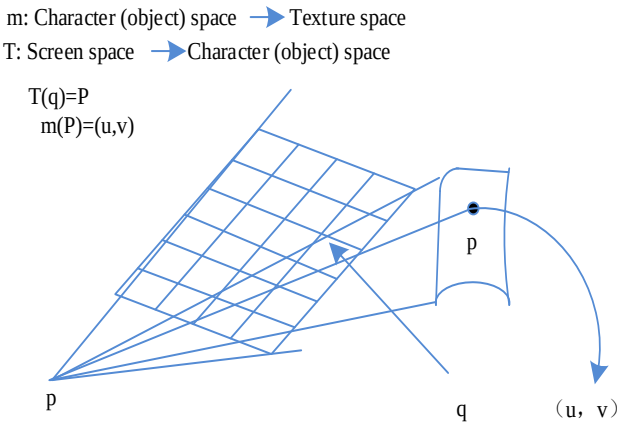

Fig. 3. Mapping definition.

Just basic contour characteristics, i.e., lack of surface texture details, can decrease the realism. It needs to map each module's texture to raise the model's realism.

The general direction of the surface patch specifies which space plane the surface patch projects to and projects to the plane with the smallest angle between the whole direction of the surface patch and the plane. As some parts of the person (object) surface are curved, it is necessary to calculate the overall direction of the curved surface. The computation method can be summarized as follows:

Assume that v_1, v_2, v_3 are three vertices of a triangular patch and cross product $[v_1 - v_2] * [v_2 - v_3]$ is perpendicular to the patch and normalized to get the normal vector of the triangular patch V the average vector sum of the module can be obtained by averaging the sum of all patch normal vectors, and then the general direction of the module can be obtained. The equation is as follows:

$$C = \sum_{i=1}^{PolyNum} \frac{v_i k}{PolyNum} \quad (5)$$

Where, $PolyNum$ indicates the total number of vertices.

To study the mapping relation between the surface patch and its related texture coordinates, the texture coordinates of

the grid points is computed through the perspective projection transformation, and the formula is as follows:

$$V = kX' = CHX \tag{6}$$

In which h_1, h_2, h_3, h_4, h_5 belongs to an unknown parameter, and (u, v) is the texture coordinate, the corresponding homogeneous texture coordinate is X', grid point space homogeneous coordinate is X, the perspective projection matrix of $3 * 4$ is H and the constant coefficient is k. Based on the Eq. (5) and Eq. (6), two independent linear equations exist for each group of corresponding mesh and texture vertices. To transform the matrix H, selecting three sets of feature points is necessary.

Analyzing all texture mapping processes, and setting the texture image size to $m * n$ simplify Eq. (7), and the process is as follows:

$$H = \begin{bmatrix} h_1 & 0 & 0 & h_4 \\ 0 & h_2 & 0 & h_5 \\ 0 & 0 & h_3 & 1 \end{bmatrix} \tag{7}$$

where, s and t is an unknown parameter, (x, y, z) is the surface vertex coordinate.

For Eq. (8), only a set of characteristic points can be used to calculate the unknown parameters. When extracting textures, all textures are made into the smallest bounding box. There are many tangent points at the edge of the image [26], which is very easy to get a group of feature points. Set texture coordinates(u', v') and surface vertex coordinates$(x', y', z')$is a group of characteristic points, which can be obtained by substituting into Eq. (8):

$$H' = \begin{bmatrix} 1/m & 0 & 0 \\ 0 & 1/n & 0 \\ 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} 1 & 0 & 0 & s \\ 0 & 1 & 0 & t \\ 0 & 0 & 1 & 1 \end{bmatrix} \begin{bmatrix} x & y & z \end{bmatrix}^T \tag{8}$$

$$F = H'V \tag{9}$$

After the above steps, the texture mapping of the 3D movie animation scene model is completed.

D. Character Modeling of 3D Film and Television Animation

According to the 3D animation character model and action library, users should just choose their required role prototype, modify the parameters like the height and body proportion of the role prototype, and get the 3D animation target character. The 3D animation target character matches the prototype 3D animation character's skeleton, mask, controller, and original actions in the action library. Fig. 4 is the composition diagram of the 3D animation character.

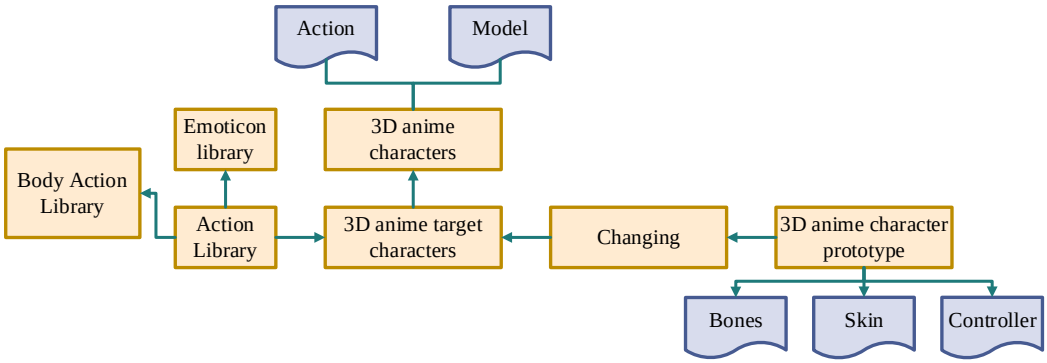

Fig. 4. Composition of 3D anime characters.

Components of a 3D animation character template include a virtual skeleton, skin, and controller, and it is a prototype for 3D animation. A set of basic actions allocated for 3D animation character prototypes is the 3D animation character action library. Users can freely modify the proportions and shapes of 3D animation characters based on the graphical interface, design the 3D animation character they want, or create new 3D animation characters.

E. 3D Animation Character Simulation

Motion capture technology is used to store many motion instances of character motion in the concerned motion library. The attained motion instances are represented in 3D form through virtual artificial synthesis software so that the 3D animation system is visual and convenient to change the action of the character model. The Newtonian Euler motion model is used to verify whether the new action studied is reasonable.

The character action is set as motion (t) by the 3D animation system, and the character's original pose (ti) is changed to gain a new character pose (ti). These operations lead to visual interactive action design. The user window is $O \times G$ in size. By moving the character model with the mouse, the variation in direction f will be Δf and the change in direction g will be Δg. According to Euler's theorem, for $< \alpha, \beta, \gamma >as$ representatives of d, f and g, the relationship of direction rotation after reasoning is as follows:

$$\begin{aligned} \sin\alpha &= aF\Delta f/[O(1-a)\Delta g/G] \\ \sin\beta &= bF\Delta f/[O(1-b)\Delta g/G] \\ \sin\gamma &= cF\Delta f/[O(1-c)\Delta g/G] \end{aligned} \tag{10}$$

In Eq. (10), the influencing factors are a, b and c representing d, f, g in three directions. Δf and Δg are opposite Euler angles and $< \alpha, \beta \; and \; \gamma >$ are the degree of

influence. Calculations achieve the newly pose of the character model, and the 3D animation character model is simulated.

F. 3D Animation Model Optimization Method based on Improved Quadratic Error Measure Algorithm

The edge collapse algorithm, also known as the Quadric Error Metric (QEM) algorithm, is not only fast in running speed, low in memory consumption, and simple in calculation but also has a very high overall similarity between the simplified mesh and the model. This paper improves the original quadratic error measure algorithm (QEM) and uses the improved QEM algorithm to optimize the scene modeling.

The specific steps are as follows:

1) Read in the original mesh data, which contains the vertex coordinates in the mesh and the vertex, sequence and other data information of the connected triangular patch.

2) Find the discrete curvature of each vertex in the mesh $K(h)$ the area of the local area is obtained from the formula $LRA(h)$, and compare the two weighting factors with the matrix $Q(h)$ weighting to obtain the quadratic error matrix of each vertex in the network $Q'(h)$:

$$Q'(h) = \frac{K(L_h)K_H}{\sin\alpha \sin\beta \sin\gamma} \tag{11}$$

where, $K(L_h)$ include vertices for Gaussian curvature of the edge of h,K_H is Gaussian curvature of a vertex h.

The expression of K_H is:

$$K_H = 2\pi - \frac{\sum_n \theta_h}{S_{\sum}(h)} \tag{12}$$

where, θ_h is an adjacency angle of vertex v;n is the number of triangles associated with vertex h; $S_{\sum}(h)$ is a vertex h the sum of adjacent triangular mesh areas, that is the local area.

3) The appropriate threshold through which the input is low $w = 0.9$, determines whether it is a boundary. If it is a boundary, set $\Delta(h) = inf$.

4) Get the quadratic error matrix of each vertex according to step $2Q'(h)$. To calculate the shrinkage cost of each edge ζ, if $(h_1, h_2) \to \tilde{h}$ the shrink cost is put on the stack, the higher the value of ζ, the more backward it is in the stack, and on the contrary, the more forward it is.

5) Take the edge with the lowest shrink cost from the stack to perform the shrink operation, that is, the top of the stack. Simultaneously, update the data structure of the network, calculate the new edge collapse cost, and update the stack sequence.

6) If the ideal simplification requirements are met, the algorithm ends; otherwise, the above process continues until the simplification requirements are met.

After the above steps, the optimization of the 3D animation model is realized, and the resulting film and television animation screen is more fluent, and the structure is more reasonable.

G. Interaction Mode of 3D Film and Television Animation Scene based on Unity3D

Unity3D software is designed with the interaction mode of 3D film and television animation scenes based on the improved A * algorithm. The improved A * algorithm is used to plan the interaction path in the 3D film and television animation walkthrough, obtain the optimal interaction path, and avoid collision in the interactive display process of the 3D film and television animation walkthrough.

The key part of the A * algorithm is the evaluation function $f'(n')$, that is, the source point in the 3D movie animation model p_0 to end p_{end} passing through nodes n' the total cost of $B(n')$ and estimated cost $h'(n')$ add to get.

The collective steps of the A * algorithm to search for the best path in the 3D movie animation model are summarized as follows:

Step 1: Initialize the 3D movie animation model data and add it to the open table of the open list p_0, select in open table $f'$the node with the lowest value is regarded as the current node p_1, if none p_1, then the 3D movie animation model interactive display path search fails, and the path search ends; if $p_1$is p_{end}, then the 3D film and television animation model interactive shows that the path search is successful, and the path search ends; With p_1 by $p_{end}$the path from the source node to the destination in the interactive presentation process of 3D film and television animation model is the search path.

Step 2: In the closed table, add p_1, traversal p_1 all adjacent nodes of p', if close-table exists p', no processing is required; If the close-table does not exist p', you need to solve again the value of $B(n')$, $h'(n')$, set $O_1$by $p'$and add it in the open-table p'; if p'in open-table, comparative analysis p_1 to p' of $B(n')$ is the value below p' of $B(n')$ value, if lower than p' of $B(n')$ value, then no processing is required. If the value exceeds p' of $B(n')$ value, then p_1 to p' of $B(n')$ value is changed to p' of $B(n')$ value with the predecessor node of p_1 by p'.

Step 3: Repeat step 2 to process the remaining adjacent nodes in order until the open table is empty.

To speed up the search efficiency of the interactive display path of 3D film and television animation roaming, a hierarchical strategy is introduced into the A * algorithm, and the 3D film and television animation model is regarded as a complete map divided into several areas of consistent size. For the obstacles within the boundary line, it is necessary to remove the obstacles first, then solve the scale of the obstacles within the boundary line, add the obstacles within the boundary line in the area with the highest scale, and complete the area division of 3D movie and television animation model in this way.

By setting parameters E and R, and designing fixed rules, the search algorithm is obtained and used in each area, and the proportion of obstacles in the 3D film and television animation model, is E which is the ratio of the total number of nodes occupied by obstacles in the current area to the total number of nodes in the area, and the threshold coefficient is R.

Adopt E determine that a certain search algorithm needs to be used in this area and determine that further subdivision is required; The value R has a negative correlation with the area division size, a positive correlation with the number of expansion nodes, and a positive correlation with the path search time. According to the relationship between E and R to establish the following rules:

1) On $E = 0$, it represents no obstacle in the area, and the shortest optimal path can be obtained directly according to the straight line between two points. If p_0 and p_{end} both are in this area, then this path is the optimal path; if p_0 and p_{end} are not in the same area, search for the middle point between the optimal path and the boundary line of the area in the area and regard the middle point as that of the next area p_0.

2) On $E < R$, means there are fewer obstacles in the area, and the hierarchical strategy is still adopted to subdivide the area further.

3) On $E \geq R$, the number of representative obstacles is consistent with the threshold, or even exceeds the threshold. In this case, the A * algorithm is directly used to search the path.

According to the above rules, searching the path in the interactive display process of 3D film and television animation roaming can effectively divide the big map into small maps, which is conducive to processing, selecting the optimal path search method for small maps, speeding up the path search efficiency, and effectively avoiding collision events in the interactive display process of 3D film and television animation roaming.

IV. Experimental Analyses

Taking an animation design scheme as the experimental object, the method in this paper is used to integrate virtual reality technology and 3D film and television animation and present the animation design scheme to validate the practical application impact of the method proposed in the present paper.

Take a scene of the animation design scheme as the experimental object, and present the scene using the method in the current investigation. The results are illustrated in Fig. 5.

It is clear from the analysis of Fig. 5 that the application of the method used in the present paper can effectively establish the 3D film and television animation virtual scene. From the 3D film and television animation virtual scene established in this paper, it can be seen that the color of trees, grass, and flowers is real, and the three-dimensional effect is good. The water body can not only map the scene in the sky but also show a clear effect, and the river bottom can be seen through the water body. These results indicate that the 3D film and television animation virtual scene built by this method has good stereoscopic and real effects.

The texture coordinate calculation results are used to measure the texture mapping effect of this method on 3D film and television animation scenes. With 15 texture coordinate points as experimental objects, this method calculates the texture coordinates. The results are presented in Table I.

Fig. 5. Virtual scene of 3D film and television animation.

TABLE I. Texture Coordinates of 3D Film and Television Animation Scene (cm)

Texture coordinate encoding	Calculated value		Actual value	
	X-direction	*Y-direction*	*X-direction*	*Y-direction*
1	3.24	8.54	3.24	8.54
2	4.06	10.34	4.06	10.35
3	1.58	2.88	1.58	2.88
4	2.79	9.17	2.79	9.17
5	11.07	5.97	11.07	5.97
6	25.13	14.96	25.13	14.96
7	10.25	11.85	10.25	11.85
8	6.98	8.97	6.98	8.97
9	8.94	16.34	8.94	16.34
10	15.27	16.85	15.28	16.85
11	30.17	22.13	30.17	22.13
12	2.89	6.84	2.89	6.84
13	16.63	20.57	16.63	20.57
14	13.79	19.82	13.79	19.82
15	21.11	18.84	21.11	18.84

From the analysis of Table I, it can be seen that the texture coordinates of 3D film and television animation scene texture mapping are calculated using the method in the present research. In the calculation results, only the texture coordinates coded as 10 and 2 have deviations from the actual results in the X and Y directions, but the deviation value is only 0.01cm, which is small. Other texture coordinate values calculated are identical to the actual coordinate values. These results imply that the texture coordinates of 3D film and television animation scene texture mapping calculated by the method in this paper are more accurate, and it has a strong ability for 3D film and television animation scene texture mapping.

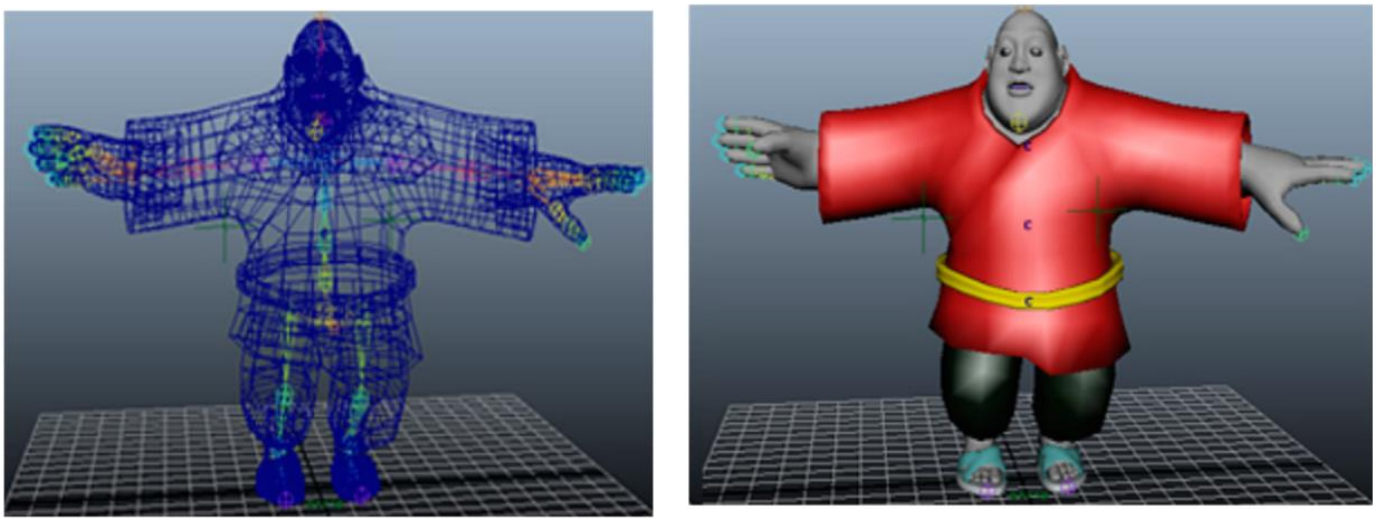
To further verify the texture mapping capability of this method, take a 3D movie animation scene as the experimental object and use this method to conduct texture mapping processing. The texture mapping results are shown in Fig. 6.

(a) Before mapping (b) After mapping

Fig. 6. Texture mapping effect in 3D film and television animation scenes.

According to the analysis of Fig. 6, after applying the method in this paper to texture map the 3D film and television animation scene, the entire 3D film and television animation scene has bright colors, and the texture map position is not prominent or concave, indicating that the method of the current paper has better texture mapping effect on 3D film and television animation scene.

Take an animated character in the animation design scheme as the experimental object, use the method in this paper to establish its virtual character model, and the establishment results are shown in Fig. 7.



(a) Design base drawings (b) Achievement

Fig. 7. Animated character virtual character model.

It is clear from the analysis of Fig. 7 that this method can effectively establish the 3D model of the animated character virtual character based on the base map of the animated character virtual character. The 3D model of the animated character virtual character established has a good three-dimensional effect, and the character's facial expression is more real. To sum up, the method in this paper can better build virtual character models of animated characters.

Taking a 3D movie animation scene as the experimental object, the method in this paper is used to optimize the 3D movie animation scene, and the optimization results are illustrated in Fig. 8.

It is evident from the analysis of Fig. 8 that after the optimization of 3D film and television animation scenes using the method in this paper, the contrast of 3D film and television animation scenes has been improved, and the clarity of the entire 3D film and television animation scenes has also been effectively improved, making the visual effect of 3D film and television animation scenes better. In conclusion, the present research method can effectively optimize 3D film and television animation scenes and has a relatively significant application effect.

Verify the roaming ability of the 3D film and television animation scene established by this method, and test the

roaming ability of the 3D film and television animation scene established by this method with the roaming path as the measurement index. To make the experimental results more sufficient, the methods utilized in the references [12]- [16] are used to experiment. The experimental results are illustrated in Fig. 9.

It is obvious from the comprehensive analysis of Fig. 9 that when the method in this paper is used to roam and interact with 3D film and television animation scenes, the shortest roaming path selected in this method is only 30 nodes, while the path nodes selected in other reference methods when roaming and interacting with 3D film and television animation scenes are higher than those of the method proposed in the current study. The results show that the method in this paper can effectively combine virtual reality technology with 3D film and television animation design and select the shortest path when roaming 3D film and television animation scenes, which has a strong application effect.

V. Discussion

This paper successfully establishes a realistic and interactive 3D film and television animation virtual scene by studying the integration method of virtual reality technology and 3D film and television animation design. According to the above theories and experiments, it can be concluded that:

By analyzing Fig. 5, it can be seen that the 3D film and television animation scene established in this paper exhibits more realistic colors and three-dimensional effects in areas such as trees, grasslands, and flowers. In addition, water bodies not only reflect scenes in the sky, but also present a clear effect, through which the riverbed can be seen. These results indicate that the 3D film and television animation virtual scene successfully established by the method proposed in this paper has good stereoscopic and realistic effects.

The method used in this paper has high accuracy in calculating texture maps for 3D film and television animation scenes. Most texture coordinates are exactly the same as the actual coordinates, while only a few texture coordinates have slight deviations in the X and Y directions. However, these deviations are only 0.01cm and belong to smaller values. Therefore, the method proposed in this paper demonstrates high accuracy and capability in calculating texture maps for 3D film and television animation scenes.

After applying the method described in this paper to texture map 3D film and television animation scenes, the entire scene presents bright colors and uniform texture map positions, without any protrusions or depressions. This indicates that the method proposed in this paper has shown good performance in texture mapping of 3D film and television animation scenes. Further analysis of Fig. 7 reveals that based on the virtual character base map of animated characters, our method has successfully established a three-dimensional model with good stereoscopic effects and real facial expressions. This indicates that the method presented in this paper demonstrates excellent ability in establishing virtual character models for animated characters.

After optimizing the 3D film and television animation scene using the method described in this paper, the contrast of the scene is improved, and the clarity of the entire scene is also significantly improved. This makes the visual effects of 3D

film and television animation scenes more outstanding. In summary, the method proposed in this paper has significant application effects in optimizing 3D film and television animation scenes. For the roaming interaction of 3D film and television animation scenes, the method selected in this paper has the least number of roaming path nodes, only 30 nodes, which is significantly less than the number of path nodes selected by other literature methods. This indicates that the method proposed in this paper has shown significant advantages in integrating virtual reality technology and 3D film and television animation design, and has chosen the shortest path in the roaming of 3D film and television animation scenes, demonstrating strong application effects.

In summary, through the analysis of various experimental results, it can be concluded that the fusion method of virtual reality technology and 3D film and television animation design proposed in this paper demonstrates excellent capabilities and effects in the establishment of 3D film and television animation virtual scenes, texture mapping, character simulation, optimization processing, and roaming interaction. This is of great significance for promoting the development of 3D film and television animation design, improving user experience, and expanding the application fields of virtual reality technology. Future research can further optimize and expand this method to provide a more satisfactory virtual reality experience.

VI. Conclusion

The continuous integration and complementation of 3D animation technology and virtual reality technology can bring new breakthroughs to the two technical fields and make this virtual 3D animation system exert the best guiding force. The integration of virtual reality and 3D animation technologies makes the expression of 3D animation more diversified. Through the technical support of virtual reality technology, 3D animation can bring more real resonance of literary and artistic ideas to the experience. Therefore, integrating virtual reality technology with 3D animation technology is an inevitable trend, which can bring more opportunities for the future development of both technologies.

Considering that real-time rendering is crucial in virtual reality technology. How to improve rendering speed and efficiency while maintaining high-quality rendering, and ensure smooth operation on virtual reality devices, is an unresolved issue. Therefore, in the future, new real-time rendering algorithms and hardware acceleration technologies will be explored to achieve higher quality graphics rendering and faster rendering speed, providing users with a smoother virtual reality experience.

Classification Method of Traditional Art Painting Style Based on Color Space Transformation

Xu Zhe
School of Art and Music, Anyang Vocational and Technical College, Anyang, 455000, Henan Province, China

***Abstract*—In order to improve the accuracy and efficiency of traditional art painting style classification, a classification method of traditional art painting style based on color space transformation is proposed. This method preprocesses the traditional artistic painting style, improves the contrast of the image, makes the color and details of the image more vivid, and provides the basis for the subsequent color space conversion. After the traditional artistic painting style is stretched by automatic contrast stretching method, the color space is transformed. The purpose is to transform the image from one color space to another, so as to better extract the features of the image. Based on the traditional artistic painting style image after color space conversion, the traditional artistic painting image is balanced by the adaptive histogram equalization method with limited contrast, and an enhanced traditional artistic painting image is obtained, which further enhances the contrast of the image, makes the details in the image more prominent, and also enhances the overall visual effect of the image. Taking the enhanced traditional art painting images as input, the fuzzy C-means method is used to classify the traditional art painting styles, and the images are effectively divided into different categories according to the characteristics of the images. The experimental results show that this method can effectively enhance the image of traditional art paintings and effectively classify traditional art paintings with different styles, which has strong application effect.**

Keywords*—Color space; traditional art; painting style; classification method; fuzzy c-means

I. INTRODUCTION

In the development of human civilization, culture, and art play a very important role. Painting is an important form of culture and art [1]. It is an important part of a nation's culture. Rooted in the soil of national culture, it reflects a wide range of real-life content through beautiful art forms, thus reflecting the cultural outlook and aesthetic taste of all nations. It is a unique and important way for human beings to observe and express the world. For thousands of years, a large number of paintings have been produced. The study of these paintings is an important means for people to understand the history of human history, culture, art, and the development of science and technology to promote the development of human civilization further. It has been in the ascendant for many years. In reality, painting samples as research materials are often not easy to obtain, which has brought various inconveniences to the research work of art researchers for a long time. With the development and wide application of digital technology, more and more paintings are digitized [2] and saved in various forms such as images, videos, 3D models, multimedia documents, etc. The development of the network makes it possible for anyone to obtain digital works of art through the Internet, which brings great convenience to the majority of art researchers. The acquisition of large quantities of painting images has become a reality, which also makes large-scale art analysis possible. While digital technology has brought researchers a wealth of research materials [3], it has also provided them with many new research topics. For example, after the digitization of the murals in Mogao Grottoes in Dunhuang, art researchers need to process a large amount of data on the flying frescoes in order to study the comparison of different styles of different dynasties and classify them according to the styles of the dynasties before conducting research. Such a huge amount of data, if only classified manually by researchers, obviously requires huge and repeated work, which is undoubtedly feasible and has lost the significance of digitization [4]. In recent years, it has become an important research direction in the field of computer image processing to combine computers with art and use the powerful storage and computing power of computers [5] to realize the processing of large-scale digital painting images [6]. It is one of the research hotspots to study the classification of painting works of art according to the unique artistic style characteristics of painting images.

The artistic style of painting works generally refers to the artistic style, characteristics, style, style, and style shown in the painting works [7], which is a relatively stable and overall artistic feature presented by the interaction between the personality shown by the artist in the creation process and the semantics and context of the art works. The evaluation of the artistic styles and similarities of different paintings [8] is an important means for art researchers to classify paintings. At present, there are also many scholars studying painting image style classification methods, such as Hassanzadeh, T et al. [9], who proposed an evolutionary depth convolution neural network for image classification, input painting images into the evolutionary depth convolution neural network, and output painting image style classification results through the network model. Phasinam, K et al. [10] proposed a framework for real-time image classification. From IoT cameras to mobile applications to machine learning methods, there is everything. Arduino Uno, sensors, and Wi-Fi devices make up the hardware. The computer can "learn" from previous examples and use the machine to detect patterns from noisy or complex data sets, input the painting image into the frame, and then output its style classification results. Arco J et al. [11] proposed a feature space block sparse coding method for image classification. The image in this method is first divided into different tiles, and a dictionary is constructed after PCA is applied to these tiles. Then, the original signal is transformed

into a linear combination of dictionary elements. Then, refactor each component by iteratively activating its associated elements.Finally, the subsequent reconstruction error is used as the feature for classification. Ciga, O et al. [12] proposed the method of learning to use classification labels to segment images, which realizes the style classification of painting images by annotating a few regions of interest. Fernandes, J et al. [13] proposed an end-to-end depth learning method for table detection and table image classification in data table images. This method first learns basic feature representations, such as different types of edges and contours, through the convolution layer of the basic network. Then, using the long-term memory mechanism of the Long Short-Term Memory Network (LSTM), the spatial correlation is modeled in both horizontal and vertical directions. Finally, the spatial correlation features learned are used to construct a classifier for classification.

Although these methods can realize the classification of painting styles, they are affected by the clarity and contrast of painting images. These methods have defects in practical applications. Color space conversion is a method of exchanging different color spaces to obtain texture details and image enhancement in the image [14]. This paper proposes a traditional art painting style classification method based on color space conversion based on color space conversion, so as to improve the level of painting style classification technology. The advantage of this method is to transform the image from one color space to another, so as to better extract the features of the image, further improve the contrast of the image, make the details in the image more prominent, and at the same time enhance the overall visual effect of the image. The technical route of this paper is as follows:

1) This method preprocesses the traditional artistic painting style, improves the contrast of the image, makes the color and details of the image more vivid, and provides the basis for the subsequent color space conversion.

2) After the traditional artistic painting style is stretched by automatic contrast stretching method, the color space is transformed. Based on the traditional artistic painting style image after color space conversion, the traditional artistic painting image is balanced by using the adaptive histogram equalization method with limited contrast, and the enhanced traditional artistic painting image is obtained.

3) Taking the enhanced traditional art painting images as input, the traditional art painting styles are classified by fuzzy C-means method, and the images are effectively classified into different categories according to the characteristics of the images.

II. Classification Method of Traditional Art Painting Style

A. Image Enhancement Processing of Traditional Art Painting based on Color Space Conversion

1) Automatic contrast stretching: Before classifying the style of traditional art painting images [15], it is necessary to enhance them to make their image features more obvious. Automatic contrast stretching is a point operation [16] whose purpose is to change the pixel gray value of the current image so that the pixel value distribution of the resulting image covers all available ranges of pixel gray value. This algorithm maps the current darkest and brightest pixel gray values to the minimum and maximum values in the range of available gray values. Then, it makes the middle gray values linearly distributed. In the classic automatic contrast stretching algorithm, the gray value of each input pixel is calculated using the following formula:

$$f_{ac}(e) = e_{min} + (e + e_{low}) \times \frac{e_{max} - e_{min}}{e_{high} - e_{low}} \quad (1)$$

Where: e_{max}、e_{min} represents the maximum and minimum values of pixel grayscale, e_{low} and e_{high} are the minimum and maximum values of pixel gray values in the current image, and the range of image pixel gray values can be $[e_{max}, e_{min}]$.

The mapping function in Formula (1) is only strongly affected by several extreme values, which may not represent the main content of the image. Therefore, this scheme adopts the modified automatic contrast stretching algorithm, and the formula of the modified automatic contrast stretching algorithm is:

$$f_{mac}(e) = \begin{cases} e_{min} & e \le \hat{e}_{low} \\ e_{min} + (e - \hat{e}_{low}) \times \frac{e_{max} - e_{min}}{\hat{a}_{high} - e_{low}} & \hat{e}_{low} < e < \hat{e}_{high} \\ e_{max} & e \ge \hat{e}_{high} \end{cases} \quad (2)$$

In the above formula, $\hat{e}_{low}$、$\hat{e}_{high}$ represent two thresholds respectively. These two thresholds depend on the content of the image and can be represented by the cumulative histogram of the image $H(i)$ calculated:

$$\hat{e}_{low} = M \times N \times f_{ac}(e) \quad (3)$$

$$\hat{e}_{high} = M \times N \times f_{mac}(e) \quad (4)$$

Where: $M \times N$ is the number of pixels in the image. All pixel values can be derived from the formula $\hat{e}_{low}$ and $\hat{e}_{high}$ values other than (including) are mapped to extreme values respectively e_{min} and e_{max}, intermediate values are linearly mapped to $[e_{max}, e_{min}]$. It can be seen that the mapping function is not only affected by several extreme values but also depends on a group of representative pixel values. In this algorithm, the contrast stretching of gray image Eq. (2) is applied to the R, G, and B color channels of the color image, respectively, to complete the automatic contrast stretching of traditional art painting images.

2) Color space conversion of traditional art painting based on polynomial regression: Based on the traditional art painting image after automatic contrast stretching [17], the color space is converted by polynomial regression.

Polynomial regression belongs to linear regression. In practical application, the independent variable is constructed by selecting the number of polynomial terms x and dependent variable y in the polynomial regression model, the dependent variable y and multiple arguments $x_1, x_2, \cdots, x_M$ with linear relationship, where is the number of independent variables, there are:

$$X_{DF} = (x_{t1}, x_{t2}, \cdots, x_{tN}), t = 1,2, \cdots, N \quad (5)$$

Where, N indicates the number of dependent variables. The relationship between the dependent variable and independent variable can be described as:

$$\begin{aligned} y_1 &= \alpha_0 + \alpha_1 x_{11} + \alpha_2 x_{12} + \cdots + \alpha_M x_{1M} + \varepsilon_1 \\ y_2 &= \alpha_0 + \alpha_1 x_{21} + \alpha_2 x_{22} + \cdots + \alpha_M x_{2M} + \varepsilon_2 \\ y_N &= \alpha_0 + \alpha_1 x_{N1} + \alpha_2 x_{N2} + \cdots + \alpha_M x_{NM} + \varepsilon_N \end{aligned} \quad (6)$$

Among them, $\alpha_0, \alpha_1, \cdots, \alpha_M$ represents the coefficient to be determined $\varepsilon_0, \varepsilon_1, \cdots, \varepsilon_N$ represents an independent random variable.

If the parameter $b_0, b_1, \ldots, b_M$ is estimated by the least squares method β the regression formula obtained by fitting is:

$$\hat{y} = b_0 + b_0 x_1 + \cdots + b_M x_M \quad (7)$$

According to the principle of least squares, the coefficient $b_0, b_1, \ldots, b_M$ all measurements shall be obtained y_t, and regression value $\hat{y}$ minimum sum of residual squares of Q:

$$Q = \sum_{i=1}^{N} (y_t - \hat{y}_t)^2 \quad (8)$$

The polynomial regression method can describe not only linear problems but also nonlinear problems [18]. When describing nonlinear problems, the dependent variable needs to be y and arguments x a selected polynomial model is constructed, which can be correctly applied to the actual color signal processing system. Build the conversion between RGB color space and CMYK color space as fixed K. The polynomial of the conversion between RGB and CMY in the case of value is as follows:

$$C = \sum_{i=0}^{n} \sum_{j=0}^{n} \sum_{p=0}^{n} \alpha_C R^i G^j B^p \quad (9)$$

$$M = \sum_{i=0}^{n} \sum_{j=0}^{n} \sum_{p=0}^{n} \alpha_M R^i G^j B^p \quad (10)$$

$$Y = \sum_{i=0}^{n} \sum_{j=0}^{n} \sum_{p=0}^{n} \alpha_Y R^i G^j B^p \quad (11)$$

where, α is a polynomial coefficient, n is the order of a polynomial, and $i + j + p \leq n$, the polynomial is represented by a matrix as follows:

$$\begin{bmatrix} \boldsymbol{X} & \boldsymbol{Y} & \boldsymbol{Z} \end{bmatrix}^{\boldsymbol{T}} = \boldsymbol{B_{3L}} \times \boldsymbol{\rho_L} \quad (12)$$

where, B_{3L} represents the coefficient matrix, ρ_L represents a polynomial matrix.

After the above steps, the traditional art painting image RGB color space and CMYK color space can be converted.

3) Adaptive histogram equalization with limited contrast: The Histogram equalization (HE) method has the advantages of fast speed and an obvious effect in enhancing image contrast. Histogram equalization can improve the overall image contrast [19]. Still, after processing, the image will appear "too bright or too dark," and local details cannot be processed, resulting in a loss of details and poor effect. Considering this, adaptive histogram equalization (AHE) based on the idea of block processing has been proposed to solve the problem of local highlight or too dark. Still, these two methods also amplify noise while enhancing contrast. Based on the advantages of the AHE algorithm, the concept of limiting contrast is proposed to solve the problem of amplifying noise. CLAHE algorithm not only effectively improves the contrast but also suppresses the generation of noise.

The specific steps of the CLAHE algorithm are as follows:

1) Divide the image into $n \times n$ there are rectangular sub blocks of the same size and non-overlapping each other. As the number of sub blocks increases, the enhancement effect of the image becomes more significant, but more details are lost [20].

2) Calculate the sub-block histogram.

3) Solve restricted values η.

$$\eta = \chi \times \frac{n_x n_y}{\widehat{K}} \quad (13)$$

where:$n_x$represent Subblock x number of direction pixels; n_y express y number of direction pixels; $\widehat{K}$ is the gray level; χ is the limiting factor.

4) Crop the histogram and reassign the pixels. Cut sub-block histogram $h(x)$ restricted value η constraints, the exceeding part of the number of pixels is evenly distributed to other gray levels, and the pixel points are cut and reallocated, as shown in Fig. 1.

5) Sub block histogram equalization.

6) The bilinear difference reconstructs the gray value.

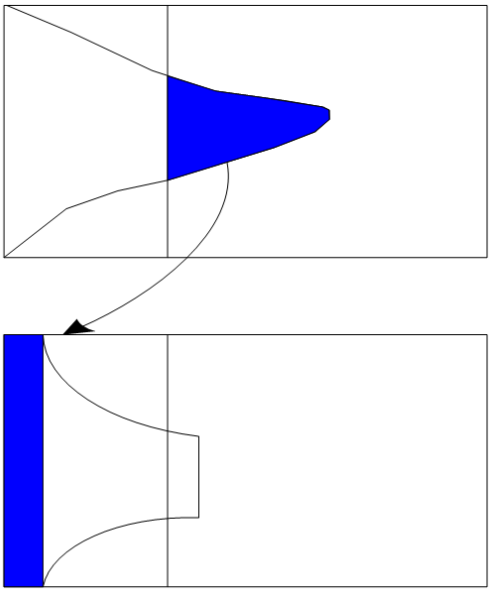

Fig. 1. Pixel cropping and reassigning.

The pixel value obtained only by mapping function transformation will cause the image to be blocky, and the bilinear difference processing for each point of the image can effectively avoid blocky.

The bilinear difference is only for the area surrounded by the center points of four blocks. The center of each sub block is taken as the reference point and recorded as $\theta_{11}(x_1, y_2)$、$\theta_{12}(x_2, y_2)$、$\theta_{21}(x_1, y_1)$、$\theta_{22}(x_2, y_1)$. Points to be calculated: The pixel value of P is determined by four adjacent reference points.

After the above steps P, after pixel reconstruction, traditional art painting image enhancement is realized.

B. Extraction of Salient Information from Traditional Art Painting Images

After the enhancement of traditional art painting images, extract its significant information to prepare for classification [21]. In the traditional art painting image, the image edge is usually used as the image background area, away from the image center of the target and surrounded by the position where the image's prominent target exists. The image background area is used as the super pixel block of the image edge, and the background area is compared with the remaining area from the perspective of color space to obtain the significance information of different areas [22].

The acquisition process of prior significance information of digital painting image background is as follows:

1) Get image manifold sorting: Set the background area of the traditional art painting image as the super pixel block at the image edge, and compare the color space of all the super pixel blocks with that of the background super pixel block to obtain the significance information of all parts of the image [23]. The manifold sorting algorithm is used to calculate the salient information of traditional art painting images. The algorithm obtains the sorting function by setting the correlation between fixed nodes and other nodes. It sets the correlation between nodes and other nodes according to the obtained sorting function measurement [24]. The correlation of each point is obtained by using the sorting method of the internal manifold structure of the data. Set data vector $M = [m_1, m_2, \cdots, m_n]^T$, assign the sorting value to each point in the data vector m_i, and get the final output of the function $g = [g_1, g_2, \cdots, g_n]^T$. Set up $p = [p_1, p_2, \cdots, p_n]^T$ as a marker vector, when $p_i = 1$ as well as $p_i = 0$ respectively m_i set query nodes and non set query nodes for. Set existence diagram $Q = (U, R)$ in the dataset, where U and R represent data node set and image edge set respectively, and use weighted similarity matrix $Q = [q_{ij}]_{n\times n}$ the above parameters can be obtained.

Using an optimization problem to express the optimal ordering of nodes $g*$, the calculation formula is as follows:

$$g* = (B - \alpha Q)^{-1} p \tag{14}$$

where:B represents a diagonal matrix; α represents the Plath coefficient.

2) Significant information calculation: The input digital drawing image is converted to the diagram structure representation according to Formula (14). Select the super pixel segmentation method to represent the image graph structure with multiple super pixel blocks [25], where each super pixel and node $U_i(1 \le i \le |U|)$ correspondingly set the query node as the super pixel node at the edge. The regular graph is used to represent the graph structure of the image [26]. That is, each node in the image is connected to the adjacent node, and the graph is connected to the adjacent node. The weight formula of the image edge is as follows:

$$k_{ij} = exp(-\frac{\sqrt{(L_i - L_j)^2 + (A_i - A_j)^2 + (B_i - B_j)^2}}{\delta^2}) \tag{15}$$

Where: L_i, A_i, B_i represent super pixels in color space i average of LAB value; δ indicates the node edge coefficient. The significance information of each node in the image is represented by the ranking value obtained by Formula (15). The query node is set as the upper boundary, and the ranking vector is obtained by using the significance information of the upper boundary and the significance information of other nodes $g*(i)$, using $\bar{g}*(i)$ indicates the significance information obtained by normalization to $[0,1]$ interval, set $\bar{g}*(i)$ use 1 as a difference to obtain the foreground significance information map.

Obtain saliency information map through image upper boundary $O_t(i)$. The formula is as follows:

$$O_t(i) = 1 - \bar{g}*(i) \tag{16}$$

Repeat the above steps to obtain the significance information map of the left, right, and lower boundaries $O_t(i)$, O_r, O_d means that the four saliency information maps obtained are multiplied to obtain the saliency information map of the final digital painting image, and the formula is as follows:

$$O\ \ (i) = O_t(i) \times O_d(i) \times O_r(i) \times O_l(i) \tag{17}$$

After the above steps, the salient information of traditional art painting images is obtained.

C. Traditional Art Painting Image Style Classification Method based on Improved Fuzzy C-Means Algorithm

The salient information of traditional art painting images obtained in the above sections is used as input, and the improved fuzzy C-means algorithm is used to realize the classification of traditional art painting styles.

The fuzzy C-means algorithm is a local search algorithm that mainly constructs the Lagrange function and iteratively calculates the minimum of the sum of squares of the global weighted distances from each sample to the cluster center to obtain the optimal cluster center. If the sample set is U, the cluster center set is V, the objective function can be expressed as:

$$min\, J\,(U, V) = \sum_{k=1}^{n} \sum_{i=1}^{c} (u_{ik}) m (d_{ik})^2 \tag{18}$$

where: n and c are the number of samples to be classified and the number of clusters; m is the fuzzy degree coefficient,

which is responsible for controlling the sharing degree between fuzzy classes; u_{ik} is a sample pair k clustering i and has $0 \le u_{ik} \le 1$, $\sum_{i=1}^{c}(u_{ik}) = 1$; d_{ik} is a sample k to clustering i the Euclidean distance of the center.

Because the fuzzy C-means algorithm is prone to the local optimal solution, slow convergence, and poor classification effect under high-dimensional data, we use the differential evolution algorithm to improve the fuzzy C-means algorithm and use the improved fuzzy C-means algorithm to classify the traditional art painting image style.

The differential evolution algorithm is used to improve the fuzzy C-means algorithm. First, a group of initial centers is randomly generated, and the non-center points are grouped into the center point area one by one according to the principle of minimum distance. Then, the differential evolution algorithm is used to carry out parameter adaptive adjustment, mutation, crossover, and selection operations for the current partition so that the search process changes from an unsupervised state to a dynamic information-guided optimization and performs the second assignment operation on the current part of non-optimal individuals to enhance the small range of the later stage of the algorithm fine search capability. The specific steps are as follows:

Step 1: Initialize the parameters. Determine various control parameters required by the algorithm and make the number of iterations $T = 0$.

Step 2: Initialize the population. The cluster center is used as a population individual to code. First, the initial cluster center is randomly generated, and the individual coding method is as follows:

$$\boldsymbol{X_i} = (\boldsymbol{x_{1,1}}, \boldsymbol{x_{1,2}}, \cdots, \boldsymbol{x_{1,s}}, \boldsymbol{x_{2,1}}, \cdots, \boldsymbol{x_{2,s}}, \cdots, \boldsymbol{x_{c,s}}) \tag{19}$$

where: s is the dimension of the cluster center; c is the number of individuals. Then, the differential evolution algorithm is used to generate a random initial population:

$$x_{i,j} = xi, jmini, jmax_{i,jmin} \tag{20}$$

where: $x_{i,j}$, $x_{i,jmax}$, $x_{i,jmin}$ individual set of population X_i of j components and their upper and lower bounds; r is a random number in the range of [0,1].

Step 3: Formula (18) is taken as the objective function, and the adaptability evaluation function, so the objective function value is the population fitness evaluation result. The smaller the objective function value, the higher the quality of the population of individuals. Calculate the fitness of the current population and determine whether the maximum number of iterations of the algorithm is reached T_{max}.

Step 4: Adaptively adjust the mutation factor F and hybridization factor C. The variance of population fitness can effectively reflect the individual distribution of the contemporary population and dynamically adjust the control parameters in a targeted way, thus having good results. The variance of group fitness σ^2 can be expressed as:

$$\boldsymbol{\sigma^2} = \sum_{\boldsymbol{I=1}}^{\boldsymbol{n}} (\frac{\boldsymbol{\delta_i - \delta_{av}}}{\boldsymbol{\delta_b}})^2 \tag{21}$$

where: N is the population size; δ_i is for i individual fitness; δ_{av} is the average fitness of the population; δ_b is the best fitness of the group.

Based on the above calculation σ^2, the adjustment parameter changes from a fixed value to the following dynamic form:

$$F_k = F_{\min} + (F_{\max} - F_{\min} - \frac{\sigma_k^2 (F_{\max} - F_{\min})}{N} \tag{22}$$

$$\hat{Z}_k = \hat{Z}_{\min} + (\hat{Z}_{\max} - \hat{Z}_{\min}) 1 - \frac{\sigma_k^2 (\hat{Z}_{\max} - \hat{Z}_{\min})}{N} \tag{23}$$

where: F_{max} and F_{min} are the upper bound and the lower bound of the variation factor; $\hat{Z}_{max}$ and $\hat{Z}_{min}$ are the upper bound and lower bound of hybridization factors respectively; σ_k^2 is for k generation population fitness variance.

Step 5: Conduct mutation and crossover operations on the population, generate a trial offspring population, recalculate the fitness, and use the "greed" strategy for selection operations to form a new generation of population.

Step 6: Secondary assignment. Randomly select some individuals from the non-optimal individuals of the current population according to the previously specified probability distribution function for secondary assignment:

$$X_{i,re} = X_i(1 - \delta_{rand}) + O\delta_{rand} \tag{24}$$

$$O = \frac{\lambda_{ad} I X_{optimal} + r X_{r1} - r X_{r2}}{\lambda_{ad} I} \tag{25}$$

where: X_i is the individual value of the current population; δ_{rand} is a binary random decision variable; O is the local search adjustment operator defined in this paper; $X_{optimal}$ is the best individual in the contemporary population; λ_{ad} is an adjustment factor, which is used to adjust the local search sensitivity of the differential evolution algorithm. The larger the value, the stronger the local search ability of the algorithm; I is the number of iterations; X_{r1} and X_{r2} are from a new population of randomly selected individuals and meet $X_{r1} \neq X_{r2}$.

As the number of iterations increases, the optimization scope of the algorithm gradually shrinks, and finally, the optimal clustering division result is obtained, which is the classification result of traditional art painting image style.

III. Experimental Analysis

With 5000 traditional art paintings of different styles as experimental objects, including comics, sketches, ink paintings, watercolors, and other painting styles, this paper uses this method to classify the 5000 traditional art painting styles and analyzes and verify the practical application effect of this method.

Set the parameters needed for the experiment, as shown in Table I.

Taking a traditional art painting as the experimental object and contrast stretching as the measurement index, the enhancement ability of this method to the traditional art painting image is tested. To make the experimental results more sufficient, the literature [9] method, literature [10] method, literature [11] method, literature [12] method, and literature [13] method are used at the same time. The test results are shown in Fig. 2. Analysis of Fig. 2 shows that the overall color of the original traditional art painting image is dark, and the internal details of the image are not clear enough. After using six methods to enhance the traditional art painting image, the clarity and contrast of the traditional art painting image enhanced by this method have been significantly improved. Although the contrast of the traditional art painting image enhanced by the literature [9] method, literature [11] method, and literature [13] method is effectively prompted, the contrast is too large, which leads to the disappearance of the internal details of the traditional art painting image, while the traditional art painting image enhanced by the literature [10] method and literature [12] method has a low lightness and darkness. The details in traditional art painting images cannot be clearly presented. To sum up, this method can effectively stretch the traditional art painting image and has a strong traditional art painting image enhancement effect.

TABLE I. CONFIGURATION TABLE OF PARAMETERS REQUIRED FOR EXPERIMENTS

Serial number	Parameter	Content
1	Color space conversion parameter	From RGB color space to HSV color space, it is necessary to convert the coefficients in the formula.
2	Automatic contrast stretching parameter	Relates to parameters such as tensile strength or tensile ratio.
3	Adaptive histogram equalization parameters with finite contrast	Parameters such as contrast limit threshold and the number of histogram partitions are involved.
4	Fuzzy c-means clustering parameters	When using fuzzy C-means method to classify styles, it is necessary to set parameters such as the number of clusters (that is, the number of styles) and fuzzy factors.
5	Relevant parameters of training and testing data sets	Including the ratio of training set to test set, data enhancement parameters (such as rotation angle, cutting size, etc.), batch size, learning rate, etc.

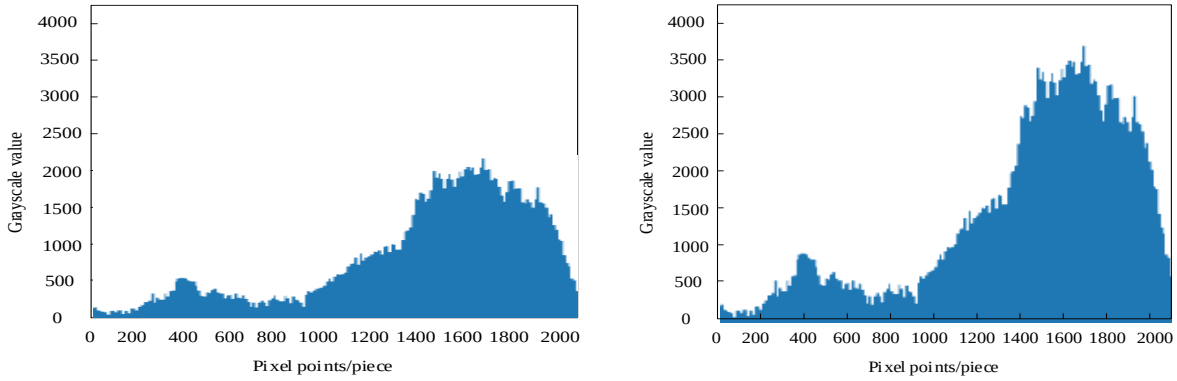
(e) Reference [11] method (f) Reference [12] method (g) Reference [13] method

Fig. 2. Test results of image enhancement in traditional art painting.



(a) Before enhancement (b) After enhancement

Fig. 3. Test results of image enhancement in traditional art painting.

To further verify the enhancement effect of this method on traditional art painting images, take a traditional art painting image as the experimental object and use this method to enhance it. Additionally, the histogram is employed to showcase the grayscale values of the traditional art painting image both before and after undergoing enhancement processing. The test results are shown in Fig. 3.

According to the comprehensive analysis of Fig. 3, after applying the method in this paper to enhance the traditional art painting image under the same pixel situation, the pixel gray value can be effectively improved. This result further verifies that the method in this paper has a good enhancement effect on the traditional art painting image.

The color space conversion accuracy is taken as a measure to test the color space conversion ability of the method in this paper for traditional art painting images under different color space lightness and color saturation. The test results are shown in Table II.

According to the analysis of Table II, when using this method to convert the color space of traditional art painting images, the separation accuracy value is higher than 0.9 under the conditions of different color space lightness and color space saturation. This value shows that this method can effectively convert the color space of traditional art painting images and also confirms from the side that this method has a strong ability to classify traditional art painting styles.

Take a large number of traditional art painting images as experimental objects and use the method in this paper to classify their styles. In order to make the verification results more sufficient, the style classification is carried out respectively under the conditions of no rotation, 30-degree rotation, and 70-degree rotation of traditional art painting images. The results are shown in Fig. 4 to Fig. 6, respectively.

TABLE II. PRECISION VALUES OF COLOR SPACE CONVERSION IN TRADITIONAL ART PAINTING IMAGES

Color space brightness	Color space conversion accuracy	Saturation	Color space conversion accuracy
5	0.95	50	0.98
10	0.95	55	0.95
15	0.96	60	0.96
20	0.94	65	0.93
25	0.95	70	0.98
30	0.97	75	0.94
35	0.92	80	0.97
40	0.96	85	0.92
45	0.93	90	0.95
50	0.95	95	0.94
55	0.94	100	0.96

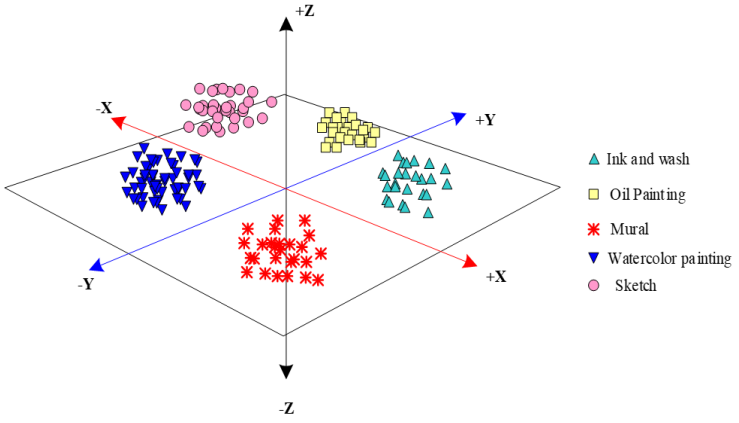


Fig. 4. No rotation.

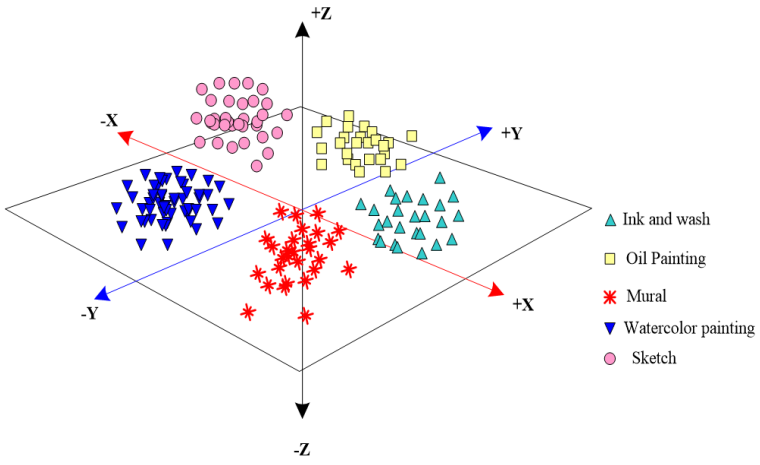

Fig. 5. Rotate 30 degrees.

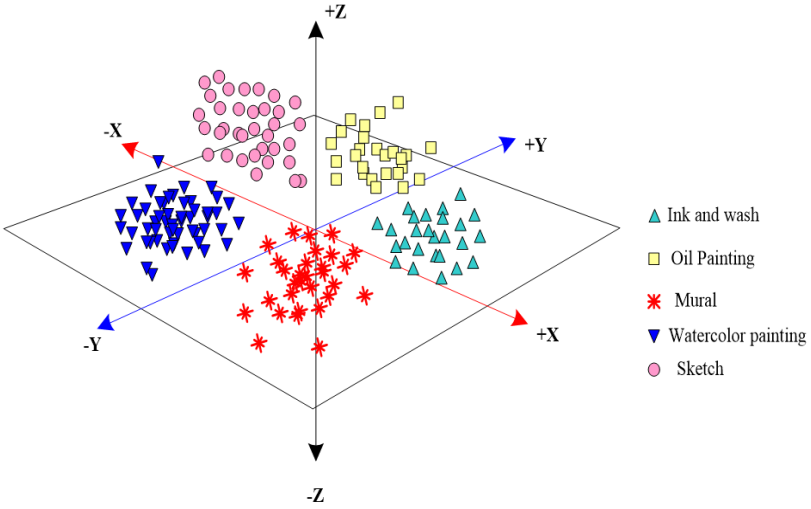

Fig. 6. Rotate 70 degrees.

From the analysis of Fig. 4 to Fig. 6, it can be seen that when the traditional art painting images are not rotated, the distance between different clusters is far when this method classifies their styles, and the distribution of traditional art painting images in the same cluster is relatively dense. When traditional art painting images are rotated 30 degrees and 70 degrees, respectively, the distribution distance of different clusters is shortened when the method in this paper is applied to classify traditional art painting styles, and the distribution of traditional art painting images within the same cluster becomes sparse, but the differences between different clusters are still obvious. The aforementioned findings indicate that the utilization of this approach leads to an efficient classification of traditional art painting styles. When classifying, the density between class clusters is better, and the classification of traditional art painting styles is more accurate, which is not affected by the rotation of traditional art painting images.

The Xie Beni (XB) index is used to measure the classification accuracy of traditional art painting styles. The smaller the value, the higher the classification accuracy of traditional art painting styles. With 15 traditional art painting images as the experimental objects, this paper analyzes the changes in the Xie Beni index when classifying the magnification of traditional art painting images by this method and sets the threshold value of the Xie Beni index to 0.4. The test results are shown in Table III.

TABLE III. CLASSIFICATION OF TRADITIONAL ART PAINTING STYLES BY XIE BENI INDEX

Traditional Painting Image Coding	Magnification		
	1	*1.5*	*2*
1	0.12	0.21	0.32
2	0.11	0.23	0.33
3	0.19	0.25	0.31
4	0.08	0.19	0.28
5	0.07	0.19	0.24
6	0.12	0.25	0.26
7	0.15	0.29	0.27
8	0.09	0.31	0.31
9	0.14	0.24	0.33
10	0.16	0.25	0.35
11	0.08	0.26	0.28
12	0.17	0.22	0.29
13	0.15	0.21	0.31
14	0.16	0.27	0.25
15	0.11	0.18	0.24

Analysis of Table III shows that with the increase of magnification of traditional art painting images, the Xie Beni index when classifying traditional art painting styles in this method shows an upward trend, but the increase is not significant. When the magnification of the traditional art painting image is 2, the maximum value of the Xie Beni index when this method classifies the traditional art painting style is only 0.35, which is lower than the preset threshold value of the Xie Beni index. The above results show that the method in this paper has a high accuracy in classifying traditional art painting styles and has a relatively significant application effect.

IV. DISCUSSION

1) The traditional art painting style classification method based on color space transformation has obviously improved the clarity and contrast of the traditional art painting images, which can effectively stretch the traditional art painting images and has strong traditional art painting image enhancement effect.

2) After the traditional art painting style classification method based on color space transformation is applied to enhance the traditional art painting image, the gray value of each pixel is effectively improved under the same pixel, which further verifies that the method in this paper has a good enhancement effect on the traditional art painting image.

3) When the traditional art painting style classification method based on color space conversion is used to convert the color space of traditional art painting images, the separation accuracy values are all higher than 0.9 under different color space lightness and color space saturation, which shows that the method in this paper can effectively convert the color space of traditional art painting images, and also proves from the side that the method in this paper has strong ability to classify traditional art painting styles.

4) The traditional art painting style classification method based on color space transformation is far away between different clusters, and the traditional art painting images in the same cluster are densely distributed. The application of this method can effectively classify the traditional art painting styles, and the density between clusters is good, and the classification of traditional art painting styles is more accurate, which is not affected by the rotation of traditional art painting images.

5) With the increase of the magnification of traditional art painting images, the Xie-Beni index of the traditional art painting styles classified by this method shows an upward trend, and the classification of traditional art painting styles by this method has a high accuracy and a remarkable application effect.

V. CONCLUSION

The classification of traditional art painting styles is one of the more efficient applications of deep learning methods in the field of traditional art painting. It can effectively enhance the performance of both classification and imitation of traditional art painting styles. This paper studies the classification algorithm of art-style images and proposes a traditional art painting-style classification method based on color space conversion. The salient information contained in traditional art painting images can effectively reflect the image's salient features, improve the accuracy of style classification, and combine the salient information with the fuzzy C-means algorithm. According to the characteristics of traditional art painting images, the salient features contained in different styles of painting images are extracted. Then, the extracted features are passed on to the fuzzy C-means algorithm in order to accomplish the classification of traditional art painting styles. Through the actual verification of the method in this paper, based on the verification results, it is evident that the approach presented in this paper exhibits a high level of effectiveness in categorizing traditional art painting styles, yielding notable practical applications.

Although the traditional art painting style classification method based on color space transformation has certain effectiveness, it also has some limitations.

1) Dependence on color space transformation: One of the core of this method is color space transformation. However, the conversion of color space may be influenced by many factors such as lighting conditions, pigment types and painting techniques. For some special cases, the transformation of color space may not accurately capture the essential characteristics of painting style, which leads to the error of classification results.

2) Limitations of feature extraction: This method mainly relies on image features such as color and contrast for classification. However, the traditional artistic painting style is not limited to color and contrast, but also includes many characteristics such as texture, composition and brush strokes. These methods fail to fully consider other features, which will limit the accuracy and comprehensiveness of classification.

3) Requirements of data set: The method based on color space conversion has higher requirements for training data set. It needs enough diverse and representative samples for training in order to obtain an accurate classification model. If the data set is small or the samples are not rich enough, the generalization ability of the model will be insufficient, and the new paintings cannot be accurately classified.

To sum up, the traditional art painting style classification method based on color space transformation has achieved certain results, but it still faces some limitations. Future research can further combine advanced technologies such as deep learning to improve the accuracy and efficiency of classification.

Research on Image Algorithm for Face Recognition Based on Deep Learning

Qiang Wu
School of Information Technology, Jiangsu Open University, Nanjing, 210036, China

***Abstract*—As people's requirements for applications are getting higher and higher, the recognition of facial features has been paid more and more attention. The current facial feature recognition algorithm not only takes a long time, but also has problems such as large system resource consumption and long running time in practical applications. Based on this, the research proposes a multi-task face recognition algorithm by combining multi-task deep learning on the basis of convolutional neural network, and analyzes its performance in four dimensions of face identity, age, gender, and fatigue state. The experimental results show that the multi-task face recognition algorithm model obtained through layer-by-layer progression takes less time than other models and can complete more tasks in the same training time. At the same time, comparing the best model M44 with other algorithms in four dimensions, it is found that the Mean Absolute Error lowest is 3.53, and the highest Accuracy value is 98.3%. On the whole, the multi-task face recognition algorithm proposed in the study can recognize facial features efficiently and quickly. At the same time, its training time is short, the calculation speed is fast, and the recognition accuracy is much higher than other algorithms. It is applied to intelligent driving behavior. Analysis, intelligent clothing navigation and other aspects have strong practical significance.**

***Keywords*—Multi task deep learning; face recognition; convolution neural network; multi task; dimension**

I. INTRODUCTION

The rapid development of artificial intelligence has made it the core driving force of industrial transformation. It is also widely used in the fields of speech recognition and image recognition, and has gradually replaced human resources [1-3]. As an important pillar in the field of image recognition, face recognition has been widely used in business, identity authentication and other fields, and has gradually received attention. In addition, face recognition is no longer limited to a single task, and the needs of multi-task face recognition. It is also constantly improving [4-5]. In this context, many domestic and foreign scholars have conducted in-depth research on it. Khan AA et al. built a face recognition image model on the basis of neural network and integrated genetic algorithm and principal component analysis, which provided help for face matching in forensic investigation [6]. Srivastava S et al. proposed a new method of biometric authentication face recognition based on artificial neural network, which effectively reduces the error rate of face recognition [7]. Karanwal overcomes the problem of low image recognition rate in local binary patterns by proposing descriptors [8]. However, although the current feature matching algorithms using similarity measures in single task face recognition are simple and fast, they are difficult to robustly determine the threshold size. Although feature matching algorithms using feature subspaces can map intra class differences to subspaces for compression, their noise will also be mapped to subspaces and easily amplified. Although feature matching algorithms using statistical models have good robustness and identification, they are prone to data overfitting, and many deep learning methods also have shortcomings such as low accuracy and high hardware requirements. The methods in multitasking facial recognition have drawbacks such as multiple parameters, slow running speed, and high resource consumption. Based on this, the research proposes a multi-task deep learning algorithm by integrating deep learning on the basis of Convolutional Neural Network (CNN). The purpose is to effectively improve the accuracy of face recognition through a new face recognition algorithm. At the same time, it reduces its recognition time and provides effective suggestions for artificial intelligence face recognition.

The research is divided into six sections. Section I is the introduction, Section II is about related work. Research on Face Recognition image algorithm is mentioned in Section III, results and discussion in Section IV and Section VI concludes the paper.

II. RELATED WORK

With the development of artificial intelligence, face recognition technology is gradually applied to all walks of life, and it is also a very important link in biometrics. Compared with fingerprint recognition, iris recognition and other recognition technologies, it can better meet the needs of users, and the recognition accuracy and recognition speed are very fast [9]. The current face recognition technology has many defects in practical application. How to improve face recognition has become the focus of current research. Based on this, scholars at home and abroad of Everbright have conducted in-depth research on it. Chen et al. proposed a new Collaborative Representation Based Fuzzy Discriminant Analysis (CRFDA) algorithm based on collaborative representation, and effectively extracted the relevant features of the image through dimension reduction, which effectively improved the feature extraction standard and improved the face recognition accuracy [10]. Alami et al. proposed a new model of quaternion discrete orthogonal matrix neural network, thereby reducing the time consumption of the model in face recognition training, and further effectively improving the accuracy of color face recognition [11]. Tripathi et al. effectively improved the accuracy of face age recognition by using descriptors in local gradient relationship patterns [12]. Singh et al. put forward a new and robust description of color texture, thus emphasizing the advantages of related color

models in identifying color components, so as to help improve the accuracy of color face recognition [13]. Soni et al. proposed a hybrid optimization algorithm based on bird search to remove image noise and improve face recognition accuracy [14]. Sharma et al. designed a face recognition system based on field programmable gate array to improve the security of face recognition [15], aiming at the problem of imperfect user data protection at present. Long et al. have effectively improved the recognition performance of face recognition by using singular value decomposition (SVD) to solve the problem of poor face recognition technology [16].

In addition, Sharma et al. used the depth learning method to achieve multi-modal determination of personal recognition and improve the robustness of face identification [17]. On the basis of deep learning, Han et al. proposed a new personalized convolution method, which significantly improved the efficiency of face recognition [18]. Srivastava et al. used deep learning to build a hybrid model to improve the accuracy of personal face recognition involving violence [19]. Zhao et al. aimed at the problem that face recognition takes too long; they reduced the time consumption in face recognition by building an unsupervised deep learning network [20]. Vedantham has constructed a classifier by using depth learning to improve the accuracy of facial expression recognition [21]. Deshmukh et al., aiming at the low efficiency of biometric feature extraction in face recognition, built a multi-mode biological learning system using deep learning networks to improve the efficiency of biometric feature extraction [22]. Silva et al. have effectively improved the accuracy of individual identification of wild Asian elephants by using deep learning methods, thus providing help for the protection of wild Asian elephants [23].

From the research of scholars at home and abroad, the current face recognition technology has problems such as long model training time, high resource consumption in practical applications, and deep learning has a good effect on collaborative operation. Therefore, it is of great significance to study the algorithm proposed by combining the depth learning algorithm with human face recognition in practical application. In addition, the face recognition algorithm proposed in the study creatively uses the relevance of multi task reflection to achieve the multi task recognition requirements of the algorithm, which effectively changes the simplification of traditional face recognition.

III. Research on Face Recognition Image Algorithm Based on Multi-Task Deep Learning

A. Analysis of Convolutional Neural Networks in Multi-Task Deep Learning

Aiming at the problems of slow training time and large system resource consumption for the current face attribute recognition task, the research conducted a related analysis on the face recognition image algorithm on the basis of multi-task deep learning. Deep learning includes two parts: deep and learning. Specifically, deep learning is a deep network model and has a suitable training learning method. The current fast-developing deep learning method is CNN, and for multi-task depth in terms of learning, convolutional neural networks are the basis for face recognition [24]. CNN uses a large amount of data for learning, and performs multiple multi-level convolution and non-linear mapping on it, so as to achieve the purpose of feature extraction or classification. It has the advantages of high accuracy and strong robustness. In other words, the working principle of CNN is to simulate the recognition process of the human brain [25]. Strictly speaking, CNN imitates the human brain to process information in more detail, and its principle structure is shown in Fig. 1.

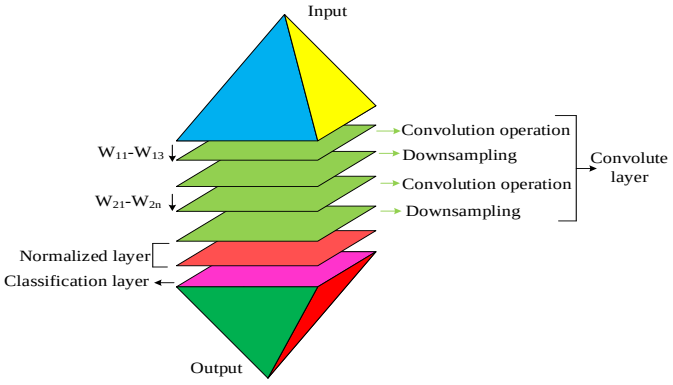

Fig. 1. Principle and structure of CNN.

It can be clearly found from Fig. 1 that the principle structure of CNN includes five levels of input, convolution, normalization, classification and output, which are progressive until the desired information is output. Specifically, after inputting the initial training data, CNN uses the reverse transfer algorithm to perform repeated learning, revise the parameters of different neurons, and finally obtain a convergent neural network model. On this basis, by inputting the image into the trained CNN model, a large number of abstract expressions ranging from low-level intuition to high-level can be obtained, and then through linear or nonlinear combination, accurate representation can be obtained to complete classification and feature extraction. Therefore, the basic structure of CNN can be divided into two parts, namely the feature extraction part and the fully connected part, and the more important ones are the convolution layer, the activation function layer and the fully connected layer (Softmax). At the signal level, the image of the convolution layer can be regarded as a visual signal, and its convolution operation can be understood as a process of filtering the signal, and its related calculation expression is shown in Eq. (1).

$$I(x,y'')*W(x,y'')=\sum_{s=-w}^{w}\sum_{t=-h}^{h}(s,t)I\left(x-s,y''-t\right) \quad (1)$$

In Eq. (1), I represents the pixel value; x represents the row; y'' represents the column; represents the convolution kernel; W the t parameter w represents the width of the convolution kernel; h represents s the height of the convolution kernel; At the matrix level, the convolution operation of the image is to use the convolution core to perform continuous convolution on the perceptual region of the image, and finally use it as the feature value of the region to obtain the feature map. The specific operation process is shown in Fig. 2.

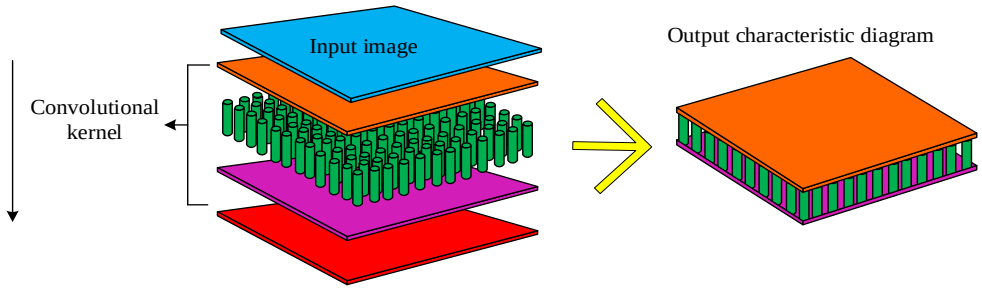

Fig. 2. Operation process of convolution.

It can be seen from Fig. 2 that the operation process of convolution is relatively simple. First, input the corresponding image into the convolution kernel, and then output the feature map after the operation. For the convolution layer, the convolution layer is usually composed of multiple convolution cores to better extract the image features. In CNN, the convolution layer uses a variety of convolution to check the local receiving area of the image, and obtains the feature maps of different convolution cores through the sliding convolution operation. It can be seen that CNN can effectively detect the features of the face in face recognition by recognizing the local feature map, thus improving the accuracy of face recognition. In this process, the corresponding calculation formula is shown in Eq. (2).

$$h_{ij}^{k} = f\left(\left(W_k * x'\right) + b_k\right) \tag{2}$$

In expression (2), x represents the convolution result, where i and j represents the position in the matrix, specifically represented as rows and columns, k represents the number of convolution kernels; f represents the activation function; x' represents the input image; b represents the convolution The corresponding bias of the kernel. The activation function layer is also known as the normalization layer. Its purpose is to use the relevant activation function to add corresponding nonlinear correlation factors, so as to ensure that the features are unique and invariant, thereby improving the overall expression ability of the model. The linear activation function is the Linear Rectification Function (RELU) [26]. Its related expression formula is shown in Eq. (3).

$$f\left(z\right) = \max\left(z, 0\right) \tag{3}$$

In Eq. (3), it $\max$ represents a comparison function that takes a larger value; z it represents the size of the input. However, in the actual training process of CNN, if the backpropagation presents a large gradient, if a RELU neuron flows through it, the neuron will always be in a "dead" state, which will as a result, the parameters of CNN are no longer continuously updated, thus consuming too many resources and related operations. The activation function selected for the study can be understood as a layer of network in the neural network, namely the Maxout activation function, which is relative to the sparse feature of the RELU activation function. It is more compact, and feature selection and dimensionality reduction can also be performed at the same time, and the calculation formula of its related neurons is shown in formula (4).

$$h_i\left(x\right) = \max_{j\in[1,k']} z'_{ij} \tag{4}$$

In Eq. (4), it $h_i\left(x\right)$ represents i the output of the neuron of the Maxout layer; it represents k' the number of input layers connected to the Maxout layer; j it represents the j input layer; z' it represents the input layer connected to the neurons of the Maxout layer. value, and its evaluation formula is shown in Eq. (5).

$$z'_{ij} = W_{\cdots ij} * x^{T} + b_{ij} \tag{5}$$

In Eq. (5), it $W_{\cdots ij}$ represents a certain convolution kernel among multiple convolution kernels; x^{T} it represents the input. For the Maxout layer, the dimensions of each CNN layer input must be consistent. On this basis, the maximum value is selected as the value of the same coordinate of the output layer after each input of the same coordinate is compared. This can be seen. The Maxout function is a piecewise function, and its input gradient formula is shown in Eq. (6).

$$\frac{\partial hi\left(x\right)}{\partial z'ij} = \begin{cases} 1 & if\ zij > ziq \\ When\, q \neq j\ and\ q \in [1,k] & \\ 0 & otherwise \end{cases} \tag{6}$$

In Eq. (6), q represents the input value. It can be clearly seen from the Eq. (6) that the slope exhibited by each segment of the Maxout function is determined by the output value, so it presents a dynamic change and does not completely fix a certain value. In addition, the Softmax layer is essentially a nonlinear classifier. In deep learning, it is often used as the output layer of CNN to output a probability vector. The output probability correlation calculation formula of the Softmax layer is shown in Eq. (7).

$$p\left(y' = i \middle| x', \theta\right) = \frac{e^{\theta j^{T} x}}{\sum_{j=1}^{k} e^{\theta j^{T} x}} \tag{7}$$

In the output probability calculation expression (7), θ represents the bias term; y' represents the output category, T represents transposition. On the whole, the Softmax layer is to map the multiple outputs after the original convolution to

the values 0 to 1 with the Sofmax function, and the accumulation of these values is 1, which satisfies the characteristics of probability. On this basis, it selects the final output. As a result, the largest prediction result can be selected to achieve multi-classification tasks, and in actual face recognition, multi-task face recognition can be effectively achieved. In face recognition technology, there are three very important technologies, which are the recognition of face age, gender, and fatigue status, which together lay the foundation for face recognition technology. Specifically, face recognition technology includes face-related feature extraction and comparison technology.

B. *Research on Multi-Task Face Recognition Algorithm based on Convolutional Neural Network*

CNN is a relatively common deep learning method, which is also the basis of multi-task face recognition algorithm. To understand multi-task face recognition algorithm, you need to understand the principle of multi-task learning. The current deep learning methods for multitasking mainly have the following two characteristics: one is structurally speaking, shallow parameter sharing between tasks; the other is that, in terms of impact, the common data characteristics hidden between different tasks are excavated. This requires that a model can handle multiple tasks at the same time, and also requires multiple tasks to work together to enhance the generalization ability. The overall structure is shown in Fig. 3.

It can be seen from the overall structure of multi task learning in Fig. 3 that its specific content includes model input, shared parameters and relevant parameters of specific tasks. By inputting relevant values in model input, shared parameters are obtained, and relevant parameters of specific tasks are output in subsequent output. An important premise of multi task learning is that there is a certain correlation between multiple tasks, so learning efficiency can be improved through the correlation between tasks. Although there is no clear definition, when looking for related tasks, a basic assumption is that the characteristics concerned by each task are interrelated, or the learning process is beneficial in different tasks. In the research, there is some correlation between facial features and features. Through the association training of multiple tasks, the accuracy of multiple tasks can be effectively improved. In the actual face recognition, the task is no single, and the improvement of the accuracy of multi task recognition can also effectively improve the overall recognition accuracy.

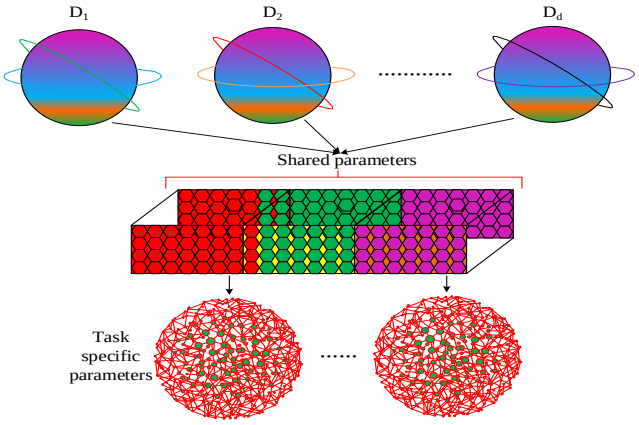

Fig. 3. The overall structure of multi task deep learning.

The traditional face recognition algorithm has the problem of low recognition task accuracy. Aiming at this problem, a multi-task deep learning face recognition algorithm is proposed. This algorithm uses the relatively strong correlation of face identity, age, and gender and fatigue recognition. To carry out research, in order to build a multi-task face recognition model in a short time, and to complete the relevant recognition tasks under the premise of maintaining high precision and high speed. High accuracy depends on the relevance of multiple learning tasks, and high-speed operation requires optimization of model parameters. Therefore, the research integrates CNN to construct a CNN network for multi-task face recognition. Its structure is shown in Fig. 4.

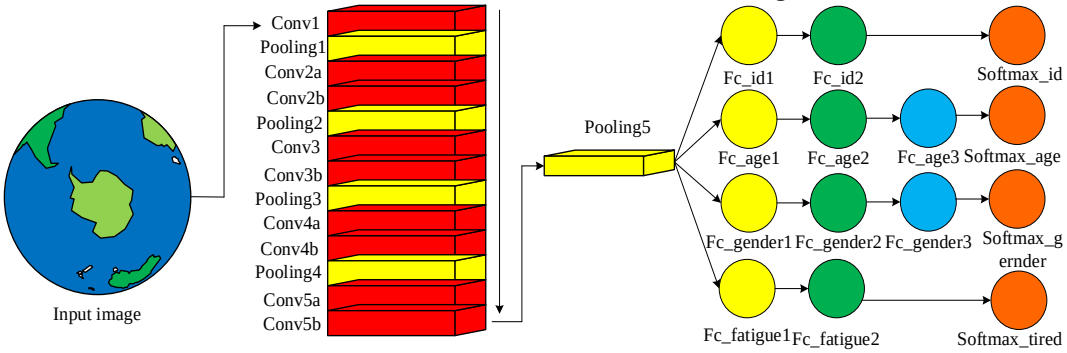

Fig. 4. Multi task face recognition network structure.

As can be seen from Fig. 4, the overall network structure of CNN has a total of nine convolutional layers, the pooling layer uses the maximum pooling function, the activation function selects the Maxout function, and all tasks in the training select the Softmax function to perform related classification training tasks for face recognition. It is worth noting that before constructing the actual network training, it is necessary to set the objective function and the training algorithm. This is because the work related to face recognition is closely related to the data, including identity, gender, age, etc. It is very difficult to generate a multi-label data set with information such as fatigue, fatigue, etc. Therefore, after setting the two in detail, the multi-label data set can be trained synchronously, and the multi-task training on the basis can be

obtained. Same result. In the proposed multi-task deep learning face recognition algorithm, a brief description of the relevant forward propagation expression is shown in Eq. (8).

$$output_{k'} = f(W_{k'}X + b_{k'}) \tag{8}$$

In the expression Eq. (8), it k' represents the first k' face recognition task; $W_{k'}$ it represents the convolution related parameters. In contrast, the formula expression of backpropagation is shown in Eq. (9).

$$W_{k'} = W_{k'} - \eta_{k'} \frac{\partial L_{k'}}{\partial W_{k'}} \tag{9}$$

In the Eq. (9) of backpropagation, η it represents the learning rate; L it represents the loss of identifying characters. It is worth noting that the overall back-propagation formula of the recognition task can be divided into two parts: the independent parameter part of a single task, whose back-propagation formula is consistent with Equation (9), and the back-propagation formula of the common parameter segment of multiple tasks is as in Eq. (10).

$$W_{share} = W_{share} - \sum_{k'=1}^{M} \eta_{k'} \frac{T_k \partial L_{k'}}{\partial W_{share}} \tag{10}$$

In Eq. (10), it W_{share} represents the shared parameters between multiple tasks; M it represents the total number of face recognition tasks; and $T_{k'}$ it represents the weight of the task. It can be seen from Eq. (10) that the training strategy given by the study is consistent with the training of multiple tasks at the same time, except that there is a sequence in the training time of each task. Therefore, for different recognition tasks, the specific training strategy not only grasps the three important foundations of face recognition, but also introduces identity recognition. In face recognition, the forward propagation calculation formula of the deep learning model CNN structure is shown in Eq. (11).

$$o = g\left(f_n\left(W_n \cdots f_2\left(f_1\left(W_1 X_0 + b_1\right) + b_2\right) \cdots + b_n\right)\right) \tag{11}$$

In Eq. (11), o represents the forward propagation training value; W_n represents the n weight of b_n the first n layer; represents the displacement bias of the first layer; and $g()$ represents the final classification function. The ultimate goal of network training is to obtain the minimized loss function value loss, so the Softmax-loss function is selected to calculate the loss rate, and its specific formula is shown in Eq. (12).

$$Loss\left(y, o_y\right) = -\log\left(o_y\right) = -\log\left(\frac{e^{z_y}}{\sum_{j=1}^{m} e^{z_j}}\right) \tag{12}$$

In Eq. (12), it y represents the real label of the face image; o_y it represents the probability value of the position in the output probability vector when Softmax outputs y. In addition, in face age recognition, a unique loss function is selected to speed up the training process, and its specific expression is shown in Eq. (13).

$$G\_Loss\left(y, o_y\right) = \mu G(y, o_y) + \left(1-\mu\right) Loss\left(y, o_y\right) \tag{13}$$

In Eq. (13), it μ represents the weight of loss; $G(y, o_y)$ it represents the special loss function selected by the research, and its calculation formula is shown in Eq. (14).

$$G(y, o_y) = \left(1 - \exp\left(-\frac{o_y - y}{2\delta^2}\right)\right) \tag{14}$$

In Eq. (14), it δ represents the standard deviation of the age distribution in the training data set, and its calculation formula is shown in Eq. (15).

$$\delta = \sqrt{\frac{1}{N}\sum_{i=1}^{N}\left(x_i - \mu'\right)^2} \tag{15}$$

In Eq. (15), it N represents the total number of pictures of human faces; x_i represents i the age of the th face photo; μ' represents the mean value.

IV. Application and Performance Analysis of Face Recognition Image Algorithm based on Multi-Task Deep Learning

In order to verify the performance of the multi task deep learning face recognition algorithm proposed by the research, the research selects the face recognition training data set (CASIA Webface), human age recognition data set (IMDB-WIKI 500k+), face gender recognition data set (Celeba) and face fatigue recognition data set (bus driver face fatigue data set) before the experiment, and the test sets are respectively IJB-A, FG-NET, Celeba and human eye closure data set (CEW). It is worth noting that the data sets selected for the study are all found on the Internet, part of which are internet data (such as Wikipedia) and part of which are intranet data. In addition, in the experiment, the deep learner Aki chose Caffe, and the processor chose Intel (R) Core (TM) 7-7700 CPU @ 3.6GHz, with 8-core 8GB of memory; Select 64 bit Ubuntu 16 04 for the operating system; Choose NVIDIA GeForce GTX1070 graphics card with 8G memory; Select the Python 27 environment and Anaconda related scientific computing library for the development environment and tools. At the same time, before the experiment, the dataset was preprocessed for possible missing faces or imbalanced data, mainly through three steps: affine transformation, random cropping, and data balancing. The specific content of the dataset is shown in Table I.

It can be clearly seen from Table I that in the training data set selected for the experiment, the CASIA-Webface data set contains 494,414 identity photos of 10,575 people, and the training data set IJB-A data set contains the face pictures of 500 people, including 5,396 still images, 20,412 frames of video images; IMDB-WIKI 500k+ dataset contains 524,230 face images of 82,612 people, of which 460,723 are from the Internet Movie Database (IMDB) and 62,328 are from WiKi ,

its test set contains 1,002 photos of 1,297,028 people; the Celeba data set divides 202,599 face images of 10,177 people into training and test sets in a ratio of 9:1; the bus driver's face fatigue data set contains There are 47,500 photos of 10,100 individuals, including 10,000 photos of fatigued state, 30,000 photos of normal state, and 7,500 photos of standing wearing sunglasses. The test set CEW contains 2,423 photos of 40 individuals, including 1,192 photos of closed eyes, and 1,231 photos of closed eyes. Open-eye photos, closed-eye photos are obtained from a web crawler, and open-eye photos are obtained from the face database (Labeled Faces in the Wild, LFW). According to the four parts of the dataset, the research first analyzes the face recognition task, and its experimental results on the training set LFW are shown in Fig. 5.

TABLE I. SPECIFIC CONTENTS OF TRAINING DATA SET AND TEST DATA SET SELECTED BY THE EXPERIMENT

Training Set	Number of people	Number of photos			Test Set	Number of people	Number of photos	
CASIA-Webface	10575	494414			IJB-A	500	5396 (static state)	20412 (Video image)
IMDB-WIKI 500k+	82612	460723 (IMDB)	62328 (Wiki)		FG-NET	1297028	1002	
Celeba	10177	182339			Celeba	10177	20260	
Bus drivers face fatigue	10100	10000 (Fatigue state)	30000 (Normal state)	7500 (Wear sunglasses)	CEW	40	1192 (Closed eye photograph)	1231 (Eye opening photo)

In Fig. 5, Fig. 5(a) is the loss function curve obtained by using the loss function. Using this loss function curve, the model to be verified for face identification is divided into five models, which are respectively used M_{11} to M_{15} represent, and through the analysis of the five models The model's rate of change (Rate of Change, ROC) and the area under it (Area Under Curve, AUC) are compared, and Fig. 5(b) is obtained. It can be seen from Fig. 4 that the AUC value is the highest M_{13}, and the AUC value is 0.982 at this time. Therefore, the study uses it as the subsequent face age recognition pre-training model, and the relevant formula is used to obtain the threshold value of 0.35, and the accuracy rate is as high as 92 %. The experimental results show that the preprocessing model can effectively extract the identity features of the face. In the face gender experiment, the research uses the face identification with the highest AUC value M_{13}, trained for four hours in the same equipment environment, and obtained the corresponding loss curve, and also obtained five models according to the obtained loss function curve, respectively. Used M_{21} to M_{25} represent, and the corresponding face gender experiment is on the model with the best performance in the face age recognition task, after 10 minutes of training, the obtained 5 models are respectively used M_{31} to M_{35} represent, the two are respectively in LG- The experimental results on the NET and Celeba training sets are shown in Fig. 6.

Fig. 6 (a) is the loss convergence scatter and Mean Absolute Error (MAE) obtained in the face age recognition training process, and Fig. 6(b) is the loss obtained in the face gender recognition training process Convergence curve and face recognition accuracy value (Accuracy, Acc). It can be seen from Fig. 6(a) that the MAE minimum value appears at the model M_{22}, and the algorithm has the highest accuracy at this time, so it can be used as the pre-training model for face gender recognition in Fig. 6(b). It can be seen from Fig. 6(b) that the Acc value M_{34} is the highest at the model, which is 0.983. The experimental results show that with the continuous optimization of the model accuracy, the training time for the algorithm to obtain loss convergence is decreasing, indicating that the error of the algorithm is decreasing, and it is continuously improving the accuracy of the model until it is optimal. Finally, the loss convergence curve was obtained after only two minutes of training in human fatigue state recognition. The experimental results on the CEW dataset and the total convergence time of the four identification experiments are shown in Fig. 7.

It can be clearly seen from Fig. 7 that the recognition accuracy of face fatigue M_{44} appears on the model, which is 0.983. In addition, in the introduction of three deep learning models (Facenet), Face Recognition Based on Visual Geometry Group Network (Vggface) and Levi G's four best models in the research itself From the comparison, it can be found that on the basis of the algorithm proposed by the research, the four tasks can complete the continuous training of the optimal mode within 10 hours, which is much shorter than the training time of deep CNN networks such as Facenet and Vggface; Compared with the face feature recognition method proposed by Levi [27] et al., this method can only recognize the age and gender of the face, but the algorithm proposed in the study can complete the face recognition identity within the same training time. On the basis of gender, it can also realize the recognition of face age and fatigue state. The research results show that the multi-task training method can effectively reduce the completion time of training tasks.

In order to further verify the effectiveness of the proposed algorithm, the research M_{44} evaluates the performance of the final multi-task face recognition model. Chen algorithm, Webface algorithm and block cipher algorithm (Gosudarstvennyi Standard, GOST) algorithm are introduced again in the experiment. The experimental results are shown in Table II.

TABLE II. PERFORMANCE COMPARISON OF MULTIPLE ALGORITHMS

Model	Feature extraction time	Number of parameters	Enter image dimensions	Accuracy (%)	FAR=0.1	FAR=0.01	FAR=0.001
$M44$	41ms	5555K	64×64×1	97.88 0	0.951	0.844	0.790
Chen	67ms	5004K	100×100×1	97.71 0	0.966	0.837	-
Webface	-	5011K	31×36×3	97.49 0	-	-	-
Facent	>558ms	140690K	224×224×3	99.62 0	0.950	0.834	0.750
Vggface	>528ms	134249K	224×224×3	97.27 0	0.936	0.804	0.603
GOST	-	-	-	-	0.620	0.400	0.190

As can be seen from Table II, in the LJB-A dataset with more complex actual scenes, M_{44} the model performance of the model is better than other models, and the accuracy reaches 97.880%. In addition, when the False Accept Rate (FAR) value is 0.01, the True Accept Rate (TAR) value at this time is 0.844, indicating that the M_{44} model has higher robustness in actual complex situations, which can distinguish face identities well. At the same time, the research compares the performance and accuracy of different algorithms (methods) in the recognition of face age, gender, and fatigue state. Among them, multi region convolution neural network (MR-CNN) and two ranking based methods are introduced into face age recognition, namely OH ranker and OR-CNN; panda recognition (PANDA-1), hyperspectral face recognition (Hyperspectral Face Recognition, Hyperface), LNet+ANet, based on deep learning are introduced in face gender recognition Face detection and alignment based on depth learning (MT) and walk recognition (Walk); in face fatigue recognition, Support Vector Machines (SVM) are added, and linear inverse Projection algorithm (Local Binary Patterns, LBP), Gabor and multimedia algorithm (Multi), the specific experimental results are shown in Fig. 8.

It can be clearly seen from Fig. 8 that M_{44} the value of the model MAE is 3.53, which is much lower than other algorithms; in addition, its ACC value is 98.3% in face gender and fatigue recognition, which is also higher than other algorithms. The experimental results are obvious. Compared with other face recognition algorithms and depth algorithms, the performance of the proposed algorithm has higher recognition performance, and it also speeds up the training time and improves the recognition accuracy.

Fig. 8. Performance comparison of different algorithms in face recognition.

V. Results and Discussion

The demand for multitasking facial recognition has significantly improved in many current fields. In order to achieve multitasking facial recognition, existing technologies generally use multiple models in parallel to complete multiple different recognition tasks, which may have serious problems in some cases. Firstly, multiple models have slow training time and long application cycles. Secondly, in practical use, there is a problem of high system resource consumption, which also means high hardware requirements and increased usage costs. Based on this, a multi task face recognition algorithm was proposed by combining CNN with multi task deep learning.

The experimental results show that the Acc value is the highest at model M34, at which point it is 0.983. As the model accuracy is continuously optimized, the training time for the algorithm to achieve loss convergence is continuously decreasing. When the FAR value is 0.01, the correctly accepted proportional TAR value is 0.844, indicating that the M44 model has higher robustness in practical complex situations and can distinguish facial identities well, which is better than the results of Basil et al. [28]. In addition, the MAE value of the M44 model is 3.53, which is much lower than other algorithms. Its ACC value in facial gender and fatigue recognition is 98.3%, which is also higher than other algorithms. This result is also superior to the results of Vu et al. and Mohammed Ali et al. [29-30].

In the dataset LFW, the highest AUC value appears in M13, at which point the AUC value is 0.982; In the dataset LG-NET and Celeb, the minimum MAE value appears at model M22, the Acc value is the highest at model M34, and the accuracy of facial fatigue recognition appears at model M44, which is 0.983. This result shows that the research algorithm has high performance on different datasets, and the final optimal model has the best performance, indicating the generalization of the algorithm.

Overall, the algorithm proposed in the study not only consumes less training time, but also has higher accuracy and lower error values, indicating good performance.

VI. Conclusion

In order to solve the problems of long training time and high consumption of face recognition, the research proposes a multi-task face recognition algorithm based on CNN and multi-task deep learning, and conducts experimental analysis on its performance and application. Four dimensions of face identity, age, gender and fatigue state are used to verify the performance of the proposed algorithm. The experimental results show that the AUC value of the best model for face identity recognition is 0.982, indicating that the extracted face identity features are very effective; in face age recognition, the absolute error value of the best model is 3.43, while the in the gender experiment, the highest ACC value was 0.983, the average accuracy rate was 98.04%, and the average accuracy rate of fatigue state recognition also reached 97.5%. In addition, in the experiment of the same four dimensions, when comparing the performance and accuracy of it with other algorithms, the time-consuming feature of the proposed algorithm for face identification is only 41ms, which is much lower than other algorithms; face age recognition The MAE value of Acc is 3.53, the Acc value of gender recognition is 0.983, and the Acc value of fatigue state recognition is also 0.983. The three actually show far lower errors than other algorithms and far higher accuracy than other algorithms. On the whole, the proposed algorithm not only consumes less training time, but also has higher accuracy and lower error value, and has better performance. However, although the

study utilized the Maxout function to extract features, there is still room for expanding the inter class spacing between different individuals in facial identity recognition tasks. Later work can incorporate the triplet loss function for further research.

A Model for Analyzing Employee Turnover in Enterprises Based on Improved XGBoost Algorithm

Linzhi Nan[1], Han Zhang[2*]
School of Economic and Trade, Haojing College of Shaanxi University of Science and Technology, Xi'an, 710000, China[1]
Shaanxi Hantong Consulting Services Co., LTD, Xianyang, 712000, China[2]

***Abstract*—To accurately predict the possibility of employee turnover during enterprise operation and improve the benefits created by talents in the enterprise, research based on the limit gradient enhancement algorithm has received widespread attention. However, with the exponential growth of various types of resignation reasons, this algorithm is not comprehensive enough when dealing with complex character psychology. To solve this problem, this study uses the limit gradient enhancement algorithm to predict employee turnover in the Company dataset, and uses differential automatic regression moving average variable optimization to generate a fusion algorithm. The research first involves stepwise regression processing of the training data, expanding the objective function to a second-order Taylor expansion; Then variance coding is added to the square integrable linear white noise, and the step cooling curve is smoothed by changing the temperature control constant; Then to calculate the root mean square error of Newton's law of cooling, and obtain its derivative loss variable. Linear white noise is the chaotic data produced by the improved extreme gradient lifting algorithm in forecasting the original data of enterprise employees, which will affect the results of data preprocessing in the loss analysis. In order to reduce the operation error of the algorithm, the step cooling curves are drawn according to the cooling law, and then their root mean square errors are calculated. Finally, the fusion algorithm studied was applied to the Company dataset and the prediction accuracy of the particle swarm optimization algorithm was tested and compared with the fusion algorithm. A total of 400 experiments were conducted, and the fusion algorithm achieved a prediction accuracy of 398 times, with an accuracy rate of 99.5%; The accuracy of particle swarm optimization algorithm is close to that of fusion algorithm, at 83.2%. The experimental results indicate that the algorithm model proposed in the study can accurately predict the possibility of employee turnover in enterprises, and the company will also receive timely information to make the next budget step.**

***Keywords*—Data preprocessing; linear white noise; root mean square error; newton's law of cooling; step cooling curve**

I. INTRODUCTION

In the rapidly advancing society of internet technology, as competition between companies intensifies, the number of employees in enterprises is gradually receiving widespread attention, and the requirements for algorithms are also increasing [1-2]. In the operation of the enterprise, talents rely on interpersonal relationships and key technologies to continuously create profits for the enterprise. Such employees will be widely valued within the company, but leaving is also inevitable. The resignation of employees is not conducive to the development of the enterprise, and may even lead to technical gaps that can lead to internal management problems. So, corporate executives are gradually paying attention to the reasons for employee turnover. In this context, algorithms for analyzing employee psychology have received widespread attention. In recent years, the Limit Gradient Lifting Algorithm (XGBoost) has attracted the attention of many scholars due to its powerful self-checking ability [3]. However, XGBoost is only suitable for analyzing differentiable loss variables. For non-differentiable variables, the algorithm marks them as isolated points, which affects the accuracy of the detection data. To address this issue, this study is based on Differential Autoregressive Moving Average Variable (DAMAV) to optimize XGBoost and generate a fusion algorithm (DV-XGBoost) pioneering. This algorithm calculates the root mean square error of non-differentiable variables and can convert non differentiable variables into differentiable loss variables. For the experimental design of the analysis model of employee turnover in enterprises, the research first collects the human resources data of enterprises, and determines the completeness of employee turnover prediction according to the relevant experience of employee turnover in the past; Then clean the collected data to ensure the availability of the data, and extract the characteristics of the data according to the business needs of the enterprise. For the key characteristics of employee turnover, DV-XGBoost algorithm is used to judge it, and the data is divided into training set and test set. The evaluation indexes include accuracy, accuracy and F_1 value. The innovation of this study is mainly reflected in the following two points. First, aiming at the limitations of XGBoost algorithm, this study proposed a fusion algorithm based on DAMAV to optimize XGBoost (DV-XGBoost). This fusion algorithm shows its unique innovation when dealing with underivable variables. The second innovation is that for the non-derivable variable, the traditional XGBoost algorithm will mark it as an isolated point, while the DV-XGBoost algorithm converts it into a derivable loss variable by calculating the root-mean-square error of the non-derivable variable. This method is innovative in solving the problem of non-derivable variables. The contribution of this research is mainly reflected in the following three points. First, DV-XGBoost algorithm improves the accuracy of detection data by converting non-derivable variables into derivable loss variables. It is of great practical significance for enterprises to analyze the reasons of employee dimission and then make corresponding strategies. The second is to broaden the application range of XGBoost, a powerful algorithm that is widely used in all kinds of data contests and real-world

problem solving. However, it is only suitable for analyzing derivable loss variables; DV-XGBoost algorithm further broadens the application range of XGBoost by solving the problem of non-derivable variables. Finally, it can promote the progress of talent management, and enterprises can better understand the reasons for employees' dimission, so as to improve the company's talent management strategy, reduce the employee dimission rate, improve employee satisfaction, and promote the stable development of enterprises.

The research is mainly divided into six sections. Section I mainly analyzes and summarizes the application and effectiveness of the current XGBoost model. Section II introduces the factors that affect the employee turnover model and constructs the DV-XGBoost model. Section III is the experimental study on enterprise characters. Result and discussion is mentioned in Section V and Section VI concluded the paper.

II. Related Works

A very important branch of human psychological prediction technology, namely employee turnover prediction in enterprises, plays a very important role in computer learning and the rational use of human resources in enterprises [4]. Lu et al. designed real driving tasks to extract data and proposed a stress monitoring model based on driving behavior. Driving is described by the acceleration of the vehicle, and the driving environment is quantified using an extended residual network model. According to the distribution range of driver ambiguity, the video image is segmented into sub regions. They constructed an Extreme Gradient Enhancement (XGBoost) model to monitor stress, and compared it with other models, the XGBoost model outperformed mainstream learning algorithms. It can also surpass most traditional models without using psychological data [5]. Deng et al. combined XGBoost and multi-objective optimization genetic algorithm for cancer classification. They first sort genes based on XGBoost ensemble selection, effectively removing unrelated genes and generating the most relevant genome for this class; then, their fusion algorithm searches for the optimal subset based on gene groups. They conducted comprehensive experiments using learning classifiers on publicly available microarray datasets to compare state-of-the-art feature selection methods. Their experiments have shown that the algorithm outperforms existing algorithms in multiple evaluation indicators such as accuracy, precision, and recall [6]. Li et al. developed a reliable prediction method that estimates the sink area of the road surface based on the main feature of road surface temperature. They proposed chaotic particle swarm optimization and segmented regression strategy to optimize the XGBoost model. Compared with the classical learning algorithm, their experimental results show that the root mean square error and absolute error of XGBoost algorithm are increased by 5.80 and 1.59 respectively. This algorithm has obvious advantages in dealing with nonlinear problems, and can also reduce the frequency of deflection without affecting its estimation accuracy, promoting rapid evaluation of road conditions [7]. Tao et al. proposed a robust method for diagnosing turbine blade icing. They extracted features of short-term icing effects based on icing physics to establish stacked XGBoost models for blade icing diagnosis. They evaluated the methods proposed in the wind farm and further compared them with models based on a single algorithm. The results indicated that their mixed features enhance the similarity between different datasets, and their model has higher accuracy and better generalization power compared to models based on a single algorithm [8].

Li et al. proposed an orthopedic classification prediction model based on the XGBoost algorithm. After building the XGBoost model, they also built the same model based on the random forest algorithm, and made a comparative analysis of them. Compared with random forest model, XGBoost algorithm prediction model has higher accuracy and is more suitable for orthopedic clinical data. The XGBoost algorithm can handle diverse medical data and better meet the requirements of diagnostic timeliness and accuracy [9]. Gu et al. proposed a new LC decision model that enables automated vehicles to make human decisions. Their method combines a deep encoder network with the XGBoost algorithm, using time series from multiple sensors to establish a robust multivariate reconstruction model; then, they reconstructed the error using normal data for training data extraction. They adopted the XGBoost algorithm with Bayesian optimization for the multi-parameter problem of autonomous LC decision-making process. This model can accurately identify the LC behavior of vehicles [10]. Li et al. cross matched the bass with the spectral database of the Sloan Digital Telescope to obtain the spectral categories of known samples. Then, the samples were cross matched with the ALLWISE database, and they constructed different classifiers using the XGBoost algorithm based on the optical and infrared information of the samples. Finally, all selected items in the bass directory are classified by these classifiers. When the prediction results of binary classification are the same as those of multi class classification, the prediction results of light sources without infrared information can be used as a reference. Their classification results have great reference value for future research [11]. Osman et al. developed a model for predicting groundwater levels. They tested three machine learning models: Xgboost, artificial neural network, and support vector regression. The experiment shows that if the combination of rainfall data with a delay of 3 days is used as input, the performance of the model is the worst; For all input combinations, their proposed Xgboost model outperforms the other two models. When using groundwater level with a 1-day delay as input, the performance of the Xgboost model is significantly improved. Their research results provide application prospects for the Xgboost algorithm to predict future groundwater levels [12].

The research of multiple scholars mentioned above has found that the predictive ability of Xgboost algorithm is very popular internationally, but there is still little research on fusion algorithms. This study pioneered the introduction of differential autoregressive moving average variables, taking into account the impact of employee personal factors and internal control within the enterprise, and generated a fusion algorithm (DV-XGBoost).

III. Construction of Employee Turnover Information Model based on XGBoost

With the development of the human resources industry, in order to rationalize the distribution of employees in enterprises, research on various information has become increasingly popular, and the probability of employee transfer is the most important part [13]. However, objective factors such as the variety of resignation data and the complexity of employee psychology have increased the workload of predicting employee turnover information devices. This study combines the XGBoost algorithm with DAMAV, first introducing a model built on XGBoost, and then describing the fusion method of the two.

A. Establishment of XGBoost Model for Enterprise Employee Resignation

Before analyzing data on employee turnover in enterprises using models, it is first necessary to preprocess the data. Preprocessing is the most complex part of the experiment, and the results of this part not only occupy time, but also determine the predictive ability of the data. Real data often contains a large amount of data noise and data redundancy [14]. These artificially generated abnormal data are very detrimental to the results, so these data need to be cleaned. The preprocessing work for the data is Fig.1.

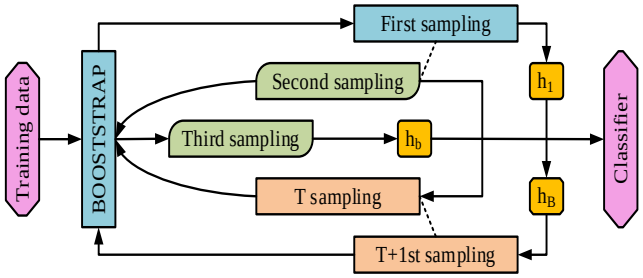

Fig. 1. Diagram of data preprocessing process.

From Fig. 1, the cleaning of training data is first run in the boot program, improving missing values and noise during each sampling process; Then oversampling and under sampling the data, and then transforming the data into a whole smooth curve to get the final output results. The variables selected through Fig. 1 can be used for stepwise regression, and the complex collinear data that meets the requirements is called biased estimation. The data that conforms to the characteristics of continuity can be obtained through a penalty function, as Formula (1).

$$p_\lambda\left(B_j\right)=\begin{cases}\lambda\left(B_j\right) & \left|B_j\right|\le\lambda \\ -\dfrac{\left(\left(B_j\right)^2-2a\lambda\left(B_j\right)+\lambda^2\right)}{2(a-1)} & \lambda\le\left|B_j\right|\le a\lambda \\ \dfrac{(a+1)\lambda^2}{2} & a\lambda\le\left|B_j\right|\end{cases} \tag{1}$$

In Formula (1), a is a constant with a value of, and the adjusted parameter is denoted as λ, with a range of non negative values. B_j is called effective data set, which is often based on natural logarithm [15]. At this point, the unit of random entropy is recorded as bits and is only related to B_j. As the value of B_j increases, the range of random entropy variables becomes larger. The relationship between them is Formula (2).

$$H\left(B_j\right)=-\sum_{i=1}^{n}p_i\log p_i \tag{2}$$

In Formula (2) above, p_i is a random variable with a value range over $[0,+\infty]$. The improvement of XGBoost algorithm relative to decision trees lies in gradient correlation, which is a running model that enhances decision-making ability. The range of regularization terms determines the complexity of the algorithm, and the objective function determines its optimal solution, as shown in formula (3).

$$\underline{y}=\sum_{t=1}^{T}f_t\left(x_i\right),\ f_t\in F \tag{3}$$

In Formula (3), the number of XGBoost decision trees is denoted as T, the decision forest is represented as F, and the specific XGBoost decision tree is denoted as f_t. If the previous prediction for round t is denoted as $\underline{y}$, then the objective function can be expanded using second-order Taylor expansion. In order to measure the quality of the decision tree, the scoring function of XGBoost is introduced, as listed in Formula (4).

$$Mark=0.5\left[\frac{G_L^2}{\alpha_L+\lambda}+\frac{G_R^2}{\alpha_R+\lambda}-\frac{\left(G_L+G_R\right)}{\alpha_L+\alpha_R+\lambda}\right]-\gamma \tag{4}$$

In Formula (4), G_L, G_R represent the segmentation points on the left and right sides of the mean, respectively; The mean values of multiple segmentation points are denoted as α_L, α_R; The difference in the parameters of the decision tree is called γ. The higher the value of $Mark$, the better the quality of the XGBoost decision model. The decision tree is continuously segmented according to this method, and the existing nodes in the time series can be predicted according to the past segmentation points and linear white noise, as expressed in Formula (5).

$$Y_t=\varphi_1 y_{t-1}+\varphi_2 y_{t-2}+\ldots+\varphi_p y_{t-p}+u_t \tag{5}$$

In Formula (5), the predicted value of the existing nodes is Y_t, and the autoregressive coefficients between the segmentation points are represented by φ_p, with a range of positive integers of $(1,p)$. Linear white noise is recorded as u_t, and white noise sequence in regional time can be calculated by Formula (6) [16].

$$W_f\left(\phi,\chi\right)=\chi^{-0.5}\int_{-\infty}^{+\infty}\delta(t)\eta^*\left(\frac{t-\phi}{\chi}\right)dt=\left\langle\delta,\kappa_{(a,b)}(t)\right\rangle \tag{6}$$

In Formula (6), the shift factor and displacement factor are denoted as ϕ,χ, and their value ranges are non negative.

$\delta(t)$ represents a square integrable signal, complex conjugation is denoted as $*$, and $\kappa_{(a,b)}(t)$ is used to represent the cluster function [17]. When XGBoost calculates the importance of features, it studies the method of selecting and calculating the obtained values. By traversing all intermediate nodes, it maps the number of feature times of the branch. The trained tree model in XGBoost regression tree is exhibited in Fig. 2.

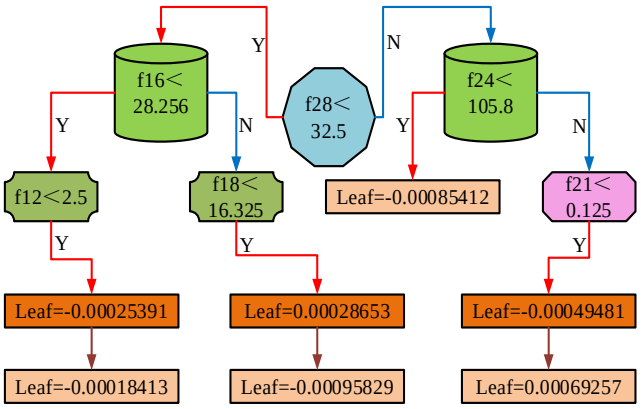

Fig. 2. XGBoost regression tree model trained in.

There are seven leaf nodes in Fig. 2, represented by rectangles, with the remaining shapes serving as attribute partitioning conditions. From Fig. 2, the complete XGBoost regression tree model has a total of four layers, including 13 nodes. The importance of customer data in the features can be intuitively seen in the figure, which provides guidance for the selection of later features. Dimension explosion is prone to occur during encoding extraction, leading to an increase in the working time and isolated points of the model. To avoid this issue, the study used variance encoding to change qualitative features by labeling samples, and the formula for calculating sample labels is Formula (7).

$$P\left(y=Y\middle|k=K\right)=\frac{N_Y^K}{N^K} \tag{7}$$

In Formula (7), $P\left(y=Y\middle|k=K\right)$ is called the posterior probability of sample labels, y is the selected number of target classes, the total number is recorded as Y, k is the value of qualitative characteristics, and the number of samples under this condition is recorded as E. When the feature value is K, the sample size is converted to N^K. In order to balance the mean effect between prior probability and posterior probability, conditional parameters with multiple repetitions and variability are introduced. The calculation method is Formula (8).

$$Q\left(y=Y\middle|k=K\right)=\phi*\bar{O}\left(y=Y\right)+\left(1-\phi\right)*P\left(y=Y\middle|k=K\right) \tag{8}$$

In Formula (8), the probability of mean encoding is denoted as $Q\left(y=Y\middle|k=K\right)$, and $\bar{O}\left(y=Y\right)$ can control the slope of the conditional parameter, that is, as the value of $\bar{O}\left(y=Y\right)$ increases, the rate of change of ϕ with y,k becomes slower.

B. Fusion Algorithm based on Differential Automatic Regression Moving Average Variables

DAMAV is suitable for predicting time series and is widely used in linear regression, as expressed in Formula (9).

$$h_t=\mu_0+\mu_1 h_{t-1}-\nu_t-\nu_1\varpi_{t-1} \tag{9}$$

In Formula (9), the order of autoregression and moving average is recorded as h_t,μ_0, ν_t represents the error in stochastic process, and the number of differences made in regional time is expressed as ϖ_{t-1} [18]. On a practical basis, importing the formed dataset into the constructed model can complete autonomous training and calculate the results. The newly created dataset can also keep the model fresh, update its automation capabilities, and effectively reduce human resources, as demonstrated in Fig. 3.

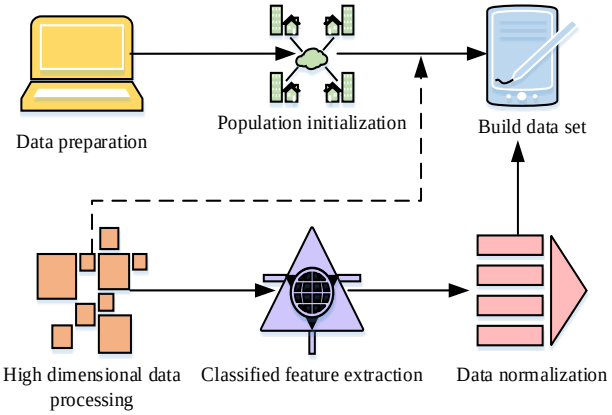

Fig. 3. XGBoost regression tree autonomous learning flow chart.

Fig. 3 shows the self-learning process of XGBoost regression tree. Firstly, it is necessary to collect a complete and comprehensive dataset, which can be formed on the network or experimentally measured; Then, set the data format for the algorithm, which is the target variable or feature value; Next, the outliers in the data set are screened, such as outlier and noise; Finally, the formatted data is run in the algorithm to extract the corrected values of the parameters [19]. Among them, to determine the indicators of predictive performance, this study selected Root Mean Square Error (RMSE) to consider it, as displayed in Formula (10).

$$RMSE=\sqrt{\frac{\sum_{i=1}^{n}\left(\theta^i-\overline{\overline{\theta}}^{=i}\right)^2}{n}} \tag{10}$$

In Formula (10), the true value is denoted as θ, and the predicted value is represented by $\overline{\overline{\theta}}$. In employee turnover in enterprises, temperature values are used instead of turnover values. The lower the temperature, the more severe the employee turnover in the enterprise is. In the iterative process of the algorithm, the training results will make the weight larger, so that the model can be steadily improved on the basis of the mean value, which can be described by the Newton's

Cooling Law (CL). The formula for CL is Eq. (11).

$$T'(t) = -\vartheta\left(T(t) - H\right) \tag{11}$$

In Formula (11) above, the temperature of the object is denoted as T, t represents the operating time, and the cooling rate is the derivative of T changing with t, called $T'(t)$. Room temperature is represented by H, where ϑ is a constant with a value range of $[0.1,1.0]$ to control the cooling rate. When the value of ϑ is fixed, the larger the temperature difference in the environment, the faster the cooling rate. In the employee turnover model, when compared to the average salary of all enterprises, the lower the salary, the faster the employee turnover rate. To describe the degree to which employees attach importance to the company, sample weights were introduced to simulate the degree to which employees pay attention to nearby companies, and Formula (12) was established.

$$w_k = w_0 e^{-\sigma\varsigma_k} \tag{12}$$

In Formula (12), the popularity of company k in the training set is denoted as w_k. The average treatment of all companies is represented by w_0. The heat loss coefficient of the model is denoted as σ. The company's decay rate over time is represented by ς_k. The XGBoost model is a foundational learner suitable for various types, which can transform linear problems into regression problems and is suitable for most work environments. XGBoost's loss function is composed of regularization terms, and its expansion is Formula (13).

$$\Omega = \omega\xi + 0.5\psi\sum_{j=1}^{\psi}\zeta_j^2 \tag{13}$$

In Formula (13), ξ represents the richness of the decision tree, and ω is the weight of the decision tree. The work done by the leaves in unit time is recorded as ζ, and the output regularization weight is expressed as ψ. When the XGBoost model predicts employee turnover, missing values in features can be ignored and assigned to leaves, thereby improving the overall training speed. In the working process of the decision tree, out of pocket errors are obtained from out of pocket data. The performance used to calculate the decision tree is Formula (14).

$$\text{Im } por\tan ce\left(FeatureX\right) = \left(\sum_{i=1}^{N} errOOB_2 - errOOB_1\right)/N \tag{14}$$

In Formula (14), the importance of the feature is denoted as $\text{Im } por\tan ce\left(FeatureX\right)$, and the bag contains a total of N data, where $errOOB$ represents the out of bag error value [20]. To train all samples in the dataset, a random variable is randomly extracted from the type features, and then converted into a numerical value based on the label of the previous sample. The weight coefficient of the priority is adjusted as Formula (15).

$$E_k^i = \frac{\left(\sum_{j=1}^{p-1}\left(E_{\Delta j,k} = E_{op,k}\right)Y_{\sigma j}\right) + ap}{\left(\sum_{j=1}^{p-1}E_{\Delta j,k} = E_{op,k}\right) + a} \tag{15}$$

In Formula (15), $E_{\Delta j,k}$ represents the training set in the input algorithm model, and the differentiable loss variable is denoted as $E_{op,k}$. a, p is a constant, and its value size reflects the priority of the sample. This study is based on the improved XGBoost regression tree algorithm model of DAMAV (DV-XGBoost), as listed in Fig. 4.

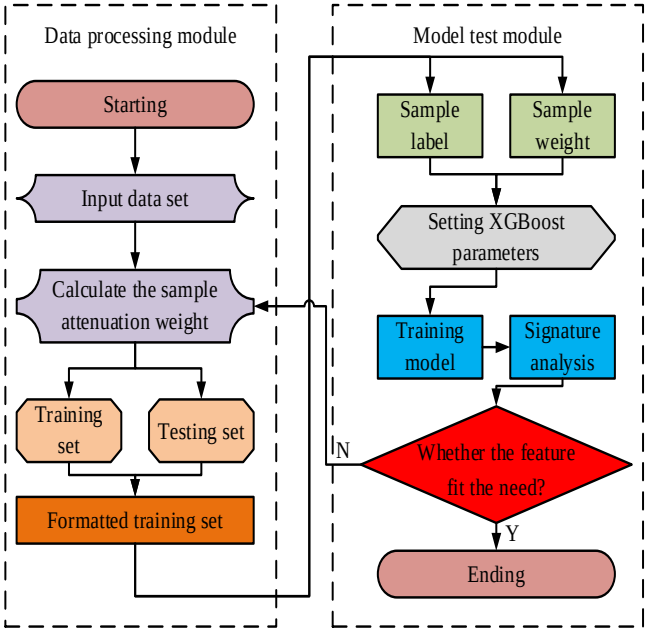

Fig. 4. Flow chart of improved DV-XGBoost regression tree algorithm model.

The DV-XGBoost model in Fig. 4 can be divided into two modules, totaling four parts. Firstly, to calculate the attenuation weight of the input dataset and divide it into a test set and a training set; Then, format the training set in the data preparation module and input it into the model test set; Next is to iterate the labels and weights of the samples to analyze the parameters of the DV-XGBoost model; Finally, the feature is judged. If it meets the requirements, the final value is output. Otherwise, the data preparation process is returned and the attenuation weight is recalculated.

IV. Experimental Study on Enterprise Character Loss Information Based on XGBoost

To verify the effectiveness of the DV-XGBoost algorithm in practical applications, iteration and accuracy verification were conducted. Finally, the DV-XGBoost model was applied to the Company dataset for simulation experiments.

A. DV-XGBoost System Development Environment and Model Parameter Determination

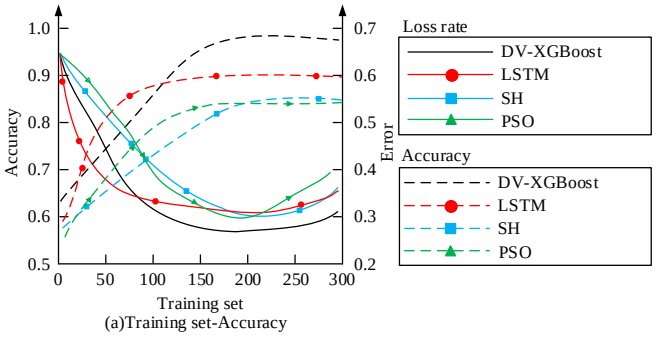
This study selected a self-collected Company dataset, including four types of companies: fine organic, electronic

engineering, aerospace, and automation, with a total of 6523 enterprises. Considering the limited types of data, the dataset will be divided into a training set and a testing set in a ratio of 2:3. The specific equipment and software used in the experiment are Table I. In the experiment of DV-XGBoost, the research first sets the necessary experimental conditions. There are some key parameters to be set in DV-XGBoost algorithm, including iteration times and acceleration factor because the problem of employee turnover in enterprises is difficult to predict and the computing resources are limited. Therefore, the optimization objective function is studied to solve the optimal solution of DV-XGBoost. The objective function has a clear optimization goal, and there are constraints on the range of the number of brain drain for each iteration of DV-XGBoost algorithm, the position, velocity and fitness data of each particle are collected and used to calculate the convergence performance of DV-XGBoost algorithm.

Experimental Parameters

Data set	Development language	Number of cores	Internal storage
Company	Python 8.5	8	1024 G
Operating system	Display card	Database	Processor
127Ubnutu 22.01.21	37.0 GHz	Mysqppl 5.30.2023	Intel Core i9
Web development framework	Language	Operator	Model
Django2.22.3	Easy Chinese	Electric, orangic...	F2.9LII-US M

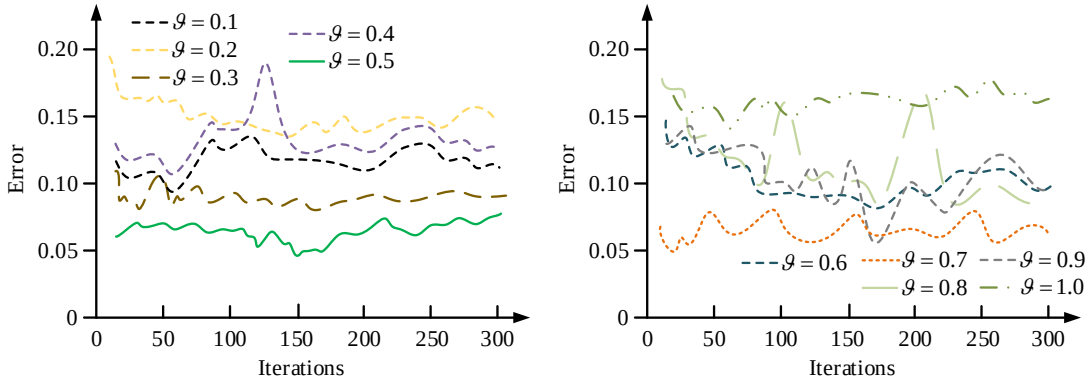
The collected dataset needs further processing to enable the studied algorithm to learn. The dataset was processed using DV-XGBoost for iterative optimization. To verify its accuracy, traditional Spotted Hyena Algorithm (SH), Long Short Term Neural Network (LSTM), and Particle Swarm Optimization Algorithm (PSO) will be compared with it. The accuracy and error rate results in the training set are Fig. 5.



(a)Training set-Accuracy

Fig. 5. Comparison of accuracy-training set image and error rate-training set image.

From Fig. 5, before 100 training sessions, the accuracy of DV-XGBoost algorithm is slightly lower than that of SH and PSO, and the error rate is higher. However, when the iterations reaches 100 or more, the accuracy of DV-XGBoost is higher than both algorithms, and tends to stabilize at 190 iterations, which is higher than the other three algorithms. Although increasing the iterations may reduce the operational efficiency of the model, after comprehensive consideration, the accuracy weight of the model is higher. Therefore, the DV-XGBoost algorithm proposed in the study has better performance. After the learning of the DV-XGBoost algorithm is completed, it is also necessary to consider the parameter determination during testing, as demonstrated in Fig. 6.



(a) The rate control constant of the step cooling curve is 0.1-0.5

(b) The rate control constant of the step cooling curve is 0.6-1.0

Fig. 6. Error-training times image of regularization term.

The parameter of this study is the rate control constant $\vartheta \in [0.1,1.0]$ of the cooling curve between the enterprise and employees. From Fig. 6, when the rate control constant of the step cooling curve is 0.5 and the number of iterations is 150, the error rate is the lowest, which is 0.042. Therefore, the final number of iterations was determined to be 150 and the rate control constant was taken as 0.5.

B. Experimental Verification of Employee Turnover Prediction in Enterprises based on DV-XGBoost

To verify the accuracy of the DV-XGBoost model in predicting employee turnover in enterprises, simulation experiments were conducted. It evaluates the practicality of the DV-XGBoost algorithm by observing whether an employee has resigned. First, the DV-XGBoost algorithm is initialized, and then the employee enterprise information flow is entered in the data preparation module. Finally, the rate control constant of the step cooling curve is set to 0.5, and the

employee dynamics and resigned employee information within 60 days are collected. The image drawn after calculating the error is Fig. 7.

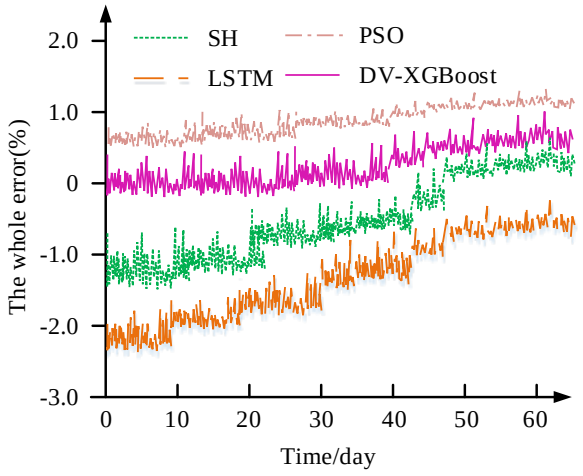


Fig. 7. Total error-time image of four algorithms.

Fig. 7 shows the error comparison of four algorithms in the experiment. In Fig. 7, after 38 days, the error of DV-XGBoost in determining employee turnover has approached zero, while the other three algorithms have a wide range of error fluctuations. Especially for the PSO algorithm, on the third day, the highest error value of the four algorithms was -2.94%. The total error range of DV-XGBoost, SH, LSTM, and PSO is significantly different, making it easy to compare algorithm performance. However, relying solely on the analysis of total error is not objective enough, so the study analyzed the four model analysis errors caused by individuals or enterprises, as shown in Fig. 8.

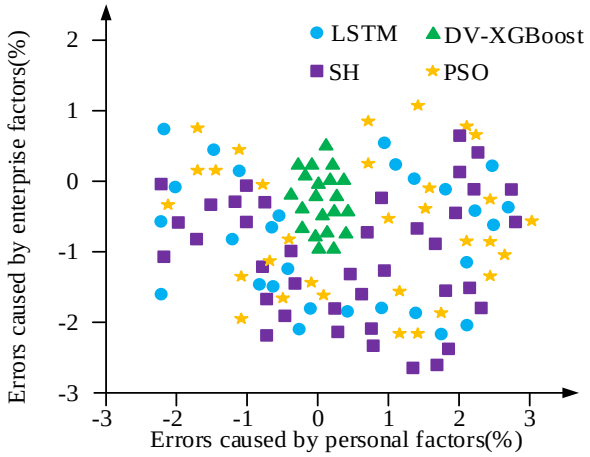

Fig. 8. The types and genres errors of the four algorithms.

From Fig. 8, it can be clearly seen that the experimental results of the DV-XGBoost model are concentrated in the range of total error of 0. The error range caused by personal factors is [-0.6%, 0.8%], while the error range caused by corporate factors is [-1.0%, 1.1%]. The error distribution of the remaining three algorithms is wide, and the distribution of larger errors is sparse. To more intuitively distinguish the ability of the four algorithms to correct errors, 400 experimental data records were conducted and the images displayed in Fig. 9 were plotted.

From Fig. 9, in 400 error testing experiments, LSTM has the largest range of error variation, with the highest frequency of errors recorded as [-0.75%, 0.62%]; Next is the SH algorithm, which is between [-0.18%, 0.23%]. The error variation range of PSO is close to DV-XGBoost, with values above [-0.12%, -0.04%]; the error curve of DV-XGBoost fluctuates between -0.03% and 0.02%, with the smallest fluctuation range. Excluding the LSTM and SH algorithms with the highest error ranking, only comparing the experimental results of DV-XGBoost algorithm and PSO for correct prediction, and drawing the error matrix. The resulting image is Fig. 10.

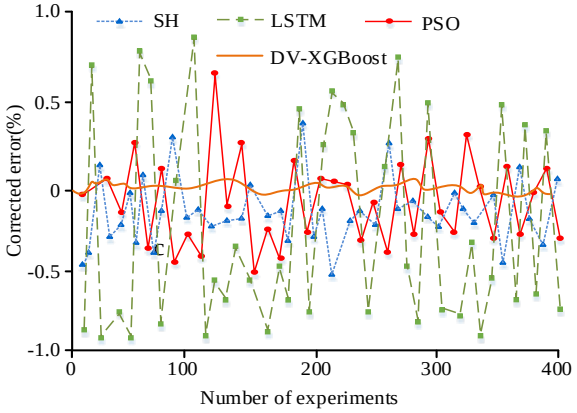

Fig. 9. Error changes of four algorithms in four hundred calibration experiments.

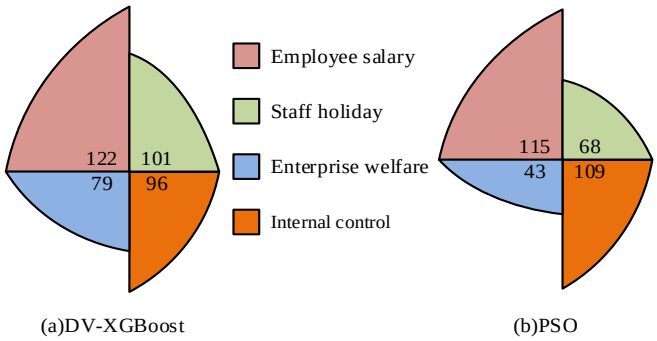

Fig. 10. Error matrix of DV-XGBoost algorithm and PSO algorithm.

Fig. 10 predicts four types of employee turnover in companies based on four conditions: employee salary, employee leave, and enterprise characteristics, as well as internal control, based on employee differences. The experimental results accurately predicted by DV-XGBoost and PSO are presented. The prediction accuracy of DV-XGBoost reached 398 times, with an accuracy rate of 99.5%, and the accuracy rate of PSO was 83.2%. To observe the experimental results of DV-XGBoost and PSO more intuitively, a linear fitting graph based on matrix drawing of two algorithms and Golden Sine algorithm (GS) was studied. The predicted values of the two were compared with the true values, as expressed in Fig. 11.

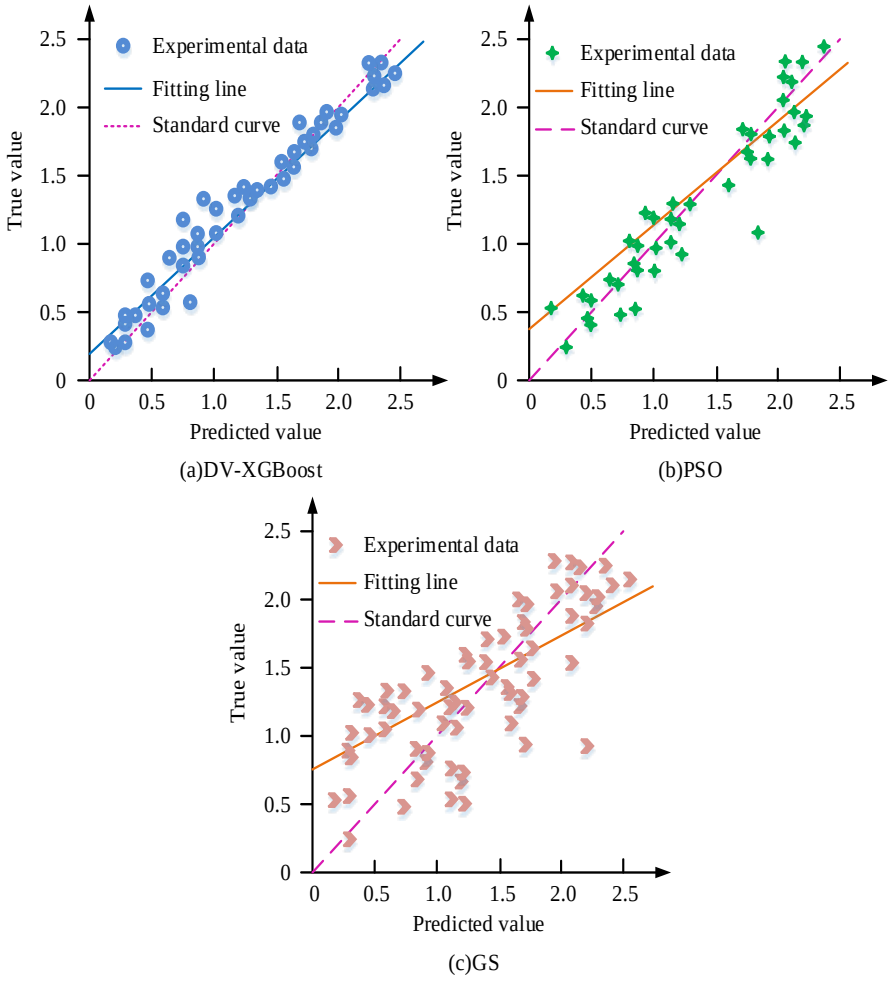

Fig. 11. Linear fitting diagram of DV-XGBoost PSO and GS.

Fig. 11 shows the comparison of three algorithms on predicted and true values. From Fig. 11, the linear fit (R^2) of the DV-XGBoost algorithm is 0.9914, the R^2 of PSO is 0.9547, and the R^2 of GS is 0.8825, indicating that there is no underfitting in the model. In summary, it can be concluded that the DV-XGBoost algorithm model can accurately predict the situation of employee turnover in enterprises, provide internal control warnings, or notify the human resources department (HR) of the company to release recruitment information.

V. Results And Discussion

With the increase of employee turnover rate in enterprises, the utilization rate of human resources is in a downward trend. In order to predict this kind of problem, and then make relative measures as early as possible, this study uses the improved limit gradient lifting algorithm to draw a step cooling curve for the collected employee's psychological data according to the cooling law, so as to predict their turnover possibility. In order to reduce the chaotic data during the running of the algorithm, the experiment was carried out in the Company data set. In order to analyze the proposed DV-XGBoost algorithm extensively, the experimental results are compared with PSO, SH and GS, and finally the number of iterations is 150, and the rate constant is 0.5. In the error analysis experiment, the error curve of DV-XGBoost fluctuates between-0.02% and 0.04%, with the smallest fluctuation range. The prediction accuracy of DV-XGBoost is 99.5%, and that of PSO is 83.2%. The linear fitting of DV-XGBoost is 0.9914, the linear fitting is excellent, and the linear fitting of PSO is 0.9547. The experimental results show that the DV-XGBoost model proposed in this study has strong robustness in predicting employees' psychology and is suitable for improving the utilization rate of human resources for the company. However, the algorithm is only applicable to companies, and the research on the employment factors of school employees is still insufficient, which will be gradually improved in future research.

VI. Conclusion

With the growth of internet technology, predicting the turnover psychology of enterprise employees is becoming increasingly important, such as increasing work efficiency for the administrative department of the company and providing early warning for the talent gap period of the enterprise. This study is based on XGBoost and DAMAV to generate the fusion algorithm DV-XGBoost. The experiment took into account both personal and corporate factors during resignation,

and conducted simulation experiments on the Company dataset, comparing with three algorithms such as LSTM. 40% of the Company dataset was extracted and trained on the DV-XGBoost model. Through controlling the rate constant of the cooling curve, the final iteration number was determined to be 150 times, with a rate constant value of 0.5. In the error analysis experiment, a total of 400 experiments were conducted, and the errors of the SH and LSTM algorithms fluctuated within the range of [-2.3%,1.4%] and [-2.2%,1.9%], respectively. The error curve of DV-XGBoost fluctuates between -0.02% and 0.04%, with the smallest fluctuation range; The variation range of PSO is close to DV-XGBoost, between [-0.13%, -0.03%]. Draw an error matrix for the experimental results of DV-XGBoost algorithm and PSO. In 400 experiments, the prediction accuracy of DV-XGBoost is 99.5%, and the accuracy of PSO is 83.2%. This study drew linear fitting graphs for two algorithms based on matrices. The R^2 of DV-XGBoost was 0.9914, indicating excellent linear fitting, while the R^2 of PSO was 0.9547. In summary, the DV-XGBoost model can accurately predict employee turnover in enterprises, improve the efficiency of human resources departments, and enable enterprises to cope with talent shortages. However, the DV-XGBoost model is only suitable for analyzing companies with employees from the same location. For comprehensive companies from multiple regions, it is difficult to analyze the emotional changes caused by local customs among employees, and the model will label them as noise. This is because human psychology is complex and diverse, and the dataset for research and analysis contains fewer types. With the increase of volunteers, it is believed that future research can be improved.

Intelligent Design of Ethnic Patterns in Clothing using Improved DCGAN for Real-Time Style Transfer

Yingjun Liu, Ming Wu*
School of Art, Guangxi Minzu Normal University, Chongzuo 532200, China

***Abstract*—In view of the problems that traditional real-time style transmission technology requires a large number of sample map training, low image quality, lack of realism and detail, this study combines the improved generative adversarial network (GANs) with real-time style transfer technology, and enhances the real-time style transfer calculation with adaptive instance normalization. As a result, a novel intelligent clothing ethnic pattern design model is developed. Experimental results show that the model reduces physical memory usage by 45.7%, with only 453MB, and utilizes only 26% of CPU resources in terms of CPU usage. The training time is approximately 20 minutes and 48 seconds. This model performance is obviously higher than other models. The designed intelligent clothing ethnic pattern design model in this study demonstrates higher clarity and shorter processing time, and has potential applications in the field of image generation.**

Keywords*—Computer vision; improved DCGAN; style transfer; adaptive instance normalization; intelligent design of patterns

I. Introduction

In today's era, clothing design plays a crucial role in personalization and innovation. With the growing demand for unique styles and cultural diversity, ethnic patterns have become a popular design element. However, manually drawing and applying these patterns require a significant amount of time and labor, limiting their application in large-scale production. To address this issue, computer vision and deep learning technologies have been widely applied in the field of fashion design [1]. In particular, style transfer methods based on Generative Adversarial Networks (GANs) have made significant progress. Among them, Deep Convolutional GAN (DCGAN) is a powerful generative model that can learn from input data and generate realistic images [2-3]. Style transfer is a technique of applying the style of one image to another image, which is widely used in artistic creation and design. AdaIN is an instance normalization technique that is adaptive to adjust the style of an image, making the result of style transfer more natural and realistic.However, there are some defects in the traditional intelligent design technology. On the one hand, traditional techniques often require a large number of sample images for training, which can be very difficult and time-consuming for specific ethnic patterns. On the other hand, traditional techniques may lead to a low quality of the generated images and a lack of realism and detail. Moreover, traditional techniques may not very well preserve the style and character of the original pattern. For the above problems, this study proposed a series of improvement measures for standard DCGAN, introduced in the decoder network, the generated false image more close to the real image, adopted the method of multi-scale feature extraction and fusion in the generator and discriminator network, makes the generated false image more real, by stacking the convolution layer and deconvolution layer to improve the quality of the generated image, and an improved algorithm of deep convolution generation against network (IDCGAN) is developed. In addition, the adaptive instance normalization (AdaIN) is also applied to the real-time style transfer technology to design an intelligent model for the clothing ethnic pattern design. The study aims to achieve image generation through adversarial learning, allowing DCGAN to learn specific ethnic patterns from a small number of samples and generate high-quality, realistic images. The article consists of four main parts. The second part provides a comprehensive review of the current research status of intelligent clothing design and style transfer systems. The third part establishes an intelligent model for ethnic pattern design in clothing based on improved DCGAN for real-time style transfer. The fourth part includes comparative experiments and efficiency verification to evaluate the optimization effects of the model.

II. Related Works

As people's pursuit of personalization and unique styles continues to grow, traditional clothing design no longer meets the demands of consumers. In order to meet this demand, researchers have been exploring intelligent design technologies that are adaptable to these needs. Ding et al. addressed the issues of low accuracy and stability in traditional manual crown design by developing an automatic crown design strategy with DCGAN, and the outcomes indicates that it had the smallest morphological differences compared to natural teeth [4]. Abd Al et al. proposed a DCGAN based algorithm and a novel Capsule Network to assist semiconductor manufacturers in identifying defect patterns in wafers, and the experimental results showed that the method achieved a training accuracy of 99.59% and a validation accuracy of 97.53% [5]. Bian et al. developed a compound screening model based on DCGAN to screen and design novel compounds with target-specificity for cannabinoid receptors, and the experimental results showed that the model had the highest accuracy compared to other models [6]. Cheng et al. proposed a Data Enhancement Communication Behavior Recognition (DECBR) scheme to

address the limitations of traditional communication behavior recognition techniques in accurately analyzing communication behaviors, and the DECBR scheme significantly improved the accuracy and efficiency of behavior recognition under small sample conditions [7]. Li et al. designed an image classification model that combines DCGAN and AlexNet for rapid differentiation of multiple forms of glioblastoma images, and the experiment outcomes indicates that the model reached 0.920 accuracy and an AUC of 0.947 for distinguishing PsP and TTP after 10-fold cross-validation [8]. Ni et al. addressed the issue of large deviations in carrot quality identification using traditional visual inspection methods by designing a carrot quality identification model that combines DCGAN and Squeeze-and-Excitation Deep Networks, and the experiment outcomes showed that the model reached 98.36% accuracy [9].

Jing et al. proposed a new normalization module called Dynamic Instance Normalization (DIN) to address the deployment challenges of style transfer systems in resource-constrained environments. DIN allows for flexible and more efficient transfer of arbitrary styles. The experimental results showed that this approach reduced computational costs by more than 20% compared to existing methods [10]. Reimann et al. addressed the issue of one-shot stylization in existing style transfer computations, which mostly limit the style elements interactive adjusting. They designed a fast style transfer network which is stroke-adjustable. It can simultaneously control stroke intensity and size. The experimental results showed that the model make users achieving resolutions exceeding 20 million pixels and good output fidelity [11]. Hollandi et al. developed a deep learning-based cell nucleus segmentation framework that utilizes image style transfer to automatically generate cell nucleus segmentation masks. This framework aims to find a method for locating 2D cell nuclei in different regions. The experimental results showed that the model effectively identifies cell nuclei in different experiments without the need for expert annotations [12]. Huang et al. addressed the lack of diversity in traditional style transfer by designing a style transfer model that combines region semantics with multi-style transfer. The experimental results showed that the model seamlessly combines multiple styles together, and, with the assist of semantic matching, assigns corresponding styles to content regions [13]. Xu et al. tackled the problem of indistinguishable details between different types of objects caused by single-band imaging. They designed a target detection-oriented style transfer network for panchromatic remote sensing images. After style transfer, the target detection accuracy on panchromatic remote sensing images significantly improved [14]. Zhou et al. proposed a new approach that combines attention mechanism with style transfer models to enhance the flexibility of style transfer tasks. The experimental results showed that this approach is effective and produces high-quality images [15].

In summary, DECBR and style transfer have a solid theoretical and implementation foundation in the field of intelligent clothing design. However, there is limited research that combines the two for ethnic clothing design. Therefore, the study aims to improve DECBR and combine it with style transfer computations to develop an intelligent clothing design model, in order to further advance the clothing design industry.

III. Improvement of DCGAN Algorithm and Establishment of Intelligent Pattern Design Model

This chapter contains two sections. The first gives an introduction on the standard Deep Convolutional Generative Adversarial Network (DCGAN) and proposes some improvement strategies to address its limitations. The second section focuses on improving traditional real-time style transfer networks and establishing an intelligent design model based on real-time style transfer networks.

A. Improvement of DCGAN Algorithm Design

DCGAN is a neural network model used for generating realistic images. It combines the ideas of generative models and adversarial training, mainly containing two components: the generator and the discriminator [16-17]. The former is a network that uses random noise vectors to do input and attempts to bring up images similar to the training data. The generator gradually constructs the image through multiple convolution, deconvolution, and activation function operations. The discriminator is also a convolutional neural network whose goal is distinguishing between the images generated and real ones. The discriminator extracts image features through operations such as convolution, pooling, and activation functions, and outputs a probability value between 0 and 1, indicating the likelihood that the input image is a real image [18]. In DCGAN, the two components are alternately trained. The generator manufacture images that is real enough for deceiving the discriminator, while the later strives to differentiate between the images generated by the generator and real images [19]. This process stimulates the generator to continuously enhance the generated images' quality and makes the discriminator more accurate, as shown in Fig. 1.

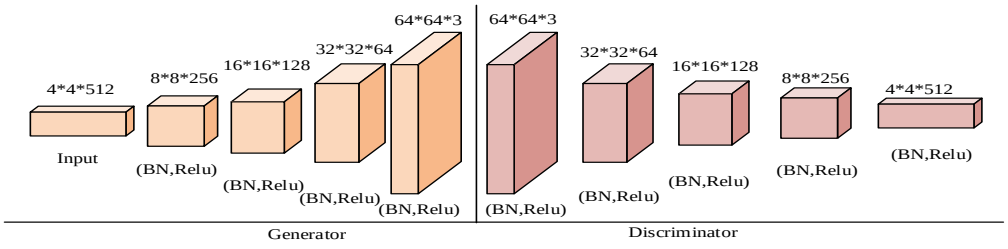

Fig. 1. Schematic diagram of DCGAN structure.

Although DCGAN is a widely used entity in the studying areas of image synthesis, editing, and super-resolution reconstruction, there are some limitations when applying DCGAN to real-time style transfer of ethnic clothing patterns' intelligence design. Firstly, DCGAN has relatively weak feature extraction capabilities. Despite using convolutional neural networks (CNN) to learn image features, it may not fully capture the complex features of ethnic patterns due to network structure and training data limitations. This can result in generated clothing that is not realistic enough and deviates significantly from the target style. Secondly, there is a lack of overall style transfer constraints. DCGAN primarily focuses on generating realistic images during the training process, with less emphasis on maintaining consistency and layout of local patterns. In clothing design, maintaining pattern consistency is crucial, but DCGAN may not fully consider the layout and details of patterns in different parts of the garment, resulting in clothing that does not resemble a normal garment and lacks coherence and integrity. To address these limitations, a modified DCGAN approach is proposed, and the network structure during the training phase is shown in Fig. 2.

Fig. 2 illustrates the network structure during the training phase of IDCGAN. At the beginning of training, random noise is input into the generator. The generator processes the noise through decoding and encoding operations to generate fake images. These fake images gradually approach real images through the generator. At the same time, real and fake images are simultaneously input into the discriminator. It is another network responsible for classifying the input images and outputting the feature space Z. This feature space represents the representation of the images in the discriminator. Next, the classification loss and the real/fake loss are calculated by comparing the classification results of real and fake images. The classification loss measures the accuracy of the discriminator in distinguishing real and fake images, while the real/fake loss reflects the adversarial training process within the two components. Throughout the training process, the two components engage in a competitive dynamic, continuously optimizing their parameters. The generator's objective is to produce increasingly realistic fake images to deceive the discriminator, while the discriminator aims to distinguish between real and fake images, improving its accuracy. The algorithm flow is shown in Fig. 3.

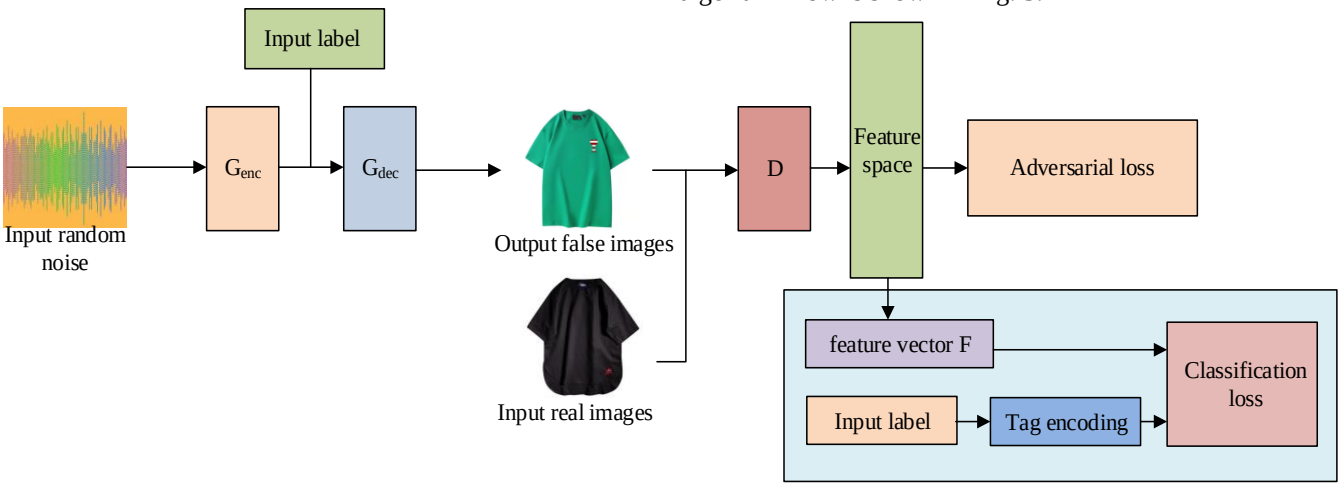

Fig. 2. Improved DCGAN network training stage structure diagram.

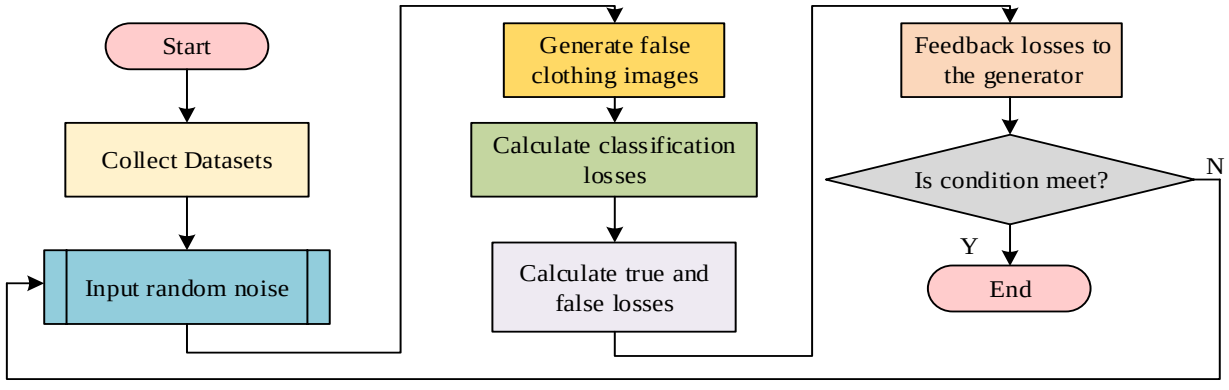

Fig. 3. IDCGN algorithm flowchart.

Fig. 3 shows the flowchart of the IDCGAN algorithm. Firstly, a dataset is collected for model training. Next, random noise is input into the encoding network of the generator to extract feature tensors. The third step is to input the extracted feature tensors and the specified style to be transformed into the decoding network of the generator, generating fake clothing images. Then, the discriminator is trained to improve its discriminative ability to distinguish the true and fake images. At the same time, the classification loss is calculated based on the feature space Z to measure the performance of the generator in generating different categories of clothing. The sixth step is to calculate the real/fake loss based on the feature space Z, which helps the generator generate more realistic clothing images. Next, the loss is fed back to the generator to adjust its strategy for generating images. Finally, steps two to seven are repeated in a loop until the total loss of the network converges, achieving the desired training effect. Through this iterative process, the IDCGAN algorithm continuously optimizes the balance between the generator and the discriminator, achieving better quality in generating fake images. The loss function used in the training process is the conditional contrastive loss. To further explain this loss function, it is necessary to first explain the NT-Xent loss function, which is expressed as Eq. (1).

$$A=\{x_1,T(x_1),...,x_m,T(x_m)\}=\{a_1,a_2,...,a_{2m}\} \quad (1)$$

In equation (1), $T(x_m)$ represents the random data augmentation for this loss function. After some transformations, the expression of the NT-Xent loss function is shown in Eq. (2).

$$\delta(a_i,a_j,t)=-\log(\frac{\exp(l(a_i)^T l(a_j)/t)}{\sum_{k=1}^{2m}\exp(l(a_i)^T l(a_j)/t)}) \quad (2)$$

In Eq. (2), t is the temperature that controls the push and pull forces. By incorporating the embedding equation into Eq. (2) and (3) is obtained.

$$\delta(x_i,y_j,t)=-\log(\frac{\exp(l(x_i)^T l(y_j)/t)}{\exp(l(x_i)^T e(y_j)/t)+\sum_{k=1}^{m}\exp(l(x_i)^T l(x_k)/t)}) \quad (3)$$

In equation (3), $e(y)$ represents the embedding equation. By adding the cosine similarity of negative samples in equation (3), the final loss function is shown in Eq. (4).

$$\delta(x_i,y_i,t)=-\log(\frac{\exp(l(x_i)^T e(y_i)/t)+\sum_{k=1}^{m}y_k=y_i\cdot\exp(l(x_i)^T l(x_k)/t)}{\exp(l(x_i)^T e(y_i)/t)+\sum_{k=1}^{m}k\neq i\cdot\exp(l(x_i)^T l(x_k)/t)}) \quad (4)$$

B. Intelligent Design Model Based on Real-Time Style Transfer Network

Real-time style transfer network is a computer vision technique used to transfer the style of an input image to another target style while preserving the content of the input image. Typically, this network combines CNN with methods for image stylization. The goal of real-time style transfer network is to perform style transformation on an image in a short period of time, making it appear as if it was drawn or rendered using the target style. By minimizing a loss function, the real-time style transfer network can generate an output image with the desired target style. The network structure is shown in Fig. 4.

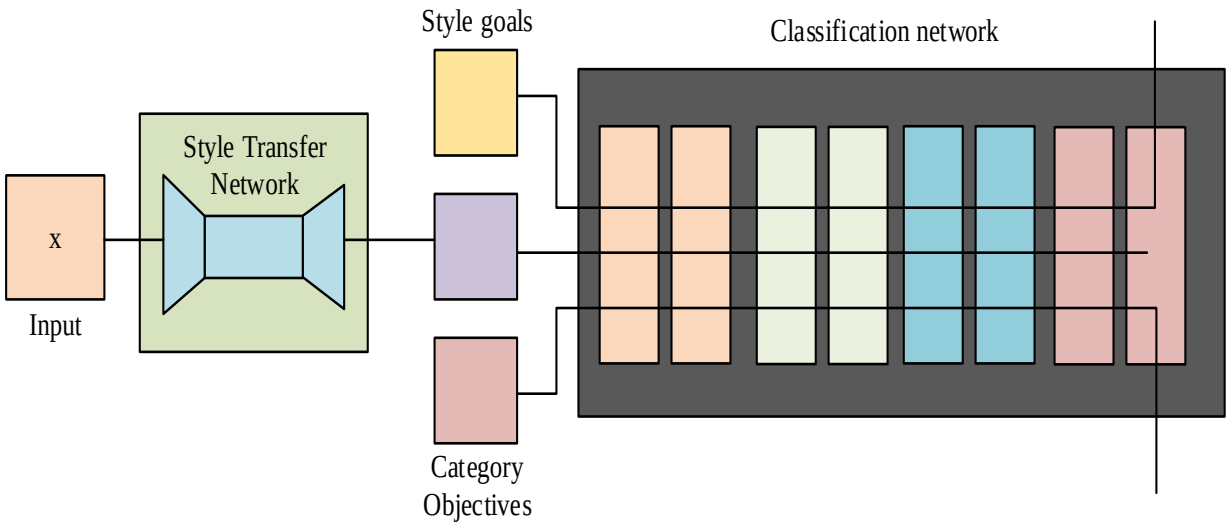

Fig. 4. Network structure of real-time style transfer network.

Fig. 4 illustrates the network structure of the real-time style transfer network. The left half represents the image transformation network, which consists of a series of CNN layers and deconvolution layers. These layers are used to gradually transform the input image into an output image with the target style. Each CNN layer can extract different features

from the input image, while the deconvolution layers are used to synthesize these features into the final output image. The right half represents the loss network, which is used to calculate the content loss and style loss. The content loss ensures that the output image preserves the content information of the input image by comparing the feature representations of the input and generated images. The style loss captures the target style features by comparing the feature statistics of the input image, generated image, and target style image. The loss function is shown in Eq. (5).

$$L = \gamma_1 L_1 + \gamma_2 L_2 \quad (5)$$

In Eq. (5), L_1 represents the content loss function, and L_2 represents the style loss function. The formula for the content loss function is shown in Eq. (6).

$$L_1^{\varphi,j}(\hat{y}, y) = \frac{1}{C_j H_j W_j} \| \phi_j(\hat{y}) - \phi_j(y) \|_2^2 \quad (6)$$

In Eq. (6), y represents the original image, and $\hat{y}$ represents the generated image. The formula for the style loss function is shown in Eq. (7).

$$L_2^{\varphi,j}(\hat{y}, y) = \| G_j^{\varphi}(\hat{y}) - G_j^{\varphi}(y) \|_F^2 \quad (7)$$

In Eq. (7), G_j^{φ} represents the Gram matrix, which is a matrix that describes the correlations between features by taking the inner product between different channels in the feature map of the j th layer. The formula for the Gram matrix is shown in Eq. (8).

$$G_j^{\varphi}(x)c, c' = \frac{1}{C_j H_j W_j} \sum_{h=1}^{H_j} \sum_{w=1}^{W_j} \phi_j(x)_{h,w,c} \phi_j(x)_{h,w,c'} \quad (8)$$

In Eq. (8), ϕ represents the pre-trained network model, and $\phi_j(x)_{h,w,c}$ represents the values of the feature map in the image network with a height of h, width of w, and c channels. The detailed structure size of the generator network is shown in Fig. 5.

Fig. 5 shows a detailed schematic diagram of the network structure size for real-time style transfer. The network includes one reflection padding layer, six convolutional layers, and five residual blocks. With this network, style transfer between images can be achieved, and the time required to generate images is significantly reduced. However, although this network has achieved certain results, there is still room for improvement. For example, there are still areas that can be optimized in terms of image quality, detail preservation, and style restoration. In addition, the current network structure needs to be trained for each specific style, which limits its applicability. To address these issues, some improvements have been made to the network, as shown in Fig. 6.

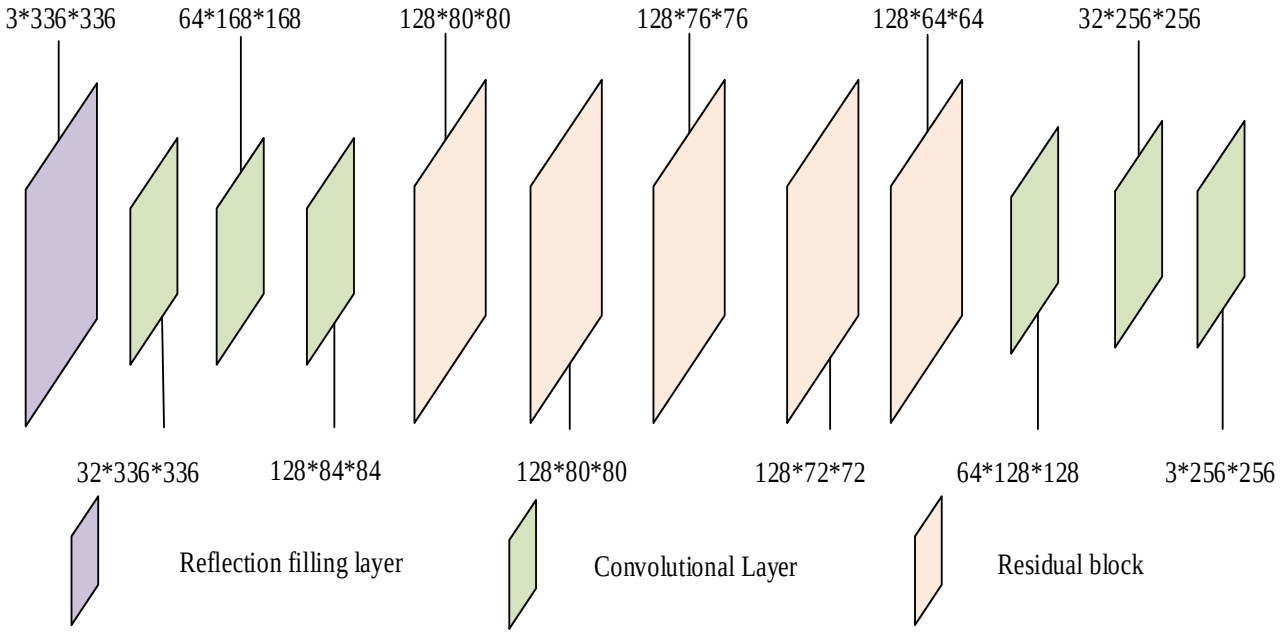

Fig. 5. Generate a detailed schematic diagram of the network structure size.

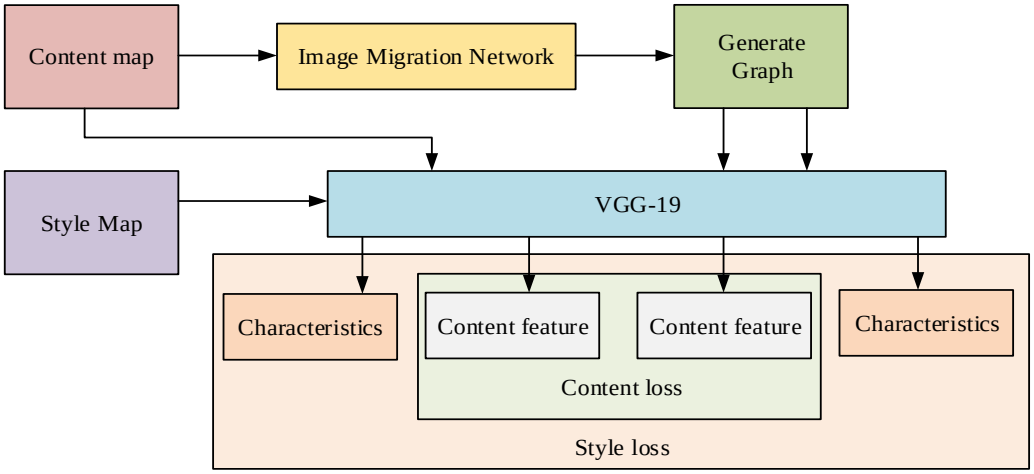

Fig. 6. Improved real-time style migration network structure diagram.

Fig. 6 shows the structure diagram of the improved real-time style transfer network. The network consists of two main components: the upper part and the lower part. In the upper part, the input content image is passed through an image encoder network to generate the generated image. This network can be a CNN that encodes the content image into an initial version of the generated image. The generated image and the style image are then passed through the VGG-19 model for feature extraction [20]. In the lower part, the content loss and style loss are propagated back through the process of backpropagation, and the pixel values of the generated image are updated using the gradient descent optimization algorithm. The optimization objective is to minimize the content loss and style loss, thereby preserving the content and matching the target style in the generated image. Additionally, the research addresses the issue of traditional normalization methods struggling to learn highly nonlinear features by introducing Adaptive Instance Normalization (AdaIN), which is formulated as Eq. (9).

$$Z_{bcwh} = \frac{x_{bcwh}}{\sum_{w=1}^{W}\sum_{h=1}^{H} x_{bcwh}} \quad (9)$$

In Eq. (9), $x \in R^{B\times C\times W\times H}$. W and H represents the width and height of the image, respectively. To allow Eq. (9) to be fitted by the ReLU activation function, a transformation is applied to the equation, as shown in Eq. (10).

$$Z_{bcwh} = \frac{x_{bcwh} - \eta}{\sqrt{\sigma^2 + \varepsilon}} \quad (10)$$

In equation (10), b represents the image index in the batch, σ^2 represents the variance, and ε represents the mean. The calculation of the variance is approximated as shown in Eq. (11).

$$\sigma_{bc}^2 = \frac{1}{HW}\sum_{h=1}^{H}\sum_{w=1}^{W}(x_{bcwh} - h\eta_{bc})^2 \quad (11)$$

In Eq. (11), c represents the number of channels in the image. Compared to traditional instance normalization (IN), AdaIN only requires one forward pass, as shown in Eq. (12).

$$Z = \sqrt{\sigma^2 + \varepsilon}\,\frac{x - \eta_x}{\sqrt{\sigma_x^2 + \varepsilon}} + \eta_y \quad (12)$$

In Eq. (12), y represents the input values for style, and x represents the input values for content. In addition, the style loss needs to be optimized by removing the Gram matrix from the loss function of AdaIN, as shown in Eq. (13).

$$L_2^{\varphi,j}(\hat{y}, y) = \| \eta\phi_j^{\varphi}(\hat{y}) - \eta\phi_j^{\varphi}(y) \|_2 + \| \lambda\phi_j^{\varphi}(\hat{y}) - \lambda\phi_j^{\varphi}(y) \|_2 \quad (13)$$

In Eq. (13), $\|.\|_2$ represents the L2 norm.

IV. Performance Testing and Application Analysis of Pattern Intelligent Design System

This chapter is divided into two sections. The first section mainly verifies the improvement effect of the IDCGAN algorithm by comparing it with the standard DCGAN algorithm. The second section focuses on the application analysis of the pattern intelligent design system and its application in practical clothing design.

C. Comparative Experiment of IDCGAN Algorithm

In order to address some limitations of the standard DCGAN algorithm in the field of clothing design, the study made a series of improvements and finally formed the IDCGAN algorithm. To verify whether this improved algorithm is superior compared with standard DCGAN algorithm, the study used PyTorch 1.4 software on Ubuntu64-bit platform, the learning rate starting value can be set to 0.0002, batch size using batch size such as 16,32 or 64, noise dimension set to 100, loss function as binary cross-entropy loss function, IDCGAN and DCGAN using the CV-PTON dataset for 40,000 iterations. The PR curves were used as an assessment criterion. The results are shown in Fig. 7.

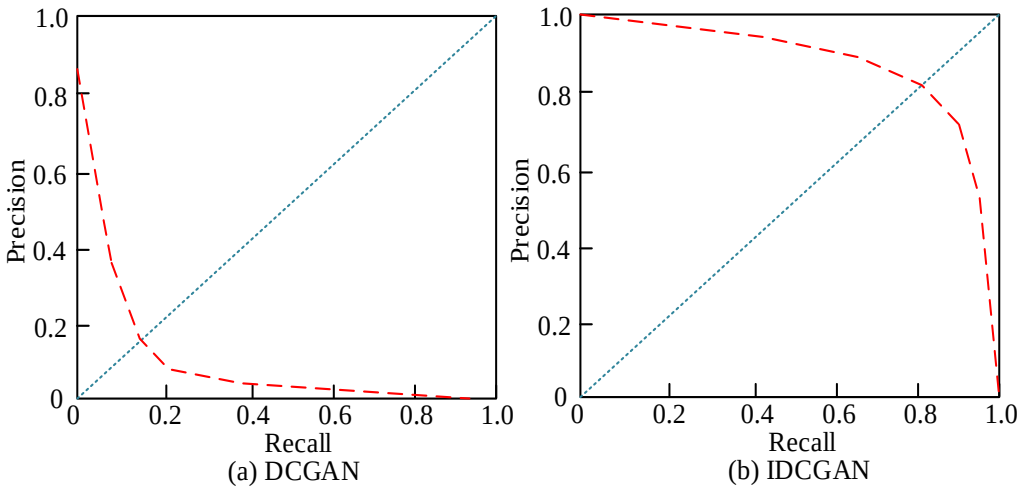

Fig. 7. Comparison of PR curves before and after DCGAN improvement.

Fig. 7 shows the changes in the PR curves before and after the improvement of the DCGAN algorithm. From Fig. 7(a), after the model convergence, the recall rate of the DCGAN algorithm has improved, but the precision has significantly decreased. This indicates that the original DCGAN algorithm may have some noise or errors in generating samples. From Fig. 7(b), it can be seen that by using a deep feature extraction network to improve the algorithm, the feature extraction capability of DCGAN is significantly enhanced. This allows the improved algorithm to generate samples with better style transfer effects while maintaining high recall rate and precision. To verify the improvement effect of the loss function comparison in this study, a similarity heatmap of the IDCGAN during the experimental process was visualized, as shown in Fig. 8.

Fig. 8 shows the similarity heatmap of IDCGAN. By observing the results in the figure, it can be seen that the contrastive loss used in this algorithm is very effective in distinguishing between input and generated patterns of the same category, with a similarity score of 1. This means that the improved algorithm can accurately identify and generate samples that are similar to the input pattern. Additionally, for different categories of style patterns, the similarity score is close to 0. This indicates that the improved algorithm can differentiate between samples of different categories and will not mistake them for similar patterns. Furthermore, a series of experiments were conducted to evaluate the resource consumption of IDCGAN and DCGAN, and the results are shown in Fig. 9.

Based on the results in Fig. 9, it can be observed that IDCGAN and DCGAN differ in terms of CPU resources, memory resources, and training time. By comparing Fig. 9(a) and Fig. 9(b), IDCGAN reduces the physical memory usage by 45.7% compared to DCGAN, with only 453MB compared to DCGAN's 834MB. Additionally, in terms of CPU resource utilization, IDCGAN only utilizes 26% of the CPU resources, indicating its relatively low computational demand. This is advantageous for devices or environments with limited resources. Furthermore, it is worth noting that the training time of IDCGAN is approximately 20 minutes and 48 seconds, while DCGAN takes about 34 minutes and 49 seconds. This comparison shows that the training time of IDCGAN is reduced by approximately 70%. This means that IDCGAN is more efficient in terms of training speed and can complete training tasks faster.

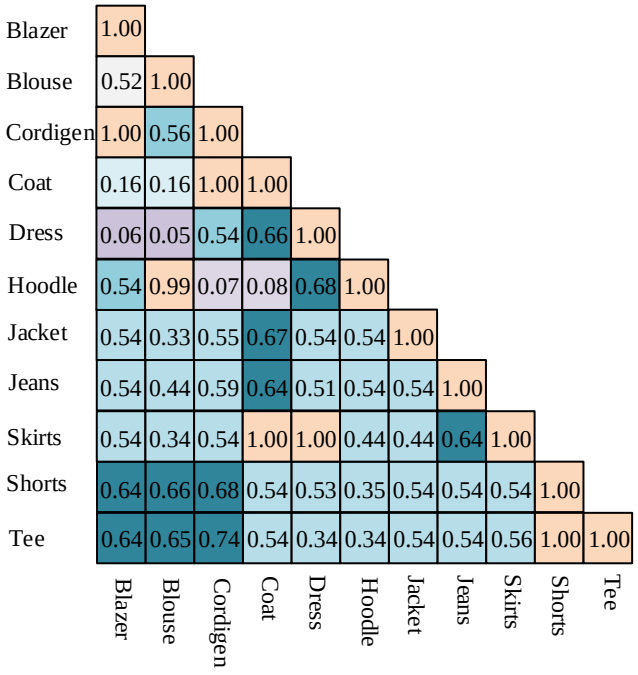

Fig. 8. Improving DCGAN similarity thermal map.

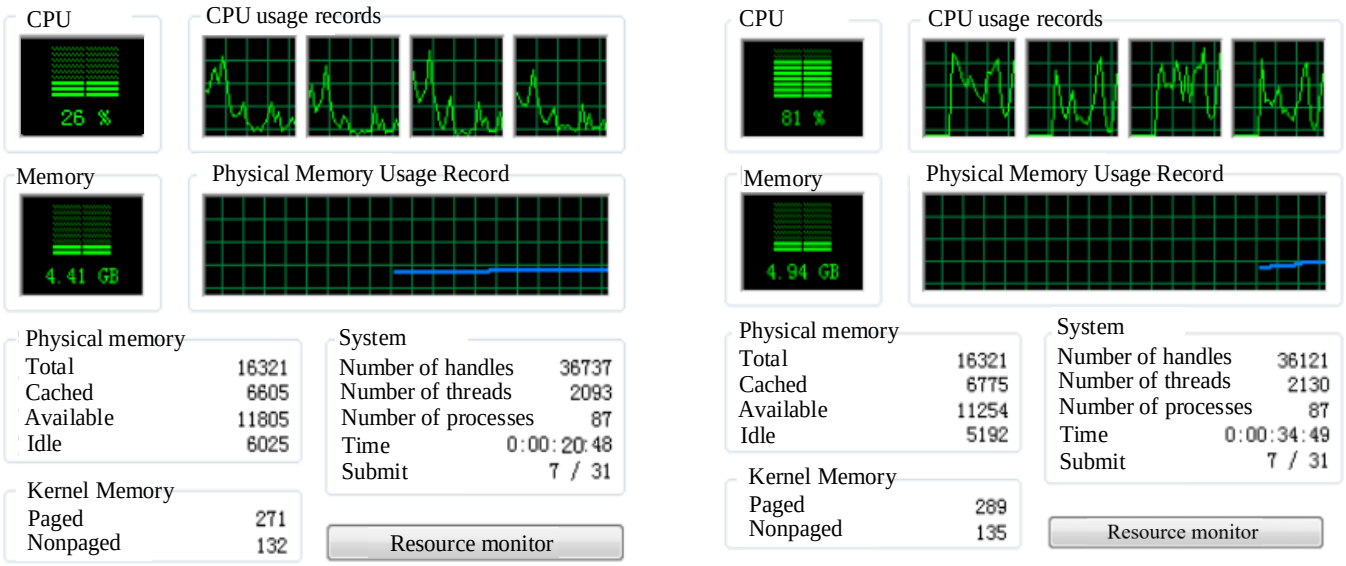

Fig. 9. Resource consumption of DCGAN and IDCGAN in various aspects.

D. Application Analysis of Style Transfer Network and Intelligent Design System

To address the limitations of real-time style transfer networks in terms of generated image quality, detail preservation, and style restoration, an improved real-time style transfer network was designed. The experiment first verified the optimization effect of the style transfer network based on AdaIN. For this purpose, batch normalization (BN) and instance normalization (IN) were introduced as control groups. The experiment was conducted using PyTorch 1.8 software on the Windows 10 platform, and the three models were trained for 62,500 iterations each. The results are shown in Fig. 10.

Fig. 10 displays the correlation of the loss and the iterations in the training based on three different normalization methods. From the figure, the loss values of the three models rapidly decrease in the first 5,000 iterations, then stabilize in the range of 50,000 to 45,000 iterations, and then decrease rapidly again. The final loss values of the models based on BN, IN, and AdaIN normalization converge to 1.02, 0.83, and 0.52, respectively. The real-time style transfer network based on AdaIN achieves the lowest loss value. To analyze the application of the proposed improved transfer model in this experiment, the trained model was applied to actual clothing design and evaluated by 36 professional fashion designers. Aesthetic quality scores and visual realism were used as evaluation criteria. The experimental results are shown in Fig. 11.

Fig. 11 provides a detailed display of the evaluation results of the images generated on AdaIN by 36 professional fashion designers. This chart clearly reflects that the proposed style transfer network has received widespread acclaim among the fashion designer community. Designers evaluated the images generated by the model rigorously and comprehensively from their professional perspectives. The results show that the 36 designers gave high aesthetic quality ratings to the images, with an average score of 96, indicating the excellent performance of the model in terms of aesthetic representation. Additionally, the designers highly recognized the visual realism of the images generated by the model, with an average score of 94.7. This score demonstrates the model's ability to successfully transfer the target style while preserving the original image content. To validate the superiority of the proposed intelligent design system in this study, comparative experiments were conducted with classical style transfer networks and standard real-time style transfer networks, as Fig. 12.

Fig. 12 displays the application effects of the three different style transfer networks. By observing Fig. 12(a), the images generated by the classical style transfer network are relatively blurry and lack detail. However, Fig. 12(b) shows that the real-time style transfer network has made significant progress compared to the classical style transfer network, but there is still room for improvement in terms of detail. In contrast, Fig. 12(c) demonstrates that the style transfer network proposed in this study preserves more details and generates style transfer results that are clearer. In conclusion, the style transfer network in this study has achieved significant improvements in image quality and detail expression.

V. Conclusion

To address the issues of long manual design pattern creation time and low flexibility, an intelligent image design model based on the IDCGAN real-time style transfer algorithm was designed. IDCGAN The innovative content of the algorithm mainly includes the introduction of encoder and decoder network, the introduction of style vector, the method of multi-scale feature extraction and fusion, the use of conditional constraints and multi-task learning. These innovations enable the IDCGAN algorithm to generate more realistic and constrained fake images, and improve the efficiency and effect of the algorithm. For actually verifying the superiority of this improved algorithm compared to the standard DCGAN, experiments were conducted using PyTorch 1.4 software on a 64-bit Ubuntu system platform for 40,000 iterations. The results showed that after the model iterations converged, the recall rate of the DCGAN algorithm improved, but the precision significantly decreased. This indicates that the original DCGAN algorithm may have some noise or errors when generating samples. However, by using a deep feature extraction network to improve the algorithm, IDCGAN significantly enhanced the feature extraction capability of DCGAN. Additionally, the final loss values of the models based on BN, IN, and AdaIN normalization converged to 1.02, 0.83, and 0.52, respectively. The real-time style transfer network based on AdaIN achieved the lowest loss value. By comparison, IDCGAN can reduce physical memory usage by 45.7% to only 453MB, compared with DCGAN by 834MB. Moreover, in terms of CPU resource utilization, IDCGAN occupies only about 26% of the CPU resources, showing relatively low computational requirements. This is a very important advantage for scenarios where devices or environments are limited. Thus, this result indicates that IDCGAN not only generates more realistic false images, but also improves the efficiency of the algorithm. Finally, the proposed improved transfer model was subjected to application analysis, and the outcomes tells that the images generated by the classical style transfer network were relatively blurry and lacked detail. Furthermore, the aesthetic quality ratings given by the 36 designers were high, with an average score of 96, indicating that the model was well-received by the designers. On the other hand, the style transfer network proposed in this study preserved more details and generated clearer style transfer results. However, it should be noted that the model still required at least 45,000 iterations to stabilize during training, which is an aspect that needs improvement in future research. Future research will try to apply this method to more areas of image generation, such as art creation, interior design, game development, film and television special effects, etc.

***Abstract*—Numerous artificial intelligence (AI) techniques are currently utilized to identify planning solutions for supply chains, which comprise suppliers, manufacturers, wholesalers, and customers. Continuous optimization of these chains is necessary to enhance their performance. Manufacturing is a critical stage within the supply chain that requires continuous optimization. Mass Customization Manufacturing is one such manufacturing type that involves high-volume production with a wide variety of materials. However, genetic algorithms have not been used to minimize both time and cost in the context of mass customization manufacturing. Therefore, we propose this study to present an artificial intelligence solution using genetic algorithm to build a model that minimizes the time and cost which associated with mass customized orders. Our problem formulation is based on a real-world case, and it adheres to expert descriptions. Our proposed optimization model incorporates two strategies to solve the optimization problem. The first strategy employs a single objective function focused on either time or cost, while the second strategy applies the multi-objective function NSGAII to optimize both time and cost simultaneously. The effectiveness of the proposed model was evaluated using a real case study, and the results demonstrated that leveraging genetic algorithms for mass customization optimization outperformed expert estimations in finding efficient solutions. On average, the evaluation revealed a 20.4% improvement for time optimization, a 29.8% improvement for cost optimization, and a 25.5% improvement for combined time and cost optimization compared to traditional expert optimization.**

I. Introduction

Technological breakthroughs often give rise to new and persistent optimization dilemmas. To address these real-world challenges, metaheuristics (MHs), characterized as versatile and general-purpose methods, have been suggested as effective tools [1]. Metaheuristic optimization is focused on resolving real-world optimization problems by employing a range of metaheuristic algorithms, such as genetic algorithms, particle swarm optimization, bee algorithms, ant colony optimization, and memetic algorithms. Supply chain management poses a formidable task in the domain of continuous optimization using the power of metaheuristic optimization. It involves the simultaneous minimization of time, cost, and distance, or the maximization of quality and profit, as dictated by the problem's specifications. A supply chain is a cohesive group of organizations that are interconnected through the flow of materials, information, logistics, and finances. Each organization within this collective consists of enterprises responsible for manufacturing raw materials and components and offering services such as distribution, storage, wholesale, and retail. The ultimate customers are regarded as the concluding segment within this chain [2]. Typically, a supply chain encompasses diverse facilities such as suppliers of raw materials, manufacturers, warehouses, wholesalers, retailers, distribution hubs, and customers. The movement of materials and information occurs within and between these organizations [3].

In simpler terms, the supply chain comprises diverse components working together in a network that commences with raw material manufacturing and culminates in its shipment to storage facilities, distribution centers, and ultimately ensuring customer satisfaction [4]. The optimization of the supply chain network holds great importance when it comes to minimizing time and cost or maximizing profit. One area that requires particular attention is the manufacturing component of the supply chain. Manufacturing strategies, including make to stock, make to order, engineer to order, and mass customization, play a significant role in this regard. Mass customization revolves around producing a diverse array of products in large volumes. However, executing mass customization orders successfully poses various challenges, with a major focus on formulating a compelling value proposition that ensures customers' utmost satisfaction [5, 6], which creates the need for the optimization of the complete value creation process, the other challenge and the important one is that the mass customized products usually consume time and cost money more than the standard manufacturing forms.

In order to optimize the manufacturing lines inside the manufacturing floor, it is required to minimize the time and the cost of producing mass customized products which is the objective of this paper. The objective is not only the optimization of selecting the suitable manufacturing operations, but also the selection of proper or suitable supplier that help in minimizing time and cost. One of the AI methods for reaching this objective is genetic algorithms (GA). This includes formulating the supplying and manufacturing of mass

customization processes as an optimization problem, in addition to applying two optimization strategies, single objective time and cost separately, and multi-objective time and cost together.

The core motivation behind our proposed model is to apply genetic algorithms for the optimization of supply and manufacturing processes for mass-customized products. After constructing the model and implementing genetic algorithms, we observed substantial improvements, including a 20% reduction in time, a 30% reduction in cost, and a 25% reduction in both time and cost when compared to estimations provided by experts and consultants. This paper is structured into six sections. Section II provides an overview of existing research in the domains of supply chains and mass customization optimization from diverse viewpoints. Section III is the proposed model, followed by a discussion of Genetic Algorithms will be illustrated in the Section IV. Section V encompasses the discussion of results. The conclusions are detailed in the Section VI, and the presentation of future research directions in Section VII.

II. Related Work

Mass customization entails a highly complex supply chain with distinct features that can be classified into two key branches. The first branch encompasses the intricate relationship between the random information provided by clients' orders and the supply chain partners. This connection often gives rise to numerous scheduling conflicts and introduces dynamic or random elements into the process. The second aspect revolves around the collaborative benefits and the inherent risks within this intricate environment [7]. Therefore, this paper aims to investigate how to effectively manage these characteristics, analyze the advantages and risks associated with collaboration in mass customization, and present previous research on supply chain optimization, mass customization manufacturing and the application of GA either in supply chain or mass customization optimization in next three separate sections.

A. Supply Chain Optimization

The escalating global population and the increased demand for food, especially in aquaculture [8], have led to a surge in research focusing on the food supply chain. One notable study in this domain presented an innovative bi-objective and multi-period mathematical model for a closed-loop supply chain (CLSC) specifically tailored to the fish industry. The model is designed by using the multi-objective Keshtel algorithm (MOKA), NSGA-II, and MOSA. In addition, the Taguchi method is applied to harmonize these meta-heuristics to reach higher performance, and the ε-constraint method is used to solve small-sized problems to validate them. The results showed that the exact method cannot solve large-sized problems. The solutions are compared in terms of different performance metrics. Also, a case study with a trout CLSC in the north of Iran is investigated. The results and the case study showed that the implemented model can be applied to the suggested solution approach. The focal point of the food supply chain model mentioned is to enhance the chain's performance, prioritizing improvements regardless of time or cost implications.

A supply chain optimization problem could decide where to locate and relocate mobile and modular production units to convert biomass waste to energy [9]. Both deterministic and two-stage stochastic designs were introduced, accounting for the inherent uncertainty of how much and where biomass is produced. The framework was applied to case studies analyzing the states of Minnesota and North Carolina. Results from both states were that mobile production modules lead to reduce supply chain cost around 1–4%, or millions of dollars per year. Furthermore, this framework shows the benefit of mobile modules as a means of protection against uncertainty. Authors in that model directed their contribution to save cost by choosing the best location of the production units regardless the time.

A blood supply chain network (BSCN) [10] was formulated to minimize the total cost of the supply chain system for demand and transportation costs. The network stages considered for modeling was containing of blood donation clusters, major laboratory centers, permanent and temporary blood transfusion centers, and blood supply hubs. Other goals included determining the optimal number and location of potential facilities, optimal allocation of the flow of goods between the selected facilities and determining the most suitable transport route to distribute the goods to customer areas in uncertainty conditions. Given that the model was implemented by using NP-hard, the MFGO algorithm to solve the model with a priority-based solution. The results of the experiments' design showed the higher efficiency of the MFGO algorithm than the PSO algorithm in obtaining efficient solutions. Also, the mean of the objective function in robust approach was more than the one in the deterministic approach, while the standard deviation of the first objective function in the robust approach was less than the one in the deterministic approach at all levels of the uncertainty factor. In BSCN model time was not a factor in optimization process.

A location-inventory optimization model for supply chain (SC) configuration was presented in [11]. It included a supplier, several distribution centers (DCs), and several retailers. Customer demand and replenishment lead time were considered to be stochastic. Two classes of customer orders, priority and ordinary, were assumed based on their demand. The goal was to find the optimal locations for DCs and their inventory policy simultaneously. For this purpose, a two-phase approach based on queuing theory and stochastic optimization was developed. In the first phase, the stock level of DCs was modeled as a Markov chain process and is analyzed, while in the second phase, a mathematical program was used to determine the optimal number and locations of DCs, the assignment of retailers to DCs, and the order quantity and safety stock level at DCs. As solving this problem was NP-hard, a hybrid Genetic Algorithm (GA) was developed to make the problem computationally tractable. In location-inventory optimization model, the time and destination were considered to be factors in optimization process which were two dependable factors regardless the cost of the destination.

In time of pandemic (COVID 19), a novel multi-objective optimization model for the vehicle routing problem from suppliers of raw material to manufacturer were introduced within the realm of a factory-is-a-box framework [12]. The

key objective is the minimization of both the cumulative cost incurred while traversing network edges and the total cost accrued by visiting network nodes. This solution approach incorporates a specialized multi-objective hybrid metaheuristic algorithm that explicitly incorporates problem-specific characteristics. This model's primary objective was to optimize vehicle routing for raw material delivery to the manufacturer. In contrast, our proposed model is dedicated to optimizing the entire supply chain for raw materials and the manufacturing process, particularly for mass customization products.

B. Mass Customization Optimization

This section presents some authors who handled the manufacturing and mass customization manufacturing optimization. For optimizing manufacturing problems, a literature review was done to focus on reconfigurable manufacturing systems (RMS) optimization. This literature was classified in two scenarios. The first scenario, different optimization problems uprising in RMS were introduced and discussed. The second classification scenario presented solution approaches used to solve these problems. This work was intended to help scientists identify potential research areas in the domain of optimization for RMS. This literature showed the optimization process for reconfigurable manufacturing systems using different techniques such as mathematical programming (MP) models [13, 14], dynamic programming [15, 16], meta-heuristics [17] and heuristics [18]. RMS optimization concerned of maximizing the profit or quality or minimizing the cost regardless the time which is considering in our research. On the other hand, Mass Customization Manufacturing (MCM), existing research fingered to optimization.

A research was pointed to the fourth industrial revolution and the digital transformation of consumer marketplaces and its need in manufacturers to reshape their business models to deal with the continuous changing in customer needs and market fluctuations [19]. Currently, manufacturers are tending toward product variation strategies and more customer oriented methods to keep the competitive advantage in the Industry 4.0 environment, and mass customization is among the most famous implemented business models. Under such circumstances, an economical material supply to assembly lines has become a significant concern for manufacturers. Consequently, the proposed study concerned about optimizing the material supply to mixed-model assembly lines that contributed to the overall production cost efficiency, mainly by decreasing both the material holding and material transportation costs across production lines, while satisfying certain constraints. Given the complexity of the problem, a new two-stage heuristic algorithm is applied in such study to enable a cost-efficient delivery. To evaluate the efficiency and effectiveness of the proposed heuristic algorithm, a set of test problems were solved and compared versus the best solution found by a commercial expert. The results of the comparison reveal that the proposed heuristic offered reasonable solutions, thus presenting huge opportunities for production cost efficiency and manufacturing sustainability under the mass customization viewpoint. As seen, that research focused on minimizing the cost only without putting the factor of time into consideration.

The current global unpredictable market is characterized by increasing demand for highly customized products [20]. To thrive in this scenario, it becomes necessary to establish a closer interaction between product and manufacturing system, keeping the main focus on the customer. This paper presented a Modular Product Design (MPD) as a best strategy to produce a large product variety. MPD's configuration stage represented a key step for mass customization because it allows customers to be integrated into the value-creation process. Reconfigurable Manufacturing Systems (RMS) appear to be the most suitable manufacturing system to manufacture mass customized products due to their ability to be quickly reconfigured, adjusting their production capacity and functionality to fit new market demands. Pointing to integrate single customer needs with the decisions taken for the product and manufacturing process, this paper suggested a new 0-1 nonlinear integer programming model to optimize the configuration of modular products and RMS, driven by individual customer requests. A genetic algorithm based approach was proposed to solve this model, and its parameters were tuned with a two-full factorial design. A case study of customizable office chairs was used to illustrate the proposition, and several scenarios of customer requirements and RMS configurations were presented. Results showed that varying initial machines' configurations could highly affect the process plan and the total manufacturing costs; but, there was no confirmation that changes in initial design of configurations caused weighty effects. In summary, this work confirmed the relevance of integrating modular product and RMS configuration decisions for decreasing costs of producing mass-customized products. In RMS model, time was not considered in the optimization process.

A distributed approach for smart production management in a cellular manufacturing system was presented for offering mass-customized products [21]. This approach was based on three decision stages: factory-stage (master planning module), shop floor stage (bidding system) dealing with unexpected actions, and cell stage. The approach integrated planning, scheduling, and material handling allocation while considering real-time data from the supply chain. A mathematical model for factory-stage planning was proposed with two sequence-based resolution approaches implemented on two meta-heuristics, NSGAII and SMPSO.

C. Genetic Algorithm with Supply Chain Management and Mass Customization Manufacturing

A literature review of the application of GA on supply chain management (SCM) was published [22]. It consists of several complex processes and each process is equally important to maintain a successful supply chain. The literature review contained the eight processes of supply chain as given by Council of SCM Professionals. This literature review illustrated that there are no contributions of applying bi-objective function of minimizing the time and cost together which we focused on in our proposed model.

On the other hand, some models were designed to solve the problem of optimization of manufacturing sector [23].

However, very few models that concerned about mass customized manufacturing. Moreover, a few numbers of these models were implemented using genetic algorithm and no models were implemented using bi-objective function of minimizing time and cost in such sector [24, 25].

It was proven regarding the related work section that there were infrequently highlighted points in the optimization process in supply chain management, mass customization manufacturing and using genetic algorithm in these two fields. The following section will discuss the proposed model which takes into consideration what was neglected previously in the related work.

III. The Proposed Model

This research focuses on creating a model that integrates cost and time considerations in the optimization of mass customization. It emphasizes the collaboration between suppliers and manufacturers involved in the supply chains for mass customized products. The primary goal is to identify the most effective combinations of these entities to achieve desired objectives. To accomplish this, the study suggests the utilization of evolutionary algorithms, which are ideal for generating suitable combinations and yielding favorable results.

The suggested solution is based on using the evolutionary algorithms especially genetic algorithms to optimize the best scenario of selecting the best supplier, best operation type (either manual or automatic) and best number of manufacturing lines in order to minimize time, cost or both in a mass customized order. The definition of the mathematical formulation of the objective functions designed to obtain the optimal solution or scenario will be clarified in next paragraphs. Fig. 1 clarifies some abbreviations that will be used in the mathematical model of the proposed problem.

Before commencing a comprehensive explanation of our mathematical model, it's essential to recognize the importance of considering specific manufacturing rules. These rules play a critical role in clarifying the methods for calculating time and cost, and they are informed by the collective expertise of consultants. These rules are:

- Automatic Time = Manual Time/2.
- Automatic Manufacturing Cost = 1.6 * Manual Manufacturing Cost.

According to real-world manufacturing metrics, manual manufacturing consumes double the time of automated manufacturing, while the average cost of the automated process is 1.6 times that of manual manufacturing.

Generally, the mathematical formulation for the optimization process is being built according to an objective function and constrains that controls this function. Here, the suggested solution was divided into three choices according to the order demander priority. The customer may need to minimize the time only, cost only, or both of them. Table I illustrates the objective functions and the constraints of each priority. Within the context of the cost objective function, we come across TotSC, or total supply cost, which is subject to the influence of numerous variables such as supplier selection, category, color, and operation type. These factors are collectively evaluated to ascertain the overall cost. In the following three paragraphs, we will illustrate the three objective functions specified in Table I, encompassing a breakdown of their individual terms.

MLQ_n = Manufacturing Line Quantity for n (n: 1, 2, 3,..etc.)
MLT = Manufacturing Lead Time.
ML= Manufacturing Line.
SLT= Supplying Lead Time.
TotLT: Total Lead Time.
TotSC: Total Supplying Cost
TotMC: Total Manufacturing Cost
TotC: Total Cost.
SCO: Supplying Cost Order
TQ: Total Quantity
Op: Operation Type

Fig. 1. Abbreviations.

TABLE I. Objective Functions and Constraints

Priority	Objective Function	Subject to
Time	Min (Y) = $\sum MLT + SLT$	$1 \leq Order \leq 3$ $1000 \leq TQ \leq 6000$ $0 \leq Op \leq 1$ $1 \leq Supplier \leq 2$
Cost	Min (Y) = $\sum TotSC + TotMC + Overhead$	$1 \leq Order \leq 3$ $1000 \leq TQ \leq 6000$ $0 \leq Op \leq 1$ $1 \leq Color \leq 12$ $1 \leq Size \leq 2$ $1 \leq Supplier \leq 2$
Time and Cost	Min (Y) = $0.5(\sum (TotSC + TotMC + Overhead)) + 0.5(\sum (MLT + SLT))$	$1 \leq Order \leq 3$ $1000 \leq TQ \leq 6000$ $0 \leq Op \leq 1$ $1 \leq Color \leq 12$ $1 \leq Size \leq 2$ $1 \leq Supplier \leq 2$

When discussing the Time objective function, MLT, representing manufacturing lead time covering all phases of the manufacturing process (including assembly, painting, and packaging) is a key factor. Notably, manufacturing lines employing automatic processes outperform their manual counterparts in terms of time efficiency. In our model where the priority is for minimizing the time only, the quantity is distributed equally over the four manufacturing lines, so the time consumed is equal to any of manufacturing line. Furthermore, SLT, denoting supplying lead time, relates to the time required to deliver the components from two distinct suppliers, with Supplier A exhibiting superior delivery speed compared to Supplier B. In our model Supplier A takes half time of Supplier B. So, the total time will be MLT+SLT.

Within the context of the cost objective function, we come across TotSC, or total supply cost, which is subject to the influence of numerous variables such as supplier selection, category, color, and operation type. These factors are collectively evaluated to ascertain the overall cost.Conversely, TotMC, denoting total manufacturing cost, is predominantly governed by the choice between manual and automatic operation modes distributed over manufacturing lines, with manual operations being the more cost-efficient alterna additionally, there exists an overhead factor, representing a fixed monetary addition to the unit cost, covering various expenses like utilities (electricity, water, maintenance), and labor.

The third objective function can be regarded as a consolidation of the two objective functions discussed above. Nonetheless, in any multi-objective function, it is crucial to assign weights to individual terms during the optimization process. In this scenario, we have opted for an equal allocation of 50% weight to both time and cost, signifying their equal importance. Under these conditions, the quantity is allocated among the four manufacturing lines as detailed below:

- ML1 = Automatic = 2/5 from the Total Quantity.
- ML2= Manual = 1/5 from the Total Quantity.
- ML3= Manual = 1/5 from the Total Quantity.
- ML4= Manual = 1/5 from the Total Quantity.

This division into fifths is based on the principle that the automatic line processes double the quantity of the manual line within the same time interval.

Now that we have clarified the terms associated with each objective function in Table I, it's time to provide a comprehensive explanation of our model.

The suggested model consists of three scenarios of mass customization optimization process. The model depends on entering five inputs which are quantity, color, category, size, sub-size, and priority. The priority input is the key of which objective function will be executed.

Fig. 2 illustrates the inputs, GA processing and the output of these scenarios.

The suggested model has five inputs:

- Color: Black, Silver, White, Red, Blue, Green, Red, Brown, Pink, Purple, Golden, or Yellow.
- Category: Mountain, Tour, Road, or Folded bikes.
- Size: Child or Adult.
- Sub – Size: Small, Medium, or Large.
- Priority: Time only, Cost only, or Both.

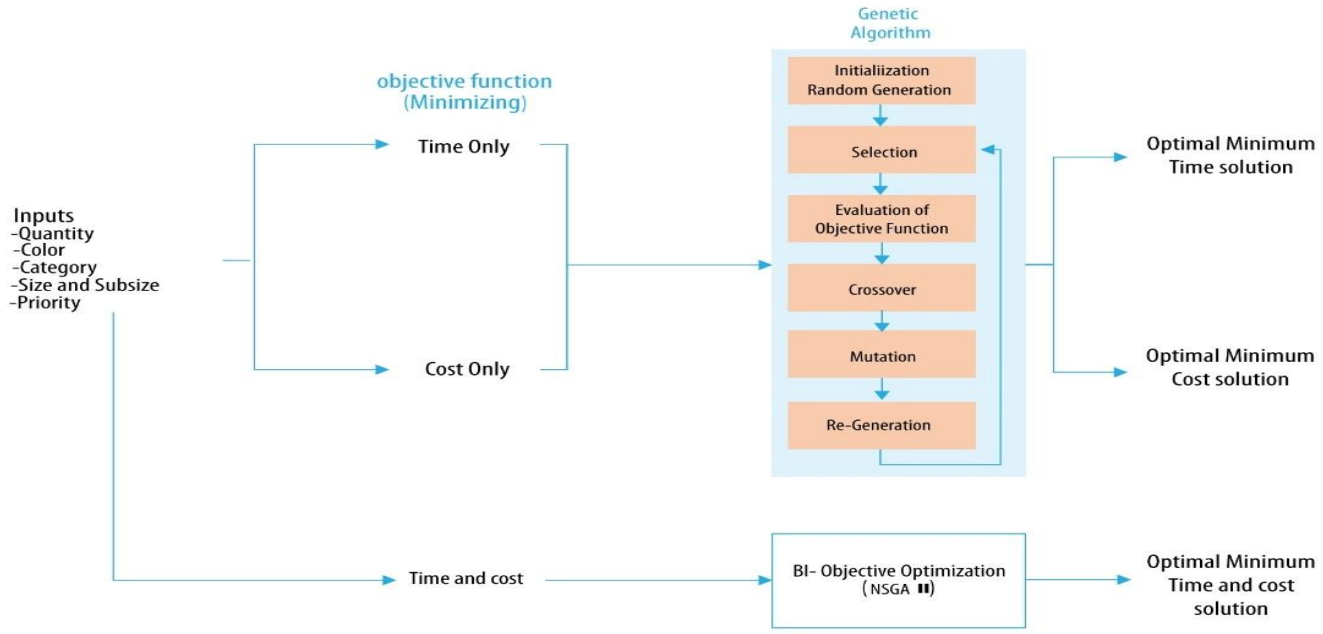

Fig. 2. The suggested optimization model.

The customer requests his/her order by determining the above inputs. However, the values of each input are limited which is considered as constrains in genetic algorithm point of view. These constraints (see Table I) are:

- Quantity : $1000 \leq TQ \leq 6000$
- Color: $1 \leq Color \leq 12$
- Category: $1 \leq Category \leq 4$
- Size: $1 \leq Size \leq 2$
- Sub-Size: $1 \leq Sub\text{-}Size \leq 3$
- Priority: Time, Cost, or Both.

From manufacturer side, there three values must be clarified which are the operation type, number of manufacturing lines and which supplier will supply the material. These values are:

- Operation Type (Op): Manual or Automatic.
- Supplier: A or B

The customer may request up to 3 different orders per one request. In addition, there are three constrains for optimization process but from the manufacturer side which are:

- Operation Type : $1 \leq Op \leq 2$
- ML=4
- Supplier = $1 \leq Supplier \leq 2$

The customer requests will be optimized using genetic algorithm to find the optimal solution of minimized time, cost or both of them. The proposed model is using two techniques of GA. For time only and cost only, single objective optimization technique is being used, while for both time and cost bi-objective optimization techniques is being implemented. Next section will explain the genetic algorithm and how the proposed model is being implemented by it.

IV. Genetic Algorithm

In recent times, meta-heuristic algorithms have gained significant popularity for addressing complex real-world challenges across various domains including engineering, manufacturing, economics, healthcare, and politics. Among these algorithms, the genetic algorithm (GA) stands out as a widely recognized approach, drawing inspiration from the process of biological evolution. Meta-heuristics can be categorized into two groups: single-solution based and population-based meta-heuristics [24]. GA falls into the category of population-based meta-heuristic algorithms.

The new populations are produced by iterative procedure of genetic operators on individuals existing in the population. The chromosome structure, selection, crossover, mutation, and evaluation of objective function computation are the basic elements of GA [24]. The GA chromosome representation and GA operators (Selection, Crossover and Mutation) will be explained and how GA was applied on the proposed solution.

A. Chromosome Representation

Genetic Algorithm draws inspiration from the evolutionary process, selecting elite solutions (chromosomes) for optimal outcomes in the search space. Chromosome in GA represents a solution and it is also called individual. Each chromosome consists of many genes according to the solution parameter.

The chromosome of our proposed solution consists of five genes. Fig. 3 represents the chromosome which represents the form of solution that the manufacturer will execute. First gene describes the supplier group that suits to the objective function. Rest of genes is the manufacturing lines (MLi) and if it will operate automatically or manually according to the objective function as well.

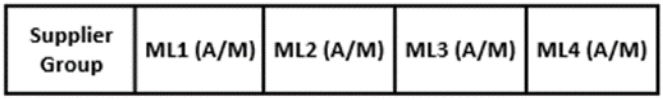

Fig. 3. The chromosome representation.

In the first gene of the Supplier Group, there are two categories. The first category is associated with higher expenses but faster raw material deliveries; whereas the second category offers cost savings but slower material delivery. The subsequent genes in the sequence represent the manufacturer's internal manufacturing lines. When these lines operate manually, manufacturing time increases but cost decreases.

Conversely, automatic operation reduces manufacturing time but increases cost. Within genetic algorithms, there are two terms called "genotype" and "phenotype" which signify the relationship between the proposed genetic chromosomes and their actual chromosomes post-processing. In the realms of artificial intelligence optimization and computer science, these two terms are fundamentally interchangeable. Hence, there is no inherent difference, eliminating the necessity to define a distinct ratio between them.

B. Selection Process

Selection is a first feature to go forward of finding the nearest solution, which commonly services Evolutionary Computation (EC) [26]. In general, there are many selection techniques in GA, such as roulette wheel, tournament, rank, Boltzmann, and stochastic universal sampling [24]. The most usable technique and it is used in the proposed solution is roulette wheel selection (RWS). It works on selecting specific solutions that will share in forming the next generation. It gives each solution or individual of the recent generation the probability to be selected in the next generation according to its proportionality to the objective function value [27].

C. Crossover

It is one the GA operators that is done between two chromosomes called parents by choosing randomly either single point or multiple points to swap what beyond these chosen point(s) [28]. The result of the crossover process is new modified chromosomes called off-springs. Fig. 4 describes the implementation of crossover types in the suggested solution. It describes a single crossover

implementation and a multi crossover implementation in the proposed solution.

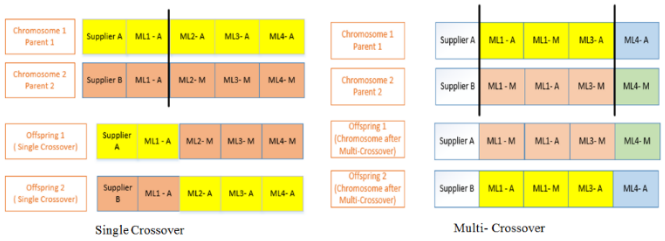

Fig. 4. Crossover operator single crossover, multi crossover.

D. Mutation

Mutation is another operator that keeps the genetic variety and diversity from one population to the succeeding population [29]. It is performed by choosing at least one or more genes randomly and changing their values. The value of the objective function is then recalculated. Fig. 5 gives an example of mutation process by choosing a random gene and changing its value according to the proposed solution.

Fig. 5. Applying mutation operator

The steps of implementing the GA can be clarified through the pseudo-code as shown in Fig. 6.

Parameter(s): C- set of Chromosomes

Output: super-offspring of set C

Initialization:
$t \leftarrow 0$
Initialize I_t *to random individuals from* C^*
Evaluate the solution objective value
while *stop criterion not met*
Do
    Select individuals from I_t
    Crossover individuals
    Mutate individuals
    Re- Evaluate the solution objective value
    $I_{t+1} \leftarrow$ *new created individuals*
    $t \leftarrow t + 1$
End Do
return (*super-offspring derived from best individual in* I_t)

Fig. 6. Genetic algorithm pseudocode.

V. Discussion and Results

To the best of our knowledge, this is the first study to solve the problem through applying the optimization methodology; moreover, the problem was formulated mathematically according to the real manufacturing case, and according to the consultants inside the manufacturer and experts in mass customization manufacturing field. So, they are our reference and benchmark in our proposed study. In a practical case study focused on a mass customization bicycle manufacturer, the proposed model was put into action. Customers had the option to place orders for bicycles in diverse categories, sizes, and colors, as previously mentioned. Moreover, they were able to order bicycles in large quantities.

The objective is to optimize the combination of supplying and manufacturing processes from the manufacturer to execute the orders in minimum time, minimum cost or both to achieve the customer goal. The three mathematical models and GA were implemented using MATLAB [30]. Two of these mathematical models used the single objective GA.

However, the third model was implemented using NSGAII technique [31] to solve the multi-objective optimization problem. Table II illustrates the values of each parameter used in GA implementation. Each genetic algorithm code asks for assigning values of 4 main parameters. These parameters are population size [24], number of generations, crossover rate and mutation rate.

Each objective function is tested on three different quantities 2000, 3500 and 5500 bicycles with different categories, colors, sizes and sub-sizes. Table III illustrates the enhancement of solutions in form of enhancement of GA generations.

The results in Table III shows the modifications of solutions for time only and cost only columns versus the number of generations. While the last column shows the modifications of time and cost together over the number generations using NSGAII technique. In bi-objective function mode, time is being represented in Y-axis and cost is in X-axis. In Table III, the graphs in each row determine the values of the most optimum time, cost or time and cost with every round of generation (100 rounds) until reaching the minimum optimum solution.

When examining the time column graphs, it becomes evident that values are progressively minimized with each generation. Conversely, the cost column experiences abrupt reductions, primarily because cost is subject to fixed prices determined by various factors, leading to the characteristic sharp curve.

After the observation of 100 solutions per each iteration, eight forms of solutions were noticed but different objective function values. Fig. 7 presents these forms of these solutions (chromosomes that mentioned in Fig. 3).

TABLE II. GA Parameter Setting

Parameter	Value
Population Size	100
Number of Generation	100
Crossover Rate	0.85
Mutation Rate	0.01

TABLE III. ENHANCEMENT OF GA GENERATIONS FOR THREE DIFFERENT CASES

Quantity	Time	Cost	Time and Cost
2000			3500			5500			
Solution 1	Supplier A	ML1 - A	ML1- A	ML3- A	ML4- A
Solution 2	Supplier B	ML1 - A	ML1- A	ML3- A	ML4- A
Solution 3	Supplier A	ML1 - A	ML1- A	ML3- A	ML4- M
Solution 4	Supplier B	ML1 - A	ML1- A	ML3- A	ML4- M
Solution 5	Supplier A	ML1 - A	ML1- A	ML3- M	ML4- M
Solution 6	Supplier B	ML1 - A	ML1- A	ML3- M	ML4- M
Solution 7	Supplier A	ML1 - M	ML1- M	ML3- M	ML4- M
Solution 8	Supplier B	ML1 - M	ML1- M	ML3- M	ML4- M

Fig. 7. Forms of solutions.

The evaluation of the results involved consulting production management experts in the bicycle manufacturing industry. Their estimations, obtained using traditional computation techniques, were compared with the outcomes generated by GA and NSGAII, as shown in Table IV. The table presents numerical data for three different cases, each involving different quantities. The evaluation considered time, cost, and a combination of both for each quantity. The results section of the table includes the expert estimation, GA results, and the percentage improvement achieved by our proposed models over the expert estimation. The findings clearly indicate that treating time and cost as a multi-objective functions leads to optimal results. Additionally, it was observed that higher quantities ordered corresponded to greater enhancements achieved through GA.

The expert estimations documented in Table IV are cited in order to facilitate a comparison between our GA-generated results and the authentic data stored within the database of a prominent bicycle manufacturer.

Table V illustrates the average of enhancement percentage of GA and NSGAII versus the experts estimates.

TABLE IV. SAMPLE OF NUMERIC RESULTS

Solution Forms	Time (Week)			Cost (x10^6)			Time (Week) and Cost (x10^6)					
	Expert Estimation	GA Result	%	Expert Estimation	GA Result	%	Expert Estimation		NSGAII Result		%	
							Time	Cost	Time	Cost	Time	Cost
	Quantity : 2000 Bicycles											
Solution 1	8	6	25	6.3	4.2	33.3	8	6.3	6	4.2	25	33.3

TABLE V. GA AND NSGAII AVERAGE OF REFINEMENT PERCENTAGE

Quantity	2000	3500	5500	Total Average
Time	17.6%	20.7%	22.9%	20.4
Cost	25.8%	27.7%	36.03%	29.8
Time and Cost	20.5%	25.6%	30.5%	25.5

VI. CONCLUSION

In this paper, a genetic-based approach was introduced for the supply and manufacturing of mass customization products. The approach integrated the supply and manufacturing phases to achieve the best possible solution with minimal time and cost.

The study presented two techniques utilizing Genetic Algorithms: one for solving single objectives of time and cost, and another for optimizing both objectives simultaneously using the multi-objective NSGAII.

Experimental results, including numerical and graphical analyses, demonstrated the significant improvements of the proposed approach compared to traditional factory methods. On average, the proposed model enhances time optimization by 20.4%, cost optimization by 29.8%, and both time and cost optimization by 25.5%.

VII. FUTURE WORKS

Optimization constitutes a vast and dynamically evolving field that accommodates numerous artificial intelligence technologies. In the context of our planning model, we have the flexibility to refine and tailor it further by adopting novel hybrid heuristics and metaheuristic search techniques, including adaptive algorithms, self-adaptive algorithms, or combinations of existing methods. Moreover, our future work includes exploring the potential of applying machine learning

as an optimizer within our model. On a parallel front, the domain of supply chain optimization offers a rich landscape for exploration. We aim to extend the horizons of optimization by considering the comprehensive optimization of the entire supply chain network, employing new evolutionary algorithms, machine learning, and deep learning approaches.

ACKNOWLEDGMENT

We thank everyone who helped us in manufacturing field to apply, test and evaluate our proposed model in minimizing cost and time for supplying and manufacturing mass customization products.

Application Model Construction of Emotional Expression and Propagation Path of Deep Learning in National Vocal Music

Zhangcheng Tang*
Music and Dance Academy, Hunan First Normal University, ChangSha, 410205, China

***Abstract*—Emotional expression is important in Chinese national vocal music art. The emotional expression in national vocal music is based on the art of national vocal music, with distinct characteristics and requirements. The ultimate goal is to spread the expression of various emotions in the national vocal music art. Promoting the spread of national vocal music singing art using modern media is an urgent requirement for the inheritance and development of national vocal music singing art. With the rapid development of science and technology, integrating deep learning and traditional music has become the general trend. It has been gradually applied to melody recognition, intelligent composition, virtual performance, and other aspects of traditional music and has achieved good results, but also hidden behind a series of ideas and technical and ethical issues. In this paper, the application of deep learning has been discussed and prospected. The recognition rate of emotional expression in national vocal music is 92 %. In terms of communication, combined with the deep learning algorithm, this paper analyzes the characteristics and requirements of emotional expression in the art of national vocal music singing and puts forward a new method of promoting the development of the art of national vocal music singing, hoping to attract more attention and enhance the social awareness of the application field, to promote the steady development of Chinese traditional music in the information age.**

***Keywords*—Deep learning; national vocal music; innovation; emotion; dissemination**

I. INTRODUCTION

Emotional expression has always been particularly valued in national vocal music. The emotional expression running through the art of national vocal music is the soul of the art of national vocal music. The art of national vocal music without emotional expression will lose its significance. The emotional expression ability of singers is the focus of national vocal music singing art. The emotional expression of Chinese national vocal music singing art has accumulated rich levels and diversity in the development of thousands of years, with its unique characteristics and requirements. As the pearl in the art treasure house, the inheritance of national vocal music singing art is related to the integrity of traditional art [1], [2]. While analyzing the emotional expression of national vocal music singing art, continuously improving its artistic and emotional expression ability and meeting the current social and cultural needs, the inheritance of national vocal music singing art has also become a social problem. In the face of the new era of openness and diversification, how to take effective communication paths to make the national vocal music singing art occupy a place in the field of communication and inherit it for a long time is a problem that must be thought and solved simultaneously in addition to paying attention to the emotional expression of the national vocal music singing art.

Music education is gradually developing towards intelligence and online in the Internet era. As an emerging discipline, deep learning is mainly used to research, develop, and extend the method theory of human intelligence. Nowadays, many things are related to deep learning, such as fingerprint recognition, intelligent search, face recognition, language translation, and automatic planning. Deep learning and hearing has a great relationship, and deep learning for music education has a unique advantage. The breakthrough of material civilization also accompanied the development of music art. Deep learning will change music education's teaching mode and theory, especially in teaching means and methods, to provide positive practical value for music education in the Internet era [3].

Combining deep learning algorithms and traditional national vocal music has become an important research direction in the future. The singing of traditional national vocal music will usher in great changes under the impetus of deep learning. It makes the emotional expression of traditional folk music singing easier to identify and push to the audience who like to change the type of folk music so that it is not limited to the nation. The technology of retrieving music based on music's emotional attributes has also been developed. Many kinds of music are stored in the network music database. The essence of music information retrieval is music recognition and classification. Most music end users often like a certain type of music, and the diversity of music gives it unique attributes [4], [5]. Therefore, a music recognition and classification system can help people retrieve and manage music more effectively. MIR contains many sub-tasks, such as music emotion recognition, instrument recognition, genre recognition, and author recognition [6].

The traditional extraction of music emotion features often lacks the temporal structure and related semantics of music because it is usually extracted in frames, and the deep semantics of chords, melody, and rhythm in music that change with time is important for music emotion recognition. To analyze the correlation between temporal information and emotional expression in the research process, some scholars have done verification experiments in 2014: First, the music is

transformed into a feature vector of the time structure, and then the Gaussian mixture model, Markov and Hidden Markov model and other generative models are used to form the temporal characteristics of the music. Finally, the model is passed through the Probability Product Kernel for music emotion recognition. Traditional folk music has been rapidly upgraded, making full use of the convenience of the mobile Internet and spreading through more channels. Therefore, the mobile Internet has unprecedented advantages for promoting music works and the comprehensive utilization of traditional Internet, mobile communication networks, mobile phone ringtones, and other wired and wireless platforms for communication [7]–[10]. This mode of creation, production, dissemination, and acceptance of music products mainly relies on digitalization, reflecting technological and cultural progress and transforming and upgrading communication modes. The Internet and mobile terminal technology have achieved unprecedented development speed since the 21st century, especially in the past five years. It has not only formed a pattern of national coverage of online music but also gradually replaced the traditional music platform as the main channel in the rapid development of this mode of communication and platform. The mode of communication has developed into one of the most fashionable ways of music communication. Some scholars have applied deep learning to music content analysis, especially style, and artist recognition, producing meaningful features from the preprocessed spectrum. The deep learning features have higher accuracy than those standard Mel Frequency Cepstral Coefficients features for music style recognition. There is also a convolutional neural network (CNN) that MFCC features vectors and inputs them into three hidden layers. Finally, it can automatically extract image features for classification, indicating that CNN can capture changing image information features [11]–[13].

The role of national vocal music art in the mass media has also changed; specific singing techniques and emotional expression also began to change. Although from the perspective of modern communication, this is the development and progress of national vocal music art, to some extent, it can also be said to be desalination. In the modern media environment, maintaining a proper relationship between the dissemination of national vocal music singing art and the ' native ' cultural roots and maintaining unique characteristics in emotional expression, artistic technology, and other aspects is a problem facing the inheritance of national vocal music singing art. National vocal music technology should effectively use modern media to explore new communication paths. Based on this article, the convolutional neural network in deep learning is combined to realize the recognition and propagation path optimization of emotional expression in national vocal music. Firstly, the emotional feature extraction of vocal music signals is carried out, and then the time and frequency domain features are analyzed. The different emotions of vocal music signals in national vocal music are labeled and classified through feature extraction. The signal feature is the input index, and the emotional label is the output feature. Finally, the effective identification of emotions in national vocal music singing based on a deep learning algorithm is obtained, which provides efficient national vocal music classification based on a machine learning algorithm for following different categories of listeners and realizes targeted dissemination for different users.

II. Research on Deep Learning in National Vocal Music

A. National Vocal Music Multi-Vocal Emotion Parameter Recognition Design

In the expression of national vocal music, it is necessary to present different national vocal music styles and emotions by concretizing the abstract space of national vocal music. Effectively determining the similarity of two music points is an important part of concreting the abstract space of national vocal music. Music emotion recognition has become a popular trend. Under this condition, it is necessary to study how to enhance the accuracy of music emotion recognition and provide support and help for music search [14].

Currently, the mainstream music emotion recognition classification structure is shown in Fig. 1. There are three main steps:

1) Select the emotion model (continuous emotion model and discrete emotion model).

2) Preprocessing music, extracting useful music features and information as input.

3) Input into the recognition model for emotion recognition.

The most important part is extracting music emotion features and constructing the recognition classification model. Previous studies often used single emotional features or classifiers based on traditional machine learning models. A single emotional feature often does not have unity and cannot fully express musical emotions. It needs to be re-extracted when performing different recognition tasks. Although the recognition effect has been improved, the efficiency is too low. The traditional machine learning model only in the unique music feature recognition results; strange music is not ideal, and poor generalization ability shows the main breakthrough in the second and third steps.

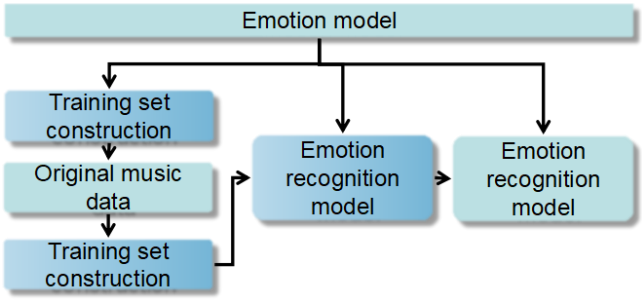

Fig. 1. Deep learning music emotion expression recognition basic structure.

Previously, music expression produced a series of music with the same style, whether relying on artificial technology or automation technology. In the abstract space of music, it isn't easy to have a variety of different styles of national vocal music at the same time. The reason for this phenomenon is that there is a certain probability of large similarity between national vocal music points with similar or different styles in the abstract space, which leads to an uneven transition between

different styles of national vocal music. Therefore, in the expression of national vocal music, the determination of the style of national vocal music creation needs to adopt some attributes as the characteristics of learning, and the style of national vocal music is numerically expressed. The objective function expresses the style value, and the national vocal music style is expressed based on the value of different objective functions.

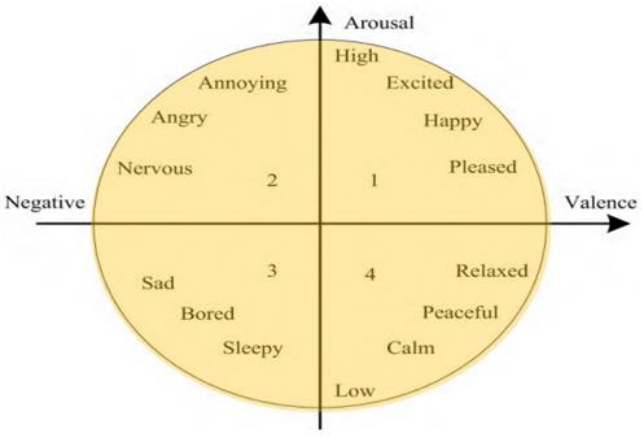

Fig. 2. National vocal music emotional space.

Different emotions are distributed in the two-dimensional space shown in Fig. 2, which is the emotional space. Based on the two-dimensional emotional space, in the expression of national vocal music, it is only necessary to project the emotional characteristics of music into the two-dimensional emotional space, take the coordinate scale value in the emotional space as the input information, and then use the artificial neural network to train the sample information. In this process, first, judge the various national vocal music elements in the training set, give the emotional category to determine its position in the emotional space, one-to-one correspondence with the emotional characteristics in the figure, obtain the emotional scope of the national vocal music, and determine the emotion and style of national vocal music creation.

The data of national vocal music is regarded as a time series, two different national vocal music sequences Y1 and Y2, their characteristic quantities are (a1μ, b1μ) and (a2μ, b2μ), and μ=1, 2,..., n represents the time length of national vocal music Y1 and Y2. At each time point μ, the Euclidean distance D (μ) between (a1μ, b1μ) and (a2μ, b2μ) is calculated, and then the similarity between the national vocal sequence Y1 and Y2 can be defined as μ = 1, 2,..., n.

$$S_{Y_1Y_2} = \frac{1}{n}\sum_{\mu=1}^{n} D(\mu) \tag{1}$$

However, the above similarity calculation process only applies to the same time length of two national vocal music sequences. For two different time lengths of national vocal music sequence, let the two-time series are X = (x1, x2,..., xi) and Y = (y1, y2,..., Yi), and set the metric function k (x1, y1), can measure the distance between component x1 and y1, namely (a1μ, b1μ) and (a2μ, b2μ) Euclidean distance.

B. A New Model of National Vocal Music Communication Under Deep Learning

1) The traditional 'live' mode of transmission of national vocal music mainly is the early context of national vocal music; people can sing works, watch, listen to activities in indoor and outdoor places, and participate in live communication activities. These modes of transmission, especially the performance of the 'stage' as a platform to sing, appreciate the more common way. At this time, the music performers and the audience of the works are in the same space-time environment for close emotional and artistic information exchange, which is a materialized, information-sharing, face-to-face communication mode. This traditional communication mode, which has lasted for many years, emphasizes that both the dissemination of song information and the acceptance of songs in the activities show the characteristics of face-to-face and the same time and space. This traditional mode of creative song transmission does not even need the assistance of other media. The instant communication and feedback of national vocal music and emotional information can be realized between the information disseminator and the song receiver, which has a strong feature of real-time information sharing.

However, there have been new changes in the current model - with live video support; people can achieve instant information exchange and communication in different times and spaces. Disseminators of songs can achieve 'off-site instant' information exchange through mobile Internet through performances anywhere. In the high development of modern mobile media, the "on-site" communication of this kind of creative song has developed into a new "on-site" communication mode relying on live video broadcast, which has become one of the most important forms of contemporary creative song communication.

2) New deep learning model in disseminating national vocal music. Deep learning in various national vocal music communication modules has been innovative from the basic information dissemination acquisition-generation distribution process. From the perspective of music information collection, a deep neural network (DNN) has many applications in music information retrieval (MIR), including beat estimation, melody mining, music emotion recognition, etc. If music is regarded as a binary data stream, Convolutional Neural Network (CNN) can efficiently mine the feature attributes of musical moments. A recurrent neural network (RNN) can analyze the characteristics of music at different times, mining its more macro features, such as emotion. QQ music, Netease cloud music, and other platforms ' listening song recognition function is the basic application of MIR. Deep learning has made more innovative attempts from the generation of music information. Nowadays, deep learning technology uses generative adversarial networks (GAN) and reinforcement learning (RL) to inject data into music and dynamically evaluate it in real-time. Deep learning can complete the evaluation of music emotion only by relying on the binary

representation of music; it can also judge the good and bad after creating and generating music and modifying it. Deep learning technology to generate music is a process of repeated creation and reflection. From the distribution of music information, the network distribution platform of music has become the world of deep learning. Music platforms rely mainly on recommendation algorithms to accurately distribute music resources to corresponding users. Deep learning represented by recommendation algorithms can process a large amount of data faster and more accurately and make more accurate recommendations for users to get a better experience.

C. Opportunities and Challenges brought by Deep Learning to National Vocal Music

1) Deep learning enables people who do not understand music theory to create music and have ownership. Then, the problem arises. If the creator creates music without knowing how it is created, it goes beyond the scope of ordinary 'music creators'. At the same time, if deep learning music creation tools create new music based on imitating existing music, then defining similarity becomes a problem. A similar piece of music, the ownership of its creative subject, is the owner of the tool, the creator of the original music, or belongs to the tool? These are issues that need careful consideration.

2) Deep learning brings great convenience to music creation, but many creations can create, far from 'can create well'. Like other arts, music creation needs to think, feel, and understand. Only in this way can it be truly appreciated and endowed with value. The music constructed by deep learning technology only proves that deep learning can generate music. This music can only be used as experimental products, which cannot make waves and even reduce the quality of the whole music.

3) Music copyright is a behavior of endowing value for art, a very important issue on the road of music commercialization. Attaching importance to copyright is to protect creators and make them have a healthy creative environment. Deep learning allows online music resources to be easily collected and quickly spread on a large scale, which increases the difficulty of tracing the path of music transmission. With such speed and breadth of transmission, the traceability of music copyright and other audio and video resources, software copyright, etc., can only be out of reach. In addition, the difficulty of positioning the creative subject will lead to copyright issues. If a piece of music cannot clarify its subject attribution, it cannot discuss its proper attribution.

4) Deep learning technology originates from the deep neural network constructed by computer scientists to imitate the ' neurons ' of the human brain, which promotes the rapid development of music communication. Music's collection, generation, and differentiation are more intelligent with the participation of deep learning. Our in-depth understanding of deep learning technology will make related concepts' definitions more mature. After jumping out of the 'learning' mode, deep learning may truly perform music creation with machine rationality.

From the current technical level, artificial intelligence has achieved computational and perceptual intelligence, but cognitive intelligence is still insufficient and needs to continue developing into cognitive intelligence. To achieve breakthroughs in national vocal music, it is necessary to combine new things such as artificial intelligence, deep learning, and machine learning to achieve more efficient emotional expression and classify national music with different emotions to share with audiences of different preferences.

III. Analysis and Implementation of National Music Deep Learning System

As the main component of music, audio plays a vital role in music emotion recognition. As an important part of music information retrieval, music emotion classification based on audio has attracted more and more attention. The second-level emotional expression in national vocal music mainly refers to the singer's realization of the emotional state through deeper excavation, such as through sound, expression, and movement form [15]. The article builds the model shown in Fig. 3.

A. Network Structure

The first few layers of the CNN network structure are feature extractors that automatically get image features through supervised training; the last layer is classified and identified by the SoftMax function. The CNN network structure is shown in Fig. 4, which shares the basic framework with the traditional AlexNet. It contains eight layers; the first five layers are convolutional layers alternating with the pooling layer, and the remaining three layers are fully connected layers for classification. The input images of the CNN network are harmonic spectra and shock spectra separated by HPSS and the spectra of the original music signals. The input image size is normalized to 256 * 256, and then it is input into the first convolution filter. In the deep network structure, the first convolution layer uses 96 kernels with a size of 11*11 and a step size of 4 pixels (the distance between the receptive field centers of adjacent neurons in the same kernel mapping) to filter the input image. Next, the max pooling layer takes the output of the first convolution layer as input and filters with 96 kernels with a size of 3*3, and the response is normalized. Using these five convolutional layers, 256 feature maps of size 6*6 were finally obtained, fed to three fully connected layers containing 4096, 1000, and 10 neurons, respectively. The final identification result is the output of the last fully connected layer, as shown in Fig. 4.

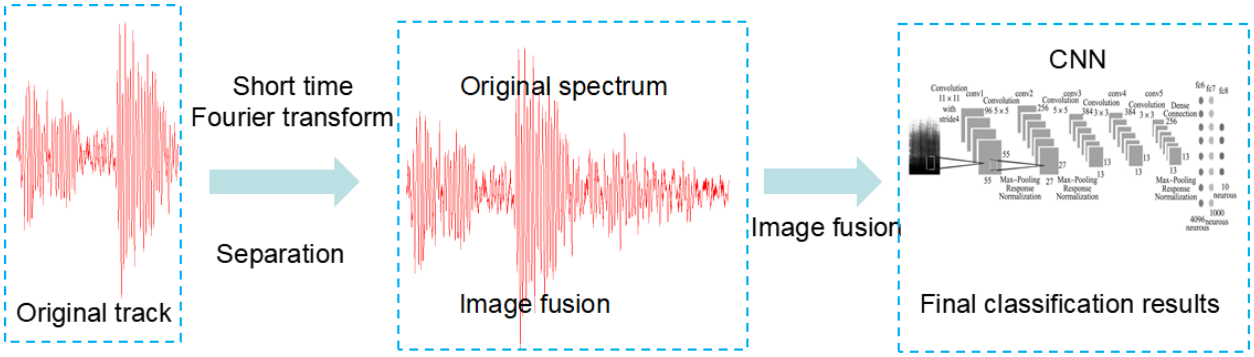

Fig. 3. CNN classification research model.

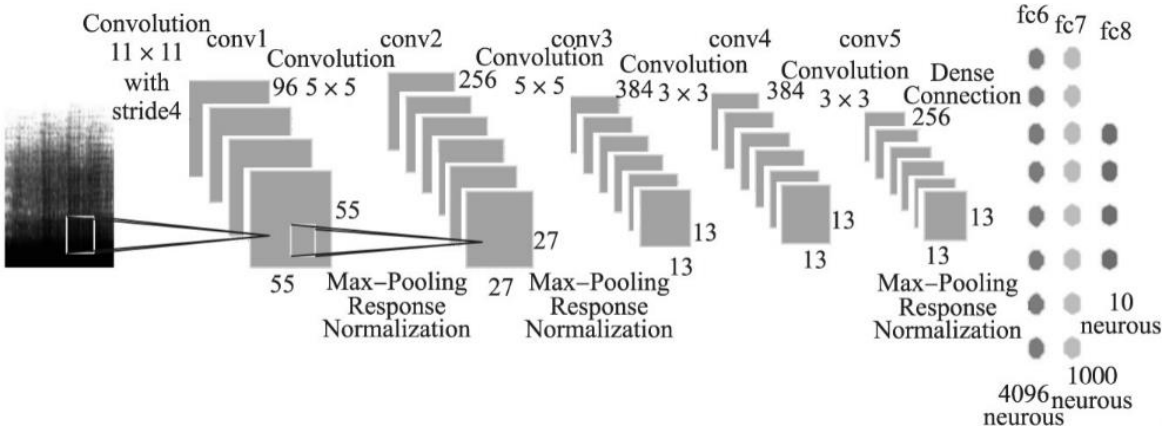

Fig. 4. CNN model.

B. Methods of Network Training and Learning

The Pooling layer uses Max Pooling, and the convolutional and pooling layers appear alternately in the convolutional neural network. Using the stochastic gradient descent (SGD) training network model, it is found that smaller weight attenuation is very important for model learning. Weight attenuation can decrease the training error in the model. Therefore, in the experiment in this paper, fine-tuning to 0.0005 usually, dropout and momentum can improve the learning effect. Since the convergence for all layers using dropout is time-consuming, the dropout value is set to η=0.5, μ= 0.9, λ = 0.0005 in the fully connected layer in the experiment of this paper. There are three fully connected layers in the network structure. The last fully connected layer, i.e., the eighth layer, is the output layer, and the output of the seventh layer is its input, which contains m neurons corresponding to m types of music styles. The output probability is p = [p1, p2,..., pm] T. The SoftMax regression formula is as follows.

$$p_j = \frac{\exp\left(X_8^j\right)}{\sum_{i=1}^{m}\exp\left(X_8^i\right)} \tag{2}$$

where, Xj 8 is the input of the SoftMax function, j is the current class being computed, j = 1,..., m ; pj represents the true output of class j.

C. Model Results and Analysis

In the experiment, the Caffe framework is utilized to train the CNN model to realize the recognition of music style. Using the recognition rate as the performance index, the music signal on the Chinese folk music collection database is the input index, and the 8 types of emotions are the output indexes. Each style category contains multiple audio recordings. The folk music emotion classification model is in Fig. 5.

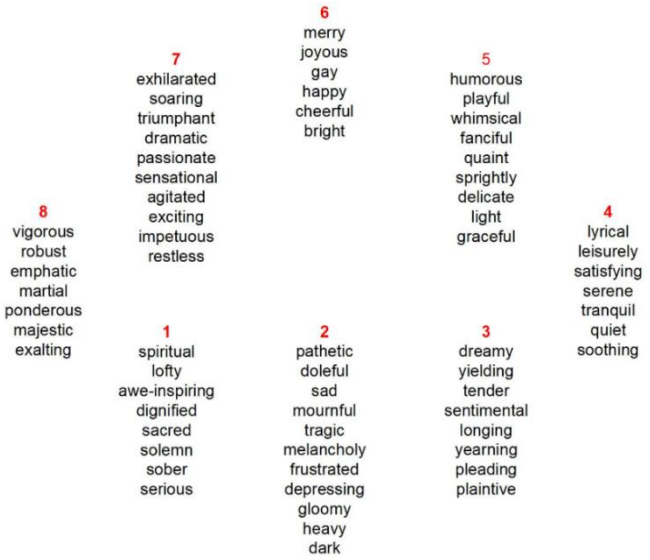

Fig. 5. Folk music emotion classification model.

TABLE I. TRAINING-RELATED HYPERPARAMETERS

Hyperparameters	η	Size	μ	λ	Dropout
Value	0.02	15	0.9	0.0004	0.45

The parameter is to be adjusted when the error rate of the training set becomes small enough and stable. The hyperparameters obtained through this adjustment process are summarized in Table I.

Relation image between iteration times and hyperparameters is shown in Fig. 6 to Fig. 9.

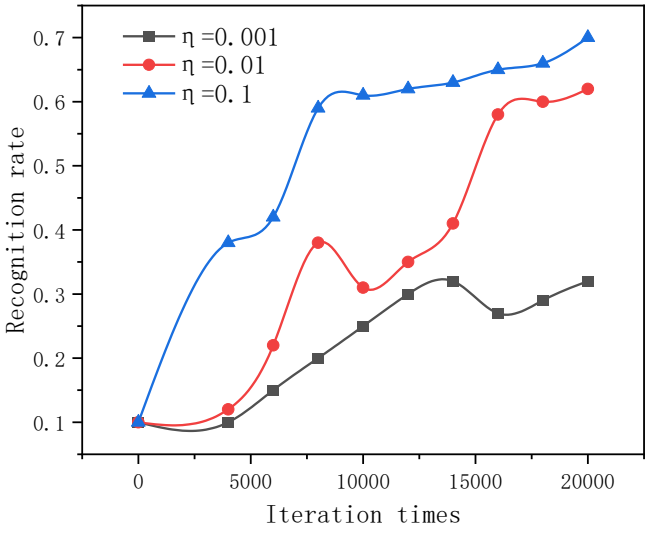

Fig. 6. Learning rate and number of iterations.

Fig. 6 shows that the learning process will be very slow, and the recognition rate is unstable when the training samples are 20000 iterations, and the learning rate η is relatively small as 0.001. Appropriately increasing η can effectively improve learning efficiency. At the same time, if η is too large as 0.1, the learning process will be unstable, and the classification performance will be decreased. Fig. 8 and Fig. 6 illustrate the influence of momentum μ and weight attenuation λ, respectively. Fig. 7 indicates that using momentum μ can accelerate the learning process well.

As shown in Fig. 9, Dropout is a technique for preventing overfitting during the training of neural networks. In the literature, dropout with a 70 % reduction in output is applied to the last fully connected layer. This experiment adopts this technique and scrambles the training data in each round to reduce overfitting. In such research, the output of hidden layer neurons is usually set to 0 with a certain probability, so such neurons will not play any role in forward and backpropagation.

In this experiment, using the hyperparameters set in Table I, the recognition rate is about 73 % without data expansion. The index to realize the correct classification of national vocal music emotion is on the diagonal of the matrix in Table II.

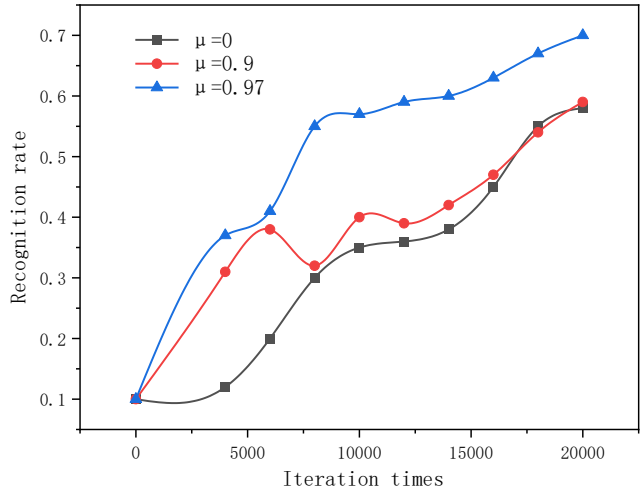

Fig. 7. Momentum coefficient and number of iterations.

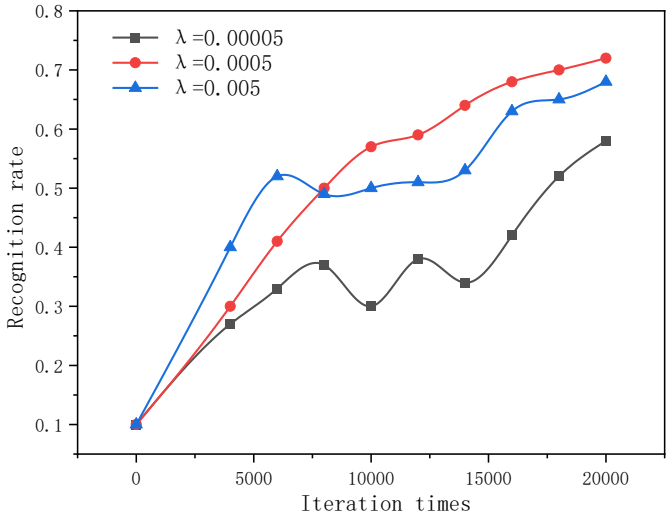

Fig. 8. Attenuation coefficient and iteration times.

D. Research on National Vocal Music Dissemination Mode of Different Emotion Types

After getting different emotional types of folk music, the emotional types of music can be classified and put on the corresponding label in the current mainstream music software. Take the dissemination of national music in microblogs as an example. After researching and analyzing the elements in the communication mechanism, it is not difficult to find that the music communication mode in microblogs is similar to the epidemic communication theory on complex networks. On this basis, by transforming the classic infectious disease communication model, a model consistent with the music communication information in microblogs is constructed to describe the communication process of music information in microblogs and a series of behavioral characteristics to facilitate the study of music communication mode in microblog in the future. Disseminating music information in Weibo, when the communicator sends out the music information, it can be seen by its friends and fans on Weibo. When the recipient receives the information, it can have one or more behaviors, such as forwarding, commenting, and liking, paying attention to private letters, and collecting the choice of music information feedback. Music knowledge, hobbies, friend intimacy, mood, and other conditions influence this choice. Similarly, the complexity of the information itself also determines its communication effect. Whether different music information has a certain value is the basis of its broadcast. The source of music information also restricts the spread of this music. The music information sent by the disseminator with high popularity and great influence is more likely to be disseminated among the audience. This music information can be more identified as meaning or value. Affected by this, the disseminator has a certain probability to choose to forward the content of the entry containing the music information. It can be regarded as an 'infected person', and the music information transmitted can be compared to the 'virus' of an infectious disease. The audience is not interested in the music information contained in this microblog and is regarded as an 'immune person'. They may hinder the praise of friends, spit in the comments or even directly ignore this information. That is the termination of music transmission. Because the music communication network in microblogs is complex and diverse, the scope of the music audience is wide, and the behavior is random and uncertain. To facilitate the research, the music communication is set in microblogs that can only spread from the music communicator to the music audience as its fans. The communicator is set as a node; lines connect the relationship among them, and the music information can only be transmitted through lines. Combined with the influence of the factors in the music communication mechanism, the classical SIR model is improved, and the music communication mode in the mechanism is modeled and studied in Fig. 10.

When the public in the micro-blog does not receive the music information, its node is S after it is 'infected' by the music information, it will be converted to the I state or IR state and the probability of converting into two states is uncertain. If it is transformed into state I, it continues to propagate along the line through the node it is concerned with and eventually transforms into state R; if it is transformed into IR state, it may need to be transformed into R state, or I state through the influence of some other information. In Weibo, music information often has certain timeliness. After some time, the heat of information will gradually decrease, so the characteristics of relay propagation will decrease. At a certain point, the IR state will also change to the R state until only two nodes, S and R, are on Weibo. In studying the music transmission mode in the music transmission mechanism in microblogs, the SIR model of music transmission is constructed by improving the SIR model of classical infectious diseases. It fully considers the rules of music transmission mode in microblogs as much as possible and discusses the influence of nodes and transmission lines. Based on the SIR model of classical infectious diseases, it can combine the dynamic principle of infectious diseases and complex networks to further study the music transmission mode in the microblog. It provides a reference basis and maybe another new direction for music transmission research.

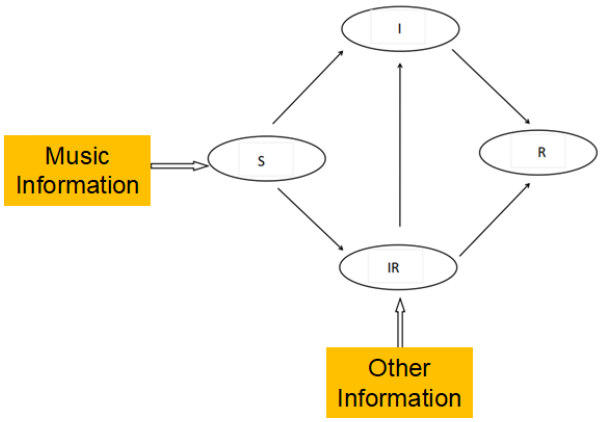

Fig. 10. National vocal music propagation model.

IV. Conclusion

Deep learning accelerates the scope and speed of information dissemination and expands the impact of various disciplines on music dissemination. Based on the innovation of deep learning in music communication, the present work analyzes the challenges brought by deep learning to music communication and looks forward to the future development of the rational application of deep learning in music communication activities. The efficient identification of emotional expression in national vocal music singing through the CNN model has been realized, and the identification accuracy is as high as 92%. With the help of microblog software in China, a new national vocal music promotion model has been designed. The article research is a new attempt at national vocal music research and has certain research value.

Music emotion recognition is an important research direction in music information retrieval. The research of music emotion involves many interdisciplinary such as music and psychology. In this paper, before the model construction, some Chinese folk music was mobile phoned, and a database was established, including eight different types of folk music audio with different emotional characteristics. Firstly, the music features are filtered and extracted, then the deep learning network model is used to process the music, and the features are used as the input of the CNN model to realize the emotional classification of Mongolian music. The final study shows that the accuracy of emotional identification of national vocal music is as high as 92 %, and the new national vocal music communication mode can achieve more efficient national music sharing. Although many researchers have conducted some research on some of these sub-areas and have achieved initial results, music emotion recognition is still in its infancy; there is still a lot of research space. The music emotion recognition work based on Mongolian music faces many problems due to limited conditions and late start.

Availability of Data and Materials

The datasets used in this paper are available from the corresponding author upon request.

Conflicts of Interest

The authors declared that they have no conflicts of interest regarding this work.

Abstract*—The research suggests a unique ensemble learning approach for precise feature extraction and feature fusion from multi-modal medical pictures, which may be applied to the diagnosis of uncommon neurological illnesses. The proposed method makes use of the combined characteristics of Convolutional Neural Networks and Generative Adversarial Networks (CNN-GAN) to improve diagnostic accuracy and enable early identification. In order to do this, a diverse dataset of multi-modal patient medical records with rare neurological disorders was gathered. The multi-modal pictures are successfully combined using a GAN-based image-to-image translation technique to produce fake images that effectively gather crucial clinical data from different paradigms. To extract features from extensive clinical imaging databases, the research employs trained models using transfer learning approaches with CNN frameworks designed specifically for analyzing medical images. By compiling unique traits from each modality, a thorough grasp of the core pathophysiology is produced. By combining the strengths of several CNN algorithms using ensemble learning techniques including voting by majority, weight averaging, and layering, the forecasts were also integrated to arrive at the final diagnosis. In addition, the ensemble approach enhances the robustness and reliability of the assessment algorithm, resulting in increased effectiveness in identifying unusual neurological conditions. The analysis of the collected data shows that the proposed technique outperforms single-modal designs, demonstrating the importance of multi-modal fusion of pictures and feature extraction. The proposed method significantly outperforms existing methods, achieving an accuracy of 99.99%, as opposed to 85.69% for XGBoost and 96.12% for LSTM. The proposed method significantly outperforms existing methods, achieving an average increase in accuracy of approximately 13.3%. The proposed method was implemented using Python software.

Keywords*—Multi-modal medical images; ensemble learning; CNN; GAN; neurological disorders; image-to-image method; transfer learning; feature extraction

I. INTRODUCTION

A neurological condition called Alzheimer's disease (AD) causes diminished cognitive abilities as well as memory and mobility problems. As civilization gets older, this illness affects a growing number of elderly people. According to research, poorer nations have a significantly greater incidence of AD than advanced economies do [1]. MCI gradually develops into AD as the disorder progresses, and early mild cognitive impairment (EMCI) and late mild cognitive impairment (LMCI) are transitional states among healthy normal persons and those with Alzheimer's. Therefore, it is crucial to understand the best way to properly diagnose MCI and AD. The prevalence of brain illnesses has increased recently all across the world. One of the world's most prevalent neurological conditions is Alzheimer's disease (AD) that primarily manifests clinically as diminished memory and loss of mental abilities, along with difficulties with language and abnormalities of movement. AD is currently the fifth most common cause fatalities in the United States. The Alzheimer's Disease Association of USA published an article in 2018. The information provided by the Center for Health Statistics on the rate of change in death from a variety of hazardous illnesses in the US [2]. The number of fatalities from various risk conditions has increased. Moreover, 123% rise in AD prevalence has been reported. Another study found that in 2050, there will be around one million new instances of dementia caused by Alzheimer's, with a fresh case being identified every 33 seconds. One of the main illnesses endangering the well-being of elderly people and having an impact on social sustainability is AD. Presently, only a few medications have proven effective for the medical management

of AD, and no medication has been proven shown to slow or stop the progression of the disease.

Brain tumors currently have the highest early cost per the patient among malignancies. Tumors can develop in humans of any age due to the enormous cell growth in some areas of the cerebral cortex. Brain lesions are caused by uncontrolled growth of cerebral or central spine tissue that can impair cognitive function [3]. These enormous cells of tumors can be divided into two distinct groups: malignant and non-malignant lymphocytes depending on the region, magnitude, and location. The primary and subsequent tumor sites are the intense regions of cancerous cells. The initial tumor region is defined as the first, harmless stages of cancerous cells. According to similar research, numerous medical CBIR approaches have recently been introduced. Most advanced CBIR recovery techniques utilize just one kind of illumination [4]. One method to find the necessary healthcare images over huge collections of images is to employ resemblance contrast, and extraction techniques can allow the user to select the image category first. A CBIR algorithm may gain a lot from effective picture classification because it could eliminate the need to look over pointless images, cutting down on the total amount of images the software must look through.

Non-invasive cerebral imaging techniques have become popular in the past few decades for diagnosing AD. According to these benefits, this method of imaging is both extremely efficient and benign to human cerebral regions [5]. With regard to these benefits, doctors frequently select non-invasive clinical imaging of the brain as one of the most significant medical assessment tools. The images from multiple modes can emphasize various topographical features and geographical aspects of the brain due to the various image philosophies and techniques. Researchers are able to categorize and recognize sufferers more accurately via acquiring these traits, enabling early identification and treatment of diseases. Although modern deep learning techniques are efficient in assessing clinical images of disease progression in AD. In earlier times, scientists have employed spectral evaluation and time-frequency distribution methods like the discrete wavelet transformation method (DWT) and the Fourier transformation method (FT). It is difficult to establish a generic approach for studying different feelings, nevertheless, considering how complicated and personal the mental state is. Frequency component knowledge is insufficient for classifying human feelings for non-stationary EEG signals since it changes over time [6]. Consequently, a continuous wavelet transform (CWT) is yet another method utilized to obtain the complete understanding of frequency of signals in the temporal and spatial arena.

Nowadays, numerous neuroimaging techniques offer different kinds of data. A single method may not always yield enough data to pinpoint the distinguishing characteristic needed to locate AD in a patient. This makes it challenging for therapists to detect AD in its infancy by looking solely at the evidence from a single therapy [7]. Brain structural inequality, neurochemical, and behavioral investigations have investigated and studied a number of biomarkers and provided a variety of information. To enhance the diagnostic efficiency of a computer-aided diagnosis (CAD) framework, it is crucial to incorporate the complementing elements from several modalities. Medical image fusion integrates multiple images collected with different methods to improve the image's quality while maintaining the minute details of a single image. The method of fusion enhances visual data and simplicity, which aids in the diagnosis and evaluation of the condition by physicians [8]. Due to the rapid advancement of high-tech and modern devices, diagnostic imaging has become an integral component of a vast array of applications, including evaluation, investigation, and treatment.

Data that covers multiple kinds and situations is referred to as multimodal information. The main goal of techniques employed for combining multimodal information is to combine the data with characteristics of various dimensions and dispersion into a worldwide space of features so that the information can be expressed more accurately [9]. When performing tasks like categorization and estimation, this homogeneity can be utilized. For instance, data from significant bio banks like the UK Biobank, the Million Veterans Program, and the National Institutes of Health All of Us effort include specific to patient's genome data, diagnostic investigations, and behavioral information from electronic medical records and surveys. Consequently, it is crucial to effectively mix all of the fusion procedures [10]. With minimal computing difficulty, an effective multi-modal fusion technique ought to maximize collaboration among different modes. The Siamese networks have demonstrated outstanding efficiency in a variety of programs, including facial and recognition of handwriting. Furthermore, people transitioning to Alzheimer's disease are identified utilizing an array of recurrent neural network. Although their method is intriguing, it lacks a joint education component that does not calculate ROI-based statistics, which can be inaccurate and cause detection mistakes. To overcome these issues the research produces an ensemble learning approach for multi-modal medical image fusion and feature extraction using convolutional neural networks and generative adversarial networks in diagnosing rare neurological disorders.

The key contributions of the research are given as follows:

- The goal of data collection is to gather multi-modal diagnostic information for neurological illnesses using an ensemble learning approach built on the CNN-GAN technique.
- In order to assure data quality, a thorough data cleaning procedure is used to remove artifacts, noise, and superfluous data.
- The proposed research employs Convolutional Neural Networks, which are recognized for their capacity to automatically collect pertinent organizational traits, are used for feature extraction.
- This work utilizes Generative Adversarial Networks (GAN), which trains on a wider variety of samples to prevent overfitting, are used for data augmentation and picture fusion. In this framework, the discriminator separates created fused pictures from actual images, while the generator aims to create better fused images

that can trick the discriminator and promote adversarial learning.

- When diagnosing unusual neurological illnesses, ensemble learning is used to train several classification models utilizing chosen features, improving accuracy, dependability, and generality.
- To further improve diagnostic accuracy, particularly for illnesses with a low prevalence, ensemble learning incorporates anticipated results from many simulations.

The remaining sections of the research are given as follows. Literature Review is given in Section II. Problem Statement is discussed in Section III. Then Section IV that discusses about the proposed method for diagnosing neurological disorders. Results and Discussions are discussed in Section V. Conclusion is discussed in Section VI.

II. Related Works

Khan et al. [11] discussed in the paper that the body's center of control is the cerebral cortex. As years goes on, more and more brand-new brain disorders have been identified. As a result of the variety of neurological conditions, current diagnosing or detection methods are growing difficult and remain an unsolved scientific issue. Early diagnosis of brain disorders can have a significant impact on efforts to treat them. Artificial intelligence (AI) has been increasingly prevalent in the past few decades, altering virtually every aspect of research, including neuroscience. The deployment of AI in clinical studies has improved the accuracy and precision of neurological conditions diagnosis and treatment. In this research, researchers evaluate current advances in machine learning and deep learning for the detection of four distinct brain disorders, including Parkinson's illness, seizures, brain tumors, and Alzheimer's disease.

Brain disorders are mostly brought on by aberrant brain cell proliferation, which can harm the neural network of the central nervous system and finally result in aggressive cancer of the brain said by Musallam, Sherif, and Hussein [12]. Significant challenges exist when utilizing a Computer-Aided Diagnosis (CAD) technology to make an accurate diagnosis that would allow for effective medication, particularly when it comes to accurately identifying various illnesses in magnetic resonance imaging (MRI) images. In this research, a novel Deep Convolutional Neural Network (DCNN) design for effective identification of tumors such as meningioma, and pituitary tumors is put forward with a three-step pre-processing method to improve the presentation of MRI images. For quick instruction with a greater rate of comprehension and simple startup of the component measurements, the structure leverages sequential normalization. The method of detecting brain deviations, which is crucial for determining the extent to which they are present in MRI scans, is regarded as the biggest downside.

Hashem et al. [13] exposed in the paper that in terms of anatomy, the palate and face house 30–40% of the human body's motor and sensory neurons, showing the intimate link between the cavity in the mouth and the nervous system in general. The duties of an oral surgeon are directly related to the detection of orofacial symptoms of neurological conditions. In order to effectively recognize, diagnose, and make the right choices while managing these related neurologic disorders, dental practitioners must become acquainted with these specific presentations. These symptoms should be thoroughly evaluated with cutting-edge methodologies because it's crucial to spot any associated neurological conditions before they have major repercussions. Additionally, much-planned and successful innovative techniques are required for all types of rehabilitation therapies as well as dental treatment for individuals with neurological conditions.

A comparatively recent innovation called the Internet of Medical Things (IoMT) enables the transmission of health information across a safe network of wearables and healthcare sensors. The disadvantage of this research is that IoMT for dental care concentrates mostly on proactive maintenance methods by identifying the root of tooth decay at the earliest opportunity and disseminating information with the oral surgeon and the consumer round-the-clock. The precise identification of Alzheimer's disease (AD) has been made possible by the integration of multi-modal data, such as magnetic resonance imaging (MRI) and positron emission tomography (PET), which both provide complimentary functional and structural data said by Ning et al. [14]. While their fundamental connections might offer additional distinguishing traits for AD detection, the majority of the present approaches merely combine multi-modal characteristics in the initial location. The issue of the overfitting problem brought on by highly dimensional multimodal information that continues to be intriguing. In order to do this, researchers suggest a relation-induced multidimensional shared representational method of learning for identifying AD. The suggested approach combines reduction of dimension, classification simulation, and representational training into a single architecture.

Rathore et al. [15] discussed in the paper that classifying various patterns of attack for profound implants in the brain is the goal of the deep learning approach. The restricted accessibility of labelled information and the substantial patient-to-patient variation in cerebral implantation impulses pose challenges, though. It is crucial to guarantee the model's accuracy and comprehension for healthcare providers and patients as well as its durability over prospective hostile assaults. In order to allow efficient operation on cerebral implantation gadgets, immediate processing and hardware constraints have to be conquered. Issues over patients' privacy and confidentiality, as well as security concerns, must be carefully taken into account. In order to provide an efficient and safe deep learning system for categorizing assault behaviors in profound cerebral devices, it is going to be essential to overcome these challenges.

Around one percent of the global population suffers from epilepsy, a persistent neurological illness that is defined by an increased frequency of uncontrolled convulsions. The majority of the present epilepsy detection techniques depend heavily on historical patient information, which makes them ineffective when trying to identify fresh patients in a patient-independent environment Zhang et al. [16]. To get across this issue, researchers offer a successful framework for detecting seizures

caused by epilepsy that improves from epileptic events while reducing inter-patient interference. To identify the original seizure-specific information from the unprocessed non-invasive electroencephalography (EEG) recordings via adversarial learning, a sophisticated deep neural network framework is suggested.

The research examines the significance of accurate diagnosis and early treatment of a variety of brain illnesses and emphasizes the contribution of AI and deep learning to increasing diagnostic precision. Brain tumor identification or facial signs of neurological diseases, IoT in dental care, deep learning for brain implant security, and enhanced epilepsy diagnosis are some of the subjects discussed. The study on utilizing technology to improve our comprehension and treatment of neurological diseases is expanding, and these studies add to that body of knowledge.

III. Problem Statement

From the above discussion the literature reveals that the Siamese networks have demonstrated outstanding efficiency in a variety of programs, including facial recognition [17]. The current approach of detecting uncommon neurological illnesses is promising, but it has flaws in terms of accuracy and robustness, largely because it lacks a collaborative education component that includes trustworthy indicators other than ROI-based data. ROI-based data may be inaccurate and might result in missed diagnoses of neurological illnesses that are infrequent. This research suggests an ensemble learning strategy that incorporates multi-modal medical picture fusion and feature extraction approaches to solve these problems and improve the accuracy and reliability of diagnosis. This method uses generative adversarial networks (GANs) and convolutional neural networks (CNNs) to offer a more thorough and efficient diagnosis for uncommon neurological illnesses.

IV. Proposed Methodology

The approach employed for the research concentrates on creating an innovative technique to identify rare neurological disorders by utilizing the combined strength of Convolutional Neural Networks (CNNs) and Generative Adversarial Networks (GANs) for multi-modal medical imaging. The Harvard Atlas Brain dataset is utilized for the process of testing and training. This dataset contains the modality of MRI brain images. This is secondhand to validate the efficiency of the investigation and to diagnose rare neurological disorders. Then, the gathered data are cleaned and any undesirable artifacts, noise, or unimportant data are removed by employing preprocessing procedure. Then, the ensemble learning based on CNN-GAN is utilized for the process of diagnosing neurological disorder. Moreover, it is hired in demand to upsurge accuracy. The recommended CNN-GAN outline's architectural illustration is publicized in Fig. 1.

A. Data Collection

The process of collecting knowledge, data or evaluations from multiple sources to use in investigation, evaluation, decision-making or any other type of specified objective is known as data collection [18]. The Harvard Atlas Brain dataset is utilized for the process of testing and training. This dataset contains the modality of MRI brain images. This is secondhand to validate the efficiency of the investigation and to diagnose rare neurological disorders.

B. Pre-processing

In data analysis and machine learning, pre-processing is a critical phase where unprocessed data is cleaned, converted and structured to render it appropriate for future analysis or model training [19]. Preprocessing aims to enhance the integrity of the data eliminate noise and discrepancies and guarantee that the information arrives in a manner that can be utilized successfully for its intended purpose.

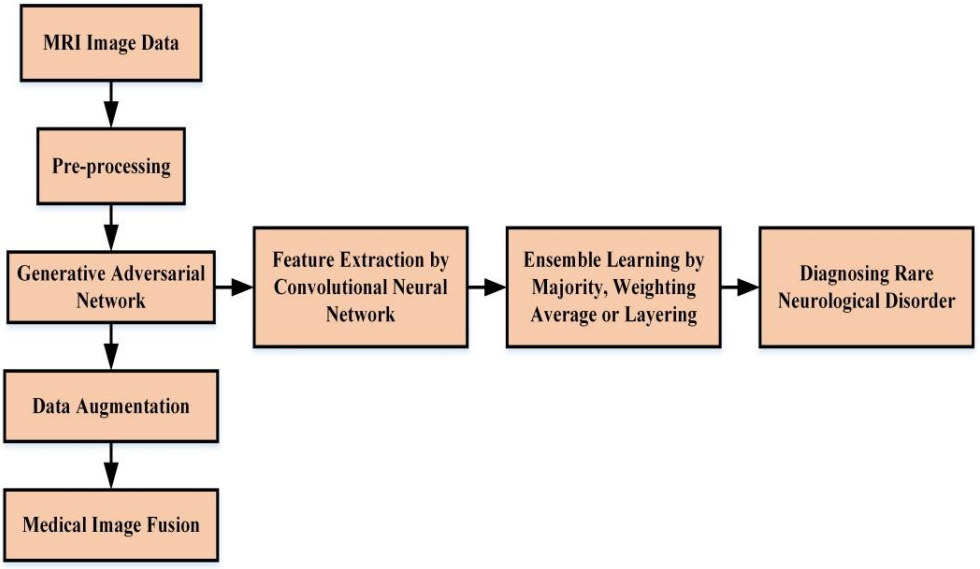

Fig. 1. Proposed ensemble learning based CNN-GAN method.

C. Generative Adversarial Network (GAN)

A machine learning model called a generative adversarial network (GAN) consists of two distinct neural networks such as a discriminator and a generator. Although the system for discrimination attempts to separate genuine data from produced data, the generator creates samples of artificial data. The generator seeks to provide convincing samples to deceive the discriminator, and the discriminator attempts to increase its capacity to distinguish between actual and false information. They are trained in an adversarial manner. GANs can produce high-quality and different information samples via this competitive approach, which makes them valuable for projects like image synthesizing, data enhancement, and style transfer. In Fig. 2, the diagrammatic representation of GAN is depicted.

GANs are employed in multi-modal fusion for the diagnosis of neurological disorders for the reason they are efficient at capturing complicated trends and variations from diverse sources of data, integrating information from multiple sources, performing data enhancement, enabling transfer learning, and aiding in the creation of accurate images or depictions of neurological conditions. By utilizing these skills, GANs improve illness diagnosis' precision, durability, and generalization. The equation for generator and discriminator is given in Eq. (1) below.

$$min_G\, max_D * L(D,G) = F_x{\sim}P_{data}(x)\big[log\big(D(x)\big)\big] + F_y{\sim}P_y(y)[log(1 - D(G(y)))] \quad (1)$$

Here, y is represented as the input of the image; D is the denoted as the Discriminator; G is represented as the generator; F is denoted the expectation operator; x is represented as the real samples. This research's efficacy is considerably increased by including generative adversarial networks by tackling major difficulties in identifying uncommon neurological illnesses. When working with little or unbalanced datasets, as is frequently the case with uncommon conditions, GANs excel at producing synthetic data that closely resembles actual medical pictures. In order to ensure a more varied and representative set of medical pictures for training, GANs can help supplement the dataset, which will ultimately result in a more robust model.

1) Data augmentation by GAN: It is a collection of methods for changing duplicates of already-existing data or creating fresh copies of the database intentionally utilizing the data already present [20]. It serves as normalization during machine learning model training and lessens over fitting.

2) Medical image fusion using GAN: Various medical images possess certain distinctive qualities that call for concurrent observation for clinical diagnosis [21]. Therefore, multi-modality image fusion is used to merge the characteristics of several image detectors into a single image. A cutting-edge method called medical image fusion utilizes GAN to combine data from many healthcare imaging techniques into a single, improved representation. The GAN develops to produce combined images that capture crucial elements from each modality by being trained on pairs of medical images from multiple sources. To provide realistic results with an adversarial loss and to protect important anatomical components with a content loss, this technique improves a loss function. The created composite image can be very helpful in enhancing medical analysis, helping to diagnose diseases, organize treatments, and track patients. Utilizing GANs for medical image fusion has the ability to deliver more and thorough educational data, thereby enabling medical practitioners to make better choices for the welfare of their patients. Before implementing an AI-driven strategy into the healthcare sector a thorough validation and compliance to legal requirements are essential.

D. Feature Extraction by Convolutional Neural Network (CNN)

A key step in deep learning for pattern and image recognition applications is feature extraction and here it is done by Convolutional Neural Networks (CNN). CNNs were created in order to automatically pick up organizational and discriminating characteristics from the raw input images. Small filters are convolved throughout the input image in a sequence of convolutional layers in order to gather regional patterns and characteristics. The boundaries, surfaces, and contours that make up the graphical world are captured by these features [22]. The feature maps are then down sampled by pooling layers, which reduces the computational burden while preserving crucial information. Fully connected layers receive the outcomes of the characteristics learned and use them for categorization or similar tasks in the future. With contemporary effectiveness in challenges like recognition of objects, segmenting an image, and image analysis for medicine, CNNs have achieved impressive results in a variety of applications that use computer vision. This is attributable to their capacity to spontaneously acquire and retain significant characteristics from images. The CNN-based multi-modal fusion technique harnesses the advantages of each method, making up for the limits associated with particular techniques and offering a more thorough understanding of the neurological state by combining data from various modalities. This comprehensive representation improves the model's capacity to provide more accurate and reliable diagnoses, allowing physicians to learn more about the condition of the patient and formulate effective therapies. The diagrammatic representation of CNN is depicted in Fig. 3.

E. Ensemble Learning

A machine learning technique known as ensemble learning integrates the projections of various designs, known as base learners and it is utilized to produce an end result that is more accurate and trustworthy. Ensemble learning tries to enhance efficiency, generalization, and dependability by utilizing the variety of distinct models [23]. The base learners may consist of multiple algorithms or modifications of the exact same algorithm that have been trained on various data groups. The ensemble aggregates its forecasts via techniques like vote by majority, weighted average or layering. Ensemble learning is utilized extensively over multiple fields, such as regression, classification, detection of anomalies and has been demonstrated to be highly efficient in solving complicated issues and producing better final results comparing to individual methods.

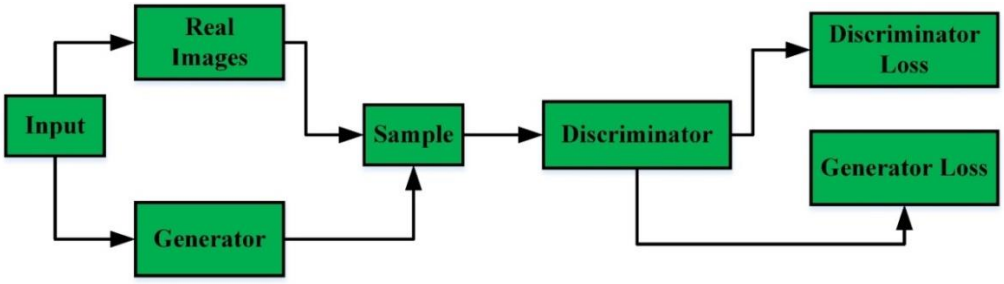

Fig. 2. Generative adversarial network.

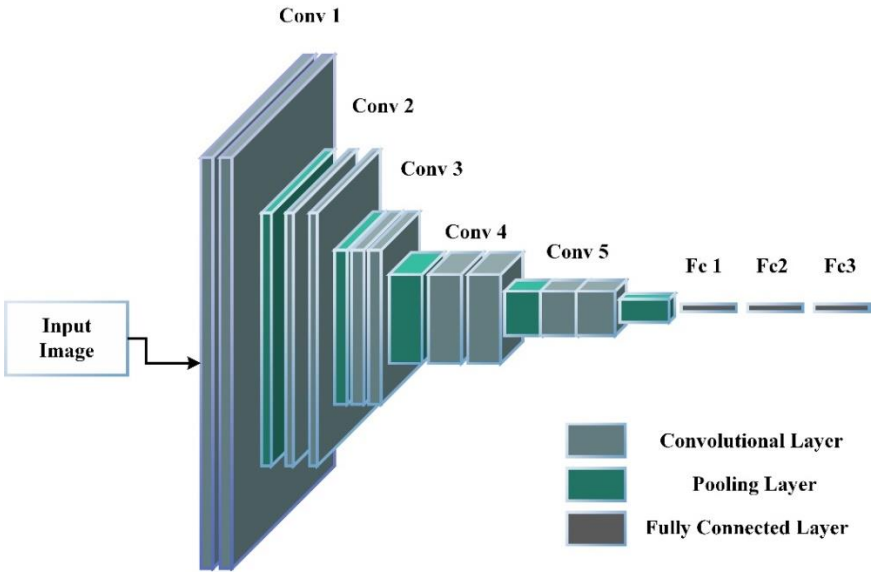

Fig. 3. Convolutional neural network.

1) Vote of majority: A straightforward and well-liked technique for merging the projections of base learners in the classification issue is the vote of majority. The classification for an input provided is predicted by every base learner in the ensemble and the final guess is the collective label that all base learners agree on. In the event of a tie, the category label having the greatest level of probability or likelihood will win. Although the base learners possess a low correlation and prone to engage in various errors, the vote of majority works well because it lessens the effect on particular errors.

2) Weighted average: In problems with regression where the base learners estimate constant outcomes instead of binary class labels, weighted average is frequently utilized. The ultimate prediction is derived by adding the weighted predictions after multiplying each base learner's forecast by the weight. The weights may be chosen independently or by using methods like the cross-validation or minimization.

3) Layering: The process of layering sometimes referred to as stacking, is a sophisticated ensemble learning technique that entails teaching a meta-model, or stacker, to draw knowledge from the forecasts of numerous base learners. Utilizing the provided data as a starting point, the base learners produce guesses; these hypotheses then serve as new characteristics for the meta-model. After learning via these preliminary estimates, the meta-model can subsequently anticipate the outcome. The utilization of stacking enables the ensemble to make the most of the abilities of various base learners and may enhance effectiveness. The algorithm of the proposed ensemble learning is given below and followed by that Fig. 4 depicts the flowchart of the proposed method.

V. Results and Discussions

The recommended method has been inspected by means of some datasets. Here, Ensemble Learning based Convolutional Neural Network and Generative Adversarial Network framework (CNN-GAN) is secondhand in this investigation for the diagnosis of multi modal fusion neurological disorders. Python is the programming language that was employed to construct and carry out the computational methods described in the suggested technique, which were executed utilizing Python software. The description of the recommended technique is reflected by certain features such as Accuracy, Recall, Precision, F1 Score, ROC, Training Accuracy and Training Loss.

A. Performance Metrics

1) Accuracy: The statistic that is the simplest to understand is accuracy, which is expressed as a proportion of all instances that occurred when a data set has been correctly classified. It provides a comprehensive indication of overall correctness. The accuracy calculation is offered in Eq. (2) below.

$$Accuracy = \frac{(TP+TN)}{(TP+TN+FP+FN)} \quad (2)$$

2) Precision: Precision is the ratio of exactly predicted favorable outcomes to all other instances. The precision equation is offered in Eq. (3) below,

$$Precision = \frac{TP}{(TP+FP)} \quad (3)$$

3) Recall: Remember to compute the proportion of correctly anticipated beneficial actions that actually materialized amongst all favorable situations. It increases up how well the algorithm can categorize every favorable circumstance. In Eq. (4), the recall formula is presented.

$$Recall = \frac{TP}{TP+FN} \quad (4)$$

4) F1 Score: Precision and recall are effectively added to create the F1 score. It combines both dimensions to provide a single number that provides a precise evaluation of a representation's effectiveness. In Eq. (5), the F1-Score equation is distributed.

$$F1 - Score = 2 \times \frac{(Precision \times Recall)}{(Precision+Recall)} \quad (5)$$

In Table I and Fig. 5 it shows the values of Accuracy, Precision, Recall and F1 Score of the existing i) XGBoost method [24] ii) LSTM method [25] and the proposed method produces more accuracy of about 99.99%, precision of about 99.13%, recall of about 98.21% and f1 score of about 98.99% than the existing methods.

TABLE I. Comparison Table of Accuracy, Precision, Recall and F1 Score

Method	Accuracy (%)	Precision (%)	Recall (%)	F1 Score (%)
XGBoost	85.69	57.62	63.21	60.22
LSTM	96.12	97.87	90.32	92.96
Proposed Method	99.99	99.13	98.21	98.99

B. Training Accuracy and Training Loss

The proportion of occurrences in the training dataset that were properly anticipated is known as training accuracy, and it shows the extent to which the model works on the data it was developed on. High training precision alone is not enough to guarantee effective generalization to new data because over fitting could lead to poor generalization. The difference among the forecasts made by the model and the actual goals achieved over training is quantified as training loss. By changing the parameters of the model, the goal is to increase the effectiveness of the model on the training data while minimizing the training loss. Considering optimization excessively for training data it can result in inadequate results on new, unforeseen data, finding a balance between low training loss and high generalization is a significant difficulty in machine learning. For the algorithm to produce precise forecasts on new information and to gauge its learning progress, it is critical to track both measures. Fig. 6 depicts the diagram of Accuracy vs. Loss graph.

C. Area under the ROC Curve (AUC-ROC)

A binary classification model's efficacy can be evaluated graphically utilizing the Receiver Operating Characteristic (ROC) curve. For the algorithm's predictions, it displays the true positive rate (sensitivity) versus the false positive rate (1-specificity) across different threshold values. The ROC curve enables users to see the trade-off among the model's tendency to attribute negative examples wrongly and its capability of correctly recognizing positive instances.

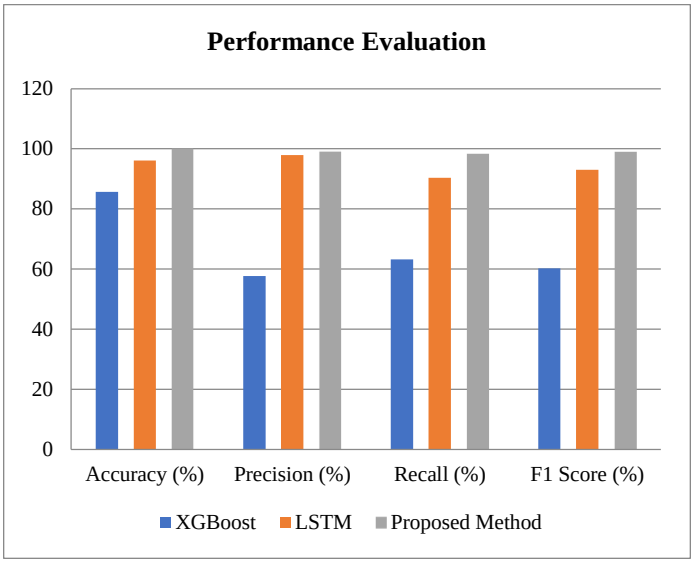

Fig. 5. Comparison graph of accuracy, precision, recall and f1 score.

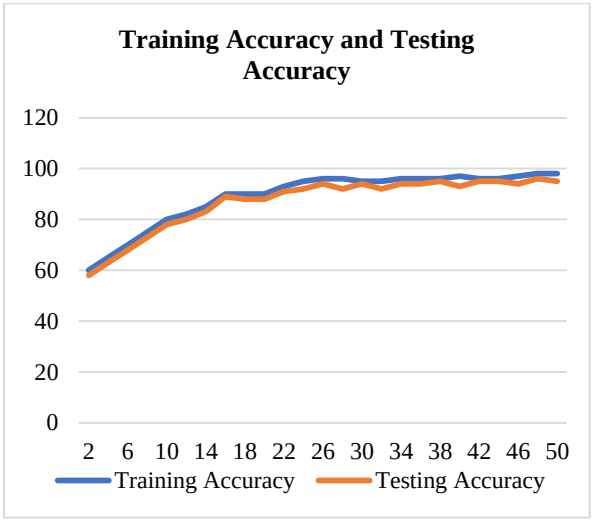

Fig. 6. Accuracy vs loss.

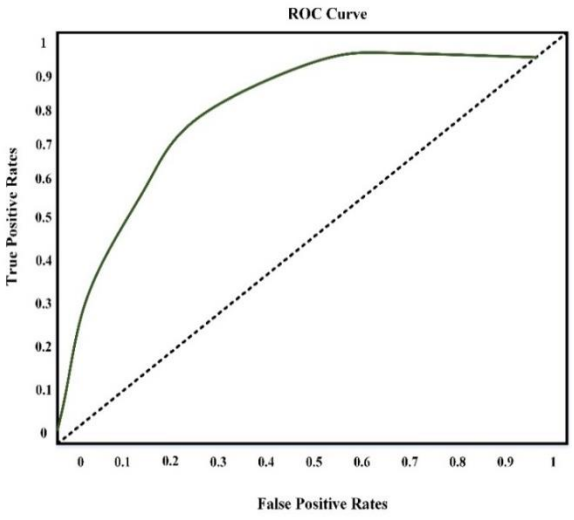

Fig. 7. AUC-ROC.

An ROC curve that crosses the top-left corner of the plot, which denotes a high degree of sensitivity with a low false positive rate, represents the ideal classifier. An AUC-ROC number below 1 implies high classification abilities, while a value near to 0.5 denotes random or poor performance. The area under the ROC curve (AUC-ROC) is an individual scalar statistic calculated from the curve that provides an overview of the model's general efficacy. ROC analysis is utilized frequently in machine learning to evaluate and contrast the performance of classifiers in a variety of programs, including detecting fraud, identifying anomalies, and medical diagnosis and its diagram is depicted in Fig. 7.

D. Discussions

The cumulative corpus of research highlighted highlights the changing face of neurological healthcare, with a focus on the amalgamation of cutting-edge technologies and artificial intelligence (AI). Khan et al. address the growing difficulty of diagnosing and treating an increasing range of brain illnesses,

arguing for the central function of the cerebral cortex as the body's centre of control. The potential transformative influence on diagnostic and treatment precision is highlighted by their investigation of AI applications, particularly in machine learning and deep learning, for the early detection of illnesses like Parkinson's, seizures, brain tumours, and Alzheimer's. Musallam, Sherif, and Hussein [12] offer insightful observations about the connection between neurological illnesses and abnormal brain cell growth. They also suggest a unique Deep Convolutional Neural Network (DCNN) that can be used with advanced pre-processing techniques to improve tumour identification. On the other hand, there is still a significant drawback in the proper diagnosis of many disorders from magnetic resonance imaging (MRI) images. The investigation by Hashem et al. [13] of the relationship between the neural system and the oral cavity emphasizes the importance of oral surgeons in identifying orofacial symptoms of neurological disorders. Although the significance of state-of-the-art techniques for comprehensive assessment is emphasized, the restriction is the narrow emphasis on preventive dental care approaches, which may obscure more general dental health issues. Although novel, the use of the Internet of Medical Things (IoMT) to dentistry is criticized for its restricted focus on preventative maintenance, especially when it comes to detecting tooth decay. Ning et al.[14] 's proposal to integrate multi-modal data for Alzheimer's disease detection tackles the issue of overfitting in highly dimensional data. Deep learning for the purpose of classifying attack patterns in cerebral implants is being investigated by Rathore et al. [15] their work highlights issues with labelled information accessibility, patient-to-patient variability, and the critical need for accuracy, comprehension, and security considerations, including patient privacy. With an emphasis on epilepsy detection, Zhang et al.[16] expose the shortcomings of methods that rely on patient history data and present a deep neural network architecture that is highly intelligent and can learn from epileptic episodes to improve seizure diagnosis. As a whole, these studies highlight the exciting possibilities that artificial intelligence (AI) and technical advancements hold for improving neurological healthcare. However, they also highlight ongoing obstacles that require additional study and improvement before being put into practice.

A novel ensemble learning approach for precise feature extraction and feature fusion from multi-modal medical images to identify uncommon neurological illnesses is suggested in this research. Convolutional neural networks (CNNs) and generative adversarial networks (GANs) are utilized in the suggested strategy in a CNN-GAN combined strategy, with the goal of improving the diagnostic precision and enabling rapid diagnosis. In a broad collection of multi-modal health records, crucial clinical data is effectively combined from multiple approaches by constructing artificial images via GAN-based translation. The assessment of the method's robustness and reliability are increased by the ensemble technique, which employs voting by majority, weighted average, and stacking to combine estimates in order to arrive at the ultimate diagnosis. As a result, it is more effective in identifying unusual neurological illnesses. The technique functions better than single-modal concepts showing the significance of multi-modal fusion of images and feature extraction, possibly offering a quick and reliable detection of unusual neurological disorders, with a combined approach resulting to about 99.99% diagnostic accuracy. To verify the generality and usefulness of this suggested strategy in actual clinical circumstances, further verification on a bigger and more varied dataset will be required.

VI. Conclusion and Future Works

Convolutional neural networks (CNNs) and generative adversarial networks (GANs) are being combined in this study to improve diagnostic accuracy and enable early detection. In order to diagnose unusual neurological illnesses, this work offers a unique ensemble learning technique that successfully mixes and segregates characteristics from multi-modal medical pictures. Critical health data is effortlessly incorporated from diverse medical records using GAN-based translation. The research extracts distinguishing characteristics from sizable clinical imaging databases by utilizing transfer learning inside specialized CNN frameworks, giving a thorough knowledge of the basic pathophysiological concepts. Voting, weight averaging, and stacking ensemble approaches all effectively include hypotheses, greatly improving the identification of uncommon neurological illnesses. With a diagnostic reliability of over 100%, this combination strategy performs better than single-modal approaches. This novel approach has a great deal of promise to transform medical image processing, possibly enabling quick and precise diagnosis, and eventually enhancing patient outcomes. But further testing and real-world applications are necessary. Future research can broaden the ensemble learning strategy to incorporate more sophisticated fusion methods and apply it to different medical specialties. Comprehensive research studies and validation across a larger and more varied patient group are necessary to evaluate the method's practical efficacy and generalizability.

***Abstract*—Patient satisfaction is an assessment that assesses how effectively a company's goods or services fulfil consumer expectations. This study aims to design an architectural framework for a care needs hub for people with disabilities and senior citizens. Using systems modelling for crafting architectural frameworks, the researchers used a 4+1 view model with UML to intensively describe the features of the care needs hub. Quality attributes were used to indicate how well the system would satisfy the needs of the stakeholders beyond its basic functions. The design includes the system's functional and non-functional features, as well as their corresponding diagrams drawn in a unified modelling language in accordance with the 4+1 view model, to assist the system's developer in mapping the system's functionalities correctly and accurately. Architecture models and design patterns are developed and executed to understand how the system's primary components fit together, how messages and data move effectively across the system, and how other structural issues work. The proposed model includes verified and validated development paradigms and architectural and design patterns that may help accelerate the development process. The architecture and design patterns fulfil all of the system's criteria. The researchers designed a comprehensive tool for the completion of the development of the care needs hub, which would greatly help the developers of the system in crafting the correct features and data abstractions needed to build and implement the said system. This research aims to develop an innovative solution that addresses the current challenges faced by persons with disabilities and senior citizens in accessing care services and provides a comprehensive and accessible platform for their care.**

Keywords*—Care need framework; persons with disability; CareAide; 4+1 view model; CareNeed

I. INTRODUCTION

Health and disability are inextricably linked to the housing requirements of senior families. Physical as well as mental performance tends to deteriorate with age, raising the prevalence of limitations linked to movement and activity, self-care, and the capacity to operate a home, all of which may impede older individuals' capabilities to live freely in society [1]. This study examined current levels of disabled people, health developments that may affect the above rates in the future, and the forecasting of both the number and size of prospective families in which one or more people are highly likely to have a disorder in order to best explain the accommodation and care requirements for the older community by 2035. The next section examines our aging population's financial well-being to better understand their ability to fulfil their own housing and care demands.

The World Health Organization says that "health" is a state of complete physical, mental, and social health, not just the absence of illness or incapacity [2]. For our purposes, we're curious about how health, or the lack thereof, impacts housing demands. As a result, we investigate health in terms of how it impacts people's ability to do daily self-care and housekeeping duties autonomously, since such tasks are inextricably linked to mobility about the home as well as prospective demands for help and care. In that facility, not being able to do a key daily task on your own is seen as a useful limitation or handicap.

The phrase "activities of daily living" (ADLs) means personal care responsibilities such as showering, dressing, using the toilet, transporting, and eating. Accessible housing may partially address ADLs inside the home; for instance, issues with bathing and toileting might be improved by the installation of walk-in showers, grab bars, and raised toilet seats. In contrast, those with ADL issues often need the aid of caregivers [3]. "Instrumental activities of daily living" (IADLs) are supportive housing skills related to a person's ability to interact with his or her environment, incorporating tasks like marketing, preparing food, cleaning, mobility, financial management, medication administration, and communication utilization [4]. Physical weakness is a common source of IADL-related difficulties; for instance, laundry and routine house-work might require more endurance or ability than an individual possesses. Nevertheless, some responsibilities, including bill payment, food preparation, and medication administration, may have a stronger correlation with mental wellbeing. People with disabilities are often assessed using a combination of ADL and IADL tests, and their impairments may be both neurological and physical. In this research, we also look at mobility issues such as difficulty traveling, walking, and transporting. Certain movement issues may be resolved by using assistive equipment, such as wheelchairs or walkers. Physical improvements to the house may also be used to solve mobility issues. A single-floor living layout, for example, may reduce the difficulty of ascending steps.

We utilize the National Institute on Aging's 2014 Health and Retirement Study (HRS), a continuous information gathering project, to explore the housing repercussions of impairment in the older population. HRS is unique among many disability assessments for the reason that it provides thorough information on healthcare, including functional limitations for any and all persons in the primary participant's

home, allowing us to evaluate disability and residential consequences for both individuals and households [5]. This research may help us determine the number of elderly families affected by impairment, individual attributes (such as ownership and family structure), as well as the scope of the demand for home modifications and assistance. To implement movement limitations, ADLs, and IADLs, we selected specific activities from the disability research that are evaluated by HRS and categorized them into the following categories: movement liabilities, soul functional limitations, and domestic behavior impairments. Mobility restrictions include difficulties walking, transferring in and out of bed, and climbing stairs. In the literature, the ability to transfer is classified as an ADL because.

Neither moving nor climbing stairs are often considered ADLs or IADLs [4]. Nevertheless, we formed the subcategory of flexibility difficulties in order to examine older people's ability to move into residential houses. The literature classifies eating, Dressing, using the toilet, and bathing independently as ADLs, which are among the four self-care limitations. Limitations at work and at home have included the requirement for assistance with IADLs such as meal preparation, shopping, money management, housework, traveling, using the telephone, and medication administration.

An extensive body of work on ADL and IADL limitations that has developed because the two indicators were established in the 1960s and 1970s also indicates that the frequency of impairment drastically rises with age [6, 7]. There is a correlation between income, educational attainment, ethnic origin, relationship status, and the incidence of disability in the elderly. The unmarried, Hispanics, and non-Hispanic blacks have the highest disability rates, as do individuals with low incomes or poor educational attainment. 5. Our examination of HRS data confirms these findings.

As 41 percent of older adults aged 65 to 79 must have had at least one personality, family activity, or movement limitation, but the proportion increases to almost 71 percent for those aged 80 and beyond. Household activity disability is the most prevalent impairment (see Table I). This is a broad category, with elevated numbers generated most often by observed difficulty with housekeeping and driving, both of which are much more prevalent among older age groups [8, 9].

When addressing the consequences of impairment for older individuals' living arrangements, individual occurrence is less important than family occurrence. For instance, if just one member of a newlywed family has a transportation impairment, the housing unit must be adapted to accommodate that individual, regardless of whether the other spouse doesn't seem to [9].

Disability rates are higher for minority families across all three forms of impairment. Hispanic households had the greatest percentage of mobility disabilities among older households (48%), followed by non-Hispanic Asians or other households (41%). Hispanic homes had the greatest percentage of house-hold activity disabilities (62%), followed by non-Hispanic black households (60%).

In the same way, minority families had a higher rate of self-care handicaps than non-Hispanic white households: 31% of non-Hispanic black households and 35% of Hispanic households aged 65 and older have a self-care handicap, compared to 21% of non-Hispanic white households of the same age [8].

Lower-height appliances may eliminate the need for users to raise their hands above shoulder level. Individuals who use mobility aids, such as wheelchair users, may benefit from wider hallways and entrances that allow them to move around the house more easily. Customer happiness is a metric that reflects how well a company's products or services meet consumers' aspirations. It ranks among the most influential indicators of future sales, customer happiness, and loyalty [11]. Since the coronavirus pandemic began, delivery apps have become increasingly important for both business owners and their customers as more individuals order takeout and groceries. There are delivery apps to get individuals food, groceries, and other necessities, but somehow, they have left a segment of the population in need of care and nursing, the PWDs and seniors who have been abandoned by their loved ones for various reasons, without any outside assistance that can provide the same level of trust and security that have developed in some merchants and delivery apps. Based on the 2015 Census of Population and Housing, 1.44 million Americans, or 1.57 percent of the current population of 92.1 million, have a disability. People with disabilities (PWD) were 935,551 in CPH in 2000, or 1.23 percent of the population. [12-14] Region IV-A has the most PWD among the 17 regions, at 193 thousand. The National Capital Region (NCR) ranked second with 6 million people with disabilities (PWD). The Cordillera Administrative Region (CAR) has the fewest people with disabilities (26 thousand) [2]. Thirteen regions had a higher proportion of PWD than the national average. The top five (1.58 percent) were as follows: Region VI (1.95 percent), Region IVB and Region V (1.85 percent each), Region VIII (1.75 percent), Region II (1.72 percent), Region I (1.64 percent), CAR (1.63 percent), Region XI and Region VII (1.60 percent each), and CARAGA (1.60 percent) [15–20].

TABLE I. DISABILITY MEASUREMENT CHART [9, 10]

Disability related to	Difficulty with
Movement	Walking
	Transferring in and out of Bed
	Climbing Stairs
Personal care	Eating
	Dressing
	Toileting
	Bathing
In-house activities	Meal Preparation
	Food Shopping
	Using Telephone
	Taking Medication
	Money Management
	Housework
	Driving

In 2015, men comprised 50.9% of all PWDs, while females comprised 49.1%. Based on these statistics, there are 104 disabled males for every 100 disabled women. Men with disabilities outnumbered females in the 0–64 age categories. The age range of 0 to 14 years had the greatest surplus of men, with a sex ratio of 121 males per 100 females. In the age range of 65 and above, however, a greater number of females than men have disabilities. This is because females have a higher survival rate than males. In this age group, there were 70 males with impairments for every 100 females. One in five people with disabilities were between the ages of 0 and 14; three (59.0 percent) resided between the ages of 15 and 64; and one (22.1 percent) was 65 or older [21]. Individuals with impairments were more likely to be 5 to 19 years old and 45 to 64 years old. Youngsters between the ages of 10 and 14 were the largest age group among the overall impaired population by five-year age group (7.2 percent). This was followed by those aged 15 to 19 (6.9%), 5 to 9 (6.7%), and 50 to 54 years (6.9%). (6.6 percent) [22–24].

The new model indicates that, with the statistics presented, the researcher is considering creating an app that would allow caregivers, nurses, and other individuals to showcase their services, along with fees and locations, and for PWDs and senior citizens to search for these types of services. Ranging from simple tasks such as pushing their wheelchair to specific locations, such as in the park or outside of their home, to more intensive tasks such as bathing, giving them medicine, and taking care of them as a whole. The researcher introduces the CareAide+ app, a mobile software that allows these consumers to experience and care for those who have been unintentionally or intentionally neglected. The purpose of this study is to design a framework for the development of the CareAide+ mobile application, which is a care-needs hub for people with disabilities and senior citizens. This platform will serve as a hub for people with disabilities and senior citizens who seek care that ranges from simple to intensive; at the same time, it will also create a hub for caregivers, freelance practitioners of caregiving, nurses, and other related services. The hub will open up different types of services and different disabilities that most normal people will never know about. This application can also be used by the loved ones of persons with disabilities or seniors in order for them to check all the necessary things. This CareAide+ app would open a different market that would connect this type of person, find what they need, and showcase what they can offer.

The increasing aging population and the prevalence of disabilities among individuals of all ages have created a growing need for accessible and comprehensive care services. The current pandemic has highlighted the difficulties faced by people with disabilities and senior citizens in accessing essential care services. Therefore, developing an app for a care needs hub can help address these challenges by providing a centralized platform that offers a range of care services and resources for people with disabilities and senior citizens. The research motive for creating an app for a care needs hub for people with disabilities and senior citizens could be to: (a) explore the current challenges faced by persons with disabilities and senior citizens in accessing care services, including issues related to accessibility, affordability, and availability. (b) Identify the specific needs and preferences of persons with disabilities and senior citizens regarding care services, such as personal care, medical support, and social interaction. (c) Evaluate the effectiveness of existing care services and resources, including government-funded programs, private initiatives, and community-based organizations. (d) Examine the potential of technology, such as mobile apps, to enhance the accessibility and quality of care services for persons with disabilities and senior citizens. (e) Develop a user-centered design for the app that considers the unique needs and preferences of persons with disabilities and senior citizens, including accessibility features such as voice recognition and text-to-speech capabilities. (f) Conduct user testing and feedback sessions to assess the usability and effectiveness of the app and identify areas for improvement. (g) Assess the impact of the app on the quality of life and well-being of persons with disabilities and senior citizens, as well as their caregivers and families.

Overall, this research aims to develop an innovative solution that addresses the current challenges faced by persons with disabilities and senior citizens in accessing care services and provides a comprehensive and accessible platform for their care needs.

In this paper, the researchers presented our work part by part and described our relations with others work, which is an overview of the work presented in Section I of the Introduction. Working methods and new models are described in the Section II. Methodology is described in Section II. Results and outcomes are described in Section III. A summary of this research is described in Section IV.

II. METHODOLOGY

To completely envision the functional requirements and necessary processes from the target users' perspectives, a qualitative research design was used in the study. This research design was used for the reason that it is mainly focused on the "why" rather than the "what" of the given situation. The 4+1 view model was also utilized to fully forge the designs for the architectural framework of the study. 4+1 is a view model used for "describing the architecture of software-intensive systems, based on the use of multiple, concurrent views" [31].

The gathered data was mainly from observations and unstructured interviews. An in-depth, unstructured interview with random people with disabilities from different group chats on social media and selected senior citizens was conducted to identify and understand the requirements needed to be incorporated into the study. Through these unstructured interviews, the researchers learn more about the different types of disabilities in different forms, what their current situation is, and how and when they get the care they need for the specifics and for the things that they do not understand about the care given by a non-care practitioner family member. To support the unstructured interviews, observations were made on the situational impacts of people with disabilities and senior citizens. From this data, Fig. 1 shows 4+1 view model was adopted with unified modeling language.

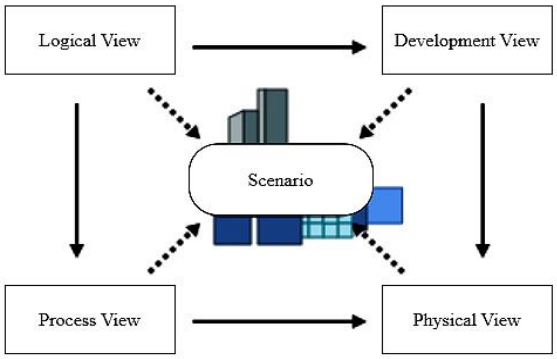

Fig. 1. 4+1 Architectural view model.

A. Related Work

Using a neuromuscular interface controller, a Human Adaptive Mechatronics (HAM) device is controlled. Electromyogram (EMG) signals are used to evaluate muscle movement. A few electrodes placed on the skin's surface can detect the change in signal intensity caused by the voluntary movement of body parts. The EMG signal is employed as the control signal and provides coordination of movement. The signal's amplitude varies in response to muscle activity. The operation of the HAM device is dependent on the amplitude changes in the produced EMG signal. The availability of a cybernetic loop helps balance the system's control error and delayed reaction time. This study describes the operation of a human adaptive neuromuscular interface controller in a mechatronics device with simulations conducted in real time for the various muscle activities, primarily between two actions: voluntary motion and desired motion [25].

The ATM (automated teller machine) system exists to enable a computerized banking network shared by a consortium of banks that includes both human cashiers and ATMs [26]. Each bank maintains its own accounts and processes financial transactions using its own computer. The ATMs interact with the consortium's central computer, which clears transactions with the relevant banks. The ATM interacts with the user, connects with the central computer to conduct transactions, distributes cash, and produces receipts. The system needs proper documentation and security measures. The system must appropriately manage concurrent access to the same account. On their own computers, banks will supply their own software [27].

The architecture of software is concerned with abstraction, deconstruction, and composition, as well as style and aesthetics. In addition, it addresses the design and execution of the software's high-level structure. Architects are responsible for constructing structures utilizing a variety of architectural components in well-considered shapes. These aspects meet the system's primary functionality and performance needs, in addition to non-functional criteria such as dependability, scalability, portability, and system availability [28].

The 4+1 View Model is intended to describe the architecture of software-intensive systems using numerous concurrent views. Each of the five viewpoints focuses on a particular aspect of the system and is detailed with an accompanying notation. These diverse perspectives permit the respective resolution of the issues of the different parties. It may display the architecture from many perspectives and provide the required perspective to various stakeholders. Using an architecture-centered, scenario-driven, iterative development methodology, these perspectives are created [29].

The physical view focuses mostly on non-functional needs and depicts the mapping of software to hardware. The configuration of the hardware has been shown in the physical view. It is necessary to map the many identified components, such as networks, processes, tasks, and objects, onto the various nodes. Certain configurations are used for development and testing, while others are utilized to create the system for different locations or clients [30].

The suggested technique is to assist in resolving the disparity between CRPD guiding principles and regional and national legal practices of interpretation. This technique intends to execute a rhetorical strategy tied to the Thirdness thesis in order to develop a new disability legal culture. Through a thirdness theory, the law of disability, conceived as a unitary figure and inspired by a rhetorical methodology, can contribute to the theoretical evolution of the methodology of legal interpretation without limiting itself to raising fundamental questions of justice philosophy [30], such as a new theory of the concept of a legal person. So, the rediscovery of the rhetorical approach might result in a metamorphosis of legal thinking capable of transcending certain aporia inherent to the positivistic idea of law. In addition, the reintroduction of the rhetorical approach may make it feasible to comprehend the structural function of fiction juris in legal reasoning. A few concluding remarks might be made on the link between ethics and rhetoric with respect to the rhetorical structure of thirdness in the trial, in which the judge is positioned after the parties [31].

Utilizing the Delphi research approach, a search strategy of sites, publications, and research papers was done to design a survey comprising questions about the information, abilities, and actions required to aid a person with an intellectual impairment who has been having mental health issues. A panel of experts evaluated these issues over the course of three polling rounds to determine if they should be included in the recommendations [30].

In total, 53 experts completed all three survey rounds (a retention rate of 67%). During the course of three rounds, 202 items were evaluated, resulting in 170 recommended items that have been put into the guidelines. The recommendations emphasize the necessity of recognizing the distinctive indicators of mental health issues in individuals with an intellectual impairment and of providing appropriate assistance, understanding, and compassion for these individuals. The recommendations will also strengthen caregivers' abilities to confront concerning or economically restrictive behaviors or to access professional assistance whenever necessary. The criteria are going to be employed to create a course on psychological disorders and first aid [31].

III. Results and Discussion

After measured consideration of all gathered data, the following system models were crafted to create a framework for the study, shown in Table II.

A. Scenarios

A limited selection of use cases, or scenarios, are used to show an architecture's definition, resulting in a fifth perspective. The purpose of the diagram was to assist in understanding how the proposed system would function in relation to the actors. They are used for high-level system condition analysis. Fig. 2 depicts the system's overall use case diagram from a higher-level perspective.

The PWD/senior, healthcare professionals, hospitals, administrators, and customer support are the characters in the use case diagram in Fig. 2. The diagram's purpose is to help users update their inquiries and grievances so that the customer service module can deal with them later. Use cases associated with it at a more fundamental level of abstraction include filing complaints about abuse, getting compensation, scheduling meetings with management, and contacting management.

B. Logical View

- The conceptual perspective is centered on the service's final functioning. A static view of the program is provided by the class diagram. One of the key factors in its use during building is that it can be directly mapped with object-oriented languages [32].
- Fig. 3 displays the class diagram for the suggested application. The objective is to make it easier to understand the subtleties of the interactions between various classes. Each class consists of a rectangular box that operates in a different method and accepts attributes [33].

TABLE II. Users Stories from Public Survey

As a	I want to...	so that...
Care Giving Individual	Add a service	I can showcase my services to the needs of PWDs and Seniors and have a decent fee for it
Care Giving Individual	Specify my service	My clients/patients will have accurate knowing of the services and care they need for them or their patient
Care Giving Individual	Upload my credentials and experiences	My clients/patients will have an idea of my credibility to take this service and gain their trust
Care Giving Individual	Write a description of my services	I can describe and thoroughly explain what are this type of services
Care Giving Individual	Specify the fees or amount of my services	My client/patient will have accurate expectations
Care Giving Individual	Specify my location range	My client/patient will have accurate knowing of my location
Care Giving Individual	Specify and list my policies for my service	My client/patient understands my expectations for them.
Care Giving Individual	Respond to messages from clients/patients	I can quickly respond on inquiries about my service listing
Care Giving Individual	Accept requests	I can accept or reject requests to whom I want to have my services
Care Giving Individual	See past reviews of the requester (as client/patient)	I can assess the quality of the requester before I allow them to have my service rendered
Care Giving Individual	See a message history between myself and the requester	I can remember what was communicated between me and my client/patient
Care Giving Individual	Leave a review of a client/patient with an overall rating (1-5)	I feel assured the client/patient will treat me with respect.
Client/patient	Browse services	I can look for certain services upon my needs
Client/ patient	See past reviews of services of care giving individuals, and other services by the same care giving individuals	I can assess the quality of the services and the Care Giving Individual as to the matter of professionalism
Client/ patient	Send a message to the care giving individual as to the services offered	I can ask the care giving individual about anything not covered in the services page.
Client/ patient	See the schedule of a care giving individual if available for	I can plan for the said service offered
Client/ patient	Send a request for available schedule for the service	I can quickly lock down a service offered by the care giving individual
Client/ patient	Include an introduction of myself	I can make the care giving individual feel comfortable about having me as a client/patient and increase the likelihood that they will approve my request.
Client/ patient	Leave a review of the service	I feel assured that the care giving individual will care about my experience.
Client/ patient	Review the accuracy of the service offered (1-5)	I feel assured the care giving individual will be truthful in their service offered page description.
Client/ patient	Review the communication of the host (1-5)	I feel assured the care giving individual will be responsive to my messages.
Client/ patient	Leave a written review (in freeform text)	I can describe my experience in my own words.

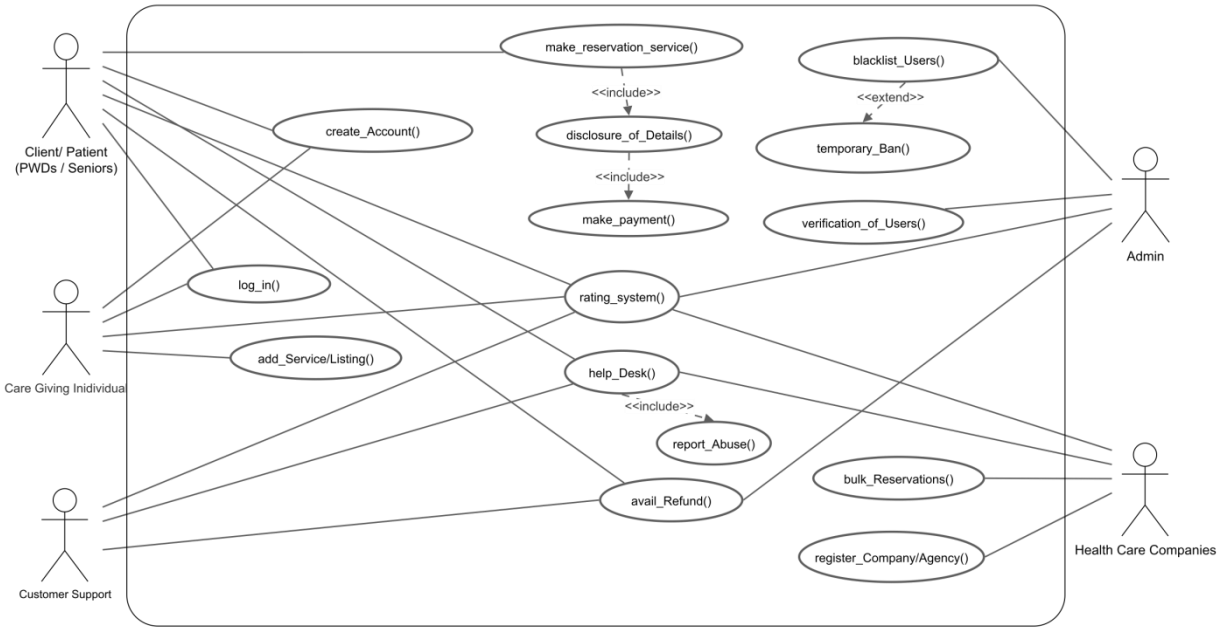

Fig. 2. Use case diagram of CareAide+.

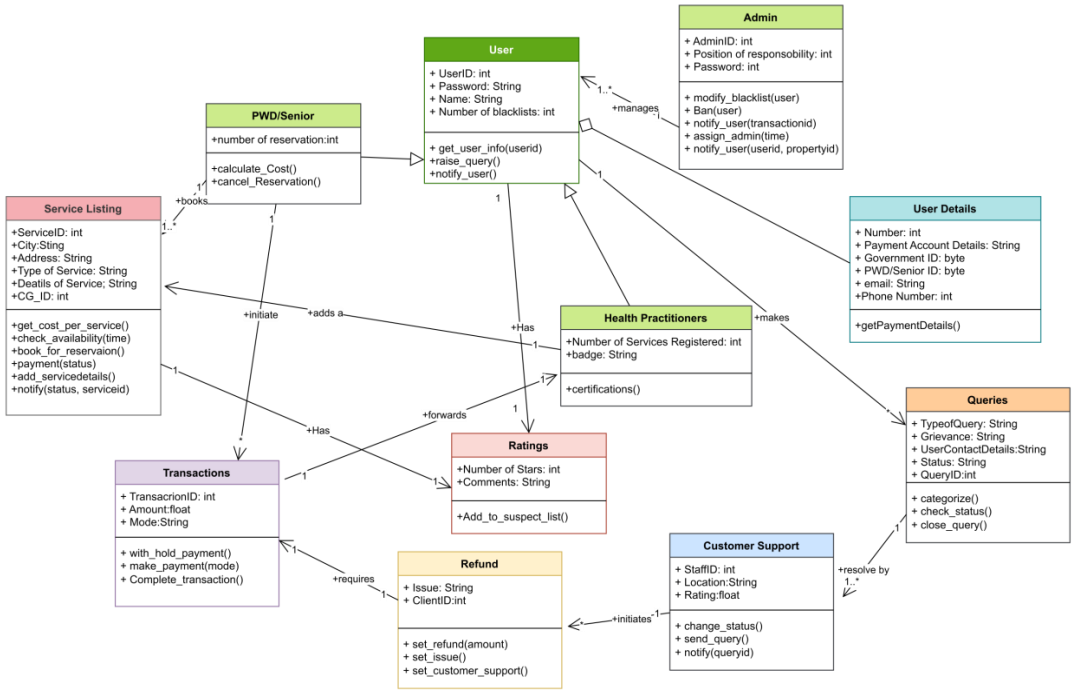

Fig. 3. Class diagram for the CareAide+.

C. Process View

The process perspective focuses on the performance of the service and is concerned with the flexible aspects of the system. It also describes system activities and interactions.

Fig. 4 shows graphical representations that simulate the logic of a complex method, function, or action and describe the intricate details of a UML use case. The flow charts attempted to illustrate the idea of the project's key processes, including developing services, utilizing facilities, and paying for interactions.

According to the flowchart in Introducing a Platform, the current variables are client, service description, administrator, and user information. The administrator must confirm the patient's identity and financial information when the user adds a support showing, which disables the Care Review component and notifies the administrator via the Communication Lineup. If the status is successful, the client or patient is informed and the property listing is updated; if it is unsuccessful, the client or patient is informed. A reference is used to notify the user of a status change in order to avoid cluttering the diagram and make it easier to understand.

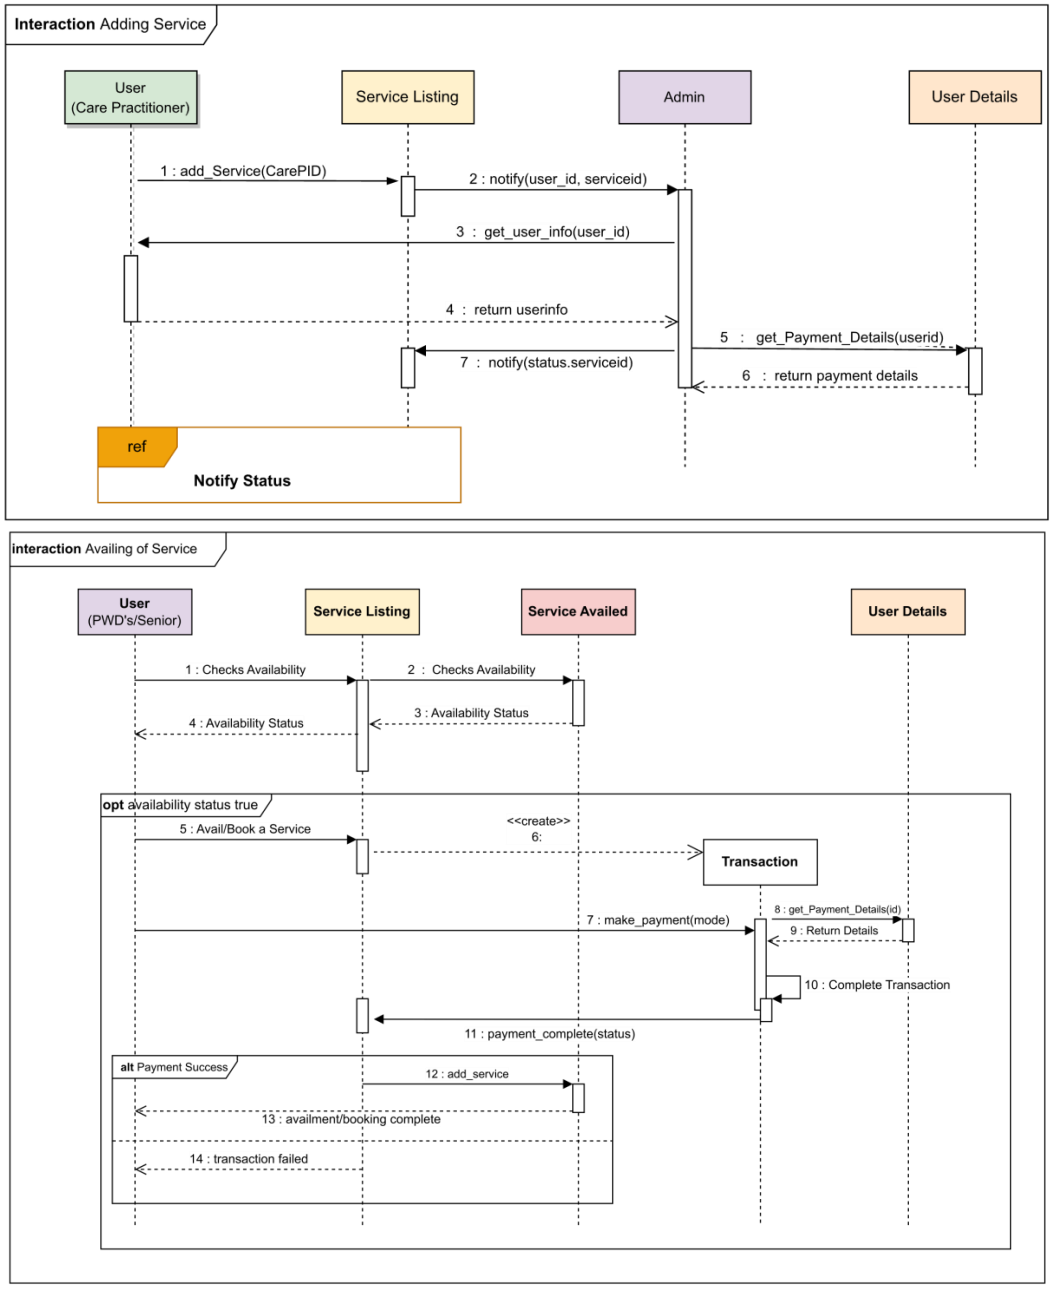

Fig. 4. Sequence diagram for the CareAide+.

In the Availment of a Service, the objects involved are the user, the service listing, the service availed, and the user details. The steps involved in a user requesting a service are shown in this flowchart. The user must first check whether the service is accessible on the date or at the time specified, and only then may the user use the service. When a service is requested, a new instance of the transaction class is created.

The actual perspective, also known as the implementation perspective, illustrates the infrastructure as a technical team would see it. Both the physical connections between software components and their layer-by-layer structure are of interest. Fig. 5 shows how the Layered and Model View Controller architecture pattern worked in the implementation of the visualization services of the CareAide+ application. The Presentation layer adopts the View component to display various visualization layouts and widgets, especially user reviews and ratings. The application or business layer implements the controller component in processing requests and then communicates the result to the persistence layer, where the model component retrieves and updates data with the database layer. The database layer then sends the updates to the persistence layer through the model component until they are displayed in the presentation layer through the view component.

The forecasting model contains data along with the explanation associated with that as well. It describes data transmitted among controlling sections or even other relevant circuitry. A control system module, for example, will fetch

client or patient details from the database. Before putting the data back into the repository or using it to create data that is somewhat similar to it, it tries to manipulate the data. A view is an interface element that contains and presents data. Presentations are made using the information obtained from the model data. A viewpoint asks the model for information in order to give the client a special highlight. The Control System is the system element in charge of interactivity. The controller evaluates the inputs from the user's input devices before deciding how the model and views should react. The model receives instructions from a controller to modify its state (for instance, by saving a specific document). The controller can modify how a view is displayed by sending commands to views that are related to it. For example, scrolling while turning the page.

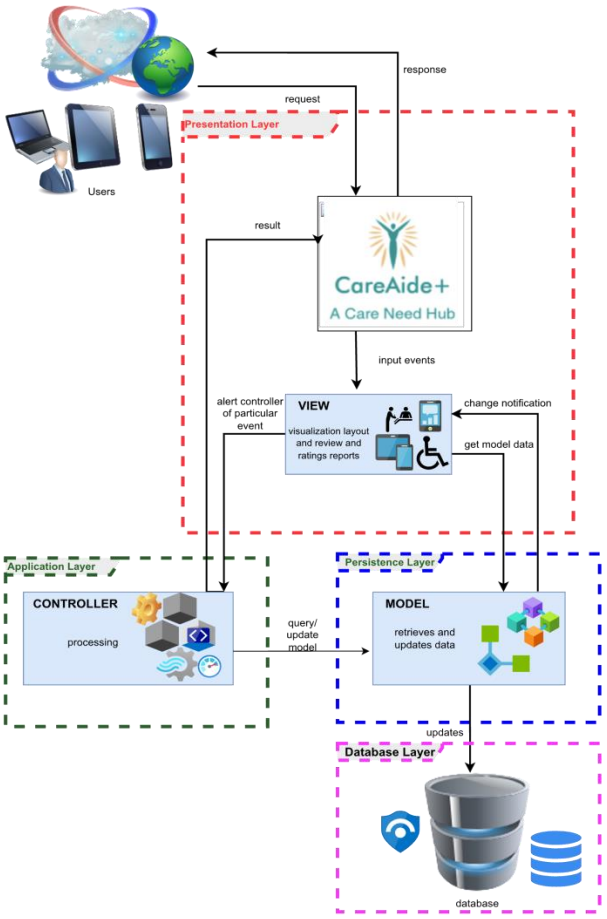

Fig. 5. Architecture design pattern using model-view-controller pattern mapped in a layered architecture for the CareAide+.

The MVC Pattern Interface has advantages such as simple code that is easy to grow and expand. MVC model elements may be tested without the involvement of the user. Assistance for various clienteles is now simpler. It is possible for various components to evolve. By dividing an application into three parts, it helps to avoid complexity. Components include the model, view, and controller. It only uses the Front Controller design pattern, which uses a single controller to route requests from custom applications. It presents the toughest development assistance. It works well for websites that are supported by large teams of web designers and engineers. It guarantees a distinct separation of concerns (SoC) [34]. Search engine optimization (SEO) is friendly since, each class and object is self-contained, you can test each one separately. The MVC design pattern [35] makes it possible to logically group related controller operations. The drawbacks are as follows: Understanding, modifying, unit testing, and reusing this model are challenging. Because the framework introduces additional levels of abstraction that force users to adapt to the MVC decomposition requirements, navigating the framework can occasionally be difficult. No explicit validation support is provided. Data inefficiency and complexity have grown. the difficulty of using MVC with a modern graphical user interface [36]. The use of many programmers is required for parallel programming. It is necessary to be familiar with a variety of technologies and management of several codes in the controller.

IV. Conclusion

The crafted architecture design for the care needs hub application would be a comprehensive tool for the completion of the development. This would greatly help the developers of the system in building the correct features and data abstractions needed to build and implement the said system. The researchers then recommend conducting an in-depth analysis of the features to be included in the application and considering adding payment alternatives or revising payment modules to other modes, like non-monetary things, if it would be possible. According to the research, a hub of helping hands is very important for senior citizens around the world to survive their daily lives. Our model helps to increase humanity, reliability, and confidence all over the world for overaged people. It is possible that in the future, with the help of artificial intelligence, it will be developed for automatic operation. If we are able to develop a model for the care hub that operates on its own, it will be more accurate and have lower costs for individuals.

Implementation of Cybersecurity Situation Awareness Model in Saudi SMEs

Monerah Faisal Almoaigel, Ali Abuabid
Informa Technology Department, College of Computing and Informatics, Saudi Electronic University, Riyadh, Saudi Arabia

***Abstract*—Saudi Small and Medium-sized Enterprises (SMEs) are witnessing rapid growth in technology and innovation. However, this growth is accompanied by increased cybersecurity threats, which pose significant challenges for SMEs. Cyber threats are becoming more complex and sophisticated, with SMEs becoming prime targets due to their weaker cybersecurity defenses. Hence, there exists a rich literature on critical challenges facing SMEs. Existing literature on these challenges addresses many research issues (e.g., finance, technology adoption, and management) associated with SMEs. However, one critical issue that has so far received no rigorous attention is cybersecurity situation awareness for research in the SME context. Thus, this study used a quantitative approach aiming to empirically test a model of cybersecurity situational awareness that can support SMEs in Saudi Arabia to implement cybersecurity measures and precautions with efficacy. An online survey of 350 participants was conducted to collect the research data. The study identified a significant positive relationship between Cyber Situational Awareness (Csa) and Implementation of Cybersecurity Controls (Icsc), suggesting that enhancing awareness can contribute to better control implementation. The study identified a significant positive relationship between Cyber Situational Awareness (Csa) and Implementation of Cybersecurity Controls (Icsc), suggesting that enhancing awareness can contribute to better control implementation. Finally, the paper provides several interesting findings and outlines future research directions.**

***Keywords*—Cyber situation awareness; cybersecurity control and precaution; Saudi; SMEs**

I. Introduction

The Kingdom of Saudi Arabia is rapidly growing in technology and innovation, with Small and Medium-sized Enterprises (SMEs) playing a significant role in this growth. However, this growth comes with increased cybersecurity threats, which pose significant challenges for SMEs. Cyber threats are growing in complexity and sophistication, and SMEs are becoming a primary target for cyber attackers due to their weaker cybersecurity posture. Therefore, SMEs might adopt a robust cybersecurity strategy that includes cyber situation awareness (CSA) to combat cyber threats effectively. SMEs are increasingly becoming targets for cyber attackers. SMEs in the UK alone are targeted by cyber-attacks more than seven million times yearly [1]. Similarly, in Saudi Arabia, a study by [2] found that SMEs were particularly vulnerable to cyber-attacks due to their limited resources and expertise.

One of the main reasons for the high rate of cyber-attacks on SMEs is their perceived vulnerability. Hackers often assume that SMEs have weaker security measures than larger organizations, making it easier to attack targets [3]. Furthermore, SMEs often lack the resources to invest in advanced cybersecurity technologies and hire dedicated staff [2]. As a result, they may be more susceptible to common attacks such as phishing, ransomware, and social engineering.

Cyber-attacks' impact on SMEs can be significant regarding financial losses and reputational damage. A study by [4] found that SMEs in the Netherlands lost an average of £65,000 per cyber-attack. Furthermore, the reputational damage caused by a cyber-attack can be particularly damaging for SMEs, as they may struggle to regain the trust of their customers and partners.

Researchers have proposed various solutions to address these challenges to improve SMEs' cybersecurity posture. These include investing in essential security measures such as firewalls and antivirus software, implementing employee training programs to improve cybersecurity awareness, and developing incident response plans to ensure businesses are prepared to respond to cyber-attacks [5].

Despite the serious consequences of cyber-attacks, SMEs often lack the resources and expertise to implement effective cyber security measures. Therefore, there is a need for a cyber situational awareness model that can assist SMEs in Saudi Arabia to implement cyber security controls and precautions effectively. Thus, this study aims to empirically test a model of cybersecurity situational awareness that can support SMEs in Saudi Arabia to implement cybersecurity measures and precautions with efficacy. Specifically, this study aims to validate the proposed model using empirical data collected from SMEs in Saudi Arabia to ensure its applicability and usefulness in the local context.

Overall, this paper is expected to contribute by providing a practical and effective framework for SMEs in Saudi Arabia to implement cyber security measures, thereby reducing their vulnerability to cyber-attacks. In other words, the extension of Endsley's theory of situation awareness to the cyber security domain can contribute to developing a more comprehensive understanding of how situational awareness can be leveraged to enhance cyber security in SMEs.

The remainder of this paper offers a comprehensive analysis of related literature in Section II. Then, the research approach used in this paper is discussed in Section III and followed by the findings that are presented and discussed in Section IV. Finally, the paper ends by summarizing the key findings, contributions, limitations, and future work in Section V.

II. Literature Analysis

A. Cybersecurity Situation Awareness Model

Situational awareness is a term that originated in the field of aviation in the 1940s and refers to a pilot's ability to accurately understand their current situation and the potential risks and opportunities in the environment around them [6]. Over time, situational awareness has been applied to various fields, including military operations, cybersecurity, and emergency response [7]. In the context of cybersecurity, situational awareness refers to the ability of an organization or individual to understand the current state of their cyber environment, including potential threats and vulnerabilities, and to use this understanding to make informed decisions about how to protect their assets and respond to potential incidents [1].

A cyber situation awareness model is a framework or methodology designed to help organizations improve their situational awareness in the cybersecurity domain. Such a model typically includes a set of processes and tools that enable an organization to monitor its network infrastructure and collect and analyze data about potential threats and vulnerabilities. It makes informed decisions about responding to incidents or improving its security posture [8]. Many different cyber situational awareness models have been developed, each with strengths and weaknesses. Some models are designed for specific industries or organizational contexts, while others are more general. Some models rely heavily on automated tools and data analytics, while others emphasize human expertise and decision-making.

One of the most widely used frameworks in the field of cybersecurity is the Kill Chain framework, which was first introduced by Lockheed Martin in 2011 [9]. The Kill Chain framework is designed to help organizations understand the different stages of a cyber-attack, from initial reconnaissance to final data exfiltration, and to develop appropriate defenses at each stage. The cybersecurity industry has widely adopted many organizations' frameworks to guide their cybersecurity strategies.

Another framework that has gained traction is the Diamond Model, introduced in 2014 by a group from the US Army Research Laboratory [10]. The Diamond Model is based on the premise that cyber-attacks are dynamic. Understanding the relationship between an attacker, a victim, an infrastructure, and an impact helps organizations better understand the threats they face and develop appropriate defenses. The US government and other organizations have used the framework to improve their situational awareness and incident response capabilities [11].

Moreover, the Cyber Security Situation Awareness Framework (CSSAF) was developed by researchers from the University of Plymouth in the UK and is designed to help organizations improve their situational awareness by integrating data from multiple sources, including network traffic, system logs, and threat intelligence feeds [12]. Several organizations have used the CSSAF to improve their cybersecurity posture, and the framework effectively detects and mitigates cyber-attacks.

The MITRE ATT&CK framework is a relatively new situational awareness framework introduced in 2015 [13]. The framework is designed to help organizations understand the tactics, techniques, and procedures (TTPs) that attackers commonly use and to develop appropriate defenses based on this knowledge. Many organizations use the MITRE ATT&CK framework to guide their cybersecurity strategies [14]. The following section will detail the cyber situation awareness models for SMEs in Saudi Arabia.

B. Cybersecurity Situation Awareness Model and Saudi SMEs

Saudi SMEs are businesses with less than 250 employees and annual revenue of less than 200 million SAR [15]. SMEs play a critical role in the economy of Saudi Arabia. Moreover, SMEs represent about 99% of all businesses in the country and employ around two-thirds of the private sector workforce [16].

Despite their significant contribution to the economy, SMEs in Saudi Arabia face several challenges, including access to financing, limited access to skilled labor, and a complex regulatory environment [17]. These challenges can be particularly acute in cybersecurity, where SMEs often lack the resources and expertise to effectively protect themselves against cyber threats. One of the main reasons for the high rate of cyber-attacks on SMEs is their perceived vulnerability. Hackers often assume that SMEs have weaker security measures than larger organizations, making it easier to attack targets [3]. Furthermore, SMEs often lack the resources to invest in advanced cybersecurity technologies and hire dedicated cybersecurity staff [2]. As a result, they may be more susceptible to common attacks such as phishing, ransomware, and social engineering. Cyber-attacks' impact on SMEs can be significant regarding financial losses and reputational damage. The research in [4] found that SMEs lost an average of £65,000 per cyberattack. Furthermore, the reputational damage caused by a cyberattack can be particularly damaging for SMEs, as they may struggle to regain the trust of their customers and partners.

Several recent studies have examined SMEs' challenges and opportunities in Saudi Arabia. For instance, the study in [18] found that accessing finance was one of the most significant challenges facing SMEs in Saudi Arabia. With struggling to secure funding, SMEs needed to grow and expand. The study also identified a lack of skilled labor and bureaucratic red tape as significant obstacles to growth. In addition, the study in [2] found that many SMEs in Saudi Arabia were not adequately prepared to protect themselves against cyber threats. This study also highlighted that only 30% of Saudi SMEs had implemented cybersecurity controls or precautions. Among those that had, many were using outdated or ineffective approaches, such as antivirus software and firewalls.

To address these challenges, researchers (e.g., [19], [20], and [1]) have proposed a range of solutions aimed at improving the cybersecurity posture of SMEs. These include investing in essential security measures such as firewalls and antivirus software, implementing employee training programs to improve cybersecurity awareness, and developing incident

response plans to ensure businesses are prepared to respond to cyberattacks. Overall, the high cyberattack rate on SMEs highlights these businesses' need for greater awareness and investment in cybersecurity measures. While there is no one-size-fits-all solution to these challenges, a proactive and comprehensive approach to cybersecurity can help SMEs mitigate the risks of cyberattacks and protect their businesses.

SMEs should adopt a robust cybersecurity strategy that includes cyber situation awareness (CSA) to combat cyber threats effectively and benefit from greater access to training and resources on cybersecurity best practices. For instance, [21] proposed a framework for improving cybersecurity awareness and education among SMEs. This might help to reduce the risk of cyberattacks and improve the overall security posture in Saudi SMEs.

Furthermore, the research in [22] proposed a model that includes the following components: data collection, data processing, threat identification, and response. They suggest that the model can be used to develop effective cybersecurity strategies for SMEs. Similarly, [23] proposed a cybersecurity awareness model that includes four components: data collection, data analysis, data dissemination, and response. The model can enhance cyber security control and precaution in SMEs.

To gain a comprehensive understanding of the actual cybersecurity practices in Saudi SMEs. The researchers use the proposed model by [1], an extension of Endsley's situational awareness theory [6], to portray SMEs' cybersecurity situational awareness. Fig. 1 portrays the proposed SME cyber security situational awareness model.

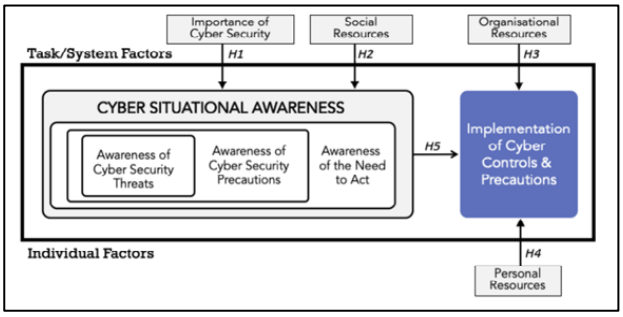

Fig. 1. Cyber security situational awareness in SMEs. (Karen et al., 2021).

The importance of cybersecurity helps SMEs administration understand that maintaining cyber security mechanisms enhances their business continuity. The availability of social resources enhances the awareness of SME administration about cybersecurity threats, precautions that should be applied to respond to these threats, and how they act accordingly. In contrast, the availability of organizational and personal resources facilitates the implementation of cyber controls and precautions. Table I summarizes the hypothesis that needs to be tested to validate the model.

- The first hypothesis (H1) suggests that the level of cyber situational awareness, which refers to understanding potential cybersecurity threats and vulnerabilities, is influenced by how much the SMEs understand the importance of cyber security in the context of Saudi SMEs [1]. This means that SMEs in Saudi Arabia are more likely to better understand potential cybersecurity threats and vulnerabilities if they recognize the importance of cybersecurity.
- The second hypothesis (H2) proposes that social resources influence the level of cyber situational awareness in Saudi SMEs [2] . This means that Saudi SMEs are more likely to be aware of potential cybersecurity threats and vulnerabilities if they access relevant social resources such as expert advice, training, or support from other SMEs.
- The third hypothesis (H3) contends that organizational resources influence the implementation of cyber security controls and precautions in Saudi SMEs [2]. This means that Saudi SMEs are more likely to implement cybersecurity controls and precautions effectively if they have the necessary organizational resources, such as funding, technology, and personnel.
- The fourth hypothesis (H4) presents that personal resources influence the implementation of cyber security controls and precautions in Saudi SMEs [1]. This means that individuals within Saudi SMEs are more likely to implement cybersecurity controls and precautions effectively if they have the necessary personal resources, such as technical skills and knowledge.
- The fifth hypothesis (H5) proposes that the level of cyber situational awareness influences the adoption of cyber security controls and precautions in Saudi SMEs [1]. This means that Saudi SMEs are more likely to adopt adequate cybersecurity controls and precautions to protect their information systems if they are aware of potential cybersecurity threats and vulnerabilities.

TABLE I. PROPOSED RESEARCH HYPOTHESIS

No.	Hypothesis Description
H1	The level of cyber situational awareness in SMEs is influenced by their understanding of the importance of cyber security.
H2	Their social resources influence the cyber situational awareness in SMEs.
H3	Implementing cyber security controls and precautions in SMEs is influenced by their organizational resources.
H4	Implementing cyber security controls and precautions in SMEs is influenced by their personal resources.
H5	Their level of cyber situational awareness influences the adoption of cyber security controls and precautions in SMEs.

III. RESEARCH APPROACH

This study used an online survey approach to understand SME perceptions of factors affecting cybersecurity situational awareness. An online survey was considered appropriate due to fast access to individuals, increased ability to reach difficult contact participants, and ease of having automated data collection, which reduced researchers' time and effort [24]. Furthermore, online surveys save researchers money due to the electronic data collection [25].

The study was conducted in the spirit of the positivist research tradition and followed four stages: literature analysis to develop the theoretical concepts, survey instrument development, administration of the survey, and empirical data analysis. The literature analysis identified a set of cybersecurity situational awareness factors. These served as the foundation for developing an initial survey instrument divided into four parts: profile of responding managers, characteristics of participating business, factors affecting cybersecurity situational awareness in SMEs, and implementation of cybersecurity controls and precautions.

The target online survey participants are SMEs in Saudi Arabia registered with the Small and Medium Enterprises General Authority (Monsha'at) (Small and Medium Enterprises General Authority, 2023). It develops several supporting programs and projects that advance a culture of self-employment, private enterprise, and innovation. It also provides funding sources and develops standards and policies for SMEs.

The online survey was sent (via email and SMEs' social media accounts) to the Saudi SMEs, and 350 responded to the online survey. The obtained low response was not a shock, [26] stated that online survey has often been plagued by low response.

IV. Results and Discussion

A. Importance of Cyber Security (Ics)

The research aimed to assess the importance of cyber security for SMEs, and the participants were asked two items to gather insights into the importance of cyber security in their SMEs. The results revealed that 54.7% of the participants acknowledged that cybersecurity is critical to their business. In contrast, only 5.1% believed it to be of very low importance. Fig. 2 shows descriptive statistics of the importance of cybersecurity 1 (Ics1).

To further understand the participants' approach to recognizing cyber security risks that may affect their business, they were asked about the measures they had taken in the previous year. The responses were diverse, with most participants (a significant portion) indicating that their companies had implemented 10 or more measures to mitigate risks. The second-highest response came from participants who were unsure about the measures taken by their organization. Surprisingly, the lowest response came from participants who felt that none of the options provided were suitable, suggesting a lack of proactive measures. Fig. 3 shows the descriptive statistics of the importance of cybersecurity 2 (Ics2).

Upon analyzing these results, it became evident that participants who perceived their businesses to be at a very high risk of cyber security threats were more inclined to implement more measures to safeguard their operations. Conversely, those who considered the risk shallow exhibited either a lack of awareness regarding the measures taken or a complete absence of proactive actions. Interestingly, despite acknowledging a high risk, some participants did not appear concerned or motivated to take appropriate measures.

		Frequency	Percent	Valid Percent	Cumulative Percent
Valid	High	68	19.4	19.4	19.4
	Low	21	6.0	6.0	25.4
	Neutral	52	14.8	14.8	40.2
	Very High	192	54.7	54.7	94.9
	Very Low	18	5.1	5.1	100.0
	Total	351	100.0	100.0	

Fig. 2. Descriptive statistics of the importance of cybersecurity 1(Ics1).

		Frequency	Percent	Valid Percent	Cumulative Percent
Valid	1-5 Times	64	18.2	18.2	18.2
	10+ Times	97	27.6	27.6	45.9
	6-10 Times	47	13.4	13.4	59.3
	I Don't Know	94	26.8	26.8	86.0
	None	49	14.0	14.0	100.0
	Total	351	100.0	100.0	

Fig. 3. Descriptive statistics of the importance of cybersecurity 2(Ics2).

These findings highlight the varying levels of awareness and response to cyber security risks among businesses. While some organizations take significant measures to protect their assets, others may not fully recognize the potential consequences or lack the necessary resources or knowledge to address these risks adequately. It emphasizes the importance of raising awareness, enhancing education, and promoting a proactive approach to cyber security across all businesses, regardless of their personal resource levels. Fig. 4 shows the correlation between Important of Cybersecurity (Ics1) and (Ics2).

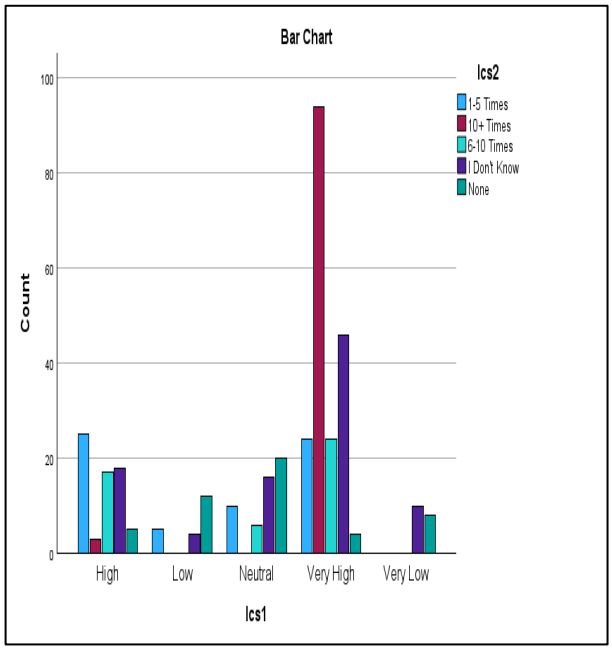

Fig. 4. Correlation between Importance of Cybersecurity (Ics1) and (Ics2).

B. Social Resources (Sr)

As part of the social analysis, the researchers formulated three items for the participants to gather insights into the perceptions surrounding cybersecurity practices in Saudi SMEs. The questions focused on competitor measures, customer data safety, and B2B suggestions regarding cyber security. The responses to these questions were consistent, with the highest number of participants strongly agreeing that cybersecurity practices are in high demand across all cases. This indicates a widespread recognition among participants that implementing robust cybersecurity measures is crucial in various aspects of business operations. Fig. 5 illustrates the correlation analysis of Social Resources (Sr1), (Sr2), and (Sr3).

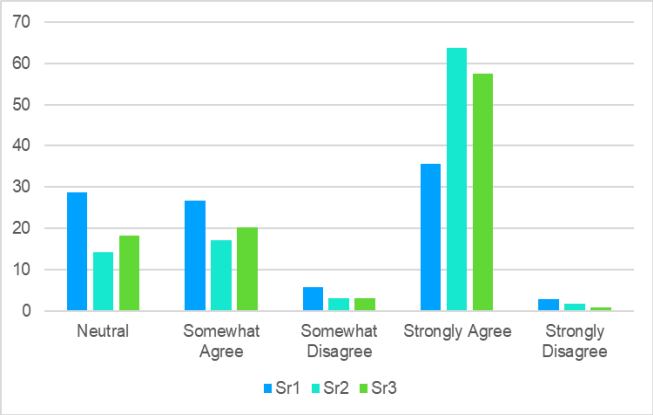

Fig. 5. Correlation analysis of social resources (Sr1), (Sr2) and (Sr3).

Firstly, when asked about their competitors' measures in implementing cybersecurity, many participants strongly agreed that such practices are highly sought after. This suggests that businesses in the same industry increasingly adopt cybersecurity measures to protect their valuable assets and sensitive information. Secondly, participants were asked about the safety of customer data. Once again, a considerable majority strongly agreed that ensuring customer data security is paramount. This underscores the growing awareness among businesses regarding the potential risks associated with data breaches and the need to safeguard customer information. Lastly, regarding B2B suggestions regarding cybersecurity aspects, participants strongly agreed that cybersecurity practices are in high demand. This indicates that Saudi SMEs engaging in B2B relationships are becoming more proactive in emphasizing the importance of cybersecurity and expecting their partners to implement robust measures to protect shared information and maintain a secure business environment.

Taken together, these findings paint a clear picture that in the context of Saudi SMEs, cyber security practices are highly regarded and in-demand from a social perspective. SMEs and their stakeholders recognize the significance of implementing effective security measures to mitigate the risks posed by cyber threats. This growing emphasis on cybersecurity highlights the need for continuous improvement and adaptation to address the evolving landscape of cyber threats in the SME's environment.

C. Organizational Resources (Or)

To perform organizational analysis, the researchers devised four items to gain insights into participants' perspectives on cybersecurity within their respective organizations. These questions focused on organizational-provided cybersecurity information, information-seeking behaviors, agreement that SMEs struggle to manage all the advice provided, and the impact of on-air cybersecurity advice on their work. Upon analyzing the responses, varied opinions across all question designs within this category were observed. Most participants tended to provide responses leaning towards the Neutral or Somewhat Agree spectrum. This indicates a lack of strong agreement or certainty regarding the organizational perspectives on cybersecurity or the scenarios presented.

Firstly, participants were asked about the availability of cybersecurity information provided by their organizations. The responses varied, with many participants expressing neutrality or a somewhat agreeable stance. This suggests that the participants may not view the organizational provision of cybersecurity information as highly reliable or effective. Secondly, participants were asked about their information-seeking behaviors regarding cybersecurity. Once again, the responses tended towards a neutral or somewhat agreeable position. This implies that participants may not actively seek out additional cybersecurity information beyond what is provided by their organization, or they may feel uncertain about the effectiveness of their information-seeking efforts. Fig. 6 displays the correlation analysis of Organizational Resources (Or1), (Or2), (Or3) and (Or4).

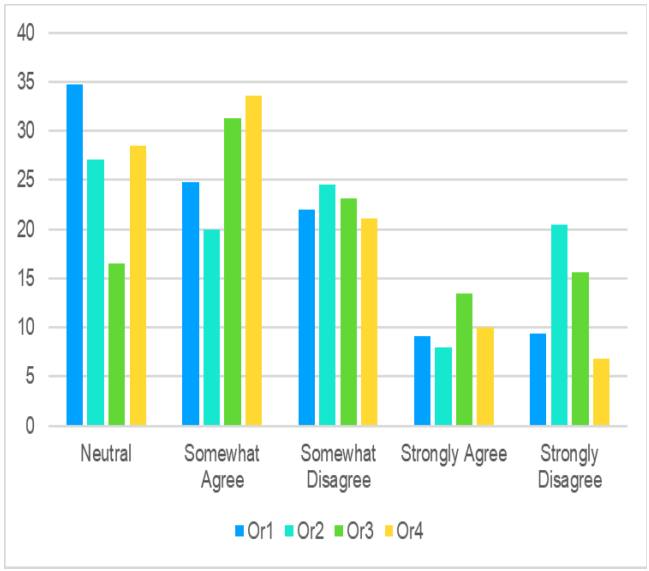

Fig. 6. Correlation analysis of organizational resources (Or1), (Or2), (Or3) and (Or4).

Furthermore, participants were presented with a statement regarding SMEs' ability to manage all the cybersecurity advice provided to them. The responses predominantly reflected a neutral or somewhat agreeable perspective. This suggests that participants may perceive SMEs to face challenges in effectively managing and implementing the abundance of

cybersecurity advice available. Lastly, participants were asked about the impact of on-air cybersecurity advice on their work. The responses once again leaned towards a neutral or somewhat agreeable standpoint. This indicates that participants may find it difficult to assess the relevance or applicability of on-air cybersecurity advice to their specific organizational context, potentially making their work more challenging.

The analysis of these independent responses reveals a lack of solid agreement or certainty among participants regarding their organizational perspectives on cybersecurity. The prevalence of neutral or somewhat agreeable responses suggests that participants may harbor reservations or uncertainties about the effectiveness, relevance, or practicality of their organizations' cybersecurity measures and advice. This highlights the importance of addressing these concerns and fostering more precise communication and understanding between organizations and employees regarding cybersecurity practices.

D. Personal Resources (Pr)

In personal resource analysis, the researchers posed five items to participants regarding their personal abilities in handling, managing, or implementing cybersecurity measures on their own. Additionally, they were inquired about their perceptions of personal information safety. The responses from participants yielded various results, mirroring the findings from the analysis of organizational resources. In many cases, participants expressed a somewhat agreeable or disagreeable stance toward the statements, indicating a potential lack of knowledge or familiarity with cybersecurity. Most participants may possess limited understanding or proficiency in this area, while a minority group demonstrated strong knowledge and capability to handle unforeseen cybersecurity situations.

Firstly, participants were asked about their personal abilities in managing cybersecurity. The responses revealed a range of opinions, with many participants leaning towards a somewhat agreeable or disagreeable standpoint. This suggests that many participants may lack the necessary skills or knowledge to handle cybersecurity matters on their own effectively. Fig. 7 illustrates the correlation analysis of Personal resources (Pr1), (Pr2), (Pr3), (Pr4) and (Pr5).

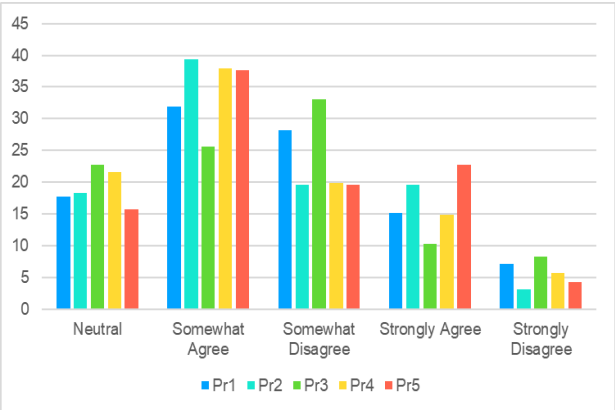

Fig. 7. Correlation analysis of personal resources (Pr1), (Pr2), (Pr3), (Pr4) and (Pr5).

Furthermore, participants were questioned about their personal information safety. The responses showcased a mixture of perspectives. Many participants tended to express a somewhat agreeable or disagreeable viewpoint, indicating that they may not have a strong confidence in the security of their personal information.

The analysis of these personal resource responses highlights a significant knowledge gap or lack of familiarity with cybersecurity practices among the participants. While a minority group demonstrated competence in handling cybersecurity matters, most appear to possess limited understanding or capability in this domain. This emphasizes the importance of raising awareness and providing education and resources to enhance individuals' personal cybersecurity skills and knowledge. We can collectively strengthen our overall cybersecurity posture by empowering individuals to protect their personal information better and effectively respond to cybersecurity threats.

E. Implementation of Cyber Controls and Precautions (Icsc)

To gain insight into the organizational setup, the researchers gathered information from the participants regarding the number of cybersecurity controls implemented by their SMEs and the extent to which their security policies covered various aspects. Upon analyzing the responses, the researchers observed a higher frequency of participants, indicating a lack of knowledge about these aspects. This suggests that many participants were unsure or unaware of the specific controls in place within their organizations. However, it is worth noting that the second and third most common responses indicated that their businesses had implemented between 1 and 5 controls and 10 or more controls, a positive indication of proactive security measures being taken. Fig. 8 displays the descriptive statistics of Implementing Cyber Controls and Precautions (Icsc1). Nevertheless, the fourth highest response rate was recorded for the option "none," implying that there may be certain aspects of cybersecurity that were overlooked or not adequately covered by our survey questions. This signifies a potential gap in assessing the participants' understanding of their organization's cybersecurity practices.

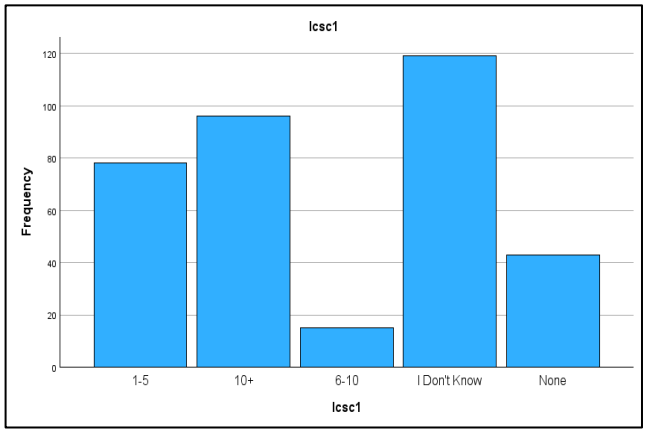

Fig. 8. Descriptive statistics of implementation of cyber controls and precautions (Icsc1).

It is crucial for the researchers to address this limitation and explore additional areas of concern that might have been missed in the initial survey design. Another significant finding is that most participants expressed a lack of awareness regarding their business's actions pertaining to cybersecurity. This highlights a concerning lack of knowledge or visibility among participants regarding the specific measures and initiatives their organizations undertake to mitigate cybersecurity risks. Fig. 9 shows the descriptive statistics of Implementing Cyber Controls and Precautions (Icsc2).

These findings underscore the importance of enhancing communication and awareness within organizations regarding cybersecurity practices. Providing employees with comprehensive information about the implemented controls is crucial, and ensuring they understand their roles and responsibilities in maintaining a secure environment is crucial.

Additionally, conducting more comprehensive assessments and addressing the areas of uncertainty can help organizations identify and rectify potential gaps in their cybersecurity strategies.

F. Reflective Measurement Model

In this research paper, the researchers analyzed several factors representing underlying factors presented in Table II. These factors include "Importance of Cybersecurity," "Social Resources," "Organizational Resources," "Personal Resources," and "Implementation of Cybersecurity Controls." The researchers also have a formative construct called "Cyber Situational Awareness."

To evaluate the reflective constructs, we examined the item loadings of their indicators. Item loadings indicate the strength of the relationship between each indicator and its respective factor.

Most of the item loadings were slightly below the recommended threshold of 0.708. (Hair Jr et al., 2021) suggested a relatively strong association between the indicators and their factors. However, five items, specifically Or2, Or3, Or4, Pr2, and Pr5, had item loadings below the threshold.

The researchers also assessed the internal consistency reliability of the reflective factors using composite reliability and Cronbach's alpha. Composite reliability values measure the reliability of the items in capturing the factors, while Cronbach's alpha estimates the internal consistency of the item set. Although most composite reliability values were below the satisfactory threshold of 0.70, none were problematically high (above 0.95) [27].

The researchers examined the average variance extracted (AVE) for each factor to evaluate convergent validity. AVE represents the proportion of variance in the items explained by the factor. Three factors had AVE values above the acceptable threshold of 0.50, indicating that they explain significant variance in the items [28]. However, "Organizational Resources" and "Personal Resources" had AVE values below 0.50, suggesting that they explain a relatively smaller proportion of variance in their items.

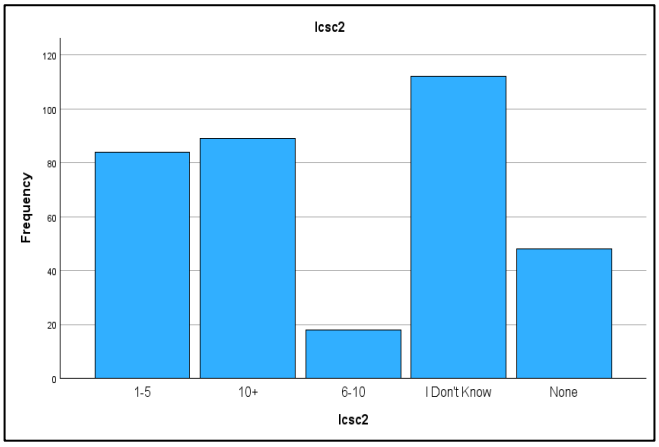

Fig. 9. Descriptive statistics of implementation of cyber controls and precautions (Icsc2).

TABLE II. RESULT SUMMARY FOR REFLECTIVE MEASUREMENT MODEL

Factor	Items	Loadings	Indicator reliability	AVE	Composite reliability	Cronbach's alpha	Discriminant validity
Importance of Cybersecurity	Ics1	.829	.702	.6408	0.69576	.415	Yes
	Ics2	.771	.731				
Social resources	Sr1	.718	.706	.5430	0.659471	.324	Yes
	Sr2	.765	.692				
	Sr3	.727	.694				
Organizational resources	Orl	.756	.694	.4608	0.611686	.299	Yes
	Or2	.648	.699				
	Or3	.680	.692				
	Or4	.624	.699				
Personal resources	Pr1	.719	.699	.4783	0.68684	.354	Yes
	Pr2	.669	.693				
	Pr3	.736	.706				
	Pr4	.748	.696				
	Pr5	.571	.690				
Implementation of cyber security controls	Icsc1	.898	.725	.8227	0.884216	.542	Yes
	Icsc2	.916	.724				

G. Result for Formative Construct Significance Testing

Table III displayed the results of a statistical analysis conducted on a formative factor named Cyber situational awareness "Csa category." This factor comprises four formative items: Csa1, Csa2, Csa3, and Csa4. Examining the outer weights column, it was observed that the relative importance of each item in shaping the overall formative factor. Higher values indicate a more significant influence of the respective item on the factor. Notably, Csa1 possesses the highest outer weight of 0.766, signifying its prominent role in defining the factor compared to the other items. Moving on to the T-value column, the statistical significance of the relationship between each item and the formative factor was assessed. Higher T-values indicate a more substantial relationship. All items exhibit considerable T-values, with Csa1 boasting the highest at 72.801. These results suggest that all items significantly contribute to the formative factor. The P-value column enables evaluating the level of significance associated with each item. P-value lower than the chosen significance level (typically 0.05) indicates statistical significance, implying that the indicator's relationship with the factor is unlikely to occur randomly [28]. In this analysis, all items demonstrate exceptionally low P-values (0.000), confirming their statistical significance.

In the 95% BCa confidence interval column, the researchers encountered a range that estimates the true relationship between each item and the formative factor. Narrower intervals indicate higher precision in estimating these relationships. Notably, all items exhibit relatively tight confidence intervals, suggesting high precision in capturing their relationships with the factor. The "Significance" column provides a succinct indication of the statistical significance of each item. In this case, all items are marked as "Yes," signifying their significant impact on the formative factor. These findings underscore the substantial importance of all four items (Csa1, Csa2, Csa3, and Csa4) in defining the formative factor. The high outer weights, significant T-values, low P-values, and narrow confidence intervals collectively provide strong evidence of the meaningful contribution of each item. Consequently, these results significantly enhance our understanding of the investigated phenomenon.

H. Results of the Structural Model Path Co-Efficient

In Table IV the hypothesis column represents the specific hypotheses being tested in the analysis. The hypotheses are labeled as H1, H2, H3, H4, and H5, indicating different relationships between the dependent and independent variables. Where D-I column specifies the dependent and independent variables involved in each hypothesis. It indicates the direction of the relationship being examined. For example, H1: Cyber situational awareness - Importance of cyber security (Csa-Ics) indicates that the independent variable Cyber situational awareness "Csa" is hypothesized to influence the dependent variable Importance of cyber security "Ics." The path coefficients in the hypothesis table indicate the strength and direction of the relationships between variables. Positive coefficients in H1 and H2 suggest that increasing Csa positively impacts Ics and social resources (Sr), respectively. The negative coefficient in H3 indicates that an increase in Icsc is associated with decreased organizational resources (Or). However, the relationships in H4 and H5 are not statistically significant, suggesting that the coefficients may not accurately represent the true impact.

Overall, the path coefficients provide valuable insights into the relationships between variables, highlighting significant associations and the need for further investigation in non-significant cases.

T-value provides information on the statistical significance of each path coefficient. The T-values indicate the degree to which the observed path coefficients deviate from zero. For H1, the T-value of 1.999 indicates a statistically significant relationship between Csa and Ics. Similarly, H2 shows a highly significant relationship between Csa and Sr, with a T-value of 4.837. In contrast, H3 reveals a statistically significant negative relationship between Icsc and Or, as indicated by the T-value of -2.492. However, H4 does not exhibit a significant relationship between Icsc and Pr, with a T-value of -1.010.

TABLE III. RESULT SUMMARY FOR FORMATIVE CONSTRUCT SIGNIFICANCE TESTING

Formative Factor	Formative items	Outer weights	T value	P value	95%BCa confidence interval	Significance P<.05
Cyber situational awareness (Csa_category)	Csa1	.766	72.801	.000	4.231 – 4.456	Yes
	Csa2	.651	34.550	.000	2.826 – 3.154	Yes
	Csa3	.725	44.251	.000	3.336 – 3.632	Yes
	Csa4	.736	43.310	.000	3.336 – 3.641	Yes

TABLE IV. SIGNIFICANCE TESTING RESULTS OF THE STRUCTURAL MODEL PATH CO-EFFICIENT

Hypothesis	D-I	Path coefficients	T value	P value	95% confidence intervals	Significance P<.005	R square
H1	Csa-Ics	.106	1.999	.046	.003 - .353	Yes	.011
H2	Csa-Sr	.251	4.837	.000	.143 - .340	Yes	.063
H3	Icsc-Or	-.132	-2.492	.013	-.171 - -.020	Yes	.017
H4	Icsc-Pr	-.054	-1.010	.313	-.107 - .034	No	.003
H5	Icsc-Csa	.079	1.488	.138	-.023 - .163	No	.006

The P-value column complements the T-values by providing the level of significance associated with each path coefficient. In H1, the P-value of 0.046 confirms the statistically significant relationship between Csa and Ics. H2 demonstrates a highly significant relationship between Csa and Sr, indicated by the P-value of 0.000. H3 exhibits a statistically significant relationship between Icsc and Or, with a P-value of 0.013. Conversely, H4 suggests no significant relationship between Icsc and Pr, with a P-value of 0.313.

The 95% confidence intervals offer a range within which the true population parameter is likely to fall. For H1, the confidence interval of 0.003 to 0.353 reinforces the statistical significance of the relationship between Csa and Ics. Similarly, the narrow interval of 0.143 to 0.340 for H2 supports the significance of the relationship between Csa and Sr. H3's confidence interval of -0.171 to -0.020 suggesting a significant negative relationship between Icsc and Or. However, caution is necessary when interpreting H4's confidence interval of -0.107 to 0.034, as the relationship between Icsc and Pr is not statistically significant. Fig. 10 shows the results of PLS-SEM analysis.

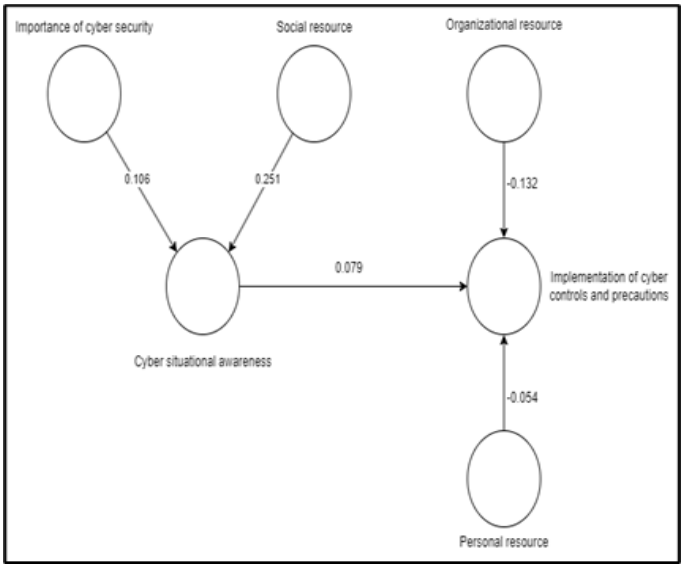

Fig. 10. Results of the PLS-SEM analysis.

I. *Impact of Negative Path Coefficient Values among Hypotheses*

Hypothesis H3 examines the relationship between the implementation of cyber security controls and precautions (Icsc) and organizational resources (Or), while Hypothesis H4 explores the relationship between Icsc and personal resources (Pr). Although both hypotheses have negative path coefficients, H3 (-0.132) is statistically significant, whereas H4 (-0.054) is not. Here is a detailed justification for these findings:

Hypothesis H3: The negative path coefficient (-0.132) in H3 suggests that as the implementation of cyber security controls and precautions (Icsc) increases, the availability or allocation of organizational resources (Or) decreases. Several reasons contribute to this relationship:

- Resource Reallocation: When organizations prioritize the implementation of cyber security controls and precautions, they often allocate resources, such as financial investments, personnel, and technology, to support these measures. This reallocation of resources can lead to reduced availability or allocation of resources for other organizational activities, resulting in a negative relationship between Icsc and Or.
- Trade-offs: Implementing cyber security controls and precautions often involves making trade-offs in resource allocation. Organizations may need to invest in security technologies, employee training, or hiring specialized personnel, which could lead to limited resources for other organizational needs. As a result, the negative path coefficient indicates that an increase in Icsc is associated with decreased available resources.
- Efficiency and Effectiveness: Implementing cyber security controls and precautions effectively requires utilizing resources efficiently. Organizations with limited resources may face challenges in implementing comprehensive security measures, leading to increased vulnerability and organizational risk. Consequently, the negative relationship between Icsc and or may arise from the difficulty in maintaining sufficient resources for cyber security and other organizational functions.

Hypothesis H4: Although H4 suggests a negative relationship between Icsc and personal resources (Pr), the non-significant p-value (0.313) indicates that this relationship is not statistically significant in the given sample. Several reasons may contribute to this result:

- Individual Factors: Personal resources encompass an individual's capabilities, knowledge, skills, and access to relevant information. The negative path coefficient implies that, in theory, as Icsc increases, personal resources (Pr) should decrease. However, in the context of the specific sample or survey respondents, other factors such as individual characteristics, experiences, and attitudes may overshadow the impact of Icsc on personal resources.
- Complexity of Personal Resources: Personal resources in cybersecurity could include individual knowledge, expertise, awareness, and adherence to security practices. Assessing personal resources accurately can be challenging, as it involves subjective factors and self-perception. Measurement limitations or insufficient sensitivity in capturing personal resource variations may contribute to the non-significant findings.
- Indirect Relationship: The relationship between Icsc and personal resources may be indirect, mediated by other variables not considered in the hypothesis. Factors such as organizational culture, training programs, or information-sharing practices might influence personal resources, moderating the relationship between Icsc and Pr. Not accounting for these mediating factors could result in a non-significant direct relationship between Icsc and Pr.

By considering a more extensive and diverse sample, conducting qualitative investigations, or refining the measurement instruments, researchers can better understand the relationship between Icsc and personal resources in the specific context of cyber security.

V. Conclusion and Future Work

Based on the research findings, several fruitful insights can be drawn that shed light on the relationships between cybersecurity items within organizations. The study identified a significant positive relationship between Cyber Situational Awareness (Csa) and Implementation of Cybersecurity Controls (Icsc), suggesting that enhancing awareness can contribute to better control implementation. In simple terms, Saudi Arabia should focus on raising cyber situational awareness among SMEs so that the SMEs have implementation of cyber security controls in their companies. Additionally, a significant positive relationship was found between Csa and Social Resources (Sr), emphasizing the importance of promoting awareness to enhance organizational resilience. Saudi Arabia should promote awareness among the SMEs so that the SMEs can have better organizational resilience to different cyber-attacks. Furthermore, a significant negative relationship between Icsc and Organizational Resources (Or) indicates that robust control implementation can potentially reduce organizational risk. SMEs in Saudi Arabia should implement robust cyber security mechanisms in their companies to reduce organizational risk. However, no significant relationships were found between Icsc and Personal Resources (Pr). In the context of Saudi Arabia, implementing cyber security does not rely on the personal resources of the employees of the SMEs. These findings provide valuable insights for organizations seeking to improve their cybersecurity practices.

While the study provides valuable insights, some limitations should be acknowledged. Firstly, the effect sizes observed were relatively small, suggesting that there may be other factors at play that were not considered in the analysis. Additionally, the study relied on self-reported data, which may introduce biases and inaccuracies. Data was collected from different sectors. The sample size and composition could also affect the generalizability of the findings. Furthermore, the study focused on specific variables and did not consider potential mediating or moderating factors. These limitations should be taken into account when interpreting the results.

Future work can focus on several areas to address the limitations and extend the research. Firstly, qualitative research can provide a deeper understanding of the underlying mechanisms behind the identified relationships. This qualitative exploration can help identify specific aspects of Cyber Situational Awareness and Personal Resources that impact control implementation most. Additionally, future studies can delve deeper into the dimensions of Cyber Situational Awareness, such as knowledge of threats and risk assessment capabilities, to develop targeted interventions and comprehensive training programs. Exploring additional contributors to Organizational Resources, such as human factors, supply chain vulnerabilities, and emerging technological threats, can also provide a more holistic understanding of risk management. Furthermore, investigating the role of communication strategies, organizational culture, and individual cognitive biases can assist in designing effective risk communication campaigns and tailored training programs. Integrating technical controls with organizational and behavioral aspects in comprehensive frameworks can enhance the effectiveness of cybersecurity initiatives. These future directions can further advance the understanding and practice of cybersecurity within organizations.

Network Security Detection Method Based on Abnormal Traffic Detection

Tao Xiao*, Yang Ke, Hu YiWen, Wang HongYa
State Grid Jiangxi Electric Power Co, Ltd. Training Center, Nanchang 330013, China

***Abstract*—To discover potential risks and vulnerabilities in the network in time and ensure the safe operation of the network, a network security detection method based on abnormal traffic detection is studied. Construct network security detection architecture from several aspects, including the front-end interface module, control center module, network status extraction module, anomaly detection module, alarm module, and database module. Use NetFlow technology to capture network traffic from the network in the form of flow, and use the KNN algorithm in the traffic filtering submodule to filter network traffic packets and eliminate duplicate traffic data. After filtering traffic, the traffic data is transmitted to the feature selection sub-module. PCA-TS algorithm is used to reduce the dimension of the network traffic data and select the network traffic characteristics, and then it is input into the SVM classifier. The improved SVM multi-classification algorithm is used to classify normal and abnormal traffic, complete abnormal traffic detection, and achieve network security detection. Experimental results show that the time for feature selection of this method does not exceed 3.0s, and the G score in the detection process also remains above 0.70, indicating that this method has strong network security detection capability.**

***Keywords*—Abnormal traffic; network security detection; data dimensionality reduction; flow characteristics; traffic capture; alarm module**

I. INTRODUCTION

Network security detection refers to a comprehensive security assessment and inspection of the computer network system to find potential security risks and vulnerabilities and take corresponding measures to protect the security and integrity of the network system [1]. Its significance lies in preventing potential threats, protecting important data, maintaining business continuity, improving user trust and complying with regulatory requirements. By preventing potential threats, vulnerabilities and weaknesses in the network system can be found and repaired in time to avoid security attacks [2]. At the same time, security incidents such as hacker intrusion, data leakage and malware infection can be avoided by timely finding and solving security problems [3]. Network security detection can help enterprises and individuals protect important business and personal data. Data security and confidentiality can be ensured by detecting vulnerabilities and risks in the network system [4]. It can also ensure the normal operation of the network, reduce business interruption and loss caused by security vulnerabilities and attacks, find and repair the vulnerabilities in the network system in time, and ensure the continuity and stability of the business [5]. By improving network security through network security detection, users can use online services more confidently without worrying about personal information leakage or account theft [6]. Therefore, network security detection is of great significance.

With the popularization of computer network applications and services, the number of Internet users continues to increase, and the demand for Internet information sharing continues to expand [7]. The threat of network security attacks has become more serious, and network anomaly detection has become an increasingly important task in network security research [8]. There are many reasons for network exceptions, such as network overload, worm network intrusion, routing policy modification, and distributed denial of service attacks. Network traffic anomaly is the most common threat in network anomaly. Abnormal network traffic may reduce the central network speed or even cause network paralysis, which will cause serious damage to the network environment [9]. Weihai caused by abnormal network traffic is generally characterized by bandwidth occupation, network blocking, failure to send normal information on time, network packet loss, etc. [10]. For computer systems, servers, and clients, the harm caused by abnormal network traffic is shown as occupying a large amount of memory space, and data responses are transmitted to the server normally with different responses [11]. Many scholars have studied network security detection methods to solve these threats to network security and achieve timely hazard warnings and other functions.

Wozniak M et al. [12] studied the cyclic neural network model for threat detection of the Internet of Things and network malware. This method classifies the information in the network through the cyclic neural network to detect malicious threat information, but this method cannot achieve security alarm in the detection process, and the detection results of multiple attacks are not clear enough; Steno P et al. [13] studied uses deep learning to detect threat objects in security screening. This method uses deep learning network and cross-entropy loss calculation to realize risk screening in network objects, but this method cannot detect the degree of flow fluctuation in the network, resulting in a small detection range; Gaber T et al. [14] studied an injection attack detection method for intelligent Internet of Things applications using machine learning. This method detects network attack traffic in smart cities, uses constant removal and recursive feature elimination methods to achieve feature selection, and uses machine learning classifiers to classify attack traffic. Although the accuracy of this method is as high as 99%, this method needs a lot of time in feature extraction and detection.

The abnormal traffic detection method identifies and detects abnormal situations inconsistent with normal network traffic behavior by analyzing the network traffic changes. This

detection method can help find abnormal activities in the network, such as network attacks, malware propagation, data leakage, etc., to ensure the network's security and stability [15]. There are many methods to detect abnormal network traffic, such as traffic analysis methods, machine learning methods, etc. The traffic analysis method determines whether the traffic is abnormal by capturing and parsing the network data packets, analyzing the source address, destination address, protocol type and other information of the data packets, as well as the size, frequency and other characteristics of the data packets. For example, an exception may exist if an IP address sends many data packets quickly or a port receives abnormally large data traffic. The machine learning method uses algorithms to analyze and model network traffic to identify abnormal traffic. Machine learning can automatically identify abnormal data packet size, abnormal connection behavior, etc. [16] by learning the characteristics of normal traffic behavior. Therefore, this paper proposes an abnormal traffic detection method based on support vector machine (SVM). The innovation lies in the construction of a network security detection architecture, which uses NetFlow technology to capture traffic data from the network and uses KNN algorithm to remove duplicate data. In the feature selection submodule, PCA-TS algorithm is used to reduce the dimensionality of network traffic and select features. An improved SVM multi classification algorithm is used to classify normal and abnormal traffic, achieving efficient abnormal traffic detection and network security detection.

II. Design of Network Security Detection Method

A. Construction of Network Security Detection Architecture

To improve the network security and operation status, this paper studies the network security detection architecture, shown in Fig. 1. The architecture is divided into a foreground interface, control center, network status extraction, anomaly detection, alarm, and database modules. Feature selection and anomaly detection modules are the architecture's main parts.

The specific contents of the network security detection architecture are as follows:

1) Front-end interface: The main functions of the front-end interface module include network topology node display function, user information display and user login function, system working status display function, log information display function and abnormal flow alarm display function. The main function of the foreground interface is to provide users with a good and beautiful interface display function and provide users with a good interaction function. The network topology node display function can view the current network's working nodes and the current network's topology. The alarm display function can more intuitively see the attacked node. The log information display function can view the system log, including user login information and running status record information on the architecture.

2) Control center: The main functions of the control center module include user authority management function, configuration function, alarm function, task allocation function, etc. The user authority management function can ensure that the authority is not abused. Only super users have administrator authority to modify sensitive content such as network configuration information. The alarm function makes it possible to quickly give feedback to the foreground interface to prompt network exceptions when the detection architecture is abnormal and even locate the attacked node in time. The task allocation function mainly includes switching between the network status extraction function, normal detection status, and log viewing function.

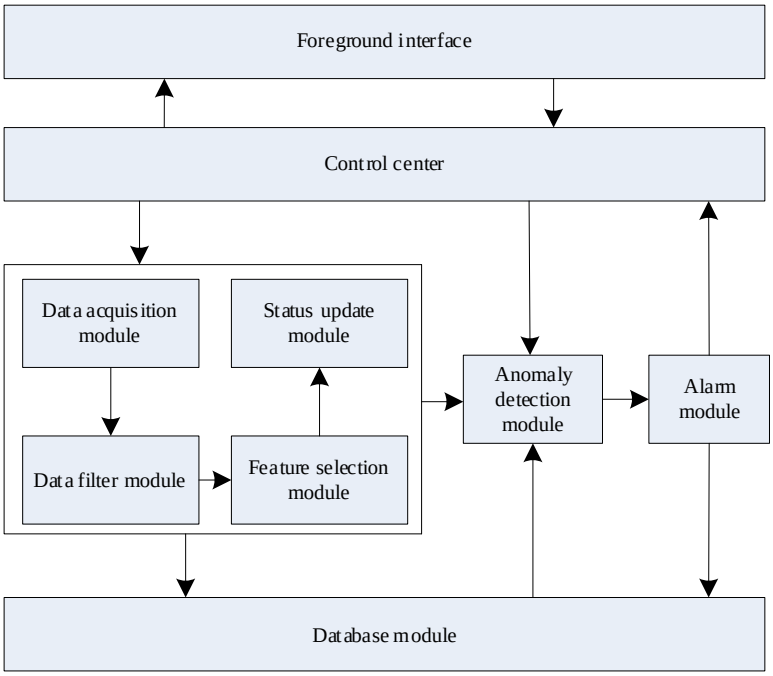

Fig. 1. Overall design of network security detection architecture.

3) Feature selection module: The main function of the feature selection module is to capture network traffic through the function of collecting data and selecting the features of the captured traffic to achieve feature extraction. In the safe working mode, the module saves the extracted feature information to the database. In the normal working mode, the extracted features are transmitted to the abnormal flow detection module to judge the abnormal flow of the network. In the update mode, the extracted features are updated to the database. Feature selection module is one of the most important functional modules, including four sub-modules: traffic capture module, traffic filtering module, feature selection module and network status update module.

The traffic capture submodule's main function is to capture each node's data packets and then save the data packets to the packet queue. The main function of the traffic filtering sub-module is to filter the redundant content and duplicate content captured and then wait for the feature selection sub-module to extract features. The feature selection sub-module is the core module of the architecture. It receives the data package of the filter sub-module, selects its features, and saves the extracted state information to the database. The status update sub-module mainly updates the recorded standard status information.

4) Anomaly detection module: The anomaly detection module is mainly responsible for judging whether the network has been attacked by abnormal traffic and passing the detection results to the alarm module. At the same time, the detection results are saved in the database as log management, which can facilitate viewing historical record information. The algorithm implements this module. At the same time, this module is one of the most important functional modules and is the key judge of whether an intrusion occurs.

5) Alarm module: The main function of the alarm module is to send an alarm to the user when the abnormal flow detection module judges that an intrusion has occurred. The alarm module receives the result of the abnormal flow detection module. If the result is true, the alarm information will be written into the database and sent to the control center simultaneously. The alarm can be sent out an alarm tone or pop up a window light on the foreground interface.

6) Database module: The main function of the database module is to record various types of information, including log information, user information records, alarm information records, etc. The database module is the information center of the entire architecture. All data extraction, information exchange and record-keeping between modules are completed in this module. The database module requires the physical support of the database software, or it can be deployed to an independent server separately.

B. Network Traffic Capture

Based on NetFlow technology, the traffic capture sub-module under the feature selection module in the network security detection architecture captures network traffic in flow. Use the V9 NetFlow technology as a sniffer or probe in the network to transmit the traffic records to a data collector with a specified IP address. The output package format of NetFlow V9 is shown in Fig. 2. FlowSet represents the collection of traffic records. The Template Flowset in Fig. 2 is the template for subsequent data records, enhancing network traffic records' flexibility.

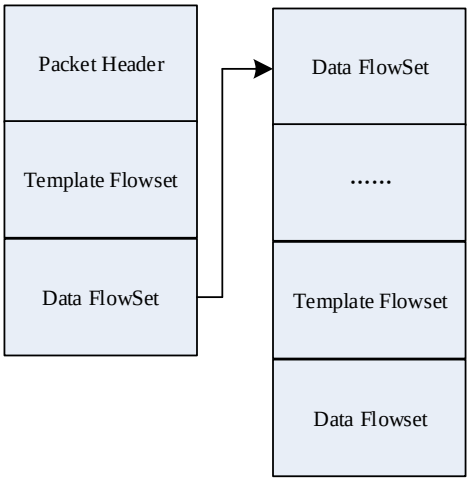

Fig. 2. Analysis of the output package format of NetFlowV9.

Encapsulates the network traffic records into UDP packets and transmits them to the collector with UDP protocol to ensure high efficiency when transmitting a large number of traffic records. To prevent NetFlow from generating a large amount of data and causing network congestion, a dedicated link is designed for the traffic record output to the collector in the congestion-sensitive network. When the collector cannot be placed at the router's next hop or the transmission link cannot be exclusive to NetFlow, a special link needs to be designed to handle the large amount of data NetFlow generates.

C. Traffic Filtering of KNN Classification Algorithm

After capturing the network traffic data, due to the huge amount of network traffic data [17], and some botnet traffic and duplicate content, effective measures must be taken to filter the traffic. Through reasonable filtering means, the traffic data can be more conducive to subsequent network security detection [18]. This paper uses the KNN algorithm to filter traffic in the traffic filtering sub-module under the feature selection module.

1) Filtering analysis: KNN algorithm realizes classification by measuring the distance between different eigenvalues to achieve a data filtering effect. If most of the k, that the most similar samples belong to a category, the samples also belong to that category. The most similar definition here is that the eigenvalue of the sample is the nearest in the feature space. Among K is an integer less than or equal to 20. In the KNN algorithm, the most similar samples are correctly divided into corresponding classes [19]. When this method is used for classification, the possible classification of samples is determined according to the classification of the nearest one or several samples. Fig. 3 shows the operation mode of the algorithm.

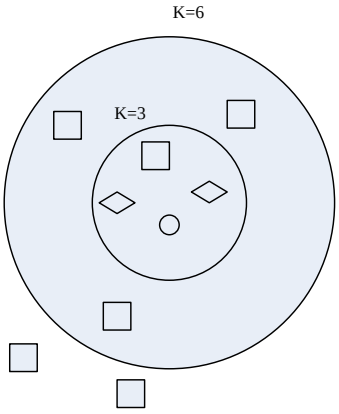

Fig. 3. Analysis of KNN algorithm operation mode.

It can be seen from Fig. 3 that when $K = 3$, the grey filled circle shall belong to the hollow triangle type. When $K = 6$, the grey filled circle shall be classified as a hollow square. Therefore, it can be concluded that the selection of values K affects the filtering results; the optimal value can make the filtering effect the best.

2) Flow filtration: Due to the large difference between normal traffic and abnormal traffic caused by attacks, the external parameters of abnormal traffic can be filtered out from the external parameters of mixed traffic, including normal and abnormal traffic, using the KNN method to achieve faster traffic data processing [20]. The implementation process is:

The obtained labelled data (packet length, URL length) and unlabeled data (packet length, URL length) are regarded as vectors, and their Euclidean distances are calculated. European distance can be calculated by Formula (1):

$$dist(X,Y) = \sqrt{\sum_{i=1}^{n}(x_i - y_i)^2} \qquad (1)$$

In Formula (1), $dist(X,Y)$ represents a data set between European distance of X and Y; x_i and y_i respectively represent i of the labeled data and unlabeled data; n indicates the number of traffic data. This formula can measure the absolute distance between points in multidimensional space.

3) The first one closest to the unlabeled data is counted K the labelled data with the most occurrences among the data will be marked with the same label as the unlabeled data. Obtain a batch of labelled data, which can support subsequent work in terms of data quantity.

D. Design of Network Traffic Feature Selection Method

Real network traffic contains many feature attributes, and the existing anomaly traffic detection methods based on feature analysis cannot meet the real-time requirements of high-dimensional feature analysis [21], [22]. Therefore, when this paper filters the traffic data through the KNN algorithm, the feature selection submodule uses the traffic feature selection algorithm based on principal component analysis (PCA) and tabu search (TS) to conduct feature reduction and near-optimal feature subset selection for high-dimensional features through PCA-TS, providing reliable feature data for subsequent abnormal traffic detection.

1) Dimension reduction of traffic data: The dimensionality of the traffic data filtered by the KNN algorithm is reduced to facilitate the subsequent feature selection [23]. Principal component analysis is an effective method of analyzing data in statistics, mainly used for feature extraction and data dimension reduction. The idea is to reduce the dimension of a data set with high dimension and correlation by using the feature space transformation of statistical properties of the data set [24]. PCA transforms the original space into a new principal component space, and the principal components are unrelated.

Assume that the network traffic data set contains N samples $N = \{x_1, x_2, \ldots, x_m\} \in R^n$, where,$R^n$is the feature space,$m$ is the characteristic dimension. Find variable space $Z = \{z_1, z_2, \ldots, z_k\}$, satisfied $k < m$ and $cov(z_i, z_j) = 0$, through transformation k new variables Z can represent most of the information of m original variables X, as shown in Formula (2):

$$Z = \kappa N dist(X,Y) \qquad (2)$$

In Formula (2),κ is a one $m \times m$ orthogonal matrix and is the covariance matrix of the eigenvalue matrix of data samples $C = \frac{1}{N}\sum_{i=1}^{N}(x_i - u)(x_i - u)^T$, where, $u = \frac{1}{N}\sum_{i=1}^{N} x_i$. Therefore, it is transformed into solving the eigenproblem as shown in Formula (3):

$$\lambda_i = CPZ \qquad (3)$$

In Formula (3), λ_i is characteristic value of C, P is the corresponding eigenvector. Principal component analysis selects several characteristic values with a high contribution rate $\lambda_i$corresponding eigenvector Pas the principal component, to achieve the purpose of dimension reduction. The characteristic contribution rate is shown in Formula (4):

$$\frac{\sum_{i=1}^{m}\lambda_i}{\sum_{i=1}^{p}\lambda_i} = \frac{\sum_{i=1}^{m}\lambda_i}{n} \geq R \qquad (4)$$

In Formula (4), R is the threshold value of the feature contribution rate, feature dimension m is selected according to R to determine the general choice R85%~95%. When using PCA for analysis, different variables in the data often have different dimensions, leading to a large difference in the dispersion of the values of each variable, thus affecting the calculation accuracy. To eliminate the possible impact of different dimensions, the variables need to be standardized first, and then the dimension can be reduced by PCA.

2) Feature selection based on the tabu search algorithm: After the dimensionality reduction of traffic data through the PCA algorithm, feature selection can be done. Tabu Search (TS) algorithm is a heuristic global optimization search method, which obtains the global optimal solution by marking the searched local optimal solution and avoiding repeated search in the iterative calculation [25]. The main idea of the algorithm is first to determine an initial effective solution z, for each solution z define a neighborhood $Y(z)$, determine

several candidate solutions from the neighborhood of the current solution, and select the best candidate solution from them. Selecting the best candidate solution is a search process. To avoid the search process being limited to cycles, TS avoids the local optimization of the search algorithm by constructing a tabu table and defining stop rules. Tabu list before saving n the second taboo length avoids returning to the original solution, thus improving the search ability of the solution space; Stop rule defines that when the optimal solution cannot be improved within several iterations, the algorithm stops. In addition, neighborhood, tabu list, tabu length, amnesty rule and initial solution in the tabu search algorithm will directly affect the search optimization results.

Feature selection based on tabu search is an optimization problem constrained by the objective function, and the appropriate objective function improves the quality of search and optimal feature selection. A good feature solution should guarantee as much classification information as possible on the minimum number of features. In information theory, the greater the information gains of an attribute, the greater the amount of information it contains [26]. Based on the information gained, the classification information of feature vectors can be effectively evaluated. Therefore, this paper selects information gain as the objective function and defines the objective function as shown in Formula (5):

$$G_T = R\sum_{i=1}^{m} C(i) \times \frac{\sum_{j=1}^{n} G(A_j)}{n} \quad (5)$$

In Formula (5), $C(i)$ represents sample i whether it is correctly classified, m is the number of samples; $G(A_j)$ is information gain of features i. Ensure that the maximum classification information is guaranteed with a small number of features through Formula (5), and select divided by n that can ensure faster tabu search speed and avoid overfitting.

The selection of the initial solution in tabu search greatly impacts the effect of tabu search. In the calculation process of other optimal feature selection algorithms, due to the large feature dimension of actual network traffic, it will affect the efficiency of the tabu search algorithm, and feature redundancy will also affect the selection of the optimal feature set. Therefore, the initial solution of tabu search has an important impact on search efficiency and quality.

Generally, the larger the feature, the higher the accuracy of the analysis is. However, in practice, too large a feature space will cause two problems: (1) The huge feature space not only needs higher storage space but also increases the measurement time, which is difficult to apply to real-time traffic analysis; (2) In some applications, such as anomaly detection, service classification, etc., the characterization of different network services requires different feature attribute vectors. If all features are used to represent different service flows, not only the learning effect is reduced, but also the learning time is increased. So, feature selection is to mine the best feature set to describe network traffic; best and tabu search provides a near-optimal solution.

3) Feature selection design based on PCA-TS algorithm: The statistical characteristics of network traffic refer to the characteristics of extracting ports and protocols from the attributes of packets or flows. Such as message length, arrival interval, number of messages, flow duration, number of messages in the flow, etc. Feature vectors represent these statistical characteristics. Such as a network flow F, the characteristic description based on the flow can be expressed as $F = \{y_1, y_2, \ldots, y_n\}$, where y_i represents the value of the feature. The feature set of a flow may contain as many as hundreds of features. Finding a small number of optimal feature subsets to describe the flow is important to improve learning efficiency.

Therefore, this paper makes full use of the feature that PCA can perform fast and effective feature reduction on high-dimensional data, and improves the efficiency of solving the optimal solution of the tabu search method by eliminating feature redundancy and reducing the dimension space. To this end, this paper selects network traffic characteristics by combining PCA and TS algorithms. The flow chart of the PCA-TS feature selection method is shown in Fig. 4.

In Fig. 4, the specific implementation steps of the PCA-TS algorithm are as follows:

1) The tabu table is empty, and initialization parameters are set: tabu length $L_J = 13$, maximum iterations $D_{max} = 600$, maximum improvement times $\bar{D}_{max} = 100$.

2) Use PCA to reduce the original network traffic characteristics and obtain the reduced feature collection $G'_T = \{T_1, T_2, \ldots, T_p\}$, p is the number of feature sets after reduction.

3) To feature set G'_T perform binary coding to obtain the initial solution R_{init}.

4) Set termination conditions, when getting $\bar{D}_{max}$, the search stops; When the best solution cannot be improved by passing R_{init}, stop searching.

5) Judge whether the termination conditions are met. If the termination conditions are met, end the operation and output the optimal flow feature subset. Otherwise, go to the next step.

6) Initial solution R_{init} brings into the neighborhood structure to calculate the neighborhood solution, and the best candidate solution is selected through the objective function.

7) Judge whether the candidate solution meets the amnesty rule. If yes, update the optimal solution in the tabu list and go to step (4), otherwise go to the next step.

8) Calculate the tabu attribute of the candidate solution, select the initial value of the optimal replacement tabu table for non-tabu objects, and go to step (4).

9) End, output the optimal flow characteristic subset G'_R.

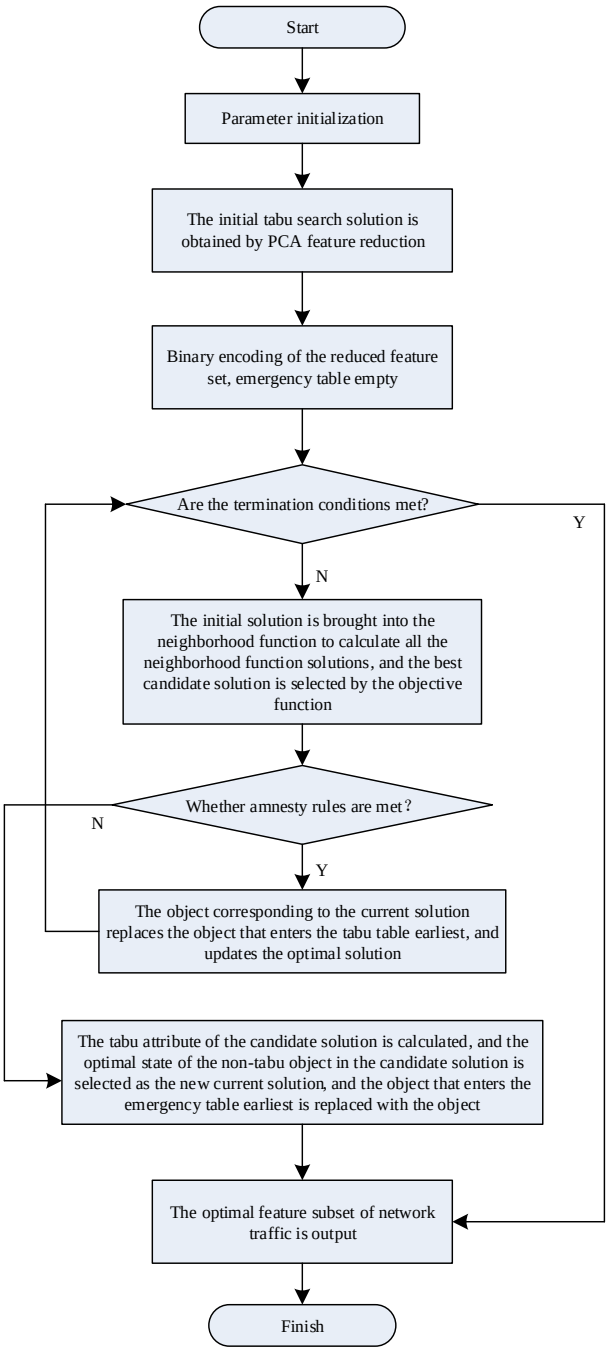

Fig. 4. Process of feature selection method based on PCA-TS.

In Fig. 4, the specific implementation steps of the PCA-TS algorithm are as follows:

1) The tabu table is empty, and initialization parameters are set: tabu length $L_J = 13$, maximum iterations $D_{max} = 600$, maximum improvement times $\bar{D}_{max} = 100$.

2) Use PCA to reduce the original network traffic characteristics and obtain the reduced feature collection $G'_T = \{T_1, T_2, \ldots, T_p\}$, p is the number of feature sets after reduction.

3) To feature set G'_T perform binary coding to obtain the initial solution R_{init}.

4) Set termination conditions, when getting $\bar{D}_{max}$, the search stops; When the best solution cannot be improved by passing R_{init}, stop searching.

5) Judge whether the termination conditions are met. If the termination conditions are met, end the operation and output the optimal flow feature subset. Otherwise, go to the next step.

6) Initial solution R_{init} brings into the neighborhood structure to calculate the neighborhood solution, and the best candidate solution is selected through the objective function.

7) Judge whether the candidate solution meets the amnesty rule. If yes, update the optimal solution in the tabu list and go to step (4), otherwise go to the next step.

8) Calculate the tabu attribute of the candidate solution, select the initial value of the optimal replacement tabu table for non-tabu objects, and go to step (4).

9) End, output the optimal flow characteristic subset G'_R.

E. Abnormal Flow Detection

After selecting network traffic characteristics, you can use the selected traffic characteristics to detect abnormal traffic through the network security architecture abnormal traffic detection module. Improve the detection efficiency of abnormal flow and improve the detection accuracy. This paper uses the SVM algorithm to detect abnormal traffic, assuming there is k type of samples, and then it is necessary to construct k two class classifiers. Each classifier is used to separate one class from the rest. During training, please take one of them as positive, and the rest $k-1$ class is negative. When judging, the sequence of the tested samples passes through k, the total of two class classifiers k output values is $f_i(x) = sgn(g_i(x)), i = 1,2,\ldots,k$. If the decision result contains only one+1, the corresponding classifier's sample class to be detected is the positive class. Suppose there is more than one+1 in the decision result, that is, classification overlap. In that case, it is also necessary to compare the decision function value of the classifier whose output is+1, and the positive class of the classifier with the largest value represents the class of the sample to be detected. If the judgment result is -1, the sample is considered to be indivisible. Therefore, this paper proposes an improved SVM multi-classification algorithm. The idea of class distance in clustering analysis is used as the basis for sorting the second-class classifiers in the detection model.

About k class flow characteristic samples, calculate the center distance from each class to other classes, and then calculate the average distance from each class to other classes. The class with the largest average distance is the class with the most obvious specificity, and such class is preferred as the positive class of the second-class classifier ranking first. The relevant definition of distance is:

Definition 1: Center distance. The center distance of the flow characteristic samples of class i and j is defined as the Euclidean distance in the space of the spherical center that can contain all class i traffic characteristic samples to the spherical center that can contain all samples of class j traffic characteristics, recorded as d_{ij}.

Definition 2: Average distance. The mean distance between the class $i$traffic characteristics and the remaining categories is defined as the mean of the center distance from the class i traffic characteristics to the other samples of the traffic characteristics, recorded as γ_i, and meet:

$$\gamma_i = \left(\frac{G'_R}{k-1}\right)\sum_{j=1}^{k} d_{ij}(i \neq j).$$

The specific implementation steps are as follows:

1) Calculate the center distance of $d_{ij}(i, j = 1,2,\ldots,k, i \neq j)$between various flow characteristic samples and other flow characteristic samples according to definition 1.

2) Calculate the average distance of $\gamma_i(i = 1,2,\ldots,k)$ between various flow characteristic samples and other flow characteristic samples according to definition 2.

3) Compare the size of step $2\gamma_i$, and then follow the categories that numbered in descending orderγ_i.

4) Construct one by one according to the sample number sequence obtained in step (3) the k two class classifiers. The sample with the first number is the positive class of the first second-class classifier, the sample with the second number is the positive class of the second-class classifier, and so on.

During abnormal flow detection, let the sample to be tested pass through each two-class classifier in turn. If the decision result of the sample to be tested in a classifier is+1, then it is determined that the sample is the positive class of the corresponding classifier, and the detection of this sample is terminated. If the output result of samples passing through all the second-class classifiers in turn is - 1, it is determined as unknown flow, added to the set to be verified, and waiting for re training. The sample decision process is shown in Fig. 5.

The distance first SVM multi-classification algorithm can improve the classifier's detection accuracy. Therefore, although k class two classifiers were constructed when building model sets. However, in the improved SVM multi-classification algorithm, when a classifier is judged as+1, the judgment is terminated to shorten the sample detection time.

At this time, according to the specific process of abnormal network traffic detection method, abnormal traffic detection can be realized by the following methods:

1) NetFlow technology captures network traffic packets through flow.

2) The captured data packets are used in the KNN algorithm to filter traffic and eliminate duplicate traffic packets.

3) After data filtering, the traffic packets are input into the PCA-TS algorithm for data dimensionality reduction and feature selection.

4) After obtaining the traffic characteristics, the structure contains N sample a set of traffic, including normal traffic and $N-1$ abnormal flow with obvious difference in the distribution characteristics of three kinds of flow.

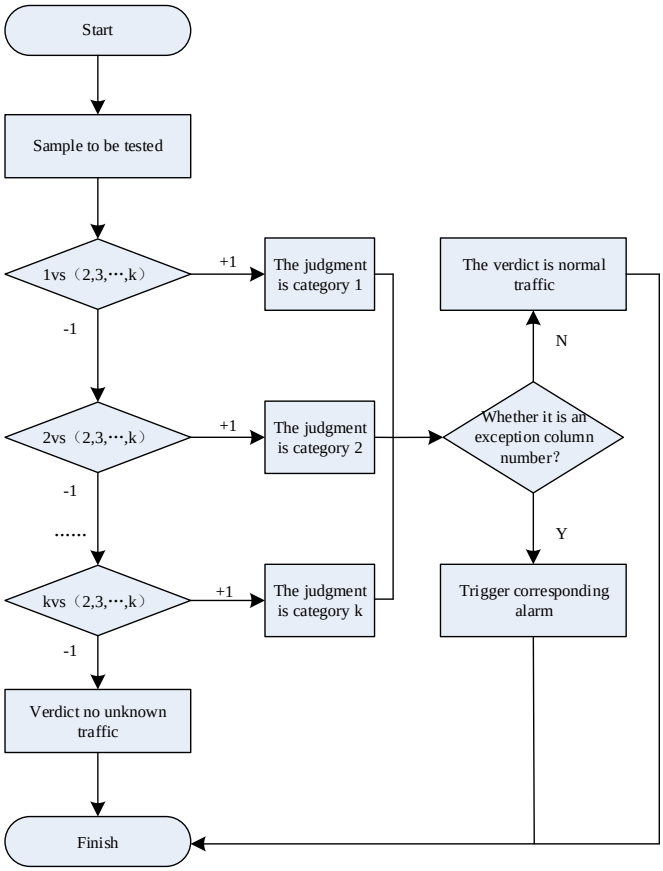

Fig. 5. Sample decision process.

5) The improved SVM multi - classification method is used to input the characteristic samples of the traffic to be measured into the SVM multi-class classifier. If the second-class classifier can recognize the characteristic samples of the traffic to be measured, it is determined that the traffic of the corresponding category is detected. If the detected flow is normal, continue; if it is abnormal, send an alarm. Repeat step (5). If the flow characteristic sample to be detected is determined to be an unknown flow, perform step (6).

6) Add unknown traffic to the collection to be verified. If the traffic in the set to be verified can be clustered and is significantly different from the normal traffic, it can be considered that a new anomaly has occurred.

7) Add new exceptions to the training samples in step (1) for re training to obtain a new model set, and repeat step (5) to achieve network security detection.

III. Experimental Analyses

To verify the effectiveness of the network security detection method in this paper, this paper constructs a simulation experiment through the NS2 simulation platform and shows the network topology in Fig. 6.

In Fig. 6, R1, R2 and R3 are routers, of which R2 is the "key router". The link between R2 and R3 is the bottleneck link, with a bandwidth of 10Mbps and a delay of 30ms. All other links have a bandwidth of 100Mbps and a delay of 15ms. The network contains 25 legitimate TCP connections, 10 of which are background traffic.

Meanwhile, attack parameters are designed: attack cycle is 1s, attack pulse duration is 150ms or 200ms or 250ms, and attack pulse intensity is 30Mbps or 40Mbps. The observation time window WS duration is 90s, and the attack packet types are UDP, ICMP, and invalid TCP.

The experimental data set uses the Honeynet Challenges data set provided by the HoneyPot Project. HoneyPot Project is a non-profit network security research institution committed to studying the latest network attacks and developing open-source security tools to improve the network environment. The organization has volunteers from all over the world. On its official website, many open-source security tools are developed to improve the network security environment. Table I shows some network traffic attributes of the experiment.

Analyze this method's abnormal feature selection ability before abnormal flow detection, and analyze the time required for different abnormal flow feature selections. The analysis results are shown in Table II.

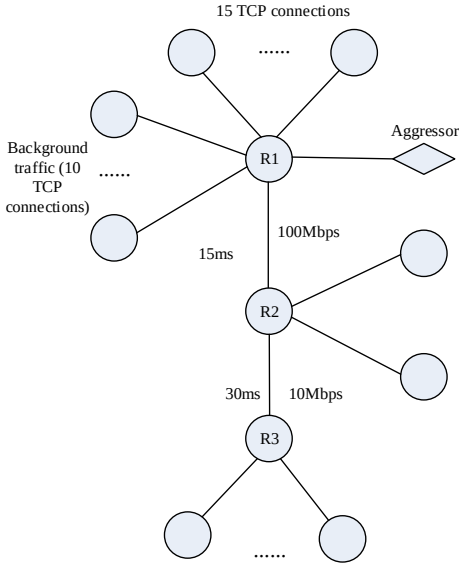

Fig. 6. Topology structure of the experimental network.

TABLE I. Attribute List of Network Traffic Status

Serial number	Symbolic representation	Feature description
1	outPckets	Total number of egress packets
2	outBytes	Total size of the egress packet
3	inPckets	Total number of incoming packets
4	inBytes	Indicates the total packet size of the entry
5	minOutpktLen	Indicates the minimum Byte of the egress packet
6	maxOutpktLen	Indicates the maximum Byte of the egress packet
7	meanLenOutsm	Average Byte of the egress packet
8	minInpktLen	Indicates the maximum Byte of the incoming packet
9	maxInpktLen	Indicates the maximum Byte of the incoming packet
10	meanLenInsm	Average Byte of an incoming packet
11	Outtotalduration	The total duration of the exit flow
12	Outavgduration	The average duration of the exit flow
13	Intotalduration	The total duration of the inlet stream
14	Inavgduration	The average duration of the inlet stream
15	OutavePktPerSecond	Average outbound packet size per second
16	InavelPktPerSecond	The average size of an entry packet in seconds
17	InnerOneToMulty	Indicates the number of one-to-many internal IP addresses
18	OutOneToMulty	Indicates the number of one-to-many external IP addresses
19	stdLenOutqsm	Mean square error of the egress message
20	stdLenInqsm	Mean square error of the incoming message

TABLE II. TIME REQUIRED FORABNORMAL FEATURE SELECTION

Feature sequence number	Feature type	Specific description	Time required for feature selection /s
1	duration	Connection duration	2.4
2	service	The network service type of the target host	2.6
3	src_bytes	Number of bytes of data from the source host to the destination host	2.1
4	land	Determine whether the connection is coming from the same host or port	1.5
5	urgent	Number of urgent packets	1.7
6	num_failed_logins	The number of failed login attempts	1.5
7	num_compromised	Compromised frequency	1.7
8	num_access_files	The number of times the control file was accessed	1.5
9	is_hot_login	Whether the login belongs to the hot list	1.6
10	protocol_tyoe	Protocol type	2.6
11	flag	The connection status is normal or incorrect	1.4
12	dst_bytes	The number of bytes of data from the destination host to the source host	2.1
13	hot	The number of times to access system-sensitive files and directories	2.5
14	wrong_fragment	The number of incorrect segments	1.9
15	dst_host_diff_srv_rate	Among the top 100 connections, the proportion of connections that have different services to the same destination host as the current connection	1.5
16	dst_host_srv_diff_host_rate	Among the top 100 connections, the number of connections that have the same destination host as the current connection and the number of connections that have a different source host from the current connection	1.5
17	srv_count	Number of connections that have the same service as the current connection in the last two seconds	1.6

According to Table II, this method can effectively select multiple features during feature selection to provide reliable data for subsequent network security detection. At the same time, in the feature selection process, the time for this method to realize feature selection does not exceed 3.0s. Therefore, this method has a strong feature selection ability, which provides a reliable guarantee for subsequent abnormal traffic detection.

This paper uses the G score to evaluate this method's abnormal traffic detection effect. G score is defined as:

$$G = \sqrt{precision \times recall} \quad (6)$$

In Formula (6), $precision$ and $recall$ indicate the accuracy rate and recall rate in turn. The higher the G score, the stronger the method's ability to detect abnormal traffic is. Test the G scores of different numbers of packets when they are attacked by different traffic and show the experimental data results through Fig. 7.

As shown in Fig. 7, with the increase in the number of test packets, the G scores obtained by this method begin to decline under attacks of different attack data types. Among them, when being attacked by UDP, the G score obtained by the test is the lowest among the three attack types, but not less than 0.70. It shows that this method can maintain high performance in the detection process. This paper can get a higher G score for detecting ICMP and invalid TCP attacks. It can be seen that this detection method can effectively detect multiple types of attacks.

This study selected three different scenarios for verifying abnormal traffic detection. In scenario B1, there are no attacks in the network, or the attacks present in the network have no direct impact on TCP data traffic. In the B2 scenario, the attacks present in the network have a direct impact on TCP data traffic, but there are no serious attacks. In the C3 scenario, there are serious attacks in the network. Verify the detection effectiveness of our method by analyzing the degree of traffic fluctuations in different scenarios. The analysis results are shown in Fig. 8.

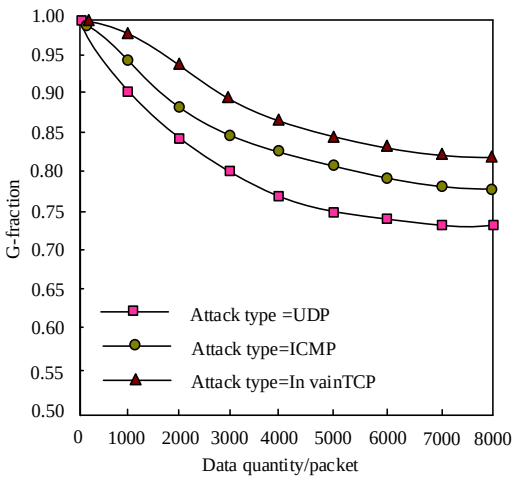

Fig. 7. Analysis of G score test results.

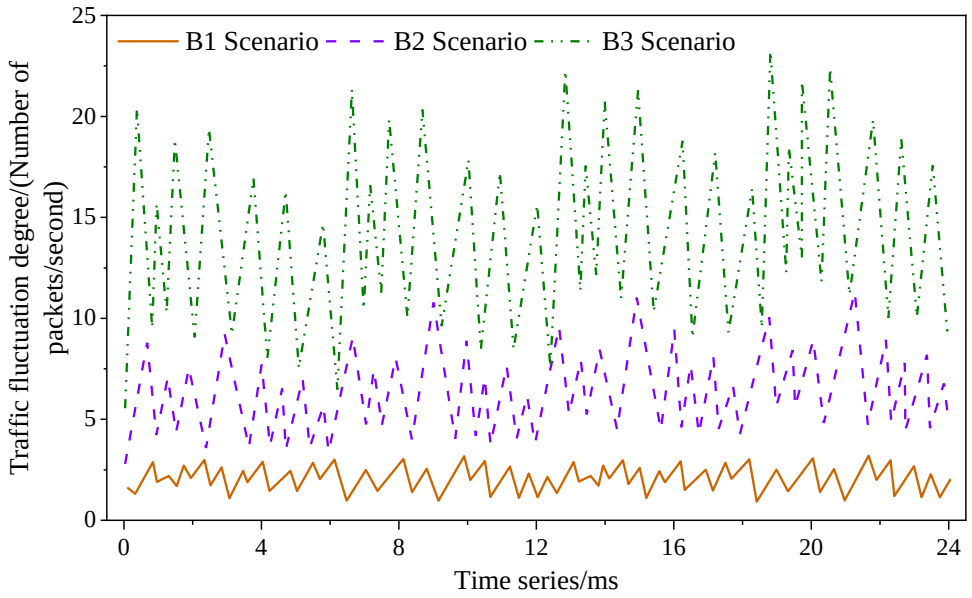

Fig. 8. Analysis of traffic fluctuation degree.

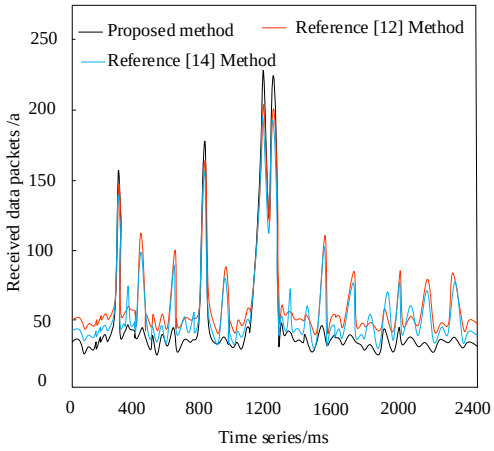
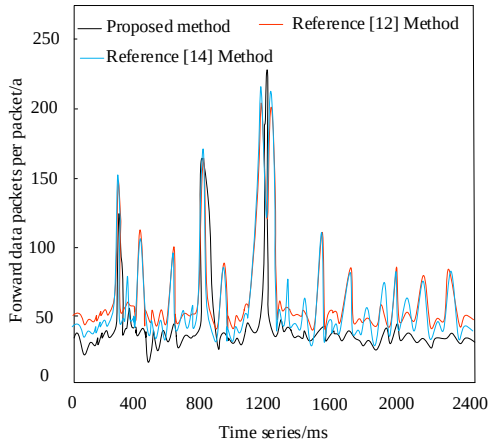
According to Fig. 8, when there is no attack in the network or the attack has no direct impact on TCP data traffic, the traffic always fluctuates below five packets/second, with a small fluctuation degree. When attacks in the network directly impact TCP data traffic, the fluctuation of network traffic increases. When serious attacks exist in the network, the traffic amplitude exceeds 20 packets/second fluctuations. From the above analysis, it can be seen that this method can effectively detect flow fluctuation.

Injecting attack traffic at different times, namely 400s, 800s, and 1200s, analyze the changes in the number of received and forwarded packets detected by the method proposed in this paper, the method proposed in reference [12], and the method proposed in reference [14]. The analysis results are shown in Fig. 9.

As shown in Fig. 9, after applying the method proposed in this article, under normal circumstances, the number of received packets is approximately equal to the number of forwarded packets; After injecting an attack, it will restrict the forwarding of abnormal packets, resulting in a lower number of forwarded packets than received packets. At this point, the number of forwarded packets shows a significant decrease. In response to persistent attacks, the number of packets forwarded by the port gradually decreases until the normal number of forwards is restored. From this, it can be seen that the method proposed in this article has strong ability to detect abnormal traffic and can achieve network security detection. By comparing the methods in reference [12] and reference [14], it can be seen that although the overall trend of the two methods is similar to that of the method in this paper, both methods show abnormal increase or decrease, indicating that the two comparison methods are affected by attacks and have misidentification phenomena..



(a) Analysis of changes in the number of received data packets.



(b) Analysis of changes in the number of forwarded packets.

Fig. 9. Analysis of changes in the number of packets during injection attacks.

IV. CONCLUSION

This paper studies the network security detection method based on abnormal traffic detection, uses this method, and applies this method to the experimental detection process. Experiments show that this method has a good detection effect on the common abnormal traffic and attacks in the network. Given the shortcomings of the current research, the following aspects can be improved in the future research work:

1) Find or build appropriate data sets. The existing real data sets have some shortcomings, lacking real attack data. Most researchers use traditional network data sets for experiments. However, due to the network environment's limitations, the simulation data cannot fully reflect the real network conditions.

2) Accurately identify the types of network attacks and make reasonable solutions. At present, this method can only achieve the detection and early warning of abnormal traffic and cannot achieve the processing of abnormal traffic. In the future, some effective abnormal traffic processing methods can be designed to improve network security.

ODFM: Abnormal Traffic Detection Based on Optimization of Data Feature and Mining

Xianzong Wu
College of Intelligence and Computing, Tianjin University, Tianjin, China

***Abstract*—The booming of computer networks and software applications has led to an explosive growth in the potential damage caused by network attacks. Efficient detection of abnormal traffic in networks is appealing for facilely mastering the traffic tracking and locating for network usage at low resource cost. High quality abnormal traffic detection of Internet becomes particularly relevant during the automated services of multiple application situations. This paper proposes a novel abnormal traffic detection algorithm called ODFM based on the optimization of data feature and mining. Specially, we develop a feature selection strategy to reduce the feature analysis dimension, and set a peer-to-peer (P2P) traffic identification module to filter and mine the related service traffic to reduce the amount of data detection and facilitate the abnormal traffic detection. Experimental results demonstrate that the proposed algorithm greatly improves the detection accuracy, which verifies its effectiveness and competitiveness in the general tasks of abnormal network traffic detection.**

***Keywords*—Abnormal traffic; detection; data mining; feature dimension optimization; network security**

I. Introduction

With the increasing complexity and volume of network traffic, the need for effective anomaly traffic detection algorithms is essential to ensure the security and reliability of networks. Anomaly traffic, which deviates significantly from normal patterns, can indicate potential cyber threats, network performance issues, or abnormal user behavior [1]. Anomaly traffic detection involves the identification of abnormal patterns or behaviors within network traffic that deviate significantly from the expected norm. The study has drawn great attention in recent decades due to the strong security demands on the network communications. However, traffic detection is deemed to be a developing and challenging issue since it needs to deal with various difficulties coming from imbalanced data, increasing network traffic volume, evolving and sophisticated attacks, as well as dynamic and variable network environments [2-5]. Various techniques have been developed to detect and analyze such anomalies, ranging from statistical-based methods [6-8], time series analysis [9-11], machine-learning based methods [12-14], deep-learning based methods [15-17], ensemble methods [18-20], flow-based analysis [21-23], hybrid methods [24, 25], to unsupervised clustering methods [26, 27].

Statistical based methods analyze network traffic data statistically to model normal behavior and detect anomalies [8]. These methods include mean-based models, standard deviation-based models, moving average models, and Gaussian distribution modeling. Time series analysis techniques model network traffic as a time-ordered series of data points, capturing temporal dependencies and patterns. Techniques such as Autoregressive Integrated Moving Average (ARIMA) [28], Hidden Markov Models (HMM) [29], and Wavelet Transform [30] is commonly used for time series analysis in anomaly detection. On the other hand, machine learning algorithms leverage historical network traffic data to distinguish between normal and anomalous patterns. Supervised learning algorithms like Support Vector Machines (SVM) [31], Random Forests [32], and Neural Networks classify traffic based on labeled datasets. Unsupervised learning algorithms, such as clustering and density estimation, detect anomalies without prior labeling. Deep learning algorithms, such as Convolutional Neural Networks (CNN) and Recurrent Neural Networks (RNN), automatically learn hierarchical and temporal patterns from raw network traffic data, excelling in detecting complex and evolving anomalies. However, they require significant computational resources and large labeled datasets. Ensemble methods combine multiple anomaly detection models to improve overall detection performance. Techniques like bagging, boosting, and stacking reduce false positives and enhance accuracy. Flow-based analysis aggregates network traffic into flows, representing communication between specific source and destination IP addresses. Flow-based anomaly detection uses flow features such as traffic volume, duration, or byte count to identify deviations from normal flow behavior. Besides, hybrid methods integrate multiple detection techniques, such as statistical, machine learning, and rule-based methods, to enhance accuracy. These approaches leverage the strengths of each technique to effectively identify a wide range of anomalies. Unsupervised clustering methods group network traffic instances into clusters, identifying anomalies as instances that deviate or form separate clusters. Clustering algorithms like k-means [33], DBSCAN [34], and self-organizing maps (SOM) [35] are commonly employed for anomaly traffic detection.

These mentioned methods have been faced with various difficulties and challenges. For instance, many continually develop sophisticated techniques to evade detection, employing tactics like traffic encryption, obfuscation, and mimicry. This poses a challenge for anomaly detection systems to identify and classify these evolving attacks accurately. Network traffic

often exhibits an imbalanced distribution, where normal traffic significantly outweighs anomalous traffic. Imbalanced data can lead to biased models that exhibit a higher false positive rate or overlook certain types of anomalies. Handling imbalanced data and addressing the bias towards the majority class is critical for effective anomaly detection. Network environments are dynamic, constantly evolving with changing user behavior, new applications, and network configurations. Anomaly detection algorithms need to adapt and remain capable of detecting novel or emerging anomalies. This requires continuous monitoring, model updates, and the ability to adapt to evolving network dynamics. Besides, real-time anomaly detection places stringent requirements on processing time and scalability. Efficient and scalable algorithms are necessary to handle large-scale network traffic, detect anomalies within strict time constraints, and ensure real-time analysis. Moreover, deep learning and complex machine learning models, while powerful in detecting anomalies, often lack interpretability and explain ability. Understanding the rationale behind anomaly detection outcomes is essential for effective response and decision-making by analysts. Ensuring transparent and interpretable anomaly detection models is a challenging task [36]. These challenges are actively being explored and addressed through ongoing research and development efforts. Advancing anomaly traffic detection techniques requires focusing on handling evolving attacks, addressing imbalanced and limited labeled data, enhancing adaptability to dynamic environments, reducing false positives, and improving interpretability. By addressing these challenges, the future advancement of anomaly detection systems in network traffic analysis can be achieved.

Developing appropriate anomaly detection method need to consider several factors, including the specific network environment, the characteristics of the anomalies, computational resources, and available data. Ongoing research and studies are actively exploring novel algorithms, advancements in machine learning techniques, and the integration of domain knowledge to enhance the accuracy and efficiency of anomaly detection in network traffic. These efforts aim to improve the detection capabilities in diverse network environments and adapt to evolving threat landscapes. In this paper, we propose a new approach called ODFM to anomaly traffic detection that jointly optimizes the data volume and feature dimension to achieve high-accuracy detection results. The main contributions of the paper include:

1) The paper propose a novel method of combining feature dimension reduction preprocessing with data mining optimization to general tasks of anomaly traffic detection, which takes into account the P2P traffic identification and the related-service traffic filter.

2) We introduce a feature selection strategy to achieve the feature dimension reduction, which can automatically locate key traffic information, speed up the anomaly detection and then propel the data optimization and engine extraction. It effectively addresses the issue of feature vector construction of data mining model.

3) An elaborate system design is conducted to verify the effectiveness of the proposed ODFM algorithm. Experimental evaluations have demonstrated its efficacy and great potential under various traffic anomaly detection conditions.

II. The Proposed ODFM Method

A. Foundation Statement

The proposed ODFM method is designed to address the issue of anomaly traffic detection. To achieve the goal of ODFM, we develop an ODFM based anomaly network traffic detection system that can effectively identify and classify abnormal patterns within network traffic data. The system aims to enhance network security, mitigate potential threats, and optimize network performance. The system mainly involves data mining mechanism to complete the network anomaly traffic detection.

Data mining mechanism aims to facilitate advanced anomaly detection and prevention in network traffic through the application of association mechanisms. When employing association mechanisms, it becomes feasible to effectively detect patterns and hidden knowledge between diverse and interconnected data items. By combining various data attribute values, these mechanisms can predict attribute values for a certain class of data, which provides significant advantages in acquiring and utilizing patterns from massive datasets. Within computer information systems, the utilization of association mechanisms enables precise analysis of network anomalies, fault information, and user network data. The formation of fault factor sets and the integration and analysis of related information categories enhance the scrutiny of traffic data and management processes. Moreover, potential rules between different network information and data are derived, thereby lessening the likelihood of network risks and achieving efficient early warning and handling of abnormal network traffic.

The primary objective of this anomaly network traffic detection system is to reduce the data volume and feature dimensions processed by the anomaly detection module, thereby enhancing the detection accuracy. This system focuses specifically on detecting malicious scanning and denial of service (DoS)/ distributed denial of service (DDoS) anomalies under the transmission control protocol, making it particularly applicable in transmission control protocol environments with a certain scale of hosts. Traditional anomaly traffic detection systems typically involve dealing with massive input data and implementing high-dimensional feature models for training. In contrast, the design of this system develops a feature selection strategy to reduce the dimensionality of feature analysis, and includes a P2P traffic identification module to filter relevant business traffic, thus reducing the data processing load and improving the accuracy of the detection process.

B. The Workflow of ODFM System

Fig. 1 depicts the detailed workflow of the proposed ODFM system architecture, which is designed with two primary phases, off-line training and online classification. In the off-line training phase, real-time network traffic and the corresponding known traffic labels are processed to create labeled training data. Through the application of hybrid feature extraction techniques in data preprocessing, an offline traffic

classification model is developed. During the online classification stage, the system performs real-time network traffic collection and an off-line data file analysis within the traffic collection and analysis module. All essential field information related to the traffic is stored in the database for further analysis. In the data preprocessing module, the feature selection algorithm and feature extraction engine are utilized. The former is employed in an offline state for comprehensive analysis, while the latter conducts secondary statistical analysis, reorganization, and calculation of the original traffic data from the database. This facilitates the construction of feature vectors for subsequent data mining models.

The data preprocessing module encompasses some vital components such as data storage and access, key table structural design, storage design, and trigger design. These elements ensure an efficient handling of the data during processing. Within the abnormal traffic classification detection module, the primary objective is to identify and filter P2P traffic, construct a weak classifier, and enhance its performance. By following this system design, it is possible to improve the accuracy and effectiveness of online traffic classification, enabling efficient detection and analysis of abnormal network traffic.

C. The Architecture Design

To achieve comprehensive maturity and facilitate modular construction in developing the proposed ODFM system for general anomaly network traffic detection, it is imperative to design and establish a corresponding software architectural framework. Maturity, in this context, refers to universally recognized technology that guarantees superior system performance, ultimately enhancing the system's long-term viability. Modular construction involves methodically dividing software functionality into autonomous modules, thereby streamlining software maintenance and facilitating seamless upgrades.

The ODFM system is meticulously constructed upon the robust Model-View-Controller (MVC) design pattern, adopting a multi-layered approach. The design ensures an efficient segregation of crucial elements, encompassing business logic, interface display, and data models. As a result, the ODFM system achieves parallel operations, which can bolster its computational capabilities, and thereby optimizing the overall performance of network anomaly traffic detection.

The software technology implemented in the proposed system predominantly encompasses three distinctive layers. Fig. 2 illustrates the three-layer technical architecture. Firstly, Presentation Layer unveils an intuitive and user-friendly interface for seamless system operation and discernible result display. It adeptly handles the input data, promptly forwarding it to the Business Processing Layer or, in turn, receiving pertinent data communicated from the Business Parallel Processing Layer. Secondly, Business Processing Layer encompasses specific business logic, which is further partitioned into three sub-layers, including data acquisition, business applications and external interfaces. Notably, the external interfaces facilitate seamless data exchange and robust sharing capabilities between the ODFM system and other compatible systems, fostering optimal data application. Web Services has been judiciously chosen as the technology of choice for shaping these external interfaces. Lastly, Data Layer assumes the responsibility for efficient storage and meticulous management of indispensable network traffic information. It reliably provides indispensable data that fuels the construction of intricately designed classification models within the system. By harnessing the power of this meticulously crafted software technology architecture, the ODFM system confidently attains exemplary levels of maturity, modularity, and operational efficiency. With this robust framework in place, the system flawlessly accomplishes reliable network traffic analysis and impeccable management.

D. Implementation of Modules in ODFM

The ODFM design implementation adopts the Java programming language. For the proper functioning of the windows packet capture (Winpcap) in Java, it relies on utilizing Winpcap at the data link layer control level. Winpcap provides the required network underlying resource access interface for Java, offering extensive capabilities to interact with the network resources. This implementation ensures the advantage of maintaining system independence during the operational process.

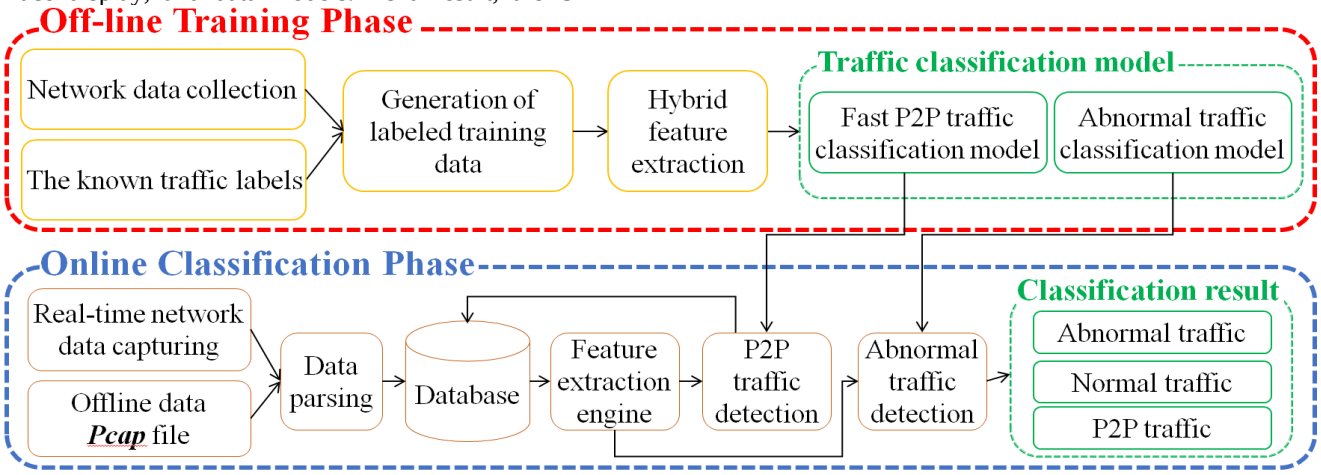

Fig. 1. The detailed flow of the proposed ODFM, which contains an off-line training phase and an online classification phase.

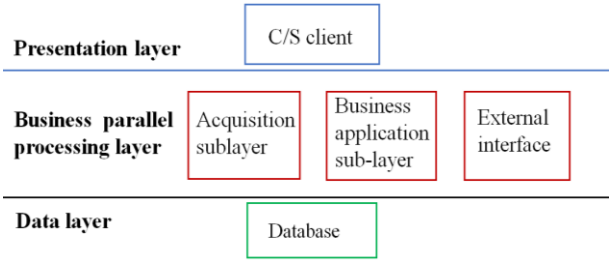

Fig. 2. The three-layer technical architecture of ODFM system.

In the module of traffic collection and parsing, Winpcap serves as a network data capturing framework, which offers excellent application performance in practical scenarios. It consists of filters, wpcap.dll, and packet.dll components. During the data capturing, the JpcapCaptor class provided by Jpcap enables the capture of network traffic. Typically, an instance object of this class is suited for specific network adapter devices, allowing various specified operations to be carried out. Firstly, network device selection is performed using the JpcapCaptor.getDeviceList() function of Java, which returns an array of NetworkInterface objects, representing the available network devices. Opening the network interfaces is done in a static mode through the openDevice() method, which requires four parameters, including enabling promiscuous mode. Secondly, packet capture is conducted using the processPacket() and loopPacket() callback methods within the JpcapCaptor class. The former is commonly used and supports non-blocking and timeout policies, while the latter does not provide these features. Thirdly, filtering rules can be set using Jpcap to achieve the filtration of unwanted packets. For instance, using an IP filter expression would only retain IP packets. Applying such filter rules not only reduces the system's data processing load but also improves application performance significantly. During the system operation, once network traffic capture is realized, the data packets need to be analyzed and processed. By extracting key header fields and conducting comprehensive data and feature extraction, the groundwork is laid for future anomaly traffic detection.

In the module of data storage, traffic storage mainly lays the data foundation for the data mining model. In the construction of the ODFM system, the open-source MySQL database server is selected as the database management system. To enhance data storage efficiency and application performance, the c3p0 connection pool technology is also utilized. This involves submitting the opening and closing of database connections to the connection pool, which significantly improves the efficiency of data access at the application level. For the data parsing, the c3p0-config.xml is configured with the necessary database parameters. The inclusion of jar packages such as c3p0-0.9.1.2.jar, mysql-connector-java-5.08-bin.jar (the MySQL database driver package), and commons-dbutils-1.4.jar (JDBC encapsulation library) enables simplified development using the dbutils framework. This framework streamlines development by encapsulating result sets, managing resource releases, and facilitating database transactions. The database storage module design primarily focuses on table, trigger, and stored procedure implementations to fulfill the requirements of business needs. Trigger design plays a pivotal role in connecting the P2P traffic identification module with the abnormal traffic detection module. It enables the effective filtering of P2P traffic within transmission control protocol (TCP), thereby enhancing the accuracy of abnormal traffic data processing and reducing false positives. This is accomplished through a trigger that automatically deletes P2P traffic in the tcp_table based on IP addresses when a result is inserted into the p2p_result_table, thereby facilitating data filtering. These implementations are critical in meeting the functional requirements of the ODFM system while optimizing database storage efficiency and supporting accurate traffic analysis.

In the module of feature extraction engine, effective feature extraction provides corresponding feature samples for the traffic classification model. Fig. 3 provides a complete transition diagram of a TCP connection state. During the implementation of this module, statistical analysis of traffic information is conducted, and certain TCP sessions are maintained. For instance, non-three-way handshake RST packets are eliminated. The module's core revolves around the utilization of different network connection states and the sequence of state transformations. This allows for the description of traffic information and enables the incorporation of state statistics mechanisms for analyzing packets in various states. In a TCP connection, if a TCP flow is initiated by the SYN initiator, the first forward starting point is determined. All directions are indicated as forward, denoted by "+", while the direction of packets transmitted by the counterpart is represented by "-". In a complete TCP connection process, both nodes involved in the connection can initiate the connection, resulting in a symmetrical transformation graph. However, statistical analysis is typically performed based on one of the states. A complete TCP connection usually comprises three stages: the three-way handshake, data exchange, and connection release. Generally, only the relevant states are iterated in a self-looping manner. The application of this module allows for a comprehensive analysis of TCP traffic, ensuring accurate tracking of connection states and statistical analysis of corresponding packets. By considering the unique characteristics of each state, the module enables effective traffic analysis and facilitates the identification of potential anomalies or irregularities within TCP connections. During the operation of data feature extraction, this study focuses on analyzing packets that fall within {SYN, SYN/ACK, ACK, RST/ACK, RST, FIN, FIN/ACK, Data} categories. Any malformed packets that do not adhere to the RFC specification are promptly flagged for immediate alarm. In cases where the TCP connection is normal or RST packets are detected, the stream recording is halted, and the packet information is recorded and the connection is cleared. To effectively maintain the same flow information, the TCP packet sequence number is leveraged. Suppose the sequence number is denoted as S, the load size of the current packet is represented as L, and the sequence number of the subsequent TCP packet is $S+L$. This approach allows for accurate tracking and management of the flow information. On the other hand, the feature extraction of P2P traffic identification is relatively straightforward. It involves that extracting the payload length information from each UDP stream and realizing packet statistics using a List set. By focusing on these specific packet categories and applying appropriate techniques for maintaining flow information and

P2P traffic feature extraction, the ODFM streamlines the traffic analysis process and ensures the identification of abnormal or irregular packets while adhering to standardized protocols.

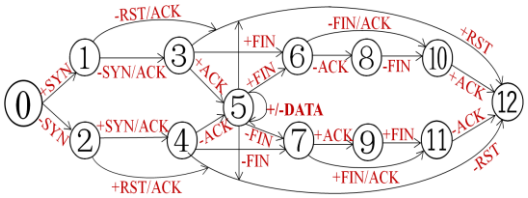

Fig. 3. The transition diagram of a TCP connection state.

In the module of abnormal traffic classification module, we analyze the relevant feature samples extracted by the feature extraction engine module in the traffic classification module to obtain classification results. This allows us to construct a decision tree classifier and apply the AdaBoost algorithm [37] in the anomaly traffic classification module. With this operation, the classifier can be transformed into a strong classifier, which further enhances the accuracy of P2P traffic identification without the need for additional boosting.

In the anomaly traffic classification process, we primarily focus on the off-line training and online classification calculations. For practical classification, we need to develop additional functionality based on the related *jar* packages of *Weka*. Therefore, understanding the underlying algorithms encapsulated in Weka is crucial. Once the data mining process is complete, the anomalous network traffic is passed to the alert module, which generates alert information. The files containing non-anomalous traffic information are then deleted, completing the entire anomaly network traffic detection process. The decision tree training model is stored in memory. By loading the training samples and applying the "*buildClassifier* (Instances instances)" method, the trained classifier model is loaded into memory. Through these procedures, we can effectively analyze and classify abnormal network traffic, which ensures accurate detection and response to potential threats.

III. Experimental Evaluation

In this section, comprehensive experiments are conducted to validate the effectiveness of our proposed ODFM method in the context of anomaly network traffic detection tasks. Stress tests are carried out on each module to analyze the system's traffic processing capabilities. The average processing speed of each module is evaluated and presented in Table I, which highlights the competitive speed of the abnormal traffic classification detection module and indicates favor consumed time when processing a mass of data packets in the modules of traffic collection, parse and store. Although the system design incorporates the AdaBoost modeling strategy [37], which may initially require a longer training time, real-time classification becomes feasible after successfully completing the model building process. The trained model can be serialized in memory, enabling efficient offline training. During real-time classification, only the feature samples need to be directly input for processing.

Furthermore, the system employs multi-threaded parallel computing to pursue efficient processing times. For instance, the processing of 500,000 network data is completed in less than 180 seconds. However, in practical applications, traffic capture and statistics are typically implemented at minute intervals. In general, the statistical interval time above 180s can be considered to meet the real-time requirements of the system. The experimental results indicate the robustness and efficiency of the proposed ODFM method for anomaly network traffic detection, indicating its suitability and effectiveness for real-time applications.

TABLE I. Results of Data Processing of each Module

Module\Parameter	Packets (ten-thousand)	Time (s)
Collection, Parse, Store	19.6	60
Feature extraction engine	51.2	60
Traffic classification detection	100	5.8

IV. Conclusion

In this paper, we propose a novel anomaly traffic detection approach called ODFM that incorporates the optimization of feature dimension reduction and data mining. Different from the traditional methods that take massive data as input and implement the complex design of high-dimensional feature sample to achieve the model training, this paper first adopts the feature selection mechanism to reduce the feature analysis dimension, and sets the P2P traffic identification module to filter the related service traffic, so as to reduce the amount of data detection and improve the detection accuracy. The motivation behind ODFM is that an optimization of approximate feature dimension and normal traffic mining can complete fast anomaly detection while ensuring high detection accuracy. Experiments indicate that the whole pipeline can produce competitive detection results, and it can be able to address various challenging anomaly traffic situations, showing its obvious efficacy in the task of network anomaly traffic detection.

***Abstract*—Indeed, Image Captioning has become a crucial aspect of contemporary artificial intelligence because it has tackled two crucial parts of the AI field: Computer Vision and Natural Language Processing. Currently, Bangla stands as the seventh most widely spoken language globally. Due to this, image captioning has gained recognition for its significant research accomplishments. Many established datasets are found in English but no standard datasets in Bangla. For our research, we have used the BAN-Cap dataset which contains 8091 images with 40455 sentences. Many effective encoder-decoder and Visual Attention approaches are used for image captioning where CNN is utilized for the encoder and RNN is used for the decoder. However, we suggested a transformer-based image captioning model in this study with different pre-train image feature extraction models like Resnet50, InceptionV3, and VGG16 using the BAN-Cap dataset and find out its effective efficiency and accuracy based on many performances measured methods like BLEU, METEOR, ROUGE, CIDEr and also find out the drawbacks of others model.**

Keywords*—Bangla image captioning; image processing; natural language processing; attention mechanism; transformer model

I. Introduction

For image captioning, humans first look at the image and detect the object. Each human brain has a huge local language vocabulary. After detecting the object, it finds out the vocabulary of this respective object and generates a description of this image. This process is easier for humans but it needs some steps for our machine. For machines, it integrates two fundamental components of artificial intelligence, namely Computer Vision (CV) [1] and NLP [2]. When it comes to computer vision, various pre-trained CNN models [3] are employed to extort image features. These appearances are subsequently fed through an RNN [4] to generate captions utilizing the LSTM mechanism [5]. These days, there are several uses for picture captioning, including self-driving cars, social media, security and surveillance, travel and tourism, healthcare, robotics, and many more. Nowadays, the seventh most used language worldwide is Bangla [6]. For the huge number of populations, it is recognizable for significant research.

However, this research can find out the lack of a present days' model where existing model RNN is performed for generating word of sequences and discover the absence of context awareness where the existing model is trained using tokenizer word format without any relative positioning and attention mechanism. In this paper we try to take the following objectives:

- Build up an image captioning sculpt lying on transformers.
- Attention on the context.
- Compare the suggested model performance with other popular images captioning model.

The proposed model's performance undergoes assessment through various Natural Language Processing evaluation methods that rely on both machine-generated captions and reference captions. These methods include BLEU [7], METEOR [8], ROUGE [9], and CIDEr [10].

II. Literature Review

We discuss several approaches and cutting-edge techniques used in Bangla picture captioning in this part. This section is separated into two sections: The visual attention-based method and the CNN-LSTM-based approach. Ultimately, we endeavour to identify the limitations of the prevailing models.

A. CNN-LSTM-based Approach

The initial Bangla image captioning model is constructed based on the CNN-LSTM architecture, as outlined by [11]. These are separated into two parts :1. Image features extraction 2. Language is generated based on the features. The image feature is extracted by the VGG16 model [12]. The model operates with two inputs: the image and the tokens' order(which represent unique words in the dictionary). It employs an embedding layer to derive the respective word embeddings from the tokens. The word embedding layer's output is subsequently compressed to 512 dimensions using a dense layer. This result is reciprocated to the sequence produced by the embedding layer as its output data that is stacked on the LSTM. The stacked LSTM sequence data generate the n-length caption. Here is a blocked diagram Fig. 1.

B. Visual Attention-based Approach

The visual attention-based approach [13] is described in three parts: 1. Image feature extracted by CNN [3] 2. Attention mechanism for getting weighted image features [14]

3. GRU [13] for generating the caption. Here is a block diagram Fig. 2 of this model.

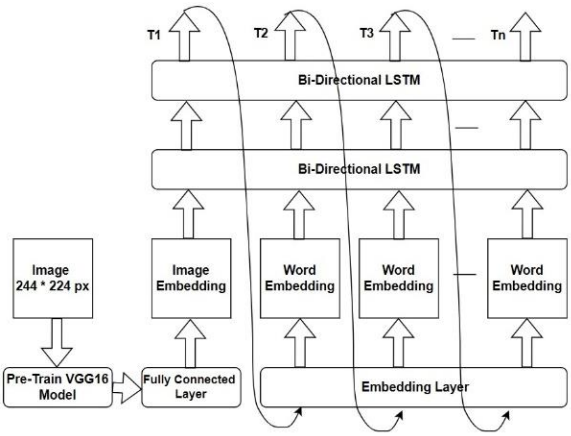

Fig. 1. Image captioning CNN-LSTM model [11].

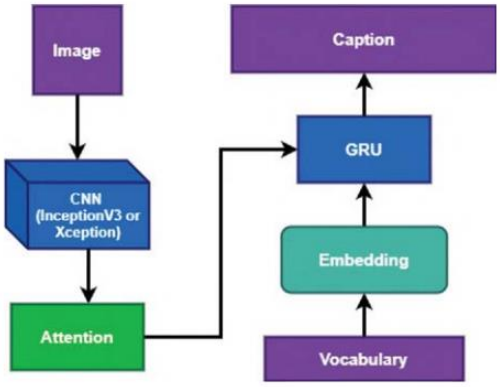

Fig. 2. Visual attention model for image captioning [13].

In this model image features are extracted by the CNN to focus on an important portion image. the image feature vector is directed to the attention mechanism, which generates a context vector specific to this image. In this attention mechanism there are three parts: 1. calculate the alignment score 2. calculate the weight 3. calculate the context vector. For the alignment score, the Eq. (1) is:

$$A_{t,i} = a(s_{t-1}, h_i) \quad (1)$$

Where $A_{t,\,i}$ is the alignment score, s_{t-1} is the previous decoder output, h_i is the encoded hidden state and a() is a function of attention. Calculating the weight is only the output of the softmax function.

$$w_{t,i} = softmax(A_{t,i}) \quad (2)$$

To calculate the context, vector the equation is as follows:

$$C_t = \sum_i^T w_{t,i}\, h_i \quad (3)$$

Where C_t is the context vector. In the Embedding section that creates the vector of words. The GRU [15] received inputs of the context vector along with the word vector from the Embedding layer, subsequently producing the caption.

After understanding on popular model, we can specify some major areas in which we can improve our Bangla image captioning model.

TABLE I. DRAWBACKS OF PREVIOUS MODEL

Model Name	Drawbacks
CNN-LSTM Model [11]	1. Limited Parallelization: Sequential execution to generate caption. 2. Context Understanding: It has no attention mechanism to keep the context of the image. 3. Complexity and Training Efficiency: Require more time to execute.
Visual Attention Model [13]	1. Position Tracking: No track on the position in caption words. 2. Sequential Computation: it has no capability of parallel processing. 3. Scalability and Generalization: GRU-based models may encounter difficulties in scaling to larger and more diverse datasets.

Using our proposed model Fig. 4 we solve the drawbacks which are indicated in Table I. In our proposed model where multi-head self-attention layer has multiple numbers of layers that help to parallel execution and the self-attention mechanism helps to focus on the contextual information in the image which eliminates the limitation of parallelization and context Understanding in the CNN-LSTM model approach. Secondly, In our proposed model (see Fig. 4) the positional embedding layer tracks the position of the input vector and the masked self-attention layer filters the key point of the Bangla caption sentences which eliminates the limitation of position tracking and scalability in the Visual attention model approach. In the word embedding layer that tokenizes the Bangla sentence and turns to convert the respective word vector which reduces the complexity of the model. All the layers are fully described in the methodology section.

III. METHODOLOGY

This section provides an impression of the operational construction of our intended model. That's are divided into two parts: Data Collection and Transformer model. In the data collection section, we describe the procedure of data collection and data pre-processing. In proposed transformer model section, we describe the model architecture.

A. Data Collection

We have used two data sets first for the image dataset Flickr8k [16] which contains 8091 images and second for the Bangla caption using the BAN-Cap dataset [17] which contains 40455 captions. Each image has five captions. Here is a Fig. 3 of the most frequent words in this dataset.

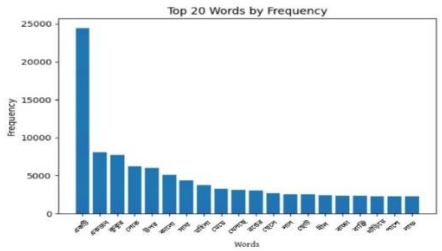

Fig. 3. Top most 20 frequently used word.

B. Transformer Model

The term "Transformers" was first used in the article "Attention is all you need." [18]. It serves as the foundation for some popular versions like GPT-2 [19] and BERT [20]. Language translation models and question-and-answer-based models are two examples of transformer models' many applications. Transformers can be utilized for a variety of application cases because of their versatile architecture**.** For Bangla image captioning, our proposed model, depicted in Fig. 4, is formulated based on the transformer model. We describe our proposed model into two parts: Encoder and Decoder.

C. Encoder

The encoder is tasked with handling the input data. The inputs may be a sequence of words in a natural language sentence, Image data, or any other sequential data. The Encoder is the main work of extracting meaningful representations from the input data that are known as "contextual embeddings". In this section, we describe several parts which are Image Feature Extraction, Positional Embedding, Multi-head self-attention, Add and normalization, and Feed Forward Layer.

1) Image feature extraction: Image feature extraction is a procedure that transforms raw data into a numerical form. Which helps us to identify and capture the relevant patterns of the image. For feature extraction we have used different pre-train models ResNet50[21], Inception V3 [22], and VGG16 models [12]. After the feature extraction, the features are represented with vectors that are shown in Fig. 4.

In our proposed model Fig. 4 we try to solve the drawbacks of the previous model. In this model first, image and captions sequential data are converted into vectors respectively patch embedding and word embedding. To track the position of this sequential data we add a positional encoder that solves the drawbacks of the previous model which are fully described below. After positional encoding the multi-head self-attention it handles every element of the input sequence in parallel, making them more suitable for parallelization during both training and inference. This capacity to handle data in parallel improves training effectiveness and lessens the vanishing gradient issue that helps the limitation of parallelization in the previous model. In the Word embedding layer, we used word tokenizers that easily tokenize the word and convert it into word vectors that store synthetic and semantic information about those words, and all the layers are described briefly in the below section.

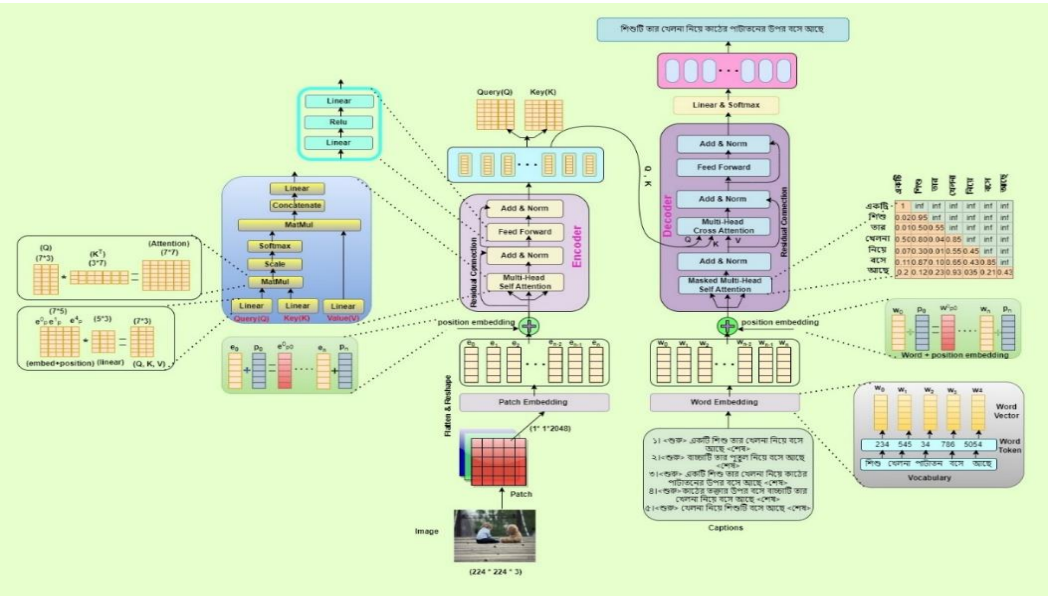

Fig. 4. Diagram of our proposed model.

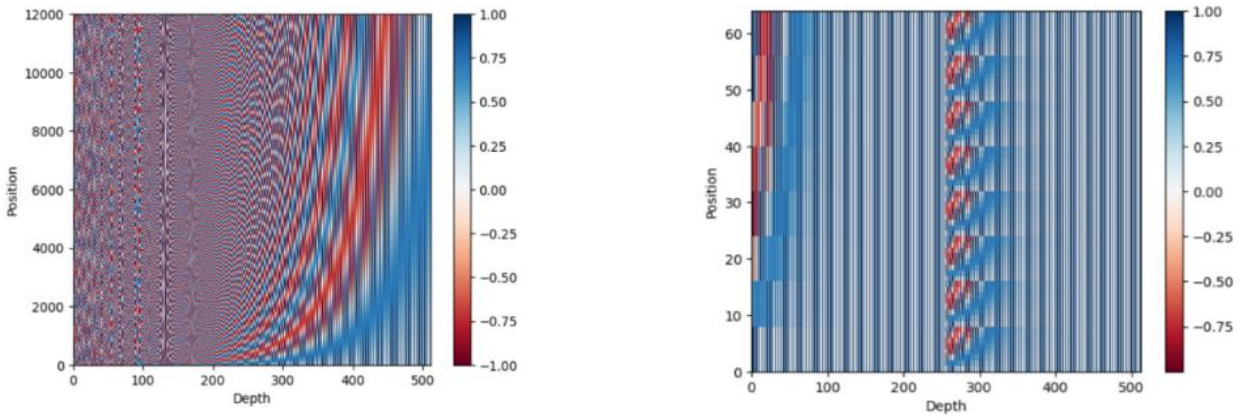
2) Position embedding: Since ours is devoid of repetition and convolution, to ensure the model effectively utilizes the sequence order, it is vital to furnish precise information about the token positions within the sequence. To achieve this, we incorporate "position encodings" into the input embeddings of both the encoder and decoder layers. For better understanding here an example "রহিমের দুটি ঘর রয়েছে, সে দীর্ঘ দশ বছর ধরে রহিমার সাথে ঘর করছে" In this sentence the first word "ঘর" meaning the number of House but the second word "ঘর" meaning the Family. For this reason, we need to track the word that's called position embedding. In Fig. 4 we see how the position value is added with an image vector in the encoder and a word vector in the decoder to track them. There are a variety of methods of position encoding systems. We use the sine and cosine functions for position encoding. The sine function is used for odd positions that are:

$$P_{(pos,2k)} = sin\left(\frac{pos}{10000^{2k/d}}\right) \quad (4)$$

The cosine function is used for even positions that are a mathematical form:

$$P_{(pos,2k+1)} = cos\left(\frac{pos}{10000^{2k/d}}\right) \quad (5)$$



(a) (b)

Fig. 5. (a) Caption position encoding (b) Image position encoding.

From Fig. 5 we show that the value of each position is represented between 1 to -1. On the graph, Position is shown by the Y axis and the associated position value by the X axis for both image and caption encoding.

3) Multi-head self attention: As the name suggests, Attention means to focus on the input data that are relatively close to the features and therefore establishing a relationship with them. Fig. 6 shows that the main three focusing points of this image are the baby, doll, and wood. There is a caption generated based on those points.

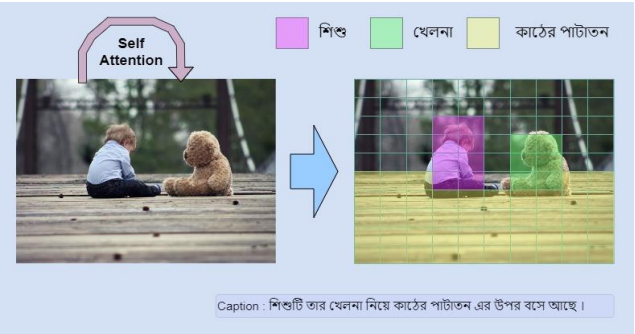


Fig. 6. Self-Attention in an image.

From Fig. 4 we show the mechanism of the multi-head attention layer with a better example. Firstly, the Linear section receives the positional embedding's output. The linear layer functions as a fully connected neural network that performs multiplication with positional encoding, thereby generating a matrix. This matrix is duplicated into the Query, Key, and Value matrices.

- Query(Q) - Represents the whose value needs to be determined
- Key(K) - Represents the features
- Value(V) - Represents the actual value of the input

Secondly, the MatMul section creates an attention-value matrix that is shown in Fig. 4. The mathematical representation is:

$$A_{(Q,K)} = Q.k^T \tag{6}$$

Thirdly, to normalize the attention values within the attention matrix, each value is divided by $\sqrt{dk}$ where (dk) is the dimension of Key metrics. The mathematical representation is:

$$s_i = \frac{A_{(Q,k)}}{\sqrt{d_k}} \tag{7}$$

Fourthly, the S_i value passed into the softmax() and the output vector of the activation function is a matrix multiplied by the Value(V) matrix in the MatMul section and creates an attention-weight matrix. Which attention weight value is high which represents the focus point. Here the final mathematical equation is:

$$A_{(Q,K,V)} = softmax\left(\frac{A_{(Q,K)}}{\sqrt{d_k}}\right).V \tag{8}$$

This attention equation is for one head. For the name multi-head, the concatenate layer Fig. 4 is added to those heads. The mathematical equation is:

$$MultiHead_{(Q,K,V)}$$
$$= concat(head_1, head_2, head_3 \ldots\ldots head_n) \tag{9}$$

n denotes the number of heads.

4) Add & Norm: This Layer does two activities, as its name indicates. The 'Add' portion of the process, which controls flow via residual connections, is the initial phase. 'Norm', the next step, accomplishes layer normalization.

5) Feed forward: This Layer incorporates a fully connected point-wise feed-forward network, employing the ReLU activation function to conduct two linear transformations, as illustrated in Fig. 4. This layer determines the weights used during exercise. The mathematical representation is:

$$FF(x) = ReLU(xw_1 + b_1)w_2 + b_2) \tag{10}$$

Weight matrices denote by W_1 and W_2, and bias denoted by b_1 and b_2, where the ReLU [23] function is :

$$ReLU(x) = max(0, x) \tag{11}$$

D. Decoder

For tasks like language translation, text generator, and text summarization, the decoder in a Transformer is in charge of producing an output sequence. It works in conjunction with the encoder, which analyzes the input sequence. In Fig. 4 Decoder is comprised of: 1. word embedding layer 2. Position embedding 3. Masked multi-head self-attention layer 4. Addition & Normalization 5. Multi-head cross attention 6. Feed Forward layer 7. Linear & SoftMax layer. In the previous Encoder section, we have already explained those layers which similar to both the encoder and decoder. So, in this section, we describe the below layer.

1) Word embedding: It is an essential component of the transformer concept. That is responsible for converting input tokens of words and generating a word vector. This vector records the word's semantic and grammatical details thereby assisting this model in acquiring a meaningful representation of the input text. Fig. 4 shows an example of Bangla words converted into word vectors by tokenization which are detonated by $w_{0.....}$ w_n.

2) Masked multi-head self-attention: This level is essential in the Transformer model because it prevents the model from attending to future locations and maintains the autoregressive characteristic while enabling it to focus on different input sequence segments. After receiving the previous decoder output stack, the first sublayer adds positional information to it and applies self-attention to it. Decoders are altered to focus exclusively on the words that come before them, whilst the encoder is made to pay attention to every word respective to the input sequence of where it appears in the sequence. Consequently, the forecast for a word at a specific position in the sequence can only rely on the known outputs for the preceding words. This is accomplished in the multi-head attention mechanism. Through the application of a mask to the outcomes of the scaled matrix multiplication, the values that would otherwise correspond to prohibited values are suppressed to achieve this masking. Fig. 4 gives a pattern of a mask filter on the words. In Fig. 4 infinity(inf) means that has no probability with the next words and maximum value means the high probability of the next word. Here is a simple representation of the mask filter.

$$mask(Q, K^T) = mask\left(\begin{bmatrix} w_{11} & w_{12} & \dots & w_{1n} \\ w_{21} & w_{22} & \dots & w_{2n} \\ \dots & \dots & \dots & \dots \\ w_{k1} & w_{k2} & \dots & w_{kn} \end{bmatrix}\right) = \begin{bmatrix} w_{11} & inf & \dots & inf \\ w_{21} & w_{22} & \dots & inf \\ \dots & \dots & \dots & \dots \\ w_{k1} & w_{k2} & \dots & w_{kn} \end{bmatrix} \quad (12)$$

E. Model Parameters

We trained our proposed model with different hyper-parameter value that's are indicated on Table II. Those internal variables are adjusted in our model during the training process to minimize the error between predicted and target captions. Those model parameters perfectly capture the features, relation, and pattern of the data.

TABLE II. EXPERIMENTAL PARAMETERS

Parameters name	Value
Vocabulary size	12000
Batch size	64
Buffer size	1000
Dropout rate	0.001
Number of Layer	8
Dimension of model	512
Number of head	8
Number of Epoch	40
Maximum length of sentence	25

IV. RESULT AND DISCUSSION

This part describes the functionality and visualization of the model we've suggested, and then we compare it to other models. Here in Table III, we show our proposed model's performance with different pre-train CNN models. The performance is measured by BLEU [7], METEOR [8], ROUGE [9], and CIDEr [10]. In Table III, the ResNet50+Proposed model gives the maximum output. Ok, Table IV compares our model to several model methodologies.

Now, here below in Fig. 7, 8, and 9 show the accuracy and loss curve of our model. The validation curve is represented by a yellow color line and the training curve is represented by a blue color line. The learning curve is the identifier of model overfitting and underfitting evaluation. From Those figures, we see that the accuracy curve of our model is closely together and gradually increasing. Other side, the loss curve is closely together and gradually decreasing. For this, the model is free from overfitting and underfitting issues and called it is called a good fit model. We hope that our model are more balanced fit for large datasets like Flick30k [25].

TABLE III. PERFORMANCE TABLE FOR OUR PROPOSED MODEL

Model	Dataset	BLEU1	BLEU2	BLEU3	BLEU 4	METEOR	ROUGE	CIDEr
Resnet50+ proposed model	Flick8k+ BAN-Cap_captiondata	**64.38**	**58.58**	**43.40**	**24.30**	**0.31**	**0.39**	**0.28**

V. Conclusions and Future Work

This study presents a transformer-based paradigm for captioning images in Bangla. This proposed model is turned up with better efficiency and performance based on different evaluation methods. It also proves that this model is a good fit for Bangla image captioning on the Flick8k+BAN_Cap dataset. we expect that this paper will help to encourage to others develop more efficient transformer-based models in different NLP and Computer Vision tasks. We also expected that it would be helpful for Image Captioning on higher datasets like Flick30k and others datasets and in the future, we also try to do this.

The Hybrid Jaro-Winkler and Manhattan Distance using Dissimilarity Measure for Test Case Prioritization Approach

Siti Hawa Mohamed Shareef, Rabatul Aduni Sulaiman*, Abd Samad Hasan Basari
Department of Software Engineering, Faculty of Computer Science and Information Technology,
University Tun Hussein Onn Malaysia, Batu Pahat, Malaysia

Abstract*—Software product line (SPL) is a concept that has revolutionized the software development industry. It refers to a set of related software products that are developed from a common set of core assets but can be customized to meet specific customer requirements. Integrating SPL techniques into test case prioritization (TCP) can greatly enhance its effectiveness. By considering variability across different products within an SPL, it becomes possible to prioritize test cases based on their relevance to specific product configurations. However, the concept itself still has certain issues, such as in finding the highest rate of early failure detection. Various solutions have been proposed to mitigate this problem, among them is to improve the calculation of string distance using hybrid technique to achieve a high degree for similarity. Dissimilarity-based Technique (DBP) is the basis for our ranking method. The objective is to identify further weaknesses in the product lines as well as the differences between the experiment and real-world applications. Our focus is to enhance hybrid techniques that produce the highest rate of early failure detection. In this paper, early fault detection is selected as the performance goal. In order to choose the optimal methods for DBP for TCP, a comparison between several string distance measures was conducted. This study proposed hybrid techniques that combined Jaro-Winkler and Manhattan string distance namely New Enhanced Hybrid Technique 1 (NEHT1), New Enhanced Hybrid Technique 2 (NEHT2) and New Enhanced Hybrid Technique 3 (NEHT3). The case study was generated using the PLEDGE tool based on a Feature Model (FM). Six test cases were used in the experiment. Result shows the effectiveness of the combination where it achieved higher degree of similarity for T1 vs. T4, T2 vs. T3, T2 vs. T6, and T3 vs. T6, as well as perfect degree of similarity for NEHT1 (100.00%). The result proves that the combination of both techniques improve SPL testing effectiveness compared to existing techniques.

Keywords*—Test case prioritization; software product line; dissimilarity-based technique; string distance; new enhanced hybrid

I. INTRODUCTION

Software product line (SPL) is a collection of related software products that share a common set of core assets while also offering variations to address diverse customer needs [1]. The characteristics may be constant throughout all SPL-derived products, or they may be varied and present in only some of them [2]. Instead of building each product from scratch, SPL approach emphasizes systematic reuse, enabling efficient development and maintenance of multiple products. SPL streamlines development, reduces redundancy, and enhances consistency across products [3]. Many industries implement SPL due to its ability to handle different phases of development using the commonality and variability concepts [4].

Software product line testing (SPLT) involves testing the shared components and individual product variants within an SPL [5]. It ensures the quality, compatibility, and correctness of both the common core assets and the unique features of each product. This type of testing addresses the challenges posed by varying configurations, shared components, and differing features, while maintaining overall product line quality [6]. Similar to testing in non-configurable code, testing in SPL experiences the coincidental correctness phenomena, which makes it more challenging to detect errors in these systems [7]. However, the testing of a single software system is a highly difficult and expensive stage of the software development process, according to the author [8].

Test case prioritization (TCP) is the process of ordering test cases based on certain criteria to optimize testing efforts [9]. Even though a few trailing test cases are not exercised, these test suites uncover bugs at the earliest possible time [10]. It presents a significant difficulty for software testing [11]. In the context of SPL, prioritization becomes complex due to the diversity of features and configurations [12]. Researchers suggested TCP procedures, where test cases were restructured and carried out in accordance with a given objective, to boost the efficacy and efficiency of testing [13]. A hybrid approach that considers both similarity and dissimilarity should be adopted for effective TCP in SPL development. Similarity refers to the degree to which two or more test cases share common characteristics or requirements while dissimilarity refers to the differences between test cases [14]. Techniques like Jaro-Winkler distance and Manhattan distance can be used to compare test cases for similarity, dependencies, and impact. Prioritizing test cases ensures that critical defects are identified early and that testing resources are allocated efficiently.

SPL has gained prominence in modern software development by allowing the creation of multiple products with shared features and components. TCP plays a vital role in ensuring the quality and reliability of these products. Hybrid string distance, a combination of various string similarity metrics, presents a promising approach to enhancing TCP in

SPL [15]. Hybrid string distance for TCP in SPL faces challenges such as diverse feature sets, low scalability, requires careful consideration of appropriate metrics, and low adaptability to dynamic changes [16]. Managing multiple product variants, selecting appropriate metrics, and ensuring the hybrid approach remains effective and adaptable to evolving requirements are essential for successful implementation. To optimize outcomes in TCP using hybrid string distance in SPL, several objectives should be pursued including comprehensive metric selection, feature-driven prioritization, and scalable algorithm design, adaptability to changes, and empirical validation and evaluation. The hybrid approach should consider specific product variant features, create a mechanism for prioritizing test cases based on these features, and ensure scalability without compromising performance. Finally, the approach should be tested on real-world SPLs to demonstrate improvements in TCP accuracy, coverage, and overall software quality.

This paper addresses the limitations of current TCP methods that struggle to accurately gauge the semantic similarity between test cases, resulting in less than optimal prioritization outcomes. To tackle this issue, the study poses a research question: "Which new hybrid technique can offer the highest early failure detection rate in TCP?"

The research introduces an innovative TCP approach that combines Hybrid Jaro-Winkler and Manhattan distance, integrating a dissimilarity measure. The main contribution lies in enhancing the precision and efficacy of TCP. This technique is used to overcoming the difficulties linked to precisely measuring semantic similarity. This method aims to advance software testing by significantly enhancing prioritization outcomes by providing a more robust and dependable approach for early failure detection in TCP.

The following section outlines the relevant literature. Section III present the proposed approach in detailed, incorporating the experimental settings and a combination of string distance measures whereas Section IV discuss on the results and discussion are presented, leading to the conclusions, in Section V.

II. Related Work

Incorporating TCP techniques like reordering test cases based on fault detection rate can significantly enhance the effectiveness of software testing by enabling early fault detection [17]. In the context of TCP for SPL, the term string distance refers to the measurement of the similarity or dissimilarity of various strings that stand in for test cases [8]. With this method, test cases are ranked according to how distinctive or diverse they are from one another in terms of the testing functionality, or the areas of the code covered. String distance allows for better resource allocation by identifying redundant or overlapping test cases [18]. However, according to Halim et al. [1], neglecting string distance would result in inefficient testing processes and delayed bug fixes. Therefore, incorporating string distance in TCP is essential for efficient software development [19, 20].

Similarity-based prioritization (SBP) focuses on identifying test cases that are similar to each other based on certain criteria, such as code coverage or functionality [1, 21]. The idea behind SBP is that if one test case covers a particular aspect of the software, then similar test cases are likely to cover the same aspect as well [22]. This approach is effective in reducing redundancy in testing efforts by selecting a representative subset of test cases [23]. However, dissimilarity-based prioritization (DBP) considers the diversity among test cases. DBP aims to select a diverse set of test cases that covers different aspects of the software under test [23, 24]. By considering dissimilarities between test cases, this approach ensures comprehensive coverage and reduces the risk of missing critical defects [25].

Sulaiman et al. [25] suggested a measurement based on maximal distance of dissimilarity measure for SPL, which assures thorough coverage and lowers the possibility of overlooking important faults. The study is based on the test case generated from a statechart in comparison to current work, which is based on the FM in the context of the SPL domain. By increasing string distance and prioritizing based on similarity, Halim et al. [1] suggested rearranging test cases to increase the rate of problem identification. The work compared various string distance measures and prioritization algorithms in order to determine the best methods for similarity-based on hybridization of Jaro-Winkler and Hamming distance equation.

Fault detection has been improved in existing studies via the use of new and enhanced hybrid techniques for string distance equations. Recent work by Pospisil et al. [26] aimed to enhance adaptive random TCP for model-based test suites using original technique for Jaccard, Manhattan distance and similarity functions. All of the examined systems achieved improved fault detection performance as a result of the proposed improvement. Another study by Kumar et al. [9] employed Item-based Collaborative Filtering (ICF) to prioritize and decrease the number of products before testing. Hamming string distance was used to calculate the degree of similarity between products. Results of the study show that this approach was able to reduce test suite size. Compared to the works by Pospisil et al. [26] and Kumar et al. [9], the current study concentrated more on using a hybrid string distance method to determine the degree of dissimilarity and then locate the distance with the greatest similarity reading.

III. Proposed Approach

The ranking method we use is based on dissimilarity. Our objective is to find further weaknesses in the product lines being evaluated as well as the point of difference between test case and real world. The study concentrates on the following research question:

RQ1: Which new enhanced hybrid technique produces the best early failure detection rate?

We start by outlining the conditions of our experiment before going on to describe the findings.

A. Experimental Settings

The experiment was carried out on Windows 11 with an AMD Ryzen 5 5625U processor running at 2.30 GHz and 8GB of RAM. The authors developed a New Enhanced Hybrid Techniques (NEHT) by improving string distance using three

hybrid techniques to evaluate the comparability of similarity and dissimilarity measures. For the purpose of generating configuration and prioritizing processes, this technique's similarity and dissimilarity measures will be assessed using current Feature Model (FM), Software Product Line Online Tool (SPLOT) and Product Line EDitor and tests GEneration (PLEDGE) tools. In SPL, FM allows for the systematic representation and management of features, their dependencies, and variations across different products [27]. SPLOT is a web-based tool that allows users to create incredibly dynamic Ajax-based setup and reasoning user interfaces [28], while PLEDGE is an open-source tool that selects and prioritizes product configurations, maximizing the feature interactions covered [29]. In order to test the SPL, the author selects an FM for machine learning based on the Global Positioning System (GPS) created by Saini et al. 2023 [8] as in Fig. 1. Due to the fact that not all possible feature combinations are viable, feature diagrams are used to limit the variety of a product line. Based on the FM in Fig. 1, the *.xml* files will be produced using SPLOT. The *.xml* file will be used to generate the six test cases displayed in Table I after being run using PLEDGE. An ordered list of configurations is often the outcome of a sampling method.

B. Hybrid of String Distance

The purpose of the proposed approach is to find dissimilarity between two test cases. Two strings distances were chosen to develop the proposed approach which is Jaro-Winkler and Manhattan distances. Jaro-Winkler distance is a string distance algorithm that measures the similarity between two strings [30]. It has been widely used in various fields, including TCP. Meanwhile, Manhattan distance is a popular metric used in TCP and works by first creating a matrix of all possible pairs of test cases [15]. It is used to measure the distance between two points on a grid-like system, where the distance is calculated by adding the absolute differences of those coordinates. In software testing, this metric helps prioritize test cases based on their proximity to each other.

The selection of the Hybrid Jaro-Winkler and Manhattan Distance Using Dissimilarity Measure for TCP Approach is grounded in its distinctive ability to address the challenges prevalent in existing TCP approaches. The hybrid nature of the chosen method combines the strengths of Jaro-Winkler and Manhattan string distance, offering a comprehensive solution for accurately capturing semantic similarity between test cases. The integration of a dissimilarity measure further enriches the approach, enhancing the precision of TCP. The decision to adopt this method is motivated by its potential to significantly improve prioritization results and contribute to more effective early failure detection in TCP.

By improving two string distance techniques, this method will produce a new hybrid technique that is precise in obtaining faster early failure detection rate. Fig. 2 describes the combinations of two string distance to develop the three new enhanced hybrid techniques. New enhanced hybrid technique 1 (NEHT1) modifies existing Jaro equation, and Manhattan equation replaces value of m and t with value of test cases *(T1, T2)*. New enhanced hybrid technique 2 (NEHT2) combines Jaro-Winkler and Manhattan equations, replaces m value with n value and t with value of test cases *(T1, T2)*, adds value of test cases, divides with n value and multiply with 1-dj. New enhanced hybrid technique 3 (NEHT3) combines Jaro and Manhattan equations where the formula replaces value of m with n and t with value of test cases *(T1, T2)*.

TABLE I. CONFIGURATIONS OF GPS FEATURE MODEL

Test Case	Configuration

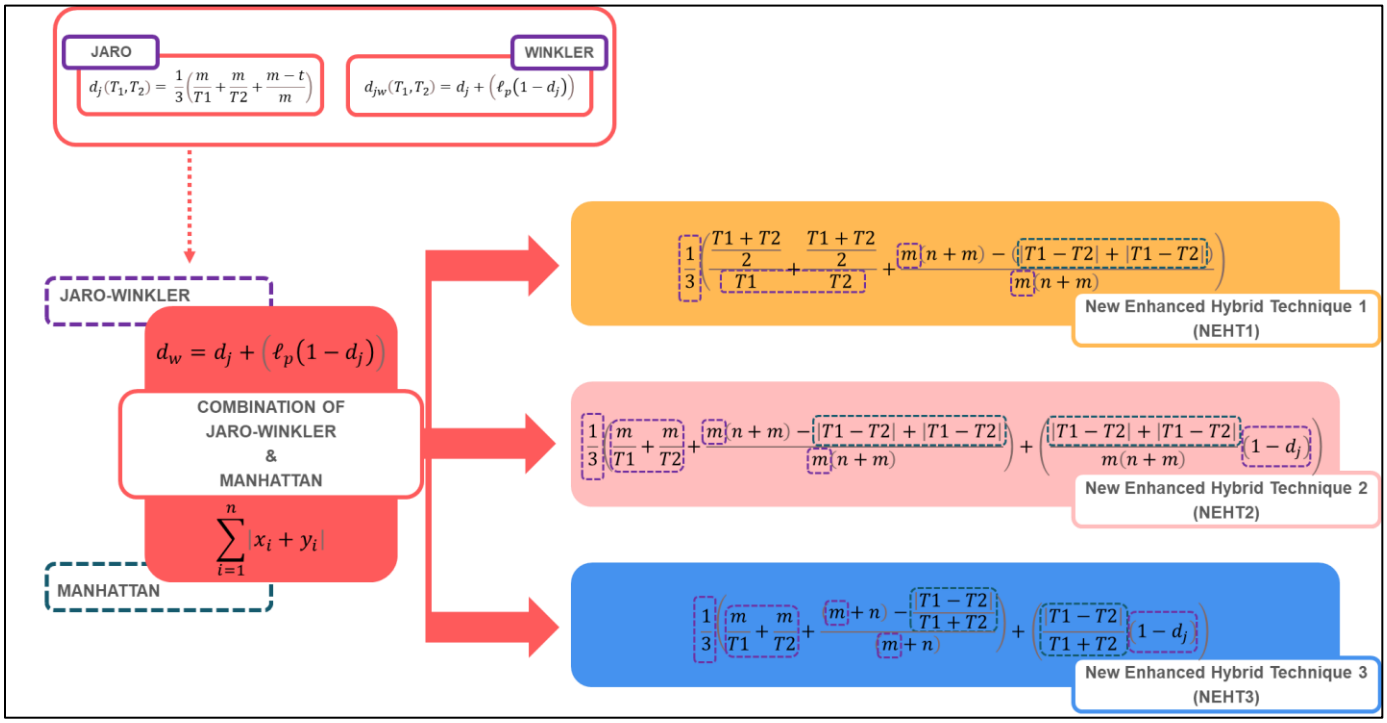

Fig. 2. New enhanced hybrid techniques.

IV. Result and Discussion

Table II shows the similarity and dissimilarity percentages between different pairs of test cases *(T1, T2, T3, T4, T5, T6)*, with NEHT1, NEHT2, and NEHT3 representing different methods or conditions. The values range from 0% *(complete dissimilarity)* to 100% *(complete similarity)*. Since this is an initial result, results use a single FM to represent a dataset. For NEHT1, T1 vs T4, T2 vs T3, T2 vs T6, and T3 vs T6 recorded complete similarity (100.00%), proving the formula is very effective in similarity calculation. Values for NEHT2 and NEHT3 were similar in T1 vs. T4, T2 vs. T3, T2 vs. T6, and T3 vs. T6, which means both proposed techniques provide a consistent way to determine similarity level. The majority of the results show that NEHT1 is effective at determining the degree of similarity.

TABLE II. Calculation for Degrees of Similarity and Dissimilarity

Test Case	NEHT1	NEHT2	NEHT3	NEHT1	NEHT2	NEHT3
	Similarity (%)			*Dissimilarity (%)*		
T1 vs T2	86.79	82.25	70.95	13.21	17.75	29.05
T1 vs T3	97.90	83.40	83.79	2.10	16.60	16.21
T1 vs T4	100.00	71.42	71.42	0.00	28.58	28.58
T1 vs T5	99.56	95.92	95.95	0.44	4.08	4.05
T1 vs T6	97.90	83.40	83.79	2.10	16.60	16.21

Fig. 3 and Fig. 4 show similarity and dissimilarity rates of fault detection for the proposed methods *(NEHT1, NEHT2, NEHT3)*. The similarity percentages vary for different methods and test cases. Similar variations may be seen in the dissimilarity percentage, which illustrates how the different approaches of assessing differences differ. There is no uniform trend in how the methods rank similarity or dissimilarity across all test cases. Some test cases consistently show high similarity across all methods, while others show varying degrees of dissimilarity. The author claims that this enhancement will increase the SBP technique's effectiveness [1]. Sulaiman et al. [25] stated that similarity and dissimilarity strategies were introduced to tackle scalability problem in the current priority technique. This method provides a straightforward, scalable, and efficient method for prioritizing and reducing the number of test cases. TCP for SPL can be significantly improved by leveraging high similarity in calculation of string distance. High similarity values are advantageous in locating similar test cases across various SPL. As a result, fewer testing efforts are duplicated, and the existing test cases can be reused. Furthermore, low dissimilarity values can improve coverage, ensure effective bug correction, and improve the fault localization.

V. CONCLUSION

One of the main advantages of SPLT is its ability to save time and resources. Testers can concentrate on the common characteristics shared by all products in the software family rather than testing each product individually. This makes it possible to quickly find and fix errors, at the same time shortens the development process and lowers expenses. For DBP, dissimilarity test case has been proven to be one of the techniques that can speed up failure detection process. This research employed six different test cases to be tested using three proposed hybrid techniques based on the combination of Jaro-Winkler and Manhattan string distances for early fault identification rate. The findings indicated that NEHT1 has a higher rate of fault identification compared to the other two proposed techniques. In order to increase the success rate of NEHT1's fault identification, we plan to make improvements to it in the future. In addition, we intend to use a variety of case study types for this research project. The limitations of current test case prioritization methods, particularly their struggles in accurately capturing semantic similarity, render them unsuitable for the challenges at hand. Traditional approaches fall short in providing a comprehensive solution for the nuanced characteristics of test cases. The proposed method is chosen to overcome these limitations by introducing a hybrid technique that specifically addresses the semantic aspects of test cases. This strategic choice is aimed at mitigating the deficiencies of existing methods and advancing the field of TCP towards a more precise and effective paradigm.

A Novel CNN-based Model for Medical Image Registration

Hui GAO, Mingliang LIANG*
Zhengzhou Railway Vocational and Technical College, Henan, 451460, China

***Abstract*—The registration of the deformable image is applied widely to image diagnosis, the monitoring of the disease, and the navigation of the surgery with the aim of learning the correspondence of the anatomist among an image of motion and an image of static. The procedure of the registration of an image mainly includes three steps: the creation of a model of the deformation, a function design for the mensuration of the similarity, and the step of learning for the optimization of the parameter. In the current article, 2-stream architecture is designed, which has the ability to sequentially estimate the fields of the registration of the multi-level by a couple of the pyramids of the feature. In this paper, a 3D network of the encoder-decoder with the 2-stream is designed, which calculates 2 pyramids of the feature of the convolutional as separately by 2 volumes of the input. Also, the registration of the pyramid of the sequential is proposed, which in it, a trail of the modules of the pyramid registration (PR) for the prediction of the fields of the registration of the multi-level is designed as straight by the pyramids of the feature of the decoding. In addition, the modules of PR can be augmented with the computation of the 3D correlations of the local among the pyramids of the feature, which this work leads to the further improvement of the presented approach. Thus, it is capable of collecting the detailed anatomical structure of the brain. The proposed method is tested in three criterion datasets about the registration of MRI of the brain. The evaluation outcomes display that the presented approach outperforms the advanced approaches with a big value.**

***Keywords*—Image registration; convolutional neural network; Pyramid Registration (PR); encoder-decoder**

I. INTRODUCTION

Today, various imaging methods such as MRI, CT, PET, SPECT, and ultrasound imaging are used for the identification of the anatomical structure and the physiological performance of the human body so that each one of them provides specific information to doctors [1], [2]. The medical images usually do not match each other, and to use their information together, it is necessary to apply the methods of the registration of the image [3], [4], [5], [6], [7]. The registration of the image is the procedure of the orientation of the spatial of 2 images from the same scene in a way that their features can be easily related to each other. These images may be created by different sensors or one sensor at different times [3].

Due to the used images, the registration of medical images can be divided into two types: (1) the registration of the same type; (2) the registration of the different types [3]. In the registration of the same type, the used images are prepared by the same type of sensor. For example, to check the drug performance on cancer tumors, the MRI image is recorded from the patient at certain time intervals. With the registration of these images, it is possible to check the progress of the disease or the progress of its improvement [8]. However, in the registration of the different types, the goal is the registration of the recorded images by two different types of sensors. For example, it can refer to the registration of image of MR anatomical by functional (physiological) PET image and with the registration of these two types of images, can achieve the anatomical features and the functional features in an image [9].

The registration of medical images is divided into two categories in terms of the application: 1) The image registration of various persons. 2) The registration of 2 images from the identical person. The registration of images from the different persons is used for their physiological anatomical comparison and also in the preparation of the medical atlases. Also, the image registration of one person is more used to integrate the information of the different images or to evaluate the treatment by observing the changes in the recorded images at different times [3]. In the image registration process, the motion image $I_M(x)$ ($I_M: \Omega \to R$ which in it, Ω displays the image scope of I) is transformed for the matching on the fixed image $I_F(x)$ ($I_F: \Omega \to R$) which in it, $\mathrm{x} = (\mathrm{x}.\mathrm{y}.\mathrm{z}) \in \Omega$ is the coordinates of spatial of the pixels. Namely, in the image's registration, the purpose is the finding of the transformation $y = T(x)$ ($such\ that\ \mathrm{T}: \Omega \to \Omega$) in the way that the points of the corresponding on 2 images $I_F(x)$ and $I_M(y)$ are coincided with each other. For this purpose, different transformations can be used, and these transformations differ from each other in terms of the computational complexity and the flexibility [4].

The transformations used in the image registration are distributed into 2 general groups: the non-hard transformations and the hard transformations. The hard transformations (such as the common geometric transformations including the Affine, the rigid body, the translation, the rotation, the rescaling, etc.) can be parametrically defined, and they are the same for all image pixels. These types of transformations are usually used in the preparation of the medical atlases and in the general registration of the medical images [5], [6], [7], [9], [10], [11], [12], [13], [14]. On the other hand, the non-hard transformations (in comparison to the hard transformations) have more flexibility for image registration. In this type of transformation, a vector field is transferred for the description of the changes between the static image and the motion image so that with the use of it, the corresponding point with each pixel of the static image can be identified in the motion image. Usually, to achieve a proper registration between 2 images, it is essential to use the hard transformation and the non-hard transformation together. In this way, first, by finding the

appropriate hard transformation, the images are generally matched with each other, and then, by optimizing the appropriate non-hard transformation, the remaining local differences between them are compensated [15].

In this paper, a non-hard transformation is used for the image registration. In the current article, a 2 -stream architecture is designed, which has the ability to sequentially estimate the fields of the registration of the multi-level by a couple of the pyramids of the feature. In this paper, a 3D network of the encoder-decoder with the 2-stream is designed, which calculates 2 pyramids of the feature of the convolutional as separately by 2 volumes of the input. Also, the registration of the pyramid of the sequential is proposed, which in it, a trail of the modules of the pyramid registration (PR) for the prediction of the fields of the registration of the multi-level is designed as straight by the pyramids of the feature of the decoding. In addition, the modules of PR can be augmented with the computation of the 3D correlations of the local among the pyramids of the feature, which this work leads to the further improvement of the presented approach. Thus, it is capable of collecting the detailed anatomical structure of the brain.

This article is introduced with the aim of improving the registration of successive pyramids. This is done with advanced PR modules that increase performance. The overall contributions can be summarized as follows: (1) a two-stream 3D encoder-decoder network is designed to compute two convolution feature pyramids separately from two input volumes, and generate more robust deep features for deformation estimation. (2) Sequential pyramid registration is proposed in which a sequence of registration fields is estimated by a set of designed pyramid registration modules. The estimated registration fields perform successive sweeps on the decoding layers, which gradually refine the feature pyramids from coarse to fine. It equips the model with a strong ability to handle large deformations. (3) The PR module can be enhanced by computing local 3D correlations (between two feature pyramids) followed by multiple residual convolutions, which gather richer local details of the anatomical structure for better estimation of deformation fields. It leads to the improvement of previous methods. In addition, 3D correlations with more complex layers in the advanced PR module can enlarge the receiver field, which further increases the ability to handle large deformations. The continuation of the current article is as follows. Section II presents an overview of related works. Section III, the proposed two-stream architecture is presented. Section IV, the used datasets, the designed experiments, and the obtained outcomes are provided. Eventually, Section V presents the general conclusions and suggestions for future research.

II. Related Works

So far, the researchers have used the non-hard transformation and the hard transformation for the registration of the images of the medical on various works. In the current part, in summary, the articles in this field are provided. For example, Horm and Schunk [16], for the first time, have used the optical flux model for the non-hard registration of the images. This model is proposed by adapting the motion of the relative of objects and also the motion of the relative of the viewer. In this method, the authors suppose the brightness intensity of pixels corresponding to the static images and the motion images do not differ as significantly. In this way, by writing the Taylor series on the brightness intensity function of the motion image, the light flux relation can be obtained for the estimation and for the evolution of the transfer vector field (the non-hard transformation) [16]:

$$\nabla I.u + I_t = 0 \quad (1)$$

where, $\nabla = [\frac{\partial}{\partial x}.\frac{\partial}{\partial y}.\frac{\partial}{\partial z}]^T$ is the gradient operator. Also, $I(x.t)$ ($x = [x.y.z]^T$ displays the coordinates, and t is the time) represents a series of consecutive frames and $u(x) = [u_1(x).u_2(x).u_3(x)]^T$ ($u: \Omega \to R^3$) is the displacement vector that should be optimally adjusted. It should be noted that here $u_1(x)$, $u_2(x)$ and $u_3(x)$ represent the factors from the displacement vector on the axis of x, the axis of y, and the axis of z (and in coordinates of x). In the application of the optical flux method for the image registration, it is assumed that I_F and I_M are two consecutive temporal frames from I (namely, $I(x.0) = I_F(x)$ or $I(x.1) = I_M(x)$). In this case, the temporal derivative $I_t = \partial I/\partial t$ (at $t = 0$) after the discretization will be equivalent to the disagreement between the image of static and the image of motion (namely, $I_t(x.0) \approx I_M(x) = I_F(x)$). It is obvious that by solving the above equation under the latter conditions, the vector field u will be optimized to maximize the likeness among the corresponding cases in I_F and I_M.

The optical flux model has been used widely in the non-hard registration of the images of the medical, which, for example, can refer to the research of Palos et al. [15] After the general registration of the images based on the hard Affine transformation, they used the speed function of the grayscales difference in the optical flux model for the adaption of the details. In study [17], the authors have provided a novel registration method between the MRI images and the images of the ultrasound. To decrease the speckle noise in the procedure of registration, they have used the semi-automatic segmentation method for the magnetic resonance images and for the ultrasound images by using the active contour model. Then, they built a strong optical flux model between the segmented ultrasound images and the magnetic resonance images, and they estimated the flow field vector by using the Gaussian pyramid. Cooper and Ritter [18] have used the optical flux model for the evaluation of registration in 2D images of medical and 3D images of medical and also for the calculation of disagreements in images of static and images of motion. Also, Cao et al.[19] have used the symmetric optical flux model for the registration of 4-dimensional images of CT of the chest to deal with the image registration problems (which are caused by the variation of the local illumination intensity and the large displacements).

In the other article, namely in [20], the authors have applied the model of the elastic for the registration of the images of the brain of the human:

$$\mu\Delta u + (\lambda + \mu)\nabla(\nabla \cdot u) + f = 0 \quad (2)$$

μ and λ are the constants of the elasticity, and f is an external force. The above model is extended based on the relation of the linear elasticity of Navier for the field of the

displacement u. It describes the deformation of a material of the elastic of the deformable beneath the impression of the outside force f.

The model of the elastic has also been applied widely for the registration of medical images. For the example, it can refer to the work of Marami et al. [21]. They have estimated the prostate deformation, which is made from the crab of the prostate, by using the method based on the finite element and the model of the elastic. For this goal, the T2-weighted image of MRI from the prostate tumor before the treatment was compared with the T2-weighted image of MRI during the treatment. Mahapatra and Sun [22] have used the elastic model along with the field of the random of Markov and the integration of the information of the segmentation to improve medical image registration. In study [23], the authors also used the elastic model to align the perfusion sequence of the images of MRI of the cardiac. According to the assumption that states in the aligned time curve should have the property of sparseness, they have presented a framework for the alignment of the time-dependent physical phenomena. The introduced method had satisfactory results in the elastic deformation, and the efficiency of the approach had an important betterment in comparison to previous methods. Khallaghi et al. [24] have presented a dynamic three-dimensional registration algorithm based on the elastic model, and they have shown its performance by using the similarity method based on intensity and the volume overlap on three different clinical datasets (including the artery, the liver, and the kidney). Their feature-based algorithm had the proper time and the proper accuracy.

In another work, Christensen [25] provided the model of the fluid of the viscous for the registration images by using the relation of Nessavier-Stokes, which is according to the following relation:

$$\mu\Delta v + (\lambda + \mu)\nabla(\nabla \cdot v) + f = 0 \quad (3)$$

Where the velocity field $v(x) = [v_1(x). v_2(x). v_3(x)]^T$ $(\mathrm{V}: \Omega \rightarrow R^3)$ is described as a derivative of the temporal field of displacement u according to the below relation:

$$v = \frac{du}{dt} = \frac{\partial u}{\partial t} + v_1 \frac{\partial \mathrm{u}}{\partial \mathrm{x}} + v_2 \frac{\partial \mathrm{u}}{\partial \mathrm{y}} + v_3 \frac{\partial \mathrm{u}}{\partial \mathrm{z}} \quad (4)$$

In this method, in order to achieve the large transformations (while maintaining the image continuity), the field of the velocity is applied rather than a field of the displacement. In general, in elastic models and in viscous fluid models, the force of the outside changes the form of the motion image in the direction of the registration with the static image. This force is elected due to the usage of the image and the kind of the image, and it can be the similarity criterion gradient, the disagreement of the grayscale levels, or the interval among the curves of the corresponding 2 images. Another example, it can refer to the work of Agostino et al [26]. They have used the common information criterion gradient as a force of the outside on the model of the fluid of the viscous for registration of images of the non-homogeneous brain.

In 2009 [27], the authors provided a standard database to evaluate the registration accuracy in the non-hard transformation-based methods. They have identified a set of index points in the four-dimensional CT images from the chest of five patients, on the condition of the most aspiration and on the condition of the most exhalation, with high accuracy. Obviously, if the registration of two images from the above set is more accurate, next, the points of the index of the corresponding 2 images will be closer to each other. Next, they introduced the MLS method for the registration of the images. In this method, the index points are first matched based on the maximum correlation criterion, and then the optimal Affine transformation is obtained by using the least squares error method. The above database has been used in several pieces of research to evaluate the precision of registration of the image. For example, in another work, which is called 4DLTM, the same group estimated the movement direction of each index pixel as a polynomial function with the registration of the images of a period from the inhalation and the exhalation. For this purpose, they have used the assumption of the optical flux model that states that the brightness of the pixels is constant during the displacement [28]. In another research, with the presentation of the ALK method, they have improved the performance of the previous algorithm by using the polynomial estimation of the image brightness intensity and the Tikhonov regularizer [29]. Also, in the CCLG method, instead of the optical flux, the mass conservation equation has been used for the modeling of the movement of the voxels [30]. In the LFC method, the movement of the voxel is modeled by using the compressible flux based on the sum of the non-linear squares [31]. Due to the use of temporal information, the last three algorithms can be considered as the four-dimensional methods.

Also, the Demons method uses the static image as a local force for the movement of the voxels of the motion image in order to match the static image [32]. The methods below are all improved versions of the Demons algorithm for image registration based on their grayscale level difference: PF, EPF, AF, DF, ADF, and IC [33]. By using the frame registration method and also by using the improved version of the squared error sum criterion, Li et al. [34] have presented an algorithm called BM for the transformable registration of the images.

III. The Presented Approach

In the current part, the details of the presented approach are presented. The proposed method in this paper consists of three main components, which are as follows: (a) a network of the encoder-decoder of 2 -stream for the calculation of the pyramids of the feature, (b) the registration of the pyramid of the sequential, and (c) the bettered modules of PR.

A. Basic Topics

The purpose of the registration of 3D images of the medical is the estimation of the field of the deformation Φ that it can warp the volume of the motion $M \subset R^{H \times W \times D}$ to the volume of the static $F \subset R^{H \times W \times D}$ such which the volume of the warped $W = M \circ \Phi \subset R^{H \times W \times D}$ can be precisely equaled with constant F . $M \circ \Phi$ is used for the determination of the implementation of the field of the deformation Φ on the volume of motion by using the operation of the warping. The registration of the image is described as a problem of the optimization:

$$\hat{\Phi} = arg\ min_{\Phi}\ \zeta(F. M. \Phi) \quad (5)$$

$$\zeta(F.M.\Phi) = \zeta_{sim}(F.M \circ \Phi) + \lambda\zeta_{smooth}(\Phi) \quad (6)$$

ζ_{sim} displays the function which measures the likeness among the image of the warped $(M \circ \Phi)$ and the image of the static (F). ζ_{smooth} displays a regular limitation in the field of the deformation (Φ) that enforces spatial uniformity. ζ_{sim} and ζ_{smooth} can be described in different shapes. The last endeavors have been assigned to the development of a strong method for computation of the field of the deformation Φ.

B. The Proposed 2-Stream Model

The proposed method is based on an architecture of the encoder-decoder that is improved with the introduction of a two-stream design. The proposed architecture is displayed in Fig. 1. It can be seen from Fig. 1 that the base of the proposed method includes an encoder-decoder of 2-stream along with the collective factors. An encoder with a similar framework to U-Net [35] is used, which consists of 5 blocks of the convolutional. For the blocks, the bating for 1-th block of the convolution, every block has a layer of the 3D convolution for the down-sampling by the stride equal to 2, which this layer is coupled with an operation of ReLU. Therefore, the encoder decreases the resolution of the spatial from the volumes of the input with a factor equal to 16, as displayed in Fig. 2. In the step of the decoding, the connections of the skip are applied on the maps of the convolution of the corresponding procedure of the encoding and the procedure of the decoding. The maps of the convolutional with the low resolution are up-sampled. Then, they are joined to the maps with higher resolution. Next, a convolutional layer with a size equal to $3 \times 3 \times 3$ and an operation of ReLU is applied, as displayed in Fig. 1. Eventually, 2 pyramids of the feature by the features of the convolutional with the multi-resolution are achieved, which are calculated separately by the volume of the motion and by the volume of static.

The presented 2 -stream model lets us calculate the pyramids of the feature separately by 2 volumes of the input, and next, it allows us to predict the deformable fields from the more robust distinct learned features of the convolutional, that this point is the guidance for the bettered efficiency. The mentioned design differs from the existing networks with 1-stream, like [36]. These existing networks calculate the features of the convolutional by 2 integrated volumes, and they appraise the fields of the deformation with the use of the filters of the convolution with 1-stream. In addition, the presented 2-stream framework can calculate 2 pairwise pyramids of the feature, which in it, the fields of the layered deformation can be sequentially appraised in the various levels. The mentioned point permits the method to create a trail of the fields of the deformation with the designing of a novel approach for the registration of the sequential pyramid.

Advert, in the presented approach, the applied base in [37] is modified with the increment of the convolution blocks from 4 to 5. Also, for 5 layers, the channel number from 32 channels per layer to [8.16.16.32.32] is reduced. In addition, in the proposed method, the modified units in [37] have been removed for the maintenance of a lightweight, effective model. These changes lead to a significant reduction in the parameters of the model $(410K \rightarrow 175K)$, while the model maintains a similar performance.

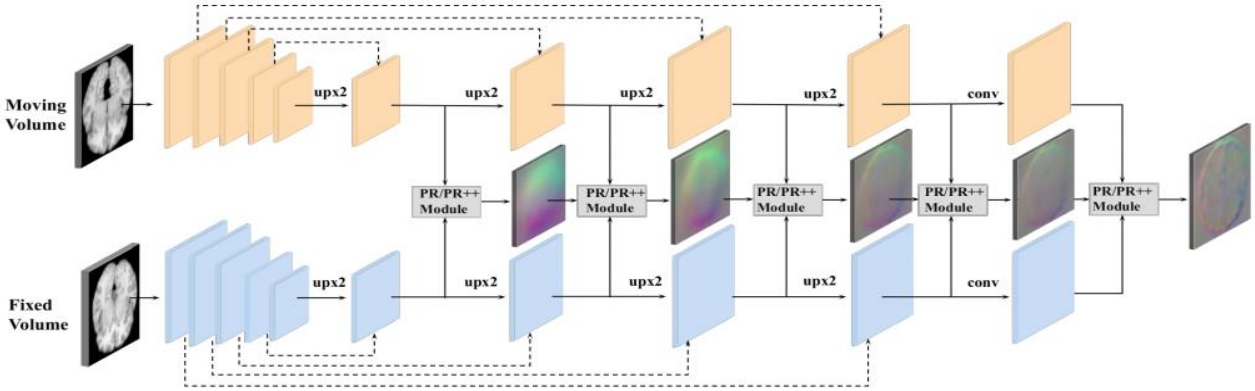

Fig. 1. The proposed method for registration of the medical image.

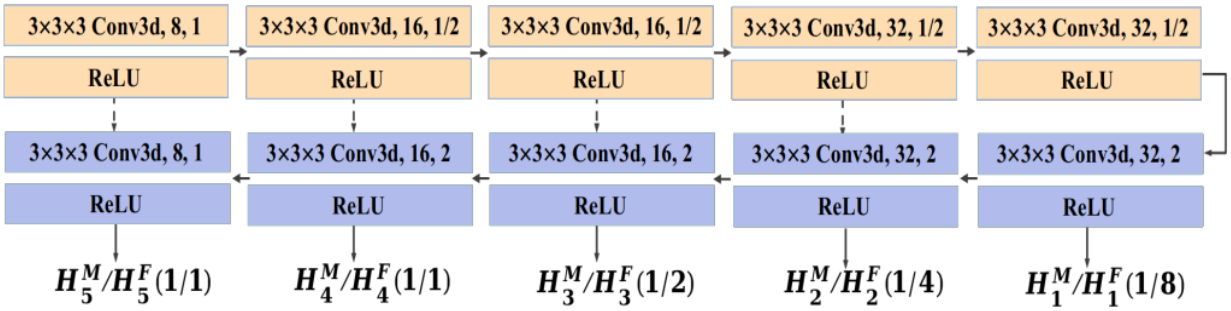

Fig. 2. The basis of our presented approach, which includes one encoder (with the color of yellow) and one decoder (with the color of blue). H_l^M and H_l^F show the computed maps of the feature by volume of motion and volume of static, respectively.

C. The Sequential Pyramid Registration

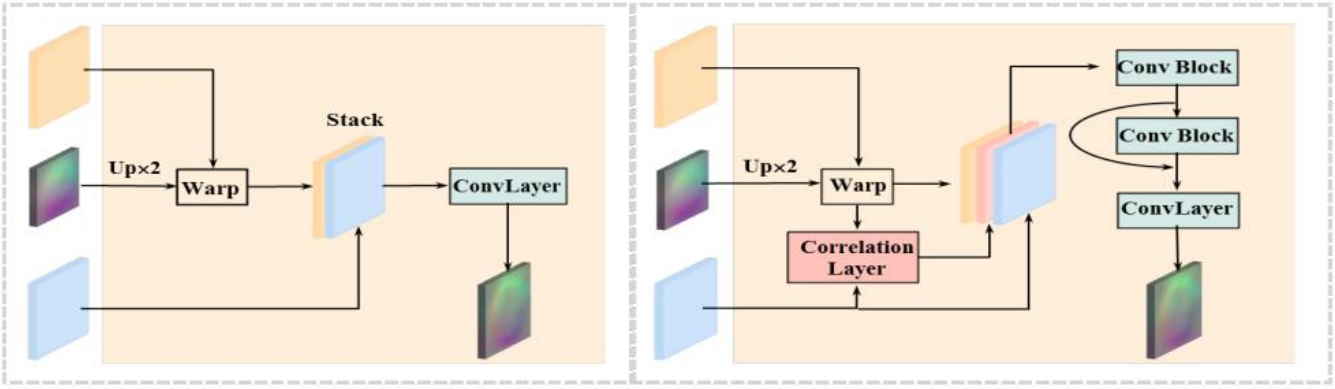
In the presented method in the current paper, a novel registration of the pyramid is provided with the designing of a collection of the modules of PR that are sequentially performed in every layer of the decoding. This work permits the method to estimate the fields of the multiscale deformation by enhancing resolution and also allows the model to create a trail from the fields of the deformation of the pyramid, as displayed in Fig. 1.

Each module of PR apprises a field of the deformation in every layer of the decoding. As the input, the module of PR applies a couple of the features of the convolutional along with a computed field of the deformation by the prior layer (the batting for the 1-th layer of the decoding in which the field of the deformation is not accessible). As the output, the module of PR obtains an appraised field of the deformation in a level of resolution, and this field is applied to the subsequent level of the pyramid. The module of PR consists of a trail from the warping operation, the stacking operation, and the convolution operation (as displayed in Fig. 3(a)). These operations are repeatedly performed on the layers of the decoding.

In the case of sequential operations, in particular, the 1-th field of the deformation (Φ_1) is calculated in 1-th layer of the decoding. First, 2 calculated features of the convolutional in 1-th layer of the decoding are superimposed, and next, one convolution of 3D by the size equal to $3 \times 3 \times 3$ is applied for the estimation of the field of the deformation. The field of the deformation (Φ_1) displays the maps in 3D with the identical form along with the corresponding maps of the feature of the convolution. It can exploit the information of the background with the coarse level, like the structure of the anatomical with top level from the brain, that this information is encoded in the computed features of the convolutional in the subsequent layer of the decoding through the warping of the feature: (1) the top field of the deformation are up-sampled with the use of the interpolation of the bilinear by the coefficient equal to 2, which it is denoted by $u(\Phi_1)$; (2) next, it is used for the warping of the maps of the convolutional volume of the motion on subsequent layers with the use of an operation of the network sampling, as displayed in Fig. 3(a). Next, the warped maps of the convolutional are superimposed anew by the corresponding features of the convolutional, which are generated from the constant volume. In the following, a convolution operation is placed for the estimation of the novel field of the deformation. The mentioned procedure is recurred in every layer of the decoding. It is described as follows:

$$\Phi_l = C_l^{3\times3\times3}(H_l^M \circ u(\Phi_{l-1}).H_l^F) \quad (7)$$

where, $l = 1.2.\cdots.N$ displays the number of the layers of the decoding. $C_l^{3\times3\times3}$ represents a three-dimensional convolution in the layer of the decoding l. The functor $\circ$ represents the operation of the warping, which this operation maps H_l^M to H_l^F by using $u(\Phi_{l-1})$. H_l^M and H_l^F are the convolutional feature pyramids, which are calculated by the volume of motion and by the volume of static in the layer of the decoding l.



(i) PR module. (ii) Improved the PR module.

Fig. 3. The presented module of (i) PR and (ii) the improved PR. The module of the improved PR betters the module of PR with the computation of the features of the correlation via the increment of the convolutions of the residual.

Regarding the 3D layer of the correlation, on the module of the improved PR, a 3D layer of the correlation is defined for calculation of the correlations of the local among 2 volumes of the input on the space of the feature of the convolution. It permits us to collect the related features that are not addressed directly in the main module of PR. However, these features can emphasize the details of the local representation of the deep. In particular, suppose P_i^W, P_j^F represent the voxels of focal of the blocks of 3D (by the size equal to $(2k+1)^3$), which are sampled by the maps of the feature of the warped motion volume and the maps of the feature of the static volume. The correlation among 2 blocks of the sampled three-dimensional can be calculated as follows:

$$C(w_i.f_i) = \frac{1}{(2k+1)^3} \sum_{n_w.n_f \in [-k.k]^3} P_{i+n_w}^W \times P_{j+n_f}^F \quad (8)$$

$n \in [-k.k]^3$ displays n iterations in a three-dimensional neighbouring equal to $[-k.k] \times [-k.k] \times [-k.k]$ from P_i^W or P_j^F. According to a block of 3D of the local in the maps of the feature of the motion volume, the computation of the correlations of the dense on total blocks of 3D sampled by the maps of the feature of the static volume is time-consuming. Thus, according to a block of 3D along by P_i^W, the correlations of the local with the sampling from a collection of P_j^F is calculated in a 3D neighborhood with a size equal to $d \times d \times d$. It can be performed as the convolutions of 3D. A stride

equal to $s_w = 1$ is applied to the sample as densely P_i^W by the maps of the features of the warped. Then, the neighboring of the correlation is adjusted by $d = 3$ in the maps of the feature of the static, which in it, P_j^F with the stride equal to $s_f = 1$ is sampled. Every block of the sampled has an identical size equal to $[-k.k] \times [-k.k] \times [-k.k]$. Also, the straight correlation among 2 blocks of the sampled is calculated with the use of the relation in Eq. (8). It produces the three-dimensional correlation maps (P^C) with the shape $[2 \times FL(d/s_f) + 1]^3 \times (H/s_w) \times (W/s_w) \times (D/s_w)$, where $[2 \times FL(d/s_f) + 1]^3 = 27$ displays the channel's number. FL represents a calculation of the floor. The created maps of the correlation have a similar form of 3D with the maps of the feature of the motion volumes and the static volumes. It ensures which 3 maps can be combined for more processing.

In the case of the convolutional enhancement, the proposed 2 -stream framework calculates 2 pyramids of the feature separated by 2 volumes of the input. Nevertheless, the funds of the work of image registration are the learning of the correspondence of the anatomical of the powerful among 2 volumes on the space of the feature, which inspired us to model a novel approach for the more aggregation of the features of the calculated pyramid. The main subordinate of the presented module of the improved PR is to present a strong method for the learning of the details of the local of the richer by 2 features, that it ensures the further precise estimation of the fields of the deformation in the different scales. To richen the features of the learned, the calculated maps of the correlation are accumulated by 2 features of the pyramid in every decoding layer: the features of the warped by the volume of the motion and the features of the pyramid from the volume of the static (as displayed on Fig. 3(b)). The maps of the correlation have 27 channels in total layers of the decoding whenever the channel number of 2 features of the pyramid changes in the various layers as below: [8.16.16.32.32].

For this purpose, as shown in Fig. 3(b), 2 blocks of the convolution of 3D are applied to process the features of the stacked. Each convolution block contains two convolution layers with a size equal to $3 \times 3 \times 3$, which in the following, an operation of ReLU is done. 1-th block of the convolution significantly decreases the stacked feature channels from [43.59.59.91.91] to [8.16.16.32.32], which this reduction is stable by the used channels number on the module of PR for the computational performance. Additionally, a connection of the residual is used on a 2-th block of the convolutional in the attempt to preserve more background information and also in the attempt to extract the distinctive features of 2 volumes. Eventually, a layer of convolution is applied for the estimation of the field of the deformation. The novel module of the improved PR is used in the proposed framework of the 2-stream registration, which this work leads to an improved version of the proposed method.

D. The Field of the Final Deformation

The presented method creates five consecutive fields of the deformation with increasing resolution, which these fields are shown as $[\Phi_1.\Phi_2.\Phi_3.\Phi_4.\Phi_5]$. To calculate the field of the final deformation, a field of the deformation of the estimated is up-sampled with a coefficient equal to 2. Next, it is warped with the field of the below deformation that this field is estimated. This up-sampling operation and this warping operation are performed as frequently and as ordinally to create the final field of the deformation (see Fig. 4) that encodes the rich information of the background of the multi-level by the deformations of the multiscale. It permits the model to propagate the robust information of the background among the layers of the decoding of the hierarchy, in which the fields of the deformation of the predicted are progressively filtered in a manner of the coarse-to-fine. Thus, it collects information on the background of the top level and the features of the low level. The information of the background of the top-level equips the proposed method to the capability for the function by the deformations of the large-scale, whenever the features of the low-scale allow it to model the detailed information of the structure of the anatomical. The modules PR and modules of the improved PR are integrated into the proposed 2-stream framework, which results in a model of the trainable end-to-end. A correlation of the cross of the local of the negative is applied as the function of the loss, and it is combined by a regularization of the smooth. For example, it can mention a diffusion regularizer, which calculates the proximate gradients of the spatial with the use of the difference among the voxels of the neighboring.

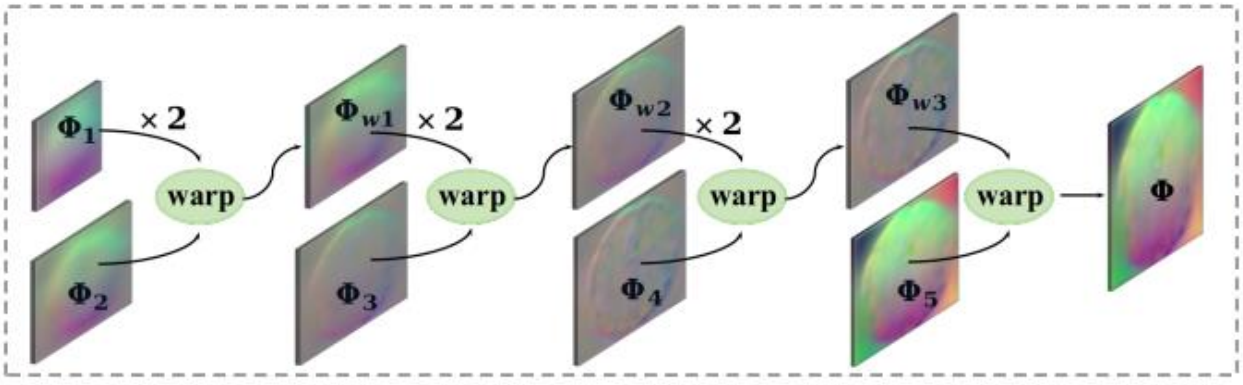


Fig. 4. The final field of the deformation is calculated from the sequential warping of the late field and the prior field.

IV. The Tests and the Analysis of the Results

In the current part, the experiments and the obtained outcomes by the proposed method of the registration of the brain MRI images are shown. In these experiments, first, a series from the atlas-based registration experiments is presented, where a field of the registration is calculated among one atlas or one volume of the reference. An atlas displays one reference or one volume of the average. Generally, it is made by frequently co-aligning the dataset from the volumes of MRI of the brain and averaging them together [40]. In this paper, a calculated atlas is used by using an external dataset [39]–[41]. Fig. 5 displays an instance from the image coupled with the use of the identical static atlas for total samples. Then, the result of the size of the dataset of the training in the image registration is briefly reviewed. Also, the results are provided in a dataset that includes the segmentations of the manual. Finally, the proposed method is trained by using a random pair of the subjects of the training as the input and the registration of the test among a pair of the subjects of the unseen. The language of the programming of Python has been used to implement these experiments. The presented method is implemented on a computer with 8G RAM and Core(TM) i7 CPU 3.0 GHz Intel(R). The network of the convolutional is performed on GPU, and the card used for the graphics on the current approach is GEFORCE 840M from NVIDIA.

A. The Used Datasets and the Evaluation Criteria

In this paper, the multi-study large-scale datasets of the scan of MRI of the brain of the T1-weighted are used from 3 publicly accessible datasets: ABIDE [42], OASIS [43], and FreeSurfer Buckner40 [39]. The details of the acquisition, the scopes of age of the subject, and the conditions of the health are various for every dataset. Total scans are down-sampled into a network with a size equal to $256 \times 256 \times 256$ and with the isotropic voxels with a length equal to $1\ mm$. The standard stages of the preprocessing (the normalization of the spatial and the extraction of the brain for every scan) were performed with the use of FreeSurfer [39], and the obtained images were cropped into $160 \times 192 \times 224$. Total MRI images were segmented as anatomically by FreeSurfer. Also, the control of the quality was applied with the use of the inspection of the visual for the detection of the errors of the gross in the results of the segmentation and in the alignment of the affine. The datasets are divided by a ratio equal to 85, 7.5, and 7.5 for validation, testing, and training, respectively. Additionally, it should be noted that the Buckner40 dataset was only used for the test step by using manual segmentation.

The obtaining of the registration of the real dense images for this data is not described as well because the multiple fields of the registration can provide analogous images of the warped. Here, first, the proposed approach is evaluated with the use of the volumetric overlay of the segmentations of the anatomical. If the field of the registration φ displays an exact match, then the areas f, $m^{\circ}\varphi$, which correspond with the identical structure of the anatomical, must be overlapped as well (see Fig. 5). The overlap of the volume among structures is quantified with the use of the score of Dice.

In addition, symmetric normalization (SyN) [42] is used and the registration algorithm with superior performance [44] in a comparative study. To implement the SyN, the software package of the generally accessible Advanced Normalization Tools (i.e., ANTs) [45] is used, which comes with a cross-correlation similarity criterion. During the experiments, a step size of SyN equal to 0.25 is used and the Gaussian parameters $(9\ and\ 0.2)$ in 3 scales by a maximum epoch equal to 201. The package of NiftyReg is used as the 2-th base. the 2D layer of the transformer of the spatial of the linear interpolation to $n - D$ is developed. Now, $n = 3$ is applied. Also, the ADAM optimizer [46] by the rate of learning equal to 0.0001 is used. The implementation includes a default with the iterations equal to 150000.

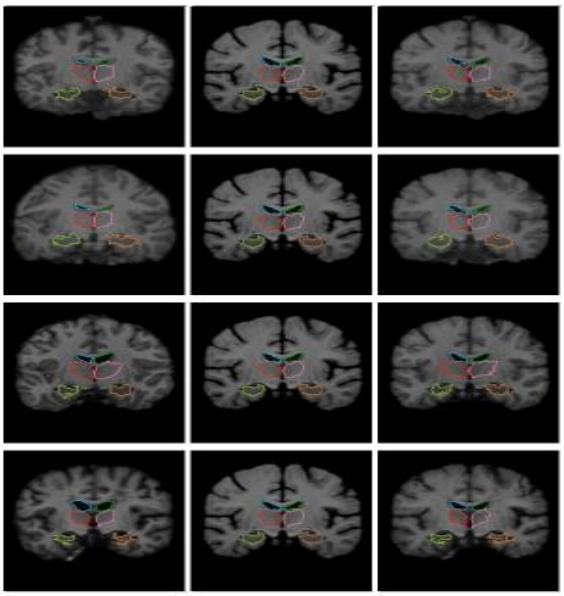

Fig. 5. The example of the extracted MRI crown crops from the couples of the input (columns $1-2$) and the obtained $M^{\circ}\varphi$ from the presented approach (third column). Our presented approach can handle the different changes in the structure form, for example, the expansion / shrinking of ventricles in row 2 and row 3 or the stretching of the hippocampus in row 4.

B. The Experiments and the Obtained Results

As mentioned, first the proposed method is trained for the atlas-based registration. First the presented network is trained. Next, the results of the Dice score on the dataset of the test are reported. Table I shows the mean of the calculated scores of Dice for total subjects in structures of the baseline method (the Affine alignment), the ANTs method, the approach of NiftyReg, and the presented approach. Due to the Dice scores, the presented approach has comparable efficiency with the ANTs method and the approach of NiftyReg, and it is significantly superior to the alignment of Affine. The examples of the outcomes of the visual images of the warped from the proposed method are displayed in Fig. 5 and Fig. 6. The proposed method is capable of performing the changes of the considerable form for the different structures. Additionally, Fig. 7 shows the scores of Dice for every method in the box form. The presented approach obtains comparable scores of Dice with the approach of ANTs and the approach of NiftyReg for all structures. It performs better in several structures, like the ventricles of the lateral, and it also performs worse in other structures, such as the hippocampus.

Table I contains the number of voxels, and in these voxels, the determinant of Jacobian is the non-positive. It is discovered which whole approaches lead to the deformations by the little islands from these voxels, yet they are different in the majority of the vast of the voxels. Fig. 6 and Fig. 8 show several examples of the deformation fields of the presented approach. The presented approach does not have any explicit restrictions for the diffeomorphic deformations. The ANTs method and the NiftyReg method include implementations that can forcefully countenance the diffeomorphic transformations. However, during the parameter searches, these cases negatively affect the time of the run or the outcomes. In the current article, the base implementations are performed by the configurations that have obtained the foremost scores of Dice. Thus, it is found that this work creates good deformation regularization.

Next, the result of the size of the dataset of the training in the precision and the relationship among the depreciated optimization and the optimization of the sample-specific is evaluated. The proposed method is trained on the subsets that are different from the dataset of the training, and then the scores of Dice are reported. The test dataset is run with the fine-tuning of the obtained displacements by the proposed method for 100 iterations per the test pair. Fig. 9 shows the obtained outcomes. The small size of the dataset of the training, equal to 10 scans, makes the scores of Dice for the training and for the test slightly lower in comparison with the bigger training dataset size. Nevertheless, there is an important disagreement on the scores of Dice when the network is trained by 100 scans or by the total dataset.

TABLE I. THE MEAN SCORES OF DICE FOR THE ALIGNMENT OF AFFINE, THE ANTS, THE NIFTYREG, AND THE PROPOSED APPROACH. THE VOXELS NUMBER AND THE PERCENT OF THE VOXELS BY A NON-POSITIVE DETERMINANT OF JACOBIAN FOR EVERY APPROACH ARE DISPLAYED

Method	Dice	$\lvert J_\varphi \rvert \leq 0$	$\%\ of\ \lvert J_\varphi \rvert \leq 0$
Affine	0.584 (0.157)	0	0
ANTs	0.749 (0.136)	9662 (6258)	0.140 (0.091)
NiftyReg	0.755 (0.143)	41251 (14336)	0.600 (0.208)
Proposed Method	0.754 (0.144)	191352 (5985)	0.374 (0.118)

TABLE II. THE RESULTS OF THE MANUAL ANNOTATION EXPERIMENT FOR THE AFFINE ALIGNMENT, THE ANTS, THE NIFTYREG, THE PRESENTED APPROACH, AND THE PRESENTED APPROACH BY OPTIMIZATION OF THE SAMPLE-SPECIFIC

Method	Dice
Affine	0.608 (0.175)
ANTs	0.776 (0.130)
NiftyReg	0.776 (0.132)
Proposed Method	0.773 (0.134)
Proposed Method with Instance-Specific Optimization	0.784 (0.132)

Since manual segmentation is not accessible for the uttermost datasets, the accessibility of the FreeSurfer segmentation enables a vast scope of the above experiments. In the current experiment, the registration test on the Buckner40 dataset (the us-seen) is used, which has 39 scans. The dataset of Buckner40 includes the specialist hand-lines from the identical used structures of the anatomical on the prior tests that here from them are used for the evaluation. The outcomes of the score are displayed in Table II. These outcomes display that our presented approach has similar behavior with the approach of ANTs and the approach of NiftyReg, which is stable with the 1-th test. The presented approach further improves the outcomes with the optimization of the sample-specific. In this dataset, the obtained results by the proposed method obtain slightly lower scores. However, they are bettered with optimization of the sample-specific to be comparable by the approach of ANTs and the approach of NiftyReg.

In the next experiment, the presented approach is trained for the registration of the subject-to-subject. In respect, there is a further variation on every registration. Thus, the feature number for every layer of the network is doubled. The efficiency of the presented approach is calculated by optimization of the sample-specific. Table III displays the mean scores of Dice of the test step in 250 test pairs, which are randomly selected for registration. The obtained scores of Dice from the presented approach (with the doubled number of features) are comparable with the approach of ANTs and the approach of NiftyReg. Also, the scores of Dice of the presented approach with the sample-specific optimization are comparable with both baseline methods.

C. Discussion

The proposed method in this paper, with the unsupervised loss, has the similar performance to the state-of-the-art methods ANT and NiftyReg, in terms of Dice score, while it reduces the computation time from hours to minutes on a CPU and less than a second on a GPU. The proposed method is flexible and it handles partial observed or coarsely specified auxiliary information during training, which this can lead to improved Dice score while maintaining improved runtime. Also, the proposed method performs the degenerate optimization and it learns general performance parameters that are optimal for the entire training dataset. The sample-specific optimization improves the performance of the proposed method by one dice point. This is a small increase and it indicates that the depreciated optimization can lead to near-optimal registration.

The performance gain varies based on the quality and number of anatomical sections available. Given a labeled anatomical structure during training, subjects' registration accuracy for that label increases without negatively affecting other anatomy. If half or all labels are observed, or even a coarser segmentation is provided in training, the registration accuracy for all labels will improve during testing. While with one type of auxiliary data, the experiment was done in this study, but the proposed method can use other auxiliary data such as different methods or anatomical key points.

TABLE III. THE RELATED RESULTS TO THE SUBJECT-TO-SUBJECT REGISTRATION BY USING THE AFFINE ALIGNMENT, THE ANTS, THE NIFTYREG, THE PRESENTED APPROACH, AND THE PRESENTED APPROACH BY OPTIMIZATION OF THE SAMPLE-SPECIFIC

Method	Dice
Affine	0.579 (0.173)
ANTs	0.761 (0.117)
NiftyReg	0.772 (0.117)
Proposed Method	0.763 (0.052)
Proposed Method with Instance-Specific Optimization	0.773 (0.119)

V. CONCLUSIONS AND SUGGESTIONS

In this paper, a two-stream pyramid registration network with the improved PR module is presented for unsupervised 3D medical image registration. The presented approach, due to the design, has a 2-stream architecture that permits it to calculate 2 pyramids of the feature of the convolutional as separately by 2 volumes of the input. Next, the registration of the pyramid of the sequential by a collection of the modules of PR is provided for the estimation of a trail from the fields of the registration that these fields can filter the learned features of the pyramid incrementally in a manner of the coarse-to-fine through the warping of the sequential. The module of PR is augmented with the residual complexity enhancement and with the computation of the local correlation features. The proposed approach has a competitive performance by the approach of ANTs and the approach of NiftyReg according to the score of Dice. The obtained results from the tests in 3 datasets show that the proposed approach is flexible, and it controls the partially observed information of the auxiliary during the training; this point can result in improved scores of Dice. The proposed method performs the depreciated optimization, and it learns the general performance parameters that are optimal for the full dataset of the training. Also, the outcomes have displayed which optimization of the sample-specific betters the efficiency of the proposed approach.

The proposed method can use the other data of the auxiliary, like the various methods or the anatomical key points, which can be addressed in the subsequent works. Additionally, the proposed approach is a generic mechanism of learning, and it is not restricted to a specific kind of image or anatomy. Its effectiveness can be checked on other applications of the registration of images of the medical, like the scans of MRI of the cardiac or the images of CT of the lung. Also, by providing a proper function of the loss, like the information of the mutual, the proposed approach can do the registration of the multimodal. Thus, it is suggested to be considered in the subsequent works.

Recognition of Depression from Video Frames by using Convolutional Neural Networks

Jianwen WANG, Xiao SHA*
Department of Computer Science, Hebei University of Water Resources and Electric Engineering, Hebei 061001, China

***Abstract*—The disturbances of the mood are relevant to the emotions. Specifically, the behaviour of persons with disturbances of mood, like the depression of the unipolar, displays a powerful correlation of the temporal by the emotional girths of the arousal and the valence. Moreover, the psychiatrists and the psychologists take into account the audible signs of the facial and the audible signs of the voice when they assess the condition of the patient. Depression makes audible behaviours like weak expressions, the validation of the contact of the eye and the use of little flat-voiced sentences. Artificial intelligence has combined various automated frameworks for the detection of depression severity by using hand-crafted features. The method of deep learning has been successfully applied to detect depression. In the current article, a federate architecture, which is the network of the neural of the deep convolutional basis on the attention of global, is proposed to diagnose the depression. This method uses CNN with the attention mechanism and also uses the integration of the weighted spatial pyramid pooling for the learning of the deep global representation. In this method, two branches are introduced: the CNN based on local attention focuses on the patches of the local, while the CNN based on global attention attains the universal patterns from the whole face area. For taking the data of the supplementary among two parts, a CNN basis on the local-global attention is proposed. The designed experiments have been done in two datasets, which are AVEC2014 and AVEC2013. The results show that our presented approach can extract the depression patterns from the video frames. Also, the outcomes display that our presented approach is superior to the best methods based on the video for the detection of depression.**

***Keywords*—Deep learning; depression recognition; Convolutional Neural Network (CNN); attention mechanism**

I. INTRODUCTION

By 2020, depression had the 4-th rank among the most earnest issues of the health of the mentally [1]. Generally, it does temperate damage to the life of the individual. Also, it has a special effect on the society and the family. In several instances, depression may cause self-annihilation. Therefore, it is essential to discover an impressive solution for the diagnosis of depression and the treatment of depression of the clinical.

In recent years, a multitude of approaches have been proposed based on the different perspectives to help psychologists or doctors with the detection and treatment of clinical depression; these methods have mainly used emotional computations, machine learning communities, computer vision, etc. for estimating the depression's severity on the basis of the audiovisual cues, the common methods usually include three sequential methods: a) The extraction of the feature, b) The aggregation of the feature, and c) The regression (the classification). The extraction of the feature acts as an important task in the detection of depression from the videos. It is very important to extract a distinctive feature descriptor for the diagnosis and the estimation of depression [1]. Due to the extraction of the feature, the approaches can be hastily distributed to the features of the hand-crafted and the features of the deep learning.

The features of the hand-crafted use the knowledge domain for the designing of the features which are relevant as closely to the depressive signs [2], [3]. Although the hand-crafted features representation is considered for the obtention of the superior performance for the depression severity assessment, the below subjects have been related by the researchers. First, the exploitation of the features of the hand-crafted is time-consuming because these features require particular knowledge. The patterns of the binary of the local consist of 3 planes of the orthogonal [4], and they are heavy in terms of computational. Second, the hand-crafted features have been criticized due to the lack of related significant information on the patterns of depression [5].

Newly, the learned deep features with the use of CNNs have been applied widely to represent the deep features, and they have done great in depression diagnosis [6]. DepressNet [6] is a new framework for the learning of annotated depression representations. The selected methods of CNN (e.g., GoogleNet [7], AlexNet [8], VGG-Net [9], etc.) are pre-trained in the big datasets of the picture of the facial [10] and then it is trained in the dataset of AVEC2013 [11] and the dataset of AVEC2014 [12] with the use of fine-tuning. Its performance surpasses the many approaches to the diagnosis of depression based on the video. [13] uses the composition from the RNN [14] and the 3D-CNN [15] for the learning of the representation of the consecutive features of the spatial-temporal in 2 various scales of the areas of the face. [6], [13] adopt the model of the deep of the pre-trained for the fine-tuning of 2 datasets of the depression for the estimation of the depression.

In general, the diagnosis of depression is a problem of regression or a problem of classification according to machine learning. The purpose of the dataset of AVEC2013 and the dataset of AVEC2014 is prediction of the depression scores. It is proposed that almost all of the non-literal behaviours in the interaction of humans are the anent of the area of the face [16]. Regarding the estimation of depression based on the video, the salient area of the face is applicable for anticipating depression severity, as has been proposed in [6].

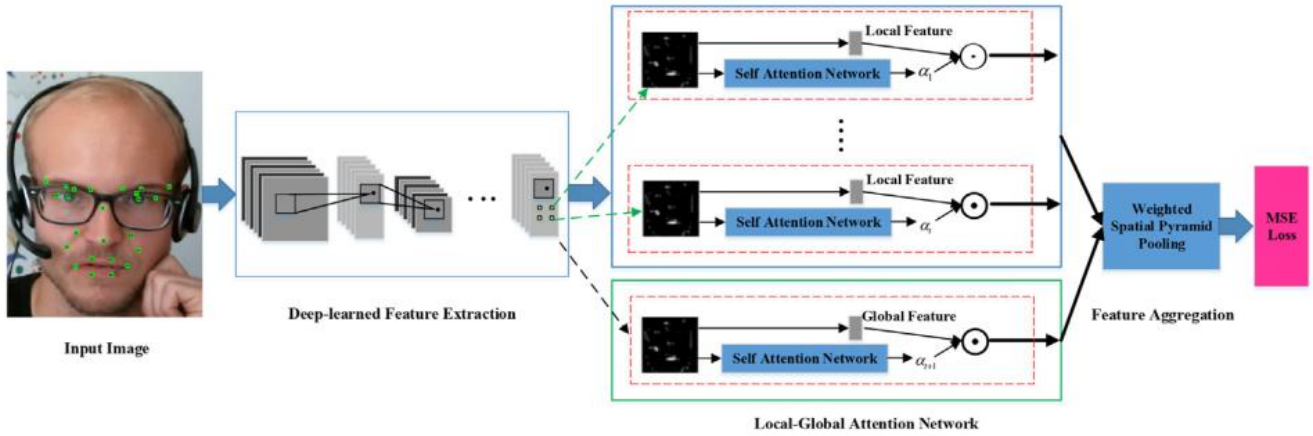

Fig. 1. Framework of our presented method to detect depression.

In the current article, the exploration of the techs on the basis of the facial look for depression diagnosis is concentrated. In order to deal with the mentioned problems, a new approach is proposed for depression detection by using the face video frames, which is called the DCNN, based on the attention of local-global. As displayed in Fig. 1, our proposed method includes 3 parts: i) The module of the extraction of the deep features learned from Depressed-CNN, ii) The convolutional neural network based on the local-global attention, iii) The module of the weighted spatial pyramid pooling (i.e., WSPP). The purpose of the universal attributes is to explain the set of depression-specific patterns, when the local attributes focus on the record of the specific patterns in the patch regions, which can extract the distinctive features in the patches of the prominent maps of the feature. The information extraction of the features of the local and the features of the global is crucial for the better performance of the depression diagnosis.

In order to clearly state the differences between the proposed method and the previous methods, we summarize the key contributions of the present paper as follows: 1) An end-to-end framework with the deep global-local attention is proposed, which effectively uses the face dynamics as a non-verbal metric to estimate the severity of the depression scale, which it has been neglected in the previous methods. 2) To encode the robust feature representations, a sophisticated CNN-based feature extraction network is designed. This network preserves the valuable and the distinctive features useful for the analysis of depression. 3) A CNN with a self-attention network effectively describes the discriminative patterns of the faces. By adopting the attention mechanism, the global-local attention-based CNN can automatically preserve the valuable feature and filter out the redundant face information. The continuation of the current article is as follows: Section II provides an overview of previous works. In Section III, our proposed approach is provided. In Section IV, the used datasets and the experiment results are provided. Section V discusses the general conclusions and future perspectives.

II. An Overview of Related Works

Many works have been done for the analysis of depression on the dataset of AVEC2013 and the dataset of AVEC2014. In the following, we introduce some presented approaches for the analysis of depression in the video frames. Liu et al. [17] have designed a region-based global network with partial attention and relational attention that this network learns the relationship between the partial features and the features of the global. In [18], the authors have introduced a framework with the use of CNN and the mechanism of attention to automatically detect depression by facial changes, whose performance overtakes most methods of facial depression detection. By focusing on the attention mechanisms and by paying attention to the facial details, this method has achieved promising results. In [19], authors have presented the deep network of the regression for the learning of the representation of the depression features visually and interpretatively, and its results show that the area near the eye plays a significant task in the diagnosis of depression. Al Jazaery and Guo [20], with the use of the 3D-CNN and the RNN, have learned as automatically the features of the spatial-temporal areas of the face in 2 various scales that can model the information of the local of the spatial-temporal and the information of the global of the spatial-temporal by the steady expressions of the facial to forecast the depression level.

On [2], the local features of the phase of the quantization by 3 planes of the orthogonal are extracted by using the coding of the sparse, and then, they are displayed with the discriminant map and by the decision surface fusion method for the generation of the features of the top-level. The regression of the vector of the support is adopted for evaluation of the severity of the depression. On [21], a new feature of the temporal dynamic, which is called the strong patterns of the binary of the average of the local by 3 planes of the orthogonal, is applied to provide the expressions of the dynamic of the temporal of the face. For the creation of a representation of the vector of the feature, the vector of Fisher of the Dirichlet process learns a richer intermediate representation from the MRLBP-TOP features in the subsequences. Next, for every sample of the video, a representation of the discriminative is generated by using the statistical aggregation approaches. In [22], the authors train an architecture of CNN for a combination of the appearance of the facial and the dynamics

of the facial to evaluate the depression diagnosis scale. The authors have related the superior outcomes over the other approaches based on the visual.

In [23], the authors design a system of artificial intelligence to estimate the depression scale. This system can combine the pattern of the supplementary among the features of the hand-crafted and the features of the deep learning. In the cues of the visual, the features of deep learning are exploited, and these features contain some related discriminative information to depression. In the cues of the audio, the features exploit the descriptors of the spectral with low level and the coefficients of the brain of the frequency of the Mel to take the expression of the vocal by the clips of the audio. The temporal movement in the space of the various features is defined with the histogram of the history of the dynamic from the feature. [6] propos Depress-Net, which is the deep network of the regression for prediction of the severity of the depression by the alone images. The map of the activation of the depression is applied in order to show the areas of the salient from the image of the face to determine the depression scale. In the meantime, the authors have designed a Depress-Net of the multi-area for modelling the various patterns of the various areas to better the total outcomes. Vast tests have been done on the dataset of AVEC2013 and the dataset of AVEC2014. Its efficiency has shown that the presented method outperforms the best visual-based methods of depression detection.

In [24], the authors extract the features of the global-local of the 3D-CNN to enhance the method's efficiency. The presented model is equipped with the 3D pooling of the average of the global for the representation of the patterns of the temporal-spatial for the diagnosis of depression. The empirical outcomes display that the integration of the features of the local and the features of the global of the 3D-CNN achieves promising efficiency. On [25], the authors have proposed to exploit automatically the basic human behaviours as the descriptors with low-dimensional from every frame. Two representations of the feature of the spectral, namely the spectral heat-maps and the vectors of the spectral, have been presented for the capturing of the associated multiscale patterns with the depression. The authors have presented these two spectral representations for the prediction of depression by using CNN and artificial neural networks. In [26], the 2-stream framework of the spatial-temporal for the depression diagnosis is presented. Eke, the researchers present the time-averaged integration method for the generation of the time-slice features. The tests on the dataset of AVEC2013 and the dataset of AVEC2014 have shown that their presented framework achieves comparable performance for depression detection.

III. Our Presented Approach

In the current part, the details of our presented approach are described. The framework of the diagnostic of depression, which is the deep and end-to-end, is shown in Fig. 1. First, the area of the face is cropped by the clips of the video with the use of the OpenFace toolbox [27]. Then, the usual CNN for the extraction of the feature is implemented, and this CNN obtains the maps of the feature of the face. In order to filter the features of the additional, the various networks of self-attention are introduced in the maps of the feature of the local and the maps of the feature of the global. WSPP is adopted to create the scale-variable features representation on the multiscale feature maps. Finally, two layers of the fully connected and a layer of the loss of the MSE are used to predict the severity of the depression. On each of the below sub-parts, the details of every part from our presented approach are provided.

A. The Extraction of Feature for the Obtention of the Face Feature Maps

The CNNs have been applied widely, and it has been proven that these networks are impressive in extracting the features in the field of emotional computations, like the recognition of the expression of the depression diagnosis and so on. To overcome the small datasets, our presented method for the analysis of depression is inspired by the described method in [28] with the un-deep frameworks. Since the deep frameworks, we are able to model a distinct presentation to predict the depression severity range. To extract the deep learning features, the presented shape of the framework of Depressed-CNN is shown in Table I. Meantime, the Depressed-CNN architecture is shown in Fig. 2.

TABLE I. Our Proposed Configuration for the Depressed-CNN Architecture

Name	Input	Operation	Kernel	Output
Conv1	224 × 224 × 3	Convolution	3 × 3, ReLu	224 × 224 × 64
Pool1	224 × 224 × 64	Pooling	2 × 2	112 × 112 × 64
Conv2	112 × 112 × 64	Convolution	3 × 3, ReLu	112 × 112 × 128
Pool2	112 × 112 × 128	Pooling	2 × 2	56 × 56 × 128
Conv3	56 × 56 × 126	Convolution	3 × 3, ReLu	56 × 56 × 256
Pool3	56 × 56 × 256	Pooling	2 × 2	28 × 28 × 256
Conv4_1	28 × 28 × 256	Convolution	3 × 3, ReLu	28 × 28 × 512
Conv4_2	28 × 28 × 512	Convolution	3 × 3, ReLu	28 × 28 × 512
CMP	28 × 28 × 512	Pooling	4 × 4	28 × 28 × 128
Con	CMP+Conv4_2	Concatenate	/	28 × 28 × 640

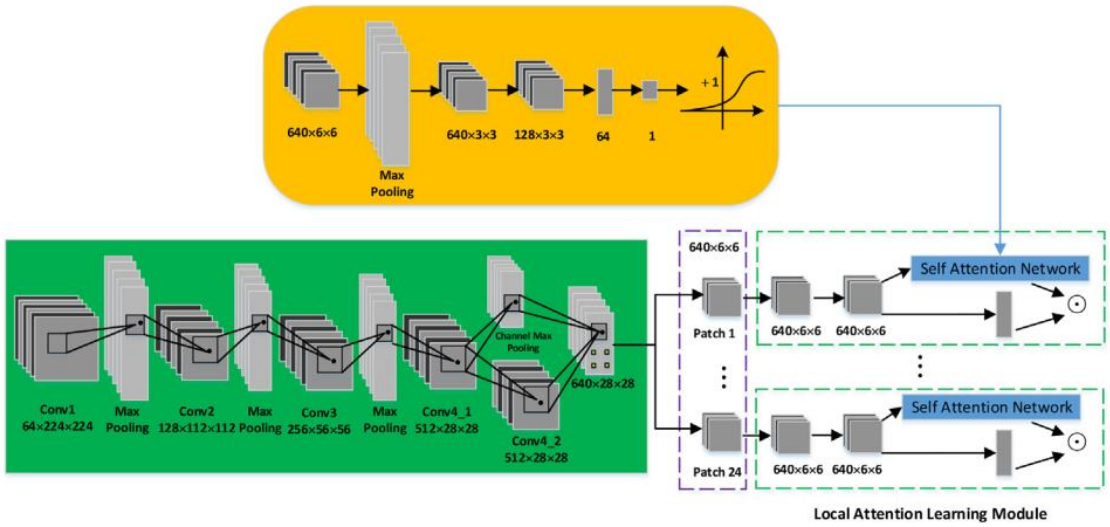

Fig. 2. Our detailed view of CNN based on the local attention.

The features of deep learning are exploited by Depressed-CNN as below. The image size input of the face is equal to 224×224 by three channels of colour. Inspired by [29], for total convolution layers, a filter by a little kernel of 3×3 is used to encode the left/right concept and the up/down concept for the extraction of the information of the spatial-temporal. After 3 operations of the convolutional and after three max-pooling operations, $Conv4\_1$ will be $[512 \times 28 \times 28]$. In the proposed method, the max-pooling is done on a window of 2×2 by $stride = 2$. To prevent the loss of information and also to preserve the distinct feature, the max-pooling of the channel (CMP) is used for the pooling of the map of the feature on the direction of the channel by the size of the kernel equal to 4, $stride = 4, pad = 0$. The output is a 3D map of the feature with a size equal to $[128 \times 28 \times 28]$. This structure is similar to this form because the popular max-pooling calculates the value of the maximum on the direction of the spatial while the max-pooling of the channel calculates the value of the maximum on the direction of the channel. In addition, for the creation of a strong representation of the feature, the map of the feature of $Conv4\_2$ is created on $Conv4\_1$. Next, CMP and the map of the feature of $Conv4\_2$ are concatenated together to achieve the feature of the final by size equal to $[640 \times 28 \times 28]$.

B. Convolutional Neural Network based on Local Attention

The various components of the image of the face have a great contribution to the diagnosis of depression. Inspired by [27], the area of the face is cropped to the various patches for the capturing of the representation of the distinct features for depression analysis. The CNN based on the local attention consists of two main steps: the generation of the patch and the capture of the salient feature. In the below, these 2 stages are described in the detail.

-The Generation of the Patch: For the analysis of the depression by using the area of the face, the patches of the local may have discriminating features to estimate the depression severity. As the popular scheme of the extraction of the feature of deep learning, the CNN restriction is the learning of the geometric transformations. Since some facial muscles contain specific information for the state recognition that is relevant as closely to the depression [30], the area of the face is cropped to the distinct patches. Also, in [31], [32], the researchers believe that the information of the multi-view from the areas of the salient is significant for image recovery. For the mentioned purpose, it is suggested that the proposed method adopts the various patches to take the distinct representations to detect depression. In the current article, the toolbox of OpenFace is used for the detection of the face region and also for the aligning of each frame from the video sequences with the size equal to 224×224 in three colour channels. Next, 68 landmarks of the face are recognized (Fig. 3). In order to find the effective patches of the face which are relevant as closely to the depression, 16 points are selected from 68 points, and these points cover the distinct face patches. Then, 8 points, which are covered on the eyes and the cheeks of the face, are recalculated. In total, 24 face patches were extracted. Our presented approach is displayed in Fig. 3.

The stages of the process of processing are as follows: (a) The OpenFace toolbox is used to discover the face zone and fix the face on every image from the trail of the video. 26 points are selected. These points cover the main areas of the face, namely, the eyes, the nose and the mouth. The elected points have the following indexes: 18, 19, 20, 37, 38, 39, 41, 42, 22, 23, 25, 26, 27, 44, 45, 46, 48, 47, 28, 30, 49, 51, 59, 53, 55, 57. (b) 4 pairs of the face landmarks (38.20), (41.42), (45.25), (48.47) are taken. Finally, 16 points from 26 points are recalculated. (c) The middle point of each pair of the points is calculated. (d) For the detection of the area around the mouth, two pairs of points (59.18) and (57.27) are selected, and then the middle points are calculated. The indices of the middle point are 22, 21. Next, 2 points, which have a similar space from the corners of the mouth, are calculated. For the coordinates of the goal edges of the direction of left, we describe it as $(U.V) = (U_{left} - 16.V_{left} - 16)$. The coordinates of the point of the target in the right direction it is described as $(U.V) = (U_{right} - 16.V_{right} - 16)$. The interval between the corner of the mouth and the edge of the target is calculated, and then the indices are determined as 24,23. (e)

Next, it selects 24 landmarks of the face, which cover the key areas of the face. (f) Due to the location of 24 points, 24 patches are cut. The patches are created by the image of the face. Nevertheless, in the proposed method, the generation of the patch is done in the maps of the feature for obtention of the areas of the salient.

The Registration of the Features of the Salient: As displayed in the box of green in Fig. 2, the process of the generation of the patch is performed with the use of the maps of the feature of CNN instead of the images of the face. This point is to maximize the utilization of the operations of the convolution and the strengthening of the fields of the receptive of the neurons, which reduces the model size. The output of the method of the extraction of the feature is the maps of the feature with a size equal to $[640 \times 28 \times 28]$. For the patch generation, 24 local zones equal to $[640 \times 6 \times 6]$ are obtained. To achieve the attributes of the salient, we apply the module of the learning of the attention of the local by CNN based on the local attention to learn the features of the patches of the face automatically. The module of learning the attention of the local is displayed on the box of yellow on the midmost from Fig. 2 by 2 dashed rectangles of green. On every module of the learning of the local attention of the patch-specific, after the generation of the patch, the created maps of the feature are entered in 2 layers of the convolution. Next, the second maps of the feature are entered into 2 branches. The 1-th branch considers the maps of the feature as the features of the local level of the vector. For the 2-th branch, a network of self-attention is applied for the focus on the distinct representation areas by the patches of the spatial. Next, the feature of the patch is recomputed by the vector of the weight.

Formally, let P_{a_j} is j-th patch of the map of the feature by the size equal to $[640 \times 6 \times 6]$. $\hat{P}_{a_j^1} = f(P_{a_j})$ is the 1-th map of the feature in the dashed rectangle of green on the top of Fig. 5, which map has a size equal to $[640 \times 6 \times 6]$. After a filter with a size equal to 1×1, the 2-th map of the feature is $\hat{P}_{a_j^2} = f(P_{a_j})$, which this map has a size equal to $[640 \times 6 \times 6]$. f represents the operation of the convolution in the architecture of CNN. Next, the 2-th map of the feature is entered into 2 branches. The 1-th branch converts the 2-th map of the feature to a vector of the local feature. Suppose φ_j is the map of the feature of the local that takes the 2-th map of the feature as the input. φ_j can be defined as the follows:

$$\varphi_j = \varphi(\hat{P}_{a_j^2}) \tag{1}$$

φ is the operation of the vector transformation. The 2-th branch is the network of self-attention. This network consists of an operation of the max-pooling, an operation of the convolution, 2 layers of the fully connected and an operation of the sigmoid. The function of the sigmoid is applied to limit the output scope α_j in 0-1. In it, 0 represents a related patch, and 1 displays a critical patch for the detection of depression. The weight α_j can be described as the follows:

$$\alpha_j = \omega_j(\hat{P}_{a_j^2}) \tag{2}$$

Where α_j is the scalar, and ω_j displays the operation of the network of the self-attention. After the operations of 2 branches, α_j is applied in the feature of the local φ_j to create a distinct feature:

$$\rho_j = \alpha_j \cdot \varphi_j \tag{3}$$

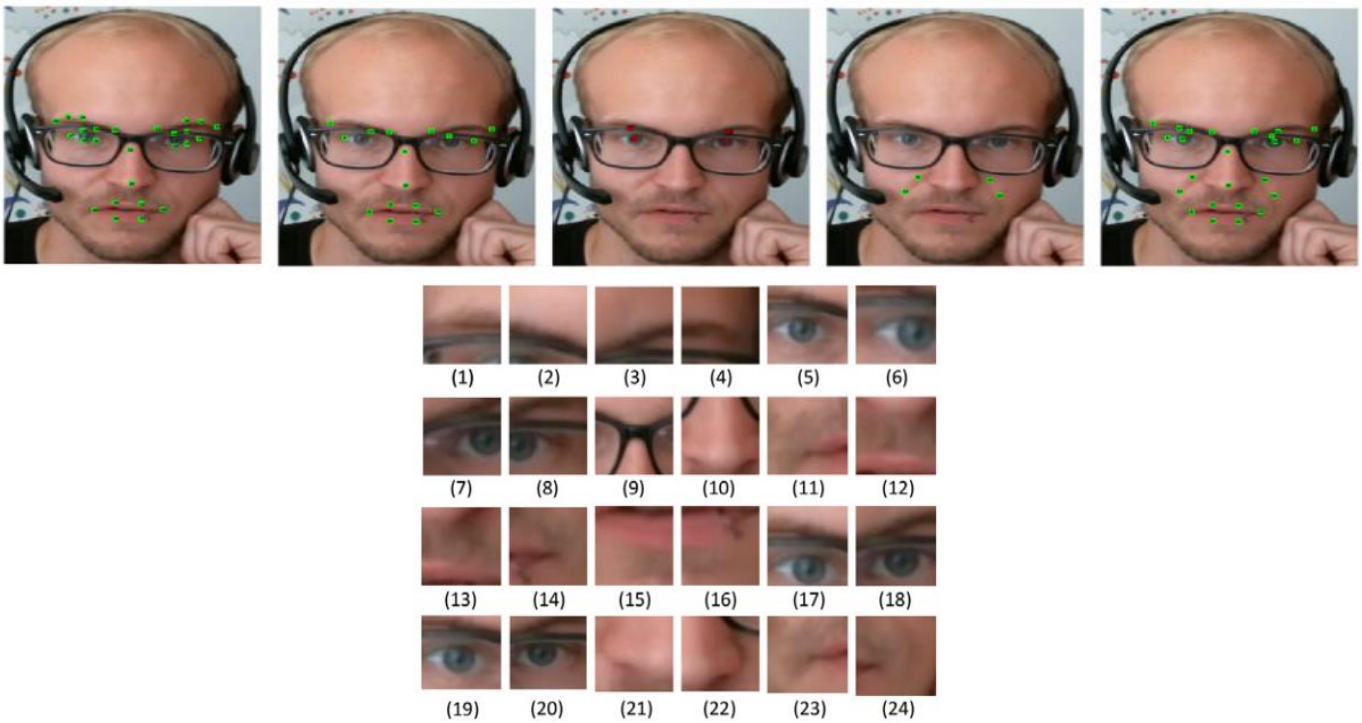

Fig. 3. An example of the face patch generation by using the mentioned patch generation process.

The output feature contains a distinct representation of the depression. Specifically, each module of local attention learning is weighted with weights, which are learned automatically with the network of self-attention. For CNN based on local attention, it is a framework of the depression of the local end-to-end with the below parts: the extraction of the deep learned features from CNN, the generation of the patch and the mechanism of the attention. The feature basis on the patch, which is learned by the proposed deep network, can discover the visual sinking pattern in the face region, and with it, the automatic estimation of the depression is feasible.

C. Convolutional Neural Network based on Global-Local Attention

In this section, we first provide a description from CNN based on global attention, and then, we state the final proposed method, namely CNN based on global-local attention. As described above, CNN, based on local attention, can automatically learn the distinctive features by using the mechanism of attention to analyze depression. Nevertheless, patches of the CNN based on the local attention may miss some additional information, which this information includes the face images and the general information of the semantics for the pattern of the depression. Therefore, for improvement of performance and also for the learning of the deep information of the semantics, the CNN based on local-global attention is proposed. For the part of the extraction of the feature, a similar operation of CNN based on local attention is used. In the presented implementation, it is proposed that the module of the learning of the attention of the global be used to represent the information of the semantics of the global in the depression diagnosis (the dashed rectangle of red in Fig. 4.

The module of the learning of global attention includes an operation of the max-pooling, an operation of the convolution and 2 operations of the branch. Ere entering to 2 branches, the map of the feature $Conv6$ can be defined as g by a size equal to $[512 \times 14 \times 14]$. The 1-th branch converts the maps of the feature g to the vectors of the feature of the global. Suppose Ψ is a feature of the global, and it is defined as the follows:

$$\Psi_{j+1} = \varphi(g) \tag{4}$$

φ is the operation of the vector transformation. The 2-th branch is the network of self-attention that includes an operation of the max-pooling, an operation of the convolution, 2 layers of the fully connected and an operation of the sigmoid. The weight α_{j+1} can be described as the follows:

$$\alpha_{j+1} = \omega_{j+1}(g) \tag{5}$$

Where α_{j+1} is the scalar, and ω_{j+1} represents the operation of the network of the self-attention. α_{j+1} is weighted in the feature of the global φ_{j+1} to obtain the feature containing the useful information ρ_{j+1}:

$$\rho_{j+1} = \alpha_{j+1} \cdot \varphi_{j+1} \tag{6}$$

In addition, to encode the complementary representations in CNN based on the local attention and in CNN based on the global attention, a final end-to-end architecture, which is called the CNN based on the local-global attention (the rectangle of red in Fig. 5) is proposed to connect this CNNs together.

D. Weighted Spatial Pyramid Pooling

The key purpose of the current article is the evaluation of depression severity. To increase the depression severity indices, the deep representation should capture the distinctive facial features at the various measures. Therefore, an important number of the samples, in total cases of the natural, are required in the training phase. The sources of the spatial of the natural changes of the face include the positions, the facial area size and the angles. In the proposed method, the features of the deeply learned local and the features of the deeply learned global by the mechanism of attention are used to obtain the information of the discriminative directly to diagnose depression. Nevertheless, the movement of the head may make changes in face size within a trail of the image. Thus, the changes may result in the blurring of the face, and this blurring affects the face image clarity.

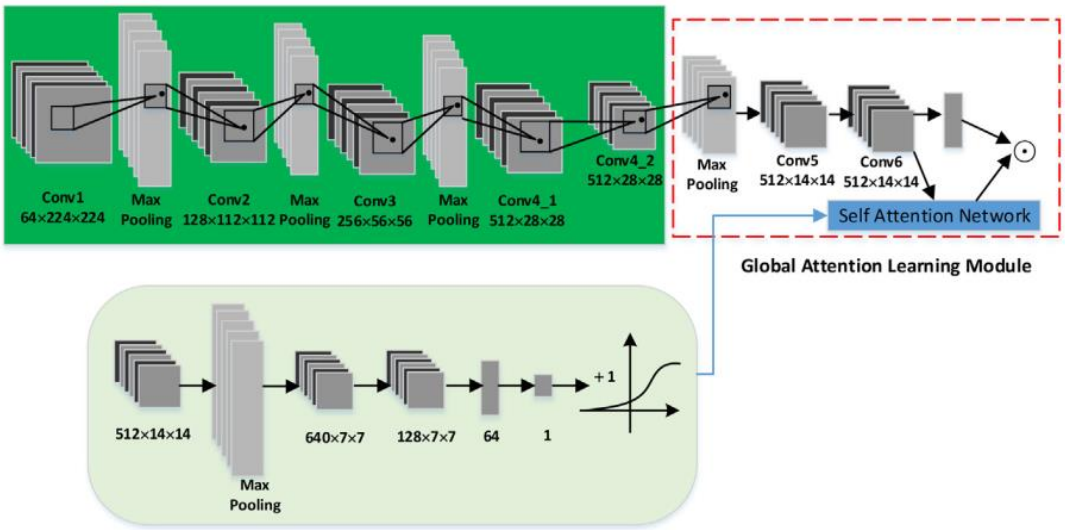

Fig. 4. Our detailed view of CNN based on the global attention.

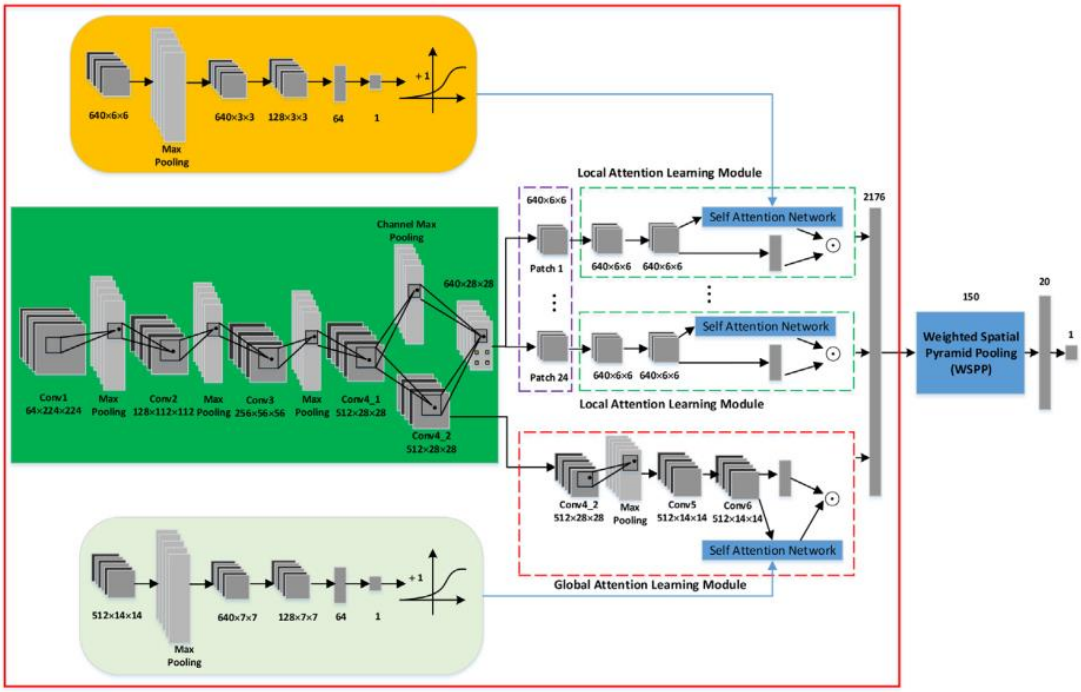

Fig. 5. Our view of the method of CNN based on local-global attention with WSPP.

To achieve a representation of the static scale, a layer of WSPP is applied for the representation of the multiple scales in the output upside of CNN based on local-global attention. The WSPP idea is to segment the map of the feature to the various parts from the scales of the finer-to-coarser, which is finished by the aggregation of the features of the local. The layer of WSPP can better the non-scaling. Also, it reduces the problem of over-fitting. In this paper, we use the definition of the initial weight on the spatial pyramid kernel, which this definition is presented in [33]. The features at the resolutions of the finer are related to the weight of the heavier ones, and the attributes of the coarser solutions are supported by the load of the lower ones. Fig. 6 describes the step of the representation of the feature of WSPP. The output shape of CNN based on the local-global attention is equal to $2048 \times 1 \times 1$.

On each spatial pyramid, the max-pooling is used for the combination of responses of every filter. The WSPP output is equal to the sum of the overall number from the pyramids. The output of CNN based on the local-global attention has the shape of $[batch\_size. 2048]$. A vector of the feature of the final by the size equal to $150D$ is obtained. The size of the window of WSPP is equal to $25 \times 151 \times 1.102 \times 1.204 \times 1$, and their corresponding stride is equal to $25 \times 151 \times 1.102 \times 1.204 \times 1$. The vectors with the fixed dimensions are fed into the layer of the fully connected.

For a network of the deep, the function of the loss plays an important task in the regression of the target. The analysis of the depression can be considered as a problem of the regression. Thus, in the proposed method, the loss of Euclidean is applied as the function of the loss, and this function is appropriate for our proposed method. The function of the loss of Euclidean L computes the squares sum of the disagreement among the values of the actual and the estimated values. It can be expressed as follows:

$$\mathrm{L} = \frac{1}{2M} \sum_{i=1}^{M} ||\hat{p}_i - p_i||^2 \qquad (7)$$

M is the sample number, and $\hat{p}_i$ displays the architecture output. Also, p_i displays the label. In this way, the final proposed architecture for the depression scale estimation is obtained, and all parts of it are shown in Fig. 5.

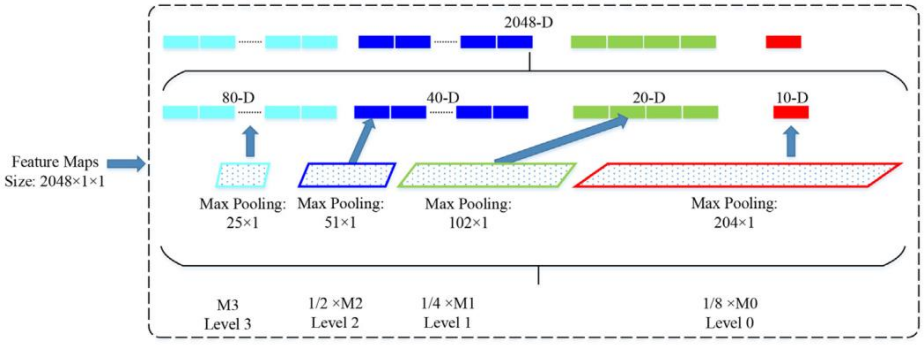

Fig. 6. Our view from WSPP.

IV. The Experiments and the Results Evaluation

In the current part, the details of our used datasets, the performed tests and also, and the obtained outcomes are presented. The Python programming language has been used for the implementation of these experiments. The presented method is implemented on a computer with 8G RAM and Core (TM) i7 CPU 3.0 GHz Intel(R). The network of the convolutional is designed on GPU, and the card used for the graphics on our approach is GEFORCE 840M from NVIDIA.

A. The Used Datasets

To prove the performance of the proposed approach for depression detection, the tests on two datasets are conducted: AVEC 2014 and AVEC 2013. The distribution of the scores of BDI-II on the dataset of AVEC 2013 and the dataset of AVEC 2014 is displayed in Fig. 7. In the dataset of AVEC 2013, 150 clips of the video exist. These clips are taken from 82 participants on the interaction of the computer-human by a webcam and a microphone for the record of the data. The scope of the age for the total people on the dataset is equal to 18 years to 63 years by a mean age equal to 31.5 years and also with a standard deviation equal to 12.3 years. The recorded clips are adjusted to 30 frames every second by a resolution equal to 640×480. The dataset of AVEC 2013 is distributed to 3 partitions: the development, the test and the training. In each partition, this dataset has 50 videos. Every video has a corresponding label with its level of depression intensity, and this level is evaluated based on the questionnaire of BDI-II.

The dataset of AVEC 2014 is the subset of the dataset of AVEC 2013. In it, there are 2 works: Northwind and FreeForm. These two works have 150 clips. In the work of FreeForm, the persons answered multiple questions, like the description of a sorrowful memory in childhood or the expression of popular food. In the work of Northwind, the persons had to study a selective from a fairy tale aurally. Similar to the AVEC 2013 dataset, the AVEC2014 dataset has 3 partitions: the development, the test and the training. The tests are done by using the partition of the training and the partition of the development from two tasks as data of training, and then, the partition of the test is applied for measurement of the model performance.

B. The Experiment Settings and the Evaluation Criteria

To obtain fast convergence and the optimization of the model, we apply the AdamW [34] by the adaptive learning rate strategy. The size of the batch is adjusted to 64, the rate of the dropout is adjusted to 0.2, and the learning coefficient is adjusted to 0.1. Regarding the rate of learning, the tests are done to check the efficiency of our presented approach at different rates.

The efficiency of base approaches in the AVEC 2013 dataset and the AVEC 2014 dataset is evaluated based on two evaluation criteria: the MAE and the RSME. MAE and RMSE are considered as criteria during the experiment for a fair comparison. These criteria are defined as follows:

$$\text{MAE} = \frac{1}{M}\sum_{j=1}^{M}|\hat{p}_j - p_j| \tag{8}$$

$$\text{RMSE} = \sqrt{\frac{1}{M}\sum_{j=1}^{M}(\hat{p}_j - p_j)^2} \tag{9}$$

Where M displays the overall number of samples of the video and p_j and $\hat{p}_j$ represent the actual score and the estimated score of BDI-II from j-th video.

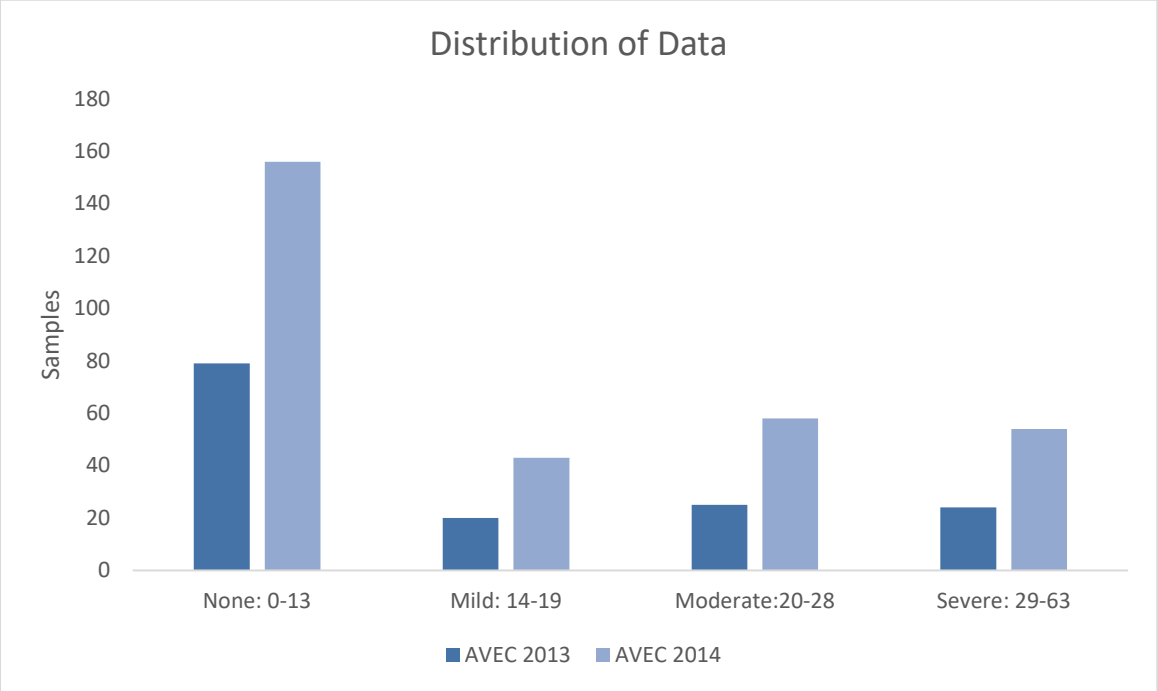

Fig. 7. Distribution of the scores of BDI-II on the dataset of AVEC 2013 and the dataset of AVEC 2014.

C. Evaluation of the Obtained Results

In the current part, first, we conduct an erosion check to investigate the performance of the components of the individual on our proposed approach. Next, our proposed framework is compared by the multiple other methods in this field to demonstrate its promising performance. The initialization of the model by LA-CNN (CMP-) and LA-CNN (CMP+), respectively, indicates the use and the non-use of the CMP technology in CNN based on local attention. The initialization of the model by GA-CNN shows that just the mechanism of the attention of the global is applied to the diagnosis of depression. The residual of the initialization of the model in Table II and Table III combine 2 or 3 separate components to take the information of the supplementary among them. Table II shows the detection results in the partition of the test from the dataset of AVEC2013. It is seen that $G1$ achieves the foremost efficiency. For the dataset of AVEC2014, we conducted various experiments for the verification of the efficiency of our presented approach. In Table III, it can be seen that similar perceptions with the AVEC2013 dataset are obtained. Additionally, from the 2 tables, it can be seen that the various approaches of CNN based on local attention have better performance than the different models of CNN based on global attention and $C1$. The performance in two depression datasets displays which capability of our presented approach is suitable for the evaluation of the depression severity scale from the video sequences. These observations show that with the combination of the components of an individual, the total efficiency is improved more over the use of a component of an individual. This point implies that we need to integrate the models of local and the models of global to diagnose depression. For a fair comparison with the other methods, just $G1$ and $G2$ are adopted to evaluate the depression diagnosis models, which are the foremost outcomes of our presented approach.

Regarding the learning rate, we changed this rate in the scope of 0.000001-0.1 and other parameters are static. As displayed in Tables IV and V, the increment of the rate of learning decreases the efficiency. Since the larger rate of learning leads to poor performance, the minimum rate of learning is appropriate for our presented approach to learn the significant patterns which are relevant to depression closely.

TABLE II. THE EFFICIENCY OF THE VARIOUS COMBINATIONS OF OUR PRESENTED METHOD IN THE AVEC2013 DATASET

Model Setting	RMSE	MAE
LA-CNN (CMP-)	8.74	7.19
LA-CNN (CMP+)	8.65	7.12
A1: LA-CNN (CMP-)+WSPP	8.56	6.81
B1: LA-CNN (CMP-)+WSPP	8.40	6.52
GA-CNN	9.05	7.43
C1: GA-CNN+WSPP	8.98	7.36
D1: LA-CNN(CMP-)+GA-CNN	8.71	7.15
E1: LA-CNN(CMP+)+GA-CNN	8.63	7.02

D2: LA-CNN(CMP-)+GA-CNN	8.62	6.91
E2: LA-CNN(CMP+)+GA-CNN	8.57	6.82
F2: LA-CNN(CMP-)+GA-CNN+WSPP	8.48	6.70
G2: LA-CNN(CMP+)+GA-CNN+WSPP	8.19	6.42

TABLE IV. THE RESULT OF THE RATE OF LEARNING IN THE EFFICIENCY OF OUR PRESENTED METHOD BY USING THE AVEC 2013 DATASET IN THE $G1$ MODE

Learning Rate	RMSE	MAE
0.000001	8.28	6.48
0.00001	8.50	6.79
0.0001	8.69	7.11
0.001	9.01	7.38
0.01	9.18	7.42
0.1	9.27	7.54

TABLE V. THE RESULT OF THE RATE OF LEARNING IN THE EFFICIENCY OF OUR PRESENTED METHOD BY USING THE AVEC 2014 DATASET IN THE $G2$ MODE

Learning Rate	RMSE	MAE
0.000001	8.18	6.40
0.00001	8.46	6.78
0.0001	8.71	7.13
0.001	8.94	7.37
0.01	9.12	7.39
0.1	9.26	7.55

In the following, to prove the efficiency of our presented approach, the comparison is made between the existing methods and our presented approach. It should be kept in mind that, as mentioned, the outcomes of our presented approach to compare the existing methods are provided on $G1$ mode and $G2$ mode. The quantitative performance comparison results for the dataset of AVEC 2013 and the dataset of AVEC 2014 are presented in Tables VI and VII. In particular, the presented models in [35]–[39] are based on the representations of the hand-crafted. Our approach performs better than the other approach in terms of the features of the hand-crafted emphasis on the experiences of the researchers, and it is hard to describe fully the depressive symptoms. In the approaches with the use of the DCNN, the presented method in [40] trains the deep methods in the big dataset, and next, it fine-tunes the dataset of AVEC 2013 and the dataset of AVEC 2014.

As shown in Tables VI and VII, our approach obtains the foremost efficiency between the approaches of the end-to-end in the used datasets. The presented method in [40] proposes a model of CNN based on the visual for depression detection by dividing roughly the area of the face into 3 parts and, next, by combining the total image of the face to better the model's detection performance. Our superior efficiency is according to the combination of the mechanism of the attention of the local and the mechanism of the attention of the global to extract the depression features. The results of the presented method in [40] display that their approach relies on the attention to just an area and also relinquishes other details of the face, which helps in depression detection. Reciprocally, the presented method in [41] obtains the acceptable efficiency sans a pre-trained network. The researchers segment the face area based on the points of the facial feature, and then, they clog the map of the feature to extract the information of the feature of the local. Our presented approach performs superior over these approaches with a significant margin.

D. Discussion

The obtained results from the experiments show that the proposed hand-crafted features as well as the feature aggregation method do not obtain higher RMSEs in compared to the method proposed in the present paper. From these results, it can be concluded that the proposed method in AVEC2013 and AVEC2014 can automatically learn the local and global feature information of the face area and outperform the best advanced methods for depression diagnosis. This further shows the effectiveness of the proposed method for diagnosis and analysis of depression.

In compared to the obtained results by similar methods, our method has improved the accuracy of depression diagnosis. There is a potential reason that the two-stage framework (eg, pre-training, fine-tuning) can effectively use their advantage to detect depression. By comparing the obtained results from similar methods, the RMSEs do not exceed them, our method is trained from scratch to be an end-to-end design for depression detection. For AVEC2014, as shown, our method achieves the comparable results to most video-based depression detection methods on the test set. In addition, these results of different components are better than the results obtained in AVEC2013.

Finally, in order to have an intuitive view of the prediction of the depression score from the images of the face, the images of the visualized face are provided in Fig. 8. The 1-th column from Fig. 8 displays the basic images. 2-th column to 5-th columns show the different areas from the facial image. The heat map on the images of the face is the fireplace area that the approach has learned. Before the merging of the attention maps, the proposed method can refer to multiple locations simultaneously. The proposed approach, in particular, relies on the areas of the movement of the associated facial muscles with depression, like the eyes, the mouth and the eyebrows. However, it ignores the irrelevant areas.

TABLE VI. COMPARISON OF OUR PRESENTED APPROACH TO SIMILAR APPROACHES BASED ON THE DATASET OF AVEC 2013

V. CONCLUSIONS AND SUGGESTIONS

In this research, CNN, by the mechanism of attention, is used for the designing of an end-to-end integrated approach to the diagnosis of depression based on the video. We ratiocinate which a functional ability to take the feature pattern from the "encoded" depression on the areas of the face is important. In particular, a new framework is proposed. This framework consists of two branches: CNN based on local attention and CNN based on global attention. A CNN based on the local attention focuses only on the local patches. A CNN based on global attention learns the patterns of the global from the total area of the face. To take the information of the supplementary among 2 branches, a CNN basis on the local-global attention is presented. Finally, to achieve the informative patterns of the depression, a WSPP is applied to learn the final feature representations. The extensive tests in 2 datasets, namely AVEC2014 and AVEC2013, have displayed that the ability of our presented approach is higher than the diagnosis models of depression that are almost video-based.

Hereafter, the dataset from the further depressed patients will be gathered for the learning of the stronger features representation by the various appearance images. Additionally, the examination of learning of the multimodal depression representation (the audio, the video, the text, etc.) seems to be an interesting topic. In addition, we will investigate the more explainable patterns of the representation and the stronger approaches of the regression by the discriminant DCNN. Also, the presented model based on deep learning can aid doctors in the evaluation of depressed people.

MG-CS: Micro-Genetic and Cuckoo Search Algorithms for Load-Balancing and Power Minimization in Cloud Computing

Jun ZHOU*, Youyou Li
College of Artificial Intelligence, Jiaozuo University, Jiaozuo, Henan, 454000, China

***Abstract*—Cloud computing has emerged as a transformative technology, offering remote access to various computing resources. However, efficiently managing these resources while curbing escalating energy consumption remains a critical challenge. In response, this paper presents the Micro-Genetic Algorithm with Cuckoo Search (MG-CS), a novel approach for enhancing cloud computing efficiency. MG-CS optimizes load balancing and power reduction and significantly contributes to reducing operational costs, ensuring compliance with service level agreements, and enhancing overall service quality. Our experiments showcase MG-CS's versatility in achieving a well-balanced distribution of workloads, resource optimization, and substantial energy savings. This multifaceted approach redefines cloud resource management, offering an environmentally sustainable and cost-effective solution. By introducing MG-CS, this research addresses the pressing challenges in cloud computing, aligning it with environmental responsibility and economic efficiency.**

***Keywords*—Resource utilization; cloud computing; energy consumption; optimization**

I. INTRODUCTION

Cloud computing enables cloud users to access a wide range of configurable computing resources, such as networks, servers, storage, services, and applications, conveniently and on-demand [1]. It has become a transformative technology widely discussed and currently prevalent in numerous commercial sectors. The cloud environment is categorized into private, public, and hybrid/federated clouds [2]. A private cloud represents a dedicated computing environment exclusively utilized by a single organization. It offers benefits like isolation, customization, and heightened security. The hosting can either be on-premises or managed by a third-party provider [3].

On the other hand, a public cloud operates as a shared cloud computing environment accessible to the general public. It provides advantages such as convenience, cost-effectiveness, and scalability, with resources delivered by third-party service providers via the Internet [4]. A hybrid/federated cloud integrates elements of both private and public clouds. This approach enables organizations to distribute workloads across multiple cloud deployment models, offering flexibility, seamless integration, and redundancy. Multi-provider clouds are becoming increasingly popular in cloud infrastructure, where multiple providers are used to distribute workloads across the environment. Organizations can enhance flexibility, redundancy, and resource allocation by leveraging multiple providers. Moreover, there are specialized cloud environments designed to cater to specific services [5]. IoT cloud services are a prime example that caters to IoT devices' data analysis and management. These services are equipped with capabilities to process and derive insights from the massive volumes of IoT-generated data efficiently. Mobile cloud services employ cloud computing to provide applications and services to mobile devices. This approach allows mobile users to access cloud applications and data, providing flexibility, scalability, and improved performance [6].

Cloud computing encompasses three primary cloud service models, each catering to specific needs: Software-as-a-Service (SaaS), Platform-as-a-Service (PaaS), and Infrastructure-as-a-Service (IaaS) [7]. Software applications are provided to users over the Internet by SaaS, a cloud computing model that uses a subscription-based approach. SaaS enables users to access and utilize these applications via a web browser, eliminating the need for local installation and maintenance. The responsibility of hosting, maintaining, and updating the software lies with the SaaS provider. PaaS, however, provides developers with a platform and environment to build, deploy, and manage applications without the complexities of managing the underlying Infrastructure. PaaS includes essential tools, runtime environments, databases, and other services required for seamless application development and deployment. Finally, IaaS grants users' access to virtualized computing resources via the Internet. Users can rent virtual machines, storage, and networking components pay-as-you-go. IaaS empowers organizations with the flexibility to create and manage their virtual data centers without the burden of owning physical hardware.

Cloud computing is built upon service-oriented architecture, which enables it to offer various services such as Database-as-a-Service (DbaaS), Identity-as-a-Service (IDaaS), and the broader concept of Anything-as-a-Service (XaaS). This architecture has revolutionized resource management in industry and academia, providing an efficient and dynamic approach [8]. The cloud system's dynamic nature is a crucial characteristic, accommodating numerous users, devices, networks, organizations, and resources that frequently connect and disconnect from the system. This adaptability is essential for meeting the diverse needs of cloud users. Several factors come into play when deciding on the appropriate cloud service model to implement. These factors include flexibility, scalability, interoperability, and service control. Evaluating

these aspects is crucial in determining the best-fit cloud service model to address specific requirements and optimize performance.

In the context of cloud computing, users have the flexibility to request resources from both the cloud service provider and the cloud resource broker. When functioning as a cloud service provider, the cloud resource broker is responsible for selecting the most suitable resource, considering the user's stipulated time constraints and budget considerations. This dynamic approach ensures the seamless delivery of on-demand services to users. Nevertheless, the proliferation of users and applications within the cloud ecosystem can lead to an escalation in workload and web application traffic, particularly for those deployed on virtual machines (cloud resources). To manage this expanding landscape effectively, the cloud resource broker necessitates a proficient algorithm capable of distributing tasks equitably among the active virtual machines. Such an algorithm becomes instrumental in minimizing the proportion of tasks that are rejected due to resource constraints. The overarching goal of load distribution within the cloud milieu is to optimize several critical aspects, including scalability, response time, and resource utilization.

Effective load-balancing not only leads to the attainment of minimum makespan times for tasks but also contributes to overall system performance enhancement. Furthermore, load-balancing acts as a preventive measure against system bottlenecks stemming from disparities in load distribution. This realm presents substantial research challenges within the realm of cloud computing, focusing on the equitable distribution of workload among virtual machines. Load-balancing in the cloud encompasses two pivotal stages: task scheduling and virtual machine monitoring. Task scheduling, a well-recognized optimization problem (NP-Complete), becomes intricate due to the heterogeneous resource configuration within the cloud and the swift fluctuations in on-demand requests. The intricate nature of this landscape renders the prediction and computation of all conceivable task-resource mappings within the cloud environment arduous.

Consequently, the development of an efficient task-scheduling algorithm assumes paramount importance. Such an algorithm is instrumental in the judicious distribution of tasks, thereby mitigating scenarios where certain virtual machines endure overload or under-load conditions. These algorithms play a pivotal role in fostering balanced resource utilization and fostering optimal performance within cloud computing systems. As a result, they constitute an indispensable component in the pursuit of achieving equilibrium and excellence within the dynamic cloud computing landscape.

Various techniques, including meta-heuristic algorithms, machine learning, and deep learning, have been integrated into cloud load balancing strategies to address the increasing demand for cloud services and ensure optimal resource utilization. Meta-heuristic algorithms, such as Ant Colony Optimization (ACO) [9], Particle Swarm Optimization (PSO) [10], sine cosine algorithm [11], and imperialist competitive algorithm [12], provide efficient methods for task scheduling and resource allocation, contributing to equitable workload distribution and enhanced system performance. Machine learning techniques enable cloud systems to learn from historical data, adapt to changing workloads, and make real-time load-balancing decisions [13-15]. Deep learning, with its neural networks, enhances predictive accuracy and aids in proactive load management [16, 17]. Cloud load balancing ensures that the various components of these transportation systems, such as ticketing, scheduling, and real-time tracking, operate efficiently and respond to dynamic demands [18, 19]. By utilizing the power of cloud computing and the aforementioned advanced techniques, public transportation services can offer improved reliability, scalability, and cost-effectiveness, ultimately benefiting commuters and the environment.

The demand for cloud services has led to the rapid expansion of extensive data centers, resulting in a significant increase in electricity consumption. This heightened energy consumption has raised concerns about its environmental impact and economic sustainability. Researchers have explored innovative approaches to optimize cloud resource management to address these challenges while simultaneously upholding high-quality service levels. In this context, the integration of metaheuristic algorithms has shown great promise in tackling complex optimization problems frequently encountered in cloud computing. Our paper introduces a novel approach, the Micro-Genetic and Cuckoo Search (MG-CS) algorithm, which is tailored for power reduction and load-balancing in cloud computing. The primary contribution of this research is the development of an efficient and multifaceted approach that concurrently addresses various critical objectives:

- Load balancing excellence: MG-CS aims to achieve a well-balanced distribution of workloads across cloud resources, ensuring optimal resource utilization and averting potential performance bottlenecks.
- Dedicated power minimization: Our approach reduces energy consumption within cloud data centers, promotes environmental sustainability, and optimizes operational costs.
- Strategic cost reduction: We target minimizing resource wastage and optimizing cloud service delivery to make cloud infrastructure more cost-effective.
- Time optimization initiatives: MG-CS endeavors to improve response times and task completion rates, enhancing the overall user experience and operational efficiency of cloud services.
- SLA compliance assurance: Our approach ensures that cloud services meet predefined service level agreements (SLAs), aligning with performance and availability requirements defined by consumers.
- QoS elevation strategies: The research aims to elevate the quality of cloud services, covering aspects of reliability, scalability, and data security, thereby providing an enhanced user experience and meeting customer expectations.

The paper is organized as follows: Section II provides an overview of related work, Section III details our proposed load balancing framework using the MG-CS algorithm, Section IV

presents the experimental results, and Section V concludes our research, summarizing the contributions and potential future directions.

II. Related Work

Yakhchi, et al. [20] presented a method rooted in the CS algorithm to identify over-utilized hosts within a cloud environment. Subsequently, they employed the Minimum Migration Time (MMT) policy to systematically transfer VMs from over-utilized hosts to alternative hosts, ensuring that the migration process did not inadvertently lead to new instances of over-utilization. Following this, the researchers categorized all hosts except the over-utilized ones as underutilized, aiming to efficiently relocate VMs from these underutilized hosts to different hosts and transition the former to a sleep mode. This strategic maneuver effectively optimized both resource utilization and energy consumption. The research employed simulation using the CloudSim simulator, yielding compelling results. Specifically, their approach yielded the lowest energy consumption compared to several well-established algorithms, reaffirming the efficacy of their proposed method.

Sharma, et al. [21] have employed the bat algorithm as an approach to cloud load balancing. The bat Algorithm draws inspiration from the echolocation behavior of bats and has been proposed for this purpose. Bats, in their pursuit of prey, exhibit erratic flight patterns by altering various parameters such as velocity, pulse emission rate, position, frequency, and loudness. These alterations are made based on the proximity between the bat and its prey. The adjustment of velocities and positions of bats is incorporated in a manner similar to the PSO algorithmic. The bat algorithm is structured to achieve optimal results by running the algorithm through multiple iterations. In the context of this study, the bat algorithm is utilized to determine the most suitable server from a pool of available servers for the execution of incoming tasks. When a new task is introduced into the task pool, the load balancer initiates the bat algorithm to identify the best-suited server that matches the requirements of the incoming task. The bat algorithm takes into account factors such as task type and required resources when selecting the optimal VM for task execution. Upon selecting the appropriate server, the load balancer allocates the task to that server. If the load on the chosen server surpasses that of all other servers, the task is then distributed across multiple servers.

Devaraj, et al. [22] introduced an innovative load-balancing algorithm named FIMPSO, which represents a hybrid amalgamation of the Firefly (FF) algorithm and the Improved Multi-Objective Particle Swarm Optimization (IMPSO) technique. The FIMPSO algorithm synergizes the strengths of the FF algorithm to effectively narrow down the search space while harnessing the capabilities of the IMPSO technique to attain enhanced responsiveness. The IMPSO algorithm takes a unique approach to select the global best (gbest) particle. It does so by considering the proximity of a point to a line, enabling the identification of candidates for the gbest particle. This method significantly refines the search process, ultimately facilitating the pursuit of an optimal solution. The proposed FIMPSO algorithm is validated through its notable accomplishment in load balancing. This achievement translates to improved resource utilization and diminished task response times. The outcomes of simulations underscore the superiority of the FIMPSO model in comparison to alternative methods. Specifically, the FIMPSO algorithm exhibited exceptional performance metrics such as average response time (13.58ms), CPU utilization (98%), memory utilization (93%), reliability (67%), and throughput (72%). Additionally, the FIMPSO algorithm achieved an impressive makespan of 148, outperforming all other methodologies considered for comparison.

Jena, et al. [23] introduced an inventive approach to dynamically balance the load across VMs utilizing a hybrid strategy named QMPSO, which amalgamates a modified Particle Swarm Optimization (MPSO) technique with an enhanced Q-learning algorithm. Within the QMPSO algorithm, this fusion mechanism fine-tunes the velocity of MPSO by incorporating insights from both the global best (gbest) and personal best (pbest) solutions. These solutions are derived from the optimal actions identified through the improved Q-learning algorithm. The primary objectives driving this hybridization are to elevate the performance of virtual machines through load balancing, amplify the throughput of VMs, and uphold equilibrium between task priorities by optimizing their waiting times. To validate the robustness of the QMPSO algorithm, a comprehensive comparison was conducted. The algorithm's outcomes, gleaned from both simulation-based assessments and actual platform measurements, were juxtaposed with those generated by existing load-balancing and scheduling algorithms. The empirical evidence unequivocally demonstrated the superiority of the proposed QMPSO algorithm, underscoring its prowess in achieving load-balancing and fine-tuning the performance of virtual machines within a cloud environment.

Sefati, et al. [24] harnessed the Grey Wolf Optimization (GWO) algorithm as a means to attain effective load-balancing while considering the resource reliability capacity. In this endeavor, the GWO algorithm was employed to discern nodes that were either idle or occupied within the cloud environment. Once these nodes were identified, the algorithm proceeded to compute the threshold and fitness function for each node. The researchers conducted a simulation using CloudSim, wherein the proposed approach, leveraging the GWO algorithm, was assessed in comparison to other load-balancing methods. The results of this assessment highlighted significant advantages, including reduced costs and response times. Moreover, the solutions obtained were deemed optimal, serving as a testament to the efficacy of the load-balancing methodology founded on the GWO algorithm.

Latchoumi and Parthiban [25] have introduced a groundbreaking approach, termed the Quasi-Oppositional Dragonfly Algorithm for Load-balancing (QODA-LB), with the primary aim of attaining optimal resource scheduling within a cloud computing framework. The QODA-LB algorithm strategically integrates three pivotal variables – execution time, execution cost, and charge – to formulate an objective function. This objective function serves as the foundation for task allocation to Virtual Machines (VMs), predicated on their inherent potential. A noteworthy aspect of the QODA-LB algorithm is the incorporation of the Quasi-

Oppositional Based Learning principle. This principle confers a distinctive edge by elevating the standard convergence rate of the Dragonfly algorithm (DA). The integration of this principle enhances the efficacy of load-balancing and resource scheduling within the cloud environment. A comprehensive series of experiments was meticulously conducted to assess the QODA-LB algorithm's performance. The ensuing results were scrutinized from diverse angles to validate its heightened efficiency. The outcomes of simulations substantiated the algorithm's exceptional load-balancing efficiency, positioning it as a superior alternative to other foundational approaches for load-balancing and resource scheduling in the realm of cloud computing.

Haris and Zubair [26] introduced a dynamic load-balancing algorithm named Mantaray modified multi-objective Harris hawk optimization (MMHHO) that draws inspiration from hybrid optimization algorithms. This innovative approach leverages the strengths of the Harris Hawk Optimization (HHO) algorithm, enhancing its search space through integration with the Manta Ray Foraging Optimization (MRFO) algorithm. The hybridization process strategically melds various factors, including cost, response time, and resource utilization, to streamline the load-balancing process. The MMHHO algorithm sets its sights on optimizing system performance by bolstering VM throughput, achieving equilibrium in load distribution among VMs, and harmonizing task priorities by adjusting their waiting times. The implementation of the MMHHO-based load-balancing algorithm is realized through the utilization of the CloudSim tool. This platform provides the means to assess the algorithm's effectiveness across various parameters and compare its performance against other established load-balancing algorithms. Upon meticulous analysis and simulation, the results unequivocally underscore the supremacy of the proposed MMHHO load-balancing scheme. In terms of system performance and efficiency, the MMHHO algorithm surpasses its counterparts, thereby validating its potential to elevate load-balancing processes and enhance the overall effectiveness of the system.

III. Proposed Load-Balancing Framework

A. Problem Statement

The importance of autonomic load-balancing in the cloud computing domain stems from its capacity to elevate throughput through the optimized utilization of resources. The load-balancing strategies and power management strategies put forth in this proposal are geared towards the automatic and efficient allocation of computational resources within the cloud infrastructure. This is achieved by evaluating the suitability of all tasks concerning resource availability. The effectiveness of the load-balancing approach is determined using intersection formulas, with the most common ones being represented by Eq. (1) and Eq. (2). These formulas play a crucial role in the assessment of task-resource mapping, enabling the system to achieve improved performance and better resource allocation in the cloud environment.

$$K = (G + 2\sqrt{g})/3G \quad (1)$$

$$X = \begin{bmatrix} 0 & gen \\ 1 & gen \end{bmatrix} X \frac{\pi}{2} \quad (2)$$

Fig. 1 depicts the architecture of the load-balancing framework, encompassing three fundamental stages:

- Optimal resource utilization: This phase focuses on achieving efficient resource utilization by effectively managing cloud resources and handling the workload coming from cloud users. Clustering and VM deployment support are employed to ensure optimal resource provisioning.
- Workload submission and demand-based processing: During this phase, cloud users submit their requests and workloads based on their specific demands. The system takes into account energy consumption while processing and managing the workload.
- Minimizing power consumption: The framework emphasizes minimizing power consumption to reduce the environmental impact and operational costs within the cloud.

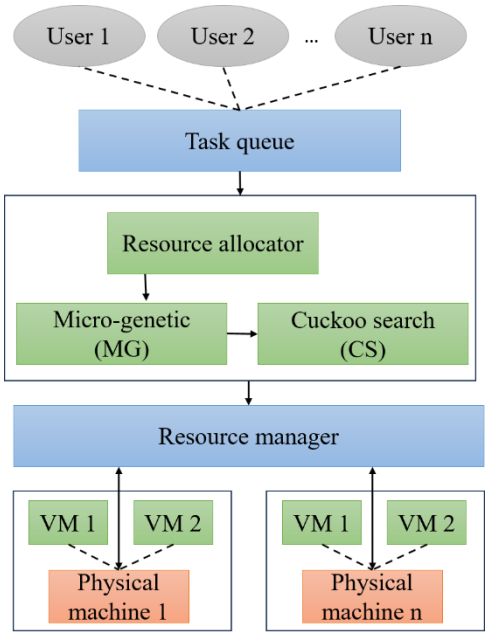

Fig. 1. Proposed load-balancing framework

Key terminologies and components within the load balance framework are as follows:

- Cloud users: Entities, whether individuals or businesses, who make use of cloud storage services to conveniently manage, store, and access their computing resources from any location.
- SLA administration: Service-level agreements (SLAs) provide assurance to customers and enable cloud providers to prioritize the fulfillment of their particular needs and expectations. Active management of SLAs is crucial, as they represent more than just guidelines and function as contracts.

- Workload scheduling and clustering: This method clusters and schedules similar workloads to the corresponding virtual machines based on Quality of Service (QoS) and SLA considerations.
- QoS management: This component is responsible for managing any Quality of Service (QoS) specifications linked to workload access, ensuring that the workload is effectively handled in accordance with its specific QoS requirements.

Algorithm 1 outlines the process of grouping workloads based on their center points by optimizing an objective function to achieve the minimal value. The algorithm aims to create clusters by utilizing the designated center points as group representatives. Each workload in a cluster is highly likely to belong to the cluster represented by its nearest center point. However, workloads can only belong to a single cluster, except for the center point, which may be part of multiple clusters.

Algorithm 1. Workload clustering

No of Clusters commit to complete which will be decided by C.

STEP-1: START

STEP-2: The non-empty subclasses of object C will be divided at random.

STEP-3: Cluster centroids are currently the separating seed points of clusters.

STEP-4: An object will be paired with another object whose seed points are closer.

STEP-5: END

B. Micro-genetic Algorithm

Genetic Algorithms (GAs) belong to the family of Evolutionary Algorithms (EAs) and are widely recognized as one of this family's earliest and most well-known members. In GAs, elitism, which involves preserving the best individuals (solutions) in the population, is promoted through two fundamental mechanisms:

- Environmental selection: Environmental selection aims to remove the worst-fitted individuals from the current population, ensuring they do not contribute to the next generations. This allows the fittest individuals to have a higher chance of survival and progression.
- Parent selection: In the parent selection process, the algorithm promotes generating offspring solutions from the population's best individuals (the elite solutions). Non-elite solutions are excluded from this process, further reinforcing the elitism aspect of the algorithm.

Micro-GAs (MGs) are a specific type of GA with minimal populations. Due to the use of such small populations, MGs exhibit a high level of elitism. In MGs, the environmental selection has lower survivor rates than canonical GAs, as the focus is on preserving only the best solutions. Additionally, the parent selection process only allows elite solutions to generate offspring, further enhancing the elitism effect. The genetic algorithm demonstrates the capability to quickly generate high-quality local optimal solutions while maintaining competitiveness in the long term. This makes it an effective approach for solving problems with computationally intensive fitness functions.

Nevertheless, when dealing with problems that encompass high-dimensional parameter spaces, attaining the convergence of all model parameters within a specified margin of error can present difficulties and consume a substantial amount of time. As the count of model parameters expands, the genetic algorithm necessitates a larger population size, resulting in an increased volume of cost-function analyses. This can be computationally expensive, especially when dealing with high-dimensional problems. In such scenarios, micro-genetic algorithms offer a viable alternative. These algorithms operate with very small populations, which help reduce the computational burden while maintaining a high level of elitism. The smaller population size allows for a more focused search, and the algorithm can swiftly converge to promising solutions without the need for a large number of cost-function evaluations.

C. Cuckoo Search Algorithm

The CS algorithm is inspired by the egg-laying strategy of cuckoo birds, where they lay their eggs in the nests of other bird species. This nature-inspired optimization technique simulates this behavior to explore complex search spaces and discover optimal solutions. Cuckoos employ a Levy flight strategy to select nests, frequently opting for nests where the host bird has recently deposited its own eggs. This behavior enhances the likelihood of their eggs successfully hatching. Notably, certain female cuckoos mimic the colors and patterns of host eggs to decrease the chances of their eggs being rejected, thereby amplifying their reproductive success. The foraging behavior of animals, including insects, follows a quasi-random pattern, effectively resembling a random walk. This behavior has been observed in many animals and has been mathematically modeled as Lévy flights. Lévy flights involve making successive movements with step lengths drawn from a Lévy distribution, which allows for long jumps that facilitate efficient exploration of large search spaces. Based on this concept, researchers have applied Lévy flights to optimization and search problems, resulting in the development of the CS algorithm. Preliminary results have shown promising capabilities of this algorithm in finding optimal solutions for a wide range of optimization problems. By imitating the natural behavior of cuckoos and incorporating Lévy flights, the Cuckoo Search Algorithm offers a powerful and efficient approach for tackling complex optimization challenges. The CS algorithm models the natural behavior of cuckoos and can be described using the following idealized rules:

- Each cuckoo lays a single egg at a time, selecting a nest at random for deposit. Nests with superior egg quality (improved solutions) are more likely to persist across subsequent generations.
- The count of available host nests is constant, represented as 'n,' and the host bird has a probability of detecting an alien egg within the range of [0, 1].

- When an alien egg is detected, the host bird has the choice to either discard it or desert the nest to construct a new one at a distinct location.

To simplify, this final assumption can be approximated using a probability of pa for each of the n nests. With these rules in mind, the fundamental steps of the CS algorithm can be succinctly summarized in pseudocode as follows:

1) Initialize the population of cuckoos (solution candidates).
2) Evaluate the quality (fitness) of each cuckoo.
3) Identify the best cuckoos and their nests for further reproduction
4) Repeat until stopping criteria are met:
5) Generate new cuckoo solutions by performing Levy flights
6) Evaluate the fitness of newly generated cuckoos
7) Replace the old cuckoos with the new cuckoos in the nests based on their fitness
8) Abandon and rebuild nests (cuckoos) with a probability of p_a
9) If a host bird discovers an alien egg with probability p_a:
10) Throw away the alien egg or abandon the nest and build a new one
*11) Identify t*he best solution found and return it as the final result

In the CS algorithm, the movement of each cuckoo from generation *t* to *t+1* is represented by a vector *x* with entries $X_i(t+1)$ and is calculated by Eq. (3).

$$X_i(t+1) = X_i(t) + \alpha \oplus \text{Lévy}(u) \quad (3)$$

Where $X_i(t)$ is the current position of the i^{th} cuckoo at generation *t*, $\alpha > 0$ is the step size, which depends on the scale of the given problem, $\oplus$ represents entry-wise multiplication, and *Lévy(u)* is determined using the Lévy flight, a random step-length process. The expression for *Lévy(u)* is given by:

$$\text{Lévy}(u) = t^{(-\lambda)} \quad (4)$$

Where λ is a parameter, typically within the range $1 < \lambda \leq 3$, *t* is the current generation. The Lévy flight results in a power-law step-length distribution with a heavy tail, making cuckoos more exploratory. In the real world, if a cuckoo's egg closely resembles the host's eggs, it is less likely to be discovered by the host bird. To mimic this behavior, the CS algorithm performs a random walk in a biased way with some random step sizes. This biased random walk, guided by the Lévy flight, allows the algorithm to explore the search space more effectively, discovering better solutions in complex optimization problems.

D. MG-CS Algorithm

Consider a cloud environment with multiple VMs where diverse workloads are dynamically generated based on user demands. The goal is to efficiently distribute these workloads across the available VMs to ensure optimal resource utilization, prevent overloads or under-utilization, and ultimately enhance the overall performance of the cloud system. The algorithm follows the steps described below.

- Initialization: The algorithm begins by randomly entering tasks into a task memory divided into replaceable and non-replaceable tasks. Various parameters such as states, positions, steps, and visual parameters are set up during this phase.
- Task selection: The algorithm selects tasks from the task memory for further processing.
- Crossover and mutation: The selected tasks undergo crossover and mutation operations to generate new potential solutions.
- Patronize: The algorithm evaluates the fitness level of each potential solution.
- New tasks and convergence: The algorithm tracks the best MG values and investigates their behaviors. If the fitness of MG exceeds the predefined threshold (bulletin value), the MG's fitness is updated in the bulletin.
- Filter and external memory: The algorithm uses a filter to refine the solutions and stores valuable information in the external memory, facilitating feedback with both sides of the task memory.
- Final solution: The CS step performs the optimal solution chosen from the population and decodes it to determine the most appropriate resource assignment to tasks based on their availability and throughput.

IV. EXPERIMENTAL RESULTS

The experiment was conducted in CloudSim, a simulation tool devised by cloud laboratories situated in Melbourne. Within this experiment, a total of 50 tasks were examined within a simulation framework encompassing 25 VMs. Each VM was equipped with 2048 MB of RAM. Fig. 2 to 7 present various performance metrics and comparisons of the proposed MG-CS method with existing approaches in a cloud simulation environment. The experiments were conducted with different numbers of workloads and servers. Fig. 2 depicts the availability rate in relation to various workloads. MG-CS exhibited a diverse spectrum of results, with an availability rate of up to 55% with 500 workloads. As the workload increased, the availability rate decreased, reaching 90% with 3000 workloads. Fig. 3 provides an illustration of the reliability rate as it correlates with different workloads. The MG-CS again demonstrated a diverse range of results. It achieved a reliability rate of up to 48% with 1000 workloads, which decreased as the workload increased. Ultimately, it achieved a reliability rate of 72% with 3000 workloads, outperforming the existing system's performance.

In Fig. 4, the resource utilization pattern is displayed alongside varying workloads. The MG-CS approach demonstrated notable efficacy, achieving a peak resource utilization of 80% when subjected to 2500 workloads. Fig. 5 provides a visual representation of the SLA violation rates in relation to varying workloads. Notably, the MG-CS system presented a remarkably low violation rate compared to its counterparts. Specifically, it exhibited a mere 4% violation rate when confronted with 500 workloads and a slightly higher

10.5% violation rate when handling 3000 workloads. Fig. 6 presents the energy consumption during workload processing. The introduced MG-CS approach effectively minimized energy consumption in comparison to comparative ones. To illustrate, when subjected to 2000 workloads, the energy consumption was notably reduced to 400 kW. Fig. 7 provides a visual contrast of execution times across diverse methodologies and workloads. Impressively, the MG-CS system consistently accomplished the processing of 500 to 3,000 workloads within a time span of 5000 to 6,000 seconds. This remarkable efficiency in execution time sets the MG-CS approach apart from existing techniques, highlighting its superior performance.

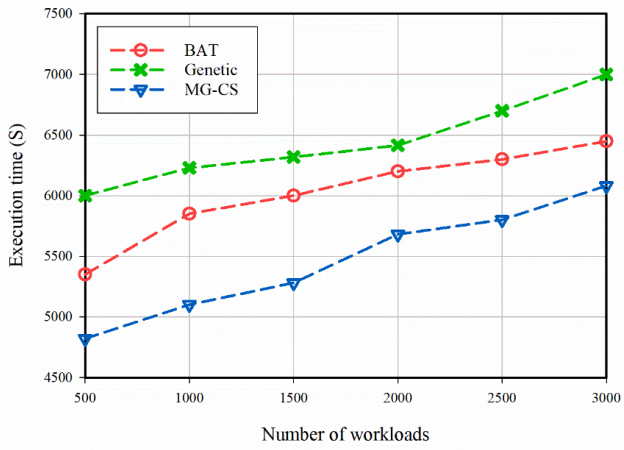

Fig. 7. Execution time comparison

The experimental results, as presented in Fig. 2 to 7, reveal the significant impact of the proposed MG-CS approach on various performance metrics in a cloud simulation environment. Notably, the results illustrate the adaptability and efficacy of MG-CS across a range of workloads and server configurations. In terms of availability, Fig. 2 demonstrates that MG-CS exhibited a diverse spectrum of results, achieving an availability rate of up to 55% with 500 workloads. As the workload increased, availability decreased but remained robust, reaching 90% with 3000 workloads. Similarly, in Fig. 3, the reliability rate showcased a wide range of outcomes. MG-CS achieved a reliability rate of up to 48% with 1000 workloads, surpassing existing systems. Fig. 4 showcases the resource utilization pattern, with MG-CS achieving a remarkable peak utilization of 80% when subjected to 2500 workloads, signifying its efficiency. In terms of SLA violation rates (Fig. 5), MG-CS demonstrated an impressively low violation rate, with just 4% for 500 workloads and a slightly higher 10.5% for 3000 workloads, highlighting its ability to meet service level agreements. Furthermore, Fig. 6 illustrates the energy consumption during workload processing, with MG-CS effectively minimizing energy consumption, reducing it to 400 kW when subjected to 2000 workloads. Lastly, Fig. 7 provides a visual contrast of execution times, underscoring MG-CS's remarkable efficiency in processing 500 to 3,000 workloads within a period of 5,000 to 6,000 seconds. These findings emphasize the significance of the MG-CS approach in enhancing cloud resource management, achieving load balance, and optimizing operational efficiency while meeting service level agreements and reducing energy consumption.

Table I presents the dimensions of diverse synthetic datasets along with the associated task quantities. The "extra-large" dataset encompasses 800-1000 tasks, and each task's magnitude falls within the range of 100,000-200,000MI. Similarly, the "large" dataset comprises 600-700 tasks, with task sizes ranging from 70,000-100,000MI. Correspondingly, the "medium-sized" dataset entails 400-500 tasks, and the tasks vary in size between 50,000-70,000MI. Likewise, the "small-sized" dataset encompasses 100-200 tasks, with task sizes spanning from 30,000-50,000MI. It is noteworthy to mention that task sizes were generated randomly during runtime, and their size is denoted in Millions of Instructions (MI). Moreover, the research utilized a total of 80 servers, each characterized by distinct resource capacities and loads. Each server hosted different types of VM instances, featuring varying CPU and memory capacities, as outlined in Table II. Fig. 8 illustrates the outcomes obtained through the proposed method concerning CPU utilization. The graph clearly demonstrates that, in comparison to FIMPSO, MG-CS consistently achieved the highest CPU utilization across all task categories.

TABLE I. DATASETS DESCRIPTION

Type of tasks	Size of tasks (MI)	Number of tasks
Small	100-200	30000-50000
Medium	400-500	50000-70000
Large	600-700	70000-100000
Extra-large	800-1000	100000-200000

TABLE II. TYPES OF VM INSTANCES

Type of tasks	Memory capacity (GB)	CPU capacity (MIPS)
Small	5	10000
Medium	10	20000
Large	15	25000
Extra-large	20	35000

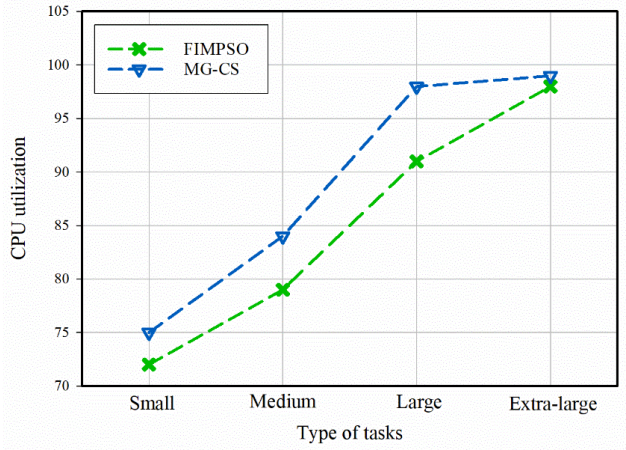

Fig. 8. CPU utilization comparison.

V. CONCLUSION

This paper presented MG-CS, a load-balancing resource allocation approach aimed at improving the utilization of cloud resources. The proposed method's experimental results demonstrate its effectiveness in addressing various QoS factors, including availability, reliability, resource utilization, SLA violation, energy Consumption, and execution time. The proposed method is compared with existing algorithms for QoS parameter efficiency, and the experimental results show that the MG-CS technique outperforms existing GA and BAT algorithms in terms of cost, timing, and energy. The experimental findings prove that MG-CS is the effectiveness of MG-CS in accomplishing both optimal scheduling and load-balancing objectives. Furthermore, the approach ensures the preservation of superior QoS standards while steadfastly adhering to SLA requirements during cloud services. In the

future, the researchers plan to incorporate artificial intelligence self-learning methods to facilitate large-scale data sources. The method can enhance its performance and adaptability by integrating AI capabilities in handling complex and dynamic cloud environments. These advancements are expected to contribute to more efficient and robust cloud resource allocation, making cloud services more reliable and cost-effective for users.

MG-CS offers several notable benefits in the context of cloud load balancing and power minimization. It excels in achieving superior load distribution across cloud resources, ensuring optimal resource utilization, and averting performance bottlenecks. Moreover, the MG-CS algorithm effectively reduces energy consumption within cloud data centers, promoting environmental sustainability and cost efficiency. The method optimizes cloud service delivery, enhancing resource utilization and minimizing operational expenses. Furthermore, the approach enhances response times, task completion rates, and overall QoS, improving the user experience. However, like any approach, there are limitations to consider. The computational complexity of MG-CS may pose challenges in large-scale cloud environments. Additionally, the algorithm's performance could be influenced by the specific workload characteristics, and it may require fine-tuning for optimal results. Moreover, while MG-CS demonstrates robust performance in our experiments, its generalizability to diverse cloud infrastructures and real-world scenarios may need further investigation. These limitations underscore the need for ongoing research to fine-tune and adapt MG-CS for various cloud computing contexts and scenarios.

A Focal Loss-based Multi-layer Perceptron for Diagnosis of Cardiovascular Risk in Athletes

Chuan Yang*
School of Public Utility Management, Chongqing Vocational College of Transportation, Chongqing 402247, China

***Abstract*—Cardiovascular diseases (CVDs) are a prevalent cause of heart failure around the world. This research was required in order to investigate potential approaches to treating the disease. The article presents a focal loss (FL)-based multi-layer perceptron called MLP-FL-CRD to diagnose cardiovascular risk in athletes. In 2012, 26,002 athletes were measured for their height, weight, age, sex, blood pressure, and pulse rate in a medical exam that had electrocardiography at rest. Outcomes were negative for the largest majority, leading to class imbalance. Training on imbalanced data hurts classifier performance. To address this, the study proposes a training approach based on focal loss, which effectively emphasizes minority class examples. Focal loss softens the influence of simplistic samples, enabling the model to concentrate on more intricate examples. It is useful in circumstances when there is a substantial class imbalance. Additionally, the paper highlights a challenge in the training phase, often characterized by the use of gradient-based learning methods like backpropagation. These methods exhibit several disadvantages, including sensitivity to initialization. The paper recommends the implementation of a mutual learning-based artificial bee colony (ML-ABC). This approach adjusts the primary weight by substituting the food resource candidate, which is selected due to superior fitness, with one based on a mutual learning factor between two individuals. The sample obtains great outcomes, outperforming other machine learning samples. Optimal values for important parameters are identified for the model based on experiments on the study dataset. Ablation studies that exclude FL and ML-ABC of the sample confirm the additive effect of, which is not negative and dependent, these factors on the sample's efficiency.**

Keywords*—*Cardiovascular diseases; multi-layer perceptron; focal loss; artificial bee colony; imbalanced classification

I. Introduction

As per the World Health Organization's discoveries, cardiovascular diseases are responsible for the most deaths across the globe, leading to 17.9 million fatalities every year [1]. Smoking, obesity, high blood pressure, and physical inactivity are the most significant risk elements. Even though the risk of cardiovascular diseases can be minimized through regular exercise, athletes competing or training with intensity and frequency remain at risk due to the intensity and frequency of their activities. Athletes are consistently monitored by sports physicians, who gain biomedical and personal information, along with executing electrocardiography screenings (ECG). According to the ECG results, people are classified as either a risk factor or not a risk factor. Those deemed at risk may not gain medical clearance for participation in sports and will be subject to further assessments. There is an unequal ratio between the two categories, as the N class contains a larger percentage of individuals, while the more remarkable P class is not very common. Generally speaking, a false negative (FN) may have severe consequences, potentially including a human fatality. In contrast, a false positive (FP) would lead to additional medical examinations and temporarily halt sports practice [2].

Classification is indeed a method of machine learning that can expect binary classification values, such as P or N, and it could have great use in the health world, particularly in diagnostics. Several machine learning techniques have already been implemented in medical diagnosis systems to assist decision-making. These techniques may estimate health risks from huge datasets. Wong et al. [3] utilized Bayesian networks to uncover past disease outbreaks and achieved remarkable outcomes on actual data taken from a database that contained seven years of medical records from an emergency region. The dataset was collected from unwell patients in a hospital, indicating that the research was aimed at epidemiological investigation rather than diagnostic purposes. This strategy could also be implemented in counterterrorism to discover biological attacks. Campbell et al. [4] utilized a kernel-based approach that effectively identified a rare disease from medical data. However, the size of the dataset was limited, and the proportion of noteworthy instances in the test set was considerably greater than the prevalence of the disease among the overall population. Fontaine et al. [5] investigated methods of data mining to enhance the clinical assessment of patients with brain disorders. Salam and McGrath [6] conducted a machine-learning strategy for dermatology. In this study, a classifier for multiple diseases improved the identification of skin infections. Sacchi et al. [7] applied a Naive Bayes classifier for glaucoma prediction. Because of the small and unbalanced dataset, resampling and bootstrapping were employed to train their model. Numerous authors [8, 9] have suggested comparing different classification methods in medical statistics to identify the significant benefits of one approach compared to others. There is still a dearth of studies using large datasets in regions where diseases have a low prevalence, but individuals may face increased risks due to heightened levels of pressure or stress. Moreover, there is a continuous debate about the necessity for affordable and efficient healthcare, as well as the more cautious utilization of medical tests.

In machine learning approaches, the strategy for extracting features is inflexible, resulting in poor generalization ability, rising time, and low precision [10]. With the emergence of profound learning methods in numerous usages [11], numerous investigators have employed those for categorization [12].

Deep learning can accurately learn high-level features due to its layered structure. Multi-layer perceptron is a universal approximation initially developed for nonlinear XOR and has been implemented effectively for diverse combinatory enhancement issues ever since [13]. MLP is widely utilized for a variety of tasks, including information processing, pattern recognition, classification issues, image processing, linear and nonlinear optimization issues, and real data prediction. MLP functions as a universal approximation where input signals propagate forward. The processing node related to a human neuron is the fundamental component of the ANN method. Each processing node gets a collection of intake deals, adds them, and after that, passes this sum through an activation function that determines the node's output value. In MLP, nodes comprise fully interconnected layers, with the exception that nodes within the same layer are not interconnected [14].

Medical classification faces significant challenges due to data imbalance, which can significantly lower performance because there are far more negative instances [15, 16]. Over-sampling, under-sampling, or a compound of both are used in the data-level strategy to mitigate the negative effects of imbalanced classification [17, 18]. Approaches at the algorithmic level give the minority class more weight [19]. Additionally, profound learning techniques can be used to solve the categorization balancing problem [20]. Huang et al. [21] formulate a process to identify distinguishing features of imbalanced data while upholding inter-cluster and inter-class margins. Yan et al. [22] suggested a technique using the bootstrapping method to balance data of convolutional networks across mini-batches.

Deep models are widely used in natural language processing, computer vision, and medical image analysis [23, 24]. The best solution for optimizing the neural network can be selected from a population of created models using population-based training. This approach is less likely to get stuck in local optima than traditional training methods [25, 26]. Indeed, a simple evolutionary algorithm was found to rival stochastic gradient descent for neural network training. Jaderberg et al. [27] applied population-based training to state-of-the-art models of deep RL, machine translation, and generative adversarial networks and demonstrated consistent improvements in accuracy, training time, and stability. In [28] and [29], effective training of the weights of neural networks was achieved using a differential evolution-based strategy and Artificial Bee Colony (ABC), respectively. The ABC algorithm can be improved by the mutual learning-based ABC [30], which changes the algorithm to use mutual learning between two selected position parameters instead of choosing the candidate food source with the highest fitness [31].

In response to the challenges outlined, this article introduces an FL-based MLP, designated as MLP-FL-CRD, for diagnosing cardiovascular risk in athletes within an imbalanced dataset. The proposed MLP-FL-CRD model contains an MLP for sick and healthy inputs that employ FL to class imbalance. An ML-ABC is utilized for weight initialization to identify a promising area within the study environment for initiating the BP method in the model. This process involves continuous evaluation of the understanding of athleticism, achieved through shared knowledge among current and nearby nutrition resources, to develop a more valuable nutrition resource. The MLP-FL-CRD model is assessed on a dataset comprising medical examinations of 26,002 athletes, demonstrating its superiority over other approaches. Furthermore, ablation studies are conducted to evaluate the relative contributions of the FL and pre-training strategies. Various alternative model component options, e.g., evolutionary algorithms and loss functions, are tested and compared in a series of experiments on the same dataset to investigate how to obtain the best results.

The main contributions of the proposed model are as follows:

- Innovative Use of FL for Class Imbalance: The model employs focal loss to effectively manage the class imbalance in the dataset. This approach is particularly beneficial in circumstances with substantial class disparities, as it reduces the impact of simpler, more common examples (negative outcomes in this case). This allows the model to focus more on complex, minority class examples (positive cases), which are crucial for accurate diagnosis in medical settings.
- Identification of Optimal Model Parameters: The research has also led to the identification of optimal values for key parameters in the model, which is crucial for its application in real-world scenarios. This ensures that the model can be fine-tuned for maximum efficiency and accuracy in diagnosing cardiovascular risk.
- Enhanced Training Approach with ML-ABC: The model introduces a ML-ABC for the training phase. This method innovatively addresses the sensitivity to initial weight settings inherent in gradient-based learning methods like backpropagation. By using ML-ABC, the model adapts the primary weights based on mutual learning factors between two individuals, leading to a more efficient training process and potentially better performance.

The organization of this paper is as follows. Section I is about the Introduction, Section II delves into related work. Method is proposed in Section III. Section IV presents the experimental results and proposes ideas for further endeavors and Section V concludes the conclusion.

II. Related Work

In the past few years, the health sector has witnessed notable progress in data analysis and the application of machine learning methods. These approaches have been extensively embraced and proven effective across a range of medical applications, especially within cardiac medicine. The burgeoning growth of medical data affords scholars a unique chance to devise and evaluate novel algorithms in this domain. CVDs continue to be a predominant cause of death in less developed countries [32, 33], and pinpointing risk elements and preliminary indicators of such illnesses is now a crucial research endeavor. The adoption of data analysis and machine learning strategies in this realm could substantially contribute to the timely detection and deterrence of cardiac diseases.

To date, research employing machine learning techniques has been advanced for CVD. The research conducted by Narain et al. [34] aimed to develop a sophisticated, machine-learning-driven CVD prognosis model to enhance the accuracy of the established Framingham risk score (FRS). Utilizing data from 689 subjects exhibiting CVD symptoms and a validation cohort from the Framingham study, the newly proposed model, employing a quantum neural network to discern CVD patterns, underwent experimental validation and comparison with the FRS. The model's proficiency in predicting CVD risk was ascertained to be 98.57%, substantially surpassing the 19.22% accuracy of the FRS and other current methods. The findings suggest the model could serve as a valuable asset for medical professionals in predicting CVD risk, thus aiding in the formulation of superior treatment strategies and promoting prompt diagnosis. Shah et al. [35] sought to construct a cardiovascular disease prediction model using machine learning tools. The data, comprising 303 records and 17 attributes, were sourced from the Cleveland heart disease database available in the UCI machine learning repository. The team employed several supervised classification techniques, including naive Bayes, decision tree, random forest, and k-nearest neighbor (KKN). The study's outcomes revealed that the KKN model demonstrated the highest predictive accuracy, reaching 90.8%, underscoring the promise of machine learning methods in forecasting cardiovascular disease and the importance of model and technique selection for best results. Drod et al. [36] embarked on a study to pinpoint crucial CVD risk factors among patients suffering from metabolic-associated fatty liver disease (MAFLD), utilizing machine learning methodologies. They performed blood biochemistry analyses and subclinical atherosclerosis assessments on a cohort of 191 individuals diagnosed with MAFLD. The research team crafted a model that incorporated ML techniques, including a multiple logistic regression classifier, univariate feature ranking, and principal component analysis (PCA). This model aimed to identify patients at heightened risk for CVD. The findings highlighted hypercholesterolemia, plaque scores, and the duration of diabetes as the most critical clinical indicators. Employing the ML approach, the study was able to effectively distinguish 85.11% of patients at high risk and 79.17% of those at low risk for CVD, achieving an Area Under the Curve (AUC) of 0.87. This underscores the efficacy of ML tools in identifying high-risk MAFLD patients for CVD using basic patient data. In research by Alotalibi et al. [37] the aim was to explore the effectiveness of various machine learning (ML) methodologies in forecasting heart failure incidents. Utilizing patient data sourced from the Cleveland Clinic Foundation, the research applied a variety of ML algorithms, including decision tree, logistic regression, random forest, naive Bayes, and support vector machine (SVM). Predictive models were developed using a rigorous 10-fold cross-validation approach. Among these, the decision tree algorithm was identified as the top performer, achieving a remarkable prediction accuracy of 93.19%, closely followed by SVM with an accuracy of 92.30%. This study highlights the significant potential of ML strategies in predicting heart failure, particularly underlining the decision tree algorithm's efficacy, making it a prime candidate for further research endeavors. Comparing various algorithms, Hasan and Bao [38] undertook a research project focused on identifying the most efficient feature selection technique for forecasting cardiovascular diseases. The study initially evaluated three well-known feature selection strategies—filter, wrapper, and embedded methods—and generated feature subsets using a standard "True" condition in a Boolean framework. This dual-phase selection procedure was then applied across various models such as random forest, support vector classifier (SVC), k-nearest neighbors, naive Bayes, and XGBoost, to assess their predictive accuracy and establish the best performing model. The study used the artificial neural network (ANN) as a reference point for these comparisons. Results from the investigation highlighted that the XGBoost classifier, combined with the wrapper feature selection method, was the most effective in predicting cardiovascular diseases. XGBoost recorded a 73.74% accuracy rate, closely trailed by the SVC with 73.18% and the ANN with 73.20%.

Research in the realm of cardiovascular diseases utilizing deep learning techniques has yielded promising results. Mohan et al. [39] developed a Multi-Task Deep and Wide Neural Network (MT-DWNN) designed for simultaneous multiple tasks, aiming to predict critical incidents during hospitalizations. This algorithm was evaluated using an extensive dataset covering 18 years, encompassing 35,101 instances of hospital admissions due to heart failure and 2,478 cases of renal failure at the Chinese PLA General Hospital. The MT-DWNN's ability to forecast renal complications (with an AUC of 0.9393) outperformed conventional approaches, surpassing the AUC scores of standalone deep neural networks (0.9370), the random forest model (0.9360), and logistic regression (which scored below 0.9233). The results of these experiments indicate that the MT-DWNN is highly effective in predicting renal issues in heart failure patients. In a separate study, Arslan and Karhan [40] introduced a duo of sophisticated deep neural networks, specifically aimed at accurately predicting the risk of coronary heart disease. Common prediction models often struggle with the inconsistencies typical in many real-world datasets. To overcome this, the researchers proposed a unique approach for assembling training data by dividing the original dataset into two parts: one with a general distribution and the other with a significant bias. They employed a two-phase data processing technique, wherein variable autoencoders initially split the training data into these two distinct categories. Following this, two separate deep neural network classifiers are trained on these datasets. The efficacy of this method was evident, as it achieved an AUC of 0.882 and an accuracy rate of 0.892, outshining conventional methods in several key metrics, including specificity, accuracy, precision, recall, and the F-measure (0.915).

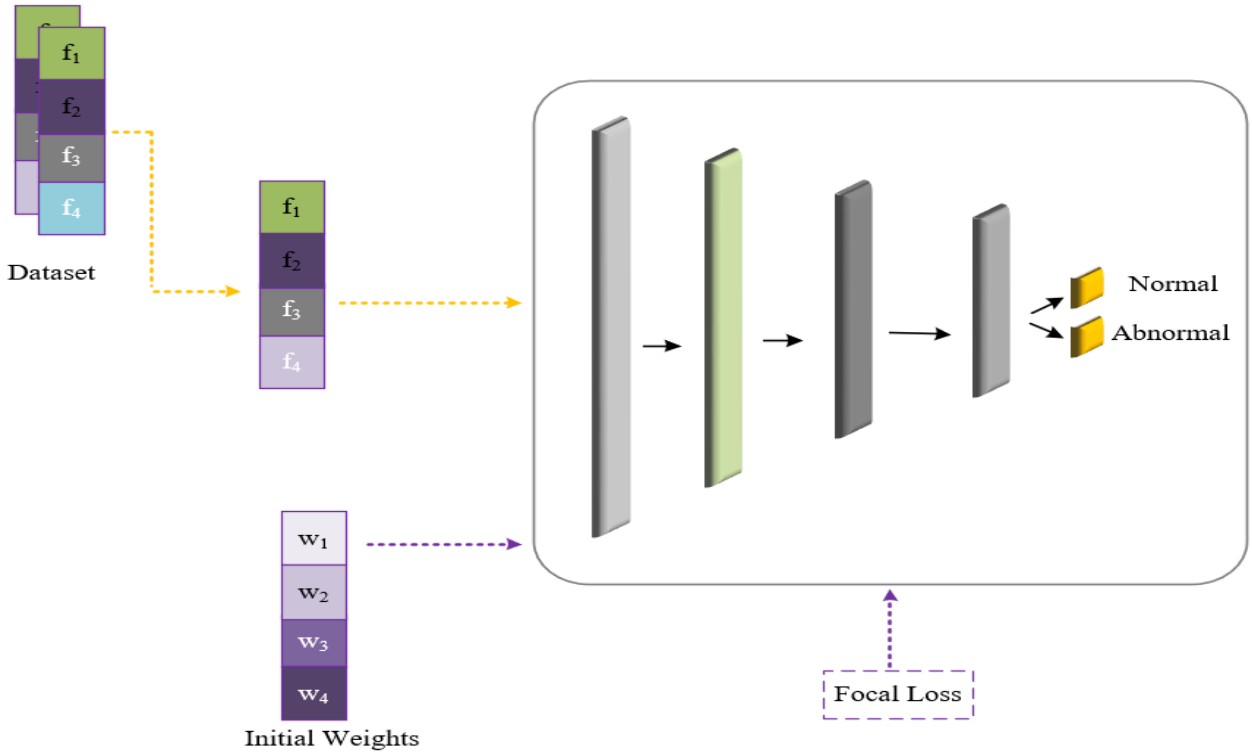

Fig. 1. Overview of the MLP-FL-CRD model.

III. Proposed Method

The structure of the MLP-FL-CRD model is shown in Fig. 1. MLP-FL-CRD is specifically engineered to augment the diagnosis of cardiovascular diseases, addressing key challenges such as imbalanced class distribution and the essential need for accurate initial weight determination. The integration of ML-ABC and RL within the framework effectively tackles these pivotal issues where conventional models often falter.

Traditional algorithms typically lack a structured approach for selecting initial weights, potentially impeding the learning process. This can lead to slower rates of convergence and the possibility of converging on less than optimal minima. Furthermore, prevalent models struggle with the issue of class imbalance, a common obstacle in cardiovascular diagnosis where significant events are infrequent. Such models usually exhibit bias towards the majority class, leading to the critical underrepresentation of minority classes. These minority classes are particularly vital to identify accurately in cardiovascular diagnostics. The proposed method, utilizing ML-ABC, introduces a thoughtfully curated and varied assortment of initial weights. This diversity aids the model in avoiding local minima and facilitates more effective convergence towards a comprehensive global solution.

Additionally, the RL aspect of the model is meticulously designed to provide greater rewards for accurately classifying the minority class, thus recalibrating the model's focus towards these crucial predictions. This marks a significant enhancement over traditional supervised learning techniques, which might lack adequate representative data for effective training across diverse classes. The flexible learning policy of RL fosters a more equitable exploration of the decision-making space. This leads to the formulation of strategies that prioritize the precise classification of lesser-represented classes. The adaptive capacity of RL within the model distinctly differentiates it from existing methodologies, rendering it capable of surmounting the intrinsic challenges typically encountered in conventional classification models, particularly in the realm of cardiovascular diagnostics.

A. Artificial Bee Colony Method

ABC [10] is a sophisticated optimization technique that simulates the foraging behavior of honey bees. Central to the ABC algorithm are four key components: employed bees, onlookers, scouts, and food sources. Employed bees are responsible for exploring nearby areas around an initial food source. Once they gather information, they return to the hive and share this knowledge with onlooker bees [41]. These onlooker bees, in turn, evaluate the potential of the food sources based on the information conveyed, including the likelihood of finding nectar. The decision-making process of onlooker bees involves assessing the probability of a food source's availability and its richness in nectar. Should a particular food source become depleted or no longer viable, the employed bee associated with that source undergoes a transformation. This bee becomes a scout, embarking on a random search for new and potentially more lucrative food sources [30]. This aspect of the algorithm exemplifies a dynamic optimization process, mirroring the adaptive and efficient foraging strategies of real-world honey bees. This bee-inspired algorithm is particularly effective in solving complex optimization problems due to its ability to explore and exploit resources. The ABC algorithm's balanced approach to exploration (via scouts) and exploitation (through employed

and onlooker bees) ensures a comprehensive search of the solution space, avoiding premature convergence on suboptimal solutions. This makes it an ideal choice for applications in various fields requiring robust optimization solutions, including data mining, engineering, and, as demonstrated in this study, healthcare analytics.

Eq. (1) presents a methodology for recalculating the position of an employed bee within the context of the ABC algorithm. This reformation of position is contingent upon the nectar quality associated with the new potential location. If the new position offers a higher nectar quality compared to the previous location, the bee is programmed to remember this new position and discard the previous one. This decision-making process is based on the principle of seeking the most rewarding nectar source, which in algorithmic terms translates to finding a more optimal solution. Conversely, if the nectar quality at the new position does not surpass that of the original location, the bee retains its prior position. This aspect of the algorithm ensures that beneficial positions are not forsaken for lesser or equivalent ones, thereby optimizing the search process. The emphasis on comparing and selecting positions based on nectar quality (or solution fitness) mirrors natural foraging behaviors and is a key factor in the ABC algorithm's ability to effectively navigate and exploit the solution space. This rule of position updating based on nectar quality highlights the algorithm's capacity for adaptive learning. It allows the algorithm to dynamically adjust its search strategy based on the evolving understanding of the solution landscape, enhancing its efficiency in locating and converging on optimal or near-optimal solutions.

$$v_i^j = x_i^j + \varphi_i^j (x_i^j - x_k^j) \tag{1}$$

where, j is the $j-$th place, and each answer x_i contains a size of D. D represents the principles to be enhanced, while k represents an arbitrary answer $(k \neq i)$. φ_i^j shows a number randomly selected on the scale of $[0,1]$. Modifying a single element of x_i, the potentially novel solution v_i can be realized.

In the framework of a D-dimensional optimization process, a key strategy involves selectively altering the value of a randomly chosen dimension. Following each iteration, the selection of an improved solution is based on its 'athleticism' worth, a term used to signify its fitness or suitability within the context of the problem being solved. According to Formula 1, the newly generated solution v_i^j is dependent primarily on x_i^j and x_k^j, which ensures that the new food source v_i^j remains unpredictable and dynamic. This element of variability is crucial in preventing the algorithm from stagnating at local optima and aids in exploring a broader range of potential solutions. The study's approach in considering the concept of 'athleticism' is drawn from a collective understanding derived from both current and nearby nutrition resources. By utilizing shared knowledge and insights gathered from these resources, the algorithm continuously seeks to develop a food source with a higher value. This method is in alignment with the principles of the ABC algorithm, where the objective is to discover and exploit resources that possess superior 'athleticism' worth, or in algorithmic terms, higher fitness values. Such an approach not only enhances the diversity of the solutions explored by the algorithm but also ensures that the process of optimization is dynamic and adaptive. By continuously updating the solution based on shared knowledge and the comparative worth of nearby resources, the algorithm can effectively navigate the solution space, moving towards more promising areas while avoiding less fruitful ones. This dynamic nature of solution generation and selection is integral to the success of the ABC algorithm in solving complex, multi-dimensional optimization problems.

$$v_i^j = \begin{cases} x_i^j + \varphi_i^j (x_k^j - x_i^j), & Fit_i < Fit_k \\ x_k^j + \varphi_i^j (x_i^j - x_k^j), & Fit_i \geq Fit_k \end{cases} \tag{2}$$

where, Fit_i and Fit_k represent the fitness values or the athleticism worth of the nearby and current food resources, respectively. The parameter φ_i^j is defined as a uniformly distributed random number within the range [0, F], where F, a positive value, is known as the mutual learning factor. This factor plays a crucial role in the algorithm by guiding the fitness values of newly generated solutions towards superior food sources. It does this by evaluating and contrasting the current food resources with those in proximity. The candidate solution undergoes modification depending on the quality of the current food sources. If the existing food sources are found to be sufficiently rewarding, the solution will be further refined based on these sources. Conversely, if the current sources are deemed inadequate, the solution will shift towards the nearby, potentially more promising food source. This dynamic allows for a balanced approach between exploration of new possibilities and exploitation of known good solutions. The mutual learning factor F is pivotal in regulating the extent of perturbation between the positions of different food sources. A non-negative value of F is crucial to ensure that the resultant changes lead to an improved solution. As F increases from zero, the impact of perturbation on the corresponding food source diminishes, implying that the fitness value of the alternative resource is almost equal to that of the current, superior resource. Conversely, a higher value of F can reduce the algorithm's ability to effectively explore and exploit, as it lessens the impact of contrasting different food resources. Hence, the choice of a suitable value for F is vital in preserving a balanced interplay between exploration and exploitation. This balance is key to the ABC algorithm's ability to effectively navigate and identify optimal or near-optimal solutions in intricate optimization scenarios. The proper calibration of F ensures that the algorithm is neither overly explorative, risking inefficiency, nor excessively exploitative, which might lead to premature convergence. This careful tuning is essential for the algorithm's success in addressing complex optimization challenges efficiently.

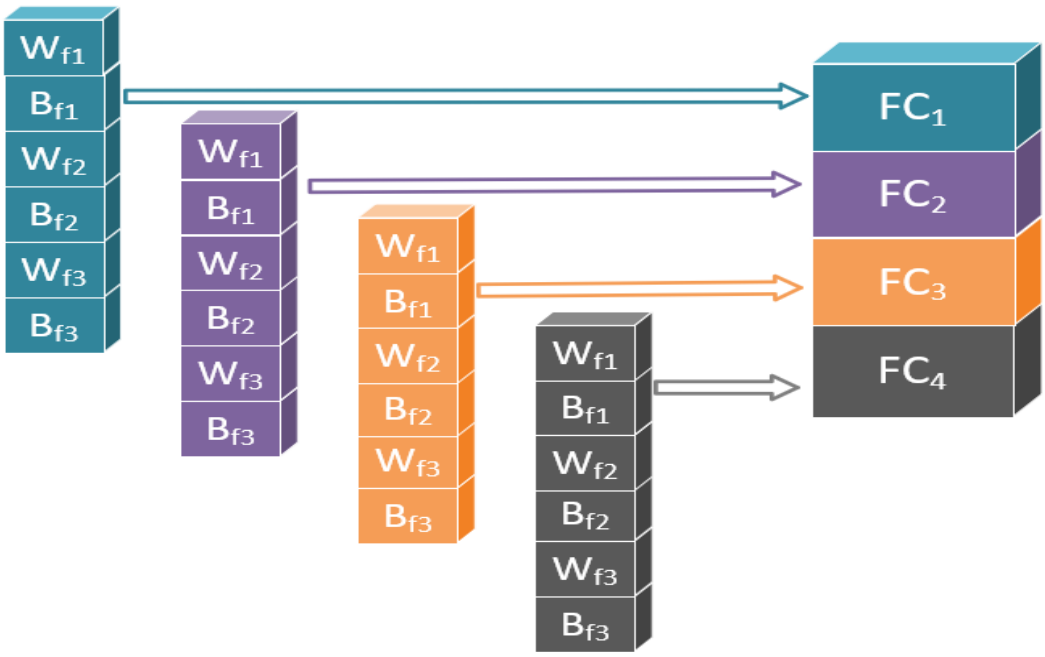

Fig. 2. Encoding approach in the offered method.

B. Model Architecture

1) Pre-Training: In this particular scenario, the management of the MLP's weights is executed through an ABC algorithm, which is enhanced by the principles of mutual learning. The encoding procedure is a critical step that involves arranging these weights into a vector, a process that symbolically represents the positioning of bees within the ABC paradigm [42, 43]. This strategic alignment of weights into a vector format is not just a mere arrangement; it is conceptualized as mirroring the bees' placements in the ABC algorithm, thus establishing a direct correlation between the weights' configuration and the algorithm's operational mechanics. Achieving the optimal configuration for this encoding is a complex task that demands meticulous attention to detail. Despite the inherent challenges, a series of methodical experiments were conducted to ascertain the most effective encoding strategy, ensuring that the weights are optimally aligned for the ABC algorithm's functioning. This experimental approach was crucial in refining the encoding process, thereby enhancing the overall efficiency of the algorithm. As illustrated in Fig. 2, the comprehensive approach to this encoding process is evident. Here, not just the weights but also the bias terms are meticulously arranged into a vector. This arrangement is more than a mere collection of numerical values; it forms the foundation of a candidate solution within the ambit of the proposed ABC algorithm. This candidate solution, representative of the bees' locations in the ABC model, is instrumental in the algorithm's problem-solving process, highlighting the synergy between the MLP's weight management and the ABC algorithm's operational framework.

For assessing the caliber of a candidate solution, the fitness function is delineated as

$$Fitness = \frac{1}{\sum_{i=1}^{N}(y_i - \tilde{y}_i)^2} \quad (3)$$

where, N is the training examples number, with $\tilde{y}_i$ and y_i indicating the i -th sample-estimated and goal outcome, respectively.

2) Focal loss: In this research, the detection problem is defined within the framework of binary classification, where instances are divided into positive and negative classes. A significant challenge faced is the imbalance in the dataset, particularly manifested in the limited number of samples representing the negative class. This imbalance can adversely affect the model's ability to learn from the underrepresented class. To address this issue, the study employs focal loss (FL) [44], a modified version of the binary cross-entropy (CE) loss function. FL is specifically engineered to refocus the training process on the more complex, less represented samples, which are often crucial for accurate classification but are overshadowed in imbalanced datasets [45]. FL achieves this by adding a modulating factor to the traditional cross-entropy loss, which adjusts the contribution of each sample to the loss based on the ease or difficulty of classifying it. This ensures that the model does not become biased towards the majority class and pays adequate attention to the minority class samples, which are pivotal for a balanced and comprehensive learning process. Such an approach is particularly beneficial in scenarios where the minority class is not just numerically fewer but also qualitatively more challenging to predict. By effectively targeting these challenging samples, FL aids in enhancing the overall robustness and accuracy of the model in

dealing with binary classification tasks under imbalanced conditions.

CE is conceptualized as:

$$CE = \begin{cases} -log\ (p), & y = 1 \\ -log(1-p), & \text{otherwise} \end{cases} \quad (4)$$

where, $y \in \{-1,1\}$ represents the actual class label, while $p \in [0,1]$ denotes the model's predicted probability for the class that corresponds to the label $y = 1$. The predicted probability is

$$p_t = \begin{cases} -p, & y = 1 \\ 1-p, & \text{otherwise} \end{cases} \quad (5)$$

Hence,

$$CE\ (p,y) = CE\ (p_t) = -\log(p_t) \quad (6)$$

FL introduces a modulating factor to the standard cross-entropy loss, resulting in the following modification:

$$FL\ (p_t) = -\alpha_t(1-p_t)^{\gamma}\ \log(p_t) \quad (7)$$

where, $\gamma > 0$ is a positive parameter (notably, when γ=1, FL resembles the CE loss), and α lies within the range of 0 to 1, representing the inverse of the class frequency.

IV. Experimental Results

In 2012, healthcare practitioners at the Polyclinic for Occupational Health and Sports in Zagreb assembled a comprehensive dataset from 26,002 medical examinations. These examinations were conducted on athletes seeking medical clearance for participation in competitive sports. The collected data encompassed a wide range of vital health parameters for each athlete, including their sex, age, height, weight, resting pulse rate, as well as both diastolic and systolic blood pressure measurements. Additionally, resting electrocardiogram (ECG) data were meticulously recorded for each individual. The dataset revealed a significant imbalance in the classification of results, with a dominant majority, 91.2%, being categorized as N (negative), indicating no apparent risk or health concern that would preclude sports participation. Conversely, a smaller fraction, 8.8%, fell into the P (positive) category, suggesting potential health risks or conditions that required further medical evaluation and could potentially restrict the athlete's ability to engage in competitive sports. This disproportionate distribution between the N and P classifications underscores the challenges faced in medical diagnostics, particularly in accurately identifying and diagnosing conditions in smaller, potentially high-risk groups. The dataset, therefore, provides an invaluable resource for developing and testing medical diagnostic models that can effectively manage such imbalances, ensuring that high-risk cases are accurately identified and addressed, despite being numerically fewer in the dataset. This approach is crucial in enhancing the safety and health management of athletes, aligning with the overarching goal of ensuring their well-being and fitness for competitive sports participation.

The model put forth operates on a 64-bit Windows OS, supported by a robust 64 GB of RAM, and is further enhanced by a graphics processing unit (GPU) with a capacity of 64 GB. Table I presents the hyperparameters applied to the MLP-FL-CRD model.

The MLP-FL-CRD model is first trained and tested on the introduced dataset in parallel with 6 computer learning samples (SVM [46], Naïve Bayes [47], KNN [48], Random forests [49], Logistic Regression [50], and Decision tree [51]) and two smaller parts of the proposed model, i.e., Proposed+ random weights (which possesses a base architecture similar to the model but uses random weights instead for initialization), and Proposed+ random weights+ FL (which uses FL for classification). Table II shows the parameters applied to machine learning models.

TABLE I. Parameter Setting for the MLP-FL-CRD Model

Parameter	Value
Epoch	256
Batch size	128
Learning rate	0.03
Discount factor	0.4

TABLE II. Parameter Setting for Machine Learning Models

Algorithm	Parameter	Value
Naïve Bayes	α (Lidstone smoothing parameter)	0.5
KNN	k (Number of neighbors)	5
	Distance Metric	Euclidean (p=2), Manhattan (p=1)
SVM	Kernel	polynomial
	γ (Kernel coefficient)	0.5
Random Forests	Number of trees	20
	Max depth of tree	10
Logistic Regression	C (Inverse regularization strength)	0.3
	Solver	liblinear
Decision Tree	Criterion	entropy
	Max depth	10

The results are compared using standard performance metrics (see Table III), of which F-measure and geometric mean are the preferred metrics for imbalanced data [52]. The MLP-FL-CRD model outperforms other models, including the closest competitor, the Decision Tree, across all evaluation metrics. Specifically, this model achieves a reduction in error exceeding 59% and 34% for two primary metrics, namely the F-measure and G-means, respectively. A comparative analysis of the MLP-FL-CRD model against variants such as Proposed+random weights and Proposed+random weights+FL reveals a notable decrease in error rates, approximately 70%. This significant reduction underscores the effectiveness of the enhanced ABC and FL methodologies.

A. Impact of other Metaheuristics

The next experiment involved comparing the improved ABC algorithm with various metaheuristic optimization algorithms. In this experiment, the initial model parameters were obtained using different metaheuristics while retaining the other model components. Six algorithms were tested, including standard ABC [53], FA [54], BA [55], COA [56], DE [28], and GWO [57]. The default configurations are detailed in Table IV. The results obtained are presented in Table V. The findings indicated that the suggested ABC algorithm reduced the error by approximately 48% compared to the standard ABC algorithm. This result showed that the proposed model outperformed the standard one. Furthermore, the ABC algorithm delivered better results than others, including DE, GWO, and BA.

B. Impact of parameter F on the model

The performance of the suggested approach is heavily influenced by the mutual learning factor *F*, as expressed in Eq. (2). When *F* is set too low, the algorithm may not be able to take full advantage of the mutual learning process, and thus, the performance of the algorithm may suffer. However, if *F* is excessively increased, the algorithm may become too ambitious in its learning, resulting in overfitting and poor generalization. Therefore, it is essential to find the optimal value of *F* those balances between the benefits of mutual learning and the risks of overfitting. As shown in Figure 3, the performance of the algorithm improves significantly as *F* increases from 0.5 to 2.5. This is because a higher value of *F* allows the models to exchange more information, leading to better generalization and higher accuracy. However, when *F* is increased beyond 2.5, the performance of the algorithm starts to deteriorate. This is because the models become too aggressive in their learning and start to overfit the data. Overall, these results demonstrate that the mutual learning factor *F* is a critical parameter in the proposed approach, and its value should be carefully chosen to achieve optimal performance. A moderate value of *F* between 1.5 and 2.5 may be a good starting point, and the optimal value can be determined through experimentation and cross-validation.

C. Exploring the Number of MLP Layers

The article highlights that as the number of layers in a multi-layer perceptron (MLP) increase, the model's complexity increases, leading to a higher risk of overfitting. Conversely, having too few layers may limit the model's ability to represent essential features in the training data. In the proposed approach, six different values (1, 2, 4, 8, 10, 12) are tested as the number of layers in MLP to study its effect on the model's performance. Table VI displays the achieved results, which show a descending trend for the number of layers from 1 to 4 and an ascending trend for values from 4 to 12. This finding suggests that having four layers in MLP is the optimal value for achieving the best results.

D. Impact of Loss Function

There are several methods to address data imbalances in machine learning models, including arranging info-augmenting strategies and the choice of the dropping operation or LF. Along with the methods, the choice of the dropping operation or LF is particularly critical since it can help the model learn from the minority class. To test the effectiveness of different loss functions, five functions were chosen, including weighted cross-entropy (WCE) [58], balanced cross-entropy (BCE)] [59], Dice loss (DL) [60], Tversky loss (TL) [61], and Combo Loss (CL) [62]. The BCE and WCE loss functions are commonly used to treat both positive and negative examples equally. However, these loss functions may not be suitable for imbalanced datasets where the minority class needs to be emphasized. The DL and TL loss functions are more suitable for imbalanced datasets, as they perform better on the minority class. The CL function is a promising loss function that can benefit applications using unbalanced data. The CL method can decrease the importance of straightforward examples and emphasize learning intricate instances by modifying the weights of the loss function. To evaluate the effectiveness of these loss functions, experiments were conducted and the results are reported in Table VII. According to the findings, the performance of the CL function was better than that of the TL function. It reduced the error rate by 39% and 25%for the F-measure and accuracy metrics in order. However, the CL function operates 60% worse than the FL, which is a specialized loss function for binary classification tasks.

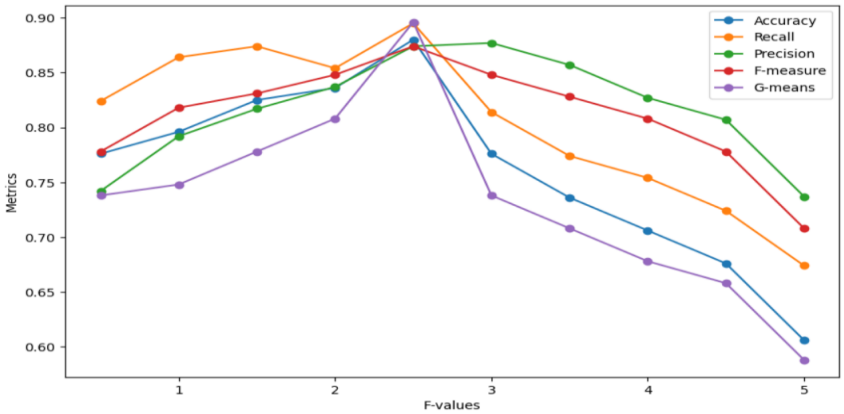

Fig. 3. The performance metrics of the MLP-FL-CRD model in relation to the *F* value of the proposed model.

E. Discussion

This article proposed a novel approach to identifying athletes at risk of developing CVDs by utilizing a multi-layer perceptron model enhanced with focal loss and a ML-ABC optimization technique. This model specifically addresses the challenge of class imbalance in datasets through focal loss, which effectively de-emphasizes simpler cases to focus on more complex ones, thus improving diagnostic accuracy in scenarios with significant class disparities. Additionally, the article introduces the ML-ABC method as a solution to overcome the limitations of traditional gradient-based learning methods, such as sensitivity to initial weight settings. By adjusting candidate food sources based on mutual learning factors and considering initial weights, the model shows improved performance. The effectiveness of this approach is validated through extensive experiments and ablation studies, demonstrating its superiority over other models in accurately assessing the risk of CVDs among athletes.

The susceptibility of the MLP-FL-CRD model to class imbalance, even with the integration of FL, presents a notable constraint in accurately diagnosing cardiovascular risk among athletes. In the referenced 2012 dataset, which included data from 26,002 athletes, there was a pronounced imbalance, predominantly skewed towards negative outcomes. While the implementation of focal loss aims to accentuate the learning from minority class examples, the preponderance of negative results can still hinder the model's ability to generalize across varied scenarios effectively. This imbalance in the dataset could induce a predictive bias within the model, potentially leading to an underestimation of risk in cases that are actually positive but less frequent. Such a bias is particularly concerning in a medical context, where failing to identify at-risk individuals can have serious, if not fatal, consequences. The model's overexposure to negative outcomes might condition it to lean towards these predictions, potentially missing out on identifying athletes who are genuinely at risk of cardiovascular issues. To address this limitation, additional strategies may need to be considered. One approach could involve incorporating more sophisticated balancing techniques that go beyond focal loss, such as synthetic data generation methods like SMOTE (Synthetic Minority Over-sampling Technique) [63] or adaptive resampling [64]. These methods can help in creating a more balanced training environment for the model, thus enhancing its capacity to learn from both majority and minority classes more effectively [65]. Another potential solution lies in expanding and diversifying the dataset. Gathering more comprehensive data that includes a wider range of cardiovascular conditions and outcomes could help in creating a more representative dataset. This expanded dataset would not only provide a broader spectrum of cases for the model to learn from but also reduce the likelihood of predictive bias, thereby improving the model's accuracy and reliability in real-world applications.

The dependency of the model's performance on the initial weight settings is a critical aspect, particularly prevalent in gradient-based learning methods such as backpropagation. While the model employs a ML-ABC methodology to mitigate this issue by dynamically adjusting the primary weights according to fitness, the inherent reliance on initial weights remains a significant vulnerability. Inadequate calibration of these initial weights could lead to the model converging towards suboptimal solutions, thereby affecting its overall effectiveness and accuracy. The initial weight setting acts as the starting point for the learning process and heavily influences the trajectory of the model’s convergence. If these weights are not set in a manner that reflects the complexity and nuances of the data, the model may find itself trapped in local minima, or on a prolonged path towards the global optimum. This challenge is further amplified in the context of complex and high-dimensional data typically encountered in cardiovascular risk assessment. To enhance the resilience of the model against potential pitfalls associated with initial weight selection, exploring alternative strategies for initialization is imperative. One such approach could involve the use of advanced heuristics or algorithms that analyze the data distribution to determine more effective starting weights. Techniques like Xavier or He initialization [66], which consider the size of the network layers in setting the initial weights, could offer more reliable starting points for the model's training. Additionally, incorporating more robust weight optimization methods could further strengthen the model. Techniques like stochastic gradient descent with momentum or adaptive learning rate algorithms like Adam could provide more nuanced adjustments during the training process. These methods help in navigating the weight space more effectively, increasing the likelihood of the model finding a more optimal solution.

The success of the model in the specific context of the study dataset focusing on athletes' cardiovascular risk assessment does not automatically translate to its efficacy in other scenarios or datasets. This limitation in generalizability and adaptability poses a significant challenge, especially considering the diverse nature of CVDs and the varying characteristics of different patient populations. The model's parameters, which have been fine-tuned for this particular dataset, may not be directly applicable or optimal for other datasets that differ in demographics, prevalence of CVD types, or other clinical factors. When transitioning the model to different populations or conditions, it may encounter data that significantly deviates from the characteristics of the original dataset. This deviation can result in reduced accuracy and reliability, as the model’s learned patterns and parameters may

not align well with the new data. Consequently, substantial re-tuning of the model's parameters becomes necessary, along with rigorous validation processes to ensure its efficacy in the new context. This re-tuning process can be resource-intensive and time-consuming, requiring a thorough understanding of the new dataset's attributes and underlying distributions. To address these challenges, developing more flexible learning algorithms that can easily adapt to varying data characteristics is essential. Such algorithms should be capable of identifying and adjusting to the nuances of different datasets without extensive manual intervention. This flexibility can be achieved through approaches like meta-learning, where the model learns to quickly adapt to new tasks using only a small amount of data, or through the development of models that are inherently more robust to changes in data distribution. Moreover, incorporating transfer learning techniques can significantly enhance the adaptability of the model. Transfer learning allows a model trained on one task to apply its learned knowledge to a different but related task. By leveraging pre-trained models or transferring knowledge from the original dataset to new ones, the model can achieve better performance with less need for re-tuning. This approach can be particularly beneficial in medical applications like CVD risk assessment, where similarities exist across different datasets, even though they may vary in specific characteristics.

V. Conclusion

CVDs remain a significant global health issue, and identifying individuals at risk of developing CVDs is crucial for early intervention and effective treatment. To this end, the article presents a model based on a multi-layer perceptron that employs focal loss to identify athletes who may be at risk of developing CVDs. Focal loss is a useful technique that reduces the significance of straightforward instances, enabling the model to concentrate on more difficult instances. This technique is particularly useful when dealing with a large disparity between classes. Usually, the training process of the model relies on gradient-based learning methods like backpropagation. These techniques have several limitations, including initialization sensitivity. The article suggests a solution for this problem, which involves utilizing ML-ABC. This approach involves modifying the candidate food source with higher fitness between two individuals using a mutual learning factor. This method takes into account the initial weights of the model and can improve its performance. The offered sample performs better than the rest of the samples, achieving excellent results. Experiments conducted on the study dataset help to determine the ideal values of the critical parameters in the model. Ablation studies further confirm the positive impact of the proposed components on model performance.

Despite these promising results, the article acknowledges the need for further research to test the efficacy of this model in non-athletic and older populations. Additionally, it is necessary to determine an appropriate classification performance measure that balances medical risk and welfare. This research is crucial to ensure that the proposed data mining methods can be effectively applied to improve healthcare policies and reduce unnecessary examinations. The potential impact of this research is significant. By identifying individuals at risk of developing CVD early, healthcare professionals can intervene with targeted prevention strategies and treatments. This could ultimately lead to improved health outcomes for individuals and reduced healthcare costs for society.

Furthermore, the methodologies integrated into this model hold potential for application beyond the realm of sports medicine, offering opportunities to enhance disease detection and management across various healthcare sectors. The adaptability of these techniques could play a pivotal role in refining diagnostic processes and treatment strategies for a range of medical conditions, thereby contributing to the overall advancement of healthcare practices. To summarize, the research detailed in this article introduces a robust model adept at identifying athletes who are at an increased risk of developing CVDs. Its effectiveness, as demonstrated in the specific context of sports healthcare, offers valuable insights into CVD risk assessment. However, it is imperative to extend this research to encompass a more diverse range of populations. Such expansion is essential to fully ascertain the model's efficacy across different demographic and health profiles. Developing and fine-tuning classification performance metrics tailored to varied populations will also be crucial in this regard. While the model shows considerable promise, its broader applicability and effectiveness in general healthcare settings remain areas for future investigation. Pursuing this line of research is vital for realizing the model’s full potential in enhancing early detection and intervention strategies for CVDs. Ultimately, the advancements in early identification and treatment strategies for CVDs, as suggested by this research, could lead to improved patient health outcomes and a reduction in healthcare costs. This underscores the significance of this research as a meaningful contribution to the field of medical diagnostics and patient care.

***Abstract*—With the increasing number of online users, constructing user behavior profiles has received widespread attention from relevant scholars. In order to construct user behavior profiles more accurately, the research first designed an adaptive fuzzy neural network algorithm based on the momentum gradient descent method. It uses momentum gradient descent to optimize and learn the parameters adjusted by error backpropagation algorithm and least squares estimation method and optimizes the structure of the fuzzy neural network through subtraction clustering. Finally, the improved algorithm is applied to the construction of user behavior profiles. The results showed that in error analysis, the error range of the improved algorithm was within [-0.10, 0.10], and the accuracy was relatively high. In indicator calculation, the improved algorithm had a recall rate of 0.07 and 0.09 higher than the other two algorithms, an accuracy rate of 0.03 and 0.07 higher than the other two algorithms, and an F1 score of 0.07 and 0.08 higher than the other two algorithms, indicating good overall performance. In the ROC curve, the average detection rate of the designed user behavior profiling model was 0.065 and 0.155 higher than the other two models, respectively, with higher detection accuracy. These results demonstrated the effectiveness of improved algorithms and design models, providing certain reference value for the development of related fields.**

Keywords*—User behavior profiling; momentum gradient descent method; adaptive fuzzy neural network; error backpropagation algorithm; least squares estimation method; subtractive clustering

I. Introduction

In today's increasingly data-driven society, user behavior profiling is an important research object in data analysis [1]. User behavior profile construction can help enterprises gain a deeper understanding of users and develop more personalized and refined service and marketing strategies. In the process of constructing user behavior profiles, traditional user behavior analysis methods often struggle to handle such large-scale and complex data. Meanwhile, user behavior data often contains a large amount of uncertainty and ambiguity, making it a challenge to accurately analyze and predict user behavior. Fuzzy Neural Network (FNN) is an important modeling tool, which combines the adaptive learning ability of neural networks and the ability of fuzzy logic to handle uncertain and fuzzy information and can effectively learn and process nonlinear and complex data patterns [2]. Therefore, FNN is widely regarded by researchers as a powerful tool for dealing with various data problems in user behavior profiling, such as the nonlinearity and dynamic changes of user behavior, as well as the fuzzy relationship between user attributes and behaviors. However, although the theory and technology of FNN have developed to a considerable extent, its application in constructing user behavior profiles is still in the exploratory stage. On the one hand, due to the complexity of user behavior, applying FNN to practical user behavior profiling still faces many challenges; On the other hand, compared to other machine learning and data mining technologies, the superiority and adaptability of FNN in constructing user behavior profiles have not been fully demonstrated [3].

In this context, the study first utilizes the Back Propagation (BP) and Least Squares Estimation (LSE) to adjust the network parameters of FNN and then utilizes the Gradient Descent with Momentum (GDM) method to optimize and learn the adjusted parameters. The structure of FNN is optimized using the Subtractive Clustering Method (SCM) to shorten training time, and an MGD-ANFIS algorithm is designed for the model construction of user behavior profiling, in order to have a positive driving effect on the theory and practice of FNN. Compared to traditional methods, this algorithm can better process and parse user behavior data, thereby more accurately constructing user behavior models. The innovation of this study lies in the use of the BP algorithm and LSE algorithm to optimize FNN, which can more accurately characterize user behavior characteristics and provide strong support for enterprises to develop more refined service marketing strategies. The value of this study lies in providing a new type of user behavior analysis method, which has higher accuracy and predictive ability compared to traditional analysis methods and can better meet the needs of modern data-driven society for user behavior analysis.

The research content consists of six sections. Section I introduce the background of the research and propose methods. Section II is a review of online user behavior research at home and abroad, summarizing and summarizing existing research, and pointing out the shortcomings of existing research. Section III mainly constructs a network user profile model using MGD-ANFIS. Section III (A) is the design of the MGD-ANFIS algorithm, which provides a detailed introduction to the design ideas and implementation process of the MGD-ANFIS algorithm and Section III (B) is based on the MGD-ANFIS algorithm and constructs a user profile model. Section V and Section VI provides the conclusion and acknowledgment respectively.

II. Related Works

With the acceleration of the Internet process, network user behavior has been digitized, and constructing user behavior profiles through complex algorithms is currently a hot research topic. Kumar S and other researchers designed a semi-local algorithm based on the correction degree centrality exclusion ratio to maximize influence through user behavior. It used the correction degree centrality exclusion ratio idea to ensure minimal overlap between the regions affected by selected diffusion nodes. Results showed that the algorithm output value outperformed other methods [4]. Zhao and other scholars designed a spatiotemporal gated network method to recommend interest points to network users. It can use interest point context prediction to assist the next interest point through joint learning and jointly train interest point context prediction and next interest point recommendation. The results showed that this method had high accuracy [5]. Wu et al. designed a recommendation algorithm to predict user behavior using anonymous sessions. The algorithm constructed sequences, captured them using graph neural networks, and combined session representations that met conditions through attention networks. The results showed that this algorithm outperformed other methods [6]. Kumar designed a speed learning-based classifier method to predict children's behavior based on their current emotions. The probability model was introduced into the deep learning classifier and multiple sample emotions were used for prediction. The results showed that the method had high recognition rate and prediction accuracy [7]. Chen and other researchers designed a graph convolutional network method based on linear residual to model the interaction behavior between users and the network. This method can alleviate the over-smooth problem in graph convolutional aggregation operations of sparse user and network project interaction data, and the results showed that this method was highly efficient [8]. Adam et al. designed an artificial intelligence-based chat system for real-time communication with users in an e-commerce environment. Through random online experiments, they empirically tested the impact of verbal anthropomorphic design prompts and entry techniques on user request compliance. The results showed that the system had good interaction effects with users [9].

Zhang and other scholars designed a multi-scale application programming interface graph sequence model to detect the dynamic behavior of users using malicious software. It concatenates graph features from different time periods and graph scales to detect whether the software is malicious. The results showed a good performance [10]. Zhang and other researchers designed a network attack detection method that combines traffic calculation and deep learning to detect unknown attacks in high-speed networks. It utilized sliding window flow data processing to achieve real-time detection and improved classification accuracy through deep trust networks and support vector machines. The results showed that this method had high efficiency and accuracy [11]. Boone et al. designed a data-driven technology using big data technology and the Internet of Things to better execute user management and meet user needs. It can collect and analyze large amounts of data in real time, and results showed high technology accuracy [12]. Ullah and other researchers designed an Apache web server intelligent intrusion detection system using machine learning methods to enhance the security of communication between suppliers and users. It utilized naive Bayesian machine learning algorithms for training, and results showed that this system had a high validation accuracy [13]. Chen et al. designed an attention evaluation method based on multimodal data and multi-scene modeling to evaluate users' psychological states and provide early warnings. The method analyzed the relationship between emotional data and attention in-depth and corrected labels with emotional data. Results showed a high prediction efficiency [14]. Scholars such as Cui designed a combined model using the time correlation coefficient and improved K-means clustering with cuckoo search to help users obtain real-time information. Through K-means clustering, similar users were gathered together and their behavior was analyzed. Results showed a high model accuracy [15].

In summary, many scholars have improved their understanding and predictive ability of user behavior through different algorithms and models, utilizing data on online user behavior. At the same time, they have also provided new solutions for areas such as network security, e-commerce interactivity, and mental health warning. However, these methods still have certain shortcomings in terms of algorithm generalization ability and model robustness. Therefore, the study utilizes GDM to optimize and learn the network parameters after BP and LSE optimization and then uses SCM to optimize the network structure, and design the MGD-ANFIS algorithm to construct a user behavior portrait model.

III. Method

The first section of this chapter is to improve FNN and design the MGD-ANFIS algorithm. The second section is to construct a user behavior profiling model using the MGD-ANFIS algorithm.

A. MGD-ANFIS Algorithm Design

FNN is a hybrid model that combines fuzzy logic and neural networks [16-17]. Its goal is to handle fuzzy and uncertain problems through the reasoning ability of fuzzy logic and the learning ability of neural networks. In traditional neural networks, both input and output are fixed values, while in the real world; many problems have ambiguity and uncertainty. FNN can better handle these problems by introducing the concepts of fuzzy sets and fuzzy reasoning. The basic structure of FNN includes the input layer, hidden layer, and output layer. Its inputs and outputs can be fuzzy sets, rather than just fixed values. Fuzzy sets are mathematical tools used to represent fuzziness and uncertainty, which can describe the degree of membership of a value within a certain range. When training FNN, fuzzy inference, and fuzzy set methods are usually used to define the objective function and error function of the network. The BP algorithm can update the weights and biases of the network to minimize the error function [18]. FNN has extensive applications in fields such as fuzzy control, pattern recognition, and decision support systems. The FNN structure is shown in Fig. 1.

In Fig. 1, the first four layers are the precursor network,

the first layer is the input layer, the second layer is the fuzzification layer, the third layer is the fuzzy rule calculation layer, and the fourth layer is the normalization layer. The last two layers are the post network, the fifth layer is the fuzzy rule output layer, and the sixth layer is the output single node layer. FNN can handle fuzzy and uncertain inputs, providing more flexible and robust decision-making and reasoning capabilities. However, due to the complexity and computational overhead of FNN, its training and inference process may be more time-consuming than traditional neural networks [19]. Therefore, the study used the BP algorithm and LSE algorithm to adjust the parameters of the FNN's antecedent and consequent networks to minimize errors. At the same time, GDM was used to optimize and learn the adjusted parameters, and SCM was used to optimize the structure of the FNN to shorten training time. MGD-ANFIS algorithm was designed. Firstly, define a fuzzy set, and the calculation formula is shown in Eq. (1).

$$A = \left\{ (x, \mu_A(x)) \middle| x \in X \right\} \tag{1}$$

In Eq. (1), A represents a fuzzy set, x represents any feature, X represents a set of all features, and $\mu_A(x)$ represents the membership function. In the input layer, components of the input vector are directly connected to the nodes. The commonly used membership function shapes are shown in Fig. 2.

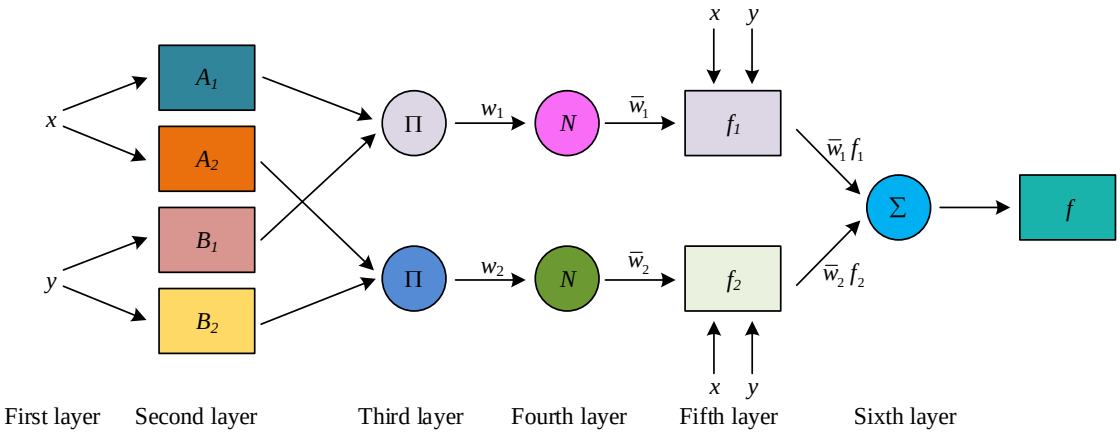

Fig. 1. Fuzzy neural network structure diagram.

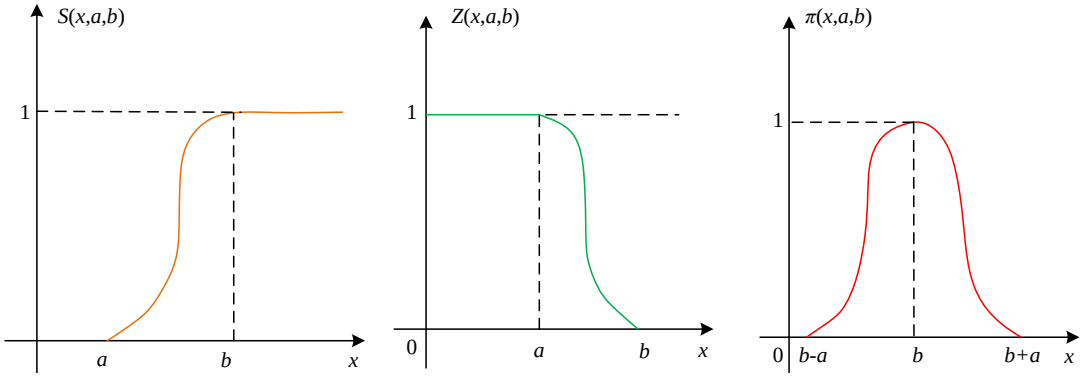

Fig. 2. Common membership function shapes.

In Fig. 2, common membership functions are divided into S-type, Z-type, and bell-type. The study adopts a Gaussian function with a bell shape as the membership function, and its expression is shown in Eq. (2).

$$f(x, \varepsilon, c) = e^{\frac{(x-c)^2}{2\varepsilon^2}} \tag{2}$$

In Eq. (2), c represents the membership function center value, and ε represents the membership function width. The next step is to map the input data onto a fuzzy aggregation through a fuzzification layer and describe the degree of membership of the input data through a membership function. The specific calculation method is shown in Eq. (3).

$$O_{1,i} = \begin{cases} \mu_{A_i}(x_1), i = 1,2 \\ \mu_{B_{i-2}}(x_2), i = 3,4 \end{cases} \tag{3}$$

In Eq. (3), $O_{1,i}$ represents the degree of membership of the input variable, x_1 and x_2 represent node i's input, and A_i and B_{i-2} represent two different fuzzy sets. The next step is to use the BP algorithm to adjust the antecedent parameters, where the momentum gradient descent method is used for BP propagation, as shown in Eq. (4).

$$\begin{cases} \dfrac{\partial E}{\partial w_{iq}} = -\delta_k^4 \times N_h^3 \\ \delta_h^3 = \delta_h^4 \times \dfrac{\sum_{s=1,s\neq h}^{m} N_h^3}{(\sum_{n=1}^{m} N_h^3)^2} \quad ,h=1,2,...,m, m=\prod_{j=1}^{n} m_j \\ \delta_{ij}^2 = \delta_h^3 \times s_{ij} \times e^{\frac{(x_j - c_{ij})^2}{\varepsilon_{ij}^2}} \end{cases} \tag{4}$$

In Eq. (4), ∂ represents the derivative, w_{iq} represents the point where the membership function value is 1, N_h^3 represents fuzzy rule calculation layer input value, δ represents the variance, s_{ij} represents the number of rules, k represents a certain rule, i and j represent nodes, and e represents natural constants. The specific expression form of the updated parameters is shown in Eq. (5).

$$\begin{cases} V_{dc} = \lambda \times dc + (1 - V_{dc}) \times dc, c = c + \alpha \times dc \\ V_{db} = \lambda \times db + (1 - V_{db}) \times db, b = b + \alpha \times db \\ V_{dw} = \lambda \times + (1 - V_{dw}) \times dw, w = w + \alpha \times dw \end{cases} \tag{5}$$

In Eq. (5), b represents the bias term, dc, db, and dw represent the differentiation of the parameters, V_{dc}, V_{db}, and V_{dw} represent the exponentially weighted average of each parameter, λ represents the momentum coefficient, and α represents the learning rate. Then the LSE algorithm can adjust consequent parameters, and the basic function of the LSE algorithm is shown in Eq. (6).

$$f(x) = a_1\varphi_1(x) + a_2\varphi_2(x) + ... + a_m\varphi_m(x) \tag{6}$$

In Eq. (6), $\varphi_m(x)$, $m=1,2,...,m$ represents a set of linearly independent functions, and a_m represents the undetermined coefficients. The calculation method for optimizing parameters using the least squares method is shown in Eq. (7).

$$\min F(x) = \sum_{i=1}^{m} f_i^2(x) \tag{7}$$

In Eq. (7), min represents the minimum value and $F(x)$ represents the objective function. The next step of the SCM algorithm is to cluster the input feature values to find the clustering center, thereby determining fuzzy rules and membership functions. The density index calculation method for feature data is shown in Eq. (8).

$$D_i = \sum_{j=1}^{n} \exp\left(\frac{\left\|x_i - x_j\right\|^2}{(\gamma_\alpha / 2)^2}\right) \tag{8}$$

In Eq. (8), D_i represents the density index, exp represents the exponential function with a base, and γ_α represents a positive number that can define a neighborhood of feature point x_i. The density index calculation method for each feature point is shown in Eq. (9).

$$\begin{cases} D_i = D_i - D_{cl} \times \exp\left[-\left(\dfrac{\left\|x_i - x_j\right\|^2}{(\gamma_\beta / 2)^2}\right)\right] \\ \gamma_\beta = k\gamma_\alpha \end{cases} \tag{9}$$

In Eq. (9), D_{cl} represents the density index corresponding to each cluster center x_{cl}, while γ_β and k both represent a positive number. The SCM clustering process is shown in Fig. 3.

In Fig. 3, the parameters are first initialized, then the density indicators of each sample point are calculated. Next, the density indicators of the remaining sample points are corrected, and whether the termination condition is met can be finally determined. If it is met, the density indicator can be output. Otherwise, recalculate. Fuzzy rules are calculated after SCM clustering, as shown in Eq. (10).

$$O_{2,i} = \mu_{Ai}(x_1)\mu_{Bi}(x_2), i = 1,2 \tag{10}$$

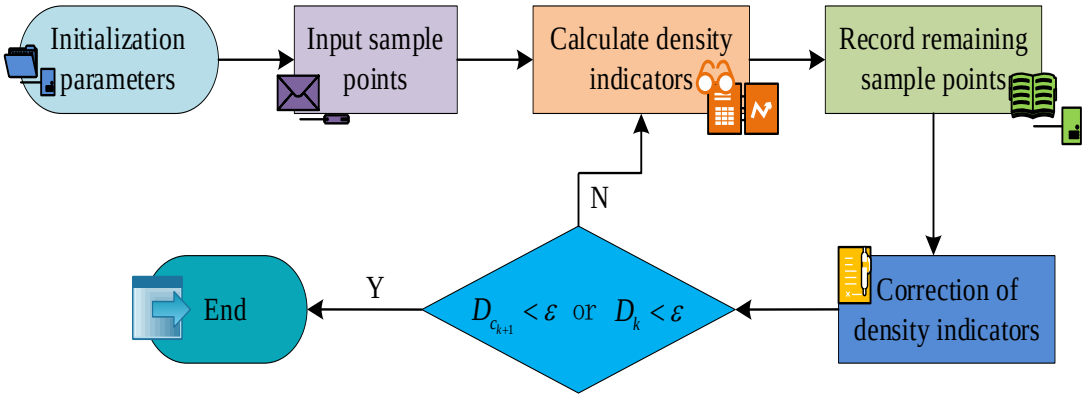

Fig. 3. SCM clustering process.

In Eq. (10), $O_{2,i}$ represents the strength of the fuzzy rule. The next step is to normalize, and the calculation method is shown in Eq. (11).

$$y = \frac{x - MinValue}{MaxValue - MinValue} \tag{11}$$

In Eq. (11), x represents the original value, y represents the converted value, $MaxValue$ represents the maximum feature value, and $MinValue$ represents the minimum feature value. The normalization results are shown in Eq. (12).

$$\begin{cases} O_{3,i} = \dfrac{w_i}{w_1 + w_2}, i = 1,2 \\ w_i = O_{2,i} \end{cases} \tag{12}$$

In Eq. (12), $O_{3,i}$ represents the normalized fuzzy rule, and w represents the numerical value of the fuzzy rule. The next step is to output the fuzzy rule, as shown in Eq. (13).

$$O_{4,i} = \bar{w}_i f_i = \bar{w}_i (p_i x_i + q_i x_2 + r_i), i = 1,2 \tag{13}$$

In Eq. (13), f_i represents the output function, and p_i, q_i, and r_i represent the node parameters. The total output can be obtained from the node output as shown in Eq. (14).

$$O_{5,i} = \sum \bar{w}_i f_i = \frac{\sum_i w_i f_i}{\sum_i w_i} \tag{14}$$

In Eq. (14), $O_{5,i}$ represents the total output of MGD-ANFIS. When determining the parameters of the current component network, the output expression is shown in Eq. (15).

$$O'_{5,i} = (\bar{w}_1 x) p_1 + (\bar{w}_1 y) q_1 + \bar{w}_1 r_1 + (\bar{w}_2 x) p_2 + (\bar{w}_2 y) q_2 + \bar{w}_1 r_2 \tag{15}$$

In Eq. (15), $O'_{5,i}$ represents the final output value.

B. Construction of Network User Behavior Portrait Model

The construction of a network user behavior profiling model aims to identify unknown intrusions and profile user behavior. The MGD-ANFIS algorithm is used to construct a user behavior profiling model. This model can efficiently collect network user behavior data, and through filtering and compression, recombine feature vectors to generate records with various meanings to accurately identify malicious users and provide early warnings. The specific framework of the model is shown in Fig. 4.

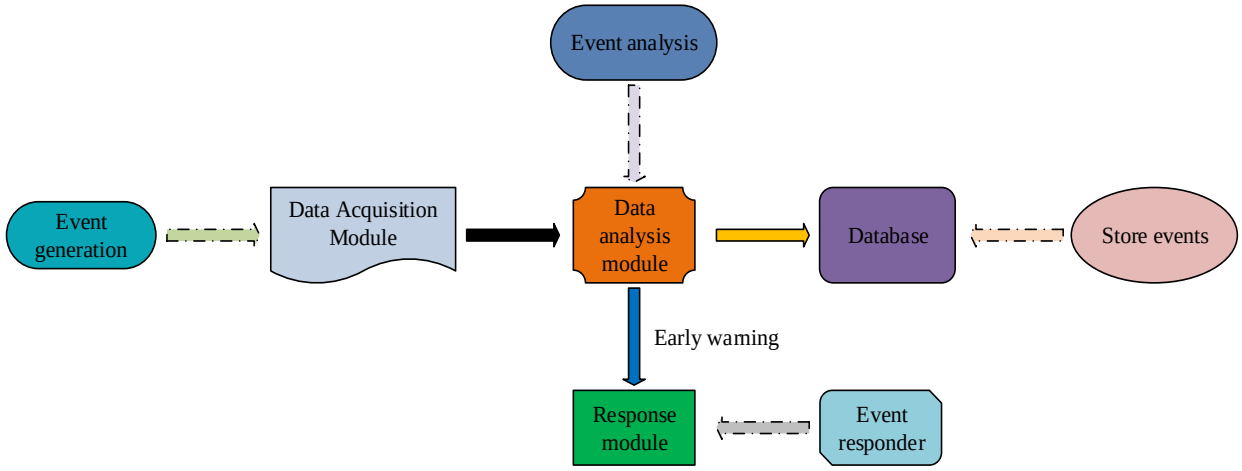

Fig. 4. User behavior portrait model framework.

In Fig. 4, the model includes four parts: data collection, data analysis, response module, and database. The data collection module is to build a user behavior database, and the integrity of the obtained database is related to the accuracy of user behavior judgment. It refers to the collection and processing of user behavior data on the network, and the use of the MGD-ANFIS algorithm for modeling and learning, by adjusting network structure and parameters to adapt to different user behavior characteristics. Data analysis is the most important component of user behavior profiling models, which obtains data from the data collection module and analyzes it, including data cleaning, data preprocessing, and feature extraction. Data cleaning refers to denoising, deduplication, recombination, and restoration of collected data to ensure data quality. Data preprocessing involves normalizing the data, and feature extraction involves extracting an appropriate number of features from the original data to distinguish whether user behavior is normal. The response module is to record, prevent, and alarm users with abnormal behavior, and can also be expanded based on the current user's input or environmental variables. The database mainly records users with abnormal behavior. Meanwhile, in user behavior profiling models, statistical feature quantity is an important factor affecting the performance of user behavior detection [20]. The research aims to determine whether a user's behavior is normal or malicious through a small number

of statistical features, and statistical features need to be designed for different types of attacks. The current common types of attacks include attacking through network vulnerabilities, exploiting network protocol flaws, and using illegal and irregular operations to enter the system. Therefore, the study designs feature quantities from three aspects: content, time traffic, and host traffic, as shown in Fig. 5.

In Fig. 5, feature statistics are in the data restoration section of data collection, which includes basic feature quantities, content feature quantities, time traffic characteristics, and host traffic characteristics. The basic feature quantity mainly counts the connection time, bytes, and network protocol types between users and the cloud. The content feature quantity mainly counts the number of access privacy and login failures. The time traffic characteristic mainly counts the connections to the same host and server. The host traffic characteristic mainly counts the connections to the same host and server in a relatively small number of connections. After designing each module, parameter settings are required. The parameters studied in this study mainly include input layer nodes, membership function, number of fuzzy subsets, and number of output layer nodes, training frequency, and radius of subtractive clustering. Finally, the obtained samples are trained and tested, and the specific process is shown in Fig. 6.

In Fig. 6, the training process and testing process correspond to the set training data and testing data, respectively. During the training process, the data consists of users with normal behavior and users with abnormal behavior, and the expected output is sent to the data analysis module as its input. Before training, it is necessary to initialize the parameters, LSE algorithm is used to identify the subsequent parameters, and continuously adjust precursor network parameters through the BP algorithm to minimize the difference between the predicted and actual output. During the detection process, data composition is consistent with the training process, but the test data is directly sent to the data analysis module as its input. After analysis, the detection rate and false alarm rate are calculated separately and compared with the results of the training data, to evaluate user behavior profile model performance based on the MGD-ANFIS algorithm.

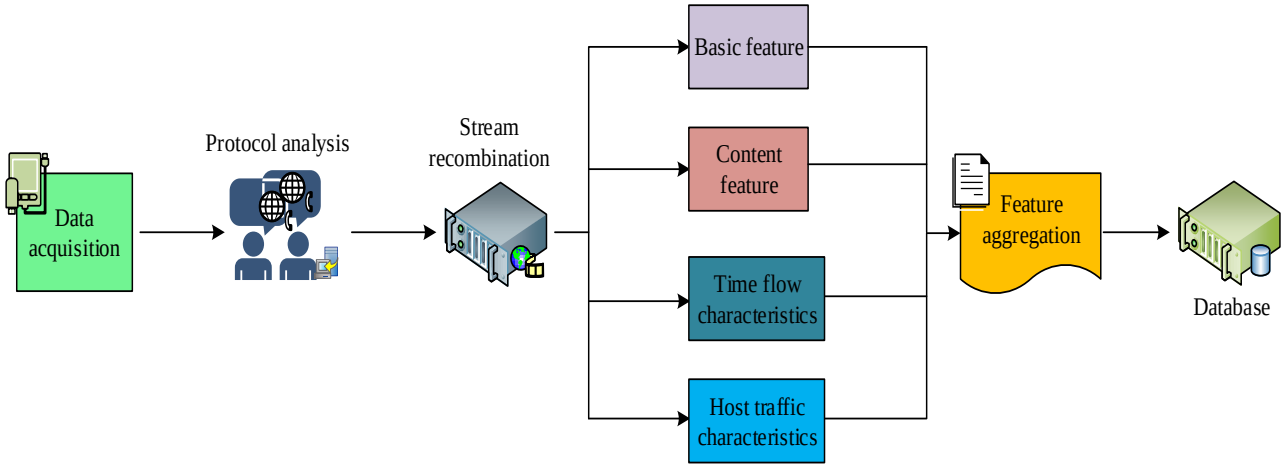

Fig. 5. Overall composition of characteristic quantities.

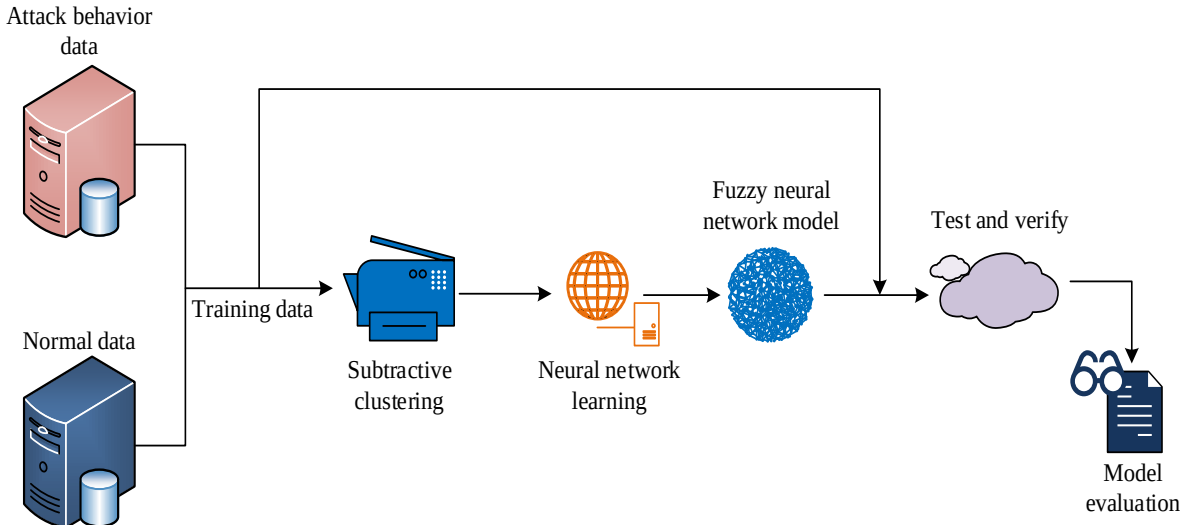

Fig. 6. The process of obtaining feature statistics.

IV. Results and Discussion

Section III (A) of this chapter analyzes the performance of the designed MGD-ANFIS algorithm, and the second section analyzes the actual application effect of the user behavior portrait model designed on the basis of the MGD-ANFIS algorithm.

A. MGD-ANFIS Algorithm Performance Analysis

To verify the designed MGD-ANFIS's performance, this study first generated 1000 pairs of datasets using the Sphere test function, and divided them into training and testing sets in 4:1. The maximum number of iterations was set to 500, and simulation comparisons were made with the MGD-ANFIS algorithm and ANFIS algorithm, respectively. The optimization results are shown in Fig. 7.

From Fig. 7(a), it can be seen that the optimization results of the ANFIS algorithm have a low fit with the test function. In Fig. 7(b), the optimization trend of the MGD-ANFIS algorithm was basically consistent with the results of the test function, with a high degree of fit. The above results indicated that the MGD-ANFIS algorithm had high accuracy and proved its effectiveness. The next step was to calculate the recall, accuracy, and F1 score of the MGD-ANFIS algorithm separately, and compare them with the ANFIS algorithm and FNN algorithm. The results are shown in Fig. 8.

In Fig. 8, the recall, accuracy, and F1 score of the MGD-ANFIS algorithm are 0.23, 0.99, and 0.20, respectively. The recall, accuracy, and F1 score of the ANFIS algorithm are 0.17, 0.96, and 0.13, respectively. The recall, accuracy, and F1 score of the FNN algorithm are 0.15, 0.92, and 0.12, respectively. Analysis shows that the MGD-ANFIS algorithm had a recall rate of 0.07 and 0.09 higher than the other two algorithms, an accuracy rate of 0.03 and 0.07 higher than the other two algorithms, and an F1 score of 0.07 and 0.08 higher than the other two algorithms. The above results demonstrate that the MGD-ANFIS algorithm had good overall performance. Finally, the MGD-ANFIS algorithm was used to perform error analysis on the training and testing sets, and compared with the ANFIS and FNN algorithms. The results are shown in Fig. 9.

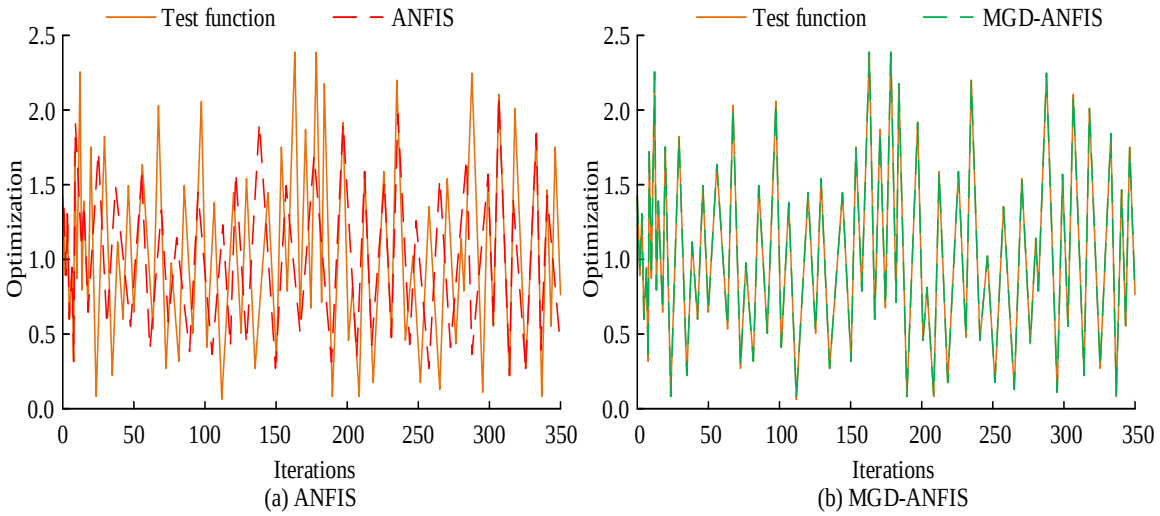

Fig. 7. MGD-ANFIS and ANFIS simulation comparison.

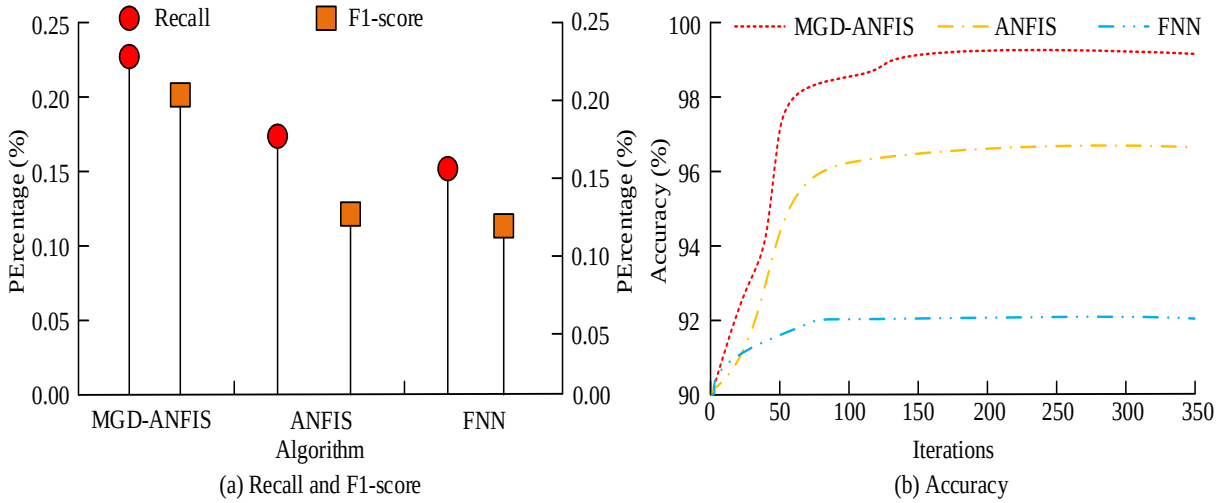

Fig. 8. Recall rate, accuracy rate, and f1 score of different algorithms.

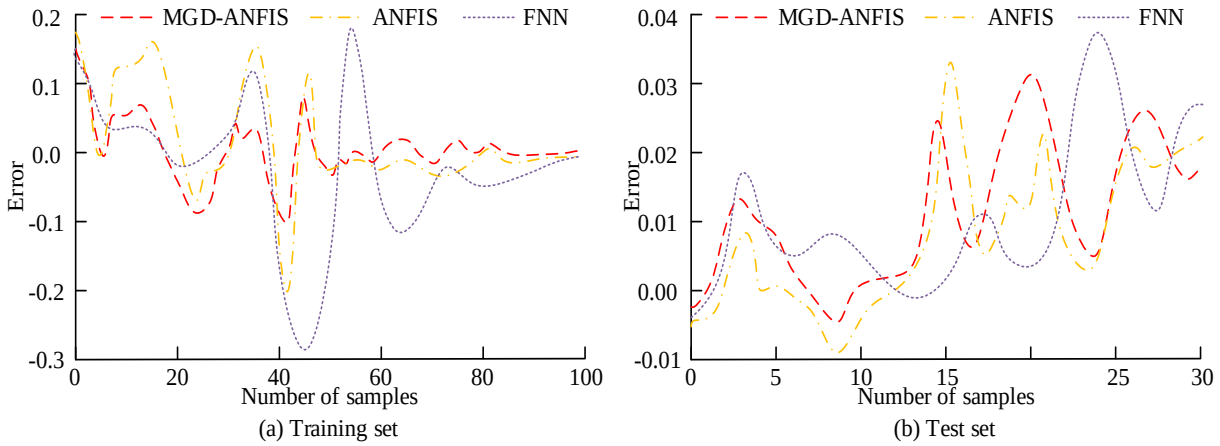

Fig. 9. Error of different algorithms on training and testing sets.

In Fig. 9 (a), in the training set error analysis, the error range of the MGD-ANFIS algorithm is between -0.10 and 0.10, the error range of ANFIS is between -0.20 and 0.18, and the error range of FNN is between -0.30 and 0.20. In Figure 9(b), in test set error analysis, the error range of the MGD-ANFIS algorithm is between -0.005 and 0.03, the error range of ANFIS is between -0.008 and 0.035, and the error range of FNN is between -0.01 and 0.04. Analysis shows that in the error analysis of the training and testing sets, the error range of the MGD-ANFIS algorithm was smaller than the other two algorithms, further indicating its high accuracy and demonstrating its good performance.

B. *Effect Analysis of User Behavior Portrait Model*

To test the performance of the designed user behavior profiling model, the study first conducted simulation experiments using the KDD99 dataset. 5 sets of data were selected with 4 training data and 1 testing data, which contained malicious user attack behavior. In training set 1, the number of normal and abnormal data was equal, and in training set 2 and the test set, the number of normal and abnormal data was also equal. Training set 2 was smaller than the training set 1 and greater than the test set. In training set 3, there was more normal data than abnormal data, while in training set 4, there was less normal data. In the network configuration, the output layer node was set to 1, with an output of 1 indicating abnormal behavior and an output of 0 indicating normal behavior. The allowable error was set to 0.2, and the clustering radius was set to 0.5. It was recommended to train the network for 50 iterations. Each training set was mixed with the test set to detect malicious user attack behavior, and the results are shown below.

TABLE I. MALICIOUS USER ATTACK BEHAVIOR IN TRAINING AND TESTING SETS

Dataset	Test error	Training Error	Training false alarm rate	Training detection rate	Test false alarm rate	Test detection rate
Training 1	0.1297	0.2673	99.2	4.9	96.3	6.3
Training 2	0.1527	0.2628	99.4	4.5	95.9	5.5
Training 3	0.2401	0.2654	98.3	4.7	94.6	6.7
Training 4	0.1399	0.2493	99.3	5.2	95.8	6.9

In Table I, the four training sets' errors are smaller than those of the test set, and the detection rate and false alarm rate are both higher than those of the test set. However, overall, different combinations of training and testing sets had higher detection rates and lower false positives and errors, indicating that the designed model had higher adaptability. The next step was to calculate the decision values for normal user behavior, vulnerability-based attacks (attack behavior 1), and network protocol defect-based attacks (attack behavior 2), as shown in Fig. 10.

In Fig. 10, users with normal behavior have a relatively small fluctuation in the judgment curve, with a maximum judgment value of 1.00, a minimum judgment value of 0.95, and an average judgment value of approximately 0.98. Attack behavior 1 involved exploiting system vulnerabilities by sending requests to the host, with a maximum decision value of 1.00, a minimum decision value of 0.58, and an average decision value of approximately 0.79. Attack behavior 2 utilized flaws in network protocols to attack, which was significantly different from normal user modes. Its maximum decision value was only 0.80, the minimum decision value was 0.10, and the average decision value was 0.45. Overall, the designed user behavior profiling model effectively distinguished between users with normal and abnormal behavior, and further proved its effectiveness. Finally, the detection rate of user behavior profiling models based on different algorithms was tested using ROC curves, and the results are shown in Fig. 11.

In Fig. 11, the designed MGD-ANFIS-based user behavior profiling model has a maximum detection rate of 1.000, a

minimum of 0.950, and an average of 0.975. The maximum of the ANFIS-based user behavior profiling model was 0.98, the minimum was 0.84, and the average was 0.91. The maximum of the user behavior profiling model based on FNN was 0.98, the minimum was 0.66, and the average was 0.82. Analysis shows that the average detection rate of the MGD-ANFIS-based user behavior profiling model was 0.065 and 0.155 higher than the other two models, respectively, proving its high detection accuracy.

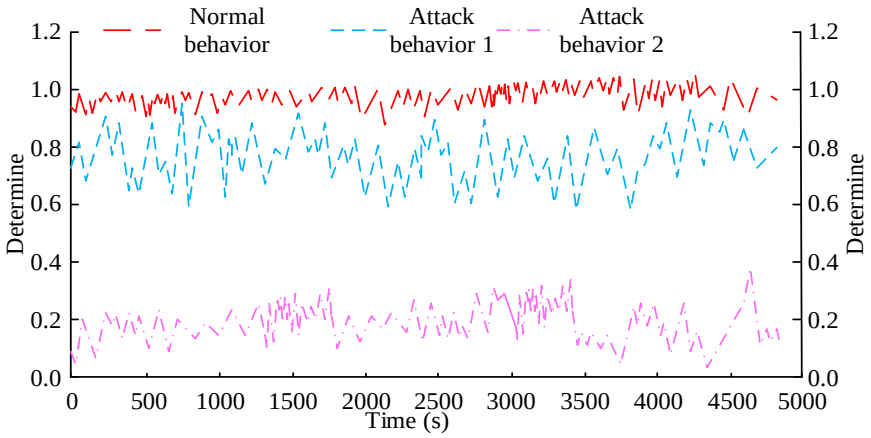

Fig. 10. Judgment values for three behaviors.

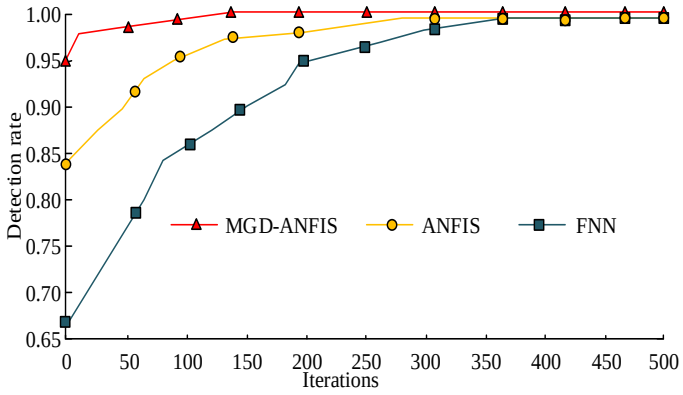

Fig. 11. Detection rate of user behavior profiling models using different algorithms.

V. Conclusion

With the popularization of mobile devices and the advancement of network technology, user behavior data have been generated in the network. How to better distinguish user behavior has become a focus of research by relevant personnel. In order to better detect user behavior, the study first adjusts the network parameters of FNN using the BP algorithm and LSE algorithm, then optimizes and learns the adjusted parameters using GDM, and optimizes the structure of FNN through SCM to shorten training time. MGD-ANFIS algorithm is designed, and finally, MGD-ANFIS is applied to user behavior profiling and a model is constructed. The results showed that in the simulation comparison, the trend of the optimization results of the MGD-ANFIS algorithm and the fitting degree of the test function were higher than those of the ANFIS algorithm, indicating its high accuracy and proving its effectiveness. In the calculation of recall, accuracy, and F1 score, the three indicator values of the MGD-ANFIS algorithm were 0.20, 0.99, and 0.20, respectively. The three indicator values of the ANFIS algorithm were 0.13, 0.96, and 0.13, respectively. The three indicator values of FNN were 0.11, 0.92, and 0.12, respectively. The three indicator values of the MGD-ANFIS algorithm were all higher than other algorithms, proving its good comprehensive performance. In the simulation experiment of the KDD99 dataset, different combinations of training and testing sets had higher detection rates and smaller false positives and errors, indicating that the designed user profile model had high adaptability. In the calculation of decision values, the average decision value for users with normal behavior was about 0.98, the average decision value for attack behavior 1 was 0.79, and the average decision value for attack behavior 2 was 0.45, proving the effectiveness of the designed model. The study only analyzed vulnerability-based attacks and protocol defect-based attacks, which had a certain impact on behavior judgment. Further exploration will be conducted in related aspects in the future. The study will conduct a more in-depth analysis of attack behavior, including the attacker's behavior patterns, attack time, and frequency, in order to better understand the attacker's motivation and strategy. Meanwhile, when constructing user behavior profiles, the quality and completeness of data have a significant impact on the accuracy and reliability of the results. Therefore, in future

research, it is necessary to consider the quality and completeness of data more comprehensively.

***Abstract*—The brain is a vital organ, and the brain tumor is one of the most dangerous types of tumors in the world. Neuroimaging is an interesting and important discussion in diagnosing central nervous system tumors. Brain tumors have several types, namely meningioma, glioma, pituitary, schwannoma, and neurocytoma. A radiologist uses magnetic resonance imaging (MRI) to detect brain tumors because of its advantages over computed tomography. However, classifying multiclass MRI is difficult and takes a long time. This study proposes an automated classification of multiclass brain tumors using enhanced deep learning techniques. Various models are used in this research, namely VGG16, NasNet-Mobile, InceptionV3, ResNet50, and EfficientNet. For EfficientNet, we applied EfficientNet-B0–B7. From the experiments, EfficientNet-B2 is the superior, with the highest level of training accuracy of 99.90%, testing accuracy of 99.55%, precision of 99.50%, recall of 99.67%, and F1-Score of 99.58% with a training time of 15 minutes. The development of this automatic classification can assist radiologists in classifying brain tumor types more efficiently.**

I. Introduction

The central nervous system (CNS), composed of the brain and spinal cord, controls all major biological systems. It consists of supporting cells (glial cells) and nerve cells (neurons) that communicate with each other and the rest of the body by sending and receiving impulses through the nerves. Magnetic resonance imaging (MRI) is an imaging technique that shows accurate anatomical images of the human body and provides valuable data for biomedical research and clinical diagnosis. For example, MRI images help diagnose brain tumors, abnormal cell growths that form an odd segment compared with normal cells. As a vital organ in the human body for speaking, thinking, and receiving environmental responses [1], any disturbance in the brain will also affect other organs. Based on the growth speed, brain tumors are classified into benign and malignant. Benign brain tumors can be cured with surgery, but malignant brain tumors are the deadliest of the cancers and can cause instant death [2]–[4]. Meanwhile, brain tumors can either be primary and secondary (i.e., metastatic). Primary tumors originate from the brain or the nerves of the brain. Metastatic brain tumors, conversely, are caused by cancer cells that spread to the brain from other parts of the body. Clinical studies show that 30%–50% of all patients with brain metastases develop multiple lesions, depending on the type of primary cancer [5], [6].

There are three types of primary brain tumors: meningioma, glioma, and pituitary tumor. Meningiomas arise from arachnoid cells in the brain and account for 37.6% of all adult primary brain tumors. The disease accounts for approximately 35,000 new cases annually, making it the most common type of intracranial tumor in the United States [7], [8]. Gliomas are found in the cerebral pedicle and spinal cord, with symptoms such as vomiting, headache, and discomfort. Glioma tumors represent nearly 30% of primary brain tumors and 80% of all malignant ones. Based on their histopathological appearance, gliomas are traditionally classified by the World Health Organization as grades I and II (low-grade glioma), grade III (anaplastic), and grade IV (glioblastoma) [9], [10]. The pituitary is a complex organ consisting of neuroendocrine cells that secrete hormones from the adenohypophysis; posterior pituitary lobe, which is modified glia; axonal extensions of hypothalamic neurons, which secrete hormones into the bloodstream; and stromal cells, which include blood vessels, nerves, meninges, bones, and other connective tissue elements. Pituitary tumors, which arise from anterior pituitary cells and are called pituitary adenomas, are generally benign and rare (about 0.2%), showing craniospinal or systemic metastases [11]–[13]. Schwannoma (neurilemmoma) is benign neoplasms derived from tumorigenic schwann cells that protect nerve cells [14]. This condition is caused by a loss of function mutation of the neurofibromatosis type 2 (NF2) tumor gene [15]. Then, apart from that, there is also a type of brain tumor called neurocytoma. This tumor is a rare brain tumor according to the world health organization (WHO). Neurocytoma arising from the ventricle accounts for 0.1% - 0.5% of all primary brains. Moreover, these tumors rarely arise from the brain parenchyma [16].

MRI is essential in detecting brain tumors, early tumors, or CNS disorders, simultaneously seeing the response to treatment. MRI has become a part of routine clinical practice, capturing various anatomical and physiological processes [17], [18]. MRI data must be analyzed, considering that brain

*Corresponding Author, alhadi@sci.ui.ac.id

tumors generally consist of distinct structural and functional areas [19]; however, analysis can take quite a long time for accurate results. Moreover, classifying brain images of the normal brain, meningioma, glioma, pituitary, schwannoma, and neurocytoma may take longer since identifying brain images is difficult. Therefore, an automated classification of brain tumors is required to ease and speed up the analysis.

Several deep learning-based models, such as CNN, VGG (visual geometry group)-16, NasNet, and support vector machine, have been used to classify features and show reliable results [20]. Most improvements of the neural networks focused on optimizing network width, depth, and resolution. Meanwhile, the EfficientNet proposed by Tan & Le (2019) combined or collaborated those three factors. Balancing the three factors aims to obtain an optimal model at a certain complexity [21]. This study proposes an enhanced deep learning model, the EfficientNet model, to classify MRI images of brain tumors into six classes: normal brain, meningioma, glioma, pituitary, schwannoma, and neurocytoma. The EfficientNet model is expected to improve classification accuracy with less computation cost. For comparison study, four deep learning-based models namely VGG16, NasNet-Mobile, InceptionV3, and ResNet50 will also be implemented to classify MRI images.

The structure for the rest of the paper is as follows. Section II provides previous works about brain tumor classifications using various models. Section III describes the data and methods used in this study. The results of the proposed brain tumor classifications are presented in Section IV. Section V concludes the paper..

II. Related Work

D. Filatov and G. N. A. H. Yar (2022) classified brain tumors into four classes, with the highest accuracy in the EfficientNet-B0 model of 87.67%, while the ResNet50 model obtained an accuracy of 72.82%. Similarly, M. A. Gómez-Guzmán et al. (2023) used the EfficientNet-B0 model and obtained a higher accuracy of 90.88%. R. Jha, V. Bhattacharjee, and A. Mustafi (2022) used TrFEMNet and obtained an accuracy of 99.39% for two classes and 78.05% for four classes of brain tumors. With the same number of classes, A. Kowshir et al. (2023) used the ResNet50 model and obtained an accuracy of 96.67%.

Using the brain MRI dataset to classify Alzheimer's, the accuracy level obtained in the Hazarika et al. study (2022) was 86.75% and 86.25% for the NasNet-A and NasNet-C models, respectively. Research conducted by [22] classified Alzheimer's using the 3D-Hog feature. Research conducted by S. R. Sowrirajan et al., (2023) using a three-class dataset, obtained accurate results for the VGG16-NADE model with an augmentation of 96.01%, and VGG16 without augmentation of 92.33%. This accuracy is the highest compared with other models in their study. The previous research summary can be seen in Table I, which shows that the highest accuracy rate is 99.39% for two classes of brain tumors. Even though the accuracy is already high, the classification is only implemented for two classes. Meanwhile, the classification of brain tumors with more than four classes has not been investigated in detail yet.

TABLE I. Comparative Research for Brain Classification

Reference	Model	Result
[23] D. Filatov and G. N. A. H. Yar, (2022)	EfficientNet-B7 EfficientNet-B0 ResNet50	84.19% 87.67% 72.82%

[27] S. R. Sowrirajan et al., (2023)	VGG16	96.01%

In this study, the classification of brain tumors into six classes, normal brain, meningioma, glioma, pituitary, schwannoma, and neurocytoma will be proposed using five types of models, VGG16, NasNet-Mobile, InceptionV3, ResNet50, and EfficientNet. Classification of six classes will provide a better level of training and validation accuracy with shorter training time using enhanced deep learning techniques.

III. Research Method

A. Dataset

Fig. 1 shows the samples of the MRI images dataset, consisting of the normal brain, meningioma, glioma, pituitary, schwannoma, and neurocytoma tumor. Meningioma is the most common CNS or primary tumor. Meningioma tumors grow from the meninges, the tissues surrounding and protecting the brain just below the skull [28].

Glioma-type tumors arise from glial cells and are intraparenchymal tumors [29], [30]. An example of glioma tumor MRI results can be seen in Fig. 1 (c). The pituitary gland is a complex organ composed of the hormone-secreting neuroendocrine cells of the pituitary gland. The MRI results for this type of tumor can be seen in Fig. 1 (d). In Fig. 1 (e) is an image of a schwannoma-type tumor and the MRI result of a neurocytoma-type tumor shown in Fig. 1 (f).

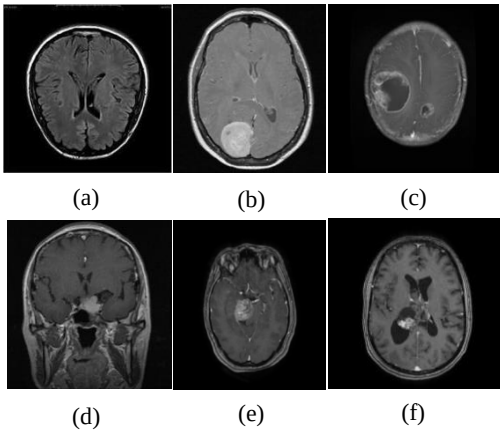

Fig. 1. MRI result (a) normal brain, (b) meningioma, (c) glioma, (d) pituitary, (e) schwannoma, (f) neurocytoma.

The dataset used in this study is retrieved from [31] and [32], and there are six types of images with a total of 7519 images. The number of details of the dataset can be seen in Table II.

TABLE II. DATASET DISTRIBUTION

Phase	Train	Test	Total
Normal	1595	205	1800
Glioma	1321	167	1488
Meningioma	1339	159	1498
Pituitary	1457	163	1620
Schwannoma	463	88	551
Neurocytoma	457	105	562
Total	**6632**	**887**	**7519**
	88.2%	11.8%	

B. VGG16 Architecture

VGG is one of the CNN architectures. VGG16 has five convolution blocks with 13 convolution layers and 3 fully connected. VGG is more capable of processing small datasets and has better recognition efficiency [33], [34]. During the training process, a loss function is used to measure the error between predicted and actual values. The following formula was applied for the cross-entropy loss function for experiments with VGG16:

$$L_{CE} = -\sum_{i=1}^{n} t_i \log p_i, \quad \text{for } n \text{ classes} \tag{1}$$

Where t_i is truth label and p_i denotes the softmax loss functions for i^{th} class. The VGG16 architecture can be seen in Fig. 2.

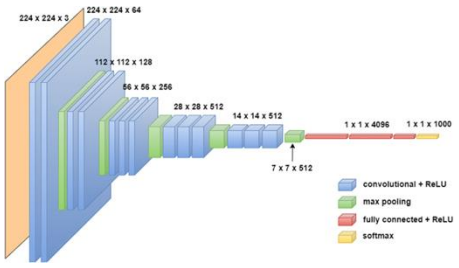

Fig. 2. VGG16 architecture [35].

C. NasNet-Mobile

NasNet is one of the CNN architectures consisting of basic building blocks optimized using reinforcement learning [36]–[38]. There are two blocks that must be considered, namely the child block and the parental block. The child block serves to adjust the network based on changes in effectiveness, while the parental block serves to evaluate the effectiveness of the child block.

NasNet development defines a high-performance building block in image set categorization (CIFAR-10). The block is generalized to a wider dataset so that it can achieve a higher classification capacity [39]. The illustration for this model can be seen in Fig. 3.

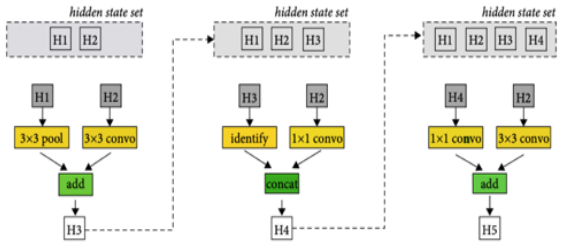

Fig. 3. NasNet architecture [55].

D. InceptionV3

InceptionV3 is the latest version of the InceptionV1 model. The InceptionV3 model has a wider network than InceptionV1 and V2. Training takes longer and is very difficult to complete. This problem is solved using transfer learning techniques [40], [41].

The structure of InceptionV3 can be seen in Fig. 4. In InceptionV3, the probability of each label $k \in \{1, \ldots, K\}$ can be determined by

$$Q(k|z) = \frac{exp(y_k)}{\sum_i^K exp(y_i)} \tag{2}$$

where, y denotes the nonnormalized log probability. The ground truth distribution on labels $p(k|z)$ is normalized by $\sum_k p(k|z) = 1$.

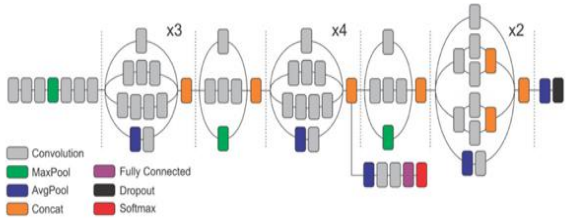

Fig. 4. InceptionV3 structure [54].

E. ResNet50

The ResNet50 model is a CNN model with a 50-layer residual network partitioned into five parts. The first part contains a convolutional layer for input preprocessing. Part 2–5 contain the bottleneck components. This model was first introduced by Microsoft in 2015 [42]. Residual building blocks can be shown in the following formula:

$$y = F(x) + x \tag{3}$$

where, $F(x)$ is the residual function, x is the input, and y is the output parameter of the residual function. ResNet50 architecture can be seen in Table III [43].

F. EfficientNet

EfficientNet has eight different architectures, namely EfficientNet-B0–B7 with the basic model being B0 obtained from neural architecture search (NAS) and B1–B7, which is an additional model with an extension of the basic model [44]. In NAS [45] to get the optimal architecture, a controller is needed to maximize the expected results represented by $J(\theta_c)$:

$$J(\theta_c) = E_{P(\alpha_{1:T};\theta_c)}[R] \tag{4}$$

TABLE III. RESNET50 ARCHITECTURE

Layer Name	Output Size	Layer
Conv1	112 x 112	7 x 7, 64, stride 2
Conv2_x	56 x 56	3 x 3 max pool, stride 2
		$\begin{bmatrix} 1\,x\,1, 64 \\ 3\,x\,3, 64 \\ 1\,x\,1, 256 \end{bmatrix} x\,3$
Conv3_x	28 x 28	$\begin{bmatrix} 1\,x\,1, 128 \\ 3\,x\,3, 128 \\ 1\,x\,1, 512 \end{bmatrix} x\,4$
Conv4_x	14 x 14	$\begin{bmatrix} 1\,x\,1, 256 \\ 3\,x\,3, 256 \\ 1\,x\,1, 1024 \end{bmatrix} x\,6$
Conv5_x	7 x 7	$\begin{bmatrix} 1\,x\,1, 512 \\ 3\,x\,3, 512 \\ 1\,x\,1, 2048 \end{bmatrix} x\,3$
	1 x 1	Average pool, 1000-d fc, softmax

List of action $\alpha_{1:T}$ is used to design the child network architecture. This child network will achieve accuracy R at the time of dataset convergence. By taking advantage of the R accuracy, it can be used as a reward signal for training controllers or as reinforcement learning. The reward signal R is not differentiable, so a gradient method is required to iteratively update θ_c by using the reinforce rule [46]:

$$\nabla_{\theta_c} J(\theta_c) = \sum_{t=1}^{T} E_{P(\alpha_{1:T};\theta_c)}\left[\nabla_{\theta_c} \log P\left(a_t \middle| a_{(t-1):1}; \theta_c\right) R\right] \quad (5)$$

The empirical approximation of the quantity (4) is:

$$\frac{1}{m}\sum_{k=1}^{m}\sum_{t=1}^{T} \nabla_{\theta_c} \log P\left(a_t \middle| a_{(t-1):1}; \theta_c\right) R_k \quad (6)$$

where, m is the number of different architectures containing example controllers in the stack. On the other hand, T is the number of hyperparameters expected by the controller to design the neural network architecture.

The validation accuracy obtained by the k^{th} neural network architecture after being trained on the training dataset is R_k. To reduce variance, the baseline function is used:

$$\frac{1}{m}\sum_{k=1}^{m}\sum_{t=1}^{T} \nabla_{\theta_c} \log P\left(a_t \middle| a_{(t-1):1}; \theta_c\right)(R_k - b) \quad (7)$$

EfficientNet is based on NAS technology as a simple, scalable, and generalizable benchmark network. In increasing the resolution and complexity of the network structure, the architecture of the EfficientNet model can be seen in Table IV [47].

By combining the three factors in the architecture, the coefficient calculation formula is as follows [48], [49]:

$$\begin{cases} depth: d = \alpha^{\phi} \\ width: w = \beta^{\phi} \\ resolution: r = \gamma^{\phi} \end{cases} \quad (8)$$

TABLE IV. ARCHITECTURE OF EFFICIENT NET

Description	Layer	Input Resolution	Channel
EfficientNet-B0	240	224x224	1280
EfficientNet-B1	342	240x240	1280
EfficientNet-B2	342	260x260	1408
EfficientNet-B3	387	300x300	1536
EfficientNet-B4	477	380x380	1792
EfficientNet-B5	579	456x456	2048
EfficientNet-B6	669	528x528	2304
EfficientNet-B7	816	600x600	2560

where, $\alpha \geq 1, \beta \geq 1, \gamma \geq 1$ and $\alpha \cdot \beta^2 \cdot \gamma^2 \approx 2$ with $w, d, and\ r$ can be used to scale network width, depth, and resolution coefficients. While value ϕ can be used to determine the number of effective resource extension models. The constants $\alpha, \beta, and\ \gamma$ are used to allocate these resources into three-dimensional network depth, width, and resolutions.

In the proposed model, the preprocessing stage will carry out a cropping process with an image size of 150×150. This aims to eliminate noise or delete unnecessary image information. The results of the cropping process can be seen in Fig. 5. After the cropping process is carried out, the new data will be saved in a new directory. Then the data will be augmented. This data augmentation functions to suppress overfitting when data is run through artificial data augmentation techniques [50].

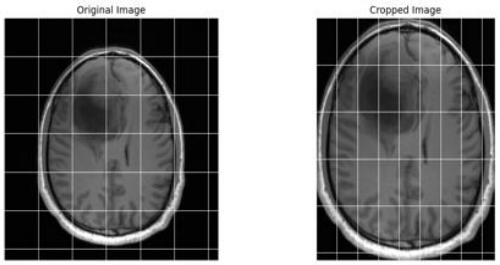

Fig. 5. Original and cropped image.

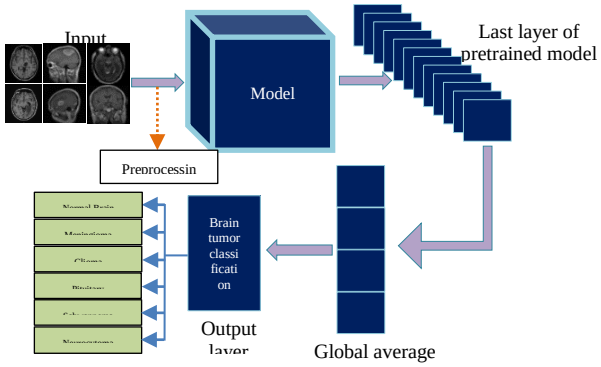

Fig. 6. Proposed model for brain tumor classification.

The complete model proposed in this study is shown in Fig. 6. The input model is the MRI image, which results in the image's class; it is detected as a normal brain or one of the brain tumors: meningioma, glioma, pituitary, schwannoma, or neurocytoma. Furthermore, the structure of the EfficientNet model is illustrated in Fig. 7.

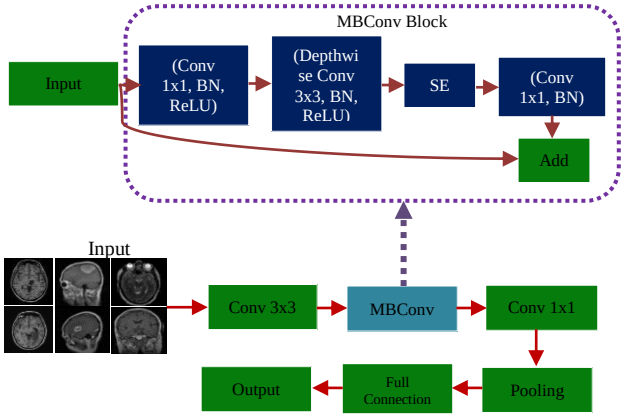

Fig. 7. The structure of the efficientnet model.

G. Model Implementation

A depth wise separable convolution (DSC) layer is used to build the base of the MobileNet block. Therefore, this hierarchical structure is also called mobile convolution (MB Conv) [51]. DSC consists of two parts: depth convolution (DWC) and point convolution (PWC). The combined convolution process between DWC and PWC is shown in Fig. 8. The goal of revealing model parameters while preserving output quality was achieved.

H. Model Evaluation

Confusion matrix provides a combination of class and actual predictions. This makes it possible to define various multiclass performance metrics as shown in Fig. 6 [52], [53]. The multiclass confusion matrix presented in Fig. 9 has dimensions of $N \times N$, where N is the number of different class labels $C_0, C_1, \ldots, C_N$. From the confusion matrix, we can compute the classification metrics: accuracy, recall, precision, and the F1-score by formulas presented in Table V.

TABLE V. PERFORMANCE METRICS FOR MULTICLASS CLASSIFICATION

Metric	Formula
Accuracy	$\frac{\sum_{i=1}^{N} TP(C_i)}{\sum_{i=1}^{N}\sum_{j=1}^{N} C_{i,j}}$
Recall of class C_i $(TPR(C_i))$	$\frac{TP(C_i)}{TP(C_i)+FN(C_i)}$
Precision of class C_i $(PPV(C_i))$	$\frac{TP(C_i)}{TP(C_i)+FP(C_i)}$
$F_1 -$ Score of class C_i	$2 \cdot \frac{TPR(C_i)\cdot PPV(C_i)}{TPR(C_i)+PPV(C_i)}$

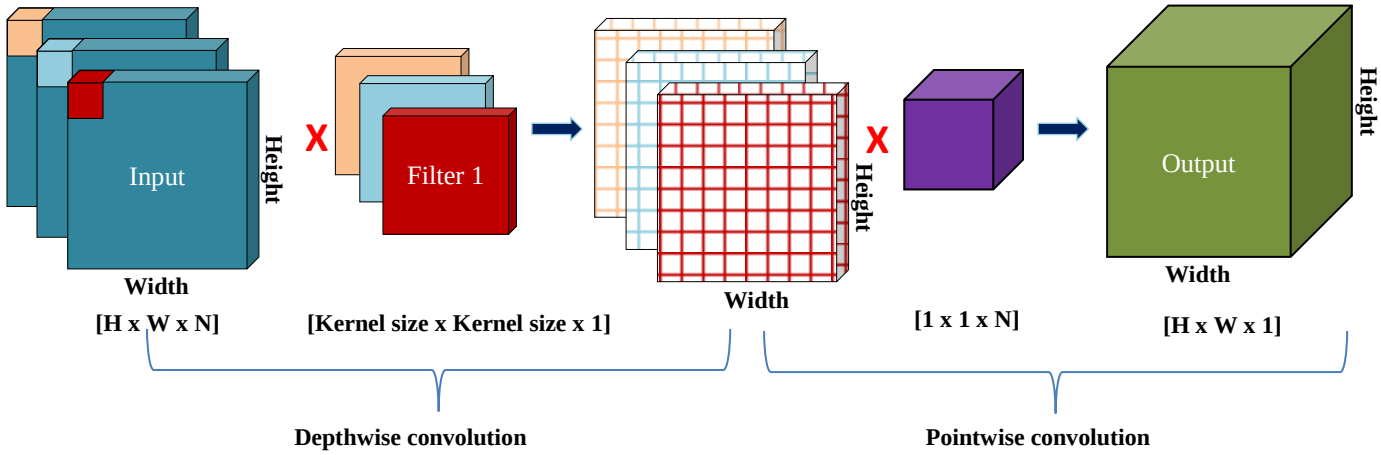

Fig. 8. Depthwise and pointwise convolution illustration.

		Predicted Class			
		C_1	C_2	…	C_N
Actual Class	C_1	$C_{1,1}$	FP	…	$C_{1,N}$
	C_2	FN	TP	…	FN
	…	…	…	…	…
	C_N	$C_{N,1}$	FP	…	$C_{N,N}$

IV. RESULT

This research conducted all experiments in the Google Colab application, with the graphic processing unit backend Google Compute Engine Python 3 A100. The RAM was 83.5 GB, disk 166.8 GB, model name Intel(R) Xeon(R) CPU@2.20GHz. The detailed parameters that have been optimized of the model experiments are shown in Table VI.

Except for the number of epochs, all models used the same parameters and loss function.

TABLE VI. PARAMETERS USED IN THE PROPOSED BRAIN TUMOR CLASSIFICATION FRAMEWORK

Hyper-parameter	VGG16	NasNet-Mobile	InceptionV3	ResNet50	EfficientNet
Optimizer	Adam	Adam	Adam	Adam	Adam
Batch Size	32	32	32	32	32
Epoch	80	40	20	20	20
Learning Rate	0.0001	0.0001	0.0001	0.0001	0.0001
Verbose	1	1	1	1	1
Loss Function	Flatten Cross-Entropy				

First, we will show the results of four models' experiments: VGG16, NasNet-Mobile, InceptionV3 and ResNet50. Initially, the performance of the training and validation of four models are presented through the loss and accuracy functions in Fig. 10. Meanwhile, Fig. 11 shows the corresponding confusion matrix that we can see that InceptionV3 only gives few false results.

Except in the VGG16 model, there is a jump in both loss and accuracy graphs of the models (see Fig. 10) (b-d). Nevertheless, as the epoch is larger the accuracy tends to improve, and the loss progressively reduces. In the accuracy graph, the initial validation accuracy is very low, 0.2 in VGG16 and NasNet-Mobile, and 0.4 in ResNet50. However, it increases to approximately 95% after the epoch is larger than 20 in the model of VGG16 and NasNet-Mobile. In InceptionV3 and ResNet50, the accuracy is already consistently more than 95% after 10 epochs. The highest accuracy of each model as shown in Table VII is achieved with epoch 24, 40, 13, and 7 for VGG16, NasNet-Mobile, InceptionV3 and ResNet50, respectively. Based on the performance results of the four models presented in Table VII, InceptionV3 achieves the best with only 13 epochs. Further, we will investigate how EfficientNet performs compared to InceptionV3, in particular.

Like the four other models, the experiments using eight varieties of EfficientNet (B0-B7) will also be compared through the loss and accuracy trend functions, confusion matrix, and the model performance metrics. Fig. 12 depicts the loss and accuracy graph of all EfficientNet models over 20 epochs. As expected, the performance of the loss and accuracy of the training are slightly better than the validation. All EfficientNet models tend to increase their performance as the epoch grows. Of the eight EfficientNet models, their performances do not differ significantly. All accuracies are mostly perfect, approximately 99%.

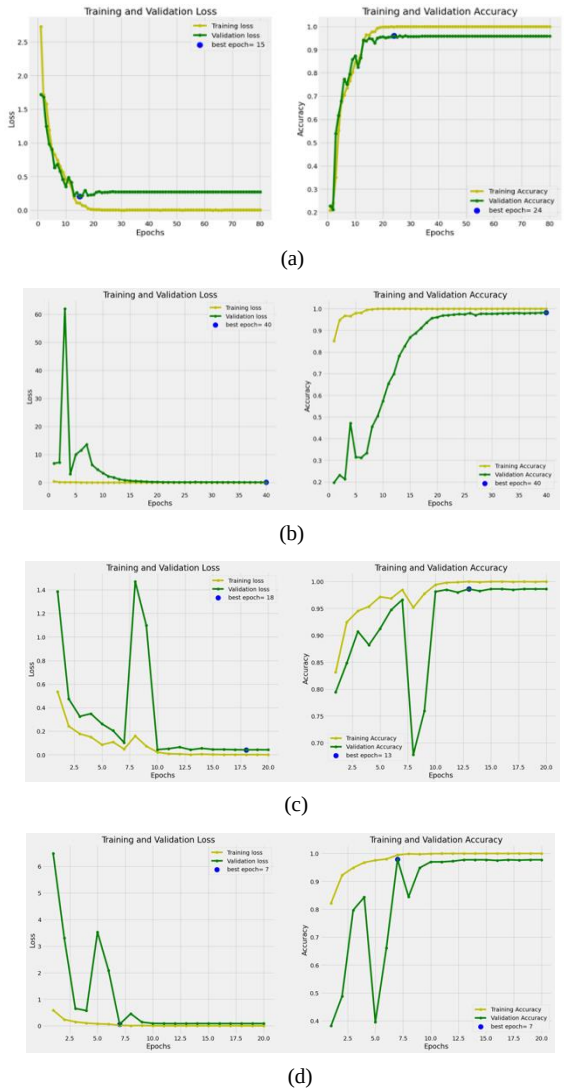

Fig. 10. The loss function and accuracy of the experiment using (a) VGG16, (b) NasNet-Mobile, (c) InceptionV3, and (d) ResNet50.

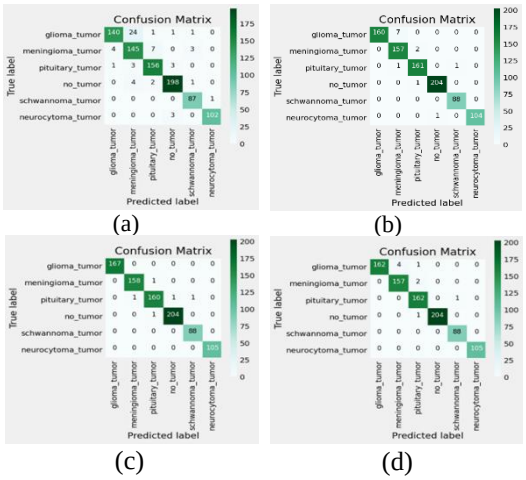

Fig. 11. The confusion matrix of experiment (a) VGG16, (b) NasNet-Mobile, (c) InceptionV3, and (d) ResNet50.

TABLE VII. PERFORMANCE MODEL

Model	Class	Precision (%)	Recall (%)	F1-Score (%)
VGG16	Glioma	97.00	84.00	90.03
	Meningioma	82.00	91.00	86.27
	Pituitary	94.00	96.00	94.99
	Normal	97.00	97.00	97.00
	Schwannoma	95.00	99.00	96.96
	Neurocytoma	99.00	97.00	97.99
	Average	**94.00**	**94.00**	94.00
NasNet-Mobile	Glioma	100.00	96.00	97.96
	Meningioma	95.00	99.00	96.96
	Pituitary	98.00	99.00	98.50
	Normal	100.00	100.00	100.00
	Schwannoma	99.00	100.00	99.50
	Neurocytoma	100.00	99.00	99.50
	Average	**98.67**	**98.83**	**98.75**
InceptionV3	Glioma	100.00	100.00	100.00
	Meningioma	99.00	99.00	99.00
	Pituitary	99.00	98.00	98.50
	Normal	100.00	100.00	100.00

	Meningioma	98.00	99.00	98.50
	Pituitary	98.00	99.00	98.50
	Normal	100.00	100.00	100.00
	Schwannoma	99.00	100.00	99.50
	Neurocytoma	100.00	100.00	100.00
	Average	**99.17**	**99.17**	**99.16**

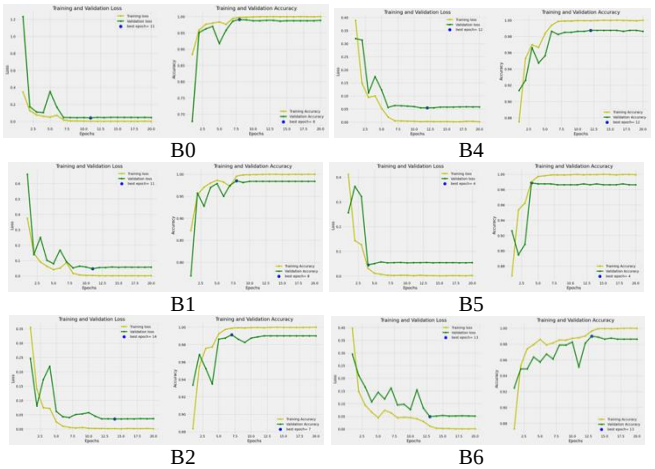

Fig. 12. The loss function and accuracy of the experiment using EfficientNet-B0-B7.

From the confusion matrix described in Fig. 13, we observe that all models only deliver a few faulty classifications. The false positives seem to be a little more than the false negatives results. There is no false negative result in EfficientNet-B1 and there is only one false negative in EfficientNet-B2, B3, and B5 while there are two false negative results in InceptionV3.

Further detail of the model performance of EfficientNet can be seen from the performance metrics of precision, recall, F1-score in Table VIII. The metrics of all EfficientNet are shown to be more than 99%.

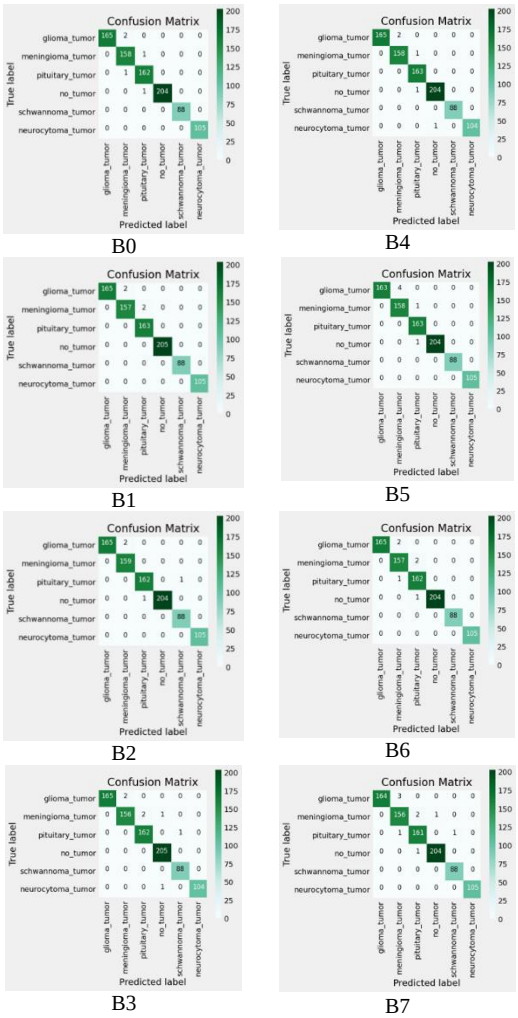

Fig. 13. The confusion matrix of the experiment using EfficientNet-B0-B7.

TABLE VIII. PERFORMANCE OF THE EFFICIENTNET MODEL

Model	Class	Precision (%)	Recall (%)	F1-Score (%)

	Average	**99.00**	**99.17**	**99.08**

Next, we compare the EfficientNet model with four previous models. The models' performances are evaluated by considering the model accuracy and the computational time, the time consuming for training. The model comparisons are presented in Table IX. Based on the model accuracy in both the training and the validation data, the EfficientNet can outperform NasNet-Mobile, VGG16, InceptionV3, and ResNet50. EfficientNet-B2 achieves the highest accuracy of 99.9% in training and 99.55% in validation. The model with the least accuracy is VGG16, with a training accuracy of 97.2% and validation accuracy of 93.35%. This model also had the longest training time of 84 minutes with 80 epochs. The selection of more epochs is due to the stability of the chart. Compared with other proposed models, VGG16 requires a long epoch to be stable. In terms of the computation time, the proposed EfficientNet model requires vary time, from 10 minute in EfficientNet-B0 up to 60 minutes in EfficientNet-B7. Meanwhile, the best model, EfficientNet-B2 requires 15 minutes for the training. It is almost double the time of InceptionV3 model which only takes eight minutes.

TABLE IX. ACCURACY AND COMPUTATIONAL TIME OF MODEL

Model	Train (%)	Validation (%)	Time (m)
EfficientNet-B0	99.89	99.44	10
EfficientNet-B1	99.84	99.55	14
EfficientNet-B2	**99.90**	**99.55**	**15**
EfficientNet-B3	99.80	99.21	19
EfficientNet-B4	99.86	99.44	25
EfficientNet-B5	99.86	99.32	35
EfficientNet-B6	99.86	99.32	46
EfficientNet-B7	99.85	98.99	60
VGG16	97.20	93.35	84
NasNet-Mobile	99.82	98.53	26
ResNet50	99.77	98.99	14
InceptionV3	**99.86**	**99.44**	**8**

V. CONCLUSION

This study applies eight enhanced EfficientNet models, namely EfficientNet-B0-B7, which is based on the concept of CNN. According to existing literature, EfficientNet is a deep learning model that modifies the model so that computational efficiency produces the best results. With its efficiency advantage, we use the model to build an automated classification of brain MRI images into six classes: normal, meningioma, glioma, pituitary, schwannoma, and

neurocytoma. In this study, the EfficientNet models are also compared to the previous models, namely VGG16, NasNet-Mobile, InceptionV3, and ResNet50. All varieties of EfficientNet perform high accuracy and the EfficientNet-B2 model is superior. The EfficientNet-B2 model achieves the highest training accuracy of 99.9% and validation accuracy of 99.55%. However, it takes a slightly longer time to do the training. It requires 15 minutes, while InceptionV3 only needs eight minutes to achieve a training accuracy of 99.86%. Both EfficientNet-B2 and InceptionV3 models are best options in classifying brain MRI images efficiently and accurately.

Nature-Inspired Optimization for Virtual Machine Allocation in Cloud Computing: Current Methods and Future Directions

Xiaoqing YANG*
Henan Technical, College of Construction, Zhengzhou 450000, China

***Abstract*—An expanding range of services is offered by cloud data centers. The execution of application tasks is facilitated by assigning (VMs) Virtual Machines to (PMs) Physical Machines. Speaking of VM allocation in the cloud service center, two key factors are taken into consideration: quality of service (QoS) and energy consumption. The cloud service center aims to optimize these aspects while allocating VMs. On the other hand, cloud users have their priorities and focus on their specific requirements, particularly throughput and reliability. User requirements are considered by the cloud service center, resulting in VM allocation that meets QoS targets and optimizes energy consumption. Cloud service centers must, therefore, find a balance between QoS and energy efficiency while considering the user's requirements. To achieve this, various optimization algorithms and techniques must be employed. The objective is to find the best allocation of VMs to PMs. Due to the NP-hardness of the VM allocation problem, nature-inspired meta-heuristic algorithms have become commonly used to solve it. However, there are no comprehensive and in-depth review papers on this specific area. This paper aims to bridge a knowledge gap by providing an understanding of the significance of metaheuristic methods to address the VM allocation issue effectively. It not only highlights the role played by these algorithms but also examines the existing methods, provides comprehensive comparisons of strategies based on key parameters, and concludes with valuable recommendations for future research.**

***Keywords*—Cloud computing; virtualization; virtual machine allocation; optimization**

I. INTRODUCTION

Cloud computing, characterized by on-demand services utilizing virtualized computing resources and streamlined software and hardware maintenance [1], has significantly shifted organizational paradigms from private infrastructure to cloud-based platforms [2]. However, the rapid growth of cloud data centers has brought about challenges, notably in energy consumption and environmental impact due to the extensive deployment of computing resources [3]. Service provisioning in cloud computing revolves around Service Level Agreements (SLAs), offering a spectrum of services encompassing hardware/software rental, resource management, and workload distribution [4]. The versatility of cloud services, encompassing Infrastructure as a Service (IaaS), Platform as a Service (PaaS), Software as a Service (SaaS), and the comprehensive concept of Everything as a Service (XaaS), optimizes IT infrastructure for enhanced service delivery [5]. The pervasive adoption of cloud computing has amplified concerns regarding the substantial energy consumption inherent in data centers, accentuated by underutilized servers leading to inefficient energy utilization [6]. Addressing this challenge necessitates optimizing server utilization in data centers while ensuring seamless service delivery [7]. However, the increasing diversity of resource types in data center architectures poses a challenge in improving resource efficiency, especially in dispersed and heterogeneous environments owned by major cloud providers. The fundamental problem centers on efficiently allocating resources based on cloud user requests while adhering to SLAs.

The convergence of Internet of Things (IoT), fuzzy logic, Machine Learning (ML), Deep Learning (DL), Neural Networks (NNs), and meta-heuristic algorithms shapes efficient cloud resource allocation. The proliferation of IoT has generated vast data streams, requiring sophisticated allocation mechanisms [8, 9]. Fuzzy logic, integrating imprecise or uncertain data, enhances decision-making in allocating resources, considering ambiguous parameters [10, 11]. ML comprising supervised and unsupervised learning paradigms, aids in predicting resource demands and pattern recognition for optimized allocations [12-14]. DL, a subset of ML, with its complex neural networks, enables automatic feature extraction, fostering accurate resource predictions, and allocation decision-making [15, 16]. NNs, mimicking human brain functions, offer robust solutions for dynamic resource allocation challenges by learning from patterns and behaviors in cloud environments [17].

By employing clustering techniques, cloud systems can categorize and group entities with similar attributes or behaviors, allowing for more efficient resource allocation strategies. This approach enables the identification of patterns and similarities among diverse entities, such as VMs or user requests, facilitating the allocation of resources based on common characteristics [18]. Moreover, meta-heuristic algorithms, drawing inspiration from natural phenomena, provide efficient search strategies in complex solution spaces, optimizing cloud resource allocation by addressing scalability, dynamicity, and diverse user requirements [19]. This convergence is pivotal in enhancing the adaptability, accuracy, and efficiency of cloud resource allocation, catering to the burgeoning demands of modern cloud infrastructures while enabling dynamic, scalable, and optimized resource

provisioning, underpinning the evolution and sustainability of cloud computing ecosystems [20].

The primary questions addressed in this study revolve around the optimization of energy consumption and resource allocation complexities within cloud computing. Firstly, how can server utilization be improved in data centers to mitigate energy wastage? Secondly, what effective strategies can manage the diverse resource types and demand patterns inherent in cloud systems? Finally, how can resources be allocated efficiently while meeting the diverse SLA requirements of cloud users? These key inquiries guide the exploration of efficient resource allocation methodologies and user-centric approaches within the realm of cloud computing. This review paper aims to address the gap in existing literature by comprehensively exploring solutions for efficient resource allocation in cloud computing. It assesses methodologies to optimize energy consumption while meeting SLAs, investigates resource allocation complexities, and suggests user-centric strategies. By offering comparative insights and recommendations, this study aims to provide a robust understanding of cloud resource allocation for future research directions.

II. BACKGROUND

Various methods have been developed to optimize the allocation of VMs on physical machines in cloud data centers. Fig. 1 presents an overview of virtual machine allocation strategies. Using multidimensional resources in an unbalanced manner can enhance resource utilization and lead to abnormalities. A balanced use of multidimensional resources refers to the use of resources in each dimension proportional to their total amount. Virtual machines may run out of resources if placed regardless of this characteristic. Placement decisions can take into account various costs, including virtual machines, physical machines, cooling, data centers, and traffic, as shown in Fig. 2. The cost of cloud services is influenced by multiple factors. One aspect focuses on reducing costs for cloud users, specifically, the expense associated with virtual machines. Simultaneously, other factors aim to decrease costs for cloud service providers. Virtual machine allocation involves assigning virtual machines to suitable physical machines. To address the complexity of the NP-hard problems involved in this allocation, meta-heuristic algorithms are employed. Virtualization technology is critical for cloud computing, and the task of assigning virtual machines to physical machines is referred to as the virtual machine allocation problem, a known NP-hard challenge.

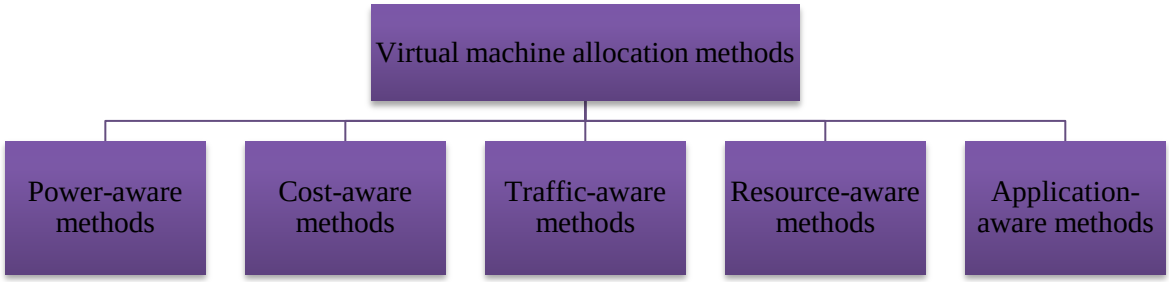

Fig. 1. Taxonomy of virtual machine allocation methods

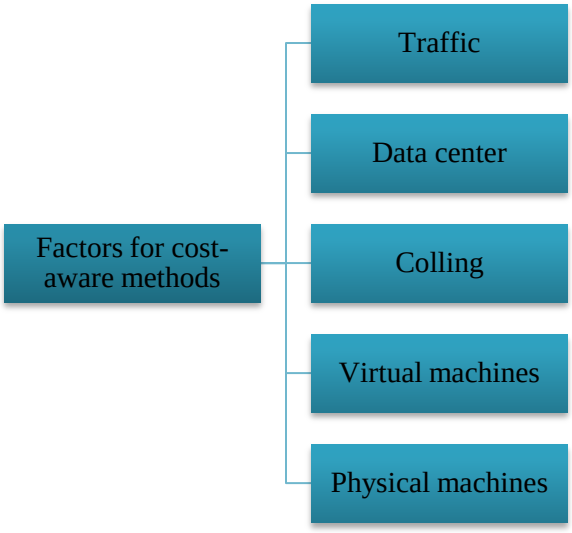

Fig. 2. Considered factors for cost-aware methods.

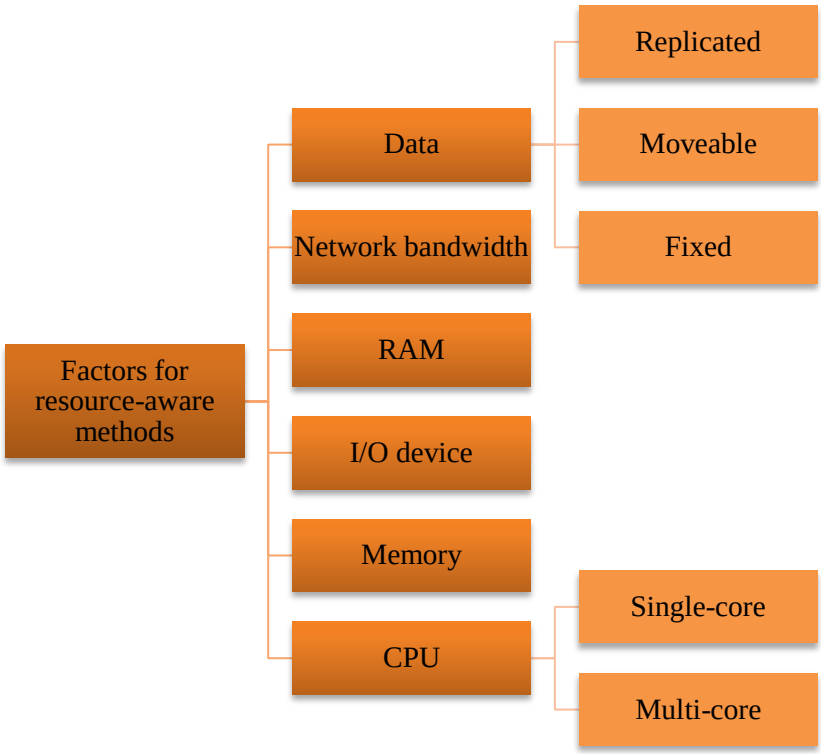

Fig. 3. Factors for resource-aware methods.

By utilizing virtualization technology extensively, data centers can optimize their resource management. The use of virtualization technology in cloud data centers optimizes the use of resources and minimizes operating costs. Cloud computing uses demand-driven resources such as VMs, to simplify the processing of complex duties. In addition, some VM allocation strategies attempt to place virtual machines at a minimum cost by considering various cost parameters. In this regard, as illustrated in Fig. 3, virtual machines or virtual data centers may be assigned different resources. Virtual machines are primarily equipped with a virtual CPU, which may either be single-core or multi-core. Virtual machines have access to crucial virtual resources, including network bandwidth and data. To optimize resource allocation for virtual machine applications, it is beneficial to place interacting virtual machines in close proximity. Additionally, the management of data, whether moveable, fixed, or replicated, depends on factors such as size and security policy.

Fig. 4 depicts the importance of considering traffic-related parameters, specifically the significant role of bandwidth, in improving the performance and efficiency of virtual machine allocation. Most approaches consider traffic between physical machines, traffic between interacting virtual machines, and traffic between virtual machines and their data repositories. Furthermore, as shown in Fig. 5, in the case of multiple-site clouds or geographically distributed clouds, a variety of factors will affect the location of the data center. Virtual machine allocation techniques, as shown in Fig. 5, depend on several factors, such as physical machine power consumption, number of physical machines, switches, and switch ports. Data centers are constructed based on specific topologies, taking into account these considerations.

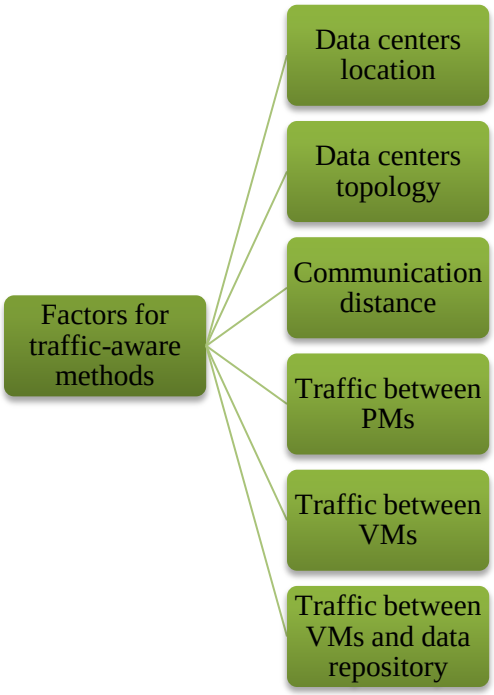

Fig. 4. Factors for traffic-aware methods.

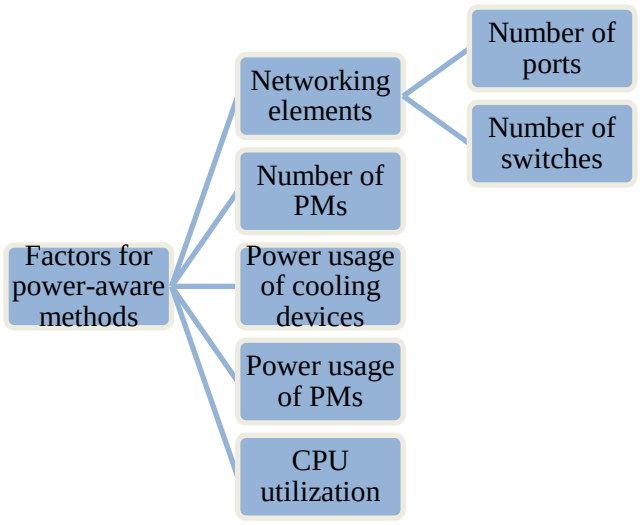

Fig. 5. Factors for power-aware methods.

Fig. 6 categorizes virtual machine allocation methods based on the availability of sites and clouds for virtual machine deployment. Both the single-cloud and multi-cloud models have the capability to utilize one or multiple sites to provide services. In the single-cloud model, services are offered from a single cloud provider's infrastructure, which may be composed of multiple sites or data centers. On the other hand, the multi-cloud model involves multiple cloud providers, each with their own sites or data centers, to deliver services. Various factors, including resources, location, performance, and cost, determine the selection of one or more sites. The aim is to ensure efficient service delivery, high availability, and scalability based on the specific needs of the applications or workloads. On the other hand, Fig. 7 classifies virtual machine allocation strategies in terms of load-aware parameters. These parameters are utilized by virtual machine allocation techniques to forecast and optimize virtual machine utilization.

Fig. 8 demonstrates the categorization of data-aware factors within a cloud data center, highlighting the significance of data characteristics in data-aware virtual machine allocation methods. Virtual machine allocation strategies are classified as dynamic and static. Virtual machine lifetime is the primary factor in static virtual machine allocation. The suitability of a physical machine to host a virtual machine is determined by its performance and longevity. During dynamic virtual machine allocation, the initial virtual machine assignment on PMs within a cloud data center can be modified based on certain factors, such as system load. Dynamic virtual machine assignment strategies can be categorized as reactive or proactive. During reactive virtual machine allocation, the initial placement changes when a particular undesirable state is reached. Modification of the initial placement of virtual machines is often necessitated by various factors such as SLA violations, load balancing, power consumption, and performance. Proactive virtual machine allocation methods proactively adjust the initial placement in advance of reaching a particular state or meeting specific demands. Virtual machine allocation techniques typically fall into one of two categories: allocation within a single cloud or allocation within a federated cloud.

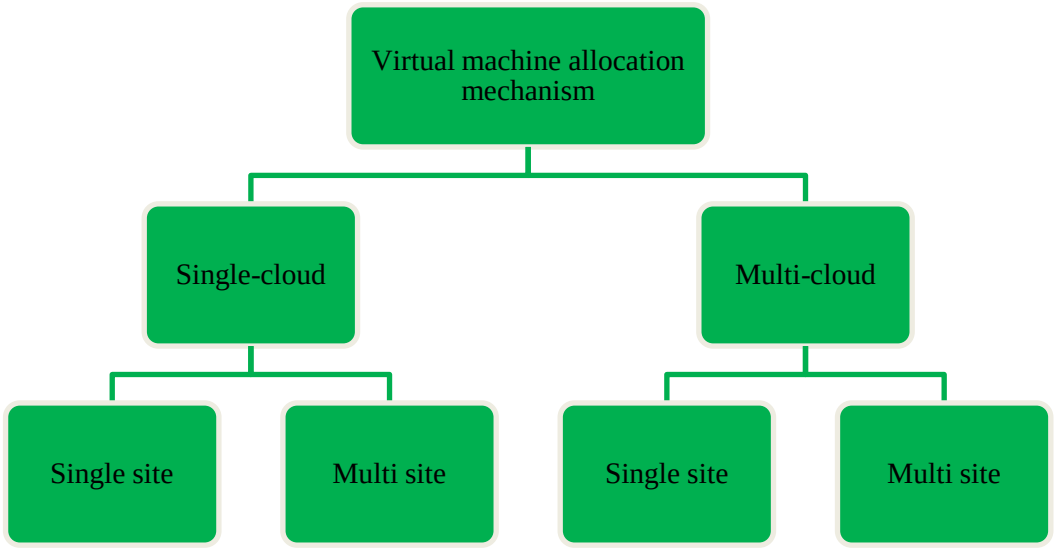

Fig. 6. Taxonomy of methods based on the number of clouds.

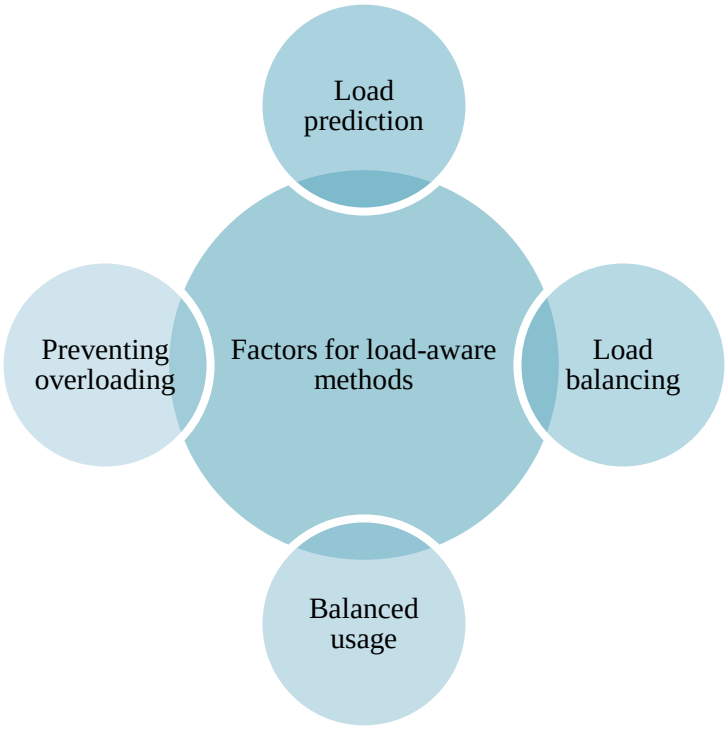

Fig. 7. Factors for load-aware methods.

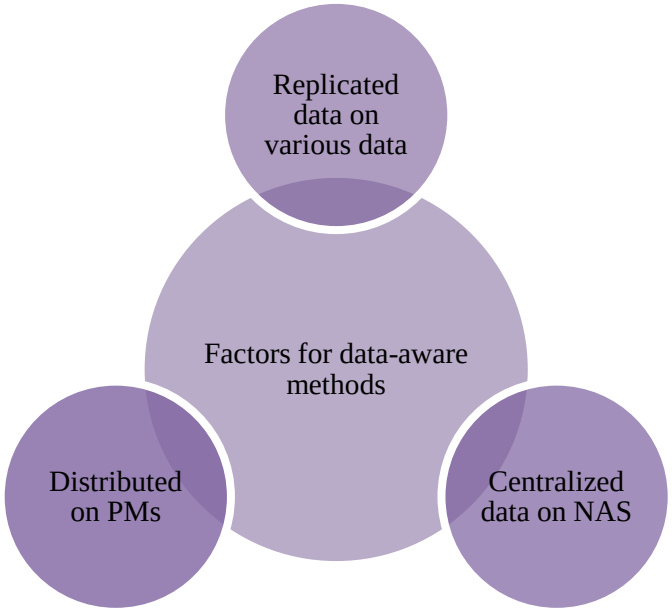

Fig. 8. Factors for data-aware methods.

Traffic in the cloud data center can be categorized into the inter-data center and intra-data center. These factors can be improved by optimizing the placement of virtual machines on physical machines. Additionally, achieving optimal allocation of virtual machines brings about significant enhancements such as increased availability, improved accessibility, higher performance, enhanced load balancing, reduced SLA violations, lowered costs in cloud data centers, decreased power consumption, and optimized resource utilization.

III. Review of the Selected Meta-Heuristic Algorithms

This section offers a detailed assessment of the selected virtual machine allocation methods, emphasizing their essential features, benefits, and drawbacks. We have conducted an analysis of nature-inspired meta-heuristic algorithms across various categories, including SA, PSO, HS, GA, FA, CSA, ABC, BBO, ACO, CSO, GRASP, SCA, PSOA, SFLA, and

TS. We examine the main characteristics and performance of these algorithms, allowing for a comprehensive understanding of their applicability to virtual machine allocation.

A. Ant Colony Optimization Algorithm

The ACO algorithm imitates how ants search for food. It has gained significant importance in addressing the virtual machine allocation problem in cloud computing. ACO employs a population of artificial ants that iteratively build solutions by depositing pheromone trails on a graph representation. These trails guide the ants to explore and exploit potential areas of the solution space. In the context of virtual machine allocation, ACO can effectively optimize resource allocation and load balancing and minimize energy consumption. By using the pheromone trails to represent the desirability of allocating virtual machines to specific hosts, ACO can intelligently guide the allocation process [21]. Due to its ability to find near-optimal solutions, adapt to dynamic environments, and deal with large-scale optimization problems, ACO provides a valuable tool for addressing VM allocation challenges in cloud computing.

Esnault, et al. [22] suggested a decentralized dynamic VM allocation method based on a Peer-to-Peer (P2P) network of PMs. The system utilizes a dynamic structure where neighborhood data is randomly exchanged among the PMs, eliminating the need for global system knowledge. This approach enables regular VM allocation within the local area, ensuring scalability even as the number of PMs increases. The neighborhood-randomized characteristics of this approach contribute to the convergence of the allocation, resulting in a performance that closely resembles a centralized one. Experimental results on the Grid'5000 testbeds demonstrate that this approach achieves global packing efficiency comparable to a centralized system, leading to increased scalability, resource utilization, and overall performance. This technique has the potential to disregard high SLA violations and create more PMs and migration overhead, which is important to keep in mind.

Feller, et al. [23] offered a novel dynamic VM allocation method to enhance resource utilization by reducing the number of running PMs according to the available resources. This is a distributed mechanism to solve two sub-problems: VM allocation optimization and PM status monitoring. The ACO algorithm has been applied to discover the best VM allocation solutions. Finally, the authors have shown that this technique on the real workload effects has improved performance and high scalability, reduced energy consumption and resource utilization, and fewer SLA violations. However, this method ignores high migration time and high migration overhead. Farahnakian, et al. [24] have suggested compatibility and integration of the ACO algorithm with optimal and balanced computing resources integrated with vector algebra. This technique minimizes resource wastage and energy consumption in virtual data centers by using the ACO-based server consolidation mechanism. Furthermore, this technique has low energy consumption, low time complexity, and high resource utilization. But this technique suffers from a high overhead VMs placement and low QoS.

Ferdaus, et al. [25] have proposed distributed system architecture to achieve a dynamic VM allocation method. The proposed method finds an optimal solution for a specified objective function. Energy consumption in data centers has decreased by assigning VMs to fewer active PMs while preserving QoS requirements. The technique incorporates inactive PMs and immigrants into a multi-objective model. Furthermore, the comparison has shown that this method reduced power consumption, increased performance, fewer SLA violations, and high resource utilization. However, this method ignores low scalability and high overhead migration.

Farahnakian, et al. [26] proposed a dynamic load balancing method based on the average load of the cloud data center. This technique has an algorithm for dynamic load balancing and VM allocation to decrease cloud data centers' energy utilization while preserving the desired QoS. In this method, the ACO-based VM allocation method is based on action artificial ants to allocate VMs to decrease the number of active PMs while satisfying the current resource requirements and also uses a dynamic threshold calculation approach to calculate the load of all active PMs and change the higher threshold value according to necessity. The comparison analysis has revealed that the method employing a static threshold scheme has effectively reduced the overall migrations of VM and power usage. The ant colony optimization approach gives a better result in combining dynamic threshold-based VM consolidation. Furthermore, low energy consumption, high QoS, and low SLA violation are some of the advantages of this method.

Matre, et al. [27] have offered a novel migration overhead-aware VM allocation mechanism based on the ACO algorithm for reducing asset usage for large info centers, computational overhead, and power usage. Data center elements and applications are also damaged by dynamic VM consolidation over VM-aware migrations. Therefore, a method for estimating migration overhead is suggested, incorporating pragmatic migration factors. Also, in this technique, to improve the system's scalability for large-scale data centers, a hierarchical, decentralized integration framework has been developed using localization of VM integration functions and minimizing their network impact. Nevertheless, this technique ignores QoS and migration time.

Ashraf and Porres [28] have presented a new workload-aware VM allocation method to reach efficient VM allocation on the basis of the MMAS (Max-Min Ant System) by applying multidimensional time-varying workloads. This method has used the perfect caseload models and multidimensional assets being heuristic variables, and the SLA model has been exploited to guarantee customer satisfaction. Also, this method examines both relations between workloads and the influence of resource-imbalanced usage, which decreases the server counts and resource waste. The proposed method offers several advantages, including resource utilization and high performance, ensuring efficient utilization of available resources in the cloud environment. Additionally, it aims to provide high QoS by optimizing VM allocation and minimizing resource wastage. Another significant advantage is the reduction in energy consumption, contributing to improved

sustainability and cost-effectiveness of cloud computing systems.

Malekloo, et al. [29] presented an energy-aware VM allocation method employing the ACO algorithm to minimize energy consumption in data centers. This method takes into account the energy consumption associated with VM migration as a key factor. As a result, it greatly decreases dynamic PMs and relocations number, leading to savings in energy utilization while ensuring QoS requirement are met through SLAs. The technique effectively decreases the migration rate and minimizes total energy waste in the network. It offers high adaptability, QoS, resource utilization, and low energy consumption. However, this method may face challenges in terms of scalability and overhead migration, which could impact its applicability in larger and more complex environments.

Aryania, et al. [30] proposed a multi-objective approach for VM allocation utilizing double thresholds and the Ant Colony System (ACS). This method focuses on VM consolidation and employs double thresholds to determine the conditions for consolidation. The authors use a mapping relation between VMs and hosts, treating the hosts as food sources, and optimize this mapping relationship through a multi-stage consolidation process based on ACS. By utilizing distributed search and the cooperation of artificial ants, the approach aims to achieve an optimal global mapping relationship between virtual machines and hosts. The performance of the proposed method is assessed by utilizing actual workload data and employing dual thresholds for CPU utilization. These thresholds help determine whether a host is experiencing an overload or underload condition. When a host falls into either of these categories, the process of VM consolidation is initiated. This consolidation process involves implementing specific policies based on the load status of the host, which in turn enables the migration of selected VMs to destination hosts using ACS. This method has some drawbacks, such as high migration time and limited scalability, which may affect its suitability for larger and more complex environments.

Xiao, et al. [31] proposed a new method called ELM_MPACS, which combines the multi-population ACS algorithm with Extreme Learning Machine (ELM) prediction. This method offers a lower complexity compared to other approaches. The ELM_MPACS algorithm operates in two steps. Firstly, it estimates the state of hosts using ELM, which helps determine whether a host is over-loaded or under-loaded. In the second step, if a host is found to be over-loaded, the virtual machine on that host is migrated to a normal host.

On the other hand, if a host is under-loaded, the virtual machine is consolidated onto another under-loaded host with higher utilization. The concentration of pheromones in the algorithm increases the likelihood of a combination being selected in the future. ELM_MPACS uses multiple populations to choose the ideal solution each time, increasing diversity and ensuring convergence. Experimental results have shown several positive outcomes, including improved resource utilization, reduced SLA violations, decreased energy consumption, and shorter migration times. This method provides promising results in terms of resource management, SLA compliance, energy efficiency, and migration efficiency.

B. Biogeography-based Optimization Algorithm

The Biography-based Optimization (BBO) algorithm is a nature-inspired metaheuristic algorithm used for solving optimization problems. It draws inspiration from the behavior of biographical organisms and applies it to various domains, including virtual machine allocation in cloud computing. BBO employs population-based techniques to efficiently explore the solution space, optimize resource utilization, and minimize energy consumption. Its adaptive nature makes it well-suited for dynamic cloud environments, leading to improved performance and resource efficiency [32].

Zheng, et al. [33] introduced a novel method for solving the VM allocation problem using the BBO algorithm. Their approach combines a Multi-objective BBO algorithm with Differential Evolution (MBBO/DE). In this method, each habitat represents a placement solution, where a vector of length n corresponds to n VMs mapped to m servers. Initially, the habitats of MBBO/DE are created using a random function to ensure diversity. Then, all habitats are evaluated using a cosine model to calculate the migration rate for each habitat. The next step involves migrating Similar Individual Vectors (SIVs) through the differential evolution strategy, where habitats in MBBO/DE share their SIVs, resulting in the creation of new habitats. Mutated SIVs are generated using a Gaussian model, producing potentially new optimal solutions. Multiple objectives are measured, and non-dominated sorting is employed to evaluate the effectiveness of each solution in MBBO/DE. Finally, a greedy one-to-one deletion mechanism based on differential evolution is used to select better habitats. If a new habitat outperforms the reserved elite habitat, it replaces the previous habitat; otherwise, the previous habitat remains. This method offers advantages such as low power consumption, reduced migration time, and improved resource utilization. However, it has some drawbacks, including lower Quality of Service (QoS), limited scalability, and higher overhead migration.

Shi, et al. [34] introduced a new multi-objective optimization method that builds upon the classical BBO algorithm to fix the allotment issue of the VM. The method proposes enhancements in the form of enhanced Cosine migration and mutation models aimed at improving the efficiency of attaining optimal solutions. By incorporating these enhancements, the algorithm aligns better with the actual VM allocation scenario. Furthermore, the algorithm focuses on optimizing three key objectives: migration resource overhead, load balancing, and server power consumption. Thus, the proposed improvements in the migration and mutation models are geared towards efficiently achieving these optimization goals in the context of VM allocation.

Zheng, et al. [35] have suggested a new approach for the VM allocation problem based on a multi-objective BBO algorithm in cloud-based environments. In this technique, after the initial parameters of the system are determined, the within-subsystem immigration is based on the ranking of the island within-subsystem, so the elementary population is the number of subsystems multiplied by the number of islands per

subsystem. Then, the subsystem migration is based on the likeness level among the subsystem pairs. The next step concerns the probability of mutation of each island, so if an island is selected for the mutation, the SIV is randomly selected from the island and replaced with a new randomly generated SIV. Finally, a modified non-dominant ranking system is used to select Nelite elites from the optimal answers of each subsystem and the elite of the previous generation. Then, if the repetition doesn't end, a new population is created for the next generation, and the Nelite matrices are replaced by the elitists generated in the last stage. Therefore, reduced power consumption, increased resource utilization, and high performance are the advantages of the method. However, this method suffers from high overhead migration, high time migration, and high SLA.

C. Artificial Bee Colony Algorithm

The Artificial Bee Colony (ABC) algorithm is a population-based metaheuristic optimization technique miming honeybee foraging behavior. It employs a diverse population of artificial bees, including employed bees, onlookers, and scout bees, to explore the solution space. The employed bees exploit food sources based on local information, while onlookers choose food sources based on quality. Scout bees introduce diversity by randomly searching for new food sources. Through iterative search processes, the ABC algorithm effectively balances exploration and exploitation, making it suitable for solving various optimization problems [36].

In their work, Jiang, et al. [37] have introduced an innovative VM consolidation policy that utilizes the ABC algorithm in conjunction with the Data-intensive Energy Evaluation Model. The objective of this policy is to minimize energy consumption costs and improve the SLAV value. By employing the ABC algorithm, the VM migration decisions are optimized, resulting in enhanced VM allocation. Moreover, the authors propose an energy efficiency evaluation model specifically designed for data-intensive tasks within green data centers. The model takes into account two influential factors: the CPU and GPU interest rates, which are observed through the behavior of data-intensive tasks in data centers. The VM allocation policy, based on the ABC utility, is then employed to minimize energy consumption and achieve satisfactory SLAV values. This approach effectively reduces energy consumption, the number of VM migrations, and SLAs while maximizing resource utilization and maintaining a high quality of service. However, it is important to note that this technique overlooks scalability and the overhead involved in the migration process.

Li, et al. [38] have introduced a novel approach called energy-aware dynamic virtual machine consolidation (EC-VMC) for VM migration. This method aims to address the constraints related to potential overloading across multiple sources. It employs a set of algorithms for selecting and placing virtual machines, taking into account the limitations of different sources within a physical machine while considering additional overhead. Additionally, the algorithm integrates and simulates the foraging behaviors of an artificial bee colony, treating the mapping relationship between PMs and VMs as a food source. By utilizing the search mechanism and optimization strategy of the ABC algorithm, the optimal mapping relationship is achieved globally, considering the multi-source constraints between PMs and VMs. Experimental results demonstrate that this method effectively reduces the VM's relocations number and power usage while ensuring large resource utilization and performance. However, it should be noted that this approach faces challenges related to overhead migration and scalability.

D. Chicken Swarm Optimization Algorithm

Chicken Swarm Optimization (CSO) is a swarm intelligence algorithm introduced in 2014 by Meng et al. It is a randomized optimization algorithm inspired by the group behavior of chickens searching for food. The CSO algorithm categorizes the chickens into roosters, hens, and chicks based on their fitness levels. Each type of chicken employs a different searching strategy, and the entire chicken swarm updates itself over multiple generations. One of the key strengths of the CSO algorithm is its ability to prevent getting trapped in local optima and instead find the optimal global solution for a given optimization problem. By mimicking the cooperative foraging behavior of chickens, the algorithm explores the search space effectively [39]. Tian et al. [40] have presented a new algorithm for Virtual Machine Consolidation (VMC) based on the Chicken Swarm Optimization model with deadlock-free migration (DFM-CSO). In this method, the consolidation VM design, which turns the VMC problem into a vector packing optimization problem according to deadlock-free migration, minimizes energy consumption. This algorithm is specified by the "one-step look-ahead with n VMs migration in parallel (OSLA-NVMIP)" method, which validates the VM migration and resets the aim physical host, also records the migration order for each solution placement so that VM transfer can be done according to the migration sequence. Furthermore, the algorithm reduces energy consumption, improves resource utilization, and reduces migration times. However, it exhibits low performance, low scalability, and a high migration overhead.

E. Cuckoo Search Algorithm

The Cuckoo Search Algorithm (CSA) is a metaheuristic optimization algorithm inspired by the behavior of cuckoo birds. It simulates the cuckoos' parasitic breeding manner, where they put their eggs in the nests of different bird species. In the CSA, each solution is represented as a cuckoo egg, and the nests represent potential solutions. The algorithm employs three key steps: (1) Lévy flights, which simulate the random walk of cuckoos, are used to generate new solutions; (2) some eggs are randomly selected for replacement to introduce diversity; and (3) the quality of eggs in the nests is assessed using an objective function, and the nests with higher quality solutions are more likely to survive. By iteratively repeating these steps, the CSA effectively explores the solution space and converges toward optimal or near-optimal solutions for optimization problems [41].

Joshi and Kaur [42] have proposed a new approach to solving the virtual machine consolidation issues based on a cuckoo search to save both power consumption and resource utilization in cloud space. The cuckoo search has been used to solve the problem of consolidation of the VM, which is similar to the bin packing problem. Therefore, in this method, it is

shown that the cuckoo search algorithm is a useful way to solve bin packing problems compared to other heuristics algorithms and can be efficiently used for the VM consolidation approach for both resource utilization and power consumption in the cloud network. This approach enables great source employment, less power usage, and great quality of service, reducing the number of PMs. Nevertheless, this method ignored overhead migration, time migration, scalability, and SLA violations.

Naik, et al. [43] have presented a new approach using a multi-objective Fruit-fly hybridized Cuckoo Search algorithm for virtual machine consolidation in the cloud environment. This algorithm is based on VM migration, which is used to reduce the over-provisioning of a PM by consolidating VMs on an underutilized physical machine. Thus, it relies on VM migration plans, which reduce the migration of PMs, consolidate under-utilized PMs, and select migrating VMs based on threshold significance. Multi-objective criteria should be used instead of single-objective criteria for placing and integrating VMs. The best host is detected from the host list. Compared with other methods, this method uses less power and resources, and it also reduces the relocations number. However, scalability, service quality, and violations of service level agreements were ignored.

F. Firefly Algorithm

The Firefly algorithm (FA), developed by Yang in 2008, was inspired by the flashing behavior of fireflies and uses swarm intelligence. Fireflies are also integrated to attract one another based on brightness. Therefore, light is considered a factor for absorption for flashing fireflies, and less brightness leads to a lighter situation. With increasing distance, attractiveness decreases directly with brightness. The goal function could be equated to the light to get the optimal solution [44].

Perumal and Murugaiyan [45] have proposed a novel for server consolidation and virtual machine placement problems that use a firefly colony and fuzzy firefly colony algorithms. The purpose of this method is to reduce the number of PMs utilized and solve the problem of VM disposition to achieve the right method with lower energy usage and lower waste of resources. Therefore, in this approach, both mentioned goals are considered simultaneously in the procedure of figuring out the ideal arrangement for setting up the virtual machine. One of the benefits of using fuzzy firefly colonies to solve virtual machine placement problems is that, unlike other algorithms, this algorithm works quickly and reduces randomization when searching for the optimal solution so that it will perform well. The fuzzy firefly colony method is provided with a rule of fuzzy probability to handle the behavior of the firefly probe with uncertainty. This technique reduces power consumption, maximizes resource utilization, and enhances performance. However, it ignores the number of migrations, SLA, migration time, and scalability.

John and Bindu [46] have proposed two new methods, the first being exploratory energy and temperature-based integrated temperature (HET-VC) and the second, virtual machine-based firefly and temperature-based integration (FET-VC). These methods are used to find the best solution in the problem space in improving the integration problems of virtual machines. Besides, in the proposed method, the current position and the next position after the migration of virtual machines will be updated at regular intervals. This method tries to decrease the number of transmissions and SLA violations, as well as decrease the energy consumption of servers. Besides, these two algorithms use high-performance servers that use the least CPU and RAM, as well as low temperatures, to integrate virtual machines. It suffers from high system overhead, long migration times, and limited scalability.

G. Genetic Algorithm

Genetic Algorithm (GA) was introduced in 1975 as a population-based optimization method with an evolutionary process. GA has been widely used to optimize VM integration parameters and also to solve optimization problems. In the GA algorithm, each chromosome represents a possible solution, and these solutions are combined by a string of genes. A fitness function is also used to check if the chromosome for the environment is right, and then crossover and mutation operations are used to produce offspring for the new population. The fitness function is used to assess the quality of each offspring, and this action is repeated until sufficient offspring are manufactured. Quick convergence and high processing time are the disadvantages of this algorithm [47].

Joseph, et al. [48] has proposed a novel technique to allocate virtual machines using the Family Gene approach. In this method, the host list and VM list are used for optimal mapping, and then the whole process is distributed among different families running in parallel in this module using the FGA module. Also, by using a self-adjusting mutation operator, an attempt has been made to reduce the rate of early convergence in this approach. Simple mutations are made to construct families. The resulting chromosomes, which are slightly different from each other, are placed in a family. Each family is processed "k" times. In the absence of a better individual being found by then, the family will be destroyed, and the next family will be taken in their place. In this way, the quality of each individual is determined by the amount of fitness value associated with that individual. Physical resource utilization is the purpose of the proposed method. In order to accomplish this, each individual's performance is evaluated so that if the individual fails, the impossible solution becomes feasible. This method performs well regarding energy consumption, resource utilization, and VM migrations. Nevertheless, it endures large upward and limited versatility.

Wu and Ishikawa [49] have presented an Energy-aware method for dynamic VM consolidation to reduce the energy consumed in heterogeneous cloud environments. In this method, the migration cost of the virtual machine and the amount of energy savings through the dynamic integration of the virtual machine in heterogeneous cloud data centers are investigated. Thus, a general assessment is defined by two opposing goals, namely, the cost of migration and energy saving. For this purpose, in this method, a merge score function has been arranged for total assessment based on the immigration cost estimation method and a high-limit estimation method for maximum saving power. Therefore, the IGGA algorithm, a kind of genetic grouping algorithm, is designed to enhance the merging score by a greedy heuristic

and an exchange action. The offered method offers better scalability, migration cost, QoS, power consumption, and resource utilization. But it ignores migration overhead, migration time, and SLA violation.

Wu, et al. [50] have presented a new method based on the evolutionary computing Adaptive Genetic Algorithm (A-GA) for the VM consolidation approach. This method has good performance in issues related to virtual machine consolidation in the areas of dynamism in resource utilization, VM migration number, failure reduction, SLA breach, and energy efficiency. Therefore, the suggested system can be used to manage large-scale cloud resources, reduce energy consumption, and increase QoS. Furthermore, the Minimum Migration Time (MMT) by VM selection policy based on VM placement or allocation has performed better than the Maximum Correlation (MC) and Random Selection (RS) method for energy utilization and QoS in minimal failure time and SLA violation. Furthermore, less power usage, large source employment, less relocation duration, less SLA violation, and high QoS are some of the advantages of this algorithm. However, high migration overhead and low scalability are some of the weaknesses of this algorithm.

Theja and Babu [51] have proposed an improved energy-saving asset allotment on the basis of a genetic method taking the power usage in cooler systems and IT items into account. They have focused on the problem of resource allocation and have evaluated various important issues in the cloud network, namely power and energy usage, VM's relocations number, and SLA violations. Also, the primary importance of considering various system parameters such as CPU, RAM, and network bandwidth in the decision-making process in their work has been evaluated. Most importantly, a comprehensive multi-objective policy has been used as a solution to the problem of resource allocation based on genetic algorithms to simultaneously reduce the power consumption of IT equipment and CRAC units.

Arianyan, et al. [52] have proposed a new approach with mixed-integer nonlinear programming (MINLP) formula for virtual machine integration problems in cloud computing that uses the genetic algorithm (GA) named energy and cost-aware VM consolidation or (ECVMC). They designed a mathematical model to reduce power consumption and costs using effective VM consolidation. In this method, by decreasing the number of active servers, the use of resources is maximized and minimizes total power consumption. Besides, this method decreases the placement process cost by discovering the optimal solution. As a result, low cost, low power consumption, and high resource utilization are some of the benefits of this method.

H. Greedy Random Adoptive Search Procedure Algorithm

The Greedy Random Adaptive Search Procedure (GRASP) algorithm was presented in 1989 to solve combinatorial problems by Feo and Resende. The GRASP is a meta-heuristic exploration based on a structural exploration that can create various initial solutions. This is a repetitive random optimization method in which each iteration involves two steps: one construction step and one local search improvement step. The construction step is an iterative greedy and adaptive process, and the second phase is a method of improving the local search for the initial solution, both of which are repeated for the maximum number of GRASP iterations. In the greedy construction stage, the list of solutions is made on the basis of greedy performance by randomly demoing the resolution habitat. In the second stage, a local search is performed to detect the best present solution from the formerly created solution list [53].

Ilager, et al. [54] have suggested a new method for a dynamic consolidation framework for the comprehensive controlling of cloud sources through enhancing cooling and computing systems. Via the Energy and Thermal-Aware Scheduling (ETAS) algorithm, they have controlled the trade among aggressive consolidation and the scattered distribution of VMs, which affects energy and hotspots. Also, the ETAS algorithm is designed to handle the trade-off between expense and time efficiency and could be adjusted as needed. Besides, based on the needs of the system, this algorithm is customizable to manage computation time and solution quality. Extensive experiments have been performed using real-world traces with precise thermal and power samples on this algorithm. Furthermore, this technique has advantages such as high QoS, less power usage, large source employment, and less relocation duration. However, this algorithm ignored scalability and performance.

I. Harmony Search Algorithm

The Harmony Search (HS) algorithm is a metaheuristic optimization technique inspired by the improvisation process of musicians in a musical ensemble. It mimics the harmony creation process, where musicians adjust their musical notes to achieve pleasing melodies. In the HS algorithm, a population of solution vectors represents musical harmony, and each element of the vector corresponds to a decision variable. Initially, random solutions are generated, and a fitness function evaluates their quality. Through iterations, new solution vectors are created by considering three main operators: pitch adjustment, harmony memory consideration, and randomization. These operators guide the search process towards better solutions. By continuously refining the harmony vectors based on their fitness values, the HS algorithm aims to find the optimal or near-optimal solution for the given optimization problem. The algorithm has demonstrated effectiveness in solving various complex optimization problems [55].

Fathi and Khanli [56] have suggested a new method based on the HS algorithm for the active allotment of VMs, which has been proven to be effective in power management systems. To solve the problem of virtual machine allocation, this algorithm has been used to detect an optimal solution. It defines a multi-objective function that takes into account both the number of silent PMs and the number of migrations and data center power consumption in each state. Also, some of the benefits of this method result in faster results, such as no need for basic parameters and no need to extract data. This method dramatically reduces energy utilization, resulting in fewer active PMs while maintaining QoS service quality standards. Furthermore, this algorithm has low SLA violations, low VM migration counts, high QoS, and low migration times. However, it ignores scalability and resource utilization.

Kim, et al. [57] have proposed a new method using a grouping agent approach and a meta-heuristic harmonic search algorithm for effectively solving the virtual machine allocation problem. In this algorithm, to solve VMC, the population number should be increased in proportion to increasing the size of the problem to certify search variety. In this case, the cost of searching for a solution may increase, so knowing that the number of VMs in virtualization is greater than the number of PMs, VMCs are targeted in such environments. Reflecting on this feature, the length of the solution will be reduced if the PM-based solution agent is classified instead of the VM-based redesign. Therefore, as the size of the problem increases, population growth becomes more linear and efficient search results. In this method, VMs have a unique workload pattern because they are provided in real-time using network resources. When migrating a virtual machine, depending on the VM time-series pattern as well as the number of resources allocated, the PM could be stabled by maintaining a good PM-VM map. Therefore, some advantages of this algorithm are low migration cost, low power consumption, high QoS, and high performance. However, this method suffers from high SLA violations, high overload migration, and low scalability.

J. Sine-Cosine Algorithm

The sine-cosine Algorithm (SCA) is an optimization method based on a population that performs the optimization function by applying a set of random solutions. These solutions are computed by a target function repeatedly in each iteration. In this method, the random set is repeatedly measured by a target function and improved by using a set of rules that is the core of this optimization method. The likelihood of global optimization increases with the right number of random solutions. In the optimization algorithms with enough random solutions and optimization steps (iterations), the possibility of discovering the global optimum increases [58].

Jayasena, et al. [59] have proposed a multi-objective approach based on the Multi-objective Sine Cosine Algorithm (MOSCA) for virtual machine allocation problems. This method is presented using a Multi-objective Evolutionary Algorithm based on Decomposition (MOEAD) and a Non-Dominated Sorting Genetic Algorithm (NSGAII). This approach generally focuses on evaluating and comparing multi-objective algorithms to find the optimal solution, as well as developing the MOSCA to figure out the resolution for the proposed VMC model. In this method, three conflicting goals discussed for the high energy efficiency of VMC are to reduce power consumption, achieve better SLAVs, and maximize MTBHS time. Therefore, the advantages of this algorithm are low power consumption, high resource utilization, low SLA violation, and high QoS. However, this method endures less versatility, high upward systems, and high migration time.

K. Penguin Search Optimization Algorithm

Penguins Search Optimization Algorithm (PSOA), introduced by Gheraibia and Moussaoui [60], is a meta-heuristic algorithm based on a common penguin hunting strategy. The algorithm is inspired by the penguin's search strategy, as they can combine their attempts and synchronize their dives to optimize global energy within the collective looking out and nutrition strategy. Each of them is represented by its place as well as the number of fish consumed. The distribution of penguins is determined by the number of prior fish in the area. Penguins are divided into groups, and they search in different situations. If the result of the number of dives is successful, Penguins return to the land and share important points such as places and a set of available food resources.

Jayasena, et al. [59] have presented a new method, according to the PSOA, for consolidating multiple virtual machines in the distribution of cloud-based hosting surroundings. This method uses the PSOA algorithm to make an economic VM consolidation and also supports scheduling for multiple VMs with different applications. The system can allocate VM resources for applications, reducing the number of VMs required. Therefore, the current strategy, by automatically planning and implementing several programs simultaneously with the specified features, provides the desired thinking in a very dedicated hosting space. Therefore, this algorithm, using placement rules, can lead to the Optimization of various multi-objective problems. Finally, this algorithm provides low power consumption and high QoS and reduces the number of PMs. However, this method ignored scalability and SLA violations, as well as resource utilization.

L. Particle Swarm Optimization Algorithm

The Particle Swarm Optimization (PSO) algorithm was introduced in 1995 by Kenney and Eberhart to find suitable solutions to continuous space optimization problems. The PSO algorithm uses a set of potentially random solutions (particles) to discover proper solutions to optimization problems. For each particle, the speed required to move in the search space is allocated. In each iteration, the speed of each particle is adjusted according to its best position and the position of the best particle in the total population. In this algorithm, each particle tracks its coordinates in the problem space with the optimal solution (fitness) obtained because each particle has internal memory. This algorithm has other benefits, such as combining local search methods with global search methods and trying to balance exploration and exploitation [61].

Dashti and Rahmani [62] have proposed a new method with a hierarchical architecture to meet the needs of producers and consumers, as well as a new service for scheduling consumer tasks in the PaaS layer. They have improved the allocation of dynamic resources and gained more benefits in the Personal Data Center by using the PSO algorithm. Therefore, PSO is used to ensure the quality of user services and reduce energy efficiency in redistributing migratory virtual machines in the overloaded host. In this method, low-load hosts and their power are consolidated to save energy. Also, there are balanced overload hosts used to ensure the quality of service during response times and deadlines. Therefore, this method offers less power usage, great QoS, and high source employment but ignores SLA violations and migration time.

Li, et al. [63] have presented a new approach based on several assets and energy-saving relocation and VMs' integration method under dynamic load and have arranged a double-threshold algorithm with multi-resource utilization for the VMs migration. One of the common problems of traditional heuristic algorithms in the field of virtual machine

consolidation is falling into local optima, which is prevented by using the Modified Particle Swarm Optimization (MPSO) method. Therefore, this method can reduce energy utilization with the QoS guarantee. Finally, the advantages of this algorithm are less power usage, great source employment, great QoS, and a reduced number of PMs. However, high system overhead and high migration time are some of the disadvantages of this algorithm.

M. Simulated Annealing Algorithm

The Simulated Annealing (SA) algorithm mimics the annealing process in metallurgy, in which materials are heated and slowly cooled to reduce defects and improve structure. In SA, the search process starts with an initial solution and iteratively explores the solution space by randomly making changes. These changes can be either accepted or rejected based on a probability determined by a cooling schedule. Initially, the algorithm accepts more changes, resembling a high-temperature phase, allowing for exploration [64]. As the temperature decreases, the algorithm becomes more selective, favoring changes that lead to improved solutions. This transition from exploration to exploitation helps the algorithm escape local optima and converge towards global optima. The cooling schedule controls the balance between exploration and exploitation. SA has been widely used to solve combinatorial optimization problems and has shown effectiveness in finding near-optimal solutions, even in complex search spaces [65].

Marotta and Avallone [66] have proposed a new model for solving consolidation problems using the SA algorithm, which solves these problems by evaluating the attractiveness of possible VM migrations. In this method, the attractiveness of virtual machine migration is considered through the use of resources and the energy efficiency of physical servers. Therefore, to reduce energy waste, the consolidation of the virtual machine in live VM migration is used. Increasing the overall cost efficiency by decreasing the number of active nodes is one of the main goals of this method. Therefore, the advantages of this method are low energy consumption, high resource utilization, and high performance. However, this method ignores the scalability count of migration and time migration.

Rajabzadeh and Haghighat [67] have proposed a new method based on an energy-aware framework for the consolidation of VM to optimize energy consumption and SLA violation reduction. In this approach, the whole process of allocating and managing virtual machines is divided into smaller parts, and each of these small parts is improved by new algorithms or existing algorithms. First, the hosts are determined by the critical mode. In the first stage, the host overload status is classified once with the possibility of violating the SLA and again without considering it. Then, in the second stage, using this algorithm, virtual machines are selected to migrate from important hosts. Therefore, using the SA algorithm, according to the list of selected virtual machines for migration, new hosts are selected as the migration destination of virtual machines. Eventually, the low-load hosts are identified and selected by the low-load host selection algorithm, and then all the virtual machines deployed on these hosts migrate, and the host goes to sleep off. All steps in this method are done in the distributed mode, except for the VM's disposition, which is done in the centralized model. Finally, the advantages of this method are low energy consumption and high resource utilization, low SLA violation and low migration time, and high performance. However, high overload and low scalability are some of the weaknesses of this algorithm.

Telenyk, et al. [68] have proposed a new optimization method using the SA to solve dynamic virtual machine integration problems, an extension of the bin-packing problem. In this system, to provide a new configuration, the optimized objective function of the proposed Simulated Annealing algorithm is used. This approach uses temperature as a control parameter when exploring to optimally map the allocation of virtual machines for the objective function. At each stage of the algorithm evolution, using the search function, the virtual machine allocation map becomes a new neighborhood state. The acceptance indicator of each new VM allocation map is compared to the current allocation map indicator to decide whether it is accepted or not. Therefore, the advantages of this method are low SLA violation, high resource utilization, and low energy consumption. However, high system overload and this method suffer from low scalability, low QoS, and high migration time.

Telenyk, et al. [69] suggested a new approach to dynamic VM allocation based on the SA algorithm so that it can calculate the cost of migration by a consolidation program. In this algorithm, the overhead cost resulting from the live migration of the virtual machine is calculated using an estimated model. The goals of this algorithm are to minimize the total energy consumption and minimize the total migration overhead. A static threshold-based method can be used to identify underloaded hosts in this approach. In this method, by selecting a host as the source PM, all its host virtual machines are selected for migrated to the out. Lastly, the SA is used to select the destination host. Thus, this technique has reduced energy consumption, living migration costs, and SLA violations, as well as the overall migration overhead. This method, however, neglected migration times, quality of service, and scalability.

N. Shuffled Frog Leaping Algorithm

The Shuffled Frog Leaping Algorithm (SFLA) was proposed by Eusuff and Lansey as an intelligent optimization algorithm that mimics natural organisms' behavior. It adopts a population-based approach and cooperative search paradigm to tackle discrete optimization problems. The SFLA incorporates a shuffling approach, facilitating the exchange of information between local search and global Optimization [70]. In this algorithm, frogs in the population symbolize tasks, and the positions of the frogs denote the mapping between VMs and their respective tasks.

Luo, et al. [71] suggested a new scheme based on energy-aware resource allocation for dynamic consolidation of VMs. This approach focuses on the infrastructure in which custom VMs run on the unsuitable servers of a data center as a service-oriented model. To properly manage resources, by achieving dynamic consolidation of virtual machine host resources and changing the mode of idle or low-consumption hosts to energy-saving mode, it is possible to use more energy resources and adhere to SLAs. Thus, a new hybrid intelligent algorithm using

the Modified SFLA based on Extreme Optimization (EO) called (MSFLA-EO) is used to quickly and efficiently complete the dynamic allocation of VMs. This method increases the SFLA frog's leaping visibility and improves local search capability. Finally, low energy consumption, high performance, reduced migration cost, and high resource utilization are some of the advantages of this algorithm.

O. Tabu Search Algorithm

Tabu Search (TS) is a metaheuristic algorithm developed by Glover to address mixed optimization problems like the bin packing one. TS utilize local searching to avoid being trapped in local optima and continue the search until the desired results are satisfied. The algorithm incorporates random selection to enhance the efficiency of searching and employs a "Taboo List" to restrict search movements and avoid cycles. The Taboo list serves as a short-term memory, keeping track of recently explored solutions [72]. Nasim and Kassler [73] introduced a novel approach that addresses the trade-off between resource conflict protection and the additional energy costs associated with increased server loads while addressing uncertainties in VM resource demand. This method utilizes a TS-based method coupled with greedy heuristics to explore local issues and repetitive resistance. The proposed method demonstrates the capability to achieve near-optimal solutions through robust discoveries and accurately address time-constrained online data optimization.

Moreover, the approach can be customized to accommodate varying resistance levels required by data center operators. The benefits of this algorithm include reduced power consumption, low resource utilization, and minimal VM migrations. However, it should be noted that this method has some drawbacks, such as lower performance and limited scalability.

IV. DISCUSSION

Meta-heuristic algorithms play a crucial role in the allocation of VMs in cloud environments. This problem involves efficiently allocating VMs to physical servers in cloud infrastructure, aiming to optimize resource utilization, energy consumption, and overall system performance. Cloud environments are complex and changing, making it difficult to find the best solutions. Nature-inspired meta-heuristic algorithms draw inspiration from natural phenomena, biological systems, and evolutionary processes to solve complex optimization problems.

Table I outlines the key features, advantages, and limitations of the discussed algorithms. These algorithms offer unique advantages for tackling the VM allocation problem in cloud environments. Each algorithm has unique traits and demonstrates gradual advancements. For example, GA demonstrates significant progress in its capacity to tackle intricate challenges, demonstrating gradual improvements in exploring various arrangements for effective VM placement. FA reveals gradual improvements in achieving a trade-off between exploration and exploitation, leading to faster convergence even in dynamic contexts despite initial difficulties. In addition, ACO and PSO algorithms demonstrate improvements in their capacity to handle dynamic environments, gradually addressing the scaling issues found in their previous generations. The incremental solutions emphasize the progressive path of meta-heuristic approaches, depicting their potential to adapt and improve in dealing with the complexities of VM allocation in the constantly changing field of cloud computing.

- Global search capability: Meta-heuristic algorithms excel in exploring a vast solution space, allowing them to identify promising solutions even in highly complex and large-scale cloud environments. These algorithms, such as genetic algorithms, PSO, and ACO, utilize search strategies inspired by natural systems to navigate the search space and find good solutions efficiently.
- Robustness and adaptability: Cloud environments are dynamic, with varying workloads and resource demands. Nature-inspired algorithms possess inherent robustness and adaptability, enabling them to handle the dynamic nature of the virtual machine consolidation problem. They can quickly adapt to changes in the cloud environment, such as VM migrations, workload fluctuations, and server failures, and reoptimize the VM-to-server allocation.
- Parallelism and scalability: Nature-inspired algorithms are inherently parallelizable, allowing them to leverage the distributed nature of cloud environments. Parallelism makes it possible for algorithms to manage large-scale cloud systems with multiple VMs and servers, enhancing scalability and speeding up the optimization process.
- Exploration-exploitation trade-off: Balancing exploration and exploitation is necessary for solving the virtual machine allocation problem. Nature-inspired algorithms inherently possess exploration-exploitation mechanisms, ensuring a balance between exploring the search space for new configurations and exploiting promising solutions to optimize VM placement.

By leveraging the strengths of nature-inspired meta-heuristic algorithms, cloud providers can achieve efficient and optimized VM allocation, leading to improved resource utilization, reduced energy consumption, and enhanced overall system performance. These algorithms offer powerful tools for addressing the complexities of virtual machine allocation in cloud environments and contribute to advancing cloud computing technology.

TABLE I. COMPARISON OF META-HEURISTIC ALGORITHMS FOR VM ALLOCATION IN CLOUD COMPUTING

Algorithm	Key Features	Advantages	Limitations
Ant Colony Optimization (ACO)	Pheromone trails Inspiration from ant foraging behavior	Good exploration robustness to dynamic environments	Slow convergence Scalability issues
Biogeography-Based Optimization (BBO)	Migration and evolution-inspired algorithm	Consideration of migration rates, habitat suitability	Parameter tuning required Scalability issues
Artificial Bee Colony (ABC)	Inspired by the bee foraging behavior	Fast convergence Simplicity	May get trapped in local optima Sensitivity to parameters
Chicken Swarm Optimization (CSO)	Inspired by the chicken foraging behavior	Simplicity Good exploration	Convergence speed may be slow Performance variation
Cuckoo Search Algorithm (CS)	Inspired by cuckoo bird behavior	Fast convergence Able to escape local optima	Parameter sensitivity Scalability issues
Firefly Algorithm (FA)	Inspired by firefly flashing behavior	Exploration-exploitation balance Fast convergence	Slow convergence Difficulty with dynamic environments
Genetic Algorithm (GA)	Genetic operators: selection, crossover, mutation	Good exploration Able to handle complex problems	Selection of suitable operators Parameter tuning
Greedy Random Adoptive Search Procedure (GRASP)	A combination of greedy and random search	Simplicity Fast convergence	May get trapped in local optima
Harmony Search Algorithm (HS)	Music-inspired algorithm with improvisation and memory considerations	Good exploration Robustness to noisy environments	Parameter tuning required Slow convergence
Sine-Cosine Algorithm (SCA)	Inspired by sine and cosine functions	Simplicity Fast convergence	Sensitivity to parameters Difficulty with complex problems
Penguin Search Optimization Algorithm (PSOA)	Inspired by the hunting behavior of penguins	Good exploration Robustness to dynamic environments	Limited scalability Parameter sensitivity
Particle Swarm Optimization (PSO)	Particle movement and social interaction-based algorithm	Fast convergence Good exploration	Difficulty in balancing exploration and exploitation
Simulated Annealing (SA)	Inspired by the annealing process in metallurgy	Good exploration Able to escape local optima	Parameter tuning required Slower convergence
Shuffled Frog Leaping Algorithm (SFLA)	Simulates the frog leaping behavior	Good exploration Able to escape local optima	Slow convergence Scalability issues
Tabu Search Algorithm (TS)	Uses tabu list to avoid revisiting recently visited solutions	Good exploration Able to escape local optima	May get stuck in suboptimal solutions Parameter tuning

V. OPEN ISSUES

- Resource Utilization: One open issue is optimizing the utilization of computing resources in cloud data centers. Dynamic workload patterns pose a challenge in allocating virtual machines to maximize resource utilization and ensure efficient task execution. Efficient allocation and placement algorithms are needed to adjust resource allocation based on workload variations dynamically.
- Energy Efficiency: Another open issue is the improvement of energy efficiency in VM allocation and placement. In cloud data centers, energy consumption is a major concern, and efficient allocation of VMs can help reduce overall power usage. Developing algorithms and techniques that consider energy consumption metrics and prioritize energy-efficient VM placement is crucial for achieving sustainable and green cloud computing environments.
- Quality of Service (QoS): Ensuring QoS requirements for applications running in cloud environments is a critical challenge. VM allocation and placement algorithms should consider factors such as response time, latency, throughput, and reliability to meet the performance expectations of users. Balancing resource allocation for various applications and providing adequate QoS guarantees is an ongoing concern in cloud computing.
- Security and Privacy: VM allocation and placement involve sensitive data and require protection against security threats. Ensuring secure communication, data integrity, and privacy preservation during the allocation process is a significant challenge. Robust security mechanisms and privacy-preserving techniques need to be integrated into VM allocation algorithms to mitigate risks and protect the confidentiality and integrity of user data.
- Scalability: As cloud computing environments continue to grow in size and complexity, scalability becomes an open issue in VM allocation and placement. Efficient allocation is crucial when handling a large number of VMs, hosts, and data center resources. Developing scalable algorithms that can handle the increasing scale of cloud environments is essential for smooth and efficient VM allocation and placement.
- Multi-objective Optimization: VM allocation and placement involve conflicting objectives, including enlarging asset usage, minimizing power usage, and meeting QoS requirements. Multi-objective optimization techniques that can balance these objectives and provide trade-off solutions are necessary. Developing algorithms that can handle multiple optimization objectives and consider the preferences and constraints of different stakeholders is an open research area in VM allocation and placement.

- Dynamic and Real-time Allocation: Real-time allocation of VMs to adapt to dynamic workload changes and user demands is an ongoing challenge. VM allocation and placement algorithms should be able to handle sudden workload spikes, failures, or changes in resource availability. Designing dynamic and adaptive allocation strategies that can efficiently respond to real-time changes in the cloud environment is crucial for maintaining performance and responsiveness.

VI. CONCLUSION

The VM migration process necessitates the allocation of VMs in cloud computing. Its objective is to identify the optimal PM for each VM. With an increase in the number of VMs deployed in data centers, it becomes harder to control the utilization rate of host PMs. This study emphasized the importance of meta-heuristic algorithms to develop effective approaches to VM allocation. A description and evaluation of the algorithms in each group are presented based on a number of relevant criteria, including resource utilization, number of PMs and VMs, migration time, energy consumption, migration overhead, and SLA violation. The results of the research indicate that no meta-heuristic algorithm has been developed to allocate VMs capable of meeting all the requirements. The review has also identified several challenges and limitations associated with existing methods. These include scalability issues, high computational overhead, and the need for improved adaptation to dynamic environments. Furthermore, the lack of standardization and benchmarking frameworks for evaluating the performance of different algorithms remains a critical concern.

Investigating the Effectiveness of ChatGPT for Providing Personalized Learning Experience: A Case Study

Raneem N. Albdrani[1], Amal A. Al-Shargabi[2]
Independent Researcher[1]
Department of Information Technology, College of Computer
Qassim University, Buraydah 51425, Saudi Arabia[2]

***Abstract*—The demand for personalized learning experiences that cater to the unique needs of individual learners has increased with the emergence of data science. This paper investigates the potential use of ChatGPT, a generative AI tool, in providing personalized learning experiences for data science education, specifically focusing on Deep Learning. The paper presents a case study that applies the 5Es model to test personalized learning for students using ChatGPT. The study aims to answer the question of how educators can leverage ChatGPT in their pedagogy to enhance student learning, and whether ChatGPT can provide a better learning experience than traditional teaching methods. The paper also discusses the limitations faced during the study and the findings. The results suggest that ChatGPT can be a valuable resource for data science education, providing personalized and instant feedback to learners. However, ethical considerations such as the potential for biased or inaccurate responses and the need for transparency in AI-generated content should be carefully addressed by educators. The study highlights ChatGPT's potential as a research tool for data science educators to investigate the effectiveness of AI in personalized learning experiences. Overall, this paper contributes to the ongoing dialogue on the role of AI in data science education and provides insights into how educators can utilize ChatGPT to enhance student learning and engagement.**

***Keywords*—Personalized learning; data science education; ChatGPT; generative AI**

I. Introduction

In recent years, technology has been transforming many aspects of our lives, and education is no exception. The rise of artificial intelligence (AI) and its applications in education, known as Artificial Intelligence in Education (AIED), have opened new possibilities for personalized and effective learning. The area of Artificial Intelligence in Education (AIED) has made significant progress in the last two and a half decades, particularly in the realm of technological advancements [1]. Moreover, the COVID-19 pandemic has accelerated the shift towards online and remote learning, increasing the demand for intelligent and adaptive learning technologies [2]. The potential for AI to revolutionize teaching and learning is immense, as it can automate tasks, process large quantities of data, and provide predictive insights. Intelligent Tutoring Systems (ITS), such as Beetle II, have demonstrated the potential of AI in education by using natural language processing and interactive experimentation to provide context-specific feedback to students and improve their learning outcomes[3].While the term "artificial intelligence" is broad and encompasses a range of technologies and techniques, the development of educational chatbots (EC) has garnered attention in the field of education. Built using Natural Language Processing (NLP), ECs offer immediate feedback to learners and assist in achieving educational and pedagogical objectives. Chatbots have been recognized for their potential in the realm of personalized learning, with Chen et al. [4] noting their benefits in this area. Additionally, Garcia Brustenga et al. [5] distinguished EC into two types: those with educational intentionality, which are designed to foster teaching and learning directly, and those without, which are incorporated into teaching tasks of an administrative nature. Colace et al. [6] argued that integrating chatbots in education can result in an engaging and interactive learning environment, similar to one-on-one interactions with teachers. The key for EC, in general, is personalized learning, as emphasized by Basham et al. [7], who state that personalized learning focuses on each student's individual skills and knowledge. It empowers learners to set goals, reflect on their progress, and extend their learning beyond the classroom [8].The research at hand centers around a particular chatbot-based AI platform, ChatGPT, which has attracted significant global interest and sparked a great deal of excitement among the public. Highlighting the uniqueness of ChatGPT as an AI platform and the potential impact it can have on personalized learning, it offers an advanced natural language processing system and the ability to provide tailored guidance and support to students. Through interactive conversations, ChatGPT creates a personalized learning experience that enables learners to receive immediate feedback, adapt their learning process, and explore knowledge in a flexible manner. This innovative AI platform holds great promise for enhancing personalized learning experiences and shaping the future of education. Despite the growing interest in the use of AI in education and the potential of chat-based AI tools like ChatGPT, there are still notable gaps and problems in existing studies. First, while some studies have explored the efficacy of personalized learning approaches, few have specifically investigated the integration of AI tools within this context. This leaves a gap in our understanding of how AI can be effectively harnessed to tailor educational experiences to individual learners. Second, limited research has specifically focused on the field of data science education and the potential benefits of AI-powered tools in this domain. This is particularly important given the rapidly evolving nature of data science and the increasing demand for skilled professionals in this field. Furthermore, while there have been studies examining the impact of AI

tools in education, there remains a lack of comprehensive exploration of the pedagogical methodologies and frameworks that can be successfully employed in conjunction with such tools. This gap hinders educators' ability to effectively implement AI tools like ChatGPT in their instruction and maximize their impact on student learning outcomes. To investigate the effectiveness of ChatGPT in providing personalized learning experiences, a case study approach with two groups, namely a control group and an experimental group, was adopted. The study involved a total of 20 students, with the experimental group having access to ChatGPT and learning through the guidance of the 5Es model, while the control group followed traditional learning methods. Data was collected to analyze the interactions and learning outcomes of both groups. This comparative analysis provides insights into the efficacy of ChatGPT as a personalized learning tool and its impact on student learning outcomes. The findings from this case study contribute to our understanding of the potential benefits and limitations of using ChatGPT in educational settings and inform the future development and implementation of AI-based educational technologies. In this study, the primary research objective was to investigate the effectiveness of ChatGPT in providing personalized learning experiences. The research questions that guided this study include: How does the use of ChatGPT impact student engagement and participation? What are the effects of ChatGPT on student learning outcomes? How do students perceive the personalized learning experience facilitated by ChatGPT? By addressing these research questions, this study aims to contribute to our understanding of the potential benefits and limitations of using ChatGPT as a personalized learning tool and inform the future development and implementation of AI-based educational technologies. By addressing the existing research gaps, and providing evidence-based recommendations on the effective usage of AI-enabled tools like ChatGPT, this study has the potential to enhance the student's learning experience, particularly in the field of data science education.The paper structure provides an overview of ChatGPT and its related studies, discusses personalized learning and AI in education, introduces the 5Es model, employs a methodology to test personalized learning using ChatGPT, presents and analyzes the study results, discusses limitations and implications, and draws conclusions emphasizing the importance of ChatGPT as a resource for data science education and ethical considerations. The paper contributes to the discourse on the role of AI in education and highlights how educators can use ChatGPT to enhance student learning and engagement.

II. CHATGPT

ChatGPT is an AI-based natural language processing model developed by OpenAI and launched in November 2022. It utilizes the GPT (Generative Pretrained Transformer) architecture that employs a transformer network to generate human-like text. This model has been extensively trained on a large volume of text data, enabling it to generate responses on a wide range of questions and topics. ChatGPT has been successful in achieving state-of-the-art performance on various language tasks, including language translation, text completion, and question answering. It can be used for various applications such as chatbots, language learning tools, and text-based virtual assistants [9]. ChatGPT has revolutionized the world of AI and chatbots and has gained popularity with people relying on it in many aspects of their lives, given its ability to mimic human-like conversations and follow up responses. The popularity of ChatGPT has been rapidly increasing over time, especially on social media platforms, where people are becoming more aware of the capabilities of AI. Since its release, ChatGPT has been inspiring people to create various AI tools, indicating the growing interest in the field of AI. As AI technology continues to advance, it is becoming increasingly important to understand ChatGPT's potential use and how to leverage its capabilities in the most effective and efficient ways possible. Biswas [10] has explored the potential use of ChatGPT in climate change research, suggesting that the model could be valuable in generating and analyzing different climate scenarios using diverse data inputs, ultimately enhancing the accuracy of climate projections. Additionally, Biswas [11] also discussed the potential use of ChatGPT in military applications, such as providing instant language translation and aiding in intelligence analysis. The model can also play a significant role in public health by supporting individuals and communities in making informed decisions about their health [12]. Numerous studies have explored the potential use of ChatGPT in education. Tlili et al. [13] conducted research on the subject, analyzing tweets to gain insights into public discussions about ChatGPT's role in education. Additionally, they conducted interviews with individuals who had used ChatGPT in an educational context and found that users considered ChatGPT to be highly valuable for revolutionizing education. However, some concerns were raised regarding its use. According to UNESCO [14], for teaching and learning ChatGPT can be used as collaboration coach, personal tutor, a study buddy and more. Furthermore, Kung et al. [15] discussed the ability of ChatGPT to perform clinical reasoning by testing its performance on questions from the United States Medical Licensing Examination (USMLE) and the potential of ChatGPT to assist in medical education. While Cooper [16] conducted a study that shows ways to use ChatGPT in science education and asked questions related to science to test ChatGPT's responses. In the realm of potential applications, Ray [17] has explored the versatility of ChatGPT across different fields. In the education sector, ChatGPT has shown promise in personalized learning, language acquisition, and test preparation. It has also demonstrated potential in domains such as healthcare, law services, content generation, programming, and marketing. The broad range of areas where ChatGPT can be utilized highlights its adaptability and the wide array of benefits it can offer across various industries. ChatGPT, like any AI technology, brings forth several challenges and ethical considerations when applied in education. One of the primary concerns is data privacy [17]. As ChatGPT interacts with students and collects data, ensuring the privacy and security of sensitive information becomes paramount. Educational institutions and developers must implement robust data protection measures to safeguard student data and comply with relevant privacy regulations. Another significant consideration is algorithmic bias. AI models like ChatGPT are trained on vast amounts of data, which can inadvertently perpetuate biases present in the training data [17] . This bias can manifest in responses or recommendations provided by ChatGPT, potentially reinforcing stereotypes or discriminatory practices. It is essential to address and mitigate algorithmic bias through careful data curation, diverse training datasets,

and ongoing monitoring of model outputs. Furthermore, over-reliance on AI without human guidance can pose challenges. While ChatGPT offers personalized learning experiences, it should not replace human teachers or mentors. The role of educators in guiding and contextualizing knowledge remains crucial. Striking a balance between leveraging AI tools like ChatGPT and maintaining human interaction and guidance is necessary for effective and holistic education.

III. Related Work

In this literature, we are providing precious works, researches that discussed personalized learning and the effect of using chatbots in education. As ChatGPT is still considered to be new to its field there's not yet much case studies or researches about using it in education. However, Tlili et al. [13] conducted a study on the impact of ChatGPT on education by analyzing three stages, including tweets and interviews with teachers and students, as well as investigating user experiences. The overall findings of the study were encouraging, with positive feedback on the effectiveness of ChatGPT in revolutionizing education and providing a comprehensive understanding of complex topics in a simple language. However, the researchers also highlighted some concerns that need to be addressed to ensure ChatGPT's efficiency in education. While Cooper [16] illustrated ways where ChatGPT can be helpful to generate ideas when designing science units, rubrics, and quizzes, in his study he interacted with ChatGPT and asked questions in which he considered the answers are extraordinary however he believes that there's a lack of evidence to the answers and misleading information. And in the context of educational chatbots in general Colace et al. [6] created a EC and tested its behavior for over than 180 students especially testing behavior, keeping track of progress, and assigning tasks, in this case study researchers tested three different situations Chatbot furnishes a correct suggestion, Chatbot furnishes a correct suggestion but it does not fit with the real needs of the student, and Chatbot furnishes a wrong suggestion the result was Correct Suggestion: 133 student, Correct Suggestionn but not suitable for the needs of the student: 30 student, and Wrong Suggestion: 24 student, the students found the EC user friendly and easy to use comparing to other chatbots. Furthermore Schmulian and Coetzee [18] developed two chatbots were developed to support personalized learning by fulfilling the role of a co-teacher in finding answers to commonly asked questions. This approach was aimed at addressing some of the challenges associated with teaching large groups of students. The study revealed that the chatbots were well-received, with 72 of the respondents expressing satisfaction and even affection towards the chatbots. Additionally, the study found that many students reported higher engagement levels when interacting with the chatbots as compared to a traditional face-to-face classroom environment. According to the study by Kumar and Silva [19], they addressed the challenge of student acceptance towards chatbots for personalized learning. They created a chatbot using Telegram and the results showed a positive response. The respondents indicated that chatbots have various advantageous features such as quick responses, accessibility, mobility, user-friendliness, human-like conversation, and private interaction. The study also highlighted that chatbots could be used for personalized feedback, guidance, peer-peer assessment, critique, and communication management. These automated attributes can lead to more effective interactions while maintaining privacy boundaries between instructors and students. The findings of the study suggest that chatbots can be a useful tool for learning, with potential future applications in education. In a study conducted by J. Pereira [20] involved creating a multiple-choice question (MCQ) chatbot to assist in the training of university students. The students were receptive to the bot and expressed interest in having similar tools integrated into other subjects. The researcher predicts that in the future, there will be a significant increase in the use of learning-oriented chatbots, which will offer personalized user experiences. Each student will have access to personal teacher assistants or learning coaches in the form of chatbots. Both ChatGPT and EC have a common foundation in personalized learning, which forms the fundamental concept of their educational approaches. I believe that personalized learning serves as the fundamental building block for both tools. According to Lee, Huh, Lin, and Reigeluth [21] believed that personalized learning is an effective approach for tailoring instruction to meet the individual needs and previous experiences of learners. This customized approach allows everyone to maximize their potential by receiving instruction that is specifically designed for them.

IV. Methodology

This research study aimed to investigate the effectiveness of ChatGPT in providing a personalized learning experience in the context of deep learning. The study employed a case study design with a mixed-methods approach, combining quantitative data from quiz results and qualitative observations. A total of 20 participants were involved in the study, comprising 10 students in the experimental group and 10 students in the control group. The participants were selected based on their interest in learning about deep learning and their varying levels of prior experience with ChatGPT. The participants were enrolled in an Internet of things class at Qassim university and had a basic understanding of machine learning concepts. The procedure consisted of the several steps, The first step was Lesson Preparation, I carefully prepared the lesson materials, ensuring that they covered the essential concepts and topics related to deep learning. The content included explanations of forward propagation, activation functions, convolutional neural networks, and network architecture. I also developed a set of multiple-choice quiz questions to assess the participants' understanding and knowledge. After preparing the lesson I instructed ChatGPT to provide tailored instructions and explanations to each student from the experimental group, based on their individual learning needs and prior knowledge. Drawing inspiration from Cooper [16], the researcher developed a teaching unit based on the 5Es Model, which served as the foundation for creating an automated lesson using this approach. The effectiveness of the 5Es Model was further supported by the findings of Sibel et al. [22], who demonstrated its positive impact in a relevant case study. As a result, the lessons were meticulously designed, aligning with the structure and principles of the 5Es Model, which involved engaging the students, exploring the concepts, explaining the principles, elaborating on the ideas, and evaluating their understanding. Throughout this process, ChatGPT assumed a pivotal role as a virtual assistant, actively supporting the students by addressing their queries, presenting pertinent examples, and guiding them throughout their learning

journey. Next stage Control Group, The control group received traditional instruction from a teacher who followed a standardized curriculum for teaching deep learning. The teacher delivered the content through lectures, and practical exercises, following a well-established approach to teaching the subject matter. The control group followed a structured lesson plan that aligned with the curriculum and did not involve the use of ChatGPT. After completing the lessons, both the experimental and control groups were given the same multiple-choice quiz. The quiz assessed the participants' understanding of deep learning concepts and their ability to apply the knowledge they had acquired. The quiz questions covered topics such as forward propagation, activation functions, convolutional neural networks, and network architecture. The quiz was administered in a controlled environment to ensure consistency across both groups. The last stage of the study is Data Collection and Analysis, The quiz results were collected and analyzed to compare the performance between the experimental and control groups. Quantitative analysis involved assessing the scores and identifying any significant differences in the performance of the two groups. The data from the quiz provided insights into the effectiveness of ChatGPT in facilitating personalized learning experiences in comparison to traditional instruction. Additionally, qualitative observations were made during the lessons to gather insights into the participants' engagement, interaction, and overall learning experience.

V. Result

A. Analysis of 5ES Model Implementation

Generally speaking, The analysis of the case study highlights both the advantages and limitations of using ChatGPT to guide students through the 5Es model. Despite some limitations, the 5Es model proved to be an effective framework for student engagement and learning. One of the limitations observed was that ChatGPT occasionally provided incorrect evaluations of the students' answers during the evaluation phase. This indicates a need for caution and verification when relying solely on ChatGPT's feedback. However, the 5Es model served as an effective guide for students. It helped structure the learning process and provided a clear framework for students to follow. The sequential progression through the engagement, exploration, explanation, elaboration, and evaluation phases allowed students to have a comprehensive learning experience. The personalized nature of ChatGPT as a tool was particularly beneficial. It served as a virtual co-teacher, offering guidance and support tailored to each student's needs. This individualized approach helped foster a sense of ownership and agency in the learning process. The quiz results played a significant role in reflecting the students' experience. Some students were able to answer all the quiz questions correctly, indicating that they successfully grasped the concepts and information provided by ChatGPT. However, there were instances where students made errors or skipped questions, suggesting the need for further clarification or reinforcement in certain areas. The integration of the 5Es model as a guide alongside ChatGPT was particularly valuable, especially considering that a majority of the students were unfamiliar with ChatGPT initially. The 5Es model provided structure and support, ensuring that students had a consistent and cohesive learning experience. The students who had prior familiarity with ChatGPT had a more positive experience overall. Nevertheless, it was important to have teacher supervision to ensure smooth progress and address any errors or deviations from the 5Es model that ChatGPT occasionally encountered. In certain instances, ChatGPT would repeat certain steps or omit them, necessitating the intervention of a teacher to correct and realign the learning process. In Fig. 1 of the lesson, it can be observed that ChatGPT progressed to the next step of the 5Es framework after the student joined the conversation and completed the first E. Subsequently, ChatGPT followed the same pattern for the subsequent E, as depicted in Fig. 2.

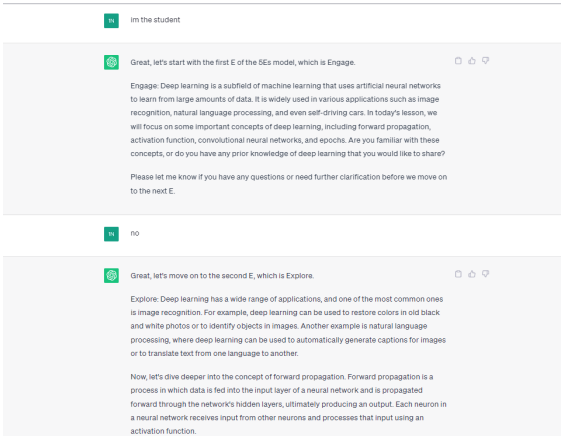

Fig. 1. ChatGPT lesson - Part 1.

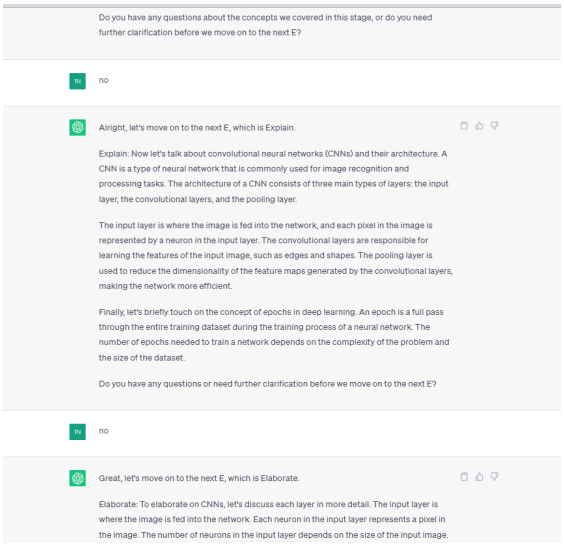

Fig. 2. ChatGPT lesson - Part 2.

In the final stage of the lesson, which was the Evaluate phase, ChatGPT effectively implemented it as a multiple-choice question (MCQ), following the instructions provided at the beginning of the lesson as shown in Fig. 3.

B. Analysis of Control Group by Teaching Traditional Way

The analysis of the control group's performance reveals important insights. Initially, the majority of students demonstrated a good understanding of the topic, as indicated by their correct

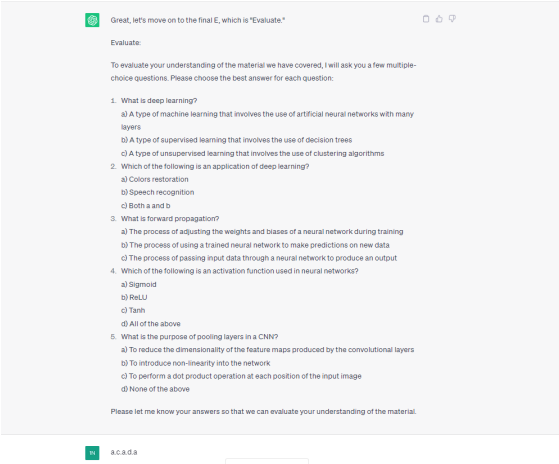

Fig. 3. ChatGPT evaluation quiz.

responses to the first question. However, there was a decline in the number of correct responses in subsequent questions, suggesting a potential decrease in comprehension over time. This raises concerns about the long-term retention of the material taught through traditional teaching methods, indicating that students may struggle to retain and apply the information beyond the immediate context. Furthermore, the varying number of correct responses across questions highlights differences in students' comprehension levels for different topics or concepts, emphasizing the need for further investigation and targeted teaching strategies. The presence of incorrect responses also signifies that the traditional teaching method may not effectively address the learning needs of all students, necessitating the exploration of alternative instructional approaches catering to diverse learning styles and abilities. These findings suggest that the traditional method of teaching has limitations in terms of long-term knowledge retention and ensuring uniform comprehension among students. To overcome these limitations, it is crucial to explore innovative teaching methods, incorporate active learning strategies, and provide personalized support to enhance student engagement and understanding. Further research and analysis are necessary to deepen our understanding of the effectiveness of traditional teaching methods and compare them with alternative approaches, ultimately leading to improved learning outcomes and student success.

VI. Discussion

The discussion in this study involved the qualitative analysis of the results from two groups, namely the experimental group and the control group, to examine the function of ChatGPT as an AI assistant in facilitating personalized learning experiences for students. While there are alternative approaches and methods that can be explored in future studies, our focus was on utilizing the 5Es model to address our research questions.

A. How Does the use of ChatGPT Impact Student Engagement and Participation?

The integration of ChatGPT in the experimental group, guided by the 5Es model, positively impacted student engagement and participation. The personalized nature of ChatGPT as a virtual co-teacher provided individualized guidance and support to students, fostering a sense of ownership and agency in the learning process. This individualized approach helped increase student engagement as they received tailored feedback and support, leading to active participation throughout the learning activities. The structured framework of the 5Es model, combined with ChatGPT's assistance, facilitated a more interactive and engaging learning environment for the students.

B. What are the Effects of ChatGPT on Student Learning Outcomes?

The implementation of ChatGPT alongside the 5Es model resulted in positive effects on student learning outcomes. The quiz results showed that a significant number of students in the experimental group were able to answer the questions correctly, indicating successful comprehension of the concepts and information provided by ChatGPT. The sequential progression through the engagement, exploration, explanation, elaboration, and evaluation phases of the 5Es model allowed students to have a comprehensive learning experience. The personalized guidance and support from ChatGPT contributed to improved learning outcomes by addressing individual learning needs, reinforcing understanding, and providing opportunities for active application of knowledge.

C. How do Students Perceive the Personalized Learning Experience Facilitated by ChatGPT?

The students in the experimental group perceived the personalized learning experience facilitated by ChatGPT positively. ChatGPT served as a virtual co-teacher, offering tailored guidance and support, which helped students feel supported and encouraged throughout the learning process. The individualized approach enhanced their learning experience, allowing them to progress at their own pace and receive immediate feedback. Students appreciated the interactive nature of ChatGPT and the opportunity to engage in dialogue with an AI-powered assistant. The integration of the 5Es model alongside ChatGPT provided a structured and cohesive learning experience, which students found beneficial in terms of clarity and organization.

Overall, the analysis suggests that the use of ChatGPT positively impacts student engagement, learning outcomes, and perception of personalized learning experiences. The integration of ChatGPT alongside the 5Es model provides an effective framework for student engagement, fosters active participation, enhances learning outcomes, and supports students in their individual learning journeys. However, it is important to acknowledge some limitations in this study. Firstly, the sample size of the experimental group may be relatively small, limiting the generalizability of the findings. Additionally, the study primarily focuses on short-term effects, and further research is needed to assess the long-term impact of ChatGPT on student learning and retention. Moreover, the reliance on technology and the potential for technical issues or errors in ChatGPT's feedback pose challenges that need to be considered. Despite these limitations, the findings highlight the promising potential of ChatGPT as a tool for enhancing student engagement and learning outcomes in the educational setting.

VII. Conclusions

This study employed a qualitative approach to investigate the effectiveness of ChatGPT, a chatbot tool, in education, particularly in the context of technology and personalized learning. By conducting a study consisting of two groups, namely the experimental group implementing the 5Es model with ChatGPT and the control group using traditional teaching methods, the analysis sheds light on the efficacy of different approaches in promoting student engagement, learning outcomes, and personalized learning experiences. The integration of ChatGPT with the 5Es model in the experimental group proved to be effective in engaging students and providing a structured learning experience. The sequential progression through the model's phases facilitated comprehensive learning, with ChatGPT serving as a valuable virtual co-teacher that enhanced student engagement and agency. However, the occasional incorrect evaluations by ChatGPT necessitated teacher supervision to ensure a smooth learning process. In contrast, the control group's traditional teaching method exhibited limitations in terms of knowledge retention and uniform comprehension. The declining trend in correct responses across questions indicated potential challenges in long-term retention, emphasizing the need for alternative instructional approaches and personalized support to accommodate diverse learning styles and abilities. These findings underscore the importance of exploring innovative teaching methods, incorporating active learning strategies, and providing personalized support to enhance student engagement and understanding. Further research is necessary to gain deeper insights into the effectiveness of traditional teaching methods compared to alternative approaches and to identify the most effective instructional strategies for improving learning outcomes and student success. In conclusion, the integration of ChatGPT with the 5Es model demonstrated promise in terms of engagement, structure, and individualized support, while the traditional teaching method highlighted the need for improvements in knowledge retention and comprehension. These findings contribute to the ongoing conversation about enhancing teaching and learning practices, ultimately aiming to create meaningful and effective educational experiences for students.

Securing Digital Data: A New Edge Detection and XOR Coding Approach for Imperceptible Image Steganography

Hayat Al-Dmour
Faculty of Information Technology
Mutah University
Mu'tah, Karak, Jordan

***Abstract*—The rapid progress of digital devices and technology, coupled with the emergence of the internet has amplified the risks and perils associated with malicious attacks. Consequently, it becomes crucial to protect valuable information transmitted through the internet. Steganography is a tried-and-true technique for hiding information beneath digital content, such as pictures, texts, audio, and video. Various methodologies of image steganography have been developed recently. In image recognition, edge detection secures an image into well-defined areas. This paper introduces a novel image steganography algorithm with edge detection and XOR coding techniques. The proposed approach aims to conceal a confidential message within the spatial domain of the original image. In contrast to uniform regions, the Human Visual System (HVS) is less responsive to variations in the sharp areas; an edge detection algorithm is applied to identify edge pixels. Furthermore, to enhance the efficiency and reduce the embedding impact, XOR operation has been utilized to embed the secret message in the Least Significant Bit (LSB). According to the results of the experiments, the proposed method embeds confidential data without causing noticeable modifications to the stego image. The proposed method system produced imperceptible stego images with minimal embedding distortions compared to existing methods. Based on the results, the proposed approach outperforms the conventional methods regarding image distortion techniques. The PSNR values achieved by the proposed method are higher than the acceptable level.**

I. Introduction

Data security is considered one of the most noteworthy factors of Information and Communication Technology (ICT) due to the rapid growth in electronic technologies and the internet. Therefore, a necessary prevention mechanism is needed to protect the data securely. Commonly, sensitive information can be protected either by using cryptography or Steganography. The technique of cryptography conceals the contents of sensitive data to unreadable text by several transformations; however, Steganography is the art of concealing data in an explicit transport file in such a manner that unapproved third parties find it challenging to discover and retrieve the concealed data [1]. An image is represented as an array of numbers corresponding to the light intensities at different points, known as pixels. These pixels collectively form the raster data of the image [2]. At the same time, digital images are the most common form of cover object used for Steganography, as they are the most prevalent carrier on the internet [3]. Image steganographic methodologies can be classified into the Spatial domain and Transform domain methods. In the Spatial domain, the intensity of the pixels is used to implant information. In contrast, information is embedded in the frequency domain of the previously transformed images in the Transform domain. In image steganography, confidential information is protected from malicious attacks by changing the pixels, and the modifications applied to the image are made unnoticeable. The original image without sensitive information is called the cover image, while the cover image with secret information embedded in it is called the stego image. Steganography requires two files: the message and the cover image, which conceal the message. Digital images are preferred over videos due to their compact and smaller size compared to the large and redundant size of the videos when transmitted over low bandwidth networks [4].

The image's detailed contents, information, and features cannot be observed by the Human Visual System (HVS) or the naked eye. Therefore, the use of techniques becomes necessary to check whether an image is an original or a stego image. It is essential to evaluate the strengths and weaknesses of steganography methods based on various characteristics [5]. Some important requirements conflict with each other to develop a reliable steganography algorithm. The three fundamental characteristics of image steganography are capacity, robustness, and imperceptibility. A cover medium's capacity refers to how many bits it can contain. Imperceptibility and robustness are standard requirements that conflict with embedding capacity. Imperceptibility refers to the quality of the stego carrier. The steganography algorithm satisfies the imperceptibility requirement, even though the stego carrier content may differ from the original one if that difference cannot be noticed by the human visual system (HVS) [6]. The imperceptibility is usually computed by the Peak Signal Noise Ratio (PSNR). Greater PSNR means higher imperceptibility. Robustness relates to the strength of the stego medium to endure different types of manipulation. It is, therefore, hard for attackers to illegally modify or remove the embedded secret data [7].

Different image steganography techniques are used to embed the information in the cover media, i.e., spatial and transform domain techniques. The Least Significant Bit (LSB) replacement is one such approach that seeks to replace the least significant bit of each pixel with the associated concealed data

pixel. As a result, such a pixel's initial magnitude changes by 0 or 1, a tendency repeated throughout the cover picture. Least Significant Bit (LSB) is the most widely used method for image steganography based on spatial domain techniques. In this method, the message is embedded in LSB directly [8].

The research problem at hand revolves around enhancing image steganography techniques to embed data securely while maintaining imperceptibility and robustness. This research aims to answer the following questions:

- How can image steganography methods be improved to enhance imperceptibility without compromising capacity?
- What novel approaches can be developed to ensure secure and undetectable data embedding in images?

The main contribution of this study lies in the proposition of an image steganography method based on edge detection, guaranteeing identical edge images in the original and stego images while securely embedding messages. This approach ensures that the concealed message can be correctly extracted from the stego image. The results of the experiments show that the proposed method embeds secret data without causing noticeable modifications to the stego image.

The rest of this work is structured as follows. Section II presents the most recent steganography techniques. The proposed scheme is explained in Section III. Section IV reports on the experimental results, analysis, and discussion. Section V brings the paper to a conclusion.

II. Steganography and its Techniques

Steganography is a scientific discipline that involves concealing data within another form of data. For example, it can include hiding a plaintext message within an image file. Throughout history, various entities such as individuals, the military, secret intelligence agencies, and governments have leveraged Steganography to covertly communicate and transmit information without arousing suspicion. Steganography has a wide range of uses, including confidential communication, electronic watermarking, reliability of data, copyright protection, and identifying manipulation of data [9]. Extensive research work has been carried out to develop digital image steganography. The LSB technique was one of the first to obscure data transmission by embedding secret data into unimportant bits of pixels. LSB approaches, in general, substitute the identical length bits in each underlying pixel with the embedding data. Nevertheless, not all pixels in the image can have equal levels of alteration without producing apparent distortion [10]. The stego image resembles the original image because altering the LSB of such a pixel does not significantly alter the color. Despite this, not all pixels in an image are capable of enduring equal amounts of modifications without noticeable distortion resulting in a low-quality stego image. To handle this issue, some image steganography methods based on LSB have used HVS features to conceal the secret bits in the cover image [11].

Image Steganography is achieved by conducting an XOR operation on the bits of pixel values. In this regard, Joshi et al., retrieved the two rightmost LSBs and two leftmost MSBs of the pixel value using their method. They combined the first and second bits using the XOR operation. The message bit 0 was concealed in the LSB of the pixel value if the result of the two XOR operations was 11 or 00, and the message bit 1 was hidden if the impact of the two XOR operations was 10 or 01 [12].

XOR is the logical operation performed on the LSB and MSB based on the technique. Based on the result of the XOR operation, the message is embedded in the LSB of a particular pixel. Baek et al., suggested a method for embedding the information in the grayscale image to share it secretly. They used the XOR operation to represent the bits at a specific location in the image [13].

Further, a previous study proposed a complicated method for image steganography to hide information in the LSB area of an image pixel. The authors used the XOR operation three times before embedding the message in the LSB. XOR operation was performed on the three MSB bits. This operation behaved as a key to embedding a message in an image. Better security was provided using this simple operation. A study proposed an alpha-trimmed mean filter to enhance the image quality, whereas they used XOR operation on 6-MSBs to add two bits of secret message in the image at 2-LSBs [12].

Additional options for concealing the information included two levels of encryption and an obfuscation phase. Two XOR operations and a private key were used to encrypt the data. The LSB method was then used to incorporate the information in the cover picture. One straightforward XOR-based process selected the colors using a sequencing technique and modified several LSB methods. Three MSBs were utilized as the key in the steganographic procedure, and they employed a triple XOR literary content that needed to be delivered [14].

The least significant bit of an image is subjected to an XOR procedure. When an 8-bit random key is used in the application, pixel 1 from the red matrix's second bit is XORed with the pixel. Because the result of the XOR of the taken bit 1 and the taken bit 0 is 1, the pixel must be satisfied by delivering an encrypted message that conceals the value of the pixel's first LSB bit. The pixel will pass if the XOR operation returns a result of 0, but the following step's process will continue using the same 8-bit random key. Based on the length of the encrypted message, this procedure will continue [15].

To find the secret message, bits from a pixel were extracted and saved in an encrypted message. In the recovery process, pixel 1 of the second bit for the red matrix and the 8-bit random key is XORed with the pixel, and the result of the XOR of bits 1 and 0 is 1. Consequently, the pixel must convey an encrypted message buried in the value from its first LSB. The pixel will pass if the supplied response during the XOR operation is 0, but the following step in the procedure will still use the same 8-bit random key. Following the completion of this phase, the decrypted image is extracted from the stego-image. These bits are taken into the LSB of the identical pixel shown in the stego-image. This process continues till the length of the message is sent [16].

III. Materials and Methods

Compared to smooth regions, the human visual system is less sensitive to modification in image regions with sharp transitions. To attain undetectable Steganography, the secret

message has to be embedded in the edge regions of the cover image. Regardless of how insignificant the changes are in the cover image, conventional edge detection methods produce sensitive edge images. Since hiding the message might cause some alterations to the cover image, this feature restricts the implementation of image steganography based on edge detection. The edge detection technique is commonly used in digital images to determine if each pixel has a high or low spatial frequency [17]. It is the technique of finding locations in a computer image where the image brightness swiftly changes, for example, pixels diverging from minimal intensities to high intensities or the other way around, displaying certain discontinuities [18]. Therefore, this paper presents a new image steganography method based on edge detection that produces identical edge images in the original and stego images. Sobel and Canny edge detection methods are used to extract edges. The Canny edge detection method was created by John Canny in 1986. It is one of the most efficient and well-known [19]. Therefore, Sobel and Canny edge detection method gives the identical edges of both the original and stego-image. In this way, the concealed message can be correctly extracted from the stego image.

In the proposed method, three bits of the message are embedded in a grayscale image intended for transmission to the receiver. The colored image has three channels: Red, Green, and Blue, each of matrix length and width of image size. In the case presented, the input image is in a grayscale where only one channel represents the image in one matrix. The method is centered on the advantage of XOR operation. The XOR operation is performed on 4-pixel values to get 3 XORed results. Three bits of message XORed with four least significant bits of the image to embed 3 bits of message in stego image. The block diagram of the proposed methodology is given in Fig. 1. The steps of the proposed image steganography algorithm are as follows:

Step 1: Convert the image into grayscale.

Step 2: Resize the image into 512 x 512 to get a uniform image size.

Step 3: Perform Edge detection on the image using Canny or Sobel edge detection methods.

Step 4: Convert the message (secret message to be sent) into decimal using the American Standard Code for Information Interchange (ASCII) code character by character.

Step 5: Convert decimal ASCII codes for each character into a binary format where ASCII-encoded data is of 8-bit length.

Step 6: Iterate over 3 bits of the message (secret message to be sent).

Step 7: Get 4-pixel locations in the cover image from the identified edges, i.e., P_1, P_2, P_3, and P_4, where P_1, P_2, P_3, and P_4 are the pixel 4-LSBs of the cover image.

Step 8: Calculate the XOR operation on P_1 and P_2, P_3 and P_4 and P_1 and P_3 as follows:

$$k_1 = P_1 \oplus P_2 \ , \ k_2 = P_3 \oplus P_4 \ , \quad k_3 = P_1 \oplus P_3$$

Step 9: Embed message bits into the stego image based on the XOR calculated by comparing the three estimated bits, $k1$, $k2$, and $k3$, with the three secret message bits according to Table I.

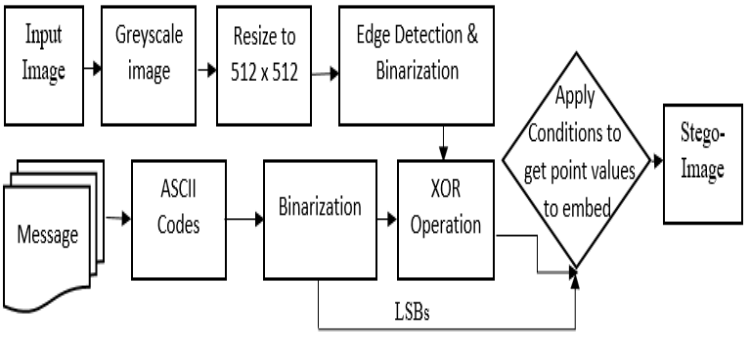

Fig. 1. Block diagram of the proposed methodology.

Step 10: Convert the image matrix from binary to decimal to get the stego image matrix.

In the first step, the RGB image is converted to grayscale. After that, the cover image is resized to a fixed size of dimensions 512×512, where the image contains 512 rows and 512 columns. Then, Canny or Sobel edge detection methods are performed to detect edges in the image.

Edge detection is the technique for identifying points in digital images with discontinuities. It is an abrupt change in the brightness of the image. The point where this change occurs is the edge. The four groups of edges are created that represent the place where the message has to be embedded. The location of four points, P_1, P_2, P_3, and P_4, are extracted from the edges. Fig. 2 shows an example of edge detection. The edges are calculated to store the message and the position for steganographic content (secret message) is calculated as X in Fig. 2. The position of x is calculated using the location of edge detection points, and then XOR these points with each other. Edge detection is performed using two types of edge detection methods: Sobel filter and canny edge detection, for images to use for XOR coding in image steganography.

The Sobel filter is an edge detection method for digital images. It is also called Sobel Feldman sometimes. Edges are the discontinuities in the image that cause a rapid change in intensity value, as discussed earlier. It uses a filter in both vertical and horizontal directions, producing thick and bright edges in every direction. It uses gradient operation. The estimated magnitude of gradient operation is measured using the sum of specific values of slope in two directions: horizontal and vertical.

Canny edge detection is the method for detecting edges in the image. It uses three criteria to detect edge detection performance: localization precision, SNR, and single-edge response precision. It produced the best results in many problems.

In order to send secret messages, steganographic codes are converted into ASCII codes. Subsequently, the binary data was obtained by converting it into binary codes (ASCII), enabling the application of embedding using the suggested XOR approach. Just on spots located using the edge detection technique, XOR was used. The process begins with the points $P1$, $P2$, $P3$, and $P4$, and then XOR is performed to

TABLE I. CONDITIONS TO EMBED THE MESSAGE

Condition Description	Action
All m bits match k bits	-
if m3 does not match k3	$\bar{P}3$ and $\bar{P}4$
if m2 does not match k2	$\bar{P}4$
m2 does not match k2 and m3 does not match k3	$\bar{P}3$
if m1 does not match k1	$\bar{P}2$
m1 does not match k1 and m3 does not match k3	$\bar{P}1$
m1 does not match k1 and m2 does not match k2	$\bar{P}2$ and $\bar{P}4$
None of the m bits match their corresponding k bits	$\bar{P}1$ and $\bar{P}4$

$P1$, $P2$, $P3$, and $P4$ and recorded the results in $k1$, $k2$, and $k3$, where $k1$, $k2$, and $k3$ are indeed the XORed results of the estimated edge point.

Based on the above conditions, shown in Table I, three message bits are embedded into four-point locations that were extracted using the edge detection method. Hence, three message bits are embedded into the image, showing the average embedding is 1.25 bits.

To extract the messages from steganographic images, it starts with calculating the edge based on the same method used during the embedding process. The points were identified using edge detection, as shown in Fig. 3. For example, a total of 1000 edges are presented in the file, enabling the embedding of three bits in four-point locations, thereby accommodating 750 bits within 1000 edges. Nonetheless, 2 bits are used to predict the threshold and 1 bit for data embedding. In every position, the first two bits are used to indicate the threshold, and then the next bit is used to embed the data; using this way, the 1000 locations will get reduced to 3 times = 333 locations. Now in 333 locations, the data is embedded, which reduces the embedding rate. Conversely, it enhances data corruption if any attack on the image happens.

As the locations chosen for embedding the data are not employed to predict the edges, this technique enhances the extraction process. These are the edge points where the XOR operation was performed to embed the secret messages. Once these points are calculated and represented to get m1, an XOR operation is performed on q1 and q2. To get m2, the XOR operation is performed on q3 and q2. To acquire m3, the XOR operation is conducted on q1 and q3. The block diagram for extracting the message is shown in Fig. 3.

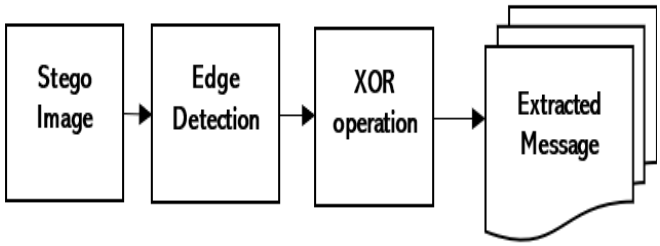

Fig. 3. Block diagram for message extraction.

IV. RESULTS AND DISCUSSION

Distortion evaluation methods are the methods that measure the distortion in the image by comparing the original image and the steganographic image. PSNR, the number of edges in the image, SSIM, MSE, and UQI are used to evaluate image distortion in the image. The proposed method is evaluated using various embedding distortion evaluation methods.

PSNR is the peak signal-to-noise ratio. It is the ratio between the peak signal, which means the maximum power of the test image, and the noise, maximum noise. Noise is the image distortion that affects the image's representation quality. It is calculated as shown in Eq. 1.

$$PSNR = 10\log_{10}\left[\frac{255^2}{MSE}\right] \ (dB) \tag{1}$$

MSE is the mean squared error in the image, calculated by the mean of squared differences between input and steganographic images. The difference is calculated from pixel to pixel in an input image and stego image. The summation of all the pixel differences is then divided by the total number of pixels, that is, width x height of the images (input and stego). Eq. 2 represents how the mean squared error is calculated.

$$MSE = \frac{1}{WH}\sum_{i=1}^{W}\sum_{j=1}^{H}(I_{ij} - SI_{ij})^2 \tag{2}$$

Where Iij and $SIij$ represent the pixel value at the location i and j in the input image and stego-image. At the same time, W and H are used to represent the width and height of both of the images.

SSIM is the structural similarity index. It is the quality measure of the image that represents the image degradation after performing the Steganography in the image. It is calculated by the lamination, contrast, and structure between the input image and the stego image. To calculate the SSIM, local mean, standard deviation, and cross-covariance are used between input and stego image. It is the perceptual difference between both images. Eq. 3 is used to calculate it.

$$SSIM(I, SI) = \frac{(2\mu_I\mu_{SI} + C_1)(2\sigma_{ISI} + C_2)}{(\mu_I^2 + \mu_{SI}^2 + C_1)(\sigma_I^2 + \sigma_{SI}^2 + C_2)} \tag{3}$$

Where I, SI,$\sigma I\sigma SI$, and σISI represent the local mean, standard deviation, and cross-covariance for both images.$C1$

and $C2$ are the regularization constants. UQI is the universal image quality. It is the ratio between the multiplicative variance and summation of variances of the input image and stego-image.

In order to perform the experimentation, the benchmark dataset of USC-SIPI is used. The experimentations are conducted on 8 images from the dataset, as shown in Fig. 4. The dimension of 512×512 is utilized, as already discussed in the methodology. The images for this experimentation purpose are (a) Baboon, (b) Boat, (c) Couple, (d) House, (e) Lena, (f) Pepper, (g) Sailboat, and (h) Tank.

Distortion evaluation is performed for two cases: Sobel filter and Canny edge detection, after completing the distortion

evaluation methods on message loads of 24000, 32000, 4000 and 48000 bits, respectively. The obtained results for tl message load of 24000 bits are shown in Table II. Tables III, IV, and V represent the results obtained on message load of 32000, 40000, and 48000 bits, respectively, for both cases. As shown in Tables II, III, IV, and V, both edge detection methods performed well. The result shows that when the message load is increased, the image quality is degraded. The image steganography can be applied on smaller message loads for better securing the data. As much as the message load increases, then the image quality degrades. Hence, it would be prone to be detected as a stenographic image.

The statistics provided show the proportion of even and odd pixels for every pairing of pictures. The cumulative numbers are quite comparable both before and after. Consider that the discrepancy between the sum of the variations and the number of manuscripts in the secret message is less. Fig. 5(a) shows the edge pixels of the cover image, which is identified by applying Sobel edge detection. Edge pixels of the stego image obtained after embedding a message are shown in Fig. 5(b), and Fig. 5(c) shows the difference between the two edge images. This indicates that the edge pixels in the cover and stego images are similar.

The image quality improves as more data is in the stego image and with the increase in the number of edges. The peak noise signal (PSNR) method for implementing the steganography procedure is the primary determinant of optimizing efficiency. The stego image will be more similar to the actual image if PSNR quality increases. The hiding capacity is increased with the pixel in stenography.

These findings show that the pictures look entirely unmodified to the unaided eye and are statistically the same. It is challenging for a person looking at both images or a computer looking at just one image to notice the possibility of increasing statistical similarity by introducing noise. Before and after changes, the ratio of even and odd dots is approximately the same. PSNR and MSE are used to assess the quality of stego images compared to cover images. Based on experimental results, the proposed method achieves a high-quality image by using the XOR operation to reduce the difference between the cover and stego images. PSNR values vary between 65 dB and 62 dB with embedding rates of 9% - 18%, where 35 dB is the minimum acceptable value.

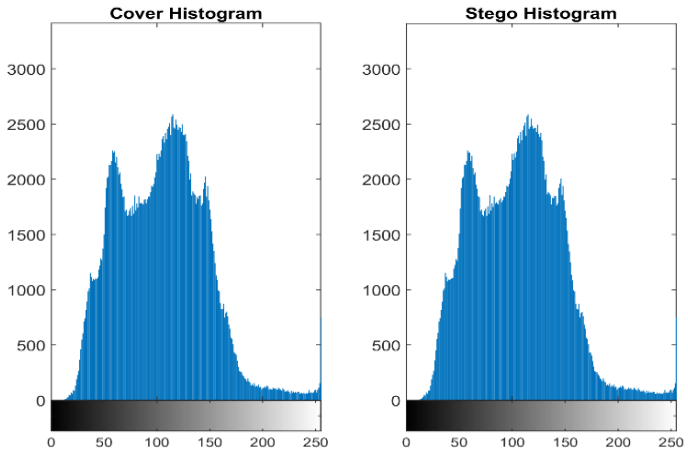

Fig. 6. (a) The cover image histogram and (b) The histogram of the corresponding stego image using the proposed algorithm.

The visual differences between the cover and stego images cannot be discovered by the human eye, and even the histograms of the stego images (illustrated in Fig. 6(a) and 6(b) are pretty similar. The algorithm's effectiveness was demonstrated by employing LSB for steganographic techniques and evaluating the histogram, PSNR, safety, and resemblance between human and machine readings.

V. Conclusion

The human eye is capable of detecting a significant variation in an image pixel. This means that the edges of an image might allow greater distortion than the other sections of the cover image since the edge portions have a sharper shift in pixel values than those that surround them. As a result, in edge-based Steganography, the majority of message bits are embedded in the edge pixels, and as one moves from the edge regions into the homogeneous areas of the cover picture, the number of bits embedded reduces, making the distortion less visible to the human eye. In this paper, an XOR-based embedding method was proposed to embed the data into the image. Sobel and Canny edge detection methods were used to extract edges. Sobel edge detection method is the traditional edge detection method used a few years ago [14], [20]. On the identified edges, an XOR operation is performed, which is a disjunction property [19]. The embedding capacity of an image is enhanced by edge detection methodology. In the presented method, a good rate of PSNR has been achieved.

Using an edge detection approach along with multiple-bit modification methods leads to high security. The contribution of this paper is embedding the message efficiently by incorporating XOR coding and identifying identical edges in the cover and stego images using the traditional edge detection methods. The technique was tested on various image distortion methods. The proposed approach performed efficiently, as shown in the results. The intensity of the edges in the input and steganographic images are estimated to be identical. The MSE is almost zero on a message load of 24000, 32000, 40000, and 48000 bits. Universal image quality and SSIM are closer to one representing the image quality, and the similarity between cover and stego images is almost the same. The approach may be expanded to several picture formats, including grayscale images, and requires no further information other than the stego image.

In terms of benefits, the suggested solution is undetectable since it only employs three LSBs to hide the secret data in the pixels of the detected edges. Furthermore, the recommended approach scatters bits of the secret data over specific regions of the identified edges rather than over all pixels of the carrier picture. A second benefit is that the buried data may be recovered. Different outputs for the same input image and secret data can be generated by hiding the secret data using a specific pattern denoted by the Canny algorithm, as well as parameterizing the algorithm to allow communicating parties to alter the effects and results of the algorithm.

Incorporating News Tags into Neural News Recommendation in Indonesian Language

Maxalmina Satria Kahfi, Evi Yulianti, Alfan Farizki Wicaksono
Faculty of Computer Science, Universitas Indonesia, Depok, Indonesia

***Abstract*—News recommendation system holds the potential to aid users in discovering articles that align with their interests, which is critical to alleviate user information overload. To generate effective news recommendations, one key capability is to accurately capture the contextual meaning of text in the news articles, since this is pivotal in acquiring useful representations for both news content and users. In this work, we examine the effectiveness of neural news recommendation with attentive multi-view learning (NAML) method to conduct a news recommendation task in the Indonesian language. We further propose to incorporate news tags, which at some levels may capture the important contextual meanings contained in the news articles, to improve the effectiveness of the NAML method in the Indonesian news recommendation system. Our results show that the NAML method leads to significant improvement (if not comparable) in the effectiveness of neural-based Indonesian news recommendations. Further incorporating news tags is shown to significantly increase the performance of the NAML method by 5.86% in terms of NDCG@5 metric.**

***Keywords*—News recommendation; recommendation systems; news tags; user modeling**

I. Introduction

A recommendation system plays a crucial role in helping users discover items that match their needs and preferences [1]. In business, it is a vital part of marketing strategies, particularly for boosting online sales by offering customers a curated selection of items tailored to their preferences [1, 2]. This process of recommendation can be automated using a wide range of techniques, such as content-based methods and collaborative filtering [3], and recently involves computing user and item embeddings which serves as a basis for predicting how much a user is likely to prefer a particular item [4, 5]. Recommendation systems have found application in various domains, including movie recommendation [6, 7, 8], news recommendation [9, 10, 11, 12, 13], and music recommendation [14, 15, 16, 17].

News recommendation stands as one of the most frequently employed use cases of recommendation systems within the digital landscape, notably embraced by online platforms and news publishers [2, 18, 10]. Given the overwhelming amount of news articles generated daily, it is impractical for users to manually sift through all of them to find content that aligns with their interests [19]. Every day, an enormous volume of news articles is generated and published online, posing a challenge for users to efficiently discover news that aligns with their interests [2, 20]. Therefore, the implementation of personalized news recommendation becomes vital, as it enables online news platforms to target user preferences effectively and alleviate the issue of information overload [10].

In the past few years, news recommendation models have benefited from the use of deep learning methods [9, 11, 10, 13, 12]. These models are often referred to as neural recommendation models. Various neural recommendation models have been introduced to tackle news recommendation challenges, including NAML (Neural news recommendation with Attentive Multi-view Learning) method [11]. The NAML method uses an attentive multi-view learning model that learns unified news representations from different kinds of news information, such as news titles, bodies, and categories. This method takes advantage of multiple useful information from news articles that could enrich the semantics captured in the news representation. As a result, this method has been shown to outperform a range of deep learning methods for news recommendation, such as Convolutional Neural Network (CNN) [21], Deep fusion model (DFM) [22], Deep news recommendation based on knowledge-aware CNN (DKN) [23], etc. The NAML method also offers the flexibility to incorporate other useful information that could be exploited from news articles to produce more accurate news representation, which may result in more effective news recommendations. With this reported effectiveness as well as the potential to utilize extra knowledge for improving news representation, we propose to use the NAML method to perform the Indonesian neural news recommendation task in this work.

As mentioned above, the NAML architecture enables us to easily incorporate extra information to produce news representation. Therefore in this work, we also want to investigate the effectiveness of integrating news tags as supplementary information into the news recommendation model, aimed at improving the news representation. We argue that news tags at some levels may capture the important points in the articles, which therefore may provide extra useful information to generate better news representation. Previous research has primarily relied on a limited set of news components, such as title, category, and subcategory [24]. To the best of our knowledge, the use of news tags to enhance recommendation performance has not been explored in previous work.

Finally, this research endeavors to address two primary research questions:

1) RQ1. How is the performance of the NAML neural recommendation method to perform news recommendation task in the Indonesian language?

2) RQ2. To what extent news encoder in the NAML model can benefit from the use of news tags in the Indonesian news recommendation task?

By providing answers to these research questions, this study contributes to the existing body of research by providing

insights into the effectiveness of a neural method, i.e., NAML, for Indonesian news recommendation systems, as well as the impact of incorporating news tags into the NAML architecture.

The rest of this paper is organized as follows. Section II is dedicated to an in-depth review of relevant literatures related to news recommendation models, news information, and text embedding. Section III outlines the research methodology adopted in this study. Moving on to Section IV, this is where the results of the data analysis are presented and discussed. Section V serves as the conclusion, encapsulating key findings and providing directions for future research based on the study's insights. Finally, Section VI provides recommendations for future work based on the findings of this study.

II. Related Works

A. Text Embedding

Text embedding is a technique that represents text as a vector of real numbers. This allows computers to process text in a more meaningful way, as the vector representations can capture the semantic meaning of the text. There are several text embedding methods that try to capture the semantic and syntactic meaning of the text input.

The Word2Vec model served as a fundamental baseline for word embedding [25]. Their work introduced two innovative model architectures specifically crafted for generating continuous vector representations of words using vast datasets. These representations were evaluated for their quality in a word similarity task. The Word2Vec model has demonstrated its capability to address various tasks, including text summarization [26, 27, 28], ranking for academic expert finding [29, 30], and text classification [31, 32, 33]. Several models similar to Word2Vec were subsequently introduced, including Glove (Global Vectors for Word Representation) [34] and FastText [35]. These models build upon Word2Vec's foundations, enhancing the learning of word representations to acquire deeper semantic insights from the corpus.

In 2017 BERT is introduced, a bidirectional model that can learn context-aware and informative representations of words and phrases [36]. BERT, as a bidirectional model, learns word representations considering both forward and backward contexts, distinguishing it from previous models limited to forward context understanding. BERT is pre-trained on a massive dataset of text and code, and it can be fine-tuned for a variety of natural language processing tasks. This model remains challenging for underrepresented languages, which face unique obstacles due to limited data availability and the substantial corpus required for effective training [37].

Notably, there have been notable works on BERT-based models created specifically for the Indonesian language. These models, known as IndoLEM [38] and IndoNLU [39], have been developed independently, each trained on a different corpus of Indonesian text. IndoLEM and IndoNLU represent valuable contributions to Indonesian NLP research. They serve as pre-trained language models that have learned to understand and encode the linguistic patterns, semantics, and contextual information present in Indonesian text data. In addition, the BERT-based model has been demonstrated to enhance performance in classification tasks [31]. In our research, we evaluate the capabilities of these two distinct BERT-based models to obtain text embeddings. Furthermore, our part of the research is to conduct a comprehensive comparison of various text embedding methods and evaluate their performance within the context of a news recommendation system.

B. News Information

In the scope of news recommendation systems, the use of news information as news representation plays a pivotal role in constructing the entire system [2, 19]. The recommendation model aims to construct a user profile customized to individual preferences through an analysis of the articles that a user reads. To achieve this, news representation involves the transformation of some or all news information into vector form [24].

Typically, the components input into the model encompass essential elements such as the article's title, abstract, body, category, and subcategory. These components collectively serve as the news representation for generating a comprehensive vector representation of news articles. This representation is instrumental in facilitating the modeling of user preferences and enabling the recommendation system to provide personalized news suggestions that align with each user's unique interests and preferences [4, 5].

Another valuable component of news information is the news tags. Although the news tags show the topic information that is closely related to the news content, the existing personalized news recommendation methods usually ignore the value of tags. News tags are usually used by users to track certain topics in the news portal which can trace other articles based on that tags. This behaviour leads to our research to check whether we add news tags as additional information is necessary for news recommendation models.

One of the methods to process the tag information is by leveraging social bookmarking [40]. The method involves the utilization of tags, which are assigned by a community of users with shared preferences. It's important to note that while tags are still employed in this method, they now signify a collective understanding within the user group, aligning with their common interests and preferences. An alternative approach involves creating a probability relation graph among tags, exploring potential correlations among different tags [41]. Building on this foundation, they employ the term frequency–inverse document frequency (TF-IDF) method to determine tag weights. Additionally, they introduce a novel approach to calculate the correlation degree between tags, utilizing conditional probability as a key metric.

C. News Recommendation Methods

In recent years, the field of news recommendation systems has received significant attention due to the exponential growth of online news consumption and the need for personalized content delivery. Several studies have been conducted to explore various approaches for improving the accuracy and relevance of news recommendations. News recommendation systems can be broadly categorized based on how they model user behavior. Two primary categories exist: Candidate-Agnostic (C-AG) models and Candidate-Aware (C-AW) models [42]. Both of the categories are illustrated in Fig. 1.

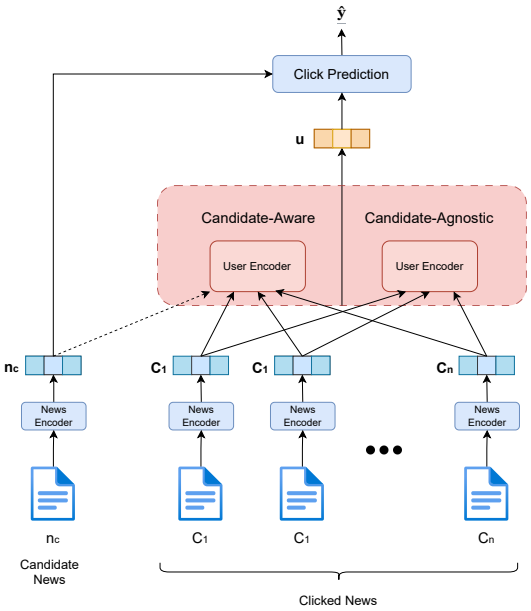

Fig. 1. News recommendation system general framework.

In C-AG Models, the User Encoder (UE) forms user embeddings exclusively from the embeddings of previously clicked news articles, without taking into account the candidate news articles [10, 9, 11, 12]. Essentially, the user embedding remains the same regardless of the specific candidate news being presented. One of the C-AG models is NAML that using a multi-view learning framework to learn unified news representations by incorporating several news information like title, body, and category. The NAML architecture is easily modified to add other news information. For the user encoder, NAML utilize a news attention network to identify crucial news articles, aiding in the acquisition of informative user representations [11]. The experimental results showcased significant enhancements in recommendation accuracy with the deep learning approach compared to traditional methods. Due to this performance, we have selected NAML as the primary model for our research focus.

Conversely, in C-AW models, the User Encoders (UEs) produce user embeddings that are influenced by the content of the candidate news articles. This means that in C-AW Models, the user embeddings can vary depending on the specific candidate news article in consideration [23, 13]. While C-AG Models maintain a consistent user embedding, C-AW models adapt the user representation to the characteristics of the candidate news, thereby potentially improving recommendation accuracy.

Considering the importance of contextual information in news recommendations, researchers have explored the incorporation of additional factors such as temporal relevance and user context. With the advent of deep learning techniques, several studies have investigated the application of neural networks for news recommendation [10, 9, 11, 13].

With the evolution of news recommendation systems, several metrics are employed to compare the performance among models. The most common ones include AUC (Area Under Curve), MRR (Mean Reciprocal Rank), and NDCG (Normalized Discounted Cumulative Gain) [4, 43]. For models treating the news recommendation task as a classification problem, the Area Under Curve (AUC) score is a frequently used metric to measure the accuracy of the model. MRR is calculated as the reciprocal of the position of the first relevant element in the ranking. NDCG considers graded relevance (rating values) along with positional information of the recommended items. Both MRR and NDCG assess the relevancy of recommendations from the news recommendation system (NRS) model.

In summary, news recommendation systems have been extensively studied, employing various approaches such as contextual information and deep learning approaches. These studies have contributed to the advancement of news recommendation systems, enhancing their accuracy, relevance, and personalization capabilities.

III. Research Methodology

A. Dataset

We conducted experiments on a real-world news recommendation dataset collected from one of the largest news portals in Indonesia. We randomly sampled users who had at least 5 news click records during 4 weeks from Feb 10 to March 16, 2023. The last 1 week was treated as a data test. We collected the behaviour logs of these users in this period, which are formatted into impression logs. An impression log is a record of the news articles that are presented to a user when they visit a news page, including information about the time of the visit and the user's interactions such as clicks on these news articles. In Fig. 2, you can see the layout of the news article page and an example of news information presented within an article.

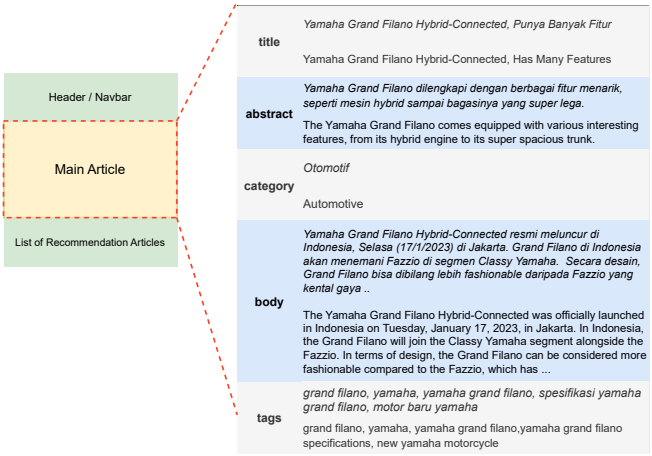

Fig. 2. Illustration of page layout and main article example.

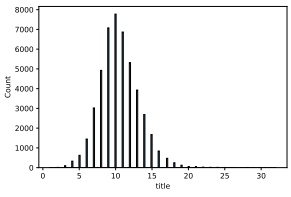
Regarding the news dataset, we focus on several news components to figure out their influence on the performance of news recommendation systems. These components encompass the title, abstract (short description), news body, category, and subcategory. Furthermore, our primary research objective is to

scrutinize the impact of news tags on the model. By examining how each of these elements shapes the model's performance, we aim to gain valuable insights into the factors that drive effective news recommendations. The statistical information about the dataset summarized in Table I.

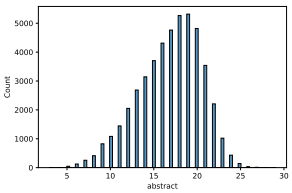
TABLE I. STATISTICAL INFORMATION ABOUT THE DATASET

Component	Value
# User	34,053
# User Logs	181,875
# News	79,041
# Category	27
# Subcategory	148
Avg. Title Len.	10.40
Avg. Abstract Len.	16.80
Avg. Body Len.	371.22
Avg. Tags per Article	4.55

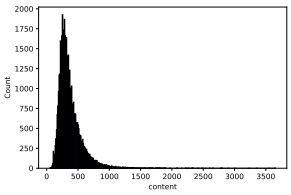
Fig. 3a, 3b, and 3c provide insights into the length distributions of news titles, abstracts, and bodies. Notably, news titles exhibit a distinct pattern of being quite short, averaging only 10.4 words. In contrast, both news abstracts and bodies present significantly longer text lengths, offering the potential for more in-depth coverage of news content. This discrepancy in text length underscores the value of incorporating diverse types of news information, including titles, abstracts, and bodies. Such integration enriches our comprehension of news articles by providing a more comprehensive and nuanced perspective on the content.



(a) Length of Title



(b) Length of Abstract

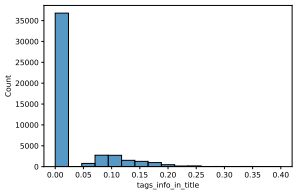


(c) Length of News Body

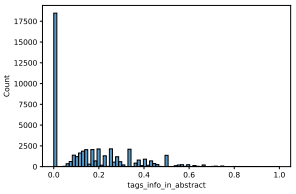
Fig. 3. Statistics of News Dataset.

In contrast to the approach outlined in [41], our methodology involves concatenating the news tags into a sentence or text format. We then treat this combined text in the same manner as other news information, such as the title and abstract. As a result, we transform the tags into a textual format, enabling them to be seamlessly integrated into the news content.

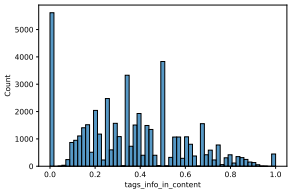
Our initial observations, as illustrated in Fig. 4, reveal an interesting connection between the amount of text data and the presence of words within news tags. With the expansion of text data, there is a higher probability of encountering shared words between the tags and other textual content. This intriguing pattern suggests that even though news tags are found within other news information, they can contribute to a more comprehensive understanding of the article. This is because the proportion of news tags included in other news information remains relatively low. This highlights the potential significance of news tags in enriching news representation.



(a) Tags information in title



(b) Tags information in abstract



(c) Tags information in body

Fig. 4. Percentage of tags information included in other news information.

B. Experiment Settings

In our study, we employed two pre-trained models of word embedding, FastText and Glove. Additionally, we utilized the feature-based approach of Indonesian BERT architecture to generate more contextualized word embeddings. We reported average results in terms of AUC, MRR, NDCG@5 and NDCG@10. For the training objective, we primarily focus on parameter tuning through minimizing cross-entropy loss (with negative sampling) as the straightforward classification objective [44].

C. Text Embedding Models

As part of our benchmarking process, we trained three word embedding models—Word2Vec, Glove, and FastText—using the Indonesian Wikipedia corpus extracted from the Indo4B corpus [39]. Furthermore, we also trained a FastText model using the entire Indo4B corpus. For our BERT-based models, we leveraged models from two distinct sources, namely indolem [38] and indobert [39]. These pretrained BERT models played a crucial role in our research, serving as integral components in our investigations into text embeddings and their impact on news recommendation systems.

D. News Recommendation Models

In this paper, we assess several C-AG models, each distinguished by their News Embedding (NE) component, which essentially determines how they embed the clicked news articles: (1) The LSTUR [9], focuses on learning user representations using recurrent networks. In this model, a short-term

user embedding is generated from the clicked news articles using a Gated Recurrent Unit (GRU) [45]. This short-term embedding is then combined with a long-term embedding, which is constructed by initializing with random values and fine-tuning it during training. In this research, we use two types of LSTUR model which is LSTUR-con and LSTUR-ini. (2) NAML [11] employs additive attention [46] to encode users' preferences. This means that NAML utilizes an attention mechanism to capture and emphasize important aspects of a user's preferences when making recommendations. Additionally, our primary focus for this experiment will be on NAML, given its strong performance and adaptability, especially in accommodating adjustments to the included news information in the model. (3) NRMS [10] adopts a more intricate approach to learn user representations. It employs a two-layer encoder, consisting of multi-head self-attention [36] and additive attention. This design allows NRMS to capture and process user information from different perspectives, potentially leading to more comprehensive user representations for improved recommendations. (4) TANR [12] propose a new encoder that is trained to learn topic-aware news representations by simultaneously training it on an auxiliary topic classification task.

On the other hand, we examine one specific C-AW model to gain insights into their performance and effectiveness. We evaluate CAUM [13], there is a fusion of two key components: A candidate-aware self-attention network, which is used to model extensive connections among clicked news items while taking into account the specific candidate news; and a candidate-aware convolutional network (CNN) employed to capture immediate user interests from nearby clicks, also influenced by the content of the candidate news. Ultimately, the user's candidate-aware embedding is derived by considering both the long-range and short-term representations.

IV. Results & Analysis

Table II shows evaluation of the NRS has produced diverse performance results across various testing scenarios. These thorough assessments have uncovered valuable insights, particularly highlighting the competitive performance of two prominent models, NAML and CAUM, in terms of accuracy and relevancy. However, a notable distinction emerges as NAML demonstrates a significant advantage in terms of runtime efficiency, notably surpassing the CAUM model in processing speed. This unique combination of high performance and reduced computational overhead presents a compelling argument.

Using the NAML model as our main framework, we conduct a more in-depth assessment of how news information influences news representation and, consequently, its impact on news recommendation model performance. The results are shown in Table III. Our approach involves the independent processing of various news text information and categories. We merge these elements using an attention network, constructing a holistic representation that encompasses the collective impact of various news components. This method enables us to systematically investigate the synergistic effects of diverse news content on enhancing model performance.

Regarding news representation, the results in Table III reveal a key insight: relying on a single source of news information may not suffice for optimal representation. The notable improvement lies in not depending solely on a single type of news information but integrating various types, such as title, abstract, and tags. This approach is suggested to potentially result in better performance, emphasizing the need to leverage the complementary aspects of diverse news components. By incorporating a variety of information sources, the model can achieve a more comprehensive and nuanced understanding of news articles, ultimately improving the quality of news representation.

Fig. 5. Recommendation results by using and without news tags for the same impression. The news clicked by the user in this impression is in blue and bold.

Table III provides further insights, notably indicating a significant improvement in model performance when news tags are incorporated alongside the abstract as part of the news information. This observation underscores the positive impact of integrating news tags into the model, particularly when combined with other textual elements like the abstract. Such integration significantly increases the performance of the NAML method by 0.88%, 3.11%, 5.86%, and 2.59% for AUC, MRR, NDCG@5 and NDCG@10, respectively.

The example of the NAML model using and without tags is illustrated in Fig. 5. Based on this example, it is evident

that the model that incorporates news tags performs better in terms of relevancy than the one that does not use tags. In detail, when evaluating the top recommendations generated by the model without incorporating tags, none of the suggested articles align with user-clicked preferences. However, with the inclusion of tags, the model's recommendations exhibit a notable improvement. Two out of the top three suggestions are now articles that users have previously engaged with, showcasing the effectiveness of integrating tags in refining the recommendation outcomes.

TABLE IV. RESULTS ON DIFFERENT NUMBER OF CLICKED NEWS BY USERS

N Clicked News	AUC	MRR	nDCG@5	nDCG@10
1	0.5418	0.1561	0.1400	0.2160
5	0.5383	0.1516	0.1344	0.2104
10	0.5385	0.1544	0.1356	0.2130
20	0.5411	0.1533	0.1358	0.2132
50	0.5413	0.1556	0.1391	0.2142

The analysis of user interactions with news articles has yielded consistent findings across varying levels of user engagement with news content. These findings have been summarized and are presented in Table IV. Surprisingly, users who interact with only a few news articles demonstrate outcomes comparable to those who engage with a more extensive collection of articles. This intriguing observation suggests that the specific selection of the last N news items may not exert a substantial influence on the observed results. This insight prompts further exploration into the dynamics of user interactions and their impact on the recommendation process, potentially leading to more refined and nuanced approaches to personalizing news recommendations.

TABLE V. RESULTS ON DIFFERENT TEXT EMBEDDING

Embedding Model	AUC	MRR	nDCG@5	nDCG@10
word2vec-wiki-id	0.5327	0.1515	0.1323	0.2086
glove-wiki-id	0.5378	0.1534	0.1345	0.2120
fastText-wiki-id	0.5355	0.1533	0.1344	0.2124
fastText-indo4b	0.5365	0.1551	0.1378	0.2120
indolem/indobert-base-uncased	0.5264	0.1499	0.1300	0.2053
indobenchmark/indobert-base	0.5354	0.1497	0.1302	0.2083
indobenchmark/indobert-large	0.5383	0.1530	0.1338	0.2123

In addition to this research, we undertook an in-depth examination of different text embedding methods and their performance when integrated into the NAML model. The comprehensive results of these evaluations can be found in Table V. Our objective was to ascertain whether utilizing BERT-based models, which have demonstrated remarkable capabilities in various natural language processing tasks, would yield a significant performance boost within the NAML method.

However, upon thorough analysis, our findings suggest that the differences in performance between word embeddings and BERT-based models are not statistically significant when applied to the NAML model. In other words, the NAML model does not exhibit a substantial improvement in recommendation performance when integrated with BERT-based text embeddings compared to more conventional word embeddings. This emphasizes carefully choosing the right models and text embedding methods when optimizing recommendation systems.

V. Conclusion

This research investigates the effectiveness of neural news recommendation with attentive multi-view learning (NAML) method to perform news recommendation in the Indonesian language. We further propose to incorporate news tags information into the NAML architecture in order to improve the semantics of news representation, which is aimed at enhancing the Indonesian news recommendation system. According to our experimental results, the NAML method can significantly outperform some state-of-the-art neural models, such as LSTUR, TANR, and NRMS, in Indonesian news recommendation task. Although NAML demonstrates effectiveness similar to the CAUM method, it maintains superiority in terms of efficiency.

Furthermore, our investigation into news representation underscores the significance of diversifying news information sources. Combining multiple types of news data, rather than relying solely on a single source, has shown promising potential for enhancing model performance. Subsequently, the incorporation of news tags into the NAML architecture has demonstrated notable effectiveness, resulting in an enhancement of 3.11% for MRR and 5.86% for NDCG@5 in recommendation system performance.

In addition, we conducted performance assessments of the NAML model using various text embeddings. Upon initial examination, it becomes evident that there's no significant improvement observed when utilizing different types of word embedding as news representations, i.e., Word2Vec, FastText, Glove, and IndoBERT. Lastly, our analysis of user interactions with news articles, has unveiled intriguing findings regarding user engagement levels and their influence on recommendation outcomes. We found that users who interact with only a few news articles demonstrate outcomes comparable to those who engage with a more extensive collection of articles. This insight encourages further exploration into personalized news recommendation strategies, with the potential to refine and tailor recommendations based on a deeper understanding of user behaviors.

VI. Future Work

This study's findings offer insights and several promising directions for future research aimed at enhancing news recommendation systems. First, we can fine-tune the model parameters using a contrastive learning objective, specifically supervised contrastive loss. This approach can be employed to improve the separation between clicked and not-clicked news articles within the representation space. Second, it is potential to explore the automatic extraction of entities from news articles using NER (Named Entity Recognition) method as an integral part of the news recommendation model process. This approach can help uncover the relatedness of entities between relevant and non-relevant news articles, providing valuable context for improving recommendation robustness. Finally, research in news recommendation systems should diversify beyond contextual user history, adopting different methodologies for broader insights and improved system performance.

Telemedicine Adoption for Healthcare Delivery: A Systematic Review

Taif Ghiwaa[1], Imran Khan[2], Martin White[3], Natalia Beloff[4]
Department of Computer Science and Information Systems, King Khalid University, Abha, Saudi Arabia[1]
Department of Informatics, University of Sussex, Brighton, United Kingdom[1,2,3,4]

***Abstract*—Telemedicine is the delivery of healthcare services using telecommunication and information technologies. The adoption of telemedicine has been promoted by advancements in technology, increased accessibility to the Internet, and the need for convenient and efficient healthcare delivery. Understanding the theoretical foundations of telemedicine adoption among healthcare providers and patients is crucial for successful acceptance and utilization. This systematic review aims to explore the theoretical frameworks and models that have been widely utilized to understand telemedicine adoption among healthcare providers and patients. A systematic search was conducted across two popular electronic databases, resulting in the inclusion of 21 relevant studies. The selected studies were analyzed to identify the theoretical perspectives employed in telemedicine adoption research. The key findings reveal that the Technology Acceptance Model (TAM), the Unified Theory of Acceptance, and the Use of Technology (UTAUT) model are the most widely models used to illustrate the factors affecting telemedicine adoption among healthcare providers and patients through different countries and telemedicine contexts. Understanding these theoretical models is crucial for policymakers and healthcare professionals as it can provide insight into the key factors influencing the widespread adoption of telemedicine. This knowledge can serve as a guidance for crafting initiatives, and tailoring policies to promote the successful acceptance and utilization of telemedicine among providers and patients in diverse healthcare environments.**

***Keywords*—Telemedicine; systematic review; technology acceptance model; adoption; telehealth; healthcare provider; patient**

I. Introduction

The integration of Information and communication technology (ICT) in healthcare systems has revolutionized the delivery of healthcare services. Telemedicine, a branch of ICT, has emerged as a promising approach for delivering care remotely, overcoming distance barriers, enhancing clinical outcomes, increasing patient engagement [1], and reducing costs [2], [3]. It can be used to provide a range of clinical services, including consultations, diagnosis, treatment, monitoring, therapy process, and exchange of medical information by using electronic communication tools such as video conferencing, phone calls, or secure messaging [4]. Broadly, telemedicine includes two different types of services which are: store and forward (asynchronous), and real-time interactive (synchronous) [5], [6]. Thus, telemedicine is an excellent opportunity for health professionals to reach a wider community through remote provision of healthcare services.

Telemedicine and telehealth are often used interchangeably, but they have slightly different meanings [7]. Telemedicine specifically refers to the remote delivery of clinical healthcare services, while telehealth includes a broader scope of remote healthcare services, including both clinical and non-clinical aspects [4], [8]. Due to the inconsistent usage of the term telemedicine in the studies, it becomes difficult to define it precisely in relation to other terms. Therefore, during the search process, related terms like eHealth, mHealth, and telehealth were also taken into consideration. The studies included in the analysis focused on telemedicine as a means of providing patient-centered healthcare services over long distances.

An increasing world population, especially the elderly, [9] will require access to remote healthcare services, such as that potentially offered by integrating telemedicine with traditional healthcare practice. The COVID-19 pandemic has significantly accelerated this trend of adopting telemedicine [10]. With the pandemic forcing many people to stay at home, the use of telemedicine has become even more necessary to ensure that patients can continue to receive uninterrupted care. Accordingly, telemedicine has become an essential component of healthcare service delivery. Despite the great promise of telemedicine, its actual use is insufficient and has not achieved a prominent utilization outcome [11], [12]. The reasons behind this are not only the technical aspect but also the human behavioral aspect [13]. Thus, the acceptance of technology plays a crucial role in successfully implementing and consistently using it and is considered a significant factor in ensuring the effective implementation of IT systems.

Investigating the literature reveals a number of models are useful in understanding individuals' intentions to adopt ICT [14]. Some of these models include the Technology Acceptance Model (TAM) [15], [16], Unified Theory of Acceptance and Use of Technology (UTAUT) [17], Diffusion of Innovations Theory (DOI) [18], Theory of Planned Behavior (TPB) [19], Theory of Reasoned Action (TRA) [20], and Health Belief Model (HBM) [21]. These models introduce different factors that influence end users' behavior to adopt telemedicine. However, limited evidence exists regarding the optimal theory or model for understanding the acceptance of telemedicine in the realms of technology adoption and acceptance.

While individual studies explore theoretical constructs as predictors for telemedicine acceptance, there is a notable absence of a comprehensive overview that systematically analyzes these constructs, models, and factors influencing the acceptance of various types of telemedicine. This evaluation is essential from the standpoint of providers and patients, who are pivotal users of the telemedicine system. Furthermore, the authors of [22] and [23] pointed out the gap in knowledge, emphasizing that existing models are limited in scope and constrained by regional or national borders. Therefore, before

suggesting a model to study telemedicine adoption, it is important to study systematically these models. Thus, this review is conducted to provide a comprehensive overview of the theories and models used to assess the behavioral intention in adopting telemedicine among healthcare providers and patients in different settings of telemedicine. The research will seek to answer:

RQ1. Which adoption theories and models are widely applied in the telemedicine context?

RQ2. What are the most prominent factors affecting telemedicine technology adoption from the end user's perspective in a different setting of telemedicine?

The rest of the paper is organized as follows: the study methods and materials are discussed in Section II, followed by Section III detailing our results. Finally, the discussion in Section IV is succeeded by an exploration of future research directions and limitations, followed by the conclusion in Section V.

II. Materials and Methods

A. Search Strategy

This systematic review was conducted based on the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) guidelines to ensure a systematic and transparent review process [24]. Two popular academic databases, including Scopus and PubMed, were selected to collect relevant studies published in the last decade (between 2012 and 2023) and available in English or Arabic languages. The Population, Intervention, Comparison, Outcome, and Study design (PICOS) framework was applied to establish the inclusion and exclusion criteria for the review [25] (see Table I). The inclusion criteria encompassed studies focusing on telemedicine adoption theories and models among healthcare providers and patients. The search terms used a combination of PICOS components and were refined using Boolean operators. The search was conducted in March 2023. A specific search string can be found in Appendix 1.

TABLE I. Inclusion and Exclusion Criteria

	Inclusion criteria	Exclusion criteria
Population	Patients, healthcare providers, nurses.	Not patient, not healthcare provider, not nurse.
Intervention	Telemedicine	Not telemedicine, no clinical services delivered to patients, no interaction with healthcare providers.
Outcome	Behavioral intention in adoption and acceptance of technologies	Not based on theory, no adoption or acceptance.
Study design	studies published in English or Arabic language,full text access.	Reviews, studies not published in English or Arabic language.

B. Search Result

The result of searching selected databases initially yielded 3,753 articles through electronic searches. In addition, manual searching yielded five articles from other sources. After removing duplicates and screening titles and abstracts, 230 articles were selected for full-text review. Finally, a total of 21 articles, meeting our inclusion criteria, were chosen for in-depth analysis. Fig. 1 displays the PRISMA flow diagram for the search and selection process.

C. Data Extraction and Organization

Data from the included studies were extracted using a standardized form (see Table II). The extracted data included study characteristics (e.g., authors, year of publication, journal, the country where the study was conducted), theoretical frameworks employed, study design, population target, sample size, key constructors affecting telemedicine adoption in different contexts, and type of statistical analysis used in the study. The findings were summarized to fulfill the review's objectives by focusing on identified theories and their constructs in understanding telemedicine adoption among healthcare providers and patients.

TABLE II. Data Extraction Form

Data Extraction	Description
Study ID	Identifier of the study.
Title	Title of the study.
Author/s	Author/s name.
Year	Year of the publication.
Journal	Published Journal.
Country	Country/place where the research conducted.
Telemedicine application	Type of Telemedicine application.
Theory/Model	Type of theory/model used in the study.
Data collection Design	Method used to collect data.
Population Focus	The target of research participants.
Population Sampling	Number of research participants.
Components of theory/model	Constructor used to build theory/model.
Moderator components	A variable that influences the presence of a relationship between variables.
Statistical Analysis type	Type of analysis used to obtain the result.

D. Quality of the Studies

A quality assessment checklist is essential for evaluating the methodological rigor and reliability of studies [26]. The quality assessment checklist of the included studies was adapted from [27] and includes five items, as presented in Table III. This checklist uses a 3-point scale where (1=Yes, 0.5=Partly, 0=No). The results of the quality assessment can be found in Appendix 2. Generally, all the included studies scored high in quality and passed the quality assessment, allowing us to proceed to the next step, which is analysis.

TABLE III. Quality Assessment Questions

No.	Question
1	Is the study related to telemedicine adoption and its application?
2	Does the study use adoption theories or models?
3	Does the study explicitly present the research methodology?
4	Does the data collection procedure outline in the study?
5	Are the study findings clearly presented and added to the literature?

III. Results

A. Characteristics of Included Studies

After reviewing studies from the last decade, the number of publications remained limited, with only a few studies until 2018. It was in that year when there was a noticeable surge in interest regarding telemedicine adoption, a trend that continued

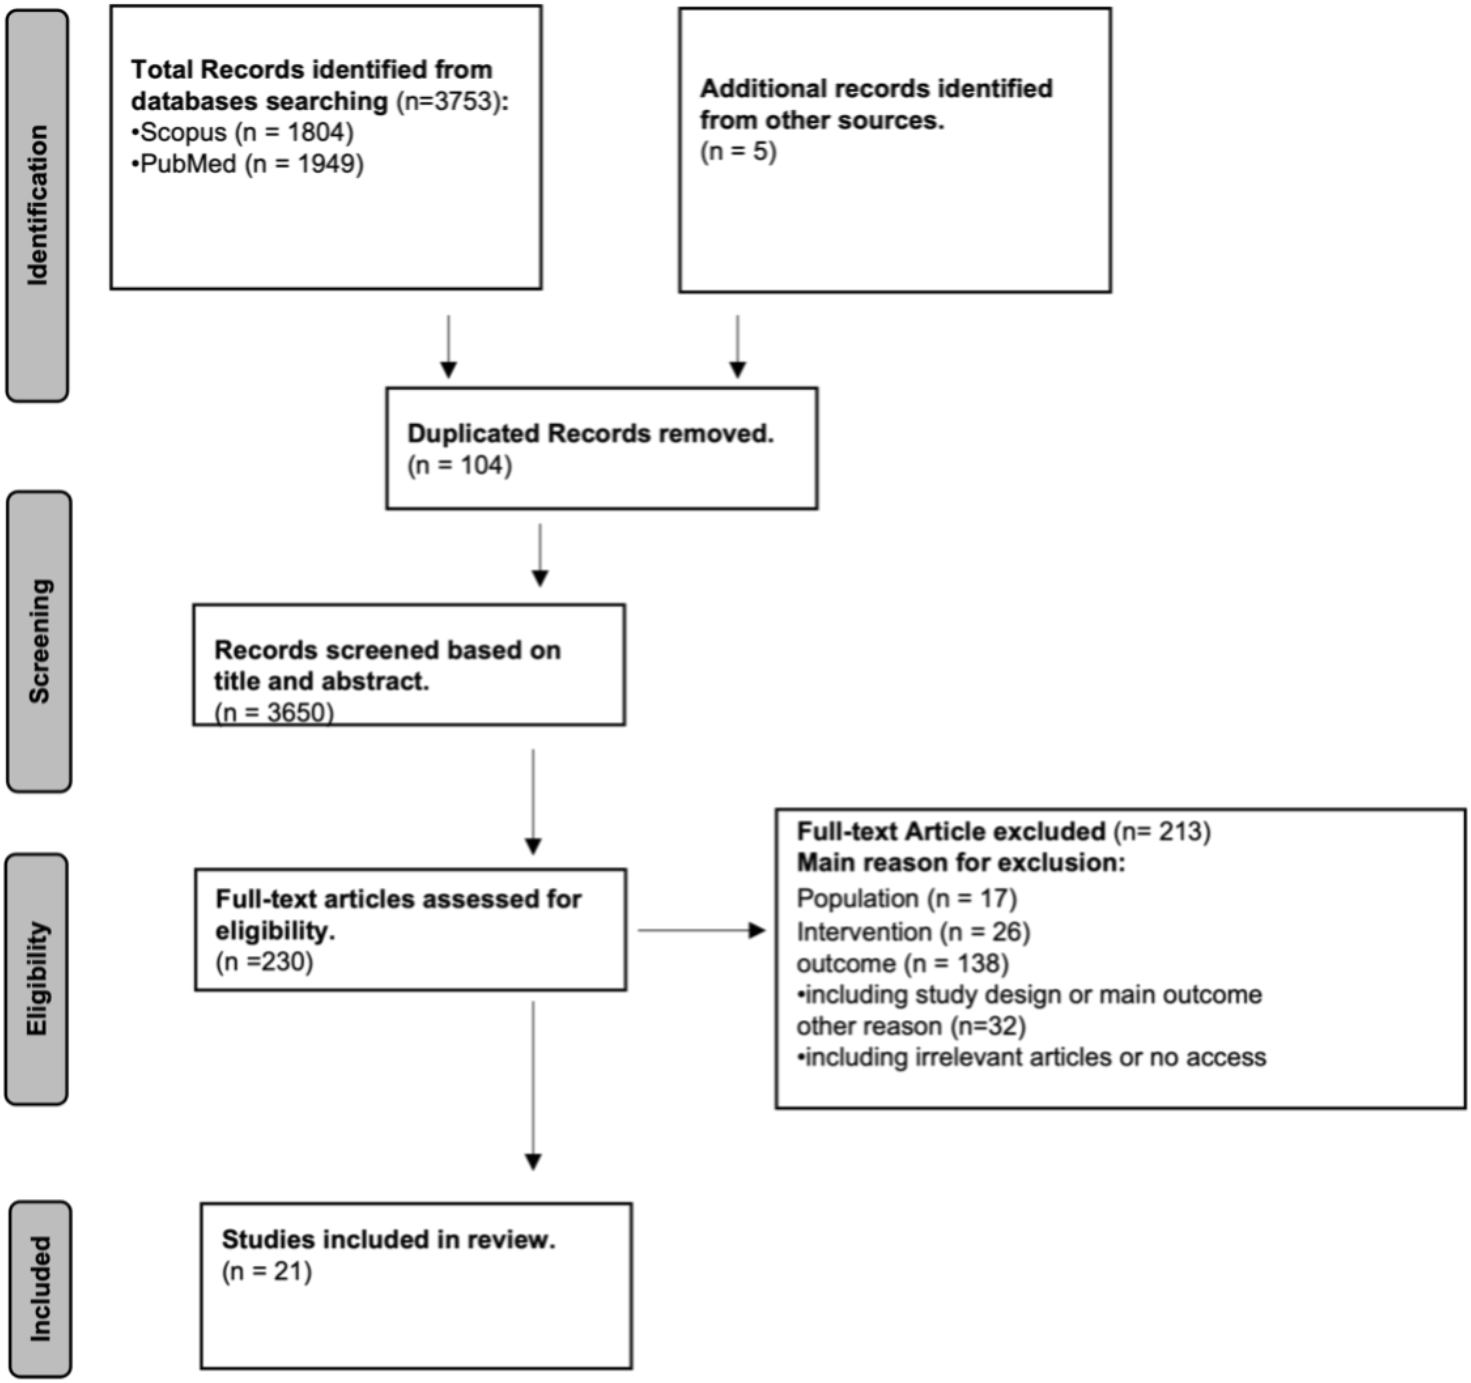

Fig. 1. The PRISMA flow diagram of studies search and selection.

during and beyond the COVID-19 pandemic. Fig. 2 illustrates the growth of publications over the last decade.

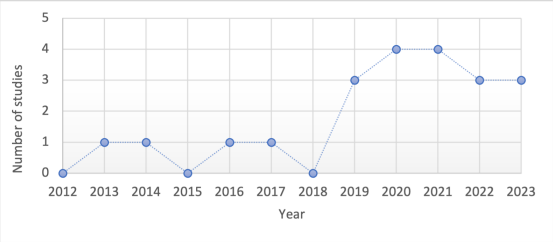

Fig. 2. Number of articles published by year.

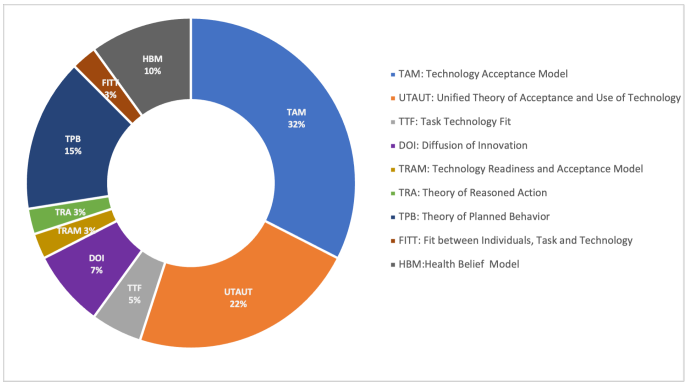

Fig. 3. Frequency of theories and models used to explain the adoption of telemedicine.

As previously mentioned, various frameworks, theoretical models, and their extensions have been developed to comprehend user intentions for adopting ICT, particularly in the context of telemedicine. Among the 21 studies included in the review, TAM and UTAUT with their extension were identified to be the highest models used compared to others. As shown in Fig. 3, the TAM model and its extension were used 13 times, UTAUT was used nine times, TPB six times, HBM four times, DOI three times, and the remaining models were used only once. This diversity of models reflects the complexity of telemedicine adoption process and underscores the importance of a different approach to understanding users' attitude toward this innovation.

The distribution of countries related to the included telemedicine studies varies. Developed countries contributed the most, with 14 studies, in contrast to developing countries, which had 6 studies. The USA had the highest number of studies, with 4, followed by Australia with 3 studies. Each of the following countries Netherlands, Canada, and Germany had 2 studies, while France had only one. In developing countries, China had 2 studies, whereas the remaining countries, including the Philippines, Malaysia, India, and Saudi Arabia, had one study each. This international diversity in research reflects the global significance and varied perspectives on telemedicine adoption especially in the developing countries.

In terms of research design, most of the studies relied on quantitative methodologies. One study employed a mixed-method approach, while 5 studies utilized qualitative research methods, including interviews (4 studies) and focus groups (1 study). There is a round balancing between publications focused on patients (12 studies) and those directed to providers (9 studies), covering a wide array of telemedicine applications. Details of the most important extracted data from these studies are presented in Table IV. For the complete set of extracted data, please refer to Appendix 3.

B. Telemedicine Applications
