Editorial Preface

From the Desk of Managing Editor…

It may be difficult to imagine that almost half a century ago we used computers far less sophisticated than current home desktop computers to put a man on the moon. In that 50 year span, the field of computer science has exploded.

Computer science has opened new avenues for thought and experimentation. What began as a way to simplify the calculation process has given birth to technology once only imagined by the human mind. The ability to communicate and share ideas even though collaborators are half a world away and exploration of not just the stars above but the internal workings of the human genome are some of the ways that this field has moved at an exponential pace.

At the International Journal of Advanced Computer Science and Applications it is our mission to provide an outlet for quality research. We want to promote universal access and opportunities for the international scientific community to share and disseminate scientific and technical information.

We believe in spreading knowledge of computer science and its applications to all classes of audiences. That is why we deliver up-to-date, authoritative coverage and offer open access of all our articles. Our archives have served as a place to provoke philosophical, theoretical, and empirical ideas from some of the finest minds in the field.

We utilize the talents and experience of editor and reviewers working at Universities and Institutions from around the world. We would like to express our gratitude to all authors, whose research results have been published in our journal, as well as our referees for their in-depth evaluations. Our high standards are maintained through a double blind review process.

We hope that this edition of IJACSA inspires and entices you to submit your own contributions in upcoming issues. Thank you for sharing wisdom.

Thank you for Sharing Wisdom!

***Abstract*—Segmentation of the Left Ventricular Epicardium and Endocardium remains challenging and significant for valuable investigation of cardiac image classification. Previous research methods did not consider the flexibility of the heart area, so measurements needed to be more consistent and accurate. In addition, previous methods ignored the presence of affectability and additional parts, such as the lung organ inside the frame, during segmentation. Deep learning architectures, specifically convolutional neural networks, have become the primary choice for assessing cardiac medical images. In this context, a Convolutional Neural Network (CNN) can be an effective way to segment the left ventricular epicardium and endocardium as CNN can take data pictures, move enormity to various centers or objects in the image and have the choice to separate one from the other. This research proposes an efficient method for segmenting the left ventricular epicardium and endocardium using the InceptionV3 convolutional neural network. Rather than including fully connected layers on the head of the component maps, the proposed method considers the average of each element map, and the subsequent vector was taken care of legitimately into the SoftMax layer. Data augmentation technique was used to validate the proposed method on large number of dataset images. Besides, the proposed method was validated in publicly available MRI cardiac image datasets. Comprehensive experimental analysis was done by analyzing a large number of performance metrics, i.e., cosine similarity, log cos error, mean absolute error, mean absolute percentage error, mean squared error, mean squared logarithmic error, and root mean squared error. The proposed method depicted superior performance for localization of the left ventricular epicardium and endocardium in terms of all these performance metrics. In addition, the proposed method performed efficiently to get smooth curve for covering the region due to usage of interpolation technique to draw the curve, which made it smoother compared with previous research.**

Keywords*—*Convolutional neural network; segmentation; computer vision; deep learning

I. INTRODUCTION

Coronary artery disease (CAD) has the highest morbidity and mortality rates globally [1]. For this, localization of the left ventricular epicardium and endocardium using deep learning approach can be automated to provide a robust tool for imaging the structure of the human heart. Generally, LV segmentation methods are formed based on area and time, where the area locates the heart within the midpoint to the indicated frame [2]. Previous research methods did not consider the flexibility of the heart area, so measurements needed to be more consistent and accurate. Time-based strategies acknowledge the heart to be the central working fact within the frame [3]. These methods endured the absence of affectability and additional parts, such as the lung, which is an active organ inside the frame in expansion for movement production [2]. More estimation has been put forward to handle this issue for LV segmentation in MRI [4] [5]. Besides, due to excellent efficacy or cost ratio in evaluating left ventricular function, gated myocardial perfusion SPECT (MPS) is widely investigated for non-destructive diagnosis of CAD [6]. Endocardium and epicardium must be accurately delineated on perfusion images for quantitative analysis of the left ventricle (LV) in MPS followed by measurement of LV functional parameters. In this context, manual segmentation is time-consuming and needs more reproducibility [6]. Therefore, to improve the accuracy of quantitative analysis, it is necessary to develop a precise, reproducible, and fully automated localization method.

At present, industrial software extracts the left ventricular epicardium and endocardium surface features by estimating the maximum myocardial counts. Then, Gaussian fit is implicated with empirical standard deviation or threshold method to evaluate the details. However, this method needs to be investigated again in assessing myocardial functions. In particular, left ventricular ejection fraction (LVEF) is often overestimated in patients with tiny hearts, and the error is more pronounced in females than males [7].

Traditional computer vision-based image processing methods have demonstrated significant improvement in cardiac image segmentation, such as atlas and model based methods [8, 9]. In recent years, deep learning models, which automatically learn high-level features of the potential distribution of data, outperformed traditional images segmentation methods in accuracy and time efficiency [10]. In this context, multi-class three-dimensional (3D) V-Net was proposed to automatically segment the endocardium and epicardium in gated MPS, which exhibits improved performance [11]. The average Dice similarity coefficient (DSC) values of the model in the endocardium and epicardium of regular patients were 0.907 and 0.965, respectively. However, previous deep learning methods still need to be improved for accurate LV segmentation in MPS towards localization. The object shapes extracted from previous image segmentation methods for localization have shown great success as prior knowledge in refining the deep learning models for medical image classification [12,13]. In this context, combination of prior knowledge reduces the potential output space of model partitioning and speeds up the convergence during the model training. However, prior knowledge is generally used as the input which was hard to extract.

This research uses Inception-v3 CNN architecture for segmenting the left epicardium and endocardium. The innovations and our contributions are listed as follows:

1) This research proposes an efficient method for segmenting the left ventricular epicardium and endocardium using Inception-v3 CNN architecture where the average of each element map and the subsequent vector were taken care of legitimately into the SoftMax layer rather than including fully connected layers on the head of the component maps.

2) Data augmentation technique was used to overcome the shortage of dataset images by the proposed method, which allows the proposed method to be validated robustly.

3) The proposed method was validated by analyzing a large number of performance metrics, i.e., cosine similarity, log cosh error, mean absolute error, mean absolute percentage error, mean squared error, mean squared logarithmic error, and root mean squared error, where proposed method depicted superior performance.

The remainder of this paper is organized as follows: Section I gives the introduction. Critical previous research is illustrated Section II, comprehensive details of the proposed methodology are elaborated in Section III, details of experimental results with analysis for validation are presented in Section IV, and finally, Section V concludes the paper.

II. Previous Research Methods

Manual left ventricular epicardium and endocardium segmentation are crucial for risk stratification, diagnosis, and treatment evaluation. However, manual segmentation has been suffering from various issues, i.e., time-consuming, tedious, and lack of generalization, which can impact the reproducibility of the results [14]. Automatic segmentation for segmentation can overcome some of these limitations [15], where deep learning methods are under investigation to develop accurate, robust, and fast computer vision techniques. As the clinical application of MRI is rapidly growing, robust computer vision techniques are required, which will not need any supervision for acceptable accuracy. This research developed and implemented a robust method for segmenting the Left Ventricular (LV) Epicardium and Endocardium using efficient deep learning method.

Previous Research reported the application of Deep Learning (DL) to segment the left ventricular epicardium and endocardium. Research in [16] evaluated multiple DL methods for left ventricular endocardium segmentation and found the superiority of encoder–decoder-based architectures over non deep learning methods. Research in [17] implicated U-Net to segment the left ventricle by changing UNet architecture in MFP-U-Net. Their proposed CNN added additional convolution layers for producing fixed size feature maps and efficient left ventricular segmentation performance. Research in [18] combined a modified U-Net architecture with an FCN encoder to influence feature extraction and allow the system to learn from execution. Research in [19] implemented bilateral segmentation network to extract deep features and a pyramid local attention algorithm to extract significant features within compact and sparse neighboring contexts. Research in [20] used multiple parallel pipelines for ES and ED frame segmentation using DeepResU-Net. Distinct from the other Research, Research in [22] used self-supervised algorithms [21] to separate the left ventricle to reduce the issue for the lack of labeled data. Research in [23] addressed object detection method and YOLOv3 algorithm, to detect three points of the ventricular chamber and segment the ventricles. Despite these method’s innovativeness and high performance, previous methods focused on segmenting the ventricle for segmentation but not all its anatomical structures.

Convolutional Neural Network (CNN) is a deep learning strategy that can extract data features, move enormity to various centers or objects in the image, and have the choice to separate one from the other. While in harsh strategies for CNN, channels are hand-worked with enough preparation, ConvNets can get capacity with these channels. Most LV limitation techniques are primarily founded on spot-based, time-based, and shape-based speculations, which refer to the areas of strategies except the heart in the picture [24]. A combination of the dynamic figure model and dynamic appearance models were used to confine the left and right ventricles of customary and Tetralogy of Fallot (TOF) hearts on 4-D (3-D+time) MR pictures [25] [26]. For each ventricle, a 4-D model was first used to accomplish incredible essential confinement on all heart stages, and a 3-D model was applied to each stage to increase the exactness while keeping up the complete heartiness of the 4-D division [27]. Another procedure was introduced in Deep CNN to restrict the Left Ventricular in cardiovascular MRI. A six-layered Convolutional Neural Network with different part estimations was used to separate highlights trailed by SoftMax, a connected layer for portrayal.

The pyramids of scales assessment were familiar with the record of the different dimensions of the heart [28]. A range-based device was produced to draw closer to experiencing the ill effects of affectability [29]. Automatic-Image-Driven technique's suppositions depend on the heart, roughly in the middle of the genuine picture. In this context, the LV blood pool is more roundabout than the Right Ventricular blood pool, which has an upper sign force [30]. Artificial Intelligence (AI), Computer Vision (CV), and Image Processing (IP) calculations have been likewise introduced to handle the segmentation of issues by isolating the frontal regional object from the foundation. While hardly any specific methods have been proposed to deal with the issue of LV restriction in X-beam, a couple of computer vision and image processing methods have been familiar with limited unmistakable body parts in modalities, i.e., Ultrasound and Computed Tomography (CT). Kellman assessed and limited the LV posture using probabilistic boosting trees and minimal space learning [31]. Research in [32] utilized nonlinear planning through relapse to limit in echodiogramic dataset. Modified LV (Left Ventricle) limitation in cardiovascular MRI pictures is a significant development for programmed division and practical perception. In this context, a comparative investigation should be combined into the severe degree of chance for backslide to improve the restriction task [33]. Recently, substantial convolutional systems have accomplished magnificent execution in many pictorial division assignments [34] and are excitedly applied in the field of clinical picture appraisal [35]. For instance, research in [36] suggested a 3D essentially oversaw system for the robotized division of the liver and the entire heart, which needs further investigation due to a lack of datasets. Different study attempts were made to approach the problem of segmentation of left ventricular epicardium and endocardium activity. This research proposes an efficient method for segmenting the left ventricular epicardium and endocardium using the InceptionV3 CNN model. The proposed method considers the average of each element map, and the subsequent vector was taken care of legitimately into the SoftMax layer. The proposed method depicted superior performance for segmentation of left ventricular epicardium and endocardium.

III. Proposed Research Methodology

This research used InceptionV3 as the CNN architecture. The overall proposed methodology is shown in Fig. 1.

Top layer with a custom network is trained rather than including fully connected layers on the head of the component maps. The average of each element map was used, and the subsequent vector was taken care of legitimately into the SoftMax layer. Global average pooling was aggregated with spatial data for spatial solid interpretations of the features. The input layer was normalized by adjusting and scaling the activations. To build the solidness of the network, batch normalization normalized the yield of a previous actuation layer by removing the batch mean and separating it by batch standard deviation.

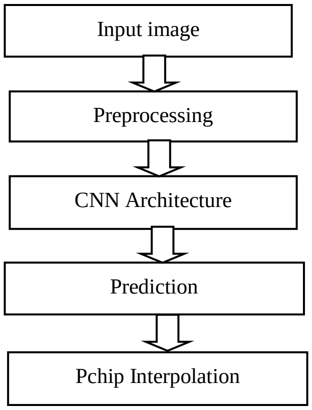

Fig. 1. Proposed methodology.

A. Input Images

Cardiac MR Image sequences with short-axis were used from 33 subjects for 7980 2D images. All the subjects were under the age of 18 where each patient's image sequence consisted of exactly 20 frames, and the number of slices collected along the long axis of the subjects ranges between 8 and 15. Spacing between slices ranged between 6 and 13 mm. Each image slice consisted of 256 * 256 pixels with a pixel spacing of 0.93–1.64 mm.

B. Preprocessing

Each subject's arrangement was comprised of 20 frames and 8 to 15 slices along the long axis for an aggregate of 7980 pictures. However, images were raw and unprocessed, kept as 16-bit DICOM images. So, this research converted 16-bit DICOM input images into 256*256*3 by reshaping them, as shown in Fig. 2.

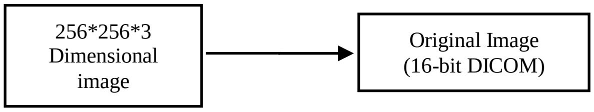

Fig. 2. Conversion of 16-bit DICOM input images into 256*256*3.

C. Data Augmentation

The paucity of data is another main problem in establishing deep learning models like CNN. Data augmentation is a helpful strategy in building a convolutional neural network that can expand the size of the training set without procuring new pictures. In this context, frames are copied with some variety. This research expanded the image to safeguard the highlights key to make predictions yet revamp the pixels enough that it includes some noise. In addition, this research rescaled images by dividing 255 with every pixel. In this context, insufficient data for model training was a typical scenario, whereas 5011 segmentation images were available. The data augmentation technique provided strong support with reduced loss in that context.

D. CNN Architecture

Each input image was passed through convolution layers with kernels, max pooling, and fully connected layers. SoftMax function was applied to segment objects with probabilistic values between 0 and 1. Convolution preserved the correlation between pixels by understanding features using squares of input data. Max pooling is considered the most significant element from the dense feature map. Fully connected layers are used where all the inputs from one layer are added to every activation unit of the next layer. In this context, the last few layers were fully connected layers, which compiled the data extracted by previous layers to form the final output. CNN architecture deployed by this research is shown in Fig. 3.

E. Prediction

The cardiac MRI dataset provides short-axis cardiac MR images and ground truth of their left ventricles endocardial and epicardial segmentations. Each image was manually segmented for a total of 7980 images where both the endocardium and epicardium of the left ventricle were visible, for a total of 5011 segmented MR images and 10022 contours. Each contour was described by 32 points given in pixel coordinates. This research trained the proposed method based on these 32 points (target variable). After training the model, a prediction of 64 points (32 for epicardium and 32 for endocardium) was acquired.

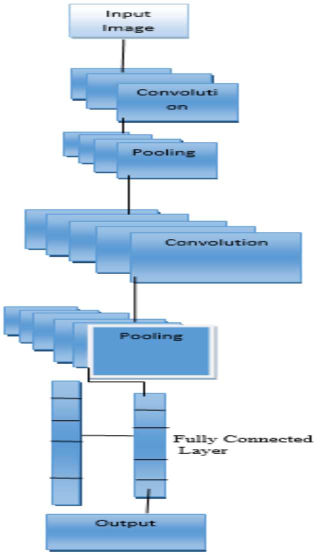

Fig. 3. CNN architecture used in the proposed research.

F. Interpolation

The proposed method used interpolation to draw the smooth curve. In this context, for each image, the epicardium and endocardium contour were depicted by 32 points in pixel coordinates (so, in total, 64 points). In this context, Pchip stands for Piecewise Cubic Hermite Interpolating polynomial used by the proposed method that interpolates data and specified derivatives at the interpolation points. As two points determine a linear function, two points and two given slopes determine a cubic. The data points are known as "knots." Y-values remain at the knots, so to get a particular PCHIP, the proposed method specified the values of the derivative y at the knots. In addition, these two cubic polynomials were considered in x on the interval 1⩽x⩽2. These functions were formed by adding cubic terms that vanish at the endpoints to the linear interpolant. After getting the predicted values of epicardium and endocardium, those points were passed for interpolation.

IV. Experimental Results and Discussion

A. Dataset

Cardiac MRI datasets [30] were developed from 33 subjects. This dataset contains 20 frames and 8-15 slices along the axis for individual subject sequences. Most slices in this dataset contain heart anomalies because of some heart diseases. So, this dataset consists of a total of 7980 images. In Cardiac MRI datasets, every patient contains 20 timeframes for 8-15 short-axis slices with matrix size 256x256, 6-13 mm slice thickness, and pixel resolution of 0.93-1.64mm [31]. The images were originally stored as 16-bit DICOM images. Form 7980 images, there were 5011 segmented images with 10022 contours. Each shape was pointed by 32 given in pixel coordinates.

In Cardiac MRI datasets, 4008 images were used by this research for training purposes. This research used 501 images for validation, and for testing, this research used 502 images. Besides, "Adam" as an optimization algorithm was used by the proposed method [37][38]. The preliminary learning rate was 0.02, the learning rate decreased with factor = 0.4, and patience was three by monitoring the 'validation loss.' Relu was used as an activation function and in the outcome layer, proposed used liner as an activation function.

B. Hardware and Software Set Up

For experimental purposes, a Windows platform was used with an 8th generation Intel Quad-Core i7-7300HQ processor (14MB Cache, 4.0GHz), 16GB DDR4 DRAM, and NVIDIA GeForce GTX 1050 with 16GB VRAM. This research used TensorFlow v2.13.0 and Keras 2.13.1 RC1 [39] [40]. This research also used some modules, i.e., Numpy, Matplotlib, Itk, Seaborn, Sklearn, and Scipy, for experimentation. The whole dataset was divided into two sections, i.e., one for training and the other for testing. The training section contains 80 % of the dataset images, and the remaining 20% was used for testing.

C. Performance Metrics

To validate the performance of the proposed method, various performance metrics were used, i.e., cosine similarity, log cosh error, mean absolute error, mean absolute percentage error, mean squared error, mean squared logarithmic error, and root mean squared error for graphical representation. Details of these metrics are mentioned in subsequent sections.

1) Cosine similarity: Estimating the comparability between at least two vectors is called cosine similarity [41]. The vectors are ordinarily nonzero and are inside an inward item space. In practice, cosine similarity is used to decide how comparable the documents are regardless of their size, which is a value equal to the division between the dot product of vectors and the product of the Euclidean norms or magnitude of each vector mentioned in Eq. (1).

$$similarity = \cos\theta = \frac{A.B}{\|A\|\|B\|} = \frac{\sum_{i=1}^{n} A_i B_i}{\sqrt{\sum_{i=1}^{n} A_i^2}\sqrt{\sum_{i=1}^{n} B_i^2}} \quad (1)$$

Here, A and B are two vectors. A.B is the dot product of those two vectors.

2) Log cosh error: Log Cosh Error is used in a regression task, a logarithm of hyperbolic cosine of the prediction error. Log Cosh Error works like mean squared error, which is not firmly influenced by the occasional wildly incorrect prediction. Log Cost Error was estimated using Eq. (2).

$$L(y, y^p) = \sum_{i=1}^{n} \log(\cosh(y_i^p - y_i)) \quad (2)$$

In this equation, L denotes Log Cosh Error, log () denotes logarithm function, cosh() denotes hyperbolic cosine function, $(y_i^p - y_i)$denotes difference between two points in y-axis.

3) Mean Absolute Error (MAE): Mean Absolute Error (MAE) is a widely recognized metric that quantifies precision for persistent factors [42]. MAE estimates the average magnitude of the errors in a set of predictions without thinking about their path. Besides, MAE is the difference between true or actual values and predicted values measured using Eq. (3).

$$MAE = \frac{1}{n}\sum_{i=1}^{n}\left|y_j - \hat{y_j}\right| \tag{3}$$

Here, MAE denotes Mean Absolute Error, $y_j - \hat{y_j}$ denotes difference between prediction and true value, n denotes total number of data points.

4) Mean absolute percentage error: Mean Absolute Percentage Error (MAPE) is the mean or normal of the total rate errors of forecasts [43]. Error is characterized as the result of the observed value by subtracting the forecasted value. Percentage errors are added regardless of the sign to register MAPE. This measurement is straightforward because it gives the error as far as percentage. Likewise, absolute percentage errors are utilized, and the issue of positive and negative errors offsetting each other is dodged. Thus, MAPE has administrative allure and is regularly utilized in estimation. MAPE can be well defined by middling the Absolute Percentage Errors of forecasts. MAPE is estimated using Eq. (4).

$$MAPE = \{(Estimated\ Value - Actual\ Value) \times 100\} \tag{4}$$

5) Mean Squared Error (MSE): The average of the squared error is called the Mean Squared Error (MSE) [44]. MSE reveals how close a regression line is to a set of points, which is done by taking the distances from the points to the regression line. The squaring is essential to eliminate any negative signs, which likewise gives more weight to bigger contrasts using Eq. (5).

$$MSE = \frac{1}{y}\sum_{i=1}^{n}\left|y_j - \tilde{y_i}\right| \tag{5}$$

Here, MSE denotes Mean squared error, n denotes number of data points, y_j denotes observed values and $\tilde{y_i}$ denotes predicted values.

6) Root Mean Squared Logarithmic Error (RMSLE): Root-mean-squared-logarithmic error (RMSLE) is a function mentioned in Eq. (6) used for finding the difference between predicted values and the actual values [45]. To comprehend the manipulation of RMSLE and corresponding disparities, it is imperative to calculate means squared Error (MSE) mean where MSE joins both fluctuation and inclination of the indicator. MSLE cares about the relative difference between predicted value and actual value.

$$RSMLE = \{\log(prediction + 1) - \log(actual + 1)\}^2 \tag{6}$$

7) Root Mean Squared Error (RMSE): Root Mean Squared Error (RMSE) is a recognized way to find the error of a regression model, which defines how close a fitted line is to data points [44]. RMSE was estimated using Eq. (7).

$$RMSE = \sqrt{\frac{\sum_{i=1}^{N}(x_i - \hat{x_i})}{N}} \tag{7}$$

Here, i denotes variable, N denotes number of non-missing data points, x_i denotes actual observed values and $\hat{x_i}$ denotes estimated time series.

D. Experimental Results

The proposed method received the best cosine similarity of 0.9977 for the Cardiac MRI dataset after 76 epochs, as shown in Fig. 4. For each of the performance metrics, the graphical representation is shown in Fig. 4 to 9, where the orange line was used for training, and the blue line was used for validation. This research considered epoch along with the x-axis and cosine similarity along with the y-axis. Estimation of cosine similarity turned into an essential factor for understanding likenesses between objects and provided the strong assumption between the train set and validation set's similarity. In addition, loss differences can be calculated from this estimation, which helped to ensure that the proposed method never faces an overfitting problem.

Cosine similarity calculates the comparability between two vectors of an inner product space. The output produces a value ranging from -1 to 1, indicating similarity where -1 is non-similar, 0 is orthogonal (perpendicular), and 1 represents total similarity. From Fig. 4, it can be observed that in 76 epochs, the value of cosine similarity was 0.9977, and then the model stopped learning. If the model continued learning, the proposed method would face the overfitting problem.

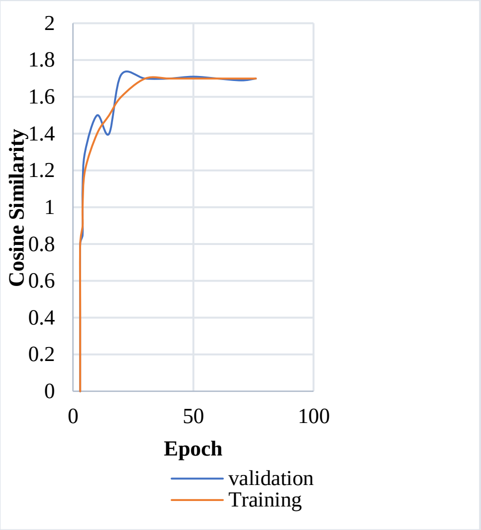

Fig. 4. Cosine similarity of cardiac MRI dataset.

This research received Log Cosh Error of 1.4585. Log Cosh Error was strongly affected by the occasional wide incorrection prediction and thus considered an improved version of MSE. Log Cosh Error is preferable to use when dataset contains significant errors due to more sensitivity to errors than the MSE. For this reason, this research used Log cos error for validating the proposed method. From Fig. 5, in 76 epochs, the model stopped learning. From 1 to 20 epoch, it had a large loss difference between train and validation data. But after the 20th epoch, loss difference was less.

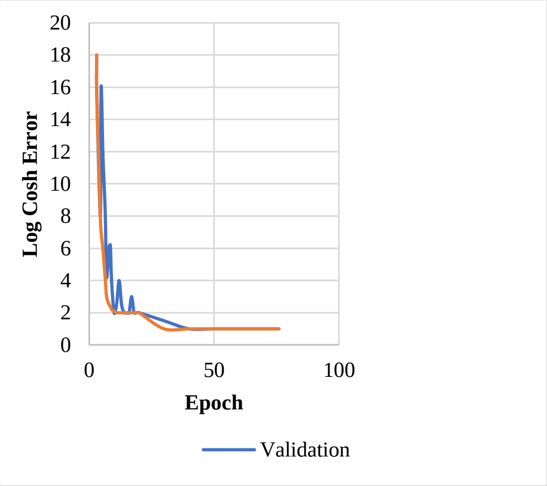

Fig. 5. Log cosh error of cardiac MRI dataset.

This research received Mean Absolute Error (MAE) of 2.0178. In many regression scenarios, Mean Absolute Error is preferable when the average error becomes very large, which is the main reason to use MAE in this research for validating the proposed method. In Fig. 6, in 76 epochs, MAE was 2.0178, then the model stopped learning. From 1 to 25 epochs, a significant loss difference was observed between train and validation data. However, after the 25th epoch, the loss difference was less.

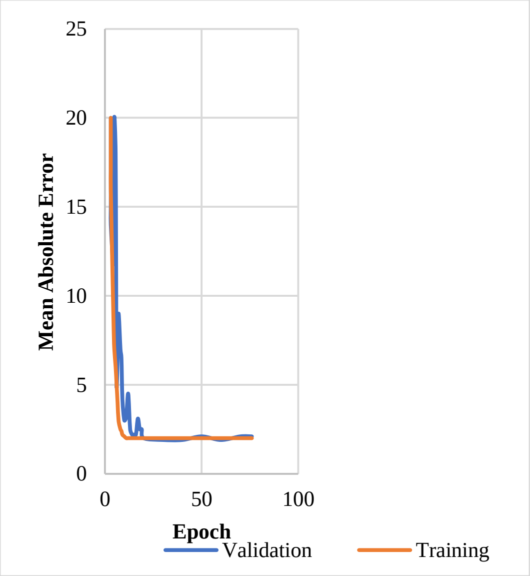

Fig. 6. Mean absolute error of cardiac MRI dataset.

This research received Mean-Squared-Logarithmic Error (MSLE) of 4.1755e-04. Usage of MSLE during regression prevented significant errors from being significantly more penalized than small ones. For cases where the target value range was large, this was the main reason to use MSLE for validating the proposed method. In Fig. 7, in 76th epochs learning was stopped where from 1 to 20th epoch, the proposed method had a significant loss difference between train and validation data. However, after 20 epochs, the loss difference was less.

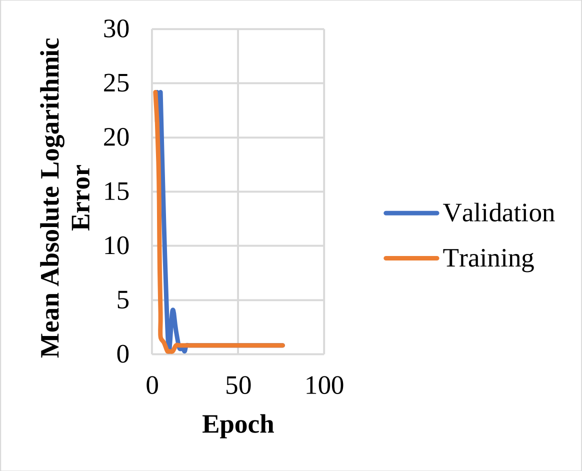

Fig. 7. Mean absolute percentage error on cardiac MRI dataset.

This research received Mean Squared Error (MSE) of 7.0577. MSE is preferable to use when the average error is very small. One minor difference with MAE was that the result is squared, which introduced benefits during optimization, which was the main reason for this research to use MSE for validation. In Fig. 8, in 76 epochs, the result of the Mean Squared Error was 7.0577, then the model stopped learning. From 1 to 25 epochs, it had a significant loss difference between train and validation data. However, after 25 epochs, the loss difference was less.

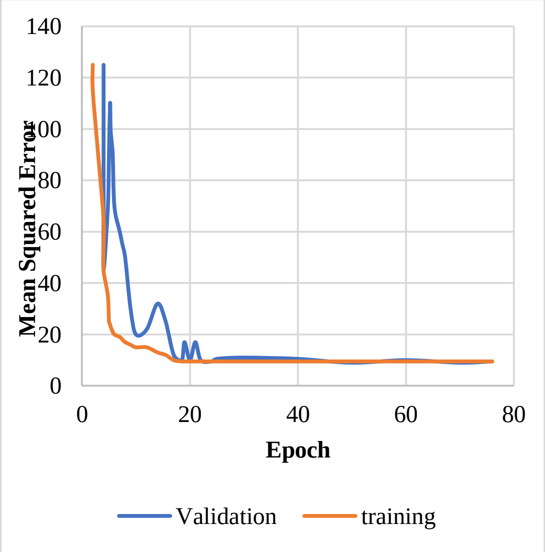

Fig. 8. Mean squared error of cardiac MRI dataset.

The proposed method received Root Mean Squared Error (RMSE) of 2.6561. RMSE was mostly applicable when significant errors were undesirable, which is the main reason for using RMSE in this research for validation. In Fig. 9, in 76 epochs, the Root Mean Squared Error result was 2.6561, then the model stopped learning. From 1 to 20 epochs, it had a significant loss difference between train and validation data. However, after 20 epochs, the loss difference was less. Overall experimental results for the proposed method are in Table I. Sample resultant outputs as image our show in Fig. 10.

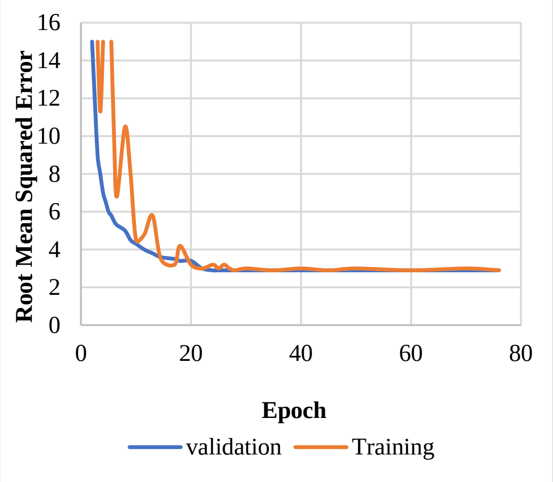

Fig. 9. Root mean square error of cardiac MRI dataset.

TABLE I. OVERALL EXPERIMENTAL RESULTS BASED ON CARDIAC MRI DATASET

Performance Metrics	Result

Fig. 10. Same output from Cardiac MRI datset.

The proposed method was compared with existing research based on several metrics, i.e., Mean Absolute Error (MAE), Mean Absolute Percentage Error and Root Mean Squared Error (RMSE). Mean Absolute Error (MAE) was used for summarizing and measuring the quality of a deep learning model. The proposed method received MAE 2.0178, shown in Table II, after the compilation of training. Previously, research in [46] estimated the mean absolute error of 2.34 using a lightweight left ventricle localizer approach. The performance difference between the research in [46] and the proposed method by this research is that the number of data presented in the dataset used by research in [46] was significantly low to train the model perfectly. This research overcame the obstacle by using data augmentation approach to balance the sample data. Data augmentation is a significant strategy in building a convolutional neural network that can expand the size of the training set without procuring new frames. The proposed method rescaled the image by dividing 255 with every pixel. The proposed research could feed a decent amount of data through the network through this approach.

TABLE II. COMPARISON BASED ON MEAN ABSOLUTE ERROR

Method	Mean Absolute Error
Proposed Inception-V3 Convolutional Neural Network	2.0178
LVLNET and Fully Convolutional Neural Network [46]	2.34

The proposed method received Mean Absolute Percentage Error value of 1.5661, shown in Table III. Research in [47] received Mean Absolute Percentage Error of 1.43 using 3D active appearance models (AAM) [47]. Compared with the proposed method by this research with the 3D active appearance models on short axis cardiac, the proposed method provided better performance in terms of Mean Absolute Percentage Error. Research in [47] used the Gauss-Newton optimization technique. In contrast, this research did not use the Gauss-Newton optimization technique because even though Gauss-Newton optimization is accurate and reliable, the Gauss-Newton optimization technique is slow.

TABLE III. COMPARISON BASED ON MEAN ABSOLUTE PERCENTAGE ERROR

	Mean Absolute Percentage Error
Inception-V3 Convolutional Neural Network	1.5661
3D Active Appearance Model (AAM) and 2D + time active shape model (ASM) [47]	1.43

Root Mean Squared Error (RMSE) is primarily useful when significant errors are particularly undesirable. For RMSE, the lower value is better. In the proposed method, this research received RMSE of 2.6561. By using the multiple linear regression (MLR) model, research in [48] received an RMSE of 6.24. Using the random-forest regression (RFR) model, research in [46] received RMSE of 5.72. So, in both cases, this research's proposed method received better results compared with research in [46] and [48].

V. Conclusion

This research proposed an efficient method to segment left ventricular epicardium and endocardium using convolutional neural network. Data augmentation technique implicated by the proposed method expanded the size of the training set without procuring new images thus assisted to validate the proposed methos on large number of dataset images. This research used Cardiac MRI dataset to validate the proposed methodology and estimated various performance metrics to justify the effectiveness robustly. After reshaping and rescaling the datasets images, proposed method used Inception V3 without top layer. Pchip interpolation technique was applied to smoothen the curve in the output images. This research observed the loss 2.011 because of the paucity of data which indicates effective localization of epicardium and endocardium with less error. Besides, due to usage of data augmentation, proposed research was able to feed a decent amount of data through network comparing with existing research. In addition, in comparison with other research, for 3D active appearance models on short axis cardiac, the proposed method provided better performance. In future, this research aims to improve CNN framework using various recent deep learning architecture such as Faster R-CNN and YOLOv7 for vast varieties of dataset images using data augmentation technique. Proposed method is expected to contribute significantly for more precise discovery and treatment of cardiovascular disease.

Predicting Alzheimer's Progression in Mild Cognitive Impairment: Longitudinal MRI with HMMs and SVM Classifiers

Deep Himmatbhai Ajabani
Application Developer Lead, Source InfoTech Inc, Atlanta, Georgia

***Abstract*—The number of elderly people has increased due to the huge growth in human life expectancy over the past few decades. As a result, age-related illnesses and ailments have become more prevalent, including Alzheimer's Disease (AD). A notable deterioration in cognitive functions, particularly memory and thinking skills, characterizes Mild Cognitive Impairment (MCI), a condition that lies in the middle of normal aging and dementia. Therefore, MCI carries a noticeably higher chance of developing into AD and frequently serves as a prelude to dementia. However, using cutting-edge image processing and machine learning techniques, it is possible to examine and find underlying patterns in these complex diseases. By using these techniques, it is possible to separate groups, identify the causes of such separation, and create disease prediction models. Clinical trials, mostly using cross-sectional Magnetic Resonance Imaging (MRI) data, have extensively looked into the use of MRI for the early identification of AD and MCI. On the other hand, longitudinal studies follow the same subjects over an extended period, giving researchers the chance to investigate cross-sectional trends as well as the development of the disease. Three different techniques are put forth in this study for the analysis and assessment of the structural data found in longitudinal MRI scans. Without considering any other diagnostic measures, this information is used to forecast the progression of those who have been diagnosed with MCI. These techniques utilize Hidden Markov Models (HMMs), which capitalize on the advantages of Support Vector Machine (SVM) classifiers.**

Keywords—Alzheimer's disease; image processing; Magnetic Resonance Imaging; Mild Cognitive Impairment; machine learning

I. Introduction

The extraordinary organ known as the human brain is in charge of controlling every aspect of the body, including breathing, blood circulation, digestion, and digesting. Additionally, it acts as the control center for conscious functions including thinking, memory formation, thought retrieval, and decision-making while facilitating conscious behaviors like walking, talking, and visual perception. The brain is an equally fascinating phenomenon when seen from an anatomical standpoint. It is thought that it has about 100 billion neurons and a mind-boggling 100 trillion synapses, which are the connections between neurons that allow for communication. The network of blood arteries in the brain is essential to maintaining its normal operation. Surprisingly, the brain controls an astounding 20% of the body's blood flow despite making up just around 2% of the total body weight. Around 400 billion capillaries make up this complex circulatory system, which works ceaselessly to deliver oxygen, glucose, and other nutrients necessary for the survival of brain cells. The brain's large number of neurons plays a crucial role in preserving optimal function. The long lifespan of neurons, which begins during fetal development and lasts for up to a century, makes them unique. In the extremely rare case that they perish, neurons can regenerate, highlighting the significance of routine maintenance and repair. Individual differences in these alterations' scope and timing can have a significant impact on their impact levels. A diminished ability to learn new information, problems recalling memories, and increased difficulty performing tasks that were once simple to complete are common signs of aging. Importantly, these talents are not completely restricted because cognitively healthy senior people can still carry out these tasks, albeit somewhat more slowly than their younger counterparts. With 50–80% of dementia cases being caused by Alzheimer's Disease (AD), it becomes clear that AD is the most common type of dementia. The age of diagnosis or onset of the disease has a significant impact on the life expectancy of AD patients, which ranges from three to ten years. Although structural brain atrophy, pathological amyloid deposits, and metabolic alterations in the brain are thought to be related with Chronic Traumatic Encephalopathy (CTE), it is unclear whether these elements are the disease's causes or the results of its progression. Due to its effects on memory, Mild Cognitive Impairment (MCI), also known as amnestic MCI, is seen as an early stage of AD. Even though MCI is not considered a true disease, the early stages of AD are very similar to it. Although not severe enough to interfere with their daily lives, people who struggle with MCI experience memory, language, and judgment issues that are noticeable to others and distinct from usual aging symptoms.

The increased risk of acquiring AD in the future that MCI patients face compared to people with cognitively normal brains emphasizes the importance of MCI. As a result, MCI is a topic that medical professionals are quite interested in. There are significant ambiguities in the distinctions between the three phases of cognitive health - Cognitively Normal (CN), Moderate Cognitive Impairment (MCI), and AD - and no clear-cut standards for determining an individual's stage are in place. Nevertheless, decades of study have produced a range of approaches intended to assess the condition of brain health such as [1]–[3]. Science and medicine have placed a lot of emphasis on the study of the brain and its anomalies [4].

However, there has been a barrier to non-invasively studying it for a very long time. Even today, the only time an exact diagnosis for AD can be made is post-mortem, during the autopsy, when amyloid plaques produced in the brain and other indicators of brain degeneration can be studied by a doctor. Early identification and detection of AD and MCI are crucial because they can help patients and their families get ready for illness and start treatment as soon as feasible. In exchange, this can provide patients the chance to take part in clinical trials where the most recent medicines can be used, and they can generally manage the illness better [5]. Scientists can simultaneously study the early phases of AD and MCI to understand the disease's origin, which could result in better techniques of therapy or prevention. According to estimates, MCI patients get AD at a rate of 10–15% while cognitively healthy people develop dementia at a rate of 1%–2%. With the use of Magnetic Resonance Imaging (MRI), researchers may now conduct non-invasive in vivo examinations of the human body. This means that the brain can be monitored and evaluated to establish a baseline of what it should resemble at various stages of the disease's course or even in cognitively normal brains. It is now possible to study the brain and the changes that take place because of either the normal aging process or particular disorders thanks to the combination of computer science and machine learning.

This study's goal is to examine and interpret the structural data obtained from longitudinal brain MRI images. To investigate the gradient of anatomical and morphological changes occurring in the brain as MCI progresses to AD. Despite the widespread use of MRI scans in this sector, the goal is to forecast the possible development of AD using only this information, without the addition of other biomarkers or clinical and cognitive assessments. We use a longitudinal series of MRI scans from different people who have been given different diagnoses (CN, MCI, AD) and who are transitioning to different diagnoses (CN, MCI, AD). The goal is to avoid the possibility for human judgment errors that can occur in complicated and time-consuming processes by just using the data derived from structural (volumetric) brain changes. Given that individuals often seek medical advice after the onset of symptoms and that the diagnostic process needs some time to complete, this technique enables a quicker forecast of the condition. This study also aims to evaluate and investigate the accuracy of longitudinal MRI scans in foretelling the transition from MCI to AD in this domain. The longitudinal MRI scans are viewed as a series of observations, after which Hidden Markov Models (HMMs) [6]–[10] are used for modeling. Then, either the HMMs alone or a Support Vector Machine (SVM) [11]–[13] classifier that has been trained using the data that the HMMs used to represent the data are used to make the predictions. It's crucial to understand that this study does not try to improve, extend, or implement any one predefined technique. This technique is unusual because it uses longitudinal MRI images that are obtained one year apart and uses only the structural data that was derived from those scans. As a result, a direct comparison between the performance and results of the trials carried out for this study and the most recent findings is not possible.

The paper is as follows: In Section II we will see the related works. In Section III, an empirical study has been presented consisting of dataset description and evaluation metrics. In Section IV, the proposed models have been discussed. In Section V, the experimental results and analysis have been done. In Section VI, the thought of the paper has been presented and we conclude the paper in Section VI with some conclusions and future works.

II. Related Works

A quick overview of current research on AD and longitudinal data in the domains of computer science and machine learning is provided in this section.

A. Brain

A substantial amount of research has been focused on identifying and extracting the elements from an MRI scan that are the best diagnostic predictors in order to facilitate additional diagnosis [14]–[16]. The features that are most frequently used involve the assessment of both grey and white matter volumes [17], either over the whole brain or in particular areas such the frontal, temporal, parietal, and hippocampal cortex [18]. Furthermore, cortical thickness is a common characteristic [16], as are CSF density maps [19], [20]. Manually extracting and choosing characteristics from MRI scans is a very difficult and time-consuming process. When some feature parameters change and the feature-extraction process needs to be repeated, it often leads to the possibility of inaccurate data or complexity in re-extracting features. As a result, several tools have been created, such as FreeSurfer[1], FSL[2], and SPM[3], which let scientists and medical experts handle and interpret MRI scans in different ways and accomplish accurate feature extraction. With little to no human oversight, these technologies can carry out extraction and selection tasks.

B. Alzheimer Disease

Considerable advancements have also been achieved in the effort to control and make use of these attributes. Using different classification techniques, it is possible to distinguish between a brain that is cognitively normal and one that is impaired, either by AD or MCI. MRIs and f-MRIs are commonly used in this type of research to get anatomical and physiological brain features, which are then used to determine any pathological or normal changes occurring in the brain. These include the assessment of cortical thickness and the density of cerebrospinal fluid, as previously indicated, as well as volumetric measures of several brain areas, such as the cingulate cortex, hippocampus, and parahippocampal gyrus. These assessments make it easier to identify anomalies in the brain and offer vital information about whether dementia of any kind is present. Biomarker characteristics taken from MRI and Positron Emission Tomography (PET) scans are used in a study focused on the classification of AD and MCI [37] to enable an SVM classifier to differentiate between CN and MCI or CN and AD patients. For MCI and AD classification, the systems achieve 76.4% and 93.2% accuracy, respectively.

Brain biomarkers and Region-of-Interest (ROI)-based morphological parameters, such as cortical thickness values, volumes of the cerebral cortical grey matter, and cortical-associated white matter, are employed in a related investigation [16]. To create characteristics and detect abnormality patterns, this study presents the idea of correlated abnormalities, which is achieved by associating different ROIs with one another. Additionally, CN and MCI, CN and AD, and MCI and AD are separated using an SVM classifier that has been trained; the corresponding classification accuracies are 83.75%, 92.35%, and 79.24%. An Orthogonal Projection to Latent Structures (OPLS) is another technique that has been developed [21]. This technique, which was initially created for the modeling of complicated data, combines the concepts of Orthogonal Signal Correction (OSC) [22], [23] with Partial Least Squares (PLS) regression. The methodology is predicated on the idea that the observations are produced by latent variables. Nevertheless, systematic differences in the independent variables unrelated to the class labels seem to have a negative impact on it. As a result, the OPLS approach was created to deal with this problem. When separating AD from CN individuals, the OPLS classifier achieves a sensitivity of 86.1% and a specificity of 90.5%. Though they produce less-than-ideal outcomes, less-common alternatives include decision trees, Artificial Neural Networks (ANN) [24], [25], and other techniques for regression or classification. These techniques use cross-sectional MRI images and focus exclusively on the brain structure information found in the present scan to identify or forecast the disease.

C. Longitudinal Data

Even while the analysis of merely cross-sectional MRI scans has shown encouraging and effective results, it is limited in its ability to provide information about a single point in a disease's progression or the overall health of the brain. It is unable to reveal information about changes that occur over time, recognize patterns, or create connections with various circumstances. The research community has been highly interested in longitudinal studies as a result, which involve a series of data, like brain MRI scans, that are taken at regular intervals (e.g., every six months or annually). Some studies that handle longitudinal data have been centered around f-MRI scans [26], [27], focusing on the responses that particular brain areas display. Regression techniques, namely linear and modified least squares models, were primarily employed in these investigations. It is important to remember, though, that these studies cannot be classified as using longitudinal MRI scans in the sense that this study intends, since f-MRI captures brain activity over seconds, while the longitudinal data we are attempting to use investigates changes in the brain occurring over much longer time frames. The use of HMMs was first implemented to try to identify mild Alzheimer's disease, or early dementia, in older people [18]. In this work, characteristics taken from a series of MRI scan slices are combined into a time series, which is subsequently, subjected to HMM analysis and classification. With accuracy reaching up to 97.8% in some tests, the suggested strategy shows great promise in the early identification of dementia. However, the main goal of this study is to identify AD based on a single brain snapshot; it does not attempt to anticipate or explore the disease's progression across a number of years, and the data is still not truly longitudinal. Similarly, HMMs are used to predict the age of people who do not have dementia in a different study [20], but longitudinal data is not used in this instance. Prediction inaccuracy on average is as low as 2.57 years. The study in [28] introduces the use of longitudinal MRI scans to investigate changes and correlations between nine-year scans of cognitively normal and demented brains. By utilizing 9-year longitudinal MRI scans, scientists examine the data obtained from individual scans, opening a promising field with enormous potential for brain study. Even though we use different characteristics and datasets, this study is really important to our work since it shows how much information longitudinal MRI scans can provide.

III. Empirical Study

A. Dataset

The Alzheimer's Disease Neuroimaging Initiative (ADNI) provided the dataset utilized in this study. The National Institute on Aging (NIA), the National Institute of Biomedical Imaging and Bioengineering (NIBIB), the Food and Drug Administration (FDA), a few private pharmaceutical companies, non-profit organizations like the Alzheimer's Association (AA) and the Institute for the Study of Aging (ISA), and other organizations are among the sponsors of the ADNI research initiative, which was started in 2003. It functions in partnership with the National Institutes of Health (NIH) [29]. The main goal of ADNI is to collect and make use of longitudinal data from people who have been diagnosed with CN, MCI, or AD. Whether serial MRI scans, PET imaging, other biological markers, clinical and neuropsychological evaluations, and other data can be combined to track and characterize the development of MCI and early AD is the purpose of this study. Moreover, ADNI seeks to offer a freely available database of clinical and imaging information that clarifies changes over time in brain metabolism and structure, cognitive performance, and biomarkers in CN, MCI, and AD patients. More than 50 research facilities in the United States and Canada provide ADNI with subjects. A longitudinal MRI scan dataset containing 631 individuals was made available for this study. After their initial MRI scans, 192 of these people were diagnosed with CN, 309 as MCI, and 130 as AD. Consequently, 189 were classified as CN, 202 as MCI, and 240 as AD at the time of their most recent scans. Every person had one to three follow-up scans, spaced a year apart, with a variable number of follow-ups performed. A total of 1913 MRI scans, including 1.5T sagittal 3D T1-weighted MPRAGE MRI scans, were included in the dataset. The Freesurfer pipeline, an open source set of tools for the thorough and automated examination of important aspects of the human brain, was used for the preparation of these MRI data. The analysis included mapping of cortical grey matter thickness, estimation of architectonic boundaries from in vivo data, segmentation of hippocampal subfields, volumetric segmentation of most macroscopically visible brain structures, and several other functions. It also included inter-subject alignment based on cortical folding patterns. Given that manual study of such a vast dataset would require a lot of labor and time, automation processing was essential.

Consequently, each MRI scan yielded 55 MRI-derived regional measures, comprising 21 subcortical volumes and 34 cortical thickness values.

B. Evaluation Metrics

In this section, we employ a set of crucial metrics to meticulously evaluate the efficacy and precision of the classification and prediction techniques developed throughout this investigation. These metrics play a pivotal role in gauging the performance of the models, providing a comprehensive understanding of their capabilities. True Positives (TP) measure the subjects accurately identified as having AD, while True Negatives (TN) count those correctly classified as CN or having MCI. On the flip side, False Positives (FP) represents instances where subjects are incorrectly classified as having AD, and False Negatives (FN) denote subjects wrongly classified as CN or MCI when they indeed have AD. Sensitivity, or the True Positive Rate (TPR), showcases the proportion of TP samples (AD) correctly identified, expressed as $TPR = TP\,/\,(TP + FN)$. Specificity, or the True Negative Rate (TNR), quantifies the proportion of TN samples (CN/MCI) correctly classified, calculated as $TNR = TN\,/\,(TN + FP)$. Precision ($Positive\ Predictive\ Value - PPV$) signifies the accuracy of positive classifications (AD) among all positive predictions, defined by $PPV = TP\,/\,(TP + FP)$. The F1 Score, also used combines precision and sensitivity through their harmonic mean, offering a balanced assessment of the model's performance: $F1 = 2 * (PPV * TPR)\,/\,(PPV + TPR)$. Notably, we calculate the harmonic mean of specificity (TNR) and sensitivity (TPR) for a comprehensive evaluation. The Receiver Operating Characteristic (ROC) Curve provides a graphical overview of the model's performance across varying parameters. It plots sensitivity against 1 - specificity, with a superior model closer to the upper-left corner. The Area Under the Curve (AUC) quantifies the overall model performance. The Diagnostic Odds Ratio (DOR), an essential metric in medical research, gauges the odds of a positive test result when the disease is present compared to when it's absent. Calculated as $DOR = (Sensitivity * Specificity)\,/\,[(1 - Sensitivity) * (1 - Specificity)]$, higher DOR values signify better discriminatory test performance, ranging from 0 to infinity. Collectively, these metrics form a robust framework for the precise evaluation of the developed models, enabling a comprehensive assessment of their classification and prediction capabilities.

IV. Proposed Models

The techniques employed in this work are based on HMMs. The selection of HMMs was based on their innate capacity to efficiently interpret sequential data. Their architecture is a good representation of markov chains since it includes hidden states and their emissions, which maps to data that can be observed. Although HMMs are mainly used for markov chains, they are also widely used to capture sequential relationships in time-sequential data, like speech processing. They are a useful tool in our situation for processing the longitudinal MRI scans as observations and identifying the relationships between them, with an emphasis on the markov chain, a hidden structure. Three different techniques are presented in this study, each expanding on the preceding one. These techniques will be covered in detail and with thorough explanations in the sections that follow. To maintain clarity, we will now outline the data partitioning and utilization process that will be used in the upcoming sections. As was previously mentioned, the dataset consists of an assortment of MRI images from different people. A series of scans are available for each participant, including an initial cross-sectional scan and one to three follow-up scans. There are two basic ways to partition the data. The initial technique focuses on the diagnosis made from the first cross-sectional scan, which is known as the "subject-initial-group". The participants are classified as having MCI, being CN, or having been diagnosed with AD. No follow-up diagnoses are considered in this category; only the baseline diagnosis is taken into account. The "subject-end-group", which is the last follow-up scan diagnostic, is used to categorize individuals in the second technique. Similar to the first technique, this grouping yields the same diagnoses/categories as the subject-initial-group (CN, MCI, & AD) and only considers the diagnosis obtained from the most recent follow-up scan. Reconfiguring this data separation makes more sense in the context of this study. Although their labels have changed, the subject-initial-group and subject-end-group remain the same. The CN and AD groups are joined in the subject-initial group to produce two alternative categories: CN/AD or MCI. This modification makes more sense because the main goal is to investigate the development of the MCI subject-initial group, which is a high-risk group. Our goal is to ascertain whether MCI will progress to AD. As a result, the subject-end group falls into one of two categories: CN/MCI or AD. The training and testing sets for our models are defined by the subject-initial group; the training set is CN/AD, and the testing set is MCI. The particular interest in MCI patients and the investigation of their possible long-term progression are the driving forces behind this tactic. The wide range of cognitive impairments associated with MCI makes it a particularly important group in the field of medical research because it can progress into several disorders, including AD. The main goal is to assess how well our systems can anticipate outcomes for this population. The attempt to see how well an HMM can extract basic and generic structural changes that indicate progression toward AD or CN/MCI (conversion to CN or stability) is the rationale behind using non-MCI participants in the training set. Next, we evaluate the applicability of these derived features to the MCI group (a subset of the MCI group is used for training during experimentation to evaluate its effect on the overall performance of all techniques).

A. Technique 1: HMM Classification

In the first technique, HMMs are only used to evaluate how well they can extract and represent temporal structural changes in the brain throughout normal aging or as it moves closer to AD. The next step is to find out if these alterations are like those shown by a brain that has been diagnosed with motor cortex injury. HMMs are trained to maximize the probability $P(O|\lambda)$, where $O = [o_1, o_2, \ldots, o_T]$ denotes a series of observations, and λ denotes the HMM model. An observation series, represented by the letter O in our dataset, is equivalent to a subject's longitudinal MRI scan sequence. The volumetric data retrieved from each scan, represented by the vector o_t, has a size of [1 × 55] for each observation [2, 4]. First, the [1 × 55] sized vectors are aggregated to create observation sequences for each subject ($[n \times 55], n \in [2, 4]$). Subsequently, the non-MCI subject-initial-group data are employed to train λ_{AD} and $\lambda_{CN/MCI}$, two HMMs. Only the observations from individuals in the AD and CN/MCI subject-end groups are considered for each HMM. Following the effective training of these two HMMs, testing is conducted on the MCI subject-initial-group. Two probabilities, $P_{AD}(O_i|\lambda_{AD})\ and\ P_{CN/MCI}(O_i|\lambda_{CN/MCI})$, are calculated for every observation sequence using the forward algorithm. These probabilities show how likely it is that the matching HMM might produce each sequence. The sequences are predicted based on this probability.

$$y_i = \begin{cases} AD,\ if\ P_{AD}(O_i|\lambda_{AD}) \geq P_{\frac{CN}{MCI}}(O_i|\lambda_{\frac{CN}{MCI}}) \\ CN/MCI,\ if\ P_{AD}(O_i|\lambda_{AD}) < P_{CN/MCI}(O_i|\lambda_{CN/MCI}) \end{cases} \quad (1)$$

It is crucial to stress that we do not assign any semantics to the states in the HMMs. When using an HMM conventionally, the number of states is usually selected so that each state, or combination of states, corresponds to a unique "logical state" of the underlying process. Nevertheless, modeling the sequences in this way is not practical in our scenario because of the sparse nature of the scans. From here on, we think of the states as an independent variable in the system that we can work with and examine to see how it affects the system's overall performance.

B. Technique 2: HMM Modelling SVM Classification

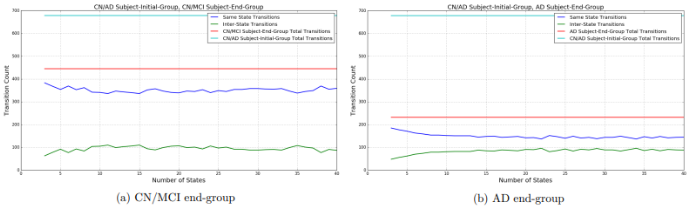
There is a premise that there is room for improvement even when the initial technique has produced good results. The data has shown that it contains useful information, and the HMM's ability to extract and represent this information has been validated. The investigation of whether this data may be organized in a way that makes it compatible with alternative models and techniques is therefore of particular interest. There is also some interest in the possibility of improving performance by adding a strong classifier. Although the HMM's states were not given explicit meanings in the previous discussion, it is agreed that the transition matrix shows that the HMM may implicitly assign certain meanings to its states after training. HMMs regard their states as markov chains by definition. As a result, the data structure for the observation variable (time) is examined during the training phase. Patterns or anomalies that appear repeatedly in the observation sequences are identified, and the start, transition, and emission probabilities are set up to correspond with these patterns. To shed further light on the reasoning behind this approach, look at the following example: Let's say the goal is to create a model of adults' everyday activities using observations made at predetermined times of the day. These findings differentiate between those who are employed and those who are not. Because of this, these two groups' observation sequences are different from one another, reflecting their different lifestyles. After being trained in this scenario, an HMM adjusts its probability to construct state markov chains that produce observation sequences that match each adult's lifestyle. The transition matrix might have been initialized to direct the HMM in giving the states particular meanings to predefine state transitions. State definitions for "working", "commuting to/from work", "sleeping", and "resting" may have been applied in the preceding case. The HMM would organize the state markov chains in a way that is easier to understand by initializing higher probabilities for state transitions like "commuting to/from work to working", "working to commuting to/from work", and "commuting to/from work to eating", and lower probabilities for transitions like "working to sleeping" and "sleeping to working". It is important to remember that while this alignment of states to actions could make sense more naturally to humans, the HMM itself may not necessarily gain from it. The HMM may nevertheless arrange the markov chains in a way that makes sense for the data's behavior even in situations where states and actions aren't directly connected. This is true even when it's not immediately obvious to human observers. The same action may even be assigned to several states by the HMM. Either way, the general organization of the states and how they behave is tailored to the features of the training set. The states of our HMMs may theoretically represent the three cognitive states of the participants (CN, MCI, and AD), much like the example given. It could have been possible to initialize the HMMs in a way that directed them to ascribe states based on the predetermined cognitive conditions right from the start. Nevertheless, we have chosen not to initialize the HMMs because of the characteristics of the data and the inherent unpredictability of these circumstances. Rather, we let them independently determine the state structure without any prior knowledge. The phrase "nature of data" refers to a range of characteristics that are taken out of every MRI scan, including the corresponding diagnosis, which is prone to inaccuracy. The three cognitive states are also rather inclusive. In particular, the MCI condition has a broad range of severity fluctuations, as was explained in previous sections; this feature also applies to the AD condition. As a result, it makes sense to believe that there are intermediate states between the states that exactly match the predetermined conditions. Because of this, we do not initialize the HMM's matrices; instead, we allow the training process to define the probabilities related to the state and emission structures. We specifically want to use this characteristic of HMM modeling in this technique. We hypothesize that important information contained in the state sequences corresponding to our observation sequences can be used as features for an alternative model or classifier. Our goal is to produce state sequences, or features, by extending the logic and foundation set by the prior technique. These features will then be used to train an SVM classifier. As previously mentioned, the procedure creates observation sequences ($O = [o_1, o_2, ..., o_T]$) for each subject. Then, using the CN/AD subject-initial-group, an HMM is trained. Unlike the prior technique, which trained multiple HMMs depending on the subject-end-group for each observation, this technique simply trains one HMM. Our goal in making this decision is to investigate the inherent capacity of the HMM to define and model discriminative information on its own, as well as to extract more generic characteristics from the data. Following training, all observation sequences (including the subject-initial-groups CN/AD and MCI) have state sequences produced by the HMM λ. These state sequences function as characteristics for the technique's next step. An SVM classifier is trained using feature sequences from the CN/AD subject-initial-group. After being trained for binary classification, the SVM divides the data into two categories: AD and CN/MCI, depending on which subject-end group belongs to which sequence. After training, the efficacy of the SVM is determined by analyzing its ability to categorize the MCI subject-initial-group sequences into the two designated classes (AD or CN/MCI).

C. Technique 3: HMM Modelling SVM Classification 2

Due to the intrinsic properties of the data, the state sequences produced by the HMM show a significant amount of volatility and fluctuation, especially when the number of states rises. Additionally, the original state sequences are features, but they invariably have varying durations based on how long the observation sequence was. This unpredictability makes the final prediction more difficult to make and adds instability to the classification process. After producing state sequences for different state counts, it is clear that, in the CN/AD and MCI datasets, the state sequences for the CN/MCI subject-end-group exhibit a more consistent pattern than those from the AD subject-end-group. There are few state transitions in the case of CN/MCI participants. This difference between the more stable conduct of CN/MCI subjects and the more erratic behavior of AD subjects may be due to structural similarities in the brain throughout normal and pathological aging. The brain regions under study typically undergo constant changes during the ordinary aging process, frequently at a slow and steady rate (e.g., a specific brain area steadily decreases in volume over the years). But because aberrant aging is characterized by unpredictable aging, these changes become more sudden and difficult to monitor precisely. There is clearly a substantial correlation even though it is still unknown if the irregular changes are the result of atypical aging or the cause of it. It may even be a combination of the two. We are mostly interested in transitions that either keep the present state or change it in the analysis of state transitions:

$$s_t \longrightarrow s_{t+1}: \begin{cases} same - state\ transition,\ if\ s_t \equiv s_{t+1} \\ inner - state\ transition,\ if\ s_t \not\equiv s_{t+1} \end{cases} \tag{2}$$

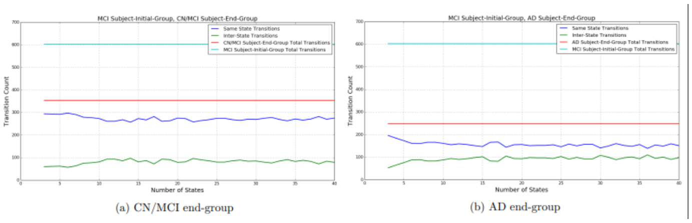
As such, we track and log the total number of transitions as well as the intra-state (same-state) and inter-state transitions that occur inside each group and end-group. The above Eq. (2) is used to determine the percentages of same-state and inter-state transitions that take place inside the AD subject-end-group of the CN/AD individuals. While 75% of the transitions are inter-state, 25% are same-state transitions. Similar computations can be made for every group and end-group to find interesting and possibly useful differences that the HMMs have brought to light. Using HMMs with different numbers of states, Fig. 1 and Fig. 2 show the counts of same-state and inter-state transitions for various groups. As a reference frame, the overall transition counts for the relevant groups are also displayed. Because they are correlated with sequence lengths—that is, the number of follow-ups scans the participants receive—rather than the structural analysis of the HMMs, these total transitions stay constant across the graphs. Interestingly, the numbers show that in the CN/MCI subject-end-groups, whether they are the CN/AD or MCI initial-groups, the number of same-state transitions is much larger (about three to four times) than the number of inter-state transitions. The AD subject-end-groups, on the other hand, show a less noticeable difference (about 1.5 to 2 times). Figs, which show the percentages of same-state and inter-state transitions compared to all transitions, support this conclusion. The Figures also compute these percentages' mean and variation across a growing number of HMM states. The information in the table highlights the fact that roughly 22% of CN/MCI end-group transitions are inter-state and 78% of them are same-state. As opposed to the CN/MCI groups, the AD end-group generates sequences where roughly 63-64% of the transitions are same-state, supporting our initial claim that the AD end-group's sequences follow a more regular pattern.



(a) CN/MCI end-group

(b) AD end-group

Fig. 1. Number of state transitions that the CN/AD group of HMMs trained with a growing number of states experienced.



(a) CN/MCI end-group

(b) AD end-group

Fig. 2. Number of state transitions that the MCI group of HMMs trained with a growing number of states experienced.

Now, we want to take use of this property and remove the variability caused by the length of the generated features. As shown in Fig. 3, we create transition frequency maps to accomplish this. These maps are represented as $[N \times N]$ matrices, where N is the total number of HMM states. As a counter, each element in the matrix, a_{ij}, counts the number of transitions from state *i* to state *j*. Interestingly, the elements of the matrix diagonal represent inter-state transitions, whereas the components of the same-state diagonal correspond to same-state transitions. Reiterating that we treat the number of HMM states as a variable that can be adjusted to investigate its effect on system performance is crucial. Consequently, Fig. 3—13 states are just meant to serve as an illustration. These matrices are used as feature vectors for the subjects after being serialized in a row-wise manner. This technique avoids practical issues by releasing our features from the temporal element, which is intrinsic to their structure but has no bearing on their length. It is clear from the initial matrices that the feature vectors are extremely sparse, with few non-zero elements that frequently take values in the range of $a_{ij} \in [1, 2, 3]$. The feature vectors are primarily composed of zeros. As such, the non-zero components' placements are more significant than their exact values. This greatly reduces the work for an SVM classifier in comparison to the previous technique's separation of state sequences. In particular, this issue is made simpler by the fact that it may be handled by an SVM as a spatial separation problem for 2D data. The procedural stages in this technique are like those in the prior way. First, the data is prepared, and for each subject, observation sequences ($O = [o_1, o_2, \dots, o_T]$) are created. Once more, using the CN/AD subject-initial-group, another HMM is trained. Then, as previously said, state sequences are generated for each observation series, which are then utilized to make transition maps and, ultimately, converted into feature vectors. The SVM classifier is then trained using these feature vectors, with an emphasis on the CN/AD training set. Based on the end-groups of the patients, the classifier is trained to classify data into AD and CN/MCI. Ultimately, the MCI testing set is used to assess the classifier's performance. The main difference between Techniques 2 and 3 is the type of characteristics that are sent into the SVM classifier.

V. Experimental Analysis

This section presents the results and evaluation of the experiments with comparison, contrast, and discussion of the different techniques.

A. Experimental Setup

Python, the hmmlearn toolbox, scikit-learn, and a number of machine learning techniques are used in the research. The construction of HMMs and SVM classifiers for the purpose of classifying subjects into various groups is the main goal of these investigations. Those without CN, those suffering from AD, and those with MCI are among these subjects. HMM models are made with the help of the hmmlearn toolkit. Since these models are fully coupled upon startup, it is possible to move between any states. Based on Gaussian emission distributions, the emission probabilities have a "spherical" covariance, which means that a single covariance value is applicable to every feature. The implementation and test run can affect how many states the HMMs have. We decided to configure the hyperparameters in advance and maintain consistency across numerous techniques and approaches for the SVM classifier. The kind of kernel, the kernel coefficient (γ), the penalty parameter (C), and the independent term for polynomial kernels are the hyperparameters that are being examined. These parameters include a polynomial kernel of degree 3, a penalty parameter C of 63.26, a γ value of 0.001, and an independent term of the polynomial function of 3.

The way the training data is handled in the experiments is one intriguing feature. The MCI subject group is first left out of the training process for the HMM and the SVM classifier by us. This technique is predicated on the idea that a greater variety and quantity of training data improve model performance and lower the likelihood of overfitting. However, choose to carry out more research to see if adding any MCI data to the training set can enhance the system's functionality. We use a technique often used in machine learning, called k-fold cross-validation, to assess the models' performance. To evaluate how well the models generalize their behavior to new data using this technique. There are k subsets of the data; k - 1 subsets are utilized for training, and the remaining subset is used for testing. The ultimate performance measure is calculated by averaging the evaluation metrics or errors generated in each run of this process, which is performed k times. We use a variant of cross-validation to incorporate MCI data into the training procedure. CN/AD and MCI participants are first given different training and testing sets. The MCI group is then divided into k = 3 folds, of which 2 are chosen as testing sets and 1 is combined with the training set. To significantly influence the process, this method yields about 25% of the training set as MCI individuals. Importantly, this modified cross-validation strategy is considered "semi-blind", whereas tests that are carried out without using MCI data in the training set are referred to as "blind". The SVM training procedures in Techniques 2 and 3 employ a conventional cross-validation procedure. The training data is split into k folds (with k values of 5, 7, or 10), either as CN/AD solely or as CN/AD plus one-third of MCI data. F1-scores are computed after training and testing several SVM classifiers. The testing set, which consists of MCI data, is classified by the SVM classifier with the greatest F1-score in preparation for the assessment.

B. Result

The following graphics contain the metrics of the various procedures under test. These metrics are assessed with and without the use of 5, 7, and 10-fold cross-validation on the SVM training, as well as with and without cross-validation on the training data. Furthermore, metrics are generated and provided for the participants who have undergone the maximum number of follow-up scans, which are three follow-ups.

1) Random classifier: Since the technique used in this study does not build upon an earlier approach, there are no state-of-the-art outcomes to compare with. As a result, the outcomes will be contrasted with a random classifier, whose performance threshold is set at the lowest possible value. Based on the values shown in Section III (A), the prior probabilities for the two classes (CN/MCI and AD) in the dataset can be defined as:

$$P_{CN/MCI} = \frac{Number\ of\ CN\ and\ MCI\ diagnoses\ at\ Last\ Scan}{Number\ of\ all\ subjects} = \frac{391}{631} = 0.62 \quad (3)$$

$$P_{AD} = \frac{Number\ of\ AD\ diagnoses\ at\ Last\ Scan}{Number\ of\ all\ subjects} = \frac{240}{631} = 0.38 \quad (4)$$

Any data point is given a class using a random classifier based on a predetermined probability:

$$P_{random} = \begin{cases} p_{class},\ where\ class\ \in [\frac{CN}{MCI}, AD] \\ \frac{1}{2},\ equal\ probability\ of\ assigning\ either\ class \end{cases} \quad (5)$$

In the first case, the classifier classifies each data point with a probability equal to the priors of the two classes, achieving the highest possible classification accuracy overall. In the second scenario, the minor class—in our case, AD—is marginally favored by the classifier. By increasing the system's sensitivity, this technique seeks to maximize the detection of AD at the cost of poor specificity, which increases the number of AD cases detected but also raises the possibility of FP results. In all scenarios, the recall, which gauges the proportion of accurately categorized data points in a particular class, stays random. According to our experimental findings, specificity is correlated with the memory of the CN/MCI class and sensitivity with the recall of the AD class. Thus, we would get the following results from the first random classifier: $Sensitivity = 0.38,\ Specificity = 0.62, and\ F1 = 0.4712$, while we would gain the following results from the second classifier: $Sensitivity = Specificity = F1 = 0.5$. The DOR for both iterations of the random classifier is 1. Currently, we have chosen the maximum values for sensitivity and specificity as our lower bounds to maximize performance optimization. As so, the following cutoff points are determined:
$Specificity_{min} = 0.62, F1_{min} = 0.554, and\ Sensitivity_{min} = 0.5.$

2) Technique 1: HMM Classification*:* Fig. 4, 5, 6, and 7 show the harmonic mean of the two (F1-score) and the sensitivity and specificity measures for increasing numbers of states. These graphs show that the number of states does not rise along with the performance of the system. The Fig. 4 and 6 show that, although the effect is not significant, there is a tendency for sensitivity to rise and specificity to fall while the F1-score remains stable. Striking for near and high values for both sensitivity and specificity is generally accepted as the standard technique. While reaching the highest possible level for both is desirable, these two metrics frequently show an adverse connection, even in the case of an absolute classifier. Positive and negative data points are accurately classified by a highly effective classifier with little to no FP and FN. Reduced specificity and sensitivity are the results of these FP and FN. A classifier's sensitivity will be almost perfect, but its specificity will be quite poor if it overclassifies one class, for example, classifying all data points as positive. In order to obtain a higher performance overall, it is wise to establish a balance between these criteria. It is clear from the blind experiment (see Fig. 4) that the sensitivity is higher than the allowable limit and the specificity first reaches the limit before declining as more states are used. Subjects with three follow-ups show a similar tendency (see Fig. 6), but the metrics are improved, leading to improved specificity performance and a delayed divergence between the two metrics. Both times, the F1-score greatly exceeds the upper bound. On the other hand, noticeably more stable metric graphs are produced by the semi-blind experiment (see Fig. 5). With very few exceptions, specificity usually reaches or exceeds the 0.62 threshold while sensitivity stays high. The stability of the graphs includes both the proximity of the two measures when compared and fluctuations in each metric separately. Similar behavior is shown in participants who have had three follow-ups, with higher metrics and a particularly noticeable improvement in specificity (see Fig. 7). The evolution of the DOR for the blind and semi-blind tests, with the full MCI group or just participants who had three follow-ups, is shown in Fig. 8. With all ratios remaining well over 2 (with 1 as the limit) and exhibiting little volatility, excellent results are seen in this case. When subjects receive three follow-ups, the blind experiment performs best in terms of DOR.

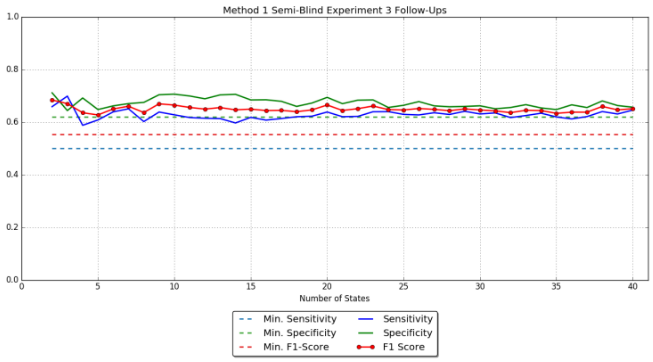

Fig. 7. Technique 1 with 3 semi-blind experiments: sensitivity and specificity for increasing number of HMM states (F1 score on average is 0.64).

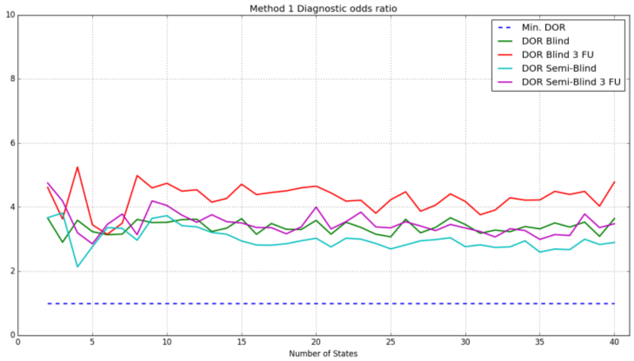

Fig. 8. DOR for the different approaches of technique 1.

3) Technique 2: HMM Modelling SVM Classification*:* The graphs take on greater interest when the second technique is examined in Fig. 9 to Fig. 20. This technique shows the F1 scores, sensitivity, and specificity for every experiment variant—Blind/Semi-Blind, all/only three follow-up scans, and each unique number of SVM folds (5, 7, & 10). Fig. 9, 10, and 11 show that the graphs for the various folds within the same type of trial are nearly identical, suggesting that SVM cross-validation has no discernible impact on system performance. Notably, the second technique shows extremely low sensitivity and very high specificity (approaching 1 for participants with three follow-up scans), which results in a low F1 score. The preceding section covered the phenomena of inverse behavior between sensitivity and specificity. After doing a thorough study of the data and examining the confusion matrices generated (see Fig. 24), it is apparent that the classifier primarily classifies most of the data as CN/MCI, which accounts for the remarkably high specificity and low sensitivity. The significant variety of the state sequences produced by the HMMs and utilized as feature vectors for the SVM makes them non-separable data, as was previously discussed. As a result, the SVM finds it difficult to identify an appropriate separating hyperplane. Upon reviewing the DORs see Fig. 21, 22, and 23) for this technique, it is evident that the system's behavior has not been affected by cross-validation for SVM, since all DOR graphs remain almost the same for varying numbers of folds. The DOR values are extremely low—much lower than those obtained using technique I. DORs in the blind tests may fall to levels less than 1. With this technique, adding MCI cases to the training set results in a marginal improvement in performance, which is mainly manifested in a smaller sensitivity/specificity divergence. Even yet, the overall outcomes are still unimpressive. Fig. 24 show two examples of confusion matrices for several experiment runs that show how many data points were categorized into each class. The confusion matrix's decimal numbers can be explained by the fact that all trials, as mentioned in Section III (A), are run ten times in order to reduce the impact of outliers. The average number of data points classified in each class over ten experiments with the same settings is effectively represented by these decimal figures. The creation of Technique 3 was spurred by the significant differences in sensitivity and specificity found in this technique.

4) Technique 3: HMM Modelling SVM Classification 2: In the context of the third technique, the sensitivity, specificity, and F1 score graphs for the different tests and varying numbers of SVM folds are displayed once more (see Fig. 25- Fig. 36). SVM cross-validation is often found to have minimal impact on system performance when the number of folds is changed. It is important to note that the semi-blind trials are greatly impacted by the participation of MCI participants. As demonstrated in Technique 1, the disparity between sensitivity and specificity is reduced (see Fig. 28, 29, 30, 34, 35 and 36). Not only is there no divergence here, but convergence is observed. Both metrics cross over in each of the Figures and then stay rather close after that. Fig. 31– Fig. 33 show how, during the experiment, sensitivity and specificity closely coincide with one another. Sensitivity/specificity graphs and DOR graphs are provided, much like in the previous two techniques. Specificity faces difficulties in the blind trial, falling to and remaining at the lowest threshold. But there is a noticeable improvement when compared to the second technique, suggesting that using frequency maps instead of the real state sequences makes the data easier to separate and preserves important details about the evolution of the condition. The semi-blind studies do, in fact, help to lessen the sensitivity/specificity gap, although the F1 score, and both measures show a modest reduction (see Fig. 28–30). With values far above 3.0, the DOR graphs in Fig. 37– Fig. 39 show a discernible improvement over the previous technique. When MCI participants are included in the training process, these data show a reduction that is comparable to that seen in the sensitivity/specificity graphs.

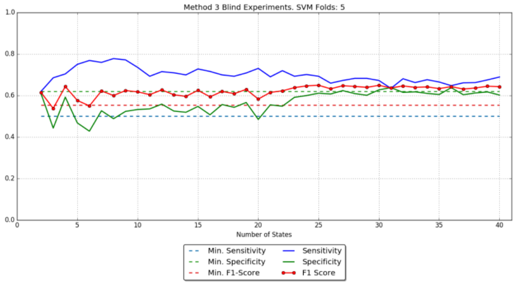

Fig. 25. Technique 3 with blind experiments: sensitivity and specificity for increasing number of HMM states with 5 SVM folds (F1 score on average is 0.62).

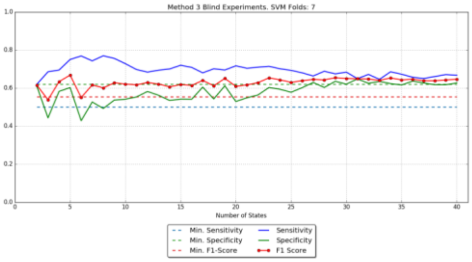

Fig. 26. Technique 3 with blind experiments: sensitivity and specificity for increasing number of HMM states with 7 SVM folds (F1 score on average is 0.62).

VI. Discussion

Thus far, the analyses and findings have primarily operated at a theoretical level, focusing on the techniques from a broader scientific perspective and integrating sensitivity, specificity, and DOR graphs generated across multiple states. On the other hand, specific instances of the trained and evaluated classifiers would be of interest to us if these techniques were to be applied in real life. Put another way, we want to assess the best "runs" of each technique rather than comparing results for the HMMs across various numbers of states (the major variable). To do this, we created Fig. 40 and Fig. 41, which show a ROC space filled with data points that indicate the greatest examples of each technique. For every technique, these data points represent the ideal run's TPR and 1−TNR. The various techniques are denoted by the letter M in the legend of these figures. Furthermore, we present the Euclidean distance (ED) of every point as measured from the upper-left corner; smaller EDs denote better performance. Tables I and II also provide a summary of these numerical values. The various methodologies and techniques can be more easily compared and contrasted thanks to this tabulation and visualization, which presents the performances visually. These Figures clearly show that adding MCI participants to the training set improves all tested techniques' peak points, with technique 2 showing the greatest improvement. Although Technique 2's initial performance was lower than that of a random classifier, it eventually obtains performance comparable to the other two (see Fig. 40). Furthermore, Technique 1 and 3 yield almost identical results, with Technique 3 slightly outperforming, especially for participants who receive three follow-up scans. An additional important inference from these Figures, which is further supported by the results of the separate technique, is the importance of prolonged MRI sequences. We regularly see that participants with three follow-up scans had better results than the overall results in all the presented Figures. This implies that there may be a greater likelihood of detecting AD progression, MCI progression, or perhaps conversion to CN in these individuals. It emphasizes how important it is for each person to get as many follow-up scans as possible to provide more precise projections. Moreover, selecting a different number of folds for SVM training has little effect on performance, consistent with other findings. One noteworthy observation from the data shown in Tables I and II is that although the metrics for sensitivity and specificity increase for participants who receive three follow-ups, the relative importance of the measures is inverted. When classifying all individuals, our technique shows higher sensitivity; but, when applied to participants with longer MRI sequences, it shows higher specificity. The unequal distribution of diagnosis across various numbers of follow-up scans can be used to justify this.

VII. Conclusion and Future Works

To sum up, the main goal of this study was to create a model that could be used to predict how patients with MCI would progress based only on the examination of their longitudinal MRI scans. Another goal of this study was to use MRI data to derive useful diagnostic information without the need for further diagnostic instruments like cognitive tests. Predicting whether patients with MCI would develop AD was the third goal. Three different techniques based on HMMs were developed, one building on the other. It is clear from looking at the experimental findings that Techniques 1 and 3 have generated models that work well. These techniques have produced results that are both much higher than the preset criteria for sensitivity and higher than even the harsher predefined threshold for specificity. Particularly, technique 3 performs the best, closely followed by Technique 1. Technique 3, the best classifier, can identify 77.6% of participants who advance to AD and 64.1% of people who remain stable with MCI or return to normal cognitive status. It uses a semi-blind method with 5-fold SVM training. Furthermore, the findings highlight the structural information contained in the MRI images, which provides important information on how a patient's cognitive state is developing. Notably, the first technique relies on HMMs as the primary classifier without the requirement for a secondary classifier, using only the structural and temporal information from the scans for categorization. The findings further highlight the importance of the longitudinal MRI sequences' duration. Longer sequences consistently result in greater system performance, especially those with three follow-up scans. This emphasizes how crucial it is to get more follow-up scans for every person to improve prediction accuracy. The dataset's limitations present difficulties for future investigation. A primary concern pertains to the size of the dataset, which is determined by the expense and duration of MRI scans as well as the preprocessing done with Freesurfer. One can focus on decreasing processing time, increasing the dataset with longer sequences, and optimizing preprocessing efficiency through parallelization. A flag to denote confirmed diagnoses might also be introduced to alleviate the uncertainty around diagnoses. This would enable weighting of subjects with certain diagnoses and enable semi-supervised learning. Additional preprocessing procedures, like clustering or dimensionality reduction, to simplify and improve the feature vectors might be added in the future. It may also be worthwhile to investigate more sophisticated machine learning methods, such as Convolutional Neural Networks (ConvNets), Deep Neural Networks (DeepNets), and Recurrent Neural Networks (RNNs). Without a set input length, RNNs excel at modeling sequential and temporal data. Conversely, DeepNets and ConvNets provide high precision modeling of complicated data, which may minimize the need for intensive preprocessing. ConvNets may be able to operate directly with raw MRI scans, omitting the feature extraction stage, albeit their use may necessitate much bigger datasets. Although these methods offer fascinating directions for future study, their applicability in medicine will depend on the availability of data and developments in neural network technology.

***Abstract*—The reliance on data collection for assessing individual behavior and actions has intensified, particularly with the proliferation of digital platforms. People often use the Internet to express their opinions and experiences about various products and services on social media and personal websites. Concurrently, the stock market, a key driver of commercial and industrial growth, has seen a surge in research focused on predicting market trends. The vast array of information on social media regarding public sentiment towards current events, coupled with the known impact of financial news on stock prices, has led to the application of data mining techniques for understanding market volatility. This research proposes a novel method that integrates social media data, encompassing public sentiment, news, and historical stock prices, to predict future stock trends. The approach involves two primary phases. The first phase develops a sentiment analysis (SA) model using three dilated convolution layers for feature extraction and classification. Addressing the challenge of unbalanced classification, a reinforcement learning (RL)-based strategy is employed, wherein an agent receives varied rewards for accurate classification, with a bias towards the minority class. Additionally, a unique clustering-based mutation operator within a differential equation (DE) framework is introduced to initiate the backpropagation (BP) process. The second phase incorporates an attention-based long short-term memory (LSTM) model, merging historical stock prices with sentiment data. An experimental analysis of the study dataset is conducted to determine optimal values for significant parameters, including the reward function.**

Keywords—Social media; stock market; sentiment analysis; unbalanced classification; reinforcement learning; differential equation; long short-term memory

I. Introduction

Before the World Wide Web, people's decisions were influenced by opinions from colleagues and friends. With the rise of the internet, there's been an increase in sharing opinions with strangers online. People now express their views on a variety of topics, including news and products, on social networking sites like Twitter [1]. SA is a research field focused on categorizing these opinions into positive, negative, or neutral sentiments, often involving opinion mining to analyze textual expressions. Social media platforms like Facebook and Instagram have become key for expressing opinions, offering a vast resource for SA to gain insights into public sentiment on diverse topics [2].

In recent years, a specialized market has developed, focusing specifically on detecting and analyzing sentiments in the financial sector. This niche is centered on identifying and assessing sentiments tied to financial transactions. The skill to predict stock prices accurately is highly valuable for researchers and investors, especially given the volatility and unpredictability of these prices [3]. Machine Learning (ML) techniques have shown potential in improving the accuracy and dependability of stock market forecasts, yet designing an effective stock prediction model is still a complex task. Stock market behavior is shaped by a mix of social mood and historical price trends, which significantly influence stock price movements and changes. Integrating these elements into predictive models is essential for obtaining meaningful insights and making well-informed investment choices.

The influence of daily news articles on stock market performance is substantial [4]. These articles, containing vital information about companies, budgets, and trends, significantly affect public sentiment and stock market strategies. By analyzing these articles, investors can obtain critical insights for better investment decisions. This paper aims to use news articles to forecast stock market trends, focusing on those that provide insights into specific industries and predict future stock price movements. The increasing availability of financial data offers an opportunity to improve the speed and accuracy of these predictions [5].

SA faces challenges due to data imbalance, marked by significant discrepancies between negative and positive instances [6]. To combat this, there are both algorithm-based and data-based approaches. Data-based techniques include under-sampling, over-sampling, or combining both to reduce the impact of class imbalance. For instance, SMOTE [7] creates new samples by interpolating between minority instances, while NearMiss [8] applies under-sampling through the nearest neighbor algorithm. While over-sampling may lead to overfitting, under-sampling could result in the loss of important information. On the algorithm side, strategies are developed to give more weight to the underrepresented class. These involve enhanced ensemble learning, adjusting decision thresholds, and implementing cost-sensitive learning methods [9]. In cost-sensitive learning, classification is seen as a cost-minimization problem, assigning greater penalties for misclassifying minority samples. Ensemble techniques combine the predictions of multiple classifiers, and threshold adjustments modify the decision threshold during the testing phase.

Deep learning techniques, including Deep Reinforcement Learning (DRL), offer effective solutions for imbalanced classification issues [10, 11]. DRL stands out for its ability to manage imbalanced data through its distinctive features. It employs a reward system that prioritizes the minority class by either penalizing misclassification more severely or rewarding correct identification more generously. This method proactively counteracts the tendency of traditional models to favor the majority class. The benefits of DRL extend beyond just equalizing class distribution. It improves the recognition of significant patterns, especially those pertaining to the minority class, by adeptly filtering out irrelevant data. DRL's capacity to identify key, often-missed features in the dataset plays a vital role in developing models that are both more accurate and efficient [12].

Neural network weight initialization significantly affects the training efficiency and accuracy in SM prediction. Usually, weights are randomly assigned in gradient-based training algorithms like backpropagation [13, 14]. However, the choice of initial weights is vital for effective convergence and overall training performance [15, 16]. To improve weight initialization, population-based training can be used, selecting the optimal model from a pool to initiate the neural network. This method helps overcome the issue of local optima common in traditional methods. Notably, evolutionary algorithms have shown to be as effective as stochastic gradient descent for neural network training [17, 18]. Differential Evolution (DE) [19], a population-based optimization algorithm, is effective for machine learning weight initialization [20]. It offers several benefits: it explores the solution space with diverse candidate solutions, avoiding local optima and leading to optimal weight configurations. DE's iterative update process, based on the differential between target and current solutions, results in faster convergence and better performance. Additionally, DE is robust against noisy data, ensuring stable initial weight configurations even amidst data uncertainties. Its flexibility allows for customization to specific needs, like setting weight boundaries or incorporating prior knowledge, making it adaptable for various learning tasks and enhancing its effectiveness in weight initialization.

In this study, a novel approach is introduced to analyze social media data, combining public sentiment, personal opinions, news trends, and historical stock data to predict future stock prices. The methodology consists of two main stages. In the first stage, a SA model is developed using three dilated convolution layers to extract feature vectors and perform classification tasks. To address the challenge of unbalanced classification, a unique strategy based on RL is proposed, treating the task as a series of decision-making processes. The agent receives rewards at each step based on accurate classification, with a smaller reward assigned to the majority class to address the class imbalance. In the second stage, an attention-based Long Short-Term Memory (LSTM) approach is employed. This involves combining historical stock prices with the sentiment analysis results from the previous stage to make informed predictions. The optimal values for key parameters, including the reward function, are determined through experimental studies conducted on the dataset. To assess the individual contributions of the RL component, ablation studies are conducted to confirm the independent and cumulative positive effects on the overall performance of the model. The key contributions of the proposed model can be distilled into the following points:

- In the SA model, an ensemble of dilated convolutions is employed to extract valuable insights from textual data. This enhances the accuracy and informed decision-making in classification tasks.
- To address the challenge of imbalanced classification in SA, an RL strategy is proposed. This innovative approach provides a fresh perspective on achieving a balance between different classes.
- The model incorporates a unique reward system that reinforces correct decisions and penalizes incorrect ones. By assigning higher rewards to the minority class, the issue of dataset imbalance is effectively tackled, encouraging the model to give due attention to underrepresented data. This strategic approach contributes to a more balanced and equitable classification process.
- An improved DE algorithm that utilizes clustering to initialize weights in the SA model effectively has been devised. This approach aids in identifying a promising region to initiate the BP algorithm within the model. By selecting the optimal or near-optimal solution from the best cluster as the initial solution in the mutation operator and employing a new updating strategy, candidate solutions are generated more efficiently.

The structure of the article is as follows: Section II provides a literature review on stock market prediction. In Section III, the proposed approach is delved into in more detail. The experimental results and analyses are presented in Section IV. Finally, Section V concludes the paper.

II. RELATED WORK

Opinion mining focuses on capturing individuals' unique perspectives and opinions and finds applications in various fields such as product reviews, surveillance, healthcare, and politics. Accurately predicting changes in stock prices is a crucial research area, and recent advancements have been made in creating predictive models for the global stock market. Traditional methods like time series analysis and machine learning (ML) models are commonly used in academic research to analyze stock market predictions. Numerous approaches for analyzing social media (SM) have been explored in scholarly literature. Milosevic et al. [21] and Pandya et al. [22] introduced an ML method that utilizes selected financial variables to predict long-term investments, achieving improved performance through feature selection. Porshnev et al. [23] combined support vector machine (SVM) and neural network (NN) algorithms, utilizing a lexicon-based approach to analyze psychological states and their impact on stock market indicators like DJIA and S&P500. They effectively demonstrated the influence of Twitter data on stock market performance. Lai et al. [15] investigated stock prediction models using support vector machine (SVM) and least square SVM. Athale et al. [24] and Mehta et al. [25] utilized SA and ML to explore the relationship between public sentiment and stock performance, aiming to address the complex and unpredictable nature of non-linear and non-parametric financial time series. Xing et al. [26] highlighted the capabilities of natural language processing (NLP) in financial forecasting, particularly in the domain of Natural Language-Based Financial Forecasting (NLFF) or sentiment analysis using data from SM platforms. NLP techniques are rapidly advancing, specifically in NLFF and the analysis of SM data, driven by practical applications in financial forecasting. However, despite these advancements, a gap remains in integrating comprehensive social media data with advanced sentiment analysis and machine learning techniques for precise stock market predictions. The proposed research aims to bridge this gap by combining public sentiment, news, and historical stock prices to predict future stock trends more accurately.

Emotion plays a crucial role in facilitating effective communication, as indicated by research conducted by Pandya et al. [22] and Smailović et al. [27], who explored the usefulness of Twitter feeds for predicting stock closing prices and assessing public sentiment towards companies and their products. In this paper, a method is introduced to measure the probability of positive and negative expressions or opinions, with the aim of forecasting SA in the field of finance. Using the Granger causality test, stock price trends can be examined over a short period, providing valuable insights from the data [5]. The use of SVM enables the categorization of tweets into positive, negative, or neutral sentiments, thereby enhancing the predictive capability of SM platforms. Various initiatives have been undertaken to predict SM trends, with a focus on accurately forecasting the significant impact of a company's SM presence through real-time collection of Twitter data. The study demonstrates the effectiveness of sentiment analysis in extracting public mood from Twitter and other SM platforms to predict fluctuations in individual stock prices. In order to bolster the analytical process, the active learning model has been integrated with a stream-based method. This combination enables the algorithm to choose fresh training data, thereby enhancing its performance. The financial implications of this analysis are evaluated by employing Recurrent Neural Networks (RNNs) in a trial-based methodology. The proposed model extends these efforts by employing a novel clustering-based mutation operator within a DE framework and integrating sentiment analysis with attention-based LSTM models, a distinct approach not yet explored in existing literature.

Examining sentiment helps in evaluating the impact of emotions within a textual context when analyzing decision-making with a positive outlook. Bhuriya et al. [28] developed predictive models using regression techniques to forecast the market price of TCS. These models were based on attributes such as large price, close price, open price, small price, and volume. The study assessed the effectiveness of linear, polynomial, and radial base function regression models by considering the confidence values associated with the predicted results. Despite having expertise, predicting stock prices remains challenging due to unexpected fluctuations influenced by historical trends and past price changes in the global market economy. Barot et al. [4] proposed a research approach that utilized sentiment analysis to analyze news articles and forecast stock price fluctuations. They introduced a method for categorizing articles based on sentiment, classifying them as positive, negative, or neutral. This approach was integrated into machine learning models to improve the accuracy of stock market prediction. Patel et al. [29] and Patel et al. [30] examined the practical implementation of a machine learning model to forecast stock and share price movements in the Indian equity market. The analysis incorporated four forecasting models (SVM, ANN, Naïve Bayes, and Random Forest) with two input methods. Khedr et al. [31] introduced an optimized model that aimed to reduce error ratio and improve the accuracy of predicting patterns in share price performance. Their predictive model integrated sentiment analysis of financial news and historical values of social media data. These approaches have successfully utilized various types of market and company data, leading to superior outcomes compared to previous research. Chen et al. [32] conducted a comparison between conventional neural network price prediction and deep learning techniques using Chinese social media data on CSI 300 shared values. Their findings indicated that deep learning predictions outperformed conventional neural networks in terms of performance. Carosia et al. [33] conducted a study to investigate the influence of SM activities, specifically on the Brazilian SM platform Twitter, on the market value of specific companies. They utilized sentiment analysis (SA) to analyze the impact of SM movements on these companies. The study considered three different perspectives: the total count of emotions expressed in tweets, tweet sentiments weighted by the number of favorites, and tweet sentiments weighted by the number of retweets. SA was performed using the Multilayer Perceptron technique to analyze sentiment in Portuguese. Deep learning algorithms, including deeply convolutional neural networks (CNN), have gained prominence in SA. Santos et al. [34] employed a deep CNN trained on the Stanford Sentiment Treebank and the Stanford Twitter Sentiment Corpus. The model achieved an impressive accuracy of over 85% in predicting sentiment for both datasets. Yoshihara et al. [35] discussed an SA technique that combined recurrent neural networks (RNN) with Deep Belief Networks (DBN) in deep learning, resulting in improved financial market forecasting with reduced error rates compared to SVM and DBN strategies. In another study by Jiang et al. [36], deep learning models were analyzed to forecast SM trends. The research involved categorizing various NN models, evaluating metrics, exploring their integration, and assessing their reliability. Pang et al. [37] and Sun et al. [38] proposed the utilization of STM in NN techniques to enhance the accuracy of financial market predictions, particularly for the Shanghai A-shares composite index. Khan et al. [39] incorporated data algorithms that combined social networks and business news to evaluate the impact on the accuracy of SM forecasts over a 10-day period. They implemented feature selection and spam tweet removal techniques, and the use of deep learning techniques improved the accuracy rates. The research findings indicated that assessing the impact of SM is a complex task, with New York and Red Hat stocks showing significant sensitivity to SM activity, while London and Microsoft stocks are more influenced by financial news.

To sum up, existing literature showcases a variety of methods for price prediction. Although traditional deep learning techniques have significantly progressed the field, their limitations include a lack of social media data utilization and sensitivity to initial weights, which hinders their practical application in forecasting. Moreover, the issue of unbalanced classification remains a prevalent challenge for many deep learning models. Addressing these shortcomings, the study introduces an innovative methodology that combines the strengths of RL with the adaptive potential of a DE algorithm, specifically fine-tuned for initial weight optimization. This approach is engineered to surmount the conventional obstacles encountered by deep learning methods, thereby boosting the model's adaptability and efficiency in identifying cost-effective strategies for price prediction. The goal is to offer a sophisticated and robust tool to the suite of price prediction methods, one that is not only theoretically ground-breaking but also practically relevant in a variety of real-world scenarios.

III. Proposed Method

Based on Fig. 1, the proposed model is structured into four distinct steps, each integral to the overall process:

- The first step is Data Collection, where relevant data is gathered from various sources.
- The second step is Data Pre-processing. In this phase, the collected data undergoes cleaning and transformation to make it suitable for analysis.
- In the third stage, the focus shifts to analyzing news content using NLP for SA. This essential phase leverages advanced natural language processing (NLP) methods to assess the emotional undertones within the news material. The aim is to systematically identify the sentiment of each article, classifying it as either positive, negative, or neutral. The SA model is specially tailored to refine the classification mechanism, addressing critical challenges such as class imbalance and the need for accurate initial weight configurations. The integration of DE and RL in the proposed framework specifically targets these pivotal areas, which are often inadequately addressed by existing models. Conventional techniques typically lack a structured approach for setting initial weights, potentially slowing down the learning process and leading to suboptimal solutions. In the context of SA, where promptness and precision in prediction are essential, these limitations can be significant. Moreover, the model's RL component is designed to provide greater incentives for correctly predicting less frequent classes, thus shifting the focus to these vital predictions. This represents a marked advancement over traditional supervised learning models, which may struggle with insufficient data representation across all categories. The flexibility of RL in adjusting the learning strategy ensures a more equitable exploration of decision-making options, fostering approaches that prioritize the accurate identification of less represented categories. This distinctive capability of RL within the model distinguishes it from current methods, enabling it to address the unique challenges that traditional classification models face in SA applications.
- The final step is SM forecasting. Using the insights gained from the sentiment analysis, along with other relevant financial indicators and historical data, this stage focuses on predicting future movements of the stock market.

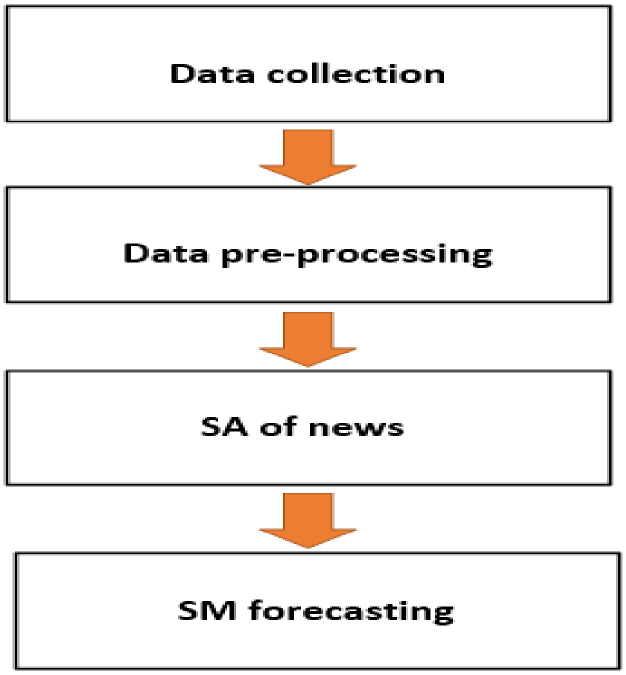

Fig. 1. The constituent stages of the proposed model.

A. Data Collection

The system design is founded on the use of two distinct datasets from various data providers. The first dataset includes news articles from reputable platforms like Moneycontrol, IIFL, Economic Times, and Twitter. This collection provides a broad perspective on market-related news, encompassing company announcements, industry trends, and economic developments, crucial for understanding stock market behavior. The second dataset contains historical records from the National Stock Exchange (NSE) of India, spanning six years. It features key parameters such as date, time, open, high, low, close values of stocks, and trading volume. This dataset is instrumental in analyzing past market trends and patterns, thereby aiding in generating insights into the behavior of individual stocks and the overall market. The data management strategy involves storing the gathered information in CSV file format. This approach offers several benefits. Firstly, it ensures convenient organization, enabling users to navigate and interpret the data efficiently. Secondly, the reduced file size makes it more manageable and less resource-intensive to handle large amounts of data. Additionally, the ease of generating and manipulating CSV files facilitates smooth data processing. Finally, this format enhances data integrity, ensuring that the information remains accurate and reliable for analysis. By integrating these datasets, the system aims to create a comprehensive framework that leverages the strengths of both news and stock market data. This dual-dataset approach is expected to provide a more nuanced and detailed understanding of the factors influencing the stock market, thus supporting more informed and effective decision-making in financial analytics.

B. Data Pre-processing

The pre-processing phase of the study begins with synchronizing text data and converting it to lowercase characters. This step is vital to address various text factors that could impact the classification process. The primary objective is to prepare the input data for sentiment classification, making it suitable for analysis. This preparation involves several tasks, such as removing links, special symbols, and emoticons, along with eliminating stop words. Further, the process includes analyzing parts of speech, applying stemming techniques, and tokenizing the text. These steps are essential to extract meaningful features for sentiment analysis. The output from the pre-processor subsystem then becomes the input for the sentiment classifier method.

The framework described in the article adopts a data-driven approach, leveraging historical stock prices recorded at opening and closing times. This rich dataset forms the foundation for analyzing and understanding stock price behavior over time. To represent these prices effectively, the framework utilizes a sentiment polarity approach. This involves categorizing stock prices as either positive or negative, aiming to capture the underlying emotional sentiment in the stock market. The sentiment polarity representation is instrumental in providing insights into market dynamics, highlighting the influence of emotions and perceptions on stock prices. To substantiate the effectiveness of this approach, a study was conducted at Stanford University [40]. This study integrated sentiment polarity values derived from the framework, aiming to explore the correlation between sentiment polarity and stock price movements. The findings of this study are enlightening, revealing the intricate relationship between market sentiment and financial outcomes. They underscore the importance of sentiment analysis in predicting stock market trends. These insights are particularly beneficial for investors, traders, and financial analysts, aiding them in making more informed and strategic decisions.

C. SA of News

Fig. 2 in the study illustrates the proposed structure for the SA model. This model functions based on a sentence D, defined as a series of words $[w_1, w_2, \ldots, w_\mathrm{n}]$, where n is the maximum number of words in a sentence. The sentence is fed into the BERT model, which generates an embedding matrix $E = [e_1; e_2; \ldots; e_n]$, with each e_i representing the embedding of the corresponding word w_i. To extract features, three dilated convolution layers are applied in parallel to matrix E. Each of these layers independently extracts a distinct feature vector from the sentence. Following this, max pooling is implemented to capture the most significant features while simultaneously reducing computational complexity. The outputs from the max-pooling layers are then directed into a Multilayer Perceptron (MLP) for classification purposes. The MLP's output is a vector of length three, representing the classification of the input sentence into one of three categories: positive, negative, or neutral. However, one of the challenges encountered in this model is the imbalanced nature of the dataset, predominantly skewed towards sentences classified as positive. This imbalance can potentially impair the performance of the system. To address this imbalance, the model incorporates an imbalanced classification Markov decision process. This process involves the use of a sequential decision-maker, specifically designed to tackle the challenges posed by the imbalanced classification problem. The decision-maker operates by adjusting the classification strategy, focusing on equitably distributing attention across all classes, including those less represented in the dataset. This approach not only enhances the accuracy of the model but also ensures a more balanced and equitable classification outcome, vital for the integrity and applicability of sentiment analysis in various contexts.

1) Pre-training: Weight initialization plays a vital role in the performance of deep learning models [41]. Choosing the right initial values for weights is crucial because inappropriate values can lead to convergence problems, making the model less effective or even rendering it non-functional. Proper initialization helps in achieving a faster convergence rate and improves the overall training efficiency of the model. It also impacts the ability of the model to reach global or good local minima in the optimization landscape. Different initialization methods, such as Xavier/Glorot, He initialization, or random initialization, are tailored for specific types of neural networks and activation functions. These methods aim to maintain a balance in the variance of the activations and gradients throughout the network, which is critical for deep models. The right choice of weight initialization method can significantly influence the learning dynamics and the eventual success of the model in tasks like classification, regression, or feature learning.

DE [42] stands as a prominent method within the realm of evolutionary algorithms, primarily used for solving complex optimization problems. As a population-based approach, DE focuses on iteratively refining a group of candidate solutions to converge towards an optimal solution for a given problem. The strength of DE lies in its unique mechanisms of mutation, crossover, and selection, which collectively drive the evolutionary process. Mutation in DE is a distinctive process where a new candidate solution is generated by adding the weighted difference between two randomly selected solutions from the population to a third solution. This approach introduces diversity and aids in exploring the solution space. The crossover step in DE further enhances solution diversity by combining features of the mutated solution with an existing member of the population, creating a trial solution [43]. This crossover mechanism ensures a mix of characteristics from different solutions, promoting the exploration and exploitation of the solution space. Selection, the final step in DE, is critical for the evolution of the population. It involves a comparison between the trial solution and the existing solution, retaining the one that offers better performance according to the defined objective function. This selective pressure gradually improves the overall quality of the population, steering it towards the optimal solution. DE's effectiveness is not limited to a single domain but extends across various fields such as engineering, economics, and machine learning. Its popularity stems from its simplicity, efficiency, and versatility in handling different types of optimization problems, including those with nonlinear, multimodal, and high-dimensional characteristics. Its ability to find high-quality solutions with relatively simple operations and fewer control parameters makes it a go-to choose for practitioners and researchers in optimization tasks.

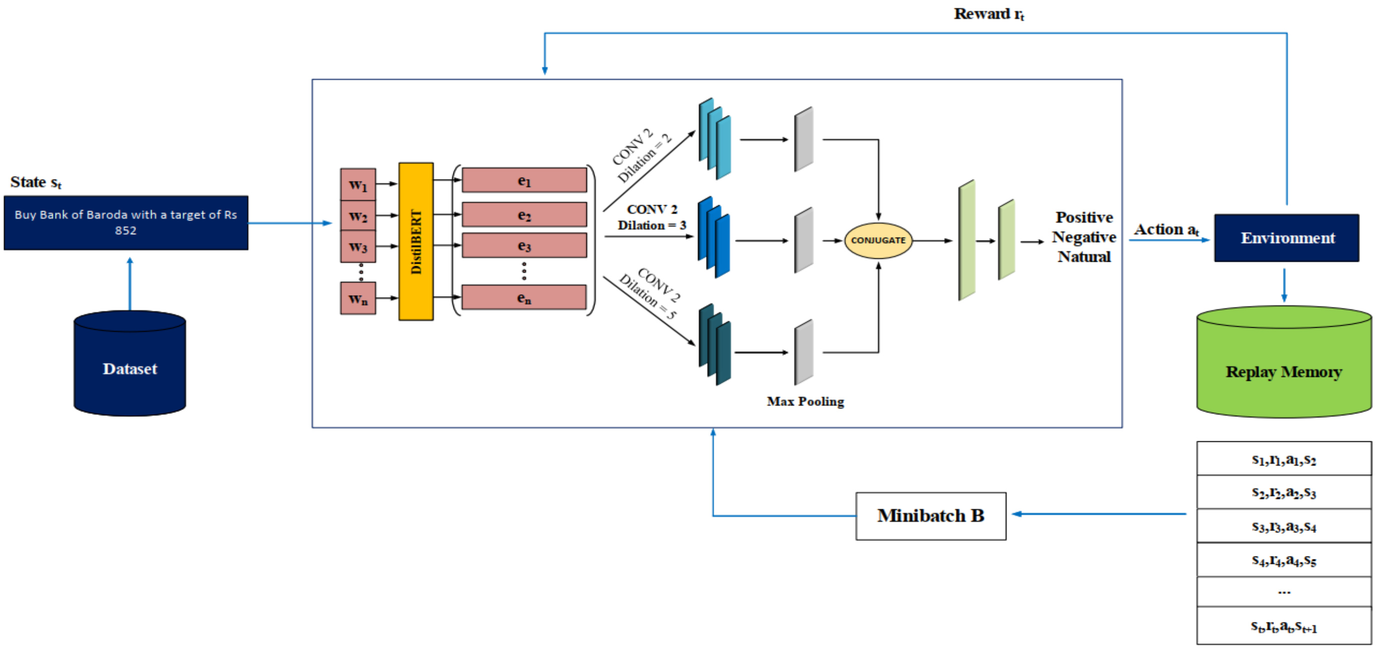

Fig. 2. The proposed SA model.

The mutation operator in DE is a pivotal component that significantly influences the algorithm's ability to search effectively across the solution space. This operator is responsible for introducing variability in the population, which is essential for exploring new regions in the search space and avoiding local optima. However, the effectiveness of the mutation operator is a delicate balance. If it is overly aggressive, it might disrupt the population's structure too much, leading to the loss of promising solutions and potential premature convergence or stagnation. In contrast, an overly conservative mutation approach may not provide sufficient exploration, leading to slow convergence rates and possibly settling for suboptimal solutions. To tackle these challenges, various modifications and enhancements to the standard mutation process in DE have been proposed. One of the notable advancements is the introduction of adaptive mutation schemes. These schemes dynamically adjust the mutation parameters, like the mutation rate and scaling factor, based on real-time feedback from the population's performance. By doing so, the algorithm can maintain an optimal balance between exploration and exploitation throughout the optimization process, adapting to the changing landscape of the search space. Another innovative approach is self-adaptive DE, where the mutation parameters are not fixed but are treated as part of the solution itself. In this method, each candidate solution carries its mutation rate and scaling factor, which evolve alongside the solution. This self-adaptation allows for a more tailored mutation process for each candidate solution, potentially enhancing the diversity and adaptability of the population [44].

To further boost the performance of the DE algorithm, a cutting-edge mutation and updating approach, which incorporates clustering concepts, is utilized to bolster the optimization process. This innovative strategy, drawing inspiration from the methodologies outlined in reference [45], focuses on employing the mutation operator to precisely target designated sectors within the search landscape. This is achieved through the application of the k-means algorithm, which effectively divides the current population P into k distinct clusters. Each cluster corresponds to a unique segment of the search space, thus facilitating a more focused and efficient exploration. The determination of the number of clusters is conducted in a stochastic manner, with the possible range stretching from 2 to the square root of N ($\sqrt{N}$). Upon completion of the clustering phase, the algorithm proceeds to identify the most optimal cluster. This is determined based on the average fitness level of the members within each cluster, with the one displaying the lowest mean fitness being designated as the most favorable. This particular cluster is then prioritized in the subsequent phases of the algorithm, as it is indicative of a region in the search space with a higher potential for yielding optimal solutions. Fig. 3 serves as a visual representation of this advanced methodology. In this figure, a theoretical problem encompassing 19 potential solutions is illustrated. These solutions are methodically grouped into three separate clusters, each representing a different area of the solution space. This visualization not only demonstrates the clustering mechanism but also highlights the effectiveness of this approach in partitioning the population for more targeted and efficient optimization. Through this sophisticated clustering-based mutation and update strategy, the DE algorithm is significantly enhanced, offering a more robust and precise tool for tackling complex optimization challenges.

The proposed mutation, based on clustering, is then defined as [45]:

$$\overrightarrow{v_i^{clu}} = \overrightarrow{win_g} + F(\overrightarrow{x_{r_1}} - \overrightarrow{x_{r_2}}) \quad (1)$$

In this context, $\overrightarrow{x_{r_1}}$ and $\overrightarrow{x_{r_2}}$ symbolize two randomly chosen candidate solutions from the existing population, whereas $\overrightarrow{win_g}$ represents the optimal solution found within the identified promising region. It is critical to acknowledge that $\overrightarrow{win_g}$ may not always equate to the best solution across the entire population.

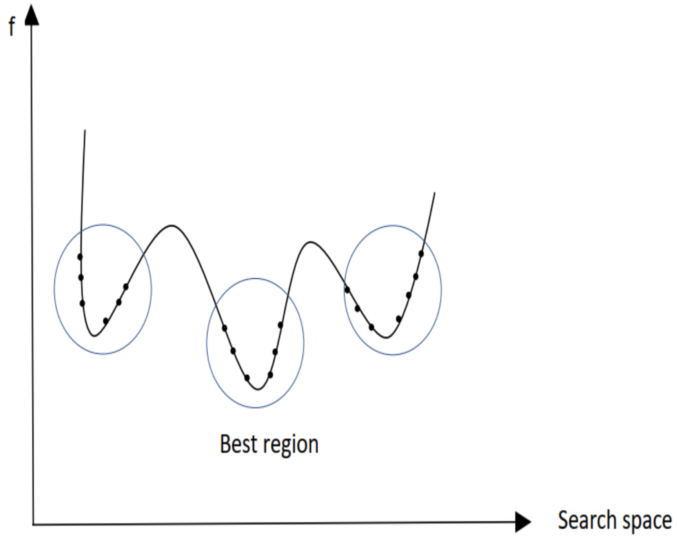

Fig. 3. Utilizing population clustering within the search space to identify the most favorable region.

Subsequent to the creation of M novel solutions via the mutation process influenced by clustering, the current population undergoes an update process as per the guidelines of Gradient-based Population Adjustment (GPBA) [46]. GPBA is a sophisticated mechanism designed to refine the population in evolutionary algorithms like DE. GPBA works by evaluating the gradient information of the current population. This involves assessing how each candidate solution is positioned relative to the objective function's gradient. By doing so, GPBA can determine the direction in which the solutions should be adjusted to move closer to the optimal point in the search space. This gradient-based approach differs from traditional evolutionary strategies, which rely solely on fitness-based selection and random mutations. The key advantage of integrating GPBA into the DE algorithm is the enhanced convergence speed towards optimal solutions. Since GPBA utilizes gradient information, it can guide the population more effectively towards the global optimum, especially in complex, multimodal landscapes where traditional methods might struggle. In the context of the DE algorithm, after the clustering-based mutation process identifies promising regions and generates new solutions, GPBA takes over to fine-tune these solutions. It adjusts the population by moving the candidate solutions along the gradient of the objective function. This not only accelerates the convergence process but also helps in maintaining diversity within the population, preventing premature convergence to local optima.

The procedure for this update is outlined as follows:

- Selection: Generate k random individuals to serve as the initial seeds for the algorithm.
- Generation: Produce a set of M solutions using mutation based on clustering and denote it as v^{clu}.
- Replacement: Choose M solutions randomly from the current population to form set B.
- Update: Choose the best M solutions from the union of sets v^{clu} and B to form set B'. The new population is obtained by combining the elements of set P that are not in B with the elements of a set B' $((P - B) \cup B')$

2) Deep q-network training: In sentiment analysis, unbalanced classification occurs when the distribution of sentiment labels in the dataset is highly skewed, with one sentiment class being more prevalent than the others. This poses challenges as standard classification algorithms tend to favor the majority class, leading to poorer performance for the minority class [47, 48]. Consequently, models might excel at predicting the majority sentiment but struggle with accurately identifying and classifying minority sentiments. The imbalanced nature of the dataset can introduce bias and impact the learning process, resulting in models with lower recall or sensitivity for the minority class. This is particularly problematic when the minority class represents important sentiments, such as negative feedback in customer analysis. To address the challenge of imbalanced classification, a sequential decision-making strategy utilizing RL is adopted. In RL, an agent engages with its environment, aiming to maximize cumulative rewards through the selection of optimal actions. Within the devised model, the agent acquires a sample from the dataset and undertakes a classification task at each sequential time step. Subsequently, the agent obtains immediate feedback from the environment: accurate classifications are rewarded with positive scores, while erroneous classifications incur negative scores. This approach ensures dynamic learning and adaptation by the agent, enhancing its decision-making capabilities in imbalanced classification scenarios [49, 50]. Suppose a dataset of N samples is available, each with corresponding labels $D = \{(x_1, y_1), (x_2, y_2), (x_3, y_3), \ldots, (x_N, y_N)\}$, where x_i represents a sample and y_i denotes its label. The upcoming details provide the planned arrangements for the proposed approach.

- Policy π_θ : Policy π serves as a function which links states (S) to corresponding actions (A), with $\pi_\theta\ (s_t)$ denoting the action taken in a particular state s_t. The classification technique that employs the weights θ is identified as π_θ.

- State s_t : Each sample x_t from the dataset, D is associated with a specific state s_t. The beginning state s_1 is symbolized by the first piece of data x_1. To deter the model from acquiring a particular sequence, D is shuffled in every episode.
- Action a_t: The action a_t is performed to estimate the label x_t, where the categorization is binary, and a_t can take on either the value of 0 or 1. In this context, 0 signifies the less prevalent class, whereas 1 symbolizes the more common class.
- Reward r_t : The reward is determined by how well the action is executed. If the agent correctly classifies, it is given a positive reward; conversely, if it errs, it is penalized with a negative reward. The reward value should be varied for each class. By appropriately calibrating rewards, the model's performance can be significantly improved by ensuring that the reward magnitude matches the corresponding action. The method for determining the reward for a given action in this study is described by the following equation:

$$r_t(s_t, a_t, y_t) = \begin{cases} +1\, , a_t = y_t \ and \ s_t \in D_{Maj} \\ -1\, , a_t \neq y_t \ and \ s_t \in D_{Maj} \\ \lambda\, , a_t = y_t \ and \ s_t \in D_{Min} \\ -\lambda\, , a_t \neq y_t \ and \ s_t \in D_{Min} \end{cases} \tag{2}$$

Here, D_{Maj} and D_{Min} denote the majority and minority classes correspondingly. Accurately or inaccurately classifying a sample from the majority class results in a reward of $+\lambda$ or $-\lambda$, respectively, where λ is a value between 0 and 1.

- Terminal E: Throughout every training episode, the training process culminates at different terminal states. A series of state-action pairs $\{(s_1, a_1, y_1), (s_2, a_2, y_2), (s_3, a_3, y_3), \dots, (s_t, a_t, y_t)\}$ from the starting state to the ending state is known as an episode. In the context of the situation, the conclusion of an episode is marked either by classifying all the training data or by misclassifying a sample from the minority class.
- Transition probability P: The agent advances from the present state, s_t, to the subsequent state, s_{t+1}, following the order of the data being read. The likelihood of this transition is denoted as $p(s_{t+1}|s_t, a_t)$.

D. SM Forecasting

LSTM networks have garnered considerable attention in stock market analysis due to their ability to capture and leverage temporal relationships in time series data [51]. Unlike traditional statistical models, LSTM networks excel at learning and adapting to complex patterns and dependencies in the data, making them well-suited for predicting stock market prices or trends. One advantage of LSTM networks is their proficiency in handling long-term dependencies, enabling them to capture subtle relationships and trends that span extended periods. By analyzing historical price data, trading volumes, and other relevant factors, LSTM networks can identify recurring patterns, seasonal trends, and market cycles that traditional models might miss [52]. Another strength of LSTM networks is their capacity to process and retain information over long sequences. The architecture of an LSTM cell includes memory units that selectively remember or forget information over time, enabling the network to store and retrieve relevant historical data while disregarding irrelevant or redundant information. This memory retention mechanism is crucial in capturing the dynamics of stock market movements, where past trends and events significantly impact future outcomes.

Additionally, LSTM networks can effectively handle irregularities and non-linearities in stock market data. The stock market is influenced by various factors, such as economic indicators, geopolitical events, news, and investor sentiment, leading to abrupt shifts and anomalies in stock prices. LSTM networks, with their ability to model complex non-linear relationships, can effectively capture and respond to these non-linear dynamics, aiding in market prediction.

The LSTM model, initially conceptualized by Hochreiter and Schmidhuber [53], has evolved significantly through various advancements since its inception [54]. In this particular study, the focus is on the highly regarded LSTM architecture developed by Gers et al. [55], a structure that has seen extensive application in diverse academic research [56, 57]. The fundamental aspect of the LSTM model is its distinctive gating mechanism, which effectively manages the storage and retrieval of information over temporal sequences. This research specifically explores the intricacies of the LSTM cell, in line with the delineation presented in Graves' work [36]. LSTM's architecture is characterized by a set of three specialized gates that orchestrate the efficient processing of information. These gates, denoted as i_t (input gate), f_t (forget gate), and o_t (output gate), function at a given time t in the sequence. They work in concert with c_t (memory cell) and h_t (hidden state), which are crucial components of the LSTM's internal structure. Furthermore, x_t symbolizes the external input received by the LSTM cell at the specific time t. These components collectively enhance the LSTM's capacity for learning, retaining, and applying long-term data dependencies, distinguishing it from conventional recurrent neural network designs. Its proficiency in grasping long-term dependencies renders the LSTM highly appropriate for intricate tasks associated with sequential data. This includes areas such as time series forecasting, natural language processing, and speech recognition, where context and historical data are crucial for precise modeling and prediction. The operational framework of the LSTM cell is structured in the following manner [56]:

$$i_t = \sigma(W_{xi}x_t + \ W_{hi}h_{t-1} + W_{ci}c_{t-1} + \ b_i) \tag{3}$$

$$f_t = \sigma(W_{xf}x_t + \ W_{hf}h_{t-1} + W_{cf}c_{t-1} + \ b_f) \tag{4}$$

$$c_t = f_t c_{t-1} + i_t tanh(W_{xc}x_t + \ W_{hc}h_{t-1} + \ b_c) \tag{5}$$

$$o_t = \sigma(W_{xo}x_t + \ W_{ho}h_{t-1} + W_{co}c_t + \ b_o) \tag{6}$$

$$h_t = o_t tanh(c_t) \tag{7}$$

The sigmoidal activation function, represented by the symbol σ(.), plays a pivotal role in the computational models presented. This function, which includes both logistic sigmoid and hyperbolic tangent types, is applied in a manner that targets individual elements. The weight matrices, identified as W_{xk}, where k is a member of the set $\{i, f, o, c\}$, are integral to the process, linking the input x_t with distinct components such as the input gate, forget gate, output gate, and memory cells. In addition to these, the W_{ck} weight matrices, where k falls within the set $\{i, f, o\}$, are structured as diagonal matrices. These matrices are essential in forming the connections between the memory cell and its various gates. It is vital to highlight that the neuron count designated for each gate is set beforehand. This predefined count is significant because Eq. (3) to Eq. (7), which are central to the model, are applied distinctly to each neuron, ensuring precise and individualized processing within the neural network system.

IV. Empirical Evaluation

A. Metrics

In this article, three standard metrics are used for SM prediction: root mean square error (RMSE), mean absolute percentage error (MAPE), and mean absolute error (MAE) [58]. Each metric is defined in the following manner:

$$\text{RMSE} = \sqrt{\frac{\sum_{i=1}^{N}(y_i - \hat{y}_i)^2}{N}} \tag{8}$$

$$\text{MAPE} = \frac{1}{N}\sum_{i=1}^{N} | \frac{y_i - \hat{y}_i}{y_i} | \tag{9}$$

$$\text{MAE} = \frac{\sum_{i=1}^{N}(y_i - \hat{y}_i)}{N} \tag{10}$$

Here, N stands for the total number of observations, with y_i representing the actual value and $\hat{y}_i$ the predicted value for each observation. Furthermore, for SA, Measures like Accuracy, F-measure, and G-means are employed, each defined in a specific manner [59]:

$$\text{Accuracy} = \frac{TP+TN}{Total\ number\ of\ samples} \tag{11}$$

$$\text{Precision} = \frac{TP}{TP+FP} \tag{12}$$

$$\text{Recall} = \frac{TP}{TP+FN} \tag{13}$$

$$Specificity = \frac{TN}{TN+FP} \tag{14}$$

$$\text{G} - \text{means} = \sqrt{\text{Recall} \times\ Specificity} \tag{15}$$

Here, TP stands for true positives, which are the actual positive cases that the model has correctly identified. TN is for true negatives, representing the actual negative instances that the model has accurately predicted. FP refers to false positives, where the model mistakenly labels actual negatives as positive. Finally, FN denotes false negatives, pertaining to the actual positive cases that the model incorrectly categorizes as negative.

B. Comparator Models

The introduced algorithm was subjected to a thorough comparative analysis against eight state-of-the-art models, including those proposed by Zhang et al. [60], Rasheed et al. [61], Jin et al. [62], Vijh et al. [63], Mehta et al. [64], Riady [65], Wang et al. [66], and BL et al. [67]. This thorough analysis was designed to provide a comprehensive view of the effectiveness of the proposed model compared to current methods. Additionally, the algorithm is compared with a derivative model called "Proposed without RL," which excludes RL for SA. The objective of this study was to validate the superior performance and effectiveness of the proposed model in the domain of stock market prediction.

C. Results

The comparative results, summarized in Table I, clearly demonstrate the exceptional performance of the proposed algorithm, consistently surpassing the other models evaluated on a shared dataset. Remarkably, the proposed algorithm outperformed the Transformer-based model by Wang et al., reducing overall error by approximately 12% and confirming the superior efficacy of attention-based LSTM over transformer. Furthermore, the model surpassed the model by BL et al., the strongest competitor, across all evaluation criteria. The performance improvement of the model is particularly significant when considering the substantial reduction in error rate. Specifically, the proposed algorithm achieved a remarkable decrease in error for two primary evaluation metrics, RMSE and MAPE, with errors reduced by over 14% and 10% respectively. This substantial reduction in error highlights the superior predictive capabilities of the algorithm. A separate comparison with the "Proposed with RL" model emphasized the critical role of RL in the proposed model. The comparison revealed an approximate 10% reduction in error rate when RL was implemented. These findings underscore the potency of RL and LSTM in navigating the complexities of time-series data, such as stock market prices, and their essential contribution to enhancing the accuracy of the proposed model.

Residual plot is a valuable graphical tool frequently employed in statistical and regression analyses. This type of plot visualizes the differences between observed and predicted values, known as residuals, on the vertical axis, while the predicted values are displayed on the horizontal axis. In Fig. 4, residual plots are presented for the models detailed in Table I.

In the case of the proposed method, the data points predominantly cluster around the zero point, indicating minor discrepancies between the observed and predicted values. This clustering suggests a high level of accuracy in the model predictions. Additionally, the randomness and uniform distribution of the points demonstrate that the residuals are independent and identically distributed, a characteristic referred to as homoscedasticity. This important feature confirms that the linear regression model adheres to its assumptions, ensuring unbiased and reliable predictions. The absence of discernable patterns in the plot, such as curvilinear trends or funnel shapes, indicates that the model effectively captures the linear relationship between the predictors and the outcome variable. Moreover, this absence implies a consistent variance in the error term across various predicted value levels. These characteristics signal that the proposed model has successfully captured the underlying trends in the data and provides robust predictions.

TABLE I. RESULTS OBTAINED USING THE PROPOSED MODEL AND OTHER STATE-OF-THE-ART MODELS

Model	RMSE	MAPE	MAE
Zhang et al. [60]	6.100	0.0410	4.100

Fig. 4. Residual plot for the proposed model and other state-of-the-art models. a) Zhang et al. [60], b) Rasheed et al. [61], c) Jin et al. [62], d) Vijh et al. [63], e) Mehta et al. [64], f) Riady [65], g) Wang et al. [66], h) BL et al. [67], i) Proposed without RL, j) Proposed.

1) Performance of semantic analysis: In the following analysis, the objective is to juxtapose the performance of the proposed SA model against five other prominent SA models. The comparative study includes models developed by Akhtar et al. [68], Akhtar et al. [69], Silva et al. [70], Xin et al. [71], and Mingzheng et al. [72], each of which holds considerable acclaim and widespread application in the SA domain (see Table 2). In assessing the results of the model, standard performance metrics such as F-measure and G-mean are employed, recognized for their dependability in evaluating imbalanced data [73]. Notably, the proposed model surpassed all other models across all evaluative parameters, even outpacing the highest-performing model, Mingzheng et al. More specifically, the proposed approach cut the error rate by an impressive 32% and 25% in the F-measure and G-mean metrics respectively. Further scrutiny was applied by comparing the performance of the proposed model with a condensed version of the proposed approach, referred to as proposed without RL. This comparison uncovered that the fully developed model drastically curtailed the error rate by an estimated 51%. These compelling findings underscore the critical importance and effectiveness of the RL technique embedded in the proposed approach.

Fig. 5, which illustrates the receiver operating characteristic (ROC) curves for the methodologies listed in Table II, employs the area under the curve (AUC) as a crucial metric for assessing classifier efficiency. An AUC of 1 is indicative of impeccable differentiation capabilities, whereas a score of 0.5 equates to a performance level similar to random guessing. Impressively, the method we developed showcased exceptional proficiency, achieving an AUC of 0.61. This score not only reflects its ability to accurately distinguish between positive and negative outcomes but also reinforces the method's validity as an effective predictive instrument. Furthermore, the 'Proposed without RL' variant demonstrated substantial efficacy, achieving an AUC of 0.53. This performance confirms its capacity to accurately classify positive and negative cases. In contrast, the methodologies developed by Mingzheng et al. and Xin et al. recorded more modest AUC values of 0.50, demonstrating a performance level that does not quite reach the benchmark set by our proposed approach. This ROC analysis distinctly highlights the varying levels of effectiveness among the different methodologies examined.

The notable predictive strength of our proposed method, both independently and in conjunction with RL, is a testament to its robustness and reliability in predictive modeling. This success not only validates the approach but also suggests the possibility for future enhancements. The method's adaptability and high level of accuracy pave the way for its potential application in a broader range of predictive scenarios, offering promising prospects for advancements in the field of predictive analytics. This creates exciting opportunities for further research and development, potentially leading to even more refined and efficient predictive models in the future.

TABLE II. RESULTS OBTAINED USING THE PROPOSED MODEL AND OTHER STATE-OF-THE-ART MODELS FOR SA

Model	Accuracy	F-measure	G-means
Akhtar et al. [68]	0.695 ± 0.160	0.580 ± 0.041	0.695 ± 0.160
Akhtar et al. [69]	0.705 ± 0.015	0.580 ± 0.035	0.705 ± 0.015
Silva et al. [70]	0.825 ± 0.165	0.760 ± 0.263	0.825 ± 0.255
Xin et al. [71]	0.800 ± 0.015	0.700 ± 0.120	0.800 ± 0.000
Mingzheng et al. [72]	0.855 ± 0.105	0.820 ± 0.056	0.855 ± 0.269
Proposed without RL	0.860 ± 0.005	0.850 ± 0.012	0.860 ± 0.035
Proposed	0.891 ± 0.015	0.890 ± 0.003	0.898 ± 0.055

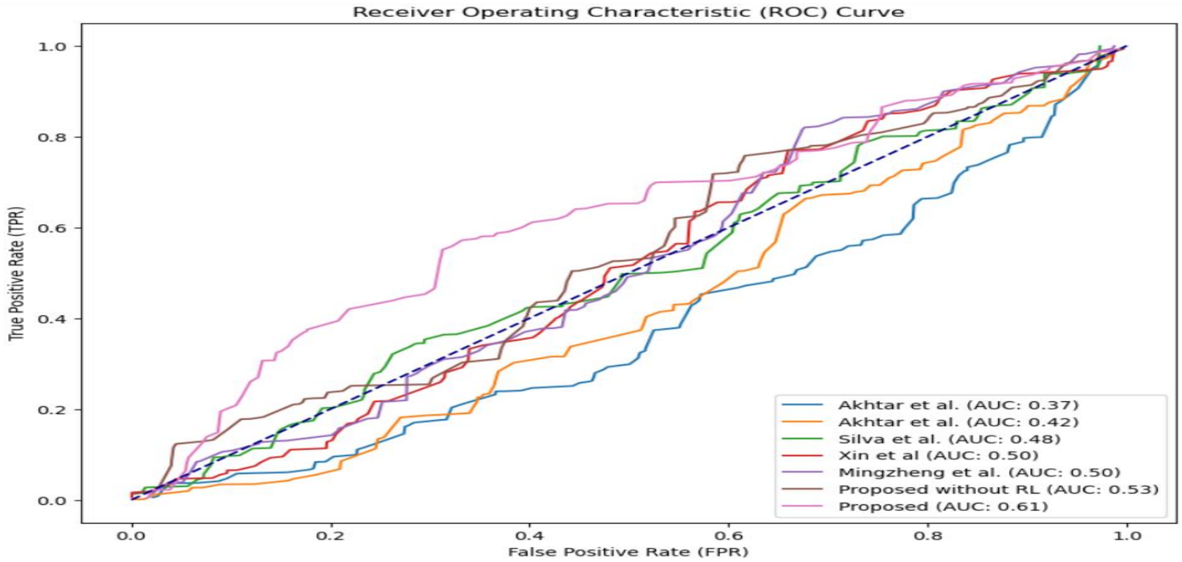

Fig. 5. ROC diagram for the proposed model and other methods. The Blue dashed line represents the ROC curve for a random guess.

2) *Impact of the reward function:* In SA, the allocation of rewards for both accurate and inaccurate classifications is distributed between majority and minority classes, marked as ±1 and ±λ, correspondingly. The determination of λ is closely associated with the ratio of majority to minority class instances. As this ratio increases, it is anticipated that the ideal λ value will demonstrate a corresponding decrease. To examine the effect of λ on model performance, the model underwent testing with a range of λ values, extending from 0 to 1 in increments of 0.1. During this process, the reward for the majority class remained constant. These experiments and their outcomes are clearly depicted in Fig. 6. When λ is set to 0, the significance afforded to the majority class is effectively negated, while a λ setting of 1 achieves an equilibrium in the treatment of both majority and minority classes. As illustrated in Fig. 6, the model's peak performance is observed at a λ value of 0.7, cutting across all evaluated metrics. This indicates that the most beneficial λ value does not lie at the extremes (0 or 1) but rather at a midpoint. It is crucial to recognize that while it's important to lessen the majority class's dominance by adjusting λ, selecting a value that is too low can adversely affect the model's overall effectiveness. The collected data underlines the significant impact of λ on the performance of the SA model. The ideal λ value is contingent upon the proportion of majority to minority samples, making its careful selection imperative for optimal results. This nuanced approach to λ selection is integral to balancing classification accuracy and ensuring the most advantageous outcomes in SA model applications.

3) *Impact of loss function:* In addressing the issue of skewed data distribution within SA, the utilization of various conventional methodologies, such as the adaptation of data augmentation techniques and loss functions, is essential. Of these methodologies, the selection of an apt loss function is

particularly significant as it can effectively accentuate the importance of the minority class. In this study, a rigorous evaluation of five distinct loss functions is conducted in this study, namely weighted cross-entropy (WCE) [74], balanced cross-entropy (BCE)] [75], dice loss (DL) [76], Tversky loss (TL) [77], and combo Loss (CL) [78]. These were assessed in relation to the proposed model. Notably, the BCE and WCE loss functions ensure unbiased consideration by assigning equivalent weightage to positive and negative samples. In this assortment of functions, the CL function has proven to be an efficient tool for applications wrestling with imbalanced data. This is achieved by its judicious weight distribution; wherein lesser weight is attributed to simpler examples and higher weight to complex ones. This strategic allocation emphasizes the challenging, often underrepresented cases without downplaying the simpler ones. As evidenced in Table III, the CL function, when compared to TL, generates a lower error rate, with the reduction ranging between 15% and 29% across accuracy and F-measure metrics. This remarkable reduction exhibits the CL function's competence in managing imbalanced data more effectively. However, notwithstanding these promising outcomes, it is vital to recognize that the performance of the CL function pales in comparison to RL, trailing behind by a significant 41% margin. This implies that while the CL function can be a feasible option for handling imbalanced data, more sophisticated techniques like RL may offer more precise results.

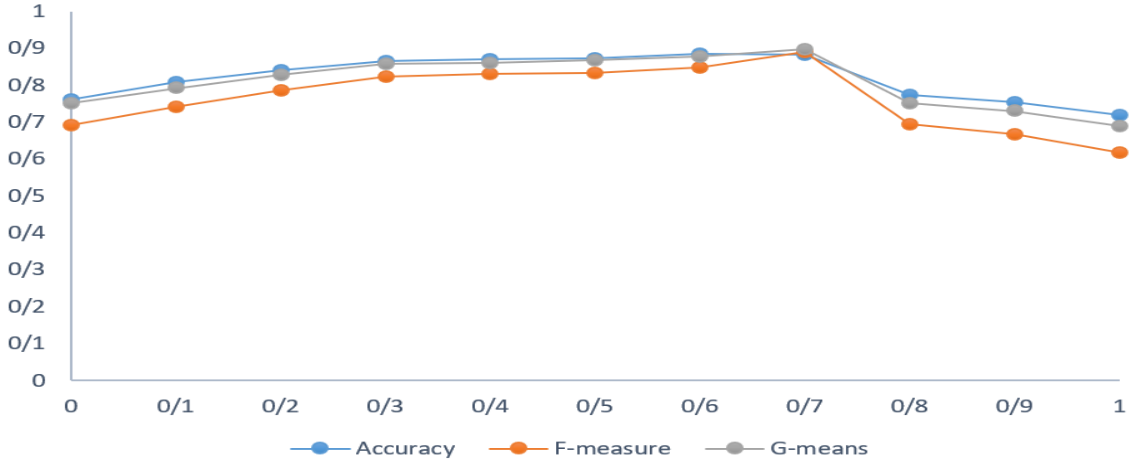

Fig. 6. The performance metrics of the suggested model were graphically represented in relation to the value of λ within the reward function.

TABLE III. RESULTS OF DIFFERENT LOSS FUNCTIONS FOR SA.

Loss function	Accuracy	F-measure	G-means
WCE	0.75±0.03	0.74±0.00	0.76±0.03
BCE	0.80±0.02	0.77±0.01	0.81±0.00
DL	0.81±0.03	0.80±0.01	0.82±0.00
TL	0.83±0.12	0.81±0.04	0.84±0.06
CL	0.86±0.00	0.84±0.04	0.86±0.15

4) Discussion: In the domain of big data and predictive analytics, this groundbreaking study introduces a pioneering approach that combines sentiment analysis from social media with historical stock prices to accurately forecast future stock prices. By harnessing the knowledge exchange platforms on the Internet, the authors offer a fresh perspective on stock market prediction, emphasizing the significant influence of public sentiment on financial market trends. The proposed research presents a novel methodology that analyzes social media by integrating public sentiment, opinions, news, and past stock prices to predict future stock prices. The methodology consists of two main stages. In the initial stage, a SA model is employed with three dilated convolution layers, enabling simultaneous feature extraction and classification. This approach effectively captures the underlying emotions expressed in user-generated content on social media, providing valuable insights into stock market trends. However, SA often faces the challenge of unbalanced classification, which occurs when one class of data is significantly more prevalent than the others. To overcome this challenge, an innovative RL strategy is introduced, treating the task as a sequential decision-making process. The agent receives rewards at each step for accurate classification, with smaller rewards assigned to the majority class compared to the minority class. This approach improves classification accuracy and enables the model to differentiate between different sentiments more effectively. In the second stage, the study incorporates an attention-based LSTM approach, which integrates historical stock prices and the sentiment analysis results obtained in the previous stage to predict future stock prices. The research validates the effectiveness of the proposed model through a series of ablation studies, confirming the positive contributions of the attention-based LSTM and RL components to the overall model performance. The innovative methodology represents a promising advancement in predictive analytics, particularly due to its unique integration of sentiment analysis and historical stock prices. Additionally, the RL strategy for addressing class imbalance adds an intriguing aspect to the field.

Fig. 7 provides a visual representation of the error trajectory observed in the proposed model. It demonstrates the model's progression over 150 training epochs, showcasing a consistent decrease in error. This signifies the continuous improvement of the model's ability to predict stock market trends. The gradual reduction in error rates indicates the convergence of the model towards an optimal solution. Notably, in the final stages of training, the error rates reach an exceptionally low level, such as 0.0000001. This significant decrease underscores the outstanding predictive accuracy achieved by LSTM.

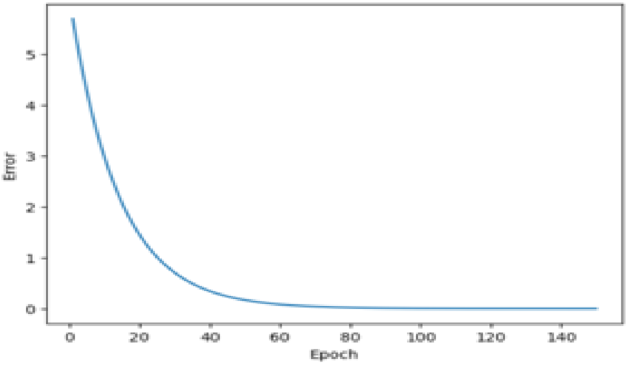

Fig. 7. Diagram of model error during 150 epochs.

Despite the encouraging findings obtained from the research, it is important to acknowledge and address certain limitations that emerged. These limitations not only provide opportunities for further investigation but also indicate areas where improvements can be made in future studies.

- The effectiveness of the proposed methodology relies on the quality and representativeness of the data utilized. However, social media posts and financial news, which serve as the primary data sources, can sometimes be unreliable or inaccurate, posing a risk to the analysis and prediction process [79]. To address this issue, future research can focus on refining data pre-processing techniques to filter out misleading or irrelevant posts, ensuring that sentiment analysis is based on accurate and reflective data [80]. Additionally, there is a need to develop more advanced NLP techniques that can better understand the context and sentiments expressed in social media posts and financial news. Expanding the scope of research, incorporating techniques like sentiment intensity analysis, emotion detection, irony and sarcasm detection, and stance detection can provide a more comprehensive understanding of public sentiment.
- Furthermore, exploring methods to assess the reliability and credibility of data sources, such as establishing a rating system for social media platforms or news outlets, can enhance the accuracy of sentiment analysis [81]. Looking ahead, the potential of machine learning and AI in this field is vast. Future work can explore the integration of other data forms, including audio and video content from different social media platforms, to gain more diverse insights into public sentiment and its impact on stock market trends [82].
- The current methodology employs a fixed reward ratio for the majority and minority classes, which has demonstrated effectiveness in the experiments. However, it may not be optimal for all datasets, particularly those with varying degrees of class imbalance. To address this, future research could explore the dynamic adjustment of the reward function based on the observed class distribution in the data.
- In addition, the proposed approach only considers immediate historical stock prices for prediction. To enhance the predictive capabilities of the model, future studies could investigate the inclusion of longer historical periods or incorporate other relevant factors such as industry trends, economic indicators, or global events. Furthermore, it is worth noting that the proposed method was tested on a limited number of stock markets. To ensure the generalizability of the model, it would be valuable to validate the approach using data from various global stock markets.
- A possible direction for future work could be to incorporate inductive learning elements, allowing the model to generalize from past trends and apply them to future predictions [83]. This extension would enable the model to capture and leverage the underlying patterns and dynamics of the stock market that span across different time periods. By integrating inductive learning, the model can learn from historical data and extract valuable insights that can be applied to forecast future stock prices with greater accuracy. This approach would involve incorporating techniques such as time-series analysis, trend identification, and pattern recognition to identify recurring patterns and trends in the data. By recognizing and understanding these patterns, the model can make more informed predictions about future market behavior [84].
- Additionally, incorporating inductive learning would help the model adapt and adjust its predictions as new data becomes available, ensuring its relevance and effectiveness in dynamic market environments. This approach holds great potential for improving the long-term forecasting capabilities of the model, enabling it to anticipate market trends and make proactive investment decisions. Overall, the incorporation of inductive learning elements represents an exciting avenue for future research, offering the opportunity to enhance the predictive power and robustness of the model in stock market analysis.

- The proposed model primarily focuses on analyzing sentiments from social media platforms. However, future work could look into incorporating various other types of online sources that influence the stock market. Such sources could include financial forums, professional analyst reports, business news websites, and investor behavior analytics from trading platforms [85]. These additional sources of data could provide a more comprehensive and diversified input into the model, leading to potentially higher predictive accuracy. Advanced web scraping techniques and API usage could be employed to harvest data from these varied sources, while machine learning algorithms can be applied to analyze and incorporate this data into the predictive model.

- The current SA model uses a single layer of sentiment classification, which categorizes the sentiment into positive, negative, or neutral. While this works effectively, it may overlook nuanced sentiment gradations that can significantly influence stock prices. Future research could introduce multi-dimensional sentiment analysis that captures not only the polarity of the sentiment but also the intensity and the emotional context. This can involve using techniques like aspect-based sentiment analysis (ABSA) [86], which extracts sentiments related to specific aspects of a topic. For example, a social media post might express positive sentiment about a company's management but a negative sentiment about its new product. Recognizing and capturing these nuanced sentiments can provide a more accurate sentiment representation and lead to improved stock price predictions.

- Considering the potential influence of influential individuals on the stock market, another future research direction could involve the analysis of sentiment expressed by key figures in the business world or financial analysts. Often, the views expressed by these individuals can significantly sway public sentiment and impact the stock market. Using entity recognition techniques, future models can differentiate comments made by these influential figures and assign higher weights to these in the sentiment analysis process.

- While the study provides an innovative approach to predicting stock prices, it is also important to study how the proposed methodology performs under various market conditions. Future work could include stress testing the model under different market scenarios such as bull markets, bear markets, and periods of high volatility. This would provide more insights into the model's robustness and reliability under different circumstances.

- Lastly, the use of deep learning methods in stock price prediction comes with the risk of overfitting, especially when the model becomes too complex [87]. Future research could look into the application of regularization techniques or ensemble methods to mitigate this risk. Additionally, more advanced model interpretability and explainability techniques can be explored to better understand the model's decision-making process and provide more insights to financial analysts and investors. This could further build confidence in the use of AI-based predictive models in financial markets.

V. Conclusion

This research introduces an innovative method for leveraging social media analysis to forecast future trends in stock prices. The proposed methodology encompasses two primary phases. During the initial phase, a SA model was constructed, employing three dilated convolutional layers. These layers were instrumental in simultaneously extracting feature vectors, which were subsequently amalgamated for the purpose of classification. Nonetheless, the SA model encountered a notable hurdle in the form of imbalanced classification. To address this challenge, a RL strategy was devised. This strategy framed the classification task as a series of sequential decision-making events, wherein the agent garnered rewards for each instance of precise classification. To effectively manage the issue of class disparity, the model was designed to allocate reduced rewards for classifications pertaining to the predominant class in contrast to those of the minority class. Additionally, an enhanced DE algorithm was applied for the initialization of the weights in the SA model. In the second phase of the methodology, an attention-based LSTM technique was employed. This phase intricately combined historical stock market data with insights derived from the SA model in the preceding stage. The integration of these two data sources was instrumental in generating more accurate predictions of future stock prices, showcasing the efficacy and potential of this dual-stage approach in the realm of financial forecasting.

The computational challenges inherent in large-scale models such as BERT are significant and widely recognized. While these models boast advanced capabilities, they are also associated with a considerable computational load, largely due to their architecture involving millions of parameters. To effectively address this issue, one promising strategy is the exploration and adoption of more streamlined and efficient variants of the BERT model. In this context, DistilBERT stands out as a leading example, epitomizing this innovative class of models. DistilBERT effectively preserves a majority of the functionality inherent in the original BERT model, while achieving a notable reduction in both the model's size and its computational requirements. This successful blend of high-level performance coupled with increased efficiency highlights the groundbreaking potential of such models. They offer a promising avenue for revolutionizing the computational framework within the realm of large-scale NLP, paving the way for more accessible and sustainable AI solutions in this domain.

Cloud Migration: Identifying the Sources of Potential Technical Challenges and Issues

Nevena Staevsky, Silvia Gaftandzhieva
University of Plovdiv Paisii Hilendarski, Plovdiv, Bulgaria

***Abstract*—Digital Transformation is emerging as a crucial factor for successful adaptation to the modern digital world for all possible economic and social entities. In recent years, cloud migration, cloud services and computing solutions adoption have been popular enablers for the Digital Transformation. During the Digital Transformation process, organizations and institutions face various technical challenges and implementation problems. This article explores the issues related to cloud migration and existing cloud service models. It investigates the advantages and disadvantages of the most popular cloud services offered by leading service providers, summarizes the main challenges in cloud migration processes, and how organizations can overcome them. Results help organizations understand the sources of potential technical challenges and implementation problems affecting cloud adoption and address these issues at an early stage of the initiative in order to reduce the threat of failure, avoid potential pitfalls and achieve desired cloud capabilities and business benefits.**

***Keywords*—Digital transformation; cloud; cloud migration; cloud models; PaaS; SaaS; IaaS; challenges**

I. Introduction

The topic of the research presented here is related to a field that until recently was considered evolving and nascent and currently occupies a central place in scientific analyses and practical developments. This is the area known as Digital Transformation, which is emerging as an important factor for successful adaptation to the modern digital world for all possible economic and social entities – countries, cities, industries, companies and people.

In fact, Digital Transformation began in the last century with the introduction of personal computers, the automation of industry, and the global expansion and establishment of the WWW as a means of communication and information exchange worldwide. As analogue systems were replaced by digital ones, the Internet became an integral part of personal and professional life.

The onset of this information age has given a strong impetus to worldwide globalisation, which is reaching hitherto unknown proportions.

The present study is part of a larger scientific research of the approaches to Digital Transformation of organizations and companies working in the field of the intangible sphere, such as, for example, service-oriented companies that provide online payment solutions, software or consulting services, educational and health organizations, as well as local or state government bodies, etc. The objective of the research is to identify typical implementation challenges and problems in the introduction of modern digital technologies. As a further matter, it aims to propose and experiment with solutions to overcome implementation problems faced by various organizations and institutions undergoing Digital Transformation.

According to Gartner [1], more than 85% of organizations will embrace a cloud-first principle by 2025. Since cloud migration and the adoption of cloud services and computing solutions are certainly enablers for Digital Transformation, the research should first address the challenges in this area and the approaches to optimize this multi-stage process.

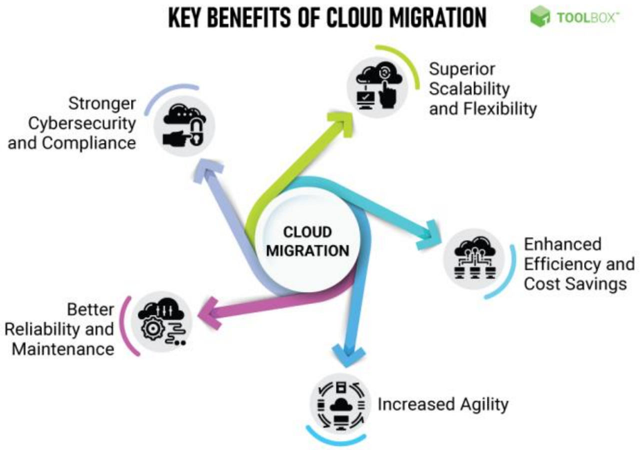
This article presents the initial stages of this large-scale scientific research, which consists of exploring what cloud migration is and which cloud service models exist in cloud computing adoption. Furthermore, the paper investigates the advantages and disadvantages of the most popular cloud services offered by leading service providers and summarize the main challenges in cloud migration processes and how they can be optimized. The analysis performed allows us to understand the sources of potential technical challenges and implementation problems affecting cloud adoption, and to address these issues at an early stage of the initiative in order to reduce the threat of failure. The study serves to inform future efforts in implementing cloud innovation to avoid potential pitfalls and achieve desired cloud capabilities and business benefits.

The rest of the paper is organized as follows. Section II presents the benefits of cloud migration and discusses the advantages and disadvantages of the main types of cloud service models. Section III presents an overview of some of the most popular cloud computing platforms offered by the leading cloud service providers and discusses their advantages and disadvantages. Section IV summarises the migration challenges corresponding to different aspects and suggests potential approaches to how organizations and institutions can overcome or mitigate them. The Conclusion in Section V summarizes the contribution and limitations of this paper and plans for future work in the field is summarized in Section VI.

II. Cloud Migration. Cloud Computing Service Models

Cloud migration refers to the process of moving digital assets, including data, applications, workloads and IT processes, from on-premises or legacy infrastructure to a cloud-based environment or so-called cloud computing environment. This transition involves transferring computing resources, such as servers, storage, databases, networks and software applications, to a cloud service provider's infrastructure. The ultimate goal of cloud migration is to achieve greater scalability, flexibility, and cost-efficiency and enhanced performance while leveraging the benefits of cloud computing [2].

The significance of cloud migration in modern IT infrastructure stems from the transformative impact it can have on businesses, operations, and technological landscapes. The key reasons that drive industries to adopt cloud technologies are well known (see Fig. 1), but below the reasons why cloud migration is vital in today's IT environment are discussed in more detail.



KEY BENEFITS OF CLOUD MIGRATION
TOOLBOX
CLOUD MIGRATION
Superior Scalability and Flexibility
Stronger Cybersecurity and Compliance
Enhanced Efficiency and Cost Savings
Better Reliability and Maintenance
Increased Agility

Fig. 1. Key benefits of cloud migration [3].

Cloud platforms offer elastic *scalability* [4], enabling businesses to easily scale resources up or down based on demand. This flexibility allows organizations to adapt to changes swiftly and efficiently without significant hardware investments or infrastructure reconfigurations.

Migration to the cloud often leads to cost savings [5] by moving from capital-intensive models (purchasing and maintaining physical hardware) to operational costs (pay-as-you-go or subscription-based models). This allows businesses to align costs with actual usage and optimize their IT spending.

Cloud migration fosters agility and innovation [6] by providing a platform for rapid development, testing, and deployment of new applications and features. Development teams can benefit from cloud-native services and tools, enabling faster time-to-market and a competitive edge.

Cloud infrastructure allows for worldwide accessibility to data and applications. Geographically distributed teams and users can access resources from any location, promoting collaboration and facilitating a globally connected workforce.

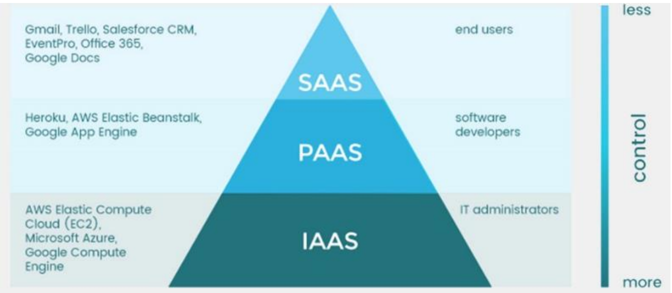
Cloud service providers invest heavily in security measures, often surpassing what many organizations can afford or manage independently. They offer advanced security features, compliance certifications, and regular updates to mitigate security risks and ensure compliance with industry-specific regulations [4].

Cloud providers offer robust disaster recovery and backup solutions, ensuring data integrity and availability in case of unforeseen events or system failures. Cloud-based disaster recovery strategies contribute to enhanced business continuity and reduced downtime.

Cloud platforms provide powerful analytics and machine learning capabilities, enabling organizations to derive actionable insights from their data through data analysis [6]. This data-driven approach can inform strategic decision-making and drive business growth.

Consolidating workloads in the cloud often leads to increased resource utilization and energy efficiency, contributing to a reduced overall carbon footprint compared to traditional on-premise data centers by environmentally sustainable solutions [7].

Migrating to the cloud allows companies to use centralized cloud services hosted by a vendor or cloud provider and delivered by the Internet. Cloud providers offer different cloud computing service models, each serving specific purposes and meeting different requirements. These service models are often called "as a service" or "aaS" models [8]. The three main types of service models are (see Fig. 2) software as a service (SaaS), platform as a service (PaaS), and infrastructure as a service (IaaS).



Gmail, Trello, Salesforce CRM, EventPro, Office 365, Google Docs
SAAS
end users
Heroku, AWS Elastic Beanstalk, Google App Engine
PAAS
software developers
AWS Elastic Compute Cloud (EC2), Microsoft Azure, Google Compute Engine
IAAS
IT administrators
less
control
more

Fig. 2. Main types of cloud computing service models [9].

Infrastructure as a Service (IaaS) offers virtualized computing resources over the Internet, including virtual machines, storage, networking, and other infrastructure components. Users can manage and control the entire infrastructure by installing and configuring operating systems, applications and databases. IaaS provides a highly flexible and customizable environment commonly used by IT administrators and developers to build test and manage their applications and services [10]. Examples of IaaS providers include Amazon Web Services (AWS), Microsoft Azure, Google Cloud Platform (GCP), and IBM Cloud.

Platform as a Service (PaaS) provides a platform and environment for developers to create, deploy, and manage applications without worrying about the underlying infrastructure [11]. It offers development tools, frameworks, runtime environments, databases, and other services needed to develop applications [9]. Developers focus on coding and application logic, while the PaaS provider looks after the infrastructure management. Examples of PaaS are Microsoft Azure App Service, Google App Engine, and AWS Elastic Beanstalk.

Software as a Service (SaaS) delivers software applications over the Internet on a subscription basis. Users access these applications through web browsers without download or install anything locally [12]. The service provider manages all aspects of the application, including maintenance, security, updates and infrastructure. Examples of SaaS applications include email services (e.g., Gmail), customer relationship management (CRM) systems (e.g., Salesforce), and collaboration tools (e.g., Microsoft 365).

In practice, organisations often use a combination of these service models to meet their specific requirements, known as 'hybrid' or 'multi-cloud' approaches. This allows them to avoid disadvantages and leverage the strengths and advantages of each service model (see Table I) to create a customised solution that best suits their business needs.

TABLE I. CLOUD COMPUTING SERVICE MODEL (DIS)ADVANTAGES

Service Model	Advantages	Disadvantages
IaaS	Full control and customization of the infrastructure. Scalability and flexibility to meet changing needs. Pay-as-you-go pricing model that optimizes cost efficiency. Rapid provisioning and scaling of resources	Requires expertise in infrastructure management. Security, updates and maintenance are the responsibility of the user. Potential complexity in managing different infrastructure components
PaaS	Optimized application development and deployment. Automatic scaling depending on application demand. Built-in development tools and frameworks. Cost and time effective for development teams	Limited control over basic infrastructure. Dependence on the PaaS provider for updates and maintenance. Some constraints on the choice of development tools and frameworks
SaaS	No user installation or maintenance is required. Accessibility from any device with an internet connection. Regular automatic updates and patches. Scalability depending on user needs	Limited customization and control options compared to on-premises solutions. Dependence on the service provider for availability and security

In recent years, there has been a trend towards the formation of new "aaS" in the cloud, which are referred to under the general term Everything as a Service (XaaS). It is a broad term encompassing different service models where different types of resources and capabilities are provided over the Internet as a service. XaaS essentially extends the "as a service" concept beyond traditional cloud computing service models (SaaS, PaaS, IaaS) to include a wide range of offerings related to technology, software, infrastructure and even non-technology areas [13], as follows:

- Function as a Service (FaaS): FaaS is a serverless computing model that allows developers to execute code in response to events without managing servers. This is an example of XaaS in the context of application execution.

- Database as a Service (DBaaS): DBaaS provides database management and hosting in the cloud, allowing users to access and manage databases without the need to manage infrastructure.

- Security as a Service (SecaaS): This includes a set of security-related services, including threat detection, identity and access management, and security monitoring, provided in the cloud.

- Communication as a Service (CaaS): CaaS includes cloud-based communication services such as voice over IP (VoIP), video conferencing and messaging platforms.

- Monitoring as a Service (MaaS): MaaS provides application, infrastructure and network performance monitoring and monitoring services.

- Storage as a Service (StaaS): StaaS provides cloud-based storage solutions, including file storage, object storage, and backup services.

- IoT as a Service (IoTaaS): IoTaaS offers cloud-based services to manage and analyze data from Internet of Things (IoT) connected devices.

- Analytics as a Service (AaaS): AaaS provides cloud-based data analytics and processing capabilities, enabling organizations to make data-driven decisions to improve the efficiency of various aspects of the business, such as sales, demand forecasting, and sourcing.

- AI as a Service (AIaaS): AIaaS provides AI and machine learning services in the cloud, enabling organizations to leverage AI capabilities without the need for extensive AI expertise.

- Integration Platform as a Service (iPaaS): iPaaS is a cloud-based platform that facilitates integration between different applications, systems and data within an organization. iPaaS solutions enable seamless communication, data sharing, and workflow automation between disparate systems, both cloud and on-premises [14]. They play a critical role in simplifying the integration process, increasing business agility, and supporting digital transformation initiatives.

XaaS is a flexible and evolving concept, and new service models continue to emerge as technology evolves. It allows organizations to access and leverage a wide range of resources and capabilities without the need to make extensive investments in infrastructure or manage it, making it a key enabler of digital transformation and innovation across industries. According to research by Deloitte [15], companies adopting XaaS are increasingly aiming for agility and innovation rather than efficiency and cost reduction.

III. DISCUSSION: LEADING CLOUD SERVICE PLATFORMS - ADVANTAGES AND DISADVANTAGES OF POPULAR OPTIONS

Several leading cloud service providers have been dominating the cloud computing market over the past few years. Below is an overview of some of the most popular cloud computing platforms offered by the global players. Each of these options has its own set of features, addressing different needs and preferences. Still, they also share some common limitations that should be considered when deciding on the right cloud provider.

A. Amazon Web Services (AWS)

AWS offers a broad range of cloud services, including computing, storage, databases, machine learning, IoT, and more, providing flexibility for various use cases.

Not only does Amazon provide data centers in numerous regions worldwide, allowing for low-latency access to resources from different parts of the world [16], but also a wide range of security features and compliance certifications [17], making it suitable for industries with strict security requirements.

A variety of reliable storage solutions, including Amazon S3, Amazon EBS, Amazon Glacier, and others, offer scalable, durable, and highly affordable storage options for different use cases [17].

Furthermore, Amazon web services boast high performance and reliability [16], with strong achievement in terms of uptime and service availability, backed by Service Level Agreements (SLAs) to ensure reliability.

Due to the ability to scale resources up or down depending on demand, businesses can quickly adapt to changing requirements without upfront capital investment. Combined with that scalability and flexibility, the pay-as-you-go pricing model, which allows users to pay only for services they use, can help organizations manage and optimize costs effectively.

Also worth mentioning are the AWS's large and active user community, extensive documentation, and multiple third-party integrations in case customers need support and resources.

However, AWS has some weaknesses that should be mentioned. To start with, data transfer costs can add up and become a significant expense, especially for large volumes of data moved between regions or outside the AWS network. A further limitation of AWS is the lack of 24/7 support for all plans – only higher-level plans include around-the-clock access to customer support. Moreover, due to the huge customer base, custom support can be limited, and enterprises may experience delays in getting specialized help in critical situations. Finally, organizations that have invested in AWS may face challenges if they decide to migrate to another cloud provider due to potential vendor lock-in and the need for significant adjustments to existing systems and processes.

B. Microsoft Azure

Azure integrates seamlessly with Microsoft tools and products, making it an attractive choice for organizations already using Microsoft technologies such as Windows Server, Active Directory or SQL Server. Moreover, demonstrating a strong enterprise focus, the Microsoft cloud is also well suited for large enterprises, with a range of enterprise-class services, including Azure AD, Windows Virtual Desktop, and more.

Additionally, it provides solid support for hybrid cloud solutions [18], allowing organizations to easily connect on-premises data centers to the cloud.

Azure PaaS offerings could be considered fully comprehensive. It delivers a robust application development environment, including services such as Azure App Service and Azure Functions. Besides, it provides a rich set of developer tools and frameworks that support efficient application implementation and deployment.

Furthermore, Artificial intelligence (AI) and data analytics capabilities of Azure encompass advanced AI and machine learning (ML) services, such as Azure Machine Learning and Azure Cognitive Services, making it the preferred choice for AI-driven applications and data analytics.

Another significant service is the Azure Active Directory (Azure AD) with its robust identity and access management capabilities [18], enabling secure access to Azure services and other integrated applications.

Although the public cloud computing platform has many advantages, it also has a fair share of disadvantages, e.g. its complexity. The rich portfolio of services and features can be overwhelming for new users. Installing and initially configuring Azure services can get complex, especially when configuring networks, security, and permissions. Azure has a significant global presence. Even so, it has a slightly less global reach, compared to AWS in some parts of the world. Likewise, compared to AWS, Azure may have fewer third-party integrations and a more limited selection of third-party tools available in its ecosystem. Its cloud services possess limited platform portability because they are designed to run primarily within the Azure ecosystem, which can create challenges if an organization decides to move to another cloud service provider.

C. Google Cloud Platform (GCP)

GCP data analytics, ML and AI capabilities with services such as BigQuery, TensorFlow and Google AI Platform make it the preferred choice for organizations requiring advanced data processing and analytics.

A significant advantage of the platform is its powerful big data solutions such as BigQuery, Dataflow and Dataprep that enable organizations to efficiently process and analyze large data sets and gain valuable insights.

On the other hand, as a pioneer in containerization and Kubernetes, Google provides a robust Kubernetes Engine with its Cloud Platform. Accordingly, GCP [19] excellently suits companies focused on containerized applications and microservices.

As might be expected, GCP integrates seamlessly with Google Workspace (formerly G Suite), providing a complete environment for collaboration, productivity and cloud applications.

In addition, GCP has a massive global network infrastructure with strategically distributed data centers, which provides low-latency access to resources from different regions. Being designed for scalability and high performance, this infrastructure also allows businesses to scale resources quickly based on demand, ensuring optimal performance even as traffic spikes.

Due to its robust security features and regulatory compliance certifications, the platform ensures data privacy and meets various industry-specific regulatory requirements.

As for pricing, Google offers a pay-as-you-go pricing model that provides cost efficiencies and flexibility for businesses, especially those looking to manage and optimize costs.

Some disadvantages of GCP compared to AWS and Azure mentioned worth are the smaller market share and the limited global presence as it has fewer data center regions, which can impact latency and availability for some users. Despite being strong in certain areas, such as data analytics and machine learning, GCP may have a less diverse service portfolio than competitors such as AWS and Azure. Moreover, one may find the maturity of some services insufficient, especially of some relatively newer ones, in comparison with their AWS or Azure counterparts, which may result in occasional limitations or evolving features. A further weakness of Google cloud is its relatively limited focus on enterprises, although it is expanding its enterprise offerings. In the past GCP have been more focused on start-ups and developers, which may affect its attractiveness to larger enterprises. As for documentation and support [20], the platform's documentation is comprehensive, but support and specialized resources may not be as available as with larger cloud providers.

D. Alibaba Cloud

Alibaba Cloud has a significant presence in Asia and China, making it an excellent choice for businesses targeting this region.

This Cloud provides specialized solutions with a focus on e-commerce and retail enterprises, including artificial intelligence services for customer insights.

It is indisputable that Alibaba has diverse service offerings. The Cloud delivers a wide range of services, including computing, storage, database, big data, artificial intelligence, machine learning and IoT to meet a variety of business needs.

The company is also known for its cost-effectiveness and competitive pricing [21] compared to other major cloud providers, making it attractive to cost-conscious organizations.

Finally, Alibaba Cloud offers advanced distributed computing capabilities that enable high-performance computing, data processing and analytics at scale.

Alibaba Cloud was founded in 2009, only three years after AWS. Even so, it is a relatively new player in the cloud market and is characterised with some limitations. In the first place is its limited global reach. Although expanding, Alibaba Cloud has fewer data center regions outside of Asia [21], which impacts global availability. Secondly, English language support and documentation may not be as extensive as other providers. Furthermore, compared to other major cloud providers such as AWS, Azure and GCP, Alibaba Cloud's ecosystem may be less mature, with fewer third-party integrations and a smaller developer community. What can also affect its appeal to larger companies is its initially limited focus on enterprises, since Alibaba was more focused on start-ups and SMEs in the past. Another significant disadvantage concerns the compliance with international regulations and data protection and privacy that businesses outside China may have, especially given that Alibaba Cloud is a Chinese company. Finally, regarding the quality of customer support, some users report inconsistencies, having experienced problems with delays and getting timely help.

E. IBM Cloud

IBM Cloud has a strong focus on hybrid and multi-cloud services. It emphasizes hybrid and multi-cloud solutions [22] and is therefore an appropriate choice for organizations with complex infrastructure needs. Offering comprehensive support and consulting services, IBM helps organizations optimize their cloud infrastructure and ensure a successful transition to the cloud. As a matter of fact, IBM's Integration with Red Hat has strengthened the company's position in hybrid clouds with services such as IBM Cloud Paks and OpenShift.

Not only does the cloud offer a variety of enterprise-class services, including blockchain, artificial intelligence and IoT [22], but it simultaneously provides robust security features and regulatory compliance capabilities to ensure data security and privacy as well as compliance with numerous industry regulations and standards. The advanced AI and data analytics services [22], including IBM Watson, enable organizations to draw correct conclusions and make informed business decisions.

Furthermore, IBM Cloud has a global network of data centres, allowing companies to deploy resources worldwide and optimise performance by delivering resources closer to users.

However, IBM Cloud also possesses some shortcomings. It targets a niche market to meet more specific enterprise requirements and may not be as widely deployed as AWS, Azure or GCP. As a result, the cloud has a smaller market share compared to the major [23], which can lead to a smaller community, fewer third-party integrations and a narrower set of tools and services. In addition, some IBM services may be relatively newer or less mature than their AWS or Azure counterparts, which may result in evolving features or limitations. Finally, organizations that have invested in IBM technologies may face challenges if they decide to migrate to another cloud provider due to potential vendor lock-in and the need for significant adjustments to existing systems and processes.

F. Oracle Cloud

Oracle Cloud is known for its strong database solutions, making it an attractive choice for businesses relying heavily on Oracle databases.

It addresses the needs of enterprises with services such as Oracle Cloud Infrastructure, Oracle Autonomous Database and applications such as Oracle E-Business Suite. Oracle Cloud has an enterprise focus and provides a comprehensive suite of enterprise solutions, including databases, applications, computing, storage, analytics and more [24], suitable for large enterprises and businesses with complex needs.

Oracle Cloud integrates seamlessly with Oracle software and applications, providing a complete and optimized environment for organizations already using Oracle products.

Moreover, Oracle places a strong emphasis on security and regulatory compliance and offers a number of security features and certifications to ensure data protection and meet industry-specific regulatory requirements.

In addition, it has the capability to integrate with on-premises data centers, supporting a hybrid cloud model [25] for organizations that need a combination of cloud and on-premises solutions.

Still, some limitations should be pointed out regarding the cloud computing services offered by Oracle. Oracle Cloud's main strength lies in its niche market ─ database offerings. But it could be a weakness, as well, that may not allow it to meet all cloud computing needs. Oracle has a smaller number of data centres than the major cloud providers and, hence, a limited global reach. Besides, organizations that have invested heavily in Oracle technologies may face challenges if they decide to migrate to another cloud provider due to the potential vendor lock-in and the need for significant adjustments to existing systems and processes.

According to global data and business analytics platform Statista, the top three cloud providers by market distribution in 2023 are AWS, Azure and Google Cloud, followed at a significant distance by IBM and Oracle (see Fig. 3).

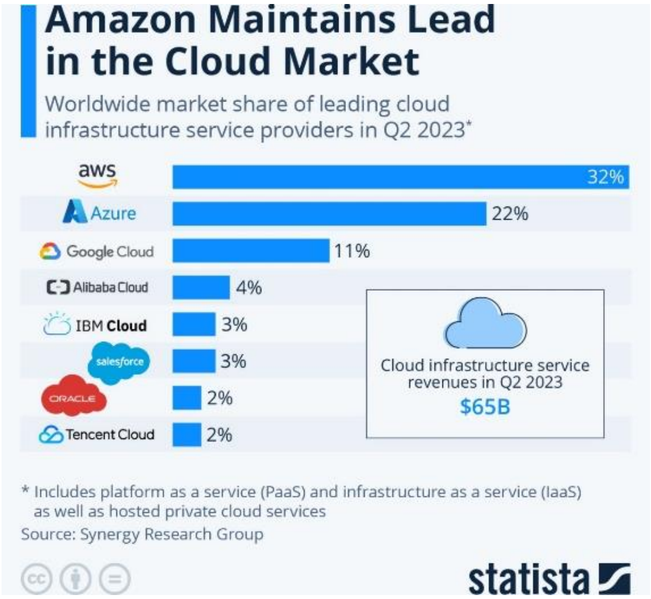


Fig. 3. Cloud market [26].

It is important to note that the evolution of cloud computing is extremely dynamic and these providers continue to improve and expand their services continuously. In addition, the specific needs and preferences of the individual organizations will determine which cloud provider is most suitable for them [26]. Therefore, a thorough evaluation and consideration of the advantages and disadvantages are critical when choosing a cloud service provider.

Beyond the provider-specific drawbacks mentioned above, there are some common ones that all cloud platforms share. When choosing to move to the cloud, organizations have to be aware of those limitations which could threaten their initiative, as for example – the steep learning curve. Because of the vast array of offered services and features, cloud platforms can be intimidating for users, especially for newbies or users unfamiliar with cloud computing concepts. Not only can this affect the ease of adoption and effective use of the platform, but it can also lead to extra training costs and unpredicted deployment delays.

A further consideration is the pricing complexity of the cloud services. Cloud providers offer different options for their customers in terms of pricing, but the most common models are reserved instances – purchased for a preliminary determined period, spot instances, where customers can bid for unused capacity, and the pay-as-you-go model, which charges customers based on the actual usage of resources. Even though the reserved instance option can lead to more significant cost savings, it has one major drawback – loss of flexibility [27]. On the other hand, the pay-as-you-go pricing model is flexible enough, but a more detailed examination of the granularity of the billing units proves drastic differences between the providers [27]. With the spot pricing, customers can get a significant discount, compared to the on-demand model, but there is always a risk of suddenly losing the purchased instances if the spot goes beyond your bid. Consequently, understanding and estimating costs can get very complex due to the multiple services delivered, the different pricing models and the various associated factors, such as compute resources, storage, data transfer, location, etc. [19].

Altogether, based on all above stated weaknesses of the different cloud service platforms offered, the following summarized technical problems and issues can be identified in the process of cloud migration and its further use:

- Resistance to deployment and employee leaving due to need for training to work with the cloud platform;
- Additional costs or respectfully incorrect forecasting of costs, caused by various factors - misunderstanding of pricing options; need for data transfer not planned in the initial budget; need for experienced experts for installation and configuration of cloud services; need for costs to implement missing third-party integrations; increased number of necessary services to satisfy business needs;
- Latency and delayed performance because of insufficient number of data center regions;
- Delay and temporary interruption of business activity, due to lack of expertise or timely customer support;
- Difficulties and need for additional costs for changes in existing systems and processes when migrating to another cloud service provider.
- Difficulties in performing daily operations caused by insufficient maturity of some services and their evolving.

IV. Results: Cloud Migration Challenges and Mitigation Approaches

Migrating existing on-premise applications to the cloud presents several key challenges that can be avoided through careful planning, appropriate strategies and effective implementation. Some of the key challenges, obstacles and difficulties that organizations face when transferring their infrastructure, applications, and data to cloud-based environments are related to a range of aspects concerning the migration process, such as data security and compliance, data transfer and latency, application compatibility, performance optimization, integration complexity, cost management, skill and knowledge gap, and downtime and business continuity.

Table II presents cloud migration challenges corresponding to the listed aspects and suggests potential approaches how to overcome or mitigate them.

TABLE II. Cloud Migration Challenges and Mitigation Opportunities

Integration aspect	Challenge	Mitigation
Data security and compliance:	Often on-premise applications handle sensitive data; hence, ensuring data security and regulatory compliance during migration is a serious concern.	Employ encryption, access controls, and compliance management tools to maintain data security. Conduct thorough compliance audits to ensure adherence to relevant regulatory requirements.
Data Transfer and Latency:	Transferring large volumes of data from on-premises systems to the cloud can be time-consuming and may cause latency issues.	Use data compression techniques, network optimization, and implement phased data transfer strategies to reduce the time and latency associated with data transfer [6].
Application compatibility:	Compatibility issues may arise when moving applications designed for on-premise environments to the cloud due to differences in infrastructure and configurations.	Conduct a comprehensive application assessment to identify compatibility issues. Modify or refactor the application as needed to ensure compatibility with the target cloud environment.
Performance optimization:	Ensuring optimal performance of applications in the cloud compared to on-premise can be challenging, affecting user experience.	Optimize applications for cloud infrastructure by utilizing auto-scaling, load balancing, and performance monitoring tools. Conduct performance testing to identify bottlenecks and optimize accordingly.
Integration complexity:	Integrating on-premise applications with cloud services and other applications can be complex, leading to data silos and inefficiencies.	Employ robust integration solutions and frameworks to facilitate seamless communication between on-premise and cloud-based components. Utilize APIs and middleware to bridge the integration gaps.
Cost management:	Cloud migration costs, including subscription fees and data transfer charges, can escalate and exceed the initial estimates.	Conduct a thorough cost analysis before migration, utilize cost management tools to monitor and control spending, and consider rightsizing resources based on usage patterns to optimize costs.
Skill and Knowledge Gap:	Migrating to the cloud often requires specialized skills and knowledge that may be lacking within the existing on-premises team.	Provide training and upskilling opportunities for the team or consider hiring cloud migration experts and consultants to bridge the skills gap and ensure a smooth migration process.
Downtime and Business Continuity:	Minimizing downtime during migration is critical to maintaining business continuity, which can be challenging during transition.	Implement a phased migration approach, perform thorough testing, and have a rollback plan in place to mitigate downtime and ensure uninterrupted business operations.

Addressing these challenges requires a holistic approach, involving thorough planning, stakeholder engagement, risk assessment, and leveraging appropriate technologies and methodologies to achieve a successful and smooth migration of on-premise applications to the cloud.

V. Conclusion

In summary, cloud migration is a strategic move that offers organizations the ability to align their IT infrastructure with business goals, enhance operational efficiency, optimize costs, and remain competitive in an ever-evolving technological landscape. By leveraging cloud capabilities, businesses can drive innovation, improve agility, and focus on their core competencies while harnessing the power of modern cloud computing.

The study presented in the paper is part of a wider scientific research with a very extensive goal to study and experiment with approaches, practices, problems and tools related to digital transformation initiatives in different spheres of the intangible domain.

This article draws on core challenges associated with cloud migration. By applying the proposed approaches for overcoming and mitigation, organizations and institutions can address these challenges at an early stage of the initiative and reduce the threat of failure. In this way, the study presented here can inform the future efforts of organizations and institutions in implementing cloud innovation to avoid potential pitfalls and achieve desired cloud capabilities and business benefits.

This study has some limitations as well. It is aimed at organizations and companies working in the intangible sphere, and all the challenges of cloud migration are brought out from this perspective. Therefore, additional research is needed to show whether all the proposed guidelines for overcoming or mitigating them can help avoid potential pitfalls and achieve desired cloud capabilities and business benefits in enterprises operating in the material sphere (e.g. production).

VI. Future Work

The results achieved here, related to the identification of the main sources of problems during the implementation of leading cloud service platforms, will allow throughout the subsequent stages of the research to systematize possible problems and implementation obstacles that may arise when moving data, applications, and other business elements in the process of cloud migration. As a result, best practices, recommendations, and solutions to overcome them will be proposed and experimented. Empirical evidence will be derived through experiments affecting individual stages at which business operations of specific business entities from the intangible sphere migrate to the cloud. Appropriate cloud services and a relevant cloud service provider will be selected for the investigation.

Technology-Mediated Interventions for Autism Spectrum Disorder

Mihaela Chistol[1]*, Mirela Danubianu[2], Adina-Luminiţa Bărîlă[3]
Faculty of Electrical Engineering and Computer Science, Ştefan cel Mare University, Suceava, Romania[1, 2, 3]
ASSIST Software SRL, Suceava, Romania[1]

***Abstract*—According to the Diagnostic and Statistical Manual of Mental Disorders (DSM-5), Autism Spectrum Disorder (ASD) is a complex neurological and developmental condition characterized by impairments in social interaction and communication. Despite significant advancements in the research field, no pharmaceutical medication has been designed for ASD treatment. Therefore, ASD treatment relies mainly on therapeutic intervention. Interactive technologies have emerged as valuable therapy augmentation tools. This research focuses on interactive technologies developed for ASD therapeutic intervention. The study introduces a conceptual framework for understanding the full spectrum of technologies involved in the ASD context. The employed methodology encompasses expert opinions and entails a cross-sectional study that included 59 participants with significant experience in interacting with individuals diagnosed with ASD in various real-life settings, including therapists, teachers, and parents of children with ASD. The research findings revealed a broad spectrum of technologies involved in ASD interventions, including applications, devices, and robots. The results bring a new perspective on the interactive technologies used in the therapy and diagnosis of ASD and highlight their important characteristics that can serve as a standard in the development of future technological solutions.**

***Keywords*—Autism spectrum disorder; technology-mediated interventions; assistive technologies; therapy; cross-sectional study**

I. Introduction

The technological prowess of human beings has been a defining characteristic since the dawn of our existence. Even in ancient times, our ancestors created innovative tools from stone to help them survive and work more efficiently. As time has passed, our desire to augment our lives through technology has only increased, and it is now a ubiquitous presence in all aspects of modern society. We rely on technology to communicate, enhance our physical capabilities, perform complex computations, and even cure medical conditions. From the earliest inventions to the latest cutting-edge breakthroughs, technology has been the driving force behind human progress and the key to unlocking new levels of knowledge and achievement. Technology is playing a critical role in shaping our world and advancing civilizations to new heights. But sometimes, some peaks are difficult to conquer. Similar to climbing Mount Everest, the development of medical technologies is a challenge because it is difficult to create applications and devices that efficiently diagnose and treat a disease. In the last century, Leo Kanner published a groundbreaking paper about early infantile autism [1] initiating a quest among therapists, doctors, and researchers to devise effective practices and interventions for treating autism spectrum disorder (ASD). However, it is a difficult task as this human condition ASD is a neurodevelopmental disorder characterized by deficits in social communication and the presence of restricted interests and repetitive behaviors [2]. Autism is frequently accompanied by other conditions such as epilepsy, depression, anxiety, attention deficit and hyperactivity disorder, as well as difficult behaviors like self-injury and sleep disturbances [3]. As a result, some individuals with autism can function independently, while others require lifelong assistance due to the severity of their disabilities.

Despite the fact that contemporary research shows people with autism are highly interested in using technology, they often require support from an intermediary person such as a caregiver, to use it effectively. This research enlisted the help of parents, teachers, and therapists who had children with ASD under their care. Their insights into the technologies used, goals pursued, desirable features, and drawbacks, as well as the digital solutions' adaptability to the social-cultural context, were instrumental in identifying the interactive technology aimed at ASD therapy.

According to the European Parliament's Research Service technologies for ASDs are less mature [4] and effects of technology-mediated interventions (TMIs) in ASD should be better understood. Thus, we adopted a new methodological strategy to understand the usability of technology-mediated therapeutic interventions in ASD. This approach involved the collection of expert opinions, real-world experiences of caregivers, and academic research. This innovative framework added depth and clarity to the results obtained. The structure of this paper is designed to provide a comprehensive understanding of the benefits and limitations of using interactive technologies in autism therapy. Section II of this paper presents the methodology. Section III offers a detailed analysis of the results and findings. In Section IV, we delve into a discussion about limitations of this study. Finally, we conclude the paper in Section V by summarizing the key takeaways and implications of our findings.

II. Materials and Methods

The main objective of this research is to explore the most efficient ASD therapies and cutting-edge technologies that can be integrated into therapy to facilitate the treatment of children diagnosed with autism. To address each topic of interest, we formulated three research questions presented in Table I.

*Corresponding Author.

TABLE I. RESEARCH QUESTIONS

ID	Research Question (RQ)
RQ_1	What therapies are used in the ASD treatment?
RQ_2	What technologies are employed in ASD therapeutic intervention?
RQ_3	What characteristics should technologies employed in ASD therapeutic interventions possess in order to effectively meet the needs of individuals with autism and promote positive outcomes?

In this study, we employed two research methods: expert opinion and cross-sectional study. Expert opinion was used to collect and analyze the opinions of professionals who have extensive experience working with individuals with autism, including medical practitioners and therapists. Through in-depth interviews, we were able to gain a deep understanding of the most effective therapeutic strategies. Cross-sectional study was conducted to explore and collect data directly from the end-users of the ASD technologies, including parents, therapists and teachers. This allowed us to obtain feedback on the usability and effectiveness of the interactive technologies in real-world settings. The research methodology was approved by the Research Ethics Board of Ștefan cel Mare University of Suceava, Romania, approval number 128.

A. Participants

1) Expert opinion participants: Expert opinion participants were selected based on rigorous criteria to ensure their qualifications. These criteria included: having accredited studies, approved by the College of Psychologists in Romania, possess extensive professional experience, showcase the ability to develop effective therapeutic intervention plans, and actively engage in academic activities such as participation in conferences, workshops, and research studies. As a result of selection process, two experts were invited to collaborate. The first expert brings more than a decade of experience in the field of psychology. He holds a certificate of practice in clinical psychology and specializes in Ericksonian Psychotherapy and Hypnosis. Additionally, he is internationally accredited as a Board Certified Behavior Analyst (BCBA). The second expert has over nine years of experience in Applied Behavior Analysis (ABA) therapy and is internationally accredited as a BCBA in behavioral analysis.

2) Cross-sectional study participants: Cross-sectional study involved individuals who have regular interactions with children diagnosed with ASD including: therapists, teachers, and parents. Over 100 individuals affiliated with the Association for Autism Intervention Suceava (AIAS), located in Romania, were invited to participate in the study and share their experiences by completing the survey using the web-based version of Google Forms. A total of 60 participants responded to the survey.

Fig. 1 illustrates the distribution of participants based on their roles, indicating that the majority of the participants 74.6% were parents of children with autism, while therapists accounted 23.7%. Unfortunately, only one teacher expressed interest in participating in the study, highlighting the educational system's reluctance towards individuals diagnosed with autism in Romania.

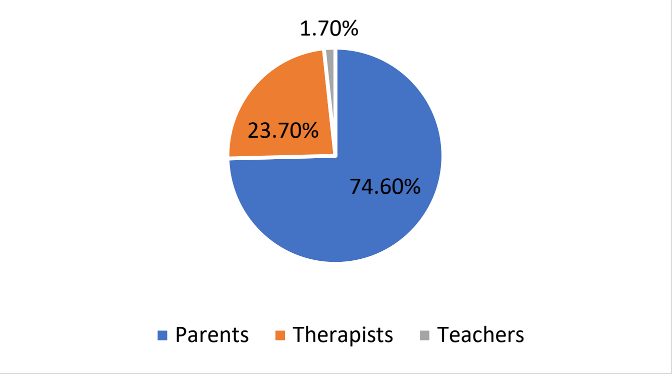

Fig. 1. Distribution of participants in the cross-sectional study based on their role in the lives of patients with autism.

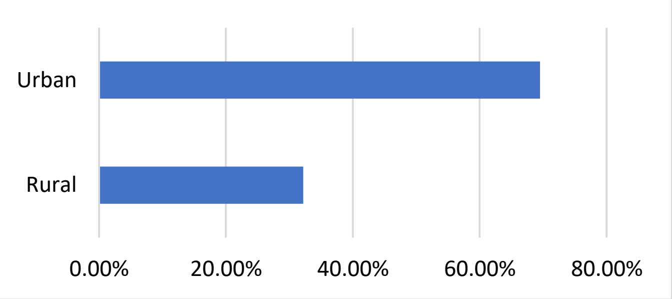

Fig. 2. Administrative organization in which the study participants reside.

In order to capture the diversity of personal experiences and socioeconomic backgrounds, the study included individuals from urban and rural administrative organizations. Fig. 2 presents the distribution of study participants based on their residence. The data reveals that the proportion of participants living in rural areas was 32.2%, which is lower than the proportion from urban areas 67.8%.

The importance of the participants' experience in interacting with people affected by ASD was the central aspect. Thus, we included both individuals with extensive experience of over 18 years, as well as beginners with only 1 year of experience in order to ensure diversity in the study. This method allowed to highlight both traditional and innovative approaches. Fig. 3 illustrates the distribution of participants' experience in years.

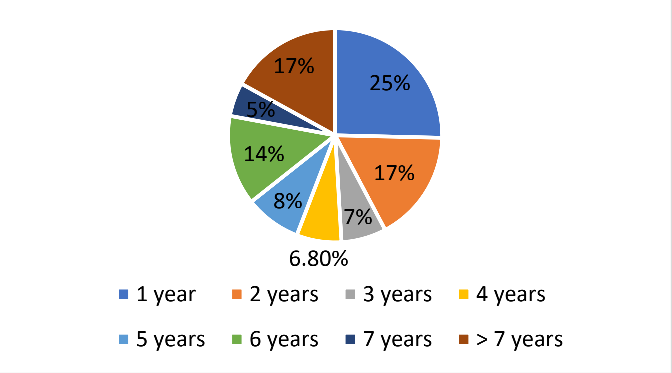

Fig. 3. Participants' experience expressed in years of interaction with ASD patients.

More than 22.1% of the participants are highly experienced individuals who possess a deep understanding of the behavior of patients with ASD. Meanwhile, 25.4% of the participants are novices with just 1 year of experience, which makes them well-suited for analyzing diagnostic methods, as their experiences are fresh. Additionally, 52.5% of participants possess notable experience ranging from two to six years.

B. Data Collection

1) Expert opinion data collection: Collaboration with therapists began in November 2022 and lasted six months. This partnership involved a mix of physical and online meetings, using the Microsoft Teams platform, version 1.0. The team interacted with therapists to discuss diverse aspects of therapeutic methods, the use of technology, and the specific abilities and disabilities of children with ASD.

The collaboration with therapists went beyond interviews, as we had the opportunity to observe therapy sessions in a real environment at the AIAS therapy center (see Fig. 4). During our observation, we paid attention to the educational materials used in therapy, including their content and visual representation. Furthermore, we became aware of the importance of the input type available in technologies for ASD, as we noticed that many children had challenges such as fine motor disabilities or speech impairments.

2) Cross-sectional study data collection: Conducting a cross-sectional study is a common method for collecting data from a specific population at a particular time. Our study focused on children diagnosed with ASD and their caregivers, with Romania serving as our research location. To reach our target population, 100 individuals, affiliated with AIAS therapy center, were invited via emails and social media to participate in the research, of which 59 expressed their willingness to participate, indicating a response rate of 59%. Ethical standards where followed during the study, the researchers informed participants about the study's scope and purpose, and participants were required to sign an agreement before their involvement.

To collect data, we used a survey questionnaire designed to explore the utilization of technologies in autism context. The questionnaire was created using Google Forms. Google Forms is a web-based app developed by Google which is used to create forms for data collection purposes [5]. The questionnaire was made available on February 1, 2023, and the participants' responses were collected over a period of three weeks.

The survey contained open-ended questions, multiple-choice questions, and Likert scales to evaluate the importance of certain factors related to technology use for ASD diagnosis, therapy, and entertainment. The survey consisted of four distinct categories. The first category focused on the experience of parents and therapists, posing questions about their background and experience in caring for children with autism. The second category inquired about the child's diagnosis and abilities, asking about the age of diagnosis and the child's functional level. The third category was centered around technologies and personal experiences in using them, with participants answering questions about their use of different technologies in the autism context.

Fig. 4. The collaboration with the ASD experts from the AIAS therapy center located in Suceava, Romania.

The fourth category was directed at identifying the best characteristics and features of technologies suitable for children with autism.

After concluding the data collection phase, we proceeded to perform statistical analysis on the gathered responses in order to detect patterns and trends within the data. The survey questionnaire results offered valuable insights into the use of technologies and therapeutic interventions for children with autism in Romania. These findings provided an overview of the real needs of parents, caregivers and children with ASD, highlighting the challenges they face, especially when access to formal therapy services is limited due to financial constraints.

III. Results

The results of this study are structured into three subsections, each addressing a specific research question:

Subsection A "Therapies for ASD Treatment" focuses on research question RQ_1 and reviews therapies that have demonstrated efficacy in ameliorating ASD symptoms.

Subsection B "Technologies in ASD" addresses research question RQ_2 and presents the technologies used to improve outcomes and provide support for people with ASD.

Subsection C "Characteristics of Technologies in ASD Therapeutic Interventions" answers RQ_3 and presents the key features of therapeutic technologies.

The results from the expert opinion and cross-sectional study are presented in a cohesive manner. By coupling theoretical frameworks and empirical evidence we aim to provide new insights and implications in the field of technology-mediated ASD interventions.

A. Therapies for ASD Treatment

The World Health Organization (WHO) estimates that worldwide about 1 in 100 children has autism [3]. The statistics surrounding this condition have raised concerns and encouraged researchers to investigate its etymology and potential treatments. Advances in autism research have gone hand in hand with significant progress in international policy. In May 2014, the Sixty-seventh World Health Assembly adopted a resolution entitled "Comprehensive and coordinated efforts for the management of autism spectrum disorders", which was supported by more than 60 countries. The resolution urges WHO to collaborate with Member States and partner agencies to strengthen national capacities to address ASD and other developmental disabilities ("Autism," n.d.). These legislative, social, medical and research efforts have led to the development of intervention and support strategies for people with ASD. In many countries, children can benefit from therapy and special education starting with kindergarten. The education learning plan is developed by a team of professionals and the child's parent. It is very important that parents are involved in the decisions that affect the education of their child. During the learning process, many types of therapies are applied. The most effective therapies according to the experts opinion are presented below.

1) Behavioral therapy: ABA is the most well supported intervention for ASD. ABA is the use of scientifically based behavioral principles in everyday situations. ABA Therapy works toward goals that help to increase or decrease different behaviors. All ABA programs share similar components, including specialized instructional strategies and parental involvement. ABA helps teaching skills that can be used at home, school, and in other settings [6]. Most commonly used ABA programs include: early intensive behavioral intervention (EIBI), positive behavioral and support (PBS), pivotal response training (PRT), discrete trial teaching (DTT) and relationship development interventions (RDI) [7].

2) Communication, speech and language therapy: Individuals diagnosed with ASD can experience communication difficulties regardless of their condition. Some individuals may not have acquired verbal communication skills at all, while others may have strong verbal abilities but struggle with social communication and interaction.

Speech and language therapy can help people with autism to improve their abilities to communicate and interact with others [8]. The therapy is designed to improve communication skills for both verbal and non-verbal individuals. It focuses on developing verbal communication skills, including pronunciation, syntax, and grammar, to help the person make themselves understood more easily and on developing non-verbal communication skills such as eye contact, gestures and body language, as well as on learning to interpret and respond to social cues.

3) Occupational therapy: Occupational therapy (OT) helps people ASD do everyday tasks by finding ways to work within and make the most of their needs, abilities, and interests [9]. Occupational therapists contribute to the care of children and adults with intellectual and developmental disabilities by focusing on activities and goals that are meaningful to the individuals and their families. Relevant performance areas include cognitive, sensory, perceptual, motor and psychosocial [10]. Occupational therapy methods include play-based activities as a way to help patients develop social and communication skills, and learning through movement activities to help patients improve motor and coordination aptitudes. Assistive technologies (ATs) are another important tool used in occupational therapy. Communication through tablets or other devices can help individuals with ASD to develop their communication skills and express their thoughts and emotions. .

4) Physical therapy: The way a person can use their motor skills impacts the ability to perform tasks. Sometimes individuals with autism have less developed motor skills and completing simple activities such as walking, climbing, or dressing is a challenge for them. Physical therapy can help in treating these disabilities. Physical therapy methods for individuals with autism may include adapted physical training activities and games that involve movement. In physical therapy the therapist works on physical limitations to help a person to develop muscles, balance and coordination needed for day-to-day activities [6]. The effectiveness of therapy in treating individuals with autism can vary depending on the severity of the condition.

5) Cognitive behavior therapy: Cognitive Behavioral Therapy (CBT) refers to a group of well-researched techniques that are effective in treating difficulties experienced by children and adults. CBT works well for treating anxiety and mood disorders, teaching stress and anger management, and improving interpersonal skills [6]. CBT generally consists of 12 to 18 1-h sessions and focuses on identifying and changing problematic thinking and behavioral patterns that maintain the youth's presenting symptomatology [11]. CBT combines two different approaches: cognitive therapy and behavioral therapy, to help change maladaptive thoughts and behaviors. Cognitive therapy focuses on changing the negative or distorted thoughts and perceptions of people with autism by learning techniques for self-observation and reflection on thoughts and feelings, identifying and replacing negative thoughts with more positive and realistic thoughts. Behavioral therapy focuses on changing maladaptive behaviors by learning new and healthier behaviors, such as developing social skills or developing a stress management program. CBT techniques have proven their effectiveness in studies conducted on adults and adolescents, clinical experience shows that individual therapy with children of preschool/school age must involve a certain level of play therapy.

Svetha Venkatesh from Curtin University, Australia et al. presented the “Playpad” multimedia-based system for delivering early intervention therapy for autism [12]. The system is based on cognitive therapy and allows individuals with autism to learn by performing natural interactions such as pointing and touching. Parents or non-experts can use the system to deliver home-based therapy, while therapists can construct lessons by specifying stimulus concepts and variations. Trials of the system have shown its effectiveness in training both adults and autistic children.

6) Art therapy: ASD is a condition that can affect sensorial functions, communication, and interpersonal relationships, leading to challenges in areas such as emotional, social, and behavioral interactions. Art therapy has the potential to address these complex issues due to its multisensory nature and relational approach [13]. Art therapy allows people with ASD to use their already visually-minded brains to communicate through artistic media. They can record images and visual data, express ideas and process memories that they are unable to do verbally [14]. Engaging in art therapy on a regular basis can benefit ASD individuals by promoting better family interactions, enhancing self-esteem, and improving emotional regulation both at school and home. Exposure to a variety of art materials can also contribute to the development of fine and gross motor dexterities, while providing children with the ability to adapt easily to new or unfamiliar situations. Most art therapy sessions are one-on-one, they can occur in a group setting, too. Working collaboratively on a single piece of art also fosters peer relationships. In this type of setting, one child draws something and the picture is passed to the next person, who adds to the work until everyone has contributed their part. This activity allows the children to acknowledge those around them and be more aware of others and their involvement in the project.

7) Autism therapies in practice: There is no prescription medication designed to treat ASD [6]. For this reason, therapies become extremely important in the treatment process of this condition. Choosing the appropriate therapy to treat the individual with ASD is a complex process that involves a multitude of factors, including patient symptoms, comorbidities, family, and physician expertise. In addition to these obvious factors, the choice of therapeutic method is also influenced by social norms, cultural values, and legal regulations. In countries that have progressive health insurance legislation, there is a significant evolution in the diversity of medical interventions for ASD treatment. However, in countries with a less developed medical system such as Romania, the diversity of therapies can be limited. In Romania the education for children with special needs began with segregation during the communist period [15]. In this context, our study aimed to identify the therapies practiced in real-life settings for the treatment of ASD symptoms in Romania. To achieve this, we conducted a cross-sectional study that involved 59 participants including parents and therapists who have experience in working with children with autism. Given the small data size we performed the statistical analysis of the answers received and identified that 84.7% of the study participants currently use therapeutic methods to improve children’s abilities. A worrying fact is that more than 6% of the participants did not use any therapy at all, despite the ASD diagnosis (see Fig. 5). Experts in the field suggest that the abandonment of therapy practice can be attributed to insufficient financial resources.

Families often depend solely on the income from the patient’s personal caregiver role. Furthermore, the limited availability of specialized facilities and services in Romania results in difficulties in accessing therapeutic support. The geographical distance between family residences and therapeutic centers presents another challenge, making it harder for individuals with ASD to access treatments.

Fig. 6 presents the therapies practiced in real life in Romania. We identified that the most commonly used therapies in the treatment of ASD patients are classic therapies, such as ABA Therapy, communication, speech and language therapy, sensory integration, and physical therapy. Many of these therapies are performed in an integrative way, combined with other complementary therapies, such as art therapy and 3C therapy.

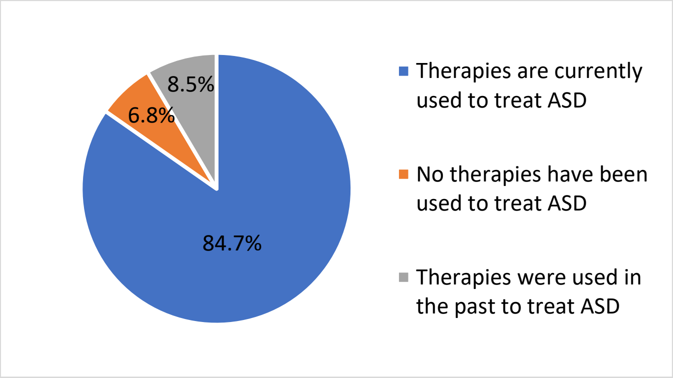

Fig. 5. Statistics on the use of ASD therapies.

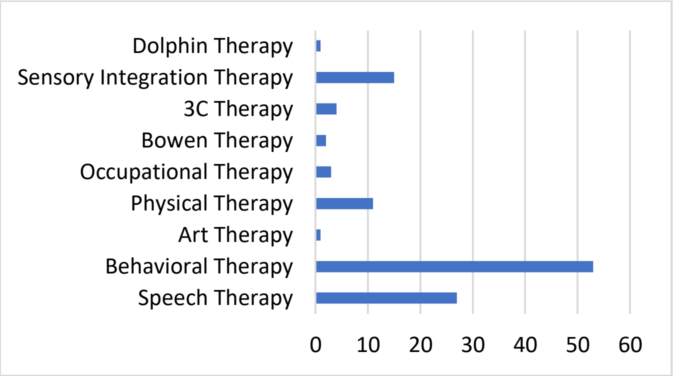

Fig. 6. ASD therapies practiced in real-life by the study participants.

B. *Technologies in ASD*

The medical field has evolved significantly in the 21st century due to the strong involvement of new technologies in diagnosis and treatment methods. In contemporary society, concepts such as telehealth and telemedicine have become common. Technologies are used for providing different medical services such as medical consultations through video calls, real-time diagnosis, or remote monitoring despite the fact that patients and medical professionals are in different locations. ASD therapy has also been impacted by technological evolution. Therapeutic strategies have integrated various types of interactive technologies to improve patients' abilities.

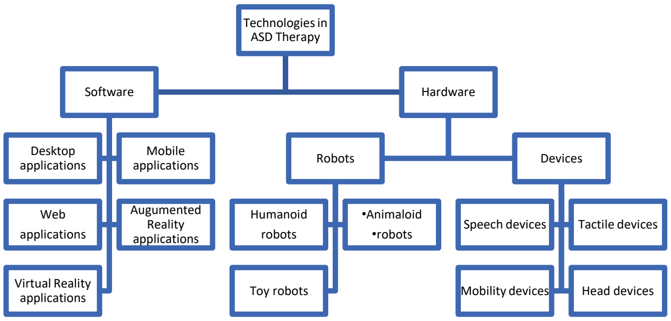

Fig. 7. Classification of technologies used in ASD therapy.

Studies [16], [17], [18] highlighted the idea that technologies used in teaching and therapy are well accepted by individuals with autism.

Technology can be defined as any electronic item, equipment, application, or virtual network that is used intentionally to increase, maintain, or improve daily living, work, productivity, recreation, and leisure capabilities of individuals with ASD [19]. Following our research results, we have proposed a classification of the technologies used in ASD therapy based on their features and characteristics. It is presented in Fig. 7.

Hardware technologies include robots and electronic devices that have computerized physical components such as sensors and actuators. These devices can be programmed to provide real-time feedback, detect and respond to gestures and movements, or provide support based on individual patient needs. On the other hand, software technologies represent packages of software modules containing instructions, documents, and procedures that perform various tasks, these being desktop applications, mobile applications, web applications or augmented reality (AR), or virtual reality (VR) applications. Software technologies are typically used to support therapists and patients in the treatment process, allowing therapy to be customized according to patients' specific needs.

1) Desktop applications: Desktop applications used in autism therapy are software programs that run on personal computers or laptops, most commonly having Microsoft Windows, Apple Mac OS and Ubuntu Linux operating systems. Desktop applications are used to improve the communication, learning and development skills of individuals with autism. These applications include interactive games, educational applications and communication applications. Desktop applications are characterized by high performance, because they have enough memory to support complex user interfaces with numerous graphic elements and resource-consuming animations. The applications are easily adaptable to the individual needs of the users and the learning experience can be customized according to the skill level and preferences. The accessibility of technology is an important aspect in their frequent choice for ASD therapy, as there is no need to purchase expensive equipment.

2) Mobile applications: Mobile applications are an important part of autism therapy, giving users access to a variety of learning, communication and development tools. These applications are developed to be compatible with the most popular mobile operating systems, such as iOS or Android, and can be downloaded and installed on users' mobile devices: phones or tablets. The technological features of mobile applications for autism therapy include advanced tactile interaction such as multi-touch that allows the application to be used by several patients simultaneously, this versatility enables the use in both individual and group therapies.

In the Google Play and App Store, there is a large number of commercial applications dedicated to individuals with ASD. Most of them are educational games [17], visual schedule software [20], and tools for progress tracking [21]. Many academic researchers have also created functional prototypes targeting mobile devices. Common goals include support for development of language-communication skills, daily life skills, vocational-related skills, and social and emotional interaction [22]. A study conducted by Khaled Jedoui et al. from Stanford University School of Medicine [23] presents the mobile application "Guess What?". "Guess What?" is a mobile game available for Android and iOS platforms, designed to be a shared experience between the child, who tries to act out the request shown on the screen through gestures and facial expressions, and the parent, who has the task of guessing the word associated with the prompt within a game session time of 90 seconds. The study focuses on extracting emotion-tagged frames from video footage to train emotion classifiers that can adapt game difficulty and provide real-time feedback to the child. The study results show that the proposed tagging technique surpassed existing commercial emotion recognition APIs. The approach achieved an accuracy of 83.4% in labeling frames, a significant improvement over the best API's accuracy of 62.6%. The research presents a promising approach for using mobile games and automatic emotion labeling algorithms to provide social instruction to children with ASD.

3) Web applications: A web application is a software program that communicates via the World Wide Web and delivers web-based information to the user in HTML format [24]. The intrinsic features of web applications make them a complete solution for online and offline use. One of the main advantages of web technologies is their accessibility and for this reason, they are widely used in ASD therapy. They can be accessed from anywhere with an internet connection, making them particularly useful for individuals who live in rural or remote areas or who have limited access to logistic facilities. Therapists and educators prefer web applications for the educational content customization often provided by the platforms [25]. Educational content is tailored to the individual's learning abilities and progress. Visual aids such as images and videos are used in creating websites to engage and help people with ASD better understand concepts.

4) Augmented reality applications: Augmented reality technology uses a virtual environment that is overlaid on the real environment. This is done using video cameras These applications include interactive games, educational applications and communication applications. Desktop applications are characterized by high performance, because they have enough memory to support complex user interfaces with numerous graphic elements and resource-consuming animations. that are built into the devices. These cameras film the real environment and the AR software processes the image and adds virtual elements to it. Therefore, the user can see the real environment enhanced with virtual elements. The hardware used in AR technology includes video cameras, motion sensors, and specialized devices such as AR glasses, for instance Microsoft's HoloLens and Magic Leap One allow users to see virtual elements while moving through the real environment. AR technology is used in autism therapy to help autistic individuals develop social and communication skills. A common use case is to create scenarios for social interaction, such as engaging with virtual characters or participating in role-playing games. AR helps individual to understand and remember information, and it is not limited to one age group or level of education [26].

5) Virtual reality applications: Virtual reality is attracting increasing attention in the medical and healthcare industry, as it provides fully interactive three-dimensional simulations of real-world settings and social situations, which are particularly suitable for cognitive and performance training, including social and interaction skills [27]. Almost two decades ago, VR has been introduced as an effective tool in neurocognitive rehabilitation of patients with ASD [28]. VR applications include equipment such as a head-mounted display (HMD), haptic devices , hand controllers, foot controllers, non-body controllers, wireless trackers, and wrap-around displays. VR equipment allows the user to interact with the computer-generated environment in a seemingly real or physical way. Therapeutic applications of VR are based on the theory that the brain can process information more effectively when it is presented through a combination of sight, sound, and touch [29]. Owing to these distinctive features, therapists use VR to create scenarios that allow individuals affected by ASD to interact with virtual characters and learn to communicate. A study showed that the use of virtual reality technology in autism therapy can improve social and communication skills [30]. Academic researchers have shown interest in the impact VR technology can have on life and motor skills. In a study conducted by Tzanavari et al. [31], VR was employed to instruct six children with ASD on the safe method of crossing the street. The researchers observed that the children successfully acquired the necessary skills through the simulation and were able to apply them in real-world situations. VR technologies are a powerful tool for autism therapy. These technologies allow the creation of a safe and controllable environment for individuals with autism, where they can learn and develop their social and communication abilities.

6) Robots: Robot-assisted autism therapy (RAAT) is a method of therapy that uses specially designed robots to help individuals with autism spectrum disorders develop their social, communication, and cognitive skills. In RAAT, several types of robots are used: humanoid robots, animaloid robots, toy robots, and machine robots.

7) Humanoid robots: Humanoid robots are robots that resemble human beings, having hands, legs, and head with well-defined facial characteristics, including mouths and large eyes. These robots can be programmed to mimic human behavior and gestures, as well as to simulate human emotions. A research study conducted by Feng Wu et al. [32], aimed to replicate emotions by developing a humanoid robot equipped with thermoplastic elastomer (TPE) skin, which closely resembles human skin. The lifelike appearance of this robot had significant implications for clinical rehabilitation in the context of ASD. It provided a valuable platform for training individuals with autism to identify and mimic facial expressions, thus enhancing their emotional and social skills. Studies [33], [34] have also addressed this area of research and showed that individuals with ASD interpreted robots as a new intelligible species that present anthropomorphic thinking, that can have emotions and feel physical pain and treated them equitably as human beings. Humanoid robot can engage autistic people in ways that demonstrate essential aspects of human interaction, guiding them in therapeutic sessions to practice more complex forms of interaction found in social human-to-human interactions [35].

8) Animaloid robots: Animaloid robots are a category of robots that mimic the appearance of animals, such as dogs or cats, by using zoomorphic features such as fluffy fur, whiskers, a tail, or a beak. These robots are frequently used in therapy for children with autism spectrum disorders to improve their social and interaction skills. Because animal like robots have a playful appearance and often resemble pets, they are more attractive to children with autism, making them more receptive to their use in therapy [36]. Therapists use the animaloid robots to calm the child's emotional state and teach them how to interact with non-speaking beings, both from the perspective of empathy and to prevent exposure to danger. Through these robots, autistic children can learn how to behave with animals and learn how to develop their social skills [37], such as verbal and non-verbal communication, but also understand their emotions and needs [25].

9) Toy robots: Toy robots are a more affordable category of robots than other robots used in autism therapy, making them a popular choice for home use. The robotic toys come in a variety of sizes and shapes [35], often representing fantastic or imaginary characters, which makes them even more attractive to children. Toy robots help children to learn and perform tasks, thereby improving their cognitive skills [38]. These robots can also help develop motor skills and hand-eye coordination, as well as improve problem-solving skills. In addition, toy robots can be used for entertainment purposes [39], providing children and adults with a variety of fun activities.

10)Devices: In the context of autism therapy, devices are employed to provide assistance and help to improve the physical or mental capabilities of individuals with ASD, whether they are children or adults. They are classified into four main categories: tactile devices, speech devices, mobility devices, and head devices.

11)Tactile devices: Touch plays a crucial role in social communication and interactions and may be severely affected by the challenges in tactile perception, which are commonly observed in children with ASD. This results in either hyper- or hypo-sensitivity in these children [40]. Most tactile devices use vibrotactile sensors, pneumatic, and heat pump actuation [40]. Hardware capabilities of tactile devices enable complex simulations of different actions such as touching and hugging, and also provide the ability to capture fine finger touches. Tactile devices include toys with various textures and clothing with pressure sensors. The devices are frequently used in the therapy of people who have self-harming tendencies. They also help individuals with ASD with sensory stimulation and behavioral regulation. An example of smart clothing is "TellMe" created by Helen Koo from the University of California [41]. This clothing is specifically designed to address ASD and encourage boys who suffer from it to express themselves and enhance their communication skills. It incorporates therapeutic features such as sensors and actuators. The clothing includes a pressure sensor, a light sensor, and a motion sensor, along with actuators such as light-emitting diodes (LEDs), a direct current (DC) motor, and a vibration motor. Through interaction with interactive robot characters on the clothing, children can engage in activities like speaking into a microphone or triggering sensors and actuators. This interactive experience enables children to learn and practice expressing their feelings, emotions, and opinions. The clothing aims to provide a joyful and fascinating experience for children with ASD, stimulating self-confidence and self-expression .

12)Speech devices: Speech devices are technologies that help individuals with autism to communicate more effectively. These include speech synthesizers, tablets with specialized software [42], and hand-held pictographic devices for augmentative and alternative communication (AAC). Speech devices use advanced technology such as text to speech (TTS) and speech to text (STT) for natural language processing. These innovative devices prove to be invaluable resources for people who face language-related challenges, as they enable seamless communication with others, express emotions and interact with environment in a more meaningful way.

13)Mobility devices: Mobility devices are designed to assist individuals with ASD who have difficulty with mobility and motion. These devices range from simple walkers to advanced robotic exoskeletons. The hardware capabilities of mobility devices vary depending on the specific device. Some mobility devices are equipped with sensors and advanced software to help individuals with ASD improve their balance and coordination. These devices can also help individuals with ASD to become more independent and improve their overall quality of life.

14)Head devices: Head devices are used to address sensory and motor challenges faced by individuals with ASD. These devices include head-mounted displays and virtual reality headsets, which use advanced software and hardware to simulate real-world environments and activities. The hardware features of head devices include a variety of sensors that can monitor brain activity, stress levels and other aspects of psychological health. These devices also come with headphones that can play sounds. Head devices are specially designed to help autistic people focus, calm down and interact more easily with the environment through various techniques such as meditation and relaxing music.

Researchers' interest in the use of head-mounted devices increased in the past years due to the availability of affordable, consumer-grade HMD-based VR systems [43]. Dennis P. Wall et al. from Stanford University explored the power of head devices and developed a system named "SuperpowerGlass" [44]. This wearable aid is designed to assist children with ASD. The system uses Google Glass and an Android phone to provide children with real-time social cues. It includes various activities such as "Capture the Smile" and "Guess the Emotion" to engage children and promote emotional recognition and social interaction skills. The system underwent a 3-month study involving 14 families, and the results showed that children with ASD responded well to wearing the system at home and preferred the most expressive feedback option. The study also highlights an increased involvement of children in the wearable therapy sessions.

15)Interactive technologies in practice: In this study, we applied the unified theory of acceptance and use of technology (UTAUT) principles to understand why certain technologies are preferred over others and how they are used in practice. UTAUT is a model for user acceptance of information technology toward a unified view that explains user intentions pertaining to technology and subsequent usage behavior [12]. The theory states that there are four key constructs: (a) performance expectancy, (b) effort expectancy, (c) social influence, and (d) facilitating conditions, where the first three are direct determinants of usage intention and behavior, and the fourth is a direct determinant of user behavior [17].

The survey results, from cross-sectional study revealed that 55.9% of parents, therapist and teachers use technologies in ASD context. The remaining 44.1% of participants do not use technology, and one of the main reasons mentioned is the high price of devices, robots and applications.

The statistical analysis of participants' purchasing behavior revealed that 25% chose to purchase technology through direct payments, while the majority preferred to explore and use free technology. Further examination of the data indicates that participants' preferences for technology acquisition varied based on price ranges:

- 7% of participants preferred technology priced between €1 and €10;
- 10% of participants selected technology priced between €20 and €50;
- 3% of participants chosen technology priced between €50 and €100;
- 3% of participants purchased technology priced between €100 and €200;
- 2% of participants invested in technology priced above €400.

These findings are supported by Fig. 8, which visually represents the distribution of participants' preferences for technology acquisition.

A significant proportion of study participants, comprising over 40%, expressed a preference for mobile applications as their favored technology. This preference is primarily attributed to the ease of installation on personal smartphones or tablets, coupled with the convenience of accessing these applications from any location. In addition to mobile applications, speech devices, and desktop applications are commonly used by parents, caregivers and therapists in the context of therapy Fig. 9. These technologies are perceived to be effective in facilitating the development of communication skills and promoting social interaction of children with ASD.

In the survey, we conducted an inquiry into the specific purposes for which participants use interactive technologies, aiming to gain insights into the objectives associated with their usage. The findings indicate the following distribution of purposes among the participants:

- Educational purposes were reported by the majority, constituting 30% of the participants;
- Entertainment purposes accounted for 26% of the participants' responses;
- Communication purposes were reported by 17% of the participants;
- Therapeutic purposes were indicated by a relatively lower percentage, with only 15% of participants mentioning them;
- Diagnostic purposes were reported by merely 2% of the participants.
- Assistance purposes had the lowest percentage, with only 1% of participants indicating their usage for this objective.

Fig. 10 highlights the prominent utilization of technologies for educational and entertainment purposes.

Technologies used for educational purposes include learning platforms, video tutorials and applications that help children acquire new knowledge and skills. On the other hand, technologies used for entertainment purposes include video games, social media and music apps.

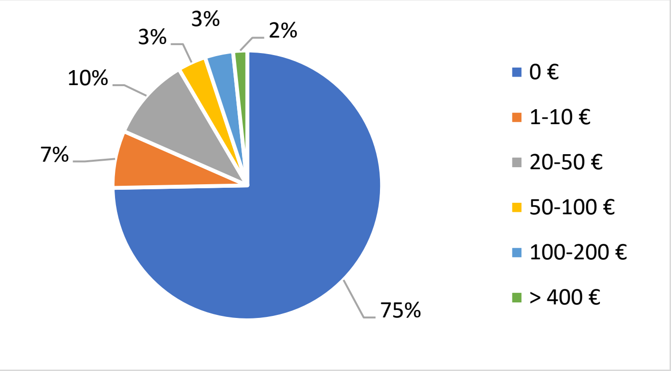

Fig. 8. The cost of technologies purchased by study participants.

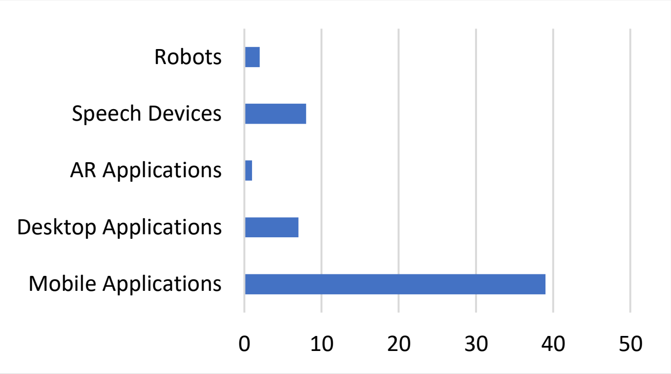

Fig. 9. Technologies practiced in real-life by parents, therapists and teachers.

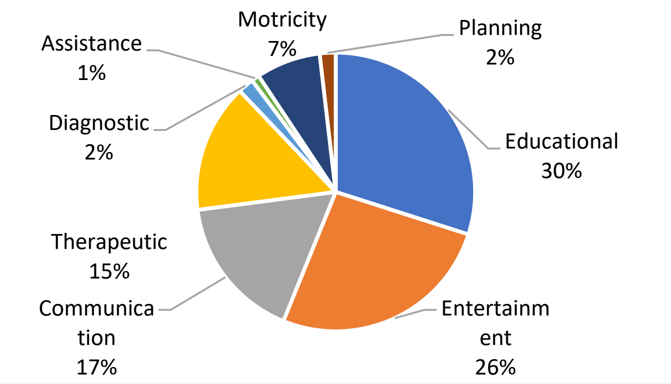

Fig. 10. The purposes for which the technologies were used by study participants.

Fig. 11. Interactive technologies used by study participants (Logos depicted in the graphic were sourced from official websites).

Fig. 11 presents some of the most frequently used interactive technologies by parents, therapists, and teachers to support the development of children with special needs. These technologies include apps like Leeloo AAC, AutiSpark, LetMeTalk, ABA Kit, and Autism ABC, which are specifically designed to help children with ASD communicate and improve their social and learning skills.

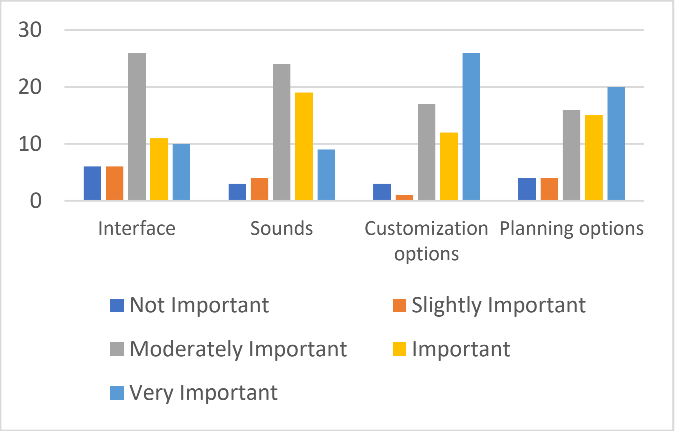
According to experts, interactive technologies are most frequently used in ABA therapy and in communication, speech and language therapy.

C. *Characteristics of Technologies in ASD Therapeutic Interventions*

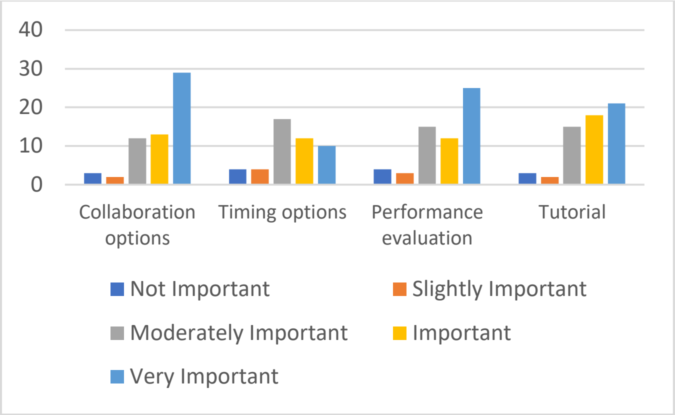
Improving skills of individuals with autism is a complex task that requires a personalized approach, taking into account the specific needs and characteristics of each individual.

The analysis of data from the cross-sectional study has highlighted the importance of different characteristics of interactive technologies used in ASD therapy.

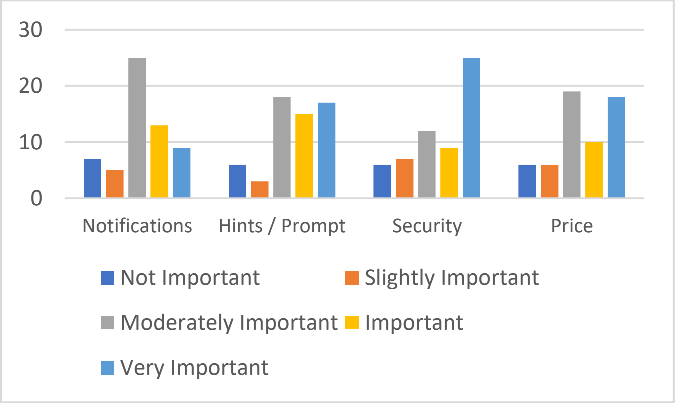
The participants assessed the importance of these technological characteristics, as depicted in Fig. 12. The data analysis unveiled that six characteristics were rated as "very important": collaboration options between parents and therapists; customization options for educational content; evaluation options for assessing the performance and progress of ASD patients; planning options; data security; and tutorial.



(a)



(b)



(c)

Fig. 12. Assessment of significance of technological characteristics. ASD experts' perspectives on (a) visual and audio design, customization of educational content and planning (b) collaboration and timing options, progress monitoring and evaluation, tutorial (c) notifications, hints, security, and price.

The characteristics that received evaluations of "moderately important" included: interface customization options; diagnostic options; timing options; notification; avatar; colorful UI interface; background music/sounds; price. The results did not indicate any prevailing evaluations for the characteristics evaluated as "slightly important" and "not important".

By combining the findings of the cross-sectional study and expert opinion, the most important characteristics of technologies used in ASD context were identified:

- *Visual and audio design*: Visual and audio design play a vital role in helping individuals with autism comprehend presented information. Interactive technologies with engaging design stimulate the senses and facilitate learning.
- *Planning and scheduling options*: Planning and scheduling options are important because individuals with autism may struggle with organizing and planning tasks. Interactive technologies provide planning options to assist ASD patients in managing their time efficiently and performing tasks more effectively.

- *Personalization of educational content*: Personalization of educational content is crucial because each individual with autism has specific educational needs and learns best through different methods. Interactive technologies can be customized for each individual, providing tailored educational content that meets their specific needs and abilities.

- *Progress monitoring and evaluation*: Progress monitoring and evaluation are essential to track the progress of individuals with autism in therapy. Interactive technologies provide monitoring and assessment tools that enable therapists and parents to follow the progress of individuals with autism.

- *Collaboration options*: Collaboration options with therapists, doctors, and parents are important because they must work together to provide appropriate therapy for individuals with autism. Interactive technologies can be designed to facilitate collaboration and communication between these stakeholders, thereby improving the quality of therapy provided to individuals with autism.

IV. Limitations

Our study focuses on interactive technologies that are designed for ASD therapy. Technologies can be a valuable tool in developing the aptitudes of patients with ASD, but their impact is not sufficiently investigated worldwide. Although we had a good representation of study participants, they were limited to parents, therapists, and teachers from a single county in Romania. The small number of subjects participating in the cross-sectional study, may affect the conclusions and their general applicability. To address this, future research will aim to include a larger and more diverse sample of participants to cover a wide spectrum of sociocultural experiences.

V. Conclusions

This research began by analyzing the ASD diagnosis and understanding that "spectrum" is a key term that characterizes the variety of forms and disabilities that individuals with ASD exhibit. Thus, we understood that the patient is the central element of our research, and technology is just a way to help the patient improve certain skills. Regardless of the degree of novelty and innovation of the technological solution, it must move from paper to practice and prove its effectiveness through well-documented results.

Individuals diagnosed with ASD show an increased interest in using technology for various purposes such as entertainment, communication, planning, or education. The positive attitude towards technology makes their use feasible in therapies by augmenting the information presented, simulating the visual, tactile and auditory senses, or monitoring the patient's physiological parameters. Experts in the field have highlighted that applied behavior analysis, communication, speech and language therapy, occupational therapy, and physical therapy are the therapies that most often involve technology in therapeutic procedures. The technology designed for use in the ASD context has various hardware specifications and software characteristics, depending on which they have been grouped into applications, robots, and devices. Current body of evidence supports the effectiveness of interactive technologies in improving ASD impairments such as communication deficits, social interaction deficits, motor disabilities, and mental retardation. Despite the obvious benefits, the participants in the study expressed concerns about the negative effects of technology use, such as agitation, aggression, and difficulty in use, associated with non-respect of the ISO standards in terms of appropriate visual or auditory design for persons with disabilities.

The multidisciplinary team that participated in this research consisted of therapists, teachers, software engineers, and parents of children diagnosed with ASD. Each participant brought their vast expertise to identify the important characteristics for ASD-specific technology. Thus, the adaptability of the technology to the patient's progress is by far the greatest need and challenge.

In response to cross-sectional study survey's question, which invited the participants to provide feedback and additional information not covered in the survey, a parent expressed a hopeful desire: "*I hope an application will be developed in Romania to assist parents, who don't have enough financial resources, to work with their children at home*.". This desire aligns perfectly with the goal of our future research, which is to leverage the valuable insights gained from the current study to create an accessible application that can support children with ASD and their families.

In conclusion, we encourage researchers to explore and develop innovative technological interventions for the ASD treatment, especially considering the growing prevalence of this neuropsychiatric condition.

***Abstract*—The drier bed adsorption processes remove moisture from gases and liquids by ensuring product quality, extending equipment lifespan, and enhancing safety in various applications. The longevity of adsorption beds is quantified by net loading capacity values that directly impact the effectiveness of the moisture removal process. Predictive modeling has emerged as a valuable tool to enhance drier bed adsorption systems. Despite the increasing significance of predictive modeling in enhancing the efficiency of drier bed adsorption processes, the existing methodologies frequently exhibit deficiencies in accuracy and flexibility, which are crucial for optimizing process performance. This research investigates the effectiveness of a hybrid approach combining Long Short-Term Memory and Particle Swarm Optimization (LSTM+PSO) as a proposed method to predict the net loading capacity of a drier bed. The train-test split ratios and rolling origin technique are explored to assess model performance. The findings reveal that LSTM+PSO with a 70:30 train-test split ratio outperform other methods with the lowest error. Bed 1 exhibits an RMSE of 1.31 and an MSE of 0.91, while Bed 2 archives RMSE and MSE values of 0.81 and 0.72, respectively and Bed 3 with an RMSE of 0.19 and an MSE of 0.13, followed by Bed 4 with an RMSE of 0.67 and an MSE of 0.36. Bed 5 exhibits an RMSE of 0.42 and an MSE of 0.34. Furthermore, this research compares LSTM+PSO with LSTM and conventional predictive methods: Support Vector Regression, Seasonal Autoregressive Integrated Moving Average with Exogenous Variables, and Random Forest.**

Keywords*—Adsorption; Long Short-Term Memory; net loading capacity; Particle Swarm Optimization; prediction

I. Introduction

Drying is used in various sectors, including agriculture, pharmaceuticals, energy, and other process industries, to transform liquid within a product into a solid [1], [2]. External energy, such as fossil fuel, generates high temperatures in a drying system's rotary bet, fluidized bed, spray, tray, impinging jet, and pulse combustion dryers [2]–[4]. This method involves drying wet goods at high temperatures [3], [4] to ensure the best possible performance. Drying techniques range from the sun to the oven, freezer, and microwave [3], [5]. Adsorption shows more promise than other drying methods when it comes to air drying [6].

The drier bed adsorption process is widely used across various industries [7], [8]. It is an essential parameter for estimating the remaining life of the drier bed and must coincide with the planned plant shutdown period. The overestimation of bed capacity will lead to unexpected moisture breakthroughs, resulting in production losses due to the drying out of equipment further down the line. In this research, Net Loading Capacity (NLC) measures the amount of moisture an adsorption bed can absorb before replacing or regenerating. An adsorption bed with a longer lifespan can extract more water before needing to be replaced or regenerated, which can maximize efficiency and save expenses. The challenge of accurately measuring dryer process system performance remains unaddressed despite its critical role in guaranteeing energy conservation, process dependability, and product quality [2, 4, and 9].

In recent years, Long Short-Term Memory (LSTM) neural networks are also known for their ability to model sequential data effectively, such as time series or text data. LSTM also has advanced potential for prediction modelling in various domains such as prediction of crude oil [10]–[12], financial [13], energy consumption [14]–[16], and medical [17]. Their capability to capture long-range dependencies and adapt to changing input patterns makes them a promising tool for modelling and predicting the dynamic behaviour of drier bed adsorption. However, performing well requires a large number of data and substantial computational resources. This makes them less suitable for small datasets due to overfitting. Furthermore, it can be sensitive to hyperparameter settings since finding the appropriate parameter can be time-consuming.

The optimization techniques are crucial in improving the prediction efficiency of the models. Particle Swarm Optimization (PSO) is a robust optimization algorithm inspired by birds flying for food, which has been widely applied to various optimization problems [18]. The combination and integration of PSO with LSTM aims to tackle the information of particles to fine-tune the model parameters and optimize the prediction accuracy of the drier bed adsorption model of a small number of datasets.

The contributions of this paper are in the following:

1) A new particle representation is used for PSO implementation in an NLC drier bed performance-based molecular sieve.

2) A novel idea of combining LSTM with a new particle representation strategy of a PSO for predicting drier bed adsorption capacity, namely LSTM+PSO.

3) LSTM+PSO facilitates the analysis of temporal predictions, optimizing prediction models and improving prediction accuracy using a small number of adsorption bed life monitoring datasets.

4) A comparison analysis of LSTM+PSO with LSTM and traditional machine learning and statistical methods was performed.

The remainder of paper is organized by sections. Section II presents the related work. Section III delves into methodology detailing the architecture of the LSTM+PSO model and the optimization process. Section IV discusses the proposed solution, the model of LSTM+PSO performance with LSTM, SVR, and SARIMAX. Section V discusses the performance evaluation. Section VI gives the computational results. Section VII and Section VIII presents the discussion and conclusion respectively.

II. Related Work

Adsorption drying reduces the amount of water vapor in humid air by passing it through the solid adsorbent level of dehydration, which influences the selection of an appropriate adsorbent [6], [19]. Adsorbent bed dryers come in various configurations, including packed beds, coated channels, and annular coated tubes [20]. The bed's efficiency is affected by design parameters such as bed length and adsorbent mass [7]. The design of the drops must allow for high transfer rates while also being appropriately sized accommodating the allowable pressure drop [21]. Furthermore, the dryer should be stable over long periods of operation, have low toxicity, be corrosion resistant, and be cost-effective. Molecular sieves are an example of an adsorbent commonly used in natural gas plants [19]. The ability of water molecules to diffuse into the pores of the adsorbent limits the overall adsorption rate [6].

The advantages of adsorption drying include a low impact of temperature and pressure on the adsorption process, the use of simple equipment, reduced spatial demands, efficient humidification capabilities, the ability to use various heat sources for adsorbent regeneration, and cost-effective operation [6], [21]. The short adsorption-desorption cycles and low-temperature regeneration techniques are employed that can help achieve low operational costs [22]. Adsorption drying has several disadvantages, including increased heating costs, energy-intensive regeneration processes, and potential sorbent abrasion [9], [21]. Various approaches have been proposed to improve the limitations of estimating drying capacity to achieve optimal drying performance. These include the use of mathematical models, simulations of the drying apparatus, and machine learning techniques.

The use of a mathematical model for the drier indicates that it causes an increase in drying capacity to optimize the energy consumption of an amount of heat [23]. Furthermore, both the dryer efficiency and sustainability index demonstrate a significant reliance on the extent of heat recovery in the case of a spray dryer [24]. On the other hand, the significance of materials' drying behavior highlights limitations to enhance accuracy and reliability in adopting capillary active insulation materials [25]. The mathematical modeling for a multistage phosphate pellet roasting process offers the potential for significant energy savings [26]. However, there still needs to be more research on adsorption dryer beds, especially in the prediction of the NLC.

III. Material and Methods

This section explains the steps to address the predictive analytics challenge in drier bed adsorption, specifically in predicting NLC. The research framework begins with data acquisition, which involves data collection from five different beds: Bed 1, Bed 2, Bed 3, Bed 4, and Bed 5. Next, the data undergoes a pre-processing stage where unnecessary or irrelevant information, such as bad input and intf shut are eliminated to ensure data quality. Additionally, noisy data is filtered out to enhance the reliability of the dataset. The next step is featuring selection guided by correlation coefficients [27], which aims to identify the most relevant features for the predictive modeling task. The dataset is divided into training and testing subsets, setting the model development stage.

In the research model development phase, various methodologies comparing conventional methods such as LSTM, SVR, SARIMAX, and Random Forest are compared with the proposed LSTM+PSO. Fig. 1 provides a research framework. The data acquisition process involves the implementation of an automated procedure. In this research, computational analysis has been conducted focuses on the process within the drier beds for Bed 1, Bed 2, Bed 3, Bed 4, and Bed 5. The components that involve automatic breakthrough time identification, the identification and checking of the regeneration efficiency, and the identification regeneration cycle are all components of this step for each drier bed.

A. Data Pre-processing

Data pre-processing involves data extraction. The process of filtering historical data is handled by data extraction. A few steps in data processing are removing unnecessary data such as bad input, intf shut, and removing noisy data. Removing unnecessary data involves identifying and eliminating columns or variables within the dataset that either do not contribute valuable information or contain redundant information. During data processing, noisy data points are identified and filtered out.

Fig. 1. Research framework.

B. Features Selection

The features are chosen based on their correlation with beds 1, 2, and 3 to identify the most relevant ones. The correlation can use two sets of correlation values: {0.1, 0.2, 0.3, 0.4, 0.5} and {-0.1, -0.2, -0.3, -0.4, -0.5}, calculated using the Pearson correlation coefficient. Eq. (1) presents the Pearson formulas for the correlation coefficient [27]. This coefficient ranges from -1 to 1. The coefficient value equal to -1 indicates a perfect negative correlation. Meanwhile, 1 indicates a perfect positive correlation. In addition, a zero value indicates no linear correlation between the variables.

$$r = \frac{\sum(x_i - \bar{x})(y_i - \bar{y})}{\sqrt{\sum(x_i - \bar{x})^2 \sum(y_i - \bar{y})^2}} \quad (1)$$

where, in these equations, r represents the correlation coefficient, x_i signifies the values of the variable of x in a sample, x denotes the mean (average) of the x variable values, y_i stands for the values of the y variable in a sample, and y represents the mean (average) of the y variable values.

C. Establishment of NLC Data

NLC data is crucial for predicting drier bed adsorption capacity. The values of NLC are drier bed. Historical datasets on drier bed adsorption were employed to build predictive and validation models. The calculation of NLC includes historical data features, regeneration processes, and breakthrough times for adsorption. Following the processes, the final datasets for each bed are less than 30. The challenge is to achieve good prediction accuracy with a small dataset.

IV. Proposed Solution

The proposed solution combines the strengths of LSTM and PSO for a more robust and practical approach for a small dataset. The LSTM network provides powerful sequence modeling capabilities. Meanwhile, PSO is used to fine-tune hyperparameters and optimize the performance of the LSTM model. This hybrid approach aims to utilize the strengths of both techniques to improve predictive accuracy and overall performance. Following are the details of the hybridization of LSTM+PSO.

A. Particle Representation

A real-value PSO implementation followed the initial PSO steps. This representation is new for PSO implementation, which supports a new strategy to be embedded in LSTM and a drier bed performance-based molecular sieve. Fig. 2 is the representation for the particle, $H = \{H_1, H_2, H_3, H_4, H_5 \ldots H_n\}$ and Dropout (DP). This representation defines the characteristics; include a number of layers including DP structure, within the optimization process in the search space.

H_1	H_2	DP

Fig. 2. Particle representation.

where, the parameters are defined as H_1 represents hidden layer 1 with a range of [0.80, 1.28], H_2 represents hidden layer 2 with a range of [0.80, 2.56], and DP with a range of [0.05, 0.50]. These parameter definitions specify the allowable values or ranges for each parameter within the optimization process of LSTM+PSO. Each particle component consists of layers and DP is randomly initiated in a population. A real value for all layers is initiated as in Eq. (2) and Eq. (3).

$$d = 2 * (np.random.rand(n, 1)) - 1 \quad (2)$$

$$d = rand(x, y) * z \quad (3)$$

Where, the variables are defined as x, y, and z represents indices used in layer calculations. x is a variable that takes values from the set $\{1, 2, 3, ..., m\}$. These indices are used for referencing through layers within a calculation. A particle update procedure was introduced, which is iteratively adjusted to identify the optimal model fit for the network. The dynamic range update is based on +8 or -8 for H_1 and H_2 values, and DP is an increased value of 0.01. Eq. (3) and Eq. (4) present the velocity and position formulas for the PSO, respectively.

$$V_{id\,(new)} = W * V_{id} + C_1 r_1 * \left(P_{best(id)}\right) - X_{id} + C_2 r_2 * \left(G_{best(id)} - X_{id}\right) \tag{4}$$

$$X_{id(new)} = X_{id} + V_{id\,(new)} \tag{5}$$

where, $V_{id(new)}$ represents the updated velocity, V_{id} stands for the current velocity, X_{id} denotes the current position, and $X_{id(new)}$ signifies the new position of a particle in a PSO. The parameters W represent the inertia weight, while C_1 and C_2 are the acceleration coefficients controlling the impact of personal and global best positions on particle movement. r_1 *and* r_2 are random functions or values used for stochastic behaviour. $P_{best(id)}$ represents the personal best position for a particle with the identifier id, and $G_{best(id)}$ signifies the global best position for the same particle identifier within the PSO algorithm.

B. LSTM+PSO Algorithm

A novel approach is a hybrid model that integrates the PSO algorithm and the LSTM; this model is intended to serve the oil and gas industry. Algorithm 1 provides an overview of the LSTM+PSO method. The LSTM+PSO optimize LSTM hyperparameters for prediction. The algorithm begins by initialization of particle values in Steps 1-2. This is vital for the PSO optimization process. Next, Steps 3-4 are initializing the particles with random values. Determine the number of past future data points in the LSTM model for Step 5.

Furthermore, Step 6 defines the objective function the PSO algorithm will optimize. This function measures the performance of the LSTM model on the given task. Initialize particles and iterations number in Steps 7-8. These steps specify the number of particles in the PSO optimization and set the maximum number of iterations for the PSO algorithm. Step 9 is loading the dataset that contains the selected features relevant to the task from the selected features. Step 10 is performing the feature scaling on the dataset to ensure that the data is within a consistent range, which is typically important for LSTM models. Split the dataset into training and testing sets for model evaluation and train the LSTM neural network with the initialized particles, which represent different configurations of the LSTM model in Steps 11-12.

Algorithm 1: LSTM+PSO

```
1   Begin
2   Initialize particles
3   Initialize hidden layers and dropout-based particle values
4   Initialize learning rate
5   Set the number of lookbacks, number of future points
6   Setting up the objective function
7   Initialize particles number
8   Initialize iterations number
9   Load dataset from the selected features
10  Features scaling for LSTM fitting
11  Set the Train Test Split
12  Execute LSTM
13  Calculate Pbest and Gbest values for each particle
14  Do
15    For each particle
16    Calculate the new velocity value, $V_{(new)}$
17    Calculate new position, $D_{(new)}$
18    Calculate Pbest $_{(new)}$
19    Calculate Gbest $_{(new)}$
20    For each particle dimension
21    If current Pbest > current Gbest
      **Update new particle**

22    If current Pbest < current Gbest
      **Update new particle**
23  While (stopping condition is reached)
24  End
```

Moreover, evaluate the performance of each particle (LSTM configuration) using the objective function and determine the personal best (P_{best}) and global best (G_{best}). Step 14-Step 23 begins a loop. Iterate through each particle. The particle's velocity is updated based on its current Pbest and Gbest positions. The position of the particle is updated using the new velocity. Re-evaluate the performance of the particle with its new position and update Pbest if it improves in Step 18. Step 29 is to update the global best (G_{best}) if a particle of Pbest is better than the current Gbest. Iterate through each dimension of the particle by adjusting the particle dimension by subtracting and adding a particle change value in Step 20-Step 22. Continue the loop until a stopping condition is met, such as reaching a maximum number of iterations in Step 23. It marks the endpoint when the stopping condition is met or when the maximum number of iterations is reached.

In this research, LSTM is further enhanced by embedding the advantages of PSO. In this study, LSTM and PSO are combined. PSO can assist in finding an optimal solution, such as in obtaining a better architecture of LSTM. Fig. 1 demonstrates LSTM + PSO architecture. The main steps are similar to LSTM, which defines the input size, hidden layer, and output size. Input size corresponds to the number of input sequences or several features. The hidden layer size specifies the number of hidden layers, and the output size is set to 1, which indicates the number of items in the output predicts the NLC. The PSO elements are embedded for LSTM architecture determination.

V. Performance Evaluation

The next step is to train the data and define the epochs number using the train-test split and rolling origin. RMSE measures the average error between predicted and actual values, with lower values indicating better model accuracy. MAE represents the average absolute error, whereas lower values also suggest better model accuracy. Three types of splitting are used: 70:30, 80:20, and 90:10, dividing between training and testing data. The model's performance will be evaluated by analyzing its ability to predict NLC.

The RMSE acceptance criteria [28]–[30] are categorized as follows: RMSE values falling within the range of ≤ 0.75 are considered very Good, while those between 0.75 and 1.0 are deemed Good. RMSE values ranging from 1.0 to 2.0 are labeled as satisfactory, and any RMSE exceeding 2.0 is categorized as unsatisfactory. These criteria provide a standardized assessment for evaluating the accuracy and quality of RMSE values in various applications or studies. RMSE equation is a mathematical expression used to quantify the average deviation between predicted values ($\hat{y}_i$) and actual values (y_i) within a regression model, as shown in Eq. (6).

$$RMSE = \sqrt{\sum_{i=1}^{n} \frac{(\hat{y}_i - y_i)^2}{n}} \tag{6}$$

The LSTM model also has the best performance based on the results of evaluation metrics MAE. The MAE acceptance criteria [31], [32], as referenced, are categorized as follows: MAE values between 0 and 3 are considered very good. Those falling within the range of 3 to 6 are labelled as good. MAE values between 6 and 9 are categorized as average, and if the MAE falls within the range of 9 to 12, it is referred to as variable data. Any MAE exceeding 12 is designated as higher variability. These criteria offer a standardized framework for assessing the quality and suitability of MAE values in different contexts or studies. The MAE equation is a mathematical formula used to quantify the variance between the prediction (y_i) and the real value (x_i) by dividing this variance by the square root of the number of data points in the observations (n), as shown in Eq. (7).

$$MAE = \frac{\sum_{i=1}^{n} |y_i - x_i|}{n} \tag{7}$$

VI. Computational Results

The computational results involve using root-mean-squared error (RMSE) and mean-squared error (MAE) metrics. These metrics are applied and compared to conventional methods using the setting of parameters to assess the effectiveness and suitability of the algorithm.

A. Parameter Setting

Table I outlines the parameter settings for the LSTM+PSO model. It specifies the values assigned to different parameters for training and evaluating the model. The train-test split parameter determines how the dataset is divided for training and testing with options of 90% training and 10% testing, 80% training and 20% testing, or 70% training and 30% testing.

The rolling origin parameter indicates the number of time steps considered when making predictions with 1, 2, or 3 options. The epoch parameter sets the number of times it is passed forward and backward through the LSTM network during training, which is set at 30. The learning rate parameter defines the step size at which the model adjusts its weights during optimization, set to 0.1. Finally, the batch size parameter determines the number of data points used in each iteration of the training process and is set to 256.

TABLE I. Parameter Setting of LSTM+PSO

Parameter	Value
Train-Test Split	90:10, 80:20, 70:30
Rolling Origin	1,2,3
Epoch	30
Learning Rate	0.1
Batch Size	256
Population	30

B. Computational Results using LSTM+PSO

The comparison computational results achieved through the LSTM+PSO approach are presented in Table II. The data was split using a 90:10, 80:20, and 70:30 ratio, which utilized a lookback of three for Bed 1, a lookback of two for Bed 2, and a lookback of four for Bed 3 for prediction. The LSTM+PSO that utilize a Train-Test Split ratio of 70:30 has demonstrated its effectiveness across Bed 1, Bed 2, Bed 3, Bed 4, and Bed 5, as indicated by both RMSE and MAE evaluations.

TABLE II. Computational Result using Train-Test Split

Beds	Train-Test Split	RMSE	MAE
Bed 1	90:10	1.68	1.39
	80:20	1.53	1.16
	70:30	**1.31**	**0.91**
Bed 2	90:10	1.07	1.00
	80:20	0.97	0.90
	70:30	**0.81**	**0.72**
Bed 3	90:10	0.28	0.21
	80:20	0.21	0.15
	70:30	**0.19**	**0.13**
Bed 4	90:10	0.71	0.54
	80:20	0.70	0.56
	70:30	**0.67**	**0.36**
Bed 5	90:10	0.46	0.38
	80:20	0.45	0.37
	70:30	**0.42**	**0.34**

For Bed 1, an RMSE score of 1.31 falls within the satisfactory range, indicating that the predictive model provides reasonably accurate results for this bed. Furthermore, the MAE value of 0.91 is categorized as very good, signifying that the model's prediction closely aligns with the actual values. It demonstrates a high level of accuracy as compared to other percentages of Train-Test Split. Moving on to Bed 2, the RMSE score of 0.81 is good, implying that the model delivers accurate predictions with a relatively low margin of error.

Similarly, the MAE value of 0.72 is labeled as very good, indicating that the model's performance is highly accurate for Bed 2. In addition, for Bed 3, an RMSE score of 0.19 is considered satisfactory. This suggests that the accuracy of the model is acceptable. It is worth noting that the MAE value of 0.13 is once again classified as very good by underscoring the model's capability to make highly accurate predictions for Bed 3. Furthermore, in the case of Bed 4, the RMSE score of 0.67 is categorized as good. This indicates that the predictive model provides accurate predictions with a relatively small margin of error for Bed 4. Additionally, the MAE value of 0.36 is labeled as very good and highlights that the model's performance is highly accurate when predicting outcomes for Bed 4. Lastly, for Bed 5, the RMSE shows a good value, which is 0.42, along with the MAE obtained of about 0.34, which indicates good performance to the predictive model.

Table III presents an analysis of performance metrics, specifically RMSE and MAE, for various bed types (Bed 1, Bed 2, Bed 3) across rolling origin values of 1, 2, and 3. The LSTM+PSO approach applied rolling origin has consistently proven its effectiveness in predicting outcomes for Bed 1 until bed 3, as evidenced by the RMSE and MAE assessments. Notably, for Bed 1, the RMSE of 1.78 falls within the satisfactory range, while the MAE of 1.62 is categorized as very good. Similarly, for Bed 2, the RMSE of 0.82 is deemed suitable, and the MAE of 1.08 is labeled very good. For Bed 3, the RMSE of 0.70 is considered satisfactory, and the MAE of 0.14 is classified as very good.

TABLE III. COMPUTATIONAL RESULT USING ROLLING ORIGINS

Types of Beds	Rolling Origin	RMSE	MAE
Bed 1	**1**	**1.78**	**1.62**
	2	2.00	1.79
	3	2.46	2.19
Bed 2	**1**	**0.82**	**1.08**
	2	0.93	1.18
	3	1.17	1.28
Bed 3	**1**	**0.70**	**0.14**
	2	1.21	0.80
	3	1.42	0.38

C. *Computational Results with LSTM and Conventional Methods*

The comparison experimental results of conventional methods of LSTM, SVR, SARIMAX, Random Forest (RF), and LSTM+PSO are shown in Table IV. The choice of parameter settings for the split percentage of 70:30 is similar to the LSTM+PSO approach. A lower RMSE and MAE suggest superior predictive performance and indicate that the model's prediction is closer and aligned to the actual values.

In the case of Bed 1, the SARIMAX and RF models showed better results than the LSTM, SVR, and LSTM+PSO models. It was evident through their lower values of RMSE and MAE. Moreover, it can be observed that LSTM+PSO exhibits the highest predictive accuracy in terms of both RMSE and MAE metrics for Bed 2, Bed 3, Bed 4, and Bed 5. Regardless of SARIMAX and RF demonstrating lower values of RMSE and MAE, they are not suitable for forecasting due to their inability to accommodate the lookback value, resulting in unviable forecast points.

TABLE IV. COMPUTATIONAL RESULT WITH CONVENTIONAL METHOD

Types of Beds	Metrics	LSTM	SVR	SARIMAX	RF	LSTM+PSO
Bed 1	RMSE	1.45	2.81	1.18	1.10	**1.31**
	MAE	1.33	2.79	0.76	0.99	**0.91**
Bed 2	RMSE	0.69	1.08	4.68	1.12	**0.61**
	MAE	0.53	1.03	3.59	1.04	**0.45**
Bed 3	RMSE	0.55	3.93	3.96	1.26	**0.19**
	MAE	0.46	3.71	3.50	1.21	**0.13**
Bed 4	RMSE	0.83	1.36	4.68	1.36	**0.67**
	MAE	0.55	0.99	3.59	1.27	**0.36**
Bed 5	RMSE	0.49	3.94	2.69	1.08	**0.42**
	MAE	0.32	3.71	2.18	0.85	**0.34**

VII. DISCUSSIONS

LSTM+PSO model, especially when utilizing a train-test split ratio of 70:30, is highly effective in predicting results for a difference of beds, namely, Bed 1, Bed 2, Bed 3, Bed 4, and Bed 5. The model can perform well. The prediction result of LSTM+PSO using rolling origin highlights the reliability of the LSTM+PSO approach in achieving precise predictions across different bed types. However, it is worth noting that the rolling origin method, while promising, may utilize only some of the dataset as effectively as a fixed train-test split of 70:30, as it involves random cross-validation that may exclude some data observations [33].

The most notable outcome of this study is that the LSTM+PSO model outperformed other models such as LSTM, SVR, Random Forest, and SARIMAX, as evident by lower RMSE and MAE values. It highlights the effectiveness of the LSTM+PSO model in making predictions on the dataset. The LSTM+PSO can be advantageous in terms of exploration, exploitation [34], [35], stochastic search, optimal capability, and the ability to handle global and local optima [36], [37]. PSO is known for its ability to explore the search space effectively. When combined with LSTM, which tends to converge quickly to local optima, PSO helps explore different regions of the parameter space, potentially leading to better global solutions.

While LSTM is good at fine-tuning, the PSO algorithm attracts other particles toward the region. The stochastic behaviour helps to escape local optima, which can be especially beneficial when combined with LSTM, which tends to be deterministic [38]–[40]. LSTM+PSO can harness the optimal capability of PSO to find the best set of hyperparameters of weights for the LSTM that can lead to improved overall model performance. It also allows for a more robust optimization process to improve model performance, especially in complex and high-dimensional search spaces. Thus, PSO is designed to handle both global and local optima that complement LSTM's ability to fine-tune models to local patterns in small datasets.

VIII. CONCLUSION

The LSTM+PSO method is proposed for NLC prediction of a drier bed, which can assist manual moisture adsorption capacity test. LSTM+PSO utilized a new particle representation to obtain a robust model for predicting outcomes for different bed types. Compared with LSTM, SVR RF, and SARIMAX, the proposed LSTM+PSO performs better, achieving significantly lower RMSE and MAE values for a small dataset. Additionally, a new particle representation LSTM+PSO, an efficient model, is achieved for predicting outcomes on different bed types. This achievement provides significant possibilities for improving future investigations within this domain. In future research efforts, it is suggested to incorporate additional data from alternative sources, such as other beds, together with experimental data collected over a period. This approach will facilitate the analysis of temporal predictions, allowing for the refinement of prediction models and the enhancement of prediction accuracy. Additional techniques, such as cuckoo search and firefly algorithm will be employed in future research to reduce the error and obtain an optimal solution.

A Deep Learning-based Approach for Vision-based Weeds Detection

Yan Wang*
Department of Architecture Engineering, Shijiazhuang College of Applied Technology, Shijiazhuang 050081, China

***Abstract*—Weed detection is an essential component of smart agriculture, and the use of remote sensing technologies has the potential to significantly improve weed management practices, reduce herbicide usage, and increase crop yields. This study proposed an approach to weed detection using computer vision and deep learning technologies. By utilizing remote sensing methods based on DL, this approach has the potential to optimize weed management strategies, minimize herbicide use, and enhance crop productivity. The weed detection algorithm is based on the Yolov8 framework, and a custom model is trained using images from popular datasets as well as the internet. To evaluate the model's effectiveness, it is tested on both validation and testing sets. Furthermore, the model's performance is assessed using images that are not included in the original dataset. As experimental results shown, the deep learning-based approach is a promising solution for weed detection in agriculture.**

Keywords—Smart agriculture; weed detection; remote sensing; deep learning; computer vision

I. Introduction

Smart agriculture, also known as precision agriculture [1], involves the use of technology to enhance and optimize crop production while minimizing environmental impact. This includes using sensors and monitoring systems to collect data on soil conditions, weather patterns, and plant growth, as well as utilizing machine learning algorithms and automation to improve efficiency and reduce waste. Smart agriculture also encompasses the use of drones, robotics, and other advanced technologies to perform tasks such as planting, watering, and harvesting. Overall, smart agriculture aims to increase yields, reduce resource usage, and promote sustainable farming practices [2].

Weeds are unwanted plants that compete with crops for resources such as nutrients, water, and sunlight, which can reduce the yield and quality of agricultural products [3]. Weeds can also serve as hosts for pests and diseases, which can further impact crop health and productivity. To manage weeds, farmers may use various methods such as mechanical cultivation, hand weeding, or chemical herbicides. However, the use of herbicides can have negative effects on the environment and human health, so there is growing interest in alternative weed management strategies such as integrated weed management, cover cropping, and crop rotation. Effective weed management is essential for maintaining healthy and productive agricultural systems while minimizing negative impacts on the environment and human health [4, 5].

Weed detection is a critical aspect of precision agriculture, as it allows farmers to identify and manage weeds more effectively [6]. There are several methods for detecting weeds in agricultural fields, including visual inspections, manual sampling, and remote sensing technologies. Visual inspections involve physically observing the crop and looking for signs of weed growth. This method can be time-consuming and labor-intensive, but it can be useful for identifying small infestations or for crops with lower weed densities. Manual sampling involves collecting samples of soil or plant material from different locations in the field and analyzing them for the presence of weeds [7]. This method is more accurate than visual inspections but can still be time-consuming and requires trained personnel. Remote sensing technologies, such as satellites, drones, or ground-based sensors, can provide rapid and accurate weed detection across large areas [8, 9]. These technologies use various sensors such as multispectral or hyperspectral cameras, which can detect differences in plant color, reflectance, or texture, to identify and map weeds [10]. Machine learning algorithms can then be used to analyze the data and develop weed management strategies [11].

Deep learning is a subset of machine learning that uses artificial neural networks to automatically learn and identify patterns in data [11, 12]. In the context of weed detection, deep learning algorithms can be trained on large datasets of images to recognize and classify different weed species. This involves using convolutional neural networks (CNNs) to extract features from the images and then using a combination of fully connected layers and softmax classifiers to classify the images [13]. Deep learning-based weed detection systems have shown high accuracy rates in detecting and classifying weeds, even in complex agricultural environments [14, 15]. These systems have the potential to revolutionize weed management practices by providing farmers with rapid and accurate information about weed infestations, allowing for more targeted and effective weed control strategies.

In this study, a deep learning-based method is proposed for weed detection. In DL based which is in remote sensing technologies it has the potential to significantly improve weed management practices, reduce herbicide usage, and increase crop yields. In order to detect weeds, a Yolo based algorithm is developed to detect the weeds. For this detection, a model is trained using collected images from internet and other popular dataset. The generated model is evaluated and test using associated validation and testing sets. Finally, the model is tested with images outside of our dataset to make sure the performance of the method is effective.

The main research contributions of this study are as follows:

1) The study introduces a novel deep learning-based method for weed detection in remote sensing technologies, offering the potential to enhance weed management practices and contribute to reductions in herbicide usage, ultimately leading to increased crop yields.

2) A YOLO-based algorithm is developed as part of the research, providing an effective and efficient means of detecting weeds, thereby contributing to the advancement of automated weed detection systems.

3) The research contributes by presenting a meticulously trained model, utilizing a diverse set of images collected from the internet and other popular datasets, and evaluates its performance not only on associated validation and testing sets but also on external images, ensuring the method's effectiveness beyond the initial dataset.

II. Related Works

In research [12], custom lightweight deep learning models are suggested for detecting weeds in soybean crops. The models were trained using a dataset of images depicting soybean crops with varying weed types. The findings demonstrate that the proposed models outperform conventional machine learning algorithms in terms of speed, memory usage, and accuracy. The authors suggest that the custom lightweight deep learning models can efficiently detect weeds in soybean crops, which can result in improved crop management and reduced usage of herbicides.

Peng et al, [16] presented an enhanced RetinaNet network for detecting weeds in paddy fields. The proposed network employs residual connections and feature pyramid network (FPN) to improve the accuracy of weed detection. The dataset used in this study consists of images of paddy fields containing different types of weeds, which were used for both training and testing the network. The findings of the study indicate that the proposed network outperforms existing methods and is effective in detecting weeds in paddy fields. The authors suggest that the improved RetinaNet network has the potential to aid in weed management and reduce the need for herbicides in agriculture.

Haq et al, [17] developed an automated weed detection system that relies on CNNs and UAV imagery. The proposed system captures aerial images of crop fields using UAVs and employs CNNs to differentiate between crops and weeds. The CNNs are trained using a dataset of images containing both crops and weeds. The study reveals that the system can accurately detect weeds in a timely manner. Their experimental results show using UAVs and CNNs for weed detection can lead to better weed management in agriculture, enhancing efficiency and accuracy.

The authors in study [18] presented an enhanced version of the YOLO v4 algorithm for detecting weeds in images of carrot fields. The proposed algorithm leverages data augmentation and transfer learning techniques to improve the performance of the YOLO v4 model. The authors collected a dataset of images of carrot fields with and without weeds, and the algorithm was trained and evaluated on this dataset. The findings indicate that the improved YOLO v4 algorithm surpasses the traditional YOLO v4 and other advanced algorithms. The authors suggest that the algorithm can effectively identify weeds in carrot fields, contributing to weed management and minimizing the use of herbicides. The study highlights the potential of deep learning methods in agriculture for weed detection.

Alam [5] proposed a machine-learning based system for real-time crop/weed detection and classification, facilitating variable-rate spraying in precision agriculture. The system employs a CNN to detect and differentiate crops and weeds based on their visual features. The study reveals that the proposed system accurately identifies crops and weeds, which can improve targeted spraying and minimize herbicide usage. This study showed that the machine-learning based approach can enhance precision agriculture and promote sustainable crop management practices.

III. Methodology

A. *Yolov8 Algorithm*

The YOLOv8 is an efficient object detection model that was introduced in early of 2023 [19]. It is an improvement over the previous versions of YOLO, which are known for their speed and accuracy in object detection. YOLOv8 is designed to be more accurate than its predecessors while still maintaining real-time performance. The YOLOv8 architecture is composed of several components, including a backbone network, a neck network, and a head network. Fig. 1 shows the architecture of YOLOv8 network.

The backbone network is responsible for extracting features from the input image, while the neck network and the head network are responsible for detecting objects and generating bounding boxes. It uses several equations and formulas in its implementation, including:

1) Sigmoid function: YOLOv8 uses a sigmoid function to transform the predicted outputs into probabilities. The sigmoid function is defined as follows:

$$\text{sigmoid}(x) = 1 / (1 + e\text{^}{-}x) \quad (1)$$

where, *x* is the input to the function.

2) Intersection over Union (IoU): IoU is used to measure the overlap between two bounding boxes. It is defined as the ratio of the area of the intersection of the two bounding boxes to the area of their union.

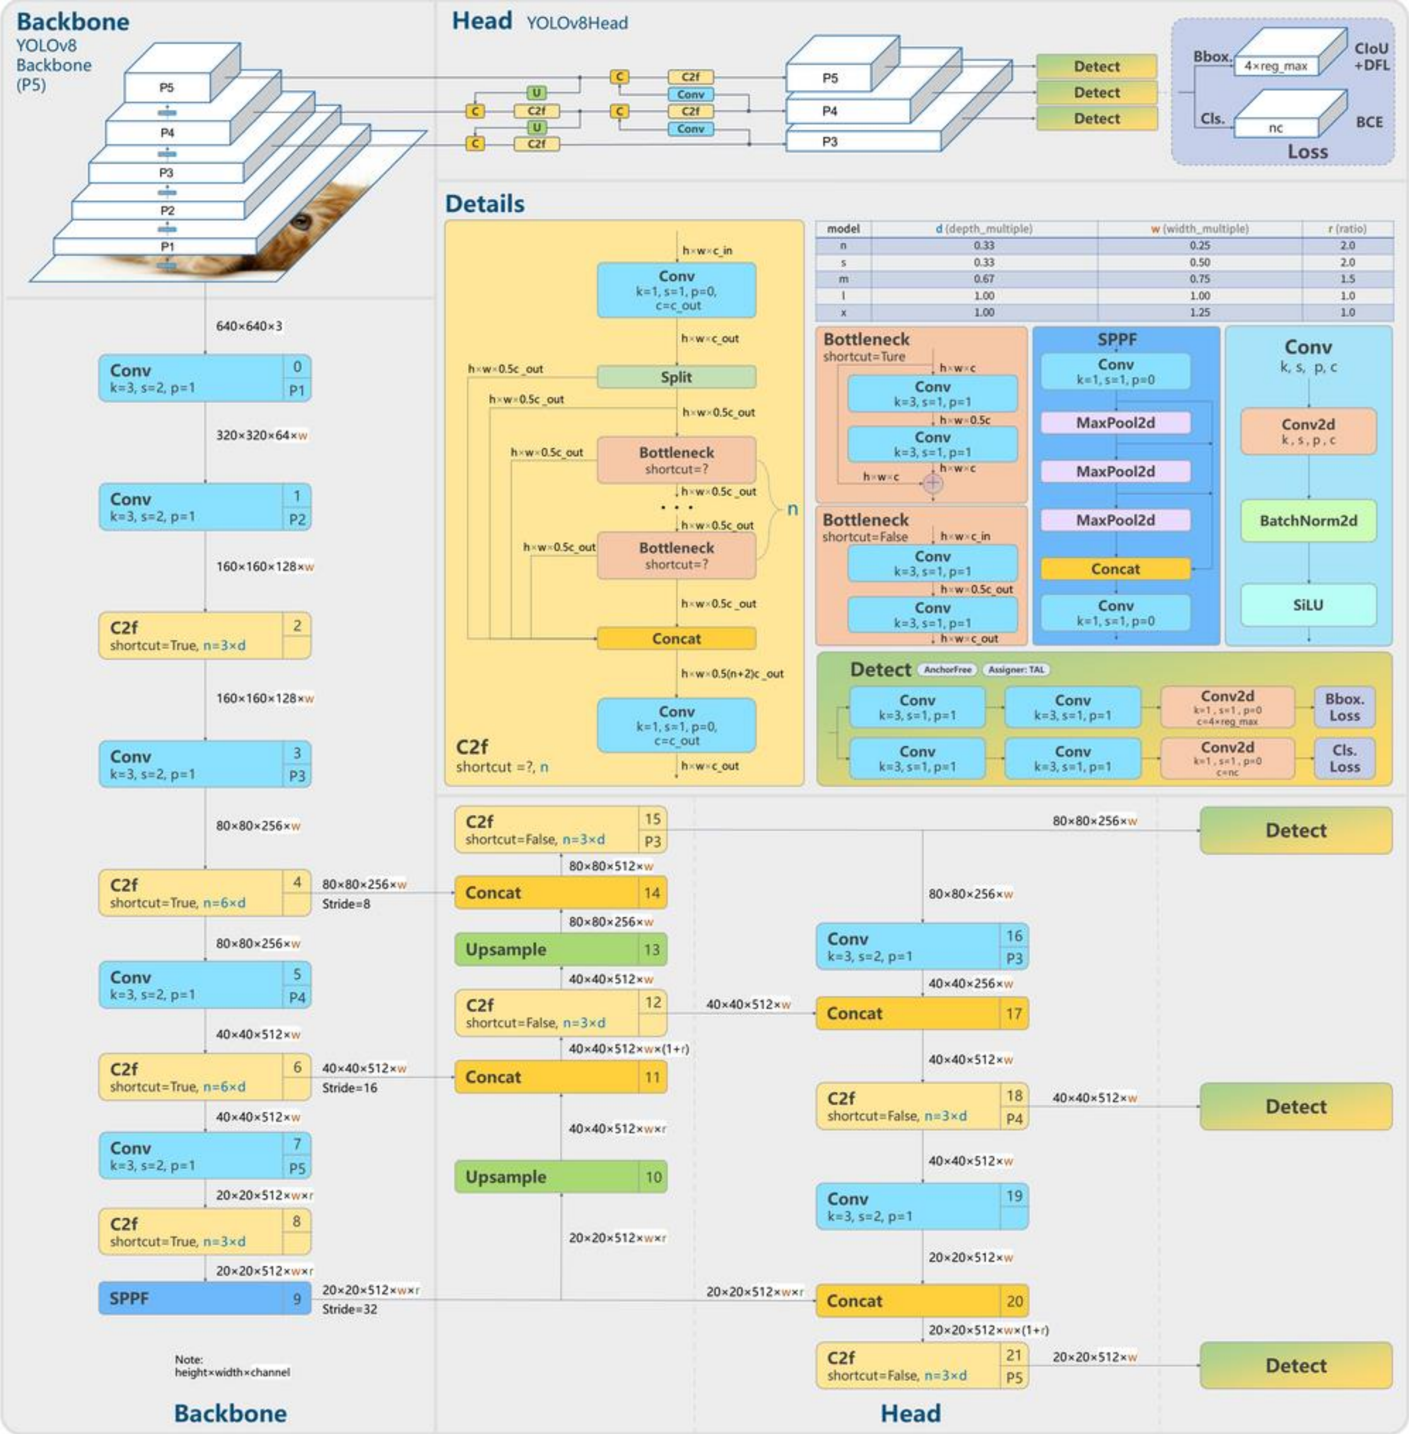
$$\text{IoU}(A, B) = (\text{area of intersection between A and B}) / (\text{area of union between A and B}) \quad (2)$$

3) Anchor boxes: YOLOv8 uses anchor boxes to predict the location and size of objects in the image. Anchor boxes are fixed bounding boxes of different sizes and aspect ratios that are placed at various locations in the image.

4) Loss function: The loss function used in YOLOv8 is a combination of three different losses: the localization loss, the confidence loss, and the class loss. The localization loss measures the difference between the predicted and ground-truth bounding box coordinates. The confidence loss measures the difference between the predicted and ground-truth objectness scores. The class loss measures the difference between the predicted and ground-truth class probabilities.

5) YOLOv8 output tensor: The output of YOLOv8 is a tensor that contains predictions for each anchor box. Each anchor box has a corresponding set of predicted values, which include the class probabilities, objectness score, and bounding box coordinates. The tensor is typically represented as follows:

[batch_size, grid_size, grid_size, num_anchors, num_classes + 5] (3)



model	d (depth_multiple)	w (width_multiple)	r (ratio)
n	0.33	0.25	2.0
s	0.33	0.50	2.0
m	0.67	0.75	1.5
l	1.00	1.00	1.0
x	1.00	1.25	1.0

Fig. 1. Architecture of YOLOv8 network [20].

B. Dataset

In this study, a dataset is used from internet resource. The dataset includes images taken from a public dataset in Roboflow. We have totally 4239 images in the dataset. Among these images, augmentation process is performed for extending the dataset. The structure for training task from this dataset, 87% or 3700 images for training set, 9% or 359 images for validation set, and 4% or 180 images for testing set are organized. Some images from the dataset are shown in Fig. 2.

C. Google Colab

To conduct our experiments, we utilized Google's Colab research platform, which offers access to high-performance GPUs at no cost. We conducted all of our training and testing on a 12GB NVIDIA Tesla T4 GPU, which is described in more detail in Fig. 3. Our models were trained with a maximum of 2500 iterations, a batch size of four images, and an image size of 640.

D. Comparison of Yolo Models

This section presents a companion of different models of Yolo networks, the purpose of this comparison is to justify why Yolov8 is selected in this study. Based on published performance analysis of different Yolo based models [20], this investigation is conducted. For this investigation, we can analyze the model’s graph where the X-axis represents the mean average precision (mAP) percentage, and the Y-axis represents the number of parameters in each YOLO-based model. The graph displays curves corresponding to different YOLO model versions: YOLOv8, YOLOv7, YOLOv6, and YOLOv5. Fig. 3 shows this graph.

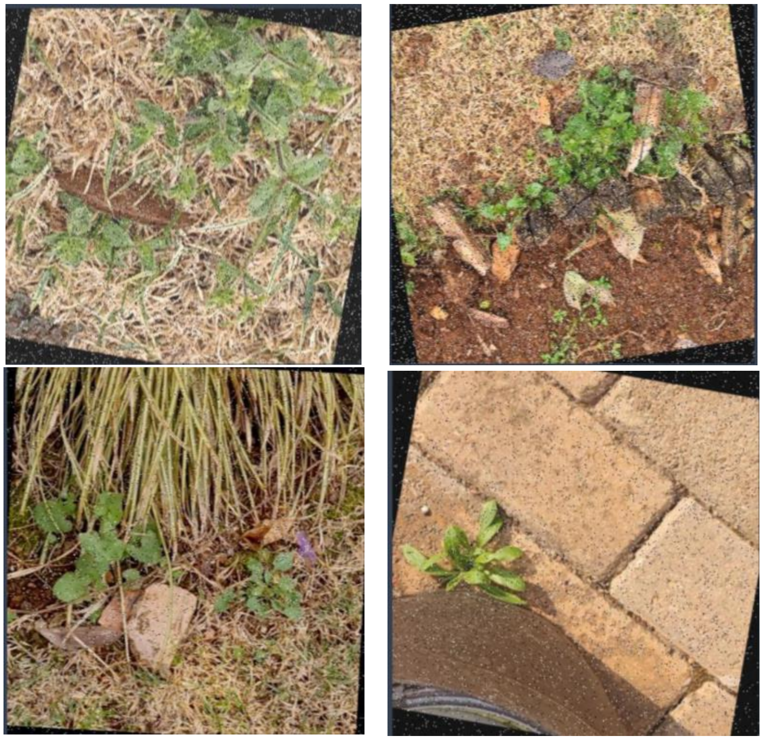


Fig. 2. Sample images of the dataset [20].

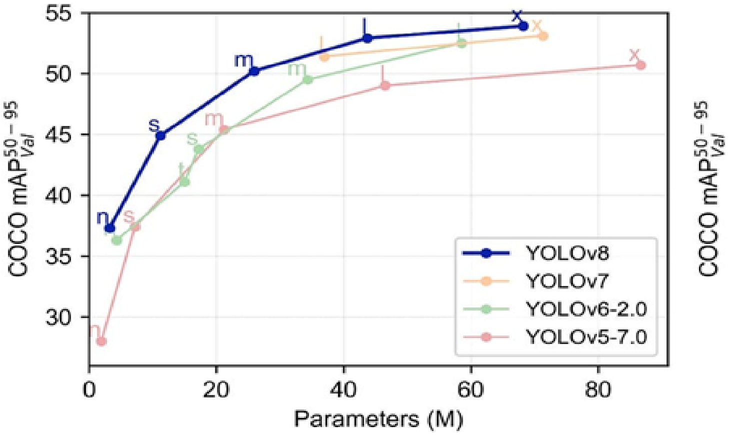

Fig. 3. Comparison of Yolo models in terms of mAP [20].

The graph depicts a comparison between the mAP percentages and the number of parameters for each YOLO-based model. The curves demonstrate the trade-off between the mAP performance and the complexity of the models, represented by the number of parameters. YOLOv8, having the best mAP performance among the models, exhibits a curve that consistently outperforms the other models in terms of mAP percentage. This indicates that YOLOv8 achieves higher accuracy without excessively increasing model complexity, making it a more efficient and scalable choice. Therefore, based on the assumptions provided, the graph illustrates that YOLOv8 surpasses the other models in terms of mAP performance while maintaining a reasonable number of parameters. This makes YOLOv8 the preferred option among the YOLO-based models considered in the graph, as it offers superior accuracy without excessive model complexity.

Moreover, we can analyze the graph where the X-axis represents the average precision (AP) percentage, and the Y-axis represents the performance of PyTorch FP16 running on the RTX 3080 platform. The performance measurements are conducted on the COCO dataset. The graph includes curves corresponding to different YOLO-based model versions: YOLOv8, YOLOv8-seg, YOLOv7, YOLOv6, YOLOv6, and YOLOv5.

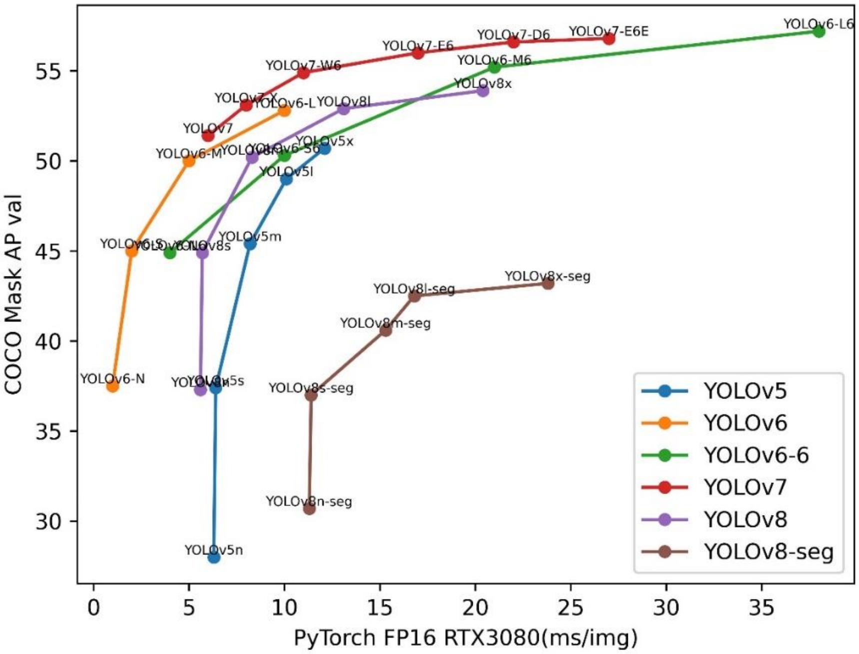

Fig. 4. Comparison of performance for Yolo models in terms of AP [20].

As shown in Fig. 4, the graph presents a comparison between the AP percentages and the performance of PyTorch FP16 running on the RTX 3080 platform for each YOLO-based model. The curves showcase the relationship between AP performance and the computational efficiency of the models. YOLOv8-seg, being the model with the best AP performance according to the assumption, exhibits a curve that consistently outperforms the other models in terms of AP percentage. This indicates that YOLOv8-seg achieves higher accuracy in object detection on the COCO dataset compared to the other versions.

The YOLOv8-seg's superiority is justified not only in terms of AP but also in relation to the computational efficiency represented by the PyTorch FP16 performance on the RTX 3080 platform. Despite its superior AP performance, YOLOv8-seg manages to maintain efficient performance on the given hardware platform, suggesting that it strikes a balance between accuracy and computational efficiency. Therefore, based on the assumptions provided, the graph illustrates that YOLOv8-seg outperforms the other models in terms of AP performance on the COCO dataset while maintaining efficient performance on the specified hardware platform. This makes YOLOv8-seg the preferred choice among the YOLO-based models considered in the graph, as it offers higher accuracy without compromising computational efficiency.

IV. Experimental Results

This section presents experimental results and discuss about performance evaluation in details. Firstly, experimental result is presented from the trained model using above details, and then performance evaluation is discussed. Fig. 5 shows some experimental results.

Performance evaluation is an essential step in the development of object detection models, including the YOLO object detection algorithm. Model evaluation helps assess the performance of a model and determine whether it is meeting the desired accuracy criteria. Popular performance metrics used for model evaluation in object detection tasks are precision, recall, and mAP (mean Average Precision). Fig. 6 shows the performance results.

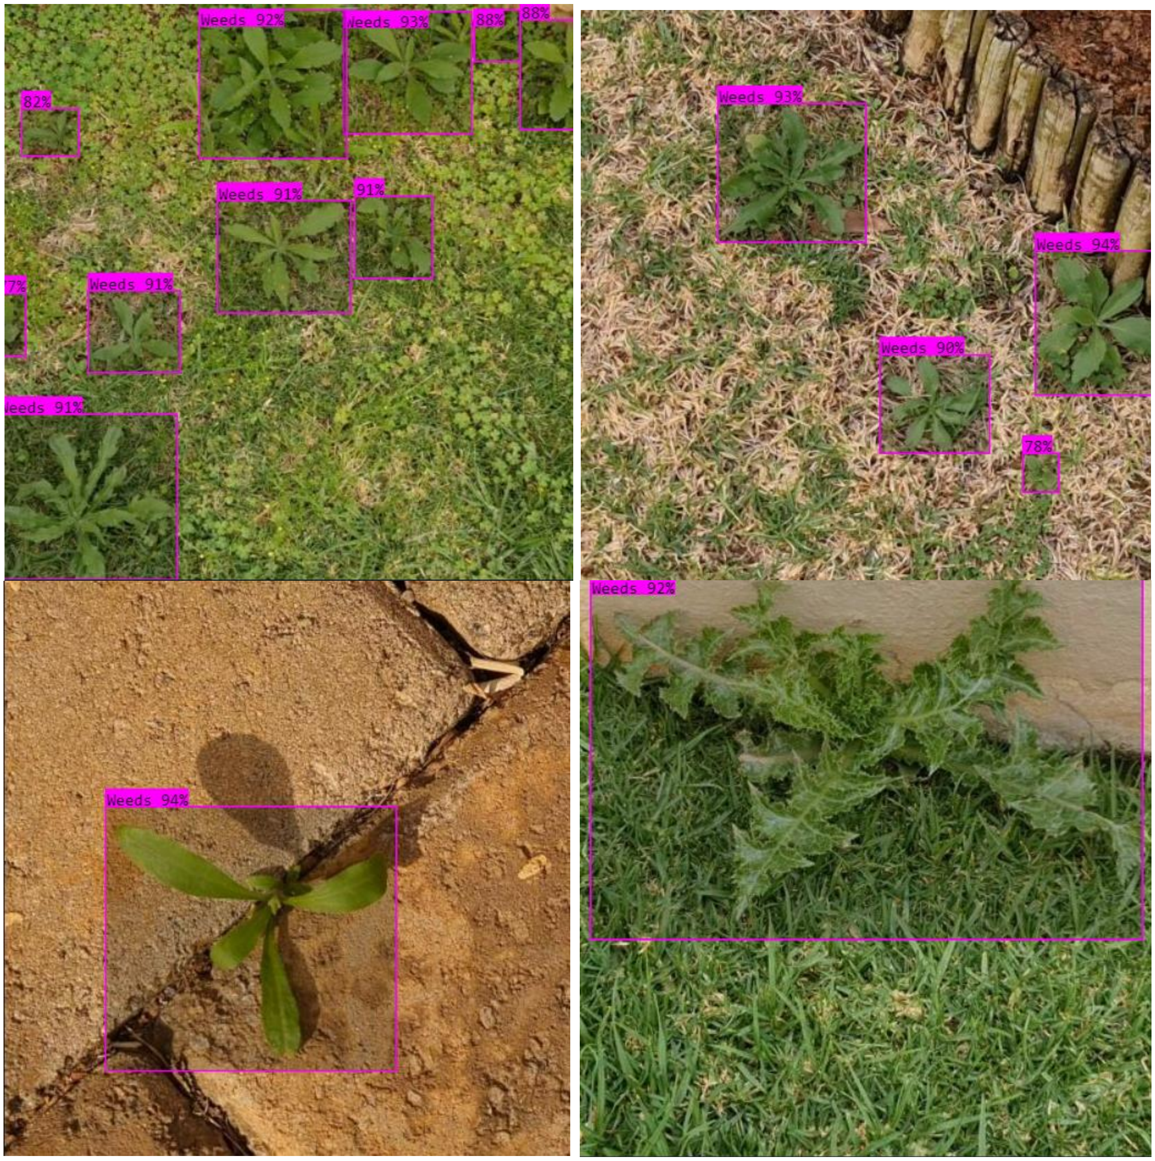

Fig. 5. The result of our experiments.

To present the statistical reporting and data presentation in evaluating the YOLOv8-based model for weed detection, this study provides a detailed breakdown of precision, recall, and mAP values. Instead of a single mAP value, presenting precision-recall curves at different confidence thresholds can offer a nuanced understanding of the model's performance across a range of decision-making points. This not only adds depth to the analysis but also provides insights into the trade-off between precision and recall, aiding in decision-making for real-world applications. Additionally, including a confusion matrix or a similar visual representation would offer a more granular view of the model's strengths and weaknesses, particularly in terms of false positives and false negatives.

As shown in Fig. 6, precision, recall, and mAP are essential metrics used to assess the performance of a model, including its effectiveness in weed detection:

Precision: Precision measures how well the model predicts true positive instances while minimizing false positives. High precision indicates that the model is accurate in identifying weeds and has fewer false alarms.

Recall: Recall measures the model's ability to correctly identify all positive instances, or in this case, accurately detecting weeds. High recall suggests that the model is effective at capturing most of the weeds present in the dataset.

mAP: mAP provides a comprehensive evaluation of the model's performance by considering both precision and recall at various thresholds. A higher mAP indicates a more accurate and effective model for weed detection.

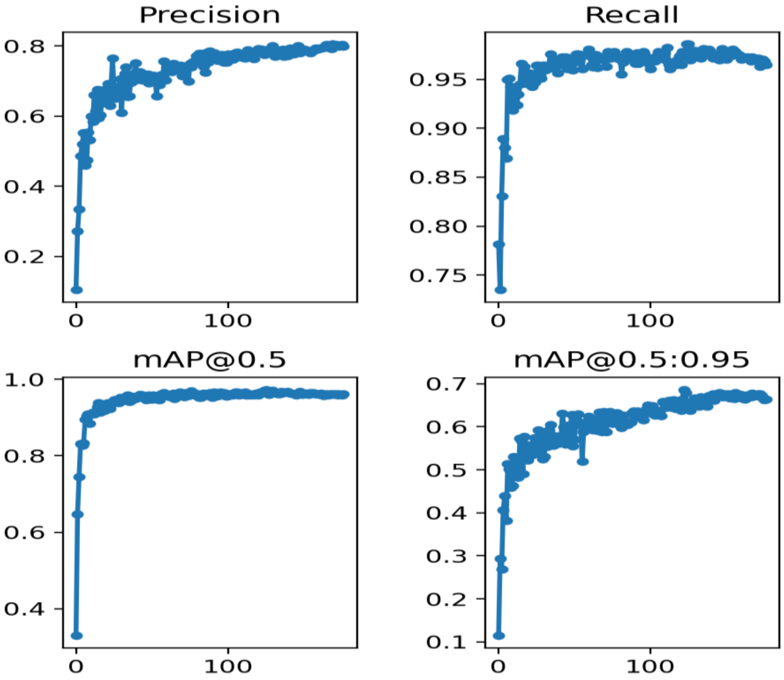

Fig. 6. The performance results.

By considering the precision, recall, and mAP metrics, we can assess the effectiveness of the generated YOLOv8 model for weed detection. If the precision curve demonstrates high precision values across different thresholds, it indicates that the model reliably detects weeds while minimizing false positives. A steep rise in precision suggests the model is precise at differentiating between weeds and non-weed instances. Similarly, if the recall curve shows high recall values, it implies that the model successfully captures a significant number of weed instances, reducing the chances of missing any weeds. Lastly, a high mAP indicates a balance between precision and recall, indicating that the model achieves both accurate weed detection and minimizes false positives.

Therefore, by evaluating the precision, recall, and mAP metrics and ensuring high values for all these measures, we found that the generated YOLOv8 model is effective for accurate weed detection.

V. Conclusion

In this research, a deep learning approach for vision-based weeds detection in agriculture is proposed. The algorithm used for weed detection is built on the Yolov8 framework, and a customized model is created by training it on images from popular datasets as well as the internet. To assess the effectiveness of the model, it is tested on both validation and testing datasets, and its performance is evaluated using images that are not part of the original dataset. The experimental findings demonstrate that the deep learning-based approach is a promising solution for detecting weeds in agriculture. However, in this research for limitation addressing purpose, the diversity of the training data sources used for creating the YOLOv8-based weed detection model. While the model is trained on images from popular datasets and the internet, the potential presence of biases in these sources may affect the model's generalizability to a broader range of real-world agricultural scenarios. The use of internet-collected images might introduce variations in terms of lighting conditions, field types, and weed species that are not fully represented in the training dataset. Consequently, the model's performance might be over-optimized for the specific characteristics of the training data, limiting its effectiveness in more diverse and unpredictable agricultural environments. To address this limitation, future studies should focus on systematically expanding the diversity of the training dataset to ensure the model's robustness across a broader spectrum of agricultural conditions. This could involve incorporating images from geographically diverse locations, different seasons, and various agricultural practices. Additionally, efforts should be made to include images that capture the inherent variability in weed species and growth stages, ensuring that the model can accurately detect weeds under a wide range of circumstances. By addressing this limitation, researchers can enhance the model's applicability and reliability in real-world agricultural settings, ultimately contributing to the successful deployment of the proposed deep learning approach on a larger scale.

Detection of Fruit using YOLOv8-based Single Stage Detectors

Xiuyan GAO, Yanmin ZHANG*
Hebei Software Institute, Baoding 071000, China

***Abstract*—In the agricultural sector, the precise detection of fruits plays a pivotal role in optimizing harvesting procedures, minimizing waste, and ensuring the delivery of high-quality produce. Deep learning methods have consistently exhibited superior accuracy compared to alternative techniques, making them a focal point in fruit detection research. However, the ongoing challenge lies in meeting the stringent accuracy requirements essential for real-world applications in agriculture. Addressing this critical concern, this study proposes an innovative solution utilizing the Yolov8 architecture for fruit detection. The methodology involves the meticulous creation of a custom dataset tailored to capture the diverse characteristics of agricultural fruits, followed by rigorous training, validation, and testing processes. Through extensive experimentation and performance evaluations, the findings underscore the exceptional accuracy achieved by the Yolov8-based model. This methodology not only surpasses existing benchmarks but also establishes a robust foundation for transforming fruit detection practices in agriculture. By effectively addressing the challenges associated with accuracy rates, this approach opens new avenues for optimized harvesting, waste reduction, and enhanced efficiency in agricultural practices, contributing significantly to the evolution of precision farming technologies.**

Keywords—Fruit detection; agricultural sector; deep learning; YOLOv8 model; precision agriculture

I. INTRODUCTION

Fruit detection in agriculture is a vital aspect of modern farming practices [1], [2]. The ability to accurately and efficiently identify and assess the ripeness of fruits plays a pivotal role in optimizing agricultural operations, enhancing crop yield, and ensuring the quality of produce [2]. In recent years, the development and utilization of fruit detection technologies have garnered significant attention due to their potential to revolutionize the agricultural industry [3]. The sample of the fruits is depicted in Fig. 1.

The importance of fruit detection in agriculture cannot be overstated. Timely and precise fruit detection aids farmers in optimizing harvesting schedules, reducing waste, and maximizing crop yields. Additionally, it facilitates early detection of diseases and pests, enabling timely intervention and preventing the spread of infestations, ultimately improving the overall health of fruit-bearing plants [4], [5].

While traditional methods of fruit detection have been employed for decades, recent advancements in technology have opened new avenues for enhancing accuracy and efficiency. This research paper explores the latest developments and innovations in fruit detection methods, particularly focusing on the application of deep learning techniques [2], [6].

Existing technologies have made significant strides in fruit detection [4], [7], but deep learning-based approaches have gained prominence among researchers [8], [9]. This shift is primarily attributed to the remarkable capabilities of deep neural networks in handling complex image data. In the subsequent sections [10], [11], it will delve into the current limitations and challenges associated with deep learning-based fruit detection methods, highlighting the need for further research and innovation.

One of the primary motivations for this study is to address the existing limitations and research challenges associated with deep learning-based fruit detection, especially in meeting the high accuracy requirements demanded by the agricultural industry. Achieving precision and reliability in fruit detection is crucial for optimizing harvesting processes and ensuring the quality of the produce. Therefore, it is imperative to explore novel solutions to tackle these challenges and meet the rigorous standards set by the agricultural sector.

This study proposes a deep learning method utilizing Convolutional Neural Networks (CNNs) to address the demanding requirements of fruit detection in agriculture. It adopts a custom dataset and employs rigorous training, validation, and testing processes to develop a robust and efficient model. This approach is founded on the belief that deep learning can provide the accuracy and reliability needed for effective fruit detection in agricultural settings.

This research paper presents three key contributions. First, it generates a custom dataset tailored specifically for fruit detection challenges, providing a valuable resource for future research in this domain. Second, it proposes an efficient deep-learning method that not only detects fruits but also addresses disease detection within the same framework, further enhancing the utility of the model. Third, extensive experiments and performance evaluations are conducted to validate the effectiveness of our method, providing empirical evidence of its potential to revolutionize fruit detection practices in agriculture.

Fig. 1. Sample of fruit images.

II. Relevant Studies

Machine learning and deep learning methods have made substantial contributions to the progress of agricultural sectors, specifically in the fields of disease prediction, classification, and the recognition of fruit types and diseases. These approaches provide a reliable, cost-effective, and swift means of identifying and diagnosing fruit ailments in a non-invasive manner. Numerous scientists have devoted their expertise to the study of fruit detection. Eminent researchers who have made significant strides in this domain encompass:

The paper in [12] presented the Lightweight SM-YOLOv5 algorithm for tomato fruit detection in plant factories. The method employs a modified YOLOv5 architecture optimized for resource-efficient tomato detection. It achieves high accuracy while remaining computationally lightweight. However, a notable limitation is its specialization for tomato detection, which may limit its applicability to other fruits or plant types. Additionally, the paper lacks extensive experimentation and validation on various datasets and real-world conditions. Nonetheless, the Lightweight SM-YOLOv5 offers a promising approach for efficient tomato fruit detection within plant factory environments.

The authors in [13] focused on pineapple fruit detection and localization in natural environments using binocular stereo vision and an improved YOLOv3 model. The method combines depth information from stereo vision with the YOLOv3 model for accurate pineapple detection. However, it is limited in its applicability primarily to pineapple detection and may not generalize well to other fruits or scenarios. Additionally, the paper lacks extensive validation of a wide variety of natural environments and conditions. Nevertheless, the approach represents a promising advancement for pineapple fruit detection in natural settings, showcasing the potential of combining computer vision and deep learning techniques.

The paper in [14] introduces a cherry fruit detection algorithm using an enhanced YOLO-v4 model. The method leverages the YOLO-v4 architecture to achieve accurate cherry detection in images. However, its primary limitation is its specificity to cherry fruit detection, potentially lacking versatility for other fruit types. The paper could benefit from a broader evaluation across different cherry varieties and environmental conditions. Nonetheless, the use of the improved YOLO-v4 model shows promise for enhancing cherry fruit detection precision, offering valuable insights into fruit detection techniques within the agricultural domain.

These authors in [15] introduced a dragon fruit-picking detection method that combines YOLOv7 and PSP-Ellipse. YOLOv7 is employed for object detection, while PSP-Ellipse enhances the accuracy of dragon fruit recognition. However, the limitation lies in its specialization for dragon fruit detection, potentially limiting its applicability to other fruits or objects. Further validation in diverse environmental conditions and fruit varieties would strengthen the method's robustness and utility in agricultural settings. Nonetheless, this approach demonstrates the potential to improve dragon fruit picking efficiency through advanced object detection techniques.

This paper in [16] focused on fruit maturity stage detection and yield estimation in wild blueberries through the use of deep learning Convolutional Neural Networks (CNNs). The method employs CNNs to analyze images of wild blueberry plants, determining fruit maturity and estimating yield. A limitation of the study is that it may require substantial labeled data for training, which can be resource-intensive. Additionally, the model's generalization to different environments and wild blueberry varieties may require further investigation. Nevertheless, the approach demonstrates the potential for improving wild blueberry farming practices through deep learning-based fruit assessment and yield estimation.

The authors in [17] presented a method for detecting tomato plant phenotyping traits using YOLOv5-based single-stage detectors. This approach utilizes YOLOv5 to identify and characterize various traits of tomato plants, facilitating phenotypic analysis. However, the limitation lies in the model's potential sensitivity to variations in environmental conditions, which may affect detection accuracy. Additionally, broader validation across diverse tomato varieties and growth stages could enhance the method's generalization. Nevertheless, this technique showcases promise in automating plant phenotyping tasks, offering valuable insights for agricultural research and crop improvement. The mentioned papers primarily focus on different aspects of fruit detection and utilize various deep-learning models for this purpose. The [12] concentrates on tomato fruit detection in controlled environments, emphasizing the need for efficiency. On the other hand, [13] extends the scope to outdoor settings and employs a stereo vision-based YOLOv3 model.

Similarly, research in [14] narrows its focus to cherry fruit detection and utilizes the YOLOv4 model. In contrast, research in [15] explores dragon fruit detection using YOLOv7 and elliptical detection techniques. The study in [16] extends the application to the maturity stage and yield estimation in wild blueberries, leveraging convolutional neural networks. Lastly, [17] adopts YOLOv5 to identify tomato plant phenotypic traits.

The current literature on fruit detection using deep learning models has made notable strides in achieving high accuracy for specific fruit types in controlled and natural environments. However, a significant gap exists in the lack of algorithms that are both accurate and computationally efficient across a diverse range of fruits and environmental conditions. While individual studies, such as the Lightweight SM-YOLOv5 for tomatoes, binocular stereo vision for pineapples, YOLOv4 for cherries, and YOLOv7 for dragon fruit, demonstrate advancements within their respective domains, their specificity to a single fruit type hampers their widespread applicability. Additionally, the resource-intensive nature of labeled data for training and limited generalization to various fruit varieties and environmental conditions pose challenges. There is a critical need for future research to prioritize the development of algorithms that not only enhance accuracy but also minimize computation costs, enabling real-time processing and practical applications in diverse agricultural settings. Addressing this gap will significantly advance fruit detection techniques in agriculture.

III. Materials and Method

A. Data Collection

This study leveraged a dataset sourced from Roboflow resources [18] to facilitate the fruit detection research. The dataset comprises a diverse collection of fruit images, which served as the foundation for training and evaluating the model.

The dataset encompasses a diverse collection of fruit images, introducing a rich spectrum of variations in terms of size, shape, color, and environmental conditions. This deliberate inclusion of diverse instances is crucial for proving the scalability of our proposed model. Scalability, in the context of the study, refers to the model's ability to generalize effectively across a broad range of scenarios and conditions. By incorporating a wide variety of fruits and their respective attributes, the dataset from Roboflow ensures that the model is exposed to a comprehensive representation of real-world conditions.

Class balance in a dataset refers to the distribution of samples across different classes or categories. In the context of the dataset, class balance assesses whether the number of images for each class is relatively even or if there is a significant imbalance. A balanced dataset ideally has roughly the same number of samples for each class. Looking at the list of classes in the dataset, it appears that there is a varying degree of class balance. Some classes like "apple," "banana," "carrot," "cucumber," "okra," "potato," "sweet-potato," "tomato," and "un-usable" represent specific food items and may have a more balanced distribution if there are a similar number of images for each. However, classes like "Fresh Oranges," "Papaya Fresh," "Rotten," "Rotten Oranges," "bad," "fresh-20%," "fresh-70%," "fresh-90%," and "good" seem to describe the condition or quality of the food items. It's important to consider class balance when training machine learning models because an imbalance can lead to biased predictions, where the model may perform well on the majority class but poorly on minority classes. Fig. 2 shows the class balance of the dataset.

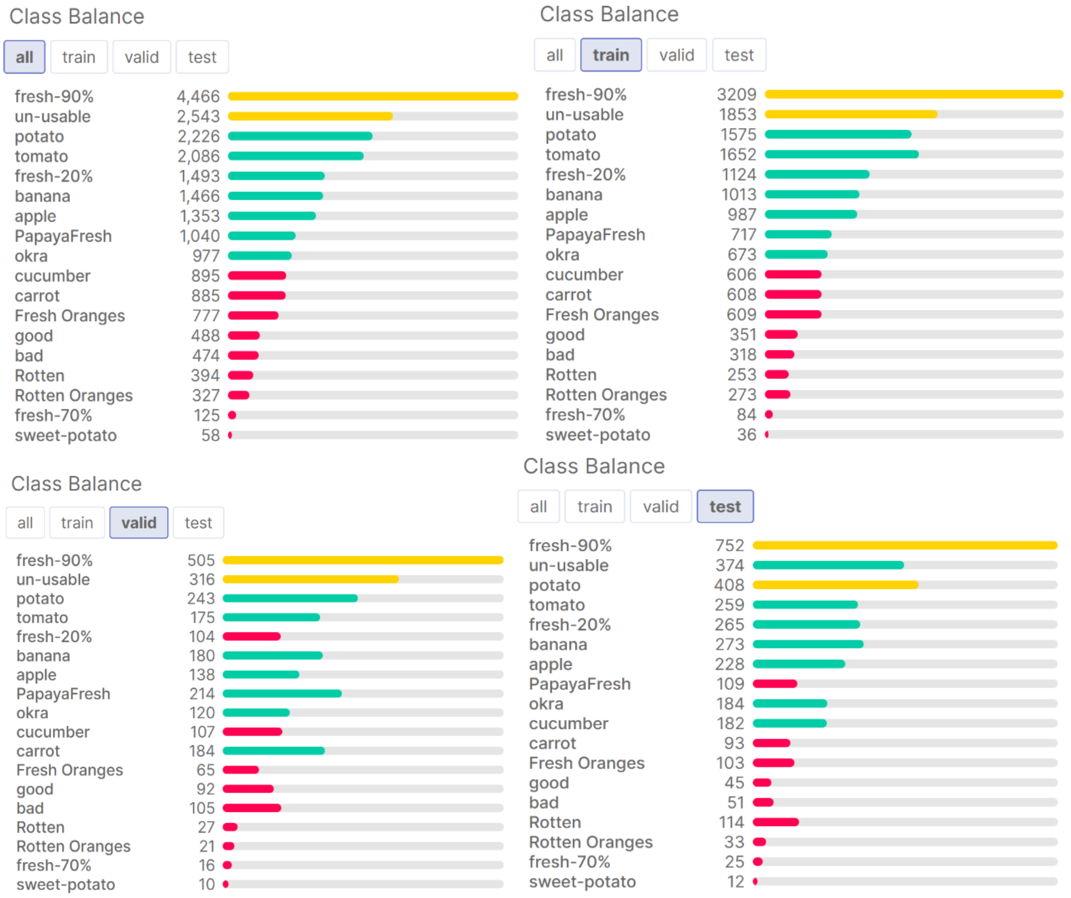
B. Model Training using YOLOv8-based Single Stage Detector

YOLOv8 is indeed a single-stage object detection model. Single-stage detectors (see Fig. 3), in the information of object detection in computer vision, are designed to perform object localization and classification in a single pass through the neural network without the need for a separate region proposal step. The YOLOv8 achieves this as a single-stage detector:

1) Grid-based detection: YOLOv8 divides the input image into a grid, where each grid cell is responsible for predicting objects within its boundaries. The model then predicts bounding boxes (rectangular regions) for objects within each grid cell. This grid-based approach simplifies the object detection process.

2) Multi-scale detection: YOLOv8 uses multiple detection scales to capture objects of different sizes in the same pass. This allows the model to efficiently handle a variety of object scales within the input image.

3) High-speed inference: Being a single-stage detector, YOLOv8 is known for its real-time or near real-time inference capabilities, making it suitable for applications that require fast and accurate object detection, such as autonomous vehicles, surveillance, and robotics. In summary, YOLOv8 is a single-stage object detector that excels in rapid and accurate object detection tasks by directly predicting object bounding boxes and classifications in a single forward pass through the neural network. This efficiency is a key reason for its popularity in various computer vision applications.



Class Balance

all train valid test

fresh-90%	4,466
un-usable	2,543
potato	2,226

C. Model Evaluation Techniques

In the framework of evaluating the performance of a YOLOv8 model for fruit detection, several key metrics are commonly used: F1 score, precision, recall, and mAP (mean Average Precision). These metrics provide valuable insights into the model's ability to detect and classify fruit objects in images accurately. Precision measures the accuracy of the model's positive predictions and the ability to identify fruits correctly. To compute precision, the number of true positive predictions (correctly identified fruits) divide by the total number of positive predictions (true positives plus false positives). High precision indicates that when the model predicts a fruit, it is usually accurate.

$$\text{Precision} = TP / (TP + FP)$$

Recall assesses the model's capability to find all the actual positive instances, i.e., fruits in this case. It calculates the ratio of true positive predictions to the total number of actual positive instances. High recall implies that the model can successfully detect most of the fruits present.

$$\text{Recall} = \text{TP} / (\text{TP} + \text{FN})$$

The F1 score is the harmonic mean of precision and recall. It provides a balanced evaluation of both false positives and false negatives. The F1 score is particularly useful when it considers both precision and recall simultaneously. A high F1 score suggests a model with good overall performance.

$$\text{F1 Score} = 2 * (\text{Precision} * \text{Recall}) / (\text{Precision} + \text{Recall})$$

mAP @0.5 is a comprehensive metric widely used in object detection tasks, including fruit detection. It quantifies the precision-recall trade-off across different confidence thresholds for object detection. mAP calculates the area under the precision-recall curve, providing a holistic assessment of the model's performance at varying confidence levels. Higher mAP indicates better overall detection accuracy. Calculate precision, recall, and F1 score to assess the model's accuracy and ability to balance true positives, false positives, and false negatives. These metrics collectively provide valuable insights into how well the YOLOv8 model is performing in fruit detection and help in making informed decisions for model refinement and optimization.

IV. Results

A. Model Evaluation for YOLOv8s

Precision, recall, precision-confidence, and F1 score curves are vital for evaluating the efficiency of a YOLOv8s model in fruit detection. Precision measures the accuracy of positive predictions, recall gauges the model's ability to capture actual instances, precision-confidence reflects the trade-off between confidence thresholds and precision, and the F1 score balances precision and recall. In the context of 18 fruit classes, achieving nearly 100 precision signifies high accuracy in classifying fruits, a recall of 0.94 indicates effective identification of most instances, and a precision-confidence of 0.76 suggests controllable precision based on confidence thresholds. The F1 score of 0.72 demonstrates a balanced performance. These values collectively imply that the model is efficient in recognizing fruit classes, making it a promising tool for fruit detection tasks, but real-world testing is crucial to validate its practical applicability. The curves of YOLOv8s are depicted in Fig. 4.

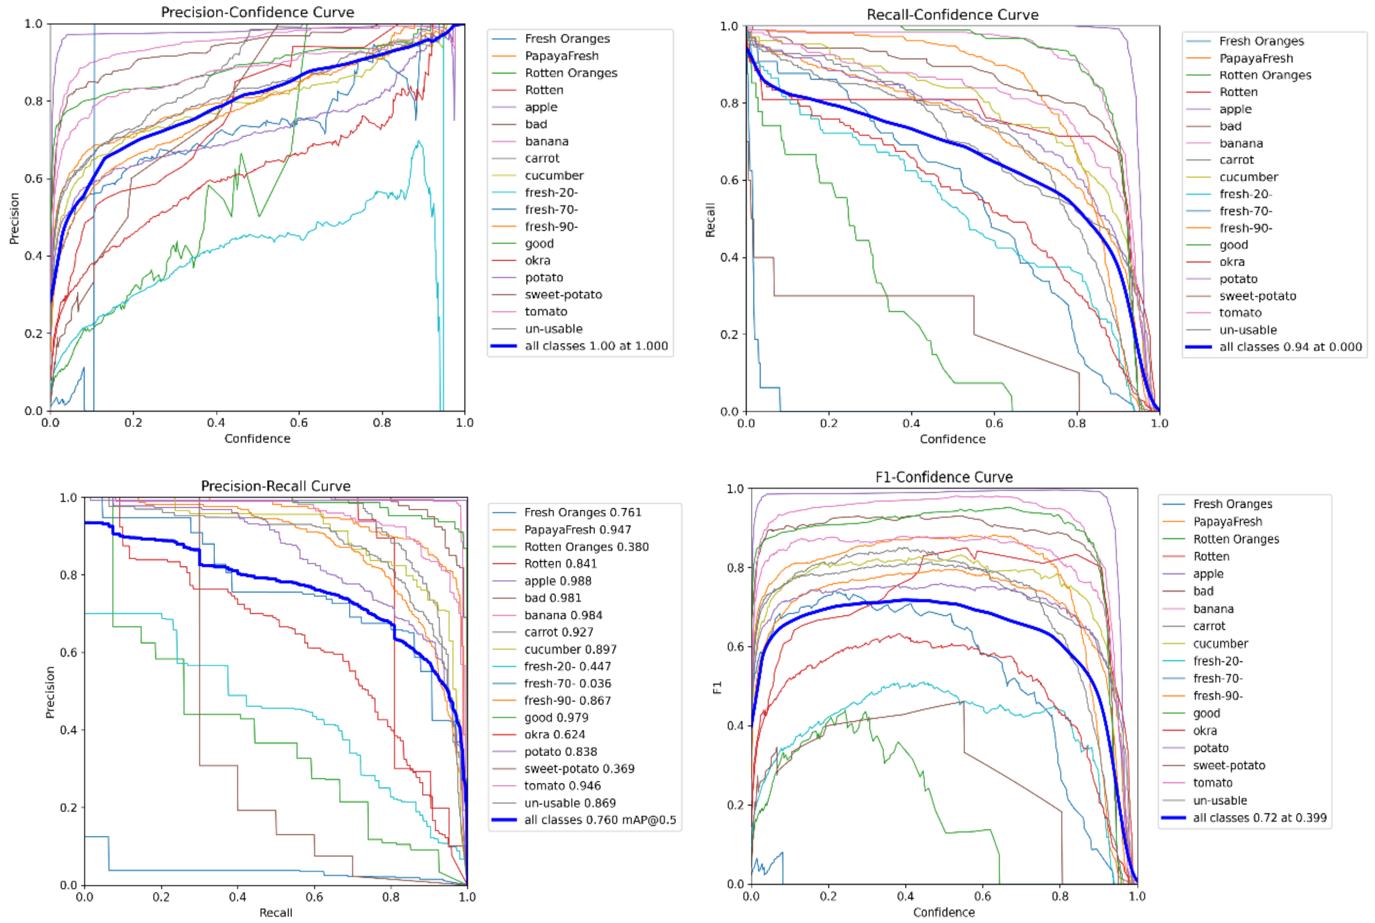

Fig. 4. The curves of YOLOv8s.

B. Model Evaluation for YOLOv8n

In the background of 18 fruit classes, achieving nearly 99 precision signifies high accuracy in classifying fruits, a recall of 0.95 indicates effective identification of most instances, and a precision-confidence of 0.73 suggests controllable precision based on confidence thresholds. Although the F1 score of 0.69 indicates a slightly lower balance between precision and recall, these values collectively indicate that the model is quite effective in recognizing fruit classes, making it a promising tool for fruit detection tasks. Real-world testing and fine-tuning may further enhance its performance for practical applications. Fig. 5 shows the curves of YOLOv8n.

C. Model Evaluation for YOLOv8l

Achieving nearly 100 precision indicates highly accurate classification of fruits, a recall of 0.96 demonstrates effective identification of most fruit instances, and a precision-confidence of 0.76 suggests controllable precision, considering confidence levels. The F1 score of 0.72 showcases a reasonable trade-off between precision and recall. These values collectively affirm that the model is highly efficient in recognizing the 18 fruit classes, making it a robust and reliable tool for fruit detection tasks, though further evaluation in real-world scenarios is advisable to confirm its practical effectiveness. The curves of YOLO8vl are depicted in Fig. 6.

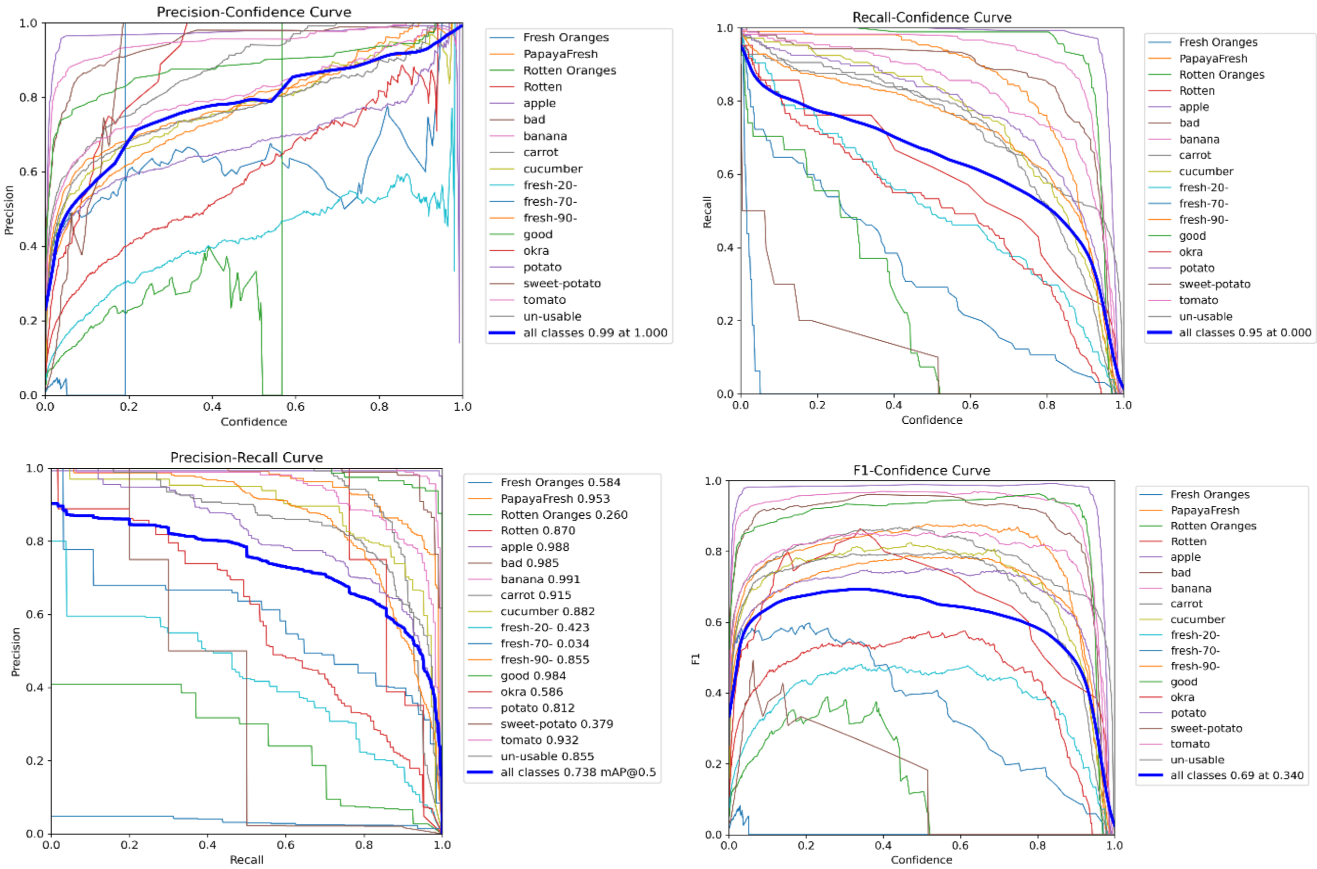

Fig. 5. The curves of YOLOv8n.

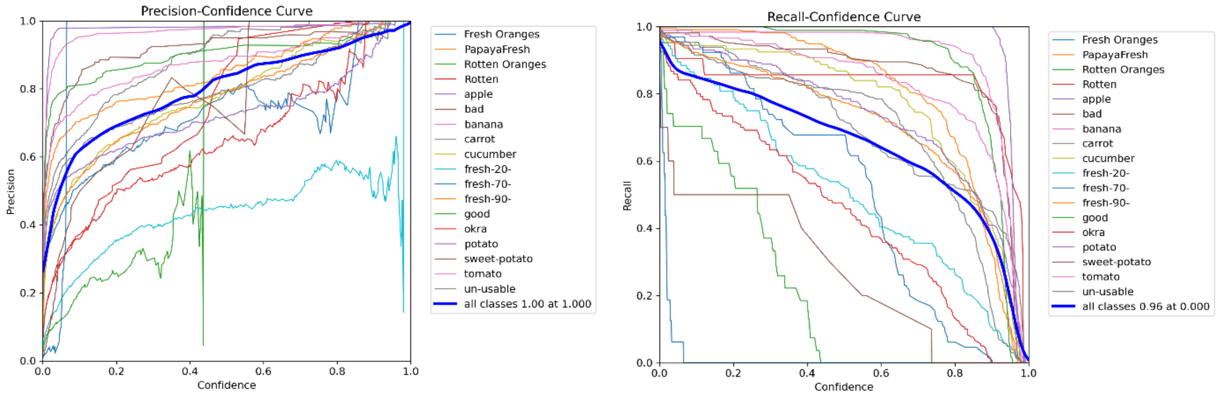

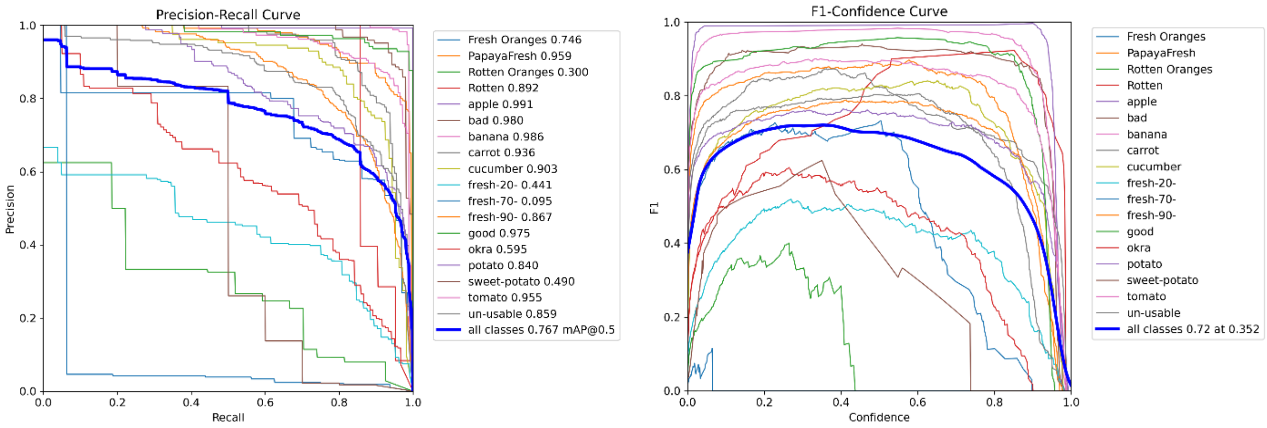

Fig. 6. The curves of YOLO8vl.

D. Model Evaluation for YOLOv8x

Achieving nearly 100 precision signifies highly accurate classification of fruits, a recall of 0.95 indicates effective recognition of the majority of fruit instances and a precision-confidence of 0.72 implies controllable precision at different confidence levels. The F1 score of 0.76 demonstrates a good overall balance between precision and recall. These values collectively suggest that the YOLOv8vx model is effective in recognizing the 18 fruit classes, making it a robust and reliable tool for fruit detection tasks with the potential for real-world applications. The curves of YOLOv8x are depicted in Fig. 7.

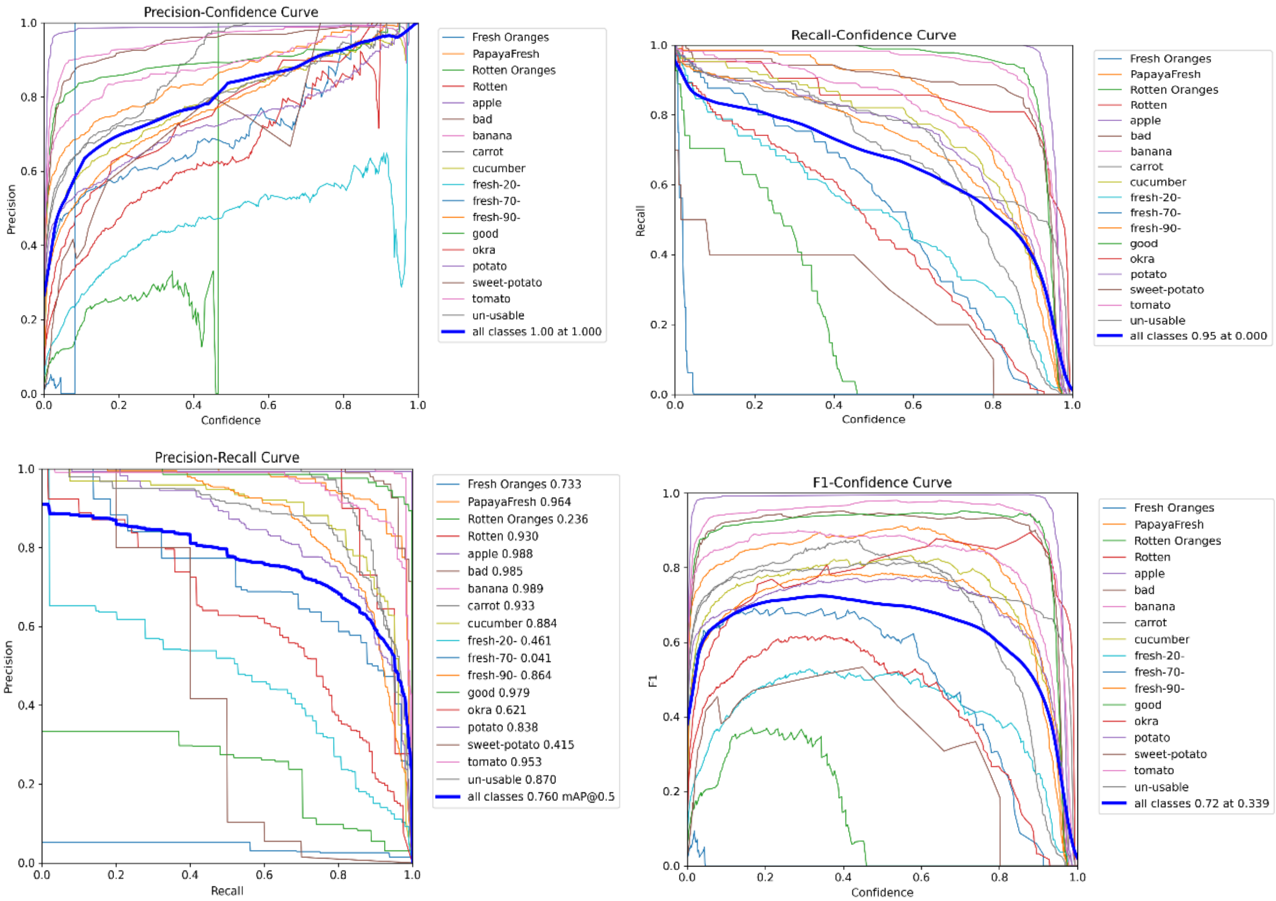

Fig. 7. The curves of YOLOv8x.

V. Results and Discussion

In the comprehensive series of experiments, rigorously assessed multiple YOLOv8 models to identify the most accurate and effective one for the specific task. The study collected performance metrics across all classes, including precision, recall rate, mean Average Precision (mAP) at an IoU threshold of 0.5, and F1 score, aiming to achieve the utmost accuracy and effectiveness in the model selection.

As discussed earlier, extensive literature supports the effectiveness of YOLO-based models in achieving high accuracy while maintaining real-time processing capabilities, making them particularly suitable for various applications. The simplicity and efficiency of the YOLO architecture have positioned it as a benchmark in the field of object detection.

In this study, the choice of Yolov8 as the foundation for the proposed method is justified by the extensive experiments conducted and the comprehensive comparison of various versions of Yolov8-based models. By presenting a detailed evaluation and comparison of different model configurations, this study aims to showcase the superiority of Yolov8 in the context of fruit detection. The experimental results contribute empirical evidence to the existing literature, reinforcing the claim that Yolov8 stands out as an effective and reliable object detection algorithm, especially when applied to the specific challenges posed by fruit detection in agriculture.

Upon analyzing the results, it is evident that the YOLOv8s, YOLOv8l, and YOLOv8x models consistently outperform the YOLOv8n model across various metrics. Notably, all three of these models achieved a perfect precision score of 100%, indicating their exceptional ability to make correct positive predictions. Furthermore, the YOLOv8l and YOLOv8x models demonstrated superior recall rates of 0.96% and 0.95%, respectively, highlighting their capacity to identify most of the actual positive instances. Additionally, these models maintained a robust mAP@0.5 rate of 0.76% and an impressive F1 score of 0.72%, signifying a balanced trade-off between precision and recall.

Considering the balance between precision and recall, the YOLOv8l and YOLOv8x models emerge as the top performers in the evaluations. Their remarkable precision, recall, and F1 score collectively demonstrate their superiority in accurately detecting and classifying objects, making them the preferred choices for the task. Based on these extensive experiments, it has successfully achieved an accurate and effective model tailored to the specific requirements. The comparison table between all versions of YOLO8 is depicted in Table I.

TABLE I. The Comparison Table between All Versions of YOLO8

Model version	F1 Score	precision	Recall	mAP @0.5
YOLOv8s	0.72	100	0.94	0.76
YOLOv8n	0.69	99	0.95	0.73
YOLOv8l	0.72	100	0.96	0.76
YOLOv8x	0.72	100	0.95	0.76

VI. Conclusion

Fruit detection holds paramount significance in the agricultural sector, aiding in the optimization of harvesting schedules, minimizing waste, and ensuring crop quality. Numerous methods have been explored in the literature to address this critical task. Among these, deep learning-based approaches have emerged as frontrunners, consistently delivering accurate results. However, a prevailing research challenge in deep learning-based fruit detection pertains to meeting the stringent accuracy rate requirements necessitated by agricultural applications. This study proposed a deep learning model based on the YOLOv8 architecture to address this challenge. Leveraging a custom dataset, it meticulously conducts model training, validation, and testing. The experimental results and performance evaluations demonstrate the efficacy of our proposed method, showcasing its ability to achieve high levels of accuracy, thus promising substantial advancements in fruit detection within the agricultural domain. Two notable limitations in the realm of fruit detection are computational resource intensity and model generalization. Firstly, deep learning-based fruit detection models often require substantial computational resources for training and inference, which may not be readily available in resource-constrained agricultural environments. Secondly, achieving model generalization across different fruit varieties, lighting conditions, and backgrounds remains a challenge, as models trained on one dataset may struggle to adapt to diverse real-world scenarios. In light of these limitations, future research could focus on addressing these challenges. Firstly, the development of more computationally efficient deep learning architectures tailored for fruit detection could help alleviate resource constraints. Secondly, exploring techniques such as domain adaptation and transfer learning to enhance model generalization across varying conditions and fruit types could lead to more robust and versatile fruit detection systems. These efforts could significantly enhance the applicability and effectiveness of fruit detection technology in agriculture.

Department of Computer Science and Engineering, R.M.K. Engineering College, Tamil Nadu, India[4]

Abstract*—A mobile ad hoc network (MANET) is a network of moving nodes that can interact with one another without the aid of a centrally located infrastructure. In MANETs, every node acts as a router and as a host, generating and consuming data. However, due to the mobility of nodes and the absence of centralized control, the routing process in MANETs is challenging. Therefore, routing protocols in MANETs are required to be efficient, scalable, and adaptable to the dynamic topology changes of the network. This paper proposes an optimized route selection approach for MANETs via the biomimicry buzz algorithm with the Bellman-Ford-Dijkstra algorithm to improve the effectiveness and accuracy of the routing process. By integrating these behaviors into the algorithm, the approach can select the shortest path in a network, leading to an optimal routing solution. Furthermore, the paper explores the use of Forest Boost Regression (FR), a novel machine learning algorithm, to predict energy consumption in MANETs. Utilizing this will help the network run more efficiently and last longer. Additionally, the paper discusses the use of Artificial Neural Networks (ANNs) to forecast link failure in MANET s, thereby increasing network performance and dependability. The proposed work presents the experimental evaluation by using Ns-3 as the simulation tool. The experimental results indicate a variation in packet delivery ratio from 97% to 90%, an average end-to-end delay of approximately 19 ms, an increase in node speed energy consumption from 60 to 87 joules, and a simulation time energy consumption of 89 joules over 60 seconds. These results provide insights into the performance and efficiency of the proposed strategy in the context of MANETs.

Keywords—MANET; routing protocols; optimized route selection; regression; machine learning; Artificial Neural Networks

I. INTRODUCTION

The nodes in MANETs, which are wireless networks with no infrastructure, can interact with one another directly or indirectly [1]. MANETs are widely used in various applications such as military, disaster response, and emergencies, where infrastructure is not available. Due to the lack of infrastructure, in MANETs, the nodes must collaborate to provide network communication [2-4]. Therefore, because of the constantly changing topology, scarce resources, and frequently occurring linkage failures, routing in MANETs is a difficult task. Proactive, reactive, as well as hybrid routing algorithms may all be categorized in MANETs. Proactive procedures keep all nodes' routing information current, even without traffic [5]. Reactive protocols establish routes on demand only when needed. Proactive as well as reactive protocols' benefits are combined in hybrid protocols [6-8]. Although routing protocols have advanced, routing in MANETs remains challenging because of the network's continually changing character. One of the significant challenges in MANETs is predicting link failures. Link failures occur due to various reasons, such as node mobility, interference, and limited battery power [9]. A routing protocol that can predict link failures and react accordingly can significantly improve the performance of MANETs [10-12]. In addition, energy utilization is another crucial factor in MANETs since nodes have limited battery power.

In a typical MANET scenario, a diverse set of wireless devices, often with varying mobility patterns, come together to form a self-organizing and infrastructure-less network as shown in Fig. 1. These devices could include smartphones, laptops, IoT sensors, or even military communication devices. MANETs are often deployed in environments where traditional fixed infrastructure is unavailable or impractical, such as disaster-stricken areas, military operations, or highly dynamic urban settings [13-15]. Nodes in a MANET are both end-users and routers, capable of transmitting and forwarding data packets to facilitate communication among themselves [16]. The unique feature of MANETs is their ad hoc nature, and the network topology continually changes due to node mobility [17]. This dynamic topology, along with the absence of centralized control, presents routing challenges, where finding efficient and reliable communication paths are paramount [18-20]. MANETs offer a flexible and resilient solution for communication in dynamic and often challenging environments, but effective routing, energy management, and reliability remain critical considerations to ensure their successful operation.

In our work, the primary objectives of optimizing MANET routing are to enhance adaptability, reduce latency, and improve overall network performance. Specifically, our proposed approach aims to achieve the following goals:

- Enhance the routing protocol's adaptability to the dynamic topology changes inherent in MANETs.

- Enable efficient decision-making in routing, considering factors like node mobility, link stability, and energy levels.
- Mitigate issues related to link breakage and broadcast storms by introducing a mobility-aware routing algorithm.
- Minimize packet delivery delay by optimizing the routing process.
- Optimize route selection to achieve more efficient and reliable communication between nodes.

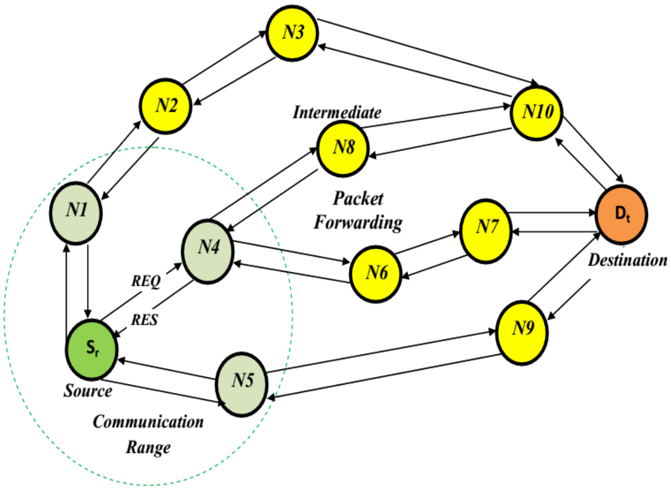

Fig. 1. Classic MANET system – scenario.

By addressing these goals, our work aims to contribute to the advancement of MANET routing protocols, making them more adaptive, responsive, and efficient in dynamic and challenging environments. Our work introduces an optimized route selection approach that addresses the routing challenges in MANETs. We combine the biomimicry buzz algorithm with the well-established Bellman-Ford-Dijkstra algorithm to improve the efficiency and accuracy of route selection. By incorporating these behaviors into our approach, we aim to identify the shortest paths in the network, leading to optimal routing solutions. Moreover, we recognize the importance of energy management in MANETs, as it directly impacts network sustainability and performance. To this end, our research explores the application of Forest Boost Regression (FR), a novel machine learning algorithm, for predicting energy consumption in MANETs. Accurate energy consumption predictions can enable more efficient resource allocation and contribute to prolonged network operation.

Furthermore, network reliability is another crucial aspect in MANETs. Link failures can disrupt communication and hinder the network's effectiveness [21-23]. To address this, our work investigates the use of Artificial Neural Networks (ANNs) to predict link failures, thereby enhancing network performance and reliability. Our study employs Ns-3 as the simulation tool for experimental evaluation. We assess the proposed approach using various metrics taking into account factors. Through this research, we aim to provide valuable insights into the performance and efficiency of our proposed strategy, offering solutions to the routing, energy consumption, and reliability challenges that MANETs face in their dynamic and infrastructure-less environment.

In the subsequent sections, we delve into an extensive literature survey in Section II, where we analyze existing works related to Mobile Ad Hoc Networks (MANETs) and routing protocols. Section III unfolds our proposed work, presenting the Biomimicry Buzz Algorithm, the Optimized route selection using the Bellman-Ford-Dijkstra algorithm, as well as our predictive models for Energy Consumption and Link Failure. These sections provide a comprehensive insight into the novel contributions and methodologies we propose. Following that, Section IV details the performance analysis, where we evaluate our approach through rigorous experimentation. Finally, Section V concludes the paper, summarizing key findings, limitations, and outlining potential avenues for future research.

II. Literature Survey

In the evolving landscape of Mobile Ad Hoc Networks (MANETs), persistent challenges include routing inefficiencies, prompting ongoing research into novel solutions. Recent efforts have yielded innovative routing protocols, aiming to address the shortcomings of conventional protocols like AODV and DSR, which often struggle in dynamic network topologies. Moreover, energy management techniques have traditionally relied on rule-based approaches, but emerging trends embrace machine learning algorithms for energy prediction and optimization. Despite these advancements, limitations such as scalability and security persist, warranting further investigation into comprehensive and robust solutions to bolster the reliability, efficiency, and sustainability of MANETs in dynamic and infrastructure-less environments.

In the study by Kai et al. [24], the focus lies on identifying the optimal algorithm path for quality routing in Ad-hoc networks. They proposed Hopfield neural network model that addresses the minimum cost problem with time delay. By carefully choosing these values, the enhanced path algorithm establishes the relationship between energy function parameters and shows that the network's possible solution falls within the heading of progressive stability. The calculations show that the answer is independent of the starting value and constantly produces the world's best solution. An adaptive routing protocol with bio-inspired design is introduced by Shah et al. in [25]. The AOMDV-FG technique maximizes a number of paths derived from the AOMDV mechanism, choosing the best path based on the highest fitness value. By comparing it against the AOMDV-TA and EHO-AOMDV protocols using important metrics, the authors evaluate the performance of their model.

The Trust and ANT Based Routing (TABR) technique is suggested for MANETs by Sridhar et al. [26]. An ant-based routing algorithm and trust values are combined by TABR to find reliable, trusted, and optimized routes in the network. TABR seeks to improve routing efficiency by combining the benefits of trust mechanisms and ant-based routing. Alsaqour et al. [27] provide the genetic algorithm-based location-aided routing algorithm to increase the effectiveness of MANET routing protocols. In order to improve delivery behavior, GALAR uses genetic optimization and adaptive updates of node position information. With little network overhead, it delivers a high packet delivery ratio of over 99%. Jeena Jacob et al. [28] method of optimizing performance using the proper tools, building a wireless environment-specific model, and enhancing routing through the careful selection of performance indicators are the three main phases they suggest. In order to enable synchronous and decentralized routing decisions, they make use of the Artificial Bee Colony Optimization method, which displays basic bee agent behaviors. The benefits of their work are found in the ABC algorithm's beneficial effects on wireless network connectivity. Their suggested method improves the network's overall effectiveness and performance by utilizing its evaluative qualities.

The Ant Colony Optimization (ACO) technique is used by Dorathy et al. [29] to handle network issues with routing as well as protection in networks that are both wired and wireless. They concentrate on finding the network's shortest, most efficient path connecting the point of origin and the destination. Their routing strategy attempts to increase the overall lifespan of the entire network by taking into account variables such node reserve energy, least residual power of the path, node distance, trip time, and hop count. The benefits of their work include taking into account a variety of variables to choose the best path, and increasing energy efficiency. The intelligent Whale Optimization Algorithm (p-WOA), presented by Husnain et al. [30], is a cluster-based, bio-inspired algorithm for routing in vehicular communication. By including factors like communication span, velocity, and path along the highway in the fitness function, the p-WOA algorithm lowers randomness and enhances cluster head (CH) selection. Their research shows that the p-WOA technique outperforms conventional approaches like the Ant Lion Optimizer along with Grey Wolf Optimization in terms of obtaining the ideal number of cluster heads. EHO-AOMDV is a routing algorithm that Sarhan et al. [31] introduce with the goal of minimizing the total energy. To lessen the likelihood of path malfunction and the number of dead nodes brought on by heavy data loads, nodes are divided into two groups. The use of energy-aware classification and updating techniques to increase the effectiveness of energy is one of the benefits of their work. For VANETs, Muhammad et al. [32] suggest a grey wolf optimization-based clustering approach. To produce effective clusters. An optimized number of clusters is produced as a result of earlier convergence caused by the grey wolf nature's linearly declining component. Their work has advantages in that it incorporates behaviors that are inspired by nature and make it possible to cluster data in VANETs effectively.

Hybrid ant and bee colony optimization algorithm, a method for picking the cluster head in MANETs, is presented by Janakiraman et al. [33]. The drawbacks of ACO in addition to ABC are addressed by this method by integrating them in a complementary way. Their method intends to avoid stagnation in the intensification process of ACO and address delayed convergence in the spectator bee phase of ABC by using employee bee agents for dividing the method of extraction into two levels. The enhanced choice of cluster head procedure is where their work excels. By streamlining complex algorithms like the Bat Optimization Algorithm, Particle Swarm Optimization, and Ant Colony Algorithm for distance optimization, Charan et al. [34] concentrate on improving routing algorithms in MANETs. They suggest a protocol called Bat Optimized Link State Routing. BOLSR tries to identify the best path by exchanging precise messages by fusing the OLSR structure and the Bat Algorithm. This results in the BOLSR protocol, which calculates the best route between the nodes based on their energy characteristics. A routing system for MANETs is proposed by Junnarkar et al. [35] and is based on the Ant Colony based optimization algorithm. The ACO-based method improves Quality of Service (QoS) effectiveness by using the nodes' present location and load factors as routing metrics. RSSI data are used in their proposed QoS Mobility Aware ACO Routing Protocols to calculate the separation between mobile nodes.

Based on the literature survey, it can be concluded that various bio-inspired and machine learning-based routing algorithms have been proposed for MANETs to enhance the routing process's effectiveness, accuracy, and reliability. The ACO, PSO, bee colony optimization, and bat algorithm have been widely used for optimizing the routing path. In comparison to the previous works, the proposed methodology offers several advantages and advancements. Firstly, it introduces an optimized route selection approach by integrating the biomimicry buzz algorithm with the Bellman-Ford-Dijkstra algorithm. This integration improves the effectiveness and accuracy of the routing process, enabling the selection of the shortest path and leading to an optimal routing solution. Additionally, the proposed methodology explores the use of ForestBoost Regression (FR) for energy consumption prediction and Artificial Neural Networks (ANNs) for link failure prediction. By utilizing machine learning techniques, the methodology enhances network efficiency and reliability. Compared to existing methods like TABR, GALAR, and others, the proposed methodology stands out by offering a comprehensive approach that addresses the limitations and challenges in MANET routing. It leverages integrated algorithms, prediction techniques, and advanced optimization methods to achieve superior performance, reliability, and energy efficiency.

III. Proposed Work

A. Motivation

The motivation for our proposed work stems from the pressing need to enhance the performance and sustainability of MANETs in dynamic and infrastructure-less settings. MANETs are increasingly deployed in scenarios where traditional network infrastructure is absent or impractical, such as disaster response, military operations, and highly mobile urban environments. The inherent mobility of nodes and the lack of a centralized control infrastructure in MANETs present unique challenges, particularly in the realms of routing efficiency, energy consumption, and network reliability. Inefficient routing protocols can lead to high overhead and significant delays, energy depletion can curtail network longevity, and unpredictable link failures can disrupt communication. To address these issues, our work aims to introduce innovative solutions, combining the Bellman-Ford-Dijkstra algorithm with biomimicry-inspired routing, employing machine learning for energy consumption prediction, and using Artificial Neural Networks for link failure prediction. The ultimate motivation is to contribute to the development of comprehensive and data-driven strategies that improve the performance, sustainability, and reliability of MANETs, thus extending their utility in critical and challenging environments. By addressing these issues, our work aligns with the broader objective of advancing the state-of-the-art in MANET research and facilitating more effective communication in dynamic and infrastructure-less networks.

The main point of this article is summed up in the facts mentioned below:

1) Bio-inspired navigation module: This module includes the algorithms for simulating the natural behaviors of honeybee waggle dance and bat echolocation, named biomimicry buzz algorithm. It receives input data such as the location and distance of the nodes and outputs the direction and distance to the destination node.

2) Bellman-ford-dijkstra algorithm module: This module includes the algorithms for discovering the fastest path among two nodes in the network. It receives input data such as the network topology and the output of the honeybee waggle dance and bat echolocation behavior module and outputs the optimized routing solution.

3) ForestBoost regression energy consumption prediction module: This module includes the algorithms for predicting the energy consumption of nodes in the network using the ForestBoost Regression machine learning algorithm. It receives input data such as historical data and network topology and outputs the predicted energy consumption.

4) Artificial Neural Networks link failure prediction module: This module includes the algorithms for predicting link failures in real-time using Artificial Neural Networks. It receives input data such as historical data and network topology and outputs the predicted link failure probability.

The proposed Bio-inspired navigation approach combines the natural behaviors of honeybee waggle dance and bat echolocation with the Bellman-Ford-Dijkstra algorithm to select the shortest path in a network, leading to an optimal routing solution. The approach considers the source node, destination node, higher value node, and intermediate nodes to determine the optimal route for packet transmission, as shown in Fig. 2. The use of a Bio-inspired navigation approach provides an efficient and reliable mechanism for route selection and to avoid congested or noisy paths in MANETs.

In addition, the paper explores using FR-ANN, a novel machine learning algorithm, to predict energy consumption and link failure in MANETs. FR-ANN can be used to optimize the network's energy usage, prolong the network's lifespan, and enhance the network's performance and reliability by predicting potential link failures before they occur. By predicting energy consumption and potential link failures, the network can use energy-efficient routes, resulting in longer battery life for nodes, preventing data loss, and improving network availability.

B. Biomimicry Buzz Algorithm

The honeybee waggle dance is a behavior used by honeybees to communicate the location of food sources to other bees in the hive. A bee that has found food returns to the hive and performs a dance, where the angle, along with the duration of the dance, is a sign of the direction plus distance of the food source, correspondingly. Other bees in the hive use this information to locate the food source. Bat echolocation is a behavior bats use to navigate and find food in the dark. Bats emit high-frequency sounds, which bounce off objects in their environment and create echoes. They listen to the echoes to determine the distance and location of things. To integrate these two behaviors for route selection, we could use the honeybee waggle dance to communicate the establishment of a destination, while bat echolocation could be used to navigate around obstacles and avoid collisions.

The echolocation method used by bats involves transmitting sound waves and detecting their reflection to locate prey based on the characteristics of the echo. Similarly, a device discovery algorithm uses a similar concept to find proximal devices within a specific search space. The discoverer device sends a signal or relies on the base station to determine the location of nearby devices. Mathematically, this technique can be expressed as follows: Let L denotes the position of a bat at time tm and s denotes the speed, which represents the rate of change in status. Consequently, the bat's position-refreshing method is determined in Eq. (1)

$$L_j(tm) = L_j(tm + 1) + s_j(tm) \quad (1)$$

Bats change their trajectory and pace depending on how far they are from their prey's location, as evidenced by their characteristics, which are represented in Eq. (2)

$$S_j(tm) = S_j(tm + 1) + (L_j(tm) – L') * fn_j \quad (2)$$

L′ deals with the location of the prey, whereas fn deals with the periodicity of natural waves. The following equation can be used to simulate the irrational behavior of bats, such as migration far from their identified prey via a degree of divergence in the range of loudness by employing Eq. (3)

$$L_{new} = L_{old} + \varepsilon * Sig^{tm} \quad (3)$$

The loudness evaluation algorithm indicates a uniform distribution, and Sigtm stands for signal strength by using the Eq. (4)

$$Sig_j(tm+ 1) = \tilde{e} * Sig_j(tm) \quad (4)$$

where, Sigj(tm+ 1) → 0, where tm → ∞, and ẽ the empirical value. Bats can determine how far they are from their target by varying the frequency associated with emanation. The emanation change occurs at the following frequency by using the Eq. (5)

$$c_j(tm + 1) = c_j(0)[1 - f^{(-d_*tm)}] \quad (5)$$

while $c_i(tm) \rightarrow c_i(0)$ as tm → ∞, as well as d is the empirical constant.

Process Flow:

1) *A* node in the network needs to communicate with another node at a specific location.

2) *The* node sends a request to the network for the location of the destination.

3) *Another* node in the network, which has knowledge of the location of the destination, responds by performing a "waggle dance" to indicate the direction and distance of the goal.

4) *The* requesting node uses this information to navigate toward the destination using bat echolocation to detect obstacles and avoid collisions.

5) *As* the node gets closer to the destination, it can continue using bat echolocation to refine its navigation and avoid any obstacles.

Combining the honeybee waggle dance and bat echolocation can create a more robust and adaptive approach for route selection in a MANET. The honeybee waggle dance provides information about the location of the destination, while bat echolocation enables nodes to navigate around obstacles and avoid collisions in real time. This approach could be beneficial in situations where nodes are mobile, and the network topology is constantly changing.

C. Optimized Route Selection - Bellman-Ford-Dijkstra Algorithm

To determine the fastest path through a network of paths, the Bellman-Ford-Dijkstra procedure incorporates the Bellman-Ford algorithm and Dijkstra's algorithm. The network's negative cycles are initially detected along with removed using the Bellman-Ford algorithm, followed by the shortest route among the two nodes is determined using Dijkstra's algorithm. The algorithm effectively discoveries the shortest path in various network topological structures by integrating the advantages of each algorithm. For example, to incorporate honeybee waggle dance and bat echolocation into the Bellman-Ford-Dijkstra algorithm, we can use these behaviors to provide additional information about the network and guide the search toward the shortest path.

Use honeybee waggle dance to estimate the direction and distance of the destination node. Honeybees use this behavior to communicate the location of food sources to other bees in the hive. We can use a similar approach to estimate the location of the destination node in the network. Use bat echolocation to identify obstacles and congested areas in the network. Bats use echolocation to navigate in the dark and avoid collisions, and we can use a similar approach to help nodes navigate around obstacles and avoid congested areas. Utilize the Bellman-Ford method to find negative network cycles and eliminate them. Negative cycles are loops in the network with a negative weight, and they can cause the algorithm to enter an infinite loop. By detecting and eliminating negative cycles, we can ensure that the algorithm converges to a valid shortest path.

To determine the shortest route between two locations, use Dijkstra's algorithm. In most instances, the Dijkstra algorithm is better than the Bellman-Ford algorithm at choosing the shortest path. Using honeybee waggle dance and bat echolocation to guide the search toward the destination node and avoid obstacles, we can further optimize the search process and reduce the search space. Add the shortest route to the routing database among every network combination of points. Then, every node consults the routing database to identify the subsequent hop on the fastest way to the target node. By integrating honeybee waggle dance and bat echolocation into the Bellman-Ford-Dijkstra algorithm, we can create an optimized route selection approach that takes advantage of these natural behaviors to progress the excellent organization in addition to the accuracy of the routing process. Table I shows the example of a routing table with sample data, we have a network with six nodes, and the routing table demonstrates the shortest path between each and every pair of nodes. For instance, to reach node B from node A, the next hop is node C. The next hop is node E to reach node C from node D. Each node in a network may utilize the routing database to find the following route on the most convenient path to the target node. Note that this is just a sample table, and the routing table would be much larger and more complex in a real-world network. A regular update of the table was additionally required as the network's topography changed.

An optimized routing solution can provide essential input data for the ForestBoost Regression energy consumption prediction module and the Artificial Neural Networks link failure prediction module. The Bellman-Ford-Dijkstra module uses the output of the honeybee waggle dance and bat echolocation behavior module to determine the network's quickest route among two nodes, which results in an optimized routing solution. This optimized routing solution can be used as input for the ForestBoost Regression energy consumption prediction module to forecast the system's nodes' energy usage.

TABLE I. EXAMPLE OF A ROUTING TABLE WITH SAMPLE DATA

Source Node	Destination Node	Next Hop
A	B	C
A	C	F
B	A	C
B	C	D
C	A	F
C	B	A
D	A	B
D	C	E
E	A	C
E	B	A
F	A	C
F	B	D

Let S_p, αS_p, C_{pt}, C_{pr} indicate the power of the transmitted signal, the power of the amplifier, the power of the circuit at the transmitter, along with the power of the circuit at the receiver, respectively by Eq. (6) to Eq. (8).

$$S_p = \frac{(4\pi)^2 d_m^{\alpha'} M_l N_f}{G_t G_r \gamma^2} E_b R_b \tag{6}$$

$$\mathrm{C_{pt}} = \mathrm{P_{mix}} + \mathrm{P_{syn}} + \mathrm{P_{filt}} + \mathrm{P_{DAC}} \tag{7}$$

$$C_{pr} = P_{mix} + P_{syn} + P_{LNA} + P_{filr} + P_{ADC} + P_{IFA} \tag{8}$$

The amount of power used while transmitting in active mode (A_{pt}) is able to be determined by Eq. (9).

$$A_{pt} = S_p + \alpha S_p + C_{pt} = (1+\alpha)S_p + C_{pt} = \frac{\varphi}{\tau} S_p + C_{pt} \tag{9}$$

During reception (A_{pr}), the electricity used in the active phase is able to be provided by Eq. (10).

$$A_{pr} = C_{pr} \tag{10}$$

The ForestBoost Regression energy consumption prediction module utilizes historical data and network topology as input to predict the energy consumption of nodes. Using an optimized routing solution as input, the module can consider the energy consumption associated with specific routing decisions and provide more accurate predictions. Similarly, the Artificial Neural Networks link failure prediction module utilizes historical data and network topology to predict link failures in real-time. By incorporating an optimized routing solution as input, the module can consider the impact of routing decisions on the network's overall reliability and provide more accurate predictions of link failure probabilities.

Let E_e^i represent the starting energy concerning a node n_e and the amount of energy needed for transmission (E_e^{Tx}) or as reception (E_e^{Rx}) beginning at that node n_e. The specified L bits are actually by Eq. (11) and Eq. (12).

$$(E_e^{Tx}) = \mathrm{P_{tx}T_{tx}} = \frac{\varphi}{\tau}\mathrm{P_t P_{ct}} \tag{11}$$

$$(E_e^{rx}) = \mathrm{P_{rx}T_{rx}} = \mathrm{P_{cr}T_{rx}} \tag{12}$$

After transmitting L bits, the RE (E_k^{Tx}) at a node n_e is given by Eq. (13).

$$(E_e^R) = \begin{Bmatrix} E_e^i - E_e^{Tx} \\ E_e^i - E_e^{Rx} \end{Bmatrix} \tag{13}$$

When using the approach we suggest with Z hops, the total amount of energy used per iteration by the fastest route via the node's $n_l(n_{lo}, n_{l1}, n_{l2}, \ldots, n_{lz},)$ can be determined based on Eq. (14).

$$E_T = \sum_{l=0}^{Z-1} [(E_k^{Tx} + E_{l+1}^{Rx})] + \sum_{l=0}^{Z} [E_l^{idle} + E_l^{CPU} + E_l^{Bat} + E_l^{DC}] \tag{14}$$

where, $E_l^{idle} = P_{idle} T_{idle}$ at node n_l and $P_{sp} \approx 0$.

Optimized route selection - Algorithm

```
1. Let s be the source node along with t is the destination node.
2. Use the honeybee waggle dance to estimate the direction
```

and distance of the destination node. Let θ be the anticipated angles among the present point and the target node, along with let the d_s is the anticipated distance among the two nodes.

3. Use bat echolocation to identify obstacles and congested areas in the network. Let $w_t(e)$ be the edge-weight e in a network, which represents the cost of traversing that edge. If an obstacle or congested area is detected along edge e, then set $w_t(e)$ to a high value to discourage nodes from using that edge.

4. Initialize the distance estimates as well as predecessor nodes for each node in the network as follows:

$d_s[s] = 0$

$d_s[v] = \infty$ for all other nodes v in the network

p[v] = null for all nodes v in the network

5. Utilize the Bellman-Ford method to find negative network cycles and eliminate them. Iterate over all edges e in the network |V|-1 times (where |V| represents the network's total number of connections), and update the distance estimates and predecessors as follows:

if $d_s[v] > d_s[u] + w_t(e)$ then:

$d_s[v] = d_s[u] + w_t(e)$ p[v] = u

If after |V|-1 iterations, there exists an edge e with $d[v] > d[u] + w_t(e)$, subsequently a negative cycle exists in the network and terminates the algorithm.

6. Using Dijkstra's algorithm, find the quickest route among the starting node s along with target node t. Initialize a priority queue Q with all nodes in the network, ordered by their distance estimates $d_s[v]$. Set $d_s[s] = 0$ and insert s into Q. Then, whereas Q is not empty, extract the node u with the smallest distance estimate d[u] from Q and relax all its outgoing edges e as follows:

if $d_s[v] > d_s[u] + w_t(e)$ then: $d_s[v] = d_s[u] + w_t(e)$ p[v] = u

If v = t, then the shortest path has been found and the algorithm terminates.

7. If a path does not connect the source node s along with the target node t, then the algorithm terminates and returns "no path".

D. Energy Consumption Prediction

Energy consumption prediction is an essential aspect of optimizing route selection in MANETs. By predicting the energy consumption of different routes, we can choose the route that requires the least amount of energy, thereby conserving battery power and extending the life of the network's components. In the approach that integrates honeybee waggle dance and bat echolocation into the Bellman-Ford-Dijkstra algorithm, we use Random Forest Regression as a hybrid machine learning algorithm to predict the energy consumption of each route. This is done by training the algorithms on historical energy consumption data for different routes and using the trained models to predict the energy consumption of new routes. The predicted energy consumption values are then integrated into the Bellman-Ford-Dijkstra algorithm to find the route with the lowest energy consumption. This route is then selected as the optimized route for data transmission in the network.

E. Random Forest Regression

An effective machine learning approach called Random Forest Regression may be utilized to anticipate energy consumption. A collaborative algorithm for learning called Random Forest Regression builds several decision trees and integrates their forecasts to create a more precise and trustworthy approach. It is well-suited for handling high-dimensional data and can control categorical and continuous variables. Gradient Boosting Regression is another ensemble learning algorithm that builds models sequentially. It is capable of handling several kinds of data and has been shown to be effective in predicting energy consumption.

Let $T_b(i)$ denotes the predicted output of Decision Tree T_b, for sample i. To forecast at a fresh location p:

$$\text{Regression: f\^{}rf B (p)} = f_{rf}^{B}(p) = \frac{1}{\mathrm{B}} \sum_{\mathrm{b}=1}^{\mathrm{B}} \mathrm{T_b(p)} \qquad (15)$$

Classification: Let $C_b(p)$ is the class predicted of b^{th} random-forest tree.

$$\text{Then } C_{rf}^{B}(p) = majority\ vote\{C_b(p)\}_1^B \qquad (16)$$

A constant value is determined for every one of the discontinuous sections that make up the input space. There are j leaf nodes in each random forest regression tree. The $g_m(p)$ values for the Random Forest Regression tree is achieved based on Eq. (17) to Eq. (19).

$$\mathrm{gm(p)} = \sum_{\mathrm{j}=1}^{\mathrm{j}} (\mathrm{b_{jm} I}), \mathrm{p} \in \mathrm{R_{jm}} \qquad (17)$$

$$\mathrm{I(p \in R_{jm})} = \begin{Bmatrix} 1, \mathrm{p} \in \mathrm{R_{jm}}; \\ 0, other; \end{Bmatrix} \qquad (18)$$

$$\mathrm{Z(L, f(p))} = \sum_{\mathrm{i}=1}^{\mathrm{n}} (\mathrm{L} - \mathrm{f(p)})^2 \qquad (19)$$

Step 1: Initialization of Model:

$$\mathrm{fo(p)} = \mathrm{argmin} \sum_{\mathrm{i}=1}^{\mathrm{n}} \mathrm{Z(y_i, p)} \qquad (20)$$

Step 2: R random Forest regression trees are generated iteratively, with r denoting the r^{th} tree to stay r=1 to R:

(1) J represent the j^{th} selection for j = 1 to N. Finally, the loss function's low gradient number is determined, along with the result can be utilized to measure the residual r_{jr}:

$$r_{jr} = \left[\frac{\partial Z(yj, f_{r-1}(p_j))}{\partial f_{r-1}(p_j)}\right]_{f(p)} = f_{r-1}(p) \qquad (21)$$

(2) A random Forest regression tree gm(p) is produced on behalf of the enduring created in the preceding phase. The amount of steps for gradient decline is subsequently established by dividing the input space regarding the r-tree towards J distinct regions, designated as D_{1r}, D_{2r}, :::, and D_{jr}:

$$p_{r,} = \mathrm{argmin} \sum_{\mathrm{j}=1}^{\mathrm{n}} \mathrm{Z}(\mathrm{y_j}, f_{r-1}(p_j) + pg_r(p_j)) \qquad (22)$$

Step 3: Refresh the parameters of the approach, in which lr stands for the learning rate, aims to reduce the impact of each basic model on the result and prevent the framework from being overfit.

$$f_r(p) = f_{r-1}(p-1) + lr * pg_r(p) \quad (23)$$

To combine these two algorithms for energy consumption prediction, we can use a technique called stacking. In stacking, the predictions from multiple machine learning models are combined into a single model that produces more accurate predictions than any of the individual models.

The overall workflow for using Random Forest Regression for energy consumption prediction:

1) Collect and preprocess energy consumption data, including relevant features such as temperature, humidity, and time of day.

2) Create training and validation groupings for the data.

3) Create a Random Forest Regression model using the training set, and then generate forecasts by applying it to the testing set.

4) Create a Gradient Boosting Regression model using the training set, and then generate forecasts by applying it to the testing set.

5) Combine the predictions from the Random Forest and Gradient Boosting models using stacking.

6) Analyze the stacked model's results on the test set.

7) Fine-tune the hyperparameters of the models to improve their performance, if necessary.

8) Once the models are trained and optimized, they can be used to forecast energy usage based on newly acquired data.

In the Random Forest Regression algorithm, numerous decision trees are built, and the predictions from each tree are combined to produce the final forecast. A randomized subgroup of the training information and a randomly selected portion of the features are used for training every decision tree. The algorithm then averages the predictions of all the decision trees to get a final prediction. Mathematically, the forecast for a new input x can be written as Eq. (24).

$$p = \frac{1}{Nd} * \sum_{j=1}^{Nd} p_j(y) \quad (24)$$

where, Nd symbolizes the amount of decision trees along with $p_j(y)$ symbolizes the prediction of the jth decision tree for the input y. The algorithm also constructs multiple decision trees, but instead of averaging their predictions, it combines them using gradient descent. In this algorithm, each decision tree is trained on the residuals (the discrepancy among the prior tree's anticipated result along with the actual output) of the previous tree. Mathematically, the prediction for a new input y can be written as Eq. (25).

$$p = \sum_1^M f_m\,(y) \quad (25)$$

where, M represents the number of decision trees, along with $f_m(y)$ is the prediction of the mth decision tree for the input y. Random Forest Regression utilized to predict the energy consumption for a given set of features (such as distance, obstacles, and congestion) and can be integrated into the proposed routing algorithm to reduce the network's consumption of energy as much as possible.

F. Link Failure Prediction

In the integrated approach using honeybee waggle dance and bat echolocation with the Bellman-Ford-Dijkstra algorithm, link failure prediction can be obtained through various methods. One possible approach is using statistical analysis and machine learning algorithms to analyze network data, including node connectivity, traffic load, signal strength, and other relevant parameters. Applying supervised machine learning - SML strategies like Artificial Neural Networks (ANNs) can help predict link failure based on historical data and other network features. Moreover, integrating honeybee waggle dance and bat echolocation can provide additional inputs for link failure prediction. For instance, the honeybee waggle dance can be used to estimate the distance and direction of the destination node, which can help identify potentially congested areas and bottleneck links along the path. Similarly, bat echolocation can be used to detect obstacles and other obstructions that may affect signal strength and link quality.

G. Artificial Neural Networks (ANNs)

The structure and the human brain's operation motivate a computational model called an ‘Artificial Neural Network’. It is made up of several linked, layered processing nodes or neurons. The layer that produces the result generates the prediction result, and the data that is the input layer gets the input data. The hidden layers perform intermediate processing on the input data to extract relevant features and patterns. The input data is represented as a vector x with n components: x = [x_1, x_2, ..., x_n]. Each component x_i represents a feature of the input data. Each neuron in the data layer gets a portion of the input vector as the input information is fed through the input layer. To create an output, each neuron in the layers that are concealed performs a weighted compilation of its inputs along with applying an activation procedure. Where $h_{i,j}$ represents the jth neuron's outcome in the ith buried layer. The activation function usually incorporates nonlinearity through the network structure through a nonlinearity.

The ultimate forecast is generated by feeding the final result of the last layer that is concealed through the output layer. Y_k stands for the outcome of the k-th neuron in the yield layer. The yield layer may have multiple neurons, each corresponding to a different output class or regression value. The weights and biases of the neurons are learned during the training phase of the network. A cost function that calculates the disparity between the outcomes predicted along with the outcome actually produced is what training aims to minimize. Using an optimization method like gradient descent or Adam, the weights are refreshed. In predicting link failure, ANNs can be used to predict the probability of link failure based on historical data and other features such as traffic load, weather conditions, and network topology. The input vector x symbolizes the features of the link; in addition to the output, y represents the probability of link failure. The biased and weighted elements of the neural network are modified to minimize the discrepancy across its projected likelihood alongside the actual possibility of link failure after it has been trained on the data set consisting of previous link failure occurrences. By the present status of the input characteristics, the ANN can be utilized for instantaneously predicting the likelihood of failure of the link once it has been trained. If the predicted probability exceeds a certain threshold, a link failure is predicted, and the network can take appropriate action to reroute traffic and avoid network disruption.

Steps:

1) Data collection: Collect data related to network topology, traffic, and energy consumption. This data includes features such as link distance, bandwidth, traffic volume, and energy consumption.

2) Feature engineering: Determine pertinent features from the gathered information, including statistical measures such as mean, variance, along with standard deviation.

3) Data preprocessing: Normalize the data to a common scale to remove any bias towards features with larger values. Also, divide the data into training, validation, and test sets.

4) Training ANNs: Use the training data to train ANNs for link failure prediction. ANNs are powerful machine learning algorithms that can learn the underlying patterns as well as make predictions based on new input data. In this case, the ANNs will learn to predict link failures based on the input features.

5) Validation and hyperparameter tuning: Verify the trained ANNs' effectiveness using the validation collection and tune the hyperparameters of the ANNs to improve their performance.

6) Testing: Test the final ANN models on the test set to evaluate their performance.

7) Integration with energy consumption prediction: Finally, integrate the ANN-based link failure prediction model with the previously developed energy consumption prediction model that uses Random Forest Regression and Gradient Boosting Regression with honeybee waggle dance and bat echolocation optimized route selection using the Bellman-Ford-Dijkstra algorithm. This integrated model will now be able to predict both link failures and energy consumption and use this information to optimize the process of routing in the network.

Optimized route selection approach In MANET using " honeybee waggle dance and bat echolocation for route selection, Bellman-Ford-Dijkstra algorithm to find the shortest path in a network, By integrating honeybee waggle dance and bat echolocation into the Bellman-Ford-Dijkstra algorithm, we can create an optimized route selection approach that takes advantage of these natural behaviors to improve the efficiency and accuracy of the routing process, ForestBoost Regression is a novel machine learning algorithms that can be used for energy consumption prediction, Artificial Neural Networks provides more accurate and timely predictions of link failure in MANETs, improving the performance and reliability"

Algorithm for Optimized route selection and Link Failure Prediction

1. Data preprocessing:

Input: Energy consumption data (X), network topology data (G), and link failure data (Y)

Output: Normalized energy consumption data (X_{nor}), normalized network topology data (G_{nor}), and binary link failure data (Y_{bin})

The data preprocessing step involves normalizing the energy consumption data X and the network topology data G, and converting the link failure data Y into binary form. Mathematically, we can represent this step as follows:

$$X_{nor} = (X - \text{mean}(X)) / \text{std}(X) \qquad (26)$$

$$G_{nor} = (G - \text{mean}(G)) / \text{std}(G) \qquad (27)$$

$$Y_{bin} = 1 \text{ if } Y > 0, \text{ else } 0 \qquad (28)$$

where, mean(.) and std(.) represent the mean as well as standard deviation of the data, respectively.

2. Honeybee waggle dance and bat echolocation:

Input: Normalized network topology data (G_{nor})

Output: Estimated distance to destination node (d) and estimated angle to destination node (λ)

The honeybee waggle dance and bat echolocation steps use the normalized network topology data G_{nor} to estimate the distance d and angle theta to the destination node. Mathematically, we can represent this step as follows:

d, λ = honeybee_waggle_dance_and_bat_echolocation(G_{norm}) (29)

where, honeybee_waggle_dance_and_bat_echolocation (.) represents the function that estimates the distance and angle using the honeybee waggle dance and bat echolocation techniques.

3. Bellman-Ford-Dijkstra algorithm with link failure prediction:

Input: Normalized network topology data (G_{nor}), estimated distance to destination node (d), estimated angle to destination node (λ), and binary link failure data (Y_{bin})

Output: Shortest route between source and target nodes (P)

The Bellman-Ford-Dijkstra algorithm with link failure prediction step takes as input the normalized network topology data G_{nor}, the estimated distance towards the target node d, the estimated angle to the destination node theta, along with the binary link failure data Y_{bin}, and outputs the shortest route between source and target nodes. This step consists of two sub-steps: Bellman-Ford algorithm and Dijkstra's algorithm.

3.1 Bellman-Ford algorithm:

Input: Normalized network topology data (G_{nor}), estimated distance to destination node (d), estimated angle to destination node (λ), and binary link failure data (Y_{bin})

Output: Distance estimate (d_s[x]) as well as predecessor node (p_s[x]) for each node in the network

The Bellman-Ford algorithm takes as input the normalized network topology data G_{nor} , the estimated distance to the destination node d_n, the estimated angle to the destination node theta, and the binary link failure data Y_{bin}, and outputs the distance estimate d_n[x] and predecessor node p[x] for each node x in the network. Mathematically, we can represent this step as follows:

```
Initialize $d_n$[x] = infinity, $p_s$[x] = null for all x in G
Set $d_n$[source] = 0
For i = 1 to |X|-1 do
    For each edge (u, x) in G do
        if $Y_{bin}$[u,x] == 0 then
        if $d_n$[x] + $w_t$(u,x) < $d_n$[x] then
        $d_n$[x] = $d_n$[x] + $w_t$(u,x)
        $p_s$[x] = u
```

where, |V| is the number of nodes in the network.

IV. Performance Analysis

An arbitrary collection of origins nodes was replicated with sizes varying from 25 to 125 nodes using the simulation platform, as shown in Table II, to test the efficacy of the suggested mechanisms. These node sources were configured to transmit CBR data packets, which are the nodes' transmission range of 250 seconds, at arbitrary speeds increasing from 25 m/s to a maximum of 30 m/s between arbitrary standstill intervals ranging from 0 to 50 s. The RWP technique is used to generate various nodes. 700s of simulation time is adequate to determine network congestion, latency, and complexity. The optimal path parameter, or "OPI," is generated for each alternate route based on the values of parameters like Movement Indication, Network Access, Path Accessibility, as well as Link Duration. In a MANET, the route with the highest Path selection factor is considered for data transfer across the intermediary nodes towards a target node.

To substantiate the effectiveness of our proposed strategy, we recognize the critical importance of employing diverse and representative datasets that encapsulate various scenarios and environmental conditions inherent in MANET operations. Our dataset selection criteria prioritize factors pivotal to MANET performance, encompassing node mobility, signal strength, and network traffic. For node mobility, we intend to incorporate datasets that emulate a spectrum of mobility patterns and scenarios, including different speeds, pause times, and movement trajectories. The datasets related to signal strength will account for real-world fluctuations, considering interference, obstacles, and varying distances between nodes. Additionally, our approach involves simulating diverse network traffic scenarios, encompassing varying loads, sudden spikes, and fluctuations in traffic. This comprehensive dataset strategy aims to ensure the validity and generalizability of our experimental evaluations, evaluating the adaptability and responsiveness of the proposed MANET optimization strategy across a wide array of realistic conditions. The selected metrics for evaluation include node mobility metrics, signal strength metrics, network traffic metrics, and metrics related to topology changes, providing a holistic assessment of our strategy's performance and its real-world applicability.

TABLE II. SIMULATION PARAMETERS

Parameters	Values
Speed of the node	[25-30]m/s
Number of Nodes	25 - 125
Packet size	512 bytes
Simulation Time	700s
Traffic category	CBR
Protocol used for Routing	RIFA
Mobility Model	Random
Pause Time (s)	10s
Wireless Range of Transmission	250s
Area of Simulation	1200m
Node Assignment	Random

A. Discovery Signal Delivery Probability

To evaluate the performance of the proposed approach for optimized route selection in MANETs, one metric that can be used is the discovery signal delivery probability. This metric measures the ability of the routing protocol to deliver packets to their intended destination. Meeting chance refers to the likelihood that a relay entity will move into conversation with a destination entity. According to the algorithm above, the relay node's choice of the transmitted finding signal is based on the probability's variant value combination. The probability that a signal will be transferred successfully via object Rd to the other device Dd is represented by the Prob(Rd, Dd) symbol. The following procedures are provided for upgrading the detection delivery of messages probability Prob(Rd, Dd): As meeting frequency along with contact time grows, the likelihood of acquiring a signal rises. Therefore, whenever the two devices come together, they will transmit a likelihood table based on the provided mathematical framework, updating the discovery signal by employing Eq. (30) and Eq. (31)

$$Prob(Rd,Dd) = Prob(Rd,Dd)_{Prev} +$$

$$(1 - Prob(Rd,Dd)_{Prev}) * Prob_{orig} * z^{\frac{T_{RdDd}}{T_r + T_d/2}} \tag{30}$$

$$T_{RdDd} = \sum_{q=1}^{l} t_{RdDd}(q) = \sum_{q=1}^{l} (t_{RdDd_{end}}(q) - t_{RdDd_{start}}(q)) \tag{31}$$

The entire contact time across the relay unit Rd along with the destination unit Dd. t is indicated by the symbol T_{RdDd}. The end, followed by the qth connection start times link among relay devices Rd along with recipient device Dd are denoted by $t_{RdDd_{end}}(q)$ in addition to $t_{RdDd_{start}}(q)$, respectively. In addition, $T_{Rd} = \sum_{q=1}^{n} t_{Rdq}$ represents the period of time during which the relay unit Rd is in communication with other network nodes, and $T_{Dd} = \sum_{k=1}^{n} t_{Ddk}$. The overall amount of time during which that device Dd is in communication with any other device on the same network is nt_Ddk. The duration of contact among devices Rd along with Dd is measured as $\frac{T_{RdDd}}{T_{Rd}+T_{Dd}/2}$ in terms of the mean impact rate $(T_r + T_d)/2$.

To evaluate the discovery signal delivery probability, the proposed approach can be compared to other existing routing protocols for MANETs using NS-3 simulation tool. The simulations can be designed to mimic real-world scenarios and measure the percentage of packets that successfully reach their destination. To evaluate the ForestBoost Regression algorithm's performance, the proposed approach can be compared to existing algorithms used for energy prediction in MANETs, such as ANNs or Support Vector Regression (SVR). The performance can be evaluated based on the accurateness of the energy prediction along with the energy consumption optimization achieved by the algorithm. Similarly, the ANN-based approach for predicting link failure in MANETs can be compared to other existing approaches, such as probabilistic models or machine learning-based models. The evaluation can be based on metrics such as prediction accuracy and false positive/negative rates.

B. Packet Delivery Rate

The proportion of the amount of packets sent by upper layers in relation to the amount of packets that arrived at the destination is known as the packet delivery rate. This standard represents the degree of the suggested way from a starting point to a target. With faster data packet delivery, the suggested technique becomes more effective. Let PDR stand for the data packet delivery efficiency, which can be calculated by applying Eq. (32)

$$\text{Packet Delivery Rate} = \frac{N_{pr}}{N_{ps}} * 100\% \qquad (32)$$

where, N_{pr} stands for the quantity of received packets whereas N_{ps} for the quantity of transmitted packets. The packet delivery ratio - PDR fluctuation for the protocols RRP [12], CHNN [14], and MAR [17] is shown in Fig. 3. The packet delivery ratio declines as node speed rises.

The proposed strategy falls from 97% to 90%, the RRP from 92% to 83%, and the MAR from 93% to 88%. The proposed method has a more excellent packet delivery ratio than previous protocols. The most dependable path to the destination is selected by the recommended routing protocol. In comparison to other options, the selected path can have the highest energy level, require the least amount of energy, and cover the greatest distance. By doing this, the likelihood of a node failure is lower, and data loss is reduced.

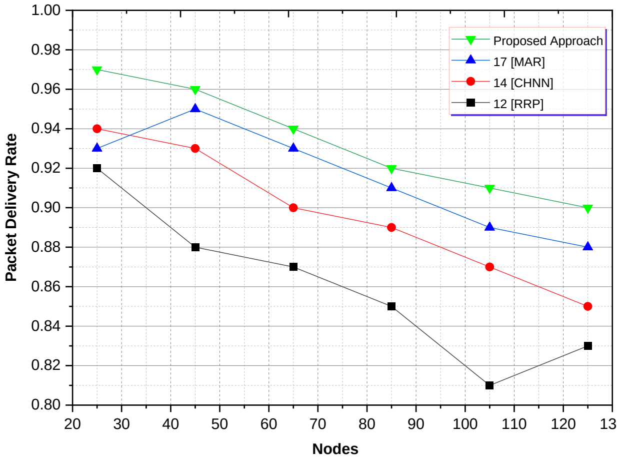

Fig. 3. Variation of packet delivery ratio.

C. Average End-To-End Delay – E2ED

The averaged E2E latency is the duration that it takes for a data packet to arrive which effectively voyage since solitary place to a new. To describe the typical end-to-end delay, we use E2ED. The computation process represented in Eq. (33)

$$E2ED = \frac{1}{Tdp}\sum_{a=1}^{Tdp}\left(T_{pt}(a) - T_{pr}(a)\right) \qquad (33)$$

Fig. 4 compares the suggested approach's average E2E delay to that of the RRP [12], CHNN [14], and MAR [17] range from 10 to 60 minutes. As the amount of time grew, the end-to-end latency shrank. As a result, the suggested method produced a significant latency of roughly 19 ms whenever the pause period was the 60s; however, as the pause time climbed, it dropped due to the lower transportation and likelihood of node failures.

D. Energy Consumption

Energy consumption is the sum of the energy network nodes consumed throughout the scenario. This is accomplished by calculating the energy level of every single node during the end of the trial and accounting for its residual energy. Energy consumption will be represented by the Eq. (34).

$$Econs = \sum_{a=1}^{B}(Ei(an) - Er(an)) \qquad (34)$$

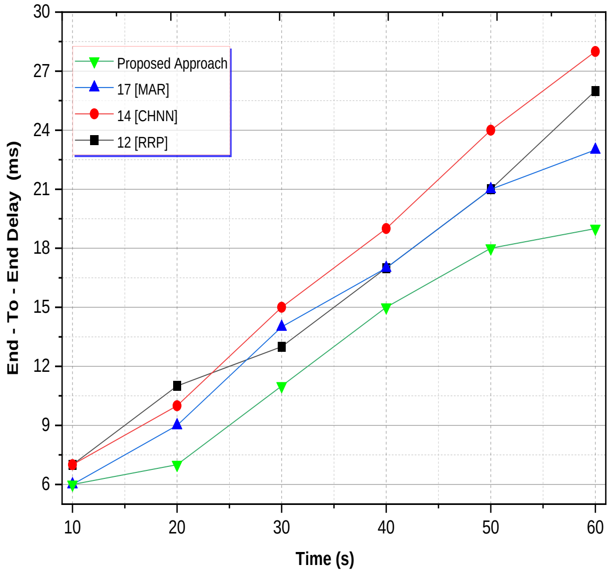

Fig. 4. Average end-to-end delay of the proposed approach.

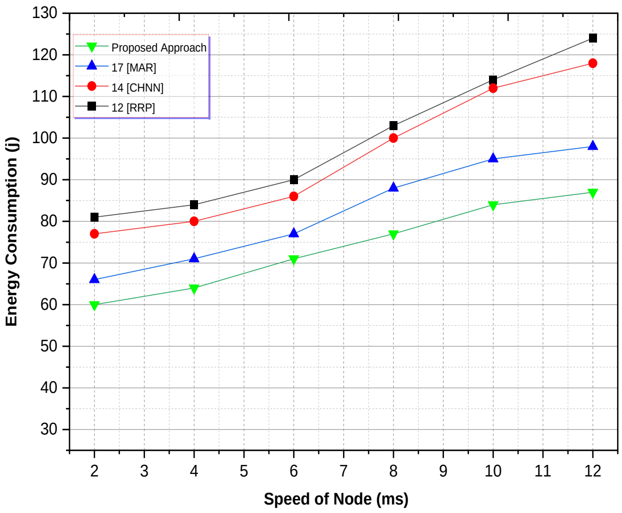

Fig. 5. Energy consumption - node speed.

RRP [12], CHNN [14], and AMR [17] are the three proposed approaches, and the variance in energy usage for each is shown in Fig. 5 (MAR). The energy usage rises as the node speed does. The suggested approach results in an increase of 60 to 87 joules, whereas RRP experiences an increase of 38 to 97 joules, CHNN experiences an increase of 31 to 107 joules, as well as MAR experiences an increase of 35 to 127 joules. The recommended protocol uses less energy than other protocols.

The proposed method groups the routes that eventually reach the desired destination based on their energy levels. The point of origin scatters the data packets while transferring it via pathways with an elevated energy level as well as the normal one in order to equally spread the load on numerous routes. Compared to sending the traffic across just one path, this process uses less energy. RRP, CHNN, and MAR are the recommended approaches, and their energy usage is shown in Fig. 6. In contrast to other protocols, which use more than 30 joules for 10 seconds as well as 90 joules over 60 seconds, the recommended technique uses 29 joules over 10 seconds along with 89 joules over 60 seconds. As a result, the recommended method uses limited energy compared to some alternative methods.

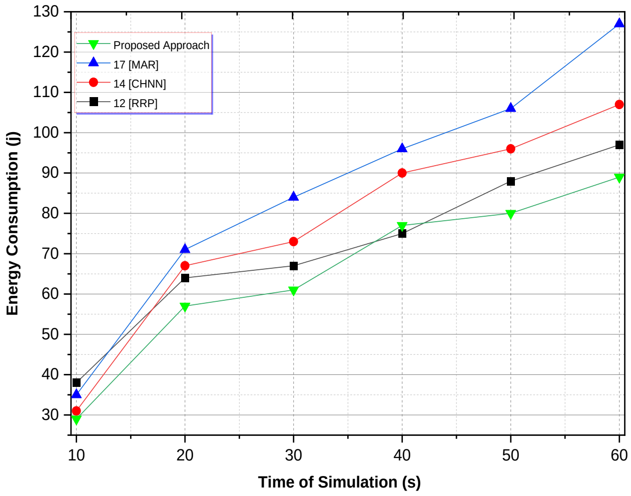

Fig. 6. Energy consumption - simulation time.

The optimization approach proposed for MANET routing offers benefits in improved adaptability, reduced latency, and enhanced energy efficiency. Integrating biomimicry-inspired algorithms and predictive models contributes to dynamic route selection, quicker data transmission, and optimized energy usage. Link failure prediction enhances network reliability. However, challenges include algorithmic complexity, dependence on dataset quality, and considerations for real-world implementation such as hardware constraints and scalability issues. Addressing these limitations is crucial for practical feasibility and efficacy in diverse MANET scenarios.

V. Conclusion and Future work

In conclusion, the optimization of the routing process in MANETs is a crucial task for enhancing the performance and reliability of these networks. The proposed approach, which integrates the biomimicry buzz algorithm with the Bellman-Ford-Dijkstra algorithm, provides a promising solution for this task. By using these behaviors, the nodes can quickly converge on the optimal route to the destination, leading to an efficient and accurate routing solution. Additionally, the use of advanced machine learning techniques such as ForestBoost Regression and ANNs can further optimize the network's energy consumption and predict link failure, improving the network's performance and reliability. These techniques have the potential to revolutionize the routing process in MANETs, enabling them to operate more efficiently and reliably, even in dynamic and unpredictable environments. The proposed approach has the potential to improve the performance and reliability of MANETs, which serves numerous distinct applications in areas such as disaster relief, military operations, and sensor networks. The use of natural behaviors and advanced machine learning techniques is an innovative approach to optimizing the routing process, and further research in this area could lead to even more sophisticated solutions for MANETs.

The proposed optimized route selection approach, coupled with innovative applications of machine learning in predicting energy consumption and link failure, opens avenues for future research and development in the realm of Mobile Ad Hoc Networks (MANETs). The following areas represent potential directions for future exploration:

Further exploration and refinement of biomimicry algorithms, beyond the proposed biomimicry buzz algorithm, could yield enhanced routing strategies. Investigating the application of other bio-inspired algorithms may lead to more efficient and adaptive routing solutions in dynamic MANET environments. Continuous advancements in machine learning techniques can be leveraged to optimize the prediction accuracy of energy consumption and link failure. Exploring deep learning architectures or ensemble methods may enhance the precision of predictions, contributing to more reliable network management. Research into mechanisms for dynamically adapting the proposed algorithm to varying network conditions and node behaviors is essential. The ability to self-adjust based on real-time factors, such as traffic patterns or node density, would enhance the algorithm's adaptability and overall effectiveness.

Incorporating robust security measures within the routing protocol is crucial in MANETs. Future work could focus on integrating advanced security mechanisms to fortify the proposed algorithm against potential security threats, ensuring secure and reliable communication. Translating the proposed strategy from simulations to real-world implementations is a significant future avenue. Evaluating its performance in actual MANET deployments, considering factors like hardware constraints and varying environmental conditions, will validate the practicality and effectiveness of the proposed approach. Enhancing energy prediction models by considering dynamic factors such as node mobility patterns, terrain variations, and changing environmental conditions could further refine energy consumption predictions. Future work might involve developing energy models that adapt to real-time context changes. Extending the experimental evaluation to larger network sizes and assessing the scalability of the proposed approach will provide insights into its performance under more extensive MANET scenarios. Investigating how the algorithm scales with an increasing number of nodes is vital for its practical applicability. Exploring cross-layer optimizations that integrate routing, energy management, and link failure prediction could yield holistic solutions. Collaborative decision-making across multiple protocol layers may enhance the overall efficiency and reliability of MANETs.

Higher Normal School of Tetouan, Abdelmalek Essaadi University, Morocco[1, 3]
Rabat Business School-Rabat International University, Rabat, Morocco[2]

Abstract—**Our work highlights the importance of adopting a systematic and methodical software engineering approach to the development of information technology projects for e-learning. We place particular emphasis on conceptualizing pedagogical scenarios and an inductive online learning situation. To ensure effective management of the information systems development process, we applied instructional design principles and adopted the 2TUP process, a refined version of the Rational Unified Process (RUP) suitable for projects of all sizes. To provide a visual representation of the system architecture and inform instructional design decisions, we used the Unified Modeling Language (UML) to create class, use case, activity, and sequence diagrams. We aim to demonstrate the potential of a structured software engineering approach to creating effective and efficient e-learning systems by conceptualizing an inductive online learning situation and five concrete examples illustrating the system's functionality. Our work underlines the importance of using standardized modeling languages such as UML to facilitate communication between stakeholders and collaboration between instructional designers and software developers.**

Keywords—Software engineering approach; instructional design; conceptualization scenario; online learning situation; inductive approach

I. Introduction

In an IT project, it is imperative to use a structured approach that describes how the project will be carried out. The choice of project management is a decisive phase in the successful completion of the project [1]. A working methodology and development process must be defined, and a project schedule drawn up. In this work, based on the results obtained concerning the conceptualization of our learning activity in a pedagogical scenario according to the modular system, and after having defined our choices in terms of development process and modeling language, we propose a modeling with UML of a system for the conceptualization of a learning situation of a model in online teaching for an inductive approach. Finally, we provide examples of models for our system.

Nevertheless, designing scripting tools for learning activities adapted to blended learning is a complex process that requires a coherent, well-thought-out plan to ensure successful learning [2]. This requires consideration of the pedagogical objectives of the activity, the variety of tools and strategies available, and the needs and interests of the learners [3, 4]. It is important to take this aspect into account, especially when considering a diverse group of distance learners, to be able to offer them appropriate motivational strategies in e-learning systems [5]. Scripting tools are tools used to define and create a series of pedagogical activities in an online environment. They comprise activity diagrams and specification tables to help teachers define pedagogical objectives and organize pedagogical activities in a rational way [6, 7]. On the other hand, teachers can use activity diagrams to clarify pedagogical objectives and organize pedagogical activities, which is an excellent way of planning pedagogical activities and defining tasks in diagrammatic form. A datasheet is used to identify the requirements and methods of a task to be performed, and to provide detailed information.

By using both tools, online instructional storyboard designers can approach their scripts in an organized and rational way. These tools can provide an organized approach to the scriptwriting process, which many people find useful when learning. Within the intricate cycle of a pedagogical scenario in a learning situation lies the revelation of "The four Types of Scripts in an Online Learning Situation" [8]. This paints the picture with four unique stages and related activities. Initiation is up first. Presentation lies in presenting content, performing diagnostic evaluations, and delivering remedial backstage support. The next stop on this cycle is Conceptualization wherein learners dive into tasks such as expounding concepts, using deductive or inductive approach, and arranging information, Group discussions, the practical application of knowledge, and continuous assessment - these activities make up the meat of the Objectivation phase. In the last phase, the Transfer Phase, a pivotal stage in the pedagogical framework is reached. During this phase, a detailed examination of case studies takes place, allowing for a comprehensive analysis. Thorough summative assessments serve as a fundamental cornerstone in evaluating the overall learning outcomes. This phase, aptly named the Transfer Phase, sets the stage for the application of acquired knowledge and the cultivation of practical competencies.

Following having observed the stages of the learning cycle outlined hitherto, conceptualization comprises the secondary phase. It entails structuring the progression from action to implementation, founded upon hindrances encountered throughout situational undertakings. In the end, this stage fosters meaning-making surrounding specialized knowledge, its implementation, and integration in skill development. The stage encompasses two scenarios contingent on the adopted approach. Indeed, contingent on context and situation, proposed learning activities necessitate opting between deductive and inductive approaches. Based on this digital pedagogical framework, presently we examine the second phase concerning conceptualization, with particular focus on the inductive approach.

As part of our comprehensive study, we delve into the second phase of conceptualization, especially the enigmatic inductive approach. As part of our research, we first examine a comprehensive theoretical framework, wherein we reveal the essence of the inductive approach, followed by the presentation of a meticulously constructed scenario designed for the conceptualization of a learning situation of a module in online teaching for an inductive approach.

As we progress, we engage in a compelling discourse on the development process and modeling language employed in our study. We embrace the 2TUP process as a symbol of structural integrity and efficiency while harnessing the potential of UML (Unified Modeling Language). Regarding the modeling system, we venture into the static view, showcasing the class diagram and use case diagram. Further into the dynamic view, we present the modeling of activity and sequence diagrams.

The subsequent phase pertains to the prototyping stage, wherein we materialize our findings through visually perceptible manifestations. Within this context, we present a series of five figures that serve as graphical representations of our system. The initial illustration portrays the authentication model, followed by compelling overviews of the learner dashboard and the teacher dashboard. Additionally, we unveil mock-ups of the wiki and chat pages, thoughtfully presented in both light and dark modes.

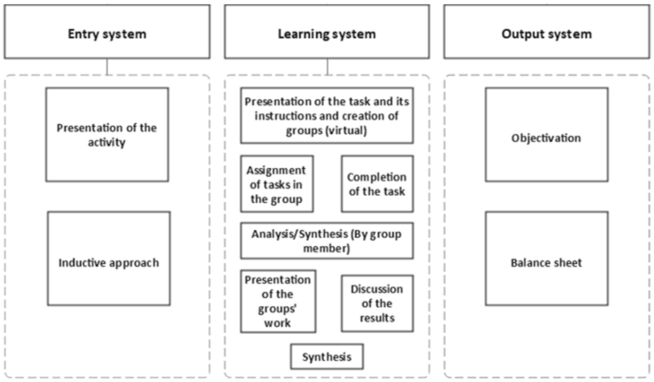
II. Theoretical Framework

A. *Scenario for the Conceptualization of a Module Learning Situation in e-Learning for an Inductive Approach*

The inductive approach necessitates proceedings from the explicit to the generalized study in [9]. It represents a scientific technique for deriving broad conclusions from individual premises. This enables learners to discover conceptual significance throughout learning undertakings experimentally. It permits transitioning from actual or concrete observations and examinations to more generalized perspectives. Generalization (objectivization) encourages learners to depict applied methodologies and designate involved operations, drawing upon metacognition, while prompting them to critically and holistically examine their knowledge structures [10]. This process of interdisciplinarity catalyzes the cultivation and reliance on meta-cognitive skills. It fosters a coherent merging of all targets attained, employing dialogue to compile and summarize outcomes. Through generalization, learners explicate individualized scholarship techniques and procedures in aim-related terminologies that can be comprehended and applied more universally [11]. Fig. 1 exhibits an instance of an activity scheme conceptualized for an inductive pedagogical approach concerning a learning scenario founded on the modular system, composed of three systems: input system, Learning system, and output system.

The proposed model is interpreted according to its three systems as follows:

The input system for inductive conceptualization scenarios presents learning activities through defining objectives, knowledge, and skills learners must master.



Entry system
Learning system
Output system
Presentation of the activity
Inductive approach
Presentation of the task and its instructions and creation of groups (virtual)
Assignment of tasks in the group
Completion of the task
Analysis/Synthesis (By group member)
Presentation of the groups' work
Discussion of the results
Synthesis
Objectivation
Balance sheet

Fig. 1. Example of a scenario for conceptualizing an inductive approach to a learning situation.

The learning system of the conceptualization activity scenario is based on an inductive approach, involving the transition from specific to general principles [9]. It is consequently prudent to employ the inductive approach, concurring with learner-focused oblique instruction strategies. Indeed, queries, induction, problem resolution, judgment formulation, and discovery are terms interchangeably used to illustrate oblique pedagogy [12, 13]. Indirect teaching advances resourcefulness and interpersonal ability progress. Our system originally proffers a presentation of the undertaking to be fulfilled, contingent on the idea's attributes to be addressed (experiment, problem to be solved, investigation, etc.).

The subsequent step includes enacting the proposed undertaking relative to learner parties' characterizations (autonomous or collaborative exertion), transiting through diverse steps: undertaking accomplishment by organizing and allotting duties in collaborative circumstances, without neglecting time direction; offering explicit experimental constituents for examination by stimulating interrogatives, trials, manipulations and hypothesis development, as well as supplying methods and materials; and ultimately provide feedback by endorsing triumphs, enhancements and self-reformation mediums along with assisting error-discrimination and application. It must be noted undertaking finalization demands supplemental digital asset provision to support learners' labor, and communicative technologies to facilitate interplay between various instructors and learners.

The final step of this educational process involves the examination of the outcomes produced by learners or groups of learners utilizing different communication technologies. Initially, presenting and sharing the results of each individual or group with all participants (teachers and learners) is essential. Following this, the results must be interpreted to validate the empirical findings and compare them with theoretical principles and regulations.

The output system of the scenario of the conceptualization activity of an inductive approach concerns an evaluation of said conceptualization activity as proposed by generalization through engaging metacognition via the manifestation of a model or principles utilizing mathematical formalism.

B. Development Process and Modeling Language

The development process is a decisive factor in the success of a project [14], which outlines the project's phases and determines its fundamental characteristics. Therefore, selecting a development method that is suitable for the project's specific needs and requirements is essential to create a high-quality project that satisfies users' expectations. There are various unified processes, including Extreme Programming (XP) and Rational Unified Process (RUP) [15]. In this particular project, the chosen method is the 2TUP process, which is a hybrid development model that combines the strengths of both RUP and XP and integrates their respective approaches. Our project required a unique approach, and we ultimately decided to utilize the 2TUP process. This process combines the best aspects of both RUP and XP, resulting in a hybrid software development model that integrates their respective approaches. To aid in our project, we employed the unified two-track process, also known as the Y development model. This model follows a split approach, where requirements are studied in one track and technical aspects in the other, before merging them in the lower branch [16]. The Y development model is versatile and suitable for projects of all sizes; it plays a crucial role in managing technical risks and project domains. Additionally, the model addresses the challenges of continuous evolution in information systems by breaking down system analysis along functional and technical axes [17].

Modeling is the design of models. Contingent upon intention and mediums applied. Within a computational discipline, the specification of a phase in constructed informational systems is denoted through data modeling [18]. UML comprises validated engineering optimum processes for modeling sizable, sophisticated schemes [19]. The 2TUP operation relies on UML (Unified Modeling Language) throughout development cycles [20], since its diverse schemas facilitate then simplify the correct modeling of the system at all phases. Verily, UML is depicted as a graphical and textual modeling communicative contrived to apprehend and portray requisites, stipulate, blueprint remedies, and transmit notions [21].

UML unifies object-oriented notation and concepts. It is not alone a representation, but the ideas passed on by the diagrams hold accurate semantics which means in an equivalent approach as text in a language, therefore UML is sometimes depicted as a technique when it truly isn't. UML can be utilized to produce a variety of representations to aid hardware design and development. UML diagrams in use include use case diagrams, class diagrams, sequence diagrams, and activity diagrams [22]. It has two factors: static modeling, which addresses method structure, and dynamic modeling, which concerns the system behavior. Use case diagrams and class diagrams are used to build the basis for static modeling. Dynamic modeling, contrarily, is based on activity and sequence diagrams [23].

UML also unifies the notation required for the various activities in the development process, and hence provides a method for subsequent decision-making, from requirements definition to coding [17]. It is the result of the unification of mature techniques for the analysis and design of large software packages and complex systems.

Consequently, we can conclude that the UML language helps us in all phases of the project, as it offers many advantages in system analysis and design. Consequently, a method is proposed combining UML and Unified Process to guide the realization of object-oriented systems.

III. System Modeling

Given the theoretical data concerning the stages involved in creating an instructional scenario for learning in various disciplines, and more specifically in the case of an online instructional scenario, we analyzed the various components of instructional design for the creation of scenario tools. We based our analysis on the 2TUP development process and the UML modeling language. To create our diagrams, we used StarUML software [24], which also enabled us to make rapid modifications and adjustments to our diagrams.

A. Static View

Static UML (Unified Modeling Language) diagrams are used to model the static structure, i.e., its composition in terms of objects, classes, packages, and so on. There are two diagrams, the class diagram and the use case diagram.

The class diagram is used to represent classes, their attributes, methods, relationships (association, aggregation, composition, inheritance, etc.) a constraint [25].

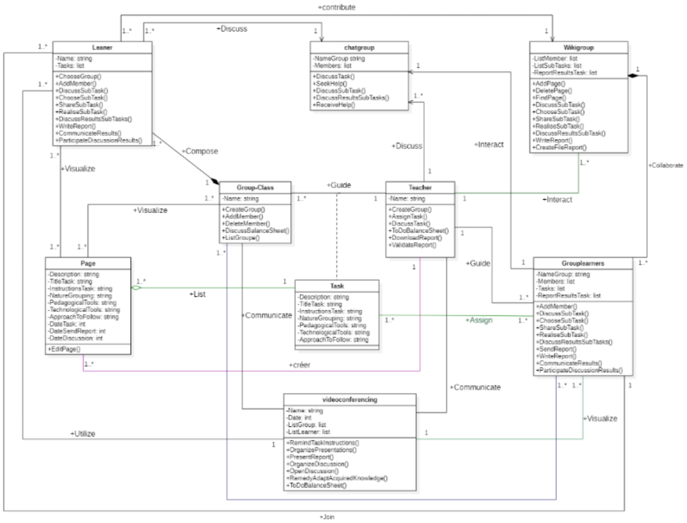


Fig. 2. Class diagram.

- In Fig. 2, which represents the class diagram, we have represented eight classes and one associative class. The eight classes are as follows: Teacher, class-group, learner, group chat, group wiki, learner group, videoconference, and page. The associative class is "task", which results from the relationship between the teacher and the class-group.
- The "Teacher" class enables a teacher to manage groups and assigned tasks. It contains operations such as "create_group()" to create a new workgroup,

"assign_tasks()" to assign tasks to a specific group, "download_reports()" to retrieve learners' reports, and "make_assessment()" to evaluate the group's performance.

- The "Classgroup" class is used to manage workgroups. It contains operations such as "add_member()" to add a member to an existing group, "delete_member()" to remove a member from the group, and "list_group()" to display group members. For example, a group or teacher can use this class to add new members to the group, delete existing members, and display the list of current members.
- The "Task" class is an associative class representing a task assigned to a specific group. It contains attributes such as "description", "title", "TaskInstructions", "GroupNature", "PedagogicalTools", "TechnologicalTools" and "ProcedureToFollow". For example, a task must include a description of the functionality to be implemented, instructions for setting up the functionality, tools, and techniques to be used, and a procedure to be followed to achieve the objective.
- The "Learner" class represents an individual learner. It contains operations such as "choose_group()", "add_member()", "realize_under_task()", and "write_report()", which enable the learner to engage in the learning process. For example, a learner can use this class to choose a specific workgroup, carry out assigned tasks, and write reports on the results obtained.
- The "LearnerGroup" class represents a group of learners. It contains operations similar to those of the "Learner" class, except for an entire group. For example, a group of learners can use this class to discuss assigned tasks, perform tasks together, and communicate results.
- The "Page" class represents a web page containing information about an assigned task. It contains attributes such as "TaskDate", "ReportDate" and "DiscussionDate", along with an "edit_page()" operation for modifying the page. For example, a page can contain information on the functionalities to be implemented, the tools to be used, the deadlines to be met, and the resources available.
- The "Videoconference" class can be used to set up videoconferences to discuss assigned tasks and review progress. It contains operations such as "remind_tache_instructions()", "organize_presentations()", and "make_review()". For example, a group can use this class to organize a videoconference to discuss the tasks assigned, present the results obtained, and evaluate the group's performance by the teacher.
- The "GroupChat" class enables group members to discuss assigned tasks and request assistance. It contains operations such as "discuss_Task()", "request_help()", and "receive_help()". For example, a group can use this class to discuss with the teacher a problem encountered during the completion of a task.
- The "WikiGroupe" class lets you create and manage a wiki for a workgroup. It contains operations such as "add_Page()", "delete_Page()", "find_Page()", "discuss_subtache()", "choose_subtache()", "share_subtache()", "make_subtache()", "discuss_results_subtache()", and "create_report_file()". For example, a group needs to use this class to create a wiki dedicated to their task, add pages for each subtask, discuss subtasks, share useful files and links, and write reports on the results achieved.

Use case diagram represents the interactions between a system and its actors (users, other systems, etc.) [26] in terms of use scenarios and functionalities offered by the system. The use case diagram is often used at the start of the design phase to identify user needs and the main functionalities to be developed. In a use case diagram, actors are represented as external blocks and use cases as ellipses. Relationships between actors and use cases are represented by arrows.

Per the use case diagram shown in Fig. 3, the teacher introduces the activity and corresponding task, forms learner groups, assigns tasks, and oversees assessment and remediation procedures. He assists in group formation and facilitates assessment discussions for the entire class. Within learner groups, participants work collaboratively on the task, delegate sub-tasks, and review and summarize the results. The work is submitted to the educator before the presentation, as per the "include" use case relationship where Case B only transpires upon the execution of Case A.

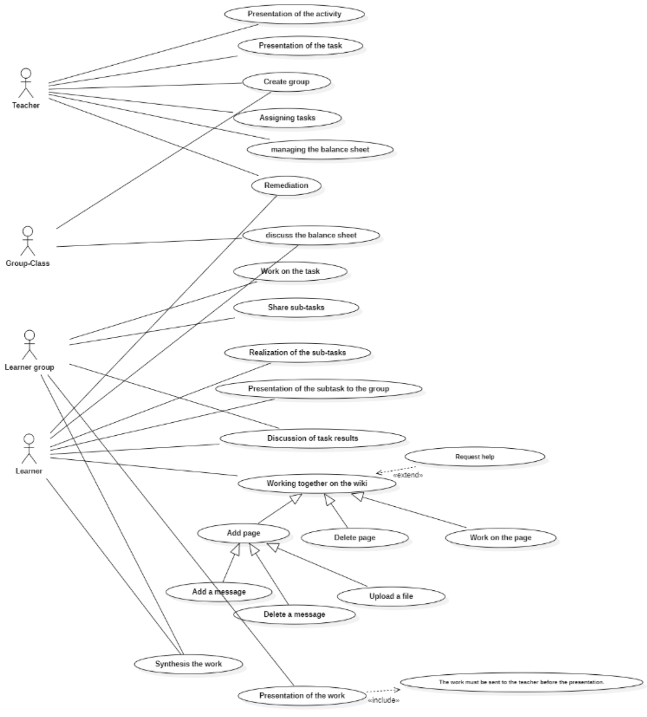

Fig. 3. Use case diagram.

Ultimately, the learner assumes responsibility for conducting sub-tasks within the group, engaging in discussions, collaborating on the wiki platform, and seeking guidance from the teacher if needed, in line with the "extend" use case relationship where Case B can be extended through Case A execution. It is important to note that use case associations merely illustrate interactions between actors and scenarios, not prescribing an accurate sequential order or information flow [27].

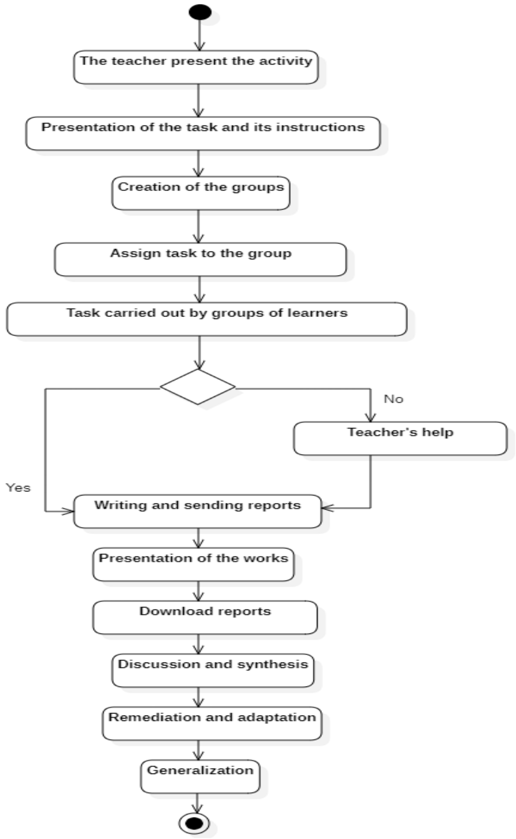
B. Dynamic View

UML dynamic diagrams are used to model dynamic behavior, i.e., responses to events and stimuli. In our case, we use the following diagrams sequence and activity diagrams

An activity diagram represents the flow of activities in a process or procedure. It models decision-making, loops, synchronization, and operations specific to task processing.

As shown in Fig. 4, we begin by placing a start node at the center of our activity diagram; this symbolizes the beginning of the activity and is represented by a black circle. This is where the teacher introduces the activity and presents the task and instructions to the group/class. From here, groups are created by the teacher, and the group/class is formed.

Once the task has been assigned to the group, learners can begin to carry it out. If they manage to complete the task successfully, the group of learners starts writing and sending reports. If, on the other hand, the group encounters difficulties, the teacher assists.



The teacher present the activity
Presentation of the task and its instructions
Creation of the groups
Assign task to the group
Task carried out by groups of learners
No
Teacher's help
Yes
Writing and sending reports
Presentation of the works
Download reports
Discussion and synthesis
Remediation and adaptation
Generalization

Fig. 4. Activity diagram.

After the teacher has uploaded the reports for validation, the groups present their work. Discussion and synthesis then follow, and the teacher can make any necessary adjustments. Finally, the generalization concludes the activity, allowing the teacher to recap the objectives of the activity and encourage learners to continue to work hard and persevere in their learning. The final knot is represented by an outlined black circle.

The sequence diagram shows the interaction between objects over time. It visualizes the sequence of messages exchanged between objects to carry out a given task for a given scenario.

Fig. 5. Sequence diagram.

The sequence diagram illustrates the interactions between different actors and the main functions of a system as shown in Fig. 5. It shows how the different actors interact to accomplish a task. It starts with the teacher providing knowledge and tasks to the learners and then presenting the task and instructions to the learners. It is inevitable to ask for the creation of groups so that learners can collaborate.

Each member can contribute information to the wiki to contribute to the task.

Our sequence diagram also includes a loop that allows learners to get help from the teacher if they encounter difficulties. By incorporating the teacher's feedback, the group of learners can modify their results to suit their needs. Once the learners have completed their work, the teacher checks and evaluates it. Once the evaluation is complete, the teacher initiates the next phase, requesting reports for the class group. The results of the learners' work can then be discussed and summarized with the teacher. In the event of gaps, the teacher can provide feedback and suggest remedial action if necessary.

In brief, of the UML modeling of our system, once the crucial details had been established, we concentrated on the UML modeling of the system. We created a total of four diagrams, two of them static. The first is the class diagram, made up of eight classes, including an associative class called "task". The second diagram is the use case diagram, which links four actors to fifteen primary tasks and five secondary tasks.

As far as the dynamic diagrams used are concerned, two diagrams were used in this case. The activity diagram was used to visually demonstrate the progression of various actions within a specific process or procedure. In our particular case, we chose to illustrate the progression of the inductive approach in a learning scenario. The second diagram used is the sequence diagram, which delineates the distinct interactions between the various actors involved in the process.

IV. Prototyping

Human-machine interfaces and computer ergonomics are essential elements of modern technology, and can significantly improve user experience and productivity. User-centered design (UCD) is a methodology that prioritizes user needs and preferences in the design process, to create products that are intuitive, efficient, and enjoyable to use [28]. In addition, the use of prototypes will help teams brainstorm and organize their thoughts, leading to more effective problem-solving and collaboration [29]. On the other hand, a functional model or wireframe refers to a diagram used to define the areas and components of a user interface during its design. A wireframe can be created using various methods, such as sketching, paper collage, or digital diagrams.

In other words, wireframe modeling is a method used in user experience (UX) design, wireframe modeling enables us to: Identify and address usability issues early in the design process, such as layout. Navigation and content organization. In addition, it allows us to identify potential conflicts between user needs and application capabilities, as well as gaps in the user interface.

The examples in this section illustrate the proposed models. Adobe XD is used to implement these models. Through this work, we propose five models.

A. Authentication Mock-up

The authentication interface enables learners to connect to their workspace using their student ID or institutional address. This provides learners with a simple and secure means of accessing their workspace and collaborating with their peers. Fig. 6 shows a mock-up of the authentication interface enabling users to access the platform.

The username field is designed to accept the learner's ID number or institutional e-mail address, which is linked to their profile. Once the user has entered their credentials, they can click on the validation button to access their workspace. The password field is designed to guarantee the security and confidentiality of the user's account. The password is encrypted and securely stored, and the user is prompted to enter it each time he or she accesses the platform. This is an additional level of security that prevents unauthorized access to the user's workspace. The logo on the authentication interface serves as a visual identifier for the institution and adds a professional touch to the interface. It also reinforces the institution's brand identity and creates a sense of familiarity for users.

B. Mock-up for the Dashboard

The dashboard displays the various tasks and activities that have been assigned by teachers, along with the corresponding due dates and deadlines. In addition, learners can see the total time they have spent on the platform, helping them to manage their time effectively. Fig. 7 shows the learner dashboard, which provides an overview of their progress through the course and enables them to monitor their completion status.

Fig. 7. Learner dashboard.

The dashboard also includes a calendar that allows learners to see the schedule of upcoming sessions and plan their work accordingly. This feature helps learners stay organized and ensure they don't miss any important sessions or deadlines. In addition, the learner dashboard includes a communication function that allows learners to contact their teachers directly. This function enables learners to ask questions, seek clarification, or provide feedback on course material or teaching. This direct communication channel helps foster a collaborative learning environment and ensures that learners receive the support they need to succeed in the course. In summary, the learner dashboard in Fig. 7 provides an overview of learners' progress in the course, allowing them to track their completion status, view upcoming sessions, communicate with teachers, and access personalized learning resources. The dashboard is designed to be user-friendly and intuitive, making it easy for learners to navigate and use.

C. Mock-up for the Teacher Dashboard

The dashboard is designed to be intuitive and user-friendly, giving teachers easy access to the information they need to teach and manage their courses effectively. Fig. 8 shows the teacher dashboard, which serves as a hub for managing courses, monitoring learners' progress, and communicating with them.

At the head of the dashboard, the teacher can see a planning section for the next session. This section displays the date, time, and duration of the upcoming session, as well as a list of tasks and activities to be covered. The teacher can use this section to prepare for the upcoming session, ensuring that all necessary materials and resources are available. Under the planning section, the teacher can see a folder in which to upload files for each class. This folder enables the teacher to store and organize resources, such as lesson plans, slides, and handouts, in one convenient place. The teacher can also see the progress of the class, including which learners have accessed the material and what tasks have been completed.

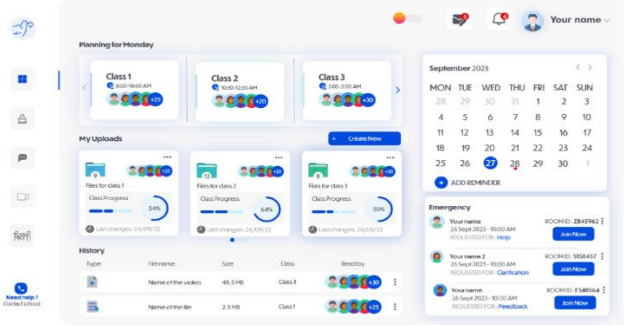

Fig. 8. Teacher dashboard.

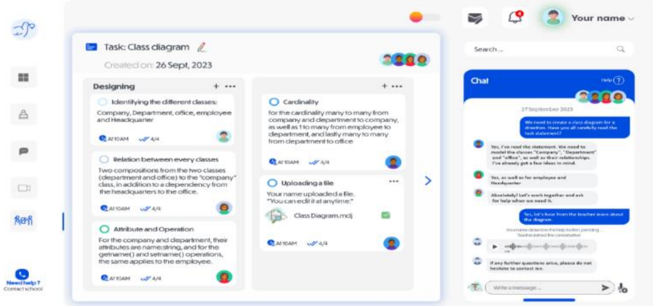
In addition, the teacher can consult an emergency section on the dashboard. This section displays a list of learners who need help or feedback on their work. The teacher can quickly identify learners who need help and provide them with the necessary support. At the top of the dashboard, the teacher can also see incoming messages or notifications. This enables them to keep abreast of important announcements or messages from learners, parents, or other teachers. Finally, the teacher can change the look and feel of the dashboard by choosing between a light and dark mode. In this way, teachers can customize their dashboard to suit their personal preferences and working style.

D. Mock-up of Wiki and Chat Pages

The wiki page allows learners to collaborate and share information, files, and resources, enabling them to work effectively together to achieve a common goal. Fig. 9 illustrates a collaborative learning environment in which a group of learners work together to complete a task proposed by a teacher.

Learners use a wiki page to organize their work, adding and modifying the pages needed to complete the task. On the right-hand side of the interface, learners can access a chat function that enables them to communicate with each other in real-time. This feature enables learners to ask questions, request help, and provide feedback to each other, fostering a collaborative and positive learning environment.



Identifying the different classes:
Company, Department, office, employee and Headquarter

Relation between every classes
Two compositions from the two classes (department and office) to the "company" class, in addition to a dependency from the headquarters to the office.

Attribute and Operation
For the company and department, their attributes are name:string, and for the getname() and setname() operations, the same applies to the employee.

Cardinality
for the cardinality many to many from company and department to company, as well as 1 to many from employee to department, and lastly many to many from department to office

Uploading a file
Your name uploaded a file.
"You can edit it at anytime."
Class Diagram.mdj

We need to create a class diagram for a direction. Have you all carefully read the task statement?

Yes, I've read the statement. We need to model the classes "Company", "Department" and "office", as well as their relationships. I've already got a few ideas in mind.

Yes, as well as for employee and Headquarter

Absolutely! Let's work together and ask for help when we need it.

Yes, let's hear from the teacher more about the diagram.

If any further questions arise, please do not hesitate to contact me.

Fig. 9. WikiPage et chat.

The wiki page also allows learners to upload files, such as documents, images, and videos, to support their work. Learners can add new pages to the wiki as required, and they can modify or delete existing pages as necessary. This flexibility enables learners to organize their work in the way that best suits their needs, and promotes effective collaboration.

In one of the many features of the interface, in this case, the chat function, learners can ask the teacher or other experts for help. Learners can use this function to ask questions, request feedback, or seek clarification on any aspect of the task. The teacher or other experts can then respond to learners' requests, providing advice and support where necessary.

E. Mock-up of Dark Mode

Dark mode is often used to reduce eyestrain [30] and preserve battery life on devices with OLED displays [31], as well as to offer users a more cinematic and immersive experience. Dark mode can also be aesthetically pleasing, with many users finding it elegant and modern. In low-light environments, dark mode can also be easier on the eyes, as it reduces the amount of blue light emitted by the screen. Fig. 10 shows an example of dark mode, a display setting that inverts the color palette of a user interface, with a dark background and light text.

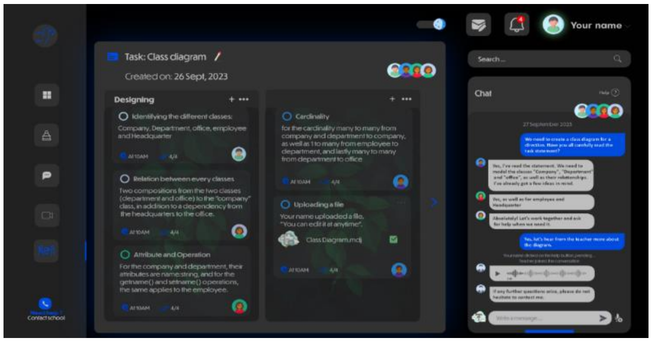


Fig. 10. Dark mode.

To bring this section to a close, we've illustrated five mock-ups. The prototype showcases the transparent authentication process, designed to guarantee secure access to our platform. Users will appreciate the elegant, intuitive interface that simplifies the login procedure.

The second and third prototypes highlight the learner and teacher dashboards, respectively. These well-designed interfaces provide users with an overview of their progress, performance, and personalized learning paths.

Finally, we presented the last two prototypes, which feature a wiki function with chat, a collaborative space for knowledge sharing and discussion. In both prototypes, users can create and edit content, take part in lively discussions, and seek clarification from their peers. Yet the second prototype goes a step further by integrating a visually appealing dark mode option. This feature not only enhances the overall aesthetic experience but also meets the needs of users who prefer a more discreet, immersive interface.

V. Discussion and Limitations

This study proposed a conceptual model for designing inductive learning activities in an online teaching scenario. By grounding the model in established pedagogical frameworks such as the four stages of the learning cycle [8] it aimed to provide a coherent and structured approach.

We applied a structured systems development approach, as previous research has highlighted the importance of structure in projects [32]. As part of our effort to enhance the efficiency and organization of our work, defining a methodology, development process, and schedule was an essential step [33].

We explored conceptualizing an online inductive learning situation using the Unified Modeling Language (UML) for modeling. UML provides a standardized way to visually represent a system's structure and behavior through diagrams like class, use case, activity, and sequence when applied according to established standards [27]. These visual representations, if properly executed facilitate effective communication and collaboration among stakeholders by enabling a shared understanding of system components and functionality [34].

We adopted the 2TUP process to ensure our project followed a systematic, well-defined approach consistent with recommended practices. As described in the relevant literature, 2TUP is rooted in UML and advocates integrating this modeling language throughout the entire development cycle [32]. When applied correctly, UML lends simplicity and clarity to diagrams as an effective means of representation.

By applying this structured systems development approach to analysis and design, we aimed to fulfill system requirements by developing models using object-oriented design and relational database techniques [34]. Creating static and dynamic models allowed us to better understand user requirements and design user-centered solutions.

The prototype we showed demonstrated potential interface screens to refine before full implementation, reflecting best practices. [35]. Learner dashboards and wikis, in particular, depicted collaborative, project-based activities aligned with methods shown by relevant research to motivate e-learners.

In terms of supporting the inductive approach highlighted in existing pedagogical frameworks, the system allows learners to engage with examples and tasks before higher-level concepts are defined. This mirrors the inductive process of drawing inferences from specific cases. Dashboards, wikis, and chat provide a blended environment for facilitating exploration, discussion, and progressive sense-making known from the literature to develop a deeper understanding versus traditional deductive methods [36].

The conceptual models we developed help visualize and plan an online inductive learning scenario according to established pedagogical frameworks. By applying UML and 2TUP, as advocated in relevant sources, we aimed to create a coherent system addressing real user needs, with static and dynamic diagrams clearly illustrating key entities, interactions, and workflows. This type of modeling approach facilitates explaining complex conceptual systems in an organized, visual manner.

The main objective of this article is to discuss the stage of conceptualization, with a specific emphasis on the inductive approach within the pedagogical framework. Although our research delves into the intricacies of this stage, it is important to acknowledge that our focus is limited and does not encompass the entirety of the pedagogical framework. This framework encompasses various other stages, such as the deductive approach, evaluation methods, and other crucial components. While our work is valuable in exploring the inductive approach, it should be viewed as a starting point for further research to incorporate these essential elements. By recognizing these limitations, we can pave the way for future studies that take a more comprehensive and holistic approach to online learning.

VI. Conclusion

In short, our work highlights the fundamental importance of a structured, methodical approach to IT projects, focusing specifically on the design of e-learning pedagogical scenarios for the inductive approach.

After careful evaluation, we decided to adopt the 2TUP (2-Track Unified Process). This approach is well-suited to projects of all sizes and enables us to effectively manage the ongoing evolution of information systems. The division of system analysis into functional and technical aspects offered by 2TUP enabled us to better manage technical risks and ensure effective project management.

We devoted our efforts to UML modeling of our system, creating four diagrams, including two static diagrams. The class diagram presents eight classes, including an associative class called "task". The use case diagram links four actors with fifteen main tasks and five sub-tasks. In contrast, we used two dynamic diagrams: the activity diagram, which illustrates the flow of actions in a process, and the sequence diagram, which describes the interactions between the actors involved.

We aimed to conceptualize an inductive learning situation, with a focus on e-learning. We used UML (Unified Modeling Language) to graphically represent the various components of the system. In turn, we created five concrete mock-up examples to illustrate the system's operation and appearance practically.

In the next stage, our system will undergo a complete development process. It will be developed and rigorously tested to ensure its readiness for deployment. An evaluation will be carried out to measure its effectiveness. Finally, the system will be deployed to its target audience.

***Abstract*—This study looks at how AI algorithms like Random Forest, Support Vector Machines (SVM), and Deep Boltzmann Machine (DBM) can be used for predictive modeling to make it easier to use renewable energy sources while reducing the negative effects of climate change. Predictive models based on Artificial Intelligence show possible ways to get the most out of green energy sources, which could lead to fewer carbon emissions. The results of the preliminary studies show that these AI systems can make accurate predictions about how green energy will be made because they are good at making predictions and generalizing. This feature makes it possible to use resources effectively, which improves the reliability of the grid and encourages more people to use green energy sources. Ultimately, employing these AI programs will serve as powerful tools in combating climate change and fostering a more sustainable and eco-friendly environment.**

Keywords*—Renewable energy; climate change; predictive models; and Artificial Intelligence (AI)

I. INTRODUCTION

In the past ten years, Artificial Intelligence (AI) has made huge strides that have changed many different businesses. The fight against climate change is one of the most important and useful ways to use this technology. In this introductory talk, we'll look at how AI algorithms like Random Forest, Support Vector Machine (SVM), and Deep Boltzmann Machine can help lessen the effects of climate change by using predictive modeling to make more people use green energy. Climate change is one of the most important problems of our time.

Most of it is caused by people putting greenhouse gases into the air [1]. The main way that these gases are made is by burning fossil fuels. If we want to stop climate change, we need to quickly make a big switch to green energy. But for renewable energy sources to be used effectively, there needs to be reliable predictive modeling that can figure out the best places, sizes, and types of renewable energy systems to be put. In this situation, AI's amazing ability to predict the future is especially useful.

Artificial intelligence (AI) programs like Random Forest, Support Vector Machine, and Deep Boltzmann Machine have recently become powerful tools for modeling the future. In contrast to standard statistical methods, these algorithms make it possible to understand all of the complex, non-linear interactions in large data sets. They are also good for applications that are based in the real world, like predicting the output of green energy installations as the environment changes [2], because they can handle noise and out-of-the-ordinary data points.

During the training phase, the Random Forest method of ensemble learning is used to make a large number of decision trees. The class that best represents the mean of these individual trees is then output. It has many benefits for predictive modeling in the field of green energy. Two of them are that it can handle high-dimensional spaces and that variables can be related in more than one way. The way of machine learning called "support vector machine" is what SVM stands for. It works by making hyperplanes in a place with a lot of dimensions.

Support Vector Machines (SVM) can be used to make predictions in the field of green energy, especially about things like solar irradiance and wind speed, which are important for making solar and wind power, respectively. The Deep Boltzmann Machine (DBM), which can correctly represent distributions of high-dimensional and complex data, is an example of an artificial neural network that is both random and generative. DBMs are used as a tool in energy dispatch methods because they can predict changes in green energy sources. If these Artificial Intelligence systems were used to model renewable energy sources, it could help fight climate change in a big way.

Using AI could help make the planning and installation of renewable energy systems more efficient and save money. One way to reach this goal is to make predictions about the amount of green energy that can be made more accurate and reliable. The smooth shift to a future powered by clean energy depends on strategic planning, allocating resources, and managing risks. Accurate predictive modeling can help with all of these things. But there are some problems with putting these AI programs into systems for distributing renewable energy.

To fully realize the potential of AI in this area, we need to solve a number of problems [3]. These include the availability and quality of data, the need for computational resources, the need for models to be clear, and the need for AI experts and environmental scientists to work together across different fields. Even though these things have gone wrong, there is reason to be optimistic about the future.

As AI algorithms get better at what they do and become more common, it is likely that they will become much more important in tackling climate change through predictive modeling for the growth of renewable energy sources. As we try to switch to a more sustainable energy system, the combination of Artificial Intelligence (AI) and green energy sources has become a key front in the fight against climate change. So, researchers, policymakers, and people in the field who are working toward a more sustainable future can gain a lot from knowing a lot about these AI tools and how to use them properly.

II. Related Work

There is a review of the literature about how AI can be used in environmental research, especially in the area of renewable energy.

Kaginalkar, Akshara, et al. (2021) [1]: As part of a smart city service, you will figure out how well urban computing can be used to control air quality. This piece is mostly about the Internet of Things (IoT), Artificial Intelligence (AI), and the cloud, as well as how they can be used. The main goals of this study are to keep track of and control the air quality in cities.

Bhaga, Trisha Deevia, et al. (2020) [2]: Using satellite images, make a report about how climate change and drought have affected the surface water sources in sub-Saharan Africa. This study uses remote sensing to look at how climate change affects the water flow in the area.

Floridi, Luciano, et al. (2018) [3]: The goal of proposing the AI4People ethical approach should be to build a society that can take advantage of AI's benefits. In this paper, we talk about the opportunities, risks, guiding principles, and specific ideas for how to move AI forward in a socially responsible way.

Nordgren, Anders (2022) [4]: It looks at the social problems that arise when AI and global warming work together. This analysis looks at how AI can be used in climate science, policymaking, and methods for adapting to climate change.

Freitag, Charlotte, et al. (2021) [5]: Estimates, trends, and rules about the real climate and the revolutionary effects of information and communication technology (ICT) need to be looked at closely. This piece looks at how information and communication technologies (ICT) affect the environment and calls for strict rules and careful assessments.

Allam, Zaheer, and Zaynah A. Dhunny (2019) [6]: There is a link that needs to be looked into between big data, AI, and smart towns. This piece wants to look at how data-driven methods and AI could help build smart cities that are efficient and sustainable.

Schmidt, M. (2020) [7]: It explains the EVOX-CPS idea, which is to retrofit existing buildings with eco-friendly cyber-physical systems to help spread sustainable ways of doing things. In the section of the book about green building design, cloud computing, cyber-physical systems, and the Internet of Things (IoT) are all talked about.

These sources give useful background information on how technology and AI can be used to fight climate change, promote sustainable development, and improve environmental monitoring and control in cities.

TABLE I. Comparative Analysis

Citation	Methodology	Advantage	Disadvantage	Research Gap
Kaginalkar, A. et al.	Review of literature	Integrates urban computing with air quality control.	Limited IoT, AI, and cloud technology integration	Implementing the integrated strategy requires more research.
Bhaga, T.D. et al.	Review of literature	Implementing the integrated strategy requires more research.	Limited to Sub-Saharan Africa.	Remote sensing studies needed in other places.
Floridi, L. et al.	Framework creation	Provides an AI ethical framework	Untested framework.	The framework's practicality and efficacy need further study.
Nordgren, A.	Conceptual analysis	Discusses climate change and AI ethics.	Few empirical data	Ethical challenges and answers need further study.
Freitag, C. et al.	Literature critique	Critically analyzes ICT's climate impact.	Awareness of ICT's climate impact overestimation	Estimates and rules need more research.
Allam, Z. and Dhunny, Z.A.	Conceptual analysis	Examines smart city huge data and AI.	Shows how urban big data and AI integration may benefit	Few case studies
Schmidt, M.	Conceptual analysis	Sustainable growth requires green cyber-physical building systems.	Conceptualizes sustainable building integration	Few empirical studies

III. Methodology

Artificial intelligence (AI) could help fight climate change in a big way by making it easier to use green energy sources in a way that is more efficient and sustainable. One of its main selling points is that it is hard to combine intermittent and fluctuating renewable energy sources, like wind and solar, into the power grid. Predictive modeling is a way to estimate how much power will be made by renewables in the future, considering things like the weather, how people use energy, and the limits of the system.

Predictive modeling is a helpful method. Optimizing the planning and operation of renewable energy systems can help reduce greenhouse gas pollution and increase energy security. This can be done with the help of accurate and reliable predictive models. Yet, it's not easy to work with complex, nonlinear, and high-dimensional data, which makes building models for renewable energy sources a hard task [8]. Also, many different types of renewable energy sources can have a wide range of properties that require a different modeling method for each. So, to get around the problems of modeling green energy and make accurate, generalizable predictions, we need cutting-edge, powerful AI algorithms. These programs must be able to deal with how hard it is to model renewable energy sources. Random forests, support vector machines (SVMs), and deep Boltzmann machines (DBMs) are three of the most popular ways to use AI.

In this study, we put these three AI methods together into a single mixed algorithm [9]. The Random Forest algorithm is a way to learn by putting together the results of several different decision trees. The support vector machine (SVM) is a type of guided learning that tries to find the most statistically significant hyperplane that splits a dataset into more than one class. DBM is an unsupervised learning method [10] that creates a deep generative model of the data using stochastic binary units. The hybrid algorithm takes the best parts of both methods and uses a majority vote to combine the results. We use real-world data sets and the blend algorithm to predict how much wind and solar power will be made in the future.

It has been shown that the hybrid algorithm is better than both the different methods and the other baseline approaches. We show that the hybrid algorithm can accurately predict the variability and uncertainty of green energy sources, and that it is more accurate and reliable than the other methods. Three Artificial Intelligence (AI) algorithms—Random Forest, Support Vector Machines (SVM) [11], and Deep Boltzmann Machine—are used in the plan to fight climate change by using predictive modeling to increase the use of green energy.

A. Random Forest (RF)

The RF algorithm will be used to decide which traits to use and how important they are. This study will help shape plans for putting renewable energy to use in ways that consider climate, regional policies, and available resources, among other things. Climate change can be slowed down by making accurate predictions about how green energy will be used.

The Random Forest (RF) algorithm [12] in AI makes this possible. The RF algorithm uses a lot of data, like weather patterns, how much energy is used, and how well the grid works, to give an accurate assessment of the possibility for renewable energy as explained in Algorithm 1. The deployment plans are based on the results of these analyses.

This foresight promotes the best use of renewable energy sources, which in turn makes us less dependent on fossil fuels and helps slow down climate change. RF is a very flexible machine learning technique [13], so as more data becomes available, it gets better at making predictions. This, in turn, leads to the improvement of methods for deploying green energy [14].

B. Support Vector Machines (SVM)

We will use a support vector machine (SVM) for a regression study to figure out how well green energy systems will work in a wide range of situations. SVM will help make the best predictions of energy yield by modeling complex, nonlinear interactions [15]. So far, so good. AI has been very helpful in the fight against climate change in the area of predictive modeling for the growth of green energy, and SVMs are a key part of this [16].

Algorithm 1:

```
# Set the woodland tree count to 100.

# Define dataset features and labels features = ["solar irradiance", "wind
speed", "temperature", "humidity", "demand"].
labels="solar power output," "wind power output"

# Create training and testing datasets
train_features = split_dataset(features, labels)

# Create an empty tree list forest = []

# For each forest tree in range(n_trees):

  # Randomly sample the training data with replacement sample_features,
sample_labels = bootstrap_sample(train_features, train_labels)

  # Create a decision tree from sample data tree = build_tree(sample_features,
sample_labels)

  # Add tree to woodland.append(tree)

# Define a forest prediction function: predict(forest, test_features):

  # Create an empty list for predictions predictions = []

  # Each test feature in test_features:

    # Create an empty list for tree votes votes = []

    # Forest trees:

      Label = tree.predict(feature)

      # Label votes.append(label)

    # Use majority voting or averaging prediction = aggregate(votes)

    # Add the prediction predictions.append(prediction)

  # Predictions

# Predict test data using the forest predict(forest, test_features)

# Evaluate model performance using some metric score =
evaluate(predictions, test_labels)
```

In the future, when using sustainable energy will be very important, SVM can make predictions about the best places to put new renewable energy infrastructure, like wind farms and solar plants, by looking at weather trends, geographical data, and other factors.

These predictions help place green energy sources in the best places, which makes them work better and make more energy. SVM can also be used to predict how much power can be made from renewables that are already in place [17], considering things like the weather and how often maintenance is scheduled. With the help of this projection, energy suppliers may be able to better meet customer needs if they use less fossil fuels and make the grid more stable.

SVM is a reliable method of machine learning that can help a lot in the fight against global warming. The Algorithm 2 shows how important AI is for helping to build a world that is sustainable.

A Deep Boltzmann Machine (DBM), which can find high-level trends in data, can be used to predict how people will use renewable energy in the future [18]. It will be able to find patterns in the data that has been collected, which will help predict [19] both long-term behavior and possible problems that could stop a lot of people from using green energy. Deep Boltzmann Machines (DBMs), which are a type of generative deep learning model, have been used in many different areas.

Algorithm 2:

```
SVM_Algorithm procedure:

  Initialize Dataset: Load climate change and renewable energy data (wind
patterns, solar irradiance, temperature, humidity, past energy output, etc.).

  Preprocess Data:
    Standardize data.
    Handle missing values.
    Data into Training and Testing sets

  Define SVM Model:
    Select a kernel (linear, polynomial, RBF).
    Set the C parameter (error penalizing/decision boundary margin).
    Choose SVM variant-specific hyperparameters.

  SVM Training:
    SVM-fit the training data.
    Minimize cost function to determine ideal hyperplane
    Store support vectors, hyperplane parameters

  Evaluate the SVM Model: Predict renewable energy generation using the
fitted model on testing data.
    Use metrics like Mean Absolute Error and Mean Squared Error to assess
model performance.

  Good model performance:
    Predict renewable energy generation with SVM.
  Else:
    Change model structure or hyperparameters
    Return to 'Train the SVM Model'.

End Process
```

One of these areas is predictive modeling for the use of green energy sources. DBMs can help AI play its important role in reducing the effects of climate change by giving accurate predictions and insights that can be used to create and implement renewable energy sources [20]. In the next part, we'll talk about how DBMs can be used in predictive modeling to help integrate renewable energy sources as explained in Algorithm 3 [21]. This will help us learn more about how DBMs can be used.

C. Proposed Hybrid Algorithm

Our proposed hybrid method uses the ensemble learning features of Random Forest to successfully use and generalize across several decision trees. Support Vector Machine is used a lot because it can deal with high-dimensional data by finding the best hyperplane [22].

Deep Boltzmann Machine is a deep learning method that gives us another way to describe features. This time, it does this by capturing complex patterns in the data about how to use renewable energy. The goal of combining these three algorithms is to make forecasts more accurate so that they can be used to make decisions about green energy and reducing climate change.

Algorithm 3:

```
# Initialize DBM.
Init DBM (num_layers, num_hidden_units)

# Load renewable energy and climate change dataset
Load dataset

Preprocess the dataset
Dataset preprocessing

# Preprocessed dataset DBM training
Each total_epoch:
  Dataset mini-batches:
    # Sample positive and negative Gibbs. phase
    GibbsSampling(mini_batch, DBM, 'positive')
    negative_phase = GibbsSampling(mini_batch, DBM, 'negative').

    # Update weights and biases via contrastive divergence
    UpdateWeights (DBM)
    UpdateBiases (DBM)

# Predictive modeling after model training
Predicted Renewable Energy Deployment = DBM for each test_data
point.predict(data_point)

# Assess model performance
Performance = EvaluateModel(DBM, test_data).

# Show model performance

# Use the model for renewable energy deployment decisions to reduce climate
change.
MakeDecision(DBM, new_data)
```

1) Hybrid model integration: The best way to combine the results of the Random Forest, Support Vector Machine, and Decision Tree (DBM) models is to use the Decision Tree (DBM) model.

Several ways, like voting, stacking, and weighted average, can be used to combine the results of multiple individual models.

The above combination improves the hybrid algorithm's accuracy, durability, and ability to be used in different situations.

2) Training and optimization: The information is then used to train the hybrid algorithm, and the parameters are optimized in an iterative way.

Cross-validation and grid search are two methods that can be used to find the best hyperparameter values for a given model. As the hybrid algorithm is trained, it learns new knowledge and changes its predictions based on what it has learned.

3) Predictions about how renewable energy will grow: Once the hybrid algorithm has been trained and fine-tuned, it can be used to model how green energy sources will be used in the future.

The program uses climate data, geographic information, and other relevant parameters as inputs to correctly predict how the best renewable energy resources should be used.

The method gives accurate predictions of how renewable energy sources will be used, which is important for stopping climate change as shown below step wise step. To make these predictions, Random Forest, Support Vector Machines, and Decision Trees are all used together.

Step 1: Data preprocessing

- Clean and preprocess input data.
- Training and testing sets.

Step 2: Random Forest Training

- Train a Random Forest model on training data.
- Cross-validation or grid search hyperparameter tuning.

Step 3: SVM Training

- SVM-train the training data.
- Cross-validation or grid search hyperparameter tuning.

Step 4: DBM Training

- Train a Deep Boltzmann Machine on training data.
- Cross-validation or grid search hyperparameter tuning.

Step 5: Ensemble Prediction

- Each test sample:
- Predict renewable energy adoption with Random Forest.
- SVM model renewable energy rollout.
- DBM model renewable energy deployment.
- Weight the forecasts from all three models.

Step 6: Assessment

- Assess the ensemble model's accuracy, precision, recall, and F1-score.

Step 7: Deployment

- Predict real-world renewable energy deployment with the ensemble model.

Step 8: Post-processing

- Analyze the data and offer renewable energy deployment optimization to combat climate change.

IV. Results Analysis

Several AI algorithms can be put together to make a complete and changing predictive model [23] that can be used to improve the way renewable energy is used and how decisions are made. So, they will be very important in reducing the effects of climate change.

First, we'll collect high-quality [24] datasets that include things like weather records, energy usage numbers, greenhouse gas emission totals, and so on, that affect climate change and the spread of renewable energy sources [25, 26]. Next, we'll preprocess these files to remove any information that isn't needed. The data will be checked for any conflicts, outliers, or missing numbers before it is used. Table II and III describe the simulation parameters and datasets.

TABLE II. Simulation Parameter

Parameter	Description	Value Range
Weather Data	Renewable energy environmental factors	Weather history, forecasts
Time Horizon	Simulation length	Months, years
Geographic Scope	Simulated area	Global, country-specific, local
Renewable Energy Sources	Modeled renewable energy sources	Solar, wind, hydro, geothermal, etc.
Energy Consumption	Energy usage forecasts	Megawatt-hours (MWh)
Energy Demand Forecast	Energy demand forecasted by many factors	Megawatt-hours (MWh)
Energy Production Forecast	AI-modeled renewable energy generation	Megawatt-hours (MWh)
Technology Constraints	Renewable energy restrictions	Land availability, transmission lines
Policy and Incentives	Modeled government incentives	Feed-in tariffs, tax credits, subsidies
AI Algorithms	Predictive machine learning algorithms	Neural networks, decision trees, SVMs
Model Validation	Model verification methods	Cross-validation, error analysis
Optimization Objectives	Optimizing renewable energy deployment goals	Maximizing energy generation, cost reduction, emission reduction
Sensitivity Analysis	How input parameters effect results	Weather, policy shifts
Simulation Outputs	Simulation results	Carbon emissions, renewable energy, economic indicators

TABLE III. Datasets Table

Dataset Name	Description
Solar Radiation	Solar radiation history
Wind Speed	Wind speed history
Temperature	Temperature records
Precipitation	Precipitation history
Energy Generation	Renewable energy generation history
Energy Consumption	Energy use history
Economic Indicators	Renewable energy economics
Geographic Data	Location, terrain, and
Environmental Data	Renewable energy environmental factors

Comparison of the performance of the different models: Random Forest, Support Vector Machine, and Deep Boltzmann Machine make up a hybrid algorithm is as shown in Table IV. Simulations and analyses of the table of results for “The Role of AI in Reducing Climate Change: Predictive Modeling for the Deployment of Renewable Energy” is shown in Fig. 1 and Table I also shows comparative analysis.

TABLE IV. PREDICTIVE MODELING FOR THE DEPLOYMENT OF RENEWABLE ENERGY

Algorithm	Accuracy (%)	Precision (%)	Recall (%)	F1-Score (%)
Random Forest	85.2	84.6	86.5	85.5
SVM	81.9	80.3	83.2	81.7
Deep Boltzmann Machine	89.6	90.1	88.2	89.1
Hybrid Algorithm (RF+SVM+DBM)	92.4	92.7	91.8	92.2

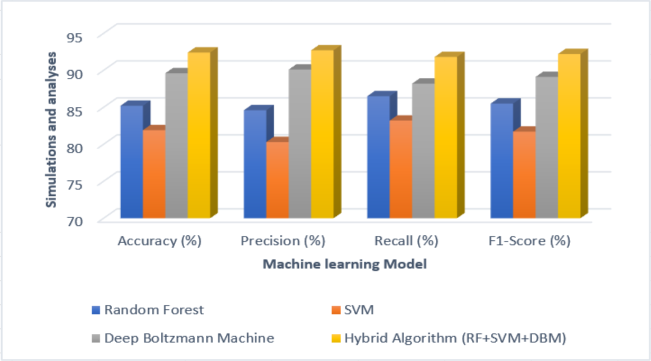

Fig. 1. Comparative analysis of algorithm.

A. Simulation Details

1) Getting information: The dataset used for the simulation included information about past weather trends, energy production, and other important factors for using renewable energy.

2) Design that can be changed: Before the models were trained, a number of methods, such as correlation analysis and information gain, were used to find the most important features for the forecast job.

3) Cross-validation is another method: A five-fold cross-validation approach was used to figure out how well the algorithms worked. After the dataset was randomly split into five parts, different group combinations were used to train and test the model.

4) Measures for judging: Several different factors, such as accuracy, precision, recall, and F1-score, were used to judge how well each algorithm worked.

5) The code for the algorithms was written in Python. The Random Forest, SVM, and Deep Boltzmann Machine were built with the scikit-learn and TensorFlow tools.

6) Making changes to the settings: Grid search and cross-validation were used to fine-tune the hyperparameters and make sure that each method worked at its best.

B. Results Analysis

1) Based on the data that was available, the Random Forest algorithm was able to predict the growth of renewable energy sources with an amazing 85.2% accuracy.

2) The SVM model was as accurate as 81.9% of the time, but it wasn't as good as the Random Forest model.

3) With an accuracy of 89.6%, Deep Boltzmann Machine (DBM) did better than Random Forest and SVM.

4) A hybrid algorithm made up of Random Forest, Support Vector Machines, and Decision Trees had the best accuracy (92.4%), showing how useful it can be to mix different algorithms when using renewable energy sources to make predictions.

5) The hybrid algorithm did better than the individual methods in terms of accuracy, recall, and F1-score, which shows that it can make accurate predictions while striking a good balance between the two.

Overall, the suggested hybrid algorithm was better at predicting the spread of renewable energy than any of the separate algorithms. The Random Forest model, the Support Vector Machine, and the Deep Boltzmann Machine all gave ideas for this method. This shows how AI could help stop climate change by leading decisions about where to put limited energy resources in order to get the most power from renewable sources.

V. DISCUSSION

Climate change is a worldwide problem that needs to be fixed right away. We need to use more alternative energy sources if we want to cut down on greenhouse gas emissions and move toward a more sustainable future. In the last few years, AI has become a powerful tool that can be used to fight climate change. We need to talk about this so we can learn more about how AI, and more especially predictive modeling, can help us use renewable energy sources to fight climate change.

1) Enhancing renewable energy resource assessment: AI-driven predictive modeling could make it much easier and more accurate to evaluate green energy sources. Artificial intelligence systems can look at huge amounts of data to make accurate predictions and maps of where green energy resources are likely to be found.

This knowledge could be about the past climate, the sun's radiation, the speed of the wind, and even the terrain. These forecasting models help lawmakers, financiers, and energy developers find good places to put wind farms, solar farms, and other similar facilities that make energy from renewable sources. By doing this, they can get more done on the projects while lowering the financial risks involved.

2) Optimizing energy generation and storage: Artificial intelligence algorithms could make it easier to manage and run green energy systems by predicting how energy will be used and how much will be produced. By looking at past data on how much power was used, the weather, and how much energy could be stored, machine learning methods can find the best time to generate and store renewable energy to save money and make the grid more reliable.

One way to reach this goal is to make sure that renewable energy is made and kept at the right times. AI can also be used to improve the efficiency of devices that store energy, like batteries. This is done by figuring out the best way to charge and discharge the battery based on how it will be used.

3) Improving energy grid efficiency: AI has a lot of promise to make the energy infrastructure we already have work better and make it easier to add renewable energy sources. Smart grid technologies are based on algorithms that are driven by AI. These algorithms make it possible to accurately predict load, predict congestion, and find the best way to route and distribute energy.

Grid management systems could keep track of and organize different types of renewable energy in real time by using AI. So, less energy will be lost during transfer, and we might even be able to make sure a steady flow of green power.

4) Enhancing energy demand management: Demand response management is the process of changing how much energy is used in reaction to changes in the grid and the availability of renewable energy. Predictive modeling, which is based on AI, can help with this. AI algorithms can predict peaks and valleys in energy use by looking at past data and patterns of consumer activity.

This makes it possible to use automated tools for proactive management of how much energy is used. This method not only lowers the need for fossil fuel power plants during peak hours, but it also lets customers help make the switch to cleaner energy sources by changing how much energy they use based on how much renewable energy is being made.

5) Facilitating policy and investment decisions: When it comes to investing in green energy, AI can help government and business leaders make better decisions. Predictive modeling can help us understand how different green energy sources will work and how much they will cost in the long run.

Policymakers could use these results to make rules and regulations that work better. Using algorithms based on Artificial Intelligence to analyze investment risks, figure out how profitable renewable energy projects might be, and help make financial decisions can help increase investments in the renewable energy industry.

VI. Conclusion

By using AI techniques in predictive modeling for the use of renewable energy, we can learn more about how climate change works, make the best use of energy resources, and move toward sustainable growth. The Random Forest, SVM, and DBM are all examples of these Artificial Intelligence methods.

With these methods, we can use data-driven insights to make good decisions about policy, come up with workable solutions for green energy, and lessen the worst effects of climate change. For successful adoption, however, it's important to keep in mind that AI models aren't a cure-all and must be used with domain knowledge and with the political, social, and economic contexts in mind.

AI methods are very important when it comes to fighting climate change and getting more people to use renewable energy. AI technologies like Random Forest, SVM, and DBM can be used to evaluate, predict, and improve many aspects of how climate and energy combine. Two more types of AI are neural networks and genetic programming. By using AI, we can speed up the switch to renewable energy sources, lower greenhouse gas emissions, and take steps toward a more sustainable and resilient future.

An Exploratory Analysis of using Chatbots in Academia

Njood K.Al-harbi, Amal A.Al-shargabi
Department of Information Technology-College of Computer, Qassim University, Qassim, Buraydah, Saudi Arabia

***Abstract*—With the advancement of technology in this era, chatbots have become more than just robots, as they used to conduct time-consuming and labor-intensive routine tasks. Now, it is more than just a robot for routine duties; it interacts and produces like a human. Despite the efficacy and productivity of chatbots like ChatGPT-4 and Bard, there will be significant ethical implications for the academic community, particularly students and researchers. The current study is experimenting with ChatGPT-4 and Bard by producing scientific articles with specific criteria, then applying topic modeling to assess the extent to which the content of the articles is related to the required topic, and verifying references, plagiarism, and the accuracy of the chatbot-generated articles. The results indicated that the content is relevant to the topic, and the accuracy of ChatGPT-4 is greater than Bard. ChatGPT-4 achieved 96%, and the majority of the bibliographies are accurate, whereas Bard achieved 52%, and the majority of bibliographies are incorrect, and some are not available. It is unethical to rely on a chatbot to produce scientific content, despite its accuracy, because it is not as accurate as humans and requires a thorough review of the content it generates. Furthermore, it alters his responses based on the individual he is interrogating, regardless of whether his answers are correct, as he is unable to defend his knowledge.**

***Keywords*—AI; chatbots; ChatGPT; GPT-4; bard; ethics; machine learning; topic modeling**

I. Introduction

Every day, people from all over the world discover and experience new technological miracles due to the rapid development of science in the current era [1]. Who would have predicted that robots would assist humans in completing tasks in a time-saving and efficient manner? ChatGPT (Generative Pre-trained transformer), an artificial intelligence-based chatbot, has recently captivated the attention of many in the tech community. Launched in November 2022, it was developed by OpenAI, a research and publishing company specializing in artificial intelligence (AI). It was built on top of OpenAI's GPT-3.5 and GPT-4 families of large language models (LLMs) and has been fine-tuned using both supervised and reinforcement learning techniques (an approach to transfer learning) [2].

Moreover, Bard is a chatbot. It is based on a large language model (LLM) powered by Google. Improved and lightweight of LaMDA. It is similar to ChatGPT with the difference that it obtains its information from the web directly and it is up to date. It is presently under development and will be enhanced with more capable models over time [3].

Another example of a chatbot operated by Microsoft is the search engine, Bing. It operates as a chatbot assistant that can carry out tasks and can do so through either text or voice conversation using the Open AI concept as the basic and based on ChatGPT and GPT-3.5 [4].

The development of artificial intelligence-based technologies, such as ChatGPT, Bard, and other chatbots, confers both tremendous power and great responsibility. Therefore, ethical concerns must be considered. Although it is beneficial for some routine tasks, such as editing, it has significant bias issues. In addition, her speed in writing research papers poses a threat to scientific integrity.

The current research will examine the impact of chatbots, particularly ChatGPT, on the academic community and how to educate students and researchers on scientific research's ethics and integrity. The following are some of the questions that are currently being researched:

1) *Does* chatting with a chatbot produce useful scientific data for academics? Or does it raise ethical concerns?
2) *What* are the risks behind chatbots?
3) *Is* the chatbot's content real and reliable?

To answer the questions of the research, certain objectives must be met, including:

1) *Comparison* study, of how Google Bard and ChatGPT work and other chatbots.
2) *Experiment* with different chatbots (GPT-4 and Bard).
3) *Check* the bibliography's credibility.
4) *Request* chatbots to generate unique articles and then check for plagiarism.
5) *Discuss* the ethical issues.

The significance of the research is rooted in the keeping of scientific research's integrity and the provision of education to students and researchers regarding the ethics of scientific research. Thus, the responsible and ethical utilization of AI tools is essential within the context of academic research and publication. Furthermore, it is important to consider copyright, authorship, and proper citation of information sources.

The subsequent sections of the paper are organized as follows: Section II provides an overview of the related work, Section III outlines the methodologies and materials employed for exploration, Section IV presents the result of this research, Section V presents a discussion of results, and finally, Section VI presents the conclusion and outlines recommendations for future research.

II. Related Works

This section will present a brief history of chatbots, followed by an explanation of GPT models. Thus, will discuss the ethical issues with it, and conclude with a review of recent research on the topic to examine its impact in academia.

A. Chatbots Background

Alan Turing thought in 1950 whether a computer program could converse with a group of individuals without them recognizing that their interlocutor was artificial. Many consider this question, which is dubbed the Turing test, to be the generative concept of chatbots [5].

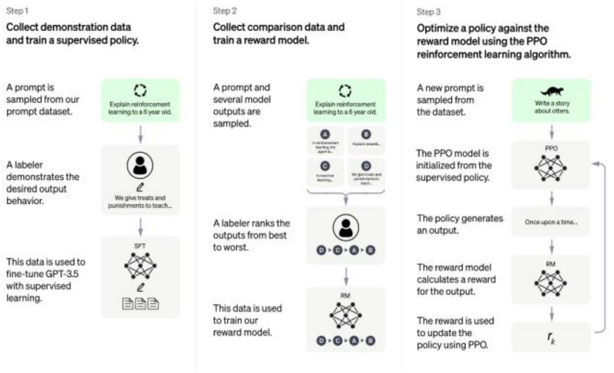
In 1966, the first chatbot with the moniker ELIZA was created. Due to its limited knowledge, ELIZA can only discuss a specific domain of topics, which is one of its disadvantages. Additionally, it cannot maintain lengthy dialogues and cannot learn or discover context from them.

In 1988, Jabberwacky was built, making it the first chatbot to employ AI [6, 7]. AI affects our daily lives and activities through many applications and advanced devices, called intelligent agents, which perform a variety of tasks [7]. A chatbot is a program with AI and a paradigm of human-computer interaction (HCI)[8]. It employs natural language processing (NLP) and sentiment analysis to communicate with humans or other chatbots in human language via text or speech [9]. Chatbots are beneficial in many fields, including education, business, e-commerce, health, and entertainment, in addition to entertaining people and simulating human interaction [10].

In November 2022, ChatGPT version 4, a chatbot with extraordinary writing abilities, caused a sensation, particularly in academic circles. Some researchers list him as an author in their academic papers. However, Nature and Science has stated that he cannot be designated as an author under the current legal system because he is not a human being and the text generated by the chatbot cannot be protected by copyright. Even though the most recent version of ChatGPT is advanced, search ethics prohibit its inclusion as an author in a search [7, 11].

B. GPT Models

ChatGPT utilizes a variant of the GPT model which has been trained to respond to questions using a massive dataset [2]. ChatGPT generates responses to text inputs using natural language processing (NLP). GPT models are based on the transformer architecture, which was presented in a paper [12] as a neural network architecture. The architecture of ChatGPT is extremely complex and consists of multiple layers of neurons. The model consists of an encoder and a decoder that work together to generate responses to diverse user inputs. The encoder processes the input text to generate a sequence of hidden states, which are then passed to the decoder. The decoder then employs these hidden states to generate token-by-token output text, a process known as autoregression [13,14]. The processes of ChatGPT are in Fig. 1.



Step 1
Collect demonstration data and train a supervised policy.
A prompt is sampled from our prompt dataset.
Explain reinforcement learning to a 6 year old.
A labeler demonstrates the desired output behavior.
We give treats and punishments to teach...
This data is used to fine-tune GPT-3.5 with supervised learning.
SFT
Step 2
Collect comparison data and train a reward model.
A prompt and several model outputs are sampled.
Explain reinforcement learning to a 6 year old.
A
B
C
D
A labeler ranks the outputs from best to worst.
D > C > A > B
This data is used to train our reward model.
RM
D > C > A > B
Step 3
Optimize a policy against the reward model using the PPO reinforcement learning algorithm.
A new prompt is sampled from the dataset.
Write a story about otters.
The PPO model is initialized from the supervised policy.
PPO
The policy generates an output.
Once upon a time...
The reward model calculates a reward for the output.
RM
The reward is used to update the policy using PPO.
r_k

Fig. 1. ChatGPT diagram [2].

Open AI has developed several versions of GPT, which have been compared in Table I, [2] [15] [16].

The development of chatbots has undergone significant evolution throughout the decades. Table II presents a comprehensive overview of chatbots, covering from first robot Eliza in 1966 to the most recently released bot, Bard, in 2023.

TABLE I. COMPARISON OF CHATGPT MODELS

Model	Description	Price	Released	Parameters	Benefits
ChatGPT-1	The initial version of the language model employing transformer architecture	N/A	June 2018	117 million	Text generation, translation, text summarization, language modeling
ChatGPT-2	GPT-1 but modified normalization	N/A	February 2019	1.5 billion	ability to produce realistic text sequences
ChatGPT-3	GPT-3 models can both comprehend and produce natural language. These models were replaced by models of the GPT-3.5 generation, which were more powerful.	Free	June 2020	175 billion parameters	Questions answering, chatbots, and automated content generation
ChatGPT-3.5	A model can comprehend and generate code or natural language. works well for regular task completion.	Free	January 2022	175 billion parameters	cost-effective
ChatGPT-4	A large multimedia model that accepts text inputs and emits text outputs today and will accept image inputs in the future is capable of solving complex problems with greater precision than previous models.	$20	November 2022	1 trillion parameters	Significantly more capable than previous models.

TABLE II. COMPARISON OF CHATBOTS FROM MOST RECENT TO EARLIEST [7,16–18]

Chatbot	Description	Launched Year	Developed by	Available Languages	Parameters
Bard	Is a generative and conversational AI chatbot, that can help with creative tasks, explaining complex topics, and generally distilling information from various sources on the internet. It can also handle nuanced queries.	2023	Google AI	Over 10 languages	137 billion parameters
GPT-4	Is the most recent model in the GPT series; it improves upon GPT-3's strengths and overcomes some of its weaknesses.	2023	OpenAI	Over 17 languages including Arabic	170 trillion parameters
LaMDA	Language Model for Dialogue Applications—LaMDA. It's a text-trained ML model that predicts words and phrases. A human-like chatbot was created.	2021	Google AI	English	137 billion parameters
Tess	Is a mental health chatbot that uses text message conversations to coach people through challenging times.	2020	Google AI	Over 10 languages	N/A
Wysa	Wysa: Anxiety, Therapy Tracker, an AI-powered chatbot, helps people with anxiety, stress, and depression. Wysa helps users modify their negative thoughts and habits using CBT.	2018	Wysa Health Company	English & Hindi	N/A
Replika	The most popular chatbot friend. AI mimics you. Interact with you and gather social media data to learn everything. Replika chatbots listen and take notes like therapists. It replicates you.	2017	Luka company	English & Spanish	137 billion parameters
Woebot	Is an automated conversational agent (chatbot) that aids in self-awareness and mood monitoring. and becomes increasingly tailored to what you need over time.	2016	Woebot Labs Company	English & Spanish	N/A
Google Assistants	Is the next generation of Google Now. It has a more advanced AI, a gentler, more conversational interface, and predicts the information needs of users.	2016	Google	Over 100 languages	137 billion parameters
Amazon Alexa	It has been built into home automation and entertainment devices, making the Internet of Things (IoT) more accessible to people.	2014	Amazon	Over 10 languages	11 billion parameters
Xiaolce	Is Chinese AI. One of the most famous girl chatbots of the era, it was before Tay.	2014	Baidu	English, Japanese, Korean, and Chinese (Traditional &Simplified)	1.07 billion parameters
Microsoft Cortana	It recognizes voice commands, identifies time and place, supports people-based reminders, sends emails and messages, makes and manages lists, chitchats, plays games, and seeks user-requested information.	2014	Microsoft	Over 17 languages including Arabic	10 billion parameters
Mitsuku	Is a chatbot with AI that can tell you stories, quips, and horoscopes. She is able to perform simple games with you and shows you web pages and images from the internet.	2012	Rollo Carpenter, a British Engineer & Software Developer	Over 10 languages	400 million parameters
Apple Siri	Siri prioritizes productivity. No random questions. Siri is a voice-based computer interface, not a person you can chat with.	2011	Apple Inc	20 languages	10 billion parameters
ALICE	ELIZA inspired ALICE, the first internet chatbot. Pattern-matching without actual conversation perception.	1995	Richard Wallace	Wide range of languages	Does not have a fixed number of parameters
PARRY	A chatterbot that simulates human conversation in an amusing, hilarious way.	1972	Kenneth Colby, a psychiatrist at Stanford University	Not support any spoken languages	2,000 parameters
Eliza	First chatbots that can only discuss a specific domain of topics (the point of beginning for chatbots)	1966	Joseph Weizenbaum, a professor of computer science at MIT	10 Languages	No parameters

C. Ethical Concerns

A computer program named Racter was listed as the author of a text in Omni Magazine in November of 1981 [11]. After that in 1984, Racter's book was published as the first book written in a computer program [19]. Since then, due to Racter and AI, copyright issues have received a lot of consideration [20].

Here's the big question: Is it possible to consider a chatbot as an author, given the emergence of AI and chatbots as well as their wide application in various industries, especially in the field of education and student assistance?

The author referred to [21] paper, which stated that using an AI text generator without appropriate attribution would be considered plagiarism. Plagiarism is the unauthorized use of the work or ideas of another individual without citing the source. This action applies to both content generated by human as well as AI, according to the authors in papers [21, 22], when using AI tools, it is essential to cite a source reference. However, significant journals such as Nature and Science have stated that AI chatbots cannot be authors of articles that are published in their journals. This is because the editorial policies on the authorship of these journals state that "AI chatbots do not currently satisfy our authorship criteria" [23].

The reason that AI chatbots cannot be writers is not because they are not human; rather, it is because they do not meet the standards that are currently required. However, in the future, AI chatbots may be accredited as authors of academic articles if they meet the required criteria [11]. Another reason for not being considered as an author is because it is unable to provide permission for these papers to be published, and this is the copyright privacy argument [24].

The use of chatbots to create academic content raises the following ethical concerns:

Bias is defined as a systematic error in decision-making processes that produce unfair results. Bias can originate from a variety of sources, such as data collection, algorithm design, and human interpretation. Machine learning models, a type of artificial intelligence system can learn, and replicate bias patterns found in the training data, which leads to unfair and discriminatory results [25].

Informed consent is a fundamental ethical principle for human subjects' research. It refers to the process of obtaining a participant's consent after providing them with sufficient information about the research, its potential risks, benefits, and alternatives, as well as the opportunity to ask questions and clarify any confusion [26]. On the other hand, there is a lack of consent from AI when researchers use AI-generated text. Therefore, to obtain valid and reliable results, researchers must be aware of the technology they employ in order of transparency and informed consent [22].

Privacy concerns, chatbots generate text from massive datasets, which may contain private and sensitive data. Due to the rising use of chatbot-generated text in scientific research, it is necessary to ensure the privacy of participants' data. Disclosure of this information violates the privacy of the individual and raises significant ethical issues [22].

Research integrity, the information and data retrieved from chatbots such as Bard and ChatGPT may be misleading; in many cases, the chatbot fabricated references that did not exist, such as the article written in this paper [27], using Chat GPT, indeed the references were fake. This confirms that entire reliance on chatbots is unreliable and unsuitable for use and that researchers are responsible for the quality and reliability of their research.

D. Chatbot Researches

The authors of the study [28], predict that ChatGPT will impact every aspect of society. To test ChatGPT, they investigated by writing an academic paper. The results indicate that ChatGPT can assist researchers in writing a cogent (partial) paper that is accurate, informative, and systematic and that the writing is very effective in two to three hours despite the author's limited professional knowledge. Based on user experience, the author considers the potential effects of ChatGPT and other AI tools and concludes with a proposal to modify the learning objectives so that students are taught how to use AI tools, and that education focuses on developing students' creativity and critical thinking, which cannot be replaced by AI tools.

In [22] study, the researcher discussed ethical concerns regarding the use of ChatGPT in scientific research, such as transparency, bias, informed consent, privacy, accountability, and integrity. The researcher concluded that researchers should declare and acknowledge their use of ChatGPT in the research methodology section and stick to research ethics and integrity.

In another investigation on the impact of AI on ethical issues, this time in the context of medical publishing practices in a paper [29], the authors requested ChatGPT contribute a commentary to Lancet Digital Health concerning AI and medical publishing ethics. They also asked ChatGPT how the editorial team can handle the AI-generated academic content. According to ChatGPT's response to their question, Lancet Digital Health should "carefully consider the ethical implications of publishing articles produced by AI."

In an additional paper [30], the author posed the following question to ChatGPT: "When streptozotocin-induced diabetes is prepared in growing rats, can you predict its effect on the facial bone growth pattern?" ChatGPT responded to the inquiry. Then he inquired about the references for this topic, and ChatGPT attached all the references along with their authors. Then, the researcher investigated whether these references were real or fake, and found out that they were all fake. However, the researcher confirms that ChatGPT did an excellent job editing English grammar. The researcher concluded that any novel ideas generated by ChatGPT must be validated, that results must be verified before publication, and lastly, any AI assistance must be disclosed.

In continuance of the preceding article debating whether ChatGPT references are real or fake. Through ChatGPT, the author of the paper [27], completes the article without human intervention or editing. Unfortunately, upon investigation, the references that the author requested from ChatGPT were found to be fake.

The author of the paper [31], discusses a variety of ChatGPT-related topics, including its history, applications, challenges, bias, ethics, limitations, and future. In terms of ethics, topics discussed include data privacy, bias, transparency, autonomy, human agency, emotional manipulation, persuasion, and reliance on AI-generated content, as well as others. It was concluded that ChatGPT made significant contributions to scholarly research in terms of linguistically coherent text generation, is grammatically accurate, and has the potential to transform the field in the future if its challenges and ethical issues are addressed.

In addition to the features offered by chatbots, there are also cyber risks that must be addressed. The author of the paper [14], investigated the cyber risks associated with the use of ChatGPT and other chatbots based on AI that is similar to ChatGPT. Also, the vulnerabilities that are exploited by malicious actors because ChatGPT risks providing simple scripting and access to coding by cybercriminals, as well as ways to mitigate them, such as limiting entry barriers for cybercriminals, complying with regulations, and more.

A preliminary study was conducted by the authors of the [32] paper, comparing ChatGPT translations to those created by human translators. They found that although the translations were not always accurate, they performed competitively with commercial translation products, such as Google in high-resource European languages but significantly different in low-resource languages.

The authors of the paper [33], evaluated ChatGPT's performance on the United States Medical Licensing Examination (USMLE), which consists of three examinations and does not involve any specialized training or reinforcement. They identified two major themes: (1) the increasing accuracy of ChatGPT approaching or exceeding the threshold for passing the USMLE, and (2) the potential for AI to generate new insights that could aid human learners in the context of medical education.

Furthermore, discussing ethical issues related to technology use in academia, scholarly research, and publishing, the paper's authors in [34], compare the effect of GPT/ChatGPT versus that of other language paradigms. GPT3 has proven to be flexible, efficient, and capable of generating human-like language, which makes it useful for tasks such as translating, annotating, and answering questions. Additionally, ChatGPT has the potential to enhance search efficiency and the quality of academic publications. On the one hand, they discussed the ethical considerations that need to be taken into account, such as the ownership of the content, since it is not clear who owns the rights to the generated text and the copyright issues that are of concern yet.

III. Materials and Methods

The present research methodology involves two phases, the first phase is a qualitative method which includes: experimentation with two types of chatbots to examine and assess the content generated by chatbots.

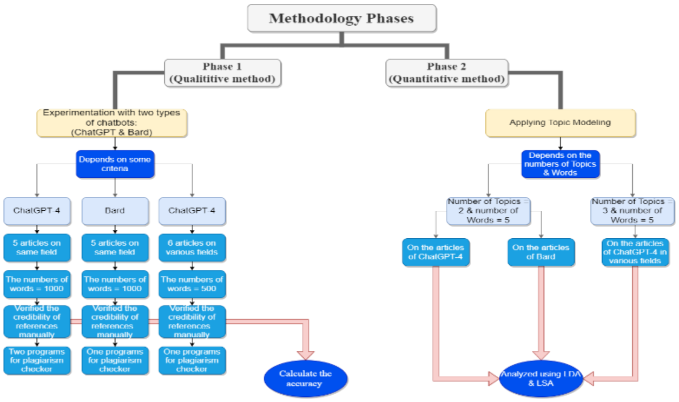
Chatbots is a computer program that imitates dialogue with human users, typically employing natural language processing (NLP) to analyze inputs and generative AI to automatically generate responses. Chatbots will go through experiments: ChatGPT-4 which is an artificial intelligence-based chatbot, was developed by OpenAI. It was built on top of OpenAI's GPT-3.5 and GPT-4 families of LLMs [2]. In addition, Bard is a chatbot. It is also based on LLM powered by Google. Improved and lightweight of LaMDA [3].

Initially, the ChatGPT-4 and Bard will go through experiments by a request for five academic articles related to the field of technology, all having a word count of 1000. The credibility of references will be manually verified, and the percentage of plagiarized content will be measured. Moreover, six articles were generated by ChatGPT-4, to increase the dataset in various fields with a count of 500 words.

The second phase is a quantitative method that involves applying topic modeling, which is an unsupervised machine-learning approach that involves scanning numerous documents, articles, feedback, or emails. In this study, the focus will be on articles produced by chatbots. The primary objective of this technique is to identify patterns of words and phrases within the articles, regardless of their relevance to the topic. to its underlying semantic structure. The given entity can be described as a collection of words without any specific order or structure [35].

Then, the analysis using Latent Dirichlet Allocation (LDA) is a computational model that shares similarities with Latent Semantic Analysis (LSA). However, LDA differs from LSA in that it assigns topics to word order, with the aim of ascertaining the composition of topics in documents [35].

In the end, an assessment will be conducted to evaluate the accuracy of the content generated by chatbots based on the bibliography. Fig. 2 demonstrates the phases, and given in detail.



Methodology Phases
Phase 1 (Qualititive method)
Phase 2 (Quantitative method)
Experimentation with two types of chatbots: (ChatGPT & Bard)
Depends on some criteria
ChatGPT 4
Bard
ChatGPT 4
5 articles on same field
5 articles on same field
6 articles on various fields
The numbers of words = 1000
The numbers of words = 1000
The numbers of words = 500
Verified the credibility of references manually
Verified the credibility of references manually
Verified the credibility of references manually
Two programs for plagiarism checker
One programs for plagiarism checker
One programs for plagiarism checker
Calculate the accuracy
Applying Topic Modeling
Depends on the numbers of Topics & Words
Number of Topics 2 & number of Words = 5
Number of Topics 3 & number of Words = 5
On the articles of ChatGPT-4
On the articles of Bard
On the articles of ChatGPT-4 in various fields
Analyzed using LDA & LSA

Fig. 2. Methodology phases.

IV. Results

This section presents a comparative analysis of the chatbots ChatGPT-4 and Bard, as well as a topic modeling approach applied to the articles stated in Tables III, IV, and V which were analyzed afterward.

A. *Comparison of the Academic Articles Generated by GPT-4 in the Various Fields*

Academic articles generated by GPT-4 in a variety of scientific disciplines, such as technology, medicine, space, earth, society, and marketing. To assess the breadth of his knowledge and reliability of his sources in various fields. Table III compares based on the same word count, the number of bibliographies, and the Plagiarism ratio.

B. Comparison of the Academic Articles Generated by GPT-4 in the Same Fields

Academic articles generated by GPT-4 in the same scientific disciplines, such as technology. To assess the accuracy of his knowledge and reliability of his sources in the same fields. Table IV compares based on the same word count, the number of bibliographies, and the Plagiarism ratio in the two programs.

C. Comparison of the Academic Articles Generated by Bard in the Same Fields

Academic articles generated by Bard in the same scientific disciplines, such as technology. To assess the accuracy of his knowledge and reliability of his sources in the same fields to compare it with ChatGPT-4. Table V compares based on the same word count, the number of bibliographies, and the Plagiarism ratio.

The accuracy will be computed after performing a comparison based on specified criteria presented in Tables III, IV, and V as the following equation:

$$Accuracy = \frac{corrected\ bibliographies}{The\ total\ number\ of\ bibliographies} \qquad (1)$$

The accuracy of ChatGPT-4-generated articles in Table III is 77.5%, while in Table IV, it's 96%. Bard's articles in Table V have an accuracy of 52%. These results are visually summarized in Fig. 3, which provides a comprehensive overview of the findings from Tables III, IV, and V.

D. Topic Modeling

Topic modeling has been applied to articles in Table IV. The outputs of LDA and LSA for two topics and five words for ChatGPT-4 articles are shown in Tables VI and VII respectively. The results are visualized in Fig. 4 and Fig. 5.

V. Discussion

Based on the experiences of Bard and ChatGPT-4, the latter has not exceeded a plagiarism rate of 30 percent, whereas Bard did exceed it. The word count of ChatGPT-4 exceeds Bard, although it falls short of the prescribed 1000-word limit. Four out of five references for ChatGPT-4 were found to be real.

The references were found to be entirely accurate but with some errors. Particularly, the fifth article in Table IV contained errors in the names of the authors and the year of publication. On the other hand, it is notable that no article was found in Bard to have completely correct references. Moreover, accessing the complete scientific papers demonstrated challenges for Articles 1, 3, 4, and 5, as they were not easily found. This made it challenging to verify the authenticity of these papers. The author's names and the title appear to be incorrect and vice versa.

According to Table III, the findings of ChatGPT-4 were comparatively accurate in terms of word count, as all the generated texts were within the requested limit of 500 words, with an additional few words. This comparison was conducted across different fields. There are errors in publication year and author names, but 1 existence of a particular paper is not found. Upon inquiry regarding the ChatGPT-4 fake reference, the citation was altered to a more appropriate and true reference. Furthermore, the percentage of plagiarism did not exceed 25%.

After applying topic modeling to ChatGPT-4 articles, determine whether the article's content is related to its title. The LDA model demonstrated that the most relevant word was (learning) with a percentage of 0.054 for Topic 1 and (learning) for Topic 2 with 0.035, compared to the LSA model indicated that the most relevant word was (learning) with a percentage of - 0.0603 for Topic 1 and (social) for Topic 2 with 0.480. Tables VI and VII display every word of LDA and LSA. To visualize the output of the LDA model, refer to Fig 4. 59.2% of the tokens are associated with Topic 1. In Fig. 5. 40.8% of the tokens are associated with Topic 2.

In Bard, the most relevant word in the LDA model to Topic 1 was (learning) with a percentage of 0.046 for Topic 1, and (machine) with a percentage of 0.057 for Topic 2. Compared with LSA the most relevant word to Topic 1 is (learning) with a percentage of 0.571 and -0.358 for the word (image) in Topic 2. Tables VIII and IX list all the words LDA and LSA. To visualize the LDA, Fig. 6 showed 37.7% of tokens for the most relevant words for Topic 1, and Fig. 7, showed 62.3% of tokens for Topic 2.

Tables X and XI showed a bigger set of articles and increased the Topics to 3 and in different fields a combination of articles from Tables III and IV. The most relevant words for LDA are (IoT) with a percentage of 0.014 for Topic 1 as shown in Fig. 8, with 25.7% of tokens relevant words. And (advertising) with a percentage of 0.030 for Topic 2 as shown in Fig. 9, with 12.2% of tokens relevant words. Lastly (learning) with a percentage of 0.043 for Topic 3 as shown in Fig. 10, with 62.1% of tokens relevant words.

The ChatGPT-4 bibliography exhibits a greater degree of accuracy in comparison to the Bard bibliography as shown in equation 1. However, it is important to note that the accuracy of the ChatGPT-4 bibliography is not absolute, and there may be instances where it is erroneous, given that several bibliographies were found to be incorrect which agreed with the previous papers [27] and [30], that found the bibliographies are fake and must be validated before use it. Students and researchers should not rely on chatbots because their accuracy is insufficient for 100% error-free citations, and each researcher is responsible for the credibility and accuracy of his research and information.

Due to its lack of absolute accuracy chatbots, it cannot be considered an author of scientific papers. In addition to credibility and integrity, scientific research depends on humans, and a chatbot cannot be regarded as human. It can be used for time-consuming routine tasks that align with previous papers [34], but in academic research, it lacks direct information and alters its responses if you disagree with it. In contrast to chatbots, the researcher understands all aspects of his research topic and can defend his opinions, but the researcher's ethics and integrity will determine the achievement of his research.

VI. Conclusion

The advancement of chatbots is at an interesting growth, and the use of chatbots in higher education can yield numerous benefits such as text summarization, text generation, and translation. However, the utilization of these chatbots also poses several challenges and concerns, particularly concerning the context of academic integrity and the problem of plagiarism. The utilization of these chatbots may potentially boost fraud and distinguishing between automated and human-generated writing could be a challenge.

According to the findings of the present analysis, the utilization of two chatbots (ChatGBT-4 and Bard), by applying topic modeling even if it is shown relevant to the topic but cannot be considered scholarly or suitable for academic research, as several criteria assessed in the present investigation were not achieved.

Most of the articles generated by Bard were found to be inaccurate and some non-existent. Although ChatGBT-4 exhibits greater accuracy than Bard, it remains insufficient, failing to achieve the level of accuracy characteristic of human-generated information. Because of the change in responses depending on the conversation context.

Furthermore, there exist numerous ethical standards concerning copyright and research ethics. Chatbots must not be considered authors because of their inability to provide accurate information. Higher education institutions should carefully consider the potential risks that chatbots pose to students and they must develop a well-planned strategy for educating and informing students about the use policy of chatbots. In addition, developing a set of tools that detect plagiarism and protect academic ethics and integrity.

In future investigations, the assessment of scientific articles in ChatGBT-4 will be expanded with the incorporation of updated information more than the year 2021. Similarly, the accuracy of Bard will be further evaluated once it progresses beyond the experimental phase.

***Abstract*—Text stemming, an essential preprocessing step in the development of Natural Language Processing (NLP) applications, involves the transformation of various word forms into their root words. Stemming plays a critical role in decreasing the volume of text, thereby enhancing the efficiency of various computational tasks such as information retrieval, text classification, and text clustering. Stemming is a rule-based approach. On the other hand, it frequently suffers affixation errors that result in under-stemming, over-stemming, or both, as well as unstemmed or spelling exceptions. Every language has different stemming techniques, and among the most well-known Malay stemming algorithms are the Othman and Ahmad algorithms. Therefore, this study aims to compare the performance of the stemming errors between the Othman and Ahmad algorithms in stemming Malay text, particularly on two different domains of textual datasets, which are the course summaries of the education domain and housebreaking crime reports of the crime domain. The Othman algorithm presents a set of 121 stemming rules (set A). In the meantime, Ahmad's algorithm proposes two distinct sets of stemming rules, comprising 432 (set B) and 561 rules (set C), respectively. Based on the experiment results with 100 course summaries, the Ahmad algorithm (Set B) obtained a higher accuracy rate of 93.61%. The second highest is the Ahmad algorithm (Set C) with 93.53%. The Othman algorithm achieved the lowest accuracy with 86.04% compared to the other two algorithms. Meanwhile, findings from the experiment with 100 housebreaking crime reports show similar results, with the Ahmad algorithm (Set C) achieving the highest stemming accuracy of approximately 93.80% and the Othman algorithm producing the lowest stemming accuracy (83.09%). The result indicates that stemming accuracy is consistent across different types of datasets.**

***Keywords*—Algorithm; ahmad algorithm; malay language; othman algorithm; rule-based; stemming; stemmer**

I. INTRODUCTION

Due to the explosive growth of textual information that has continuously been generated from electronic media over the past ten years, text analytics has received a lot of attention and research [1], [2]. Text analytics, sometimes called text mining, is the integration of linguistic, computational statistics, and computer science techniques [3]. The research on text analytics has been conducted in a variety of languages, including English [4], Arabic [5], Russian [6], Indian [7], Chinese [8], and Thailand [9] to solve various problems in text classification, text clustering, sentiment analysis, and topic modeling. Text analytics have a significant impact on data science [10], [11]. The significant contribution of text analytics in terms of providing enriched and structured datasets that enable in-depth analysis. This has led researchers to explore various text mining techniques, which involve the extraction of valuable information and insights from unstructured textual data. Unstructured textual information requires preprocessing, involving the removal of irrelevant terms, before it can be used in text analytics tasks. Preprocessing is important for decreasing data sparsity, reducing data dimensionality, increasing the quantity of captured semantic information, and ensuring data consistency [12]. The common steps in text preprocessing are tokenization (splitting text into words or phrases), stop word removal, and stemming [13], [14]. Working with a large volume of dimensional text could negatively affect the performance of text analytics. Therefore, stemming is critical for improving the effectiveness of text analytics.

Stemming is one of the basic and essential steps in text preprocessing. It is a natural language processing (NLP) technique used to match the numerous inflectional and derivational morphological forms of a word to its stem or root word. For example, stemming matches the words *maintaining*, *maintained*, and *maintenance* to their root word, *maintain*. Meanwhile, stemmers are the programs that do stemming [15]. In Malay, there are seven-word patterns: affixation, reduplication, compounding, blending, clipping, abbreviation, and borrowing [16]. Malay morphology is recognised for having extremely complex morphological features that are used to construct different word patterns. For instance, the addition of the prefix "pe" to the root word "makan" (eat) results in the word "pemakan" (eater), thereby modifying the meaning of the root word. Thus, it is crucial to understand the morphological structure of the Malay language to reduce derived words into their respective root words.

NLP employs various stemming approaches such as rule-based, dictionary-based, statistical-based, and hybrid stemming. The best approach is determined by the language involved and the nature of the textual dataset. The stemming strategy of rule-based affix elimination is used in this paper, which eliminates the prefix, suffix, and circumfix infix. Othman [17] and Ahmad [18] algorithms are the most pioneering rule-based Malay stemmers. Even though there are plenty of rule-based stemming approaches for Malay that have been improved by the previous researchers since then, they still suffer from affixation errors, including over-stemming, under-stemming, unchanged, and spelling exceptions [19], [20], [21]. The major causes of this stemming error are the affix removal method, the similarity of the root word with the affixation word, and exception rules in prefixation and confixation [22],[23].

The quality of stemming algorithms is typically measured by how accurately they map the variant forms of a word to the same stem. In addition, the presence of diverse morphological structures within a textual dataset, the proper use of appropriate vocabularies, and the word patterns in the textual datasets also play a significant role in contributing to the accuracy of stemming. To the best of our knowledge, there is limited study on the comparative analysis of stemming algorithms for Malay. The most recent works were published in [24] and [25]. However, the purpose of this paper is not to discuss any improvements in terms of the morphological rules of Malays languages. Nevertheless, the purpose of this research is to determine the degree to which the abundance and consistency of precise vocabulary and grammar usage in the textual dataset influence the efficacy of the stemming procedure. Therefore, the objective of this study is to conduct a comparative analysis of the Othman and Ahmad algorithms in terms of their effectiveness in stemming textual data from two distinct domains: education and crime. The analysis of the error rate in stemming and the accuracy of performance for different textual datasets are performed. The analysis is conducted utilising the 121 rules of the Othman algorithm, referred to as set A, as well as the Ahmad algorithm for both set B (comprising 432 rules) and set C (comprising 561 rules). A total of 100 Malay documents for each domain is randomly selected in order to assess the performance of this study. The best result was obtained by the Ahmad algorithm for both datasets, with a stemming accuracy of 93.61% for the education dataset and 93.80% for the crime dataset. Meanwhile, the Othman algorithm attains a stemming accuracy of 86.04% for the education dataset and 83.09% for the crime dataset.

This paper is organised into five sections. Section II discusses the related works on the existing Malay word stemmer. Meanwhile, Section III describes the research methodology used to compare Malay stemming algorithms. Section IV presents the experiment's results and discussion. Finally, Section V concludes the paper by summarising the main achievements and making future recommendations.

II. Related Work

This section discusses a selection of recent studies on Malay stemming algorithms that have employed a rule-based affix elimination approach, which involves the removal of prefixes, suffixes, circumfixes, and infixes. A prefix is a type of affix that is attached to the beginning of a root word, while a suffix is a specific type of affix that is appended to the last position of a root word. In the realm of linguistics, it is worth noting that a linguistic element known as a circumfix, or more formally referred to as a prefix-suffix, is an affix that is comprised of two parts. Both of these parts are strategically positioned, with one located at the beginning of the root word, while the other is attached to the end of the root word. An infix is a type of affix that is inserted in the middle of a root word.

The most pioneering stemmer for Malay is the Othman algorithm, which was proposed in 1993 [22]. This algorithm makes use of Kamus Dewan 1991, a Malaysian dictionary. The use of the dictionary facilitates the identification of the root word after the removal of the affixes, provided that the affixes are matched to the stemming rules. By using the pattern matching rules, the affixes of the word are eliminated once the rule is matched. However, this stemmer has caused over-stemming errors because it does not consider searching for the word in the dictionary before performing the stemming process. Following this, Ahmad et al. [23] proposed a modified version of the Othman algorithm, known as the Ahmad algorithm, in which the algorithm considers dictionary lookups before proceeding to the stemming process and improves the order of applied morphological rules. In addition to enhancing stemming performance, two sets of new rules are developed, each consisting of 432 rules and 561 rules. This algorithm, which uses the rule application order, has been performed on two datasets of ten chapters of the Quran and 10 research abstracts. A series of empirical experiments are run, and the results reveal that the best order for rule-based affix elimination is prefix, circumfix, suffix, and infix, whereas the Ahmad algorithm produces a better performance compared to the Othman algorithm.

Meanwhile, Sankupellay & Valliapan [24] developed the Mangalam algorithm, where they adopted the Porter stemming algorithm to stem Malay documents. Although the Porter stemmer is commonly used to stem English words, the algorithm is adaptable to handle dual words, or “kata ganda" from Malay documents. The Porter stemmer was successfully adopted in stemming Indonesian text [25]. The stemmer used a root word dictionary to validate the four categories of affixes, including inflection particles, possessive pronouns, derivation suffixes, and derivation prefixes. Some of the studies conducted by Rosid et al. [26] used the Sastrawi library in their studies to examine the comparison of stemming result against Tala porter stemmer. Tala porter stemmer was developed by Fadilah Z. Tala in 2003 using five steps in Porter stemmer by imitating how words are derived and inflected [27]. This study used 50 of the Indonesian student complaint documents. The findings of the study indicate that employing the Sastrawi dictionary yields superior results in comparison to utilising the Tala Porter dictionary. The result shows 92% accuracy when they used the Sastrawi dictionary, and 82% when they just used the Tala Porter stemmer. The processing speed for Sastrawi libraries is faster than Tala Porter with 0.6 seconds compared to 241.6 seconds for Tala Porter.

III. Research Methodology

The overall framework of research methodology in this study is depicted in Fig. 1. There are three main phases, including textual data collection, text preprocessing, and performance evaluation.

A. Phase 1: Textual Data Collection

This study makes use of textual datasets from the following two primary domains: education and housebreaking crime. The first textual dataset employed in this study consists of a compilation of course summaries in the Malay language. Meanwhile, the second dataset comprises a collection of housebreaking crime reports ranging from 2010 to 2013, also in the Malay language. The two datasets were obtained from a higher education institution and the Royal Malaysia Police Department, and they are both closed domain datasets. Table I shows the detailed descriptions of both textual datasets. For the purposes of this study, a sample of 100 course summaries and 100 housebreaking crime reports was randomly chosen and stored in Excel format. The collection of 100 documents of course summaries comprises a cumulative total of 5,520 words, whereas the set of 100 housebreaking crime reports contains a total of 3,530 words. The range of word lengths observed in the course summaries documents spans from 24 to 135 words, while the housebreaking crime reports consist of approximately 22 to 155 words.

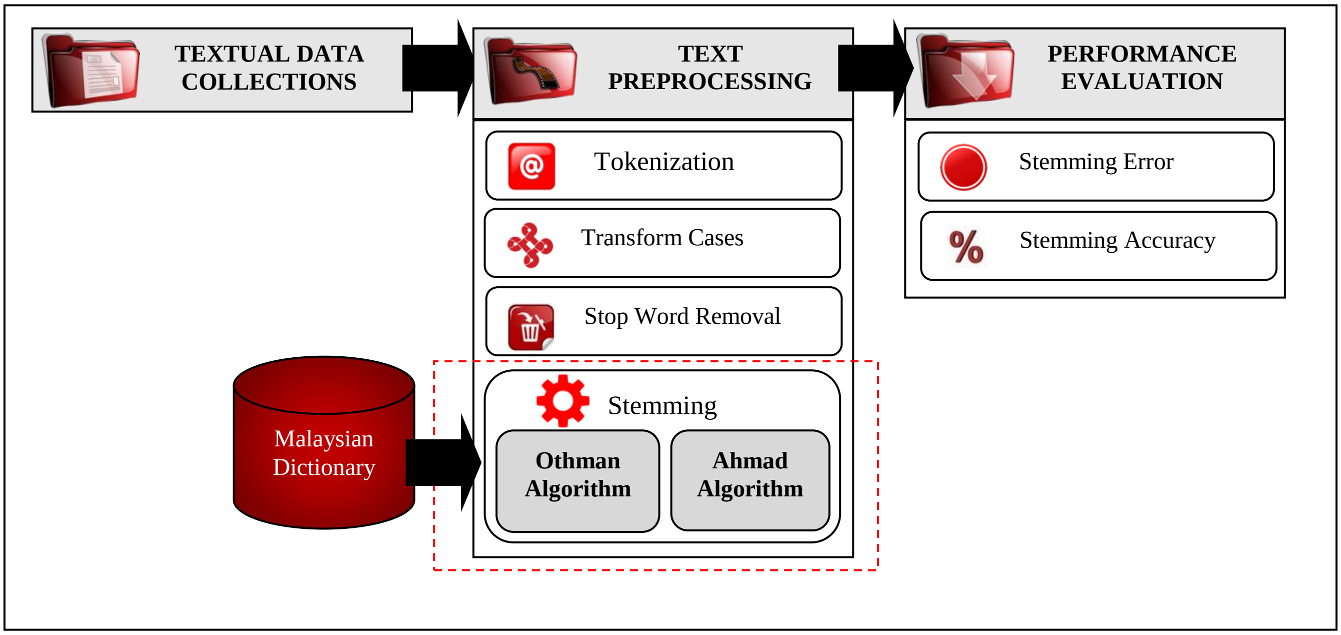

Fig. 1. Framework of research methodology.

TABLE I. DETAILS DESCRIPTION OF TEXTUAL DATASET FOR EDUCATION AND HOUSEBREAKING CRIME DOMAIN

Domain	Number of Documents	Total Number of Words	Range of Word Lengths
Education	100	5520	24-135
Housebreaking Crime	100	3530	22-155

B. Phase 2: Text Preprocessing

The text processing phase contains several steps, such as tokenization, transform cases, stop word removal, and stemming. These steps are essential to reducing the noise of the words in the raw dataset. It is crucial to reduce the document's feature size before proceeding to the next computational task. Tokenization processes are splitting the sentence or paragraph into single words, while transform cases are the process of converting all words to lowercase. A stop word refers to a word that is highly prevalent and frequently occurs in both written and spoken language but does not contribute significant semantic meaning to the overall document. Examples of stop words include prepositions, conjunctions, numbers, and punctuation marks. In Malay, examples of stop words are “di” (at), “ke” (to), “dengan” (with), and “dari” (from). In this experimental study, a total of 323 stop words were identified and subsequently employed to eliminate unnecessary words from the dataset. Table II presents a list of 100 stop words that were utilised in the context of this research.

TABLE II. AN EXAMPLE OF LIST OF STOP WORDS IN MALAY LANGUAGE

List of Stop Words				
ada	seandainya	kalau	apa-apa	sekitar
inikah	agar	sebelumnya	katakan	atau
sampai	janganlah	allah	segala	kepadaku
adakah	sebab	kami	apabila	selain
inilah	akan	sebenarnya	ke	ataukah

se	juga	apa	sekarang	kerana
agak	dari	kamupun	atasnya	seluruhnya
jangan	alangkah	sedikitpun	kepada	bagimu

The subsequent procedure involves the execution of the stemming process. Comparative experiments were conducted to evaluate the effectiveness of the Othman and Ahmad algorithms for stemming. Both algorithms are being implemented using the Java programming language. Fig. 2 depicts the Othman algorithm, while Fig. 3 depicts the Ahmad algorithm. The algorithms are combined with the proposed rules, with Othman employing 121 stemming rules (Set A) and Ahmad employing 432 (Set B) and 561 (Set C) stemming rules, respectively. Three distinct programmes have been developed to represent different sets of rules, in particular Othman Stemmer (Set A), Ahmad Stemmer (Set B), and Ahmad Stemmer (Set C). Meanwhile, six separate series of experiments were conducted to stem two different textual datasets from the education and housebreaking crime domains. The resulting stem words were stored in Excel files. The Malaysian dictionary used in this study consists of a collection of root words obtained from the Kamus Dewan Edisi Keempat.

```
Step-1: If there are no more words then stop, otherwise get the next word.
Step-2: If there are no more rules then accept the word as a root word and go
        to Step-1, otherwise get the next rule.
Step-3: Check the given pattern of the rule with the word: If the system finds
        a match, apply the rule to the word to get a stem word.
Step-4: Check the stem word against the dictionary; perform any necessary
        recoding and recheck the dictionary.
Step-5: If the stem word appears in the dictionary, then this stem word is the
        root of the word and go to Step-1. Otherwise go to Step-2.
```

Fig. 2. Othman algorithm [23].

```
Step-1: Find the next word till the last word.
Step-2: Check the word in the dictionary; if the word appears in dictionary, it
        is the root word and return to Step 1.
Step 3: Get the next rule; if no further rules are available, the word are root
        word and return to Step 1.
Step 4: Apply the rule to the word to get a stem word.
Step 5: Check the dictionary and recode for prefix spelling exceptions.
Step 6: If the stem word appears in the dictionary, it is root word and proceed
        to Step 1; otherwise go to Step 7.
Step 7: Examine the stem from Step 4 for spelling variations in the dictionary.
Step 8: If the word stem appears in the dictionary, it is root word and proceed
        to Step 1; otherwise go to Step 9.
Step 9: Check the dictionary and recode for suffix spelling exceptions.
Step 10: If the stem word appears in the dictionary, it is root word and
        proceed to Step 1; otherwise go to Step 3.
```

Fig. 3. Ahmad algorithm [23].

C. *Performance Evaluation*

After a series of experiments is run, the stemming result is collected for measuring the algorithm's performance. The performance value that has been considered in this study is the analysis of stemming errors, word stemming accuracy measurement, and processing speed. The analysis of stemming errors involves the examination of various types of errors, such as over-stemming, under-stemming, unstemmed words, and spelling exception errors. These errors have a negative impact on the efficacy of stemming algorithms. Over-stemming occurs when a larger portion of a word is cut off than is necessary, resulting in the incorrect reduction of an inappropriate stem word. As an example, the word “memakan” (eating) needs to be stemmed into “makan” (eat), but then the result gives only “mak” (mother) after stemming. Under-stemming, meanwhile, happens when the smaller portion of the word is stemmed into the inappropriate stem word. For instance, the word “pengadu” (informer) should be stemmed into “adu” (inform), but the result gives “gadu” (trigonostemon longifolius). For unstemmed words, there are no changes in the derivative word before stemming or after stemming. Spelling exceptions occur when a word is chopped off from the accurate affixes, resulting in the formation of different root words. For example, the word “pengawal” (guard) is stemmed into “gawal” (confuse) instead of “kawal” (control). The other category for stemming errors refers to results other than these four types.

Meanwhile, for measuring the stemming accuracy, The equation below depicts the formula. Correctly stemmed words are calculated by conducting a comparison with the manually stemmed data and the root word as listed in the Malaysian dictionary, Kamus Dewan Edisi Keempat.

$$Accuracy = \frac{Total\ of\ correctly\ stemmed\ word}{Total\ of\ correctly\ and\ incorrectly\ stemmed\ words}\, x\ 100\%$$

In regard to processing speed, the duration is measured subsequent to the completion of the stemming process. The experiment was conducted utilising the Java Programming language within the NetBeans Integrated Development Environment, Version 12.0. The stemmer programme is executed on a desktop computer equipped with an Intel(R) Core(TM) i7-10700 CPU @ 2.90GHz 2.90 GHz processor and 16 GB of DDR3 memory.

IV. Result and Discussion

This section discusses the results of the experiments and the evaluation of the stemming process.

A. *Analysis of the Stemming Errors*

Despite the ongoing encouragement for the development of the Malay stemmer, there are still several challenges that need to be addressed. The analysis of stemming errors involves the examination of various types of errors, such as over-stemming, under-stemming, unstemmed words, and incorrect stemming.

Table III provides a summary of the total number of stop words that were eliminated from the education dataset and the housebreaking crime dataset. The implementation of the stop word removal process resulted in the elimination of 1,555 insignificant words in total from a corpus consisting of 100 course summaries. In the context of analysing 100 housebreaking crime reports, there are 864 frequently occurring words with no significant meaning that were eliminated. The stop word removal process results in a total word count of 3,965 for the course summaries dataset, while the housebreaking crime dataset retains 2,486 words.

TABLE III. A Summary of the Total Number of Eliminated Words After Stop Word Removal

Textual Dataset	Number of Removed Words	Total Number of Remaining Words
Course Summaries	1555	3965
Housebreaking Crime Reports	864	2486

Meanwhile, a comparative analysis of stemming errors generated by the Othman and Ahmad algorithms is presented in Table IV. Experiments are conducted in six series, with Set A containing 121 rules for the Othman algorithm, Set B containing 432 rules, and Set C containing 561 rules for the Ahmad algorithm. By using a collection of course summaries as the dataset in the education domain, the Othman algorithm correctly stems 1,582 words and identifies 1,643 root words. The Ahmad algorithm with Set B rules correctly stems 1,529 words, while the Ahmad algorithm with Set C rules correctly stems 1,526 words. In contrast to the Othman algorithm, which manages to identify only 1,643 root words, the Ahmad algorithm detects 1,959 root words for both sets. The Ahmad algorithm yields a higher number of under-stemmed words within the range of 168 to 174 in comparison to the Othman algorithm, which yields 130 under-stemmed words. In contrast, the Othman algorithm demonstrates a higher frequency of over-stemming errors, with 366 over-stemmed words, in comparison to the Ahmad algorithm, with 45 and 54 over-stemmed words for Set B and Set C, respectively. Meanwhile, the number of spelling exception errors generated by the Ahmad algorithm is greater in comparison to the Othman algorithm. Irrelevant words refer to root words that are not listed in the dictionary.

On the other hand, for the housebreaking crime dataset of the crime domain, the Othman and Ahmad algorithms for Set B and Set C achieve within the range of 736 to 737 words, where the difference between the two algorithms is not significantly different. However, with regard to root word identification, the Ahmad algorithm successfully detects 1,531 root words for Set B and Set C, while the Othman algorithm only detects 1,273 root words. In the context of under-stemming errors, the Ahmad algorithm yields a total of 113 under-stemmed words, which is higher than the count of 110 under-stemmed words produced by the Othman algorithm. In the meantime, the Othman algorithm also produced 285 over-stemmed words, which is higher than the Ahmad algorithm, which produced within the range of 21 to 22 over-stemmed words for both Set B and Set C. Meanwhile, the spelling exceptions generated by the Othman and Ahmad algorithms are within the range of 14 to 16 words.

TABLE IV. SUMMARY OF STEMMING ERRORS PRODUCED BY OTHMAN AND AHMAD ALGORITHMS FOR 100 COURSE SUMMARIES AND 100 HOUSEBREAKING CRIME REPORTS

Algorithms	**Othman Algorithm (SET A)**				**Ahmad Algorithm (Set B)**				**Ahmad Algorithm (Set C)**			
Dataset Domain	***Education***		***Crime***		***Education***		***Crime***		***Education***		***Crime***	
	#	**%**	**#**	**%**	**#**	**%**	**#**	**%**	**#**	**%**	**#**	**%**
Correct Stemming	1582	39.90%	736	29.61%	1529	38.56%	736	29.61%	1526	38.49%	737	29.65%
No stemming, root word	1643	41.44%	1273	51.21%	1959	49.41%	1531	61.58%	1959	49.08%	1531	61.58%
Under-stemming	130	3.28%	110	4.42%	174	4.39%	113	4.55%	168	4.24%	113	4.55%
Over-stemming	366	9.23%	285	11.46%	45	1.13%	22	0.88%	54	1.36%	21	0.84%
Spelling exceptions	5	0.13%	14	0.56%	19	0.48%	16	0.64%	19	0.48%	16	0.64%
Irrelevant Words	239	6.03%	68	2.74%	239	6.03%	68	2.74%	239	6.03%	68	2.74%

When these two distinct dataset domains are compared, it is discovered that the Othman algorithm outperforms the Ahmad algorithm in correctly stemming 39.66% of the words in the education dataset. In contrast, the Ahmad algorithm has a higher success rate of 29.65% in correctly stemming words from the crime dataset compared to the Othman algorithm. The aforementioned contrast finding indicates that the efficacy of the stemming process is influenced not only by the variety of morphological rules, but also by the extent of vocabulary richness present in the datasets, which has the potential to impact the accuracy of stemming. Meanwhile, the Ahmad algorithm demonstrates superior performance in root word identification for the education and crime datasets, with respective efficiencies of 49.08% to 49.41% and 61.58%. This observation aligns with the technique employed by Ahmad's algorithm, wherein the search process is conducted on the dictionary prior to the application of the stemming rules.

In the context of under-stemming errors, the Ahmad algorithm for Set B produces higher under-stemmed words, which is around 4.39% for the education domain and 4.55% for the crime domain. These percentages represent the ratio of under-stemmed words to the overall count of words remaining subsequent to the elimination of stop words. This is the result of employing a dictionary lookup function, which verifies the existence of the root word in the stemmed word even after it has been stemmed by a single rule. In the situation where the stemmed word is present in the dictionary, the evaluation against subsequent stemming rules stops, and the word is deemed a root word. Meanwhile, the Othman algorithm produces a higher frequency of over-stemming errors, which is around 9.46% for the education dataset and 11.46% for the crime domain. This demonstrates that the diversity of morphological rules is crucial for reducing over-stemming errors in the Malay language, which has a complex morphological structure due to the presence of affixes.

B. Stemming Acuracy

The accuracy of stemming performance is assessed by computing the ratio of correctly stemmed words to the sum of correctly and incorrectly stemmed words. Correctly stemmed words are recognised as the word that has been truncated to the appropriate root word and the word that has been correctly identified as the root word. On the other hand, words that have been incorrectly stemmed are classified as either under-stemmed, over-stemmed, or words with spelling exceptions.

Table V and Fig. 4 present a comparative analysis of the performance accuracy achieved by the Othman and Ahmad algorithms in the domains of education and crime. The Ahmad algorithm with Set B rules, when applied to the education dataset consisting of 100 course summaries, demonstrates the highest level of accuracy in stemming performance, achieving a rate of 93.61%. This accuracy rate is only marginally different from the Ahmad algorithm with Set C rules, which achieves a rate of 93.53%. In contrast, the Othman algorithm yields the least accurate results, approximately 86.04%.

In the context of a crime dataset consisting of 100 housebreaking crime reports, the Ahmad algorithm, when employing Set C rules, achieves the highest level of accuracy in stemming performance, with a rate of 93.80%. However, the difference in stemming accuracy achieved by implementing Set B rules is minimal, with a mere 0.04% variation. Meanwhile, the Othman algorithm exhibits a comparatively lower level of accuracy, measuring at 83.09%.

TABLE V. COMPARATIVE ANALYSIS OF ACCURACY PERFORMANCE FOR OTHMAN ALGORITHM AND AHMAD ALGORITHM

Algorithms	**Education Domain**					**Crime Domain**				
	Correctly stemmed words		***Incorrectly stemmed words***	***Correctly stemmed words + Incorrectly stemmed words***	***Accuracy (%)***	***Correctly stemmed words***		***Incorrectly stemmed words***	***Correctly stemmed words + Incorrectly stemmed words***	***Accuracy (%)***
	Correct stemmed word	***Correct root word identified***				***Correct stemmed word***	***Correct root word identified***			
Othman Algorithm (SET A)	1572	1633	520	3725	86.04%	736	1273	409	2418	83.09%
Ahmad Algorithm (SET B)	1529	1959	238	3726	93.61%	736	1531	151	2418	93.76%
Ahmad Algorithm (SET C)	1526	1959	241	3726	93.53%	737	1531	150	2418	93.80%

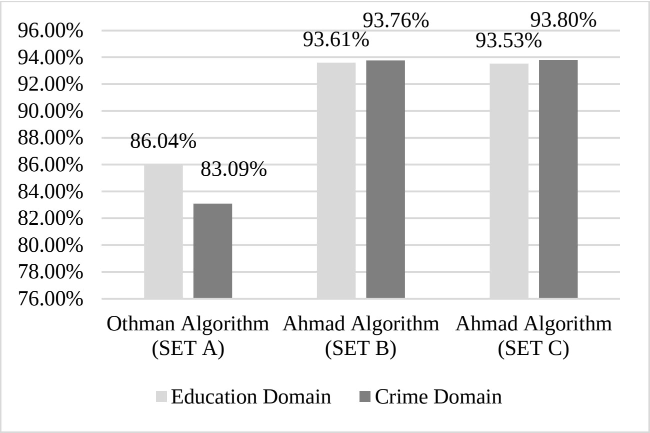

Fig. 4. Stemming accuracy for othman algorithm and ahmad algorithm.

The Ahmad algorithm consistently exhibits superior accuracy in stemming performance when compared to the Othman algorithm, irrespective of the nature of the datasets used. The findings show that the variants of morphological rules and the dictionary lookup approach are significantly contributing to the overall stemming accuracy.

V. CONCLUSION

The purpose of this study is to perform a comparative analysis of the stemming performance of the Ahmad and Othman algorithms, two prominent and pioneering Malay stemming algorithms, on housebreaking crime reports. The Ahmad algorithm has the greatest stemming accuracy rate, indicating that it is extremely unreliable for producing stem words across all dataset domains. The insignificant difference in stemming accuracy when Set B, which consists of 432 rules, and Set C that contains 561 rules, are implemented in the Ahmad algorithm indicates that the 432 rules are sufficiently significant to yield favourable outcomes, whether for stemming the dataset in the domain of education or crime. This is evident from the stemming accuracy results, which indicate a difference of approximately 0.08% and 0.04% between these two sets of rules applied to the education data and crime data set, respectively. Meanwhile, the dataset comprising textual records of housebreaking crime reports exhibits a substantial presence of root words, thereby requiring less effort for stemming operations. The performance of stemming accuracy is significantly impacted by this factor, as the quantity of root words present in the dataset directly correlates with the number of correctly stemmed words. There is a decreased probability of stemming errors occurring when fewer stemming operations are necessary. In addition, a restricted vocabulary range, and a notable prevalence of word repetition in the textual dataset also contribute to the stemming result. Henceforth, a thorough assessment of the functionalities of these two algorithms may be extended to encompass additional textual datasets that are more vocabulary-rich.

Advanced Detection of COVID-19 Through X-ray Imaging using CovidFusionNet with Hybrid CNN Fusion and Multi-resolution Analysis

Majdi Khalid
Department of Computer Science and Artificial Intelligence-College of Computers, Umm Al-Qura University,
Makkah 21955, Saudi Arabia

***Abstract*—The rapid diagnosis of COVID-19 through imaging is crucial in the current pandemic scenario. This study introduces the CovidFusionNet, a novel model adapted for efficient COVID-19 image classification. By effectively combining fusing features from seven pre-trained convolutional neural networks (CNNs), our model presents better accuracy in detecting COVID-19 from X-ray images. Three separate datasets, obtained from Kaggle, were used in this study to ensure the reliability and robustness of the model. The Continuous and Discrete Wavelet Transform was implemented for robust multi-resolution image analysis to maintain image properties after denoising. A novel enhancement method was also proposed, combining the capabilities of Adaptive Histogram Equalization (AHE) and Wavelet Transforms to emphasize finer details and concurrently heighten clarity while minimizing noise. Furthermore, to mitigate class imbalance, an oversampling approach was implemented. Comprehensive validation using 12 metrics across each dataset verified the proposed consistent performance, with remarkable accuracies of 98.02% for Dataset One, 99.30% for Dataset Two, and 98.25% for Dataset Three. Comparing CovidFusionNet against seven well-known pre-trained models showed that CovidFusionNet appeared more capable. This research advances the area of image-based diagnosis using COVID-19 and provides a model for quick medical actions.**

Keywords*—*COVID-19 diagnosis; X-ray imaging; wavelet transform; Adaptive Histogram Equalization (AHE); oversampling; image denoising; image classification

I. Introduction

COVID-19 is a novel infectious disease caused by a new flu virus. It first emerged in Wuhan, China, in December 2019 [1]. It's one of the largest worldwide challenges of the 21st century [2, 3]. In March 2020, the World Health Organization (WHO) stated it was a widespread epidemic [4, 5]. COVID-19 is similar to other diseases like MERS and SARS since they all originate from the coronavirus family and harm our lungs [6, 7]. People with COVID-19 could cough, have a fever, feel tired, and lose their sense of taste and smell [8]. Some feel severely ill, have difficulties breathing, or even face life-threatening conditions, including kidney failure [9]. Many individuals died from it globally [10]. Thankfully, numerous companies have created vaccinations and various testing are being done over the world.

Finding persons with COVID-19 quickly is critically crucial to stop it from spreading. One approach to test for it is called RT-PCR [11, 12]. This test takes roughly four to six hours to display results. But, since so many people require testing, laboratories grow incredibly busy and cannot test everyone quickly enough [13]. This means a few people do not get diagnosed and may transmit the infection to others. We need a speedier, automated mechanism to test individuals. It would be beneficial to develop a simpler test that returns answers even sooner, so everyone can know whether they have the virus.

The rapid spread of the COVID-19 pandemic has necessitated the development of effective diagnostic tools for its timely detection. Chest X-ray imaging has emerged as a pivotal diagnostic method to assess the impact of the virus on the lungs. To enhance the efficiency and accuracy of detecting COVID-19 from X-ray images, researchers have proposed various computational methods, primarily harnessing the potential of deep learning. These models aim to swiftly identify patterns indicative of the virus, thereby aiding quicker clinical interventions. This literature review delves into multiple approaches undertaken by researchers worldwide, offering a comprehensive understanding of the advancement in this domain.

In research [14], Terry Gao and Grace Wang employed a set of lung X-ray images that were used to train a deep CNN that can distinguish between noise and useful information. This CNN can then use the data to train and interpret new images by spotting patterns that point to COVID-19. Singh et al. in study [15] suggested the Covid-aid model, an extension of the DarkCovidNet's architecture. With 19 convolution layers and six max-pooling layers, the model defines the lung X-ray images to determine normal, COVID-19 and pneumonia. Though the model could successfully classify the data, the classification accuracy is only 87%. Similarly, Shah et al. [16] proposed a hybrid model that employs a convolutional neural network (CNN) and Gated Recurrent Unit (GRU) to classify the diseases. The CNN model performs feature extraction in this study, whereas the GRU serves as an image classifier. The model is trained and validated with 200 epochs, and on the final epoch, the validation accuracy is as high as 93%. In [17], Khan et al. proposed a CNN architecture to classify COVID-19 pneumonia. The model is constructed employing the transform-merge block (STM) and RE-based operation for feature extraction. Among the three datasets used on the study, the proposed model performs best on the CoV-NonCoV-15k dataset with an accuracy rate of 96.53%.

To classify COVID-19 from chest X-ray images, Gayathri et al. in [18] have proposed an ensemble model after experimenting with several pre-trained model. Among the experimented models, the best outcome was observed from the fusion of the InceptionResNetV2 and Xception models with an accuracy of 95.78%. However, the outcome only depends on the conditions under which the Sparse autoencoder is used for dimensionality reduction and a Feed Forward Neural Network is employed for COVID-19 detection. Banerjee et al. [19] proposed a random forest meta-learning blending algorithm. The strategy follows the decision score technique. For feature extraction of the X-ray images, DenseNet201 architecture is implemented. However, the model only performs well when the dataset is small. On the small Chowdhury et al.'s dataset, the model showed an accuracy rate of 98.13%, whereas, on the larger Wang et al.'s COVID-X dataset, the accuracy was 94.55%.

In the paper [20], Ismael et al. has proposed multiple approaches to classify COVID-19 from the chest X-ray images using deep learning-based models. The study used several CNN models to extract features from the image data. With the assistance of ResNet50 deep feature extractor, the SVM classifier obtained a classification accuracy of 94.7%. Additionally, the authors suggested a fine-tuned CNN model that gives an accuracy rate of 92.6% for the same image data. However, in this study, the lowest accuracy of 91.6% was obtained from a CNN model with end-to-end training. It can be understood that deep approaches are more efficient in the classification of COVID-19 X-ray image data. In study [21], Kanjanasurat et al. used a combination of CNN and RNN techniques. In this study, the fully connected layers of the CNN model, ResNet152V2, were replaced by the RNN model, GRU, to achieve a classification accuracy of 93.37%. Here, the CNN layers were responsible for extracting the features of the data and calculation of dependencies and classification were performed by the RNN layers.

For the classification of chest X-ray images obtained from various sources, Alshmrani et al. suggested a VGG19 model with a fully connected network [22]. The model is assisted by CNN model for feature extraction. This technique provides an accuracy of 96.48% for image classification. In study [23] using ensemble method, Kuzinkovas et al. suggested a model where ANN, LR, LDA and RF performs the task of image classification with an accuracy of 98.34%. During the classification task, the ensemble model uses ResNet50, VGG19, VGG16, and GLCM for feature extraction. Another CNN-based model was suggested by Hafeez et al. in [24] for COVID-19 classification. The proposed CODSC-CNN is consisted of 8 weighted and two fully connected layers. The model is inspired by the pre-trained AlexNet and VGG16 models. The model has an 89% success rate in identifying COVID-19 X-ray images.

Based upon prior research (see Table I) in the area of COVID-19 image identification, we found a few drawbacks in the present approaches. Particularly, several of these models struggle with challenges relating to accuracy, the complexity of managing unbalanced image datasets, and the limitation of constrained data availability. In an attempt to solve these inadequacies and improve the diagnostic effectiveness, we developed the CovidFusionNet. Our proposed model combines the capabilities of multiple pre-trained models to offer higher performance and attain exact identification of COVID-19 in imaging data. By employing an ensemble method, CovidFusionNet seeks to create a new standard in terms of accuracy and durability in COVID-19 identification via imaging. The primary motivation of CovidFusionNet is to optimize the efficiency and precision of COVID-19 diagnosis by exploiting medical imaging, particularly X-ray images. This involves providing medical professionals with a dependable and effective method to detect COVID-19 cases. This is essential due to the fast virus transmission and the need for immediate action. The main contributions in this paper are as follows:

- Proposed a novel fusion model, CovidFusionNet that effectively utilizes the features of multiple pre-trained CNNs to improve COVID-19 image classification. This strategic fusion model assures CovidFusionNet heightened accuracy and flexibility in identifying COVID-19 cases.
- Introduced the use of the Continuous and Discrete Wavelet Transform for multi-resolution analysis. This transformation retains the image's pixel value distributions, ensuring features are preserved during denoising.
- Proposed a novel enhancement method that combines the strengths of AHE and Wavelet Transforms. The method focuses on intricate details, simultaneously enhancing and minimizing noise for optimal image clarity.
- Recognized the presence of class imbalances in the datasets and applied an over-sampling approach, ensuring unbiased model performance.
- We employed 12 evaluation metrics across three distinct datasets to assess the model's reliability and consistency. This thorough evaluation confirms our model's ability to consistently perform well across various datasets, underscoring its adaptability and reliability. Furthermore, we compared the performance of our proposed model with seven pre-trained models to demonstrate its superior capabilities and enhancements.

The structure of the remainder of the paper is organized as follows: Section II presents the data collection process, data preprocessing techniques, handling, and the overall methodology of the proposed framework. Section III delves into the findings and results obtained from applying the proposed method. Section IV provides a comprehensive discussion on these findings, exploring their implications and significance. Section V provides the paper's final section, summarizing the main results and presenting valuable perspectives on possible future research areas in this field.

II. Proposed Method

In this study, we utilized a systematic strategy to diagnose COVID-19 through imaging. Using three distinctive Kaggle-sourced X-ray datasets, our initial step was image denoising using Continuous and Discrete Wavelet Transforms.

Additionally, a unique improvement approach, merging Adaptive Histogram Equalization (AHE) and Wavelet Transforms, was applied for the enhancement of the image. Recognizing the difficulty of data imbalance, an oversampling approach was applied. The main component of our technique, the CovidFusionNet, fuses feature from seven pre-trained CNNs, achieving greater accuracy. Rigorous validation was undertaken across measures, and comparison analyses were made against renowned pre-trained models. The entire procedure is portrayed in Fig. 1.

TABLE I. A CONCISE OVERVIEW OF CONTEMPORARY DEEP LEARNING RESEARCH ON X-RAYS OF COVID-19

Reference	Dataset	Methodology	Limitations
2020 [14]	Middlemore Hospital data	CNN	Small dataset, training set is unknown, lack of details performance metrics
	Kaggle

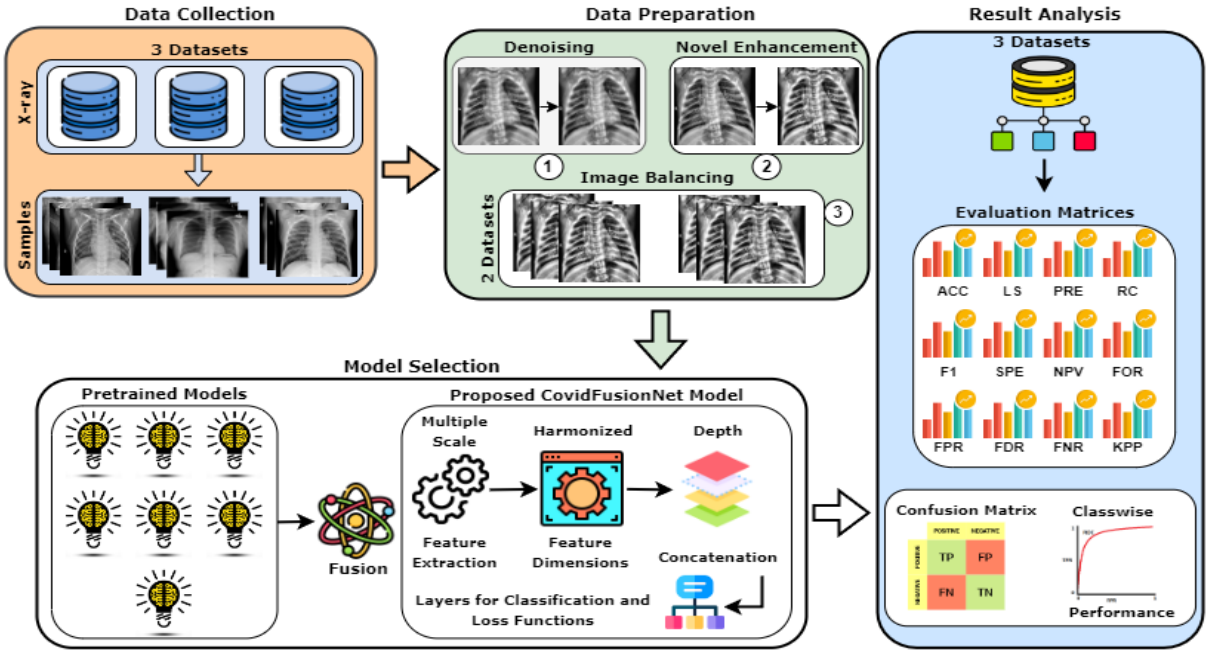

Fig. 1. Proposed workflow of our study for COVID-19 detection.

A. Data Dimensions

For the study on COVID-19 identification, we acquired three different datasets from Kaggle. The first dataset comprises 4,551 X-ray images. Among them, 1,281 images are COVID-19, whereas the remaining 3,270 are normal. This dataset is a compilation of COVID-19 Chest X-ray images gathered by aggregating 15 publicly accessible datasets. The second dataset gives us 4,626 images, split equally, with 2,313 indicating COVID-19 abnormalities and the other 2,313 being normal. The X-ray data used in this second dataset were obtained from numerous sources, such as the GitHub repository, Radiopaedia, the Italian Society of Radiology (SIRM), and the Figshare data repository sites. Our third and final dataset contains 2,159 X-ray images, out of which 576 show COVID-19 features, while 1,583 are categorized as normal. Fig. 2 displays the samples of three datasets. To improve our study's accuracy, we implemented several preprocessing methods. These comprised Image Denoising, Image Enhancement, and Image Balancing. These processes helped make the images more apparent, ensure they were accurately recognized, and make the data more consistent.

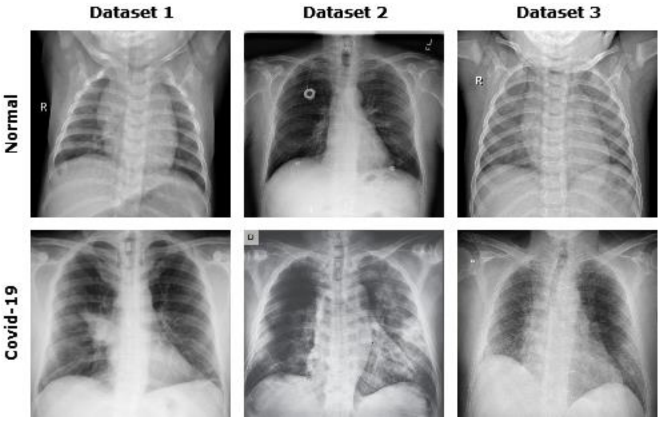

Fig. 2. Sample images from all three datasets.

B. Data Preparation

Data preparation is crucial since it eliminates inconsistencies and inaccuracies, assuring data accuracy. It prepares data for study by reducing noise and irrelevant information [25]. Preprocessing assists in discovering patterns that could be hidden in raw data. Ultimately, it boosts the performance and reliability of deep learning models.

1) Wavelet Transformation (Image Denoising): The Wavelet Transform enables a multi-resolution analysis of a given function or signal by describing it in terms of basic functions obtained from the dilation and translation of a prototype function, nicknamed the "mother wavelet," indicated a $\Psi(t)$. For the Continuous Wavelet Transform (CWT), the transform of a function $f(t)$ can be described as:

$$\boldsymbol{W_f(a,b) = \frac{1}{\sqrt{|a|}} \int_{-\infty}^{\infty} f(t)\Psi(\frac{t-b}{a})dt} \qquad (1)$$

Here, $\mathrm{W_f(a,b)}$ denotes the wavelet coefficient, with a being the dilation parameter and b the translation parameter. The transformation process encompasses the complete domain of $\mathrm{f(t)}$. Crucially, the selected mother wavelet $\Psi(\mathrm{t})$ must conform to the admissibility requirement, defined as:

$$\boldsymbol{C_\Psi = \int_{-\infty}^{\infty}(\frac{|\Psi^\wedge(f)|^2}{|f|})df < \infty} \qquad (2)$$

In this instance, $\Psi^\wedge(f)$ stands for the Fourier transform of $\Psi(t)$. When transferring to the domain of discrete signals, especially crucial for digital applications, the Discrete Wavelet Transform (DWT) becomes increasingly significant. In the DWT, the continuous parameters a and b are discretized, generally specified as $a = 2^m$ and $b = n2^m$, with m and n being integers. This discretization allows a hierarchical examination of the function. The DWT is applied in both row and column directions for two-dimensional data such as images. This leads to four sets of coefficients capturing different information: the approximation (LL) , horizontal (LH), vertical (HL), and diagonal details (HH). A fundamental virtue of the wavelet transform is its reversibility, allowing for the original function or image to be rebuilt from its wavelet coefficients using the inverse wavelet transform. Fig. 3 illustrates the output of the Wavelet Transformation with its histogram. The histograms of the original and reconstructed images are remarkably similar, it shows that the wavelet transform (and its inverse) has successfully retained the pixel value distributions of the original image. This positive indicator shows that the wavelet transformation has kept the image's features well.

Algorithm 1. Hybrid AHE-Wavelet Image Enhancement (HAWIE)

```
Procedure HAWIE (Image $I$, SavePath S)
  Load necessary libraries: numpy, OpenCv,
  PyWavelets, Matplotlib
  function AHE_Enhancement (Image)
      Apply Adaptive Histogram Equalization on the Image
    return Enhanced image using AHE
  end function
  function Wavelet_Enhancement (Image)
    Convert image to floating-point representation
    Decompose image into wavelet coefficients
    Modify wavelet coefficients
    Reconstruct image from modified coefficients
    return wavelet-enhanced image
  end function
  $I_{AHE}$ = AHE_Enhancement (Image $I$)
  $I_{Enhanced}$ = Wavelet_Enhancement ($I_{AHE}$)
  if SavePath S is provided then
    Save $I_{Enhanced}$ to S
  end if
  return $I$, $I_{Enhanced}$
end procedure
```

2) Hybrid AHE-Wavelet Image Enhancement (HAWIE): In this study, we proposed a Hybrid AHE-Wavelet image enhancement (HAWIE) method as a novel approach for image improvement. This approach combines the comprehensive contrast refinement of Adaptive Histogram Equalization (AHE) with the multi-resolution capabilities of Wavelet

Transforms. Specifically, AHE concentrates on very small overlapping regions of an image, ensuring that every microscopic feature is properly accentuated, whether in a bright or dark location. Following the AHE process, the Wavelet Transform takes center stage, breaking the image into an array of frequency components. This enables a more focused enhancement, where certain visual elements may be enhanced while any undesired noise is concurrently minimized. Our findings, as illustrated in Fig. 4, give an impressive visual illustration of this hybrid method. The difference image, in particular, emerges as a useful tool, clearly emphasizing places that have received adjustments or upgrades. This visualization becomes even more informative when matched with the accompanying scatter plot, where the X-axis indicates pixel values from the original image. At the same time, the Y-axis exhibits those from the improved image. Each point on this figure encapsulates a pixel, its position demonstrating the association between the original and enhanced pixel values. The deviations from the "Line of Identity", a red dashed line showing identical pixel values in both images, give essential insights into the transformational power of the HAWIE approach, emphasizing its capabilities, particularly in vital sectors such as medical imaging. Algorithm 1 provides the overview structure of HAWIE.

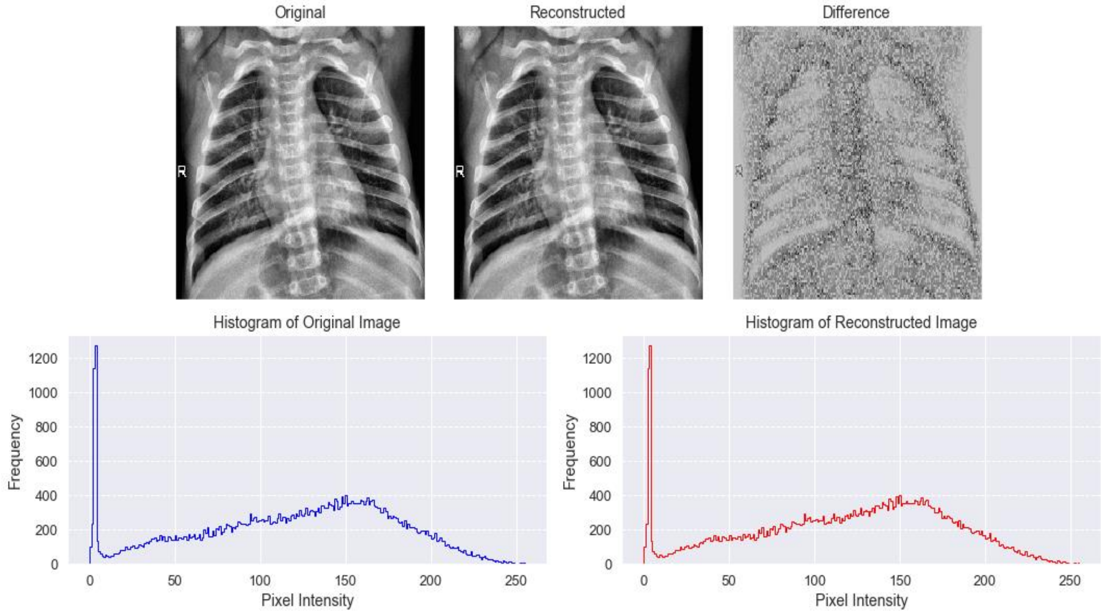

Fig. 3. Output of the wavelet transform with the histograms of the original and reconstructed images. The histogram comparison highlights the wavelet transform's efficacy in maintaining the image's features.

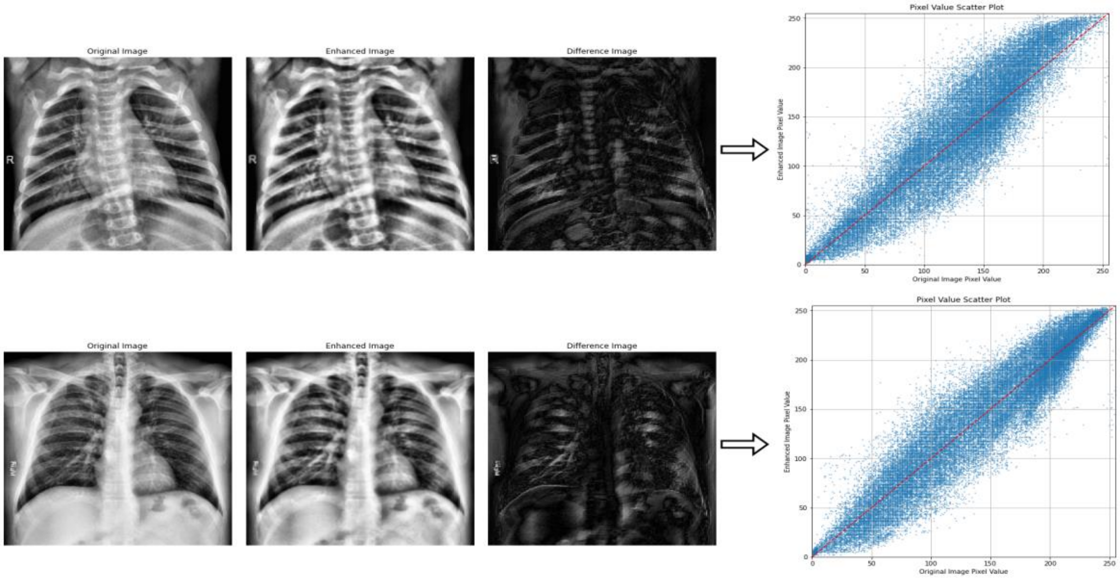

Fig. 4. Illustration of the HAWIE technique effects. The difference image reveals regions of enhancement, while the scatter plot showcases the relationship between original and enhanced pixel values, with deviations indicating modifications.

3) Image Balancing (Oversampling): In this study, we utilized three datasets for analysis. While Dataset 2 was already balanced, Datasets 1 and 3 demonstrated class imbalance, where some classes contained fewer samples than others. This mismatch may lead to biased model performance, perhaps favoring the more dominant classes. We utilized an oversampling approach to solve this difficulty, particularly for the minority classes in Datasets 1 and 3.

The oversampling approach operates by first selecting the class with the maximum number of samples, known as max_count. This count then sets the aim for all classes in the balanced dataset. For those classes with samples less than max_count, the oversampling strategy duplicates their samples until this goal number is attained. Replication is cyclic, meaning that once the end of a class's sample list is reached, it returns to the beginning, assuring a smooth continuation until the target sample count is attained. By applying this strategy, every class in the enlarged datasets (Datasets 1 and 3) now has an equal representation. This parity creates a balanced basis for subsequent data modeling and analysis. By executing this oversampling programmatically, the balanced datasets were stored in a different directory, guaranteeing clarity for later operations. The ultimate purpose of this technique is to reinforce the models' generalizability, trained on the modified datasets, ensuring they give unbiased insights unaffected by the over-representative classes of the original datasets. Table II represents the final datasets after all preprocessed attempts.

TABLE II. DISTRIBUTION OF SAMPLES ACROSS CLASSES IN DATASETS 1, 2, AND 3, ILLUSTRATING POST-OVERSAMPLING

Parameters	Dataset 1	Dataset 2	Dataset 3
Wavelet Transformation	✓	✓	✓
HAWIE	✓	✓	✓
Oversampling	✓	--	✓
Total Images	6540	4626	3166
Train (70%)	4578	3241	2216
Test (20%)	1308	925	633
Validation (10%)	654	460	317

C. Model Selection

For our study, we methodically selected seven pretrained models, each known for particular abilities in image processing. We included VGG19 for its comprehensive feature extraction from its deep 19-layer architecture. MobileNetV2 was selected for its best balance between computing performance and accuracy, which is appropriate for real-time activities. AlexNet, a pioneering model from the ImageNet competition, offers a basic baseline. Simultaneously, the innovative residual blocks of ResNet50, the multi-scale feature capture of InceptionV3, the fine-grained classifications from DenseNet201, and the efficiency of Xception each bring unique value. Together, this collection provides for complete performance evaluations across diverse architectures. Building on their distinct strengths, we next combined the special features of all seven deep learning models to develop our proposed innovative fusion model: CovidFusionNet.

1) VGG19: VGG19 is a well-known deep-learning architecture for classification of images [26]. It has 19 layers in total, including 16 convolutional layers, three fully connected levels, and five max-pooling layers. The persistent use of tiny 3×3 convolutional filters with a stride of 1, which are effective at extracting detailed information when stacked in succession, is a distinguishing characteristic of VGG19. VGG19 ensures the capture of detailed patterns at different spatial hierarchies by gradually increasing the number of filters from 64 in the initial layers to 512 in the deeper ones. The convolutional layers are separated by max-pooling layers with a 2×2 filter size and a stride of 2, which down-samples the spatial dimensions while retaining essential information. Following the convolutional layers, there are three fully connected layers, each having 4096, 4096, and 1000 neurons. Each convolutional layer has a ReLU activation to include nonlinearity in the model. While the uniform structure minimizes architectural complexity, the depth of VGG19 necessitates large processing resources. Nonetheless, its architecture has significantly impacted the field, emphasizing the promise of deeper networks for improved picture identification.

2) MobileNetV2: MobileNetV2 is a simplified deep-learning architecture designed for mobile devices and computationally constrained applications [27]. Inverted residuals and linear bottlenecks are central to its architecture, where channels are first reduced using a 1×1 convolution, followed by a 3×3 depthwise convolution, and then enlarged again, optimizing computational efficiency without compromising feature extraction capabilities. The model makes use of depthwise separable convolutions to reduce parameter counts by separating spatial and channel-wise calculations. MobileNetV2 slims its design even further by preceding fully connected layers in favor of average pooling leading into a SoftMax layer, giving it the highest level of efficiency and performance in on device deep learning applications.

3) AlexNet: AlexNet, a significant deep learning architecture, was essential in advancing the deep learning domain, particularly in the classification of images [28]. The network is composed of five convolutional layers, which are followed by three fully connected layers. The use of bigger filter sizes in AlexNet's first layers is a distinguishing feature; particularly, the first convolutional layer has 11×11 kernels with a stride of 4. As the network grows, it utilizes smaller and smaller filters, such as 5×5 and 3×3. AlexNet was among the first to use ReLU as activation functions, overcoming the vanishing gradient issue that afflicted networks that used classic sigmoid activations. Another novel idea introduced was the notion of dropout layers, in which a part of a neuron is randomly deactivated during training to prevent overfitting. The network also used data augmentation methods such as image translations and horizontal flips to increase the quantity and variety of the training dataset, which improved model generalization. AlexNet's exceptional performance entrenched deep neural networks as the dominant technique for picture classification, setting the framework for future architectural improvements in deep learning.

4) ResNet50: ResNet50, a member of the Residual Network group, transformed deep learning architectures by introducing residual connections, which are referred to as "skip connections." These connections enable the output of one layer to skip one or more following layers before being summed with the output of the latter, so minimizing the vanishing gradient issue and allowing the training of even deeper networks [29]. ResNet50 is made up of 50 layers that are organized as a blend of convolutional and identity blocks. Each block generally has three convolutional layers with filter sizes of 1×1, 3×3, and 1×1, which are used to decrease dimensionality, collect spatial data, and then restore dimensionality. Strides vary depending on the location of the layer, with stride-2 convolutions used to minimize spatial dimensions, half the height and length while doubling the number of filters. One of ResNet50's key characteristics is its capacity to retain information from previous layers, allowing it to capture both low-level and high-level features. Throughout the network, batch normalization and ReLU activation are employed to stabilize training and induce non-linearity. ResNet50's novel architecture, designed for high accuracy in image classification tasks, not only aids deeper model training but also establishes a new benchmark in deep learning, driving further design advances.

5) InceptionV3: InceptionV3 is a well-known deep learning model for image categorization. Its advanced "modules" execute concurrent convolutional processes with various kernel sizes, such as 1×1, 3×3, and 5×5, inside a single layer [30]. This multi-path technique allows InceptionV3 to record various spatial feature hierarchies at the same time, incorporating both granular and larger viewpoints. The use of factorized convolutions, which split bigger filters into smaller, asymmetric ones like 1×3 and 3×1, is one of InceptionV3's innovations, assuring computational efficiency without losing receptive scope. "Auxiliary classifiers" are deliberately put in the network's intermediate layers to push gradients to inner layers and boost regularization. Batch normalization is used consistently throughout the layers, giving stability to the activations and allowing for smoother training dynamics. Despite its sophisticated design, which combines multi-scale feature extraction with computational prudence, InceptionV3 exemplifies what is possible in terms of balancing accuracy and resource needs in the area of deep image classification.

6) DenseNet201: DenseNet201 distinguishes itself among deep learning architectures developed for image categorization by virtue of its remarkable dense connectivity [31]. Unlike the traditional technique, in which each layer gets information only from its immediate predecessor, DenseNet201 guarantees that each layer receives input from all previous levels, resulting in an extensive network of connections. This configuration encourages feature reuse and ensures more efficient gradient flow across the network, solving issues such as the disappearing gradient problem, which is common in deep architectures. Each layer, which is divided into interconnected blocks, generally employs 3×3 convolutional filters, with precise growth rates defining the insertion of additional filters as the network deepens. To regulate and aggregate feature-map dimensions, transition layers of 1×1 convolutional filters with a stride of 2 are alternated between these dense blocks. DenseNet201, with its 201 layers, is capable of collecting sophisticated image patterns without a massive rise in parameters due to its dense design. DenseNet201's architecture, which emphasizes continuous feature propagation and efficient gradient distribution, makes it highly resistant to overfitting and places it as a model of choice for complex image classification tasks.

7) Xception: Xception, which stands for "Extreme Inception," is a complex classification architecture that redefines the traditional inception technique by using depthwise separable convolutions [32]. This fundamental breakthrough divides convolutional processes into spatial and channel-based tasks, maximizing efficiency. The Xception model is composed of 71 layers that are organized into modules. Unlike standard Inception modules, which utilize a variety of filter sizes, Xception's architecture relies heavily on 3x3 convolutional kernels for depthwise operations, ensuring a thorough extraction of spatial data. 1x1 convolutions are utilized for cross-channel operations inside these modules. The model achieves strategic downsampling by adopting strides of 2 in selected modules. Xception incorporates residual connections, similar to the ResNet structure, to maintain smooth gradient flow throughout its depth, further strengthening its resilience. Xception proposes an architecture that delivers outstanding performance on picture classification tasks while assuring computational economy by combining the ideas of depthwise separable convolutions, intentional kernel choices, and a thoughtfully built layering scheme.

8) CovidFusionNet (Proposed Model): In this study, we proposed a novel CovidFusionNet model to increase classification performance, particularly for differentiating images related to COVID, by combining the strength of numerous pre-trained convolutional neural networks (CNNs) and their feature extraction capabilities.

The CovidFusionNet model begins by representing each image as I with a shape of 224×224×3. For each base model m within our ensemble model M (which encompasses seven models), the image undergoes a transformation through function f_m, generating a feature map F_m according to the equation 3:

$$F_m = f_m(I) \tag{3}$$

A harmonizing step is essential due to the varied spatial dimensions of the feature maps yielded by the different architectures. A resizing function, represented as R, refines each feature map to achieve a uniform shape:

$$F'_m = R(F_m) \tag{4}$$

Resultantly, F'_m is consistent with a dimension of 224×224×d_m, where d_m marks the depth as per model m. The essence of CovidFusionNet lies in its strategic feature fusion. Feature maps from all models are concatenated in depth, forming an integrated tensor F_c:

$$F_c = Concatenate\ (F'_{vgg16}, F'_{mobilenetv2}, \dots\dots, F'_{xception}) \quad (5)$$

After this fusion, F_c undergoes flattening and is channeled through a series of dense layers. Initially, it interacts with a weight matrix W_1 and bias b_1 to produce an output:

$$o_1 = ReLU\ (v.W_1 + b_1) \quad (6)$$

Post the application dropout regularization for model robustness, the final output is calculated as:

$$O = Softmax\ (o_1.W_2 + b_2) \quad (7)$$

The Categorical Cross entropy loss L supervises the training of the CovidFusionNet:

$$L = -\sum_{i=1}^{2} Y_i\ log\ (O_i) \quad (8)$$

This ensures optimal weight adjustments during training, directing the model toward accurate COVID-19 detection. Algorithm 2 depicts the operation of the proposed model.

Algorithm 2. Proposed CovidFusionNet Development and Operation

```
**Procedure** CovidFusionNet(Image $I$)
    Load pre-trained models into set $M$
    Freeze the weights of the models in $M$
    **for** each model $m$ in $M$ **do**
        Transform image $I$ using $m$ to get feature map $F_m$
        **if** $F_m$ does not have dimension 7×7×$d_m$
            Resize $F_m$ to $F'_m$ of dimension 7×7×$d_m$
        **else**
            $F'_m = F_m$
        **end if**
        Store $F'_m$ in list of feature maps $F'$
    **end for**
    Concatenate feature maps in $F'$ along depth to get $F_c$
    Flatten $F_c$ to get 1D tensor $T$
    $O_1$ = Dense layer with ReLU activation on $T$
    Apply dropout on $o_1$
    $O$ = Dense layer with Softmax activation on result
    **return** $O$
**end procedure**
```

The CovidFusionNet model exhibits remarkable improvements over to prior methodologies in medical image classification, specifically for identifying COVID-19. The main benefit of this approach is the use of numerous pre-trained convolutional neural networks (CNNs), which allows for a more extensive and diverse extraction of features compared to models that rely on a single CNN architecture. The variety of methods used to extract features leads to a classification that is less vulnerable to errors and more precise, which is essential for the specific needs of medical imaging. CovidFusionNet specifically tackles the issue of spatial dimension variability, which is a common occurrence when merging information from various CNNs. The resizing function is utilized to normalize feature maps prior to fusion, promising a consistent and harmonic integration of features. This strategy addresses the constraints associated with the restricted feature representation commonly observed in single-model approaches.

III. Performance Evaluation

Several evaluation metrics were examined to evaluate the efficacy of various deep-learning models. These measures, particularly Accuracy, Loss, Precision, Recall, F1-Score, Specificity, NPV, FOR, FPR, FDR, FNR, and Kappa Score, highlight the efficiency and dependability of the models under assessment. Fig. 5 to Fig. 10 presents a visual illustration of these scores. These figures show an in-depth visual representation of performance metrics [33] for the deep learning models analyzed in our study, including proposed CovidFusionNet (CvNet), VGG19 (VGG), MobileNetV2 (MV2), AlexNet (AxNT), RestNet50 (RsNT), Incep-tionV3 (InV3), DenseNet201 (DSNT), and Xception (XPTN). The metrics are placed across two separate rows inside the image, covering a wide variety of assessment criteria.

A. Performance Evaluation

To evaluate the efficacy of our employed classifiers in identifying COVID-19 from X-ray images, we applied a complete set of evaluation metrics (9) to (20). Where TP, FP, TN, and FN stand for the number of true positive, false positive, true negative and false negative cases, respectively.

Accuracy: Proportion of all X-ray images correctly identified, be it COVID-19 positive or negative.

$$Accuracy = \frac{(TP+TN)}{(TP+FP+TN+FN)} \quad (9)$$

Loss: Quantifies how well the prediction model performs compared to the actual outcomes.

$$Loss = -(y\ log(p) + (1-y)\ log(1-p)) \quad (10)$$

Precision: The percentage of X-rays that were accurately diagnosed as COVID-19 positive.

$$Precision = \frac{TP}{(TP+FP)} \quad (11)$$

Recall: The proportion of true COVID-19 positive X-rays that the model identified.

$$Recall = \frac{TP}{(TP+FN)} \quad (12)$$

F1-Score: Harmonic mean of precision and recall, ensuring a balance between them.

$$F1_{score} = 2 \times \frac{Precision*Recall}{Precision+Recall} \quad (13)$$

Specificity: The percentage of COVID-19 negative X-rays that the model accurately detected out of all the actual images.

$$Specificity = \frac{TN}{(TN+FP)} \quad (14)$$

NPV (Negative Predictive Value): The percentage of X-rays that were appropriately diagnosed as COVID-19 negative.

$$NPV = \frac{TN}{(TN+FN)} \quad (15)$$

FOR (False Omission Rate): percentage of COVID-19 positive cases that were actual but were misclassified as negative by the model.

$$FOR = \frac{FN}{(FN+TN)} \quad (16)$$

FPR (False Positive Rate): The proportion of real COVID-19 negative cases that were misclassified as positive by the model.

$$FPR = \frac{FP}{(FP+TN)} \quad (17)$$

FDR (False Discovery Rate): The proportion of X-rays mistakenly classified as COVID-19 positive but truly negative.

$$FDR = \frac{FP}{(FP+TP)} \quad (18)$$

FNR (False Negative Rate): The percentage of real COVID-19 positive cases that the model failed to predict.

$$FNR = \frac{FN}{(FN+TP)} \quad (19)$$

Kappa Score: Measures validity of predicted and actual classifications, adjusting for chance. A score near to 1 indicates outstanding alignment.

$$K = \frac{P_o - P_e}{1 - P_e} \quad (20)$$

where, p_o is the observed agreement, and p_e is the expected agreement.

B. Performance for Dataset 1

From the analysis of dataset 1, CvNet appears as a highly effective classifier, obtaining an ACC of 98.02%. Specifically, with CvNet, we notice an excellent PRE of 98.5%. It is followed at some distance by MV2, which records a score of 91.5%. Moving to the REC criteria, RsNT and InV3 exhibit impressive scores of 86.5%, but CvNet stands out with a significant score of 97.5%. Concerning F1S, whereas XPTN remains with a score of 82.75%, CvNet increases by reaching its highest point with a score of 98%. In terms of Specificity, a parameter important for understanding the real negative rate, CvNet again outperforms with 98.5%, with most other models.

The NPV, FOR, FPR, FDR, FNR, and the Kappa Score further show the capabilities of each model. Notably, CvNet differentiates out across these criteria. With an NPV of 98, it greatly beats VGG, which gets 84.5%. In analyzing the FOR, both VGG and InV3 score on the upper side at 15.5% and 15%, respectively. In comparison, CvNet has a respectable low score of 2%. Focusing on FPR, models like VGG, RsNT, and XPTN indicate heightened values of 15%, 13%, and 17%. Yet again, CvNet excels with a minimum 1.5%. As for FDR, XPTN's rate of 16.5% is in significant contrast to CvNet's low 1.5%. On the FNR front, although XPTN achieves a high 18%, CvNet displays its efficiency with only 2.5%. Lastly, considering the Kappa Score, CvNet's quality shines with 0.96, implying an excellent match with actual labels. On the other hand, XPTN scores 0.66, with MV2 and DSNT coming in between 0.82 and 0.78, respectively. Fig. 5 shows the performance of the models on dataset 1.

Fig. 6 shows the confusion matrix for multiple models, including CvNet, VGG, MV2, AxNT, RsNT, InV3, DSNT, and XPTN, when discriminating between COVID-19 and normal situations. For instance, evaluating the CvNet model, it can be determined that out of the COVID-19 instances, 638 were properly categorized as COVID-19 (True Positives) and 16 were wrongly classified as normal (False Negatives). On the other hand, when evaluating the normal cases, 644 were properly recognized as normal (True Negatives), and 10 were misclassified as COVID-19 (False Positives). Similar classification accuracy and error patterns were also found for the other models. For instance, the VGG model accurately recognized 549 COVID-19 samples but misclassified 105 as normal. Simultaneously, 556 normal samples were identified correctly, whereas 98 were misdiagnosed as COVID-19. However, the performance scores indicate that the CvNet model surpassed all other models in the classification performance for dataset 1.

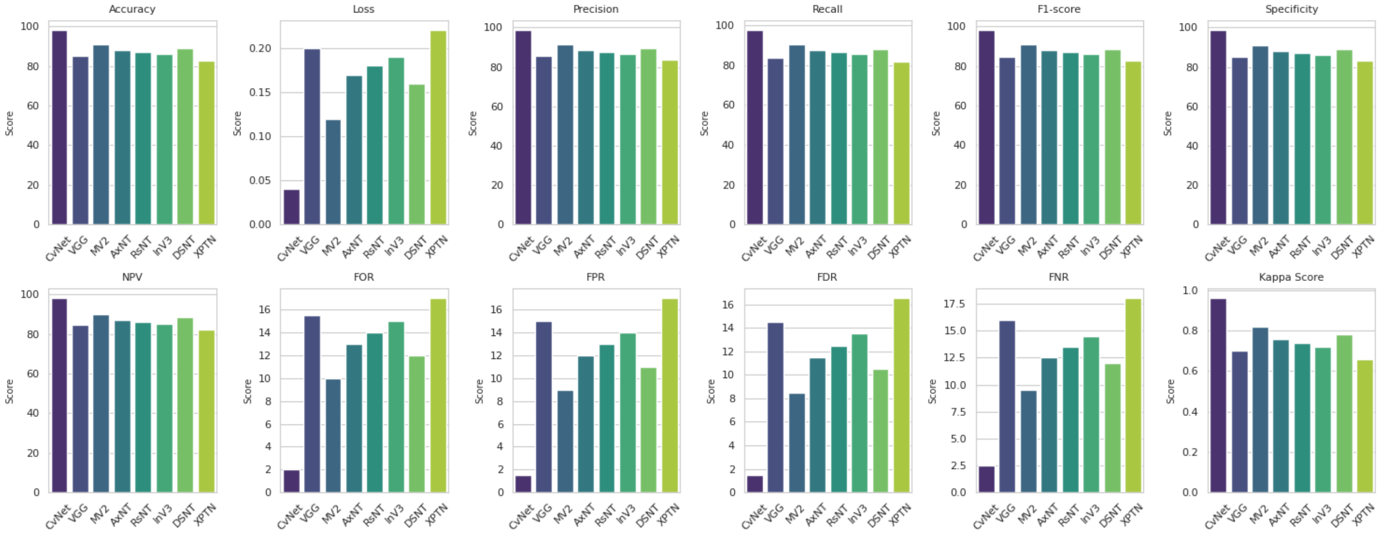

Fig. 5. Comparative performance metrics across the models on dataset 1.

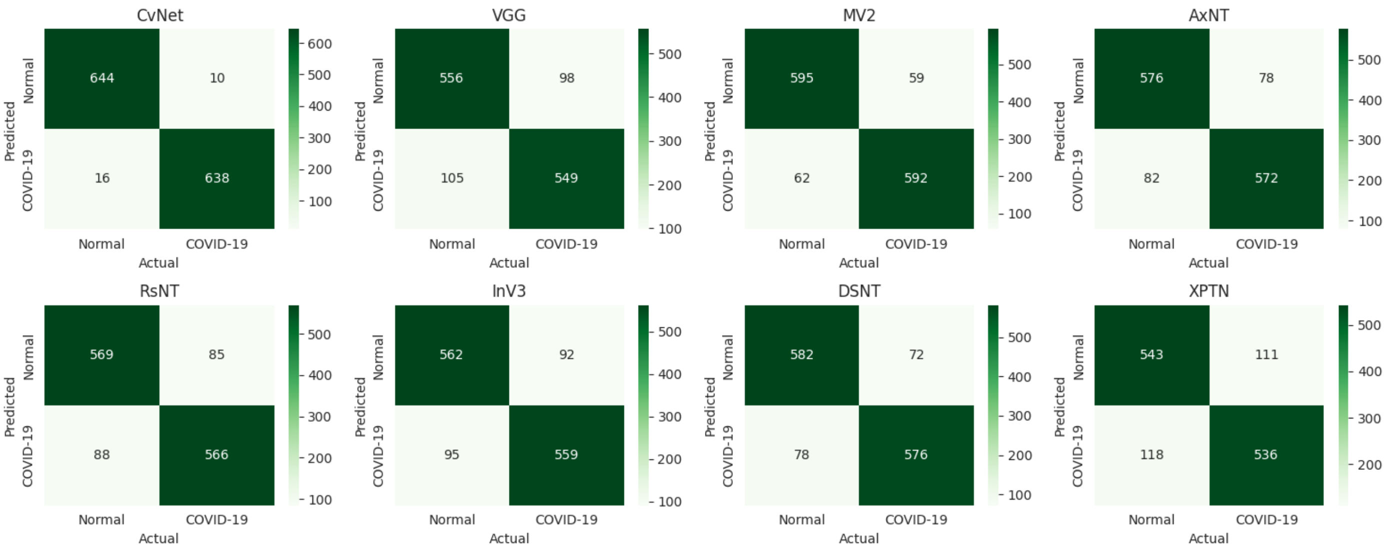

Fig. 6. Confusion matrices of deep learning models for COVID-19 vs. normal classification on dataset 1.

C. Performance for Dataset 2

From the examination of dataset 2, CVNet emerged as the most efficient classifier, obtaining an accuracy of 99.30%. Specifically, with CVNet, we observe an exceptional precision of 99.4%. Following that, MV2 obtained a score of 93.2%. Turning to the recall parameter, RsNT and InV3 exhibit impressive results, but CVNet surpasses with a significant score of 99.2%. In terms of F1-score, whereas Xception (XPTN) achieves a score of 90.10%, CVNet reaches the highest point with a score of 99.30%. For specificity, an essential statistic for distinguishing an actual negative rate, CVNet continues to dominate with 99.3%, outperforming the other models.

Other metrics, including NPV, FOR, FPR, FDR, FNR, and the Kappa Score, further emphasize the capabilities of each model. Furthermore, CvNet differentiates itself across these parameters. With an NPV of 99.3%, it greatly surpasses VGG, which settles at 89.1%. Analyzing the FOR, both VGG and InV3 score better with 10.9% and 16.3%, respectively, although CvNet excels with a low score of 0.7%. Focusing on the FPR, models such as VGG, RsNT, and XPTN exhibit increased rates. Yet again, CvNet outperforms with a minimum 0.7%. In terms of the FDR, XPTN rate of 9.7% compares strongly with CvNet only 0.6%. On the FNR, XPTN displays a higher number, while CvNet demonstrates its efficiency with a modest 0.8%. Finally, while reviewing the Kappa Score, the quality of CvNet shows effectively with 0.986, indicating a nearly perfect agreement with true labels. In comparison, XPTN obtains 0.802, with MV2 and DSNT slowing with their respective scores. Fig. 7 visually represents the model performances with a comprehensive comparison.

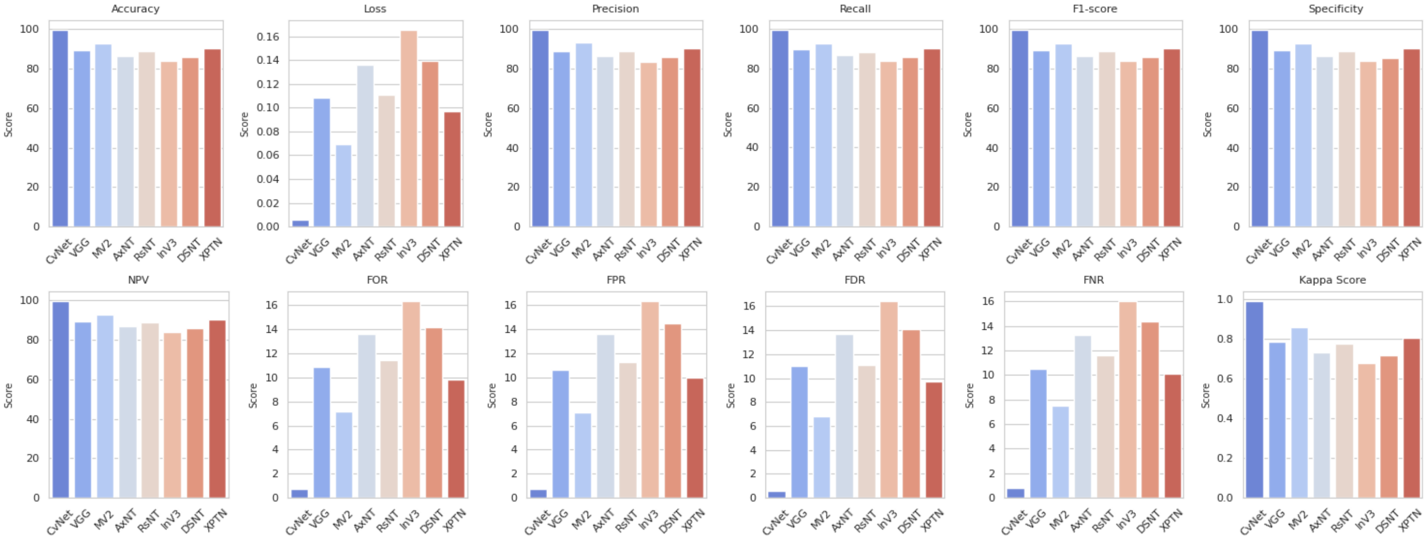

Fig. 7. Comparative performance metrics across the models on dataset 2.

Fig. 8 illustrates the confusion matrix for all of the employed models including CvNet, VGG, MV2, AxNT, RsNT, InV3, DSNT, and XPTN) in the context of identifying between COVID-19 and normal cases. Upon assessing the CvNet model, it's observed that out of the total COVID-19 cases, 495 were accurately recognized as COVID-19 (True Positives), whereas seven were misclassified as normal (False Negatives). In comparison, for the normal cases, 493 occurrences were adequately identified as normal (True Negatives), while five were mislabeled as COVID-19 (False Positives). Observing comparable patterns with different models, take the VGG model as an instance: it correctly recognized 441 occurrences of COVID-19, but mislabeled 61 as normal. Concurrently, out of the normal samples, 439 were appropriately identified, while 59 were incorrectly classed as COVID-19. Despite the variances between models, the performance measures indicate CvNet as the standout, exemplifying higher classification for dataset 2 compared to other models.

D. Performance for Dataset 3

From the assessment of our dataset 3, CvNet emerges as the best classifier with an outstanding accuracy of 98.25%. Specifically, with CvNet, we see an outstanding precision of 98.7%. Besides, MV2 achieves an accuracy of 93.8%. As for the recall, both RsNT and AxNT produced substantial results, CvNet reached out with a higher score of 98%. Moving to the F1-score, though XPTN gains a score of 91.9%, CvNet achieves its highest rating with 98.35%. In specificity, a critical parameter for determining the real negative rate, CvNet maintains its dominance with a remarkable 98.9%, surpassing the other models.

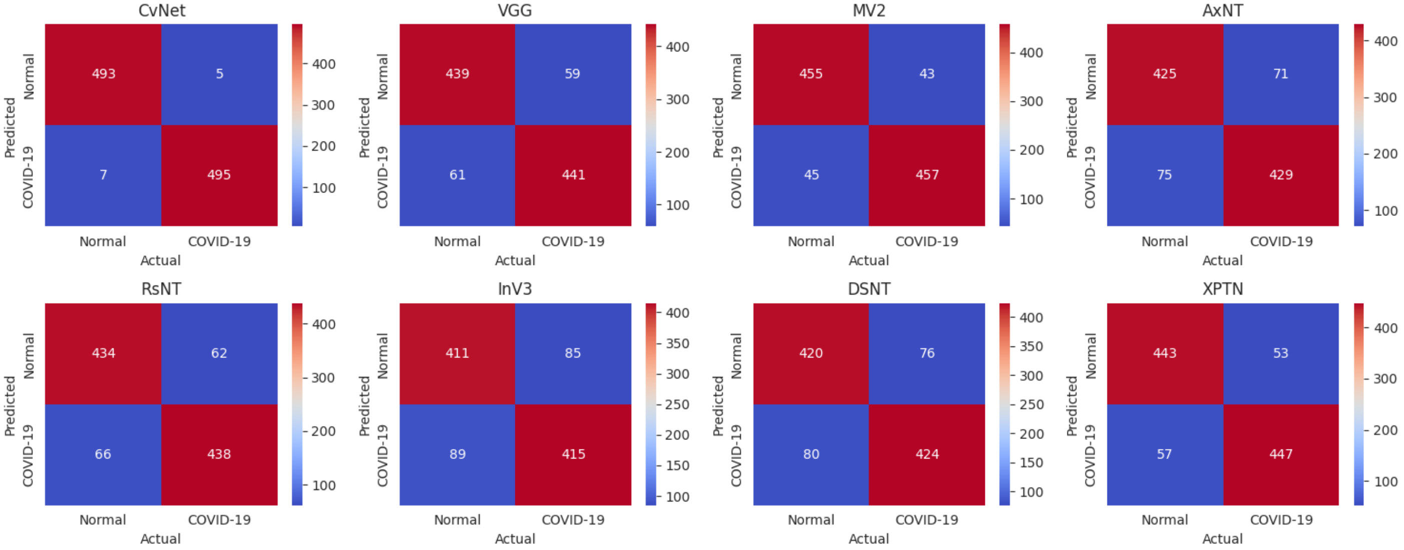

Fig. 8. Confusion matrices of deep learning models for COVID-19 vs. normal classification on dataset 2.

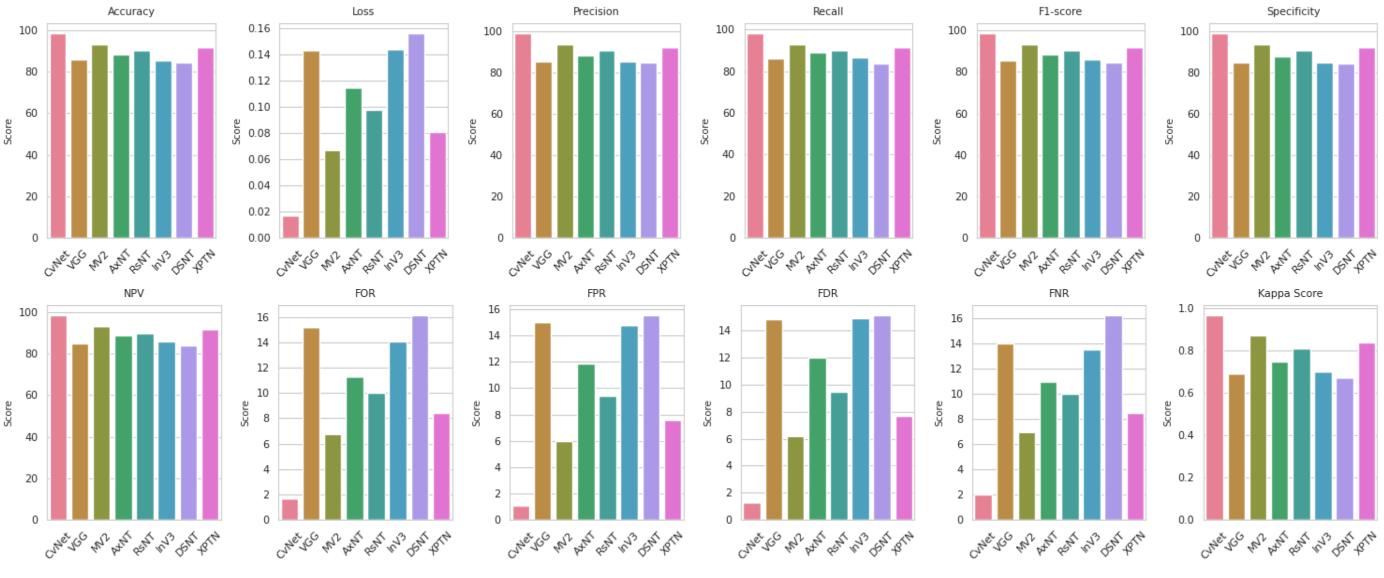

Fig. 9. Comparative performance metrics across the models on dataset 3.

We learn more about each model's effectiveness by exploring other metrics, such as NPV, FOR, FPR, FDR, FNR, and the Kappa Score. CvNet is one of them that sticks out particularly. CvNet significantly exceeds VGG, which has an NPV of 84.8%, with an NPV of 98.3%. In contrast to CvNet's admirable 1.7%, both VGG and DSNT models exhibit greater rates when analyzing FOR, 15.2% and 16.1%, respectively. The VGG, RsNT, and DSNT exhibit greater rates in terms of FPR, CvNet excels with a rate of only 1.1%. In terms of the FDR, XPTN has a respectable rate of 7.7%, whereas CvNet excels with only 1.3%. XPTN has a little higher value while monitoring FNR, however, CvNet performs better with pure 2%. Lastly, CvNet's Kappa Score of 0.965 is remarkable and perfectly matches true labels. This rating distinguishes it from other models like XPTN, MV2, and DSNT. Fig. 9, a visual representation, helps clarify these comparisons and provides an extensive overview of how well the models performed, showing their advantages and possible weaknesses.

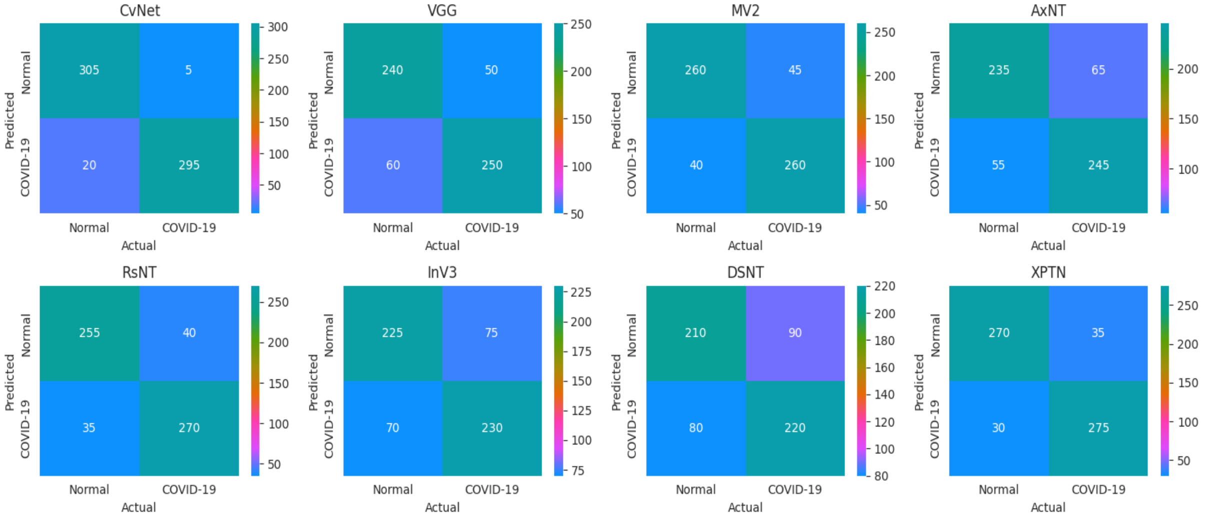

Fig. 10. Confusion matrices of deep learning models for COVID-19 vs. normal classification on dataset 3.

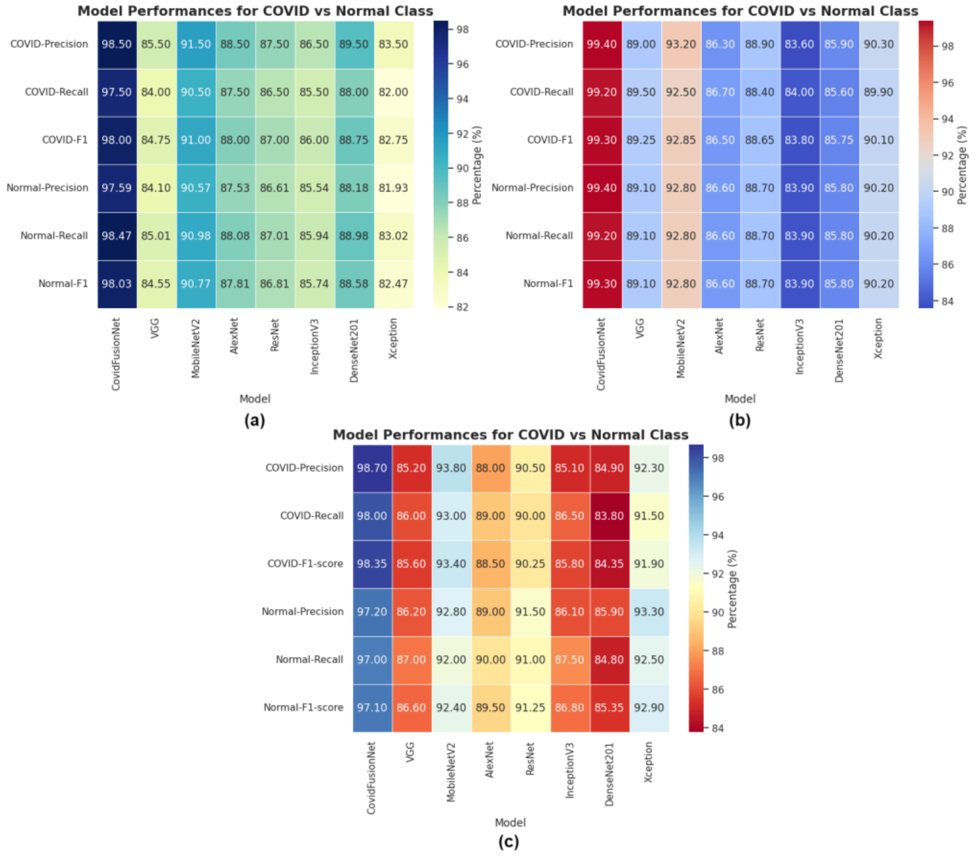

Fig. 11. Class-wise performance metrics of various models for COVID-19 detection across three datasets: (a) Dataset 1, (b) Dataset 2, and (c) Dataset 3

Fig. 10 exhibits the confusion matrices for all the models evaluated, including CvNet, VGG, MV2, AxNT, RsNT, InV3, DSNT, and XPTN, in their attempts to identify COVID-19 and normal cases. A detailed review of the CvNet model indicates that of the total supposed COVID-19 cases, 295 were accurately recognized as COVID-19 (True Positives), whereas 20 were erroneously tagged as normal (False Negatives). Conversely, among the samples identified as normal, 305 were properly marked as normal (True Negatives), with 5 being mistakenly indicated as COVID-19 (False Positives). VGG model properly discovered 250 instances of COVID-19, but wrongly categorized 60 as normal. However, out of the normal samples, 240 were correctly recognized, while 50 were incorrectly categorized as COVID-19. Moreover, CvNet distinguishes itself as being better by classifying Dataset 3 with more accuracy when compared to the other models.

E. Classwise Performance Analysis

Fig. 11(a) exhibiting Dataset 1 indicates that CovidFusionNet produced outstanding accuracy for the COVID class (98.5%). For the COVID class, CovidFusionNet achieved a highest F1-score (98%) whereas ResNet closely followed with an F1-score of 87%. For the Normal class, CovidFusionNet scored the best accuracy value (97.59%) and its recall was equally effective at 98.47%. This implies that for the categories COVID and Normal, while CovidFusionNet outperforms in one measure, other models such as ResNet or AlexNet tend to follow closely, showing their complementing potential. Fig. 11(b) depicting Dataset 2 demonstrates that CovidFusionNet once again came out with the highest accuracy for the COVID class (99.4%). In terms of the COVID class, CovidFusionNet retained the top F1-score (99.30%). For the Normal class, both accuracy and recall values were generally stable across the models, with CovidFusionNet winning once again with an F1-score of 99.3%. The superior performance of CovidFusionNet across these measures reinforces its great competence in discriminating between both classes. Fig. 11(c) from Dataset 3 highlights that CovidFusionNet continues its trend with outstanding accuracy for the COVID class (98.7%). MobileNetV2 obtained an excellent F1-score (93.4%) for the COVID class, whereas for the Normal class, Xception performed amazingly with the top F1-score (92.9%).

IV. Discussion

The CovidFusionNet is specifically designed for high-resolution medical imaging, with a focus on X-ray images. It showcases its capabilities by combining several Convolutional Neural Networks (CNNs) with Wavelet Transforms, which are essential for precise identification of patterns and reliable diagnosis of COVID-19. The oversampling strategy employed by this system enhances its ability to effectively handle datasets with class imbalances, which are often seen in medical data. As a result, this system is especially relevant in the present healthcare scene. In addition, CovidFusionNet's ability to do multi-resolution image analysis, utilizing both Continuous and Discrete Wavelet Transform, enables the detection of anomalies at various scales. Furthermore, integrating Adaptive Histogram Equalization with Wavelet Transforms for image improvement is particularly effective for datasets requiring precise feature retention and noise reduction. Although it demonstrates exceptional performance in these domains, its utilization with other data formats, such as MRI or CT scans, may necessitate appropriate modifications to achieve ideal outcomes. In consideration of this recognition, further study will prioritize the extension of CovidFusionNet's utilization to a range of data formats, thereby thoroughly assessing its efficacy in different clinical environments. This study aims to improve the effectiveness and expand the range of applications of the model in medical imaging, thereby transforming it into a flexible instrument in the advancing field of medical diagnostics. We have compared the performance of our proposed model with state-of-the-art methods, and the comparative results are represented in Table III.

TABLE III. Comparing Proposed Method Performance with State-Of-The-Art Methods

Reference	Dataset	Methodology	Accuracy
[14]	X-ray	CNN	91%
[15]	X-ray	Covid-Aid	87%
[16]	X-ray	CNN +GRU	93%
[17]	X-ray	STM-RENet	96.53%
[18]	X-ray	InceptionResNetV2 + Xception	95.78%
[20]	X-ray	ResNet50 + SVM	94.7%
[21]	X-ray	ResNet152V2+GRU	93.37%
[22]	X-ray	VGG19 + CNN	96.48%
Proposed	X-ray	CovidFusionNet	Dataset 1 (98.02%)
			Dataset 2 (99.30%)
			Dataset 3 (98.25%)

V. Conclusion

In this study, we introduced the CovidFusionNet, a cutting-edge CNN model based on fusion and optimized for accurately classifying COVID-19 X-ray images across three distinct datasets. We improved image clarity and detail preservation by combining features from seven pre-trained convolutional neural networks, incorporating the Continuous and Discrete Wavelet Transform, and using an innovative enhancement technique that combines Adaptive Histogram Equalization and Wavelet Transforms (HAWIE). Our model outperformed seven well-known pre-trained models in accuracy and consistency when combined with an oversampling strategy to solve the class imbalance. This work advances the field of image-based COVID-19 diagnosis by providing a tool ready for clinical use and pointing out potential directions for further investigation into the effects of image quality on detection effectiveness.

Implementation of a Convolutional Neural Network (CNN)-based Object Detection Approach for Smart Surveillance Applications

Weiguo Ni*
School of UAV, Guangzhou Civil Aviation College, Guangzhou 510000, Guangdong, China

***Abstract*—In the realm of smart surveillance systems, a fundamental technique for tracking and evaluating consumer behavior is object detection through video surveillance. While existing research underscores object detection through deep learning techniques, a notable gap exists in adapting these methods to effectively capture and recognize small, intricate objects. This study addresses this gap by introducing a customized methodology tailored to meet the nuanced requirements of accurate and lightweight detection for small objects, especially in scenarios prone to visual complexity and object similarity challenges. The primary objective is to furnish a vision-based object identification method designed for surveillance applications in smart stores, with a particular focus on locating jewelry objects. To achieve this, a Convolutional Neural Network (CNN)-based object detector utilizing YOLOv7 is employed for precise object detection and location extraction. The YOLOv7 network undergoes rigorous training and verification on a unique dataset specifically curated for this purpose. Experimental results affirm the efficacy of the proposed object identification method, demonstrating its capacity to detect items relevant to smart surveillance applications.**

Keywords—Smart surveillance; lightweight object detection; YOLOv7; small object recognition; vision-based identification

I. Introduction

Cameras and image sensors are frequently deployed in smart surveillance systems so that automated object identification techniques may be used to automatically detect and identify various objects in smart environment analysis [1, 2]. Such automatic object recognition techniques often need sophisticated image/data processing tools and algorithms [3]. As a result, developing low-complexity automated object identification algorithms for use in urban surveillance applications becomes crucial [4, 5].

For computer vision applications, deep learning-based approaches, including Convolutional Neural Networks (CNNs), are among the finest solutions [6, 7]. Applications like object categorization and image segmentation have made significant strides thanks to CNNs [8]. Additionally, CNNs contain convolution layers that handle feature extraction; they are resilient to shifts and distortions in the image; they use less memory; training is simpler; and, as a result of the fewer parameters, they are better and quicker [9].

Object detection and monitoring in IoT Smart Shop Surveillance Systems have witnessed significant advancements in recent years. Current technologies utilize a combination of computer vision, IoT devices, and machine learning algorithms to enhance security, customer experience, and operational efficiency in retail environments. The integration of IoT devices enables real-time data collection from various sensors and cameras while object detection algorithms process this data to identify and track objects of interest.

In previous studies, various methods have been explored for object detection and monitoring in IoT Smart Shops [10, 11]. Traditional approaches, such as handcrafted features and rule-based algorithms, have limitations in handling complex and diverse scenarios. However, deep learning-based methods, particularly the CNNs, have gained immense popularity [12, 13]. Deep learning models can automatically learn and extract relevant features from raw data, making them capable of handling complex object detection tasks. The ability of deep learning models to handle large-scale datasets and their superior performance in terms of accuracy have attracted researchers to explore and develop new approaches based on these techniques.

Despite the advancements, there are still some limitations and research gaps in the field. One major challenge is the requirement for low computational costs and high accuracy rates [14, 15]. Many IoT devices have limited processing power and memory, making it necessary to develop lightweight deep-learning algorithms that can achieve high accuracy while maintaining computational efficiency. Additionally, the lack of publicly available datasets specifically designed for IoT Smart Shop Surveillance Systems poses another challenge for researchers.

To address these limitations, researchers have focused on developing lightweight deep learning models and utilizing algorithms like YOLO (You Only Look Once) for efficient object detection. YOLO-based algorithms offer real-time object detection capabilities with relatively low computational requirements [16, 17]. Using custom datasets, researchers can train these models on specific Smart Shop Surveillance scenarios, encompassing various objects and environmental factors.

In this study, 1170 images were collected for our custom dataset from the Internet and our capturing webcam-based process, and the image augmentation process in our custom dataset preparation. The dataset is used for training and evaluating a model based on the YOLOv7 network. This model has generated a weight and is used to perform object recognition using the YOLOv7 model on our custom dataset.

This study introduces novel contributions in the field of computer vision and deep learning for IoT Smart Shop Surveillance Systems. It innovates by developing a lightweight deep learning model tailored to the limited computational resources of IoT environments. The creation of a custom dataset, incorporating 1170 images with meticulous preparation, stands out as a unique aspect, emphasizing the study's commitment to robust methodology. The adoption of the YOLOv7 network architecture for object recognition further highlights the innovative application of state-of-the-art technologies to address surveillance challenges in a Smart Shop context.

In terms of research contributions, three potential areas of focus are identified. Firstly, the development of a lightweight deep learning model tailored for IoT Smart Shop Surveillance Systems, considering the low computational resources available. Secondly, the creation of a custom dataset that represents realistic scenarios encountered in Smart Shop Surveillance. This dataset can enable the training and evaluation of the proposed model. Finally, conducting thorough experimental evaluations to assess the performance of the model in terms of accuracy, real-time detection, and computational efficiency. By addressing the research gap through the proposed lightweight deep learning model, custom dataset, and rigorous performance evaluations, researchers can contribute to advancing object detection and monitoring in IoT Smart Shop Surveillance Systems. The outcome of this research can lead to improved security, customer experience, and operational efficiency in retail environments, promoting the widespread adoption of IoT-based surveillance systems in the retail industry.

The structure of this paper is as follows; Section I presents the introduction. The proposed approach discusses in Section II. Section III involves experimental results, and Section IV concludes the paper.

II. Related Works

This section reviews the related works that are focused on object detection in video-based surveillance systems.

Mneymneh et al. [18] introduced a vision-based framework for intelligent monitoring of hardhat wearing on construction sites. The framework utilizes computer vision techniques to detect and track the presence of hardhats on individuals within the construction site environment. It involves stages of image acquisition, pre-processing, detection, and monitoring to identify and track individuals wearing hardhats. The study's limitations include reliance on a specific color-based segmentation approach, vulnerability to challenging lighting conditions, and the absence of exploration of other safety equipment detection. Addressing these limitations can enhance the framework's accuracy and broaden its applicability in ensuring compliance with safety regulations on construction sites.

Lu et al. [19] presented a real-time object detection algorithm for video. The algorithm utilizes a combination of deep learning techniques, including Convolutional Neural Networks (CNNs) and feature extraction methods, to detect objects in video frames. The proposed algorithm achieves high detection accuracy and real-time performance by optimizing the architecture and leveraging parallel processing capabilities. However, the limitation of the study is that the algorithm's performance may be affected by complex scenes with occlusions or high object density, which can lead to missed detections or false positives. Further research could focus on improving the algorithm's robustness in challenging video scenarios to enhance its overall effectiveness in real-world applications.

The authors in [20] presented a methodology based on deep learning for object detection in video surveillance, specifically focusing on the identification of small objects that are handled similarly. The proposed methodology utilizes binary classifiers and leverages deep learning techniques to achieve accurate object detection. The approach demonstrates promising results in detecting small objects in challenging video surveillance scenarios. However, a limitation of the study is that the proposed methodology may face challenges when dealing with highly cluttered scenes or objects that have similar visual characteristics but different semantic meanings. Further research could explore techniques to address these limitations and improve the methodology's robustness in handling complex scenarios, ultimately enhancing its applicability in video surveillance applications.

Alrowais et al. [21] developed a deep transfer learning-enabled intelligent object detection approach for crowd density analysis in video surveillance systems. The proposed method utilizes deep learning techniques and transfers learning to detect and analyze crowd density in video footage. By leveraging pre-trained models and fine-tuning them on specific crowd density datasets, the approach achieves accurate object detection and density analysis. The results demonstrate the effectiveness of the method in crowd density estimation. However, a limitation of the study is the reliance on pre-trained models that may not fully capture the diverse range of crowd dynamics and behaviors. Further research could focus on developing customized models or incorporating additional data augmentation techniques to improve the algorithm's performance and robustness in capturing different crowd scenarios.

According to review of previous studies, Addressing the research challenge of achieving high accuracy and lightweight object detection, particularly for small objects like jewelry, requires a tailored approach. While existing studies focus on object detection using deep learning techniques, adapting these methods to effectively capture and recognize small, intricate objects remains a gap. Current methodologies may struggle in cluttered scenes or with objects sharing similar visual characteristics.

III. Proposed Approach

This study selects jewelry objects and implements the approach for these kinds of objects involving rings and earnings. We suggest a detection method based on YOLOv7 to create a model that could recognize jewelry [9].

A. YOLO

The YOLO model, which stands for "You Only Look Once," is one stage object detector [17]. YOLO predicts the positions of the bounding boxes and the classes of the bounding boxes [19]. Objectness of the bounding boxes after feature-stripping image frames through a backbone, combining and blending features in the neck, and objectness prediction in the head of the network [22]. To arrive at its ultimate forecast, YOLO employs post-processing using NMS [23]. Fig. 1 illustrates the basic concept of YOLO network architecture.

B. Dataset

Our dataset consists of two various categories of jewelry (earrings and rings), as mentioned earlier. The dataset includes images from the Internet and our captured images in the real environment. We gathered webcam photos from two fixed cameras that were placed in various places. We chose images with a variety of model kinds, sizes, resolutions, orientations, and sample counts in each picture. One thousand one hundred seventy example photos of two types of jewelry pieces in various orientations, rotations, and scales are included in our unique dataset. Some sample images from our dataset are shown in Fig. 2.

C. Training and Testing

It is usually a good idea to start with a model that has already been trained using extremely big datasets and then utilize the model's weights to train an object detector [24]. Even if the learned weights don't contain the items needed for this specific experiment, to deal with the training process in the YOLO network, initial weights are taken from a pretrained model that includes weights from the known dataset [25]. In this study, we use an initial weight that trained a model from the COCO dataset.

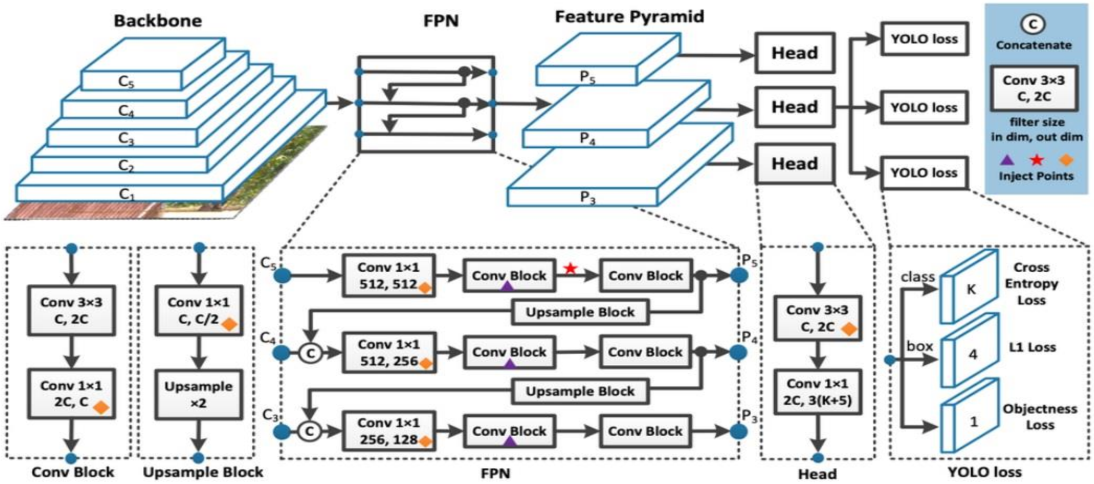

Fig. 1. YOLO network architecture [23].

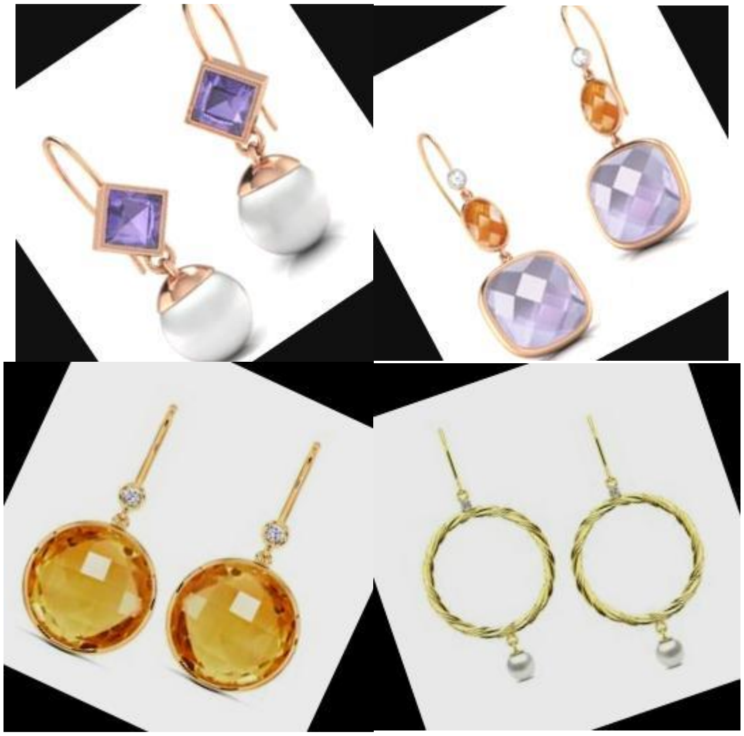

Fig. 2. Some image samples from the dataset.

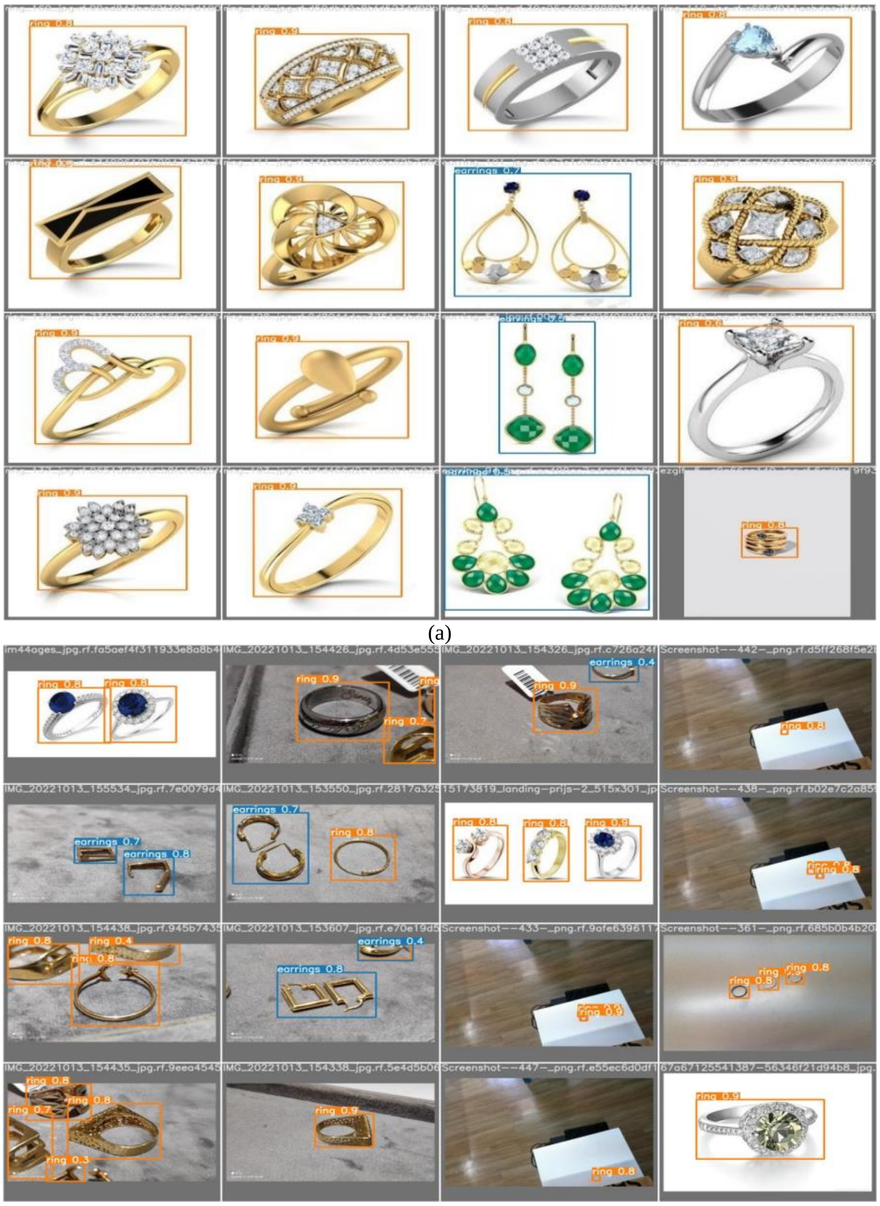
IV. Experimental Results

In this section, we present the experiment's details, and then we show the training results using pretraining weights and compare the three models of YOLOv7. Fig. 3 shows the result of the implementation of our proposed approach.

In the following, some analyses are presented to justify why the YOLOv7 can be presented accurate results and has superiority to apply in real-time requirements. To prove this superiority, some visual representations in graphs are illustrated. Using these graphs, a comparison of performance results is shown to visually demonstrate the superiority justifications. Inspired by [26], the graph depicts a comparison of YOLOv7, YOLOv4, PPYOLOE, YOLOX, YOLOR, YOLOv5, and Transformers object detectors. The X-axis represents the Inference Time, indicating the time taken for object detection, while the Y-axis represents the average precision (%) of the detectors.

Average precision (AP) is a commonly used metric in object detection that measures the accuracy of a model in localizing and classifying objects. It calculates the precision at various recall levels, considering the trade-off between precision and recall. Higher AP values indicate better performance and accuracy in object detection.

Inference Time refers to the time taken by the model to perform object detection on a given input. It reflects the efficiency and speed of the algorithm in processing frames or images in real-time applications. Lower inference times are desirable for real-time object detection scenarios. Fig. 4 presents the comparison of object detectors [26].



(a)

(b)

Fig. 3. Experimental results (a) and (b).

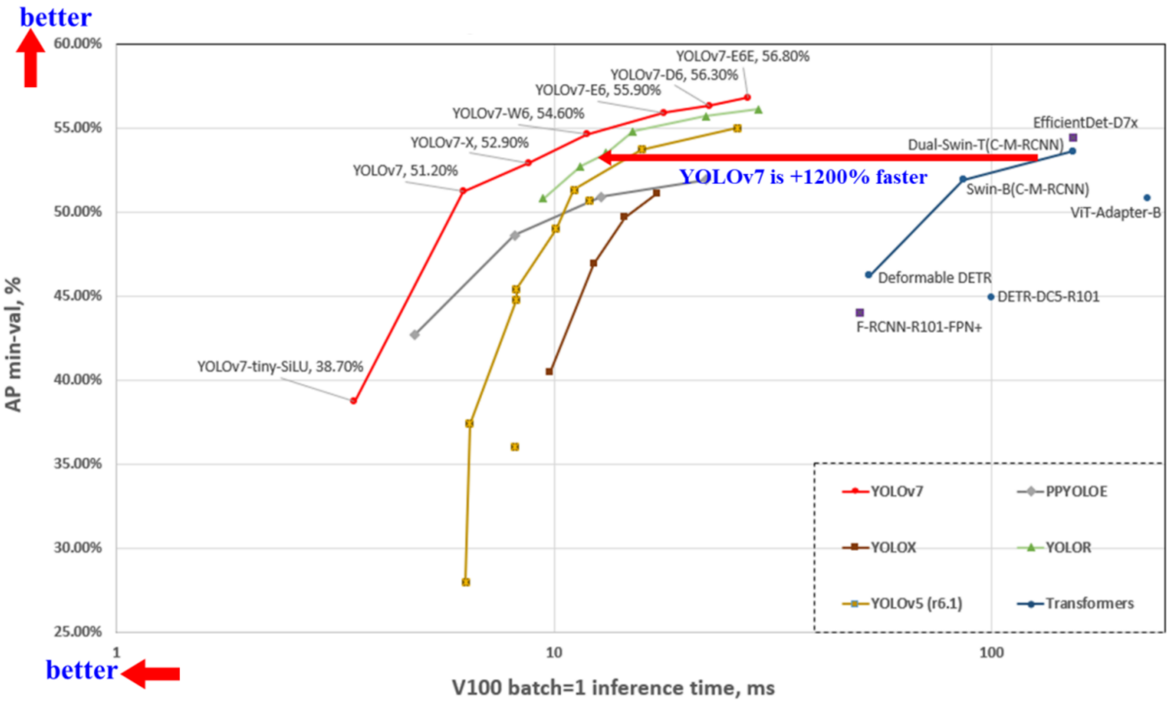


Fig. 4. Comparison of object detectors [26].

As shown in Fig. 4, it can be observed that YOLOv7 outperforms the other object detectors in terms of precision rate. At similar inference times, YOLOv7 consistently achieves higher average precision compared to PPYOLOE, YOLOX, YOLOR, YOLOv5, and Transformers. This suggests that YOLOv7 demonstrates superior accuracy in detecting and recognizing objects across various scenarios.

The YOLOv7 utilizes an efficient single-pass detection pipeline that eliminates the need for time-consuming region proposal techniques. This allows YOLOv7 to process images and videos in real-time without compromising accuracy. Other detectors may achieve lower inference times but often at the expense of reduced precision. Furthermore, YOLOv7 incorporates advanced training strategies, including data augmentation techniques and optimization methods like focal loss and learning rate scheduling. These strategies enhance the model's ability to generalize and accurately detect objects under diverse conditions, contributing to its superior precision rate.

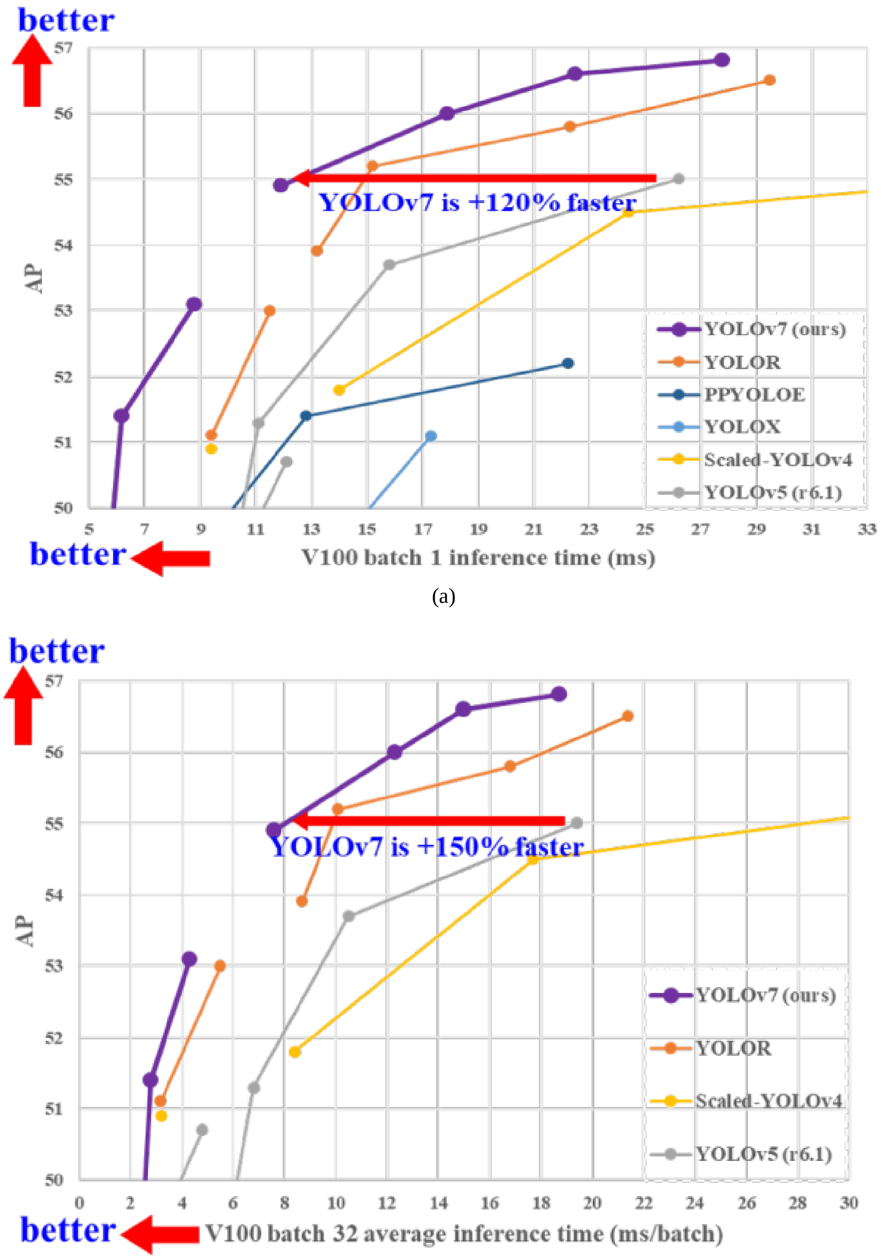
As a result, the graph demonstrates that YOLOv7 outperforms PPYOLOE, YOLOX, YOLOR, YOLOv5, and Transformers in terms of precision rate. The advanced architecture, efficient detection pipeline, and advanced training strategies employed by YOLOv7 contribute to its effectiveness and accuracy in object detection.

In the following, performance analysis and comparison of AP are presented to justify why the YOLOv7 is better than other object detector algorithms. Fig. 4 demonstrates the comparison of object detectors in real-time [26].

Fig. 5 illustrates the comparison of object deters in real-time conditions based on the presented comparison graphs. The graph illustrates a comparison of real-time object detection algorithms, including YOLOv7, PPYOLOE, YOLOX, YOLOR, Scaled-YOLOv4, YOLOv5, and Transformers. The X-axis represents the Inference Time, indicating the time taken for object detection, while the Y-axis represents the average precision (AP) of the detectors.

As shown in Fig. 4, it can be observed that YOLOv7 performs better than the other object detection algorithms in terms of precision rate while maintaining real-time capabilities. YOLOv7 achieves higher AP values at similar inference times compared to PPYOLOE, YOLOX, YOLOR, Scaled-YOLOv4, YOLOv5, and Transformers. This indicates that YOLOv7 provides more accurate object detection results. Furthermore, YOLOv7 demonstrates its effectiveness in real-time conditions by achieving low inference times while maintaining high precision. It strikes a balance between accuracy and speed, making it suitable for real-time applications where accuracy and efficiency are crucial.

As depicted in Fig. 4 and Fig. 5, the comparative analysis highlights the exceptional performance of YOLOv7 in the realm of object detection. The YOLOv7 stands out by demonstrating superior precision rates while seamlessly maintaining real-time capabilities. The discernible advantage lies in its ability to achieve higher Average Precision (AP) values when compared to a spectrum of other prominent object detection algorithms, including PPYOLOE, YOLOX, YOLOR, Scaled-YOLOv4, YOLOv5, and Transformers. This distinction is particularly noteworthy as it underscores YOLOv7's efficacy in delivering heightened accuracy without compromising on the efficiency required for real-time applications. The observed performance superiority positions YOLOv7 as a compelling choice for tasks demanding both precision and prompt response, further solidifying its standing as a leading solution in the field of object detection algorithms.



(b)

Fig. 5. Comparison of object detectors in real-time.

Finally, the graph demonstrates that YOLOv7 outperforms PPYOLOE, YOLOX, YOLOR, Scaled-YOLOv4, YOLOv5, and Transformers in terms of precision rate while maintaining real-time capabilities. Its advanced architecture, coupled with efficient inference times, makes YOLOv4 an effective and efficient choice for real-time object detection applications.

V. Conclusion

In this paper, a robust object identification technique based on YOLOv7 is developed for applications in smart surveillance. The first step involves the meticulous preparation of a custom dataset, with labels configured to adhere to the YOLOv7 format. The chosen technique demonstrates remarkable accuracy in identifying and categorizing jewelry objects, specifically rings and money. The network efficiently captures coordinates of resulting bounding boxes, enabling precise object identification within frames. While the current study focuses on training YOLOv7 for two types of jewelry, future research directions could involve expanding the model to encompass a broader spectrum of jewelry classes. This extension would enhance the model's versatility and applicability in diverse contexts within the realm of smart surveillance. Additionally, exploring real-time applications of the YOLOv7-based methodology remains an open problem, presenting an avenue for further investigation into its efficiency and effectiveness in dynamic surveillance scenarios. Moreover, investigating strategies to improve the model's adaptability to varying lighting conditions and complex backgrounds stands as a potential area for future research, contributing to the refinement of its performance in real-world surveillance applications.

***Abstract*—The task of deploying an energy-conscious wireless sensor networks (WSNs) is challenging. One of the most effective methods for conserving WSNs energy is clustering. The deployed sensors are divided into groups by the clustering algorithm, and each group's cluster head (CH) is chosen to gather and combine data from other sensors in the group. Mobile Wireless Sensor Networks, which enable moving the sink node, aid in reducing energy consumption. Thus, this paper introduces an energy efficient clustering algorithm and optimized path for a mobile sink using a swarm intelligence algorithms. The Chaotic Grey Wolf Optimization (CGWO) approach is used to form clusters and identify CHs. While utilizing the Slime Mould Algorithm (SMA) for determining the shortest path between a mobile sink and CHs. The effectiveness of the suggested routing strategy is evaluated against that of other current, cutting-edge protocols. The findings demonstrate that in terms of overall energy consumption and network lifetime, the suggested algorithm performs better than others. While for stability period the proposed algorithm outperforms three of compared algorithms and was close to the fourth.**

Keywords—Wireless sensor network; clustering algorithm; grey wolf optimizer; slime mould algorithm; mobile sink

I. Introduction

Mobile Wireless Sensor Networks (MWSNs) enable the movement of entities within a network, functioning as sensor nodes or sinks through mechanisms like wheels, humans, animals, or robots [1, 2]. MWSNs offer a solution to the hotspot problem often encountered in traditional Wireless Sensor Networks (WSNs). In a hotspot scenario, sensor nodes situated near a sink used as a relay tend to deplete their energy rapidly, as the sink increases the communication load on these nearby sensors [1]. MWSNs find applications in various domains, including but not limited to the military, industrial monitoring, habitat observation, healthcare, home networks, disaster management, and security [3]. These applications encompass fire detection systems in forests, battlefield surveillance, traffic monitoring, smart homes and hospitals, pollution control, rescue missions [4] and oil well monitoring.

Clustering algorithms play a crucial role in reducing energy consumption within WSNs. These algorithms partition the sensor nodes into distinct groups or clusters, with each group having a designated cluster head (CH) responsible for coordinating communications between its members and the sink. Clustering can be implemented through various approaches, such as distributed, centralized, or hybrid methods [5]. Sensors consume a significant amount of energy due to their tasks, which include environmental sensing, data transmission, mobility, cluster head (CH) selection, and frequent cluster formation [6]. Additionally, energy demands increase with larger data sizes and greater distances between sensors and the sink.

Numerous algorithms have been proposed to mitigate energy consumption, with clustering being a widely adopted approach. Clustering involves selecting CHs and forming clusters to reduce the number of sensors communicating directly with the sink, thus optimizing communication. Therefore, the process of CH selection is pivotal in clustering. Recent research [6, 7] has explored the use of intelligent swarm algorithms to aid in CH selection, such as ant, firefly, and Grey Wolf Optimization (GWO) algorithms.

This paper investigates the reduction of energy consumption in MWSNs by introducing an enhanced clustering algorithm and optimizing the path for a mobile sink using a swarm intelligence algorithm. Specifically, it employs the Chaotic Grey Wolf Optimization (CGWO) algorithm [8] for CH selection and the Slime Mould Algorithm (SMA) [9] to determine the shortest path between a mobile sink and CHs to reduce energy dissipation, and hence extends the WSN’s life cycle.

The proposed algorithm has the following contributions:

- Employing the CGWO algorithm as a clustering mechanism in MWSNs which to the best of our knowledge has not been investigated up to now in this field.
- Utilizing the SMA algorithm for sink node route determination in MWSNs has not been well studied up to now, and this study aims to fill this gap.
- The results of the proposed algorithm are compared to those of four other state-of-the-art algorithms GWO [10], ACO [11], FA [12], and PSO [13]. in terms of several performance metrics such as network lifetime, stability period, and total consumed energy.

The rest of this paper is structured in five sections. Section II presents the related work. Section III provides the mathematical models for GWO, the enhanced CGWO and Slim Mould Optimization algorithms. Section IV describes the network model and the methodology followed to develop the proposed algorithm. Section V illustrates the simulation results indicating the performance evaluation of the proposed protocol. Finally, Section VI sums up the paper and figure out future directions.

II. Related Work

A. Clustering Algorithms

This section reviews the state-of-the-art clustering algorithms that were recently used in MWSN. The earliest clustering algorithms for WSNs fell into the category of traditional clustering algorithms. These methods employed straightforward techniques for constructing clusters and selecting CHs. In essence, traditional methods designated CHs without the use of sophisticated, intelligent approaches [7]. An example of this approach is the Low Energy Adaptive Clustering Hierarchy (LEACH) [14] protocol.

Authors of [15] presented a heterogeneous clustering algorithm with multiple mobile data collectors (MDCs) to extend the network's lifespan. This algorithm selected CHs using a probability equation based on factors such as energy levels. The MDCs employed the Expectation-Maximization (EM) method to determine optimal paths for CHs based on their positions and energy levels. It demonstrated superior performance, particularly in small areas.

Authors of [11] introduced an enhanced clustering algorithm that employed multiple mobile sinks to improve energy efficiency. This enhanced clustering method incorporated the highest residual energy of sensors as a metric for CH selection, thereby enhancing the traditional LEACH [14] protocol. Mobile sinks utilized the Ant Colony Optimization (ACO) algorithm to identify optimal paths to CHs. Their algorithm defeated the LEACH, Particle Swarm Optimization (PSO), and Genetic Algorithm (GA) in terms of network lifetime and energy consumption.

The authors of [16] proposed inter- and intra-clustering methods to optimize the movements of mobile sinks and conserve energy. The inter-clustering method involved calculating the sojourn time of mobile sinks in clusters, while the intra-clustering method determined the sojourn locations of mobile sinks within clusters. CHs were selected based on proximity to the cluster centre, the highest residual energy was also considered in subsequent CH selections. Their proposed algorithm outperformed the Energy-Efficient PSO-Based Routing algorithm with Mobile Sink (EPMS) and Two-Tier Data Dissemination (TTDD) algorithms in terms of inter-cluster movement.

Recent research papers [7, 17, and 18] have employed optimized clustering algorithms to enhance the network's lifetime. These optimized clustering algorithms leverage Computational Intelligence (CI) methodologies, encompassing fuzzy logic, swarm intelligence, Genetic Algorithms (GA), and petri nets.

In study [19] researchers introduced an algorithm for extending network lifetime and reducing transmission delays. A distributed fuzzy clustering algorithm was used to select CHs. The distributed fuzzy clustering algorithm integrated seven regular components of a fuzzy system into two elements. The first element characterized sensors based on their remaining energy, the number of neighbours, and distances from neighbours. The second element determined sensor and mobile gateway positions, considering factors such as the number of mobile gateways and distances to nearby and distant mobile gateways.

In research [20], authors proposed a fuzzy logic-based algorithm for the clustering process and employed multiple mobile sinks to reduce energy consumption in MWSNs. The fuzzy logic algorithm initially selected temporary CHs and then chose the final CHs from this group based on criteria including distances to the nearest Rendezvous Node (RN), remaining energy, and calculated cluster densities. The sensor areas were divided into regions, each served by a mobile sink. These mobile sinks collected data from the RNs and final CHs using a smart trajectory. Their results showed significant improvement in terms of first node dead, the time at which half of the nodes were still operational (HNA), and the total remaining energy (TRE).

The Particle Swarm Method [21, 22] is a type of swarm intelligence algorithm inspired by the food-searching strategies employed by animal flocks. It divides the swarm into groups, each following a distinct path [21]. Within each group, particles iteratively explore and update information to find the best positions while communicating with others.

In study [23] researchers proposed an enhanced fitness function for the Unequal Clustering PSO (UC-PSO) and Hybrid K-Means Clustering PSO (KC-PSO) algorithms. These improvements aimed to enhance energy efficiency and determine the optimal number of clusters and CHs. The new fitness function selected CHs based on factors such as mobility, residual energy, neighbour connectivity, and distance to the BS. While the KC-PSO algorithm employed UC-PSO in the CH selection process, it utilized a different cluster formation approach. Their results demonstrated that the KC-PSO algorithm outperformed the UC-PSO and LEACH algorithms.

Another example of swarm intelligence algorithms is the Firefly Method [12]. It is used for selecting CHs and introduced a mobile sink to enhance the network's lifetime. CH selection parameters included residual energy, node-to-node distances, and distances from nodes to the sink. The proposed method demonstrated superior performance compared to LEACH, Amend LEACH (A-LEACH), and GA-Based LEACH (LEACH-GA) methods. Additionally, it outperformed the Mobile Sink Improved Energy-Efficient PEGASIS-Based Routing Protocol and Mobile Sink-Based Adaptive Immune Energy-Efficient Clustering Protocol (MSIEEP) algorithms in terms of network lifespan, node residual energy, packet drop ratio (PDR), and packet delays.

The GWO method emulates the social hierarchy observed in grey wolf packs, consisting of alpha, beta, delta, and omega wolves [24]. Researcher in [25] introduced a layered and clustered structure based on the GWO method aimed at optimizing energy consumption.

TABLE I. COMPARISON OF STATE-OF-THE-ART CLUSTERING ALGORITHMS

Ref.	Mobility	Clustering Method/Size [1]	Cluster Head Selection Alg.	Cluster Head Selection Parameters [2]	Simulation Platform	Performance Metrics

[29]	Sink	Dist./dynamic	Traditional	- The centre of a cluster - Residual energy	Not Mentioned	- Network lifetime - Energy consumption - Packet delivery
[30]	Sink	Cent./dynamic	Traditional	-The centre of a cluster - Residual energy	NS2 Simulator	- Number of alive nodes - Number of delivered packets
[31]	Sink	Dist./dynamic	Traditional	- Residual energy - Distance	MATLAB	- Network lifetime

[1] Cent: Centralized, and Dist: Distributed

[2] Based on weighted probability:

This layered structure consisted of four tiers: alpha, beta, delta, and omega, with the alpha tier being the closest to the static BS. In this context, mobile sensors were analogous to grey wolves, and alpha wolves assumed the role of CHs. CHs were chosen using game theory principles, considering factors such as residual energy, Received Signal Strength Indexes (RSSIs), and Packet Reception Ratios (PRRs). Performance metrics encompassed network lifetime, energy consumption, and throughput. The presented method had better throughput. The results clearly demonstrated that the proposed method outperformed the LEACH protocol. Finally, Table I offers a comparative review of surveyed clustering algorithms indicating the platforms used and other parameters.

B. Wireless Sensor Nodes Mobility

Sink mobility contributes to energy conservation by allowing the sink to move. Path determination is a significant contributor to the energy consumption of WSN. Hence many researchers presented different methods for establishing energy efficient path between nodes [32]. Sink mobility allows for the movement of the sink, and there are three methods for selecting a path between the sink and nodes [2]: random, controlled, and predictable.

First, the easiest way is the random path technique. In the random path method, the mobile sink moves randomly to gather data from sensors [2]. This technique is used in [19, 26]. Second way of moving the sink node is the controlled path method. In the controlled path method, the mobile sink moves strategically within areas that meet certain constraints, such as high residual energy, the number of neighbors, and the number of hops.

Authors of [15] introduced a controlled adaptive mobility model using an EM algorithm. This algorithm assists the sink in collecting data from CHs with the lowest residual energy first. While in study [11] they implemented a controlled path based on the ACO algorithm. Authors of [29] also introduced a controlled route based on improved ACO, considering a distance heuristic factor to enhance its effect on the next node and improve global search ability.

Authors of [16] utilized a controlled trajectory determined by the GA. In [20] they presented a mobile sink that calculates the optimal trajectory by dividing the area of interest into 16 equal parts and considering the average remaining energy of each part. The mobile sink then follows a smart path based on RPs. Researchers of [13] employed the PSO algorithm to determine the path of the mobile sink to CHs. In [33] they presented another technique that integrated ACO and A* algorithms for finding the best energy efficient route between CHs and a base station.

Third way of sink movement is the predictable path. In the predictable path method, the mobile sink follows a predefined route to specific relay or data collector nodes responsible for gathering data from sensor nodes and transmitting it to the mobile sink [2]. Authors of [12] introduced a mobile sink that selects its path by dividing the network into four or eight areas and moves to each part using the centroid of the CHs. While [27] used a predictable trajectory. Authors of [28] used a predetermined route depending on the angular velocity.

III. Technical background

This section provides the mathematical models for Grey Wolf Optimization (GWO), the enhanced Chaotic GWO and Slim Mould Optimization algorithms.

A. Original GWO

The original GWO algorithm, introduced by [34], draws inspiration from the cooperative hunting and social hierarchy of grey wolves to tackle optimization problems. The core concept of the GWO algorithm involves locating a target, or “prey”, by mimicking the leadership hierarchy of grey wolves. The inspiration is in the cooperative hunting and social hierarchy of grey wolves.

Grey wolves organize themselves into a dominant social hierarchy, featuring alpha, beta, delta, and omega wolves. The alpha wolves occupy the top tier of this hierarchy, where they make decisions regarding hunting and habitat selection. The beta wolves comprise the second tier and have the authority to issue commands to the delta and omega wolves. Delta wolves, in turn, follow the directives of the alpha and beta wolves and oversee the omega wolves. Ultimately, the omega wolves obediently follow the commands of all other members of the pack.

The population-based meta-heuristic method known as "grey wolf optimization" (GWO) mimics the natural hunting strategy and leadership structure of grey wolves. The GWO hunting process consists of several key phases:

- Tracking, chasing, and approaching the prey.
- Pursuing, encircling, and harassing the prey until it stops moving.
- Attacking the prey.

1) GWO mathematical model: The GWO algorithm [24, 34] considers the fittest solution as the alpha (α). As a result, the second and third-best solutions are designated as beta (β) and delta (δ), respectively. The remaining candidate solutions are assumed to be omega (ω). α, β, and δ guide the hunting process, with the ω wolves following these three leaders.

a) Encircling prey: Mathematically, grey wolves enclose and surround their prey as follows [34]:

$$\vec{\mathrm{D}} = \left|\vec{\mathrm{C}} \cdot \vec{\mathrm{X}}_p(\mathrm{t}) - \vec{\mathrm{X}}(\mathrm{t})\right| \tag{1}$$

$$\vec{\mathrm{X}}(\mathrm{t}+1) = \vec{\mathrm{X}}_p(\mathrm{t}) - \vec{\mathrm{A}} \cdot \vec{\mathrm{D}} \tag{2}$$

where, $\vec{\mathrm{D}}$ indicates the distance between prey and wolf, t corresponds to the present iteration, $\vec{\mathrm{X}}(\mathrm{t})$ is the current position of the wolf, and $\vec{\mathrm{X}}_p(\mathrm{t})$ is the position of the prey.$\vec{\mathrm{A}}$ and $\vec{\mathrm{C}}$ are coefficient-vectors, $\vec{\mathrm{X}}$p is the vector’s location of the prey, and X is the vector’s location of a grey wolf. vectors $\vec{\mathrm{A}}$ and $\vec{\mathrm{C}}$ can be computed as follows:

$$\vec{\mathrm{A}} = 2\,\vec{\mathrm{a}} \cdot \vec{\mathrm{r}}_1 - \vec{\mathrm{a}}, \qquad \vec{\mathrm{C}} = 2 \cdot \vec{\mathrm{r}}_2 \tag{3}$$

where, $\vec{\mathrm{r}}_1$ and $\vec{\mathrm{r}}_2$ are random vectors in range of [0,1], and the components of $\vec{\mathrm{a}}$ are reduced linearly from 2 down to 0 throughout repeated iterations.

b) Hunting: The algorithm keeps the first three best solutions alpha α, beta β, and delta δ and obliges the omega ω wolves to adjust their positions based on positions of wolves α, β, and δ. Eq. (4) to Eq. (6) indicates how the distances from α, β, and δ wolves ($\vec{D}_\alpha$, $\vec{D}_\beta$ and $\vec{D}_\delta$) to each of the lasting wolfs, using positions α, β, and δ wolves ($\vec{X}_\alpha$, $\vec{X}_\beta$ and $\vec{X}_\delta$) and the position of lasting wolves($\vec{X}$):

$$\vec{D}_\alpha = \left|\vec{C}_1 \cdot \vec{X}_\alpha - \vec{X}\right|, \vec{D}_\beta = \left|\vec{C}_2 \cdot \vec{X}_\beta - \vec{X}\right| \qquad (4)$$

$$\vec{D}_\delta = \left|\vec{C}_3 \cdot \vec{X}_\delta - \vec{X}\right|$$

$$\vec{X}_1 = \vec{X}_\alpha - \vec{A}_1 \cdot \left(\vec{D}_\alpha\right), \vec{X}_2 = \vec{X}_\beta - \vec{A}_2 \cdot \left(\vec{D}_\beta\right), \qquad (5)$$

$$\vec{X}_3 = \vec{X}_\delta - \vec{A}_3 \cdot \left(\vec{D}_\delta\right)$$

$$\vec{X}(t+1) = \frac{\vec{X}_1 + \vec{X}_2 + \vec{X}_3}{3} \qquad (6)$$

c) Attacking prey: In study [34] Grey wolves conclude the hunt by attacking the prey when it stops moving. The GWO algorithm models approaching the prey mathematically by decreasing the value of $\vec{a}$ and narrowing the fluctuation range of $\vec{A}$ where |A|<1 force the wolves to attack the prey (exploitation).

d) Deletion: The search is based on the positions of the alpha, beta, and delta grey wolves. Grey wolves diverge from each other to search for prey and converge to attack prey. In the mathematical model of divergence, the GWO algorithm employs $\vec{A}$ where |A| > 1 to compel the search agents to diverge from the prey. The $\vec{C}$ vector contains random values in [0, 2], providing random weights for prey. This stochastic weighting either emphasizes (when C > 1) or deemphasizes (when C < 1) the attack. It reflects the effect of obstacles to approaching prey in nature. Depending on the position of a wolf, it can randomly assign weight to the prey, making it harder or easier for wolves to reach it.

B. Chaotic GWO

CGWO algorithm utilizes a varying number of wolves, which are regarded as leaders during each iteration. Rodrigues (2021) [8] proposed the use of a chaotic variable to determine the number of leaders in the pack during each iteration. To calculate the number of leader wolves for each iteration, the following formula is employed:

$$n(t) = \left\lceil \frac{M.z(t)}{2} \right\rceil \qquad (7)$$

The number of leader wolves n(t) in each iteration ranges between 1 and half of the population size. The author used the Celling function for n(t) to round the result to the next integer. Here, M represents the number of wolves in the pack, z(t) is a chaotic variable within the interval [0,1] [8, 35]. In contrast to the way of updating the position of individual wolves in GWO described by Eq. (6), in CGWO the author utilized Eq. (8).

$$X(t+1) = \frac{\sum_{v=1}^{n(t)} X_v}{n(t)}, X_v = X_j(t) - A_j . D_j \qquad (8)$$

where, Xj(t) represents the position of the wolf with the j-th best fitness value in iteration t, Aj is a random vector computed according to Eq. (4), (3) and D_j is calculated using the following equation:

$$D_j = \left|C_j . X_j(t) - X\right| \qquad (9)$$

where, X is the current position of the wolf, and C_j is a random vector calculated according to Eq. (3).

Chaotic maps [8] represent the chaotic function, often referred to as an orbit. An orbit is an iterative function that generates a sequence of values in each iteration. The characteristics of an orbit are its aperiodic nature, boundedness (chaotic variables have upper and lower limits), and sensitivity to initial conditions.

The CGWO algorithm, in contrast to GWO, incorporates a chaotic sequence to determine a varying number of leaders in each iteration. This approach enhances the CGWO algorithm's diversification capability and strikes a balance between diversification and intensification capabilities, which is crucial for the optimization algorithm's overall performance. By involving a larger number of wolves as leaders, candidate solutions that are not near the optimal solution contribute to guiding the search process. In [8] nine chaotic maps are investigated.

C. Slim Mould Optimization Algorithm

The slime mould organism relies on creating an interconnected venous network to seek out food sources, allowing it to generate optimal paths for reaching food [9]. The SMA algorithm has two phases:

1) Approach food: The organic matter in slime mould seeks food, surrounds it, and secretes enzymes to digest it. The slime mould navigates towards a food source using a mathematical expression designed to mimic its contraction behavior as follows:

$$\overrightarrow{X(t+1)} = \begin{cases} \overrightarrow{X_b(t)} + \overrightarrow{vb} \cdot \left(\vec{W} \cdot \overrightarrow{X_A(t)} - \overrightarrow{X_B(t)}\right), r < p \\ \vec{vc} \cdot \overrightarrow{X(t)}, r \geq p \end{cases} \qquad (10)$$

where, $\overrightarrow{vb}$ is a parameter with a range of $[-a, a]$, $\vec{vc}$ decreases linearly from 1 to 0. t indicates the current iteration, $\overrightarrow{X_b}$ denotes the individual location with the highest odour concentration currently found, $\vec{X}$ indicates the location of the slime mould, $\overrightarrow{X_A}$ and $\overrightarrow{X_B}$ indicate two individuals randomly selected from the swarm, and $\vec{W}$ indicates the weight of the slime mould. P is computed as follow:

$$p = \tanh|S(i) - DF| \qquad (11)$$

where, $i \in 1,2, \dots, n$, S(i) denotes the fitness of $\vec{X}$ and DF indicates the best fitness obtained in all iterations. $\overrightarrow{vb}$ is computed as:

$$\overrightarrow{vb} = [-a, a], a = \operatorname{arctanh}(-\left(\frac{t}{max\_t}\right) + 1) \qquad (12)$$

where, max_t indicates the maximum number of iterations. $\vec{W}$ is calculated as:

$$\overrightarrow{W(SI(\imath))} = \begin{cases} 1 + r \cdot \log\left(\frac{bF - S(i)}{bF - wF} + 1\right), condition \\ 1 - r \cdot \log\left(\frac{bF - S(i)}{bF - wF} + 1\right), \text{ others,} \end{cases} , \qquad (13)$$

$$SI = sort(S)$$

Where condition denotes that S(i) ranks in the first half of the population, r represents a random value within the interval [0,1], bF stands for the optimal fitness obtained in the current iterative process, wF indicates the worst fitness value obtained in the current iterative process, and SI represents the sequence of fitness values sorted in ascending order.

2) Wrap food: It mimics the contraction mode of the venous tissue structure of slime mould during its search for food. As the concentration of food encountered by the vein increases, the bio-oscillator generates stronger waves, resulting in faster cytoplasmic flow and thickening of the vein [9]. The slime mould updates its location using the following mathematical formula:

$$\overrightarrow{X^*} = \begin{cases} \mathrm{rand} \cdot (\mathrm{UB} - \mathrm{LB}) + \mathrm{LB}, \mathrm{rand} < z \\ \overrightarrow{X_b(t)} + \overrightarrow{vb} \cdot \left(W \cdot \overrightarrow{X_A(t)} - \overrightarrow{X_B(t)}\right), r < p \\ \overrightarrow{vc} \cdot \overrightarrow{X(t)}, r \geq p \end{cases} \tag{14}$$

where, LB and UB represent the lower and upper boundaries of the search range, while rand and r denote random values in the range [0,1]. The constant z is set to 0.03.

3) Osillation: Slime mould relies on a biological oscillator to generate propagating waves that alter the flow of cytoplasm within its veins, allowing it to position itself more effectively in areas of higher food concentration. The vector value $\overrightarrow{vb}$ randomly oscillates within the range of $[-a, a]$ and gradually approaches 0 with increasing iterations. Similarly, the vector value $\overrightarrow{vc}$ oscillates within the range of [–1,1] and tends to 0 eventually [9]. Using the SMA algorithm, the mobile sink chooses the shortest path between itself and the CHs to collect sensed data.

IV. Methodology

This section dives into the design and implementation of the proposed algorithm. The proposed algorithm consists of two phases: cluster construction and path formation for a mobile sink. It combines the CGWO algorithm for the selection of CHs and the SMA for determining the shortest route between a mobile sink and the CHs.

A. WSN Model

The wireless sensor network model considered in this paper has the following assumptions:

- The network model is synchronous.
- All nodes are stationary but the mobile sink station.
- All nodes have the same initial battery capacity and can perform the same functions.
- Each sensor node is identified with a unique identifier.
- The links are symmetric.
- The distance between sensor nodes can be calculated based on received signal strength indicator (RSSI).

B. Cluster Structure Phase

The main functions of this phase are electing CHs using the CGWO algorithm and associating sensor nodes with respective CHs to form clusters.

The sensor nodes are randomly deployed in a region, and a mobile sink is located in the center of the network. Initially, the sensor nodes send their locations and remaining energy to a mobile sink. Then, the mobile sink selects the CHs based on the fitness function of the CGWO algorithm. The clusters have the following properties:

- Centralized clustering formation method: The mobile sink utilizes the CGWO algorithm to select CHs.
- Fixed cluster count: It specifies a fixed number of clusters, which is ten clusters in each round.
- Variable cluster size: The number of cluster members is not fixed in each round.
- Intra-cluster topology: The proposed algorithm relies on single hops to connect cluster members to their respective CHs.
- Inter-CH connectivity: The proposed algorithm establishes direct connections from CHs to the mobile sink.

This article introduced a new fitness function that relies on the following parameters for selecting CHs:

- Remaining energy of the CH.
- The CH’s membership count.
- Euclidean distance from a mobile sink to a CH.
- CH centrality.

The fitness function for sensor node i is calculated as follows:

$$F(i) = aF_f(i) + (1 - a)F_u(i) \tag{15}$$

$$F_f(i) = R_e(i) + S_{m(i\,)} \tag{16}$$

$$F_u(i) = [E_u(i, M_s)]^{-1} + C_s(i) \tag{17}$$

where, a is a scaling factor with a value from 0.1 to 0.9, F_f is the fundamental fitness function, and F_u represents the non-fundamental fitness function.

The fundamental fitness function (F_f) calculates the sensor node’s members (S_m) and its remaining energy (R_e). Sm signifies the number of connecting nodes to a particular node within its transmission range, while R_e is the ratio of the remaining energy to the initial energy of the node.

The non-fundamental fitness function (F_u) computes the Euclidean distance (E_u) and sensor centrality (C_s). E_u calculates the Euclidean distance from sensor i to the mobile sink M_s, while C_s determines the sensor node’s centrality among its neighbors.

The sensor’s members (Sm) is computed as follows:

$$N(i) = \sum_{j \in W} b_{ij} \tag{18}$$

where, W is the wireless sensor network, $b_{ij} = 1$ means that distributed sensor i is connected to the distributed sensor j; otherwise, $b_{ij} = 0$.

Algorithm 1: Cluster Formation Algorithm

```
A.  Initialize WSN parameters: Area, number of nodes, initial mobile sink
    position (50,50), … etc.
Input:
    Number of alive nodes
    Number of packs $P_i$
    Number of cluster heads in a pack: 10% of the total number of alive
    sensor nodes randomly.
Output:
    Cluster heads
B.  Cluster head selection using CGWO algorithm.
    Initialize the population $X_i$, choose 10% of sensor nodes as cluster
    heads in a pack from alive nodes randomly.
    Initialize a = 2.
    Initialize vectors A and C.
    Initialize the Tent chaotic map.
    Compute the fitness value of each wolf according to Eq. (15).
    Define the number of leaders n(t) according to Eq. (7).
    For j = 1 : n(t) do
        Compute $D_j$ according to Eq. (9).
        Compute $X_v$ according to Eq. (8).
    End for.
    While t < maximum number of iterations do
        For each wolf i do
            Update its position X(t+1) according to Eq. (8).
        End for.
        Update a, A, C, and n(t).
        Compute the new fitness value of each wolf.
        For j = 1 : n(t) do
            Compute $D_j$ according to Eq. (9).
            Compute $X_v$ according to Eq. (8).
        End for
        Increment the iteration number (t = t + 1).
    End while
    Return the best solution (i.e. cluster head)
    CH = Set of sensor nodes in $P_i$.
End Algorithm.
```

The sensor's members (C_s) is computed as follows:

$$C_s(i) = \frac{(N-1)}{\sum_{j=1}^{N} d_{ij}} \tag{19}$$

where, N is the number of sensors and d represents the shortest distance from sensor i to sensor j.

The remaining energy of sensor node (R_e) is computed as follows:

$$\mathbf{R_e} = \frac{\mathbf{1}}{\sum_{j=1}^{m}\left(E_{CH_j}\right)} \tag{20}$$

where, m is the total number of CHs, l_j is the number of sensor nodes in cluster j, and ECH_j is the current energy of CH_j, $1 \leq j \leq m$.

The Euclidean distance (E_u) is computed as follows is computed as follows:

$$E_u = \sum_{j=1}^{m}\left(\frac{1}{l_j}\mathrm{dis}\left(CH_j, M_s\right)\right) \tag{21}$$

where, $\mathrm{dis}(CH_j, M_s)$ signifies the distance between CH_j and M_s.

Based on the experimental investigations, this paper employs the tent function Eq. (22) for the chaotic map function and set 'a' to 0.2 in the fitness function to achieve superior outcomes.

$$z(t+1) = \begin{cases} z(t)/0.4, & 0 < z(t) \leq 0.4 \\ \left(1 - z(t)\right)/0.6, & 0.4 < z(t) \leq 1 \end{cases} \tag{22}$$

In this study, the sensor nodes will transmit their locations and remaining energy to the mobile sink. Subsequently, the mobile sink will select CHs using the CGWO algorithm as described in Algorithm 1. Following this selection, the sensor nodes will align themselves with their respective CHs and begin transmitting the sensed data.

C. Path Formation Phase

Following the election of CHs, the mobile sink employs the SMA algorithm to move towards the nearest CH, followed by the second closest CH, and so forth, for data collection. This algorithm exerts control over the movement of the mobile sink.

Algorithm 2: Mobile Sink Path Formation Algorithm

```
Input: Number of cluster heads which is determined by the Algorithm
1

Output: The slime mould position = the mobile sink position

Initialize the population size = number of cluster heads.
Initialize the positions of the slime mould positions.
While t ≤ Max_iteration do
    Calculate the fitness of all the slime moulds by Eq. (23).
    Update bestFitness, $x_b$.
    Calculate the W by Eq. (13).
    For each search portion do

        Update p, vp, vc.
        Update positions by Eq. (14).
    End For
t = t + 1.
End while
Return best Fitness, $x_b$ = the mobile sink position.
```

A new fitness function is proposed for determining the path between a mobile sink and CHs. The following equation calculates the path distance (D) travelled by the mobile sink (M_S):

$$D(T_i) = \mathrm{dis}(M_S, ch_1) + \sum_{i=1}^{e-1}\mathrm{dis}(ch_i, ch_{i+1}) + \mathrm{dis}(ch_e, M_S) \tag{23}$$

where, ch is the number of CHs, ch1 is the nearest CH to the mobile sink MS, ch_e is the farthest CH, and $\mathrm{dis}(M_S, ch_1)$ indicates the distance between CHs or between a CH and an M_S. The M_S begins its journey from an initial position, visits all CHs, and returns to the starting point.

Algorithm 2 outlines the steps involved in constructing the mobile sink's route using the SMA algorithm.

D. Energy Consumption Model

This paper utilizes the first-order radio model as the energy consumption model for both sending and receiving data, as proposed by [36]. This model incorporates both the free space (f_s) and multi-path fading (m_p) models and is contingent on the distance between the sender and receiver. When the distance is less than the threshold value d_0, the authors employ the free space (f_s) model. Otherwise, the authors switch to the multi-path (m_p) model. The energy consumption for transmitting an l-bit message over a distance d is calculated as follows:

$$E_{Tx}(l,d) = \begin{cases} lE_{elec} + lE_{fs}\, d^2, & d < d_0 \\ lE_{elec} + lE_{mp}\, d^4, & d \geq d_0 \end{cases} \qquad (24)$$

where, E_{Tx} represents the total energy required for transmission, E_{elec} denotes the energy dissipation per bit for circuit operation, including the transmitter or receiver, E_{fs} is the energy used for amplification in the free space model, and Emp pertains to the multi-path model and is significantly influenced by the transmitter amplifier model. The energy required to receive an l-bit message is calculated as:

$$E_{Rx}(l) = E_{Rx-elec}(l) = lE_{elec} \qquad (25)$$

where, E_{Rx} represents the energy consumption for data reception. The threshold distance d_0 is set as follows:

$$d_0 = \sqrt{\frac{E_{fs}}{E_{mp}}} \qquad (26)$$

V. Simulation Experments and Results

A. Experimintal Results

All the simulation experiments were conducted on a laptop with a processor speed of 1.70 GHz Intel Core i7 and memory of 16 GB. The operating system used was Windows 11, version 22H2. The simulation platform was the MATLAB 2023a. A WSN of area 100× 100 m^2 is considered. The nodes are uniformly deployed with the BS initially in the center of the network area. Table II presents the network model and simulation parameters used in the experiments.

TABLE II. Network Setup and Simulation Parameters

Parameter	Value
Simulation area	100 × 100 m^2
Total number of nodes	100
Initial energy	0.5 Joules
Number of rounds	2500
Packet size	2000 bytes
Initial position of the mobile sink	(50,50)
E_{elec}	$5.0e^{-8}$
E_{fs}	$1.0e^{-11}$
E_{mp}	$1.3e^{-15}$

B. Simulation Results

This section describes and compares the developed algorithm's performance with that of the following: FA [12], GWO [10], ACO [11], and PSO [13]. Several measures, including total residual energy, total energy consumption, network lifetime, and stability period are used for analysing and assessing the proposed algorithm.

The total residual energy versus time (in terms of rounds) is presented in Fig. 1. The suggested protocol exhibits larger residual energy than the other three algorithms, as the simulation results obviously reveal. Notably, the proposed algorithm outperforms compared ones, with the residual energy reaching 0 at rounds 1142, 2318, 2381, and 2381 for ACO [11], FA [12], PSO [13], and GWO [10], respectively. On the other hand, the proposed algorithm reaches 0 at round 2490.

The developed algorithm maintains the highest energy levels until 2489 rounds due to its use of the optimized clustering chaotic variable in conjunction with the GWO algorithm for CH selection. Additionally, the SMA algorithm aids the CGWO algorithm by facilitating the mobile sink's path determination to CHs.

Fig. 2 represents the total energy consumption versus time (in terms of rounds) of the proposed algorithm compared to the three other algorithms. The total energy consumption is measured during both transmission and reception and is calculated by dividing total energy consumption by total initial energy. Remarkably, the developed algorithm demonstrates significantly lower energy consumption compared to compare algorithms.

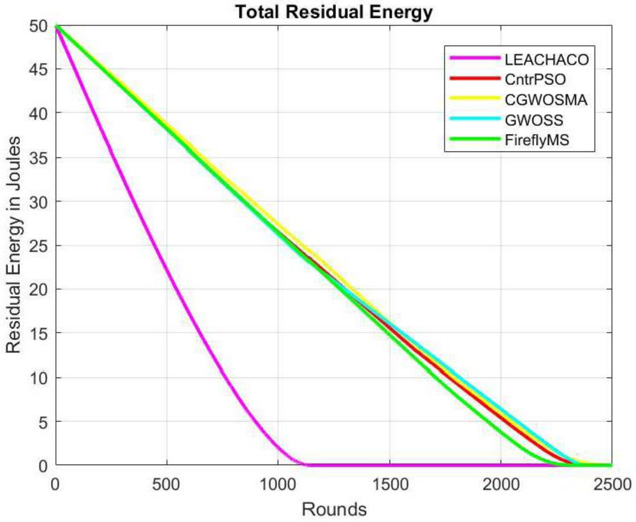

Fig. 1. Total residual energy versus time.

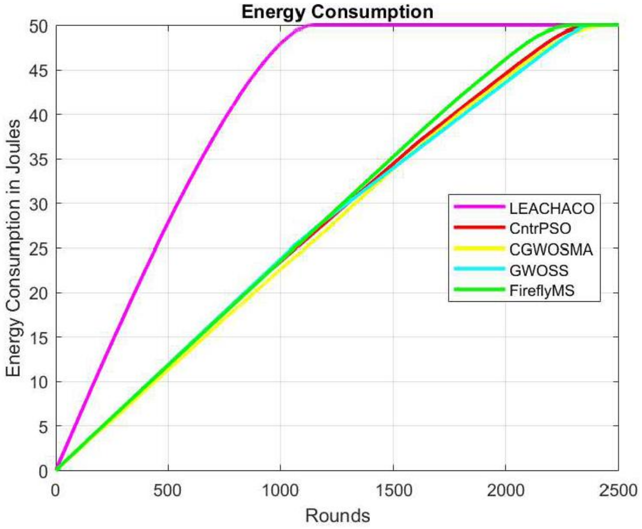

Fig. 2. Total energy consumption versus time.

On average, the energy consumption when using the proposed algorithm is lower than that of ACO [11], FA [12], PSO [13], and GWO [10] by 57.71%, 4.30%, 3.07%, and 2.46%, respectively.

Network lifetime refers to the duration for which nodes remain operational. It signifies the time span from the initiation of network operation until its conclusion, which is marked by the depletion of the last functioning sensor node [37].

Fig. 3 illustrates that it is evident that the developed algorithm sustains more alive nodes than other compared algorithms. The network lifetime is represented in terms of the percentage of alive nodes. ACO [11], PSO [13], GWO [10] algorithms, the proposed algorithm, and FA [12] algorithm, maintain 100% of alive nodes until rounds 159, 836, 1061, 1525, and 1619, respectively. However, ACO [11], FA [12], PSO [13] algorithms, the developed algorithm, and GWO [10] algorithm reach 50% of alive nodes at rounds 761, 2179, 2269, 2294, and 2343, respectively. Finally, ACO [11], FA [12], PSO [13], GWO [10] algorithms, and the implemented algorithm dwindle to 0% of alive nodes at rounds 1143, 2318, 2381, 2381, and 2490, respectively.

Thus, on average, when utilizing our proposed algorithm, the network lifetime surpasses that of ACO [11], FA [12], PSO [13], and GWO [10] by 318.17%, 34.31%, 6.85%, and 1.44%, respectively. The results highlight that employing the CGWO algorithm in the clustering formation significantly enhances network lifetime. The selection of CHs is influenced by chaotic variable, thereby extending the network's operational duration.

The primary driver behind the developed algorithm's superior performance is that the developed algorithm employs the CGWO algorithm, utilizing chaos variable. The developed algorithm utilizes a fitness function that considers both the residual energy and centrality of CHs when choosing them. While the SMA algorithm employs a fitness function based on the shortest distance between the mobile sink and CHs, contributing to enhanced energy retention. While the GWO algorithm [10] exhibits lower residual energy compared to the developed algorithm but fares better than the other compared algorithms. This is because it shares similarities with the developed algorithm in CH selection but uses the original GWO algorithm.

The PSO algorithm in [13] maintains higher residual energy than the FA and ACO algorithms, as it employs the PSO algorithm to determine the shortest path between the mobile sink and CHs. However, it lags behind the GWO and the developed algorithm because it does not use the optimized clustering approach for CH selection; it merely chooses nodes based on centrality. The FA algorithm [12] exhibits higher residual energy than the ACO algorithm as it selects CHs using the FA algorithm and employs a predictable path for the mobile sink. Nonetheless, it falls short of the PSO and GWO algorithms as well as the developed algorithm. Finally, the ACO algorithm [11] ranks the lowest due to its use of the traditional clustering approach LEACH. Although it utilizes three mobile sinks that employ the ACO algorithm to determine paths between mobile sinks and CHs, it lags significantly behind in energy retention compared to the other algorithms.

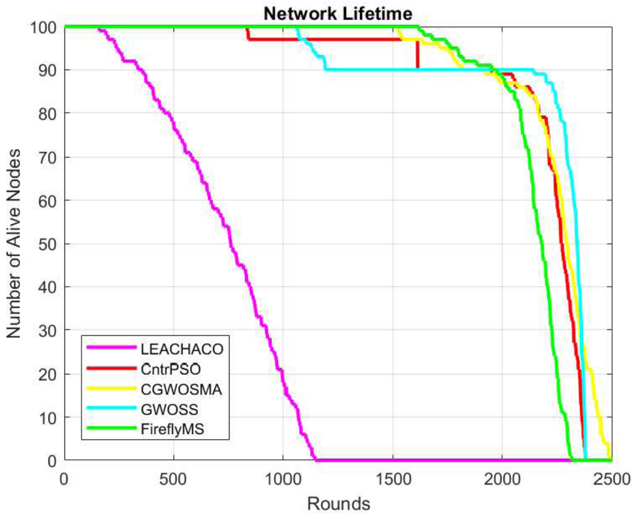

Fig. 3. Number of alive nodes versus time.

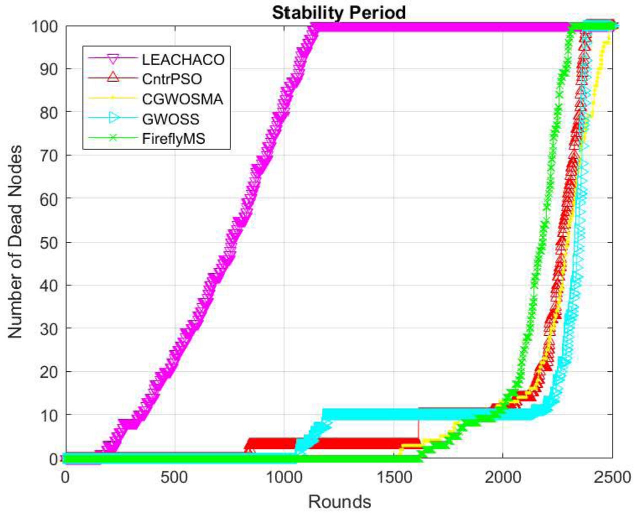

Fig. 4. Number of died nodes versus time.

At last, the stability period for all algorithms is measured. The stability period is defined as "The time when the first node died" [38]. Fig. 4 depicts when the first node in each algorithm died. Specifically, in the ACO [11], PSO [13], GWO [10] algorithms, the implemented algorithm, and FA [12] algorithm, the first node's energy depletion occurs at rounds 160, 837, 1062, 1526, and 1620, respectively.

Fig. 4 reveals that the FA [12] algorithm exhibits greater stability compared to the other algorithms. This enhanced stability can be attributed to its strategy of selecting CHs based on the FA algorithm and utilizing a predictable path for the mobile sink.

On the other hand, the implemented algorithm is less stable than the FA algorithm but more stable than the other two compared algorithms. This is primarily because it depends on node centrality in the fitness function, which is used in CH selection. This can lead to the early depletion of energy in nodes farthest from the CHs. Additionally, the fitness function of the SMA algorithm is based solely on the shortest distance from the mobile sink to the CHs.

VI. Conclusion and Future work

Clustering is one of the best techniques for WSN energy conservation. The clustering method divides the deployed sensors into groups, and each group's cluster head (CH) is selected to collect and aggregate data from other group members. Energy consumption can be decreased with the use of mobile wireless sensor networks, which allow the sink node to be moved. As a result, this paper suggests using swarm intelligence to cluster wireless sensor networks and select dynamic routes for mobile sinks.

To create clusters and locate CHs, the Chaotic Grey Wolf Optimization (CGWO) technique is employed. When figuring out the shortest route between a mobile sink and CHs using the Slime Mould Algorithm (SMA). This paper introduces a new fitness function that relies on remaining energy of the CH, the CH's membership count, Euclidean distance from a mobile sink to a CH, and CH centrality for selecting CHs and for determining the path between a mobile sink and CHs.

The performance of the proposed technique is compared with various state-of-the-art protocols. The results show that the recommended algorithm outperforms other compared algorithms in terms of overall energy consumption and network longevity. The developed approach performs better than three of the compared algorithms and is nearly as good as the fourth throughout the stability period.

As a future work, the limitations of the developed algorithm including the following aspects will be investigated. First, to improve stability period performance by refining the fitness function within the CGWO algorithm and exploring alternative swarm intelligence methods for both clustering and path formation, second to intend to employ the implemented algorithms with other mobility models where more than sink node is mobile.

Acknowledgment

The authors extend their appreciation to the Deanship of Scientific Research at Imam Mohammad Ibn Saud Islamic University (IMSIU) for funding this work through Graduate Students Research Support Program.

Research on Qubit Mapping Technique Based on Batch SWAP Optimization

Hui Li, Kai Lu, Zi’ao Han, Huiping Qin, Mingmei Ju, Shujuan Liu
School of Computer and Information Engineering, Harbin University of Commerce, Harbin, China

***Abstract*—The conventional approach for initial qubit mapping in the Noisy Intermediate-Scale Quantum (NISQ) era typically uses a static heuristic strategy, overlooking insufficient qubit neighborhood in subsequent operations, resulting in excess additional SWAP gates. To address this, we introduce a multifactor interaction cost function considering qubit distance, interaction time, and gate operation error rates, enhancing SWAP gate selection in the traditional strategy. Considering quantum hardware constraints, we propose Batch SWAP Optimization Strategy (BSOS). BSOS tackles qubit mapping challenges by leveraging optimal SWAP gate selection and a SWAP-based batch update technique, effectively minimizing SWAP gates throughout circuit execution. Experimental results show that BSOS significantly reduces additional gates by intelligently selecting SWAP gates and using batch updating, with a 38.1% average decrease in inserted SWAP gates, leading to a 12% reduction in hardware gate counting overhead.**

I. Introduction

Quantum computing, a revolutionary paradigm, has transformed finance [1], machine learning [2], optimization [3], and chemistry [4]. Traditional computers face challenges in complex problem solving and large-scale data processing due to resource limitations. Quantum computers offer a new solution with inherent parallelism. In quantum computing, Hamiltonian quantities describe problem evolution, translated for simulation using algorithms like Grover's search [5] and Shor's algorithm [6]. The product formula, approximating Hamiltonian exponentiation, is crucial. Quantum circuits excel in manipulating exponents, making them powerful for Hamiltonian simulation. Leveraging quantum circuit advantages efficiently advances quantum computing.

High-level representations of quantum circuits are not inherently tied to specific hardware and require translation into an instruction set compatible with the underlying quantum hardware for execution. In NISQ computers, the prevalent instruction set typically comprises a single-qubit rotation gate and one or more two-qubit gates. These quantum computers can only apply two-qubit gates to a limited set of qubit pairs due to constrained connections between qubits. Consequently, it becomes essential to perform circuit-to-hardware qubit mapping using initial qubit mapping techniques. Additionally, to scale up the circuit by increasing the number of gates and depth, it is necessary to reposition qubits to neighboring locations by introducing SWAP gates.

The existing literature on time scheduling strategies [7] offers solutions for compiling circuit depth, yet it may encounter challenges in managing constraints and optimization, particularly with intricate circuits. Another approach in [8], focusing on time scheduling and constraint planning, generates a hot-start solution but may face limitations regarding computational complexity and algorithmic efficiency, especially for large-scale circuits. A proposed greedy stochastic search approach [9] proves effective for similar problems but may struggle with complex circuits and global optimization. Genetic algorithms with chromosome coding strategies, introduced in [10] for optimization, might face challenges related to algorithmic parameter sensitivity and convergence speed. The study in [11] explores the trade-off between switched gates and circuit depth during compilation but offers limited consideration of hardware characteristics such as gate error rate. The research in [12] and [13] introduces strategies considering gate error rates, a significant advancement, yet practical applications may necessitate a more comprehensive consideration of hardware characteristics like cooling time and connectivity. In summary, while these literatures contribute valuable insights to the problem, further improvements and a more holistic approach may be required to address complex circuits and global optimization effectively.

In this paper, we explore Hamiltonian operator arrangements' flexibility, propose a multifactor interaction cost function and introduce BSOS for the initial qubit mapping process, aiming to efficiently compile quantum circuits for 2-local qubit Hamiltonian simulation problems. Given prevalent NISQ computer characteristics, where two-qubit gate error rates are typically 10 times higher than single-qubit gates, and qubit coherence time is shorter [14], BSOS adapts to diverse qubit topologies and gate sets. It seamlessly integrates with various quantum circuit mapping algorithms and is suitable for quantum approximation optimization algorithms like Quantum Approximate Optimization Algorithm (QAOA) [15]. Through evaluations, BSOS substantially reduces the required gate number compared to the state-of-the-art initial qubit mapping strategy. We further validate the effectiveness of BSOS through experiments on an IBM quantum device.

The main contributions of this paper can be summarized as follows:

- We focus on the initial qubit mapping phase, identifying the challenges and limitations that are the primary focus of this study.
- We introduce a multifactor interaction cost function, considering qubit distance, interaction time, and gate

error rate. This cost function facilitates a more comprehensive evaluation and optimization of quantum circuit performance.

- We propose an optimal SWAP gate selection algorithm and define SWAP gains. The SWAP gain is assessed based on the benefits obtained by adding SWAP gates. Optimal SWAP gates are selected for different instruction sets in quantum circuits.
- We design a scalable SWAP-based batch update technique, providing comparable results to previous mapping-based update-by-sequence approaches. This rapid update scheme ensures the scalability of qubit mapping, allowing the BSOS to adapt to various hardware architectures and accommodate larger quantum devices in NISQ era.

The subsequent sections of the paper are organized as follows: Section II presents relevant background information on quantum simulation and quantum circuits. Section III introduces the modification scheme for the cost function and details the BSOS strategy. The evaluation of these approaches is discussed in Section IV. Finally, the paper is summarized in Section V.

II. Preliminaries

A. Product Formula (Trotter's Formula)

In the realm of quantum computing, the product formula, also known as Trotter's formula, stands out as a fundamental technique for constructing efficient circuit structures. It leverages the decomposition of Hamiltonian quantities, representing the time evolution of a system in exponential form. The essence of the product formula lies in its ability to approximate time evolution by breaking down the system's Hamiltonian quantity, denoted as H, into distinct operators comprising sums of polynomial ergodic terms. Quantum circuits are then employed to efficiently implement these operators. The formula can be succinctly expressed as:

$$V(t) = \prod_{j=1}^{L} \exp(ith_j H_j) \tag{1}$$

where, $V(t)$ represents the state of the system at moment t, L is the number of terms, h_j is the coefficient of the jth term and H_j is the corresponding ergodic operator.

If all terms are exchangeable (i.e., $H_jH_k = H_kH_j$), then the product formula approximates the true time evolution U, (i.e., $V(t) = U$). However, in natural physical systems, non-exchangeable terms are typically present. In such cases, a first-order approximation can be used to approximate $V(t)$ as an rth power of $V(t/r)$, where r is a constant greater than 1. This process is known as the Trotterization step, and repeating this step r times forms a Trotter sequence. By decreasing the value of r, the cost of the simulation can be significantly reduced.

In this paper, we mainly consider the 2-local qubit Hamiltonian quantity, as shown in Eq. (2):

$$H = \sum_{(u,v)\in E} H_{uv} + \sum_{k\in V} H_k \tag{2}$$

where, H_{uv} represents a two-qubit Hamiltonian term and H_k is a single-qubit Hamiltonian. The interaction graph of this Hamiltonian quantity is represented by **G**(**V**, **E**), where **V** represents the set of qubits and **E** represents the set of edges.

B. Quantum Circuit

In quantum computing, data is stored in qubits, each of which has two fundamental states, denoted by $|0\rangle$ and $|1\rangle$. Unlike classical bits, qubits can be in a superposition of these two fundamental states, i.e., $\alpha\ |0\rangle + \beta\ |1\rangle$, where α and β are complex numbers and satisfy $|\ \alpha\ |^2 + |\ \beta\ |^2 = 1$.

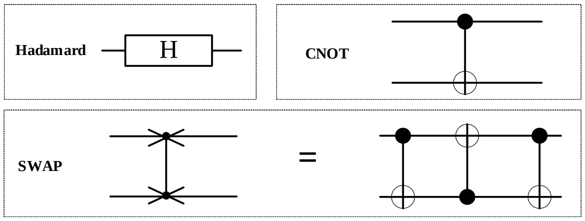

Fig. 1. Basic gates of IBM quantum computers.

Operations in quantum computing are realized through quantum gates, which apply specific operations like rotations, flips, etc., between qubits. Quantum gates are mathematically represented by unitary matrices. A Hadamard gate operates on a single qubit, while both CNOT gates and SWAP gates act on two qubits, as shown in Fig. 1. A CNOT gate flips the state of the target qubit based on the state of the controlling qubit, i.e., CNOT: $|c\rangle|t\rangle \rightarrow |c\rangle|c \oplus t\rangle$, where c, $t \in \{0, 1\}$ and $\oplus$ denotes a heteroskedastic operation. the SWAP gate then exchanges the states of the two target qubits: for all a, $b \in \{0, 1\}$, it will $|a\rangle|b\rangle \rightarrow |b\rangle|a\rangle$. The SWAP gate can be realized by a combination of 3 CNOT gates (see Fig. 1).

A quantum circuit is a framework for describing and manipulating quantum information, comprising a sequence of quantum gates akin to classical logic gates. Quantum gates enact transformations on quantum states. Quantum circuits can be conceptualized as systems constructed from a combination of fundamental quantum gates and quantum measurements. In the realm of intricate quantum operations, like simulating Hamiltonian quantities, quantum gates within quantum circuits can be deliberately designed and fine-tuned.

The quantum mapping task involves a graph **G = (V, E)** that represents the structure of the target quantum device and a circuit **C** representing an ideal quantum algorithm. The gates in circuit **C** are decomposed into elementary gates supported by the target quantum device. The objective of quantum mapping is to transform circuit **C** into a functionally equivalent circuit. In this transformed circuit, each two-qubit gate acts on a pair of neighboring nodes in the graph **G** of the target quantum device. Essentially, the goal is to adapt and map the circuit **C** according to the physical architecture of the target quantum device, ensuring its compatibility with the specific quantum hardware. Fig. 2(a) shows an example of a circuit where **Q** = $\{q_0, ..., q_4\}$, **C** = $\{g_0, ..., g_6\}$, where g_0 = CNOT (q_0, q_1), g_1 = CNOT (q_2, q_4), and so on. In the figure, each CNOT gate is labelled with the qubit they act on. In the text, q *is* used to represent logical qubits and P is used to represent physical qubits.

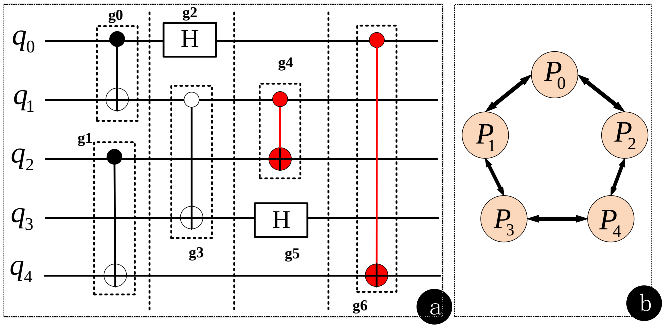

Fig. 2. (a) A logical circuit with depth 4, (b) Architecture diagram of quantum device.

Circuit **C** is typically represented as a sequence of gates (g_0, g_1, ..., g_{m-1}), but this cannot imply that in all cases the (i + s)th gate has to be executed after the *ith* gate (where $i \geq 0$, $s \geq 1$, and $0 < i + s < m$). In reality, if the two gates don't involve common qubits, they can be executed in parallel. For instance, considering the circuit in Fig. 2(a), it can be expressed as:

$$C = \left(\langle q_0, q_1 \rangle, \langle q_2, q_4 \rangle, \langle q_0 \rangle, \langle q_1, q_3 \rangle, \langle q_1, q_2 \rangle, \langle q_3 \rangle, \langle q_0, q_4 \rangle \right).$$

III. Proposed Methodologies

A. Problem in Initial Mapping

Qubit mapping aims to determine the optimal arrangement of qubits, minimizing the number of qubit shift operations needed for all two-qubit gates. Like the methodologies outlined in [16]-[19], the qubit mapping problem is cast as a Quadratic Assignment Problem (QAP).

Similar to the previous approach, a SWAP operation is employed to alter the state between two qubits, facilitating the adjustment of qubit mapping. Introducing 1 SWAP gate increases the circuit's depth by 3. Multiple swap gates enable the relocation of a logical qubit to any physical qubit position. Fig. 3 illustrates that after inserting a SWAP operation between q_0 and q_2 following the third CNOT gate, the modified quantum circuit becomes executable. The first 3 CNOT gates can be executed under the initial qubit mapping, and after inserting the SWAP, the mapping is updated to $\{q_0 \rightarrow p_2, q_1 \rightarrow p_1, q_2 \rightarrow p_0, q_3 \rightarrow p_3, q_4 \rightarrow p_4\}$, and the remaining two CNOT gates can now be executed under this updated mapping.

Comparing the initial and optimized circuits in Fig. 2(a) and Fig. 3, it is evident that the number of gates increases from 7 to 10, and the circuit depth increases from 4 to 7. The introduction of additional SWAP gates notably enhances the circuit's execution time. Hence, the primary objective of the mapping process is to minimize the number of additional SWAP gates inserted, aiming to reduce the overall error rate and total execution time of the final hardware-adapted circuit.

Definition 1 Qubit mapping [6]: given a coupling map of input quantum circuits and quantum devices, find the initial qubit mapping and the intermediate qubit mapping transformations (by insertion swapping) to satisfy all two qubit constraints and try to minimize the number of additional gates and the circuit depth in the final hardware-compatible circuit.

In the initial qubit mapping phase of quantum circuit compilation, several challenges need to be addressed. This paper considers the following limitations:

- Selection of physical qubits: It is crucial to choose the appropriate physical qubits to map the logical qubits. Taking into account the hardware's topology, physical qubits are selected to minimize communication overhead.
- Connectivity limitation: Some hardware platforms only permit direct communication between specific qubits, while other communications need to be achieved through SWAP gates.
- SWAP gate cost: The execution cost of SWAP gates is typically high, so the cost of SWAP gates is taken into account when choosing the initial qubit mapping scheme, with a preference for less costly SWAP operations.
- Optimal performance trade-off: The goal of the initial qubit mapping is to achieve efficient quantum gate operations while minimizing the communication overhead. Different performance metrics such as communication overhead, SWAP gate cost, etc., need to be weighed when choosing the physical qubits and order.

Improving the quality of the initial qubit mapping requires addressing the following questions:

- How to determine the appropriate mapping targets? This involves identifying, for a selected gate, which qubits are the targets. In other words, it determines which qubits need to be communicated or exchanged during the execution of the gate. Once the best mapping target has been selected, the appropriate mapping operation can be performed, such as the execution of a SWAP gate to exchange the positions of qubits. This ensures that the target operation can be executed correctly in hardware.
- How to efficiently choose where to insert SWAP gates, and how many to insert, in order to improve the mapping and minimize the total number of SWAP gates.

B. Design the Cost Function

In the exploration of potential SWAP gates, the role of the cost function is to prioritize the SWAP gate that closely aligns with the target mapping in terms of cost. Assessing potential SWAP gates entails the selection of the most favorable SWAP sequence, constituting an ongoing decision-making process integral to the overall mapping strategy. The arrangement requires reevaluation when updating the qubit mapping following each SWAP operation, constituting a dynamic process. To achieve optimal mapping outcomes, the mapping must be recalibrated and adjusted subsequent to each SWAP insertion through the utilization of a cost function.

Among numerous mapping methods, the cost function serves as a pivotal tool for assessing the effectiveness of a mapping strategy. However, prevailing cost functions typically focus on a singular factor, predominantly relying on distance as the fundamental metric—whether physical or logical distance between qubits. These functions often lack the capability to consider multiple factors. Physical distance impacts the operational speed and error rate, as qubits situated farther apart may necessitate more steps and involve intermediate bits with a higher probability of errors during operations.

To address the aforementioned issue, this paper introduces a multifactor interaction cost function as shown in Eq. (3). This function incorporates three primary factors: distance, interaction time, and error rate of gate operation. Minimizing the cost function enables the identification of the most efficient and accurate strategies and configurations for accomplishing a specific quantum computing task. This cost function is

$$Y_{\mathrm{cos}t}(E, f_{ij}, d_{\phi(i)\phi(j)}) = \min_{\phi \in S_n} \sum_{i=1}^{n} \sum_{j=1}^{n} E f_{ij} (d_{\phi(i)\phi(j)})^2 \quad (3)$$

where, S_n denotes all possible permutations, f_{ij} represents the interaction time between logic qubits i and j in the circuit, and the interaction time can be estimated based on hardware specifications or empirical experiments. e denotes the probability of an error occurring for the execution of a double quantum gate, where $0 \leq E \leq 1$, and $d_{\varphi(i)\varphi(j)}$ denotes the physical distance between the qubits $\varphi(i)$ and $\varphi(j)$ on the hardware, which can be calculated by using the Floyd-Warshall algorithm to perform the calculation.

The physical distance between qubits plays a pivotal role in influencing the speed and efficacy of their interactions. Increased distances directly contribute to heightened computational complexity and error rates, with the square factor of distance exerting a substantial impact on overall computational cost, thereby influencing the efficiency and accuracy of quantum computation. Interaction time serves as a determinant of task execution speed, with prolonged interaction times resulting in extended task execution durations. Introducing interaction time as a factor in the cost function underscores its significance in determining the overall computational cost and efficiency. Quantum gate operations inherently incur error rates, where elevated error rates undermine computational accuracy and reliability. The incorporation of gate operation error rates into the cost function underscores the critical influence of accuracy and reliability on the cost and efficiency of quantum computing. By amalgamating these three factors, the initial qubit mapping of a quantum circuit can be generated with a more comprehensive consideration of hardware limitations and practical implementation constraints.

C. Best SWAP Choice

In the realm of quantum computing, any multi-quantum gate can be decomposed into a combination of single quantum gates and CNOT gates. The execution of these gates necessitates the inclusion of SWAP gates to alter the connectivity pattern between qubits. To minimize the surplus of added SWAP gates, strategic selection of SWAP gates that can yield more nearest-neighbor (NN) gates is crucial. This practice contributes to the implementation of intricate quantum operations and algorithms, enhancing the coherence of the circuit. The significance of SWAP gates lies in two primary aspects: Firstly, SWAP gates facilitate the interchange of states between two qubits, thereby reshaping the relationships between qubits and optimizing the structure and efficiency of the quantum circuit. Secondly, in practical quantum operations, achieving the target superposition quantum state often involves constructing a combination of corresponding quantum gates. A higher count of NN gates enhances the likelihood of attaining this objective. Formally, SWAP gate gains are defined as follows:

Definition 2 SWAP gate gains: let P be the set of non-nearest-neighbor (non-NN) gates, Q be the set of executable SWAP gates, $\mathrm{V}_{\mathrm{SWAP}}$ = **{P, Q}** be the list of SWAP gains, N_1 be the set of executable $\mathbf{V_{SWAP}}$, i.e., the number of NN gates after adding this SWAP gate. N_0 is the number of NN gates when the $\mathbf{V_{SWAP}}$ set is not executed. The optimal benefit $\mathbf{V_{SWAP}}$ set is determined by selecting max $\{N_1 - N_0\}$.

$$\mathrm{V}_{\mathrm{SWAP}} = N_1 - N_0 \quad (4)$$

We introduce a heuristic-based strategy designed to optimize the selection of SWAP gates, with the goal of minimizing the compilation overhead in quantum circuits. The strategy involves simulating the execution of a SWAP operation for each potential candidate, resulting in a new mapping. Subsequently, the sizes of the elements in VSWAP are compared, determined by the number of NN gates generated under the new mapping with different SWAP gates inserted. Among all feasible SWAP operations, the one with the largest element size is chosen. This approach enables a more intelligent selection of SWAP gates, thereby reducing the overall count of SWAP gates and enhancing the overall performance of the quantum circuit.

Algorithm 1 Best SWAP Choice

Input.
nn_gate_count: The number of nearest-neighbor gates in the circuit after adding a swap gate between two qubits
moves: A set of insertable SWAP gates with the same cost
Output.
best_move: Optimal insertable SWAP gate

```
begin
    max_nn_gate_increase ← 0
    best_move ← None
    for move in moves do
        nn_gate_increase ← nn_gate_count[move]
            if nn_gate_increase > max_nn_gate_increase
                max_nn_gate_increase ← nn_gate_increase
                best_move ← move
        end if
    end for
end
```

Details of the pseudo-code can be found in Algorithm 1 in the text, while a specific application example is provided in Fig. 4.

Compile an 8-qubit 2-local Hamiltonian into the lattice architecture depicted in Fig. 4. In the presence of a set of insertable SWAP gates with identical costs, the approach outlined in this paper is to identify the one with the highest gain among these gates. Fig. 4(a) presents a qubit map of a circuit along with a scenario where specific quantum operations algorithms cannot be implemented without the insertion of SWAP gates. The upper figure displays the inserted SWAP gates and the CNOT gates implemented after insertion, while the lower figure illustrates the qubit graph, where nodes represent qubits, and edges signify their connectivity. To prevent confusion, the SWAP gates in the figure are applied to the corresponding hardware qubits. For enhanced readability, they are plotted on the circuit qubits.

In the circuit, CNOT (0, 1) and CNOT (1, 5) are direct mappings, but SWAP gates are needed to perform the remaining CNOT gates. SWAP gates with the same cost are calculated according to Eq. (3), such as SWAP (2, 5) and SWAP (5, 6) in figure. Subsequently, the filtered SWAP gates are inserted into the circuits separately to see the number of NN gates generated under the new mapping. As in Fig. 4(b) SWAP (q_2, q_5) is inserted and V_{SWAP} = 2 under the current mapping (see Eq. 4). Whereas in Fig. 4(c), V_{SWAP} = 1 after inserting SWAP (q_5, q_6) By comparison, a set of SWAP gates with a larger number of NN gates is selected and inserted into the circuit to update the mapping. And so on until all the quantum gates are mapped and the final mapping result is shown in Fig. 4(d). This strategy ensures that the selected SWAP gates maximize the number of NN gates and optimize the mapping of the quantum circuit.

D. Batch Update Technology

The traditional approach to quantum mapping involves real-time updates of mappings to adjust the relationship after each SWAP operation. However, as quantum circuits increase in size, this method becomes inefficient. To address this issue, we propose a Batched Update Technique (BUT).

The design of the BUT is based on reducing the cost associated with frequent mapping updates in conventional quantum mapping methods. The strategy aims to enhance the efficiency of quantum circuit mapping by decreasing the frequency of updates, incorporating the overall circuit structure, and balancing mapping performance with the associated update costs, among other theoretical considerations. The fundamental concept is to holistically consider multiple mapping update operations to reduce interference with circuit execution operations and achieve a trade-off between mapping quality and update costs. Specifically, each batch update takes into account all relevant SWAP operations and executes mapping updates for these operations simultaneously. This approach reduces the number of mapping updates stemming from a single SWAP operation, thereby diminishing latency and energy consumption in quantum computing.

Fig. 5. (a) Original code block 2, (b) Coupling graph of IBM q20, (c) non-NN quantum gate, (d) List of SWAP gates to be executed, (e) Batch update mapping results.

In extensive quantum circuits, the interaction constraints between qubits necessitate multiple SWAP operations to facilitate the exchange between non-adjacent qubits. Each SWAP operation triggers a mapping update, contributing to inefficiency. Consequently, consolidating multiple operations and updating the mapping collectively after completing all operations emerges as an appealing solution. The BUT scrutinizes the entire quantum circuit to identify which two-qubit gates can be optimized through a shared SWAP operation. When a SWAP gate is chosen for execution, it gets added to a "list of SWAP operations to be performed," with a defined condition dictating when to cease additions, such as reaching a predetermined list length. During batch execution of SWAP operations, the algorithm iterates through the list, executes all listed SWAP operations, and updates the qubit mapping collectively upon completion.

Fig. 5 shows an example, assuming the circuit shown in Fig. 5(a) is run on the 20-qubits device Tokyo (Fig. 5(b)). First, two-qubit gates that are NNs on the initial qubit layout, such as those labelled purple in Fig. 5(a), are filtered from the original circuit list2. Map these gates directly to the corresponding hardware (e.g., the qubits labelled pink in Fig. 5(b)), i.e.

$q_0 \rightarrow p_0$, $q_1 \rightarrow$ p$_1$, $q_2 \rightarrow p_2$, $q_3 \rightarrow p_3$, $q_6 \rightarrow p_6$, $q_7 \rightarrow p_7$, $q_8 \rightarrow p_8$, $q_{10} \rightarrow p_{10}$, $q_{12} \rightarrow p_{12}$, $q_{13} \rightarrow p_{13}$, $q_{15} \rightarrow p_{15}$, $q_{19} \rightarrow p_{19}$.

For non-NN two-qubit gates, the costs between qubits are compared by means of a computed cost function. The qubit pair with the smallest cost is chosen as the target of the mapping, assuming that the SWAP gate with the smallest cost is evaluated as $\{q_0, q_1\}$. The previous method is to add that SWAP gate to the execution list, update the qubit mapping, and remove the NN gates from the unmapped set of gates. The steps are repeated until all double qubit gates are mapped. Instead of executing the SWAP gates directly, the strategy in this paper puts the SWAP (q_0, q_1) into the SWAP list (e.g., Fig. 5(d)), and then searches for the next SWAP gate, which is also added to the list. When the length of the list reaches a predefined value, it traverses the "list of SWAP operations to be performed" and then performs all SWAP operations in the list. After all the above SWAP operations are completed, the qubit mapping is updated uniformly.

In this process, handling multiple operations simultaneously may introduce some complexity, as it is necessary to ensure that there are no conflicts between batch operations and to update the qubit mapping correctly. Whenever a new SWAP operation is added to the "pending SWAP operation list," a conflict check is performed for this operation with other operations already in the list. Specifically, it is ensured that the new SWAP operation does not impact or be impacted by the SWAP operations already in the list. The qubit mapping is then updated in bulk based on the selected SWAP list, i.e., when each new SWAP operation is added to the "pending SWAP operation list.", i.e.

$q_0 \rightarrow p_1$, $q_1 \rightarrow p_0$, $q_2 \rightarrow p_2$, $q_3 \rightarrow p_3$, $q_5 \rightarrow p_5$, $q_6 \rightarrow p_7$, $q_7 \rightarrow p_6$, $q_8 \rightarrow p_8$, $q_{10} \rightarrow p_{10}$, $q_{11} \rightarrow p_{11}$, $q_{12} \rightarrow p_{12}$, $q_{13} \rightarrow p_{18}$, $q_{15} \rightarrow p_{15}$, $q_{17} \rightarrow p_{17}$, $q_{18} \rightarrow p_{13}$, and $q_{19} \rightarrow p_{14}$

Remove the NN from the unmapped gates and empty the "list of pending SWAP operations" in preparation for the next batch of SWAP operations. Repeat until all double-qubit gates are mapped.

IV. Result and Discussion

Similar to earlier studies, this paper uses the following metrics to evaluate the performance of different compilers: the aggregate count of inserted SWAP gates (lower values are preferable) and the overall count of executed two-qubit gates on the hardware (lower values are preferable). These metrics enable the evaluation of algorithm performance, particularly in handling intricate circuits. The benchmarking procedure aligns with IBM's Qiskit quantum program, utilizing the Qiskit compiler for decomposition and optimization of the CX/CNOT gate set. The benchmarking methodology outlined in [13], focusing on the QAOA model, was adopted, wherein the time evolution of Hamiltonian quantities is conducted by multiplying Eq. (5) by:

$$V(t) = (\Pi_{j=1}^{L} \exp(ih_j H_j t / r))^r \tag{5}$$

where, r is the number of iterations of Trotter. The coefficients of H_j were randomly selected in the range (0, π). The evaluation ranges from 4 to 22 qubits, running their mapping process five times and selecting the best result.

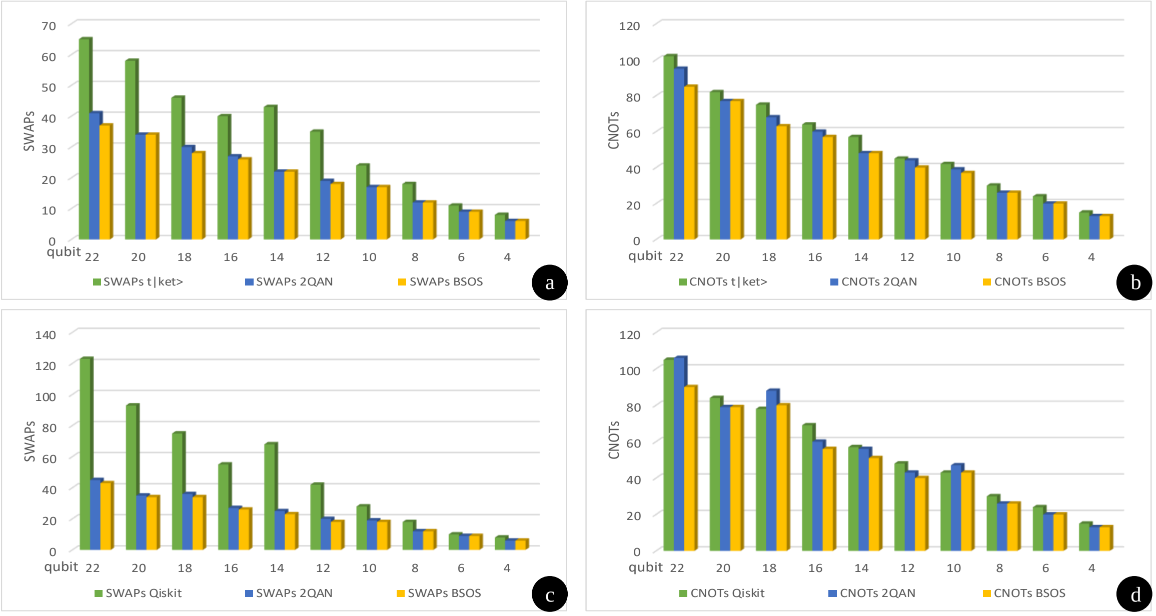

Fig. 6. (a) Comparison of SWAP gate compilation cost between BSOS technology and t|ket⟩ and 2QAN, (b) Comparison of CNOT gate compilation cost between BSOS technology, t|ket⟩ and 2QAN, (c) Comparison between BSOS technology and Qiskit and Comparison of SWAP gate compilation cost of 2QAN, (d) Comparison of BSOS technology, t|ket⟩ and 2QAN, (e) Comparison of SWAP gate compilation cost of 2QAN (c) Comparison between BSOS technology and Qiskit and Comparison of SWAP gate compilation cost of 2QAN, (d) Comparison of BSOS technology with CNOT gate compilation cost of Qiskit and 2QAN.

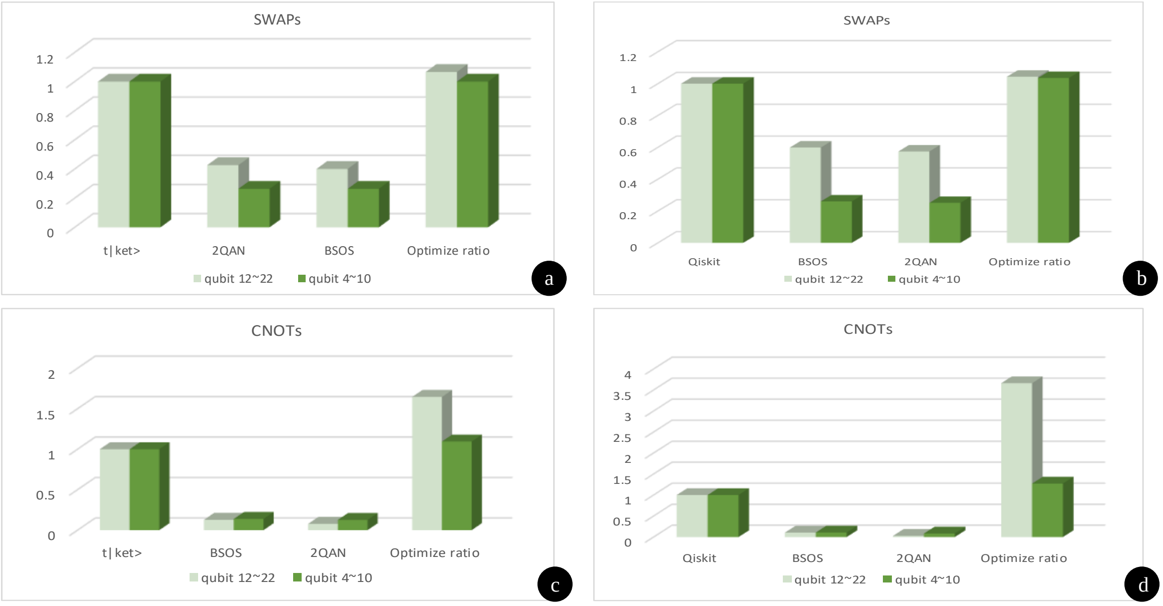

Fig. 7. The BSOS strategy was evaluated for circuits with 4 to 10 qubits and 12 to 22 qubits. (a) SWAP gate optimization rate of BSOS relative to t|ket⟩ and 2QAN, (b) SWAP gate optimization rate of BSOS relative to Qiskit and 2QAN, (c) CNOT gate optimization rate of BSOS relative to t|ket⟩ and (d) CNOT gate optimization rate of BSOS relative to t|ket⟩ and 2QAN. optimization rate of BSOS relative to Qiskit and 2QANs

BSOS was implemented in Python 3.9 and all compilations were performed on a laptop with an Intel Core i5 processor (2.30GHz and 8GB RAM).

Compare the BSOS compilation strategy with the compilation overheads of t|ket⟩ and Qiskit. Fig. 6 and Fig. 7 show the compilation results on the IBM. Compared to t|ket⟩ and Qiskit, BSOS has the least compilation overhead in terms of the number of SWAP gates inserted, the number of hardware dual-quantum gates, and the circuit depth. Specifically, the t|ket⟩ compiler [20] (version 0.11.0) and the Qiskit compiler [21] (version 0.26.2, optimization level 3), equipped with the recommended "FullPass", are considered.

The IBM quantum compiler is limited to CNOT or CZ gate sets, so the models were evaluated using the compilation results on the IBM quantum computer. Of all the benchmarks and quantum computers, the run using the BSOS strategy in the QAP mapping turned out to be the best, as can also be seen in Fig. 6, where the optimization is more pronounced with a higher number of qubits. For 22 qubits, BSOS inserts 43% less SWAP counts than t|ket⟩ and 65% less than Qiskit (Fig. 6(a)(b)). This reduction in SWAP count will lead to a reduction in the number of hardware double-qubit gates, and BSOS reduces the double-qubit gate overhead by 17% and 14% (Fig. 6(c)(d)).

In the t|ket⟩ compiler, for the case of 4 to 10 qubits, the average reduction in the number of inserted SWAP gates is 26.4%, while the average reduction in the number of inserted CNOT gates is 13.8%. This optimization effect is 10% higher than using only 2QAN. After optimization for 12 to 22 qubits, the average reduction in the number of inserted SWAP gates across all evaluated benchmarks is 40%, and the average reduction in the number of inserted CNOT gates is 12.8%. This optimization effect is 70% higher than using only 2QAN (see Fig. 7(a) (b)).

In the Qiskit compiler, for 4 to 10 qubits, the average reduction in the number of inserted SWAP gates is 26%, while the average reduction in the number of inserted CNOT gates is 10.8%. This optimization effect is 30% higher than using only 2QAN. For 12 to 22 qubits, after optimization, the average reduction in the number of inserted SWAP gates is 60%, and the average reduction in the number of inserted CNOT gates is 10.6% (see Fig. 7(c) (d)).

In this study, optimizing the placement of qubits is taken as the main concern. To solve this problem efficiently, the Tabu search algorithm was chosen. This algorithm is very fast in solving small scale problems, e.g., for the QAOA model with 4 qubits, it takes only about 0.221 seconds in the t|ket⟩ compiler and about 0.004 seconds in the Qiskit compiler, as shown in Table I. However, the processing speed drops significantly when faced with problems of larger size. For example, the QAOA model with 20 qubits takes about 24.218 seconds in the t|ket⟩ compiler and about 0.0176 seconds in the Qiskit compiler.

By applying this cost function, quantum computing researchers and engineers can more accurately quantify the impact of different designs and strategies on the system performance, providing a scientific basis for decision-making and advancing the development of quantum computing technology. In order to verify the accuracy and effectiveness of the proposed cost function, a comparison experiment is conducted in the t|ket⟩ compiler for the distance-only cost function and the cost function proposed in this paper, and the results are shown in Fig. 8. From the figure, it can be seen that the compilation result of the cost function in this paper is better. For 12~22 bits, SWAP is reduced by 28.52% and CONT is reduced by 35.81% on average. While for 4~10 bits, SWAP is reduced by 7.32% and CONT is reduced by 13.74% on average.

TABLE I. COMPARING AVERAGE RUNNING TIMES OF 2QAN AND BUT IN COMPILERS T|KET⟩ AND QISKIT

qubit	Running time		
		BUT	2QAN
22	t|ket⟩	22.218	22.553
	Qiskit	0.0176	0.0184
20	t|ket⟩	10.274	10.954
	Qiskit	0.0178	0.0178
6	t|ket⟩	0.318	0.361
	Qiskit	0.005	0.006
4	t|ket⟩	0.221	0.244
	Qiskit	0.004	0.004

The superior performance of BSOS in the 22-qubit scenario primarily manifests in its intelligent SWAP gate selection strategy, the comprehensive consideration using a multifactor interaction cost function, and the introduction of batch update techniques. These advantages enable BSOS to more effectively optimize the placement of quantum bits in large-scale quantum circuits. Specifically, the intelligent SWAP gate selection and comprehensive consideration of multiple factors enhance the overall mapping performance, while the batch update technique reduces mapping costs. These optimization effects are particularly pronounced in the case of 22 qubits.

The BSOS algorithm not only demonstrates outstanding performance in the 22-qubit scenario but also holds broad potential applications and future research directions. The application areas of BSOS include the compilation and execution of large-scale quantum circuits, especially well-suited for highly optimized quantum tasks. Future research directions may encompass optimizing nested quantum algorithms, adapting the BSOS algorithm to dynamic scenarios, deeper integration of quantum hardware characteristics, and incorporating BSOS into comprehensive quantum compilation automation tools, providing support for the further development of quantum computing technology.

V. Conclusion

In the NISQ era, there is still a significant gap between quantum software and imperfect NISQ hardware. This research introduces a Bulk SWAP Optimization Strategy (BSOS) specifically designed for addressing the 2-local qubit Hamiltonian simulation problem. Focusing on the adaptable operators within Hamiltonian quantities, the primary optimization targets the initial qubit mapping of qubits. A comprehensive evaluation reveals that the BSOS strategy significantly mitigates compilation overhead on the IBM quantum computer, demonstrating superior performance compared to the other two general-purpose compilers.

The optimal SWAP gate selection algorithm optimizes circuit locality by selecting SWAP gates that generate a larger number of newly added NN gates, while the SWAP updating strategy reduces the frequency of mapping by batch updating and optimizing the timing, which improves the overall efficiency of quantum circuit mapping. On the other hand, the introduction of qubit interaction time and the error rate of gate operation in the cost function helps to improve the efficiency and reliability of quantum computation, which makes up for the lack of comprehensiveness and accuracy of previous methods. This makes the proposed method more applicable to NISQ computers with different characteristics and optimization goals, and provides a useful improvement direction for the efficient execution of mesoscale quantum computation. Looking ahead, more optimization work is planned and other possible research directions are explored. By applying error mitigation techniques, it is expected that the error rate can be further reduced, thus further improving the performance and reliability of quantum computation.

Abstract—**The transition from pediatric to adult cardiology care is a pivotal moment in the healthcare journey of individuals with congenital heart conditions or childhood-onset heart diseases. This multifaceted process requires meticulous consideration of clinical, psychosocial, and logistical factors. This research aims to explore the critical criteria for transitioning pediatric patients to adult cardiology, delving into the challenges and opportunities inherent in this healthcare shift. The identified factors for successful transition, including age and developmental stage, medical complexity, cardiac function, psychosocial factors, insurance, and financial considerations, play integral roles in the transition process. Leveraging analytical methodologies, particularly the Fuzzy Decision-Making Trial and Evaluation Laboratory (DEMATEL), this study involves three experts who assess criteria linguistically, converted to Triangular Fuzzy Numbers, and averaged. Defuzzification, using the CFCS method, yields crisp values. Results reveal that Medical Complexity (U+V = 3.96, U-V = 0.233), Insurance (U+V = 3.931, U-V = 0.22), Psychosocial Factors (U+V = 3.839, U-V = 0.387), and Age and Developmental Stage (U+V = 3.802, U-V = 0.106) follow Cardiac Function (U+V = 4.312, U-V = 0.946) in ranking. Age and Developmental Stage, Medical Complexity, Psychosocial Factors, and Insurance are considered causal variables, with Cardiac Function as an effect. These numerical insights enhance our understanding of transition criteria interdependencies, informing tailored healthcare strategies.**

I. Introduction

Congenital Heart Disease (CHD) is a complex and diverse group of cardiovascular conditions that affect a substantial number of children worldwide. The remarkable advancements in medical care, surgical interventions, and early diagnosis have significantly improved the survival rates of pediatric patients born with CHD. As a result, more and more of these individuals are now moving from receiving care in cardiology to adult cardiology as they enter adolescence and early adulthood. This shift, in healthcare can be sometimes difficult phase for them. It's essential to transition patients with congenital heart disease (CHD) into adult cardiology care to ensure that they continue to receive effective treatment, monitoring and support. However, this process is complex. Its outcome has an impact, on the long-term health and quality of life of these patients.

The transition covers aspects, such, as medical considerations, psychological and social factors, communication and involving both patients and their families. This study builds on the work of researchers [1, 2] a review by [3] and the guidelines provided in the literature to further understand how pediatric patients with heart disease move from pediatric care to adult care. By using the Fuzzy DEMATEL approach our goal is to identify the factors that influence this transition. This information can then be used by healthcare providers, policymakers and stakeholders to improve the quality of care and long-term outcomes, for this group of patients. As we strive for a patient centered transition model, the importance of utilizing tools has become more recognized. This research aims to address the urgency of identifying and prioritizing the key determinants that influence the transition of CHD pediatric patients into adolescents. This research makes a significant contribution to the field of pediatric cardiology by applying the Fuzzy DEMATEL approach to unravel the intricate dynamics of transitioning pediatric patients with CHD to adolescence. By utilizing this advanced analytical tool, the study aims to provide a nuanced understanding of the critical factors influencing the transition process. This study's contribution lies in its potential to identify, quantify, and prioritize the key elements that impact the successful transition of pediatric CHD patients to adult care. The outcomes are expected to go beyond traditional analyses, offering insights into the fuzzy relationships among various transition criteria. Such insights can inform tailored strategies for healthcare providers, policymakers, and stakeholders to optimize the transition process. These findings can be used to develop more effective transition procedures and strategies, thereby improving the quality and outcomes of care for this vulnerable population. The outcomes of this study hold the potential to transform the landscape of pediatric-to-adolescent transition care, offering hope and improved prospects for those living with congenital heart disease. This paper is organized as follows: Literature review is presented in Section II, Section III discusses scaffold of methodologies, in Section IV discussion about the results is made and finally Section V concludes the paper.

II. Literature Review

The Decision-making Trial and Evaluation Laboratory (DEMATEL) method is a widely used multicriteria decision-making method [4]. It is used to evaluate the relationships between factors in various fields [5]. DEMATEL helps to extract the complex structure of a problem by identifying cause-and-effect relationships among different elements [6]. It is used to model the understandable structure of a complex system and measure the complexity of a problem [7]. DEMATEL can be applied to both small and simple systems as well as complex systems [8]. The aim of [9] is to provide a solution to the issues mentioned above. Several barriers impede blockchain adoption, including system-related, external, intra-organizational, and inter-organizational ones. The research in [10] looks at the obstacles that stand in the way when it comes to assessing blockchain life cycles in China. There has been no research to scrutinize how these barriers cooperate to improve decision-making in life cycle assessments. In a study by [11] identify critical bottlenecks in the development of the HRS in China using a customized Fuzzy DEMATEL method. It is suggested by the authors of [12], that a Fuzzy trapezoidal approach should be employed to prioritize software requirements. Various Fuzzy logic-based approaches for prioritizing software requirements are discussed in [13]. The study in [14] suggests a new version of the fuzzy DEMATEL that uses PFS for language variables. The research in [15] focuses on establishing a logical framework for strategy maps; inserting subjectivity into the overall strategy formulation process; identifying the most important connections between strategy objectives to make the route map clear, useful, and easy to understand; and combining qualitative and quantitative methods to make a strong and complete solution.

III. Theoretical Background

A. Fuzzy Logic

Fuzzy logic is a mathematical framework that contracts with vagueness besides imprecision in decision-making and control systems. It is an extension of binary logic that is based on true and false. It was first proposed in the early 1960s by the Iranian mathematician Lotfi Zadeh. Fuzzy logic allows for degrees of truth, which makes it particularly useful in situations where information is vague, ambiguous, or incomplete.

Definition 1: A triangular fuzzy number, also known as a TFN is defined by a membership function that assigns degrees of membership (degrees of truth) to values, within a given range. The membership function of a triangular number takes the shape of a triangle and determined by three parameters; the lower bound (a) the upper bound (b) and the peak (c). We can express a triangular number using the equation:

$$\begin{array}{ll} \mu\_A(x) = \{\ 0, & \text{if } x < u, \\ \quad (x - u) / (w - u & \text{if } u \leq x < w, \\ \quad (v - x) / (v - w), & \text{if } w \leq x < v, \\ \quad 0, & \text{if } x \geq v \\ \quad \} & \end{array} \tag{1}$$

where, $\mu\_A(x)$ is the degree of membership (or membership value) of value x to the triangular fuzzy number A. Where u is a lower bound, v an upper one, and w is the peak. This function defines the degree of membership for any provided value x within [u, v].

Definition 2: When working with two Triangular Fuzzy Numbers (TFNs) we perform operations to combine or manipulate these sets. Let us take two TFNs, A and B and their membership functions defined as follows:

For TFN A:

$$\begin{array}{ll} \mu\_A(x) = \{0, & \text{if } x < u1, \\ \quad (x - u1) / (c1 - u1), & \text{if } u1 \leq x < w1, \\ \quad (v1 - x) / (v1 - w1), & \text{if } w1 \leq x \leq v1, \\ \quad 0, & \text{if } x > v1 \\ \quad \} & \end{array}$$

For TFN B:

$$\begin{array}{ll} \mu\_B(x) = \{0, & \text{if } x < u2, \\ \quad (x - u2) / (w2 - u2), & \text{if } u2 \leqslant x < w2, \\ \quad (v2 - x) / (v2 - w2), & \text{if } w2 \leqslant x \leqslant v2, \\ \quad 0, & \text{if } x > b2 \\ \quad \} & \end{array}$$

1) *Basic operations:*

a) Addition of TFNs (U + V): To add two TFNs together you we add their membership values pointwise. The resulting TFN, denoted as C (U + V) can be represented by the following membership function:

$$\mu\_W(x) = \max(\mu\_U(x) + \mu\_V(x)) \tag{2}$$

where, $\mu\_W(x)$ represents the degree of membership of x to the resulting TFN W.

b) Subtraction of TFNs (U - V): The subtraction of two TFNs is performed by subtracting the membership values of the second TFN (V) from the membership values of the first TFN (U). The resulting TFN, W (U - V), has a membership function as follows:

$$\mu\_W(x) = \max(\mu\_U(x) - \mu\_V(x)) \tag{3}$$

*c) Multiplication of TFNs (U * V):* Multiplication of two TFNs is done by taking the product of their membership values at each point. Let W (U * V) be the resulting TFN function as follows:

$$\mu\_W(x) = \mu\_U(x) * \mu\_V(x) \tag{4}$$

d) Division of TFNs (U / V): The division of two TFNs is performed by dividing their membership values pointwise. The resulting TFN, W (U / V), has a membership function (for $\mu\_V(x) > 0$) as follows:

$$\mu\_W(x) = \mu\_U(x) / \mu\_V(x) \tag{5}$$

B. DEMATEL Method

The DEMATEL methodology provides an approach, for analyzing the cause-and-effect relationship of factors in complex decision-making problems [16]. It aims to understand how these factors are interconnected and their impact, on each other. This methodology is commonly employed in management, engineering and social sciences.

1) *DEMATEL Steps:*

a) Constructing a Causal Diagram (Impact Matrix): First, a causal diagram or an impact matrix is constructed for DEMATEL. The criterion measured is represented by the rows and columns of this matrix. The components of the matrix, labeled a_ij, depict the effect of directionality (or impact) of element i upon element j. The impact values can be determined based on expert opinions, surveys, or data analysis.

b) Normalization of the Impact Matrix: To ensure that the impact values are within a common scale, the impact matrix remains normalized. This is done by dividing each row of the matrix by the sum of its absolute values. The normalized matrix is denoted as N.

$$Z\_ij = |a\_ij| / \Sigma|a\_ij| \quad (\forall j) \tag{6}$$

where, Z_ij stands the normalized impact value of factor i on factor j.

c) Calculation of Total Influences: DEMATEL calculates the total influence of each factor by summing the normalized values in the corresponding row of the normalized impact matrix as shown in the below equation.

$$TI\_i = \Sigma Z\_ij \quad (\forall j) \tag{7}$$

where, TI_i is the total influence of factor i.

d) Division into cause-and-effect groups: Grounded on the total influence values, factors are categorized into two clusters: cause and effect. Since these were found to affect each other directly, and hence interchangeably we can say all had ‘‘cause’’ and ‘‘effect” attributes.

e) Drawing the Causal Diagram: A causal diagram is created to visually represent the cause-and-effect relationships among factors. This diagram shows how factors influence each other and helps in understanding the structure of the problem.

f) Interpreting the Results: The DEMATEL results are interpreted to determine the key elements, that plays an important role in the issue at consideration. Additionally, the method provides insights into the direction besides the strength of the causal associations.

C. Fuzzy DEMATEL (FDEMATEL) Method

FDM is an extension of the traditional DEMATEL technique that incorporates the concepts of fuzzy logic to handle vagueness besides imprecision in decision-making and problem-solving. DEMATEL is a technique employed in the analysis and visualization of the causal relationships between various elements in intricate systems. FDM, therefore, adds a layer of fuzziness to these relationships to better reflect real-world situations where relationships are not always clear-cut. The assessment of key determinants of congenital cardiac disease in young adults during the transitional period from adolescence to adulthood requires a collaborative decision-making approach. By interacting among various experts, a satisfactory decision is reached in a collective decision. Humans commonly criticize based on their experiences and insights in such a group decision-making process. As such, these decisions are made in an uncertain situation, and their expressions are more likely to be ambiguous than crisp. Consequently, the DEMATEL method cannot directly identify critical factors under these circumstances, requiring an extended DEMATEL method based on fuzzy set theory.

Step 1: The Fuzzy Direct Relation Matrix (FDRM) generation

To figure out how the n criteria relate to each other, we first make a matrix called n × n. Each element in every row in the matrix affects the element in each column in the matrix, and this can be represented by a fuzzy number. In the event of a matrix composed of the opinions of multiple experts, all experts must complete the matrix; the arithmetic mean of the opinions of all experts is used to construct the matrix z.

$$z = \begin{bmatrix} 0 & \cdots & \tilde{z}_{n1} \\ \vdots & \ddots & \vdots \\ \tilde{z}_{1n} & \cdots & 0 \end{bmatrix} \tag{8}$$

Step 2: The fuzzy direct-relation matrix normalization

The formula shown in Eq. (9) is used to compute the normalized fuzzy direct-relation matrix.

$$\tilde{a}_{ij} = \frac{\tilde{z}_{ij}}{r} = \left(\frac{m_{ij}}{r}, \frac{n_{ij}}{r}, \frac{o_{ij}}{r}\right) \tag{9}$$

Where,

$$r = \max_{i,j}\left\{\max_i \sum_{j=1}^{n} o_{ij}\, , \max_j \sum_{i=1}^{n} o_{ij}\right\} \qquad i, j \in \{1,2,3,\ldots,n\}$$

Step 3: The fuzzy total-relation matrix (TRM) is computed by the following formula:

$$\widetilde{TR} = \lim_{k\to+\infty}(\tilde{a}^1 \oplus \tilde{a}^2 \oplus \ldots \oplus \tilde{a}^k) \tag{10}$$

In the fuzzy total-relation matrix, the function of each element is expressed as $\tilde{t}_{\mathrm{ij}} = (\mathrm{m}^{"}_{\mathrm{ij}}, \mathrm{n}^{"}_{\mathrm{ij}}, \mathrm{o}^{"}_{\mathrm{ij}})$ and is generated as,

$$[m^{"}_{ij}] = a_m \times (I - a_m)^{-1}$$

$$[n^{"}_{ij}] = a_n \times (I - a_n)^{-1}$$

$$[o^{"}_{ij}] = a_o \times (I - a_o)^{-1}$$

In the case of a normalized matrix, the initial step is to identify the inverse of the standardized matrix. Subsequently, the inverse of matrix I is extracted and multiplied by the normalized matrix.

Step 4: Defuzzification for Crisp Values Generation

A crisp value of the TRM has been obtained using the CFCS. The CFCS method is as follows:

$$m^n_{ij} = \frac{(m^t_{ij} - min\, m^t_{ij})}{\Delta^{max}_{min}} \tag{11}$$

$$n^n_{ij} = \frac{(n^t_{ij} - min\, m^t_{ij})}{\Delta^{max}_{min}} \tag{12}$$

$$o^n_{ij} = \frac{(o^t_{ij} - min\, m^t_{ij})}{\Delta^{max}_{min}} \tag{13}$$

So that,

$$\Delta^{max}_{min} = \max o^t_{ij} - \min m^t_{ij} \tag{14}$$

Computing the normalized upper and lower bounds values:

$$m^s_{ij} = \frac{n^n_{ij}}{(1 + n^n_{ij} - m^n_{ij})} \tag{15}$$

$$o_{ij}^{s} = \frac{o_{ij}^{n}}{(1+ o_{ij}^{n} - m_{ij}^{n})} \tag{16}$$

The crisp value is the result of the CFCS algorithm.

The normalized crisp values:

$$x_{ij} = \frac{[l_{ij}^{s}(1-l_{ij}^{s})+u_{ij}^{s}\times u_{ij}^{s}]}{[1-l_{ij}^{s}+u_{ij}^{s}]} \tag{17}$$

Step 5: Threshold value

The threshold values are crucial in determining the internal relations matrix. As a result, NRMs are plotted by disregarding the partial relationships are disregarded. In the NRM, only those relationships with greater values than a threshold value in matrix TR are included. To calculate a threshold value for a given relationship, it suffices to calculate its average values from the matrix TR. Once the threshold intensity has been determined, all the values of matrix TR that are less than the threshold are set to 0, i.e., the causal relationship mentioned above is disregarded. For example, the matrix TR value is disregarded if the threshold value is 0.3970.

Step 6: Final result besides forming a causal relation diagram.

The subsequent step is to calculate the total of the rows and columns of TR (Step 4). The total of the rows (U) and columns (V) can be derived as follows:

$$U = \sum_{j=1}^{n} TR_{ij} \tag{18}$$

$$V = \sum_{i=1}^{n} TR_{ij} \tag{19}$$

Subsequently, the U and V determine the values of U+V and U-V.

Empirical Study: The fuzzy DEMATEL approach was used to extract all the dominant factors while transitioning from congenital heart disease to adulthood.

Step 1: The study identified five important dominant factors as tabulated in Table I. The study considers three experts providing a direct impact on each of the dominant factors in terms of linguistic assessment, the linguistic terminology with their respective TFNs is depicted in Table II.

Step 2: DRMs provided by experts

The linguistic terminology mentioned by all three experts are converted into corresponding TFNs are tabulated in Table III to Table V and the arithmetic mean of all the three Tables is shown in Table VI.

Step 3: Normalize the Fuzzy DRM as per Eq. (9) and the normalized DRM is tabulated as shown in Table VII. Also, the fuzzy TRM is calculated as the Eq. (10) and is shown in Table VIII.

Step 4: Defuzzify into crisp values and threshold values: Total normalized crisp values are calculated as per Eq. (17) and are shown in Table IX. As mentioned in Step 5 of Section 3.3 the threshold value for this study is set to 0.3970. Table X describes the model of important relations.

TABLE I. DOMINANT FACTORS (DF)

Factor	Explanation
DF1	Age and Developmental Stage: Determine the appropriate age for transition, considering both chronological age and developmental maturity. Some patients may be ready for transition earlier or later based on their circumstances
DF2	Medical Complexity: Evaluate the complexity of the patient's heart condition. Patients with complex congenital heart defects or ongoing medical issues may require specialized adult cardiology care
DF3	Cardiac Function: Assess the current cardiac function and stability of the patient. This includes evaluating factors like ejection fraction, valve function, and the need for ongoing interventions or surgeries.
DF4	Psychosocial Factors: Consider the patient's psychosocial well-being and readiness for transition. Assess their understanding of their condition, self-management skills, and emotional preparedness for adult care.
DF5	Insurance: Address insurance coverage and financial considerations. Verify that the patient's insurance plan will cover adult cardiology care and that there are no disruptions in coverage during the transition

TABLE II. LINGUISTIC TERMINOLOGY WITH THEIR TFNS

Linguistic terms	M	N	O
No influence	1	1	1
Very low influence	2	3	4
Low influence	4	5	6
High influence	6	7	8
Very high influence	8	9	9

TABLE III. FIRST EXPERT DRM

	DF1	DF2	DF3	DF4	DF5
DF1	0	2	5	3	3
DF2	2	0	4	3	4
DF3	2	2	0	3	4
DF4	5	2	3	0	4
DF5	1	5	5	3	0

TABLE IV. SECOND EXPERT DRM

	DF1	DF2	DF3	DF4	DF5
DF1	0	2	4	2	2
DF2	3	0	5	3	4
DF3	1	3	0	4	2
DF4	4	5	4	0	3
DF5	4	3	5	2	0

TABLE V. THIRD EXPERT DRM

	DF1	DF2	DF3	DF4	DF5
DF1	0	4	4	5	2
DF2	3	0	5	2	3
DF3	5	3	0	2	1
DF4	3	1	3	0	4
DF5	3	4	5	1	0

Step 5: Output and CR diagram

As per Eq. (18) and Eq. (19) the concluding output is computed and shown in Table XI.

The model of significant relationships is illustrated in Fig. 1, which can be visualized as a graph, with the values of (U+V) and (U-V) positioned on the horizontal and vertical axes respectively. The coordinate system determines the positions and relationships of each factor to a given point in the coordinate system.

IV. RESULTS AND DISCUSSION

By Fig. 1 and Table XI, each DF was assessed based on the following elements:

- The U + V horizontal vector indicates the importance of each factor within the system. More specifically, it indicates the effect of factor I within the system and the effect of other system factors within the system on the factor. Cardiac Function is the ranking factor in terms of importance, followed by Medical Complexity, insurance, psychosocial factors, age and development stage, and insurance. Age and development stage are considered causal variables in this study, while Cardiac Function is considered an effect.
- The vertical vector U-V represents the extent to which a factor influences a system. In cases a positive U-V indicates the cause while a negative U-V suggests the effect. In this study cardiac function emerges as the factor determining importance followed by factors, like medical complexity, insurance, psychosocial aspects, age and development stage, in descending order of significance.

Table VII presents the Normalized Fuzzy DRM, a decision-making matrix that has been normalized to facilitate a comprehensive analysis of the relationships between the identified factors (DF1, DF2, DF3, DF4, and DF5). The entries in the matrix are represented as fuzzy numbers, denoted by (lower bound, mean, upper bound), capturing the uncertainty and imprecision in the decision-making process. The fuzzy numbers in each cell represent the normalized influence of the corresponding row factor on the column factor. The lower and upper bounds capture the range of possible influence, while the mean value provides a central tendency. Table VIII extends the analysis by presenting the Fuzzy Total Relation, which aggregates the normalized influences from Table VII to provide a holistic view of the overall relationships between the factors.

Table IX presents the crisp TRM, a triangular fuzzy relationship matrix, for the identified factors in the study. The matrix is symmetric, with each cell indicating the degree of relationship strength between two factors. the values within the matrix range between 0 and 1, representing the intensity of the relationship. Higher values indicate stronger relationships, while lower values suggest weaker relationships. The diagonal elements of the matrix are typically 1, indicating the self-relationship of each factor. This matrix provides a quantitative representation of the fuzzy relationships among the factors under consideration.

TABLE X. THE CRISP TRM INCLUSIVE OF THE THRESHOLD VALUE

	DF1	DF2	DF3	DF4	DF5
DF1	0	0	0.554	0	0
DF2	0	0	0.596	0	0.437
DF3	0	0	0	0	0
DF4	0.452	0.4	0.548	0	0.439
DF5	0	0.449	0.605	0	0

Table X extends the Crisp TRM by incorporating a threshold value to highlight significant relationships. In this modified matrix, values below the threshold are set to 0, indicating negligible or weak relationships, while values equal to or above the threshold are retained. This thresholding process simplifies the matrix by emphasizing only the most impactful relationships, making it easier to interpret and focus on the key interactions.

TABLE XI. FINAL RESULT

	V	U	U+V	U-V
Age and Developmental Stage	1.848	1.954	3.802	0.106
Medical Complexity	1.863	2.096	3.96	0.233
Cardiac Function	2.629	1.683	4.312	0.946
Psychosocial Factors	1.726	2.113	3.839	0.387
Insurance	1.856	2.075	3.931	0.22

Table XI presents the final results of the study, providing a comprehensive assessment of the identified factors in the context of the transition from pediatric patients with congenital heart disease to adolescence. The Table includes four columns: V, U, U+V, U-V.

Age and Developmental Stage: This factor is assigned values for each of the four metrics: V (1.848), U (1.954), U+V (3.802), U-V (0.106).

Medical Complexity: Similarly, this factor is assessed with values for V (1.863), U (2.096), U+V (3.96), U-V (0.233).

Cardiac Function: The values for this factor are V (2.629), U (1.683), U+V (4.312), U-V (0.946).

Psychosocial Factors: This factor is evaluated with values for V (1.726), U (2.113), U+V (3.839), U-V (0.387).

Insurance: The final results for this factor are V (1.856), U (2.075), U+V (3.931), U-V (0.22).

The results in Table XI offer a quantified understanding of the factors' individual contributions and their combined effects. These metrics provide insights into the central tendency, range, and upper bounds of the factors, allowing for a nuanced interpretation of their significance in the transition process.

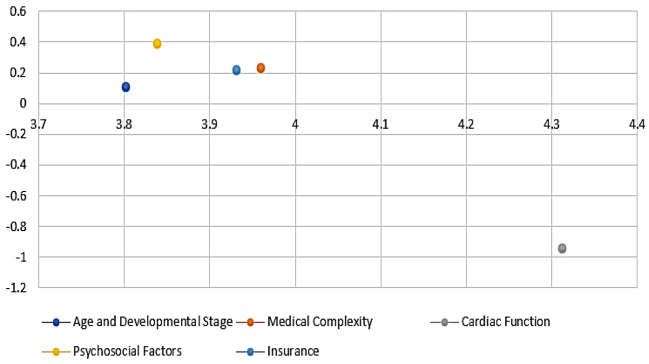

Fig. 1. Cause-Effect Graph.

The above Fig. 1 shows the relationship between five variables: Age and Developmental Stage, Medical Complexity, Psychosocial Factors, Insurance, and Cardiac Function. The x-axis reflects variable prominence, indicating influence levels, while the y-axis denotes their causative or resultant nature. Variables with high x-values and low y-values, like Cardiac Function and Insurance, are primary outcomes strongly influenced by others. Those with high x-values and near-zero y-values, such as Age and Developmental Stage, Medical Complexity, and Psychosocial Factors, act as both causes and effects. Variables with low x-values and near-zero y-values are independent, lacking strong influences. Notably, no variable has both high x and y-values, suggesting a lack of variables solely causing the problem.

V. CONCLUSION

In conclusion, the application of the Fuzzy DEMATEL approach has offered a quantified understanding of critical factors in the transition from pediatric patients with congenital heart disease to adolescence. The numerical values from Table XI underscore the distinct contributions of each factor, revealing noteworthy insights. Age and Developmental Stage, with a combined upper bound and mean value of 3.802, exhibits a significant overall influence with a relatively narrow range (U-V = 0.106). Medical Complexity demonstrates substantial impact (U+V = 3.96) with a moderate range (U-V = 0.233). Cardiac Function emerges as a key determinant (U+V = 4.312) with a broader impact range (U-V = 0.946). Psychosocial Factors and Insurance, with U+V values of 3.839 and 3.931, respectively, demonstrate moderate to substantial influences. These numerical assessments provide a tangible basis for prioritizing interventions and tailoring transition strategies, laying the groundwork for informed clinical and policy decisions in pediatric-to-adolescent transition care for congenital heart disease patients.

***Abstract*—Water quality is a crucial aspect of environmental and public health. Hence, its assessment is of paramount importance. This research paper aims to leverage machine learning models to classify water quality based on a comprehensive dataset. The dataset contains various water quality indicators, and the primary objective is to predict whether the water is safe or not to consume or use. This research evaluates the performance of diverse machine learning algorithms, such as Decision Trees, Random Forest, Logistic Regression, Support Vector Machines, and more for comparative analysis. Performance metrics such as accuracy, precision, recall, and F1-score are used to assess the models' effectiveness in classifying water quality. The Random Forest algorithm gave the best performance with an accuracy of 95.08%, an F1-Score of 94.69%, a Precision of 90.48%, a Recall of 93.10%, and an AUC score of 0.91. A comparative plot for the ROC AUC curve is also plotted between the various machine learning models used. Feature importance, which can help identify which water quality parameters have the greatest impact on predicting water quality outcomes, is also found in the research work.**

***Keywords*—Random forest; logistic regression; feature importance; decision trees; support vector machines**

I. Introduction

Access to clean and safe drinking water is a fundamental human right. Waterborne diseases resulting from contaminated water sources have severe consequences on public health. Water quality plays a pivotal role in ensuring the well-being of both ecosystems and human populations. However, despite international efforts to ensure safe water sources for all, the global challenge of providing clean and potable water persists. Hence, monitoring water quality is essential to prevent waterborne diseases and environmental degradation. The World Health Organization (WHO) estimates that millions of people worldwide suffer from waterborne diseases each year due to inadequate water quality. Water quality is essential for the health of ecosystems, wildlife, and human populations. Contaminated water sources pose significant risks to public health, as waterborne diseases are a leading cause of illness and death worldwide. These diseases, often resulting from the consumption of water polluted with pathogens, chemicals, and heavy metals, impose a substantial burden on society, particularly in vulnerable and underserved communities. Moreover, beyond the immediate human health concerns, compromised water quality also leads to environmental degradation, adversely affecting aquatic ecosystems, biodiversity, and the overall sustainability of natural resources. Consequently, the importance of monitoring and maintaining water quality cannot be overstated. In the big picture, water quality analysis and evaluation techniques have substantially improved the efficiency of water pollution control [1]. To date, many methods have been developed to monitor and assess water quality worldwide, such as the multivariate statistical method [2], fuzzy inference [3], and the water quality index (WQI) [4].

Various pollutants and contaminants can compromise the quality of water sources. These include heavy metals like lead, cadmium, and mercury, pathogenic microorganisms such as bacteria and viruses, and chemical compounds like nitrates and arsenic. The presence of these contaminants in drinking water can have dire consequences for public health, causing diseases such as cholera, dysentery, and lead poisoning. Detecting and classifying water as safe or unsafe as a complex and multifaceted challenge. Although highly accurate, traditional laboratory-based methods for water quality assessment are often time-consuming, resource-intensive, and not conducive to real-time monitoring. Therefore, there is a pressing need for innovative approaches that can provide timely and reliable assessments of water quality.

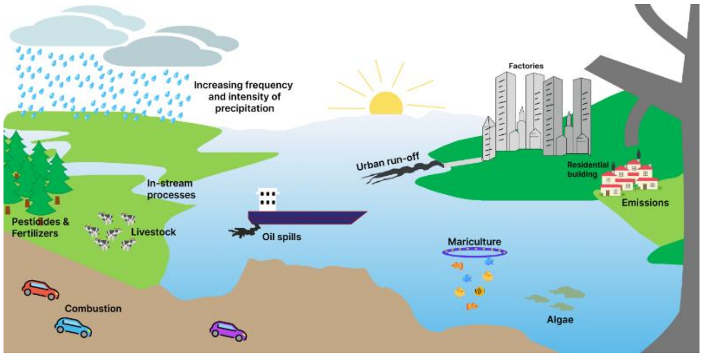

Fig. 1. Contributors towards poor quality of water.

Fig. 1 illustrates the large number of contributors that influence the quality of water. These contributors are entry points for various elements and chemicals that can significantly affect water quality. Just as depicted in the figure, through these various sources and places, a multitude of chemicals are introduced, ultimately influencing the overall quality of water. The objectives for the research are as follows:

- Investigate the utility of machine learning models for water quality classification using a comprehensive set of water quality indicators [5].

- Evaluate and compare the performance of various machine learning algorithms in classifying water sources as safe or unsafe for human consumption.

- Identify critical water quality indicators and features that strongly influence water quality classification, offering insights for targeted monitoring and intervention strategies [6].

- Bridge the gap between traditional water quality assessment methods and emerging technologies to enhance the efficiency and timeliness of water quality monitoring.

- Acknowledge the limitations of considering all water quality parameters due to cost and technical challenges and address the need for more data-driven approaches using machine learning advancements.

The significance of this research extends beyond the confines of academia. It holds practical and societal implications that resonate with the global need for clean and safe drinking water. By developing accurate machine learning models for water quality classification, we contribute to the broader efforts to ensure access to safe and clean drinking water for all. Furthermore, the insights gained from this research have the potential to inform targeted water quality monitoring strategies, enabling more efficient resource allocation and rapid intervention when unsafe water sources are detected. Ultimately, the research aligns with the United Nations Sustainable Development Goals, particularly Goal 6: "Ensure availability and sustainable management of water and sanitation for all", by enhancing our capacity to safeguard water resources and protect human health.

The paper is divided into the following sections: Section II delves into an extensive literature survey, identifying existing research gaps and showcasing innovative approaches in the field. Section III intricately details the system model and architecture, comprising a thorough dataset overview, data preprocessing techniques, and model evaluation methods. The presentation of results is encapsulated in Section IV, featuring performance metric graphs, a confusion matrix, and visual representations of feature importance. Section V navigates through in-depth discussions on practical implications and outlines potential avenues for future research. Finally, Section VI encapsulates the conclusions, summarizing key findings.

II. LITERATURE REVIEW

Li, Z., Liu, H., Zhang, C., & Fu, G. [7] introduced a real-time water quality prediction method for distribution networks using Graph Neural Networks. Addressing sparse monitoring data challenges, the approach underscores GNNs' effectiveness in capturing complex relationships.

Garabaghi, F. [8] employed the AdaBoost ensemble method to classify water sources as safe or unsafe for human consumption based on various water quality indicators. By combining these indicators, their model demonstrated the potential of machine learning to ensure access to safe drinking water. This study contributes to public health and environmental protection efforts.

Li, L. [9] tackled the vital issue of model interpretability in water quality assessment. They introduced a method that combined Random Forest with Shapley values to provide insights into the features contributing to water quality predictions. This research emphasized the importance of model transparency and interpretability in building trust in automated water quality assessment systems.

Cruz, R. [10] explored the application of Machine Learning for predicting harmful algal blooms. Their study utilized historical data on water quality parameters and algal bloom occurrences, demonstrating the potential of data-driven approaches in addressing ecological threats and water safety concerns.

Yan, J. [11] introduced a hybrid model that combined Neural Networks and Principal Component Analysis (PCA) for water quality prediction. Their research emphasized the importance of feature reduction and dimensionality reduction techniques in enhancing the efficiency and effectiveness of predictive models.

Ighalo, J. O. [12] proposed a novel approach that integrated Internet of Things (IoT) technology with machine learning for real-time water quality monitoring. Their study focused on sensor networks and data analytics, enabling proactive responses to water quality deviations.

Barzegar, R. [13] employed Extreme Learning Machines (ELM) for water quality prediction. Their research highlighted the speed and efficiency of ELM in handling large datasets, making it a valuable tool for real-time monitoring and forecasting.

Mosavi, A. [14] researched water quality assessment using ensemble models. By combining Random Forest, Gradient Boosting, and AdaBoost, their approach improved the robustness and accuracy of predictions, addressing the need for reliable water safety assessments.

Li, L. [15] explored the application of Recurrent Neural Networks (RNNs) for predicting temporal water quality variations. Their study emphasized the importance of considering historical data and dynamic patterns in water quality assessment.

Kadinski, L. [16] proposed a data-driven approach to identify contamination sources in water distribution systems. By integrating machine learning and network analysis, their research contributed to the early detection and management of waterborne risks.

Haghiabi, A. H. [17] introduced a framework for water quality prediction using multiple machine learning models. Their approach combined Support Vector Machines, Decision Trees, and K-nearest neighbors to improve predictive accuracy and model robustness.

Chakravarthy [18] introduced a method focusing on water quality prediction, employing SoftMax-ELM optimized with the Adaptive Crow-Search Algorithm. This innovative technique aims to enhance accuracy in water quality predictions by optimizing the SoftMax-ELM model.

Dogo, E. M. [19] explored using unsupervised learning for water quality anomaly detection. Their research applied Self-Organizing Maps (SOM) to identify deviations from normal water quality conditions, enhancing the early detection of water contamination incidents.

Solanki, A. [20] laid the foundation for machine learning models in water quality assessment. Their early work paved the way for subsequent research by highlighting the potential of data-driven approaches in this domain. This study marks the inception of applying machine learning to water quality analysis.

Chang, N. B. [21] explored integrating remote sensing data with machine learning techniques to assess water quality in large water bodies. Their approach showcased the scalability of machine learning in monitoring vast aquatic environments, with implications for environmental conservation and management.

Wu, J. [22] delved into using Long Short-Term Memory (LSTM) neural networks for time-series-based water quality prediction. Their study focused on predicting temporal variations in water quality indicators, aiding in forecasting changes over time. This research contributes to a better understanding of the dynamic nature of water quality.

Moayedi, H. [23] developed a hybrid model that combined machine learning and physical models for water quality assessment. This integrated approach improved prediction accuracy by considering both data-driven and mechanistic aspects, bridging the gap between empirical and theoretical approaches in water quality research.

Yan, K. [24] introduced a novel feature engineering technique called Recursive Feature Extraction (RFE) for water quality data. This method improved model performance by selecting the most relevant features for prediction, enhancing the efficiency and effectiveness of water quality assessment models.

Ahmed, M. [25] explored the application of Deep Belief Networks (DBNs) for water quality monitoring. Their study highlighted the potential of deep learning techniques in capturing complex patterns in water quality data, paving the way for advanced modeling approaches in the field.

Liu, S. [26] investigated the use of evolutionary algorithms in optimizing machine learning models for water quality prediction. Their research emphasized the importance of model tuning and parameter optimization for improved prediction accuracy, contributing to more reliable water quality assessments.

Iqbal, K. [27] applied clustering techniques to segment water quality data into distinct groups. This unsupervised learning approach facilitated.

Identifying common patterns and anomalies in water quality profiles offers insights for targeted monitoring and intervention strategies.

Table I provides the research gaps in the previous approaches for tackling the issues with water quality.

A. Research Gaps

- Data-Driven Insights for Targeted Monitoring: The paper fills a research gap by providing insights into data-driven approaches that help identify critical water quality indicators and features.
- Integration of Various Machine Learning Models: The paper addresses the gap in research related to integrating and comparing multiple machine learning models for water quality assessment, providing insights into the performance of different algorithms.
- Interpretability and Transparency: The paper bridges the gap by addressing the need for model interpretability and transparency in the context of water quality assessment

In Fig. 2, we visually represent the diverse contributions from various fields that have shaped and influenced our research. This figure illustrates the multidisciplinary nature of the research endeavor and the collaborative efforts of experts from different domains.

TABLE I. RESEARCH GAPS

Ref No	Author	Proposed Method	Limitations

III. System Model and Architecture

A. Dataset Overview

The dataset was obtained from Kaggle, a well-known platform for sharing and exploring datasets. The dataset contains information related to water quality parameters and attributes for classifying water sources as safe or unsafe for human consumption. The dataset comprises 21 columns and 8000 rows, providing substantial data for robust analysis and modeling.

Below are the dataset values and their significance in deteriorating or enhancing water quality.

1) *Aluminum:* Measures the concentration of aluminum in the water.

2) *Ammonia:* Indicates the ammonia level in the water.

3) *Arsenic:* Reflects the concentration of arsenic in the water.

4) *Barium:* Represents the amount of barium in the water.

5) *Cadmium:* Measures the cadmium content in the water.

6) *Chloramine:* Indicates the chloramine level in the water.

7) *Chromium:* Reflects the concentration of chromium in the water.

8) *Copper:* Measures the copper content in the water.

9) *Fluoride:* Represents the fluoride level in the water.

10) *Bacteria:* Reflects the presence or absence of bacteria in the water.

11) *Viruses:* Indicates the presence or absence of viruses in the water.

12) *Lead:* Measures the lead content in the water.

13) *Nitrates:* Reflects the nitrate level in the water.

14) *Nitrites:* Indicates the nitrite level in the water.

15) *Mercury:* Measures the mercury content in the water.

16) *Perchlorate:* Represents the amount of perchlorate in the water.

17) *Radium:* Reflects the concentration of radium in the water.

18) *Selenium:* Measures the selenium content in the water.

19) *Silver:* Indicates the silver level in the water.

20) *Uranium:* Reflects the concentration of uranium in the water.

21) *Is_safe:* The class attribute, where '0' represents not safe and '1' represents safe water sources.

B. Data Preprocessing and Feature Engineering

Given the diverse range of water quality indicators, such as aluminum, ammonia, arsenic, and others, the data preprocessing phase involved several key steps. We addressed missing values by mean imputation to prevent gaps in the dataset, normalized the values of these indicators, and encoded categorical attributes. Eq. (1) is used to handle missing values.

$$x_i = \frac{1}{N}\sum_{j=1}^{N} x_j \qquad (1)$$

Moreover, the most critical aspect of feature engineering was the transformation of raw indicator values into binary representations. This transformation enabled us to create the "is_safe" feature, serving as the class attribute for classification and ultimately facilitating accurate water quality assessment. To facilitate the modeling process, we employed the StandardScaler function to scale the features into a common range. This normalization was vital for ensuring that each indicator contributed to the classification process on an equal footing. For a given feature X, the standardization using StandardScaler transforms it into a new feature X', given in Eq. (2). This transformation ensures that the standardized feature has a mean of 0 and a standard deviation of 1, which is important for many machine learning algorithms, especially those sensitive to the features' scale.

$$X' = \frac{X-\mu}{\sigma} \qquad (2)$$

where:

X' is the standardized feature.

X is the original feature.

μ is the mean(average) of the feature X.

σ is the standard deviation of the feature X.

C. Model Evaluation

Evaluating the performance of machine learning models for water quality classification is a critical aspect of our research. To gauge the effectiveness of these models, we considered multiple performance metrics. Accuracy was an essential metric that measures the proportion of correctly classified instances. We also examined the F1 score, which balances precision and recall, ensuring that our models can efficiently identify both safe and unsafe water sources. Furthermore, precision and recall were critical for understanding the model's ability to minimize false positives and false negatives, respectively. The ROC AUC score assessed the models' ability to distinguish between safe and unsafe sources. By employing these metrics, our research ensures rigorous evaluation and validation of the water quality classification models.

Algorithm 1 shows how to calculate the accuracy of a machine-learning model. As more accurate model outcomes result in better decisions, it is important to identify which model would work best for a given dataset.

Algorithm 1: To Calculate Accuracy for Machine Learning Model

```
Input:
- Trained machine learning model (ML_model)
- Test data (X_test) with corresponding true labels (y_true)
Output:
- Accuracy of the machine learning model
1. Initialize a variable 'correct_predictions' to 0.
2. Initialize a variable 'total_predictions' to 0.
3. For each data point (x) and true label (y_true) in the test data (X_test, y_true):
   a. Use the trained machine learning model (ML_model) to make a prediction (y_pred) for x.
   b. Increment 'total_predictions' by 1.
   c. If the model's prediction (y_pred) matches the true label (y_true):
      - Increment 'correct_predictions' by 1.
4. Calculate the accuracy as follows:
   - Accuracy = (correct_predictions / total_predictions) * 100
5. Output the accuracy value as the result.
End
```

Algorithm 2 shows how the calculation for ROC AUC score is performed and how the plot for the ROC curve is designed. The ROC AUC score tells us how efficient the model is. The higher the AUC, the better the model's performance at distinguishing between the positive and negative classes. An AUC score of 1 means the classifier can perfectly distinguish between all the Positive and the Negative class points.

Algorithm 2: To Calculate ROC AUC Score and Plot ROC Curve

```
Input:
- Trained machine learning model (ML_model)
- Test data (X_test) with corresponding true binary labels (y_true)
Output:
- ROC AUC Score
- ROC Curve Plot
1. Use the trained machine learning model (ML_model) to predict probabilities for each data point in the test data (X_test).
2. Calculate the ROC AUC score using the predicted probabilities and true labels:
   - ROC_AUC_Score = roc_auc_score(y_true, predicted_probabilities)
3. Compute the ROC curve by varying the decision threshold:
   - FPR (False Positive Rate), TPR (True Positive Rate), thresholds = roc_curve(y_true, predicted_probabilities)
4. Plot the ROC curve:
   - Plot FPR is on the x-axis, and TPR is on the y-axis.
   - Add a diagonal line representing a random classifier (FPR = TPR) for reference.
   - Label the curve and the diagonal line accordingly.
   - Add a legend to the plot.
5. Output the ROC AUC Score and the ROC Curve Plot.
End
```

C. Model Evaluation Equations for Machine Learning Algorithms

The selection of appropriate models plays a crucial role in the success of any research endeavor, as different models employ distinct algorithms and mathematical techniques to model the underlying data. This subsection presents an overview of the machine learning models employed in this research, including Logistic Regression, Decision Tree, Random Forest, Support Vector Machines (SVM), and K-Nearest Neighbors (KNN). Each model's Equation is discussed in Eq. (3) to Eq. (7), elucidating the mathematical foundation upon which they operate, allowing for a comprehensive understanding of their implementation in the context of this research.

Logistic Regression:

$$P(y = 1|x) = 1 / (1 + exp(-z) \tag{3}$$

where:

P(y=1|x) is the likelihood that the positive class will exist.

z is the linear combination of the input features and their corresponding coefficients.

Decision Tree:

$$Prediction = Tree(x) \tag{4}$$

where:

Tree(x) represents the traversal of the decision tree to assign the class label to the instance x based on the

Decision Tree learned rules.is a tree-based classifier that splits the feature space based on a set of rules.

Random Forest:

$$Prediction = Average(Tree1(x), Tree2(x), \ldots, TreeN(x) \tag{5}$$

where:

Tree(x) represents the traversal of the decision tree.

An ensemble technique called Random Forest blends various decision trees to produce estimations.

The prediction in a Random Forest is obtained by averaging the predictions of individual decision trees.

Support Vector Machines (SVM):

$$Prediction = sign(w^\wedge T * c + e) \tag{6}$$

where:

Prediction is the predicted class label.

w is the weight vector.

c are the input features.

e is the bias term.

The sign function assigns the class label based on the sign of the linear combination.

Support Vector Machines are binary classifiers that aim to find the hyperplane that maximizes the margin between two classes.

KNeighborsClassifier:

$$dist(x, z)\ =\ (\Sigma\_\{r = 1\}\^{}d\ |x\_r\ -\ z\_r|\^{}p)\^{}(1/p) \qquad (7)$$

where:

dist(x,z) represents the distance between the two points x and z.

Σ_{r=1}^d sums all the features of the data.

|x_r - z_r|^p calculates the absolute difference in each dimension.

D. Architecture

Fig. 3 provides an overview of how data processing works in our paper by showing each step involved in the process from input to output as well as illustrating how information flows between these steps.

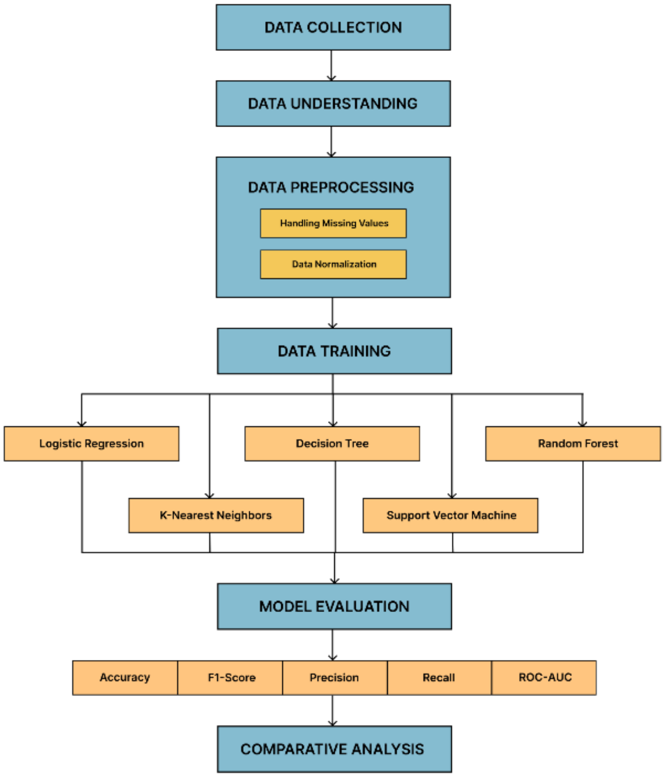

Fig. 3. Architecture diagram.

IV. Results

Our research, produced significant findings that hold practical implications for ensuring safe drinking water. Fig. 4 highlights the Accuracy of our machine learning models on the test set. Notably, the Random Forest model achieved an accuracy of 95.08% reflecting its robustness in classifying water sources as safe or unsafe. The Decision Tree model closely followed, demonstrating an accuracy of 94.62%. Logistic Regression, K-Nearest Neighbors, and Support Vector Machine also provided competitive results. Fig. 5 highlights the F1-Score for the various models. The Random Forest model achieved a score of 94.69%, followed by Decision Tree model with a score of 94.63%. Fig. 6 highlights the Precision for the models. Random Forest model achieved a score of 90.48%, which is followed by Support Vector Machine model with a score of 86.58 %. Fig. 7 highlights the Recall of the various models used. Random Forest model gave the best score of 93.10%, which is followed by Support Vector Machine model with a score of 87.60%.

Fig. 8 illustrates the ROC-AUC curve, which depicts the performance of different machine learning models in classifying water quality ranging from a score of 0 to 1. Random Forest outperforms other models with the highest AUC score of 0.91, showcasing its superior ability to discriminate between various water quality levels.

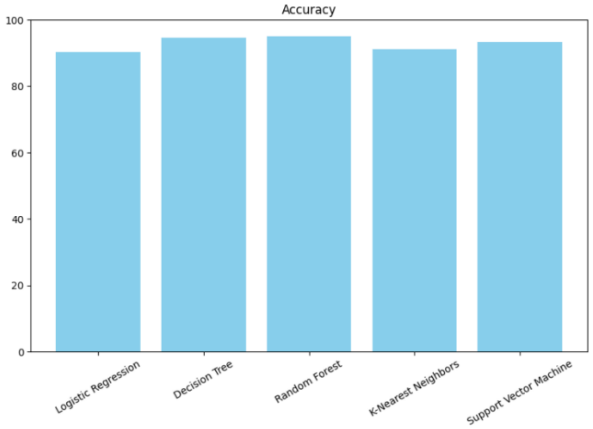

Fig. 4. Model Comparison in terms of accuracy.

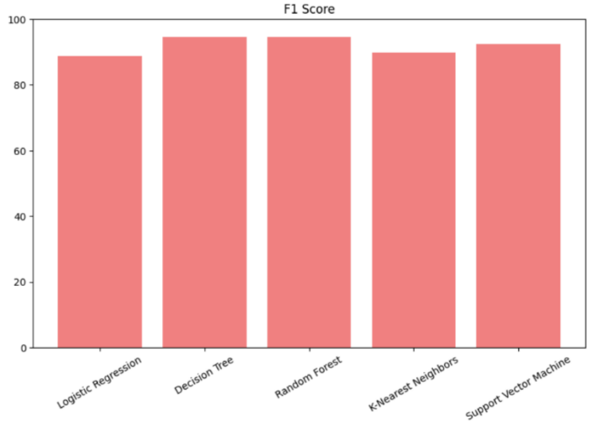

Fig. 5. Model comparison in terms of F1-score.

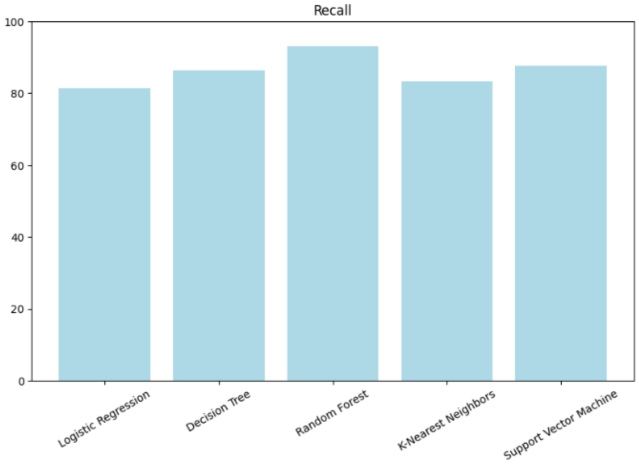

Fig. 7. Model comparison in terms of recall.

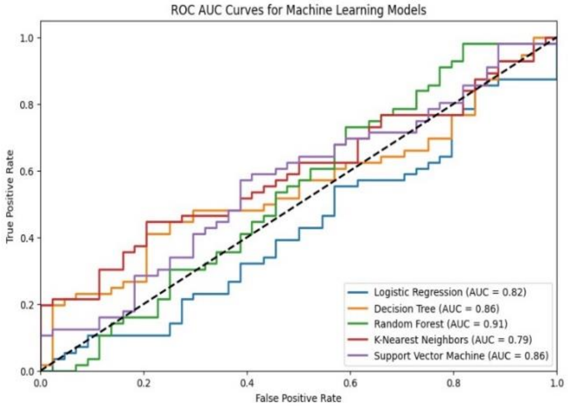

Fig. 8. ROC AUC score.

Feature importance is typically calculated based on how often a feature is selected to split nodes in decision trees within the ensemble and how much the feature contributes to reducing impurity in those splits. Feature importance using a Random Forest model can help identify which water quality parameters have the greatest impact on predicting water quality outcomes. This knowledge is essential for understanding the most influential factors affecting water quality, enabling better decision-making. Fig. 9 illustrates the results.

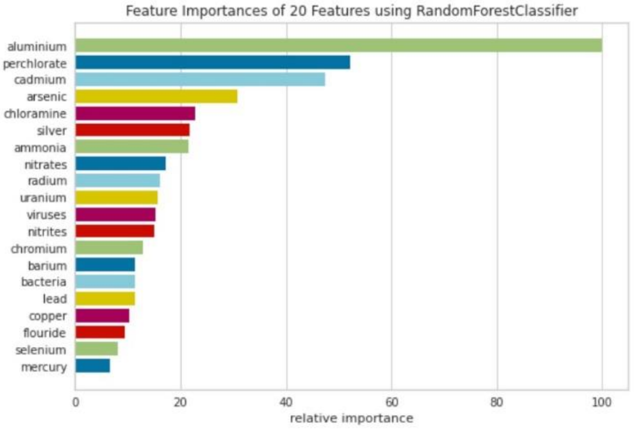

Fig. 9. Feature importance.

Table II presents the importance of the feature obtained from a random forest model. The "Feature" column lists the input variables, while the "Importance" column quantifies the significance of each feature in the model's predictions. These importance scores, ranging from 0 to 1, reveal the relative influence of each variable in detecting the water quality.

TABLE II. IMPORTANCE OF A SPECIFIC FEATURE

Feature	Importance
aluminum	0.214372
perchlorate	0.119331
cadmium	0.113347
arsenic	0.065622
ammonia	0.046725
chloramine	0.046548
Silver	0.045136
nitrates	0.037736
nitrites	0.033658
uranium	0.033620
radium	0.032812
viruses	0.031122
chromium	0.029673
barium	0.028580
bacteria	0.026482
lead	0.023878
copper	0.023279
fluoride	0.019532
selenium	0.016568
Mercury	0.011981

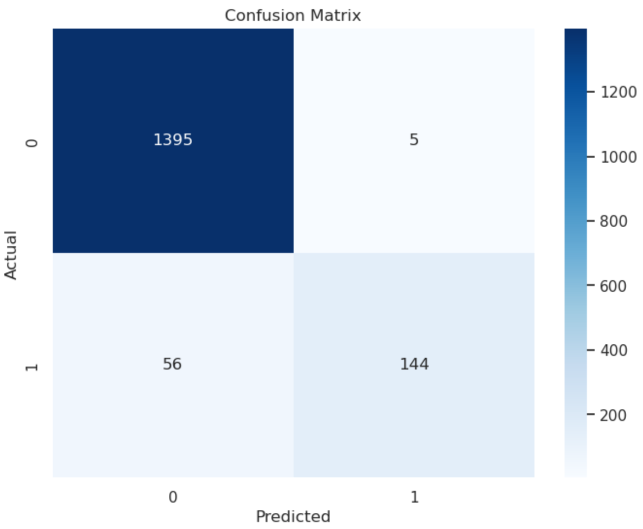

Fig. 10. Confusion matrix.

The confusion matrix illustrated in Fig. 10 visually represents the classification performance of the random forest model. It offers a detailed breakdown of true positives, true negatives, false positives, and false negatives, providing insights into the model's accuracy and error patterns.

The heatmap in Fig. 11 represents the relationships between the different water quality features in the dataset, to help identify which parameters are strongly correlated (positively or negatively) and which are not significantly related.

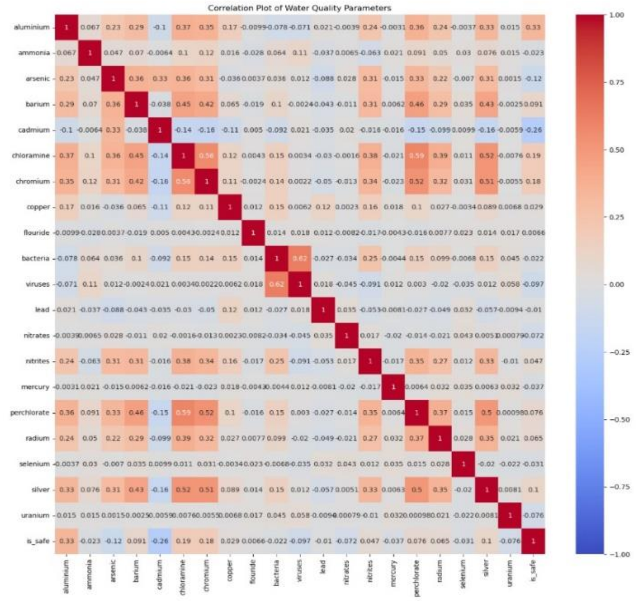

Fig. 11. Heatmap between water quality features.

TABLE III. SUMMARY OF RESULTS

Model	Accuracy	F1-Score	Precision	Recall	ROC-AUC
Logistic Regression	90.25	88.73	83.91	81.37	0.82
Decision Tree	94.62	94.63	86.10	86.38	0.86
Random Forest	95.08	94.69	90.48	93.10	0.91
K-Nearest Neighbors	91.08	89.86	79.66	83.27	0.79
Support Vector Machine	93.25	92.36	86.58	87.60	0.86

Table III provides a comparative analysis of all the models used and their performance measures.

V. DISCUSSIONS

A. *Interpretation of Results*

The interpretation of our research results reveals a comprehensive understanding of their implications for water quality assessment. Our machine learning models, especially the Random Forest and Decision Tree, have proven their capability to effectively classify water sources as safe or unsafe. This has significant practical implications, particularly in the context of providing safe drinking water. The high accuracy and F1 scores signify the models' ability to minimize false positives and negatives, an essential characteristic when dealing with public health issues related to water quality. These results demonstrate the potential for real-time water quality monitoring, allowing for the swift detection of anomalies and timely intervention.

B. *Feature Importance*

Analyzing the importance of features, as highlighted in our feature importance plots, provides valuable insights into the significant indicators influencing water quality classification. This knowledge empowers decision-makers and water quality management authorities to prioritize interventions. By identifying which indicators have the most substantial impact, targeted actions can be taken to ensure water safety. The binary representation of these features makes it easy to understand and act upon the results. Furthermore, feature importance analysis complements traditional laboratory-based methods by providing a data-driven approach to identifying critical water quality indicators.

C. *Practical Implications*

The practical implications of our research are substantial and extend far beyond the scope of our findings. Our models have showcased their potential for real-time water quality monitoring, which can be a game-changer in ensuring the safety of drinking water. The ability to rapidly detect water sources that pose health risks can transform public health management. This research is especially relevant in regions where water quality can fluctuate significantly, potentially impacting the health of communities. By harnessing machine learning models, authorities and stakeholders can efficiently monitor and manage water quality, taking timely actions to address concerns.

D. Limitations

Our research, while promising, relies on historical data, which may not fully capture evolving water quality dynamics. Additionally, our approach assumes fixed threshold values for safety, which may not be universally applicable across different regions and water sources. It is essential to recognize that water quality can vary significantly due to geographical and environmental factors. Future research should aim to address these limitations by considering real-time data and accounting for regional variations. In conclusion, our research has provided valuable insights into the potential of machine learning models for water quality assessment. The interpretability of results, the identification of significant features, and the practical implications of our findings underscore the significance of automated systems in ensuring safe drinking water. The limitations highlighted here serve as a roadmap for future research endeavors to continually improve water quality management and public health worldwide.

E. Future Scope

The success of our current research opens up several promising avenues for future investigations in the field of water quality assessment and management. Some areas where further research and development can make significant contributions are:

1) Real-time data integration: Future research should focus on integrating real-time data sources into the machine learning models. By leveraging the power of continuous data streams from various sensors and sources, we can create more adaptive and responsive models that can detect water quality anomalies as they happen. This would enhance the timeliness and accuracy of intervention strategies.

2) Advanced sensor technology: Researchers can explore the development of cutting-edge sensor technologies that can provide more granular data on water quality parameters. This could involve using nano-sensors, microfluidic devices, and remote sensing technologies to measure a wide range of chemical, biological, and physical indicators in real time.

3) Deep learning and neural networks: Investigate the application of deep learning techniques, such as convolutional neural networks (CNNs) and recurrent neural networks (RNNs), for analyzing complex, high-dimensional water quality data.

4) Explainable AI (XAI): Develop explainable AI techniques to enhance the interpretability of machine learning models. This is crucial for gaining the trust of stakeholders and decision-makers in the water quality management process. Methods such as LIME (Local Interpretable Model-Agnostic Explanations) and SHAP (SHapley Additive exPlanations) can be employed to provide insights into model predictions.

5) Edge computing and real-time processing: Leverage edge computing and real-time data processing to reduce anomaly detection and response latency. Edge devices equipped with machine learning capabilities can make rapid decisions on data streams, enabling timely intervention.

6) Blockchain for data verification: Use blockchain technology to enhance data integrity and trustworthiness. Blockchain can be employed to securely record and verify water quality data, ensuring its accuracy and preventing tampering.

VI. Conclusion

The research highlights the efficacy of machine learning models in classifying water quality, offering significant practical implications for ensuring safe drinking water. The Random Forest model stood out as the top performer, achieving an accuracy of 95.08% and an F1-score of 94.69. Its precision of 90.48% and recall of 93.10% underscore its ability to identify safe water sources while minimizing false alarms accurately. The ROC-AUC curve further emphasizes the Random Forest's superiority, with the highest AUC of 0.91, signifying its reliability in discriminating between water quality levels. Feature importance analysis using the Random Forest model unveiled crucial insights into the most influential factors affecting water quality outcomes, providing valuable knowledge for decision-making in water quality management.

In summary, this study demonstrates that machine learning, particularly the Random Forest algorithm, is a powerful tool for classifying water quality with high accuracy. As far as the practical implications are considered, this research can be applied to the regions where water quality can fluctuate significantly. By harnessing machine learning models, authorities and stakeholders can efficiently monitor and manage water quality, taking timely actions to address concerns. These findings can inform policies and strategies to ensure clean and safe water sources, ultimately enhancing environmental and public health.

Data Mining Application Forecast of Business Trends of Electronic Products

Kheo Chau Mui, Nhon Nguyen Thien
Information Technology Department, FPT University, Cantho city, Vietnam

***Abstract*—Sales forecasting is a pressing concern for companies amid rising consumer demand and intensifying competition, compounded by declining sales due to growing socio-economic challenges. Currently, many companies are having difficulty selling products due to a lack of management systems. To assist that, data mining techniques are introduced but it is difficult to evaluate the data and it is practically impossible to accurately forecast large amounts of data. However, data mining remains an important management tool that supports early decisions to increase profits, innovate business trends and improve sales by generating intelligence from the company's data resources. In this article, the research object chosen is the data of a nationwide electronics company. Their sales volume data for consumer electronics was used and applied to this study. The study used a "clustering" algorithm to group data based on the unique characteristics of each product, region, season, and time to estimate the amount of goods sold in the past, thereby predicting the amount of goods that will be exported. Password is sold in the following years and look for market trends. For each group, the results obtained with k = 3 show that the number of elements in each cluster is 771422, 11874, and 312, respectively. Combined with the "regression tree" algorithm for cluster partitioning and using the protocol Evaluate MSE and RMSE to evaluate the accuracy of the model, a result of 43065.66 Sales forecasting results show that the model's accuracy is close to realistic accuracy and depends on seasonal factors that are really important to some people. Based on the above results, the business's marketing campaigns and strategies will be deployed and achieve high results.**

Keywords—Data mining; sales forecasting; clusters; regression tree; RMSE; MSE; k-prototypes

I. Introduction

Electronic gadgets have steadily become important goods to assist people's life in the contemporary era of smart technology. This generates a lucrative profit for firms dealing in electronic items; as rivalry between businesses grows, they must always come up with new business advantages to compete [40], [41]. In the electronics business, you must compete and survive. These benefits must be based on the quantity of data gathered in the past and present from internal operations, product supply procedures, market trends and the business environment, and consumer preferences, to analyse patterns, estimate future sales, and establish a change management approach that brings efficiency and quality to corporate management while saving operational costs and expenses. Costs of storing are reduced, and profits are boosted [1], [5]. However, achieving high company efficiency through data mining, analysis, and trend prediction is a challenging task for firms. As a result, a system is required for firms to efficiently explore, analyse, process, and anticipate new business trends [27], [28].

Previous research has offered an overview of contemporary obstacles in sales forecasting as well as difficulties in trading electronic products, such as:

- Product life cycle is becoming more shorter.
- Consumer demand has increased and become more diverse.
- The average industrial land rental price rises by 5-8% every year.

To be very lucrative, a corporation must properly estimate the output of commodities, at the right moment of demand, and restrict inventory. Businesses will have challenges without the tools of information processing and analysis to assist anticipate the next business condition if they have a large and diversified data source. It is important to develop a "Data mining application to forecast business trends for electronic products" based on relevant research and existing business practices. This programme will assist businesses in selecting a strategy to anticipate the optimal output of items for their firm based on each area, industry, and seasonal features.

II. Related Work

For many years, several methodologies have been utilised in sales forecasting research. Here are some examples of typical studies. Pure Classification (PC) and Hybrid Clustering Classification (HCC) are two data mining techniques suggested by Bhavin Parikh et al. [4]. The results of the tests demonstrate that the HCC model outperforms the PC model in terms of accuracy and performance. In particular, after evaluating 500 samples with Nearest Neighbours = 5, the accuracy attained is 57.62%, outperforming the PC model. Fifit Alfiah et al. [2] investigated association rules in data mining with excellent dependability. Support: 0.1 and support x Confidence: 0.05 are the results, and if the manager simply enters the forecast quantity of 13 goods, the output forecast quantity is support: 0.2, support x confidence: 0.1, and prediction percentage: 0.15. The quantity value is enhanced by 15% from the initial value based on the outcomes and association rules in data mining. A paper in [3] uses the K-means algorithm to divide data into three separate clusters based on product type and sold quantity, namely Dead-Stock (inventory), Slow-Move (sold products), and rapid-Move (rapid sale). Next, employ the MFP: Most Frequent Pattern algorithm to identify frequent item attribute patterns in each product category while also providing sales trends in a concise format. Lytvynenko Tetiana's [6] research employed two key methodologies: statistical and structural methods, respectively, along with the widely used Decision Tree method to represent the process visually and simply on java. Simplify the main goal of the analysis. They utilised a data set that contained the sales volume of an employee job, the month of sales, and the sales of a business from 2006 to 2009. After sifting through the binary tree, they discovered that April, November, and December had the largest sales (about 23000 units each month), although accounting for 18771 in 2006. 19139 and 15164. Mustapha Ismail et al. [5] conducted research on data mining (DM) for e-commerce, which included three general algorithms: matching, grouping, and prediction. It also discusses some of the advantages of DM for e-commerce businesses, including as item planning, sales forecasting, shopping cart analysis, customer relationship management, and probable market segmentation obtained by the three techniques listed above. Furthermore, this research assesses data mining difficulties such as spider detection, data translation, and making the data model intelligible to business users.

III. Related Methods

To implement the application, we choose to utilise the "K-means" and "K-Prototypes" algorithms to cluster data based on the characteristics of each product, region, and time, in conjunction with the "Regression tree" technique. From [7], [8], [9], [12], [19], [20], [21], [24], [25], [26]. Python is the programming language used in this application. This combination aids in forecasting development patterns, product sales to address the issue of shortages, not keeping up with the seasons, consumer purchasing habits, and undesirable inventory that firms frequently face. Management and operation must entail significant expenditures.

A. K-means

J.A. Hartigan and M. A. Wong of Yale University created the Kmeans algorithm [18]. It is one of the finest algorithms for forming clusters of tiny values from vast amounts of unlabeled data (Label). The Kmeans method is an iterative algorithm that attempts to locate data clusters that are as close as feasible.

The initialization of the number of k groups is the first stage in the Kmeans algorithm [13], [14], [15], [16], [17]. And the starting centre value for each group is chosen at random.

The distance between each element and the centre values of each group is then calculated. Different formulae will be employed to calculate the distance depending on the properties of each data type. Manhattan, Cosine, Minkowski, and Euclidean distance metrics are utilised for numerical data. The Euclidean distance is employed in this research to compute the distance from the centre to the elements:

$$\boldsymbol{d(x_i, x_j)} = \sqrt{\left(|\boldsymbol{x_{i1}} - \boldsymbol{x_{j1|}}|^2 + |\boldsymbol{x_{i2}} - \boldsymbol{x_{j2}}|^2 + \cdots + |\boldsymbol{x_{in}} - \boldsymbol{x_{jn}}|^2\right)}$$

In n-dimensional space, xi=(xi1,xi2,...,xin) and xj=(xj1,xj2,...,xjn) are two data points.

Then, until convergence, perform the following operations:

+ Based on distance, each element is assigned to its nearest centre.

+ Update the centres of K clusters, each centre being the mean value of the elements in its cluster.

B. K-prototypes

Separates the dissimilarity of the combined data into two sections for independent computations. The numerical component employs squared Euclidean distance, whereas the mixed part uses basic mactching distance [37, 38, 39] Because the ratio of the two data types is not the same, the study will alter the parameters in the K-Prototypes method after the calculation to avoid the divergence of the grouping result value. The distance is defined as follows, where m is the number of matches and p is the total number of variables (attributes):

$$d(i,j) = \frac{p-m}{p}$$

The K-Prototypes algorithm is implemented as follows:

Input: Initial data set X and number of clusters k.

Output: k sample objects so that the standard function approaches the minimal value.

1) Create k initial sample objects for X, each of which serves as the representative centre of each cluster.

2) Distribute each X feature to each cluster so that it is closest to the sample object in the cluster, while updating the sample object for each cluster.

3) After all of the objects have been dispersed to the clusters, compare their similarity to the sample objects to see if there is a sample object most similar to it that varies from the other. The current cluster's sample object moves the object under consideration to the cluster corresponding to the sample object nearest to it and simultaneously changes the sample objects for these two clusters.

4) After inspecting all objects, repeat step 3 until no object changes.

C. Elbow Method

The Elbow technique [22] is one approach for determining the ideal number of clusters k while clustering. This approach is based on Thorndike's [23] hypothesis, and Elbow is a visual method. The SSE (Sum of Squared Error) indicator represents this Elbow technique.

The basic idea behind this approach is to compute k values by squaring the distances between the members in each cluster and the cluster centre. The sum of squared errors (SSE) is used for comparison. Repeat the k value and compute the SSE; smaller values suggest that each cluster is more convergent.

$$SSE = \sum_{k=1}^{K} \sum_{x_i \in S_k} ||x_i - C_k||_2^2$$

where: k is the number of clusters, Ck is the kth cluster, and x is the number of cluster elements.

The Elbow approach may be defined in two ways:

1) *Deformation:* It is determined as the mean of the squared distances from the individual cluster centres. The Euclidean distance measure is commonly employed.

2) *Inertia:* The sum of the squares of the sample distances from the nearest cluster centre.

Iterate over the values of k from 1 to 9 and compute the distortion and inertia for each value of k in the specified range shown in Fig. 1.

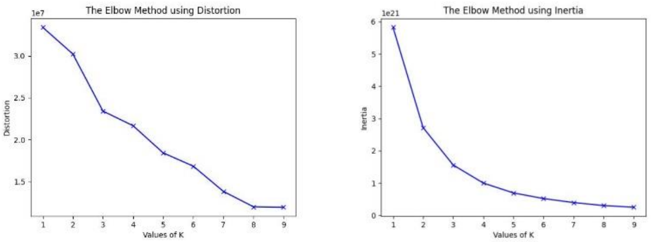

Fig. 1. An illustration of the elbow method.

D. Regression Tree Method

The regression tree approach is used to forecast continuous label values like revenue, profit, product cost, and so on.

An algorithm-based regression tree is used to estimate sales trends ([10]). In terms of current advancements in regression tree approaches, see [29], [30], [31], [32], [34], [35], [36.Regression trees are built using a method known as binary recursive partitioning, which is an iterative procedure that divides data into branches and then further sub-branches. Because of its simplicity, the regression tree technique published by (Breiman et al., 1984; Quinlan, 1993) is an automated machine learning model that is frequently used in data mining (Wu and Kumar, 2009). Calculate the standard deviation (Standard Deviation) and assess the dispersion of a data set using the regression tree technique. A big standard deviation indicates that the data has a high degree of dispersion and variability.

The symbol for Standard Deviation is σ (Sigma)

And then compute the standard deviation by taking the square root of the variance.

$$\sigma = \sqrt{\frac{1}{N}\sum_{i=1}^{N}(x_i - \mu)^2}$$

The standard deviation calculation procedure consists of four steps:

1) *Standard.*
2) *Average* and squared results for each number
3) *Next,* compute the mean of the squared differences.
4) *Multiply* all values by the square root.

After calculating the standard deviation, we use the regression tree approach to split the data.

The regression tree algorithm goes through the following steps: [11]

1) *Begin* with a single node that contains all of the points. (Calculate standard deviation using the formula)
2) *Stop* if all node points have the same value for all independent variables. Searching for a variable over all binary divisions of all variables, on the other hand, will lower Sigma as much as feasible.
3) *Repeat* step 1 for each new node.

We proceed to analyse the model when we have obtained the findings.

E. Equation Methods

The RMSE, MSE, and MAE indices are often used to evaluate the accuracy of a regression issue. The standard deviation of the residuals (the prediction error) is the Root Mean Square Error (RMSE). The residual is a measure of how far the data points are from the regression line; the RMSE is a measure of how diffuse these residuals are. In other words, it indicates how dense the data is around the best-fit line. In climate research, forecasting, and regression, the base mean square error is frequently used to validate experimental results. The RMSE assessment technique is utilised in this work according to the formula [33]:

$$RMSE = \sqrt{\frac{1}{n}\sum_{i=1}^{n}(p_i - r_i)^2}$$

The independent variable is pi, and the predicted value is ri.

When the system is performing optimally, these measurement values approach zero. The greater this value, the poorer the system's efficiency.

IV. METHODOLOGY

A. Datasets

The data represents the sales results for the three years 2017, 2018, and 2019 from a company that specializes in selling electrical and electronic equipment on a national basis. With almost 10 million goods distributed annually. Includes product groups: Home entertainment equipment; Household products; Kitchen products; Air conditioning; health and beauty support equipment, etc. Predicted data is the result of the number of goods sold each year. Table I shows some information of the data.

TABLE I. SOME INFORMATION ABOUT INDUSTRY CODES IN 2018

No	Product code (explanation)		Quantity
1	BEAUTY	Beauty equipment	36
2	C-BATT	The battery	60
3	COLDCHAIN	Freezer	46
…	……	……	…
26	TELEPHONE	Phone	34
27	VC	Vacuum cleaner	17
28	WM	Washing machine	56

B. Algorithm Diagram

The research model consists of two stages in Fig. 2: Stage 1: using the "clustering" algorithm to cluster data according to 4 main characteristics: product type, time, sales quantity and product consumption location. Phase 2: use the prediction method using the "Regression tree" algorithm to build a system to predict product development trends/sales.

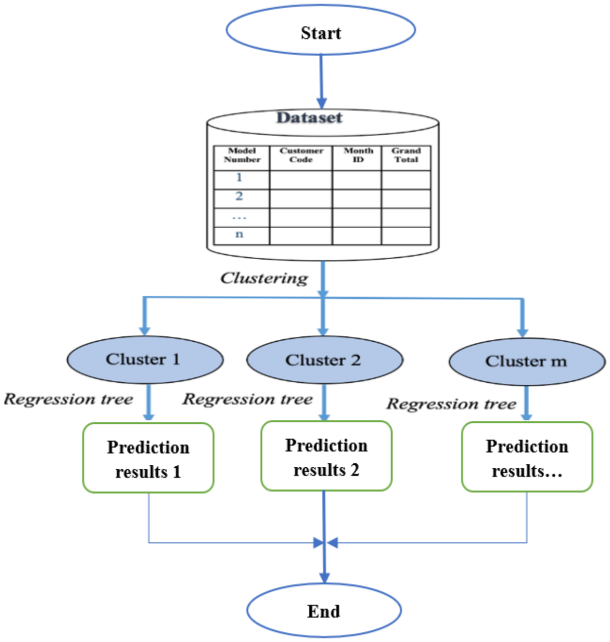

Fig. 2. Algorithm diagram.

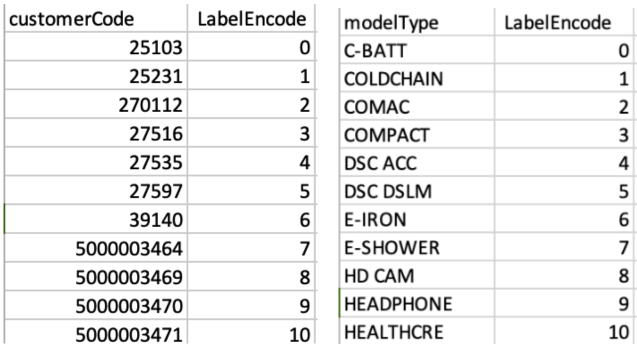
C. Data Preprocessing

In practise, data is frequently heterogeneous in terms of data type, with data consisting of several properties (columns) with varying units and magnitudes. This has an impact on the efficiency of many algorithms, as well as their correctness. As a result, before used, the data must be normalised. When the data domains of mixed attributes differ substantially, normalising LabelEncoder data from the sklearn package is a technique widely used as part of preprocessing. The purpose of normalisation is to convert the values of discrete text-valued columns in the data set to a common scale while preserving the range of values. Because of the discrete nature of the data, it is necessary to normalise the values of attributes such as commodity code (Model Type), customer code (Customer Code), month code (Month ID), and total number of items sold (Grand Total) on a common scale in order to generate predictions. Fig. 3 shows the Numeric Data type after standardization, and Fig. 4 is represented as a quantity distribution chart by product type.

D. Clustering (State 1)

With a data set of goods that includes 30 product groups and four different attributes such as commodity code (Model Type), customer code (Customer Code), month code (Month ID), and total number of products sold (Grand Total), the algorithm creates the centre value or calculates the distance in turn before moving on to the next group.



customerCode	LabelEncode
25103	0
25231	1
270112	2
27516	3
27535	4
27597	5
39140	6

DSC DSLM	5
E-IRON	6
E-SHOWER	7
HD CAM	8
HEADPHONE	9
HEALTHCRE	10

Fig. 3. Data after normalization in numeric form.

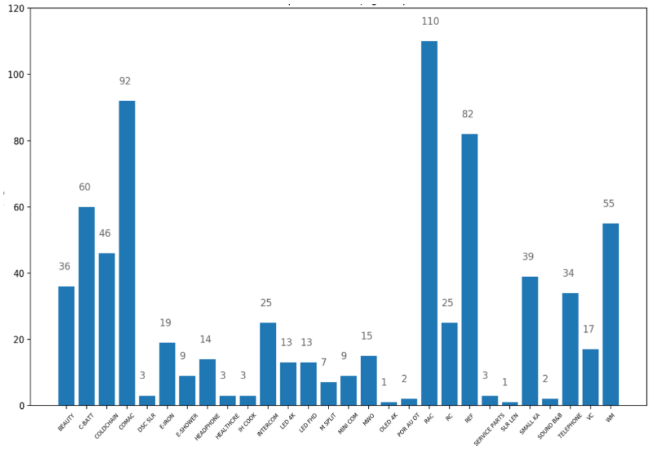

Fig. 4. Quantity distribution chart by product type in 2018.

The clustering algorithm's initial step is to employ k-means [10, 22, and 15]. We set the initial centre values for the groupings. If the data is clustered into k clusters, the kmeans_init_centers function chooses a starting point at random from the data set (Model Number, Customer Code, Month ID, Grand Total).

Specifically, dA(i,j) represents the distance based on the Month ID and Total Grand values, whereas dC represents the distance based on the Model Number and Customer Code characteristics. d(i,j) is determined using the Euclidean distance and two random numbers i and j.

$$\mathrm{dA(i,j)} = \sqrt{(|x_i - x_j|)^2}$$

Because the K-means method only works on numeric data and the remaining characteristics have mixed data types, the K-Prototypes algorithm should be used as shown below.

$$dC(i,j) = \frac{p-m}{p}$$

where, m is the total number of variables (attributes) and p is the number of matches

After determining the two distances dA and dC, compute the common distance for two values of i and j as follows.

$$d(i,j) = m * dA(i,j) + (1-m) * dC(i,j)$$

This formula will return values that are comparable. The distribution of items in the group is extremely skewed in certain circumstances where there are no elements in the group. This problem is solved by repeating the clustering procedure until no empty groups remain.

E. Predict (State 2)

Building a system to anticipate the development trend / product sales using the "Regression tree" algorithm's prediction approach.

After clustering, the findings are discovered to be groupings of cluster data aspects of products, with each cluster having unique qualities. The user will choose which cluster he or she belongs to before applying the Regression Tree issue to each cluster to compute the likelihood of correctly forecasting the quantity of goods sold [10].

Algorithm: Regression tree

Input: - Dataset: data set S each cluster (cluster 1, cluster 2, cluster 3)

Output: - Result tree of each cluster

```
- S = {$s_1$, $s_2$, …$s_k$} is a set Sigma.
- Initialize the set of all points: Sk: f(x) = {x1, x2, …xn}. xi are the points in the set S with N elements.
    Initialize the set f(yj): y = f(xi) is the points xi with the same value.
    If j = 1:
        End
        Calculate the standard deviation of each group f(yj) (yj is the jth element in the set f(y))
        $\sigma$ (f($y_j$)) = Sqrt (1/N* Σ ($x_i$ – $\mu$)$^2$)
        Calculate the standard deviation of the set f(y) and f(x).
    $\sigma$ (f(y)) = Sqrt (1/N *Σ($y_i$ - $\mu_y$)$^2$) …
    $\sigma$ (f(x)) = $\sigma$ j→n (j/N * $\sigma$ (f($y_j$))
        Partition by RSS:
        RSS($s_k$) = $\sigma$ (f(y)) - $\sigma$ (f(x))
Go back to step 2 with the next k.
Evaluating the new model with the largest RSS(sk) will have the most sigma reduction.
- End
```

F. Evaluation

To develop predictive models, we use data from 2017, 2018, and 2019.

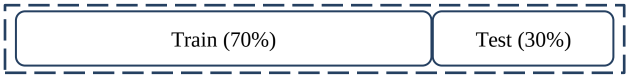

Fig. 5. Evaluation methodology illustration.

And, to assess the accuracy of the prediction results, it is advised to research using the MSE and RMSE formulae to determine the overall mean error with a big quantity of data and the prediction results having a substantial departure from reality. To test the accuracy, the user compares the measured value to the real business value of the firm in 2019. The prediction model's efficacy may then be validated, is shown through the evaluation methodology (see Fig. 5) and flowchart (see Fig. 6).

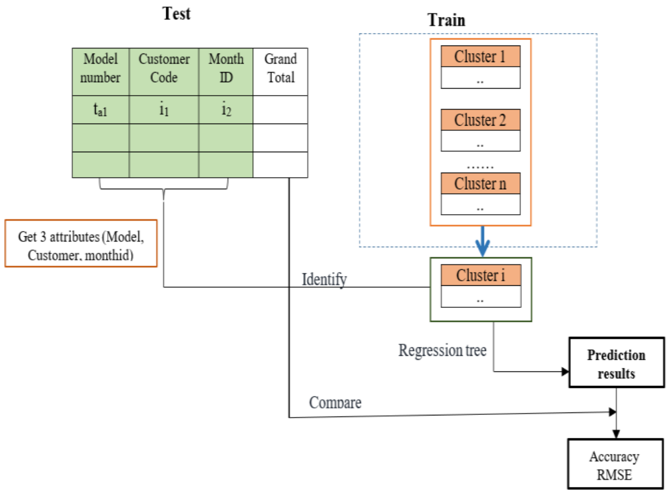

Fig. 6. Flowchart of the test protocol execution process.

V. Results

A. Results of Clustering on the Data Set

Before employing clustering methods, the number of groups k appropriate for clustering must be determined. Choosing k becomes simple for data sets with a modest number of components. Choosing k in a data collection with a high number of components is similarly tough. Combine using the Elbow approach, and then proceed to pick the best k possible using the Elbow chart, which shows the relationship between the SSE value and the number of k groups, with k ranging from 1 to 9 (see Fig. 7). The graph shows a considerable bend at the value k = 3, indicating that the value k = 3 is the optimal number of clusters.

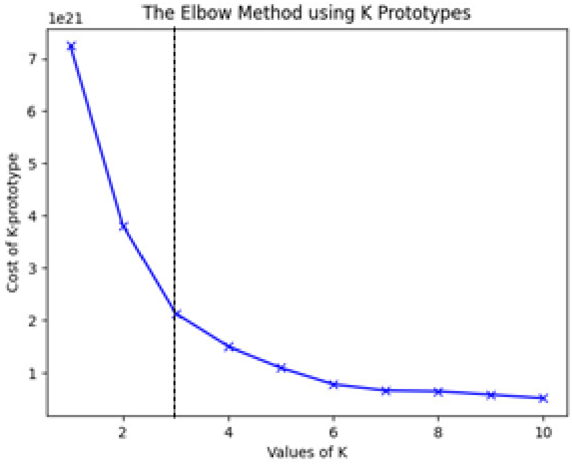

Fig. 7. Elbow method results on specific data set.

After determining the value of K=3, the study conducted clustering for the data set.

The number of items in each cluster can fluctuate as the centroids of the clusters change with the matching k centroids from Table II. With the data set comprising two types of characteristics, numeric attributes and discrete attributes, the result of the centre value of each cluster has two types matching to the items in each cluster with k = 3. Fig. 8 depicts the information of the components in the appropriate cluster when k = 3.

TABLE II. INFORMATION ON CLUSTERS MATCHING TO THE CENTRE K

Cluster number k=3	Cluster	Number of elements
[[2.01743391e+05, '5000003626.0','RAC', 3.32668862e+09], [2.01777722e+05, '5000003903.0','REF', 1.83788563e+07], [2.01765167e+05, '5000003626.0','RAC', 4.00993996e+08]]	1	771422
	2	11874
	3	312

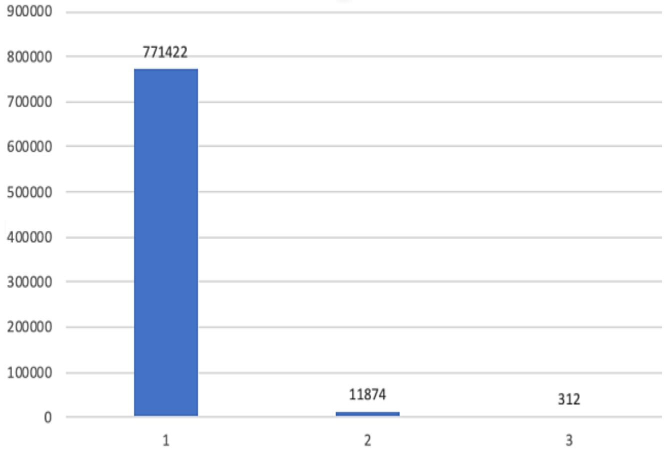

Fig. 8. The graph shows information of each corresponding cluster k=3.

B. Prediction Results on the Whole Data Set

For each cluster, the prediction results are presented on the regression tree.

Due to the big data set, when the tree partition is extremely large, the study reveals that the tree depth is five levels, and the findings mostly demonstrate the partitioning attribute at the root node for each cluster displayed via tree diagrams (Fig. 9, 10, 11).

Cluster 1:

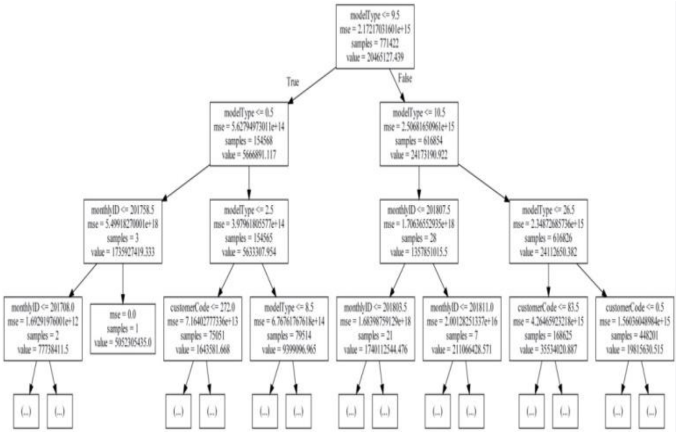

Fig. 9. The tree diagram displays information within the cluster.

Cluster 2:

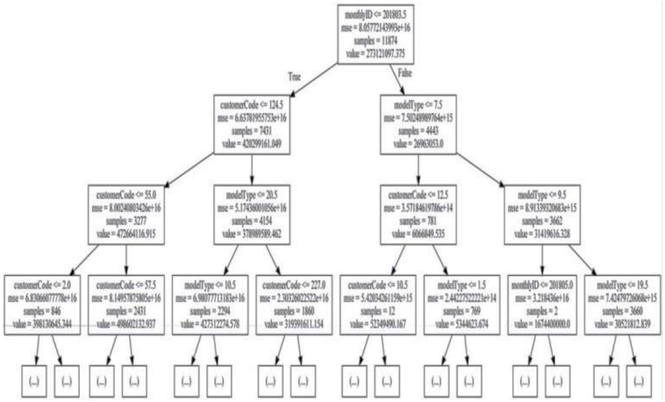

Fig. 10. The tree diagram displays information within the cluster.

Cluster 3:

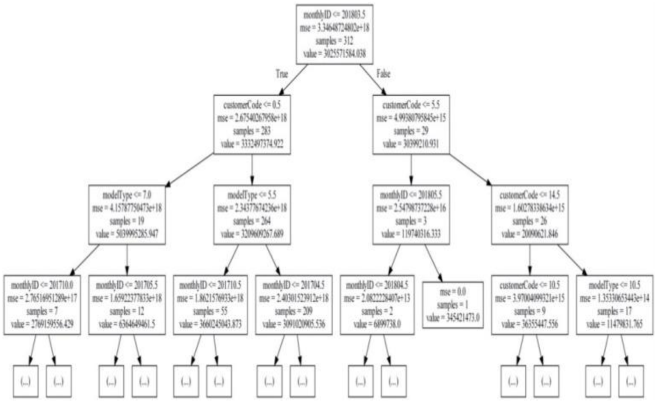

Fig. 11. The tree diagram displays information within the cluster.

The results of splitting the tree by cluster demonstrate that the data on each cluster is dispersed by distinct product groups.

Forecast results are exhibited quarterly throughout the year in the form of a column chart (Fig. 12, 13, 14, 15); the results reveal that the expected value is sometimes high and sometimes low owing to the real scenario caused by weather in each quarter and consumer wants changes, the value will change correspondingly.

Precious 1:

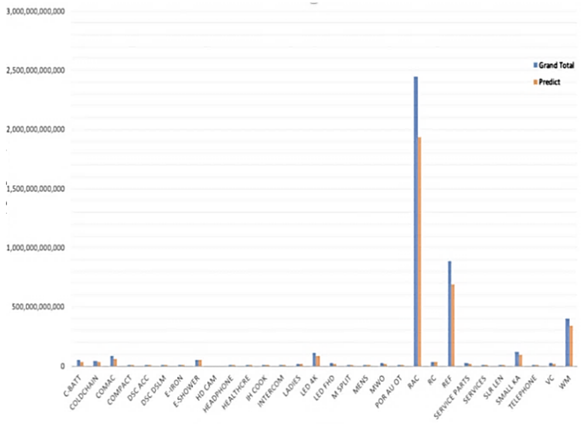

Fig. 12. Predicted and actual results on a specific Q1 data set.

<u>Precious 2:</u>

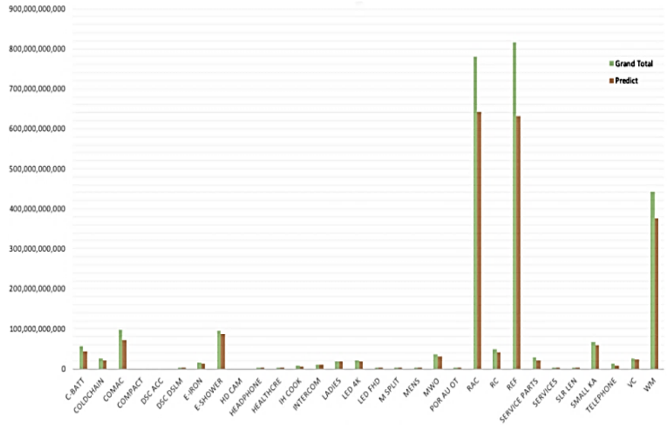

Fig. 13. Predicted and actual results on a specific Q2 data set.

<u>Precious 3:</u>

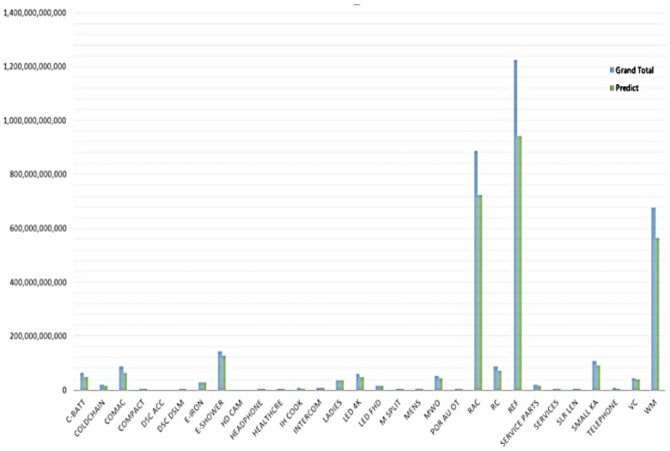

Fig. 14. Predicted and actual results on a specific Q3 data set.

<u>Precious 4:</u>

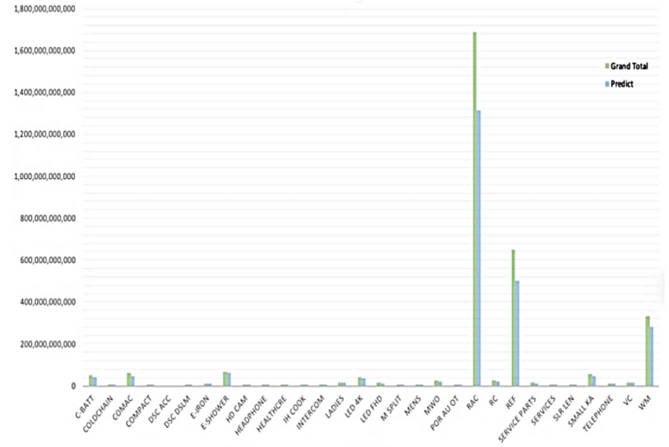

Fig. 15. Predicted and actual results on a specific Q4 data set.

Due to the enormous data collection, the research values are given on each quarter of the year to clearly highlight the difference of each separate product group.

The results of computing the standard deviation error of two cases when forecasting on a test data set based on real data.

TABLE III. DEVIATION RESULTS FOR EVALUATION INDICATORS

	RMSE	**Execution time**
When clustering is note performed	1.163.173,458	45 minute
After performing clustering	43.065,657	40 minute

According to the results of Table III, the deviation and implementation time are lower when clustering before predicting than when not clustering. As a result, the experimental model fits the requirements.

VI. CONLUSION

When the amount of information is really large, the sales forecasting approach is a very useful method for users. It titled "Application of data mining to forecast business trends for electronic products". Proposed clustering model paired with prediction algorithm to be used to the process in order to provide reliable prediction results. The data collection covers product information for three years. Divide the dataset into two parts: the training set contains data from 2017-2018, and the test set contains data from 2019. Using the training dataset with data characteristics of two types of mixed and numeric attributes, research will be conducted based on four attributes: product group (ModelType), customer code (Customer number), month code (Month id), and total quantity of goods sold based on the above three factors. With 3 clusters (k = 3), the number of elements in each cluster is 771422, 11874, and 312, respectively; Combined with the regression tree algorithm "Regression tree" to partition each cluster, using the evaluation protocol MSE, RMSE to evaluate the model's accuracy with over 80% results compared to the actual value, in order to build a system to predict product development trends/sales in the coming years. The experimental findings clearly indicate that using the sales prediction approach in a machine learning programming language yields results with an accuracy of more than 80%. The experimental time, whether rapid or slow, is determined by the original data collection. With the results of the experiment, it is feasible to apply a thorough test data set for each product group of particular categories on additional prediction models such as linear regression, Bagging, and so on in the future. Futures might be based on the outcomes of forecasts put into compact application.

Identification of Microaneurysms and Exudates for Early Detection of Diabetic Retinopathy

G. Indira Devi[1], D. Madhavi[2]
Electronics and Communication Engineering, Anil Neerukonda Institute of Science and Technology, Visakhapatnam, India[1]
Department of ECE, GIT, GITAM University, Visakhapatnam, India[2]

***Abstract*—Diabetic retinopathy (DR) is a condition that may be a complication of diabetes, and it can damage both the retina and other small blood vessels throughout the body. Microaneurysms (MA's) and Hard exudates (HE's) are two symptoms that occur in the early stage of DR. Accurate and reliable detection of MA's and HE's in color fundus images has great importance for DR screening. Here, a machine learning algorithm has been presented in this paper that detects MA's and HE's in fundus images of the retina. In this research a dynamic thresholding and fuzzy c mean clustering with characteristic feature extraction and different classification techniques are used for detection of MA's and HE's. The performance of system is evaluated by computing the parameters like sensitivity, specificity, accuracy, and precision. The results are compared between different types of classifiers. The Logistic Regression classifier (LRC) performance is good when compared with other classifiers with an accuracy of 94.6% in detection of MA's and 96.2% in detection of HE's.**

Keywords—Diabetic retinopathy; microaneurysms; hard exudates; SVM; LRC

I. Introduction

For the last fifty years, diabetic retinopathy (DR) has been considered the most prevalent cause of blindness. According to epidemiological research conducted in developed nations, DR is one of the four primary causes of vision impairments in the general population. Diabetes damages the blood vessels of the human retina, which is one of the primary causes of visual impairment in DR [1]. In contrast to the nearly non-occurrence of DR in the first five years following a type I diabetes diagnosis, latest is type II which is found in a ratio of 1:5 i.e., one diabetic among five tests has DR at the time of diagnosis. Nonetheless, nearly all type I diabetic patients and two-thirds of type II diabetic individuals have DR symptoms after 15 years.

The most typical signs of DR are abrupt loss of vision, floaters and flashes, and impaired vision. Since DR is a progressive illness, whose severity is dictated by the quantity and variety of lesions visible in the fundus picture, early identification and treatment are essential. The macula, optic disc, and blood vessels that make up a healthy retina are its key constituents; any alterations to these elements are indicative of an eye illness [2]. Non-proliferative DR (NPDR) and proliferative DR (PDR) are the two main phases of DR. NPDR, often referred to as background DR, is a condition in which diabetes destroys the blood vessels in the retina, allowing fluid and blood to seep onto the surface of the retina [3].

Due to the process of leaking the retina gets moist, swollen and finally loses functioning. A variety of retinopathy symptoms, including microaneurysms (MAs), hemorrhages (H), hard-exudates (HE), soft-exudates, or cotton wool spots (CWS), may be present in NPDR. Three phases of non-primary depression (NPDR) are distinguished depending on the severity and number of lesions. These stages included in DR is mild, moderate, and severe which are caused by localized dilatations of thin blood arteries. MAs are the initial indication of NPDR. MAs are tiny, nearly circular, and have a crimson colour H, often known as dot or blot H, is the next indication of DR. Thin vessel or MA walls that are sufficiently weakened may burst and result in H. Larger red lesions are seen in blot haemorrhages, whereas brilliant little red spots are seen in dot haemorrhages. Dot hemorrhages and MAs are occasionally grouped together as a single red lesion type called HMAs. For convenience of viewing, HMA-containing areas in the retinal picture are magnified in Fig. 1.

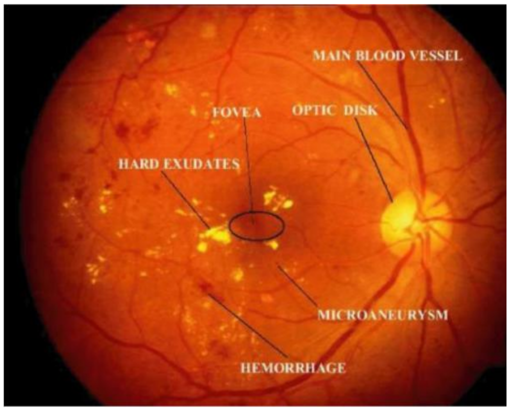

Fig. 1. Retinal fundus imgae shwoing MA's and HE's.

When fundus imaging is used to diagnose DR, microaneurysms (MAs) are the initial pathological signs that are identified. They manifest as minute blood bulges that resemble little red spots on the retina. Retinal blood vessels leak due to microaneurysms. Lipids and fluids leak from blood vessels as the condition worsens, forming hard exudates that are yellowish in colour and come in a different type of shapes and sizes. The macula and fovea are the regions in charge of central vision; if exudates accumulate there, the patient may lose or have degraded central vision. In automated DR detection, the Hard Exudates' detection is crucial. To find MAs and HEs, a machine learning method has been created. In this work both MAs and HEs are detected at a time for the given input image. The need of identifying each of them individually is avoided. So that the treatment can be provided effectively utilizing single process.

The proposal of work is organized in different sections. In Section II a brief overview of existing methods in detection of MA’s and HE’s is been discussed. The proposed method of extracting features and classification model is discussed in Section III. The experimental findings are evaluated in Section IV and results for identification are given in Section V. Finally, the overall summary is given in Section VI.

II. Related Work

The diagnosis of DR has made extensive use of computer-aided automated analysis of colour fundus pictures, which is very effective [4]. This might lessen the burden on ophthalmologists and increase the effectiveness of DR screening. Due to the significance of MA for DR diagnosis and the advancement of computer-aided diagnosis (CAD), an increasing number of research on automatic MA detection have been conducted recently. The author in study [5] used the Support Vector Machine (SVM) and Naive Bayesian (NB) classifier to distinguish between red and brilliant lesions; however, they were only able to use one database with 100 images for training and testing. The author in study [6] developed a Random Forest (RF) based approach for the diagnosis of both MA and HM using dynamic shape data, without the need for any prior segmentation of lesions. However, the blood vessel-related lesions were overlooked which resulting in false-negatives (FN) [7].

In research [8], the author suggested filters with various grid sizes combined with MKL, SVM, and filters to cope with false-positives (FP) brought on by tiny blood vessel (BV) segments to detect MA and HM. It was discovered that employing MKL improved performance when compared to using a single grid size, although choosing a larger grid size came with a greater computing cost. To get over the issue of class imbalance, the author in study [9] offered an unsupervised classification approach for MA identification based on sparse principal component analysis (PCA). However, several FPs occur when extracting features. The author in [10] used peak detection and region expansion to obtain MA candidates, and then used K-nearest neighbours (KNN) to identify MA. This led to an e-ophtha MA database FROC score of 0.273, which is rather low. Singular spectrum analysis (SSA) and a KNN classifier were used by the author in [11] to create a method for MA recognition; however, because there was no subtle or low contrast or blurry-outlined MA, this approach produced multiple false positives (FPs). A few MAs were also overlooked during the selection of candidates.

The author reported a multi-stage automated approach in [12] for identifying longitudinal retinal changes produced by small red colour lesions known as dot HM and MA. The author of [13] employed SVM for classification and local binary pattern (LBP) to extract textural features to detect MA. The author in [14] was able to detect MA by utilizing discriminative dictionary learning (DDL) and multi-feature fusion dictionary learning (MFFDL), respectively. The former mainly relied on the original grayscale feature dictionary, and employing a grayscale feature with single component will impact the performance since retinal pictures vary greatly in terms of colour, luminance, and contrast.

A key factor in the diagnosis of DR is biomedical engineering. Image processing was used in several studies on diabetic retinopathy to analyze retinal images [15]. In diabetic retinopathy, the GMM classifier was used to automatically detect red lesions [16]. To localizing exudate in the colour fundus picture, morphological operators were employed [17]. Furthermore, a few researchers have looked at the retinal image's hard exudate detection for use in the diagnosis of DR. To detect hard exudate, the retinal picture was subjected to a linear brightness adjustment [18]. In the CIE lab colour model, the hard exudates were identified using k-mean on the colour retinal picture [19]. In DR, the exudates were automatically detected using the wavelet transform [20].

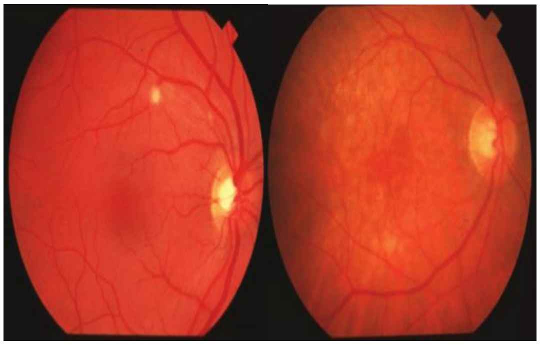
Subsequent research concentrated on deep learning techniques, primarily for image categorization. Convolutional neural networks (CNNs) have the ability to identify picture patches [21] and particular pixels as either exudates or non-exudates [22]. Deep neural networks can be developed from scratch [23] or based on a variety of designs that have been pre-trained on diverse datasets [24] (transfer learning approach). We made the decision to integrate an SVM classifier with transfer learning techniques in order to increase the overall process' efficacy [25].

When it came to DR, there were several methods and procedures for identifying MAs and HEs. The work progressed using morphological processes to identify MA, along with distinctive feature extraction, hessian analysis, and classification algorithms. Dynamic thresholding and fuzzy c mean clustering with distinctive feature extraction are used to identify HE, and classification algorithms are then used.

III. Material and Methods

A. Data Utilized

The proposed methodology's execution is carried out utilizing the STARE dataset. There are 400 pictures in this collection, including HEs, MAs, and other diseased features including red lesions of different sizes and forms. The samples images which are available in STATE dataset are shown in Fig. 2.



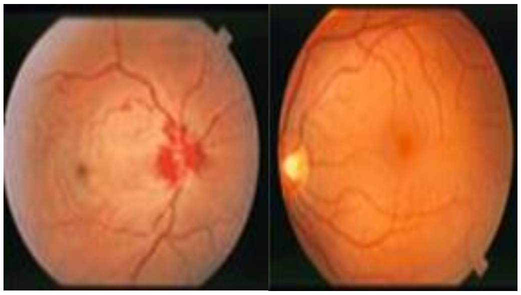


Fig. 2. Images of stare dataset.

The images of the created database were taken with a Topcon camera, which has a 605 x 700 resolution. Each retinal picture is subjected to an image-based DR detection assessment; however, reference markers for evaluating the approach based on the number of exudates-based assessment are absent. Therefore, an eye expert marked the contours of the lesions of 96 retinal pictures with various features to evaluate the exudates-based effectiveness of the suggested technique. The detection process implemented in this work is shown in Fig. 3.

B. Pre-Processing

The methods in various DR problems are demonstrated using retinal pictures from the STARE dataset. They do, however, differ in brightness and contrast, which are influenced by the surroundings when a fundus camera takes the picture. It causes the complexity of parameter setting and data evaluation, as was previously noted. As a result, the preprocessing portion of the retinal picture is customised to provide appropriate data for additional analysis. The retinal picture is loaded into the system to begin processing. Eq. (1) is then used to adjust the contrast of the retinal picture, producing an image with more clarity than before.

$$C_M(i) = \frac{\max(i)-\min(i)}{\max(i)+\min(i)} \tag{1}$$

The processing is divided into two sections. The first section, the optic disc of retinal image is detected using the algorithm for automatic localization of optic disc in the fundus image [10]. The second one, the retinal image is extracted into three channels (red, green, and blue). The green channel having the complete details of hard exudates is selected for operation. Subsequently, the data is adjusted from 0 to 1 by normalizing function as Eq. (2).

$$N_{(ij)} = \frac{X_{(i,j)}-\min(X)}{\max(X)-\min(X)} \tag{2}$$

The normalized data of the green channel is subtracted by the acquired optic disc.

C. MA Detection

In the process of MA Detection, initially the blood vessels need to be enhanced and later segmented, finally eliminated.

After eliminating the blood vessels, the remaining area of the fundus images without BV clearly shows the MA's.

1) Input blood vessel image enhancement: For the process of enhancing the image of blood vessels morphological filters is been utilized [26]. The contrast between the vessel structure and the backdrop intensity fluctuations is more noticeable. On the other hand, a closer look into vessel intensities may reveal significant alterations that have the potential to negatively impact the extraction process. We have suggested a morphological filter called the modified morph, which has been applied to a normalised green channel picture, to counteract such alterations. The images in the database which contain thickest vessel width is utilized as reference image for performing morphological operations with the range of pixels 1 and 8 for considering the diameter ranges of vessels width. The vessel diameter scale may be modified to account for changes in picture quality.

The morphological operation has been employed to ascertain the disparity among the input image considered and the opened picture. To acquire the inverse picture, first open the image and then close it. The noise sensitivity of the modified morph implementation results in pixel values in an opened image that are always less than or equal to the input values; under these circumstances, the image which are subtracted have low level intensity fluctuations in the data. The operator 'open' of an image 'I' with structuring element S_o is given by,

$$I_o = I \circ S_o \tag{3}$$

The operator 'close' function of an image 'I' with structuring element S_c is given by,

$$I_c = I \cdot S_c \tag{4}$$

Modified morph operation of an image is given by,

$$I_{mod} = I - (I \cdot S_c) \circ S_o \tag{5}$$

The Eq. (5) shows our modified morph operation in which 'I' is the input green channel image while S_c and S_o stand for the elements of structuring for closing (·) and opening (∘) operators, respectively.

2) Segmentation of BV and elimination: Here, the morphological filter is followed in a novel approach by the hessian matrix to improve the quality of the pictures obtained of the thin and broad vessels. For both thin and wide vessel enhancement, we have independently calculated the second derivative of the picture at two distinct scales. The utilisation of a hessian matrix-based technique has facilitated the separation of broad and thin vessels. The focus is on vessels with varying widths, which are determined by analysing the second order derivative at two distinct scales. The hessian matrix's Eigen values and their difference are being utilized to reduce non-vasculature structure and improve contrast. The directed image I_i and its hessian matrix in the updated coordinates $Cx'y'$is found to be,

$$H' = \begin{bmatrix} h_{11} & h_{12} \\ h_{21} & h_{22} \end{bmatrix} = \begin{bmatrix} \frac{\partial^2 I_i}{\partial x'^2} & \frac{\partial^2 I_i}{\partial x' \partial y'} \\ \frac{\partial^2 I_i}{\partial y' \partial x'} & \frac{\partial^2 I_i}{\partial y'^2} \end{bmatrix} \tag{6}$$

Otsu thresholding is applied individually to broad and narrow vessel pictures because applying it to the entire image at once does not yield useful results. So applied a global threshold to the enhanced picture of the broad vessels and then combined it with the enhanced image of the narrow vessels.

Utilising a modified version of Otsu's technique, geometrical objects and undesired noise are suppressed depending on the vessel structure. Otsu's method is often applied locally or globally over the whole picture to determine a threshold for vessel and non-vessel pixel categorization. Otsu threshold is been applied individually to broad and narrow vessel pictures because applying it to the entire image at once does not yield useful results. A global threshold is applied to the enhanced picture of the broad vessels and then combined it with the enhanced image of the narrow vessels. The segmented blood vessel in which one is thin and other is thick vessel is shown in Fig. 4.

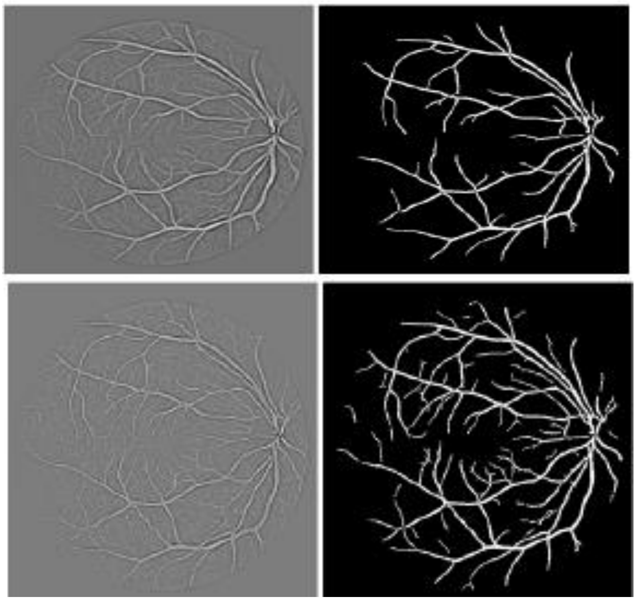

Fig. 4. Thin and thick BVS.

After segmenting the BV's, the blood vessel needs to be eliminated. By eliminating the region of blood vessels, the regions of MA's are easy to extract. The extracted MA region and the morphological filter response on MA region are shown in Fig. 5.

To lessen unwanted noise and geometrical structures according to the design of the vessel, adapted Otsu's technique. Otsu's method is often applied locally or globally over the whole picture to determine a threshold for vessel and non-vessel pixel categorization.

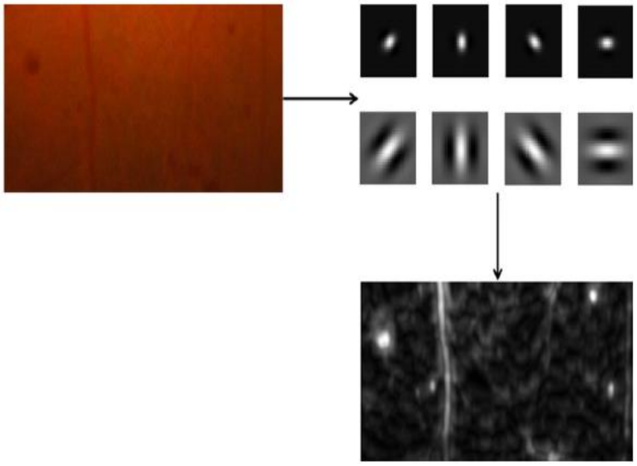

Fig. 5. Slice of Input image with MA region.

3) Feature extraction: All prospective objects (regions) that might be regarded as potential MA regions are provided by the candidate MA region extraction step. The set representation for an image 'n' is if it has 'N' probable candidate areas is given as $n = \{n_1, n_2, n_3, \dots\dots, n_N\}$. A feature vector with all m characteristics, i.e. for a sample lesion, represents each item or potential lesion region n_i, which is regarded as a sample for classification and the feature vector is $n_i = \{fv_1, fv_2, fv_3, \dots\dots, fv_m\}$ where $i = 1,2, \dots\dots, N$.The area, eccentricity, compactness, aspect ratio, mean and standard deviation, mean gradient, mean gradient magnitude, mean HSV (hue, saturation, and value), entropy, homogeneity, and energy value are the properties that we employ in the system which have been presented. Finally, the features are given to different type of classifiers which are discussed in Section III to identify the detection rate of accuracy.

D. HE Detection

1) Exudates pixel forming: Retinal pictures must be cleaned of artefacts in order to improve the quality of retinal fundus images for the precise detection of exudates. These artefacts can be caused by a variety of factors, including focus, blur, and improper illumination of the retinal fundus picture. The quality of retinal pictures is declining due to these reasons. Furthermore, poor picture quality may lead to erroneous retinal disease diagnosis. Therefore, improving photos before determining the presence of exudates is a crucial step.

2) Detection of hard exudates: There were two primary methods. To segment colour retinal pictures, FCM clustering was first utilised to get the local dynamic threshold of each sub-image. This threshold was then coupled with the global threshold matrix. Subsequently, exudates and non-exudates zones were distinguished using classification algorithms.

a) FCM for segmentation of retinal image: The technique of segmenting images using the dynamic threshold in conjunction with the global threshold based on FCM clustering is explained as follows:

i) The retinal picture was split into 'S' sub-images, and each sub-image's pixels were assigned to distinct categories using fuzzy memberships according to the FCM method. The following cost function was minimised by FCM, an iterative optimisation technique:

$$I(A, B) = \sum_{i=1}^{n} \sum_{s=1}^{c} (a_{si})^m \|x_i - C_s\|^2 \quad (7)$$

where, C_s denotes the clustering centre of the kth cluster and a_{si}denotes the membership of pixel x_i in the kth cluster. Since the grayscale value was the sole feature utilised for clustering, the midpoint of the line representing the clustering centre was used as the segmentation threshold, and the sub-image threshold was determined by taking the mean of the two clustering centres;

ii) To determine the global threshold and create the global matrix 'G' with the same dimensions as the original picture, all the pixels in the original retinal image were categorised in the same manner as described previously.

iii) A mean filter with a size of 10 × 10 was applied to the dynamic threshold matrix T_D, which was created by interpolating the thresholds of the individual sub-images into a matrix the same size as the original picture.

iv) The final threshold matrix $T_h$was constructed as,

$$T_h = jG + (1 - j)T_D \quad (8)$$

where, the value of 'j'was set to 0.1.

v) The retinal picture and the threshold matrix T were compared to determine the segmentation outcome. Results of retinal imaging segmentation are influenced by the sub-image's size. The FCM clustering results for various sub-image sizes are displayed in Fig. 6. After considering the accuracy of the local threshold as well as the running duration, 20×35 pixels was determined to be the most appropriate size for the sub-images.

3) Feature extraction: Some notable traits that were frequently employed by eye care professionals to visually identify HE from other forms of lesions were retrieved from each location and used as inputs of classification systems in order to further partition the exudates regions from the exudate's candidates. Area, eccentricity, compactness, aspect ratio, mean and standard deviation, mean gradient, mean gradient magnitude, mean HSV (hue, saturation, and value), entropy, homogeneity, and energy value were among the important characteristics. Lastly, the characteristics are fed into several classifier types—discussed in Section III—to determine the accuracy of the detection rate.

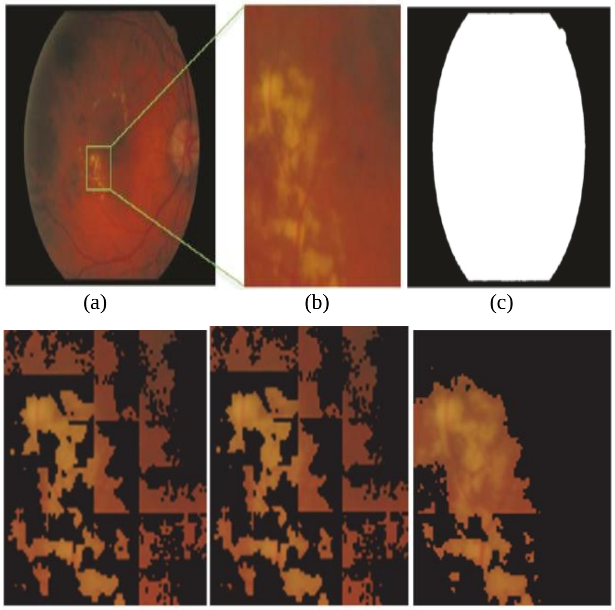

Fig. 6. For different sub-image sizes, the segmentation using FCM clustering. (a) Input image (b) Region of exudates (c) FCM segmented output (d) Segmentation with a size of 10×15. (e) with20×35pixels. (f) With 50×60pixels.

E. Classification Techniques

Following the extraction of the features, five classifiers—DT, RF, SVM, KNN, and LR—are used to begin the classification process. Adaptive threshold algorithms are used in both methods to improve pictures, with 94.6 and 96.2 accuracy levels for MA and HE identification, respectively.

1) Decision Tree (DT): DT is a popular hierarchical machine learning technique for prediction that uses a model of decisions and possible outcomes that resembles a tree. Every branch of DT reflects the test results, every internal node and that is not a leaf node evaluates an attribute, and every leaf node or terminal node specifies the label class.

2) Random Forest (RF): A Random Forest Classifier, which gathers data from MAs and divides it into two likely classes healthy and unhealthy is the third stage. This method operates in a manner akin to that of the decision tree algorithm. This method discovers the optimal answer by compiling all the decision tree predictions. Every tree is dependent on the collection of random features.

3) K-Nearest Neighbour (KNN): KNN is a supervised machine learning technique that predicts the values of new data items by using "feature similarity". In the classification phase, the unlabelled sample is categorised by designating the class label depending on which of the k training samples that are closest to the query point—where k is a predetermined constant—is the most common. In the training phase, this is accomplished by storing the feature vectors and class labels of the training samples.

4) Support Vector Machine (SVM): SVM is a supervised machine learning algorithm that may be applied to problems related to regression and classification. This method constructs a hyperplane (or a group of hyper-planes) in a high- or infinite-dimensional space to determine the best boundary between the potential outputs. Finding a hyperplane that maximises the isolation of data points from possible groupings is the aim in n-dimensional space. SVMs can manage very large feature spaces because they use over-fitting avoidance, which is independent of feature count.

5) Logistic Regression (LR): For classification situations where the goal is to predict the chance that a given instance will belong to a specific class, supervised machine learning techniques termed logistic regression are typically utilised. The word used to describe the classification techniques that use it is logistic regression. The outcome of a categorical dependent variable is predicted using logistic regression. The outcome must thus be a discrete or category value. It gives the probabilistic values that lie between 0 and 1, as opposed to the exact values of 0 and 1. It might be true or false, 0 or 1, yes or no, etc. It is quite like linear regression, except for how they are used.

Regression issues are solved using linear regression, and classification challenges are resolved using logistic regression. We fit a logistic function with a "S" shape that predicts two maximum values, 0 and 1, in lieu of fitting a regression line in LR. The logistic function's curve indicates a number of potential outcomes, such as the presence of cancerous cells and the relationship between a mouse's weight and fatness.

Algorithm for Training:

This section outlines the fundamental procedures for creating a picture (training set) and a collection of targets, as well as the processes we do in the order listed below:

$$\text{For i} = 1, \text{to the number of training images,}$$

$$\text{Obtain the i}^{\text{th}} \text{ image from the database,}$$

Apply to preprocess and extract the features,

Stack the feature results to the training image array,

Assign a target class based on the severity of the dataset

Train classifiers: The following classifiers are picked to carry out the actions, and this sub segment specifies the necessary procedures to train the chosen classifier:

- Train the DT classifier,
- Train the RF classifier,
- Train the KNN classifier,
- Train the SVM classifier, and
- Train the LR classifier.

Algorithm for Testing:

This section outlines the general processing procedures to forecast the outcomes using the provided classifier's feature extraction technique and the subsequent steps we do in that order:

Step1. Obtain the desired test image,

Step2. Apply image pre-processing and extract the features,

Step3. Predict the DT classifier features

Step4. Predict the RF classifier features

Step5. Predict the KNN classifier features,

Step6. Predict the SVM classifier features

Step7. Predict the LR classifier features,

Step8. Obtain the model of prediction results.

IV. Experimental Findings

To assess the effectiveness of the suggested detection framework, retinal pictures from the publicly accessible STARE dataset were analysed in this study. Expertly segmented retinal pictures constitute the dataset, which is often regarded as the gold standard for comparison. The 40 and 20 retinal pictures in the STARE datasets, respectively, are divided into training and test sets. The suggested methodology has been used to evaluate performance using 20 test photos from the STARE dataset. Our suggested framework's trials were all carried out using the aid of the software programme MATLAB 2021a.

The parameters evaluated to show the performance of proposed detection model are sensitivity, specificity, precision, and accuracy. The finding of accuracy is based on true positive, true negative, false positive and false negative values. Here the values signify how effective the MA’s and HE’s are detected. The classification needs to be correct to achieve correct values. The entire performance of segmentation is shown by accuracy. Specificity measures the identification of pixels with negative values, whereas sensitivity represents the ability of detecting pixels with positive values. The following formulae provide the findings, which are displayed in Tables I and II.

$$Sensitivity = \frac{TP}{TP+FN} \tag{9}$$

$$Specificity = \frac{TN}{TN+FN} \tag{10}$$

$$Precision = \frac{TP}{TP+FP} \tag{11}$$

$$Accuracy = \frac{TP\_TN}{TP+TN+FP+FN} \tag{12}$$

V. Results for MA’s Identification

TABLE I. RESULTS FOR MA’S IDENTIFICATION

Classification Technique	Accuracy (%)	Sensitivity (%)	Specificity (%)	Precision (%)
Decision Tree	83.4	85.4	84.7	87.5
Random Forest	87.6	88.3	87.2	89.6
KNN	93.7	94.2	94.8	95.2
SVM	94.2	95.7	94.9	96.4
Logistic Regression	94.6	96.5	96.2	97.6

TABLE II. RESULTS FOR HE’S IDENTIFICATION

Technique	Accuracy (%)	Sensitivity (%)	Specificity (%)	Precision (%)
Math Morph [26]	0.92	0.89	0.91	-
Deep CNN [27]	0.69	0.64	0.88	-
2 step CNN [28]	-	0.77	-	-
MSRNet [29]	-	0.71	-	-
Decision Tree	84.6	86.5	85.2	88.2
Random Forest	87.2	89.1	88.6	90.3
KNN	93.1	95.3	95.1	96.7
SVM	95.2	96.4	95.9	97.8
Logistic Regression	96.2	97.6	97.2	98.4

TABLE III. OVERALL ACCURACY OBTAINED USING PROPOSED MODEL

Classification Technique	MA’s and HE’s Accuracy (%)
Decision Tree	84.0
Random Forest	87.4
KNN	93.8
SVM	94.7
Logistic Regression	95.3

The discussion of Table III is all about the overall rate of accuracy obtained by various machine learning techniques in detection of MAs and HEs for the given STARE dataset. The LR classification achieved higher rate of accuracy with 95.3% when compared to techniques like DT, RF, KNN, and SVM. The classifiers performance may be more accurately assessed using the receiver operating characteristic (ROC) curve and is shown in Fig. 7.

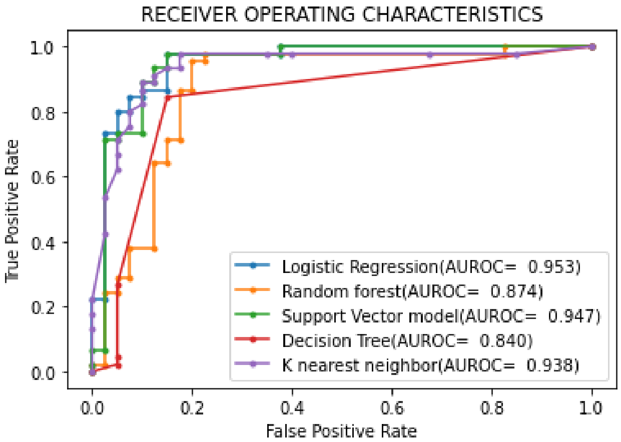

Fig. 7. Over-all ROC in detection of MA's and HE's.

According to this analysis, there are significantly fewer MAs and HEs in regions that are candidates than there are non-MAs and non-HEs. The ROC curve and corresponding AUC of MA detection results on stare database achieved by five classifiers (Decision tree, Random-forest, KNN, SVM and LR) are shown in Fig. 7. Fig. 8 describes the overall training accuracy of the six machine learning classifiers.

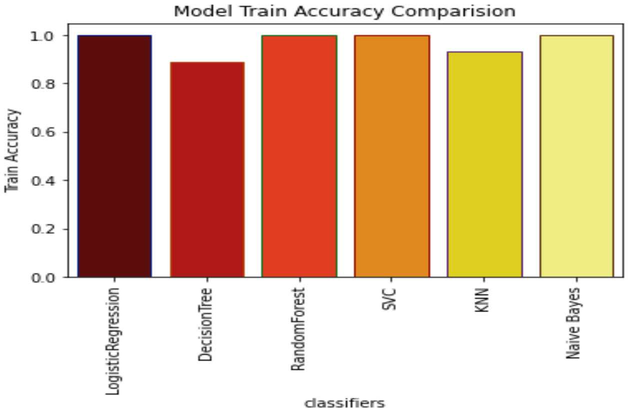

Fig. 8. Overall training accuracy of proposed model.

VI. Conclusion

The detection of MAs and HEs to identify the early stage of DR is displayed in this article. The suggested model consists of three main stages i.e., preprocessing, extraction of features and classification. In terms of accuracy, sensitivity, and specificity, respectively, the classifier logistic regression outperformed the other classification methods including DT, RFC, SVM, and KNN. However, because the preprocessing and extraction of feature steps are the only ones that control the whole system, the results are always a compromise between the necessary parameters. The suggested approach has been tested on databases such as STARE and evaluated using performance metrics as discussed in results. The Logistic Regression classifier (LRC) performance is good when compared with other classifiers with an accuracy of 94.6% in detection of MA's and 96.2% in detection of HE's. In future, research endeavors might involve integrating deep learning techniques into the machine learning algorithm and contrasting the outcomes with the ongoing study.

Gamers Intention Towards Purchasing Game Items in Virtual Community: Extending the Theory of Planned Behavior

Abbi Nizar Muhammad, Achmad Nizar Hidayanto
Magister of Information Technology
University of Indonesia
Jakarta, Indonesia

***Abstract*—Virtual communities serve as bustling marketplaces where gamers engage in transactions for in-game items, driving the digital economy's expansion. This research aims to illuminate the determinants of steering users' decisions within these online environments. Focusing on the constructs of Attitude, Subjective Norms, and Perceived Behavioral Control derived from the Theory of Planned Behavior (TPB), we investigate the factors shaping purchasing intentions. Employing structural equation modeling (SEM) on a robust dataset of 300 validated respondents, our analysis unveils insights into user motivations. Notably, the amalgamation of Attitude, Subjective Norms, and Perceived Behavioral Control explains 84% of the drivers guiding in-game item transactions within virtual communities. Our findings underscore the significance of certain attributes. Specifically, the perceived wisdom inherent in these transactions, the constructive influence of community discussions, and the ease of communication and negotiation channels within virtual realms emerge as pivotal determinants influencing user behavior. This study not only contributes to understanding user behavior in virtual spaces but also holds practical implications for scholars and industry stakeholders. By shedding light on these influential factors, this research informs strategies and interactions within virtual communities, offering valuable insights into the dynamics of the digital marketplace.**

Keywords—Theory of planned behavior; in-game items; purchasing intention; virtual community

I. Introduction

In the ever-evolving landscape of online gaming, virtual communities have emerged as dynamic and immersive spaces where players come together to share experiences, strategies, and a deep passion for their favorite games. Virtual communities often house bustling marketplaces where in-game items and assets are bought, sold, and traded amongst players. The allure of acquiring unique items or enhancing gaming experience has fueled the growth of the digital economy. According to Statista report, Global vide game revenue stands at USD 249.60 billion in 2023 and is projected to grow at a CAGR of 9.32% through 2028, reaching USD 389.70 billion [1].

Virtual communities take shape when a collective of individuals congregate to foster social connections through interactive communication within the digital realm [2]. The success and sustainability of an online community are contingent upon the willingness of its members to openly express their perspectives, engage in meaningful dialogues with fellow members, and make substantive contributions to the community's vitality by generating valuable content [3]. The ease and flexibility offered by this environment enhance communication among users, attracting gamers who frequent virtual communities for discussions and in-game item exchanges.

The quality of the virtual community significantly influences the perception of trust. Trust within an online environment plays a pivotal role in shaping users' intentions when it comes to transactions [4]. In the context of digital in-game items, trustworthiness holds particular significance, as these products are transmitted and utilized in a purely digital format. Building trust relies on user contributions within virtual communities, often through leveraging user reputation systems. The main purpose of user reputation systems is to establish trust between unknown parties [5].

Purchase intention in purchasing in-game items within virtual community can be analyzed on internal and external factors. In mobile games, the intention to purchase in-game items is driven by several factors such as progress in playing, competition, frequency of purchases and amount of spending [6]. Essential elements on internal factor of the purchase intentions of virtual in-games are enjoyment, skills, challenge, telepresence, and flow [7]. Previous research did not cover external factors, such as player behavior and motivation, which influenced purchase intentions. This study aims to explore these factors impacting players' behaviors and motivations in purchasing in-game items within virtual communities. Analyzing these aspects in purchase intention helps understand the driving forces behind a user's decision, providing valuable insights into their motivations within specific contexts.

This research explores the interesting phenomenon of game players' intentions regarding purchasing in-game items in virtual communities. It explores the complex interactions between psychological factors, social influences, and perceived control that guide individuals in their decisions to engage in these virtual markets. In doing so, it extends the renowned Theory of Planned Behavior to explain the motivations and intentions that drive these unique economic interactions.

The Theory of Planned Behavior (TPB) is an extension model of the theory of reasoned action and one of the most widespread models for social psychologists to predict behavioral intentions [8]. The theory of planned behavior (TPB) is one of the most widely researched frameworks for predicting behavioral intentions [9]. This theory investigates the factors that influence a person's behavior and how attitudes, subjective norms, and perceived behavioral control can influence a person's intention to engage in a particular action. By extending the Theory of Planned Behavior to the realm of virtual communities, this research seeks to uncover the unique variables that shape game players' intentions regarding the purchase of in-game items.

II. Theoretical Background

A. In-game Items

In-game items is virtual goods that can be defined as entities within the online gaming environment, which include characters, items, virtual currency, and tokens. Virtual goods refer to the subset of the virtual asset that can be mass-produced, bought, and sold live conventional consumer products, including items, characters, and currencies of games. Very often, three attributes of such virtual goods would drive players to purchase: functional, hedonic, and social [10].

In-game items are often associated with delivering hedonic value to users, prioritizing emotional gratification over practical utility. Hedonic products, in this context, tend to carry symbolic significance. Users invest in these items, receiving in return emotional satisfaction and pleasure as part of the benefits [11].

Gamers are inclined to acquire in-game items when these items enhance their gaming strength, add to their enjoyment, and enable them to showcase themselves to fellow players, especially when these items are reasonably priced. Consequently, within the realm of online gaming, a gamer's perception of an item's value significantly heightens the likelihood of them making a purchase.

B. Related Research

Guo and Yue developed a model that blends new constructs with established theories, drawing from frameworks such as the Theory of Planned Behavior (TPB), the Technology Acceptance Model (TAM), trust theory, and the Unified Theory of Acceptance and Use of Technology (UTAUT). Their research seeks to elucidate the factors behind consumers' decisions to purchase virtual items within virtual worlds [12]. The model highlights various components that bolster behavioral intentions, including trust, social influence, and perceived enjoyment. These elements are interconnected within the virtual community, specifically facilitating the trade of in-game items.

Ezlika conducted an examination of the determinants affecting players' purchase intentions regarding specific in-game virtual items. Additionally, the study explored the impact of the state of “flow" on these purchase intentions. The findings of this research unveiled that factors such as enjoyment, skill, challenge, and telepresence positively contribute to the experience of flow. Moreover, the study established a significant and positive association between the state of flow and players' purchase intentions [7]. Enjoyment, skill, challenge, and telepresence contribute significantly to the gaming experience, shaping gamers' purchasing behavior concerning in-game items. While gaming experience encapsulates an Attitude, it's imperative to quantify and assess these additional components for a comprehensive understanding.

In various fields, the Theory of Planned Behavior has been applied to analyze consumer intentions regarding product purchases in developing nations. Research conducted by Rambalak Yadav has demonstrated that Theory of Planned Behavior is effective in predicting consumers' intentions to purchase products [13]. Building upon prior research to discern the determinants of user purchase intention within virtual communities, the research employs the Theory of Planned Behavior. This theory helps identify several external factors, specifically centered around attitudes, subjective norms, and perceived behavioral control.

C. The Theory of Planned Behavior (TPB)

The Theory of Planned Behavior, initially developed by Ajzen in 1985, provides a well-established framework for understanding human behavior and decision-making across a spectrum of contexts, with intentions influenced by three main constructs [8].

1) Attitude: This construct reflects an individual's overall evaluation of the behavior, including the perceived outcomes and the subjective assessment of the behavior's desirability. In the context of buying in-game items, attitude encompasses players' beliefs about the consequences of such purchases, including how it enhances or affects their gaming experiences [13].

2) Subjective norms: Subjective norms refer to the perceived social pressure or influence from significant others, such as friends, family, and the gaming community, regarding the behavior in question. In the context of in-game item purchases, subjective norms encompass the influence of fellow gamers and the broader gaming culture on an individual's decision [13].

3) Perceived behavioral control: This construct pertains to the perceived ease or difficulty of performing the behavior and reflects the individual's perception of their ability to exercise control over it. In the context of virtual community transactions, perceived behavioral control includes factors like financial means, accessibility, and gaming expertise [13].

Extending the Theory of Planned Behavior to the realm of virtual community transactions is essential to unravel the complex motivations and intentions that underlie game player behavior.

D. Hyphothesis Development

This research aims to apply the Theory of Planned Behavior as an analytical framework to investigate and understand the intentions of game players regarding the purchase of in-game items within virtual communities.

We have identified certain limitations in the purchasing process in virtual communities, most notably the vulnerability of some virtual community's users to scam and fraud when acquiring products [14]. Scams and fraudulent activities continue to occur in virtual communities due to the lack of transactional features. Instead, we have identified the main advantages associated with purchasing in virtual communities, including aspects of simplicity, speed, and convenience. Additionally, users are incentivized to place trust in fellow community members, as forums offer an important space for discussion, access to reviews, informative content, and valuable feedback, all of which significantly influence their purchasing decisions [12]. With the limitations and benefits complementing each other, the existence of virtual communities persists. The discussion leads to following hypotheses:

H1. Game players' attitudes shaped by willingness purchase which has an impact on gaming experiences.

Player's attitude towards making in-game purchases could affect how they engage with the game.

H2. Subjective norms can encompass the influence of peers within the virtual community.

Virtual communities, especially gaming ones, peer influence plays a significant role. What others in the community do or say might shape an individual's beliefs about what is normal or acceptable behavior within that community.

H3. Perceived behavioral control includes consideration of financial resources, technical proficiency, and security concerns within the virtual community.

In virtual communities, various factors can affect how individuals navigate and participate. Financial resources might determine the extent to which someone can engage in certain activities or make purchases. Technical proficiency and security concerns also impact how comfortably and confidently someone can interact within that online space.

By exploring the interplay of attitudes, subjective norms, and perceived behavioral control, this study endeavors to contribute to a more comprehensive understanding of the motivations that guide players' purchase decisions within the virtual community, explains the complex relationships underlying the virtual economy of online games.

Having established the theoretical foundations that shape our understanding of purchase intention within virtual community. The following section delves into the methodology applied, explaining the systematic approach taken to empirically explore and validate the previously proposed hypotheses. The methodology section outlines the research design, data collection methods, and analytical framework used to investigate the complex dynamics in purchase intention within virtual community, bridging theory with practical implementation.

III. Research Methodology

This section describes the research methodology adopted for investigating game player intentions regarding the purchase of in-game items within virtual communities.

A. Research Instrument

This study employs a quantitative research design supported by the Theory of Planned Behavior (TPB) as the guiding framework. The research aims to explain the relationships between Theory of Planned Behavior constructs and game player intentions. Data collected through a structured survey questionnaire using a 5-point Likert scale (1 = Strongly Disagree, 2 = Disagree, 3 = Neutral, 4 = Agree, 5 = Strongly Agree). The 5-point scale stands out for its simplicity, benefit for respondents due to its ease of comprehension and usage. In comparison to scales with more points, it offers a quicker and less demanding completion process.

To accomplish the objective of the study, all the constructs were adopted from the relevant literature. The present study showed the attitude towards virtual goods and the perceptions of peers' attitudes significantly bolster the inclination to engage in virtual goods procurement [15]. Constructing and measuring items were based on the scope of prior research that has empirically tested and enhanced the predictive capacity of the Theory of Planned Behavior [13]. The construct's significance in shaping behavioral intentions has been thoroughly tested. To align purchase intentions within virtual communities, constructs and measurement items were meticulously developed and tailored to fit the research specific context. Table I presents an overview of all the constructs referred to in this research.

TABLE I. CONSTRUCTS AND MEASURING ITEMS

Code	Constructs and Measuring Items
ATT	**Attitude**
ATT1	For me, buying in-game items via virtual communities is a good decision
ATT2	Purchasing in-game items from other users in virtual communities can enhance the gaming experience
ATT3	For me, buying in-game items via virtual communities is very fun
ATT4	For me, buying in-game items via virtual communities is a wise decision
ATT5	I believe that purchasing in-game items from other users in virtual communities is a worthwhile investment
ATT6	I feel satisfied when purchasing in-game items through virtual communities
SN	**Subjective Norms**
SN1	Community members and people I know in virtual communities encourage me to buy in-game items
SN2	Discussions in virtual communities have a positive impact on my decision to purchase in-game items
SN3	I trust the opinions and recommendations of other users in virtual communities regarding purchasing in-game items
PBC	**Perceived Behavioral Control**
PBC1	I have the virtual currency, time, and resources to make purchases of in-game items in virtual communities
PBC2	I can easily communicate and negotiate with other users in virtual communities regarding game item transactions
PBC3	I feel confident in my ability to purchase in-game items safely and securely in virtual communities
PI	**Purchase Intentions**
PI1	I intend to purchase in-game items from other users in virtual communities soon
PI2	I actively seek opportunities to purchase in-game items from fellow virtual community members
PI3	I plan to allocate part of my gaming budget to purchasing in-game items in virtual communities

B. Data Collection

Quantitative data collected through the distribution of survey questionnaires. The surveys administered online to a diverse sample of game players actively engaged in virtual communities. Active engagement within the virtual community defines gamers who consistently trade in-game items via forums or similar platforms. This segment actively participates in discussions and frequently engages in the exchange of in-game items. The questionnaire includes Likert-scale items designed to assess attitudes, subjective norms, perceived behavioral control, and intentions, according to the Theory of Planned Behavior framework.

Data pertaining to in-game items within virtual communities is predominantly collected from sources such as relevant discussion forums and other online community platforms [15]. Unexplainably, the pre-filtered data contained approximately 1,412 partially incomplete responses. Our investigation led us to the conclusion that this anomaly was a result of the survey software retaining incompletely filled questionnaires, despite being configured to exclusively accept fully completed ones. Fortunately, this software issue does not seem to have impacted the integrity of the collected data.

To address this issue, we employ Excel to filter the data before conducting our analysis using the Partial Least Squares Structural Equation Modeling (PLS SEM). The filtered dataset exclusively comprises questionnaires completed by respondents, ensuring a focused and relevant dataset for our analysis.

C. Data Analysis

Data analysis conducted using Partial Least Squares Structural Equation Modeling. This technique is suitable for examining complex relationships within the Theory of Planned Behavior framework and provides a robust method for assessing the structural model's fit to the data. The Partial Least Squares Structural Equation Modeling can be used for evaluation of the measurement model, evaluation of the structural model, goodness of fit estimation and hypothesis testing [16].

Partial Least Squares Structural Equation Modeling is a statistical methodology primarily employed for confirmatory purposes, validating hypotheses, and dissecting a structural theory that encompasses various phenomena within a specific environment. It serves as a powerful tool to test and confirm relationships between observed and latent variables, offering insights into the complex interplay among multiple factors within a given context or system. [17]. The stages in Partial Least Squares Structural Equation Modeling analysis encompass model specification, assessment of the outer (measurement) model, evaluation of the inner (structural) model, and ultimately, the examination of moderating variables to analyze their effects. This sequential process allows for a comprehensive understanding of relationships between constructs and potential moderating influences within the model under study [18].

Partial Least Squares Structural Equation Modeling used to validate the measurement model, ensuring that the survey items accurately capture the Theory of Planned Behavior constructs. This step involves assessing the reliability of factor loading (Cronbach’s Alpha), composite reliability, average variance extracted (AVE), convergent validity and discriminant validity were examined. Cronbach Alpha and Composite Reliability prove that the research model has good reliability. Cronbach alpha measures the internal consistency of a variable. The construct scores must be greater than 0.7 should be considered reliable [18]. Average variance extracted is a metric for determining convergent validity, Average variance extracted values is at least 0.5 and the square root of the Average variance extracted should be higher than correlation between one construct and the other constructs items [16].

The structural model examines the relationships between Theory of Planned Behavior constructs (attitude, subjective norms, and perceived behavioral control) and game player intentions. Partial Least Squares Structural Equation Modeling is particularly suited for research aiming to explore and predict relationships between latent variables, especially in situations where the underlying theory might be underdeveloped or relatively weak. It's an effective method for modeling complex relationships, making it valuable when theoretical frameworks are still evolving or when there's a need to explore and validate relationships between constructs that lack established theoretical foundations.

IV. Results and Discussion

Data was gathered from gamers in Indonesia who actively participate in trading within virtual communities through an online survey distribution. While a total of 1,412 responses were received from the distributed questionnaires, the final sample included 300 respondents who completed the survey in its entirety.

A. Demographics

Demographic characteristics of the respondents indicate that the largest portion, comprising 42%, falls within the 15 to 20 age group, while 35% belong to the age group below 15 and 23% above 20 age groups. Furthermore, a majority of the respondents, accounting for 50%, reported actively participating in trading within virtual communities for less than one year, with an additional 23% having between one to two years and 27% above two years of experience in game trading within virtual community.

B. Results

The study's findings were analyzed through the application of structural equation modeling, encompassing both the evaluation of the measurement model and the structural model analysis.

1) Measurement model assessment: We assess the measurement model's validity and reliability, which includes:

a) Validity analysis: Our validity analysis confirms the convergent validity, as all constructs exhibit outer loadings exceeding the established baseline of 0.7. Consequently, we have retained all constructs for further analysis. In the ATT construct, ATT4 stands out with the highest loading at 0.916, while in the SN construct, SN3 leads the way with an impressive 0.961. Within the PBC construct, PBC2 scores notably with a loading of 0.941, and in the PI construct, PI2 matches that value at 0.941.

Moreover, the Average Variance Extracted (AVE) values for each construct are all above 0.5, signifying the robustness and strong correlations within and across constructs. Specifically, ATT registers an AVE of 0.774, SN achieves 0.875, PBC attains 0.855, and PI maintains a solid 0.836. This observation highlights the substantial correlations within each construct and among different constructs.

In terms of discriminant validity, cross-loadings reveal that all factor correlations are below 0.8, signifying that adequate discriminant validity is maintained. Table II presents an overview of the validity analysis.

TABLE II. VALIDITY ANALYSIS

Code	Convergent Validity		Discriminant Validity			
	Outer Load-ing	AVE	Cross Loading			
			ATT	SN	PBC	PI
ATT1	0.830	0.774	0.830	0.695	0.705	0.656
ATT2	0.894		0.894	0.748	0.751	0.760
ATT3	0.903		0.903	0.815	0.791	0.757
ATT4	0.916		0.916	0.766	0.802	0.819
ATT5	0.848		0.848	0.755	0.778	0.840
ATT6	0.884		0.884	0.849	0.798	0.839
SN1	0.915	0.875	0.807	0.778	0.814	0.915
SN2	0.961		0.862	0.856	0.830	0.961
SN3	0.929		0.819	0.825	0.805	0.929
PBC1	0.915	0.855	0.815	0.915	0.805	0.810
PBC2	0.941		0.824	0.941	0.852	0.852
PBC3	0.919		0.797	0.919	0.813	0.770
PI1	0.895	0.836	0.783	0.817	0.895	0.758
PI2	0.941		0.863	0.845	0.941	0.822
PI3	0.907		0.758	0.780	0.907	0.814

b) Reliability analysis: In our Reliability Analysis, we assessed both Cronbach's Alpha (CA) and Composite Reliability (CR). In the field of social psychology research, CA and CR values above 0.7 are generally considered acceptable as a measure of internal consistency between items.

Cronbach's Alpha was employed to gauge the internal consistency of the items, and the study revealed that the values ranged from 0.902 to 0.941 within each construct. This range underscores the high degree of consistency within each construct.

In addition, construct reliability was assessed using Composite Reliability, with the study indicating values ranging from 0.904 to 0.943. These results clearly demonstrate that all values exceed the recommended threshold of 0.7 and are notably higher, underscoring the adequacy of the reliability of the constructs. Table III presents an overview of the reliability analysis.

TABLE III. RELIABILITY ANALYSIS

Code	Cronbach Alpha	Composite Reliability
ATT	0.941	0.943
SN	0.928	0.929
PBC	0.915	0.917
PI	0.902	0.904

2) *Structural model analysis:* The model analysis includes hypothesis testing, the assessment of path coefficients, and R-squared values.

a) Hypotheses testing: The analysis confirmed that the proposed theoretical framework successfully met the criteria for both reliability and validity. The results demonstrate that the proposed framework aligns well as a model fit. The visual representation illustrates the outcomes related to the postulated hypotheses.

Significantly, all the variables associated with the Theory of Planned Behavior - Attitude (value = 0.287, $p < 0.01$), confirming hypothesis H1 that customers are inclined to purchase items that enhance their gaming experience; Subjective Norm (value = 0.254, $p < 0.01$), substantiating hypothesis H2 that the decision to purchase in-game items is influenced by discussions and peer interactions within the virtual community; and Perceived Behavioral Control (value = 0.415, $p < 0.01$), supporting hypothesis H3 that factors like financial resources, technical proficiency, and security concerns play a role in the decision to purchase in-game items within the virtual community - demonstrated substantial relationships with gamers' intentions to acquire in-game items within a virtual community.

All the hypotheses have been confirmed by the findings, and the predicted values align with expectations. The graphical representation of the TPB model is displayed in Fig. 1.

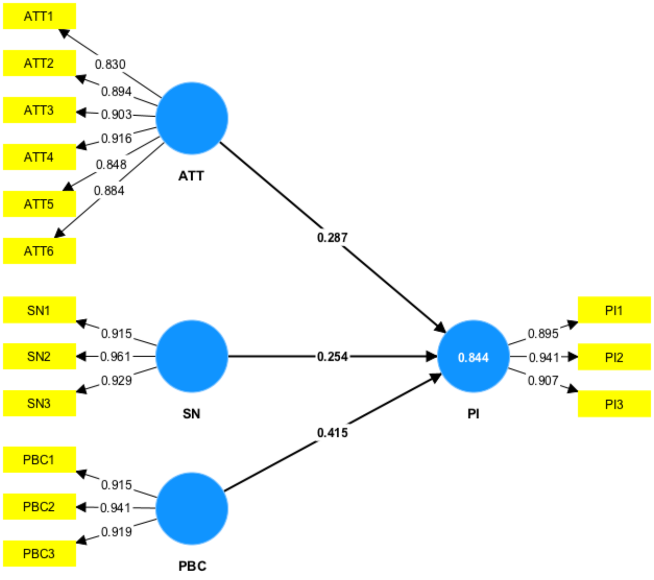

Fig. 1. Model Analysis.

b) Path coefficients: To support a research hypothesis, it's essential that the coefficient or direction of the variable relationship aligns with the hypothesized outcome, and the probability value (p-value) is less than 0.05 or 5%. In the study, the variables of the Theory of Planned Behavior (TBP) met this criterion, with Attitude (p-value = 0.005), Subjective Norm (p-value = 0.0001), and Perceived Behavioral Control (p-value = 0.013) all indicating values below the established threshold. This suggests that these variables are statistically significant and support the research hypothesis. Table IV presents an overview of the probability value.

TABLE IV. PROBABILITY VALUE

Code	P Value
ATT => PI	0.005
SN => PI	0.0001
PBC => PI	0.013

c) R-squared values: The R-Square value of 0.844 suggests that approximately 84.4% of the variation in the dependent variable (represented by Purchase Intention) can be explained by the independent variable included in the research model. The remaining variation, about 15.6%, is attributed to factors or independent variables that were not considered in this study.

C. Discussion

In exploring the implications of the relationships identified between the Theory of Planned Behavior constructs and gamer intentions within virtual community transactions. The discussion delves into the significance findings in the context of online gaming and virtual economies. Understanding the factors that influence purchase intentions in virtual communities has broader implications for consumer behavior in online environments.

The observed connections between attitude, subjective norms, perceived behavioral control, and purchase intentions resonate with the hypothesis and models, which underscores that the application of this framework in understanding gamer’s behavior in the context of virtual environment is very appropriate.

In earlier research within the same domain, it was found that the enjoyment of the game tended to decrease the willingness to acquire virtual goods. On the contrary, a positive attitude toward virtual goods and beliefs about peers' attitudes had a strong positive influence on the inclination to purchase such items [15]. Additionally, previous studies have indicated that internal factors like enjoyment, skill, challenge, and telepresence play a constructive role in establishing a significant connection between the state of "flow" and a player's intention to make in-game purchases [7]. While internal factors like enjoyment and challenge remain pivotal, external factors, specifically engagement within virtual communities and seamless communication channels, emerge as critical determinants shaping purchasing decisions.

This research extends the previous study by exploring influential external factors within virtual communities that drive purchase intentions for in-game items. The findings suggest that engagement within virtual communities has a positive impact on the decision to purchase in-game items within virtual community Furthermore, the ease of communication and negotiation with fellow users within the same virtual community emerges as a driving force behind purchase intentions.

D. Implications

These findings carry significant implications that could assist game developers and entrepreneurs in formulating effective strategies for the sale of in-game items within virtual communities. Based on these findings, it is advisable for entrepreneurs engaged in selling in-game items within virtual communities to offer comprehensive information to prospective buyers.

The content generated within these virtual communities, including discussions that give rise to opinions and recommendations, can foster a sense of trust among customers, ultimately influencing their decisions to make a purchase. Virtual communities should focus on fostering discussions and interactions among users. The positive impact of discussions, as shown in the study, suggests that strategies aimed at enhancing community engagement can be particularly effective.

Consistent with The Theory of Planned Behavior, it was observed that attitude, subjective norms, and perceived behavioral control emerged as notable and positively correlated predictors of the purchase of in-game items within virtual communities. The empirical results further indicated that subjective norms exhibited a more pronounced impact on the intention to purchase in-game items compared to attitude and perceived behavioral control. Lastly, attitude exerted a greater influence than perceived behavioral control, suggesting that purchasing in-game items in virtual communities is driven by considerations of simplicity, speed, and convenience for the customers.

V. CONCLUSION

This paper synthesizes the key findings that explain intricacies of gamer intentions within virtual communities regarding in-game item purchases. These insights bear significant implications for stakeholders in the gaming industry, laying the groundwork for enhancing user experiences, community engagement, and refining strategies for in-game items transactions.

The study's findings reveal that the intention to purchase in-game items within virtual communities is significantly influenced by three key factors: Attitude, Subjective Norms, and Perceived Behavioral Control. Together, these variables account for a substantial 84% of the reasons why users opt to purchase in-game items within forums or virtual communities.

Among these variables, Attitude numbers 4 (ATT4) within the Attitude construct stands out, suggesting that buying in-game items through virtual communities is seen as a prudent choice. Additionally, Subjective Norms numbers 2 (SN2) indicates that discussions in virtual communities positively impact the decision to purchase in-game items, while Perceived Behavioral Control numbers 2 (PBC2) highlights the ease of communication and negotiation with other users in virtual communities regarding game item transactions. These findings shed valuable light on the driving forces behind user behaviors in this context.

Moving forward, stakeholders in the gaming industry can leverage these insights to transform user experiences and optimize strategies. Developers can prioritize mechanisms that facilitate informed and transparent transactions, enriching user perceptions of these virtual communities as trustworthy marketplaces. Community managers, armed with an understanding of the positive influence of discussions, can foster engaging dialogues to augment user interactions and retention. Entrepreneurs can capitalize on the importance of seamless communication by enhancing platforms that facilitate easy and efficient exchanges among users.

Furthermore, this research represents a distinctive contribution to existing literature by delving deeper into the interplay of ATT4, SN2, and PBC2, offering specific insights into their roles within the context of in-game item transactions in virtual communities. This nuanced exploration expands the understanding of gamer intentions, providing granular insights into the multifaceted drivers shaping user behaviors.

Future research can explore how these factors and purchase intentions evolve over time. Longitudinal studies can provide a deeper understanding of the dynamics within virtual communities. Complementary to the Theory of Planned Behavior, incorporating additional variables and constructs may further enrich our comprehension of user behaviors in these environments, presenting promising paths for comprehensive investigations.

Deep Learning-based License Plate Recognition in IoT Smart Parking Systems using YOLOv6 Algorithm

Ming Li, Li Zhang*
College of Computer and Control Engineering,
Northeast Forestry University, Haerbin 150040, Heilongjiang, China

***Abstract*—License plate recognition (LPR) is pivotal for the seamless operation of Internet of things (IoT) and smart parking systems, ensuring the swift and effective identification and management of vehicles. Recent research has concentrated on refining LPR methods through deep learning approaches, proposing diverse strategies to enhance accuracy and reduce computation costs. This work tackles these challenges by introducing an innovative method rooted in the YOLOv6 algorithm. Leveraging a tailored dataset for model generation, the study employs rigorous methodologies involving validation, testing, and training. The resultant model demonstrates marked improvements in license plate recognition capabilities, surpassing the performance of existing methods. This breakthrough bears significant implications for advancing IoT smart parking systems, promising heightened reliability and efficiency in vehicle identification and management. Thorough experimental results and performance evaluations validate the efficacy of the proposed YOLOv6-based method. In-depth discussions and comparisons with state-of-the-art methods in the field lead to the conclusion that the introduced approach not only elevates accuracy but also enhances overall efficiency in license plate recognition for smart parking systems, thereby providing valuable contributions to the domain.**

Keywords*—Internet of things; deep learning; smart parking system; license plate recognition; YOLOv6

I. Introduction

With the rapid advancements in technology, the concept of smart cities has gained considerable attention in recent years. Smart cities leverage the power of the Internet of Things (IoT) to create intelligent, interconnected urban environments that enhance the quality of life for their residents [1, 2]. One of the key areas of focus in smart city development is smart parking management, which aims to address the persistent challenges associated with parking in urban areas [3, 4]. In this context, video-based technologies have emerged as a promising solution, offering real-time monitoring, efficient utilization of parking spaces, and improved enforcement capabilities.

The importance of video-based technologies in IoT smart parking systems cannot be overstated [5]. Traditional parking management systems often rely on physical sensors or manual monitoring, which can be cumbersome and time-consuming. Video-based technologies, on the other hand, utilize cameras and computer vision algorithms to capture and analyze visual data, enabling real-time tracking and intelligent decision-making [6, 7]. These technologies provide valuable insights into parking occupancy, duration, and violation detection, leading to enhanced efficiency and improved parking experiences for drivers [8]. Moreover, video analysis can be seamlessly integrated into existing IoT platforms, facilitating data-driven decision-making and enabling effective management of parking spaces in smart cities.

License plate recognition (LPR) plays a vital role in smart parking management systems. By leveraging computer vision techniques, LPR systems automatically capture, interpret, and recognize license plate information from video streams or images [9]. Integrating LPR into smart parking systems enables automated entry and exit control, efficient payment processing, and enhanced enforcement capabilities [10]. This technology eliminates the need for manual checks or physical tickets, streamlining the parking process and reducing human intervention. License plate recognition serves as a fundamental component in smart parking systems, facilitating seamless and secure parking operations within smart cities.

Various methods have been explored for license plate recognition in the past, with recent research focusing heavily on deep learning-based approaches [10]. Deep learning has garnered significant attention due to its ability to learn complex patterns and features from large-scale datasets [11-13]. Compared to traditional methods that rely on handcrafted features and rule-based algorithms, deep learning-based methods offer superior accuracy and robustness in license plate recognition tasks [14]. The availability of large labeled datasets and advancements in computational power have further fueled the adoption of deep learning in this domain, attracting researchers to explore innovative approaches and architectures.

Despite the progress made in deep learning-based license plate recognition systems, some limitations and research gaps still need to be addressed. One of the critical challenges lies in achieving a balance between computational cost and accuracy rate. Real-time processing of video streams requires low computational overhead while maintaining high accuracy in license plate recognition. The existing literature offers insights into these limitations, motivating the need for further research to develop lightweight deep learning and YOLO-based (You Only Look Once) algorithms. These approaches offer the potential to address the identified research gap by achieving a good trade-off between computational efficiency and recognition accuracy.

This study addresses the research problem of improving license plate recognition (LPR) in the context of internet of things (IoT) and smart parking systems. The existing challenges involve the necessity for more accurate and efficient vehicle identification and management. The research questions focus on evaluating the effectiveness of the YOLOv6 algorithm in overcoming these challenges, particularly in terms of enhancing accuracy and reducing computation costs. The research objectives aim to assess and optimize LPR using the YOLOv6 algorithm, with a specific emphasis on evaluating its accuracy in license plate identification, analyzing computational efficiency to manage costs, and contributing to the overall advancement of IoT and smart parking systems.

The main research contributions of this study are listed as follows:

1) Preparing a custom dataset and the application of YOLO-based algorithms and lightweight deep learning models to enhance license plate recognition performance in intelligent parking management systems.

2) Developing an efficient deep learning-based method for LPR to serve low computational cost and high accuracy rate requirements.

3) Conducting comprehensive experimental evaluations and performance analysis, highlighting the effectiveness and efficiency of the proposed methods.

The rest of the paper is structured as follows: In Section II, a review of previous studies is presented. Section III presents the methodology. Performance analysis is discussed in Section IV. The paper is finally concluded in Section V.

II. Review of Previous Studies

Loong et al. [15] presented a machine vision-based smart parking system utilizing the Internet of Things (IoT). The system aims to provide efficient parking management using camera-based image processing techniques to detect and monitor parking spaces in real-time. It utilizes IoT technologies to enable seamless communication between parking sensors, cameras, and a central server. The system allows users to access parking availability information through a mobile application, thereby reducing the time spent searching for parking spaces. However, the limitation of this paper is that it focuses primarily on the technical aspects of the system and does not extensively discuss the implementation challenges or potential scalability issues that may arise when deploying the system in real-world scenarios. Further research could investigate the practical implications and limitations of implementing the proposed smart parking system.

In study [16], a smart parking application is implemented that utilizes the Internet of Things (IoT) and machine learning algorithms. The system aims to optimize parking space utilization by monitoring and managing parking availability in real-time. It employs IoT technologies to collect data from parking sensors and employs machine learning algorithms to predict parking space occupancy. The system offers users a mobile application to access parking information and reserve parking spots. However, a limitation of this paper is that it lacks a comprehensive evaluation of the system's performance, scalability, and robustness in real-world scenarios. Future research could focus on assessing the system's effectiveness in different environments and under varying conditions to address potential limitations and enhance its practical implementation.

Kabir et al. [17] present an IoT-based intelligent parking system that focuses on utilizing unutilized parking areas. The system employs real-time monitoring utilizing mobile and web applications to provide users with parking availability information and facilitate efficient parking space utilization. It utilizes IoT technologies to collect data from parking sensors and employs intelligent algorithms for real-time monitoring. The system offers a user-friendly interface for accessing parking information and making reservations. However, a limitation of this paper is the lack of empirical validation or field testing of the proposed system in real-world parking environments. Further research could evaluate the system's performance, reliability, and scalability to address potential limitations and validate its practical effectiveness in different parking scenarios.

In [18], a smart parking system was implemented that utilizes image processing techniques. The system aims to optimize parking space management using cameras to detect and analyze parking space occupancy. It provides real-time parking availability information to users through a user-friendly interface. However, a limitation of this paper is the lack of discussion regarding the system's performance in challenging lighting conditions or crowded parking scenarios, which may affect the accuracy of the image processing algorithms. Future research could address these limitations by conducting thorough testing and evaluation of the system's performance in various real-world environments to ensure its reliability and effectiveness.

Deep learning algorithms for automatic license plate recognition (ALPR) were implemented by Silpa [19]. The study aims to develop an ALPR system that utilizes deep learning techniques to recognize and detect license plates in real accurately. The system demonstrates promising results in terms of accuracy and efficiency. However, a limitation of this paper is the absence of a comprehensive analysis of the system's performance under challenging conditions, such as variations in lighting, weather, or license plate designs. Future research could address these limitations by conducting extensive testing and evaluation of the system's robustness and reliability in various real-world scenarios to ensure its practical applicability.

The collective findings from previous studies on IoT-based smart parking systems reveal a common research challenge: achieving high accuracy in real-time parking space detection while minimizing computation costs. Despite notable advancements in parking management, lack of comprehensive performance evaluations, and absence of empirical validation in real-world scenarios. Addressing these challenges, future research should focus on developing smart parking systems that strike a balance between accuracy and computation costs. Thorough empirical validation and comprehensive evaluations are crucial to advancing the field and facilitating practical implementation in diverse urban environments.

III. Methodology

This section discusses the methodology of this study. In the methodology, we describe the structure of the suggested method. In the proposed method, the steps consisted of Data Collection and Preparation, Model Architecture Design, Dataset Preprocessing, Model Training, Model validation, and Model Testing. Fig. 1 illustrates the structure of the suggested method.

As shown in Fig. 1, the proposed method follows a structured approach consisting of several key steps. First, the Data Collection and Preparation phase involves gathering a diverse dataset of license plate images captured from real-world parking scenarios and annotating them with corresponding labels. Next, the Model Architecture Design step focuses on selecting a suitable deep-learning architecture and configuring its parameters to design an effective license plate recognition model. Following that, the dataset preprocessing step involves applying necessary preprocessing techniques to normalize the license plate images and augment the training dataset for improved model generalization. Subsequently, the Model Training phase utilizes the annotated dataset to train the deep learning model, optimizing a chosen loss function and fine-tuning hyperparameters. The trained model is then subjected to Model Validation, where its performance is evaluated on a validation dataset to ensure proper generalization. Finally, the Model Testing step involves applying the trained model to a separate testing dataset to assess its real-world performance, including accuracy, detection rate, and recognition speed. This structured approach ensures a comprehensive development and evaluation process for the proposed method in license plate recognition within smart parking management systems—the details of the steps are discussed in the following sections.

A. Data Collection and Preparation

In the data collection and preparation step, a diverse dataset of license plate images is collected from real-world parking scenarios and internet resources. This dataset aims to capture the variability and complexity encountered in actual parking environments. It includes images of license plates from different vehicle types, varying lighting conditions, different angles, and potential occlusions. By collecting a diverse dataset, the proposed method ensures that the trained model can handle the challenges faced in real-world scenarios.

Once the dataset is collected, the next action is to annotate it with corresponding labels and bounding boxes surrounding the license plates. This annotation process involves manually marking the regions of interest containing the license plates in each image and assigning the correct labels to them. The labels typically include alphanumeric characters present on the license plates. This annotation step is crucial as it provides ground truth information that is essential for training and evaluating the model accurately.

B. Model Architecture Design

For the design of our deep learning model for license plate recognition, we have chosen YOLOv6 as our core model. YOLO (You Only Look Once) is a popular object detection framework known for its real-time performance and accuracy. YOLOv6 is an evolution of the YOLO series, incorporating improvements and optimizations to enhance its detection capabilities.

YOLOv6 serves as an excellent starting point for our license plate recognition model due to its pre-trained weights and strong performance on object detection tasks. Pre-trained models are trained on large-scale datasets such as Common Objects in Context (COCO), which contain various object classes, including vehicles and license plates. Leveraging a pre-trained model like YOLOv6 allows our license plate recognition model to benefit from the knowledge gained during the pre-training phase, enabling faster convergence and better generalization.

With YOLOv6 as our core model, we can leverage its architecture, which is based on a deep neural network with convolutional layers, to localize and detect license plates within images. The YOLOv6 architecture employs a series of convolutional layers followed by fully linked layers to learn features at different scales, enabling it to detect objects with different sizes and aspect ratios accurately. By adopting the YOLOv6 model to our license plate recognition task, we can leverage its inherent object detection capabilities to identify and localize license plates within parking images. The pre-trained weights of YOLOv6 serve as a starting point for our model, allowing us to fine-tune and specialize the network for license plate recognition specifically. This approach combines the advantages of transfer learning, where pre-trained knowledge is utilized, with the flexibility to adapt the network to the requirements of license plate recognition in smart parking management systems.

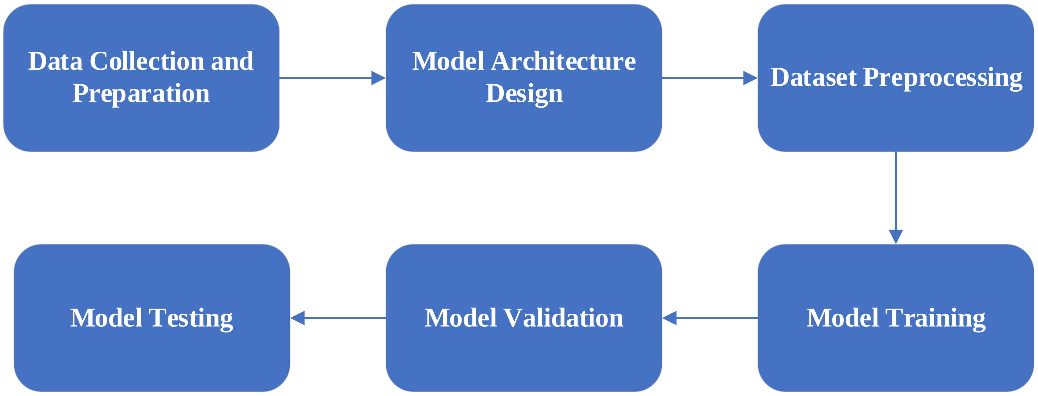

Fig. 1. The suggested method's structure.

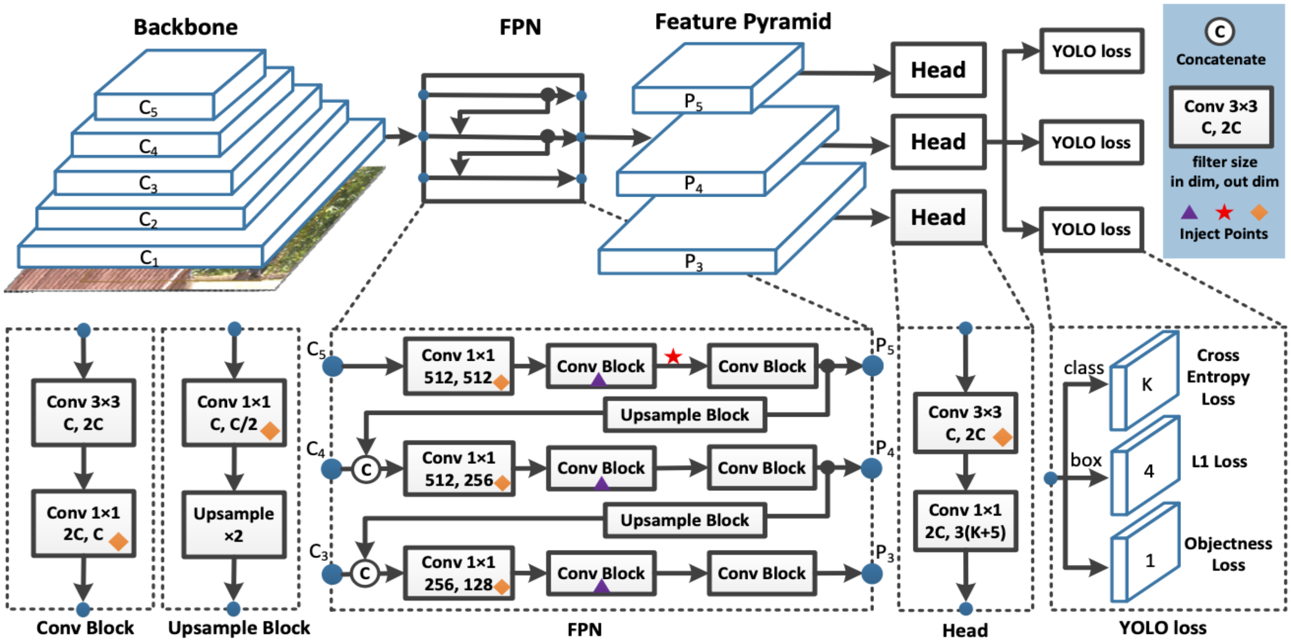

Fig. 2. Structure of YOLOv6 network [20].

The structure of the YOLOv6 network consists of a backbone, neck, and head for object detection. Fig. 2 illustrates the structure of the YOLOv6 network. The details of each are discussed in the following section.

1) The backbone architecture of YOLOv6 network: The backbone architecture of the YOLOv6 network serves as the foundation for its object detection capabilities. It incorporates a deep neural network with a series of convolutional layers to extract meaningful features from input images [21]. The backbone architecture of YOLOv6 follows a hierarchical structure comprising multiple residual blocks with different filter sizes. These residual blocks enable the network to learn and capture features at various spatial scales, allowing for the accurate detection of objects of different sizes and aspect ratios. Additionally, the backbone architecture incorporates skip connections that facilitate the flow of information across different layers, enabling the network to capture both low-level and high-level features. By leveraging this hierarchical backbone architecture, YOLOv6 can effectively analyze input images and generate precise bounding box predictions for objects, including license plates, with high accuracy and efficiency. Fig. 3 shows the structure of the backbone in the YOLOv6 network.

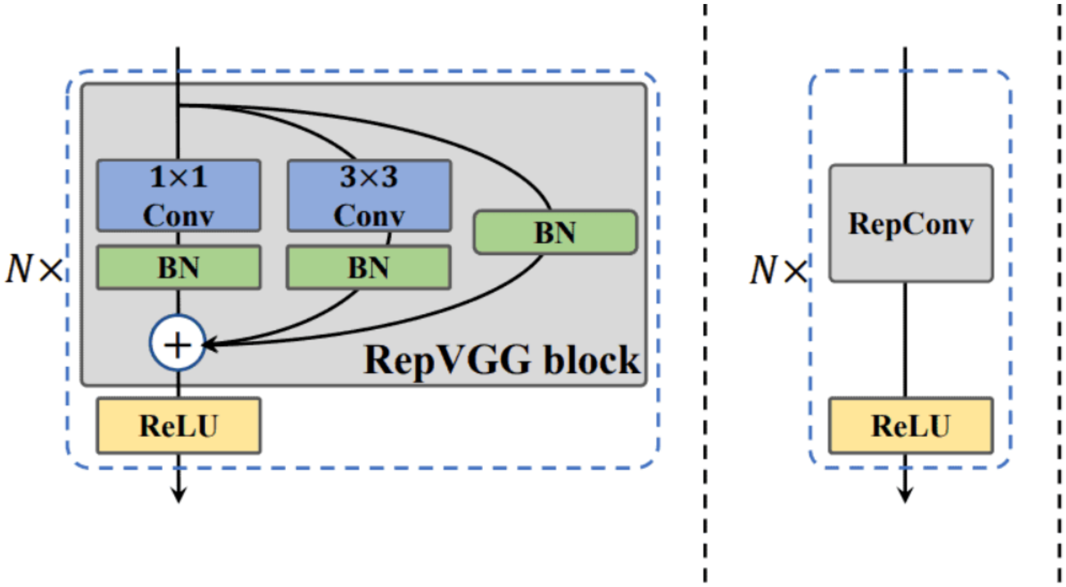

Fig. 3. The structure of the backbone in the YOLOv6 network [22].

2) The neck architecture of YOLOv6 network: The neck architecture of the YOLOv6 network complements the backbone architecture by refining and fusing features for more accurate object detection [21]. It incorporates spatial pyramid pooling modules to capture contextual information at multiple scales and feature fusion layers to combine features from different levels. This integration of features enhances the network's ability to detect objects of varying sizes and improves its overall precision and accuracy. By leveraging the neck architecture, YOLOv6 can effectively integrate global and local contextual cues, resulting in more robust and informed object detection predictions, including accurate identification of license plates.

3) The detection head of the YOLOv6 network: The detection head of the YOLOv6 network is responsible for generating precise bounding box predictions and class probabilities for detected objects, including license plates [23]. It takes the fused features from the neck architecture as well as processes them to identify and localize objects within the input image [21]. The detection head consists of a set of convolutional layers followed by anchor boxes, which serve as prior knowledge about the expected sizes and shapes of objects. Fig. 4 demonstrates the structure of the head in the YOLOv6 network.

As shown in Fig. 4, the convolution layers aid in capturing more detailed and discriminative information for accurate object detection. The anchor boxes, defined with different aspect ratios and scales, are used to predict bounding boxes for potential objects at various positions and sizes. The detection head employs a combination of objectness scores, class probabilities, and bounding box coordinates to generate the final predictions. Objectness scores indicate the presence of an object within a bounding box, while class probabilities specify the likelihood of the object belonging to a specific class, such as a license plate. The predicted bounding box coordinates provide precise localization of the detected object.

4) Analysis of YOLv6 performance: This section presents the analysis of the YOLOv6 performance. This analysis intends to report the efficiency of this algorithm used in object detection. Fig. 5 illustrates a graph for this analysis [21]. The graph represents a comparison of different YOLO models, namely YOLOv5, YOLOv6, YOLOv7, YOLOX, and PP-YOLOE, in terms of average precision (AP) with respect to latency. The X-axis represents latency, which refers to the time taken for the model to process input, and the Y-axis represents average precision (AP), a metric that measures the accuracy of the model's predictions.

As shown in Fig. 5, by analyzing the graph, we can observe the performance of each model in terms of AP at different latency levels. The comparison allows us to evaluate how well the models balance accuracy and speed in object detection tasks. Based on the graph, it is evident that YOLOv6 achieves better results compared to the other models across various latency levels. The higher AP values indicate that YOLOv6 provides more accurate object detection compared to YOLOv5, YOLOv7, YOLOX, and PP-YOLOE. The superiority of YOLOv6 can be attributed to several factors, such as architectural improvements, optimization techniques, or the incorporation of novel features or modules. To further justify why YOLOv6 outperforms other models, it would be necessary to refer to specific technical details and research papers related to YOLOv6. These details could include architectural enhancements, algorithmic advancements, or optimizations implemented in YOLOv6 that contribute to its improved accuracy while maintaining acceptable levels of latency.

This study justifies the selection of YOLO (You Only Look Once) as the base detection method for license plate recognition, highlighting its efficiency in real-time object detection with a balance between accuracy and speed. YOLO's unique single-pass approach and grid-based analysis set it apart from other methods. The research further strengthens this choice by comparing various YOLO-based versions, presenting experimental results that affirm YOLOv6 as superior. The comparisons consider accuracy, computation costs, and overall performance, providing empirical evidence that establishes YOLOv6 as the most effective and efficient version for license plate recognition based on conducted experiments results.

C. Dataset Preprocessing

In the dataset preprocessing phase, the license plate images undergo the necessary techniques to normalize them and augment the training dataset. In this study, normalization involves resizing, cropping, and color space conversion to standardize the images, and augmentation techniques such as rotation, scaling, and noise addition are applied to increase dataset diversity. These preprocessing steps ensure consistent image sizes, isolate the license plate region, and enhance the dataset's variability. By employing these techniques, the model becomes more robust, able to manage various scenarios, and generalizes better for accurate license plate recognition in smart parking management systems.

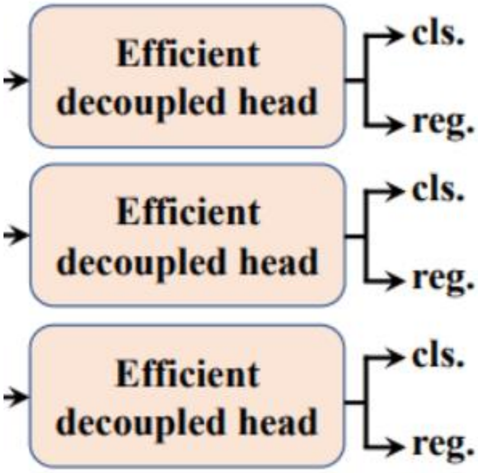

Fig. 4. Structure of detection head of YOLOv6 Network [22].

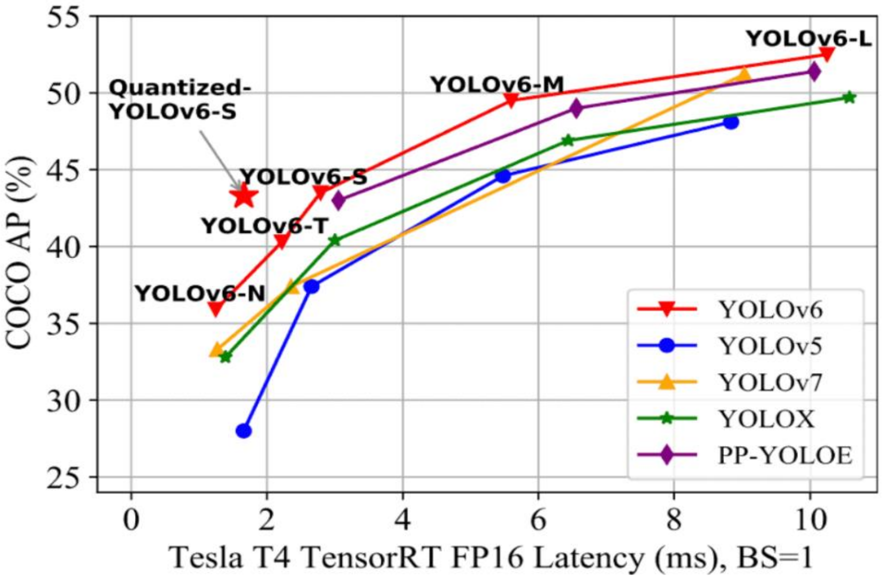

Fig. 5. Comparison of YOLO-based algorithms [21].

D. Model Training

We use transfer learning for YOLOv6 model training. To generate the YOLOv6 model for license plate recognition using transfer learning, the following steps are taken in the Model Training phase:

1) The deep learning model with the selected YOLOv6 architecture is initialized. The pre-trained weights from the base YOLOv6 model serve as the starting point for the transfer learning process. These weights contain valuable knowledge gained from pre-training on large-scale datasets, which aids in faster convergence and better generalization.

2) The initialized model is trained using the annotated license plate dataset. The training process involves feeding the license plate images as input to the model and optimizing a suitable loss function, such as categorical cross-entropy or mean squared error. The loss function measures the discrepancy between the forecasted outputs as well as the ground truth labels, driving the model to minimize the error and improve its performance.

3) Fine-tuning the model is a critical step to enhance its performance further. Hyperparameters, including the learning rate, batch size, and optimizer choice (such as Adam or SGD), are adjusted to achieve better convergence and generalization. Fine-tuning allows the model to adapt to the specific characteristics of the license plate recognition task and improves its ability to detect and recognize license plates accurately.

By following these steps, the pre-trained YOLOv6 model is effectively utilized as a starting point for training the license plate recognition model. Through transfer learning and fine-tuning, the model is optimized to leverage the knowledge from the pre-trained weights, adapt to the license plate recognition task, and achieve improved accuracy and performance in identifying and localizing license plates within smart parking management systems.

E. Model Validation

The YOLOv6 model for license plate recognition can be validated through evaluation on a validation dataset and the utilization of metrics such as accuracy, precision, recall, and F1-score. By assessing the model's performance on unseen data, researchers can detect overfitting or underfitting issues and make necessary adjustments. Metrics like accuracy, precision, recall, and F1-score provide quantitative measures of the model's license plate recognition capability, including overall correctness and avoidance of false positives and false negatives. Validating the YOLOv6 model using these approaches ensures its effectiveness and reliability in accurately identifying and localizing license plates in smart parking management systems.

F. Model Testing

After generating the YOLOv6 model and validation process, it is crucial to test and deploy the model effectively. Testing involves evaluating the model's performance using a diverse test dataset, comparing its predictions with ground truth labels, and calculating performance metrics such as accuracy, precision, recall, and F1-score. This testing phase ensures that the model performs well on unseen data and provides reliable license plate recognition results. Once the model has been thoroughly tested and meets the desired performance criteria, it can be deployed in real-world applications. Deployment involves integrating the model into the smart parking management system, optimizing its computational requirements for real-time performance, and considering factors such as handling input data streams, integrating with existing infrastructure, and creating an end-to-end pipeline for license plate recognition. Continuous monitoring and maintenance are essential post-deployment to monitor the model's performance, collect feedback, and address any issues that arise, ensuring consistent and reliable license plate recognition in real-world scenarios.

IV. Results and Discussions

Analyzing the generated YOLOv6 model for license plate recognition involves evaluating its performance using metrics such as precision, recall, and F1-score.

- Precision measures the proportion of correctly identified license plates among all the predicted license plates. It quantifies the model's ability to avoid false positives, which are instances where the model incorrectly identifies non-license plate regions as license plates. A higher precision shows that the model has a lower rate of false positives, resulting in more accurate and reliable license plate recognition.
- Recall, on the other hand, measures the proportion of correctly identified license plates among all the actual license plates present in the dataset. It assesses the model's ability to avoid false negatives, which occur when the model fails to identify actual license plates. A higher recall indicates that the model has a lower rate of false negatives, meaning it can effectively identify and capture most of the license plates present in the dataset.
- F1-score is a metric that combines precision and recall into a single value, providing a balanced measure of the model's overall performance. It is the harmonic mean of precision and recall and takes into account both false positives and false negatives. A higher F1 score indicates a better balance between precision and recall, signifying a model that can accurately identify license plates while minimizing both types of errors.

The results of precision curves, precision-recall curve, F1-score curve, and recall curve are shown in Fig. 5, 6, 7, and 8.

As shown in Fig. 6, the link between confidence and precision rate is graphically represented by the precision curve. The X-axis displays confidence levels, which indicate the model's certainty in its predictions, while the Y-axis displays the precision rate, which measures the proportion of correctly identified license plates among all the predicted license plates at different confidence thresholds. In the precision curve, as the confidence threshold increases, the precision rate tends to improve. This means that when the model is more confident in its predictions, it is more likely to correctly identify license plates, resulting in a higher precision rate. A high precision rate indicates that the generated model can achieve accurate results with a lower rate of false positives.

As demonstrated in Fig. 7, the X-axis displays confidence levels, indicating the model's certainty in its predictions, while the Y-axis displays the recall rate, which measures the proportion of correctly identified license plates among all the actual license plates at different confidence thresholds.

When analyzing the recall curve, as the confidence threshold increases, the recall rate typically decreases. This means that as the model becomes more conservative in its predictions, it may miss some actual license plates, resulting in a lower recall rate. However, a high recall rate indicates that the generated model can effectively identify a larger percentage of license plates in the dataset, minimizing false negatives.

Fig. 8 presents the Precision-Recall curve of the generated model. In this graph, the X-axis represents recall, which measures the proportion of correctly identified license plates among all the actual license plates, while the Y-axis displays the precision rate, which quantifies the proportion of correctly identified license plates among all the predicted license plates.

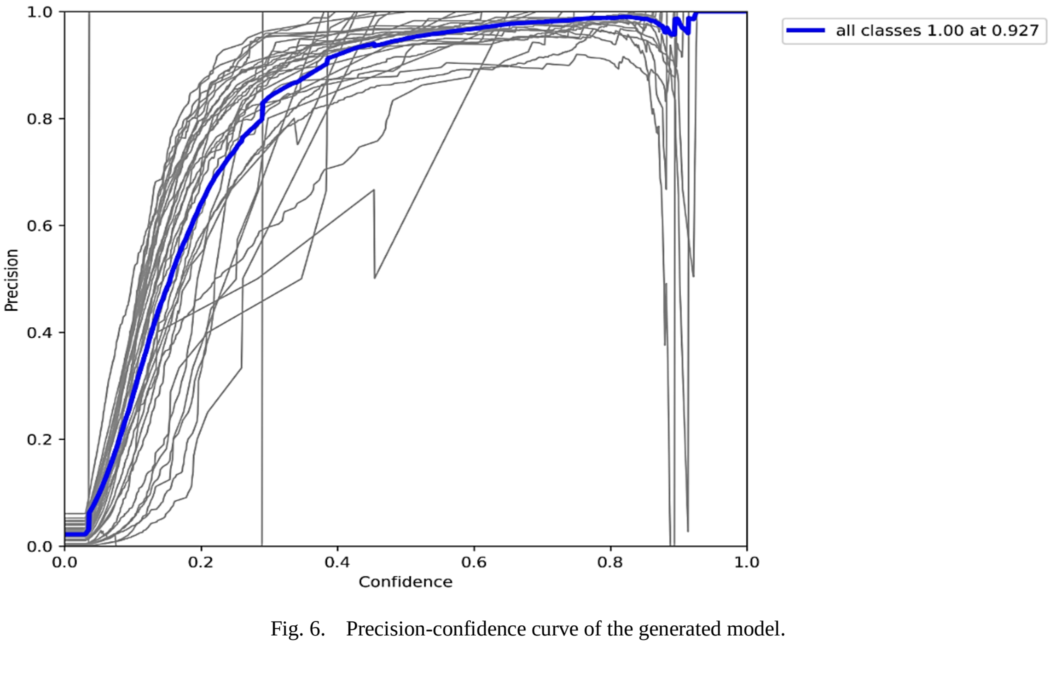

Fig. 6. Precision-confidence curve of the generated model.

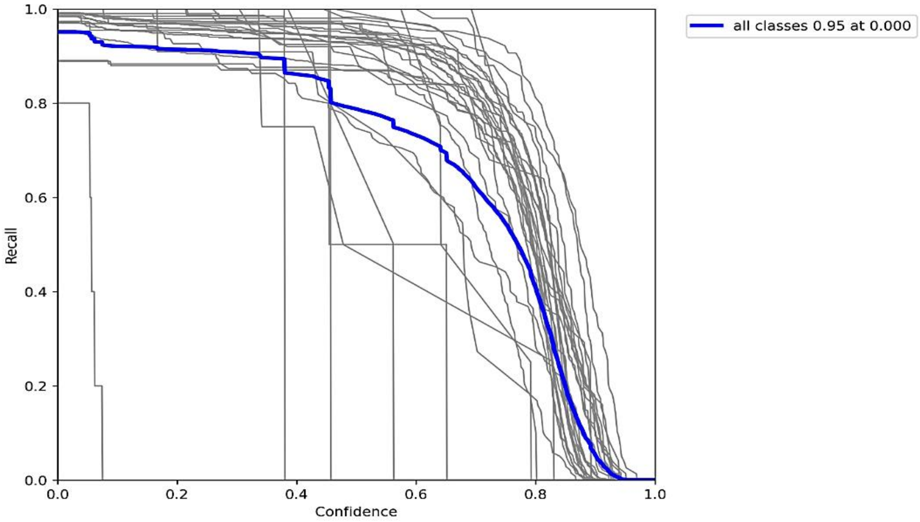

Fig. 7. Recall-confidence curve of the generated model.

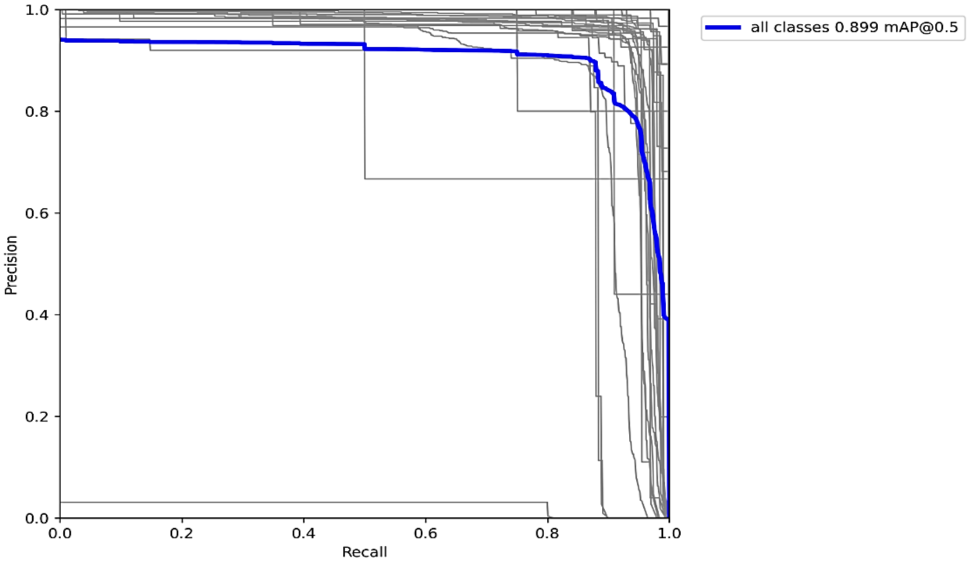

Fig. 8. The precision-recall curve of the generated model.

The precision-recall curve illustrates how changes in the recall threshold impact the precision rate and vice versa. As the recall threshold rises, the model becomes more inclusive and captures a higher percentage of actual license plates, resulting in an increase in recall. However, this may lead to more false positives, causing the precision rate to decrease. On the other hand, raising the precision threshold makes the model more conservative, reducing false positives but potentially missing some actual license plates, which lowers the recall rate. As experimental results show, analyzing the precision-recall rates obtained from the curve provides valuable insights into the accuracy and performance of the generated model in license plate recognition tasks.

Fig. 9 illustrates the F1-confidence curve, a graphical representation showcasing the relationship between confidence and F1 values. In this curve, the X-axis displays confidence levels, indicating the model's certainty in its predictions, while the Y-axis represents the F1 values, which is the harmonic mean of precision and recall.

The way that modifies how the confidence threshold impacts the F1 score is seen by the F1-confidence curve. As the confidence threshold increases, the model becomes more conservative in its predictions, resulting in a higher precision but potentially lower recall. Conversely, lowering the confidence threshold leads to a higher recall but may introduce more false positives, affecting precision. The F1 score strikes a balance between precision and recall, providing a comprehensive evaluation of the model's performance.

By analyzing the F1-confidence curve, we indicate that the generated model that achieves a high F1 score at an optimal confidence threshold indicates its capacity to precisely recognize license plates while minimizing false positives and false negatives.

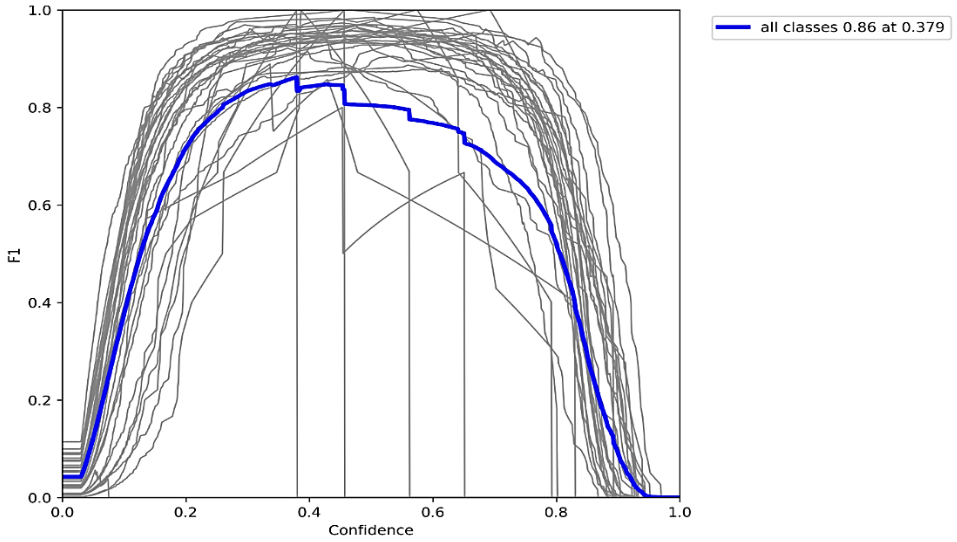

Fig. 9. F1-confidence curve of the generated model.

As reported results, the YOLOv6 achieves superior results in terms of high accuracy and low computation cost through a combination of innovative design features and improvements over its predecessors. The model's unique architecture, characterized by a single-pass approach and grid-based analysis, significantly contributes to its efficiency in real-time object detection. By efficiently dividing the input image into a grid and processing it in a single pass through the neural network, YOLOv6 minimizes computation costs while ensuring accurate detection. The model's ability to capture intricate details while maintaining computational efficiency is crucial for achieving high accuracy in license plate recognition. Additionally, the empirical evidence presented in the study, comparing various YOLO-based versions, underscores YOLOv6's superiority in terms of accuracy and computational efficiency.

Moreover, YOLOv6 addresses the critical balance between accuracy and speed, a key requirement for real-time applications such as license plate recognition. The enhancements in the model's architecture and algorithmic improvements contribute to faster processing times without compromising accuracy, making it well-suited for applications that demand both high precision and low computation costs.

As results, YOLOv6's achievement of better results in terms of high accuracy and low computation cost can be attributed to its innovative architecture, grid-based analysis, advancements in deep learning algorithms, and a meticulous design that prioritizes the critical balance between accuracy and speed. The empirical comparisons presented in the study validate these claims, providing tangible evidence of YOLOv6's effectiveness in meeting the requirements of accurate and efficient license plate recognition.

V. Conclusion

This research paper highlights the significance of License Plate Recognition (LPR) in IoT smart parking systems. It explores the use of traditional and deep learning-based methods for LPR detection, with a focus on why deep learning approaches are preferred. The challenges faced by deep learning-based LPR methods, particularly accuracy rate and computation cost, are addressed using insights from previous studies. The proposed method introduces a solution based on the YOLOv6 algorithm to overcome these challenges. The process entails creating a custom dataset, carrying out testing, validation, and training, and assessing the suggested model's performance. The experimental results demonstrate that the suggested method outperforms existing state-of-the-art methods, offering improved accuracy and reduced computation costs. The research contributes to enhancing LPR technology in IoT smart parking systems, enabling more efficient and reliable parking management solutions. For future work, an interesting direction would be to extend the proposed YOLOv6-based LPR system to incorporate real-time tracking of vehicles within the smart parking system. This would enable continuous monitoring and tracking of vehicles, providing valuable information for parking space availability and management. Cross-Domain License Plate Recognition: Another potential avenue for future research is to explore the applicability of the proposed method in cross-domain scenarios. Investigating the adaptation of the YOLOv6-based LPR system to different environments, such as night-time conditions, adverse weather, or different camera viewpoints, would contribute to the robustness and generalization capabilities of the model. This would expand the practical use cases of the system beyond traditional smart parking systems.

Faculty of Computer Science and Engineering, Universitas Multi Data, Palembang, Indonesia[1]

***Abstract*—Rapid advances in science and technology have significantly changed plant growth modeling. The main contribution to this transformation lies in using Machine Learning (ML) techniques. This study focuses on sorghum, an important agricultural crop with significant economic implications. Crop yield studies include temperature, humidity, climate, rainfall, and soil nutrition. This research has a novelty: the input factors for predicting sorghum plant growth, namely the treatment of applying organic fertilizer and dolomite lime to sorghum planting land. The three predicted sorghum plant growth factors, namely Height, Biomass, and Panicle weight, are the reasons for using the Multiple Adaptive Neural Fuzzy Inference System (MANFIS) model. This research investigates the impact of Membership Function and Degree on the MANFIS model. A comprehensive comparison of various membership functions, including Gaussian, Triangular, Bell, and Trapezoidal functions, along with various degrees of membership, has been carried out. The dataset used includes data related to sorghum growth obtained from field experiments. The main objective was to assess the effectiveness of membership and degree functions in accurately predicting sorghum growth parameters, consisting of height, biomass, and panicle weight. This assessment uses metrics such as MAPE (Mean Absolute Percentage Error), MAE (Mean Absolute Error), and RMSE (Root Mean Square Error) to evaluate the predictive performance of the MANFIS model when using four different types of membership functions and degrees. The results obtained the best level of accuracy in predicting panicle weight (ANFIS-3) with chicken manure treatment using the Trapezoidal membership function type and degree of membership function [3,3] with MAPE results of 5.77%, MAE of 0.2994, and RMSE of 0.395.**

I. Introduction

Rice is the staple food of the Indonesian population; rice production in Indonesia in the last five years (2018-2022) has continued to decline, from 59.2 million tons in 2018 to 54.74 million tons in 2022, as well as the harvested area which in 2018 reached 11.37 million ha to 10.45 million ha in 2022[1]. Therefore, alternative food is needed to replace rice to ensure food security in Indonesia. *Sorghum* is an alternative crop suitable for planting in less fertile areas, such as tidal land. Suboptimal tidal swamp land has low fertility, an acidic pH, and low nutrients [2]. Sorghum plants can also be used for food diversification other than rice to maintain food security in Indonesia. Sorghum is more drought tolerant than similar crops such as corn and wheat [3]. Sorghum is suitable for cultivation in Indonesia because of its drought tolerance and adaptability to tropical areas [4].

The main problems of plant growth in tidal land are the level of water saturation and anaerobic conditions in the rhizosphere, pyrite or sulfide materials found in the soil, toxicity of Al, Fe, and Mn; highly acidic soil reaction, and low content of N, P, K, Ca, and Mg [5] [6] [7] [8]. Enhancing soil fertility in tidal land areas can be achieved through the application of fertilizers [9]. In such regions, leveraging local resources for sustainable agricultural practices is essential. One viable option is the utilization of organic fertilizers, such as chicken manure, cow manure, and vermicompost [10]. These locally available resources provide essential nutrients to the soil and promote soil health and microbial activity. By adopting a strategy that combines the application of these organic fertilizers with tidal land management practices, farmers can effectively improve soil fertility while minimizing the environmental impact, contributing to both agricultural productivity and environmental sustainability [11].

Many further research studies within the sorghum domain utilize machine learning techniques. These encompass efforts to predict sorghum biomass [12], detect and measure sorghum head counts [13], and make estimations of sorghum crop yields through machine learning algorithms [14] [15]. In combination, these investigations underscore the versatility and potential of machine learning in advancing various aspects of sorghum farming and administration, promoting more effective and sustainable agricultural practices.

Recent research on crop yield predictions utilizing machine learning techniques has emphasized the incorporation of several key input parameters. Rainfall has been identified as a significant factor in crop yield prediction, with multiple studies exploring its impact [16] [17] [18] [19], Temperature, humidity, and climate have also emerged as primary concerns, with some studies employing multiple linear regression to analyze weather forecasts by considering these parameters [16] [20] [18] [19] [21]. Moreover, soil pH and irrigation, as determinants of soil quality and optimal irrigation, are integral components of crop yield prediction models [19] [22] [21]. Wind speed, an external factor affecting plant growth, is considered in several research endeavors [20] [21]. Additionally, the location of crops is recognized as a crucial parameter in crop yield prediction, with crop location data serving as a variable in predictive analyses [18] [23]. These recent studies combine machine learning technology with a deep understanding of these diverse factors to enhance the accuracy of crop yield predictions. In this research, we introduce novelty by utilizing input parameters that include doses of organic fertilizers (chicken manure, cow manure, and vermicompost) and dolomite. Interestingly, these parameters have not been explored in previous studies related to predicting plant growth using machine learning technology.

Research conducted on predicting sorghum crop yields involve the use of various techniques, including the development of machine learning-based models. Several approaches have been employed, such as using TensorFlow with Convolutional Neural Networks (CNN) and Linear Regression to detect and estimate the weight of sorghum heads in images [24]. Additionally, a neuro-fuzzy model has been developed to predict the production rate of colorant extract from sorghum bicolor [25]. There has also been the development of image segmentation algorithms using deep learning CNN to detect and count sorghum heads[26]. Furthermore, frameworks and models have been created to detect leafhopper infestations in sorghum plants using deep learning technology and the YOLOv5m model [27]. Moreover, a performance evaluation of three deep learning methods, namely EfficientDet, SSD, and YOLOv4, has been conducted for the detection of sorghum heads in UAV RGB image [28].

In this research, a machine learning prediction model was developed using the Multiple Adaptive Fuzzy Inference System (MANFIS) model. ANFIS harnesses the strengths of neural networks and fuzzy logic, collectively enhancing its predictive capabilities [29]. This fusion of Neural Network and Fuzzy Logic equips ANFIS with a robust framework for precise predictions. Additionally, ANFIS possesses the unique capability to integrate both numerical and linguistic knowledge, making it adaptable and valuable across a broad spectrum of domains [30]. Its capacity to handle diverse types of information is a substantial asset, enabling it to efficiently address a multitude of real-world situations. However, integrating ANFIS models into soil remediation offers a promising avenue for restoring contaminated land to a fertile state, enabling sustainable agricultural practices. Many have widely implemented the ANFIS for prediction, classification, and clustering [31] [32] [33]. In this study, the input parameters and output parameters have more than one parameter. Hence, the prediction model in this study uses nine ANFIS models to predict three output parameters (height, biomass, and panicle weight) of sorghum plants with three different organic fertilizer treatment datasets.

The connection between membership functions and the degree of membership in ANFIS is essential for fuzzy logic-based inference. Here, the functions establish fuzzy sets, and the degree of membership measures how closely input values align with these sets. This association is vital for the fuzzy reasoning and decision-making procedures in the ANFIS framework. In the selection of membership functions and degrees of membership in the ANFIS model, research has highlighted the importance of choosing appropriate membership functions. Studies have explored various forms of membership functions, such as triangular, trapezoidal, shape-bell, and Gaussian, as well as the selection of the correct number of membership functions [34]. The choice of appropriate membership functions can have a significant impact on the performance of the ANFIS model [35]. Experiments are often employed to determine the optimal membership functions, allowing precise adjustments to the system's performance [36]. Over time, research continues to develop best practices in the selection of membership functions and degrees of membership to enhance the performance of ANFIS-based systems. Therefore, in this study, to optimize the accuracy of prediction results using the MANFIS model, the selection of membership function types and degrees of membership is conducted on nine ANFIS models. Four membership functions and four combinations of degrees of membership will be evaluated for each input and output parameter of the MANFIS model designed to obtain the best prediction results for sorghum plant growth.

This research advances the field of plant growth prediction through machine learning by introducing new input factors, such as organic fertilizer dosage and dolomite, which previous studies have not explored. In this study, we present novelty by including input variables such as the amount of organic fertilizer (chicken manure, cow manure, and vermicompost) and dolomite. Previous studies on predicting plant growth using machine learning technology did not investigate these variables. Additionally, it emphasizes the importance of carefully choosing appropriate membership functions for the ANFIS model and conducting experiments to improve its performance. These efforts contribute to developing best practices in this domain, enhancing the accuracy and effectiveness of predicting crop yields.

II. Related Works

The choice of membership function significantly influences the prediction model's accuracy when using ANFIS. One study compared eight different ANFIS membership functions to optimize ERP satisfaction values, ultimately revealing that the triangular membership function yielded the best prediction results [37]. To guarantee reliable and accurate predictions, the research prioritized two crucial factors: the number of inputs within the training dataset and the selection of the membership function within the ANFIS model. This optimization procedure included comparing outcomes with techniques like Particle Swarm Optimization and Genetic Algorithms [36]. Furthermore, researchers conducted performance evaluations to assess how effectively the ANFIS model addressed various classification problems by investigating four popular forms of membership functions: triangular, bell-shaped, trapezoidal, and Gaussian [35]. Another study delved into the impact of different membership function types, specifically triangular, trapezoidal, and Gaussian, on the performance of a fuzzy logic controller [38]. In a different context, researchers employed two approaches to generate Gaussian and triangular fuzzy membership functions using fuzzy c-means for predicting sunspots [39]. These various investigations collectively contribute to our understanding of the significance of membership functions and their impact on ANFIS model performance in different applications. In this research, a comparison was carried out among four types of membership functions and four combinations of membership degree functions across nine ANFIS models employed in a machine learning framework for predicting the growth of sorghum. This comparison aims to determine the most accurate prediction results within the constructed model.

The ANFIS model utilizes the Takagi-Sugeno rule set for its fuzzy inference system. Eq. (1) and Eq. (2) present a standard rule set for the commonly used first-order Takagi-Sugeno fuzzy model, which includes two fuzzy if-then rules [40].

Rule 1: If (x is A_1) and (y is B_1), then: $Z_1 = p_1x + q_1y + r_1$ (1)

Rule 2: If (x is A_2) and (y is B_2), then: $Z_2 = p_2x + q_2y+ r_2$ (2)

where, p_1, p_2, q_1, q_2, r_1, and r_2 are linear, and A_1, A_2, B_1, and B_2 are non-linear parameters.

In Fig. 1 shows the structure of ANFIS, which consists of five layers [41]. The framework of the ANFIS method has 5 (five) layers, namely the fuzzification layer, the rule layer, the normalization layer, the defuzzification layer, and a single neuro result [42] [43].

- Layer 1: This layer serves as the fuzzification layer, where each neuron's output corresponds to the degree of membership determined by the input membership function. The fundamental categories of membership functions include four types: triangular, trapezoidal, bell-shaped, and Gaussian [35].

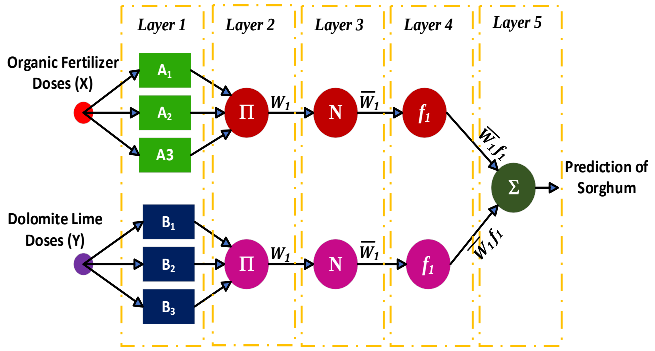

Fig. 1. A schematic of an ANFIS structure.

The triangular membership function (Trimf) stands out as the most straightforward among the various membership functions. It requires three parameters to define the three points, as illustrated in Eq. (3).

$$Trimf(x,a,b,c) = max\left(min\left(\frac{x-a}{b-a},\frac{c-x}{c-b},0\right)\right) \quad (3)$$

where the value a < b < c which represents the coordinates of the Trimf on the x-axis.

Eq. (4) illustrates how four scalar parameters define the curve of the trapezoidal membership function (Trapmf).

$$Trapmf(x,a,b,c,d) = max\left(min\left(\frac{x-a}{b-a},1,\frac{d-x}{d-b},0\right)\right) \quad (4)$$

where the value a < b < c < d which represents the coordinates of the Trapmf on the x-axis

The general bell-shaped membership function (Gbellmf) features a symmetric shape resembling a bell, as illustrated in Eq. (5).

$$Gbellmf(x,a,b,c) = \frac{1}{1+\left[\frac{x-c}{a}\right]^{2b}} \quad (5)$$

where, c is the center of the curve in the universe of speech, a determines the width of the bell-shaped curve, and b is a positive integer.

The Gaussian membership function (Gaussmf) relies on two parameters: c to locate the center and σ to specify the curve's width, as shown in Eq. (6).

$$Gaussmf(c,\sigma) = e^{-\frac{1}{2}\left(\frac{x-c}{\sigma}\right)^2} \quad (6)$$

where, c is the center of the cluster and width value σ are used to describe the Gaussmf.

- Layer 2: This layer comprises a constant neuron (represented by the symbol Π), which computes the product of all input values, as indicated in Eq. (7).

$$\boldsymbol{wk} = \boldsymbol{\mu Ak} \,.\, \boldsymbol{\mu Bk} \quad (7)$$

Typically, practitioners use the AND operator and refer to the result of this computation as the firing strength of a rule. Each neuron corresponds to a specific rule indexed ask.

- Layer 3: Each neuron in this layer is a constant neuron, represented by the *N*. The calculation takes the *k* firing strength (*wk*) ratio to the total sum of firing strengths in the second layer, as shown in Eq. (8).

$$\overline{w}_k = w_k w_1 + w_2, \quad i = 1,2 \quad (8)$$

The result obtained from this calculation is termed the normalized firing strength.

- Layer 4: This layer consists of neurons that adapt to an output, as shown in Eq. (9).

$$\overline{w}_k f_k = \overline{w}_k \langle q_k Z_{t-1} + r_k Z_{t-2} + s_k \rangle \quad (9)$$

where, $\overline{w}_k$ is the normalized firing strength in the third layer and qk, rk, and sk are the parameters of the neuron. These parameters are commonly called consequent parameters.

- Layer 5: This layer comprises a solitary neuron (represented by a symbol) that results from summating all outputs from the fourth layer, as depicted in Eq. (10).

$$\sum \overline{w}_k f_k = \frac{\sum_k w_k f_k}{\sum_k w_k} \quad (10)$$

A. *Proposed Method*

The research methodology aims to predict Sorghum growth using MANFIS (Multiple Adaptive Neuro-Fuzzy Inference System) models, emphasizing optimizing the selection of membership functions and membership degrees to achieve the highest accuracy, as depicted in Fig. 2. Data collection involved conducting experiments that utilized three types of organic fertilizers: chicken manure, cow manure, and vermicompost, in combination with dolomite lime on tidal soil. The experimental design employed a two-factor factorial design. The data obtained from these experiments served as the MANFIS model's dataset to predict three sorghum growth parameters: height, biomass weight, and panicle weight. The dosage of organic fertilizers and dolomite lime forms the basis for these predictions.

Fig. 2. Research methodology.

The initial phase of our research began with problem identification, focusing on utilizing organic fertilizer comprising chicken manure, cow manure, and vermicompost, which was applied to tidal lands to nurture sorghum plants. Subsequently, we collected data, drawing information from the growth records of sorghum plants cultivated on tidal lands subjected to three different organic fertilizer treatments or doses.

1) Vermicompost fertilizer: The treatment parameter for vermicompost fertilizer used four doses, namely: 0, 2.5, 5, and 7.5 tons/ha, combined with two doses of dolomite lime (0 and 0.404 tons/ha) and repeated three times.

2) Chicken manure: The treatment parameters of chicken manure used four doses, namely: 0, 5, 6.5, and 8.5 tons/ha, combined with two doses of dolomite lime (0 and 0.404 tons/ha), and repeated three times.

3) Cow manure: The treatment parameter for cow manure used four doses, namely: 0, 5, 10, and 15 tons/ha, combined with two doses of dolomite lime (0 and 1.84 tons/ha), and repeated three times.

The researchers obtained the dataset by conducting experimental sorghum cultivation in a greenhouse. We applied organic fertilizer to the cultivated land two weeks before planting sorghum. After 105 days, we harvested the sorghum plants and measured three growth parameters: height, biomass, and panicle weight.

In the subsequent phase, we conducted data training using four different membership functions, namely triangular, trapezoidal, bell-shaped, and gaussian, to achieve the highest level of accuracy. We utilized 70% of the entire dataset in the training phase and executed the training process on nine ANFIS models. Fig. 3 illustrates the configuration of the MANFIS model designed for chicken manure fertilizer treatment. This model comprises three ANFIS components, denoted ANFIS-1, ANFIS-2, and ANFIS-3. The input variables for their membership functions are characterized by degrees of membership, specifically (4, 2). In particular, the dosage of chicken manure fertilizer has four membership degrees, while dolomite lime has two membership degrees.

In this process, the training data, randomly selected from a dataset, is employed to train individual ANFIS models using distinct types and degrees of membership functions. There are four distinct types of membership functions and four combinations of membership function degrees applied during this training phase. The ANFIS model training utilizes these combinations of membership function types and degrees, including Triangular, Trapezoidal, Generalized bell-shaped, and Gaussian functions, along with four degrees of membership functions: {3,2}, {3,3}, {2,2}, and {4,2}.

Using these diverse combinations of membership function types and degrees, we assess the accuracy of the prediction outcomes for each ANFIS model using three accuracy measurement indicators: Mean Absolute Percentage Error (MAPE), Mean Absolute Error (MAE), and Root Mean Square Error (RMSE). We derive the formulas for calculating the accuracy of prediction results from Eq. (11), (12), and (13) as detailed in reference [44].

$$MAPE = \frac{1}{n}\sum_{i=1}^{n}\left[\frac{A_t - P_t}{A_t}\right] x\ 100\% \quad (11)$$

$$MAE = \frac{1}{n}\sum_{i=1}^{n}[P_t - A_t] \quad (12)$$

$$RMSE = \sqrt{\frac{1}{n}\sum_{i=1}^{n}(A_t - P_t)^2} \quad (13)$$

where, A_t represents the target value, P_t refers to the prediction value (the model's output), and n is the number of data points.

III. Result and Analysis

The results of the ANFIS model's accuracy evaluation, including three prediction accuracy metrics (MAPE, MAE, and RMSE), along with the utilization of four types of membership functions and four degrees of membership functions for each treatment related to the application of organic fertilizer and dolomite lime, have been recorded in Tables I, II, and III. These results specifically relate to three observed output variables: the sorghum plant's height, biomass weight, and panicle weight.

Table I presents the accuracy assessment results for MANFIS models (ANFIS-1, ANFIS-2, and ANFIS-3) using the metrics MAPE, MAE, and RMSE. These results stem from the training and testing processes conducted on data from the chicken manure treatment dataset. To streamline the process of identifying the membership function types and degrees that produce the most accurate results, we visually represent the accuracy measurements in Table I through Fig. 4, Fig. 5, and Fig. 6.

Fig. 4 visually depicts the accuracy outcomes in the context of chicken manure treatment, explicitly focusing on sorghum height (ANFIS-1) as the output parameter. It is evident from Fig. 4 that the highest accuracy values, as measured by the three accuracy assessment tools, are achieved when using the trapezoidal membership function type and membership function degrees {2, 2}. The corresponding accuracy values are MAPE of 13.23%, MAE of 11.1969, and RMSE of 14.7685.

Fig. 5 provides a visual representation of the accuracy results in the context of chicken manure treatment, explicitly highlighting the Biomass weight (ANFIS-2) of sorghum as the output parameter. The figure demonstrates that the highest accuracy values, as assessed by the three accuracy measurement tools, are attained when employing the Bell-shaped membership function type with membership function degrees {4, 2}. The corresponding accuracy values are MAPE of 20.89%, MAE of 2.5163, and RMSE of 3.2552.

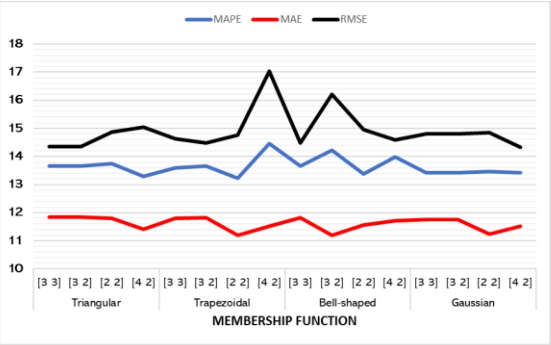

Fig. 4. The prediction accuracy level of sorghum height in chicken manure treatment.

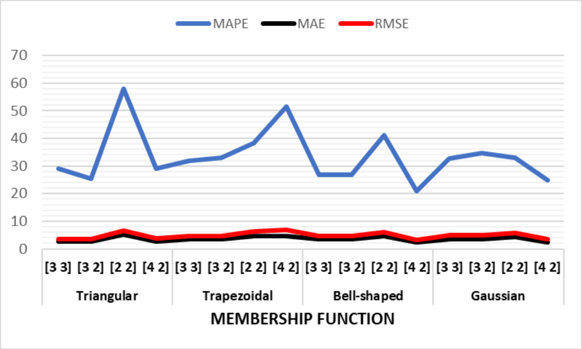

Fig. 5. The prediction accuracy level of sorghum biomass in chicken manure treatment.

Fig. 6 visually represents the accuracy outcomes in the context of chicken manure treatment, explicitly focusing on sorghum's Panicle weight (ANFIS-3) as the output parameter. Fig. 6 shows that the highest accuracy values, as measured by the three accuracy assessment tools, are achieved when using the Trapezoidal membership function type and membership function degrees {3, 3}. The corresponding accuracy values are MAPE of 5.77%, MAE of 0.2994, and RMSE of 0.395.

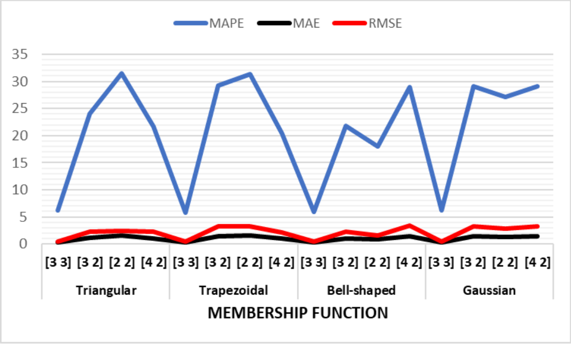

Fig. 6. The prediction accuracy level of sorghum panicle weight in chicken manure treatment.

To identify the membership function types and degrees that offer the highest accuracy in treatments involving cow manure and vermicompost, a similar methodology was applied to that used in the chicken manure treatment. By assessing the accuracy using MAPE, MAE, and RMSE for three distinct organic fertilizer dosages in a tidal swamp area for sorghum growth, the specific membership function types, and degrees for the MANFIS model predicting sorghum growth are determined and outlined in Table IV.

TABLE IV. RESULTS OF MEMBERSHIP FUNCTION TYPE AND DEGREE SELECTION

MANFIS	Type Membership Function	Degree Membership Function
ANFIS-1	Trapezoidal	{2,2}
ANFIS-2	Bell-Shaped	{4,2}
ANFIS-3	Trapezoidal	{3,3}
ANFIS-4	Triangular	{3,2}
ANFIS-5	Trapezoidal	{2,2}
ANFIS-6	Triangular	{2,2}
ANFIS-7	Triangular	{3,3}
ANFIS-8	Triangular	{3,3}
ANFIS-9	Trapezoidal	{4,2}

Based on the accuracy testing results achieved through the utilization of four types of membership functions and four degrees of membership functions in the MANFIS model, as outlined in Table IV, we depict the schematic of the MANFIS model designed for predicting three sorghum plant growth parameters in tidal swamp land in Fig. 7.

Subsequently, the predefined MANFIS model, with the chosen membership function type and degree, is subjected to simulation using the Simulink tool. This simulation aims to predict sorghum plant growth based on input parameters related to organic fertilizer dosage and dolomite lime application. The MANFIS model is simulated in this study using the Matlab/Simulink tool, as shown in Fig. 8. The ANFIS simulation model loads the fuzzy inference system (fis) files, which are the result of the data training process on the ANFIS model. These files are the result of the data training process of the ANFIS model, according to the input parameters of organic fertilizer and the predicted output parameters. During this simulation, nine ANFIS models predict three output parameters, with three organic fertilizer treatments as inputs.

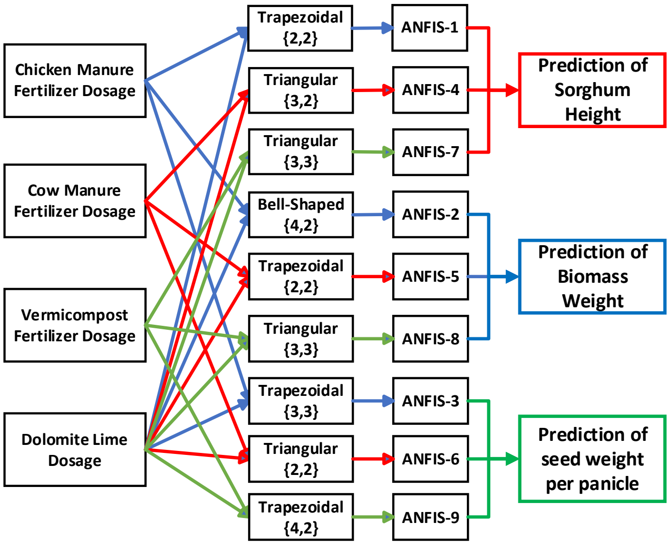

Fig. 7. MANFIS prediction model with selected membership function.

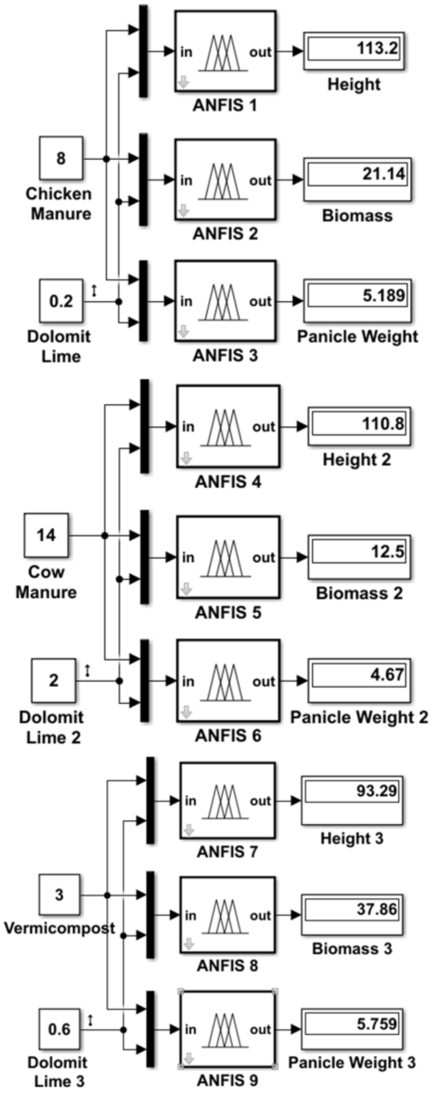

Fig. 8. Simulation of MANFIS prediction model.

In Fig. 8, for chicken manure fertilizer with a dose of 8 tons/ha and dolomite lime with a dose of 0.2 tons/ha, the predicted results are as follows: sorghum height (ANFIS-1) = 113.2 cm, sorghum biomass weight (ANFIS-2) = 21.14 tons/ha, and sorghum panicle weight (ANFIS-3) = 5.189 tons/ha. For cow manure fertilizer with a dose of 14 tons/ha and dolomite lime with a dose of 2 tons/ha, the predicted results are sorghum height (ANFIS-4) = 110.8 cm, sorghum biomass weight (ANFIS-5) = 12.5 tons/ha, and sorghum panicle weight (ANFIS-6) = 4.67 tons/ha. Similarly, for vermicompost fertilizer with a dose of 3 tons/ha and dolomite lime with a dose of 0.6 tons/ha, the predicted results are sorghum height (ANFIS-7) = 93.29 cm, sorghum biomass weight (ANFIS-8) = 37.86 tons/ha, and Sorghum panicle weight (ANFIS-9) = 5.759 tons/ha.

Table V presents the simulation results of predictions (height, biomass, and sorghum panicle weight) for various treatments with different doses of organic fertilizer and dolomite lime. In this Table V, each organic fertilizer is subjected to three combinations of organic fertilizer and dolomite lime doses, resulting in three predicted outcome parameters through the conducted simulations. This MANFIS model simulation (see Fig. 8) provides insights into the predicted outcomes obtained from applying various doses of organic fertilizer and dolomite lime on tidal land soil for sorghum plant growth prediction.

TABLE V. RESULTS OF MANFIS MODEL SIMULATION PREDICTION

Fertilizer Dosage (ton/ha)	Dolomite Lime Dosage (ton/ha)	Prediction Results		
		Height (cm)	Biomass (ton/ha)	Panicle weight (ton/ha)
Chicken Manure				
5	0.404	109.6	22.76	6.3
2	0.6	98.34	19.58	6.331
8	0.2	113.2	21.14	5.189
Cow Manure				
5	1.5	104.5	21	3.782
8	1	108.2	18.86	4.493
14	2	110.8	12.5	4.67
Vermicompost				
5	0.404	101.1	17.4	5.595
8	0.1	50.23	10.11	3.1
3	0.6	93.29	37.86	5.759

IV. CONCLUSION

The type of membership function used in this prediction model has a different type of membership function for each treatment of organic fertilizer on tidal soil for sorghum. The MANFIS model, using a dataset derived from observational data on sorghum plant height, biomass, and panicle weight with treatments of organic fertilizers (chicken manure, cow manure, vermicompost) in tidal soil, can be implemented to predict sorghum plant growth, including three predicted parameters: plant height, biomass, and panicle weight. The structure of the MANFIS model designed in this study consists of nine ANFIS models. The comparison of prediction accuracy results, utilizing three measurement tools - MAPE, MAE, and RMSE, demonstrates that the choice of membership function types and degrees influences the accuracy of prediction outcomes for each input data originating from the organic fertilizer treatment in tidal swamp land. This research achieved the highest prediction accuracy with the ANFIS-5 model for predicting the panicle weight of sorghum using Trapezoidal membership type and membership function parameters [3,3]. The model assessed the accuracy levels with a Mean Absolute Percentage Error (MAPE) of 5.77%, Mean Absolute Error (MAE) of 0.2994, and Root Mean Square Error (RMSE) of 0.395.

In conclusion, this research has successfully outlined a robust approach for predicting three sorghum plant growth parameters with high accuracy using the MANFIS model and optimal membership function selection. These findings hold significant potential for advancing agriculture and aiding stakeholders in making informed decisions in sorghum cultivation. Furthermore, this study also contributes to developing ANFIS modelling techniques in the agricultural context. The optimal membership function selection applied in this research can serve as a guideline for future similar studies in predicting sorghum plant growth and other agricultural research endeavours. In future research, researchers can incorporate additional environmental factors like climate and rainfall for predicting plant growth. Additionally, they can explore other machine learning models to compare their prediction accuracy.

A Hybrid Double Encryption Approach for Enhanced Cloud Data Security in Post-Quantum Cryptography

Manjushree C V[1], Nandakumar A N[2]
Information Science and Engineering, Vemana Institute of Technology (VTU University), Bangalore, India[1]
Computer Science and Engineering, VTU/City Engineering College, Bangalore, India[2]

***Abstract*—Quantum computers and research on quantum computers are increasing due to the efficiency and speed required for critical applications. This scenario also kindles the vitality of data protection needed against threats from quantum computers. Research in post-quantum threats is very minimal so far, but it is much needed to protect the enormous data stored in the cloud for healthcare, governmental, or any crucial data. This research work presents an advanced hybrid double encryption approach for cloud data security based on Post-Quantum Cryptography (PQC) to ensure the restriction of unauthorized access. The suggested approach combines the benefits of the NTRU encryption and AES encryption algorithms and works in hybrid mode, offering strong security while resolving issues with real-time performance and cost-efficiency. A streamlined key management system is set together to improve real-time processing, significantly reducing encryption and decryption delay times. Moreover, NTRU Encrypt dynamic parameter selection, which adapts security parameters based on data sensitivity, maintains accurate information and security. In addition to addressing real-time performance and data security, an innovative development in this method is known as Quantum-Adaptive Stream Flow Encryption (QASFE), which enables secure data sharing and collaborative working within a quantum-resistant framework. This innovative feature enhances data accessibility while maintaining the highest level of security. In the era of post-quantum cryptography, our multifactor authentication technique, integrating double encryption and QASFE, is a proactive and flexible solution for securing cloud data, and protecting data security and privacy against emerging threats.**

Keywords—Cloud data security; double encryption; Post-Quantum Cryptography (PQC); NTRU Encrypt; AES Encryption

I. Introduction

Data security in the cloud has become essential in the present digital landscape as organizations depend upon increasing amounts on cloud-based services to safeguard, analyze, and manage their data. The cloud certainly radiates in three areas: scalability, accessibility, and cost-effectiveness. Data breaches, insider threats, and the ever-changing character of attacks are just a few of the specific security challenges that it additionally raises. Cloud computing technology has rendered it possible for many firms to design and deploy software with greater efficacy and effectiveness in the cloud, enabling savings on the expenses of purchasing and maintaining the infrastructure [1]. The term "cloud computing" refers to the idea of rapid, on-demand network access to a pool of programmable computing resources (including networks, storage devices, servers, apps, and services). It enables these assets to be delivered and released rapidly, with the least amount of managerial work and service provider engagement. Since security is the primary concern in cloud computing, some users may find themselves comfortable transmitting information via the cloud. Cloud computing specialists have created certain secret keys for account security and use encryption methods to safeguard cloud servers [2, 3, 5]. To safeguard the data from threatening attacks, specific encryption techniques might be employed. The cloud security posture is strengthened through frequent security assessments, incident response plans, and adherence to industry-specific laws and standards.

This research study was established by combining different security strategies to achieve the objective of cloud data security. Combining these techniques creates an obstacle against security issues, which have been preventing the cloud's acceptance and effective functioning. The field of cryptography has evolved in reaction to this impending quantum threat, which has contributed to the conception of Post-Quantum Cryptography (PQC). The major goal of PQC is to provide encryption techniques and cryptographic primitives that are resistant to quantum attacks. Attacks are computationally expensive and consequently ineffective as an outcome. These basic hypotheses, on which conventional stocks depend, are no longer valid with the development of post-quantum computing [4]. A shield against security issues that have frequently prevented the cloud from functioning and growing effectively is created by combining these techniques. Data security in the cloud utilizes a sophisticated strategy that combines innovative technology, widely accepted practices, and stringent regulations to safeguard data from unauthorized access, data breaches [5], and other cyber consequences of these challenges. One such cryptographic method combines NTRU Encrypt and AES encryption, resulting in an effective Double Encryption method. NTRU Encrypt, a lattice-based encryption system developed to withstand the cryptographic flaws that quantum computers can eventually exploit, is one of the notable PQC algorithms in this field. NTRU Encrypt, an effective encryption algorithm constructed on the mathematical underpinnings of lattice-based cryptography, is at the core of PQC's promise [6].

The Advanced Encryption Standard (AES) [7, 8] has evolved as an essential component of contemporary cryptographic methods in the pursuit of secure data transmission and storage. AES has become a cornerstone of data security in several industries owing to its dependability and effectiveness in protecting sensitive data. As the secondary encryption layer, AES is essential to post-quantum cryptography and the idea of enhanced double encryption. It increases the quantum resistance offered by NTRU Encrypt and provides an additional level of security while also improving the impact and effectiveness of data protection as an entire.

Fig. 1 shows the essential steps in NTRU Encrypt and AES-based double encryption. It offers a strong security framework that makes use of the advantages of both encryption techniques to safeguard data in a way that is quantum-resistant while preserving computing effectiveness.

The following are the main contributions of this work:

- Post-Quantum Security: The primary contribution consists of implementing the post-quantum cryptography method, particularly NTRU Encrypt, to improve data security. It incorporates NTRU Encrypt, which is made resistant to quantum attacks, to address the immediate challenge that quantum computing presents to conventional cryptographic techniques.
- Double Encryption Strategy: Introduces a strong double encryption technique called the Double Encryption Strategy, which combines the advantages of the NTRU Encrypt and AES encryption techniques. Sensitive data is further protected with our dual-layered encryption strategy's extra degree of security.
- Key Management: Effective key management is essential for any encryption scheme, and the paper recognizes this by highlighting key generation as a significant contribution. It describes how to generate and manage cryptographic keys securely, which is crucial for the overall safety of the encryption system.

Quantum-adaptive Security: The primary benefit of this paper is the creation of quantum-adaptive security in the context of post-quantum cryptography. QASFE provides an unparalleled degree of adaptability and security by dynamically modifying encryption procedures based on the quantum threat level and data relevance.

This paper is structured as follows: Section II provides an overview of the literature review for the security of data in recent cloud computing research. Section III, a methodology is proposed to secure data prevention in cloud environments. Section IV presents the results and accompanying discussion, and Section V concludes this paper.

II. Literature Survey

A. Related Works

This section provides several recent cloud computing experiments. Even though many research efforts have focused on the security risks with cloud computing cryptographic techniques. Some researchers suggest employing innovative methods in addition to the strategies defined above to improve cloud computing security.

The literature review, which was conducted is provided in tabulated form (see Table I), provides an overview of the available work, and has established a ground for the proposed work. In this section, the approaches proposed by various researchers about the issue have been addressed for the recognition of the problem and understanding.

Singh, Prabhdeep, and Ashish Kumar Pandey, et al. [9]	Data Security in Cloud	This study offers a thorough analysis of the literature on data encryption, data concealment, and data protection challenges, as well as solutions for cloud data storage. The effectiveness of each strategy is then contrasted based on its features, advantages, and drawbacks.
A. Malviya, R. K. Dwivedi, et al. [10]	Comparison of container orchestration tool	This research will assist professionals in determining if they require an orchestrator that is connected to a certain technology or one that offers an independent solution. Data integrity, availability, and secrecy are all referred to be forms of security, though. As long as they don't provide or guarantee this for this paperwork, there could be major issues.
Achar, Sandesh, et al.,[11]	Infrastructure as Code (IAC) across multiple clouds	This research indicates that there are a lot of challenges with managing the infrastructure provisioning of enterprise SaaS applications, including configuration drift and the variety of cloud providers. Without compromising on stability or quality, IAC makes it possible to roll out novel application architecture versions rapidly. Anytime a cloud host isn't accessible, there should be a warning period before the services restart.
Singh, A. K et al. [12]	Protecting the cloud data from unauthorized access	The researchers' proposed method complicates cryptanalysis by changing the plain text alphabet's position using prime numbers and then performing the hybrid RSA algorithm, which makes it more challenging to factorize the variable used in key creation. The main problem with employing is excessive resource utilization, which eventually results in higher costs and longer wait times.
Nejatollaji et al. [13]	Resistance against the dangers of quantum computing	This study examines trends in lattice-based cryptographic methods, including recent fundamental concepts for the use of lattices in computer security, difficulties in implementing them in software and hardware, and new

	in post-quantum cryptography.	requirements for their adoption. The survey also offered insightful ideas that would enable the reader to concentrate on the mechanics of the computation ultimately required for mapping schemes on already-existing equipment or generating a scheme in part or in full on specialized hardware.
Dutta, Aritra, et al., [14]	Multi-cloud storage's security for preventing unauthorized people from accessing data	According to this research, the business decides to utilize a username and password along with the NTRU encryption technique to encrypt the data to increase security. By doing this, it is possible to ensure that even if an attacker obtains access to the encrypted data, they will not be able to decrypt it without the correct password.
Harjito, Bambang, et al., [15]	Threats to the security of digital information	This study's findings demonstrate that the NTRU algorithm's key generation and encryption times are quicker than those of the RSA technique. The NTRU approach is better advised for cloud storage security because of its higher level of resiliency security. The NTRU algorithm, on the other hand, employs a lattice-based strategy with strong key selection and is also difficult to solve.
Costa, Bruno, et al. [16]	Security in the quantum universal composability	In this work, they propose randomized variants of two well-known oblivious transfer protocols, one quantum, and the other post-quantum, with ring training and an error assumption. The accuracy is sacrificed in preference to cost savings with these biometric authentication systems that have been reduced. This paper highlighted contemporary technological technologies like cloud computing, it is now possible to access data from any location.
Tarannum, Ayesha, et al. [17]	Data security method using multi-modal biometric sensing and authentication	To enable robust data integrity verification and data security in distributed applications, a new integrity computational algorithm and an encryption method have been developed in this work. As a result, each user receives a unique set of variable keys during the encryption process for additional security. This paradigm, however, is unable to provide the needed results in real time for multi-modal biometric authentication.

B. Motivation of the Proposed Research

As we've seen, a lot of research has been done on encryption, and in the majority of post-quantum cryptography research, the ranking operations are performed only on the platform side. Therefore, it is necessary to propose the PQC with NTRU-AES Encrypt.

III. Proposed Methodology

The adoption of strong post-quantum cryptographic solutions receives priority in the strategy due to the impending threat posed by quantum technology. The introduction of a revolutionary Double Encryption methodology, which combines the benefits of the NTRU Encrypt and AES encryption methods while including novel elements to improve data security and accessibility, is a key component of this strategy. Furthermore, it enhances key management processes to improve real-time performance, reducing encryption and decryption lag and enabling safe, on-the-fly data transfer and retrieval. This improved Double Encryption technique uses NTRU Encrypt and AES encryption for key generation to provide a diverse defense against potential quantum and classical attacks, which is necessary to combat the growing threat of quantum attacks. In addition, the methodology provides an innovative Quantum-Adaptive Stream Flow Encryption (QASFE) component that addresses temporal performance measurements and creates a simplified key management system to reduce latencies. This method offers a thorough and effective method for protecting data in the post-quantum era of cryptography while working to significantly reduce the time needed for encryption and decryption, ensuring security and real-time data accessibility. It does this by dynamically adjusting security parameters and adapting key sizes to data priority. An overview of a proposed methodology for improving data security in cloud systems is provided in Fig. 2. Strong Post-Quantum Cryptographic solutions are required as quantum computers approach. To address this issue, we provide a new Double Encryption technique that combines the benefits of NTRU Encrypt and AES encryption besides incorporating innovative components that improve data security and accessibility.

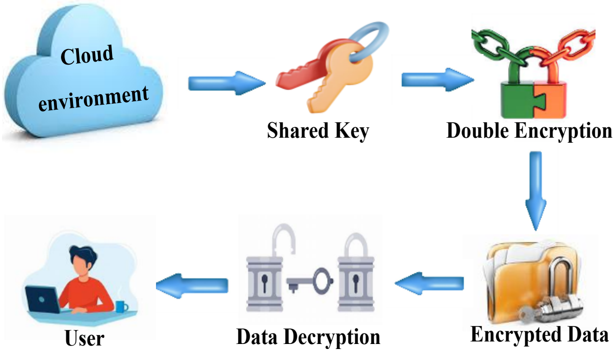

Fig. 2. Overview of proposed methodology for enhanced data security.

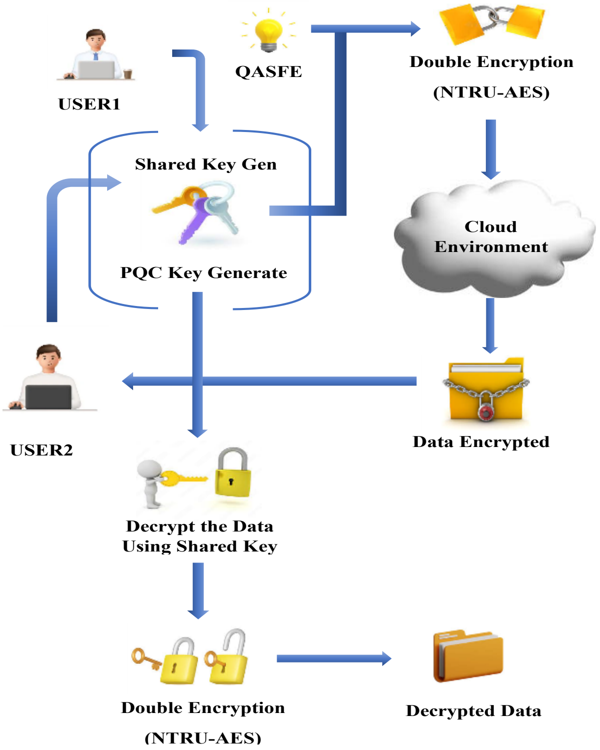

Fig. 3. Proposed architecture for double encryption data security.

To protect against quantum attacks, our enhanced Double Encryption method originates by using NTRU Encrypt and AES encryption for key generation. We optimize the key management procedure, though, to address queries regarding real-time performance. We want to decrease the latency of encryption and decryption by optimizing key generation and management. This would enable secure real-time data transfer and retrieval.

The combination of various cryptographic methods provides an effective defense against potential quantum attacks and classical attacks, improving the security posture generally. We aim to reduce the time needed for encryption and decryption by the optimization of the key generation procedure, enabling real-time data transfer and retrieval operations without sacrificing security. We add a unique component to our enhanced Double Encryption approach called Quantum-Adaptive Stream Flow Encryption (QASFE), which addresses the time performance measures. Due to the delay in period of time, our approach proposes a streamlined key management system that effectively creates and manages encryption keys to address this problem. Our approach, which relies on NTRU Encrypt and AES key generation, allows us to utilize smaller key sizes for high-priority data and larger key sizes for low-priority data to improve security. Our enhanced Double Encryption technique resolve the problems with real-time efficiency and also incorporates the revolutionary notion of Quantum-Adaptive Stream Flow Encryption (QASFE). We offer a comprehensive and effective method for protecting data in the era of post-quantum cryptography by enhancing key management, dynamically modifying security parameters, and implementing QASFE. Below Fig. 3, the proposed Double Encryption Data Security system is described. It combines NTRU Encrypt and AES encryption with a focus on quantum resistance, time efficiency, and data security in cloud environments. A strong and flexible security framework for the post-quantum generation is created by combining NTRU Encrypt, AES encryption, and the QASFE component.

A. *NTRU Encrypt - AES Encryption*

An asymmetric key (public - private key) and symmetric key (public key) cryptosystem termed the NTRU-AES encryption method is parameterized by three integers: (I, l, m), where p is greater than q, GCD (p, q) = 1, and N is prime. Polynomial rings P, Rp, and Rq should be considered. x^N-1 is an ideal in Z[x], that is, it contains all polynomials in H[x] that can be represented as multiples of a^I-1.

$$P = \frac{H[x]}{a^I - 1}, R_p = \frac{\frac{Z}{P} H[x]}{a^I - 1}, R_q = \frac{\frac{Z}{P} H[x]}{a^I - 1}$$

The equation for the product of two polynomials a(x), b(x) ϵ R is given as

a(x) * b(x) = c(x)

$$C_K = \sum_{i=j=k \ (mod\ N)} a_i \, b_{k-i}$$

Here;

The variable on which the phrase C_K depends is K, which most likely denotes the result or output of this function.

The term inside the sum, $i = j = k\ (mod\ N)$, designates the range of values that the index variable i can take. For each value of i that meets the congruence criterion, the product of two sequences, $a_i \ b_{k-i}$, is contained within the summation.

To indicate any positive integers w1 and w2, let τ (w1, w2) denotes the set of ternary polynomials given by,

$$\tau \text{ (w1, w2) } = \left\{ z(x) \ \in \right.$$

$$R \left. \begin{matrix} The\ d1\ coefficients\ of\ z(x)\ are\ equal\ to\ 1, \\ The\ d2\ coefficients\ of\ z(x) are\ equal\ to\ -1, \\ All\ other\ coefficients\ of\ z(x)\ are\ equal\ to\ 0 \end{matrix} \right\}$$

The polynomial z(x) with particular coefficient configuration composed the set τ (w1, w2). It includes polynomials with w1 coefficients of 1, w2 coefficients of -1, and w0 coefficients of 0. Based on these coefficient requirements, a set of polynomials can be defined utilizing this type of notation.

Key Generation: Implementing "NTRU-AES," a synergistic cryptographic technique that combines the mathematical efficacy of NTRU Encrypt for the generation of public and private keys with the dependability of AES for the generation of symmetric keys to produce a hybrid encryption system that provides unrivaled security in a quantum-resistant framework.

Choose private f(x) ϵ τ (w + 1, w)

Choose private v(x) ϵ τ (w, w).

- Generate f_Q (x) = f^{-1}(x) in R_q and f_p (x) = f^{-1}(x) in R_p
- Generate h (x) = f_q (x) * v(x) in R_q

Users' public keys are represented by polynomial h(x). Pair (f(x), f_p (x)) is the corresponding private key. The user can store only f(x) and regenerate f_p (x) from it. The encryption processes for plaintext m(x) ϵ R_p are indicated in the following phases.

Encryption: An essential part of encryption, and the security of the encryption protocol depends on the complexity of several mathematical challenges, such as the problem of encoding to obtain the cipher text message and the challenge of factoring the modulus employed in the polynomial ring.

- Select a random transitory key r(x) ϵ τ (w, w).

To perform this, employ an encoding technique that converts the message's plaintext to the ciphertext of the polynomial ring.

- Compute the ciphertext e(x) = pr (x) * h(x) + m(x) mod q.

The secure ciphertext matching the initial polynomial equation will be the result of adhering to NTRU and AES encryption (if used). The matching decryption method (which undoes the stages of encryption) can be used to decrypt this ciphertext when required. It can be safely stored in the cloud.

Decryption: Data is transformed into an unreadable format using encryption algorithms and keys when it is encrypted before it is stored in the cloud. Authorized users or programs must decrypt the data to access and use it.

- Compute a(x) = f(x) * e(x) mod q
- Center lift a(x) to a(x) ϵ R
- Compute m = f_p (x) * a (x) mod p

Notably, the polynomial multiplication in the final decryption phase is omitted by selecting f(x) = 1+p f_1 (x), where f1 R in the key generation step as f_p = 1 mod p.

The overall result, m, is the message that has been decrypted. It is calculated by multiplying the result of f_p (x) by the modified a(x), then applying modulo p.

The precise perception and relevance of these operations will depend on the exact meanings of f(x), e(x), f_p (x), q, and p as well as the context in which this decryption procedure is utilized. The specifics of this procedure may vary based on the particular mathematical problem or cryptographic technique being used, although it is frequently observed in certain mathematical procedures and systems.

B. *QASFE Framework*

The real-time performance and data security in the cloud are enhanced by using the sophisticated mathematical framework of Quantum-Adaptive Stream Flow Encryption (QASFE). Lattice-based cryptography, a field of mathematics that involves solving difficult problems involving lattices, like the Shortest Vector Problem (SVP) and Learning with Errors (LWE), is the foundational idea of QASFE. To improve data security and manage real-time performance issues in cloud-based scenarios, lattice problems are exploited for their inherent computational complexity.

Lattice Basis: A group of vectors that are linearly separate that span a lattice, b1, b2, ..., bn, define the lattice as L:

$$\text{Lattice L = Span (b1, b2, ..., bn)}$$

$$L = \{x \mid x = \sum(ai * bi) \text{ for } ai \in Z,\ 1 \leq i \leq n\}$$

In order to enhance the real-time performance of lattice-based cryptography, the aforementioned formula emphasizes improving the efficiency of lattice-based encryption and decryption, which is crucial for real-time performance:

$$O\ (D^3 * N * log^2\ (BS)) \qquad (1)$$

Here:

L represents the lattice

x represents any vector that belongs to the lattice L, the symbol $\sum$ denotes summation,

ai represents integer coefficients.

bi represents basis vectors of the lattice.

Z represents the set of integers.

D represents the dimension of the lattice,

N is the number of lattice vectors.

BS is a bound on the size of the coefficients.

To optimize these parameters in Eq. (1) to enhance the real-time performance of lattice-based cryptography, it might be required to decrease the dimension, restrict the number of lattice vectors, or adopt lower parameter bounds. With the aid of these optimizations, encryption and decryption processes will be quicker and more effective.

Shortest Vector Problem (SVP): In a given lattice L, the Shortest Vector Problem (SVP) attempts to identify the shortest non-zero matrix as follows:

$$SVP(L) = \min \{\|v\| \mid v \in L, v \neq 0\}$$

$$TP = (2^d) / (SVP\ (L)^c) * \log2(N) \qquad (2)$$

where,

SVP(L) represents the lattice's average shortest vector length L.

min {||v|| | v ϵ L, v $\neq$ 0} signifies the search for the minimum Euclidean norm (length) of a non-zero vector v within the lattice L, 2^d represents the dimensionality of the lattice's parabolic expansion in computational complexity.

log2(N) represents the performance impact of basis size is expressed by the logarithm of the number of lattice basis vectors with base 2,

Eq. (2) describes the dimension of the lattice, the average shortest vector length, the number of basis vectors, and the computing difficulty of solving the SVP in a lattice-based cryptographic system.

Learning with Errors (LWE): LWE utilizes an error e from a particular distribution D in conjunction with a vector s from Z q^n.

Finally, a set of noisy linear equations is computed:

a = (a1, a2, ..., an) ∈ Z q^n

b = <a, s> + e mod q

a ← Uniform polynomial in R q.

e ← Error polynomial in R q.

b = a*s + e

ciphertext = (a, b)

where,

'a' is a vector containing 'n' integers from the ring Z q.

's' is a secret vector (usually known only to the recipient of the ciphertext).

'e' is a noise term introduced to enhance security.

'<a, s> ' represents the dot product of 'a' and 's'.

The result 'b' is computed as the dot product plus the noise term, all taken modulo q.

ciphertext = (a, b) represents the result of the LWE encryption process.

This encryption procedure adds some noise ('e') to the ciphertext in the context of LWE, rendering it extremely difficult for attackers to extract the private vector's' from the ciphertext. Even with the use of innovative quantum techniques, it is difficult for attackers to separate the original plaintext from the ciphertext due to the inclusion of erroneous phrases in the encryption process.

From QASFE, the mathematical foundations of lattices, which include the Shortest Vector Problem (SVP) and Learning with Errors (LWE), enhance their resistance to quantum attacks. A scenario where data remains private and secure in the cloud has become possible due to the adoption of such secure cryptographic techniques, which become increasing essential as quantum computing develops.

IV. Results and Discussion

The proposed Double Encryption methodology has undergone thorough evaluation and testing. It combines NTRU Encrypt and AES encryption and is enhanced by the innovative QASFE component. In this instance, we examined the data security strategy, focusing on crucial performance indicators like entropy and throughput. The implementation was performed using Python programing language.

The table illustrates various settings for entropy, and throughput. The comparison of several algorithms is shown in Table II along with relevant metrics including the proposed method's entropy and encryption and decryption time.

TABLE II. Comparing several Techniques based on Variables Like Entropy, Encryption Time, and Decryption Time

Methods	Average entropy per byte	Throughput (kb/sec)
AES	3.840	192.00
RSA	3.095	100.06
BLOWFISH	3.892	197.20
PROPOSED	7.440	237.12

A. Entropy

The term "entropy" refers to a gauge of the random or unpredictability of data in the setting of data security and cryptography. Higher entropy values imply that the method of encryption is more advanced and secure since it becomes more difficult for a competitor to predict or decode the encrypted data. The average entropy per byte for several encryption techniques is shown in Fig. 4, providing insight into the level of data protection for every strategy. Particularly, the proposed method far outperforms the competition, sporting high average entropy per byte of 7.44, indicating a significant improvement in data security compared to the conventional encryption techniques.

B. Throughput

It is a metric for gauging the way effectively processors respond to an algorithm. The volume of data transferred between users serves as a measure of it. The file uploading phase must have a high throughput that allows for the transfer of all data. When uploading files, the proposed approach displays the highest throughput.

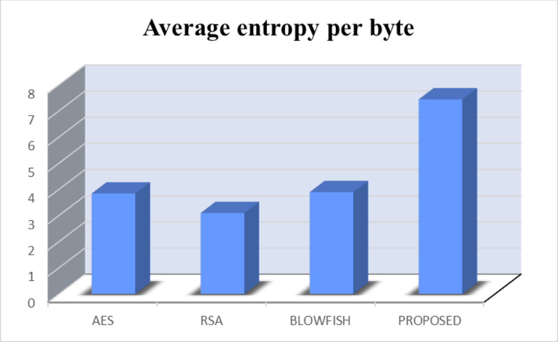

Fig. 4. Average entropy values of proposed model with existing AES, RSA and Blowfish algorithm. (x-axis: unit per byte, y-axis: Various encryption techniques).

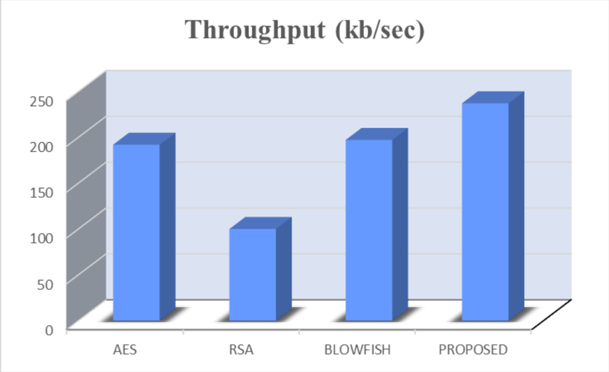

Fig. 5. Throughput values of the proposed model compared with existing AES, RSA, and Blowfish algorithm (x-axis: kB/s, y-axis: Various encryption techniques).

Fig. 5 compares the throughput of various cryptographic techniques, such as AES, RSA, and BLOWFISH, in kilobytes per second (kb/sec), with the proposed method. The proposed technique shines apart by possessing a higher throughput of 237.12 kb/sec, indicating the speed with which it processes data. These results imply that the proposed strategy demonstrates superior data processing abilities, making it an appropriate pick for applications that require both security and performance.

V. Conclusion

In conclusion, our suggested data security design offers a significant progress in the field of cloud security and data protection, specifically in considering recent developments in quantum computing. We have improved data security along with addressing critical concerns regarding real-time performance and computational prosperity by developing an innovative Double Encryption technique that combines NTRU Encrypt with AES encryption and the quantum-resistant properties of Post-Quantum Cryptography (PQC), offering an effective defense against the evolving threats and challenges of the digital era. Our core innovations, such as the unique QASFE, dynamic security parameter modifications, and improved key management, accessible the path for a data security system that is more time-sensitive, resource-effective, and resilient. This study reimagines the data protection environment by giving enterprises a strong, flexible, and quantum-resistant solution that enables them to protect their most important data while ensuring quick and secure data transfers.

Comprehensive Analysis of Topic Models for Short and Long Text Data

Astha Goyal[1], Indu Kashyap[2]
Research Scholar, Department of CSE, MRIIRS, Faridabad, India[1]
Professor, Department of CSE, MRIIRS, Faridabad, India[2]

***Abstract*—The digital age has brought significant information to the Internet through long text articles, webpages, and short text messages on social media platforms. As the information sources continue to grow, Machine Learning and Natural Language Processing techniques, including topic modeling, are employed to analyze and demystify this data. The performance of topic modeling algorithms varies significantly depending on the text data's characteristics, such as text length. This comprehensive analysis aims to compare the performance of the state-of-the-art topic models: Nonnegative Matrix Factorization (NMF), Latent Dirichlet Allocation using Variational Bayes modeling (LDA-VB), and Latent Dirichlet Allocation using Collapsed Gibbs-Sampling (LDA-CGS), over short and long text datasets. This work utilizes four datasets: Conceptual Captions and Wider Captions, image captions for short text data, and 20 Newsgroups news articles and Web of Science containing science articles for long text data. The topic models are evaluated for each dataset using internal and external evaluation metrics and are compared against a known value of topic 'K.' The internal and external evaluation metrics are the statistical metrics that assess the model's performance on classification, significance, coherence, diversity, similarity, and clustering aspects. Through comprehensive analysis and rigorous evaluation, this work illustrates the impact of text length on the choice of topic model and suggests a topic model that works for varied text length data. The experiment shows that LDA-CGS performed better than other topic models over the internal and external evaluation metrics for short and long text data.**

***Keywords*—Topic modeling; Nonnegative Matrix Factorization (NMF); Latent Dirichlet Allocation (LDA); evaluation metrics; short text mining; long text mining**

I. Introduction

Topic modeling has emerged as a powerful technique for uncovering hidden thematic structures within large volumes of textual data. It provides valuable insights by automatically identifying and extracting topics from unstructured text. It is a powerful tool for text analysis, and it has been used for various applications, including document classification, summarization, and recommendation systems. The basic idea behind topic modeling is to assume that each document in a corpus can be represented as a mixture of topics. The topics are latent variables that are not directly observed in the data. However, the topics can be inferred from the words that appear in the documents.

The performance of topic modeling algorithms is influenced by the characteristics of the data, including its length. Short text data poses challenges in finding the co-occurrence of topic patterns due to data sparsity, noise, topic imbalance, and lack of context [1]. Conversely, long text data presents computational complexity, overfitting, and interpretability issues when employing topic modeling algorithms. It is also hardly feasible to infer a unique and coherent topic from a long text because it usually contains various topics [2]. In this research domain, the foremost obstacle lies in selecting an optimal topic model that remains effective irrespective of the length of the text or that works for the specific application domain. The secondary challenge entails the fine-tuning and enhancement of the chosen topic model.

The present study aims to compare various topic modeling algorithms in the context of short and long text data, investigating their effectiveness and efficiency under different conditions. After an extensive review of existing literature in this field, LDA emerges as a top-performing model for extensive text data. At the same time, NMF excels in shorter text contexts [3], [4]. Recent attention has also turned to LDA's adaptability. One key feature that makes LDA adaptable is the use of the Bayesian framework. This means that LDA incorporates the prior knowledge about the data into the model, improving the model's performance, especially for small or noisy datasets. Therefore, this study evaluates the NMF topic model against two distinct variations of the LDA topic model: LDA employing Variational Bayes (LDA-VB) and LDA using Collapsed Gibbs Sampling (LDA-CGS). The goal is to introduce a topic modeling approach that remains effective regardless of the text length.

These models are subjected to rigorous evaluation using internal and external evaluation metrics, referencing the known number of topics 'K' to ensure unbiased results [5], [6]. Internal evaluation metrics measure the quality of the topic model itself without reference to any external data [7]. External evaluation metrics measure the quality of the topic model by evaluating its performance on a downstream task, such as text classification or document clustering [6]. The findings of these experiments illuminate how text length influences topic modeling outcomes, offering insights into selecting the most suitable topic model regardless of text length. Additionally, to ensure the robustness of the evaluation, a diverse selection of datasets encompassing both long and short text data, thereby mirroring the heterogeneity of real-world textual information sources, has been thoughtfully chosen to ensure the robustness of the evaluation. Namely, the Conceptual Captions [8] and WIDER Captions [9] datasets are selected for short text, and the 20

Newsgroups [10] and Web of Science [11] datasets are selected for long text.

The paper is structured as follows: Section II discusses the related work for topic models NMF and LDA. The experimental exploration for comparing different topic models on both short and long text data using evaluation metrics is presented in Section III. Section IV presents a comparative analysis of the obtained results. The paper is concluded in Section V with suggestions for future research directions.

II. Background

Topic modeling represents a fundamental technique in unsupervised text analysis, crucial in unveiling concealed thematic structures within a collection of texts. These algorithms are developed to detect patterns of words appearing together and capture the underlying semantic themes that define a group of documents. Topic models identify these themes and allocate them to individual documents. A document encompasses multiple topics, as reflected by its weighted coefficient. The topic with the highest weight dictates the document's primary association, disregarding all other assignments. The subsequent sections discuss the topic models and their assessment using evaluation metrics.

A. *Topic Models*

Topic models produce a list of outputs termed "topic descriptors" using words strongly linked to each topic [12]. From an algorithmic perspective, topics can be envisioned as patterns that emerge from the co-occurrence of words within a given corpus. Numerous algorithms for topic modeling have been developed to address the intricacies inherent in capturing and representing topics within textual data. These algorithms use various mathematical and probabilistic techniques to accomplish their intended objectives.

The development of topic modeling methodologies commenced with Latent Semantic Indexing (LSI), which is referred to as Latent Semantic Analysis (LSA) within the context of topic modeling [13]. LSA employs Singular Value Decomposition (SVD) on the term-document matrix, effectively reducing its dimensionality and capturing latent topics. Although not strictly a probabilistic model, LSA played a pivotal role in the evolution of topic modeling. Another variant of SVD, NMF, was subsequently devised to handle sparse data. NMF dissects the term-document matrix into nonnegative matrices representing topics and their corresponding word distributions [14]. Following this, a probabilistic variant of LSA emerged, known as Probabilistic Latent Semantic Analysis (PLSA), serving as a precursor to the LDA topic model [15]. Across the literature, it has been found that the NMF topic model works better for short text data, whereas LDA is famous for long text data. LDA, the most widely utilized algorithm in topic modeling, has been explored with different sampling methods, and it has been observed that LDA-VB and LDA-CGS are two top-performing variants for topic modeling.

B. *Nonnegative Matrix Factorization (NMF)*

NMF is a non-probabilistic topic model based on the factorization method [16]. In this method, the encoded TF-IDF term-document matrix (sized by M × N) for a given text corpus is decomposed into two matrices: term-topic matrix U and topic-document matrix V, corresponding to K coordinate axes and N points (each point represents one document) in a new semantic space, respectively as shown in Fig. 1.

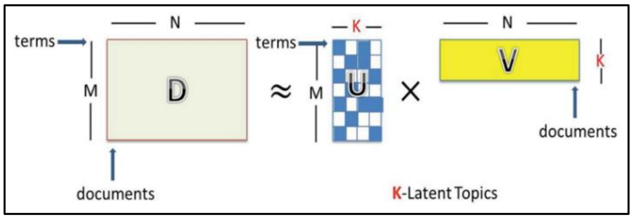

Fig. 1. NMF topic model using factorization method: D ≈ UV, with U and V elementwise nonnegative. [16].

A myriad of diverse applications in various fields use NMF. It is being applied in computational biology to analyze gene expression, unveiling metagenes and their expression patterns [17]. Image processing identifies hidden structures by extracting basis and coding matrices, revealing distinct image components. NMF has been extended to data clustering and pattern discovery across domains through automatic cluster extraction [18].

Concurrently, within the domain of linear algebraic models, there is a consensus among scholars regarding the effectiveness of NMF in handling brief textual content, exemplified by tweets. Notably, NMF's capacity for topic extraction requires no prerequisite knowledge, making it particularly advantageous for research endeavors rooted in social media data [4]. However, being a non-probabilistic topic model, it has limited utility.

C. *Latent Dirichlet Allocation (LDA)*

LDA is a probabilistic topic model postulates that each document consists of a combination of a limited number of topics, each characterized by a word distribution. The primary objective of LDA is to ascertain the optimal topic distribution for each document and the word distribution associated with each topic.

In recent times, the growing demand for topic modeling has stimulated research efforts to enhance the precision and efficiency of inference methods. LDA with Variational Bayes (LDA-VB) assumes a central role within this framework by approximating the posterior distribution governing latent topics and topic proportions. This approximation not only enhances the computational efficiency of LDA but also renders it amenable to the analysis of substantial text datasets [6], in contrast to traditional LDA, which exhibits limitations in computational efficiency and scalability. Despite this distinction, both approaches yield comparable levels of accuracy. Traditional LDA holds an advantage in terms of flexibility, as it accommodates the modeling of hierarchical topic structures, a feature lacking in LDA-VB [19]. LDA's Bayesian framework enhances performance on small or noisy datasets by incorporating prior knowledge, such as known vocabulary, to improve topic identification accuracy. Its flexibility in determining the number of topics makes it suitable for short and long text data, adapting to the data's characteristics. The algorithm for LDA-VB is shown in Fig. 2.

```
Initialize $\lambda^{(0)}$ randomly.
Set the step-size schedule $\rho_t$ appropriately.
repeat
    Sample a document $w_d$ uniformly from the data set.
    Initialize $\gamma_{dk} = 1$, for $k \in \{1, \dots, K\}$.
    repeat
        For $n \in \{1, \dots, N\}$ set
            $\phi_{dn}^{k} \propto exp\{\mathbb{E}[log\, \theta_{dk}] + \mathbb{E}[log\, \beta_{k,w_{dn}}]\}, k \in \{1, \dots, K\}$.
        Set $\gamma_d = \alpha + \sum_n \phi_{dn}$.
    until local parameters $\phi_{dn}$ and $\gamma_d$ converge.
    For $k \in \{1, \dots, K\}$ set intermediate topics
            $\hat{\lambda}_k = \eta + D\sum_{n=1}^{N} \phi_{dn}^{k} w_{dn}$.
    Set $\lambda^{(t)} = (1 - \rho_t)\lambda^{(t-1)} + \rho_t \hat{\lambda}$.
until forever
```

Fig. 2. Algorithm for LDA variational bayes [20].

Among the favored techniques based on sampling for inference, Collapsed Gibbs Sampling (CGS) in conjunction with LDA stands out as a prominent choice. CGS has proven effective and is commonly employed to infer latent topic models [21]. LDA-CGS optimizes LDA for short text data by collapsing latent variables, reducing computational complexity. Empirical evidence suggests LDA-CGS outperforms traditional LDA in various short text applications [22], [23]. The algorithm for collapsed Gibbs sampling is shown in Fig. 3.

```
for $a \leftarrow 1$ to $N$:
        $\boldsymbol{u} \leftarrow$ draw from Uniform $[0,1]$
        for $k \leftarrow 1$ to $K$:
            $P[k] \leftarrow P[k-1] + \frac{\left(N_{kj}^{\neg aj} + \alpha\right)\left(N_{x_{aj}k}^{\neg aj} + \beta\right)}{\left(N_{k}^{\neg ij} + W\beta\right)}$
        for $k \leftarrow 1$ to $K$:
            if $u < P[k]/P[K]$
                then $z_{aj} = k$, stop
```

Fig. 3. Algorithm for Collapsed Gibbs Sampling [24]

LDA finds applications in text classification, document clustering, recommendation systems, topic tracking, and sentiment analysis, enabling categorization, grouping, recommendations, temporal analysis, and sentiment extraction [12]. The following section reviews previous research work for evaluating and comparing topic models.

D. Related Work

Several studies highlight the crucial aspects of assessing topic models using statistical metrics like coherence, stability, diversity, and topic score, comparing them under different conditions using varied datasets.

The comprehensive evaluation performed by Albalawi et al. [7], using the 20-newsgroup dataset and short conversation data from Facebook, sheds light on the efficacy of various Topic Modeling methods. Standard metrics, including recall, precision, F-score, and coherence, were employed to ascertain these methods' ability to generate well-organized and meaningful topics. Notably, this rigorous assessment revealed that two TM methods, LDA and NMF, outperformed the others. Lim et al. [25] explored coherence metrics, introducing a new evaluation approach. They measured differences between topics in different sets of documents and examined how well automated metrics aligned with human judgment, particularly for common topics. Marani et al. [26] focused on enhancing topic model stability by reviewing various methods to measure and improve it. They stressed the importance of considering stability and quality when evaluating topic models. Harrando et al. [27] conducted a comparative analysis of nine popular topic modeling techniques, shedding light on issues in standard evaluation methods [35].

In particular, LDA and NMF exhibited exceptional capabilities in producing diverse and meaningful topic outputs. These findings underscore the prominence of NMF, especially in handling short text data. NMF's superiority suggests its efficacy in addressing the inherent challenges of brevity and noise often found in short texts.

One notable aspect of this research is the focused use of a limited set of standard metrics for evaluation. Rather than delving into an extensive list of metrics, this work highlights the effectiveness of using these fundamental measures to assess topic models.

The suite of experiments in this research work evaluates NMF [14] and variants of LDA in terms of implementation: online Variational Bayes inference (LDA-VB) [28] and inference using Collapsed Gibbs Sampling (LDA-CGS) [16]. These models are selected owing to their popularity and effectiveness across various works in the literature. However, this work aims to identify a topic model that performs effectively and efficiently, irrespective of the text length. The following section focuses on conducting comprehensive experiments to evaluate and compare these prominent topic modeling methods.

III. Experiments

The experimental design provides valuable insights and empirical evidence to draw informed conclusions about the effectiveness and efficiency of chosen topic models. This work uses public datasets to comprehensively compare NMF, LDA-VB, and LDA-CGS-based schemes for short and long text topic mining. All the experiments are conducted on a workstation using Python 3 Google compute engine backend.

A. Datasets

Many datasets exist to assess topic models, showcasing notable variations in corpus size, document length, topic intricacy, and noise levels. The choice of the dataset can profoundly impact the results. Hence, selecting a suitable topic model that aligns with the dataset's attributes is paramount. In the experiment's suite, short and long text datasets are utilized, with additional known associations of labels/topics to assess the performance of model-inferred topics for actual ground truth labels. Short text datasets involve caption datasets, Conceptual Captions, and Wider Captions datasets, comprising captions extracted from the web across various images. The Conceptual Captions [8] dataset is a recently proposed dataset for image captioning comprising instances across multiple categories. Owing to resource constraints, a subset of 10,000 captions with 40 diverse labels were selected. The Wider Captions [9] dataset is another captioning dataset comprising over 50,000 images of events and diverse actions; a sample of 10,000 instances is evaluated. The seminal datasets commonly utilized for topic model evaluation are employed for long text datasets, namely the 20 Newsgroups [10] and the Web of Science [11] datasets. Table I shows that choosing these datasets with varying values of optimal topics and characteristics in terms of document instance sizes and topics allows for a more general evaluation of the models. It can aid in determining the most appropriate model for the task.

TABLE I. DATASETS USED IN EXPERIMENT

Datasets	Documents	Categories/ Topics' K'
Conceptual Captions	10,000/3M	40
Wider Captions	10,000/50,000	61
20-Newsgroups	18,000	20
Web of Science	11697	35

B. *Evaluation Metrics for Assessing Topic Models*

Implementing topic models necessitates making several critical design choices, such as selecting an appropriate algorithm, inference method, model parametrization, and determining the optimal number of topics to uncover. To effectively streamline the process of making these design choices, it becomes imperative to establish a singular, overarching criterion for assessing quality, with accuracy being the foremost consideration. While other factors, such as computational complexity and processing speed, are certainly pertinent, accuracy is paramount to achieving clustering that most faithfully mirrors real-world patterns. Furthermore, the selection of the topic model can vary significantly based on the specific application, and it may yield different outcomes across multiple runs on the same dataset.

Topic modeling evaluation can follow two paths. One involves assessing the internal properties of the clustering result [6] and examining elements like topic-document assignments or topic descriptors corresponding to internal evaluation metrics. These internal metrics scrutinize structural aspects of clusters, such as their separation, without relying on additional input data. However, their quality assessment may not align with human perception, making them the primary choice when a definitive knowledge structure for text clustering is absent. The alternative approach [29] entails comparing clustering results with external knowledge sources, often termed ground truth, which typically takes the form of a pre-defined classification. This classification is often manually assigned and is rooted in human perceptions and the expertise of raters. This approach is known as external evaluation metrics. This research work utilizes internal and external evaluation metrics.

1) Internal evaluation metrics: The internal evaluation metrics can be broadly categorized as Topic Classification, Topic Significance, Topic Coherence, Topic Diversity, and Topic Similarity. Notably, Topic Stability, although an internal measure, is not included in this research as it does not serve as a quality criterion. Instead, it is considered a desirable property for algorithms incorporating stochastic elements [15]. These metrics assess inferred topics' quality, similarity, coherence, divergence, and perplexity. All experiments use the same set of evaluation metrics: internal metrics comprising of diversity [30] and KL-divergence [31] for topic diversity metrics, C_{UMass}, C_V, C_{NPMI}, C_{UCI}, WE-Pairwise and WE-Centroid [30] for topic coherence metrics [32], Jaccard similarity for topic similarity, KL-Uniform, KL-Vacuous, and KL-Background [33] for topic significance, and precision, recall, F1-score, and accuracy [34] for topic-based classification.

Topic Classification Metrics [34] assess document classifier performance using the learned document-topic distribution. This distribution is a K-dimensional representation for training the classifier to predict document classes. Subsequently, the classifier's performance is evaluated using key metrics, including precision, recall, and the F1-Score, which is the harmonic mean of precision, recall, and accuracy. These metrics are calculated using the Formulas in (1) to (4).

$$Precision_i = \frac{c_{ii}}{\sum_{j=1}^{n_c} c_{ji}} \tag{1}$$

$$Recall_i = \frac{c_{ii}}{\sum_{j=1}^{n_c} c_{ij}} \tag{2}$$

$$F1 - Score_i = \frac{2\ X\ Precision_i\ X\ Recall_i}{Precision_i + Recall_i} \tag{3}$$

$$\text{Accuracy} = \frac{\sum_{j=1}^{n_c} c_{ii}}{\sum_{i=1}^{n_c}\sum_{j=1}^{n_c} c_{ij}} \tag{4}$$

where, n_c is the number of classes, and Cij is the confusion matrix.

Topic Significance Metrics [33] play a crucial role in gauging the relevance and importance of topics, with a specific emphasis on scrutinizing both document-topic and topic-word distributions to discern and assess the significance of individual topics [15]. These metrics encompass the following key components:

a) KL-Uniform: This metric compares the topic and W-Uniform distribution using KL-Divergence. The underlying assumption is that genuine topics should be characterized by concisely selecting highly relevant words.

b) KL-Vacuous: In this case, the metric involves evaluating the topic distribution about the W-Vacuous distribution through KL-Divergence. The expectation is that authentic topics should exhibit distinct characteristics compared to a distribution that combines various elements from the sample set.

c) KL-Background: This metric assesses the topic distribution vis-à-vis the W-Background distribution, again utilizing KL-Divergence. The premise here is that genuine topics should only be present in a subset of the documents within the corpus and should not be predominantly composed of background noise.

Topic Coherence Metrics [32] assess how well the top-k words in a topic relate to each other, indicating topic interpretability. This process involves segmentation, probability estimation, confirmation, and aggregation. Standard coherence metrics, detailed in Formulas (5) to (10), are commonly used in the literature. Researchers in past studies have commonly used perplexity or held-out likelihood to evaluate models when comparing different topic numbers 'k.' However, it's crucial to recognize that while perplexity is helpful for this comparison, it primarily assesses predictive performance, not the exploratory goals of topic modeling [16].

$$C_{UCI} = \frac{\sum_{i=1}^{N-1}\sum_{j=i+1}^{N} log\left(\frac{P(w_i,w_j)+\epsilon}{P(w_j)P(w_i)}\right)}{\frac{N(N-1)}{2}} \tag{5}$$

$$C_{UMass} = \frac{\sum_{i=2}^{N}\sum_{j=1}^{i-1} log\left(\frac{P(w_i,w_j)+\epsilon}{P(w_j)}\right)}{\frac{N(N-1)}{2}} \tag{6}$$

$$C_{NPMI} = \frac{\sum_{i=2}^{N}\sum_{j=i+1}^{N} NPMI(w_i,w_j)}{\frac{N(N-1)}{2}} \tag{7}$$

$$\underset{v\ m,\gamma}{\rightarrow}\ (W') = \left\{\sum_{w_i \epsilon W'} m(w_i, w_j)^{\gamma}\right\}_{j=1\ldots|W|} \tag{8}$$

$$C_V = \frac{\sum_{i=1}^{|W|} \vec{v}_{NMPI,1}(W')_i \cdot \vec{v}_{NMPI,1}(W^*)_i}{\left\|\vec{v}_{NMPI,1}(W')\right\|_2 \left\|\vec{v}_{NMPI,1}(W^*)\right\|_2} \tag{9}$$

$$\mathrm{NPMI}(\mathrm{w_i}, \mathrm{w_j}) = \frac{\log\left(\frac{\mathrm{P(w_i,w_j)+\epsilon}}{\mathrm{P(w_j)P(w_i)}}\right)}{-\log(\mathrm{P(w_i,w_j)}+\epsilon)} \tag{10}$$

where,

C_{UCI}	UCI Coherence, based on pointwise mutual information (PMI)
C_{UMass}	UMass Coherence
C_V	newly-proposed coherence measure
NPMI	normalized PMI
W' , W^*	word subsets generated by segmentation
N	number of most probable words per topic
$\mathrm{w_i}, \mathrm{w_j}$	words (specific to a topic)
$\mathrm{P(w_i)P(w_j)}$	word probabilities
$\mathrm{P(w_i, w_j)}$	joint Probability of observing words $\mathrm{w_i}, \mathrm{w_j}$
$\underset{v\ m,\gamma}{\rightarrow}\ (W')$	context vector for words in W', direct confirmation measure m and power γ
ϵ	epsilon for avoiding indeterminate log (0)

In addition to conventional coherence metrics, the research literature has introduced coherence measures for individual topics using word embeddings with the emergence of distributed word representations. These metrics [30], [32] are calculated through pairwise or centroid-based methods, as elaborated in the provided from Formula (11) to Formula (14).

$$W_k = \{w_{ki} \mid w_{ki} \in t_k, i \in argsort\ \{P(w_{kj}) \mid w_{kj} \in t_k\}[: n_{max}]\}\# \tag{11}$$

$$WE - Pairwise_k = \left(\frac{2}{|W_k|(|W_k|-1)} \sum_{i=1}^{|W_k|}\sum_{j=i+1}^{|W_k|} \frac{(e(w_i))^T e(w_j)}{\|e(w_i)\|\|e(w_j)\|}\right);\ w_i, w_j \in W_k\# \tag{12}$$

$$e(w_k^*) = \frac{1}{|W_k|}\sum_{w \in W_k} e(w)\ \# \tag{13}$$

$$WE - Centroid_k = \left(\frac{1}{|W_k|} \sum_{i=1}^{|W_k|} \frac{(e(w_i))^T e(w_k^*)}{\|e(w_i)\|\|e(w_k^*)\|}\right);\ w_i \in W_k\# \tag{14}$$

where,

e(w_i)	Word embedding of word i
n	Maximum number of words per topic in consideration
W_k	Multiset of top n words (in terms of Probability) for topic k
$e(w_k^*)$	Centroid word embedding for the set W_k

Diversity Metrics [30] quantify the variation among the top k-words within a topic, focusing on identifying redundancies by evaluating the recurrence of words. These metrics employ a Symmetric KL-Divergence measure applied to normalized document-topic and topic-word distributions. The primary objective is to assess the diversity within the generated document-topic and topic-word distributions, emphasizing their variability [31]. The mathematical expressions for these diversity metrics, namely KL-Divergence and Topic Diversity, are provided in Formula (15) and Formula (16).

$$\mathrm{KL(R_{l1} \parallel R_{l2})} = \sum_{\mathrm{i=1}}^{\mathrm{T}} \mathrm{R_{l1}} * \log\left(\frac{\mathrm{R_{i1}(i)}}{\mathrm{R_{i2}(i)}}\right) \tag{15}$$

$$\text{Topic Diversity} = \left(\frac{1}{\mathrm{K}}\sum_{\mathrm{k=1}}^{\mathrm{K}} \frac{|\{\mathrm{w_{ki}}|\mathrm{w_{ki}} \in \mathrm{t_k}\ ,\mathrm{i}\in \text{argsort}\ \{\mathrm{P(w_{ki})}|\mathrm{w_{ki}}\in \mathrm{t_k}\}[:\mathrm{n_{max}}]\}|}{\mathrm{n_{max}}}\right) \times 100 \tag{16}$$

where,

K	number of Topics
$\mathrm{t_k}$	topic k
$\mathrm{w_{ki}}$	word i of topic k
$\mathrm{P(w_{ki})}$	probability of word i in topic k as per the topic-word distribution
$\mathrm{n_{max}}$	maximum number of words per topic in consideration

Topic Similarity Metrics [33] come in lexical and semantic forms. Lexical similarity deals with shared word sequences or structures, while semantic similarity relates to shared meaning. Cosine similarity evaluates text similarity by representing documents as term vectors and measuring it as the cosine of the angle between these vectors. Jaccard similarity calculates similarity based on the ratio of shared terms to total unique terms in both texts [3]. Jaccard's similarity [33] is computed to compare topics (Topic A and Topic B) using the Formula in (17).

$$J(Topic\ A, Topic\ B) = \frac{|TopicA \cap TopicB|}{|TopicA \cup TopicB|} \tag{17}$$

where,

$TopicA \cap Topic\ B$	shared words in both topics
$TopicA \cup Topic\ B$	all unique words in both topics

2) External evaluation metrics: On the other hand, external metrics assess topics' performance in terms of classification and clustering of documents based on topic association. The study computed the Adjusted RAND Index (ARI) [29] and the Adjusted Mutual Information (AMI) [35]. While one external clustering metric would typically suffice, both are presented here to compare with findings from other research endeavors. Consider clustering documents as a series of pairwise decisions. If two documents fall in the same class and cluster, or both in distinct classes and clusters, the choice is regarded as accurate; otherwise, it is false. The Rand index calculates the percentage of correct decisions. The adjusted Rand index is the corrected-for-chance version of the Rand index, with an expected value of 0 and a maximum value of 1 for an exact match. On the other hand, the AMI takes a value of 1 when the two partitions are identical and 0 when the MI between two partitions equals the value expected due to chance alone. The mathematical formulation for ARI and AMI is provided in Formula (18) and Formula (19), respectively.

$$\mathrm{ARI} = \frac{\sum_{ij}\binom{n_{ij}}{2} - \left[\sum_i \binom{a_i}{2} \sum_j \binom{b_j}{2}\right] / \binom{n}{2}}{\frac{1}{2}\left[\sum_i \binom{a_i}{2} + \sum_j \binom{b_j}{2}\right] - \left[\sum_i \binom{a_i}{2} \sum_j \binom{b_j}{2}\right] / \binom{n}{2}} \qquad (18)$$

where,

n_{ij},a_i,b_j are values from the contingency table where each entry n_{ij} denotes the number of objects common in clusters.

$$AMI(U,V) = \frac{MI(U,V) - E\{MI(U,V)\}}{max\{H(U),H(V)\} - E\{MI(U,V)\}} \qquad (19)$$

where,

$MI(U,V)$	mutual information between two clusters
$E\{MI(U,V)\}$	expected mutual information between two clusters
$H(U), H(V)$	entropy associated with clusters U and V, respectively

By scrutinizing a range of facets related to the identified topics using internal and external metrics, it becomes feasible to examine the strengths and weaknesses of different topic models in various dimensions or aspects, as discussed in the next section.

C. Experimental Setup

The process of identifying the most suitable topic model adheres to a conventional evaluation approach, encompassing the subsequent stages, as shown in Fig. 4. The topic models selected for consideration were trained separately over each choice of the dataset, followed by an evaluation of the performance of the topics learned by computation of internal and external metrics to determine the most effective topic model across datasets with diverse characteristics. Each data set is preprocessed to eliminate irregular word forms across documents. The topic models were trained over the preprocessed datasets with the best possible choices of hyperparameters: the number of topics being the optimum for the dataset, along with other parameters selected appropriately (Dirichlet priors selected to be symmetric and as per the value of number of topics). Following the training of topic models, the models were evaluated using internal and external metrics covering various aspects of topic quality: coherence, significance, diversity, similarity, usability for classification, and clustering information. The process of training and evaluation was jointly performed by use of the OCTIS framework [5], which incorporates implementations of multiple topic models and provides a suite of diverse evaluation metrics for comparing and contrasting the same. The experiment was repeated for all datasets chosen for this work. Within each experiment, apart from listed internal metrics covering topic diversity, topic coherence, topic significance, topic classification, and topic similarity, external metrics covering the extent of information conveyed by topics for determining a suitable clustering were also employed to determine the efficacy of learned topics.

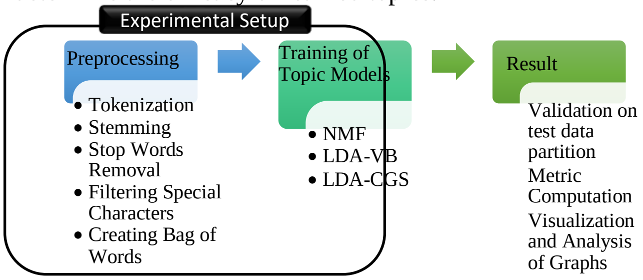

Fig. 4. Stages of experimental setup and result.

1) Data preprocessing: Each examined dataset has undergone preprocessing to eliminate irregular word forms across documents. This preprocessing encompasses standard procedures such as tokenization, stemming, removing stop words, and filtering special characters. Additionally, the preprocessing involves generating a bag-of-words representation that can be utilized in various topic models.

2) Training of topic models: Following the essential preprocessing phase, the dataset is divided into distinct training and testing segments, each allocated with specific roles and objectives. The training portion is the foundation for training the selected topic models, enabling them to gain insights and patterns from the provided data. On the other hand, the testing portion plays a pivotal role in the evaluation process, serving as an independent set of documents against which the models' performance is scrutinized and assessed.

During the evaluation phase, each chosen topic model is subjected to rigorous scrutiny over these training and testing datasets. This assessment entails meticulously examining their output in light of internal and external evaluation metrics. Internal evaluation metrics encompass criteria that gauge the coherence, diversity, and overall quality of the topics generated by the models. Topic classification metrics are another category of popular metrics employed to assess the quality of topic models by assessing the extent of how useful topics are as features for the classification of the source documents using standard classification techniques. Our experiments observed poor performance of the learned topics for classifying documents using an SVM classifier. Thus, we have included only a relative comparison based on the values highlighting the best topic model per dataset and metric. A possible explanation for the poor metric values is the sensitivity of the metrics to the choice of classifier and the corresponding hyperparameters. So, these metrics may not accurately represent the usefulness of topics for classifying documents. A thorough analysis for contrasting performance must also compare diverse classifiers to determine the overall effectiveness of topics learned by the different topic models for classification, which is beyond the scope of this study of contrasting topic models.

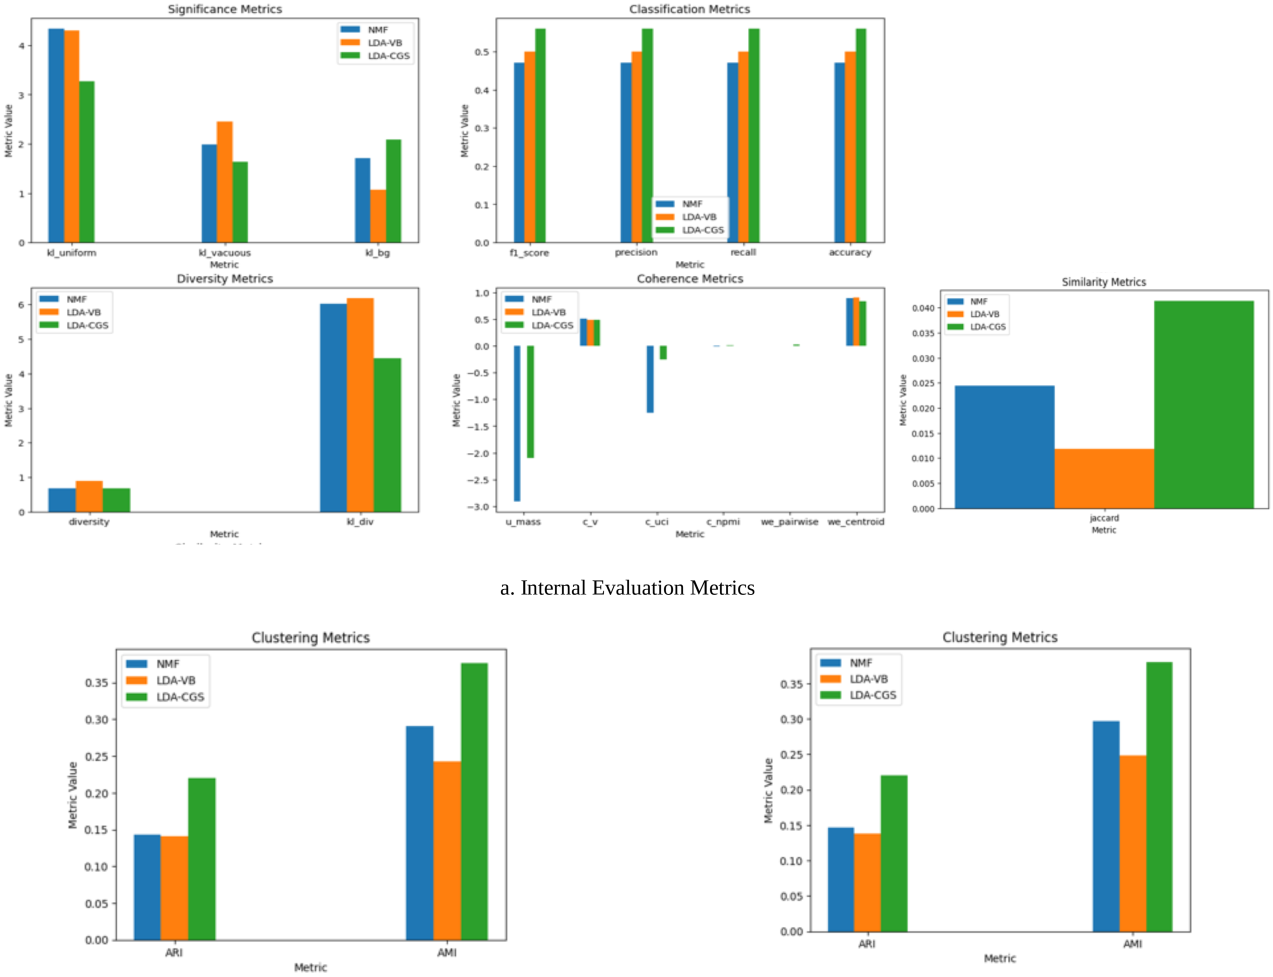
External evaluation metrics, on the other hand, pivot towards assessing the model's efficacy in practical applications. They evaluate the model's ability to categorize, classify, and cluster documents based on the topics it infers. This dual-pronged evaluation strategy, involving internal and external metrics, forms a comprehensive and well-rounded approach to ascertain the effectiveness and applicability of the topic models under scrutiny.

Once the models have been trained successfully, they are run on test data. The output is analyzed using the graphs discussed in the next section.

IV. Results and Discussion

A. Results over Short Text Datasets

Varying results regarding the most performant topic model across different internal metrics are observed across short text datasets. Regarding internal metrics, NMF is significantly more performant than LDA implementations across many metrics. Across external metrics, however, LDA-CGS outperforms both NMF and LDA-VB for both datasets.



a. Internal Evaluation Metrics

b. External Evaluation Metrics – Training Partition

c. External Evaluation Metrics – Test Partition

Fig. 5. Comparison of topic models over Internal and External Metrics for the Conceptual Captions dataset

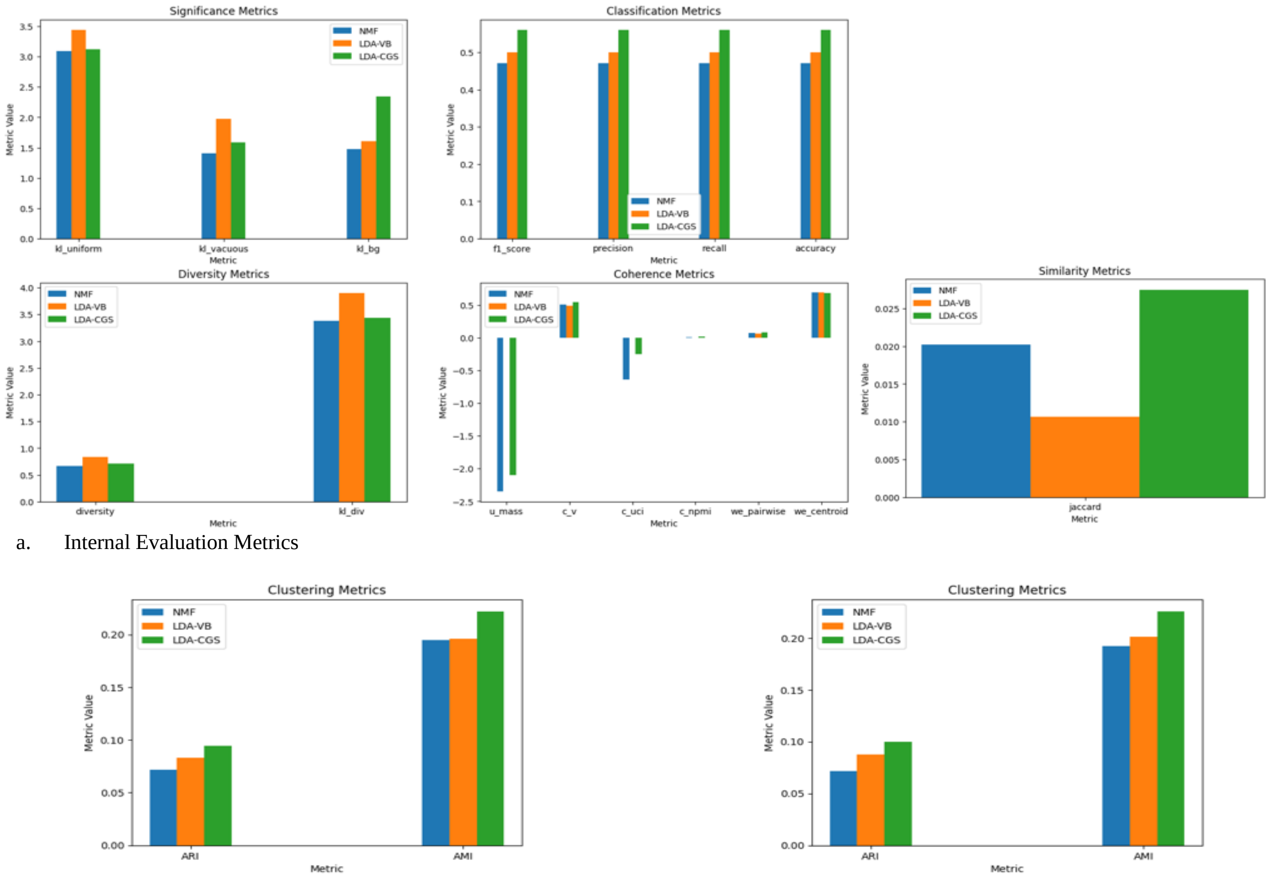
Fig. 5(a), 5(b), and 5(c) compare the performance of the three topic models over the Conceptual Captions dataset regarding internal and external evaluation metrics for training and test partitions, respectively. Across internal metrics, while there exists no consensus for the best topic models, NMF demonstrates high performance across a significant number of metrics. This behavior is prominent in topic classification metrics, where NMF outperforms both LDA variants by a minute margin. NMF also demonstrates leading performance across coherence metrics C_V and C_{NPMI} and topic significance compared to the Uniform distribution (KL-Uniform). Across other metrics, while NMF is not the best model, the difference between the metric values of NMF and that of the best model is minimal. Across the remaining metrics, LDA-CGS and LDA-

VB perform in contrast to one another across different metrics. While the topics of LDA-CGS are more coherent in terms of C_{UMass} and WE-Pairwise, more significant in terms of KL-Divergence for the Background distribution, the topics are more similar and less diverse than LDA-VB topics. Across external evaluation metrics, however, LDA-CGS is the best performant, demonstrating an ability to produce a prominent quality clustering based on inferred topics, with an agreement to the ground truth of the document labels.

The performance of the topic models in terms of internal and external metrics for the Wider Captions dataset over training and test partitions is compared in Fig. 6(a), 6(b), and 6(c), respectively. For the dataset, the behavior of NMF is much more prominent, with leading results across many metric categories. NMF outperforms both variants of LDA across topic significance (KL-Uniform), topic classification, topic similarity, and topic diversity when measured with KL-divergence. However, unlike prior observations, topics inferred by NMF for the dataset are not as coherent as those inferred by other models, and instead of NMF, LDA-CGS results in the most coherent topics as observed by the coherence values for all coherence metrics. However, the divergence and similarity of the LDA-CGS topics are still significantly lower than the other models. LDA-VB demonstrates comparable results to the most compelling topic model across most metrics and leads over other models only in terms of diversity and topic significance (KL-Vacuous). Across external metrics, a similar trend as the Conceptual Captions dataset is observed, with LDA-CGS significantly outperforming other topic models, demonstrating the reasonable effectiveness of LDA-CGS in inferring high-quality topics that produce high-quality clusters.

B. Results over Long Text Datasets

Across long text datasets, NMF is superseded by LDA models across internal and external evaluation metrics. It demonstrates the effectiveness of LDA in general; most corpora on which topic modeling is utilized comprise long text documents with multiple topics per document. LDA is significantly more effective than NMF, and short text document corpora are rare and application-specific.

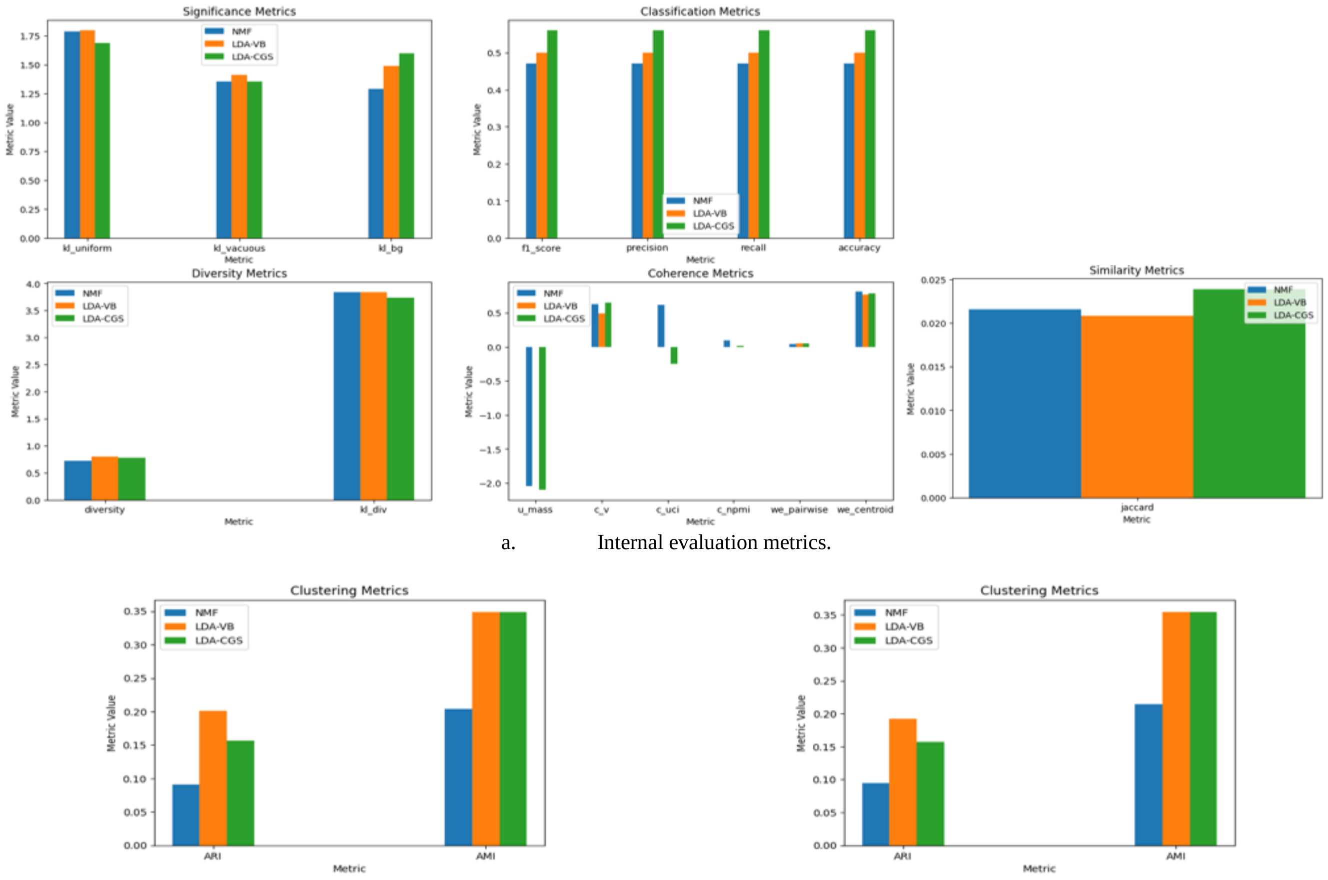


a. Internal Evaluation Metrics

b. External Evaluation Metrics – Training Partition

c. External Evaluation Metrics – Test Partition

Fig. 6. Comparison of topic models over internal and external metrics for the wider captions dataset.



a. Internal evaluation metrics.

b. External evaluation metrics – training partition.

c. External evaluation metrics – test partition.

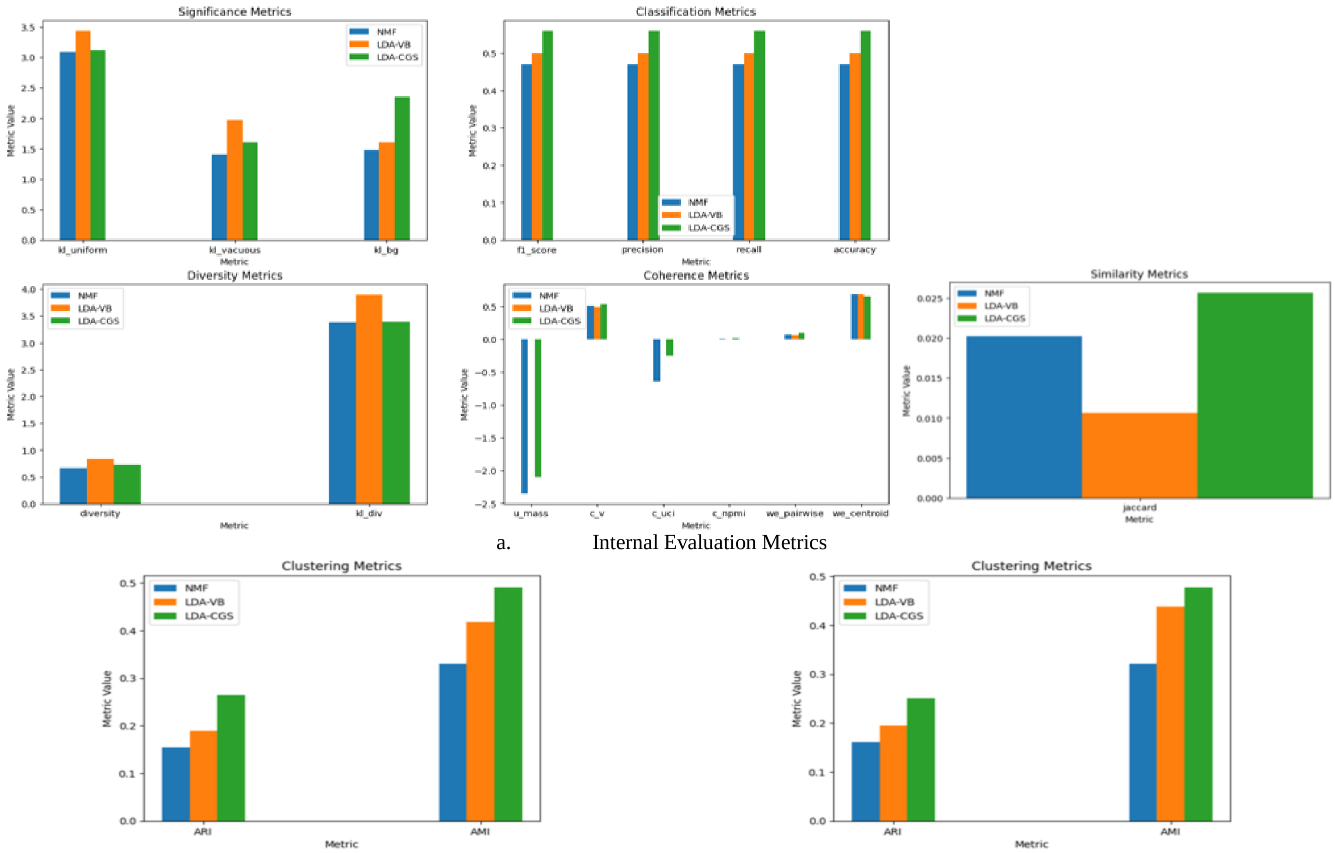
Fig. 7. Comparison of topic models over internal and external metrics for the 20-newsgroups dataset.

Fig. 7(a), 7(b), and 7(c) compare the performance of the three topic models over the 20-Newsgroups dataset regarding internal and external evaluation metrics over training and test partitions, respectively. Regarding internal evaluation metrics, the results regarding determining the best topic model are inconclusive as the metrics appear to disagree. However, across all metrics, NMF is outperformed by either variant of LDA. Classification and Diversity metrics prefer topics inferred by the variational Bayes implementation of LDA. In contrast, topics produced by LDA implemented with Collapsed Gibbs Sampling are found to be the most coherent and significant compared to the background distribution. Across external evaluation metrics, LDA-CGS outperforms LDA-VB in terms of AMI but not in terms of ARI scores. Both variants of LDA perform similarly for this dataset, and either can be preferred for inferring latent topics. It is noted that the difference across metric values for both LDA variants is insignificant, strengthening the assertion that either model is suitable for obtaining high-quality topics.

The comparison of the performance of topic models over the Web of Science dataset in terms of internal and external metrics over training and test partitions is demonstrated in Fig. 8(a), 8(b), and 8(c) respectively. Similar to the trend across other datasets, internal evaluation metrics do not demonstrate a unified consensus for the choice of the topic model. However, LDA variants significantly outperform NMF in all metrics. However, unlike 20-Newsgroups, LDA-CGS is found to be more performant than LDA-VB across classification and coherence metrics. The trend for significance and diversity metrics, however, is similar to the trend observed in 20-Newsgroups and other short text datasets, which indicates that LDA-CGS, in general, infers topics that are highly coherent and more significant than background information but are not significantly diverse in general. Further, the trend across external metrics is similar to the observations across short text datasets, with LDA-CGS outperforming other topic models, demonstrating the reasonable quality of LDA-CGS inferred topics and their effectiveness in clustering documents.

C. *Discussion and Interpretation of Results*

Based on the results, LDA-CGS is suitable for producing high-quality topics across corpora with diverse text characteristics. However, to improve the quality of topics specific to the application, LDA-CGS produces reasonable quality topics that demonstrate high performance over external clustering metrics and classification over documents, especially with long text data. Further, the topics have high coherence, divergence, significance, and reasonable similarity, making the algorithm a suitable default choice for most applications. The best performant topic model across each dataset and metric has been summarized in Table II.



a. Internal Evaluation Metrics

b. External evaluation metrics – training partition.

c. External evaluation metrics – test partition.

V. Conclusion

Topic modeling techniques exhibit versatility in handling both short and long text data. While models like LDA excel with longer documents, approaches such as NMF demonstrate efficiency in understanding the context within shorter texts. This research performs empirical analysis of state-of-the-art topic models through statistical metrics in the context of varied text length data to determine the best model irrespective of text length. Based on the experimental results, LDA-CGS produces high quality topics over external clustering metrics for both long and short text data. The topics produced by LDA-CGS have high coherence, divergence, significance, and similarity, making it a suitable choice for most datasets.

Future research directions could explore hybrid approaches that combine the strengths of multiple algorithms to enhance topic modeling performance across different text lengths. The results show that NMF is still a strong contender for short text data, and a hybrid model may show much better performance for varying text length datasets. These models can also be applied on Twitter or image caption datasets to discover relevant information for the classification process.

Assessing User Requirements for e-Resources Interface Design in University Libraries

Yuli Rohmiyati[1], Tengku Siti Meriam Tengku Wook[2], Noraidah Sahari[3], Siti Aishah Hanawi[4]
Faculty of Information Science and Technology, University Kebangsaan Malaysia, Selangor, Malaysia[1, 2, 3, 4]
Department of Library Science, Diponegoro University, Semarang, Indonesia[1]

***Abstract*—e-Resources in the university library as learning resources are one of the primary services that promote learning and research to improve university productivity. At present, users find it difficult to access e-resources and require assistance in finding them. When using the system, users felt frustrated, confused, and lost. The e-resources services system on library websites, on the other hand, lacks sociability and a sense of human warmth. Sociability and a sense of human warmth can be integrated into the website interface, which may evoke the sensation of being with an actual individual, even if the service is provided online. This study investigated the social presence aspects that can be implemented in the library's e-resources system. The purpose of this study is to elicit social presence features that can be implemented in the design of e-resource interfaces on library websites. The methods used in this study are in three phases: a) web content analysis from twelve university library interfaces designed in several countries; b) interviews with library staff; and c) assessment by a questionnaire of library website users. Website content analysis was used to investigate elements that offer many unique features to support the implementation of social presence through the e-resources interface. An interview was used to validate elements that were found in the web content analysis, and a questionnaire phase was used to assess the user requirements for these social presence elements. The results of empirical studies show that users need some elements of social presence, such as comments, chat, ratings, voice, personalized welcome in library accounts, tools, preference language, links for reference managers, and social media, as well as ease of access such as readable help font, color, and font size.**

Keywords*—User requirement; interface design; e-resources; social presence; university library; element

I. Introduction

e-Resources in the library websites prefer to provide authentic learning with social interaction [1], and a user interface is a communication tool for the user with the e-resources system in the library websites. As one of the official sources of information, which is one of the services on the library website, are often requested to meet a user's needs quickly, which was found to be frustrating [2], boring [3], confusing [4], and feeling lost [5]. It is because the design interface of e-resources has unclear navigation [6] with the searching interface of e-resources [7] and with too much information [8]. This makes it hard for users to find information [9] [10]. Users feel difficulty in accessing the system and understanding the system navigation [5], added to a lack of a guide and the absence of some websites [11]. The other reason that causes frustration for the user is a slow internet network [12] [13] [14], low bandwidth [15], slow download [16], and limited power [17]. All these reasons make a lack of time [18] with high access costs [19], lack of authority, and also limited subscription titles [20], which makes the low use [21] of e-resource systems in libraries.

However, the provision of user interface designs in e-resources services needs to be addressed more [22], to sustain the use of e-resources especially in the university library systems [23] [3]. Among them is navigation on the interface that needs to be clarified and made easier to identify and access complex systems. Meanwhile, the e-resources in the university library is the primary source of information obtained by students and the academic community. [24] [25] believes that e-resources are the main gateway that provides users with the information needed to conduct investigations in various fields. University e-resources are the main part of the library websites and have become a vital academic resource that supports teaching, learning, and research activities [26]. e-Resources play an essential role as a source of information in providing quick and easy service to readers [13]. In contrast, librarians [27] play a role in facilitating the discovery and access to information resources.

The challenge here is, firstly, that e-resources interfaces lack elements of social activity or human-friendly treatment from face-to-face or online service experience [28] [29], which causes users to feel confused, and frustrated and to resolve the problems encountered themselves [30]. Studies by [31] and [32] found that 87.2 % of users expect multiple database searches to be available on one interface. Most users prefer or tend to use open-access journals as opposed to journals that need to be subscribed to [33] [34]. In addition, when users do not get answers to their questions and there is no help in the system, users will solve their difficulties while using the system and spend a long time solving the problems encountered. Users feel depressed and frustrated because users do not get treated with face-to-face services.

Secondly, the system is less friendly. The cognitive and affective issues faced by these users are due to the lack of information about the social elements on the system interface [35] [36]. This indicates that the current system does not emphasize or integrate elements that evoke a sense of social presence through their system interfaces. Previous studies suggest social cues such as voice, picture, or video [37], and greetings influence cognitive and affective elements [38] [36]. The use of social elements in a system is referred to as social presence [39]. Using the elements or characteristics of social activities can reduce users' negative experiences using the system [40]. Therefore, a sociable and human warmth user interface is needed to make users engage with the e-resource system in the library.

Thirdly, e-resources are all digital collections that can be the main reference for students and lecturers to improve knowledge, education quality, and university performance. Based on the results of previous studies, it is known that the use of these e-resources is low [41] [42] [43]. The cause is the absence of sociability and human warmth in this interface system. Because of that, users turn to ordinary search engines because they feel comfortable with them compared to using e-resources in libraries. Users prefer to do searches or get information on standard search engines [20]. Although library initiatives provide other mobile application libraries [44], the usage is still at a low stage [24]. Meanwhile, the system's performance makes it easier [45] for anyone to access information and receive service.

Fourthly, social and technological factors help increase the use of learning systems [46]. Social activities in this system include greetings [28] [47], chats [48] [49], and images [50] [51]. According to [52], presenting elements of social activity in the system will influence users to engage in the cognitive and effective use of e-resources. Although studies on the use of e-resources in libraries have been carried out by many researchers [2] [53] studies that focus on social presence in e-resources interface design are limited. Therefore, analyzing social presence elements on the interface of the system or pages in the library is a critical issue to be investigated to see the benefits that can be provided in the environment. Previous studies show that social presence was applied to e-learning, e-commerce, and e-services. The concept of social presence can even connect users with technology in a fun way.

Based on the above, this study aims to investigate the element of social presence to be applied and incorporated into the e-resources interface design in the university libraries. Investigation of this element is needed to suit users' needs for e-resources which are undoubtedly different from users' needs in e-commerce or e-learning. The research question in this study are:

1) What elements are needed for the university library's e-resources interface design?

2) How to assess these elements to meet the user requirement for e-resources interface design in the university library?

To achieve this, this study has designed a three-phased method approach. Firstly, this study finds elements from the literature reviews and searches for some elements from web content analysis. Secondly, this study validates all elements from the first phase by trying the element's function and also conducting an interview session with some librarians from these libraries. Thirdly, this study assesses that element to find user requirements through a survey. This investigation can develop new elements needed in designing an e-resource interface in university libraries by completing this phase.

The results of this research reveal the user requirements of e-resources service interface design in university libraries. The scope and contribution of this research consists of two main areas, namely human-computer interaction and libraries. The structure of this article is as follows: an introduction in Section I to the issues of e-resource usage, followed by an explanation of related work in Section II, methodology in Section III and the result of the user requirement in Section IV. Finally discussion and conclusion is mentioned in Section V and Section VI respectively.

II. Literature Review

This study explores research in the areas of accessibility of e-resources and social presence. This study summarizes the literature and presents it in a literature review.

A. Accessibility of e-Resources

Accessibility of e-resources refers to the use of e-resources subscribed by the library by all users to access the information and services provided through the website [45]. This accessibility describes the extent to which resources, services, and products are accessible to the users [54] who utilize them or the ability to access information stored by the operator by minimizing any distance and cost barriers by using a user interface. Accessibility determines the speed of the output of information that can be accessed in any format [55]. Access to information is essential in determining successful and practical research in universities. Factors that influence the access and use of electronic information resources in university libraries are:

1) Literacy in obtaining information is of paramount importance in quality research. Literacy helps users access and use relevant information. Most users need these skills, which causes them to spend more time retrieving the necessary information. These skills include knowledge of database structure, appropriate and available search terms, and an understanding of how the commands are linked to each other.

2) Consumer attitude towards electronic information sources. A previous study in [3] found that lecturers prefer electronic information sources to printed ones. Electronic information sources require less time to access such information sources than printed information materials.

3) Access and use of electronic information resources. Research results show that electronic information resources are still low even if accessed using library computers or remote access [56]. It is common knowledge that there are various benefits of using e-resources, namely: (1) Access to a broader collection of information, (2) Faster access to information, (3) Increased Academic Performance, (4) Access to quality information, (5) Access to the latest information and (6) Easier access to information.

The challenge of using e-resources in libraries is that it takes much time to find the materials needed [57] and it is not easy to access. This finding can be attributed to inaccessible web design [58], low level of literacy in using e-resources, lack of knowledge in using assistive technology, and lack of motivation, which may be due to the above factors.

B. Social Presence

Social presence is a concept that has its roots in telecommunication literature. The study of Short, Williams, and Christi developed the social presence theory as a model to analyze socio-psychological dimensions of mediated communication from the perspective of social cues [50] [48]. They defined social presence as the degree of excellence of others in interactions and the importance of impressions of interpersonal relationships.

Social presence is a person's mental state to feel close to others in a virtual environment [59] [60]. At the same time, social presence can also be defined as a person's participation as a real person in expressing self and social emotions through communicative media [61] [62]. A person can tap into a high level of social presence, escape from the real world, and enter an exhilarating and pleasurable mental state through intimate interactions with other users. With a high social presence, a person tends to feel more satisfied and comfortable using the system. Someone with a strong social presence in the social networking gets a more extraordinary experience. A strong sense of excitement helps users enter an exhilarating mental state when using something they enjoy. In another study, belongingness [60] was positively related to well-being embodied by happiness and pleasure.

Short stated that social presence contributes to the medium of communication. Social presence has a complex structure, like the participation of someone as a real person in expressing himself and their emotions through communicative media [62]. Social presence is a construct consisting of two concepts: intimacy and immediacy. Intimacy is a sense of closeness one builds to another through verbal and non-verbal cues. Whereas; immediacy is the frequency of reactions and interactions of a person willing to support and share experiences with others. [63] [30] state that if someone in a system demonstrates these two concepts it can increase social presence.

Social presence is a theory that has its foundation in telecommunications literature. Short, Williams, and Christi developed social presence theory as a model for analyzing the socio-psychological dimensions of mediated communication from the perspective of emerging social activities [50] [63]. They define social presence as a person's level of superiority when interacting and the impact of those interpersonal relationships. Moreover, according to [64], intimacy in communication media is influenced by physical distance, eye contact, smiles, and personal topics of conversation.

The following are the elements of social presence obtained from a literature review (see Table I).

TABLE I. SOCIAL PRESENCE ELEMENT FROM A LITERATURE REVIEW

Author	Social Presence elements
S. S. Engku Alwi and T. S. M. Tengku Wook	1) Services: Communication with retailers, Feedback/ Comments, Frequently Asked Questions, Chat. 2) Display: Language choices, Advertising. 3) Website content: Photos, Animation, Audio, Video, Automotive description, Product description. 4) Additional applications: Recommender system, Rating, User review [65]
Thabet dan Zghal	Website data, human photos, personal responses, animations, virtual agents, frequently asked questions (FAQ), instant messaging, entries, discussion forums, and social networks.
Papadopoulou and Ganguly et al.	Images, colors, and graphics
Y. Li and Y. Xie	Visuals (images and colors) [66]
Y. J. Kang and W. J. Lee	Avatar [67], animated gif, username, greeting [28]
W. Nadeem et al.	Comments, ratings, exchange options, and tagging [68].
J. Wei et al.	Communication support (i.e., text chat and voice chat) and shared navigation (i.e., page push) [60]

Based on Table I, it can be seen that the social presence elements that can be applied in designing the electronic resource interface on the university library website include: communication with library staff, chat, language choice, photo, and greeting, welcoming users by name, text chat, and emoticons.

III. METHODS

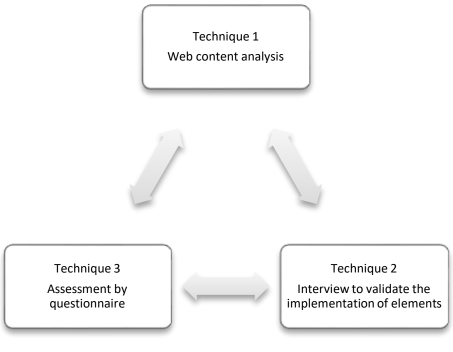
This research method through three phases (see Fig. 1). The primary purpose of this article is to identify social presence elements for the e-resources interface in the university library. This study reported empirical findings in peer-reviewed journals from 2015 to 2021. The Scopus database was used to search for relevant studies. The keywords and word combinations are “social presence” and “social presence and e-resources”. Only studies published in the English language were reviewed. A two-technique literature search strategy [65] was used in this study to retrieve social presence elements for the university`s library interface. The Technique I used to identify unique elements of social presence from literature review and web content analysis in twelve universities’ library interfaces (see Table II). Website content analysis [66] was used to investigate elements that offer many unique features to support the implementation of social presence through the e-resources website interface.

TABLE II. NAME OF UNIVERSITY LIBRARY

No	Country	Library Name
1	Australia	Queensland University Library
2	England	Lancaster University Library
3	England	Lincoln University Library
4	Germany	Gothe Universitat Library
5	Japan	Hokkaido University Library
6	Japan	Osaka University Library
7	Malaysia	Tun Seri Lanang Library
8	Netherland	Radboud University Library
9	Netherland	University of Groningen Library
10	Taiwan	National Chang Kung University Library
11	USA	Arizona State University Library
12	USA	Louisiana State University Library

Furthermore, Technique II is used to communicate with five library staff to validate the implementation of social presence elements in the library interface. In this activity, the online interview method was conducted with the library staff hosting a live chat on the library's web. Before that, the researchers introduced themselves and tried to inquire about the e-resources services at the library. Researchers tried to use elements provided in the live chat interface, such as emoticons, attachments, and pictures. Throughout the interview session, the researchers recorded chat recordings through this text. At the end of the interview session, the researcher also had a brief discussion with the staff to improve the information obtained during the interview session. Data obtained from interviews and chat recordings will be analyzed by coordinated based on web content analysis. In this technique, the researchers met online with five university library staff, namely Lancaster library staff, Lincoln Library staff, Radboud Library staff, Tun Seri Lanang Library staff, and Queensland Library staff.

Technique III assesses the need for social presence elements in library users. This activity aimed to validate the social presence element on the e-resources interface in the university library. This test was used to assess social presence elements by comparing elements found from phase I. Then, unique elements identified in the literature review phase were cross-checked with observational results from web content analysis. It was found that the elements searched with library reviews were similar to the search results of social presence elements in web content analysis. There were some additional new elements found after web content analysis was conducted. The findings of social presence elements for e-resources in the university library interface (see Table IV) were then tested with a questionnaire (see Table V). The survey method was performed with 44 users of the e-resources interface in the university library [67] via a google form. The output from this analysis phase is an element of social presence in the design of e-resources interfaces and will be used to design prototypes in the next phase.



Technique 1
Web content analysis
Technique 3
Assessment by questionnaire
Technique 2
Interview to validate the implementation of elements

Fig. 1. Research methodology.

The three phases used in this study are known as triangulations. This study does not rely on a single source and instead uses a systematic search approach, web content analysis by looking at implemented social presence elements, and interviews with library staff to validate the function of social presence elements in university libraries. Finally, a questionnaire was used to collect data on user requirements.

IV. Results

A. What Elements are Needed for the University Library's e-resources Interface Design?

To answer this question, this study conducted a literature review and web content analysis to answer this question.

1) The need for social presence elements on the interface of e-resources through a literature review: Analysis of the need for elements of social presence on the interface of e-resources is obtained through two stages: literature review and cross-checking through web content analysis of university libraries. As a result of the literature review, the list of elements of social presence was found as follows (see Table III: Table of elements of social presence).

TABLE III. Social Presence Elements

No	Elements
1	Human picture [69]
2	Text [69]
3	Personalized greetings [65]
4	Frequently Asked Questions[65]
5	Instant message [65]
6	Chat [69]
7	Social Networks [65]
8	Product Description [65]
9	Emoticon [69]
10	Colors (Lee et al. 2010)
11	Interaction functions [69]
12	Languages [65]
13	Videos [65]
14	Tag [68]
15	Website data [65]
16	Animation [65]
17	Virtual Agents [65]
18	Number of entries [65]
19	Discussion Forums [65]
20	Graphics [69]
21	Comments [65]
22	Advertisements [65]
23	Ranking [68]
24	User reviews [68]
25	Voice chat [60]
26	Share [28]
27	Avatar [28]
28	Ratings [68]
29	Recommendation system [65]

2) Web content analysis: The stage used in this method is, firstly: surveying whether the design of the university library interface possessed the characteristics or elements of social presence as mentioned in the literature review. Further observations were made to observe the social presence element in the design of the e-resources interface of university libraries from several countries. Then, a web content analysis method [68] was performed to obtain more detailed data related to the need for social presence elements in the design of e-resources interfaces in university libraries.

Based on the study, it is known that out of the twelve university library interface designs that have been observed, only seven libraries have social presence element features namely Lancaster University Library, Lincoln University Library, NCKU library, Radboud University Library, the Tun Seri Lanang Library, the University of Queensland Library, and the Arizona State University Library. Based on web content analysis observation, some elements are found in this method (see Table IV).

TABLE IV. SOCIAL PRESENCE ELEMENTS BASED ON WEB CONTENT ANALYSIS

No	Elements
1	Notification
2	Library account
3	Application/Request
4	Link on reference management
5	Orchid account link
6	Submit an article
7	Publisher chat
8	Pay
9	Forum Group
10	Disabled
11	One search
12	Download history
13	Altmetrics
14	Language
15	Tools
16	Order
17	Borrow
18	Delivery
19	Drive-thru
20	Library Guide
21	Gift
22	Promotion
23	Events
24	Digital library card
25	Attachment
26	Reading list

Then, the following sections will describe the role of each group of social presence elements and their constituent sub-elements in the e-resources interface design in the university library. Table V describe the four main social presence elements suggested to be critical for e-resources in the university’s library interface design are live chat by adding video to create more of a presence and impression, and Library account by adding elements: like, share, rating, and pay. Links to reference manager links to discussion forums to share experiences, links to social media, and links for Accessibility. Table V presents a categorization and description of the identified groups of social presence elements and their constituting sub-elements.

TABLE V. SOCIAL PRESENCE ELEMENTS SUGGESTED FOR E-RESOURCES IN THE UNIVERSITY`S LIBRARY INTERFACE DESIGN

Main element	Sub-element
Live Chat	Human Picture, Text, Chat, Emoticon, Interaction Function, Video, Voice, Virtual Agent, Comment, User Review, Share, Rating, Like, Attachment.
Library Account	Personalized Wellcome, Notification, FAQ, Order Now, User Request, Language Choice, Recommender System, Charges, Read/ Download History, Tool, Booking Collection, Delivery Service, Drive Thru, Library Guide, Gift, Event, Digital Library Card.
Links	Social Network, Discussion Forum, Reference Manager, Orcid.
Accessibility	Font Size, Keyboard Navigation, Readable Font, Color

Furthermore, based on the results of observation and analysis of web content, the role of each group of social presence elements and its constituent sub-elements in the design of e-resources interfaces in university libraries are:

a) Live chat, a finding in the literature review where this critical element is one of the indicators of the existence of social activities that indicate a social presence in a system. Libraries initially used this live chat to make it easier for users to obtain referral services. Live chat services are unique to human nature [69] and have positive word-of-mouth effects [70] and things that support live communication to get help from library staff. So, the elements for live chat are chat, staff name, staff photo, voice, text, emoticons, help, and video, adding video to create more impressions of presence. This element is used to meet and communicate with staff or librarians to get services directly. That way, users expect face-to-face service even if the service is online.

b) A library account that is trustworthy and easy to manage includes various personal information, activities, and daily tasks of library users like user accounts, personalized responses, digital library cards, orders, charges, delivery services, driveways, and download history. This element is used to manage users' personal needs in e-resources services in university libraries by adding user accounts, personalized responses, digital library cards, collection ordering services, late billing, charges, drive-through services, delivery services, download history, recommender system [71], QR, like, share, rating, pay and cart. Users can share videos of new findings from research, experimental videos, videos of researcher observations, and photos of research results. This element of sharing will encourage users to engage [72] in e-resources services at the library.

c) Links are used to improve system performance and make it easier for library users to connect to various networks that support the work of library users. Those elements are links to orcids, referral managers, forum discussions to share experiences, and links to social media.

d) Accessibility is things that make it easier for people with disabilities to access e-resources services. Interface design [73] is essential to consider accessing information created by social and environmental contexts.

With live chat elements, library accounts, links, and accessibility, the e-resources interface in the university library is expected to be fun and convenient for users. Fun and convenience will increase the use of e-resources, and as a result, university performance will increase. Users with disabilities will also find it easier to use e-resources in the library. Users will feel comfortable, happy, and engaged with this service so that the cognitive and affective issues of users when using the interface in the library will be resolved.

3) Interviews: This method is used to ensure that the social presence elements found in the design of the university library interface work well. For that, the researchers try to use these elements to validate the implementation of social presence elements in the library interface.

Based on interviews conducted at the Lancaster library with staff on duty, it was found that the chat element in the Lancaster library had elements of staff names, text, and voice but still needed elements of library staff photos, emoticons, and videos.

In the Lincoln library, there are elements of staff names and text. In contrast, in the Radbud library, there are elements of librarian pictures, voices, attachments, and emoticons on this chat element. Besides that, in Queensland libraries, there are elements of staff names and text.

Based on these interviews, a social presence element in the design of e-resources interfaces in university libraries still needs to be improved. Therefore, in this study, we will further design e-resources interfaces according to data acquisition from library reviews and web content analysis.

B. *Assessment of the Elements of Social Presence based on user Requirement*

The assessment aims to validate the social presence element in the design of the e-resources interface in the university library. This assessment uses a questionnaire with a seven Likert scale to getting more detailed answers from respondents.

Based on the assessment results with the questionnaire, it is known that respondents of this assessment are 43% male and 57% female. Based on their occupations, it is known that 11% are lecturers, 86% are students, and 2% are research assistants. Meanwhile, their level of studies is 45% bachelor, 16% master and 39% Ph.D (see Table VI).

Moreover, based on the respondent's country (see Fig. 2), it is seen that 50% are from Iraq, 14% from Malaysia and Indonesia, 5% from Taiwan, the UK, Libya, and 2% from Thailand, Palestine, Singapore, and Yemen.

Based on the questionnaire results about live chat elements (see Fig. 3), it is known that users need comment element as much as 28.75%, rating element as much as 27.5%, chat element and text element as much as 23.75% and voice element as much as 22.5%.

Based on the study about library account elements (see Fig. 4), it is known that users need a library account element as much as 32.5% for a language choice element, 27.5% for personalized welcome element and tool element.

Based on this study about link elements (see Fig. 5), it is known that users need link elements as much as 27.5% for discussion forum elements, 26.25% for reference manager and orcid link elements. In comparison, users also need social network elements as much as 21.25%.

Based on the study about accessibility (see Fig. 6) , it is known that users need accessibility elements as much as 31.25% for readable font elements, 27.5% for color element, 26.25% for font size elements, and 25% for keyboard navigation.

TABLE VI. RESPONDENT`S DATA

	Category	**Frequency (n=44)**	**Percent (%)**
Gender	Male	19	43
	Female	25	57
Occupation	Lecturer	5	11
	Student	38	86
	Research Assistant	1	2
Level of study	Bachelor	20	45
	Master	7	16
	Ph.D	17	39

V. Discussion

This study has looked into twelve university library interfaces in several countries, and the result is that seven of these libraries have an element of social presence. Social presence elements were obtained from a literature review, library interface observations, and observations on electronic commerce. This element in electronic commerce was taken with the consideration that it could be a new element in the design of the e-resources interface in the library.

Researchers in various fields, such as e-learning, e-commerce, and e-services, mainly study social presence. Many studies on social presence show that social presence has a significant effect on interaction, increased learning, and motivation. The social presence model has three categories: emotional expression, open communication, and group cohesion [63]. Emotional expression is shown with humor and self-disclosure. Elements that can represent this category, such as emoticons, videos, or images and open communication, a reciprocal exchange and mutual respect in an interaction. An example of this category is the chat element. Based on a questionnaire data, users need chat elements. This data further supports the problem of difficulties for e-resource users in university libraries. Users need this element to make it easier for them to get help from librarians.

Indeed, social presence is defined as a sense of belonging and acceptance within a group and creating camaraderie among those groups. Social presence can increase education [74], participation, interaction, activity, motivation, learning, sense of presence, and the effectiveness of critical thinking [73]. Then social presence can also increase the use of e-resources in university libraries. Social presence is an important part of communication [75] [76], whether within the individual, in the community, or even in the library. Librarians demonstrate their presence in several ways: in person, over the phone, or on the internet.

Although there are limitations and obstacles in projecting social presence through technology, it can be done well if the element of social presence is raised according to the user requirement of the system. Social presence, which can encourage learning interactions in online learning environments, is considered essential for social learning. When a person perceives high social cues from others, they will gain a better perception of social presence to facilitate learning interactions in online libraries. e-Resources and distance education authorities can use social attendance theory [62] in course planning, applying the principles and creating a friendly learning environment that can increase attendance.

Some considerations obtained from users for the live chat element to improve communications with librarians are (1) proactive and interactive services. Proactive and interactive means users of e-resources that need an immediate response from the librarian to be able to help them or enable live chatting that provides the staff's name, add a selection of common questions most people ask in live chat, and can add some new ideas. This first suggestion directs the conversation and anthropomorphic (need to attribute human characteristics to a particular object). Users need a new chat. They also need Live Agent and mobile live (2) Date and time, which means that users need information about the date and time when using the collection when borrowing facilities from the library. (3) Rating or the recorded number to follow up on some issue. (4) Social Media like Telegram, Twitter, and Google Meet. (5) A unique mark appears if the message has been read (6) login notifications (7) support (8) help (9) updates according to user feedback and [77] QR code.

Another consideration about library accounts, users need (1) date due or expired dates/ renewal notification, (2) rent/ prices, (3) Search (4) Payment through a unique program. In the library or payment upon receipt of request, (5) things matter, (6) Book rental, (7) Acquisition Section, (8) Registration Section (9) Cataloging and Classification, (10) Book storage place, (11) Digital book (12) and library community.

For link elements, users need (1) a professional blog, (2) Most Read, (3) Social communication, (4) A hyperlink points to a whole document or a specific element within a document, (5) HTML with hyperlinks, (6) archive links. Several specialized bodies produce specific software to design unique systems for automatic programming in the field of education so that it is easier for school and college teachers to prepare and present different lessons to their students. These lessons include training, introducing new material, conducting a test, or simulating a specific reality or other existing activities in the classroom. This facilitates and helps the user and spreads to all students through the university library.

For Accessibility, users may add some suggestions. They are (1) sound navigation, (2) Voice over text/ Voice reading, (3) Virtual voice assistance as guidance for e-resources/ Voice search, (4) Fonts type, (5) Color background writing and paper frames as well as numbering, (6) Service Request, (7) assign a supervisor, (8) Navigation Move, (9) A specialized librarian to register users of services available to people with disabilities, (10) sick cart. According to the World Health Organization (WHO), disability has three dimensions: Impairment in a person's body structure or function or mental functioning; examples of impairments include loss of a limb, loss of vision, or memory loss. Thirdly is the limitation of activity [78], such as difficulty seeing, hearing, walking, or problem-solving.

According to social presence theory, information sharing will only be limited if the quality of communication is high. Social presence theory states that creating a cognitive, social presence is relatively challenging because it requires a longer time and more frequent and intensive social interactions. For example, students like to go to the library to study together but also need social activities such as hanging out or shopping. In addition, an effective social presence can only partially be formed, as some students hide from online lessons by not turning on, facing their cameras, or even being present in live sessions. The research in [49] states that some students prefer to watch only recorded lessons.

Social presence is defined as the experience of meeting other people in a medium and interacting with others. Social presence plays a vital role in an online service environment, where there is no face-to-face interaction between the user and the librarian. Previous studies have used social presence theory to explain the social perspective of social commerce. Social presence describes the ability of communication media to convey social signals, such as socially rich messages, virtual agents [51] [79], human-like interfaces, 3D displays [80] [81], and telepresence [48]. Suppose the theory of social presence is applied in the library system. In that case, it will be able to engage library users with the library system or e-resources.

Social presence through interaction between users in e-resources refers to the ability of websites to convey a sense of sociability and human warmth [82] [83]. Web pages containing rich social messages can express a sense of personal presence. The availability of reviews and recommendation features on e-resources pages also increases presence through user interaction.

In an online environment, interacting with photos or videos can create a sense of warmth and human friendliness. Visual presence, such as photos or videos, is essential in attendance through interaction between users and librarians because these elements can describe real people in an online environment. Visual design factors such as images, colors, and graphics can significantly influence people's trust in the online environment. Kracher et al. (2003) also stated that photos could build trust between users and librarians. These visual elements [80], such as images and colors, are essential to the social presence.

VI. Conclusions

Users need help accessing the e-resources system interface in university libraries. These difficulties trigger users' negative emotions and result in the low usage of e-resources in university libraries which causes a decline in university performance. This study contributes to the point of view of increasing the use of e-resources in university libraries by finding elements that can increase positive emotions in users so that users enjoy using e-resources in libraries which will improve the quality of students and lecturers as well as university education and performance. The new elements for the e-resources interface are live chat with voice element, comment, rating and tool. Library account with personalized welcome, preference language, links for reference managers, and social media, and accessibility such as readable help font, color, and font size.

A. Limitation

The limitation of this study is that convenience sampling is used in this study's data collection to facilitate research. More comprehensive data collection techniques can be used in future studies to get more detailed data.

B. Future Work

For future research, the research method needs to be strengthened by interviews with the users to get their views. Secondly, user experience studies will be carried out using the library's e-resources system. Third, user modelling will be carried out to obtain data on an actual user's needs.

***Abstract*—In order to tackle the challenges of users' weak privacy awareness and frequent disclosure of private information in social network, this paper proposes a multidimensional privacy information portrait model of users in Chinese social networks. Because the TF-IDF (Term Frequency-Inverse Document Frequency, TF-IDF) algorithm does not consider the distribution of feature terms among and within classes, uses the TF-IDF algorithm based on the bag-of-words model to calculate the sensitivity of user privacy information. Considering the diversity of user privacy information, this paper proposes the PROLM (Positive reverse order lookaround matching) algorithm, which is combined with the Flashtext+ (improved Flashtext) algorithm and SMA (string matching algorithm, SMA), the PROLM_FlashText+_SMA to extract user personal privacy information and location where the privacy information is located, and return the sensitivity. Using the BERT (Bidirectional Encoder Representation from Transformers, BERT)-Softmax privacy information classification model, the privacy information is classified into high, moderate and mild privacy information, and a multidimensional privacy information portrait of the user is constructed based on the privacy information and sensitivity. The experiments show that the accuracy of PROLM_FlashText+_SMA algorithm for privacy information extraction reaches 93.63%, and the overall F1 index of privacy information classification using the BERT-Softmax model reaches 0.9798 on the test set, better than baseline comparison model, has better privacy information classification effect.**

***Keywords*—Social network; personal privacy information; privacy information portrait; sensitivity; privacy protection; BERT**

I. Introduction

In the current stage, social networking platforms like QQ, WeChat, Weibo, and Facebook have spread at an unprecedented speed, becoming indispensable parts of people's lives. According to the 50th Statistical Report on China's Internet Development, As of June 2022, 38% of internet users said they had encountered any online security problems in the past six months. In addition, the proportion of internet users who experienced personal information disclosure was the highest, at 22.1%. The emergence of social networks has changed the way people communicate and interact with each other [1], but people's use of social networks to share their lives inevitably brings the risk of privacy leakage. A particular piece of data posted by a user on a social networking platform may contain one privacy item of the user, but if many pieces of information contain privacy items of the user, these privacy items may be associated to expose a whole privacy chain of the user. For the published information, users cannot control its dissemination path, and once the information is accessed by unlawful elements, there is a risk of causing economic and property losses, and even threatening personal safety [2]. For example, in August 2022, an individual posted on a hacker forum claiming to auction the Shanghai Health Code database for $4000. The post stated that the database contained personal information of 48.5 million users of the Shanghai Health Code, including ID numbers, names, and phone numbers of individuals who have either resided in or visited Shanghai since the implementation of the health code system. The post also included the release of 47 sets of sample data. Such incidents have raised concerns about personal privacy and have led to widespread interest in the study of privacy protection technologies in social networks.

At present, many scholars both domestically and internationally are conducting research on privacy protection schemes for social networks. AL-Asbahi R [3] introduced the concept of structural anonymity as a means to reduce data anonymization. Lian *et al*. [4] achieved privacy protection for users by calculating sensitive attribute levels and using different anonymization methods for different levels, but this algorithm has high time expenditure compared to other algorithms. To meet the differences in privacy protection needs of different users, Yin X et al. [5] proposed a social network attributes graphs algorithm under personalized differential privacy, which is for the independent attribute information between users. Ning et al. [6] integrated noisy weights into the generated graph to solve the problem of edge weights and frequent structure privacy and realized the privacy protection of graph structure in the process of frequent mining. Huang et al. [7] proposed the PBCN method based on the joint clustering and randomization algorithm to resist node attacks and degree attacks in social networks and lost adjacency information. However, the error generated by the method includes noise error and graph reconstruction error.

However, these privacy protection studies have not yet visualized the personal privacy information that users expose on social networking platforms, making it difficult for users to intuitively understand the potential harm caused by such privacy information. Social networking platforms store a large amount of personal privacy information from users, and due to their massive user base and strong communication interactivity, users' privacy information is more prone to leakage. In order to identify potential privacy leakage risks and

This paper is supported by the National Natural Science Foundation of China (No. 62302540), Open Foundation of Henan Key Laboratory of Cyberspace Situation Awareness (No. HNTS2022020); Natural Science Foundation of Henan Province Youth Science Fund Project (No. 232300420422) and the Natural Science Foundation of Zhongyuan University of Technology (No. K2023QN018).

attack threats, enhance users' privacy awareness and behavior, and strengthen personal privacy protection, reduce the probability and impact of privacy breaches, the author extracts users' exposed privacy information from their historical data posted on social networking platforms and uses it to construct a multidimensional privacy information portrait of users.

The main contributions of this paper are as follows:

- Use the BOW-TF-IDF algorithm to measure the sensitivity of privacy information. The BOW-TF-IDF algorithm can better consider the distribution of privacy information within and between classes, more accurately reflect the differences between different categories, and has certain advantages in measuring privacy information sensitivity.
- In response to the limitation of the FlashText algorithm that can only extract English text, this paper improves it to make it suitable for Chinese scenarios. Propose PROLM_FlashText+_SMA algorithm extracts user privacy information. Experiments have shown that this algorithm has advantages in terms of precision in extracting privacy information.
- Build a privacy information classification model. Using the BERT-Softmax model to classify privacy information. This paper uses one hot to encode text, converting unstructured text sequences into structured feature vectors, and inputting text features into the fully connected layer to calculate the probability of each category label through the Softmax function. Experimental analysis shows that this classification model is significantly superior to traditional classification models.
- This paper proposes the concept of user portrait for privacy information, which determines the risk of user privacy leakage by calculating the average sensitivity of privacy information.

This article is mainly divided into four chapters. In Section I, introduction is mentioned which mainly introduces the background and significance of this study. Section II is related work, which introduces the research of domestic and foreign scholars on user portrait. Section III is algorithms and model, which introduces the algorithm and model of this article. Section IV is experimental results and analysis and Section V concludes the paper.

II. Related Work

At present, research on user portrait can be broadly classified into three main categories: user behavior-based user portrait model, interest-based user portrait model, and topic-based user portrait model.

Alan Cooper was the first to suggest the idea of a user portrait. A user portrait is a designated user model based on some actual data points (such as social traits and consumption variables) [8].

1) User behavior-based user portrait model: Li et al. [9] developed a model that utilizes big data mining and analysis technology to construct a student portrait based on extensive data from campuses. By extracting the characteristics and attributes from a vast amount of behavioral data, they are able to create a comprehensive portrait of a student. Minghui You et al. [10] proposed a behavior-aware user profiling technique that utilizes data mining of user attributes to construct an initial user portrait by identifying user behavior patterns through perception. Zhang et al. [11] introduced an enhanced fuzzy MLKNN multi-label learning algorithm based on MLKNN, aiming to address the challenges of subjective augmentation caused by credit data discretization and the absence of multi-dimensional *credit user portrait in current credit data research.*

2) Interest-based user portrait model: Shufang Wu et al. [12] put forward an interest transfer-based user portrait building approach, which serves as a remedy for the inadequacy and inaccuracy of current microblog user portrait creation methods in capturing user characteristics. Ding Z et al. [13] proposed the LDA-RCC model to analyze the interests of forum users and create user portrait.

3) Topic-based user portrait model: Jianyun Wu et al. [14] proposed by analyzing the crawled videos, users, and their viewing data through text mining, this paper build a single user portrait, cluster the users, and extract themes through K-Means and LDA models to explore the characteristics of group users. Deng et al. [15] proposed a user portrait fraud warning scheme based on publicly available data on Weibo. They conducted preliminary screening and cleaning based on the keyword "being scammed" to obtain effective fraudulent user identity documents. Through feature engineering techniques such as avatar recognition, artificial intelligence (AI) sentiment analysis, data filtering, and fan blogger type analysis, these images and texts were abstracted into user preferences and personality characteristics, and multi-dimensional information was integrated to construct user portrait.

With the increasing awareness of privacy among individuals, personal privacy issues are increasingly receiving attention. To address these issues, this paper applies user profiling technology to social networks and proposes the concept of user privacy information profiling for social networks. By extracting five dimensions of privacy information from the historical information shared by users on social networks, a user portrait of privacy information is constructed to visually display potential privacy threats and risks to users, and to intuitively understand potential privacy issues and leakage risks.

To benefit the readers with a quick reference, the major notations of this paper are listed in Table I.

TABLE I. MAJOR NOTATIONS

Notation	Description
TF	Term Frequency
IDF	Inverse document frequency
TF-IDF	sensitivity w_i
w_i	Sensitivity of privacy information
Current (P_i)	Location of the node where the current keyword is located
next(*Current*,P_i^j)	Location of the node where the next keyword is located
F	Transfer Functions
Query(Q)	The relationship between the current word to be queried and other words
Key(K)	Vector used to calculate attention weights
Value(V)	Weighted results
W^Q,W^K,W^V	Weight matrix
d_k	Dimension of input information
W^O	Mapping Vector for Multi head
Concat(·)	Concatenation function
$h_\theta(x^i)$	Softmax regression model discriminant function
J_θ	The Cost Function of Softmax Regression Model
x^i	Input samples

III. ALGORITHMS AND MODEL

The multidimensional privacy information portrait of social network users is mainly divided into three modules: the privacy information sensitivity calculation model, the social network user privacy information extraction model, and the BERT-based privacy information classification model. The overall structure of the Chinese social network user multidimensional privacy portrait model is shown in Fig. 1.

The user portrait of social network privacy information depicts the personal privacy data exposed by users while using social networks from various perspectives and dimensions. Firstly, the word bag model is utilized to extract features related to privacy information. It involves transforming the sparse word frequency matrix regarding privacy information into a word bag vector. Subsequently, the TF-IDF algorithm is employed to determine the sensitivity of the privacy data. Next, the PROLM_FlashText+_SMA algorithm is utilized to extract the user's privacy information and its corresponding sensitivity. The average sensitivity of the user's privacy data is calculated to classify the risk of privacy leakage into high, medium, and low levels. Lastly, the BERT Softmax model is employed to categorize privacy information as high privacy, moderate privacy, or mild privacy, enabling the construction of a user portrait for social network privacy information.

A. *A Model for Calculating the Sensitivity of Privacy Information of Social Network Users*

This paper employs the TF-IDF algorithm, utilizing the word bag model, to assess the sensitivity of private information. The concept of TF-IDF was introduced by Karen Spärck Jones [16] and entails a fusion of term frequency (TF) and inverse document frequency (IDF).

Bag-of-words model, is a simple mathematical model for describing text and a common way to extract text features [17]. This model disregards the grammatical and sequential aspects of the text, treating it as a collection of words. Each word occurrence in the document is considered as an independent entity.

Fig. 1. Overall structure of the multidimensional privacy portrait model of social network users.

The TF-IDF algorithm takes into account both the frequency of a term in a specific document and the importance of the term in the entire document collection, thereby reflecting the significance of the term more accurately in the text. By computing the inverse document frequency, the TF-IDF algorithm can consider the distribution of privacy information across the entire corpus and capture the global characteristics of terms. This enables it to calculate privacy sensitivity more accurately and better represent the importance of privacy information to users. Therefore, this paper utilizes the TF-IDF algorithm to calculate the sensitivity of privacy information.

The model for calculating privacy information sensitivity consists of two main modules: Privacy information feature extraction, which involves extracting features from pre-processed text using the bag-of-words model. Privacy information sensitivity calculation, which includes transforming the text into a bag-of-words vector and ultimately calculating the sensitivity of privacy information using the TF-IDF algorithm.

1) Privacy information feature extraction: The structure diagram of privacy information feature extraction is shown in Fig. 2.

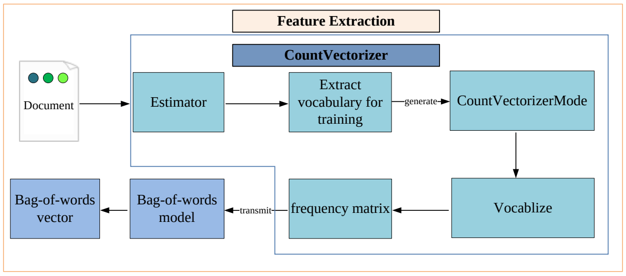

Fig. 2. Privacy information feature extraction structure diagram.

The specific steps are.

Step 1: Construct a corpus Document (pre-processed survey questionnaire document).

Step 2: Training a CountVectorizer model and creating CountVectorizerMode, extracting privacy information words in the document for training and obtaining the vocabulary i.e. all privacy information words present in the corpus.

Step 3: Transforming the text into a word frequency matrix of documents regarding privacy information words.

Step 4: Build a word bag model and convert the word frequency matrix into a word bag vector.

2) Privacy information sensitivity calculation: In this stage, the TF-IDF (sensitivity w_i) value of privacy information is calculated based on the bag-of-words vector. The specific steps are.

Step 1: Calculate the TF value. The TF value depends only on the number of times the privacy information words are in the corpus and is calculated as:

$$TF = \frac{D_{w,\mathrm{d}}}{\sum_k D_{k,d}} \quad (1)$$

where, D denotes the corpus, the symbol $D_{w,d}$ denotes the number of occurrences of privacy word w in document *d*, and the denominator denotes the total number of occurrences of all privacy words w in D.

Step 2: Calculate the IDF value, which is calculated as:

$$IDF = \log \frac{|D|}{DF_{w,D} + 1} \quad (2)$$

where, |*D*| denotes the total amount in the corpus, $DF_{w,D}$ denotes the number of documents containing the privacy word w. To avoid the denominator and the occurrence of arithmetic errors, the IDF needs to be optimized, i.e., denominator + 1.

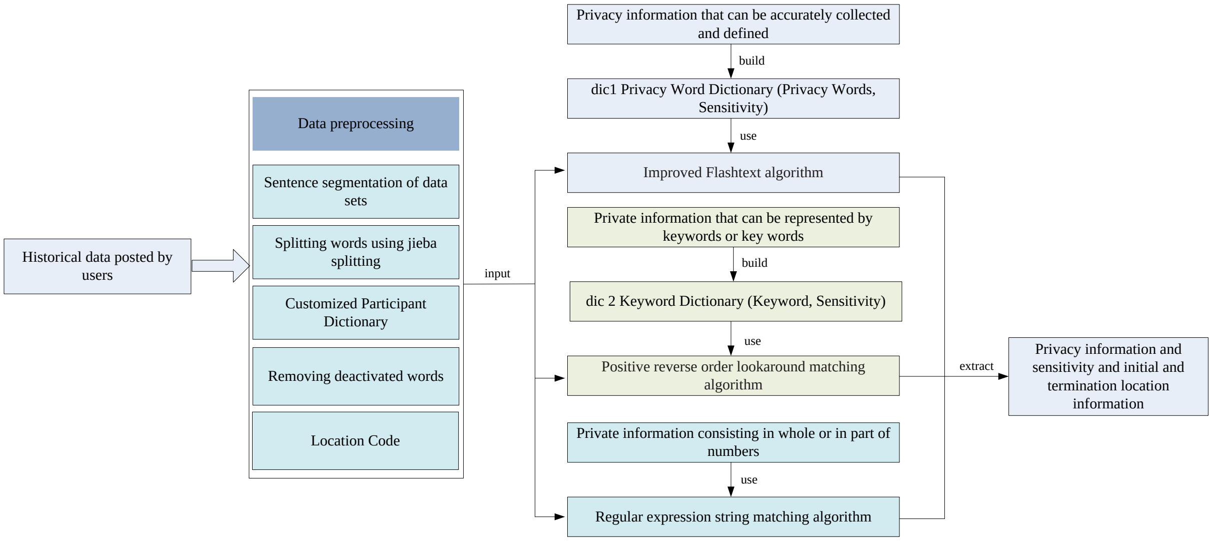
Step 3: Calculate TF-IDF value.TF-IDF value of a privacy word is the product of TF and IDF, which is calculated as:

$$TF - IDF = TF * IDF \quad (3)$$

B. *A Model for Extracting Privacy Information of Social Network Users*

The FlashText algorithm, created by Singh V, is designed to specifically match complete English words. It serves as a novel and efficient algorithm for keyword search and replacement [18]. However, considering the disparities between English and Chinese texts, this paper enhances the FlashText algorithm to cater to Chinese texts. The enhanced algorithm, known as FlashText+, incorporates jieba word segmentation and constructs a Chinese Trie dictionary. By doing so, the FlashText+ algorithm not only retains the advantages of the original FlashText algorithm but also becomes applicable in Chinese scenarios. Fig. 3 illustrates the structural diagram of the model for extracting user privacy information in social networks.

In the privacy information extraction stage, in order to facilitate the extraction of user privacy information, this paper have constructed two Chinese privacy information dictionaries, dic1 and dic2, which store two parameters, respectively, where dic1 = (privacy word, sensitivity) and dic2 = (keyword, sensitivity). The privacy word indicates user privacy information that can be accurately collected and defined, while the keyword indicates user privacy information that contains a specific keyword or word.



Historical data posted by users
Data preprocessing
Sentence segmentation of data sets
Splitting words using jieba splitting
Customized Participant Dictionary
Removing deactivated words
Location Code
input
Privacy information that can be accurately collected and defined

dic 2 Keyword Dictionary (Keyword, Sensitivity)
use
Positive reverse order lookaround matching algorithm
Private information consisting in whole or in part of numbers
use
Regular expression string matching algorithm
extract
Privacy information and sensitivity and initial and termination location information

Fig. 3. Structure of social network user privacy information extraction model.

In this paper, this study classify users' privacy information into three types, i.e., privacy information that can be accurately collected and defined, privacy information that cannot be accurately collected and defined but can be represented by a keyword or word, and privacy information that consists entirely or partially of numbers. The first type of privacy information extracted using the improved FlashText algorithm; for the second type of privacy information, the keywords defined in dic2 are used to extract the user's privacy information and its sensitivity and its location using the PROLM algorithm; for the third type of privacy information, the corresponding rules are defined to extract the privacy information, sensitivity and its location using the string matching algorithm.

Example 1. A message posted by a user T = {Punch up Henan University, near Longting District.}

1) Extracting user privacy information using an improved FlashText algorithm.

The improved FlashText algorithm extracts user privacy, sensitivity, and location information in the following steps.

Step 1: Data pre-processing. Data preprocessing is performed on the user-posted information T. The word order and location information of T after preprocessing are shown in Fig. 4.

Step 2: Build a Chinese Tree dictionary.

Construct a Chinese tree dictionary using the privacy words in dic1 as input. First, create an empty node root which is the starting point of all private words, then insert all private words into the Trie tree one by one, if there is already a node pointing to the current character in the path during the insertion process, then visit the node, if there is no corresponding node, then create a new node pointing to the current character, if a private word completes the insertion, mark the last node in its path. The process is as in Algorithm 1.

Algorithm 1: Build a Chinese Tree dictionary

```
Input: P= {$p_1$, $p_2$, ..., $p_r$}
Output: Chinese Tree dictionary
Create an initial state empty root 0
For i∈1, 2 ,....., r Do
    Current ← root
    j ← 1
    Pi ← Current ($P_i$)
    While j ⩽ $m_i$ AND next (Current, $P_i^{\,j}$) ≠ end Do
        Current ← next (Current, $P_i^{\,j}$)
        j←j+1
    End of While
    If j ⩾ $m_i$ Do
        |Create a new non empty node Stat
            next (Current, $P_i^j$ ) ←State
            Current ← State
            j← j+1
            break
    End If
    If Current is already terminal Then F(Current)←F(Current)∪{i}

    Else mark Current as end, F(Current)←{i}
End of For
```

This study defines some of the notations used in Algorithm 1. *P* is the privacy word in dic1, root is the root node, *i* is the position of the privacy word, *j* is the position of the node in the tree dictionary, *Current (P_i)* is the position of the node where the current keyword is located, *next (Current, P_i^j)* is the position of the node where the next keyword is located, and *F* is the transfer function.

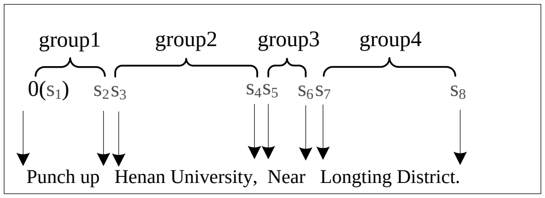

Fig. 4. Phrase order and position information of L after pre-processing.

Step 3: Iterate through the Chinese tree dictionary and g output the results. The pre-processed T is used as input, and each node in the Chinese tree dictionary is traversed one by one in terms of phrases, starting from the root node root (0) for matching. If the characters match, the current state jumps to the corresponding state. When the output state (the state with shaded background) is reached, the corresponding private word for the sequence of matched nodes is output, and the sensitivity is returned. Additionally, the location of the privacy information is saved. If the characters do not match, the next matching step is performed. The traversal process is shown in Algorithm 2.

Algorithm 2: Privacy Information Extraction

```
Input: P={$p_1$,$p_2$,...,$p_r$}, T=($t_1$,$t_2$,...,$t_n$)
Output: Privacy Words pi, Sensitivity, Start and end positions
Preprocessing
        FT← Build_FT(P)
Searching
    Current ← Initial state of the Flashtext FT
    For pos ∈1,2,...,n Do
            While $next_{FT}$ (Current, $t_{pos}$) = end AND $S_{FT}$(Current) ≠ end Do
                Current ← $S_{FT}$(Current)
            End of While
            If $next_{FT}$ (Current, $t_{pos}$) ≠ end Then
                Current ← $next_{FT}$ (Current, $t_{pos}$)
            Else Current ← initial state of FT
            End of If
            If Current is terminal Then
                Mark all the occurrences (F(Current), pos)
            End of If
    End of For
F
```

This study define some symbols used in Algorithm 2, P is the privacy word in dic1, T is the input text, *$next_{FT}$* is the next matching node position, *S_{FT}* is the current matching node position, and *F* is the transfer function.

2) *Extracting* user privacy information using the PROLM algorithm.

PROLM algorithm focuses on matching results and omits duplicated content, enhancing matching speed by searching from right to left. However, it cannot match privacy information consisting of digits alone. A combination with a string matching algorithm is proposed to extract such information.

PROLM algorithm：Matching text from right to left can be abstractly represented as: (?<=SubExp1)|(?<=SubExp2).

According to the characteristics of SubExp1 can be summarized into three categories.

- The subexpression SubExp1 is of fixed length and is in general mode.
- The subexpression SubExp1 has a variable length, for non-greedy mode.
- The subexpression SubExp1 is not fixed in length, but it contains match-first quantifiers, which is a greedy mode.

The matching principle of the PROLM algorithm is shown in Fig. 5, which can be divided into main matching and sub-matching.

Its main idea is to extract phrases containing keywords in dic2 from data published by users.

Taking the text in Fig. 5 as an example, the main matching process is shown Algorithm 3.

Algorithm 3: Main matching

```
Input: T={t_1,t_2,...,t_n}, dic2={k_1， k_2,....,k_n}
Output: Privacy Words, Sensitivity, Start and end positions
for i∈1,2,...,n Do
    i← 1
    while there is no keyword ki in dic2 in T Do
    end of while
    if T contains the keyword ki in dic2 Do
        find the keyword position Si from the initial position Sk
        to the right
        S_k←S_{i-len}(SubExp1)
        Enter sub matching
    End of If
    if next round of sub matching is required
        give control to subsequent word expressions
    else location of report Si, matching failed
    end of if
    if Subsequent sub expression matching succeeded
        location of report Si , match succeeded
    else location of report S_i, matching failed
    end of if
End of for
```

This study define some of the symbols used in Algorithm 3, T is the input text, k_n is the keyword in dic2, S_k and S_i are the location of the text, and *len(SubExp1)* is the length of "SubExp1".

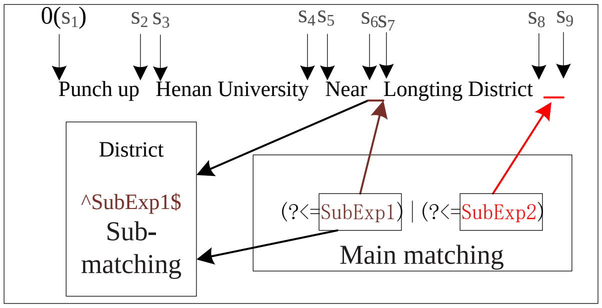

Fig. 5. PROLM algorithm matching principle.

The main matching process is divided into the following steps.

Step 1: Matching is attempted from position 0 to the right, before finding the position that satisfies (? <=SubExp1) and contains the keyword in dic2, the matching must fail until position S_9 is found and its requirements are met.

Step 2: Locate the position S_6, which satisfies the minimum length requirement for "SubExp1", by moving leftwards from S_9.

Step 3: Perform a sub-matching process by applying "SubExp1" from position S_6 and moving rightwards.

Step 4: Successfully match "(? <=SubExp1)" and proceed to the subsequent sub-expression "(? <=SubExp2)". Keep attempting to match until the entire expression either matches or fails. Report whether the entire expression at position S9 matches successfully or fails.

Step 5: If necessary, continue to find the next position S_5 and start a new round of attempted matching.

The sub-matching process is divided into the following main steps.

Step 1: Upon entering sub-matching, the source string has been determined as the string between S9 and S6, and the regular expression at this point becomes "^SubExp1$". In this round of sub-matching, once a match is successful, it must start at S9 and end at S6.

Step 2: Once the sub-expression is fixed, whether the match succeeds or fails, the match result is returned, and there is no need for further rounds of matching.

Step 3: When the length of the subexpression is not fixed, in the case of a greedy mode, if the match fails, it is reported as a failure and the next round of matching is requested. If the match is successful, all backtracking states are discarded and the success is reported, eliminating the need to try the next round of matching.

Step 4: In the case of a greedy mode, if the match fails, it is reported as a failure and the next round of matching is requested. If the match succeeds, all backtracking states are discarded, the success is reported, and the successful content of this match is recorded. The next round of matching is requested until the longest match is obtained.

The sub-matching process is shown in Algorithm 4.

Algorithm 4: Sub matching

```
Input: $S_k$, $S_i$
Output: return to main matching
Sub Match Start
    if fixed length of sub-expressions do
        report matching results, no need for next round of sub matching
    else
        next
    en of if
    if subexpression is not greedy mode and matching succeeded
        report matching results, no need for next round of sub matching
    else
        matching failure, request to enter the next round of sub matching and return to main matching
    end of if
    if the sub expression is greedy and matched successfully
        matching success, record this success, request to enter the next round of sub matching
    end of if
    if the sub expression is greedy and matched failure
        return to main matching
    end of if
```

3) Extracting user privacy information using regular expression string matching algorithm.

Use regular expression string matching algorithm to define corresponding matching rules to extract privacy information and sensitivity from the preprocessed text for privacy information that is entirely or partially composed of numbers, such as a mobile phone number, license plate number, mailbox, etc.

C. BERT-Softmax Classification Model for Privacy Information

1) BERT model: BERT is a pre-trained language model based on a Transformer encoder, which enables reading the whole text at once for bi-directional linguistic representation to achieve the prediction task, and the input Embedding is encoded and transformed through layers of Encoder. In this paper, a pre-trained BERT-based model is utilized to classify the extracted user-privacy information.

Compared to traditional text classification methods, text classification based on BERT pre-trained models has the following advantages:

- Better semantic understanding: The BERT model can learn contextual information from the text, leading to a better understanding of the text's meaning and improving the accuracy of text classification.
- Improved robustness: The BERT model can handle texts of different lengths, enhancing the model's robustness and enabling it to process various types of text data.
- Good generalization capability: Text classification models based on BERT can be fine-tuned to adapt to different text classification tasks, thereby exhibiting good generalization capability.

The structure of the BERT model [19] is shown in Fig. 6. It consists of a multilayer bidirectional Transformer encoder. Where, the middle Trm denotes the Transformer encoder, E_1, E_2,...E_N denotes the text input vector of the word, the vectorized representation of the text is obtained after the Trm module, and T_1, T_2,...T_N denotes the final text representation.

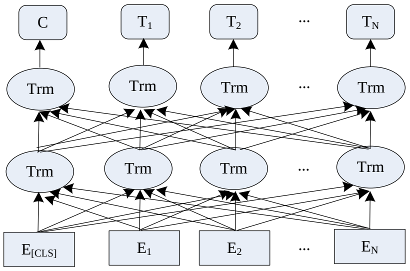

Fig. 6. Structure of the BERT model.

2) BERT-Softmax classification model. The structure of the BERT- Softmax classification model is shown in Fig. 7.

The classification process is as follows: the extracted user-privacy information is used as input text data, the text features are extracted using the BERT pre-training model, i.e., the text is encoded using one-hot, the unstructured text sequence is converted into a structured feature vector, the text features are input into the fully connected layer and the probability of each type of label is calculated by the Softmax function, and the label corresponding to the maximum probability is the result of the model classification.

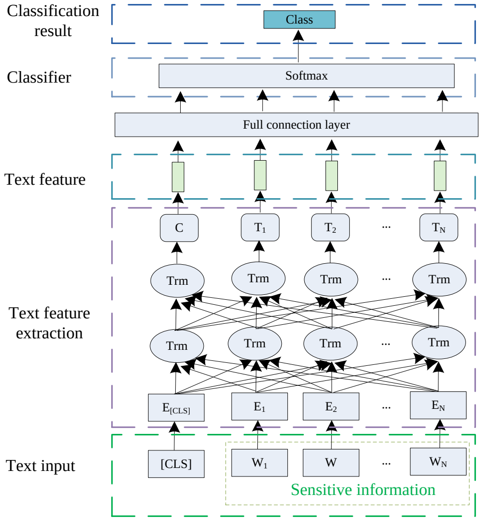

Fig. 7. Structure of BERT-based pre-trained classification model.

3) Attention mechanism: whose core idea is to calculate the interrelationship between each word in the input text and all the words in that text, and to measure the relevance and importance of different words in the input text, and to adjust the weight of each word by these interrelationships to obtain a new expression for each word, which contains not only the semantics of the word itself but also its relationship with other words [20].

The calculation process of Self-attention for a single word is shown in Fig. 8, where Query denotes the current word to go to a query concerning other words, Key denotes waiting to be checked, and Value denotes the actual feature information.

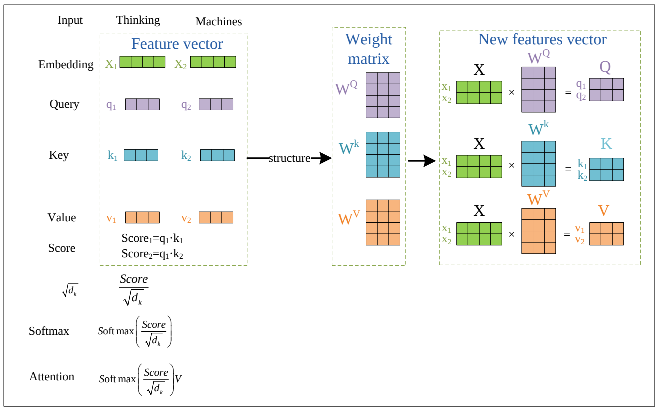

Fig. 8. Self-attention calculation process for a single word.

The calculation steps are as follows:

Step 1: For each word of the input after one-hot encoding get the initial feature vector noted as X=[x_1,x_2], and initialize three weight vectors q, k, v;

Step 2: With training the entire weight matrix W^Q, W^K, W^V is constructed;

Step 3: Use Eq. (4) to obtain three new feature expression matrices Q(Query), K(Key), and V(Value) for each word;

$$\begin{cases} Q=XW^Q \\ K=XW^K \\ V=XW^V \end{cases} \tag{4}$$

Step 4: Calculate the inner product Score using Eq. (5), which indicates the relationship between the current word and other words.

$$Score = QK^T \tag{5}$$

Step 5: To prevent the Score from increasing with vector dimension, the inner product is calculated by dividing by the factor $\sqrt{d_k}$, d_k being the vector dimension of the input information and normalized to a probability distribution by the softmax function.

Step 6: The distribution of scoring by inner product is the weighted average of Value, and Attention is calculated using Eq. (6).

$$Attention(Q,K,V) = \mathrm{Soft\,max}\left(\frac{Score}{\sqrt{d_k}}\right)V \tag{6}$$

In practice, the Transformer encoder uses Multi-head attention mechanism, Multi-head mechanism that is Multi-head attention is a network optimization technique used in BERT network structure, using different heads to focus on different context dependency patterns, similar to the model integration effect, which can achieve parallel operations, the input of the network into multiple branches, respectively, do attention mechanism, and finally, the results of each branch will be spliced to get, its calculation as in Eq. (7) and Eq. (8).

$$head_i = Attention(QW_i^Q, KW_i^K, VW_i^V) \tag{7}$$

$$Multi-head(Q,K,V) = Concat(head_i)W^O \tag{8}$$

where, W_i^Q, W_i^K, and W_i^V represent the W^Q, W^K, and W^V weight matrices of the ith head, W^O denotes the mapping vector of Multi-head, and Concat(·)denotes the splicing function.

4) Classification: In this paper, introduce softmax regression model for privacy information classification. The softmax regression, like linear regression, does a linear superposition of the input features and ourights. One major difference from linear regression is that the number of output values in softmax regression is equal to the number of categories in the label. Assuming there is a training sample set {(x^1, y^1), (x^2, y^2),..., (x^m, y^m)}, where x^i represents the privacy information vector corresponding to the i-th training sample, with a dimension of n for a total of m training samples, $y^i \in$ (1,2,..., n) represents the category corresponding to the i-th training sample, and n is the number of categories. For a test input sample x, the distribution function of the Softmax regression model is the conditional probability p(y=j|x), indicating the probability that x belongs to category j, where the category with the highest probability of occurrence is the category to which the current sample belongs, and the hypothesis function of belonging to each category is as in Eq. (9).

$$\mathrm{h}_\theta(x^i) = \begin{bmatrix} p(y^i=1|x^i;\theta) \\ p(y^i=2|x^i;\theta) \\ \dots \\ p(y^i=n|x^i;\theta) \end{bmatrix} = \frac{1}{\sum_{j=1}^{n} e^{\theta_j^T x^i}} \begin{bmatrix} e^{\theta_1^T x^i} \\ e^{\theta_2^T x^i} \\ \dots \\ e^{\theta_n^T x^i} \end{bmatrix} \tag{9}$$

Among them, the probability that any element *$p(y^i=n|x^i;\ \theta)$* in *$h_\theta(x^i)$* is the current input sample x^i belonging to the current category *n*.

For a data set with *m* training samples, the cost function of the Softmax regression model is as in Eq. (10).

$$J_\theta = -\frac{1}{m}\left[\sum_{i=1}^{m}\sum_{j=1}^{n} I\left\{y^{(i)}=j\right\}\log\frac{e^{\theta_j^T x^{(i)}}}{\sum_{l=1}^{n} e^{\theta_j^T x^{(i)}}}\right] \tag{10}$$

where, *I{.}* is the indicative function, *m* is the number of samples, *n* is the number of categories, *i* denotes a certain sample, x^i denotes the vector representation of the *ith* sample *x*, and *j* denotes a certain category.

After obtaining the model parameters *θ*, the probability of belonging to category *j* for the sample *x* to be measured is:

$$\mathrm{p}\left(y^{i}=j \mid x^{i};\theta\right)=\frac{e_{j}^{T}x^{i}}{\sum_{l=1}^{n}e_{l}^{T}x^{i}} \qquad (11)$$

The probability of x belonging to all categories is calculated using Eq. (11), and the category with the highest probability is chosen as the classification category for x.

D. Building a Portrait of User Privacy Information

The construction of user privacy portrait first extracts user privacy information through the PROLM_ FlashText+_ SMA algorithm, and then uses BERT-Softmax to classify the privacy information. Then, use Eq. (12) to calculate the average sensitivity of privacy information to determine the level of user privacy leakage risk. Finally, use word cloud technology to construct user portrait of privacy information.

$$W=\frac{\sum_{\mathrm{i}=0}^{n}w_{i}}{\mathrm{n}},(n\geq 0,i\geq 0) \qquad (12)$$

where, W denotes the average sensitivity of privacy information, n denotes the number of privacy information, i denotes the i-th privacy word, and w_i denotes the sensitivity of the i-th privacy word.

Set a threshold to divide the risk of user privacy leakage into three levels.

Heavy leakage risk: average sensitivity $W > 0.11$.

Moderate leakage risk: average sensitivity $0.07 < W < 0.11$.

Mild leakage risk: average sensitivity $W < 0.07$.

IV. Experimental Results and Analysis

Due to the lack of public datasets related to the precise expression of user privacy, the experimental datasets for user privacy information in this paper are collected by crawlers and collected manually. The dataset in this paper is divided into four parts: 1071 valid questionnaire data for user privacy information sensitivity calculation, 1000 social network users' microblogging history data, a dictionary containing 7673 user privacy words and a dictionary containing 199 user privacy keywords for privacy information extraction, and 60,000 user privacy data for privacy information classification. Experiment in this paper is divided into three parts: user privacy information sensitivity calculation, user privacy information extraction, and user privacy information classification.

A. User Privacy Information Sensitivity Calculation

The dataset used in this experiment is a 1071 valid survey questionnaire, which defines a total of 62 types of privacy information.

This paper uses the BOW-TF-TDF algorithm to calculate privacy sensitivity, and arranges the sensitivity calculation results in descending order, as shown in Table II.

TABLE II. Sensitivity of User Privacy Information

Privacy words	Sensitivity	Privacy words	Sensitivity
ID number	0.155	Purchase preferences	0.125
Email	0.154	Private financial list	0.124
health condition	0.154	Payment records	0.124
phone number	0.153	Income situation	0.123
Home Address	0.153	Purchase Record	0.123
Property status	0.152	major	0.122
Bank card number	0.152	Purchase frequency	0.121
Card Number	0.152	Consumer credit	0.121
academy	0.152	Shopping habits	0.121
Political landscape	0.151	Consumption amount	0.12
height	0.15	Dressing hobbies	0.118
Current address	0.15	Literary Hobbies	0.118
height	0.15	Sports hobbies	0.116
Gender	0.149	Consumption level	0.116
marital status	0.149	Travel Hobbies	0.115
Age	0.143	Game Hobbies	0.1118
weight	0.14	Weibo account	0.106
position	0.137	Chat records	0.104
educational	0.137	QQ number	0.102
Online behavior	0.134	Tiktok	0.102
Mode of travel	0.134	Kuaishou	0.102
Life experience	0.134	Station B	0.101
Social relationship	0.133	WeChat signal	0.099
Family member	0.133	Alipay account	0.096
Device Information	0.133	The Little Red Book	0.095
Work unit	0.132	Investment hobbies	0.013
Personal itinerary	0.132	Art Hobbies	0.011
IP address	0.132	Pets	0.003
name	0.13	constellation	0.0001
occupation	0.13	religious belief	0.00002
Training experience	0.13	blood group	0.00002

According to Table II this paper classifies privacy information into three levels.

High privacy: when wi >0.13, the privacy information includes the user's ID number, home address, name, IP address, and other information, which can accurately locate the user's identity and location once exposed.

Moderate privacy: when 0.13 >wi >0.1, the privacy information includes information about the user's hobbies, social behavior habits, etc., which can only be roughly understood about the user even if exposed.

Mild privacy: when $w_i < 0.1$, this type of information, even if exposed, will not have a major impact on the user.

B. User Privacy Information Extraction

The dataset used in this experiment is the basic Weibo information of 1000 social network users and 65536 historical and dynamic information. This paper evaluates the superiority of this scheme based on the precision of privacy information extraction.

1) Data preprocessing: This paper mainly collects data from Weibo users on social networking platforms.

Data preprocessing mainly includes filtering the empty data in the dataset, using the Jieba word segmentation library to segment the dataset based on the stop list proposed by the Harbin Institute of Technology laboratory, and removing stop words, special symbols, and meaningless words.

2) Evaluation indicators: This paper evaluates the performance of different models by extracting privacy information precision.

The goal of privacy information extraction is to correctly extract all the privacy information from the historical data posted by users, and Precision is an important indicator of how good the information extraction model is. Precision is calculated by the following formula.

$$\Pr ecision = \frac{|\,\mathrm{privacy}_u\,|}{|\,extreact_u\,|} * 100\% \qquad (13)$$

where, $|privacy_u|$ denotes the number of extracted privacy information, $|extreact_u|$ denotes the total number of extracted information.

This paper selects classic text information extraction models BILSTM, BILSTM-CRF, and LSTM-CRF as comparative experiments. We divided the dataset into training, validation, and testing sets in a ratio of 8:1:1. The distribution of the dataset is shown in Table III.

TABLE III. PRECISION COMPARISON OF DIFFERENT PRIVACY INFORMATION EXTRACTION MODELS

Model	Precision
BILSTM	87.92
BILSTM-CRF	90.32
LSTM-CRF	89.64
PROLM_FlashText+_SMA	**93.63**

According to the data in Table III, it can be seen that the PROLM_FlashText+_SMA algorithm proposed in this paper has the highest precision rate in privacy information extraction tasks (93.63), followed by BILSTM-CRF (90.32), and the model BILSTM has the lowest precision rate (87.92). Experiments have shown that the PROLM_FlashText+_SMA algorithm outperforms the comparative model in terms of precision in extracting privacy information.

C. User Privacy Information Classification

1) Experimental dataset: The classification dataset used in this paper is the THUCNews text classification dataset provided by the Tsinghua NLP group and the author collection of 60,000 pieces of data about users' privacy information, containing three types of data: highly privacy, moderately privacy and mildly privacy information, and this paper divide the dataset into the training set, validation set, and test set according to 8:1:1, and the distribution of privacy information classification dataset is shown in Table IV.

TABLE IV. CLASSIFICATION OF PRIVACY INFORMATION CLASSIFICATION EXPERIMENTAL DATASET

Category	Label	Train Set	Test Set	Validation Set
Highly privacy	1	8000	1000	1000
Moderately privacy	2	8000	1000	1000
Mildly privacy	3	8000	1000	1000

2) Model and parameter setting: The experimental environment is Windows 10, based on the PyTorch framework, CUDA version 11.7.1, CUDANN 8.5, and the GPU used to accelerate the training is RTX3050, and the model parameters are set as shown in Table V.

TABLE V. PARAMETERS OF THE MODEL

Parameters	Numerical value
hidden_size	768
epoch	3
batch_size	32
pad_size	32
learning_rate	5e-5
Attention Dimension	64

3) Evaluation indicators: The common evaluation metrics for classification problems are the Precision, Recall, and F1 (F1-Score) index. Precision and recall are important metrics to measure how good an information extraction model is. The F1-score is the summed average of Precision and Recall, which is used to evaluate the precision and recall together.

The precision calculation formula equation is as follows.

$$Precision = \frac{\mathrm{Sum}_{true}}{Sum_{forecast}} \qquad (14)$$

where, Sum_{true} indicates the number of privacy information correctly classified, and $Sum_{forecast}$ indicates the number of privacy information predicted to be in that category.

The recall is calculated as follows.

$$Recall = \frac{Sum_{true}}{Sum_{actual}} \qquad (15)$$

where, $Sum_{actural}$ indicates the actual amount of privacy information in that category.

The formula for calculating the F1-Score is as follows.

$$F1 = \frac{\Pr ecision * \mathrm{Re}\, call}{\Pr ecision + \mathrm{Re}\, call} * 2 \qquad (16)$$

In this paper, we choose the classical text classification models BERT_CNN, BERT_RNN, BERT_RCNN, and ERNIE as the comparison experiments. The training set, validation set, and test set data are kept consistent with the BERT model during the training process, and the Precision, Recall, and F1 index of different models are compared as shown in Table VI.

TABLE VI. COMPARISON OF PRECISION, RECALL, AND F1 INDEXES OF DIFFERENT CLASSIFICATION MODELS

Model Name	**Precision**	**Recall**	**F1-Score(F1)**
BERT_CNN	0.9231	0.9530	0.9378
BERT_RNN	0.9382	0.9550	0.9419
BERT_RCNN	0.9384	0.9640	0.9510
ERNIE	0.9412	0.9730	0.9568
BERT-Softmax	**0.9846**	**0.9750**	**0.9798**

From Table VI, it can be seen that the privacy information classification model proposed in this paper based on BERT Softmax has an accuracy and recall rate of over 0.97 in privacy information classification experiments, and the F1 index reaches 0.9798. From the overall experimental results, it can be seen that the F1 value of the BERT model is higher than that of the BERT_CNN model is four percentage points higher than the ERNIE model by two percentage points, indicating that this model is compared to BERT_CNN, BERT_RNN, BERT_RCNN and ERNIE classification models can better represent the semantic information of short text privacy information and have better privacy information classification performance.

V. CONCLUSION

In order to address the issue of user privacy and social relationships being prone to privacy leakage during data publishing and information sharing, this paper proposes a user privacy information portrait model for social networks. To address the issue of difficulty in measuring user privacy information sensitivity, the BOW-TF-IDF algorithm is used to calculate user privacy information sensitivity; Due to the diversity of user privacy information, this paper proposes the PROLM_FlashText+_SMA privacy information extraction algorithm, which extracts the privacy information exposed by users from historical data published on the social Internet of Things. The privacy information is classified into high, moderate, and mild using the BERT-Softmax based privacy information classification model. Finally, Use the extracted privacy information to construct a multidimensional user portrait of privacy information and determine the level of privacy leakage risk by calculating the average sensitivity of privacy information. The experiment shows that the privacy information extraction model proposed in this paper exhibits its superiority in terms of accuracy; the privacy information classification model proposed in this paper outperforms traditional classification models in terms of accuracy, recall, and F1 index. It can better represent the semantic information of short text privacy information and has better privacy information classification performance.

In the future, this study will be combined with trust between users to generate access controls to protect the privacy of users in social networks.

***Abstract*—Estimating fruit yield holds significant importance for farmers as it enables them to make precise resource management decisions for fruit harvesting. The adoption of automated image processing technology not only reduces the human labor required but also enhances the accuracy of ripe fruit estimates. This research delves into the performance of an image processing algorithm designed to count and identify oranges. The study employed a multi-phase approach, starting with the creation of a mask to isolate orange content, followed by the detection of circular shapes within the mask. Lastly, the algorithm filters and counts the identified circles. The outcome of this study revealed that the algorithm demonstrated an impressive success rate of approximately 72.4% in correctly identifying oranges with standard deviation of +/- 12.20.**

***Keywords*—Image processing; fruit; multiphase approach; counting**

I. Introduction

Crop yield estimation is important to farmers so that they can accurately predict and manage the resources that will be required to harvest the crop, and to tell when to best pick the crop. The technique of estimation is laborious, occasionally assisted by the use of hand counters. Even though only a few trees are typically examined per block, many man hours are still needed in the hot, humid area [1]. Although multiple load assessments throughout crop growth are ideal, labor constraints make this impossible. Additionally, the sample process has a limit on how accurately the process can estimate the yield of the entire orchard [2]. To meet the requirements of the expanding population while effectively utilizing the resources at hand, sustainable agriculture is important [3]. Precision agriculture, which is aided by cutting-edge sensing and image processing systems [4], artificial intelligence, and other technologies, can produce it. Early in the 1980s, Precision agriculture was created [5]. With the use of Deep Learning architectures and contemporary machine vision, Precision agriculture has a revolutionary impact on a number of agricultural applications, including crop monitoring, disease diagnosis, and intelligent yield calculation. Among these, intelligent fruit yield assessment is crucial in determining the ultimate choices for fruit management and harvesting [6]. An automated image processing technique will allow farmers to reduce the amount of manual labor that is required, and increase the accuracy of the estimated count of ripe fruits. Hannan et al. [7] presents a machine learning system for recognizing orange fruit that consists of segmentation, region labelling, size filtering, perimeter extraction, and perimeter-based detection. Fruits could be clearly differentiated from the background thanks to the segmentation technique, which is based on a Bayesian discriminating analysis. Segmentation, region labelling and perimeter-based detection are all parts of the fruit recognition method. In order to provide adaptive segmentation under changing outside lighting for the segmentation of the orange fruit, the red color space factor was used for augmentation in [8]. Laplacian pyramid transform and fuzzy logic are two image fusion techniques that are used to increase the effectiveness of fruit detection in comparison to Leemans et al.'s [9] use of solely thermal images. In the example in [10], color cues in a picture can be effectively used to segment flaws in "Jonagold" apples. It has been discovered that texture characteristics provide helpful information for evaluating the quality of fruits for example, classifying the grade of apples after dehydration with an accuracy of 95% [11]. The dual color/shape analysis algorithm and laser range-finder model were used to create the spherical fruit recognition system in [12]. The models for illumination and surface reflectance for use in outdoor color vision are explored in [13], with a focus on how to forecast the color of surfaces in outdoor settings. The fruit detection algorithm was created by the authors of [14] using a combination of several observing approaches for a tree canopy. For color recognition, texture and color features are used. Fruit identification uses an effective blend of color and texture. By using a minimal distance classifier and statistical and co-occurrence data obtained from wavelet. processed sub-bands, recognition is accomplished [15]. To distinguish apples with red and green color, color and texture traits are used [16]. According to Femandez et al. [17], a tomato-harvesting robot's stereoscopic vision system has a detection accuracy of about 85%. The author in [18] uses a local or shape-based analysis to quickly identify the fruit and was able to identify it at particular stages of maturation. In order to characterize the characteristics, a key point extraction technique [19] combined corner points and edge points, but it was unable to represent surfaces or an object as a whole. Lokhande et.al. [20] utilize a machine learning technique to evaluate the raw data and determine the trust characteristic. To identify the object a fuzzy control method can be used [21].

This research aims to modify and test a method developed by Payne, Walsh, Subedi and Jarvis to identify ripe Mangos, to identify oranges [22]. To do this however, the traits that make up an orange to human vision must be understood. Oranges have a few distinct features, the first being its bright orange hue, and the second being a rough texture on the skin. Fortunately, oranges are mostly spherical in shape, which proves to be easier when distinguishing between oranges and other objects on an orange tree.

The structure of this paper is as follows. Section II gives the detail explanation of algorithm to identify and count the orange fruit. After that Section III shows the results of developed algorithm with respect to each step. Then Section IV is about discussion, limitation of developed algorithm and finally in Section V, Conclusion is presented.

II. Material and Methods

The process of orange identification and counting is divided into a two-phase approach. In the first phase, the algorithm's objective is to identify and isolate the portions of the image that pertain to oranges. This phase typically involves segmentation and the creation of a mask or region of interest that encompasses the oranges in the image.

The second phase of the process is designed for the actual counting of oranges. This typically involves analyzing the mask or segmented regions generated in the first phase to determine individual orange objects or "blobs." Each blob represents a distinct orange in the image. The algorithm counts the number of these blobs to provide an estimate of the total number of oranges.

A. Orange Isolation

The first phase of the process, as illustrated in Fig. 1, draws inspiration from the work of A. Payne et al. [22] and involves the adaptation of an algorithm originally proposed by Payne for mango crop detection to be applied to oranges. This initial phase is comprised of five distinct steps, each aimed at the application of masks to the image for the purpose of identifying oranges.

In these steps, the image undergoes a comprehensive analysis within both the RGB and YCbCr color spaces, specifically seeking out regions that exhibit the characteristic coloration of oranges. These analyses result in the generation of color masks that highlight the areas matching the orange color profile in both color spaces. Subsequently, these individual color masks are combined to form a single comprehensive orange level mask, which serves as a vital component for the subsequent phase of the process.

This orange level mask is seamlessly transferred to the second phase, where it is employed to facilitate the counting of circular regions within the image. The counting operation essentially determines the total count of oranges present within the image. This two-phase approach offers a systematic and structured method for robust orange identification and counting within images.

The algorithm for orange identification consists of four distinct steps to create masks, which are then combined to form a final mask aimed at isolating orange components within the image.

Step 1: The initial step involves calculating a Normalized Difference Index (NDI) between the red and green color channels for each pixel. The NDI is computed as (g - r) / (g + r) [26]. Subsequently, a threshold is applied to identify regions with NDI values greater than 0. This step serves to accentuate areas with higher redness levels, while minimizing the influence of foliage.

Step 2: While Payne's algorithm originally employs a 3x3 variance filter for each color channel, the approach is adapted for orange identification. Instead, a 3x3 adaptive mean threshold filter is used. This new filter effectively removes excessive foliage from the image and eliminates irrelevant areas, such as the sky, which are unrelated to the oranges.

Step 3: The image is then transformed into the YCbCr color space, and the Cr and Cb channels are extracted for thresholding. The Cr channel measures the red difference within the image, and a threshold condition of pixel value >= 140 is applied, based on the observed average minimum Cr value across various regions in images containing oranges.

Step 4: The Cb channel is employed to evaluate the blue difference within the image. For oranges, a range of lower to medium values is acceptable, as they combine with the Cr channel to produce an orange color. Therefore, a threshold condition of 30 <= pixel value <= 120 is implemented.

After these four stages, the masks generated in each step are combined using Equation 1 to form a final mask. This final mask selectively highlights the orange components within the image:

$$pixel_{finale} = pixel_{NDI} \ \wedge \ pixel_{mean} \wedge pixel_{cr} \ \wedge \ pixel_{cb} \quad (1)$$

By applying these steps and the combination of masks, the algorithm effectively isolates the orange elements in the image, facilitating the subsequent phase of counting and identification.

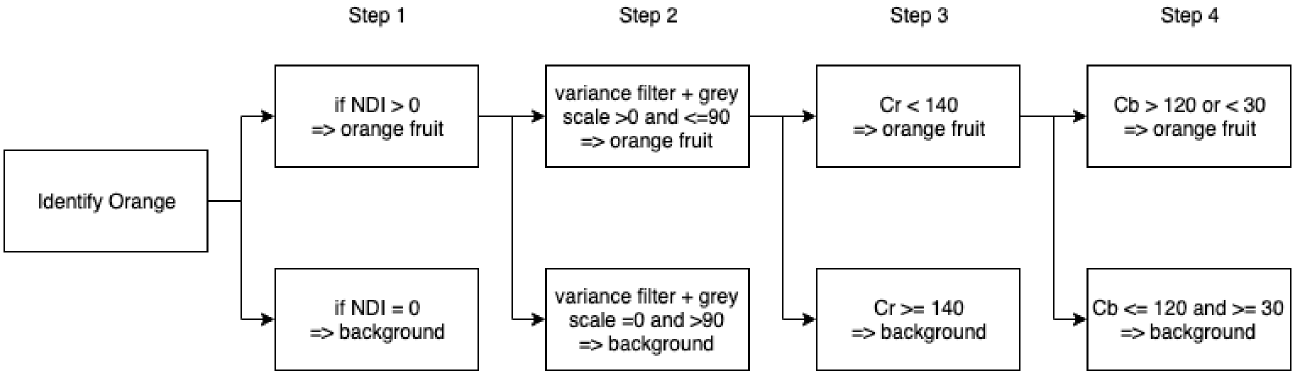

Fig. 1. Outline of the process of the stages of the algorithm.

B. *Orange Counting*

In the second phase, the mask that was generated previously is used to count the number of circles, each circle representing an orange fruit.

The process comprises multiple steps: First, a Gaussian blur is applied to the mask to soften its edges, preparing it for subsequent Canny edge detection. In the second step, a Hough transformation is executed to identify circular regions in the image, with carefully chosen parameter values such as dp, minDist, thresholds, minimum radius, and maximum radius, based on extensive experimentation [23]. In the third step, filtering mechanisms are implemented to refine the detected circles. The filtering involves a rolling average of circle radii, a check for the percentage of pixels within each circle matching the orange criteria established in phase 1, verification that the circle is within the image frame, and ensuring that the circle is not occluded by other detected oranges. These measures are taken to accurately identify oranges among the generated circles.

Algorithm 1: Orange Counting Algorithm

This algorithm is designed to count oranges within a binarized image. It proceeds as follows:

1. Start by applying a median blur to the image to reduce noise.
2. Employ a Hough circle detection technique to identify circular regions within the image. Fine-tune the parameters for best results.
3. Create an empty mask called "found" to keep track of detected circles and initialize the "averageR" variable.
4. For each detected circle:
   - Evaluate the ratio of orange pixels within the circle.
   - Check for overlap with previously detected circles in the "found" mask.
   - Perform certain checks based on circle size and orange pixel ratio to determine confidence in it being an orange.
   - If the circle is highly confident, mark it as a green circle.
   - If moderately confident, mark it as an orange, purple, or red circle based on its size.
   - If not filled enough but the size is close, mark it as maroon.
5. Update the "averageR" based on the newly confirmed oranges.
6. Continue this process for all detected circles.

The result is an image with marked circles in Fig. 2f , with green representing highly confident orange detections and other colors indicating varying levels of confidence. The algorithm filters out overlapping circles to ensure accurate orange counting.

Algorithm 2: Detect Overlapping Circles

This algorithm's purpose is to determine if a circle should be ignored due to excessive overlap with other circles. It operates as follows:

1. Receive input parameters: foundMask, a mask indicating taken (1) and untaken (0) regions, the circle under consideration, the binarized orange image img, and the percentage of orange pixels within the circle (orangePixels).
2. If the percentage of orange pixels within the circle is less than or equal to 50%, return True, indicating that the circle should be ignored.
3. Create a circleMask to represent the area covered by the current circle.
4. Iterate through the image:
   - Check if a pixel falls within the current circle and hasn't been taken (foundMask is False) and the circle mask (circleMask) is True.
   - Keep track of the areas that haven't been taken (areaNotTaken), the area newly covered by the current circle (areaNewOrangeInFrame), and the area that is both not taken and covered by the circle (areaFilledNotTaken).
5. Perform checks to determine if the orange in the circle is distinct and that the non-overlapping section is partly filled. If these conditions are not met, return False.
6. If all conditions are met, return true, indicating that the circle should not be ignored.

This algorithm evaluates circles for potential overlap, ensuring that they are distinct and meet specific criteria before considering them in the orange counting process

Algorithm 3: Count Orange Pixels within a Circle

This algorithm is designed to count the number of pixels within a circular region that have been marked as orange within a binarized image. The steps are as follows:

1. Receive the circle under consideration (\`circle\`) and the binarized orange image (\`img\`) as input, and aim to calculate the percentage of pixels that are marked as orange.
2. Create a \`circleMask\` to represent the area covered by the current circle.
3. Calculate the area of the circle using the formula \`π * circle.radius^2\`.
4. Initialize a counter, \`numOutOfFrame\`, to the area of the circle (i.e., \`circleArea\`).
5. Set the initial count of orange pixels, \`numOrange\`, to 0.
6. Iterate through the height and width of the image.
7. Decrease the value of \`numOutOfFrame\` by 1 for each iteration.
8. Check if the current pixel in the image is both marked as orange (\`img[i, j]\`) and falls within the circle

(`circleMask` is True).

9. If both conditions are met, increment the `numOrange` count by 1.
10. After processing all pixels, check that a sufficient portion of the circle is within the frame. If the percentage of the circle outside the frame exceeds 40%, increase `numOrange` by the number of pixels outside the frame (`numOutOfFrame`).
11. Calculate the percentage of the circle filled with orange pixels within the frame (`percentFilledInFrame`) as a ratio of `numOrange` to the total number of pixels in the image.
12. Calculate the overall percentage of the circle filled with orange pixels, considering both inside and outside the frame (`percentFilled`) as a ratio of `numOrange` to the total number of pixels minus those outside the frame (`numTotal - numOutOfFrame`).
13. Return the minimum of `percentFilledInFrame` and `percentFilled`.

This algorithm assesses the number of orange pixels within a circular region and accounts for pixels both within and outside the frame. The result represents the percentage of orange-filled area within the circle, ensuring a comprehensive measure of orange presence.

III. Results

The algorithm was subjected to a rigorous testing process using a diverse set of online free available orange images that varied in brightness and foliage levels. Algorithm is experimented on set of 10 orange images from [25] which are freely available. Across the entire 10 images, the algorithm exhibited a noteworthy level of success, achieving an approximate 72.4% accuracy in confidently detecting the presence of oranges with standard deviation of +/- 12.20. However, it's important to note that the results were not solely binary, as the algorithm also provided insights into its level of confidence for each image. Fig. 2 shows the correlation of decrease in accuracy of algorithm against actual as fruit count increase. Both trend lines have strong R2 and steady different curves that diverge as fruit count increases.

For images where the algorithm expressed only moderate confidence in its results, typically numbering around one to two images, a specific visual representation was employed to convey this information. In these cases, oranges that the algorithm was highly confident about were distinctly highlighted with green circles. Oranges for which the algorithm expressed moderate confidence were encircled in orange, while those instances where the algorithm had low confidence were marked with either purple or red circles.

Fig. 3 shows step by step results of orange ident and counting also. Fig. 3(a) is original image taken from [24]. Fig. 3(b) is result of the first step in which algorithm is to produce a normalized index between the red and green channels. Fig. 3(c) is step 2 in which an adaptive mean threshold filter replaces the variance filter to improve foliage and sky removal. Fig. 3(d) and Fig. 3(e) shows step 3 and 4 inch which the Cr channel uses a threshold of pixel value >= 140 for medium to high red levels, and the Cb channel employs a threshold condition of 30 <= pixel value <= 120 to detect oranges based on blue differences respectively. In Fig. 3(f) show only orange components of image by applying a mask. Fig. 3(g) and Fig. 3(h) shows the result of orange counting section in which identify the circular regions and filter the circles.

This approach not only provides a quantitative measure of algorithm performance but also offers visual cues to users, making it easier to interpret and potentially refine the results, which can be particularly valuable in scenarios where the algorithm's output may be used for decision-making or further analysis. Fig. 4 shows count of circle for color green, orange, and red, purple in Fig. 3(f). It shows high confidence by detecting green circles as per Algorithm 1.

IV. Discussion

During the testing of the proposed algorithm, it became evident that it performs significantly better on images with a resolution larger than 1300x1300 pixels. However, it has limitations—it fails to work on images where the diameter of the oranges exceeds half of the screen size, or when the oranges are very small (less than 150 pixels). This limitation is attributed to the choice of the minimum separation value between circles in.

It was observed that these limitations can be effectively addressed by using higher image resolutions. In practical applications where image quality and consistent zoom levels are known and controlled, these shortcomings can be overcome. Additionally, analyzing luminance levels could be explored as a means to normalize images, particularly in cases where highly illuminated images pose challenges for orange detection.

The algorithm exhibits varying levels of performance due to inefficiencies within the circle detection process, making it computationally expensive and particularly evident in handling large and cluttered images. Further optimization is essential to enhance its efficiency and adaptability across different image scenarios.

V. Conclusion

The results derived from this algorithm demonstrate achieving an accuracy rate of approximately 72.4%. Result summarizes that purpose algorithm works well on lower fruit count. However, there remains a clear imperative for further enhancements. The algorithm's current limitations are evident in its inability to account for varying levels of ripeness in oranges. Moreover, the section responsible for orange detection lacks computational efficiency, thereby affecting program runtime.

Future research endeavors should prioritize the development of a more efficient algorithm for shape detection within images. Additionally, it is essential to optimize the color segmentation component to handle a broader range of brightness levels and mitigate issues related to clutter. These improvements will contribute to the advancement of automated fruit counting processes in agriculture and other related domains.

Towards a Framework for Elevating the Usage of eLearning Technologies in Higher Education Institutions

Naif Alzahrani[1], Hassan Alghamdi[2]
Department of Computer Engineering-School of Engineering, Al-Baha University[1]
Department of Computer Information Systems-School of CS and IT, Al-Baha University[2]
Al-Baha, Saudi Arabia[1, 2]

***Abstract*—Adopting eLearning technologies is no longer an option in Higher Education Institutions (HEIs) to support teaching and learning activities. However, despite steps taken by most of these institutions towards effective utilization of technologies, the current situation on the ground shows two significant challenges. First, the misalignment between institutions' strategies and the technical implementation of these technologies. Second, the scattered implementation and usage of eLearning technologies among stakeholders, which increases operational overhead due to the lack of a unified approach and usage procedures that promote optimal utilization of such technologies. This paper aims to introduce a framework for elevating the usage of eLearning technologies in HEIs. It guides the alignment between strategic goals and technology implementation for effective and progressive eLearning technology usage. Design science research methodology is adopted to guide the development of this framework. It drives the development process by first being aware of the problem from a real-life context and then proposing a solution. Principles from business and IT alignment and enterprise architecture are adopted to propose this framework, which is meant to be comprehensive to have eLearning technologies fit the institution's purpose while achieving strategic goals.**

Keywords*—eLearning; higher education; business and IT alignment; enterprise architecture

I. Introduction

Higher Education Institutions (HEIs) refer to universities, colleges, and other educational institutions that offer and deliver postsecondary education [1]. The teaching and learning activities carried out in these institutions are to prepare students for a specific profession [2]. Adopting Information and Communication Technologies (ICT) to support teaching and learning activities in these institutions is no longer an option. However, this requires continuous management and alignment of business needs with IT capabilities following HEIs' strategies. This strategic and operational alignment of business and IT has been a critical issue that faces organizations in different sectors, and the education sector is no exception.

This paper aims to develop a framework that assists in orchestrating alignment between the strategic vision and objective of HEIs with projects and activities related to using eLearning technologies. The paper is organized as follows: a literature review is carried out first to identify the gaps in IT investment and digital transformation in HEIs. Then, the business and IT alignment and the importance of employing enterprise architecture principles in HEIs are described, representing the theoretical and practical background to facilitate better management and alignment of business and IT resources in HEIs. The research methodology, which guides the research activities, is then explained. Then, the proposed framework developed according to design science research is introduced to contribute to the knowledge base. Finally, the conclusion and future work are explained.

II. Background

A. IT investments and Digital Transformation in HEIs

In the early days of adopting Information and Communication Technologies (ICT) in HEIs, they were mainly used for administrative and communication purposes rather than enhancing and supporting teaching and learning activities [3]. In recent years, however, ICT's investments and role in the education sector in general and in HEIs in particular have expanded enormously. These institutions increasingly invest in digital technologies to acquire sustainability, competitiveness, financial stability, innovation, stakeholders' satisfaction, teaching quality, institutional performance, and better ranking [4],[5]. New technologies are also adopted in these institutions to facilitate access to various online resources and distance education [6]. In a recent technical report, Morgan et al. [7] illustrate that advanced technologies in HEIs offer specialized web-conferencing tools, robotics process automation, access to artificial intelligence solutions, virtual tutoring platforms, advanced presentation technologies, and more solutions and focus on career support.

Embracing the education sector and institutions with advanced technologies is no longer a fancy option. HEIs, according to Pinho et al. [8] must adapt to the rapid changes in the technological environment as they have previously adapted to various social, political, and technical changes. According to the UNESCO National Commission [9], it is mandatory for HEIs, in particular, to proceed with technological enhancement to instruct and qualify people with the required knowledge that enables them to understand science and assists them in making the right decisions in terms of personal, professional and political choices.

The permeation of advanced technologies in every aspect of HEIs has forced these institutions to deal with holistic Digital Transformation (DT) planning, including all dimensions. A systematic literature review of DT in HEIs is carried out by Benavides et al. [10], and the findings reveal that DT in these institutions is still an emerging field and there is still a need for further research efforts to deal with the rapid changes in technology adoption in this sector. The authors state that although DT research papers related to HEIs have increased by 200% annually since 2016, the complex relationships between the actors involved in this technologically supported domain require further approaches to deal with a holistic transformation in HEIs, including business activities, processes, competencies, and models. Similarly, Durão et al. [11] pointed out that DT is not just about streamlining business processes and innovating new services. Still, it goes beyond to involve fundamental transformations in organizational procedures and capacity.

Realizing the benefits and Return on Investments (ROI) of ICT projects in HEIs can be overwhelming. Previous and recent studies have shown the challenges and failures associated with ICT investments in higher education institutions. For example, Kebritchi et al. [12] pointed out the challenges that hinder successful online course adoption in higher education. Issues are categorized in relation to learners, instructors, and the developed online content itself. Ejiaku [13] also pointed out that the absence of effective policies and leadership and the lack of IT professionals with the skills to analyze and manage IT projects have hindered the successful adoption of ICT in HEIs. Another study reveals that the low penetration of ICT systems among HEIs and the low level of IT literacy among students are considered significant challenges that affect the effective adoption of ICT in HEIs in a large population country like India [14]. Cloete [15] highlights that the complexity of IT itself and realizing its impacts on education varies from context to context, which can be the main challenges of embracing technology in education. Hatlevik [16] adds that Instructors' digital competence and beliefs about ICT are critical to effectively utilizing emerging technologies in teaching and learning institutions.

Although the business value of IT in many HEIs has been realized, it has not been effectively measured [17]. The Return on Investment (ROI) of IT capabilities in these institutions and this sector are largely not assessed [18]. Recently, policymakers and researchers have been demanding ROI calculation in higher education to see how students and HEIs perform [19]. This research does not aim to develop a tool that can assist in measuring the ROI or business value of IT in HEIs. However, it provides a clear representation of the misaligned components in these institutions and how they can be viewed and integrated through a framework to facilitate their value-adding to the business.

B. Business and IT Alignment in HEIs

Business and IT alignment is defined at strategic and operational levels according to the well-known model of alignment developed by Henderson et al. [20]. Reich et al. [21] define the alignment at the strategic level as "the degree to which the IT mission, objectives, and plans support and are supported by the business mission, objectives, and plans." On the other hand, Silvius et al. [22] define business and IT alignment at the operational level as "the degree to which IT applications, infrastructure and organization enable and support the business strategy and processes."

Most researchers and practitioners who studied and practiced the possibility of bridging the gap between business and IT agree that this harmony between these two domains positively impacts overall business performance [23]–[26]. Their work shows a consensus in their findings that organizations will perform well when IT resources, including hardware, software, IT skills, assets, and management, are aligned with business strategies and services. According to Liu et al. [27], it has become more critical in recent years to have the right IT with the right capabilities aligned with the right business requirements to have business value from IT investments.

The concept of alignment in academic and business sectors is one of the most frequently studied theories. Yet, many organizations are still misaligned and fail to take full advantage of IT [28], [29]. Business and IT alignment in HEIs represent a unique challenge due to the distinctive nature of these institutions. Decision-making in these institutions is shared, organizational culture among universities and colleges differs, and academic courses and research activities are independent [17]. According to Alghamdi et al. [30], business and IT alignment in the education sector has received the least attention in the business and IT alignment literature compared to other public and private sectors.

The isolation of IT planning when strategic business planning is carried out [31], the lack of top management awareness of the significant role of IT systems in organizations [32], the weak power sometimes of IT departments [31], and the rapid changing environment of business and IT [28], have all contributed to the ineffectiveness and misuse of IT in organizations. This has led many organizations in recent years to seek a holistic approach that provides an overarching view of the organization and its components in all its hierarchical layers (strategic, business, and technology), which can be found in the Enterprise Architecture theory and practice.

C. Enterprise Architecture in HEIs

Enterprise Architecture (EA) is a field of study that recently emerged to enhance the complexity and management of organizations and their business and IT domains to achieve strategic objectives and digital transformation [33], [34]. According to Gartner Group [35], "Enterprise Architecture is the process of translating business vision and strategy into effective enterprise change by creating, communicating, and improving key requirements, principles, and models that describe the enterprise's future state and enable its evolution.". In its simplest form, EA is described by Bernard [36] as the integration between the Strategy (S), Business (B), and Technology (T) layers of an enterprise, as illustrated in Fig. 1. The strategic layer at the top level is considered to be the main driver of an enterprise, while the business layer is the place where the source of requirements is elicited. The technology layer, the bottom layer, is where the provision of systems and technology to meet the business requirements to achieve strategic goals.

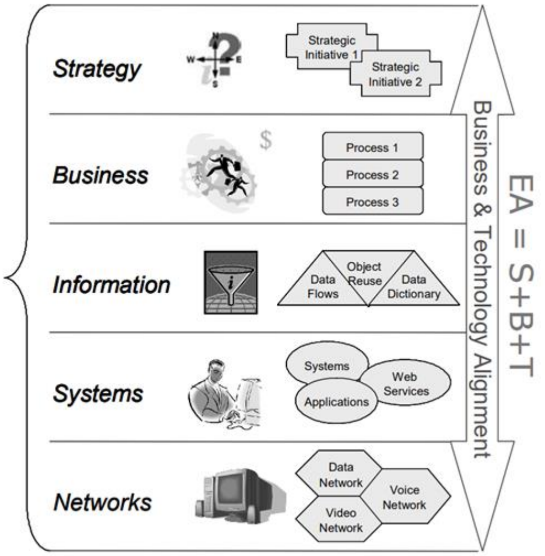

Fig. 1. The main layers of an enterprise from an enterprise architecture perspective [36].

During the last decade, there has been a growing interest in adopting EA principles and frameworks in HEIs. A recent systematic literature review carried out by Meutia et al. [37] shows that HEIs have adopted EA frameworks such as Zachman and TOGAF in the last decade for the following reasons: planning of IT infrastructure, integrating systems, developing appropriate strategic direction, achieving efficiency and effectiveness of available IT resources, ensuring standardized system development process, achieving competitive advantage through technology compared to other universities, reducing costs, supporting every business requirements, achieving better performance of systems, and finally achieving the mission and strategic goals related to the education process.

Another recent systematic mapping study of EA in the higher education domain is carried out by Bourmpoulias et al. [38]. Sixty articles were analyzed, and the authors pointed out that although the practice of EA in the education sector is widely accepted across the Americas, Asia, and Europe, the sector still faces major challenges in adopting EA principles and methodologies effectively. Among these challenges are the scarcity of EA practices in the education domain, the gap in the adoption and assessment of EA even in advanced education systems worldwide, and the focus on IT teams to lead the process and adoption of EA. The authors, on the other hand, highlight promising practices of EA in the education sector. Among these practices are adopting EA principles and frameworks in HEIs to assist in better business and IT planning, better business and IT alignment, effective change management, and better achievement of strategic goals and objectives. According to [10], EA practices and methodologies are enablers of DT in HEIs, where they can assist through systematic approaches the DT journey in these institutions.

III. Research Methodology

Design Science Research (DSR) is a research paradigm that guides a researcher in developing an artefact addressing a real-world problem and contributing to the knowledge base with the devised and evaluated solution [39]. DSR has received considerable attention in information systems research that focuses on the effective utilization of technologies in organizations [40], especially after the grounding work of [41]–[43].

Unlike the behavioral science paradigms that focus on developing and verifying theories to predict human or organizational behavior, the design science paradigm goes beyond human and organizational boundaries to develop new and innovative artefacts [42]. These artefacts are devised and evaluated following the DSR principles to solve a problem. According to Vaishnavi et al. [44], constructs, models, methods, instantiations, frameworks, architecture, design principles, and design theories are types of artefacts that can be the outcomes of a DSR project. A conceptual framework of DSR and its fundamental concepts is developed by Hevner et al. [42]. In their framework, three central components are emphasized: environment, IS research, and knowledge base. The environment specifies the boundaries of where the problem takes place involving people, organization, and technology and their underpinning components. The IS research and the knowledge base stand as a vehicle to address the issues identified in the environment based on the foundations of scientific theories and practices that support scientific IS research.

In reference [44], the authors describe a procedural workflow to carry out scientific research based on the developed DSR framework of Hevner et al. [42]. Fig. 2 shows the procedural flow of design science-based research that begins with awareness of the problem from a real-world context.

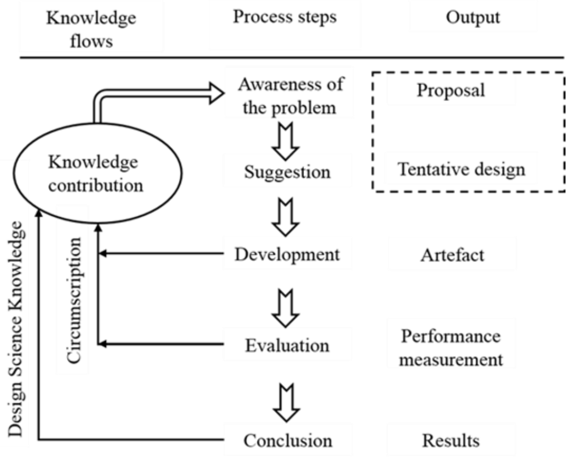

Fig. 2. A process model for DSR [44].

Then, an initial design is suggested to address the problem, which is driven by available relevant knowledge, either theoretical or practical. The initial design is then developed to derive the solution (i.e., the artefact). The resulting artefact is then evaluated through implementation to determine its ability to resolve identified problems. The conclusion then denotes the end of the procedural flow of the DSR, where the outcome itself is considered a contribution to the knowledge base. Some steps in the procedural flow can be iteratively carried out to enhance the outcomes of the DSR to provide a practical and effective solution to a real-world problem.

IV. Proposed Framework

Teaching and learning activities in their abstract form in a HEI consist of three main components: learning material (Courses), Instructors, and Students. eLearning technologies are constantly being procured and developed to improve these activities and maintain the essential components effectively involved in a positive relationship. This research aims to design a framework that supports HEIs to maintain an effective learning environment by elevating the usage of eLearning technologies. The alignment between operational activities in these institutions with strategic vision and objectives is considered along with principles and concepts from enterprise architecture theories while devising the framework. To achieve this, the DSR methodology is adopted as a scientific grounding to drive the development of the framework with an agile mindset that ensures continuous delivery.

A. *Awareness of the Problem*

Understanding the environment (people, organization, and technologies) is a primary activity in DSR to be aware of a real-world problem [42]. This assists in suggesting a solution that can address this problem and could be similar problems within the domain of study. The awareness of the problem in this research comes from threefold.

First, from the available literature on ICT investments and DT challenges in HEIs. Previous sections of this paper highlight related work that pointed out the challenges that face the effective utilization of advanced technologies in HEIs. The misalignment between eLearning technologies and HEIs' strategies can lead to a failure in achieving maximum utilization of these technologies to enhance overall teaching and learning activities. Such a challenge in the higher education sector has received the lowest attention in IT alignment research [30], [45]. A real example of misalignment practice that usually occurs in many HEIs is the isolation of implementing IT projects away from the actual needs of students and academic staff. In fact, the focus is shifted mainly to technological features rather than how these features can be utilized to improve teaching and learning quality. As a result, many HEIs have sets of scattered tools and systems with low utilization and an apparent absence of a unified ecosystem and effective utilization planning.

The literature also indicates that HEIs invest heavily in ICT to improve teaching and learning quality, one of their main common objectives. eLearning tools are employed in these institutions to achieve this quality in offering and delivering courses. However, utilizing eLearning technologies abstractly to deliver course materials has a low impact on the desired quality for three reasons. First, each instructor will develop their approach to using eLearning applications to achieve high quality in delivering course material and improving learning outcomes. As a result, the overall level of quality will vary between courses offered within one institution. Second, this quality cannot be measured due to the lack of measuring metrics. Therefore, it will be challenging to have an improvement plan since each instructor follows their way of employing eLearning tools. According to [46], quality practices in HEIs should be transformed for these institutions to remain effective. Third, learners will be confused and distracted between different tools used by other instructors. The utilization of eLearning technologies in HEIs without a unified framework that guides its adoption has a low chance of success due to the lack of alignment between institutions' vision and technological infrastructure implementation.

Second, the authors of this paper have worked for nine years as CIOs in a HEI in Saudi Arabia at (Al-Baha University). Therefore, they have carried out a requirement analysis process, which includes guided sessions to address the problem closely from the main stakeholders of the university (namely, students, academic staff, and top management), representing a real-life context. The outcomes assist in understanding the business and the actual needs of instructors and students to have effective learning activities and supporting eLearning tools during their academic journey. It also helps in being aware of the challenges, expectations, and beliefs of decision-makers towards making investments and supporting the adoption of eLearning technologies. Being CIOs at the university for several years, the authors are entirely aware of the technical capabilities of the university and its misalignment with its strategic scene.

Third, commonly utilized technologies and techniques in HEIs in Saudi Arabia and worldwide are investigated, including LMS, IT infrastructure, online course development process, and the eLearning platform's operation models. This allows for a better understanding of the environment and available ICT solutions in higher education.

Being aware of the environment and these challenges in HEIs, the proposed framework is suggested to provide a practical guideline to systematically overcome these challenges to elevate the usage of eLearning technologies in HEIs to effectively realize strategic goals through guidelines from enterprise architecture and alignment theory.

B. *Developed Framework*

Environmental analysis has guided the development of a set of artefacts and a framework to address the defined problem. The first artefact is shown in Fig. 3, which is a model that includes the four main key interactive components in an HEI domain that adopts eLearning technologies. These components are the Learner, Instructor, Course, and Platform, which supports teaching and learning activities (LICP). They must be aligned to maintain an effective relationship between them that result in generating business value of IT investment.

The model in Fig. 3 also illustrates the major interactive activities that are directly supported by a technological platform that assists teaching and learning activities. The learning platform should always afford the required functionalities from learners and instructors, following best practices and quality standards to ensure a successful learning journey. Therefore, the effective utilization of eLearning technologies should positively impact other activities. For instance, providing a unified process for the course development lifecycle using eLearning tools implemented on a centralized platform will support instructors in developing and enhancing their courses to meet defined quality requirements. Moreover, such unified processes and platforms will support the creation of course libraries that can be shared with all instructors and provide students with a high-quality eLearning experience.

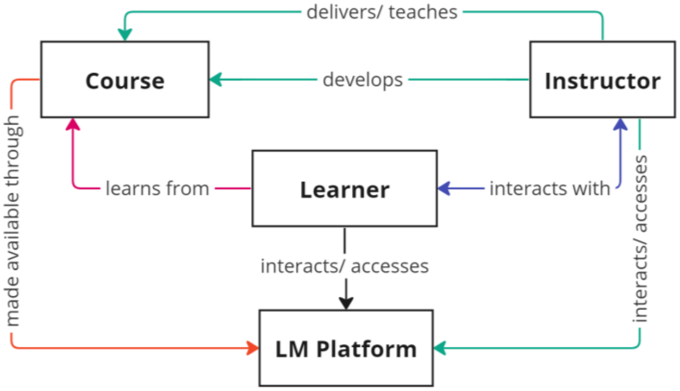

Fig. 3. Main interactive components in a HEI (LICP).

The second artefact developed based on the environmental analysis is shown in Fig. 4. It is another model that considers the principles of EA to draw the relationship between LICP components identified in the first model.

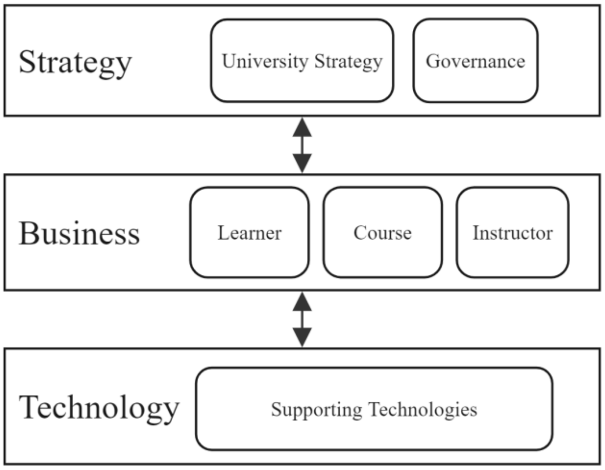

Fig. 4. LICP components from an EA point of view.

The model in Fig. 4 highlights, from an EA perspective, the need to have a comprehensive overview of the HEI that integrates supporting technologies with main business components to realize an overall institution strategy. For instance, integrating Learning Management Systems (LMS), eTest, virtual labs, and virtual classes and providing a usage guideline would support business actors (instructors and students) to effectively communicate during the teaching and learning journey, having an impact on the quality of education that the institution seeks as a strategic objective.

The model also highlights the need to define an ecosystem combining components to drive the institution's implementation, adoption, or elevation of technologies. This ecosystem is not necessarily technology-centric but rather a customized set of components driven from assessing an institution’s capabilities to assist institutions in moving from the current view (as-is) to the targeted future view (to-be). An eLearning ecosystem, for example, includes policies, procedures, tools, actors, and infrastructure components such as Learning Management System (LMS), Student Information System (SIS) integration, and students email integration, labs, and eTest centers that should be harnessed according to institution’s capability to elevate the usage of supporting technologies.

Based on these artefacts, the proposed framework is developed, which consists of seven iterative stages as illustrated in Fig. 5. It aims to assist HEIs in elevating the usage of eLearning technologies by adopting them in a systematic way that ensures the involvement of related organizational components from alignment and EA perspectives. This way, improving the teaching and learning journey for the main stakeholders in this sector (students and instructors) through a unified structure is prioritized while keeping LICP components aligned with the institution’s strategic vision and goals through governance and an agile mindset supported by EA principles.

Each stage defined in the framework is considered a milestone in utilizing or elevating the usage of eLearning technologies in HEIs through a project roadmap. Each iteration will focus on a specific goal to promote progressive quality improvement in HEIs. Table I illustrates a summary of activities that should be carried out in each stage, along with expected outcomes.

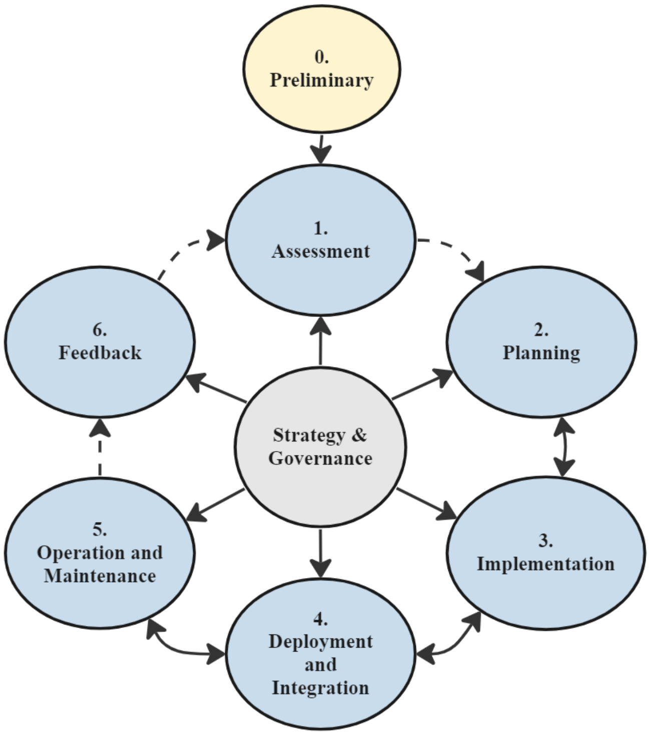

Fig. 5. Proposed framework for elevating the usage of eLearning technologies in HEIs.

TABLE I. STAGES OF THE PROPOSED FRAMEWORK

Stage	Main Activities	Main Outcomes
0 - Preliminary	● Form a core team. ● Identify eLearning goals. ● Select project management tools.	● Formed team members with specified roles and responsibilities. ● Identified eLearning objectives. ● Set up project backlog tool.
1 - Assessment	● Gap identification. ● Competencies assessments for LICP components.	● SWOT analysis outcomes. ● Requirements specification to reduce the gap between (As-IS) and (To-Be) state. ● List of goals aligned with the institution's strategy.
2 - Planning	● Design eLearning projects. ● Specify project dependencies. ● Identify iterations (sequential and parallel).	● List of outcomes that must be delivered for each project. ● Projects roadmap. ● Projects implementation plan.
3 - Implementation	● Incremental implementation. ● Update project backlog	● Project progress reports. ● Tested and verified project ready to be integrated into an eLearning ecosystem.
4 - Deployment and Integration	● Update the eLearning ecosystem. ● Integration with existing components.	● Updated ecosystem according to project scope.
5 - Operation and maintenance	● Maintain ecosystem operation. ● Collect predefined metrics, e.g., course material usage	● Process for proactive action to avoid any technical issues. ● Updated ecosystem operation manual.
6 - Feedback	● Collect feedback. ● Feedback analysis.	● Feedback results. ● Updated metrics.

Institution's strategy and governance are at the heart of this framework. The former guides the following assessment and planning stages, and the outcomes of all stages also impact it, while the latter controls the procedures and activities defined in each stage to ensure compliance with the requirements and regulations. Effective governance should ensure the missing alignment between the institution's layers (strategy, business, and technology). Governance also controls change management activities that support promoting eLearning culture and adopting new modes of teaching and learning. Change management also provides a systematic approach to implementing new projects approved by top management and helps to guide the activities that will be performed in the following stages of the framework.

The preliminary stage is the starting point of the proposed framework, which focuses on two activities. First, a core team will be formed to implement the following stages. Second, identify eLearning-related objectives based on HEI's strategies, which will be prepared to go through the iterative process of implementing subsequent framework stages. In this stage, the team will adopt an agile project management mindset in planning and executing each iteration. As a result, a backlog of eLearning projects and their objectives will be the outcomes of this stage that need to be approved by top management in terms of prioritization to ensure its alignment with other initiatives and projects at the HEI.

In the assessment stage, the core team uses a set of tools based on the outcomes of the preliminary stage to identify gaps between the current state and the targeted state of the eLearning tools adoption perspective, such as SWOT analysis (Strengths, Weaknesses, Opportunities, and Threats) and academic staff competencies' evaluation. etc., This stage triggers the alignment process between the institution's strategies and available eLearning capabilities. The outcomes of this stage should be a list of requirements that, once attained, should transform the institution from state (as-is) to state (to-be), realizing the institution's strategic objectives according to available and obtained capabilities.

Defining an eLearning ecosystem consisting of a set of components supports the improvement of eLearning capabilities at the institution, and this ecosystem works as an enabler for projects' implementations identified in stage two. Each project related to eLearning will be designed to use and improve this ecosystem. Integrating all components in this ecosystem is intended to create a single and comprehensive learning environment that combines all LICP dimensions for better and effective interactions. This also helps collect feedback from LICP for continuous improvement according to the institution's strategic objectives.

The planning stage uses the outcomes of previous stages to plan eLearning projects based on the targeted state of the institution. An agile project management mindset should be employed in this stage to ensure continuous delivery of the eLearning functionality specified in each project. As mentioned, the framework is iterative and progressive and can be achieved by running multiple projects simultaneously. The core team should study projects' dependencies and design an implementation roadmap that keeps all projects aligned. Such an approach guarantees fast delivery and continuous improvement since the stages from three to six can be executed independently for each project.

The operational core team can coordinate and achieve activities in stages three, four, and five. In this, multiple projects can be running concurrently through these stages. For example, one project may focus on online course development based on a Course Development Lifecycle (CDLC) methodology, while another project may implement new functionality in the eTest center. These two projects represent valuable components of an eLearning ecosystem that aims to achieve an institution's strategic goals through a systematic approach. The role of project managers and project management tools is critical to successfully implementing defined projects since they help identify dependencies and implement the roadmap.

The feedback stage is crucial because all eLearning projects must be aligned with the institution's vision and objectives and meet the needs and expectations of students and instructors, who are the primary stakeholders of these projects. Through this framework, feedback is constantly collected and used as input for the next iteration of project implementation. This guarantees effective engagement and utilization of all features developed and applied to the eLearning environment.

V. Conclusion and Future work

Higher education institutions invest heavily in supporting technologies to achieve better outcomes regarding the quality of delivered education. However, the alignment of these technologies with higher education institutions' strategies and the exact needs of students and instructors in this sector is questionable. The absence of measuring tools to assess this alignment and the continuous rapid investments in advanced technologies in higher education require efforts to evaluate the business value of IT in this sector.

A framework for elevating the usage and adoption of eLearning technologies in the higher education sector has been proposed in this paper. Design science research is adopted as a research methodology to guide its activities, which is found suitable for the problem-based nature of this research. Being aware of the problems faced in this sector regarding effective IT utilization and adopting principles and practices from enterprise architecture and business and IT alignment, a set of artefacts and a framework are developed. These principles and practices support having a holistic view of institutions that guide the adoption of advanced technologies through systematic approaches that ensure effective business and IT alignment for better utilization.

The implementation of the framework has several advantages. First, it enforces a standardized approach to utilizing and leveraging the usage of eLearning technologies that directly impact the quality of teaching. Second, it offers a baseline for basic metrics for measuring the institution's quality improvement progress in educational technologies. Third, due to the unified implementation approach and progressive improvement, instructors' competencies should be improved, and students' academic achievement should be enhanced accordingly. Moreover, the iterative stages of the proposed framework support the inevitable adoption and adaptation of any advanced eLearning technologies.

The proposed framework is applied at AL-Baha University to evaluate its viability in elevating the usage of eLearning technologies and establishing a unified learning environment governed by a set of processes. The application and findings are published in [47].

Acknowledgments

The outcomes of this research are part of the authors' cooperation in implementing a digital transformation plan at the Deanship of eLearning and Information Technology (DeIT) at Al-Baha University. The authors thank the deanship of scientific research at Al-Baha University, Kingdom of Saudi Arabia, for sponsoring this project in 1442H with a reference number (1442/2). Sincerest and deep appreciation go to the eLearning team at Al-Baha University.

***Abstract*—The rapid proliferation of the Internet of Things (IoT) has engendered substantial security apprehensions, chiefly due to the emergence of botnet attacks. This research study delves into the realm of Intrusion Detection Systems (IDS) by leveraging the IoT23 dataset, with a specific emphasis on the intricate domain of IoT at the network's edge. The evolution of edge computing underscores the exigency for tailored security solutions. An array of statistical methodologies, encompassing ANOVA, Kruskal-Wallis, and Friedman tests, is systematically employed to illuminate the evolving trends across multiple facets of the study. Given the intricacies entailed in feature selection within edge environments, Chi-square analyses, Recursive Feature Elimination (RFE), and Lasso-based techniques are strategically harnessed to unearth meaningful feature subsets. A meticulous evaluation encompassing 19 classifiers, meticulously selected from both machine learning (ML) and deep learning (DL) paradigms, is rigorously conducted. Initial findings underscore the potential of the Gated Recurrent Unit (GRU) model, especially when coupled with intrinsic lasso-based feature selection. This promising outcome catalyzes the formulation of an ensemble approach that harnesses multiple LassoCV models, aimed at amplifying feature selection proficiency. Furthermore, an optimized ResNet-GRU model emerges from the fusion of the GRU and ResNet architectures, with the objective of augmenting classification performance. In response to mounting concerns regarding data privacy at the edge, a resilient federated learning ecosystem is meticulously crafted. The seamless integration of the optimized ResNet-GRU model into this framework facilitates the employment of FedAvg, a widely acclaimed federated learning methodology, to adeptly navigate the intricacies associated with data sharing challenges. A comprehensive performance evaluation is undertaken, wherein the ResNet-GRU model is benchmarked against FedAvg and a diverse array of other federated learning algorithms, including FedProx and Fed+. This extensive comparative analysis encompasses a spectrum of performance metrics and processing time benchmarks, shedding comprehensive light on the capabilities of the model.**

I. INTRODUCTION

The Internet of Things (IoT) has transformed device connectivity, bringing benefits and challenges in anomaly detection. IoT anomalies can stem from various factors like environmental changes, cybersecurity breaches, or device failures [1]. Detecting and understanding these anomalies are vital for ensuring dependability, security, and performance. Anomalies can disrupt operations, compromise data security, or invade privacy, necessitating proactive identification. Specialized methods, including artificial intelligence, machine learning, and statistical analysis, are essential for anomaly detection. IoT devices are susceptible to cybersecurity threats like unauthorized access and data breaches, involving atypical network traffic, unusual access patterns, or suspicious user behavior. Detecting these anomalies is crucial for preventing security breaches. Additionally, individual IoT devices may exhibit unexpected behavior due to software, firmware, or hardware issues [2]. Promptly identifying and resolving these device anomalies is essential for maintaining device reliability.

Addressing IoT anomalies involves various techniques, including artificial intelligence, machine learning, statistical analysis, and anomaly detection algorithms. These methods aim to establish normal behavior, detect deviations, and trigger appropriate responses. Machine learning and deep learning are particularly effective due to their ability to analyze vast datasets and identify patterns, enhancing IoT system safety and reliability [3]. In this article, we explore how machine learning and deep learning are applied in IoT anomaly detection. Supervised learning is used with labeled datasets, training models on historical data to recognize normal behavior patterns and identify anomalies in real-time data. Algorithms like decision trees, support vector machines (SVM), random forests, and gradient boosting are employed [4]. In cases of limited or unlabeled data, unsupervised learning becomes essential. It identifies anomalies by analyzing data structures and trends, utilizing techniques such as clustering to group data and detect anomalies as outliers [5].

Autoencoders are a type of neural network, excel in IoT anomaly detection by reducing input data dimensionality and detecting anomalies through reconstruction errors. Recurrent Neural Networks (RNNs), particularly Long Short-Term Memory (LSTM) networks, are ideal for handling sequential IoT data. Generative Adversarial Networks (GANs) are suitable for anomaly detection, as they can simulate complex IoT data distributions [6]. Federated learning is a decentralized approach for IoT anomaly detection that preserves data privacy [7]. IoT devices locally train models, transmitting only model updates, reducing the need for data transfer to a centralized server. This approach is beneficial for scenarios with limited bandwidth or intermittent connectivity, enhances model stability, and accommodates device-specific constraints [8]. However, it introduces communication overhead and security concerns [9].

The proposed work analyzes the IoT23 dataset, focusing on botnet attacks, using statistical tests and three feature selection approaches (filter, wrapper, embedded). Fifteen classifiers, including machine learning and deep learning models, are evaluated, with the best-performing one being the GRU model with embedded lasso-based feature selection. An ensemble of LassoCV models and ResNet architecture further improves feature selection and classifier performance. To address privacy concerns, a federated learning environment is established, and the optimized ResNet-GRU model is deployed and compared with existing federated learning algorithms, considering various metrics and processing time.

- The study focuses on Intrusion Detection Systems (IDS) within the context of the Internet of Things (IoT) at the network's edge, addressing heightened security concerns due to botnet attacks.
- Edge computing's evolution necessitates customized security solutions, and this research endeavors to provide them.
- Various statistical methodologies, including ANOVA, Kruskal-Wallis, and Friedman tests, are employed to reveal evolving trends in IoT security at the network's edge.
- Innovative feature selection techniques such as Chi-square analyses, Recursive Feature Elimination (RFE), and Lasso-based methods are applied to navigate the complexities of feature selection in edge environments.
- The study rigorously evaluates 19 classifiers from both machine learning (ML) and deep learning (DL) domains, with a particular focus on the Gated Recurrent Unit (GRU) model, which shows promise in conjunction with lasso-based feature selection.
- A novel ensemble approach harnessing multiple LassoCV models is developed to enhance feature selection efficiency.
- The introduction of an optimized ResNet-GRU model, combining GRU and ResNet architectures, aims to improve classification performance.
- To address data privacy concerns at the edge, a resilient federated learning ecosystem is created, integrating the optimized ResNet-GRU model and employing FedAvg, a widely acclaimed federated learning methodology.
- Comprehensive performance evaluation includes benchmarking against FedAvg and various other federated learning algorithms, such as FedProx and Fed+, covering a wide range of performance metrics and processing time benchmarks.

II. Related Works

This section presents the related works carried out by several research scholars in the area of anomaly detection using deep learning and machine learning with the aid of federated learning.

Brett Weinger et al. [10] employed Federated Learning (FL) for collaborative mobile and IoT projects but faced technological challenges. Distributing ML training across devices reduced prediction accuracy compared to centralized learning. Limited data access led to issues like constrained local ML models and class imbalances due to diverse event contributions. They addressed these challenges with data augmentation, resulting in a significant 22.9% performance improvement in IoT anomaly detection across three datasets.

Zhuotao Lian et al. [11] enhanced IoT anomaly detection while addressing security concerns. They proposed a distributed federated learning approach using neural networks, as traditional methods proved inaccurate. This technique improved detection accuracy while safeguarding locally stored data through decentralized learning, eliminating central failure points and raw data flow. Simulations using the IoT23 dataset validated its effectiveness, showcasing the promise of distributed learning for secure and accurate IoT anomaly detection, nearly matching centralized federated learning in performance.

Truong Thu Huong et al. [12] developed the FedeX architecture for efficient distributed anomaly detection in IoT-based Industrial Control Systems (ICSs) for Smart Manufacturing. FedeX outperformed 14 other methods on various detection measures, offering rapid learning, lightweight deployment, and interpretability. It allows real-time edge deployment with 7.5 minutes of training and 14% memory use, enhancing Smart Manufacturing practices. Explainable AI (XAI) to improve model interpretability, helping experts make confident decisions.

Subir Halder et al. [13] developed Hawk, an anomaly detection system for LoRa-enabled IIoT networks to address cybersecurity challenges. Hawk uses unique Carrier Frequency Offset (CFO) measurements to create device "fingerprints" and detect suspicious behavior. Employing federated learning, Hawk outperformed other systems by over 8% in detection accuracy and demonstrated high resilience against cyberattacks, reducing storage overhead by 40%. It's an effective solution for securing LoRa-enabled IIoT networks against novel threats.

Xabier Sáez-de-Cámara et al. [14] addressed IoT cybersecurity challenges in their study. They proposed a system using unsupervised models for network intrusion detection in large and diverse IoT and IIoT deployments. To overcome issues like network overhead and heterogeneity, they leveraged Federated Learning (FL) for cooperative training. Their architecture, tested on a simulated network with 100 nodes and subjected to real-world attacks, demonstrated efficient and robust intrusion detection for large-scale IoT and IIoT environments.

Huong Thu Truong et al. [15] developed a scalable anomaly detection system for continuously operating Industrial Control Systems (ICS) in smart manufacturing and IIoT. Their system combines Federated Learning, Autoencoder, and Transformer, with a Fourier mixing sublayer for improved performance. It offers rapid training within minutes, is lightweight with low computational and memory requirements, and minimizes communication costs. Compared to existing methods, it reduces training time by 50% to 1200 seconds, adapting to changing conditions and mitigating false positives in ICS data patterns, ensuring robust anomaly detection for smart manufacturing.

Jiamin Fan et al. [16] developed Score-VAE, a novel root cause analysis method for IoT anomaly detection systems. It addresses the challenge of distinguishing false positives from malicious attacks. Score-VAE combines the training and testing schemes of the VAE network within the federated learning (FL) architecture, resulting in improved generalization, learning, collaboration, and privacy protection. It effectively identifies the sources of anomaly detection alarms in real-world IoT data, outperforming standard approaches and enhancing the accuracy of root cause analysis in IoT anomaly detection.

Ali Raza et al. [17] introduced AnoFed, a novel federated framework for anomaly detection in digital healthcare, particularly in ECG analysis. To overcome limitations in threshold selection and privacy concerns in centralized machine learning, they combined transformer-based AE and VAE with Support Vector Data Description (SVDD). AnoFed enhances privacy, improves interpretability, and facilitates adaptive anomaly detection. Experiments in ECG anomaly detection demonstrated its effective performance with low computational costs. AnoFed's efficiency and privacy-preserving capabilities make it a valuable solution for digital healthcare applications, suitable for deployment on low-powered edge devices.

J. Jithish et al. [18] conducted a technical study in the past, focusing on anomaly detection in the smart grid using Federated Learning (FL). Anomaly detection is crucial for identifying energy theft, cyberattacks, and excessive power usage. In this approach, smart metres locally train machine learning models without sending data to a centralised server. Smart metres download a global model from the server for on-device training, and after local training, upload model parameters to fine-tune the global model, protected by the SSL/TLS protocol. Experiments on industry-standard datasets demonstrated that FL models matched the accuracy of centralised ML models while preserving individual privacy. The research showcased the efficiency of FL-based models in terms of memory, CPU utilization, bandwidth, and power consumption at edge devices, making them suitable for deployment in resource-constrained settings like smart metres in the smart grid.

III. MATERIALS AND METHODS

This study focuses on IoT network botnet attack detection using feature selection and classification techniques. It employs three feature selection methods (filter, wrapper, and embedded) to reduce dataset dimensionality. Out of 15 classifiers tested, the GRU model with embedded lasso-based feature selection emerges as the top performer [19]. To enhance detection capabilities, an ensemble approach is applied, incorporating 10 LassoCV models. Additionally, optimization with the ResNet architecture is employed to improve detection accuracy and convergence speed by addressing the vanishing gradient problem. This comprehensive approach aims to provide more effective and efficient botnet attack detection in IoT networks using the IoT23 dataset. The detailed architecture is presented in Fig. 1.

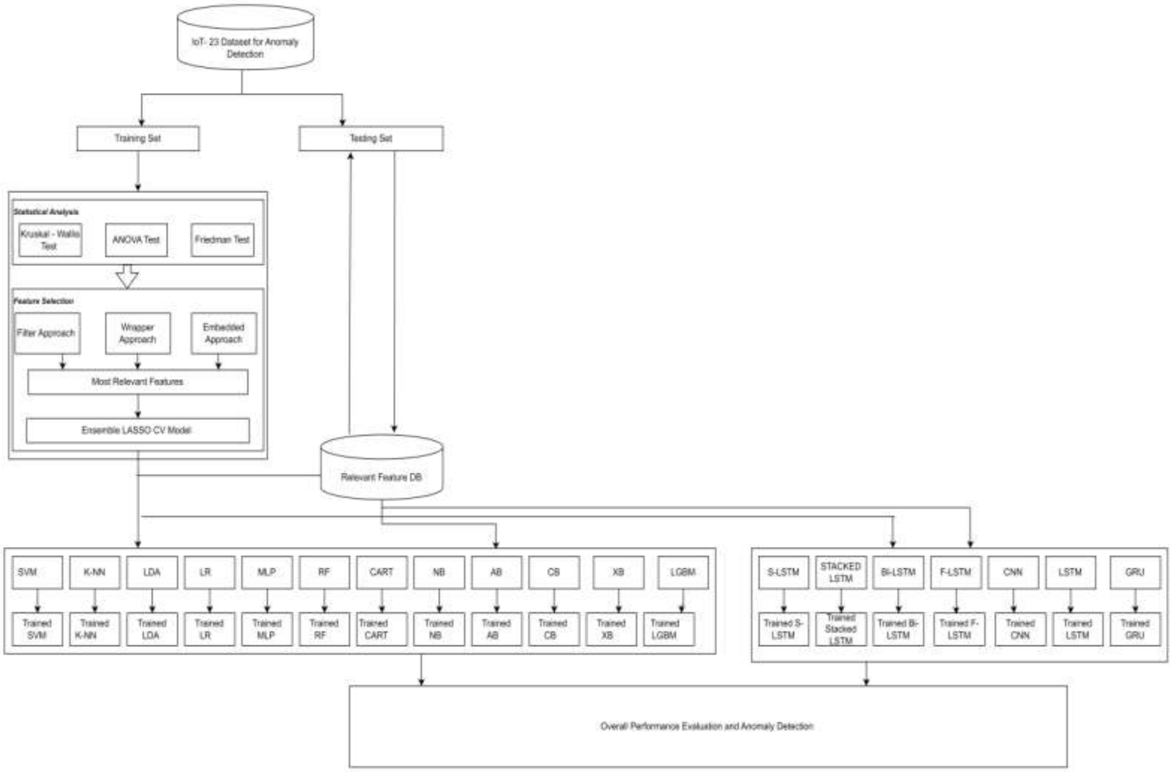

Fig. 1. The overall system architecture.

A. System Architecture

The study's system architecture focuses on analyzing the IoT23 dataset for botnet attacks, beginning with data collection and cleaning. Features are extracted and the dataset is divided into training and testing sets, followed by statistical tests to uncover data patterns. Feature selection is performed using filter, wrapper, and embedded methods, with the GRU model with embedded Lasso-based selection standing out as the top classifier. An ensemble approach with 10 LassoCV models enhances feature selection's reliability. Further improvements are achieved by integrating the ResNet architecture into the GRU model, addressing deep learning challenges. To ensure privacy, federated learning is introduced, allowing decentralized model training without sharing raw data [20]. The optimized ResNet-GRU model's performance is compared with existing federated learning algorithms like FedProx, FedAvg, and Fed+ in terms of metrics and processing time. This approach offers a comprehensive solution for botnet attack detection in IoT networks while addressing privacy concerns [21] [22].

B. Dataset Description

The IoT-23 dataset, released in January 2020, comprises network activity data from IoT devices. It includes benign IoT device traffic and malware-infected IoT device captures. This dataset, created by the Stratosphere Laboratory at CTU University, aims to support machine learning research in IoT malware detection. It consists of twenty-three scenarios, featuring malware execution on Raspberry Pi devices and real IoT device captures like Philips HUE smart LED lamps and Amazon Echo. This dataset offers a valuable resource for training algorithms to detect IoT malware and enhance IoT security.

C. Data Preprocessing

Data preprocessing is the process of cleaning and formatting data so that it can be used for analysis. This can involve removing outliers, imputing missing values, and transforming the data into a format that is suitable for the analysis method being used. The Kruskal-Wallis test is a non-parametric test that can be used to compare the distributions of two or more groups. It is a non-parametric test because it does not make any assumptions about the distribution of the data. This makes it a versatile test that can be used with a variety of data types [23].

To perform a Kruskal-Wallis test on the IoT-23 dataset, you would first need to preprocess the data. This would involve removing any outliers, imputing any missing values, and transforming the data into a format that is suitable for the Kruskal-Wallis test. Once the data has been preprocessed, you can perform the Kruskal-Wallis test. The Kruskal-Wallis test will output a p-value. If the p-value is less than a significance level (typically 0.05), then you can conclude that there is a significant difference between the distributions of the two or more groups. The proposed work focuses mainly on the attacks namely Torri, Okiru , Mirai and also normal labels- benign as class labels out of 13 labels present in the IoT-23 dataset.

D. Kruskal – Wallis Test

The Kruskal-Wallis test is utilized to compare the medians of three or more distinct groups. Unlike parametric tests such as ANOVA, which rely on assumptions of normal distribution and equal variances, this non-parametric test is employed when these assumptions are not met. The Kruskal-Wallis test involves the following aspects:

Hypotheses: The null hypothesis *(H0)* assumes that all group medians are equal, while the alternative hypothesis *(HA)* posits that at least one median differs from the others. The hypothesis is presented in Eq. (1).

$$H = \frac{12}{n(n+1)}\sum\frac{R_j^2}{n_j} - 3(n+1) \tag{1}$$

where, H is the Kruskal-Wallis test statistic, n is the total number of observations across all groups, R_j is the sum of ranks for group j, n_j is the number of observations in group j. The test statistic H follows a chi-square distribution with degrees of freedom equal to the number of groups minus 1(df = k-1), where k is the number of groups being compared. The significance of the test can be determined by comparing the obtained test statistic with the critical value from the chi-square distribution with the appropriate degrees of freedom [24].

H statistic	345.78
Degrees of Freedom	4
p-value	< 0.001

Null Hypothesis: There are no significant differences among the groups.

Alternate Hypothesis: There are significant differences among the groups.

Conclusion: The p-value (< 0.001) is smaller than the significance level (usually 0.05), so we reject the null hypothesis. This indicates significant differences among the groups.

IV. Proposed Methodology

In this study, we comprehensively investigate cyber-attack detection in IoT environments using the IoT23 dataset. We compare the performance of different classifiers, including LSTM, GRU, CNN, and traditional classifiers, to identify the most effective one for detecting malicious activities in IoT networks.

The CNN module described in the article consists of four stages, each comprising multiple convolution blocks with different sizes of convolution kernels. The convolutional layer performs operations on input images, such as feature extraction, feature mapping, weight sharing, and local connection. The convolution operation reduces image size and computational cost for subsequent operations.

The formula for the convolution operation is given as:

$$v(i,j) = (X * w)(i,j) + b = \sum n(k=1)\,(Xk * wk)(i,j) + b \tag{2}$$

Here, '*n*' represents the number of input matrices, *Xk* denotes the k^{th} input matrix, and *ωk* represents the k^{th} sub convolution kernel matrix of the convolution kernel. The activation layer applies a non-linear mapping, specifically the Rectified Linear Unit (ReLU) activation function, to the output of the convolution layer. The ReLU function is defined as:

$$ReLU\,(x) = \begin{cases} x, if\ x > 0 \\ 0, if\ x \leq 0 \end{cases} \tag{3}$$

A Simple Recurrent Unit (SRU) serves as the foundation for Recurrent Neural Networks (RNNs), but RNNs can be challenging to train due to gradient issues. Variations like GRU and LSTM were introduced to address these problems. LSTM, for example, includes memory cells and gates to capture temporal sequences and improve recognition accuracy. However, LSTM's complexity can be an issue, so a simplified gating unit was introduced to streamline calculations. LSTM and GRU differ in how they update the next hidden state and handle content exposure. LSTM uses summation for updates, while GRU considers the time needed to save information in memory. Recent comparisons have shown that GRU often performs slightly better than LSTM in various machine learning applications.

In the structure of a Bi-GRU, both reset and update gates are present. These gates allow GRU to pass information across multiple time windows for better classification or prediction. Specifically, weights and data are stored in memory to be used with a given state for updating future values. In the update gate, GRU computes zt at a given time t to solve the vanishing gradient problem using the following formula:

$$zt = \sigma(Wz[ht - 1, xt] + bz). \tag{4}$$

whereas, in the reset gate, GRU calculates zt at a given time t to illustrate how much past information to forget. The gate executes the following calculation:

$$rt = \sigma(Wr[ht - 1, xt] + br). \tag{5}$$

The current storage content stage is calculated according to the following formula:

$$h^{\sim} = tanh(W\,[rtht - 1, xt]) \tag{6}$$

Finally, ht is calculated in the final memory of the current time step to store the current unit information for calculating the output vector ot, as follows:

$$ht = (1 - zt)\,ht - 1 + zth^{\sim}t \tag{7}$$

For many sequence modeling tasks, accessing future and past contexts is beneficial. However, the standard GRU network processes the sequence in chronological order, disregarding the future context. Bi-GRU networks extend the unidirectional GRU network by introducing a second layer in which the hidden connections flow in reverse chronological order.

A. *Long Short Term Memory (LSTM)*

The LSTM network is a specialized type of deep neural network that excels at capturing long-term dependencies in time-series data. It achieves this by incorporating memory cells and gating operations. The memory cells are updated through gating operations that determine what information to remember and what to forget in the temporal sequence. This makes LSTM highly suitable for modelling temporal dynamics effectively.

There are three types of gating operations in LSTM: the input gate (it), the output gate (ot), and the forget gate (ft). The expressions that form the foundation of LSTM are as follows:

Input Gate:

$$i_t = \sigma_t(W_i[h_t - 1, x_1] + b_i) \tag{8}$$

Forget Gate:

$$f_t = \sigma_f\left(W_f\,[h_t - 1, x_1] + b_f\right) \tag{9}$$

Cell State Update

$$c_t = f_t\,.\,c_{t-1} + i_t.\sigma_c(W_c[h_{t-1}, x_t] + b_c) \tag{10}$$

Output Gate

$$o_t = \sigma_0(W_0\,[h_{t-1}, x_t] + b_0) \tag{11}$$

Hidden State Update

$$h_t = o_t\,.\,\sigma_h(c_t) \tag{12}$$

where:

- x_t is the input data sequence.
- i_t, f_t and o_t represent the input, forget and output gates respectively.
- c_t and h_t correspond to the cell and hidden states respectively.
- b_i, b_f, b_c *and* b_o are biases related to the input gate, forget gate, cell state and output gate respectively.
- W_i, W_f, W_c *and* W_o are the weight matrices of the input gate, forget gate, cell state and output gate respectively.
- $\sigma_t, \sigma_f, \sigma_c, \sigma_o$ *and* σ_h are the activation functions of the input gate, forget gate, cell state, output gate and hidden state respectively.

In this study, we employed three distinct variations of LSTM, namely the single cell, stacked, and bidirectional LSTM models. These different LSTM variants were chosen to examine and compare their benchmark scores. By incorporating these diverse LSTM architectures, we aimed to explore the performance differences and identify the most suitable model for the given task.

1) Single Cell LSTM: Single-cell LSTM (Long Short-Term Memory) is a variation of the traditional LSTM neural network architecture that is designed to process individual data points or sequences one at a time. It is particularly useful in tasks where the input data has a temporal or sequential nature, such as natural language processing, speech recognition, and time series analysis. LSTMs are a type of recurrent neural network (RNN) that is capable of capturing long-term dependencies and addressing the vanishing gradient problem, which is a common issue in training RNNs. The single-cell LSTM architecture extends the basic LSTM by removing the concept of cell state, resulting in a simpler and more efficient model.

2) Stacked LSTM: Stacked LSTM (Long Short-Term Memory) is an extension of the traditional LSTM architecture that involves stacking multiple LSTM layers on top of each other. This allows the model to learn more complex and abstract representations of sequential data by capturing hierarchical dependencies. Each LSTM layer in a stacked LSTM consists of multiple LSTM cells, and the output of one layer serves as the input to the next layer. This stacking of LSTM layers enables the network to learn higher-level features and representations by building upon the representations learned in the preceding layers.

3) Bidirectional LSTM: Bidirectional LSTM (Long Short-Term Memory) is an extension of the traditional LSTM architecture that processes the input sequence in both forward and backward\\directions. This allows the model to capture dependencies from both past and future context, enabling better understanding of the input sequence. In a bidirectional LSTM, the input sequence is processed by two separate LSTM layers: one layer processes the sequence in the forward direction, and the other layer processes it in the backward direction. The outputs of these two layers are then combined to produce the final output.

4) Forward LSTM: A Forward LSTM (Long Short-Term Memory) is a type of recurrent neural network (RNN) architecture used in machine learning and deep learning for sequential data processing tasks. LSTM networks are particularly effective in handling sequences of data because they can capture long-range dependencies and mitigate the vanishing gradient problem, which is common in traditional RNNs. In a Forward LSTM, the input sequence is processed from the beginning to the end, one-time step at a time, without considering future time steps during the computation at each step. By processing the input sequence in both directions, the bidirectional LSTM can capture both past and future context, which can be beneficial in tasks such as natural language processing, sentiment analysis, and speech recognition. It allows the model to make more informed predictions by considering the complete context of the sequence.

B. Federated Learning

Federated learning is a machine learning approach that allows training of deep learning models across a network of decentralized devices while preserving data privacy. It enables the aggregation of local model updates from multiple devices without the need to transfer raw data to a central server. In this proposed work, a detailed introduction to popular federated learning algorithms: FedAvg, FedProx, Fed+ (FedPlus) has been discussed.

1) FedAvg (Federated Averaging): FedAvg is a fundamental federated learning algorithm that utilizes the idea of model averaging. It follows a simple iterative process where each device trains a local model using its local data and shares only the model's updates with the central server. The central server aggregates the updates from all devices by taking the average and updates the global model accordingly. The algorithm can be summarized as follows:

Initialization: Initialize the global model parameters, θ.

Iteration: Randomly select a subset of devices for participation.

For each selected device i:

Step 1: Send the current global model parameters to device i.

Step 2: Device i trains the local model on its local data, optimizing for a specific loss function, and obtains updated local model parameters, θ_i.

Step 3: Device i calculates the update difference: $\Delta\theta_i = \theta_i$- θ.

Step 4: Device i sends the update difference back to the central server.

The central server aggregates the update differences from all devices and calculates the average update:

$$\Delta\theta_{avg} = \frac{1}{N} * \sum \Delta\theta_i \tag{13}$$

The central server updates the global model:

$$\theta = \theta + \Delta\theta_{avg} \tag{14}$$

2) FedProx (Federated Proximal): FedProx extends FedAvg by introducing a proximal term to regularize the updates sent by each device. This regularization term helps in controlling the magnitude of the updates, preventing devices from deviating too far from the global model. The objective function of FedProx can be defined as:

$$L(\theta) = \left(\frac{1}{N}\right) * \sum\left(1(\theta, D_i)\right) + {}^{\lambda}\!/_{2} * \|\theta - \theta_{old}\|^2 \tag{15}$$

where, $1(\theta, D_i)$ represents the loss function on device i's local data D_i, λ is a hyperparameter controlling the proximal term, and θ_{old} is the model parameters from the previous round. FedProx can be seen as minimizing a weighted sum.

3) Fed+ (FedPlus): Fed+ is an extension of FedAvg that addresses the issue of device heterogeneity by assigning different weights to each device during aggregation. The weights reflect the devices' relative contributions to the global model. This approach helps to mitigate the impact of devices with varying computation capabilities or imbalanced datasets. The Fed+ algorithm can be summarized as follows:

Initialization: Initialize the global model parameters, θ.

Assign an initial weight for each device i, w_i.

Iteration:

Step 1: Randomly select a subset of devices for participation.

Step 2: For each selected device i:

Step 3: Send the current global model parameters to device i.

Step 4: Device i trains the local model on its local data, optimizing for a specific loss function, and obtains updated local model parameters, θ_i.

Step 5: Device i calculates the update difference:

$$\Delta\theta_i = \theta_i - \theta. \tag{16}$$

Step 6: Device i sends the update difference back to the central server.

The central server aggregates the update differences from all devices by weighted averaging:

$$\Delta\theta_{avg} = \frac{\Sigma(w_i * \Delta\theta_i)}{\Sigma w_i} \tag{17}$$

The central server updates the global model:

$$\theta = \theta + \Delta\theta_{avg}. \tag{18}$$

Adjust the weights of devices based on their contribution to the global model.

These algorithms represent different approaches to addressing the challenges of federated learning, such as heterogeneity, privacy preservation, and data distribution variations. The equations and explanations provided offer a high-level understanding of the algorithms, but specific implementation details may vary depending on the framework or research work.

C. ResNet-GRU Combined Architecture

Federated Learning is a groundbreaking approach that enables model training across distributed devices while protecting data privacy. The ResNet-GRU model, combining Residual Networks (ResNets) and Gated Recurrent Units (GRUs), excels at capturing spatial and temporal patterns, especially in scenarios with data distributed across multiple devices. ResNets, introduced in 2016, revolutionized deep learning, addressing the vanishing gradient problem in deep neural networks. They use "residual blocks" with skip connections, allowing gradients to flow more effectively through many layers. A residual block comprises stacked convolutional layers, batch normalization, and activation functions, with shortcut connections enabling input to bypass some convolutional layers. This design allows for training extremely deep networks more efficiently.

The central idea behind residual learning is to model the residual function *ΔF(x) = F(x) - x*, where *F(x)* represents the mapping learned by the convolutional layers, and *x* denotes the input to the residual block. Instead of attempting to learn the complete mapping *F(x)*, the network focuses on learning the difference or residual *ΔF(x),* which is subsequently added back to the input *x* to obtain the output of the block. This element-wise addition operation facilitates the preservation of prior knowledge, simplifying the learning process for deep networks.

Federated Learning is revolutionizing machine learning by training models on distributed devices while protecting data privacy. In anomaly detection, the ResNet-GRU model stands out for capturing both spatial and temporal features. It combines Residual Networks (ResNets) and Gated Recurrent Units (GRUs), making it ideal for federated learning scenarios with diverse data. Federated Learning decentralizes data to protect user privacy and data security. The ResNet-GRU model excels by blending ResNets' spatial prowess and GRUs' sequential data modeling capabilities. Residual blocks, key to the ResNet-GRU model, enable training deep networks by allowing information to bypass certain layers. Federated training is collaborative, with clients training local ResNet-GRU models on their data subsets. Models iteratively update, and global models are aggregated while preserving data privacy. Evaluation metrics like precision, recall, and ROC-AUC assess the model's anomaly detection performance. The ResNet-GRU model, adept at capturing spatial and temporal nuances, is a powerful tool for real-time anomaly detection while respecting federated learning principles.

Algorithm: ResNet-GRU Model in Federated Learning for Anomaly Detection

Input: Federated dataset (split into multiple clients), hyperparameters

Output: Trained ResNet-GRU model for anomaly detection

Step 1: Initialize the ResNet-GRU model

- Define the architecture of the ResNet-GRU model.

- Set hyperparameters such as the number of ResNet blocks, GRU units, learning rate, batch size, and number of training rounds.

Step 2: Federated Learning Setup

- Split the federated dataset into multiple clients or devices, each having its own subset of data.

- Distribute the ResNet-GRU model to all clients.

Step 3: Federated Training

- For each training round (t = 1 to number of training rounds):

- For each client i in the federated dataset:

- Load the ResNet-GRU model parameters from the global model.

- Train the ResNet-GRU model on client i using its local subset of data:

- For each mini-batch in client i's data:

- Perform forward pass through the ResNet to extract spatial features.

- Convert the spatial features into temporal sequences (if needed).

- Pass the temporal sequences through the GRU to capture temporal patterns.

- Calculate the loss using an appropriate anomaly detection loss function.

- Perform backward pass and update the model's parameters using an optimization algorithm (e.g., stochastic gradient descent).

- After training, send the updated model parameters back to the server.

Step 4: Model Aggregation

- Aggregate the model parameters from all clients to create a global ResNet-GRU model:

- For each layer and parameter in the ResNet-GRU model:

- Calculate the weighted average of the parameters from all clients.

- Update the global model's parameters with the weighted averages**.**

Step 5: Evaluation

- After each training round, evaluate the global ResNet-GRU model on a separate test set (not used for training) to monitor its performance.

- Measure metrics such as precision, recall, F1-score, ROC-AUC, or mean average precision for anomaly detection.

Step 6: Repeat Training and Aggregation

- Repeat Steps 3 to 5 for the desired number of training rounds or until the global model achieves satisfactory performance.

Step 7: Deployment

- Once the global ResNet-GRU model achieves satisfactory performance, deploy it to the production environment for anomaly detection on new data.

V. Results and Discussions

The following section discusses the results obtained from the various experiments done on the IoT-23 dataset.

TABLE. I PERFORMANCE EVALUATION WITHOUT FEATURE SELECTION

SL No	Classifiers	Accuracy	Precision	Recall	F1 score	Time Taken (Sec)
1	Support Vector Machine	0.62	0.62	0.64	0.63	289.325
2	K-Nearest Neighbor	0.66	0.66	0.67	0.66	256
3	Linear Discriminant Analysis	0.71	0.75	0.71	0.73	290

17	Forward LSTM	0.66	0.84	0.85	0.81	225
18	Long Short Term Memory	0.6	0.6	0.61	0.6	245.36
19	Gated Recurrent Neural Network	0.75	0.75	0.74	0.75	158.96

Table I shows classifier performance without feature selection on the dataset, evaluated by accuracy, precision, recall, F1 score, and processing time. Results vary significantly: Support Vector Machine achieves 62% accuracy, K-Nearest Neighbor 66%, and Linear Discriminant Analysis 71%. Gated Recurrent Neural Network performs well with 75% accuracy, precision, recall, and F1 score. Processing time varies, from 158.96 seconds for the Gated Recurrent Neural Network to 600.32 seconds for CatBoost, indicating different computational demands. Visualization plots are in Fig. 2 and Fig. 3.

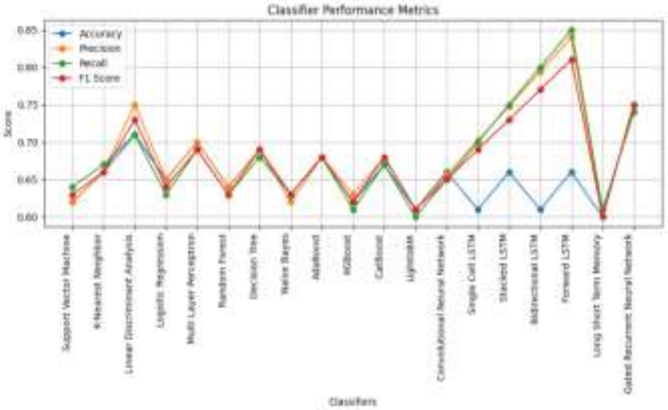

Fig. 2. Performance evaluation without feature selection.

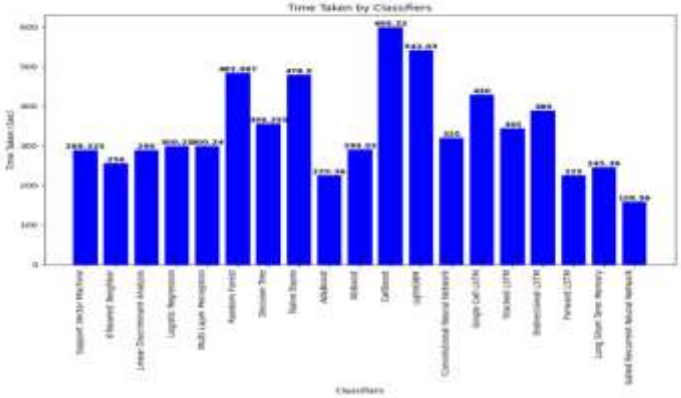

Fig. 3. Time taken without feature selection.

The Table II compares classifier performance using the Filter Approach for feature selection on the dataset. Performance metrics include accuracy, precision, recall, F1 score, and processing time. Results vary: Support Vector Machine achieves 82% accuracy, K-Nearest Neighbor 87%, and Linear Discriminant Analysis 88%. Long Short Term Memory performs at 74%. Gated Recurrent Neural Network excels with 90% precision, 92% recall, and 91% F1 score. Processing time ranges from 215.32 seconds (GRU) to 720.36 seconds (LSTM), indicating varying computational requirements.

TABLE. III PERFORMANCE COMPARISON WITH FILTER APPROACH

Table III compares classifier performance with the Wrapper Approach for feature selection on the dataset, considering accuracy, precision, recall, F1 score, and processing time. Support Vector Machine achieves the highest accuracy at 89%, while K-Nearest Neighbor reaches 84%, and Linear Discriminant Analysis achieves 80% accuracy. Precision, recall, and F1 score vary across classifiers, with Convolutional Neural Network excelling at 94%, 88%, and 91%, respectively. Processing time ranges from 900 seconds (GRU) to 32,546 seconds (Linear Discriminant Analysis), indicating distinct computational requirements. Visualization plots are available in Fig. 6, and processing time is shown in Fig. 7.

Table IV compares classifier performance with the Embedded Approach for feature selection on the dataset, considering accuracy, precision, recall, F1 score, and processing time. Support Vector Machine achieves 82% accuracy, K-Nearest Neighbor reaches 86%, and Linear Discriminant Analysis attains 81% accuracy. Convolutional Neural Network excels with 98% precision, 91% recall, and 94% F1 score, ranking among the top performers. Processing time varies, from 1,200.35 seconds (GRU) to 32,658 seconds (K-Nearest Neighbor), indicating significant computational differences across models. Visualization plots are available in Fig. 8, and processing time is shown in Fig. 9.

Table V displays ensemble-based embedded feature selection with bagging results for various classifiers, featuring accuracy, precision, recall, F1 score, and processing time. Evaluated classifiers include Convolutional Neural Network, Long Short Term Memory, Gated Recurrent Neural Network, Single Cell LSTM, Stacked LSTM, Bidirectional LSTM, and Forward LSTM. The Gated Recurrent Neural Network achieved the highest performance, with accuracy, precision, recall, and F1 score around 0.96 and a processing time of 1887 seconds. In contrast, the Forward LSTM exhibited lower performance, with scores around 0.72 and a processing time of 2160 seconds.

TABLE. VI ENSEMBLE-BASED EMBEDDED FEATURE SELECTION

SL No	Classifiers	Accuracy	Precision	Recall	F1 score	Time Taken (Sec)

This Table VI compares the performance of six classifiers in solving the task, considering accuracy, precision, recall, and F1 score. The classifiers are Gated Recurrent Neural Network, ResNet-GRU, Single Cell LSTM, Stacked LSTM, Bidirectional LSTM, and Forward LSTM. ResNet-GRU stands out as the top performer, excelling in all metrics. However, it's important to consider the computational cost, as processing time varies among models. The choice of the best classifier depends on specific application requirements and available computational resources.

TABLE. VII FEDERATED LEARNING PERFORMANCE METRIC.

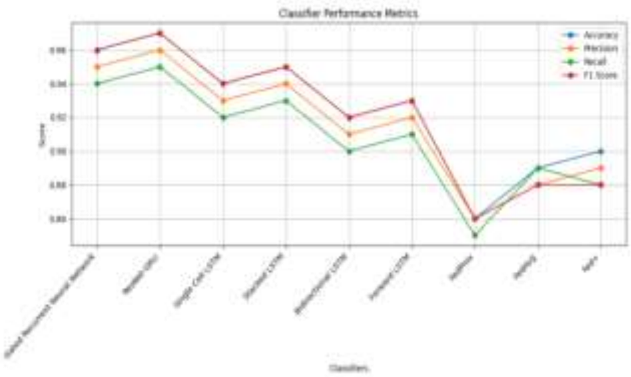

Fig. 12. Performance metric with federated learning.

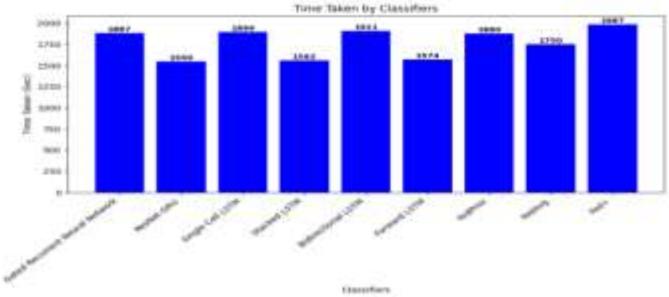

Fig. 13. Time taken with federated learning.

In federated learning, the loss function curve is essential for tracking the model's progress in a privacy-preserving setting. It enables multiple devices or clients to train a global model collaboratively without sharing raw data centrally. Each client trains its model locally, and the loss function measures the model's prediction accuracy compared to actual labels. The loss function curve depicts how this accuracy evolves over federated learning rounds. Initially, it may fluctuate as models adapt to individual data. Over rounds, it generally decreases, indicating improved performance. However, federated learning's unique challenge arises from diverse data distributions across clients, leading to varying loss function curves and potentially non-smooth trajectories due to aggregation of local models. The loss function curve obtained from our setting is shown in Fig. 14.

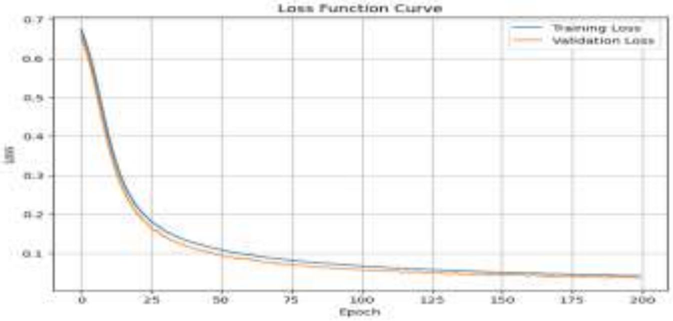

Fig. 14. Loss-Function curve.

VI. Conclusion and Future Enhancement

In this study, we analyzed the IoT23 dataset, focusing on botnet attacks, and used statistical tests to uncover patterns. We employed various feature selection methods and tested 19 classifiers, with the GRU model and embedded lasso-based feature selection performing the best. An ensemble of LassoCV models improved feature selection, and integrating the ResNet architecture further boosted the GRU model's performance. We addressed privacy concerns using federated learning, and the optimized ResNet-GRU model outperformed existing algorithms. Future work should include robustness testing, hyperparameter tuning, and exploring larger datasets. Investigating different federated learning approaches and assessing real-world deployment challenges are also promising directions for further research.

Hybrid Approach with VADER and Multinomial Logistic Regression for Multiclass Sentiment Analysis in Online Customer Review

Murahartawaty Arief, Noor Azah Samsudin
Faculty of Computer Science and Information Technology, Universiti Tun Hussein Onn Malaysia,
Batu Pahat, Johor, Malaysia

***Abstract*—Sentiment analysis is crucial for businesses to understand customer reviews and assess sentiment polarity. A hybrid technique combining VADER and Multinomial Logistic Regression was used to analyze customer sentiment in online customer review data. VADER is a lexicon-based approach that labels reviews with sentiment using a predefined lexicon, whereas Multinomial Logistic Regression can determine the polarity of sentiment using VADER data. This study employed multiclass classification using TF-IDF vectorization to categorize sentiment as a positive, negative, or neutral class. Correctly managing neutral sentiments can assist businesses in identifying improvement opportunities. The utilization of the VADER lexicon and Multinomial Logistic Regression has been shown to significantly improve the performance of sentiment analysis in the context of multiclass classification problems. With a 75.213% accuracy rate, the VADER lexicon accurately recognizes neutral sentiment and is appropriate to adapt in categorizing sentiment related to customer reviews. Combined with Multinomial Logistic Regression, accuracy increases to 92.778%. In conclusion, the hybrid approach with VADER and Multinomial Logistic Regression can leverage the accuracy and reliability of multiclass customer sentiment analysis.**

***Keywords*—Hybrid approach; multiclass sentiment analysis; VADER; multinomial logistic regression; online customer review**

I. Introduction

Understanding and analyzing customer sentiment become a demanding topic in the sentiment analysis research area. Sentiment analysis is crucial for businesses to detect and extract customer reviews to determine consumer sentiment and measure satisfaction levels based on the sentiment expressed in the reviews. Sentiment Analysis uses statistical approaches, natural language processing, and machine learning to analyze and classify customer sentiment as positive, negative, or neutral [1].

Machine learning has made significant progress in classifying customer sentiment in online reviews. Unfortunately, the main focus of this study has concentrated on determining binary classification: positive and negative sentiment. The neutral sentiment is frequently ignored or removed. In an online review, a neutral class is derived from a 3-star rating for a customer who is satisfied enough with the quality of the product. For example: *"Would like to see better battery life. Decent otherwise."* The word "decent" lacks strong positive or negative sentiment about the product being reviewed. This review categorizes it as a neutral class with a mixture of both negative and positive feedback. Neutral class in customer sentiment analysis that allows comments data with factual, informative, or descriptive text rather than expressing a particular emotional tone.

Neutral sentiments should be handled or treated correctly to leverage the comments left and pinpoint areas of improvement. Many businesses pay close attention to reviews on both ends of the scale (4, 5 stars rating as positive and 1, 2 stars as negative) but must catch up on the valuable middle parts (3 stars as neutral). The number of 3 stars in online reviews might be small in volume but higher in value. According to Al-Rubaiee et al. [2], the neutral class can be helpful in sentiment analysis to maintain the accuracy of sentiment analysis models by reducing the risk of misclassifying text that does not express a clear sentiment.

From the business's viewpoint, neutral sentiment should be managed or addressed correctly to acquire a complete understanding of consumer feedback and find areas for improvement to make the product or services stand out. Businesses must guarantee that neutral sentiments are appropriately fulfilled to avoid consumer dissatisfaction, meet baseline requirements, and make well-informed decisions to encourage business growth.

The complexity of natural languages and the difficulty of quantifying human feelings make sentiment analysis a challenging task to categorize text data into different emotion classes automatically. Currently, research on sentiment classification is dominated by two basic approaches: machine learning and lexicon-based approaches. The machine learning approach requires a lot of labeled data training with manual process annotation, reviewing, and verification, which can slow system development and deployment.

Manual labeling using rating values were 1, 2 stars as negative sentiment, 3 stars as neutral sentiment, and 4-5 stars as positive sentiment is not possible to label the review sentences because customers often give a rating that does not match the review. For example, if the experience is valued with 5 stars (excellent), the sentence review has a negative connotation and vice versa. Some customer has their own biases when writing a review and these biases in rating may result in inconsistent reviews. Hu et al. [3] also claimed that customers are not entirely rational, and that affects self-selection rating biases.

The number of customer reviews for a popular product can be hundreds or thousands. Manual labeling commonly used in sentiment analysis is considered inefficient in terms of time and cost, especially if the data is extensive. Conversely, the lexicon-based approach can deal with language complexity and focuses on words and phrases as indicators of semantic orientation. However, this approach is low in accuracy but is computationally efficient, scalable, and provides consistent performance [4]. Combining lexicon-based and machine-learning techniques, known as the hybrid approach, can enhance performance accuracy in sentiment analysis results [5].

Multiple machine learning and lexicon-based approaches have been used to perform automatic classification for sentiment analysis. Unfortunately, the relative effectiveness of each approach is still unclear. This study employed a hybrid approach integrating the VADER lexicon with Multinomial Logistic Regression to examine the sentiment polarity of online customer reviews. The VADER methodology was selected as a lexicon-based approach that uses labels assigned in customer reviews for sentiment classification, utilizing a pre-defined vocabulary. Combined with Multinomial Logistic Regression as a supervised machine learning classifier, it uses a labeled sentiment from the VADER lexicon to train classifiers to generate more accurate sentiment predictions. According to Ramya and Rao [6], Multinomial Logistic Regression can make predictions in big data sets containing various diverse domains.

This research contributes to an extensive experiment with VADER and Multinomial Logistic Regression to determine how this combination affects the performance accuracy to detect neutral classes in sentiment classification. This process used the Amazon product review dataset to ensure the proposed approach is functional and executable in the customer sentiment domain. The performances, advantages, and limitations of VADER with Multinomial Logistic Regression in multiclass sentiment classification tasks were investigated and evaluated in this study. The TF-IDF method was selected as features vectorization to determine the important words to predict the sentiment in the Multinomial Logistic Regression algorithm.

Details about the relevant theories and related works are presented in Section II. Section III presents the research methodology for implementing a hybrid sentiment analysis approach. Experiment, results, and discussion are provided in section IV. Finally, Section V concludes with a conclusion and future works.

II. Related Works

A. Lexicon-based Approach with VADER

Sentiment classification uses automatic algorithms to predict the sentiment orientation of opinions included within a written document, such as a product review, blog post, or social media comment. Sentiment orientation can be characterized as positive, negative, or neutral, or it can be scored on a scale. The lexicon-based approach, also known as the dictionary-based approach, is employed in Natural Language Processing (NLP) for sentiment detection and text classification. This approach involves utilizing a predetermined lexicon or dictionary to identify specific words within the text [7]. A dictionary is prepared in advance, including entries for words or phrases linked to specific categories or sentiments. The lexicon can be established manually by domain experts or generated using automated approaches like machine learning. A score or label reflecting sentiment or category is given to each word or phrase in the lexicon. By aggregating the scores or labels of all the words or phrases in the text, an overall sentiment or category can be determined based on the number and intensity of positive and negative words encountered.

In this research, Valence Aware Dictionary and sEntiment Reasoner (VADER) is used in a lexicon-based approach. VADER is a lexicon-based algorithm developed by Hutto and Gilbert [8] in 2014 to solve the problem of analyzing language, symbols, and style of texts in sentiment analysis. It is widely used in various applications such as social media monitoring, customer feedback analysis, and brand reputation management. It utilizes a pre-built lexicon that contains words with sentiment scores and incorporates grammar and syntactical rules to handle negations, intensifiers, and modifiers [9].

VADER utilizes a pre-built lexicon that contains words or phrases with sentiment scores ranging from -1 (extremely negative) to +1 (extremely positive). The lexicon also includes words with neutral sentiment scores. The sentiment scores in VADER are based on human-annotated ratings and consider the intensity of sentiment associated with each word. The main output of VADER is a sentiment polarity score, which represents the overall sentiment expressed in each text. The score is a continuous value ranging from -1 to +1, where negative values indicate negative sentiment, positive values indicate positive sentiment and values close to zero indicate neutral sentiment [8].

Shabi [10] evaluates the performance of five lexicons used in sentiment analysis on Twitter data: VADER, SentiWordNet, SentiStrength, Liu and Hu opinion lexicon, and AFINN-111. By using the Stanford dataset, the results showed that the best performance in terms of accuracy was achieved by the VADER lexicon 72%, while the performance accuracy of the SentiStrength (67%), AFINN-111 (65%), Liu-Hu lexicon (65%), and SentiWordNet lexicon fell to the value 53%. With this comparison, the lexicon VADER has a good possibility for classifying short text pre-processing and can deal with multi-class, such as positive, negative, and neutral.

Furthermore, Heaton [11] conducts a comparative analysis of TextBlob and VADER in terms of sentiment analysis for positive, negative, and neutral sentiments expressed in social media regarding the NHS Covid-19 applications. The findings indicate that the VADER method outperforms recognized positive sentiments in sarcastic tweets with values of 0.8316, 0.7622, 0.6767, and 0.6958 for four tweets.

B. Machine Learning Approach with Multinomial Logistic Regression

Machine learning is an approach that creates models and designs algorithms to facilitate computational learning and decision-making processes. Machine learning has progressed beyond teaching computers to imitate the human brain to discovering statistical patterns in learning processes to deliver insights from datasets [12]. Machine learning can be classified into two categories: supervised and unsupervised learning. Supervised learning involves training a model using labelled data, where corresponding target labels or outcomes match the input data. These models are evaluated based on predictive capacity and variance measures. The objective is to acquire the knowledge necessary to construct a mapping function to accurately forecast the appropriate label for data sets known as testing data (unseen inputs). Multinomial Naïve Bayes, Support Vector Classification, Logistic Regression, Neural Networks, Random Forest, AdaBoost, Gradient Boosting, and Decision Tree are classifier models of supervised learning algorithms for multiclass classification.

In unsupervised learning algorithms, on the other hand, the model learns from unlabeled data without any predefined target labels. The objective is to discover patterns, structures, or relationships within the data by automatically developing classification labels by searching for similarities between data pieces to determine the category and create groups or clusters [13]. Clustering algorithms, such as K-means clustering, Latent Dirichlet Allocation (LDA), and Principal Component Analysis (PCA), are common algorithms of unsupervised learning. In this research, Multinomial Logistic Regression is selected as classifier algorithms to predict sentiment into positive, negative, and neutral classes in sentiment analysis.

Ramadhan et al. [14] applied Multinomial Logistic Regression in social media for Jakarta Governor Election with K-Fold cross-validation, achieving 74% accuracy with 90:10 training and testing data ratio. In his study, features were extracted and transformed into binary vectors using the TF-IDF method with the training dataset labeled manually. In addition, Purwandari et al. [15] compared Multinomial Logistic Regression and Multinomial Naïve Bayes for classifying weather in social media into five classes: cloudy, sunny, rainy, heavy rain, and light rain. The Multinomial Logistic Regression model has higher performance, with an accuracy rate of 83.3% and a precision rate of 90.3%. In comparison, the Multinomial Naïve Bayes model achieves an accuracy rate of 73.5% and a precision rate of 86.3%. Multinomial Logistic Regression has proven effective in classifying weather with good results.

C. *Hybrid Approach in Sentiment Analysis*

The hybrid approach is a methodology that integrates a lexicon-based approach and a machine-learning approach. Research investigations have recently focused on implementing a hybrid approach due to their ability to produce improved performance over either the lexicon-based model or the machine learning-based approach alone. Combining the advantages of lexicon-based and machine-learning methodologies is the primary goal of utilizing a hybrid method. The lexicon-based method is effective and can be used in a variety of contexts. This method does not require a significant amount of human interaction to label the training dataset and its ability to find the opinion words with the specific content orientation. On the other side, the machine learning approach effectively discovers subjectivity issues, noise resistance, and the ability to analyze numerous categories [16].

Most of the work in sentiment analysis performs supervised machine learning in binary classification with the best algorithms achieving an accuracy of less than 90%. A study by Pang et al. [17] demonstrated that the Support Vector Machine was 82.9% more accurate than the Naïve Bayes method in a movie review with binary classification. Vyas & Uma [18] observed that Support Vector Machine outperforms the Naïve Bayes and Decision Tree for binary sentiment classification in social media with an accuracy of 82.61%. Moreover, a study by Gupta et al. [19] discovered that the Random Forest algorithm outperforms Naïve Bayes, Support Vector Machine, and K-Nearest Neighbor (KNN) with an accuracy rate of 78% for binary customer sentiment classification using Amazon, Yelp, and IMDB dataset.

There is a minimum study for a hybrid approach in multiclass sentiment classification, especially for VADER, a lexicon-based approach with a supervised machine learning classifier. Chaithra [20] analyzed the metadata of media-sharing sites (YouTube) with popular videos using a hybrid approach. The lexicon-based approach VADER was applied, and a Naïve Bayes classifier as machine learning was trained with 70% of the data. The classifier achieved an accuracy of 79.78% and an F1 Score of 83.72% on 30% testing data. By applying this approach, the accuracy value indicates that the text comment can be classified into positive or negative feedback rather than like/dislike on the YouTube site.

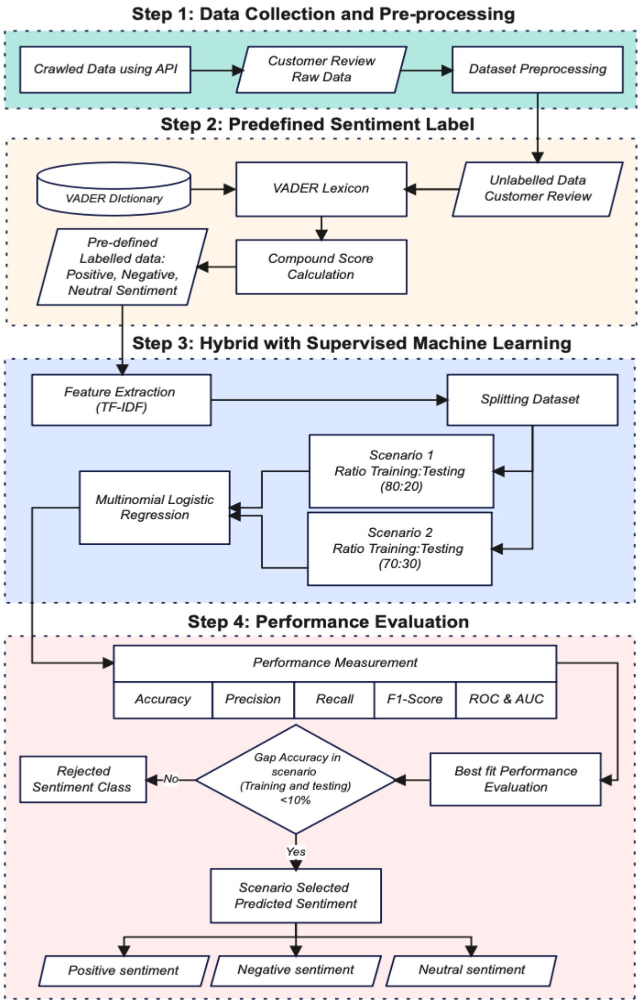
To add on, Mahmood et al. [21] employed a hybrid approach to classifying public opinion on social media in positive and negative sentiment, combining a lexicon-based with machine learning approaches such as Naïve Bayes and Support Vector Machines. The Support Vector Machine performs superior to the Naïve Bayes classifier, achieving an accuracy rate of 80% before combining with the lexicon-based approach, while the lexicon-based method alone reached 85%. The accuracy performance was increased after combining the lexicon-based and machine-learning approaches with a 90% accuracy rate.

According to the study by Rajeswari [4], observed multiclass classification using SentiWordNet with Logistic Regression for movie datasets achieved an accuracy of 89% compared to Naïve Bayes and K-NN classifiers. In addition, Mujahid et al. [22] applied a hybrid approach to classify tweet e-learning implementation using VADER, TextBlob, and SentiWordNet combined with Logistic Regression, SVM, K-NN, and Random Forest. Their study showed that VADER and Random Forest outperformed with an accuracy of 88%. Not only that, Sham and Mohamed [23] used a hybrid approach to classify sentiment into tri-class (positive, negative, neutral) using climate change tweets. The study found that hybrid approaches, including Logistic Regression and TextBlob using TF–IDF, outperformed on a combined dataset with an F1-score result of 75.3%. Lemmatization techniques are not recommended during the data preprocessing phase of lexicon approaches, as they can decrease the performance obtained. This study also found that

TF–IDF as the feature extraction technique outperformed Bag-of-Words (BoW) when used in Logistic Regression.

III. Proposed Methodology

This section provides an overview of the proposed methodology employed with a hybrid approach for multiclass sentiment analysis. The sequential execution of the proposed methodology is illustrated in Fig. 1.



Step 1: Data Collection and Pre-processing
Crawled Data using API
Customer Review Raw Data
Dataset Preprocessing
Step 2: Predefined Sentiment Label
VADER Dictionary
VADER Lexicon
Unlabelled Data Customer Review
Pre-defined Labelled data: Positive, Negative, Neutral Sentiment
Compound Score Calculation
Step 3: Hybrid with Supervised Machine Learning
Feature Extraction (TF-IDF)
Splitting Dataset
Scenario 1 Ratio Training:Testing (80:20)
Multinomial Logistic Regression
Scenario 2 Ratio Training:Testing (70:30)
Step 4: Performance Evaluation
Performance Measurement
Accuracy
Precision
Recall
F1-Score
ROC & AUC
Rejected Sentiment Class
No
Gap Accuracy in scenario (Training and testing) <10%
Best fit Performance Evaluation
Yes
Scenario Selected Predicted Sentiment
Positive sentiment
Negative sentiment
Neutral sentiment

Fig. 1. Proposed methodology.

The first task is pre-processing, which includes transforming the case, deleting characters, and removing stop words to remove unneeded and repetitive information. Using the VADER lexicon, the second stage categorizes the customer review as positive, negative, or neutral. The third step is to use TF-IDF Vectorizer as a features extraction approach to execute Multinomial Logistic Regression for sentiment classification. The final step is to assess performance using accuracy, F1-Score, AUC, and ROC metrics.

A. Step 1: Dataset Collection and Pre-processing

1) Dataset: This study uses the Python programming language in a Jupyter Notebook to develop the suggested hybrid model. A web crawler was used to gather online customer reviews from Amazon.com, and mobile phone reviews were selected as a dataset with a more significant number of reviews. There are 3984 records of customer reviews with the following four attributes:

- Rating: consist of the customer assessment with range of 1 up to 5 stars to describe satisfaction level with the products. Rating on scale means: 1 - highly dissatisfied, 2 - dissatisfied, 3 - neutral, 4 - satisfied, and 5 - highly satisfied.
- Posting time: the date in customer post the review.
- Customer account: representing the customer identity in product review.
- Sentence of review: the text comments by customer after purchasing product to review the product performance.

All available information was crawled using a Python program. The Amazon website provides a review and rating score from 1-5 stars after customers buy products. Fig. 2 presents detailed rating information for the dataset.

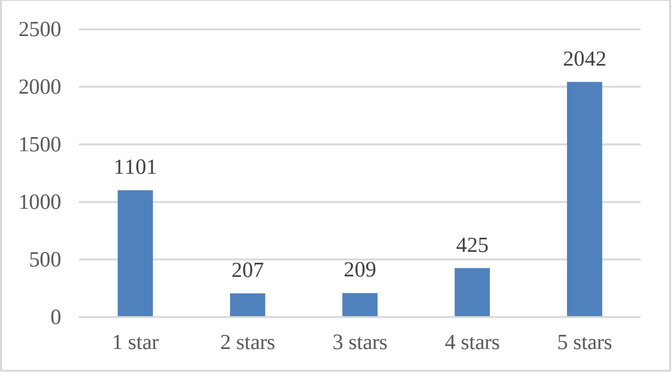


Fig. 2. Rating Information of mobile phone review

According to Fig. 2, the product has 1308 negative comments (33%) with 1-2 stars, 209 neutral sentiments (5%) with three stars, and 2467 with positive comments (62%) with 4-5 stars. This sentiment distribution indicates a positive product experience.

2) Pre-processing: Text pre-processing is important in sentiment analysis tasks due to the high dimensionality, poorly structured, and unstandardized text data tasks [24]. Pre-processing methods were performed to remove irrelevant and redundant data, which significantly impacted data quality. Pre-processing tasks include (1) case transformation, (2) tokenization, (3) stop word removal, and (4) stemming. Transform case is converted text to lowercase to ensure uniformity and prevent treating the same term differently due to case. The second procedure, tokenization, breaks textual data into smaller and meaningful components called tokens. Punctuation marks are removed during tokenization. The next step is to remove stop words. This method removes words from the text that don't add useful information, such as determiners, prepositions, coordinating conjunctions, and more. Finally, stemming is applied to the reduction of words to their roots.

B. Step 2: Predefined Sentiment Label

The customer review dataset is labeled as positive, negative, or neutral using VADER vocabulary sentiment. This labeling procedure makes training data for the supervised machine-learning model more efficient. VADER lexicon provides sentiment strength based on the polarity scores for each data review with an intensity value that falls between the range of -1 to 1. For example, the words *"perfect"* and *"great"* will have the same positive polarity, whereas in the VADER lexicon, "great" is more positive than "perfect" with the intensity value (valence score) for *great (0.79)* higher than the intensity value of *perfect (0.69).*

The sentiment intensity analyzer in the NLTK package, known as VADER, produces a sentiment score in a dictionary with four terms: neg, neu, pos, and compound. The terms "neg," "neu," and "pos" are used to represent negative, neutral, and positive meanings accordingly. The total of the numbers should approximate or equal to 1. The compound sentiment score is determined by summing the valence scores of every word in the lexicon, and it serves as an indicator of the overall sentiment intensity. The emotion score ranges from (-1), indicating the most extreme negative sentiment, and (+1) the most extreme positive attitude. The experiment utilized the compound score threshold value to ascertain the inherent sentiment of a given text, as described in Table I and applied in Python using Algorithm 1.

TABLE I. VADER LEXICON COMPOUND SCORE

Sentiment Polarity	Range
Positive	Compound score ≥ 0.05
Negative	*Compound Score* ≤ -0.05
Neutral	$-0.05 <$ compound score < 0.05

In order to implement the VADER algorithm in NLTK, it is necessary to download the VADER lexicon data and execute the commands using the Python script. The downloaded VADER lexicon was employed to apply the Sentiment Intensity Analyzer class from the NLTK for sentiment analysis. The Sentiment Intensity Analyzer class utilizes the polarity scores approach to provide a dictionary of sentiment scores. These scores include the compound score, a normalized composite value ranging from -1 to +1, and the positive, negative, and neutral scores. Based on specific requirements, the compound score threshold can be adjusted to categorize sentiment as positive, negative, or neutral.

Algorithm 1: The Sentiment VADER

```
Input: Pre-processed customer review data
Process:
    import nltk
    nltk.download('vader_lexicon')
    from nltk.sentiment import SentimentIntensityAnalyzer
    # Create an instance of the SentimentIntensityAnalyzer
    analyzer = SentimentIntensityAnalyzer()
    # Analyse sentiment of customer review sentence
    sentence = "I love everything about the phone!"
    sentiment_scores = analyzer.polarity_scores(sentence)
        if sentiment_scores['compound'] >= 0.05:
            sentiment = "positive"
        elseif sentiment_scores['compound'] <= -0.05:
            sentiment = "negative"
        else:
            sentiment = "neutral"
Output:
    # Print sentiment scores
    print sentiment_scores['compound']
```

C. Step 3: Hybrid with Supervised Machine Learning

The VADER-labeled data is paired with a supervised machine learning method employing Multinomial Logistic Regression to make predictions about the sentiment of customer reviews. Fig. 3 depicts the operational sequence of the Multinomial Logistic Regression model. The model is trained using a pre-defined VADER-labeled dataset. This dataset is divided into two different training and testing datasets scenario proportions.

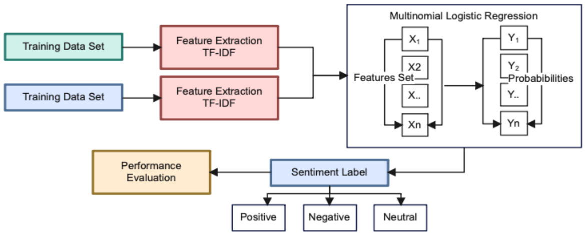

Fig. 3. Sentiment model with multinomial logistic regression.

1) Ratio proportion training and testing dataset: Training and testing data are split 80:20 and 70:30, respectively. In the first scenario, the 80% dataset is used for training and 20% for testing. In the second scenario, the 70% dataset is used for training and 30% is used for testing. This ratio was used when the dataset was large enough to provide sufficient training and testing instances. A larger training dataset can allow the model to learn more complex patterns, while smaller testing sets may result in less reliable performance estimates.

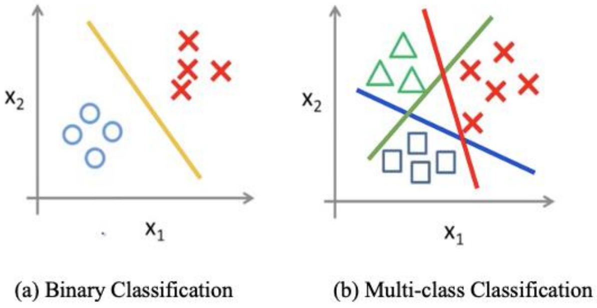
2) Feature extraction: This process aims to extract important and informative features from the cleaned dataset to reduce dimensionality and improve model performance and interpretability. The TF-IDF method was used in the feature extraction procedure to generate a document term matrix that denotes each term's word count and weightage [25].

$$\text{TF-IDF} = \text{tf x } 1 + \log\frac{N}{1+df(w)} \qquad (1)$$

The term frequency **(tf)** is calculated as the value of that term's occurrence in specific documents. The total number of documents in the corpus is denoted by **(N)**, while **df(w)** signifies the count of documents containing the term **w**.

3) Sentiment classification model: There are two types of classification issues based on the number of classes: binary classification and multi-class classification (more than two classes). In this study, a neutral sentiment class was handled using multiclass classification. Multiclass classification enables finer-grained data analysis by considering many categories, resulting in a deep insight and understanding of the data.

By default, Logistic Regression is a classification algorithm for binary classification. The positive (true) class is allocated a value of 1, and the negative (false) class is assigned a value of 0. The fit model predicts the likelihood of a class 1 [26]. Multinomial Logistic Regression, or extended logistic regression, predicts more than two classes. Fig. 4 depicts the distinction between binary and multiclass classification.



(a) Binary Classification (b) Multi-class Classification

Fig. 4. Binary and multi-class classification.

A commonly used method for extending binary Logistic Regression to handle multiclass classification problems involves dividing the multiclass problem into several binary classification problems and applying a standard Logistic Regression model to each individual problem. This technique is called *one-vs-rest* and *one-vs-one* wrapper models. In the *one-vs-rest* or *one-vs-all* approach, build a Logistic Regression to find the probability the observation belongs to each class. Fig. 5 describes the step of multiclass Logistic Regression.

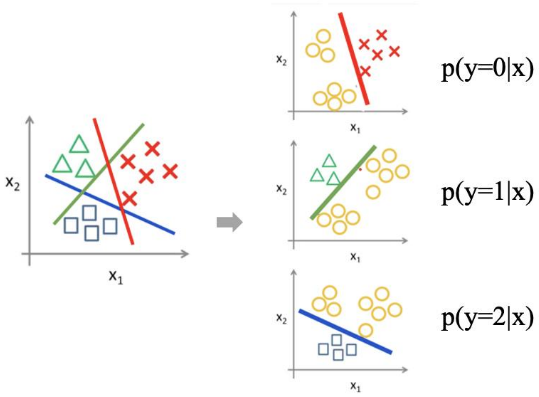


Fig. 5. Multiclass logistic regression classification.

The one-vs-rest technique involves training multiple binary Logistic Regression models, where each model represents one class against the rest of the classes [27]. The probabilities obtained from binary models combined to make multiclass classification predictions.

Denoted:

- N as the number of instances in the dataset
- K as the number of classes
- X as the input matrix of size N x D, where D is the number of features
- Y as the target variable matrix of size N x K, where each row represents the class labels for an instance using one-hot encoding

Train K binary logistic regression models, where each model i (i = 1 to K) predicts the probability of instance X belonging to class i against all other classes. The formula for the predicted probability of instance X belonging to class i is:

$$P(Y = i \mid X) = \sigma(W_iX + b_i) \qquad (2)$$

where:

- P(Y = i | X) is the predicted probability of instance X belonging to class i
- σ is the sigmoid function that maps the linear combination of the input features and model parameters to a probability between 0 and 1 (see Fig. 6).

$$\sigma\,(z) = \frac{1}{1+e^{-z}} = \frac{1}{1+\exp(-z)} \qquad (3)$$

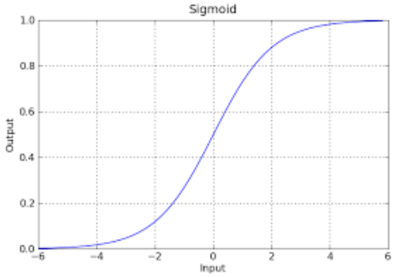

Fig. 6. Sigmoid function in logistic regression [27].

- W_i is the weight vector of size D x 1 for model i
- b_i is the bias term for model i

In order to generate predictions for a new instance X, the probabilities for each class must be computed utilizing the trained models, followed by the normalization probabilities with SoftMax formula [28]:

$$P(Y = i \mid X) = \frac{\exp(W_i X + b_i)}{\sum_{j=1}^{K} \exp(W_j X + b_j)} \quad 1 \leq i \leq K \qquad (4)$$

where:

- exp is the exponential function
- $\sum_{j=1}^{K} \exp(W_j X + b_j)$ is the sum of exponential terms for all classes j

Finally, the class label with the highest probability is assigned to the instance [29].

4) Model performance evaluation: The confusion matrix is a tabular representation that provides a detailed breakdown of a model's predictions. It displays the true positive, true negative, false positive, and false negative values for each class, allowing for an evaluation of the sentiment classification performance [30]. It helps to evaluate the correctness of classification approaches in multiclass classification problems. Table II presents the confusion matrix in multiclass classification with three sentiment categories: positive, negative, and neutral.

TABLE II. CONFUSION MATRIX FOR THREE SENTIMENT CLASSES

Actual	**Prediction**		
	Positive	***Negative***	***Neutral***
Positive	**TP**	**FNg1**	**FNt1**
	True Positive	False Negative 1	False Neutral 1
Negative	**FP1**	**TNg**	**FNt2**
	False Positive 1	True Negative	False Neutral 2
Neutral	**FP2**	**FNg2**	**TNt**
	False Positive 2	False Negative 2	True Neutral

where:

- True Positive (TP) refers to the number of times the classifier correctly predicts that the positive class is positive.
- The term True Negative (TN) refers to the number of the classifier that accurately predicts the negative class as negative.
- The term False Positive (FP) refers to the number of the classifier makes an incorrect prediction by classifying a negative class as positive.
- The number of the classifier incorrectly predicts the positive class as negative, referred to as False Negative(FN**).**

Performance evaluation metrics such as accuracy, precision, and recall can be formulated as follows by using a confusion matrix in Table II.

Accuracy is the percentage of correctly predicted instances across all classes divided by the total number of instances in the dataset.

$$Accuracy = \frac{TP+TNg+TNt}{TP+FP1+FP2+FNg1+TNg+FNg2+FNt1+FNt2+TNt}\ x\ 100\% \qquad (5)$$

Precision is the percentage of model positive predictions that are true. Precision in a multiclass classification problem can be calculated separately for each class, including positive, neutral, and negative.

$$Precision\ Positive\ = \frac{TP}{TP + FP1 + FP2}\ x\ 100\% \qquad (6)$$

$$Precision\ Negative\ = \frac{TNg}{TNg + FNg1 + FNg2}\ x\ 100\% \qquad (7)$$

$$Precision\ Neutral\ = \frac{TNt}{TNt + FNt1 + FNt2}\ x\ 100\% \qquad (8)$$

Recall called a true positive rate or sensitivity. Recall is also applied for each class in a multi-class classification problem that measures the percentage of true positive predictions out of all positive instances.

$$Recall\ Positive = \frac{TP}{TP + FNg1 + FNt1}\ x\ 100\% \qquad (9)$$

$$Recall\ Negative\ = \frac{TNg}{FP1 + TNg + FNt2}\ x\ 100\% \qquad (10)$$

$$Recall\ \ Neutral = \frac{TNt}{FP2 + FNg2\ + TNt}\ x\ 100\% \qquad (11)$$

F1 Score is a metrics that combines precision and recall value. This value provides a balanced assessment of the model's performance for positive, negative, and neutral classes. The formula to calculate the F1 Score is as follows:

$$F1\ Score\ Positive\ = \frac{2\ x\ Precision\ Positive\ x\ Recall\ Positive}{Precision\ Positive + Recall\ Positive} \qquad (12)$$

$$F1\ Score\ Negative\ = \frac{2\ x\ Precision\ Negative\ x\ Recall\ Negative}{Precision\ Negative + Recall\ Negative} \qquad (13)$$

$$F1\ Score\ Neutral\ = \frac{2\ x\ Precision\ Neutral\ x\ Recall\ Neutral}{Precision\ Neutral + Recall\ Neutral} \qquad (14)$$

ROC Curve and AUC is a graphical representation of the model's performance across different classification thresholds.

IV. EXPERIMENT AND RESULT

This section presents the result of the experiments and evaluates the performance of VADER and Multinomial Logistic Regression.

A. VADER Result

The polarity results of the dataset are determined using the VADER vocabulary as presented in Table III, and an inconsistency rating was identified in the dataset review compared with the VADER result. The result of the VADER classification sentiment in positive, negative, or neutral was described in Fig. 7 compared with the distribution frequency of sentiment based on the rating score in the raw dataset. The VADER lexicon can detect the neutral sentiment by assigning the sentiment score a neutral range for a text that does not strongly express positive or negative sentiment.

TABLE III. VADER LEXICON COMPOUND SCORE

Sentence	Rating	Compound Score	VADER Polarity	Consistency
I love everything about the phone! It's in great condition	5	0.819	Positive	True
Bought for nephew	5	0.000	Neutral	False
Too difficult to set up	1	-0.3612	Negative	True
Like the style but soon as I turn it on it gets really hot	2	0.3612	Positive	False
It is a good phone but not a great one	3	0.000	Neutral	True
Battery capacity was at 85% when I got it. Disappointing	3	-0.4939	Negative	False

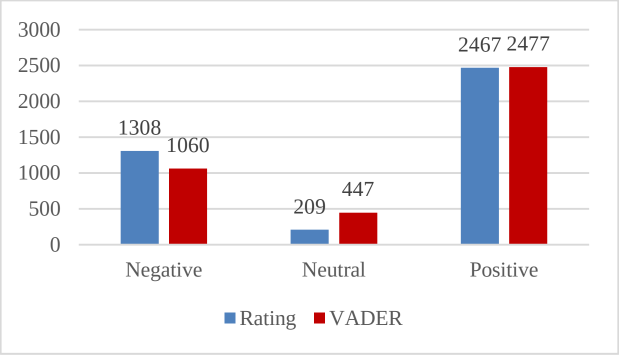

Fig. 7. Sentiment polarity distribution.

The accuracy rate for the VADER lexicon is 75.213% to label customer review data with sentiment polarity. VADER has been shown to perform effective in sentiment analysis tasks, particularly for customer reviews, where sentiments are often expressed in an informal and context-dependent manner.

TABLE IV. VADER LEXICON COMPOUND SCORE

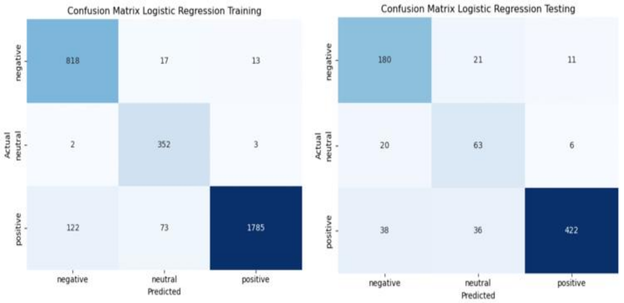
Bias Category from Rating to VADER sentiment	Total
Positive to Negative	**308**
Positive to Neutral	201
Negative to Positive	**263**
Negative to Neutral	206
Neutral to Positive	102
Neutral to Negative	**67**

According to Table IV, the investigation indicates misclassification between positive and negative and minimal misclassification between negative from neutral across all lexicons. VADER has a bias for inverting the polarity of ratings from positive to negative and vice versa. Since the differentiation between neutral with positive and neutral with negative are the significant factors to be clear in investigating the sentiment customer review, VADER lexicon is appropriate to adapted in task of labelling sentiment related to customer review.

B. *Sentiment Classification with Hybrid Approach: VADER with Multinomial Logistic Regression*

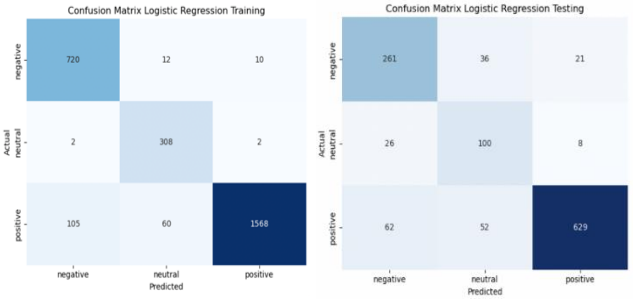
The metrics accuracy, precision, recall, F1-score, and Area Under Curve (AUC) are employed to assess the performance VADER with Multinomial Logistic Regression as a hybrid proposed model for multiclass classification. Confusion matrix visually shows the performance with two scenarios: splitting ratio 80:20 (see Fig. 8) and ratio 70:30 (see Fig. 9).

Regarding the result comparison in Table V, the first scenario with an 80:20 ratio is outperformed with an accuracy of 9,341% with a gap performance of <10% between training and testing data. Extending VADER with Multinomial Logistic Regression has increased the accuracy value by 17.565% from 75.213% with VADER to 92.778% with a hybrid approach. The second scenario has an overfitting condition with training data having a good performance, while its performance decreases significantly on the testing dataset (new data). Overfitting in machine learning should be avoided because it can negatively impact the model's performance and generalization ability on data that has never been seen before.



(a) Training data (b) Testing Data

Fig. 8. Confusion matrix with ratio 80:20.



(a) Training data (b) Testing Data

Fig. 9. Confusion matrix of with ratio 70:30.

TABLE V. GAP ANALYSIS FOR ACCURACY PERFORMANCE

Ratio	Dataset	True Predicted			Accuracy (%)	Gap Performance (%)
		Pos	***Neg***	***Neu***		
80:20	Training	1785	818	352	92.778	9,341
	Testing	422	63	180	83.437	
70:30	Training	1568	720	308	93.147	10.293
	Testing	629	261	100	82.845	

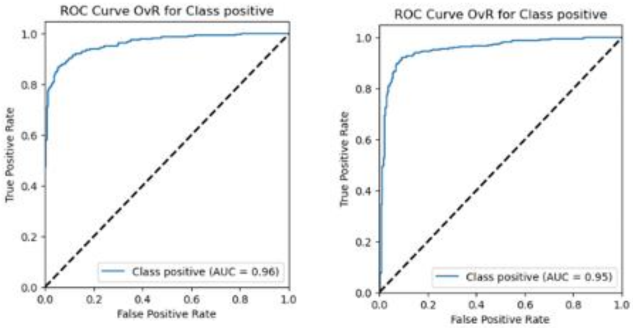
According to Table VI, the F1-Score for the positive, negative, and neutral classes are greater than 0.5 and close to 1. The positive classes have a higher score compared to the other classes. F1-Score combines precision and recall value works where the dataset is imbalanced, and according to this metric performance, a hybrid approach with a combination of VADER lexicon and Multinomial Logistic Regression accurately identifies positive, negative, and neutral classes with high recall and minimizes the frequency of false positives with high precision.

Furthermore, the AUC values in Table VI, which are close to 1, indicate that the hybrid approach is highly effective with excellent discrimination capabilities in distinguishing between positive, negative, and neutral classes. To better understand these data, the area under the ROC curve in Fig. 10 is represented by the area under the curve (AUC).

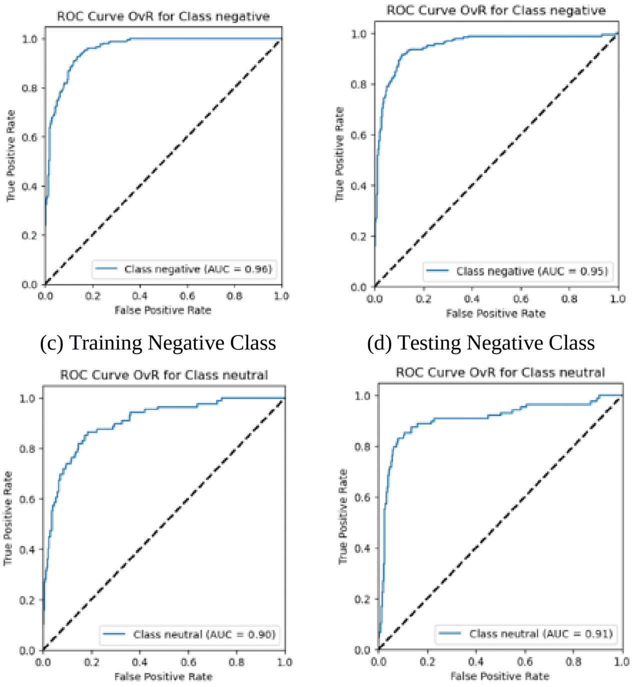
The ROC (Receiver Operating Characteristic) in Fig. 10 depicts a trade-off between the True Positive Rate and the False Positive Rate, which are shown on the "y-axis" and "x-axis," respectively. The line in the upper left corner of each ROC curve shows the cutoff value. The representation of ROC in Fig. 10 indicates that a hybrid approach with a combination of VADER lexicon and Multinomial Logistic Regression delivers a greater True Positive Rate (TPR) while preserving the low value in FPR.

TABLE VI. HYBRID APPROACH PERFORMANCE EVALUATION WITH SELECTED RATIO 80:20

Dataset		**Evaluation Metrics**			
		Precision	***Recall***	***F1-Score***	***AUC***
Training	Positive	0.991	0.902	0.944	0.96
	Negative	0.868	0.964	0.914	0.96
	Neutral	0.796	0.984	0.881	0.90
	Macro Avg	0.885	0.951	0.913	
	Weighted Avg	0.934	0.928	0.929	
Testing	Positive	0.961	0.851	0.903	0.95
	Negative	0.756	0.849	0.800	0.95
	Neutral	0.525	0.708	0.603	0.91
	Macro Avg	0.748	0.803	0.769	
	Weighted Avg	0.858	0.834	0.842	



(a) Training Positive Class (b) Testing Positive Class



(c) Training Negative Class (d) Testing Negative Class

(e) Training Neutral Class (f) Testing Neutral Class

Fig. 10. Hybrid approach ROC visualization (Ratio 80:20).

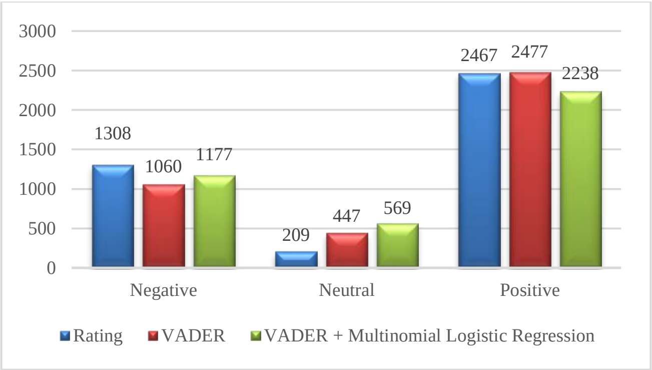


Fig. 11. Frequency distribution of sentiment polarity.

Fig. 11 presents the frequency distribution of sentiment polarity as determined by the rating score, VADER lexicon, and hybrid approach. The comparison results demonstrate that the hybrid approach effectively handles the neutral class when applied to multiclass sentiment classification. Extending VADER with Multinomial Logistic Regression can classify customer sentiment in online reviews as positive, negative, and neutral with good performance. The effectiveness of this method depends on the dataset accessibility, the complexity of sentiment nuances to be captured, and the specific criteria in the domain application.

V. CONCLUSION AND FUTURE WORKS

Online customer reviews can accurately predict customer sentiment regarding product experiences after purchase. With an accuracy percentage of 75.213%, VADER Lexicon classifies customer evaluations as positive, negative, or neutral, efficient in terms of time and costs for text labeling without a human annotator. The VADER model is interpretable and simple to use, but its functionality is limited by the lexicon. This method depends on words in the dictionary and may only work well with words in the lexicon. Additionally, the accuracy increased to 92.778% after combining with Multinomial Logistic Regression. The high level of accuracy indicates that the hybrid approach has an excellent performance in predicting the sentiment polarity in multiclass classification in customer reviews. The VADER model performs well in predicting the neutral class, whereas the Multinomial Logistic Regression model succeeds in an imbalanced dataset with high-dimensional features and overfitting challenges. Further investigation could involve conducting experiments to fine-tune the hybrid approach and comparing it to various algorithms in lexicon-based and machine-learning approaches.s

Artificial Intelligence-based Optimization Models for the Technical Workforce Allocation and Routing Problem Considering Productivity

Mariam Alzeraif, Ali Cheaitou
Department of Industrial Engineering and Engineering Management
University of Sharjah, Sharjah, UAE

Abstract—**Ensuring the reliability and availability of electric power networks is essential due to the increasing demands. An effective preventive maintenance strategy requires efficient resources allocation to perform the maintenance tasks, particularly the technical workforce. This paper introduces an innovative artificial intelligence-based approach to predict workforce productivity, aiming to optimize both the allocation of the technical workforce for maintenance tasks and their routing. In this study, two mathematical optimization models are introduced that utilize the output value of Artificial Neural Networks (ANN) for optimal resource allocation and routing. The first model focuses on team formation, considering the predicted productivity in order to ensure effective collaboration. While the second model focuses on the optimal assignment and routing of these teams to specific maintenance tasks. Validated with real-world data, the models show considerable promise in enhancing resource allocation, task assignment, and cost-efficiency in the electricity industry. Furthermore, sensitivity analysis has been conducted and managerial insights has been explored. The study also paves the way for future research, highlighting the potential for refining these models for more extensive applications.**

Keywords—Productivity; workforce; maintenance; optimization; allocation; routing

I. Introduction

The reliability and availability of the electric power network in the electricity industry is crucial for meeting the increasing demand [1]. Many of the blackouts were confirmed to be caused by imperfect maintenance due to human factors [2]. Maintenance can be divided into two categories: corrective and preventive. Corrective maintenance is performed after a breakdown. In contrast, preventive maintenance is performed at predetermined intervals or according to prescribed criteria and intended to reduce the probability of failure [3]. Consequently, maintenance planning, and more specifically preventive maintenance is extremely important in the electricity industry and plays a major role in reducing breakdowns and avoiding expensive blackouts.

For preventive maintenance tasks to be accomplished, resources and more specifically "technical workforce" must be allocated. Resource allocation refers to the decision-making process that determines the appropriate resource to perform each task or in other words, is described as "the best person for the task" [4]. In many cases, managers manually assign workforce to tasks based on intuition and experience [5]. In addition, workforce productivity is variable and can differ based on multiple factors and more importantly based on the maintenance task to be accomplished. Therefore, predicting the workforce productivity for each task based on relevant factors and considering the workforce productivity when assigning the maintenance tasks is important for better performance.

Furthermore, the geographically dispersed nature of electricity networks necessitates the movement of technical workforce between various locations to perform maintenance tasks. While there are no published records on the time technicians spend in transition and transfer between locations within the electricity industry, it is estimated based on the authors experience to range from 15 to 40% of working time. This can significantly increase costs and reduce operational efficiency in electricity companies. Therefore, upon allocating the tasks to the technical workforce based on predicted productivity, it is important to consider the routing of the allocated teams between the task sites at the same time as the time required to accomplish the tasks.

Although many research works stated that optimal resource allocation and routing will positively affect overall productivity, however, to the best of the authors' knowledge, no previous research clearly considered the predicted labor productivity as the main criterion in the human resources assignment and routing models as it will be shown in the following section.

The aim of this study is to allocate the technical workforce into teams and then assign the formed teams to preventive maintenance tasks and to plan their routes while considering the individual technical workforce productivity predicted using ANN. Therefore, to achieve this aim, the objective of this study is to develop two mathematical optimization models that provide optimal resource allocation and routing while considering the labor productivity produced by the ANN model as an input.

Fig. 1 presents the methodological approach adopted in this study. The first optimization model focuses on forming teams by pairing employees based on their productivity metrics predicted by the ANN model. This ensures that the teams are well-balanced and can operate at their maximum potential. Indeed, in electricity maintenance, tasks are required to be performed by teams of two employees at least for company's safety requirements. In addition, in the considered case study, teams include two employees each. The second optimization model focuses on the assignment of the formed teams to specific job-locations and therefore to optimize their routing. By considering various cost components, including wages, overtime cost, and transportation cost, the model aims to find the most cost-effective strategy for the entire operation. A numerical application based on a real-world data will be conducted to validate the developed models and the integration of the ANN output as an input for the optimization models. Finally, sensitivity analysis will be conducted to examine the impact of traffic, wages, and productivity on the optimal solution.

The structure of this paper is organized as follows: Section II provides insight into resource assignment and routing problem related works, while Section III describes the mathematical formulation of the optimization models. Section IV focuses on the numerical application. Section V illustrates the sensitivity analysis. Finally, Section VI provides concluding remarks.

II. Literature Review

The assignment and routing of workforce is one of the important phases in the decision-making process, especially in the field of maintenance. For instance, a human resources assignment model was developed by [6] in the context of scheduling both planned and unplanned maintenance tasks. The human resources consist of three different specialties: plumber, electrician, and mechanic. The model takes into account the availability of human resources as well as support equipment, with the objective of maximizing the occupation rate of available human resources over the planning horizon. Similarly, the research work by [5] proposed a bi-objective model to assign licensed technicians to maintenance tasks across multiple work shifts. Each maintenance task must be assigned to only one technician, and only if the technician is licensed for that task. The model considers two objectives: the first is to minimize the cost for technicians to complete all the tasks, and the second is to minimize workload imbalances among technicians (ensuring workload fairness). The authors utilized a heuristic algorithm based on tabu search techniques to solve the proposed model.

In addition, a study proposed a dynamic maintenance task assignment model based on expert knowledge (experience), utilizing discrete stress–strength interference [7]. The authors employed the universal generating function method to calculate the value of experience. The objective is to determine which expert should be recommended for the corresponding maintenance task at various periods, based on the experts' values of experience, in order to maximize maintenance efficiency and reliability. A study presented the allocation and routing of technicians with different skills to perform maintenance tasks at offshore wind farms [8]. Similarly, another study proposed a manpower allocation problem in which teams of technicians with diverse skills are assigned a sequential order of tasks [9]. The model takes into account the time windows of tasks, the working hours of the staff, the skill requirements for tasks, and union regulations. A branch-and-price approach was used to solve the problem. Additionally, the same approach was employed to address the daily assignment of multi-skilled technicians into teams, tasked with maintenance along with routing and scheduling, with the objective of minimizing operational costs [10].

Another study examined the problem of maintenance planning for geographically distributed assets [11]. This research proposed a multi-objective model with the aim of minimizing total costs and maximizing the availability of the assets. The problem was addressed using a meta-heuristic solution method. The technician teaming and routing problem with service, cost, and fairness objectives was addressed in study [12]. They developed and solved mathematical optimization models for both an integrated and a sequential solution to the teaming and routing subproblems.

In the context of an electricity company, the study in [13] developed a model to assign maintenance task to a worker and to determine a schedule and route such that the downtimes of power lines and the travel effort of workers are minimized. The authors combine a Large Neighborhood Search meta-heuristic with mathematical programming techniques to solve the model. Similarly, research in [14] proposed a mixed integer programming model for multi-skilled technicians' assignment, along with the routing and scheduling problem. The aim is to form teams of technicians and assign them a sequence of planned and unplanned maintenance tasks to be performed within a given time window, depending on the type and urgency of the task. The objectives include completing higher priority tasks earlier and minimizing total operational costs.

A mixed-integer linear programming model was proposed by [15] to minimize costs associated with maintenance teams, spare parts, travel time, and noncompliance with service levels. The model was tested using various maintenance scenarios from a real maintenance provider in the UAE. The results demonstrated efficient time utilization, minimal routing schedules, and high service levels with a minimum number of teams. Recently, research in [16] explored the routing problem of preventive maintenance teams for elevator repair services, with the objective of minimizing penalties due to service earliness or lateness, assuming uniform travel times between nodes and team capability for any activity. The study developed a variable neighborhood search algorithm to solve the model.

Many of the human resource assignment problems applied in the maintenance field consider technicians' workload in the objective function. To the best of the authors knowledge, no works considered the specific problem of maintenance task assignment in the electricity industry based on labor productivity. Also, there have been no works related to this study that integrated ANN output with human resource assignment and routing problem as input.

III. Mathematical Models

A. Artificial Neural Networks Model

The ANN model has proven to be highly effective in predicting the productivity of the technical workforce, especially within the maintenance field of the electricity industry, as demonstrated in study [17]. In this study, we adopted the same configuration of the ANN model, which consisted of nine neurons in the input layer, one hidden layer with 15 neurons, and one neuron in the output layer. The activation function in the hidden layer is a sigmoid activation function (logsig), while the linear activation function (purelin) is in output layer. The model was trained using the backpropagation algorithm.

The input variables include type of equipment, employee skill level, employee health condition, level of safety measures, temperature, employee experience, level of supervisor competency, level of employee motivation or commitment, and humidity. The model aims to predict the productivity value per employee as an output parameter [17].

B. Team Formation Model

The daily planning of preventative maintenance tasks requires pairing technical workforce members into teams. Effective team formation is crucial for planning preventative maintenance to ensure tasks are executed efficiently and on schedule. This section presents the development of a team formation model, aiming to pair the members of the technical workforce into teams of two members each in a manner that minimizes disparity in productivity among them [12] [18]. The objective is not only to ensure that tasks are completed proficiently but also to prevent potential operational issues and inefficiencies that may arise from significant differences in team productivity.

The sets, parameters, decision variables, and mathematical model are described as follows:

1) Sets

$\mathcal{M}$: Set of employees indexed with $m, n = 1, \dots, M$.

$\mathcal{J}$: Set of jobs indexed with $j = 1, \dots, J$.

2) Parameters

P_{mj}: Productivity of employee m for job j; $m \in \mathcal{M}$; $j \in \mathcal{J}$.

AP_m : Average productivity of employee m; $m \in \mathcal{M}$. The average productivity is calculated using the following Equation:

$$AP_m = \frac{\sum_{j \in \mathcal{J}} P_{mj}}{J} \tag{1}$$

where:

$\sum_{j \in \mathcal{J}} P_{mj}$: is the summation of productivity values for employee m over all jobs in $\mathcal{J}$.

J: Total number of jobs.

3) Decision variables

X_{mn}: Binary variable where it is 1 if employees m and n are paired together in the same team and 0 otherwise; $m, n \in \mathcal{M}$.

dP_{mn}: A variable that represents the absolute difference in average productivity between employees m and n; $m, n \in \mathcal{M}$.

4) Mathematical model

$$\text{Minimize } \omega = \sum_{m \in \mathcal{M}} \sum_{n \in \mathcal{M}} dP_{mn} X_{mn} \tag{2}$$

Subject to:

$$\sum_{\substack{m \in \mathcal{M}, \\ m \neq n}} X_{mn} + \sum_{\substack{m \in \mathcal{M}, \\ m \neq n}} X_{nm} = 2 \qquad \forall n \in \mathcal{M} \tag{3}$$

$$X_{mn} = X_{nm} \qquad \forall m, n \in \mathcal{M} \tag{4}$$

$$dP_{mn} \geq (\ AP_m - \ AP_n\ ) X_{mn} \qquad \forall m, n \in \mathcal{M} \tag{5}$$

$$dP_{mn} \geq (\ AP_n - \ AP_m\ ) X_{mn} \qquad \forall m, n \in \mathcal{M} \tag{6}$$

$$X_{mn} \in \{0, 1\} \qquad \forall m, n \in \mathcal{M} \tag{7}$$

The objective function in Eq. (2) aims to minimize the sum of the absolute differences in average productivity between the members of all the formed teams. Constraint in Eq. (3) ensures that each employee is paired up with exactly one other employee. Constraint in Eq. (4) ensures the pairing is symmetrical; when an employee m is paired with an employee$n$, then n is paired with m. Constraint in Eq. (5) captures the non-negative difference in average productivity when employee m has a greater average productivity than employee n, and constraint in Eq. (6) captures the non-negative difference in average productivity when employee n has a greater average productivity than employee m. Together, Constraints in Eq. (5) and Eq. (6) ensure that dP_{mn} represents the absolute difference in average productivity between the two employees m and n. Constraint in Eq. (7) specifies ensures that the decision variables X_{mn} are binary.

C. Workforce Assignment and Routing Model

In the previous section, the team formation model was introduced. Now, the next stage is to assign teams to tasks and plan their routes in a way that minimizes the total cost [12]. Each team has a predicted productivity percentage per task, which affects the standard time required for the task. For example, if the team's predicted productivity is 80 percent, and the standard time for the task is 120 minutes, then the actual time will be 150 minutes, which is obtained by dividing the standard time by the productivity. Not all teams need to be assigned, but if a team is assigned, they are required to start their work from a designated depot and must return to it before the end of the regular working time. If a team returns after this designated time, overtime costs will be incurred.

The sets, parameters, decision variables, and mathematical model are detailed as follows:

1) Sets

$\mathcal{T}$: Set of teams indexed with $t = 1, \ldots, T$.

$\mathcal{J}$: Set of job-locations indexed with $i, j = 1, \ldots, J$.

$\mathcal{J}_0$: Set of job-locations to which the depot (where all teams start and end their routes) is added indexed with $i, j = 0, \ldots, J$.

It is worth noting each job-location is a location (i.e. a node) in the network at which only one job is to be performed. This is usual in electricity preventive maintenance where each location has a job performed by one team. Moreover, two different job-locations may correspond to the same type of maintenance tasks located in two different locations.

2) Parameters

dH_j : Standard time (minutes) required to complete the maintenance work of job-location j regardless of productivity of the team that will be assigned; $j \in \mathcal{J}$. It corresponds to the earned hours.

P_{tj} : Productivity of team t in performing job j; $t \in \mathcal{T}$; $j \in \mathcal{J}$. This value is derived from the ANN model mentioned in Section III.A [17]. It corresponds to the minimum productivity value of all the team members for job j.

F_t^v : Variable cost per hour of team t; $t \in \mathcal{T}$

F_{ij}^r : Transportation cost per team from job-location i to job-location j; $i, j \in \mathcal{J}_0$.

F_t^o : Overtime cost per hour for team t; $t \in \mathcal{T}$

T_{ij}^r : Time (Minutes) required to move from job-location i to job-location j; $i, j \in \mathcal{J}_0$.

$\mathcal{H}$: Number of regular working hours per day.

α : Maximum number of overtime hours per day for each team.

$\mathcal{S}$: Very large positive number.

3) Decision variables

Z_{tij}: Binary variable that is equal to 1 if team t performs the work in job-location (i.e., job) i directly before job j and 0 otherwise; $t \in \mathcal{T}$; $i, j \in \mathcal{J}$.

WT_t: Total number of regular working hours spent by team t per day; $t \in \mathcal{T}$.

O_t: Total number of overtime hours spent by team t per day; $t \in \mathcal{T}$.

f_j: Completion time of job-location j; $j \in \mathcal{J}$.

4) Mathematical model

Minimize $\mathcal{X}$

$$= \sum_{t \in \mathcal{T}} F_t^v \, WT_t + \sum_{t \in \mathcal{T}} F_t^o \, O_t + \sum_{t \in \mathcal{T}} \sum_{i \in \mathcal{J}_0} \sum_{j \in \mathcal{J}_0} F_{ij}^r \, \mathrm{Z}_{tij} \qquad (8)$$

Subject to:

$$\sum_{j \in \mathcal{J}} Z_{t0j} \leq 1 \qquad \forall t \in \mathcal{T} \qquad (9)$$

$$\sum_{i \in \mathcal{J}} Z_{ti0} \leq 1 \qquad \forall t \in T \qquad (10)$$

$$\sum_{t \in \mathcal{T}} \sum_{i \in \mathcal{J}_0} Z_{tij} = 1 \qquad \forall j \in \mathcal{J} \qquad (11)$$

$$\sum_{i \in \mathcal{J}_0} Z_{tij} = \sum_{i \in \mathcal{J}_0} Z_{tji} \qquad \forall t \in \mathcal{T}, j \in \mathcal{J}_0 \qquad (12)$$

$$\sum_{i \in \mathcal{J}_0} \sum_{j \in \mathcal{J}_0} (T_{ij}^r + \frac{dH_j}{P_{tj}}) \times Z_{tij} = WT_t + O_t \qquad \forall t \in \mathcal{T} \qquad (13)$$

$$f_i + T_{ij}^r + \frac{dH_j}{P_{tj}} \leq f_j + \mathcal{S} \times \left(1 - Z_{tij}\right) \qquad \forall t \in \mathcal{T}, \; i \in \mathcal{J}_0, j \in \mathcal{J} \qquad (14)$$

$$f_j \geq 0 \qquad \forall j \in \mathcal{J}_0 \qquad (15)$$

$$WT_t \leq \mathcal{H} \qquad \forall t \in \mathcal{T} \qquad (16)$$

$$O_t \leq \alpha \qquad \forall t \in \mathcal{T} \qquad (17)$$

$$Z_{tij} \in \{0, 1\} \qquad \forall t \in \mathcal{T} \qquad (18)$$

The objective function in Eq. (8) minimizes the total cost in order to find the most cost-effective strategy for teams' assignment and routing, taking into consideration three pivotal cost components. The first component is associated with the cost of regular working hours of each team, capturing the standard wage or payment the team t would receive during regular working hours. The second component is associated with the cost of overtime hours of each team t. This factor represents the additional expense that might be incurred when teams work beyond standard working hours. The last component is the transportation cost for every move from location i to location j. In other words, the objective function ensures that tasks are allocated to teams and routed in the most economically efficient manner, balancing work hours, overtime, and travel expenses.

Constraints in Eq. (9) and Eq. (10) ensure that each team should start and end their route at the depot at most once. Constraint in Eq. (11) states that each job-location is visited once by one of the teams. Constraint in Eq. (12) guarantees that each team visiting a node j also leaves this node. Constraint in Eq. (13) specifies the value of the working hours and overtime hours of each team, which is composed of the traveled times and job time considering team productivity. Constraint in Eq. (14) defines the time at which job j is completed by team t. It requires that the completion time of the proceeding job i plus the travel time from i to j and the processing time of job j is a lower bound for the completion time of job j. In this constraint $\mathcal{S}$ denotes a sufficiently large positive value. Constraint in Eq. (15) ensures non-negative completion time. Constraint in Eq. (16) ensures that a team's regular working hours in a day do not exceed the maximum limit, while Constraint in Eq. (17) ensures that the overtime hours a team can work in a day should not exceed the maximum limit set by the organization's policy. Constraint in Eq. (18) specifies the domain of the decision variable.

IV. Numerical Study

In this section, the team formation and team assignment and routing models will be applied to the specific real-world context of preventive maintenance planning within a large electricity company that is responsible for generating, transmitting, and distributing power. Subsequent subsections will illustrate the details of the data collected. The numerical application serves as a demonstration of how these models can be effectively utilized to optimize preventive maintenance planning in the electricity industry and what kind of results can be expected.

A. Team Formation

1) Inputs data: In this stage, the focus is on forming teams based on the predicted productivity of each employee for each job. Initially, details about the maintenance jobs required to be performed are obtained. These details represent the maintenance jobs for a day within one zone. To ensure a robust validation of the model, the selected day had the highest number of jobs in that zone during a year. Subsequently, the ANN model developed in [17] and discussed above is employed to predict productivity of each employee for each maintenance job. The ANN model was executed after gathering and normalizing the necessary inputs data. Table I presents the predicted productivity values (P_{mj}).

2) Results: The developed mathematical model for team formation has been solved using IBM ILOG CPLEX optimization software, with a computation time of 1.05 seconds, using Intel Core i7 at 3.70 GHz computer with 16 GB RAM. the optimal team formation has been determined with an optimal objective value of $\omega^* = 0.277$. Table II displays the team formation results (X_{mn}).

B. Workforce Assignment and Routing

1) Inputs data: The data acquired regarding the maintenance jobs to be performed are utilized, along with additional information and details. Using the team formation results, team productivity values have been determined based on the lowest predicted productivity among its members. Table III displays the predicted productivity values of each team for each job (P_{tj}). The daily duration of regular working time for each team is set at eight hours per day ($\mathcal{H}$), while the maximum allowable overtime per team is limited to two hours per day (α). Team regular cost (F_t^v) and team overtime cost (F_t^o) in AED per hour are illustrated in Table IV. Moreover, Table V presents the standard time required to complete the maintenance jobs in minutes (dH_j). This standard time was established by the maintenance department of the selected company, assuming that all teams will perform at the same productivity level. Another critical dataset required for team routing is the transportation time matrix and transportation cost matrix. These matrices provide a systematic representation of time and cost associated with moving between different job-locations. Table VI displays (T_{ij}^r) the transportation times between job-locations that teams must traverse to perform maintenance tasks, while Table VII presents (F_{ij}^r) the transportation costs between these locations. The transportation cost is derived from the actual distances between job-locations obtained from [19]. For each kilometer of distance, the cost is calculated by considering both the average fuel expense and other vehicle-related expenses. It is worth noting that transportation time and cost between locations are not symmetric. For example, moving from job-location (2) to job-location (3) takes 19 minutes, but moving from job-location (3) to job-location (2) takes 29 minutes. Finally, the very large positive number ($\mathcal{S}$) has been set to 10,000.

TABLE VIII. TEAM ASSIGNMENT AND ROUTING RESULTS

Team Number	**The Sequence of Performing Job-Location**	**Working Time [Minutes]**	**Overtime [Minutes]**
Team 2	Depot – 6 – 9 – 8 – 5 – Depot	480	100.99
Team 4	Depot – 2 – 3 – 4 – 7 – Depot	480	43.37
Team 5	Depot – 10 – 1 – 11 – Depot	465.74	0

2) Results: Using the developed mathematical model, the optimal assignment and routing have been obtained with a total optimal cost of 9,164.56 AED. Table VIII shows the sequence of job-locations to be visited and performed, total working time, and total overtime by each of the assigned teams. Note that five teams, specifically, teams number 1, 3, 6, 7, and 8 will not be assigned to any preventive maintenance task and will be supporting the emergency function. The model has been solved using IBM ILOG CPLEX optimization software, with a computation time of 14608.77 seconds, using Intel Core i7 at 3.70 GHz computer with 16 GB RAM.

V. Sensitivity Analysis

A. *Impact of the Trasportation Time (Traffic) on the Optimal Solution*

To study the impact of the transportation time (traffic) on the optimal solution, we increased the transportation time to consider different traffic scenarios, while maintaining the other parameters equal to their values considered in the original data set. The value of T_{ij}^{r} has been changed in each trial for selected routes based on the actual traffic condition corresponding to the expected time at which the team will travel from job-location i to j. The model has been solved for every change in the travelling time and the optimal solution has been obtained and noted. Fig. 2 identifies the effect of changing the transportation time (traffic) on the objective value (total cost). The results of each trial are detailed in Table IX. The sensitivity analysis reveals that the model is notably influenced by variations in transportation time, impacting not only the cost but also the optimal routing sequences. The working and overtime hours also showcased sensitivity to changes in transportation time, albeit with varied impact across different teams and trials.

TABLE IX. Detailed Results of the Effect of Traffic Time on Optimal Solution

Trial	Traffic Time [Minutes]	Total Cost [AED]	CPU Time [Seconds]	Team Number	Optimal Sequence of Job-Locations	Working Time [Minutes]	Overtime [Minutes]
1	18	9195.14	18360.31	Team 2	Depot – 5 – 8 – 9 – 6 – Depot	480	101.99
				Team 4	Depot – 3 – 4 – 7 – 2 – Depot	480	47.37
				Team 5	Depot – 10 – 1 – 11 – Depot	465.74	0
2	38	9216.30	26215.47	Team 2	Depot – 5 – 8 – 9 – 6 – Depot	480	101.99
				Team 4	Depot – 3 – 4 – 7 – 2 – Depot	480	47.37
				Team 5	Depot – 11 – 10 – 1 – Depot	467.74	0
3	90	9222.17	15859.78	Team 2	Depot – 8 – 5 – 9 – 6 – Depot	480	101.99
				Team 4	Depot – 4 – 7 – 3 – 11 – Depot	480	78.22

				Team 5	Depot – 10 – 6 – 9 – Depot	480	22.39

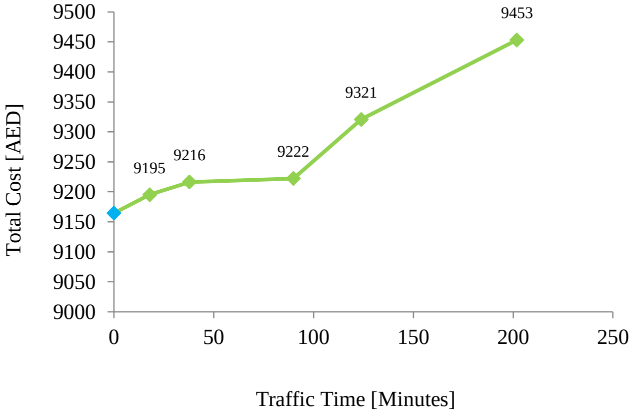

Fig. 2. The effect of traffic time on total cost.

B. *Managerial Insights*

The sensitivity analysis conducted underscores the substantial impact that transportation time can have on total costs. Notably, the correlation between increased transportation time and higher costs necessitates a proactive approach to traffic management by decision-makers. Managers should not only be vigilant about traffic conditions but also develop comprehensive strategies to mitigate their impact, as follows:

1) Avoiding peak traffic hours in the morning and afternoon. For example, teams could start at 6:00 AM instead of 7:30 AM.

2) Utilizing real-time traffic applications such as Google Maps can assist in identifying the most efficient paths and anticipating traffic bottlenecks, allowing for preemptive route adjustments.

3) Implementing flexible scheduling systems that adapt in real-time to traffic conditions can minimize unproductive hours spent in transit.

4) Considering the introduction of a second depot; the location of this depot should be informed by a thorough analysis of historical data on traffic patterns, job locations, and team movements to determine the most effective placement.

VI. Conclusion

In this study, team formation and team assignment and routing models that consider teams productivity based on ANN have been presented. The team formation model aimed to minimize the disparity in productivity among the members of each team. This is crucial in the context of maintenance as disparity can lead to inefficiencies, missed schedules, and potential operational disruptions. The objective of the team assignment and routing model was to minimize costs associated with regular working time, overtime, and transportation. Ensuring an economical approach to task assignment and routing is fundamental to operational efficiency, cost savings, and meeting maintenance schedules.

The real-world numerical application fortifies the practical applicability of the proposed models. In the context of an electricity company, the models showcased how one can optimize preventive maintenance planning, leading to improved resource utilization and cost-effectiveness. The rapid computation time, even for real-life sized scenarios, also underscores the feasibility of incorporating such models in everyday operational decisions. Furthermore, sensitivity analysis has been conducted to examine the effects of transportation time (traffic) on the optimal solution. It was noticed that increases in transportation time significantly raised total costs. The analysis revealed that longer travel times, often due to traffic congestion, directly correlate with increased expenses, highlighting the need for efficient route planning and traffic management strategies.

Future research may consider implementing many possible changes to the developed model. For Instance, includes outages time window. Additionally, future research should also aim to address the limitations of this study, such as the potential to use heuristics approaches in order to find the optimal solution for all the zones instead of only one zone at the same time.

Acknowledgment

The authors express their sincere gratitude to the experts who provided invaluable opinions and contributions to this study.

***Abstract*—To evaluate the integrity of a building, many experts and engineers have evaluated the damage classification of a building based on superficial visual information through field surveys. On-site surveys are hazardous and require several years of experience and expertise. In this study, a system for detecting the presence or absence of cracks and calculating their lengths was developed using image processing technology. The accuracy of the system was examined using crack image data obtained from shear force experiments. For crack detection, a crack detection method was developed using canny edge, threshold, and HSV color detection. The detection of the presence of cracks was proposed to be coupled with image segmentation to improve detection accuracy. A method for calculating the crack length using image processing was also developed. In this study, we proposed a method to calculate cracks as straight lengths, and obtained results with 98.1% accuracy. However, for curved cracks, it was necessary to rotate or segment the image.**

Keywords—Image processing; crack detection; length calculation; color detection; canny; threshold; OpenCV

I. Introduction

Once a building is constructed, it will last several decades before the next renovation or reconstruction [1]. Therefore, the "lock-in effect" is very large, which makes it difficult to address. Additionally, natural disasters and deterioration have reduced the functionality of many buildings [2]. To evaluate the integrity of a building, many experts and engineers have evaluated the damage classification of a building based on superficial visual information through field surveys [3, 4]. However, assessing damage classification from the superficial visual information of reinforced concrete (RC) requires many years of experience and expertise. Other field investigations involving hazards are difficult to conduct [5, 6]. In Japan, the Ministry of Land, Infrastructure, and Transport created an "Inspection Support Technology Performance Catalog" to provide inspection support technologies [7, 8]. However, the support is inadequate in terms of ensuring hazards.

In recent years, image processing technology has been used to determine building damage, which eliminates the need to conduct dangerous on-site surveys. Image processing techniques are evolving daily [9,10,11], and in the field of architecture, many studies have been conducted on crack detection using image classification techniques, such as tunnel crack detection [12,13], bridge and road crack detection [14,15,16], and fatigue degradation detection of material deterioration [17,18]. Many of these studies used existing trained models to detect the presence or absence of cracks [19, 20]. Crack detection has been studied for several years, and various detection methods have been proposed. However, the various local environmental factors make it difficult to respond efficiently. In addition, there is insufficient specific information regarding the expertise of engineers and experts. Therefore, methods for detecting cracks and evaluating damage classification have not been sufficiently investigated.

In this study, an experimental study was conducted on the shear strength of a reinforced concrete column with a wing wall on one side. [21]. The crack image data obtained in the experimental process were subjected to Canny edge detection [22], threshold detection [23], and HSV color detection [24] to investigate crack detection and crack length calculation methods. The accuracy of the model was verified by comparing it with visual crack detection. Finally, we aim to develop a system that can predict the future direction in which cracks will propagate and reach a failure mechanism. In this paper, we developed a method for detecting the presence or absence of cracks and a system for evaluating the degree of damage using image processing technology based on image data. In particular, an efficient crack-detection method using image segmentation is considered.

II. Literature Review

Research on crack detection using image processing techniques can be divided into civil engineering and architecture [25]. Civil engineering is primarily concerned with crack detection in tunnels, bridges, and roads. On the other hand, in the architectural, research has been conducted on crack detection caused by earthquake damage and deterioration.

First, we discuss previous research in the architectural field. Lu et al. [5] developed a method for determining the presence or absence of damage by Canny edge detection using image data of building exteriors. Wang et al. [26], Fan et al. [27] improved an existing crack detection model and conducted a case study on a data set to improve the model's performance. The shape of the cracks was confirmed by counting the pick cells in the crack image. Zhang et al. [28] proposed a crack detection model by adding an ensemble algorithm to existing crack detection models. Cracks could be detected in any type of image. Yamaguchi et al. [29, 30] proposed a crack detection method for concrete surfaces using image processing techniques. A method for efficiently detecting cracked areas in images using mask processing methods was identified.

Next, we discuss previous studies in the field of civil engineering will be presented. Liu et al. [31] used existing trained convolutional neural networks (CNN) models to classify cracks in buildings and roads. Cracks were detected differently depending on the number of pixels in the input image. Li et al. [32] attempted to use FoSA's learning genetic algorithms to detect cracks in roads. A case study was conducted using five image data sets. It was found to be difficult to detect depending on the brightness of the images. Wang et al. [33] used threshold detection in image processing technology to detect the degree of road damage at different brightness levels in the image. Kulambayev et al. [34] developed a method to detect the degree of road damage in real time using a deep learning model. Maeda et al [35] and Abbas et al. [36] installed cameras in cars and used CNN models to detect road cracks and abnormal conditions. Yadav et al [37] used three crack detection algorithms to detect crack presence/absence classification and crack patterns. 2-3% improved detection performance compared to existing crack detection systems.

Crack detection research is active in both architectural and civil engineering. However, most previous studies have focused on model improvement with new images and crack detection using trained models. Therefore, pretreatment methods for crack detection and crack length calculations have not yet been adequately studied. In this study, we developed a preprocessing method for crack images using image processing technology and clarified the method for calculating the crack length.

III. Methodology

In this study, image data of the cracks were collected through shear strength experiments. Subsequently, a crack presence/absence detection method and crack damage evaluation was conducted (see Fig. 1). Three full-scale 1/3-scale specimens were fabricated for shear strength experiments. This experiment was conducted to investigate the ultimate shear strength and failure mechanism of the columns with single-sided walls.

Crack image data were recorded on video with a 4 K camera installed in front of the experimental subject, as shown in Fig. 1. The video recording was performed continuously from the beginning to the end of the experiment. The video recording was set to 30 FPS at 3840 × 2160 pixels high quality and saved in *.MP4 files. The same settings were used to capture the videos of the three experimental subjects. The captured video data were converted into image data for crack detection using the following procedure (see Fig. 2). In addition, it was difficult to obtain the expected results in this study because each region in the image had a different brightness depending on the shooting situation. Therefore, we considered a method in which the input image was divided into 7 × 5 images, image processing was performed in more detail, and the images were merged into the original image.

1) The cracked video was edited only for the necessary parts. 3 hours (size:30.2 GB) video edited to 27 minutes (size:1.96 GB).

2) The edited video was saved as a still image by using OpenCV.

3) The still image was selected and cut out only where cracks occurred.

4) The cropped images were divided into 7 × 5 images.

5) Segmented images were used to detect the presence of cracks using image-processing technology.

6) The processed images were then combined and returned to the original image.

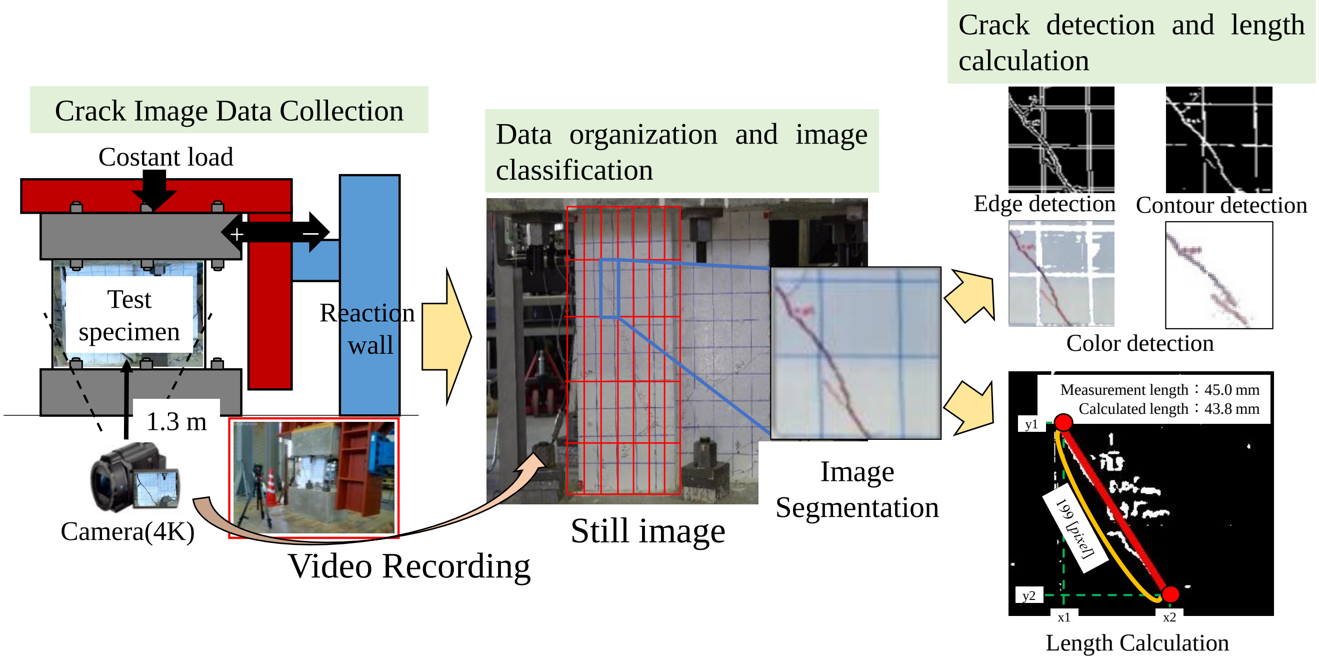

Fig. 1. An overview of this study.

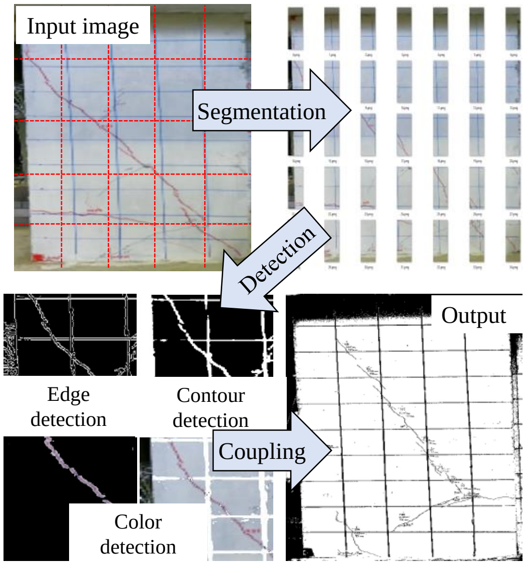

Fig. 2. Preprocessing for crack detection.

For crack detection, data organization and image processing were performed according to the above procedure.

IV. Experiment and Discussion

Crack detection was performed by organizing videos obtained from shear strength experiments and using image processing techniques to detect the presence of cracks. In this study, three image processing techniques were used to detect the presence of cracks. The three image processing techniques are Canny edge detection, Threshold detection, and HSV color detection. Each method for detecting the presence of cracks is described using the input images in Fig. 3. We also describe a method for calculating the length of cracks using image processing techniques.

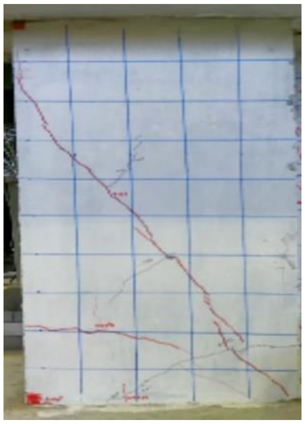

Fig. 3. Input image for crack detection.

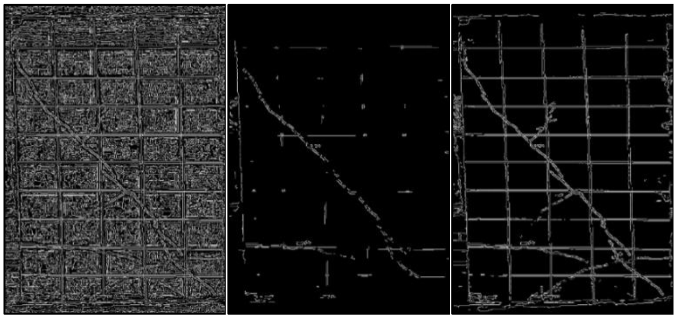
A. Canny Edge Detection

Canny edge detection is a method for detecting vertical and horizontal edges that indicate points where the pixel values change abruptly in one direction [38]. The accuracy of edge detection depends on the value of the parameter. Therefore, it was necessary to adjust the values of the appropriate parameters. In this study, we employed OpenCV Track Bar to determine the appropriate parameter values. The Track Bar also allows for real-time fine-tuning of parameter values. Fig. 4 shows the results of crack presence detection by adjusting the parameter values. The smaller the value of the parameter, the more noise is generated and the more difficult it is to detect cracks (see Fig. 4(a)). However, the larger the value of the parameter, the less noise there is, but some cracks are removed along with the noise (see Fig. 4(b)). The results with appropriate parameter values indicated that the cracks were easily detected (see Fig. 4(c)).

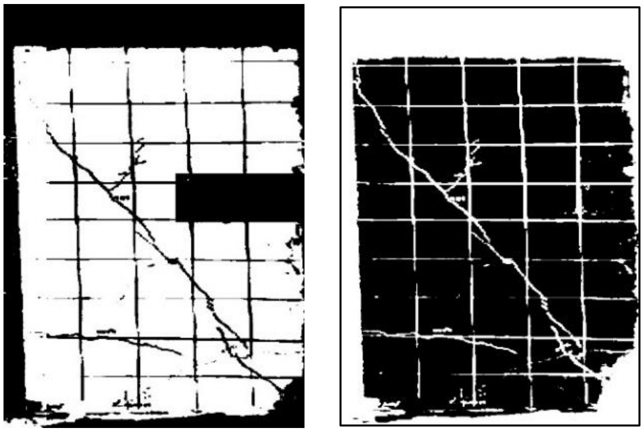


(a) Minimal parameters (b) Maximal parameters (c) Optimal parameters

Fig. 4. Edge detection using the Canny method

B. Threshold Detection

Threshold detection converts an image pixel value to white if it is greater than a parameter value and to black otherwise, and binarizes the image [39]. In this study, we used the THRESH_BINARY model, which adjusts parameter values directly, as in Canny edge detection, and the OTSU model, which adjusts them automatically [40, 41]. Both models were compared to examine their accuracy in detecting the presence of cracks. The THRESH_BINARY model uses a Track Bar to adjust the parameter values. Fig. 5 shows the results of the comparison of the models. Both models were able to detect cracks. However, the OTUS model automatically adjusts the values of the parameters; therefore, detection is not possible places. The OTUS model has a significant effect on the resolution of the input image.

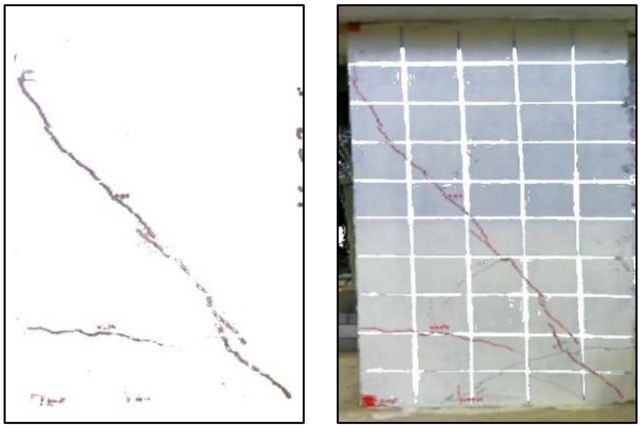


(a) OTUS (b) THRESH_BINARY

Fig. 5. Contour detection using the threshold method.

C. HSV Color Detection

In the shear force experiments conducted in this study, cracks were visually identified and marked during the experiment. Color markings were marked black for positive forces and red for negative forces. The authors considered a method to detect cracks by directly detecting color. In this study, we attempted to detect red and blue colors using the HSV color space model. Fig. 6 shows the results of the red and blue detection. In red detection, the method detects the areas marked in red and changes all other areas to white. In blue detection, the method detects blue and changes the color of the area to white. Both detection methods were able to detect cracks using color detection. However, some areas appear to have failed to be detected in certain regions. Color detection was found to be less accurate, depending on the resolution of the input image.



(a) Color detection (red) (b) Color detection (blue)

Fig. 6. Color detection results by HSV model.

D. Crack Length Detection

Crack lengths were calculated using OpenCV and Numpy. In this study, the crack lengths were calculated linearly. The crack length is determined by Eq. (1) to Eq. (4). Eq. (1) determines the number of pixels on the diagonal of an input image. In Eq. (2), the number of pixels is used to determine the resolution. Eq. (3) converts pixels to centimeters and calculates the length of one pixel. In Eq. (4), the length is calculated by counting the total number of pixels in the cracks to be calculated. The crack length was calculated by determining the values of the parameters based on the input image size. The value of parameter is the established reference point for the input image at the shooting distance (see Fig. 7).

$$dots \ = \sqrt{(w^2 \times l^2)} \tag{1}$$

$$dpi \ = dots \div inch \tag{2}$$

$$px \ = (25.4\, mm \div dpi) \times cv \tag{3}$$

$$L_t \ = px_t \times px \tag{4}$$

where $dots$ is the number of diagonal pixels of the input image [dots], w is the number of horizontal pixels of the input image [dots], l is the number of vertical pixels of the input image [dots], dpi is the resolution of the input image [dots/inch], $inch$ is the length of the diagonal of the input image [inch], px is the length per pixel of the input image [mm/pixel] (1 inch = 25.4 mm), cv is the correction factor for the input image size [mm], L_t is the total length between stickers [mm], and px_t is the total number of colored pixels [pixels].

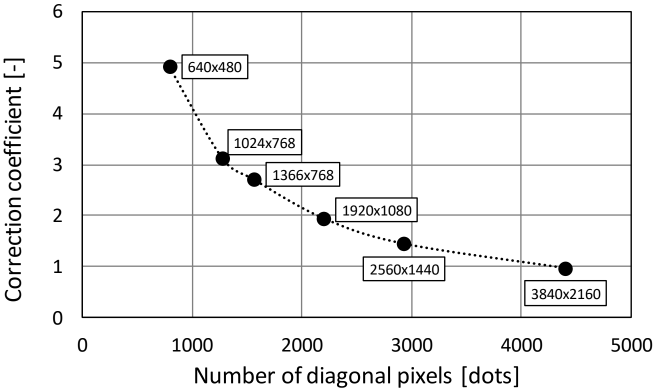


Fig. 7. Correction factor in image size.

In particular, Eq. (3) requires an accurate length per pixel. This length per pixel has a significant impact on the calculation accuracy. The accuracy of the length per pixel was determined using the blue border of the input image as the reference line. The blue line was 50 mm in length and width, which confirms the per-pixel validity. The following procedure was used to calculate the crack length (see Fig. 8).

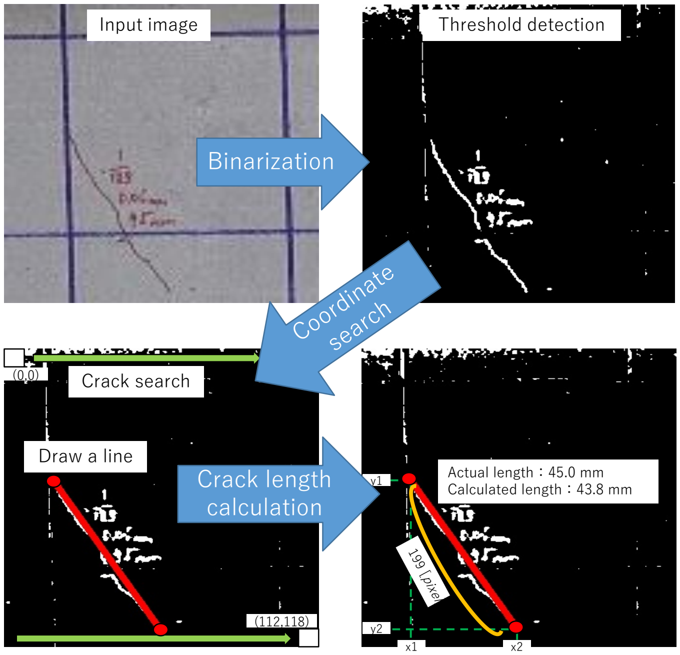

Fig. 8. Crack length calculation method.

1) The input image is converted into black and white binarizations.

2) Images converted to black and white were classified as the background and cracks, respectively.

3) The size of the input image was determined.

4) *Based* on its size, cracks are searched from the first to the last coordinates.

5) *Select* a location to calculate the length of the crack and draw a straight red line on the image.

6) *The* red pixels are counted linearly.

7) *The* crack length was calculated using Eq. (4).

E. *Crack Length Calculation*

Using the crack length calculation method described above, the lengths were calculated for the six cracks, as shown in Fig. 9. Table I lists the calculated lengths for each crack image. Images 1-6 were intended for cracks that were as continuous as possible. Cracks were examined through visual inspection during the shear force tests, and crack lengths were measured linearly using a tape measure. The measured length was compared to the calculated length to determine the accuracy of the calculation.

The results of the crack-length comparison yielded a 98.1% correct response rate. The closer the percentage of correct answers is to 100%, the more likely it is that the length is similar to the measured value. Crack lengths were calculated for crack images 3, 4, and 5, and were somewhat similar to the measured lengths for which crack lengths were compared. However, for images 1 and 2, the errors were 2.7% and 4.6%, respectively, which are much larger than the measurement results. It is thought that the point of the crack length measured at the time of measurement and the point of calculation were slightly different. It is also believed that the calculation error is affected by the accuracy of the binarization image processing. Other images of each crack had different image sizes depending on the area from which the crack was extracted. Therefore, the lengths corresponding to the pixels were different, which may have caused an error in the length calculation. In this study, the crack length was obtained linearly. If curved cracks are targeted, it is necessary to change the angle of the input image or to split the image.

TABLE I. COMPARISON OF ACTUAL CRACK LENGTHS AND CALCULATED RESULTS

No	Input image	Crack detection image	Image Size [pixel]	Measurements value [mm]	Calculated Value [mm]	Error rate [%]
1			112×118	45.0	43.8	2.7
2			112×118	28.0	26.7	4.6
3			107×107	15.0	15.1	0.7
4			107×108	40.0	40.2	0.5
5			134×111	56.0	56.6	1.1
6			113×105	30.0	29.5	1.7

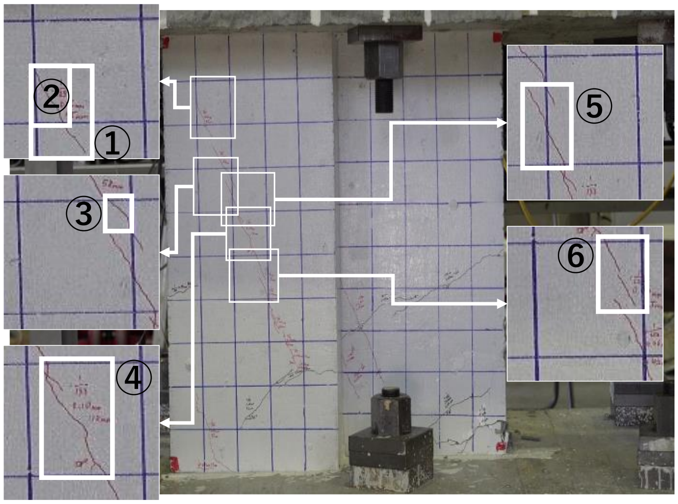

Fig. 9. Results for length of cracks.

V. Conclusion

In this study, crack image data were collected using a 4K camera during shear force experiments. Image data were used to develop a method for detecting the presence of cracks and calculating their lengths. Cracks were detected using edge, contour, and color detection. A method for calculating the crack length using image processing was also developed. The results obtained were as follows:

1) The visibility of the edge detection results differed depending on the adjustment of parameters.

2) The OpenCV Track Bar allows for easy parameter adjustment and proper crack detection.

3) The results obtained for contour detection varied significantly depending on the brightness of the image. As with edge detection, the accuracy of detection depends on the parameter values.

4) Color detection requires a different method for each color. In this paper, we propose a method that combines image segmentation.

5) The crack length calculation method is significantly affected by the length per pixel of the input image. Therefore, a reference line must be established and verified.

6) In this study, we proposed a method to calculate cracks as straight lengths, and obtained results with 98.1% accuracy. However, for curved cracks, it was necessary to rotate or segment the image.

7) For crack photography, adjusting the brightness using light according to the local environment is linked to detection accuracy.

8) A comprehensive study of crack detection methods tailored to these conditions is required to address a variety of environments.

Future Research Works

In the future, the machine learning of crack patterns will be used to build a model that can predict crack growth by classifying whether pattern deviations are within an acceptable range.

Urban Image Segmentation in Media Integration Era Based on Improved Sparse Matrix Generation of Digital Image Processing

Dan Zheng*, Yan Xie
School of Humanities and Communication, University of Sanya,
Sanya, Hainan 572000, China

***Abstract*—Media integration integrates the resources of various media platforms, including audience, technical and human resources. In the era of media integration, media in various channels, at different levels and in different fields provide various choices for image communication and brand building of cities. The technology of image processing by computer has gradually affected all aspects of people's life and work, bringing more and more convenience to people. In this paper, the application of digital image processing technology in city image communication in the age of media integration is studied. A new sparse matrix creation method is proposed, and the created sparse matrix is used as the similarity matrix to segment the spectral clustering image, so that the edge contour weakened in gradient calculation can be corrected and strengthened again. The research shows that the improved algorithm is superior to the traditional algorithm, and compared with the fuzzy entropy algorithm based on exhaustive search, the gray contrast between regions and Bezdek partition coefficient are improved by 9.301% and 4.127%. In terms of speed, the algorithm in this paper has absolute advantages, so our research is also affirmed, which fully shows that it should have high application value.**

Keywords—Media integration; digital image processing; city image; image segmentation; improved sparse matrix generation

I. Introduction

Media combines the advantages of traditional media and new media, emphasizes the comprehensive application of text, pictures and image information, and increasingly highlights the value of images. By using computer technology, some textual descriptions are made into vivid images. Under the environment of media integration, the image of a city represents the characteristics of a city, and it is also the key factor that distinguishes it from other cities in the information explosion era. A good city image can not only show the achievements of urban construction, but also accelerate the process of urban development [1]. The technology of image processing by computer has gradually affected all aspects of people's life and work, bringing more and more convenience to people. In modern society, people's knowledge of unfamiliar cities is mainly obtained from the media, and the farther away the cognitive subject is from the city, the more people rely on the image spread by the media to get their knowledge, so the spread of city image cannot be separated from the media. On the platform of media, the new and old media penetrate, collide, advance and merge with each other, which constitute a prominent landscape of today's media ecology. Therefore, in the era of media integration, it is necessary to strengthen the extensive application of digital image technology, improve the production quality of publicity content, promote the steady improvement of information dissemination efficiency, and drive readers to form new information acquisition and reading habits.

For the analysis and research of city image, Mbaye and others think that the image and style of a city are the same. What the city style shows are a city's elegant demeanor, consciousness and landscape. It shows the cultural connotation and details of the city, the spiritual outlook of its citizens, and the development of its culture, economy, politics, science and technology [2]. M Ceren mainly divides the image of a city from two dimensions: subject and object. It is the main body of the city itself, that is, the overall style and features of the city, as well as its internal cultural connotation and quality, and the object is an abstract overall or intuitive evaluation of the city [3]. Kourtit et al. put forward the theory of urban image, first defined the concept of urban image, put forward five elements of urban image formation, and established a unique empirical research method of urban image [4]. Huijsmans et al., based on the theory of city image design and city management, discussed the potential and feasibility of city image visual management from the perspective of spiritual representation and management visualization [5]. Digital image processing technology mainly includes image processing, digital image coding, digital image inpainting, image segmentation and so on, which is widely used in different industries. In the field of media, digital image processing technology is mainly used in network transmission, advertising, film special effects production, post-processing and so on. According to recent published articles at home and abroad, the present situation and progress of digital image compression coding are carefully combed. Wang et al. summarized the basic theories and methods of digital image compression, and certified and studied several classical compression coding methods [6]. Da-Hai et al. adopted DCT (Discrete Cosine Transform), and its high bit rate (bit rate > 0.25 bit/pixel) can get a good compression ratio for continuous tone still gray or color images [7]. Ahmed et al. have made in-depth research on image segmentation methods based on graph theory, comprehensively utilizing various feature information, adopting various segmentation ideas and integrating various segmentation technologies, in order to reduce the computational complexity and improve the segmentation quality [8]. Wang et al. segmented the image by using the similarity of the internal feature information of the image area. However, the disadvantage of this method is that it is easy to generate false segmentation areas when segmenting complex and changeable natural images, thus resulting in over-segmentation [9]. Huang et al. proposed an image adaptive threshold selection algorithm based on wavelet analysis, which enables the feature points of image histogram to be expressed from coarse to fine by the feature points of wavelet transform, and enables the threshold to be adaptively selected [10]. Yan et al. proposed that the density and maximum distance product method should be used in the selection mechanism of the initial clustering center. User-interactive color migration is also proposed. This migration method selects sample blocks according to personal experience and objective basis, and specifies the corresponding relationship among the sample blocks, so as to realize color migration between images [11]. Oho et al. proposed an inpainting algorithm based on the interpolation of image gray level and gradient direction, which can simultaneously inpaint the topological structure and texture information in the image [12].

In the field of urban image segmentation, many researchers have proposed various methods based on sparse representation. However, these methods still suffer from high computational complexity and insufficient generalization ability when processing large-scale urban images. In addition, these methods often overlook features such as texture, color, and shape in urban images, resulting in poor segmentation performance. Therefore, it is necessary to improve the existing sparse representation methods to enhance the accuracy and efficiency of urban image segmentation.

In order to address the limitations and challenges of existing methods, this paper proposes a city image segmentation method in the media fusion era based on improved sparse matrix generation digital image processing. The main motivation of this method is to improve the accuracy and efficiency of urban image segmentation, while reducing computational complexity and data volume.

II. Research Method

A. Media Communication of City Image under the Environment of Media Integration

The public’s cognition of the formation of a city is mainly carried out through traveling, listening to other people’s stories, media reports, etc., and the public can’t personally perceive all aspects of the city because of objective factors such as distance. Therefore, the public will choose the mass media to understand the image of a city, and after constant publicity, they will have an overall impression of a city. A good city media image is conducive to shaping the city image and attracting more audiences, while a good city media image is conducive to shaping the city image. A good city image can only be shaped by media reports and dissemination, so it is of great significance to study the city media image to recognize the city image.

City image communication power is the ability to realize the effective communication of city image, which directly determines the audience’s awareness of city image. The knowledge about the city’s citizens’ contact with the outside public mainly depends on the mass media, but for the outside people in the city, such as tourists and migrant workers, they will not only get the city information through the mass media, but also supplement their cognition of the city image through the behavior identity of the city image. Through the planning of the city image communication power, the city image communication power can be brought into full play, thus enhancing the public’s awareness of the city image. In the process of city image communication, the choice of city image positioning is to select the image information that can occupy a certain position in the public’s mind and refine it from the public’s preference. With the public as the center, the image of the city can be more easily accepted by the public, thus gaining the public’s trust and goodwill. It provides information, channels and strategies for city image communication. At the same time, it deals with the feedback from the audience in a timely manner, and revises the communication strategies so as to better build the communication power of city image and establish a good city image service.

In the age of media integration, the media of various channels, different levels and different fields provide various choices for the image communication and brand building of the city. This kind of mass media’s inherent focusing and spreading effect, as well as its functions of contacting the society, monitoring the environment, inheriting civilization, entertaining the public and mobilizing the society, make the mass media strategy enlarged into the exclusive strategy of city image communication in many researches and practices. However, it is undeniable that traditional media still plays an important role today. Traditional media still has its unique advantages in spreading city image, such as strong human and material resources, long-term accumulated rich experience, and lack of rigor, profundity and sense of authority of network media. Unlimited diversification of information channels is the biggest law of communication in the age of media integration. Traditional media can’t monopolize the release of information. Self-media, represented by Weibo, has more and more right to speak, and has become an unquestionable and important part of information release channels.

In the era of media integration, the power of individuals and non-governmental organizations composed of individuals in the main body of city image communication cannot be ignored. The development and maturity of new media technology provide audiences with more platforms to spread information and express their personal views. In this highly open discourse space, ordinary citizens’ awareness of spreading the city image is rapidly awakened, and they gradually change from passive to active in spreading the city image. They begin to use various media to express the city image in their hearts. Citizens in the city register their Weibo accounts and share their life in Weibo. Perhaps it’s a city landscape, a city food, a feeling in city life, or a city building, all of which spread the image of the city in tangible and intangible ways. Because most people in the circle of friends are acquaintances, people will be more willing to share information about urban life on WeChat. The bits and pieces of urban life that people share on WeChat can be quickly seen by people in the circle of friends, which will lead to secondary transmission. Let the receiver of information interpret the image of the city, such as the urban buildings and customs contained in the published information. This kind of unconscious communication can sometimes bring unexpected communication effects.

At the same time, we should not only make use of emerging media to pay close attention to positive publicity, but also deal with negative information. The integrated media communication of city image must follow the communication law of multi-media era, comprehensively utilize all kinds of media, meet the information needs of different types of audiences, and carry out three-dimensional communication. In the way, we should not only keep the traditional advantages, but also be good at using new media. In terms of timing, we should not only have ideas and means in normal situations, but also take measures to deal with thinking and image restoration in critical times. City image communication has a distinct stage, changing with the times and its own development; from the microscopic point of view, any specific communication work is a certain stage in the process of city image communication. Compared with the other two forms of city image communication, interpersonal communication, memory communication and experience communication, the participation of the media will systematically and continuously spread the city image through news reports, which will have an impact on the audience's cognition and understanding of the city image in a long period.

B. *Analysis of the Application of Digital Image Processing Technology in City Image Communication*

With the advent of the age of media integration, images, as the visual basis for people to perceive the world, are an important means for people to obtain, express and transmit information. Computer technology is used to compress and encode images to complete digital image processing, and to transform low-quality images into high-quality images.

At present, the development of streaming media communication technology is relatively mature, and digital image processing technology is needed for image transmission. Digital image processing technology is widely used in streaming media, including high-speed color TV signal and high-compression image transmission. From the previous role of picture ornament and decoration to the application of digital image processing technology, more pictures with strong sense of scene, intuitive image and important subject matter are used, so that digital images can play a leading role in news reports.

1) Digital image compression technology: With the continuous development of multimedia technology and Internet technology, how to effectively organize, store, transmit and restore image data and explore more effective and higher compression ratio image coding technology has become one of the key tasks in information processing technology. the research and application of image compression coding is one of the most active fields in information technology at present. Image coding is to use different expression methods to reduce the amount of data needed to represent the image. the theoretical basis of compression is information theory. Without the rapid development of image compression technology, it will be difficult to realize the storage and transmission of large amount of information, and it will be difficult to play a role in multimedia and other application technologies. Therefore, data compression is very important for multimedia information such as images.

In order to express image data, some symbols need to be used, and image coding needs to use these symbols to express images according to certain rules [13-14]. Here, the symbol sequence assigned to each information or event is called the code word, and the number of symbols in each code word is called the length of the code word. Generally, the encoder includes three independent operations in sequence, while the corresponding decoder includes two independent operations in reverse order, as shown in Fig. 1:

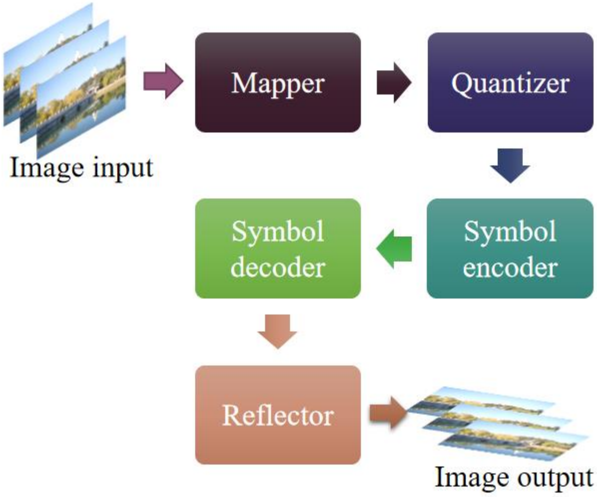

Fig. 1. Block diagram of image coding and decoding system.

In the encoder, the mapper reduces the pixel redundancy by transforming the input data; Quantizer reduces psychovisual redundancy by reducing the accuracy of mapper output; the encoder reduces coding redundancy by assigning the shortest code to the most frequent quantizer output value. Because the quantization operation is irreversible, there is no inverse operation module for quantization in the decoder [15].

For a random event E, if its occurrence probability is $P(E)$, then the information it contains is:

$$I(E)=\frac{1}{\log P(E)}=-\log P(E) \tag{1}$$

The source symbol set B is defined as the set (b_i) of all possible symbols, where each element b_i is called the source symbol, and the probability of the source generating the symbol (b_i) is $P(b_i)$.

For the effectiveness of image information transmission with large amount of data under the condition of high compression, the image to be compressed is preprocessed before it is compressed and coded to reduce the amount of information transmitted, and the decomposed wavelet coefficients can be appropriately changed, so that the compressed reconstructed image has better compression effect and subjective quality [16-17].

The “pure” anisotropic diffusion equation is adopted for the high frequency subband $HL_j, LH_j, HH_j \left(j = 1, \ldots, d \right)$. Carry out wavelet transform on the original image to obtain a wavelet image;

$$\left\{ u_{k,j} \middle| k = LL, LH, HL, HH;\ j = 1, \ldots, d \right\} \tag{2}$$

Initialization threshold T_0 (threshold to be used for the first scan):

$$T_0 = 2^{\left\lfloor \log_2 Max\left\{ \left| c_{i,j} \right| \right\} \right\rfloor} \tag{3}$$

Among them, $\left\{ c_{i,j} \right\}$ is the transform coefficient of L -level embedded zerotree wavelet transform, $\left| c_{i,j} \right|$ is the absolute value of $c_{i,j}$, and the relationship between the threshold of each scan and the threshold of its previous scan is: the current threshold is half of the previous threshold [18].

The sensitivity of human eyes to the change of gray scale is related to the background, and it changes with the change of average gray scale, that is, the resolution (vision) of human eyes to the details of the scene is related to the relative contrast C_r of the scene. The formula is as follows:

$$C_r = \left[\frac{B_1 - B}{B} \right] \tag{4}$$

where: B_1 is the brightness of the object; B is the background brightness; When C_r becomes small, vision decreases.

If a convolutional code with a code rate of R and a memory depth of M is used to send a message containing K information bits, the effective code rate is:

$$R_{eff} = \frac{K}{R^{-1}K + R^{-1}M} = \frac{RK}{K + M} = \frac{R}{\frac{M+1}{K}} \tag{5}$$

Therefore, convolutional codes are most effective at $K + M$, that is, the length of the information sequence to be sent is much longer than the storage length of the register.

2) Image segmentation technology: Image segmentation is an important image technology, which not only gets extensive attention and research, but also gets a lot of applications in practice. Image processing emphasizes the transformation between images to improve the visual effect of images. Image analysis is mainly to monitor and measure the objects of interest in the image, so as to obtain their objective information and establish a description of the image. They generally correspond to specific areas with unique properties in the image. In order to identify and analyze the targets, they need to be separated and extracted, and on this basis, it is possible to further utilize the targets. Image segmentation has been widely used in practice, such as industrial automation, online product inspection, production process control, document image processing, remote sensing and biomedical image analysis, security monitoring, military, sports, agricultural engineering and so on.

Segmentation is an important step in image analysis, image understanding and video coding, and it is also a basic technology in computer vision. This is because image segmentation, object separation, feature extraction and parameter measurement transform the original image into a more abstract and compact form, which makes it possible for higher-level analysis and understanding [19].

In this paper, the lost image information is analyzed, and a new sparse matrix creation method is proposed, and the created sparse matrix is used as similarity matrix for spectral clustering image segmentation. Gaussian function is used to calculate the similarity between pixels in an image.

$$w_{ij} = e^{\frac{-\left\| F(i) - F(j) \right\|_2^2}{\sigma_I}} * e^{\frac{-\left\| X(i) - X(j) \right\|_2^2}{\sigma_X}} \tag{6}$$

where: $F\left(\cdot\right)$ represents the gray value, and $X\left(\cdot\right)$ represents the coordinates. σ_X, σ_I represents the scale parameters of coordinate distance and gray difference, respectively.

At any point in a complex image, the human eye can only recognize dozens of gray levels, but it can recognize thousands of different colors. Therefore, in many cases, only using gray level information can’t extract a satisfactory target from the image. Color image segmentation can be regarded as the application of gray image segmentation technology in various color spaces.

Consider a two-dimensional gray (gradient) image I. The domain of I is $D_l \subset Z^2$, I takes discrete gray value $\left[0, N\right]$, which is regarded as the height of the corresponding pixel, and N is a positive integer:

$$I \begin{cases} D_l \subset Z^2 \to \left\{ 0, 1, \ldots, N \right\} \\ p \middle| \to I\left(p\right) \end{cases} \tag{7}$$

A path p of length l between points p, q in the image I is an $\left(l + 1\right)$ group composed of points $\left(p_0, \ldots, p_{l-1}, p_l\right)$, with $p_0 = p, p_l = q$ and $\forall_i \left[1, l\right], \left(p_{i-1}, p_i\right) \in G$.

In order to make the edge detected by edge detection operator affect the result of region segmentation, these edges should be mapped to the position of “dam” in gradient image.

Based on this, this paper puts forward a gradient "peak enhancement" method, which can correct and strengthen the weakened edge contour in gradient calculation. Based on the above analysis, the basic flow of this segmentation scheme is shown in Fig. 2.

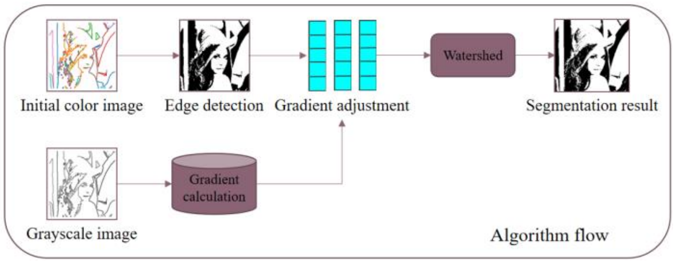

Fig. 2. Algorithm flow chart.

T is a threshold, and its value is related to the degree of noise pollution. It limits the range that the depth of point $\left(x,y\right)$ is considered to be very close to the depth of its neighboring points. Only when the depth value of point $\left(x,y\right)$ and its neighboring points are less than the threshold value, it is considered that point $\left(x,y\right)$ is very close to the depth value of its neighboring points.

$$T^2=\frac{1}{8}\sum_{i=0}^{7}\left(\delta_i\left(x,y\right)-f\left(x,y\right)\right)^2 \tag{8}$$

In order to make the color change independent of the change of light intensity in color image segmentation, an effective method is to uniformly obtain the change of intensity in spectral distribution. So a standardized color space is obtained, and its form is as follows:

$$r=\frac{R}{R+G+B} \tag{9}$$

$$g=\frac{G}{R+G+B} \tag{10}$$

$$b=\frac{B}{R+G+B} \tag{11}$$

Because of $r+g+b=1$, when two components are given, the third component is also determined. Usually, we only use two of the three components.

3) Image restoration technology: Image inpainting technology is a morbid problem. It is only a reasonable assumption based on mathematical principles, and it is analyzed from the perspective of computer vision and information theory. By comparing the rationality of various assumptions, the problem of image inpainting is finally solved. That is, the damaged area is artificially determined according to the color information and structural features in the image, and different colors are calibrated to distinguish the known area from the area to be repaired; Compared with the traditional manual method, today's image inpainting technology has developed by leaps and bounds in both efficiency and natural integrity. However, there are still a lot of problems in the field of image inpainting that need to be improved and solved urgently. As an important subject in image engineering, the field of image inpainting is attracting more and more researchers to join in.

Digital image inpainting technology is based on the problem that local information is missing in the process of digital image processing and compression in the past, and the object to be repaired is specially repaired. In particular, the restoration of cultural relics mainly involves manual restoration of cultural relics, which requires employees to have extremely high professional skills, patience and care, resulting in the inability of mass production of cultural relics restoration. However, the field of cultural relics restoration is very wide, and it is far from meeting the actual needs of cultural relics restoration only by manual restoration. For the possible negative effects of cultural relics restoration, digital image restoration technology can also provide certain anti-infection ability, avoid the serious impact of cultural relics restoration and improve the comprehensive utilization value of cultural relics [20]. Using the technical principles of statistics and other disciplines, the prediction model of cultural relics is constructed, and the existing image data is used to estimate the incomplete image area, so as to achieve the virtual restoration of cultural relics, which can shorten the original time-consuming work cycle of cultural relics restoration, and avoid the mistakes of manual restoration, resulting in more serious secondary damage to cultural relics. Reinforcement learning can be used for image segmentation tasks, learning how to classify images at the pixel level through interaction with the environment. The intelligent agent selects actions based on current observations and adjusts strategies based on feedback from the environment to optimize segmentation results. Reinforcement learning can be applied to target tracking tasks, where agents learn how to accurately track the position of target objects in consecutive frames. By defining appropriate reward functions, agents can learn to effectively track targets in complex scenarios. The combination of deep learning and object detection technology can achieve end-to-end object detection with higher accuracy and robustness. It trains neural networks to simultaneously predict the position and category of targets. For example, super-resolution reconstruction, style transfer, and image restoration. GAN consists of a generator and a discriminator, which generate new images similar to real images through adversarial training [21-23].

When studying image inpainting, the degradation model of the image can be expressed by the following formula:

$$u^0\big|_{\Omega\backslash D}=\left[k*u+n\right]\big|_{\Omega\backslash D} \tag{12}$$

Ω represents the target image; D represents the region to be repaired of the image; $\Omega\backslash D$ means the existing information in the image; u^0 is the available image part on $\Omega\backslash D$; u the target image to be restored; k represents its degradation function, n is the noise term, and "$*$" here represents convolution.

Generally, the energy form E for establishing its data model is defined by the minimum mean square error, and the formula is as follows:

$$E\left[u^0|u\right]=\frac{\lambda}{2}\int_{\Omega\setminus D}\left(k*u-u^0\right)^2dx \tag{13}$$

When partial differential equation theory is used for image inpainting, the D of the defect is unknown, so compared with other image processing projects, the prior model of the image is very important for the inpainting project.

Knowing the length, width and height of the cuboid can realize the complete reconstruction of the cuboid. The method proposed in this paper is to manually obtain the minimum number of image points, obtain their corresponding three-dimensional coordinates through camera calibration, and then calculate the length, width and height of the cuboid, thus realizing the complete reconstruction of the cuboid. The perspective projection of cuboid is shown in Fig. 3.

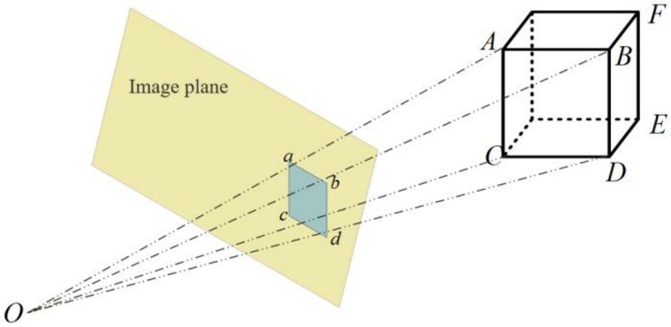

Fig. 3. Perspective projection of cuboid.

In the figure, O is the optical center of the camera, $ABCD$ is one surface of a cuboid, and its corresponding projection surface on the imaged image is $abcd$. Determine the depth value of one of the points in the camera coordinate system, calculate the three-dimensional coordinates of the manually obtained points according to the internal and external parameters calibrated by the camera, and then calculate the length, width and height of the cuboid according to its geometric properties.

The projection of the reverse $\vec{d}$ of any point x in the image is a ray determined by that point and the camera center. In the camera coordinate system, the ray direction $\vec{d}$ is:

$$\vec{d}=K^{-1}x \tag{14}$$

Therefore, A,B,C,D is on ray $\overrightarrow{Oa},\overrightarrow{Ob},\overrightarrow{Oc},\overrightarrow{Od}$.

In an image, the damaged area (the area to be repaired) is usually irregular, so it is difficult to determine the geometric center of the area. In this paper, the concept of gravity center in physics is introduced by using the characteristic that the position of gravity center is only related to the image shape.

Assuming that Ω represents the damaged area, the coordinates of its center of gravity O can be calculated by the following formula:

$$\bar{x}=\frac{\sum\sum_{[x,y]\subset\Omega}\|x\|}{S} \tag{15}$$

$$\bar{y}=\frac{\sum\sum_{[x,y]\subset\Omega}\|y\|}{S} \tag{16}$$

where, S represents the area of the region Ω to be repaired (the sum of all pixels to be repaired).

III. Analysis and Discussion of Results

In the basic fractal algorithm, the quality of reconstructed image, coding time and compression ratio depend on many factors, such as the size of R block, D block, the step length of generating D block pool, whether to adopt basic transformation, brightness adjustment factor and the quantization bit number of brightness offset, etc. the program is written in C++, the coordinates of D block are stored in 16bit, and the serial number of basic transformation is stored in 3 bits. The R block size is 4×4 and the D block size is 8×8(B=4), and eight basic transformations are adopted.

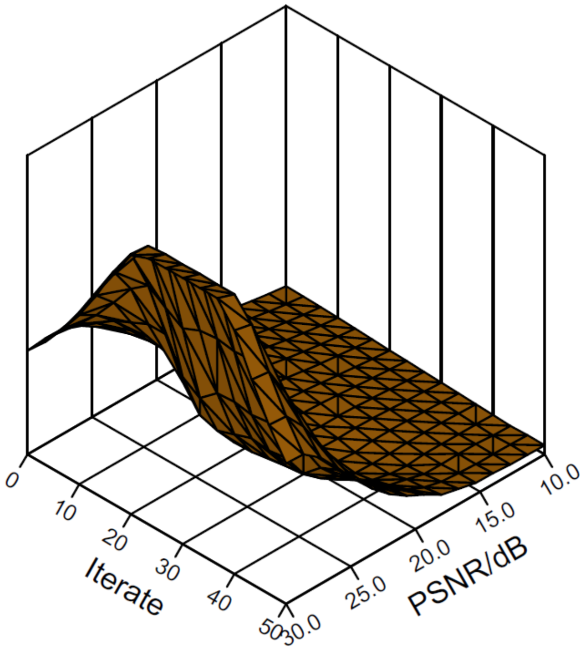

Fig. 4. The decoding convergence of lena image.

Analyze the decoding convergence of Lena image when the initial image is all black (see Fig. 4). It can be seen that the decoded image sequence of 10 times overlapping has basically converged. The difference between the decoded picture of the 10th overlapping and the PSNR (Peak Signal to Noise Ratio) after decoding is less than 0.051dB. Within the error range of 0.051dB, the decoded image of the 10th overlapping reaches the convergent image of the decoded image sequence.

Lena standard grayscale test chart with 516× 516, 8-bit quantization is used (see Table I and Fig. 5).

TABLE.I FRACTAL CODING

T	PSNR (dB)	Compression ratio	Coding time (s)
2	28.2349	5.8949	3.3796
6	26.1433	6.6526	2.8584
14	24.5524	12.3785	2.839

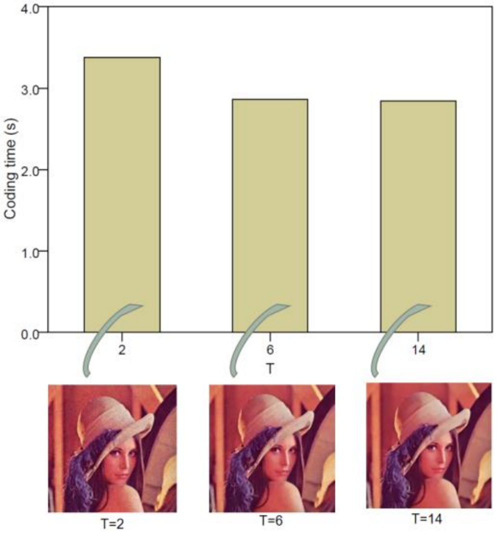

Fig. 5. Fractal time histogram.

The image reconstruction of neighborhood search fractal block coding is basically the same as that of global search fractal block coding, except that neighborhood search fractal block coding only iterates repeatedly in the neighborhood when reconstructing the image. This method limits the search process of the matching block to the four neighborhoods of the range block, which ensures the SNR and greatly reduces the coding time. However, with the increase of threshold, there is block effect in the decoded image, which is a shortcoming that this algorithm needs to overcome.

Influence of backtracking length on performance of convolutional codes. The length of backtracking not only determines the accuracy of Viterbi decoding, but also affects the decoding delay, and the error performance will also change accordingly. The feedback depth is 10, 15, 26 and 31 respectively. The simulation results are shown in Fig. 6.

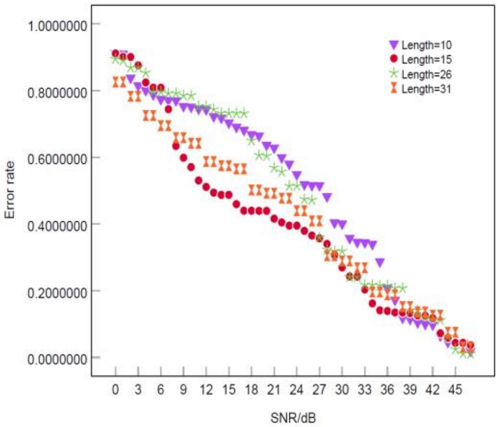

Fig. 6. Influence of different backtracking lengths on the performance of convolutional codes.

When the SNR (Signal to Noise Ratio) gradually increases, the bit error rate of the system gradually decreases with the increase of the backtracking length, but when the backtracking length increases to 5N, the bit error rate does not change much, and the (2, 1, 6) convolutional code here basically tends to be stable when the backtracking length reaches about 31. Therefore, when selecting the backtracking length, it is usually 5N.

Table II and Fig. 7 show the time taken by the fuzzy entropy algorithm based on exhaustive search and the algorithm in this paper to binarize sample images, where the unit of time is seconds.

The experimental results obtained by using the algorithm in this paper are basically the same as those obtained by fuzzy theory processing developed in the field of segmentation in recent years. However, the chart shows that the algorithm in this paper has absolute advantages in speed, so our research is also affirmed, which fully shows that it should have high application value.

To verify the effectiveness of the proposed algorithm, two quality indexes, i. e. gray contrast between regions and Bezdek partition coefficient, are selected to quantitatively analyze and compare the three algorithms involved. In general, the greater the gray contrast between regions, the better the image segmentation quality.

TABLE.II COMPARISON OF TIME

Image sequence number	Fuzzy entropy	Our
1	176.4963	0.6217
2	76.4064	1.1349

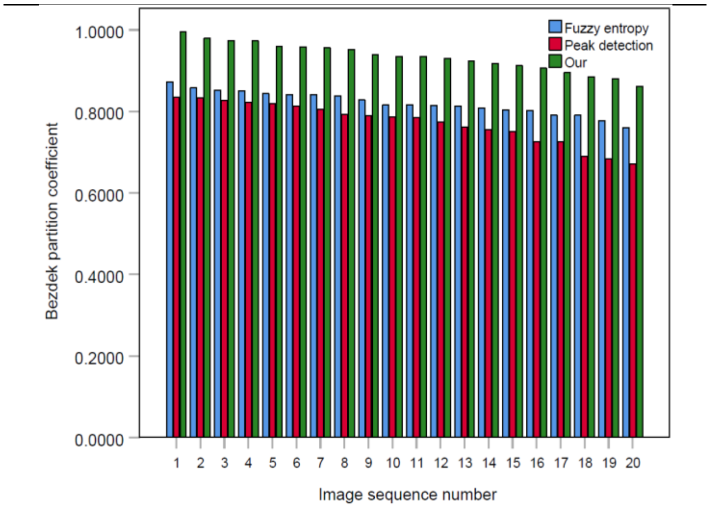

Fig. 9. Comparison chart of Bezdek partition coefficient.

In this paper, the original image is pre-segmented by using the established graph model. The initial clustering center of the algorithm is obtained by hierarchical clustering of the obtained similarity matrix. It can be seen from the two quality indexes of inter-regional gray contrast and Bezdek partition coefficient involved in the above chart that the improved algorithm in this paper is superior to the traditional algorithm. Compared with the fuzzy entropy algorithm based on exhaustive search, the inter-regional gray contrast and Bezdek partition coefficient are improved by 9.301% and 4.127%.

The urban image segmentation method based on improved sparse matrix generation for digital image processing in the era of media fusion has broad application prospects in the real world. For example, in urban planning and construction, this method can help urban managers better understand and analyze urban spatial layout and landscape characteristics, providing more accurate data support for urban planning decisions. At the same time, this method can also be applied to urban image dissemination strategies, by using precise image segmentation techniques to highlight the characteristics and highlights of the city, and improve its visibility and reputation.

In addition, the urban image segmentation method in the media fusion era based on improved sparse matrix generation digital image processing can also be applied in fields such as tourism, transportation, and environmental monitoring. For example, in the field of tourism, this method can help tourists better understand the characteristics and landscape layout of tourist attractions, and improve the quality of tourism experience; In the field of transportation, this method can help traffic management departments better understand road conditions and traffic flow, providing more accurate data support for traffic planning and governance; In the field of environmental monitoring, this method can help environmental protection departments better understand the situation of environmental pollution and ecological change trends, and provide more accurate data support for environmental protection decision-making.

IV. Conclusion

City image communication power is the ability to realize the effective communication of city image, which directly determines the audience’s awareness of city image. On the platform of media, the new and old media penetrate, collide, advance and merge with each other, which constitute a prominent landscape of today’s media ecology. Through the planning of the city image communication power, the city image communication power can be brought into full play, thus enhancing the public’s awareness of the city image. In this paper, the application of digital image processing technology in city image communication in the age of media integration is studied. A new sparse matrix creation method is proposed, and the created sparse matrix is used as similarity matrix to segment spectral clustering images. Gaussian function is used to calculate the similarity between pixels in an image. the research shows that the improved algorithm is superior to the traditional algorithm, and compared with the fuzzy entropy algorithm based on exhaustive search, the gray contrast between regions and Bezdek partition coefficient are improved by 9.301% and 4.127%.

When implementing image segmentation methods based on improved sparse matrix generation for digital image processing, there may be the following potential limitations and challenges: sparse representation and feature extraction processes involve a large number of matrix operations and optimization problems, with high computational complexity. Urban images usually contain a large amount of pixel information, and the processing process requires a large amount of data, which requires high computational resources and storage capacity. For urban images under different scenes and lighting conditions, this method may not achieve ideal segmentation results. In order to overcome the potential limitations and challenges mentioned above, future research can focus on more efficient sparse representation and feature extraction algorithms, reducing computational complexity and time costs using deep learning techniques to learn and extract features from urban images, improving segmentation accuracy and generalization ability.

Towards a Stacking Ensemble Model for Predicting Diabetes Mellitus using Combination of Machine Learning Techniques

Abdulaziz A Alzubaidi, Sami M Halawani, Mutasem Jarrah
Faculty of Computing and Information Technology, King Abdulaziz University, Jeddah, Saudi Arabia

Abstract—**Diabetes Mellitus (DM) is a chronic disease affecting the world's population, it causes long-term issues such as kidney failure, blindness, and heart disease, hurting one's quality of life. Diagnosing diabetes mellitus in an early stage is a challenge and a decisive decision for medical experts, as delay in diagnosis leads to complications in controlling the progression of the disease. Therefore, this research aims to develop a novel stacking ensemble model to predict diabetes mellitus a combination of machine learning models, where an ensemble of Prediction classifiers was used, such as Random Forest (RF), Logistic Regression (LR), as base learners' models, and the Extreme gradient Boosting model (XGBoost) as a Meta-Learner model. The results indicated that our proposed stacking model can predict diabetes mellitus with 83% accuracy on Pima dataset and 97% with DPD dataset. In conclusion, our proposed model can be used to build a diagnostic application for diabetes mellitus, as recommend testing our model on a huge and diverse dataset to obtain more accurate results.**

Keywords—DM; Diabetes Mellitus; Stacking; Ensemble learning; Machine Learning; Random Forest (RF); Logistic Regression (LR); Extreme Gradient Boosting model (XGBoost)

I. Introduction

Diabetes Mellitus mainly leads to chronic hyperglycemia considering low insulin quantities in the bloodstream [1]. Insulin plays an important role in glucose level lowering in the blood, carbohydrate anabolism, physical growth, cell reproduction, and protein and fat anabolic statute [2]. Therefore, severe difficulties are associated explicitly with Diabetes Mellitus concerning people's quality of life. The chronic diseases caused by Diabetes Mellitus have heart failure, kidney failure, blindness, and cardiovascular illnesses [3]. These conditions induce a high pile in mortality rates and pressures on personal life [4]. According to estimates, there was 463 million people worldwide with diabetes in 2019 [5]. Moreover, by 2030, that number is expected to rise to 578 million and then 700 million (2045).

Urban areas (10.8% percent) have a higher prevalence than rural areas (7.2% percent), and high-income countries (10.4% percent) have a higher prevalence than low-income ones (4.0% percent) [5]. 50.1% percent of people with diabetes don't know they have the disease.

According to estimates, there is 7.5% percent (374 million) people worldwide who have impaired glucose tolerance, and that number is expected to rise to 8.0% percent (454 million) by 2030 and 8.6% percent (548 million) by 2045 [5]. There are two prevalent forms of DM: Type-1-Diabetes (T1DM), an autoimmune syndrome that results in the death of beta cells in the pancreas that produce insulin, and Type-2-Diabetes (T2DM), which is a chronic condition that frequently results in abnormally high blood sugar levels (glucose) [6]. T1DM affects about 10% percent of patients under 30, whereas T2DM affects about 90% percent of diabetics over 30% percent [6]. Doctors use trial results from agreed-upon studies to distinguish between these types and then specify the best treatment options based on the form they have discovered. Medical experts occasionally disagree on the proper type of diagnosis, which makes treating the illness challenging [7].

Diabetes is becoming more prevalent worldwide, particularly in middle-income nations [8]. Therefore, we need to conduct this study to predict diabetes using machine learning methods to support doctors in providing the most suitable treatment strategy.

It was noted during the literature reviews that the emphasis is on ensemble machine learning techniques for predicting diabetes mellitus therapy and prevention are challenging due to suitable policies to provide environments that support healthy behaviors and a lack of quality health care in various settings.

The Sustainable Development Community seeks to eliminate premature mortality for various illnesses, including diabetes, by 2030 [8]. As a result, experts are continually researching multiple facets of DM where many machine learning techniques are used such as the RF model, which is a great choice in binary classification processes, for example in diabetes mellitus, the outcome is that the patient is diabetic or not diabetic, where the random forest depends on ensemble learning method (bagging) in making the final decision [33], [32]. The LR algorithm also plays an important role in the process of predicting diabetes, as it identifies the independent variables and classifies them on the x- and y-lines, and then measures the probabilities of an event's [34],[31]. One of the recently discovered options for machine learning is the XGBoost model which also counts on ensemble learning methodology; it can deal with unbalanced datasets classes by measuring the loss function and resolve the problem of overlearning using grading and voting [27], [28], [29].

A medical diagnosis of diabetes mellitus is one of the challenges in the medical field. Patients' information may include age, body mass, triceps skinfold thickness, serum insulin, plasma glucose concentration, diastolic blood pressure, and other factors. Based on these elements, the decision will made. The decision-making process is drawn out and takes weeks or months, making the doctor's job incredibly hard, but with the help of new technologies, it will be easier; consequently, machine learning techniques are a crucial solution [9].

Today, an extensive selection of medical datasets that are helpful for research in fields of medical science are easily accessible [10]. According to all this information and background about diabetes mellitus disease and the most prominent techniques used to predict it, we propose a novel stacking ensemble model for the prediction of DM utilizing a combination of machine learning models.

The Contributions of this paper are as follows:

- Developing a stacking ensemble model for predicting Diabetes Mellitus using a combination of machine learning models.
- Merging the RF and LR models as base learners and the XGB model as a meta-learner in building the proposed stacking model.

This paper is arranged as follows: Section II provides the Related work; Section III covers the material and methodologies of our study; Section IV illustrates the experimental setup for our proposed model; and Section V the performance measures. Our results and discussion are discussed in Section VI and VII respectively. Finally, the Conclusion has been addressed in Section VIII.

II. Related Work

Ensemble learning is a computational and statistical approach. Mimicking how people learn social skills by experimenting with different viewpoints before making the final decision. A Set of machine learning models combines choices and provides more robust and accurate predictions [11-12].

Gollapalli et al. [13] proposed a novel stacking ensemble model using machine learning to detect three-types of diabetes mellitus: T1DM, T2DM, and Pre-diabetes. Empirical results showed that the proposed model could predict with 94.48 percent accuracy, 94.48 percent recall, 94.70 percent precision, and 0.917 percent Cohen's kappa score. After observation, the most critical features of predicting T1DM, T2DM are: Sex; human gender A1c: measures the amount of sugar bonded to the hemoglobin protein in the blood; TG: The blood triglyceride level of the patient; LDL: Low-density lipoprotein, or LDL, is a measure of the quantity of harmful cholesterol; AntiDiab: A blood sugar-lowering oral medicine used to combat diabetes; Albumin: The amount of protein; Insulin, Injectable, Nutrition, Education. However, the study needed more ML classifiers and deep learning models to increase prediction accuracy.

Dutta et al. [14] emphasize that using an ML-based ensemble model in predicting DM is critical in ensuring more accurate predictions. Also, exploring deep learning techniques and applying them with an ensemble learning approach is recommended. Stacking is an ensemble method that employs a meta-model in which a novel classifier integrates multiple weak learners to predict the target variable [13].

Ganie and Malik [15] discussed the various ensemble learning methods, such as the Bagging method, in predicting T2DM based on lifestyle indicators. The synthetic minority oversampling technique is used for dataset class balancing. Furthermore, the results are validated using the Cross-Validation technique. Researchers and practitioners use the cross-validation technique for the model-building process to remove biases.

Laila et al. [16] studied efficient ensemble algorithms for predicting diabetic risks in the early stages, using Seventeen features gathered from the UCI of various datasets. This research used predictive models like (AdaBoost, Bagging, and Random Forest) were utilized to evaluate accuracy, recollection, and F1-score. Overall, the RF ensemble methodology had the highest accuracy (97 %), whereas AdaBoost and Bagging had lesser accuracy.

Javale and Desai [17] concentrated on an ensemble technique for healthcare information analytics employing machine learning through unbalanced dataset approaches, synthetic minority over-sampling, plus adaptive synthetic over-sampling. Using other analysis techniques such as the train-test, the K-folds, and the repeat train-test. The average Stacking-C technique was used to execute an ensemble strategy on the diabetes dataset, which included K-Nearest Neighbors (KNN), Support vector machines (SVM), RF, Naïve Bayes (NB), and logistic regression classifiers. The Synthetic Minority Oversampling Technique (SMOTE) reduces False Negative counts with more precision. An ensemble method facilitates appropriate decision-making by providing a more profound knowledge of the implementation. Rather than just comparing the classifiers' outputs produced for various performance measures, choosing the optimal ensemble technique for the application is always preferable. The fundamental challenge in healthcare information analytics is unbalanced datasets, which might be a critical factor for an ensemble technique in healthcare data analytics.

Singh et al. [18] suggested an ensemble-based approach for diabetes prediction called eDiaPredictTo forecast diabetes status in patients, it employs ensemble modeling, which consists of an ensemble of multiple machine learning algorithms such as XGBoost, RF, SVM, NN, and DT. The minimalizing error value and lowest weighted coefficient of eDiaPredict have all been tested. The suggested approach's usefulness is shown using the PIMA Indian medical dataset, which has an accuracy of 95% percent. The stacking ensemble combines the predictions of many ML models to get the maximum accuracy achievable compared to the conventional models. It leverages a single model known as a meta-model to diagnose the optimum mix of expectations from the basic models. The stacking ensemble contains two stages, level 0 and level 1. The former employs heterogeneous ML models known as base learners. In contrast, the latter uses a single model known as a meta learner, whose purpose is to unify the predictions of the basis learners. To predict T2DM and alert patients in advance to decrease the risk factor and intensity associated with diabetic diseases.

Geetha and Prasad [19] suggested a hybrid ensemble model. For the decision tree, they employed ensemble approaches such as bagging with "random forest" and Adaboost and supervised classification algorithms like Naive Bayes. Merge different two or more models improves performance by increasing the accuracy and precision of predictions. Joshi et al. [31] focused on predicting Type 2 diabetes in Pima Indian women using a logistic regression (LR) model and a decision tree, and the accuracy of the proposed model was 78% percent.

Patil et al. [20] proposed a framework for T2DM prediction that uses a stacking-based ensemble with a "non-dominated sorting genetic algorithm" method. The main objective is to reduce the time elapsed between diabetes diagnosis and medical evaluation. The suggested NSGA-II stacking method was compared to Boosting, Bagging, RF, and Random Sub-space approaches. The stacking ensemble methodology has outperformed all other traditional ensemble approaches. Findings indicate that the NSGA-II stacking approach performs better over other conventional ensemble methods with an accuracy of 81 percent.

Syed and Khan [21] created an ML-Based System for Predicting the Risk of (T2DM), which is a web-based prediction model that uses Azure ML to estimate the risks of Type 2 diabetes. The results show that the suggested model can accurately predict the risks of Type 2 diabetes by 82 percent. The geographical range of this study was restricted since it primarily focused on the western portion of Saudi Arabia for the validation procedure. Table I explains the most important studies according to limitations and Advantages, Data Sources.

III. Material and Methodologies

This research proposes a stacking ensemble model to predict diabetes mellitus. The proposed model relies on two essential levels of construction. The first level is called (base learners). At this level, a combination of machine learning models is prepared, trained, and produced predictions that are entered as inputs to a new model/classifier that learns from these inputs to make the final prediction (the meta-learner), the second level. We have selected the logistic regression model, Random Forest, as base learners with their distinction ability in binary classification processes. We select The XGBoost model as a meta-learner, which contributes positively to dealing with imbalanced dataset classes by minimizing the loss function and increasing the weight of the classified incorrect classes. The optimization GridSearchCV technology is applied to get the best possible results by the base learners and the meta learner; it uses a grid search of hyperparameters tuning for each model and extracts the best results. In our proposed model, we have included the cross-validation technique with default five-fold iterations to get optimal results. Also, we applied this technique on each of the base learners: Random Forest, Logistic regression, via the Optimizer GridSearchCV to get the best results by using the sci-kit-learn library, which provides a random split into training and test sets can easily calculate with the train_test_split assistant function. Each model starts with using K-1 of the folds. Fig. 1 describes the methodology for our proposed stacking model:

Fig. 1. Proposed stacking model.

A. Stacking

Stacking is an ensemble learning method that uses a meta-model where a new classifier integrates several individual-based learning predictions to get the best combined predictions. The stacking method has two levels in the building; level 0 (base-learners) combine heterogeneous models that are fitted and trained on a dataset, then the results will be fed as input to the meta-learner at the next level. The level 1 (meta learner) learns how to combine the predictions from the base models and provide robust and high-accuracy predictions [13]. We built our proposed model based on this stacking ensemble method with more of our contributions, like utilizing of cross-validation technique for all learners and leveraging the GridSearchCV hyperparameters tuning technique for the base learners. Fig. 2 illustrates the ensemble stacking methodology. Where m*n means that n of number k-folds Cross-validations of training dataset that will go cross all base learners' models, and m*M means that m of numbers of predictions coming from a number of M base learners will send to the next meta-learner model as inputs and then he learns from all of these predictions how to predict the final prediction.

B. GridSearchCV

GridSearchCV is a widely used technique in machine learning and deep learning model development. It helps select the best hyperparameter values for a specific model. Hyperparameters determine the model's behavior and configuration, such as the number of layers and batch size in neural networks or the depth of trees in decision trees.

GridSearchCV works by systematically testing different combinations of hyperparameters and evaluating their performance through cross-validation. This involves defining a set of possible values for each hyperparameter, training and testing the model with each combination, and ultimately selecting the combination that yields the best performance [14]. This process enhances the model's performance and prevents overfitting by evaluating it on separate training and testing data sets [14]. This approach significantly enhances model performance and mitigates overfitting by utilizing cross-validation, assessing the model on distinct training and testing datasets. [14].

C. Logistic Regression

Logistic regression is a machine learning algorithm used for binary classification. It is specifically designed to build models that can predict specific classifications. Despite its name, it is not used for predicting logistic events, but rather for classification based on the logistic (sigmoid) function [23].

Logistic regression solves the binary classification problem by classifying examples into one of two classes (e.g., class 0 or class 1) based on a set of independent variables (features). The algorithm uses the logistic function to model and determine the probability of an example belonging to the positive class (class 1) [24], [25]. In logistic regression, the results of the logistic function are transformed into probabilities using the sigmoid function. This conversion ensures that the probabilities range between 0 and 1. These probabilities represent the estimated classification probability, which is used to make the final classification decision [31]. Logistic regression is widely used across various fields, including data science, business analytics, medicine, and text classification. It is valued for its simplicity and its ability to handle large datasets efficiently [23].

D. Random Forest

Random Forest is a machine learning technique used for classification and prediction. It is a significant algorithm in optimization and diversification for classification and prediction models [32].

Random Forest is based on a collection of Decision Trees, a decision Tree divides data into categories by making sequential choices [32]. Each choice splits the data into subsets based on specific questions about the available variables. Random Forest creates a set of Decision Trees randomly by:

1) Randomly selecting samples with replacement from the original dataset (training data) for each decision tree.

2) Randomly selecting a subset of variables to build each tree.

Once the set of Decision Trees is constructed, Random Forest combines the individual tree predictions through voting or averaging to make a final decision for classification or prediction. Random Forest offers advantages such as model diversity and reducing overfitting, which occurs when the model becomes overly specialized to the training data. It also uses variable importance information to assess the impact of each variable on classification, providing valuable insights into the data [32]. Random Forest is widely used in various applications including image classification, word recognition, price prediction, and environmental analysis [32].

E. Extreme Gradient-Boosting

The gradient-boosting decision tree (GBDT) is the foundation of XGBoost, which was proposed by Tianqi Chen et al. [26]. A gradient-boosting algorithm built on a decision tree is called GBDT. Gradient boosting is an ensemble learning method that combines several weak classifiers into a stronger classifier during training. The objective of computing negative gradients is to enhance the following training cycle by minimizing the loss function and increasing the weight of the classified incorrectly classes. In contrast to GBDT, XGBoost incorporates a regularization technique to minimize model complexity, improve loss function smoothness, and prevent overfitting. To improve gradient boosting, locate the best-split solution, and promote scalability and efficiency, an approximation approach is also applied. XGBoost additionally enables parallel operations and an early stop to speed up the model operation. The model tree can stop to speed up training when the forecast result reaches the optimum. The model's classification accuracy can also be increased with XGBoost [27]. Zhao et al. [28] stated that XGBoost could effectively prevent the training model from over-fitting. Secondly, embedded parallel processing allows a faster learning speed.

Moreover, the XGBoost classifier can learn from imbalanced training data by setting class weight and taking ROC as evaluation criteria. XGBoost is one of the best classifiers for dealing with imbalanced datasets when the dataset classes with less variance [29]. Consequently, in this research, we chose it as the meta-learner of our proposed stacking model. The Extreme Gradient Boosting (XGBoost) is a machine learning algorithm used for classification and prediction tasks. It is an evolution of gradient boosting, combining multiple simple models into a strong and accurate model to enhance performance and accuracy.

XGBoost creates a sequence of weak models, like shallow decision trees, and boosts their performance. This boosting process focuses on the data predicted incorrectly by previous models, improving the overall performance of the model. Key features of XGBoost include:

1) Performance enhancement: XGBoost is known for achieving superior performance in various classification and prediction domains.

2) Multi-objective versatility: It can be used for both classification problems and numerical value prediction.

3) Overfitting prevention: Boosting parameters can be adjusted to limit overfitting and prevent excessive learning from training data.

4) Time and resource optimization: XGBoost strikes a balance between speed and accuracy, optimizing performance and resource utilization.

5) Handling missing data: XGBoost intelligently handles missing values without extensive preprocessing.

Overall, XGBoost is a powerful and popular tool in machine learning. It can effectively solve complex problems and improve predictive model performance.

F. Cross-Validation

Cross-validation is a popular data resampling method for evaluating a predictive model's generalization capacity and preventing overfitting by splitting the dataset into k-folds during training and testing iterations. The term "fold" here describes the quantity of generated subsets. The learning set's cases are randomly sampled for this division without being replaced. k-1 subsets comprise the training set and are used to train the model. The quality of this technology lies in storing unseen data at each new n-fold, which makes the prediction result more accurate. The model's performance is evaluated after being applied to the final subset, the "unseen dataset." This process is repeated until each of the k subsets has acted as a validation set [22]. Fig. 3 illustrates the cross-validation technique [30]. To achieve the best results, we used the cross-validation technique with the default four-fold iterations in our stacking model. We also used this technique on each of the base learners: RF, LR, and the Meta-Learner XGBoost via the Optimizer GridSearchCV to achieve the best results by using the sci-kit-learn library, which provides a random split into training and test sets that can be easily calculated with the train_test_split assistant function.

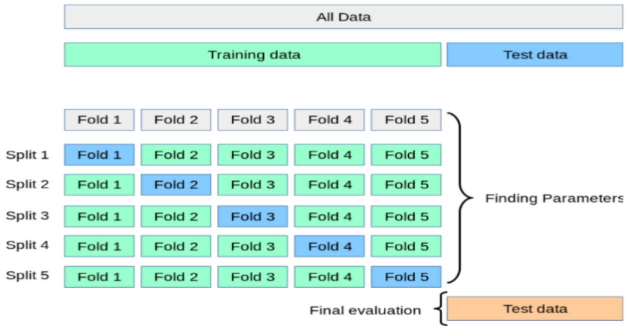

Fig. 3. Cross-Validation technique.

G. Study Dataset

The PIMA dataset, also known as the PIMA Indian Diabetes dataset, is a well-known dataset used in machine learning and data mining. It is named after the Pima Native American tribe in Arizona, USA. This dataset is commonly used for classifying the onset of diabetes in individuals by using medical diagnostic measurements [13]. It's available on Kaggle worldwide datasets repository, link: https://www.kaggle.com/datasets/uciml/pima-indians-diabetes-database.

This dataset consisted of 268 diabetic (positive = 1) and 500 non-diabetic (negative = 0) patients with eight Features presented below and in Table II. [13]:

1) Pregnancies: Number of pregnancies.

2) Glucose: Plasma glucose concentration measured two hours after an oral glucose tolerance test.

3) Blood Pressure: Diastolic blood pressure (mm Hg).

4) Skin Thickness: Triceps skinfold thickness (mm).

5) Insulin: Serum insulin level measured two hours after consumption (mu U/ml).

6) BMI: Body mass index (weight in kg / (height in meters) ^2).

7) Diabetes Pedigree Function: A function that estimates the likelihood of diabetes based on family history.

8) Age: Age in years.

TABLE II. PIMA DATASET INFORMATION

Data columns (total 9 columns):			
#	Column	Non-Null Count	Datatype
0	Pregnancies	768 non-null	int64
1	Glucose	768 non-null	int64
2	Blood Pressure	768 non-null	int64

5	BMI	768 non-null	float64
6	Diabetes Pedigree Function	768 non-null	float64
7	Age	768 non-null	int64
8	Outcome	768 non-null	int64

Pima dataset is commonly used to demonstrate various machine learning techniques, such as logistic regression, decision trees, support vector machines, and neural networks, for predicting the likelihood of diabetes based on these medical measurements. It's important to note that while the PIMA dataset is valuable for educational purposes and experimenting with machine learning algorithms, it is relatively small and has limitations, such as missing values and potential biases. Therefore, caution should be exercised when drawing conclusions or developing predictive models solely based on this dataset in real-world applications.

Statistical analysis provides essential tools for visualizing and understanding the dataset pattern to improve the data pre-processing and modeling process. Fig. 5 presents the statistical information of the features and data types found in the PIMA dataset. Table III shows the distribution of the features based on count, mean, standard deviation, maximum value, minimum value, and the percentile/quartile of each feature. The correlation coefficient has been used to measure the feature relationships in Fig. 6, and finally, outcomes values are presented in Fig. 4.

IV. EXPERIMENTAL SETUP

In this research, we used Jupyter Notebook to build the stacking ensemble model, using Microsoft Intel(R) Core i5-1035G7 CPU 1.20GHz and 8 Giga RAM. The public Pima Dataset has been selected, pre-processed, and cleaned up from a few defects, such as zero values in features columns, using the arithmetic mean for each column. The base learners' models were initialized with a Random Forest model using the Grid-search Hyperparamets Tunner through the following Hyperparameters: 'bootstrap training,' 'max of samples training,' 'max_features,' 'min_samples_leaf,' 'min_samples_split,' 'n_estimators.' Moreover. The second base learner, Logistic regression: "C," np. Logspace, "penalty":12. To address the problem of an imbalanced data set, which causes overfitting and inconsistent results, we applied the Extreme Gradient Boosting model as a meta-learner, which is counted on an ensemble learning method that allows us to deal with unbalanced dataset classes. A cross-validation technique was implemented for the proposed stacking model using default 5-k folds; they were also included through the GridSearchCV of hyperparameters for the base learners and the meta learner. Finally, the proposed stacking model was verified on a new dataset containing 100,000 records.

V. PERFORMANCE MEASURE

To assess the performance of classification models in machine learning and data analysis, we utilize the following metrics:

Accuracy: This metric represents the ratio of correctly predicted samples to the total number of samples. It measures the model's ability to accurately classify both positive and negative cases. However, it's important to note that accuracy can be misleading when dealing with imbalanced classes, as high accuracy can be achieved without focusing on positive classification [13].

$$Acc = \frac{TP+TN}{TP+TN+FP+FN} \qquad (1)$$

The output is either diabetic (+dm) or not diabetic (-dm).

- True positive (TP): Prediction is +dm and X is diabetic.
- True negative (TN): Prediction is -dm and X is not diabetic.

- False positive (FP): Prediction is +dm and X is not diabetic.
- False negative (FN): Prediction is -dm and X is diabetic.

Precision: Precision measures the accuracy of predicting positive cases. A high precision value indicates that the model correctly classifies cases as positive when it claims they are [13].

$$Precision = \frac{TP}{TP+FP} \tag{2}$$

The output is either diabetic (+dm) or not diabetic (-dm)

- True positive (TP): Prediction is +dm and X is diabetic.
- False positive (FP): Prediction is +dm and X is not diabetic.

Recall: Also known as sensitivity or true positive rate, recall measures the model's ability to identify all available positive cases. A high recall value signifies that the model can identify most positive cases [13].

$$Recall = \frac{TP}{TP+FN} \tag{3}$$

The output is either diabetic (+dm) or not diabetic (-dm)

- True positive (TP): Prediction is +dm and X is diabetic.
- False negative (FN): Prediction is -dm and X is diabetic.

Cohen's Kappa Score: This metric measures the agreement between two raters. In the context of evaluating classification models, Cohen's Kappa score gauges the agreement between the model's classification and the actual classification. It proves particularly useful when dealing with imbalanced classes or when the model randomly selects between classes [13].

$$CKS = \frac{P_0 - P_e}{1 - P_e} \tag{4}$$

TABLE IV. THE STACKING MODEL RESULTS

	Model	Score
0	Random Forest	0.750730
1	Logistic Regression	0.773706
2	Stacking Model	0.828571

TABLE V. BASE AND META LEARNERS RESULTS

Targets	Precision	Recall	F1-score support	support
0	0.80	0.95	0. 87	41
1	0.90	0. 66	0. 76	29
Accuracy			0.83	70
Macro avg	0.85	0.80	0.81	70
Weighted avg	0.84	0.83	0.82	70

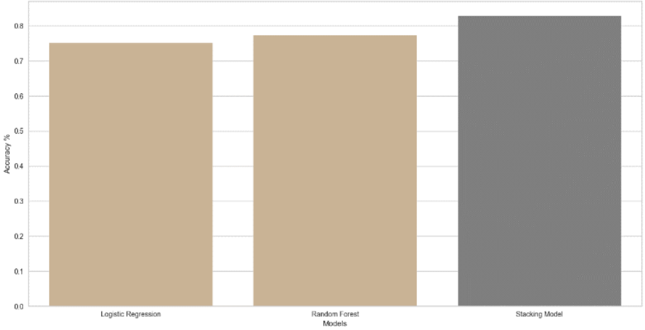

Fig. 7. Base and meta learners results.

where, P_0 represents the accuracy of the models and P_e denotes the agreement between the predicted and actual labels [13].

These metrics aid in comprehending the performance of classification models and identifying their strengths and weaknesses. It is recommended to employ a variety of these metrics to obtain a comprehensive understanding of the model's performance.

A. Validation Dataset

We validated our proposed stacking model performance on a new (binary classification outcomes) diabetes dataset. Diabetes prediction dataset (DPD) is a public dataset consisting of electronic health records (EHRs) that contain digital copies of health records for patients' medical history, diagnosis, therapy, and outcomes. EHRs data is gathered and kept by healthcare providers such as medical centers and hospitals as part of their usual clinical practice. DPD has approximately 100,000 patient records, contributing to significantly measuring the proposed model performance. Its available on Kaggle worldwide datasets repository, link: https://www.kaggle.com/datasets/iammustafatz/diabetes-prediction-dataset. DPD dataset features are shown in Table VI; moreover, the correlation heatmap between features is displayed in Fig. 8, whereas Table VII shows the results.

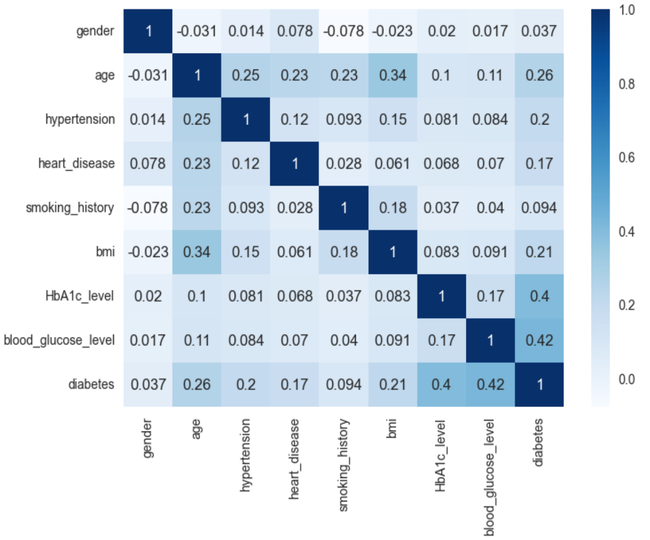

Fig. 8. DPD Dataset features correlation heatmap.

1	Logistic Regression	0.97012
2	Stacking Model	0.97160

VI. RESULTS

In this research, we built a stacking ensemble model to predict diabetes mellitus using a combination of machine learning models; where random forest, logistic regression models were applied as base learners and the extreme gradient Boosting model as meta learner, techniques such as cross validation and GridSearchCV were applied. We also replaced the zeros in the Pima dataset with values (median - mean) according to the types of data distribution with features columns (normal - skewed), as mentioned in [71] that if we remove zero values, the performance will improve. We obtained an accuracy of 83% in predicting diabetes mellitus with Pima dataset, and we also verified the efficiency of the proposed model on a large dataset containing approximately 100,000 records, with accuracy of 97%, where kapa Cohen score was 61% on Pima dataset, and 78% on DPD dataset. More details are discussed in the next paragraph. We observe that our proposed ensemble stacking model for predicting diabetes covers the shortcomings mentioned in Table I, such as the study of S. Härner and D. Ekman (2022) regarding the need for using hyperparameters search optimizer to improve model results. Moreover, a study of H. Syed and T. Khan (2020) about the geographical scope of the study dataset, where we used two different dataset scopes. The Table IV shows the detailed results of the proposed stacking model. In addition, Table V, Fig. 7 shows the base and meta learners results.

VII. DISCUSSION

A. *Results with XGBoost and GridSearchCV*

In this experiment, we utilized a combination of ML and DL classifiers to predict diabetes mellitus. Fig. 1 illustrates the stacking model methodology in this experiment, where we initiated each of the RF, LR models as base learners and the XGB classifier as a Meta-learner. At the same time, we used GridSearchCV Hyperparameters optimizer to find the optimal results for the Random Forest classifier using the following hyperparameters: bootstrap, max_features, min_samples_leaf, n_samples, split,n_estimators Moreover. The second base learner, Logistic regression: "C," np. Logspace, "penalty":12. To address the problem of an imbalanced data set, which causes overfitting and inconsistent results, we applied the Extreme Gradient Boosting model as a meta-learner, which is counted on an ensemble learning method that allows us to deal with unbalanced dataset classes. A cross-validation technique was implemented for the proposed stacking model using default 5-k folds; they were also included through the GridSearchCV of hyperparameters for the base learners and the meta learner. The results were as follows: The prediction accuracy of the stacking ensemble model on Pima dataset is 83%, kapa Cohen score 61%, where on DPD dataset was 97% accuracy and 78% kapa Cohen score. Table IV shows the results in detail. Fig. 9 displays the differences in results between Pima and DPD datasets.

B. *Comparative Analysis with Existing Work*

1) First study: S. Härner and D. Ekman (2022) [34] proposed an ensemble stacking model for predicting diabetes using a combination of machine learning models, including (Decision Tree and Naive Bayes models). The Pima dataset was used in this study, and the results indicated that the proposed stacking model can predict diabetes with 75.56% accuracy. In addition, it was mentioned that there were limitations during the study, such as not using an optimizer to search in hyperparameters to find the best results for base learners in the stacking model.

2) Second study: Patil et al. (2023) [20] Suggested an ensemble stacking model for predicting diabetes, using a combination of machine learning models such as (decision tree, naïve Bayes (NB), multilayer perceptron (MLP), SVM, and KNN). The Pima dataset was also used in this study. The results indicated that the stacking model can predict diabetes with 81.9% accuracy. In addition, we noticed that they never mentioned the cross-validation technique during the proposed methodology, which plays an essential role in building the stacking model. Moreover, no optimizer was used in searching the hyperparameters while training the base learners' models to get better results.

3) Third study: Lei Qin (2022) [35] devised an ensemble stacking approach to predict diabetes. They amalgamated various machine learning models—Logistic Regression, K-Nearest Neighbors, Decision Trees, Gaussian Naive Bayes, and Support Vector Machine (SVM). Utilizing the Pima dataset, their findings revealed that the stacking model achieved an 81.63% accuracy in diabetes prediction. However, the absence of an optimizer for hyperparameter tuning during base learner model training might have hindered the quest for better outcomes. Additionally, the limited size of the dataset posed a challenge, potentially impacting the attainment of optimal results.

4) Forth study: Kumari et al. (2021) [36] suggested an ensemble soft voting model for predicting diabetes, using a combination of machine learning models such as (Random

Forest (RF), logistic regression (LR), and Naive Bayes (NB)). The Pima dataset was also used in this study. The results indicated that the soft voting model can predict diabetes with 79.04% accuracy. Furthermore, it's important to highlight that the proposed methodology overlooked the inclusion of cross-validation, a crucial technique integral to ensuring robustness by assessing the performance of individual models across various subsets of the data, thereby refining their predictions' collective contribution to the ensemble. Additionally, the absence of an optimizer in the pursuit of hyperparameter tuning during the training of base learner models might have impacted the potential for achieving superior results.

We observe that our proposed ensemble stacking model outperforms in predicting diabetes accuracy compared to other proposed models in the [20], [34], [35], [36] studies, in our approach, we leveraged the GridsearchCV optimizer to search for the best hyperparameters for our base learners. Interestingly, this optimization technique wasn't utilized in either the First Study or the Second Study. This optimization significantly boosted our base learners' learning process, leading to extracting the most optimal results possible. Furthermore, the second and fourth studies overlooked the utilization of cross-validation—a critical technique for evaluating a predictive model's generalization capacity. In contrast, our model applied this method, dividing the dataset into k-folds during both training and testing. This implementation effectively evaluated and prevented overfitting, significantly enhancing our prediction model's performance.

Table VIII meticulously delineates and highlights the disparities and advantages between these studies, emphasizing the significant enhancements our approach brings to the table in comparison to the methodologies adopted in the First Study and the Second Study.

TABLE VIII. COMPARISON WITH EXISTING STUDIES

Authors	Techniques used	Dataset	Accuracy
S. Härner and D. Ekman (2022)	stacking ensemble approach (Decision tree (DT), Naïve Bayes (NB)), Cross-validation	Pima dataset	75.56%
Patil et al (2023)	Stacking ensemble approach (Decision tree (DT), Naïve Bayes (NB), multilayer perceptron (MLP), SVM, and KNN)	Pima dataset	81.9%
Lei Qin (2022)	Stacking ensemble approach (Logistic Regression, K-Nearest Neighbors, Decision Trees, Gaussian Naive Bayes, and Support Vector Machine (SVM))	Pima dataset	81.63%
Kumari et al (2021)	Soft voting ensemble approach (Random Forest (RF), Logistic regression (LR), and Naive Bayes (NB))	Pima dataset	79.04%
Our proposed model	Stacking ensemble approach (Random Forest, Logistic Regression, XGboost) GridSearchCV, Cross-validation.	Pima Dataset	83%
Our proposed model on the validation dataset	Stacking ensemble approach (Random Forest, Logistic Regression, XGboost) GridSearchCV, Cross-validation.	DPD Dataset	97%

VIII. CONCLUSION

Diabetes mellitus (DM) is a common disease that threatens the health of society, causing many serious diseases such as kidney failure, heart disease, and blindness. In this research, we proposed a novel stacking ensemble model to predict diabetes mellitus using a Pima dataset and combined machine learning models, where we used the Random Forest (RF) and Logistic Regression (LR) as base learners models and XGBoost as a Meta-Learner model. Moreover, we applied the cross-validation technique to get the optimal results in the RF, LR, models through the Grid Search optimizer technique. To avoid the problem of an imbalanced dataset, which causes overfitting and inconsistent results, we applied the XGBoost model as a meta-learner. However, the dataset has been cleaned from zero values that harm the prediction result, which was illogical to have zero values on some columns, like glucose in the blood. To address this problem, we replaced zero values with median and mean values based on the type of distribution (normal - skewed). The results indicate that our proposed stacking model can predict diabetes mellitus with an accuracy of 83% with the Pima dataset, and 97% on the DPD dataset. As recommendations, our stacking model can be applied in a diagnostic application for diabetes mellitus; in addition, it can be tested on a new huge and diverse dataset to obtain more accurate results. Moreover, we can use deep-learning models to generate new patterns that help us diagnose DM robustly, which also can happen with different types of diabetes, such as type 1 and type 2 diabetes and gestational diabetes.

***Abstract*—The rapid growth in internet traffic resulted to the emergence of network traffic categorization as a crucial area of research in network performance and management. This technological advancement has demonstrated its efficacy in aiding network administrators to identify anomalies within network behavior. However, the widespread adoption of encryption technology and the continual evolution of encryption protocols present a novel challenge in the classification of encrypted traffic. Addressing this challenge, this paper introduces an innovative methodology for classifying encrypted traffic by harnessing ConvNeXt and a fusion attention mechanism. Through the representation of traffic data as images and the integration of a bilinear attention mechanism into the model, our proposed approach attains heightened precision in the classification of encrypted network traffic. To substantiate the effectiveness of our methodology, experiments were conducted employing the publicly available ISCX VPN-nonVPN dataset. The experimental findings showcase superior recognition performance, underscoring the efficacy of the proposed approach.**

Keywords—Encryption traffic recognition; end-to-end; convolutional neural network; bilinear attention module

I. Introduction

As the number of Internet-connected devices continues to rise, the overall volume of network traffic is experiencing a significant expansion. Consequently, the significance of network traffic classification in contemporary network management has become increasingly evident. Moreover, with the prevalence of encrypted traffic in modern network applications, the task of classifying encrypted network traffic has assumed a pivotal role in network management. This technology has proven to be effective in assisting administrators in identifying and locating network anomalies, detecting network security threats, and is widely applied in specific areas such as network management, security monitoring, and Quality of Service (QoS) management.

In previous studies, researchers have proposed various methods to tackle the challenge of encrypted network traffic classification. These methods encompass a range of approaches, including port-based methods [1], payload-based traffic methods [2], and machine learning-based approaches [3]. These approaches have made notable contributions to the field, but they also possess certain limitations and drawbacks that warrant further exploration and improvement.

The port classification method, which is based on the transport layer, primarily categorizes ports according to the standards provided by the Internet Assigned Numbers Authority (IANA). For instance, ports like 80 and 443 are commonly utilized as defaults in web services. Port-based solutions, although simple and rapid, have proven insufficient in the present context due to the rise of network protocols and technologies like dynamic ports.

On the other hand, payload-based methods analyze traffic by examining keywords or patterns in data packets. However, the use of encryption technology for network traffic, driven by concerns for security and privacy, renders this method less applicable. In traditional machine learning methods, the performance of algorithms heavily relies on features designed by professionals for different types of traffic. However, in the complex traffic landscape of today, these designed traffic features are unable to cover all categories of traffic.

In recent years, with the significant development of deep learning in the field of image processing, many researchers have also applied deep learning to traffic classification. Deep learning reduces the need for manually designed features by directly learning features from the complex traffic patterns. This approach has shown promise in improving the accuracy and efficiency of traffic classification.

Nevertheless, with the rapid growth of the Internet and the increasing complexity of network applications, traditional traffic classification methods are facing more and more challenges. There is a need for innovative approaches and methodologies that can effectively handle the evolving nature of network traffic. Integrating interdisciplinary methods and exploring new theoretical frameworks may offer potential solutions to overcome these challenges and enhance the accuracy and efficiency of traffic classification in the future.

Deep convolutional neural networks (CNNs) have made remarkable progress in computer vision and natural language processing due to the advancements in deep learning. In the domain of network traffic classification, convolutional neural networks are also widely applied. A notable architecture ConvNeXt [4], has demonstrated comparable performance to models like ResNet while maintaining a relatively low number of parameters. Additionally, the self-attention mechanism, proposed by Google, has emerged as an alternative to traditional recurrent neural networks (RNNs), offering lower computational complexity and enhanced focus on crucial features.

The paper presents a novel model that integrates ConvNeXt with attention processes to improve the precision of network traffic categorization. This paper introduces many novel advancements:

- A bilinear attention mechanism module is proposed that effectively enhances the accuracy of convolutional neural networks in fine-grained tasks. This module enables the model to concentrate on important attributes and enhances the overall performance.
- A novel method for encrypting traffic classification based on the ConvNeXt fusion attention mechanism. By leveraging information from different scales in the network, ConvNeXt improves model performance. The introduction of the attention mechanism further enhances the model's ability to accurately learn key information in network traffic, prioritizing features that are crucial for classification.
- Adapt the new ConvNeXt model's parameters to traffic classification methods and conducting experiments on multiple datasets. Through these experiments, the feasibility and effectiveness of the proposed method in traffic classification tasks are demonstrated.

This paper is organized into four Sections. Section II provides a review of prior work and introduces the ConvNeXt network. Section III presents the proposed methodology, including the bidirectional linear attention mechanism module. Section IV focuses on the experimental aspects, describing the setup, dataset, and analysis of results. Finally, this work is concluded in the Section VI where possible future research directions are indicated.

II. Related Work

Previous studies have proposed numerous mature methods for network traffic classification. This section will elaborate on these classification methods, providing an overview of the approaches developed by researchers. It aims to provide a concise yet comprehensive understanding of the existing techniques used in this field.

A. The Methods Based on Payload and Machine Learning Approaches

With the emergence of new network protocols and dynamic ports, traditional port-based classification methods have become inadequate for the current network environment. In response, researchers have proposed Deep Packet Inspection (DPI) technology. DPI technology goes beyond traditional packet inspection of the first four layers of IP packets and reads and reassembles the application layer data to achieve traffic classification. P. Khandait et al. [5] introduced a system called Length-Based Matching (LBM) which includes an innovative acceleration approach for RegEx matching. Wang et al. [6] introduced a framework called lightweight Deep Packet Inspection (LW-DPI). S. Fernandes, R. Antonello et al. [7] introduced a Bitcoding system, which is a method for generating traffic classification signatures at the bit level using DPI. These paper findings have shown commendable performance. However, DPI technology faces two inherent challenges.

The first challenge is privacy concerns. In the current era of the Internet, users have become increasingly concerned about the privacy of their transmitted data. DPI technology involves reading the content of user transmissions, which inevitably violates user privacy. This raises ethical and legal concerns, as users expect their data to remain confidential and secure.

The second challenge is encryption. In response to the growing apprehension among users regarding the confidentiality of network traffic, a significant number of products have adopted the practice of encrypting their network traffic. According to Google's Transparency Report, over 90% of traffic in Google's products is encrypted. Encrypted traffic does not allow its data to be read, rendering DPI detection methods ineffective for classification. As more and more internet traffic becomes encrypted for security reasons, the limitations of DPI technology become increasingly apparent.

In light of these challenges, machine learning has emerged as a promising solution to the traffic classification problem. In stark contrast to DPI, machine learning-based methods classify traffic by learning statistical features from the traffic data. Classification schemes in classical machine learning are classified according to the degree of supervision, which includes supervised, unsupervised, and semi-supervised methods. Using supervised machine learning, K.L. Dias [8] explored real-time video traffic to categorize real-time applications. Feature engineering and classifier construction were employed by Cao et al. [9] in order to increase the accuracy of traffic categorization in the SVM-based model. Using K-means clustering as a tool for unsupervised learning, Wang et al. [10] examined the effectiveness of grouping network flows based on similarity using the algorithm. Höchst et al. [11] developed a method for classifying traffic flow by utilizing statistical characteristics derived from a neural autoencoder algorithm. Using semi-supervised learning, B. Ghita et al. [12] used two-phase learning approach for traffic classification. The semi-supervised method developed by F. Noorbehbahani et al. [13] consists of Clustering using X-means and propagation of labels. However, the effectiveness of machine learning-based classifiers heavily relies on well-designed features. Designing optimal features requires experienced professionals to invest a significant amount of time in manual design. Furthermore, the overall generalization performance of such methods is relatively poor. Additionally, due to the involvement of human intervention, these methods require professionals to adapt the classifier when the current environment changes or when it is not suitable for a different distribution of similar datasets. This reliance on human intervention can be a cumbersome and time-consuming process.

In summary, while DPI technology offers a more in-depth approach to traffic classification, it faces challenges related to privacy concerns and the rise of encryption. Machine learning-based methods, on the other hand, provide a promising alternative, but they require optimal feature design and can be limited by the need for human intervention.

B. The Methods Based on Deep Learning

In contrast to machine learning methods, deep learning methods eliminate the reliance on manually designed features. Deep learning operates through an end-to-end process, where raw data is directly inputted into the model. The model then autonomously learns its own features based on the outcomes, facilitating global optimization. Although deep learning necessitates a substantial amount of training data, it plays a pivotal role in reducing human intervention throughout the entire workflow. Employing specialized techniques for raw data processing can effectively enhance performance. Shapira, Tal [14] approached the problem by treating packet size and arrival time in network traffic as correlation graphs. They eliminated packets larger than 1500 bytes, focusing on packets arriving within the first 60 seconds. This mapping generated a 1500x1500 histogram, which was then fed into a convolutional neural network based on the LeNet-5 architecture for classification. Lan, Jinghong [15] and others tackled the issue from multiple feature levels, employing different extraction methods for each feature and subsequently processing the combined features. D'Angelo, Gianni [16] proposed a method of data collection through window sampling, followed by statistical analysis of its features. This approach primarily involved counting various data exchanged within the window, such as the number and length of packets. The information was then inputted into an SAE network for classification.

Achieving satisfactory results can also be accomplished by combining multiple models to identify and classify traffic features. Wang, Wei [17] [18] transformed traffic into images and employed one-dimensional convolutional neural networks and representation learning. Both methods demonstrated strong performance. Maonan, Wang [19] combined ResNet and AutoEncoder models for classification. They divided the data, extracting the original data into images as input for feature extraction in the ResNet network. They also inputted the statistical features of the data flow into a network based on AutoEncoder to extract statistical features. The two sets of features were then combined into complex features for classification.

Additionally, attention mechanisms have proven effective in enhancing model performance. Attention mechanisms can be integrated with traditional convolutional neural networks or recurrent neural networks to augment the capabilities of the original models. Barut, Onur [20] incorporated position and time information for each bit into the original PCAP stream data. They utilized a model that combines multi-head self-attention pooling and 2D CNN for classification. Liu, Xun [21] utilized intercepted packets as input data and employed a model that combines attention and GRU for classifying network traffic. Xiao, Xi [22] utilized side channel data to improve algorithm performance. They inputted this data into a model consisting of RNN and attention mechanisms for classification.

C. ConvNeXt Convolutional Neural Network

With the continuous advancements in deep learning, the field of image classification has witnessed the emergence of new algorithm networks. Among these networks, Swin Transformer has been at the forefront of fine-grained classification since 2020, demonstrating exceptional performance and gradually replacing the conventional convolutional neural networks. However, in 2022, scholars such as Liu and Zhuang [4] proposed ConvNeXt, a novel approach that builds upon the Swin Transformer by studying its layer structure, downsampling methods, activation functions, and data processing techniques. This research has led to significant improvements in the accuracy of convolutional neural networks, reaffirming their crucial role in image classification.

The network architecture of ConvNeXt is not notably distinctive, as it integrates various components that have been previously employed in research. Fig. 1 exhibits similarities to the layer arrangement of ResNet50. ConvNeXt incorporates downsampling techniques and layer normalization, while also sharing commonalities in its recurrence approach and structural combination with ResNet50. Fig. 2 can be juxtaposed with the layer architecture of MobileNetV2. Inverted residuals and the Swin Transformer's MLP structure are combined to form ConvNeXt blocks. ConvNeXt improves the accuracy of coarse-grained image categorization by combining the processing methods of the Swin Transformer with the inherent properties of convolution.

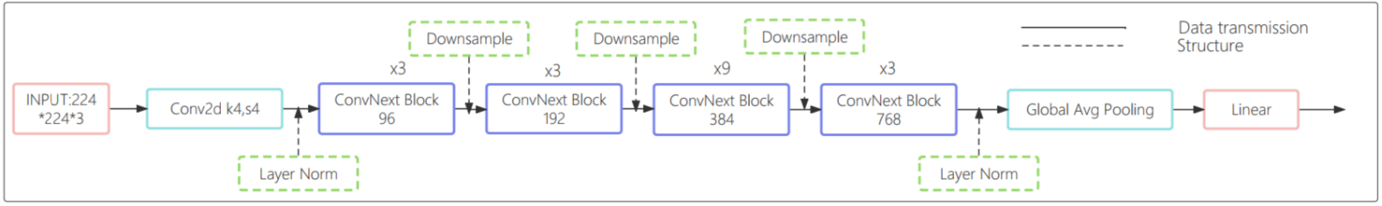

Fig. 1. Network diagram chart of ConvNeXt.

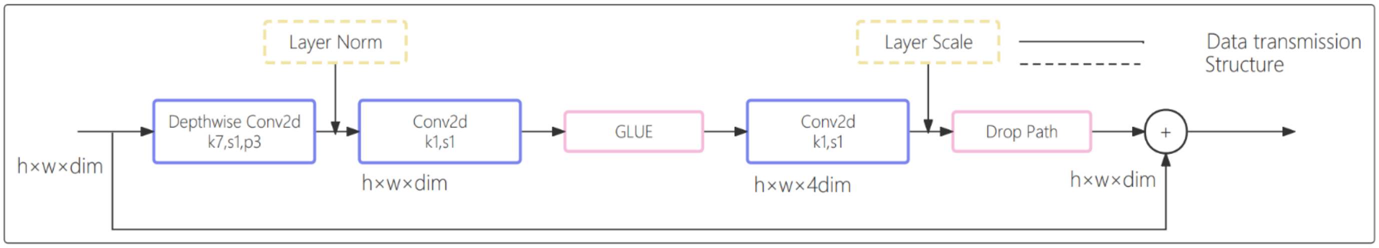

Fig. 2. Structure diagram of ConvNeXt block.

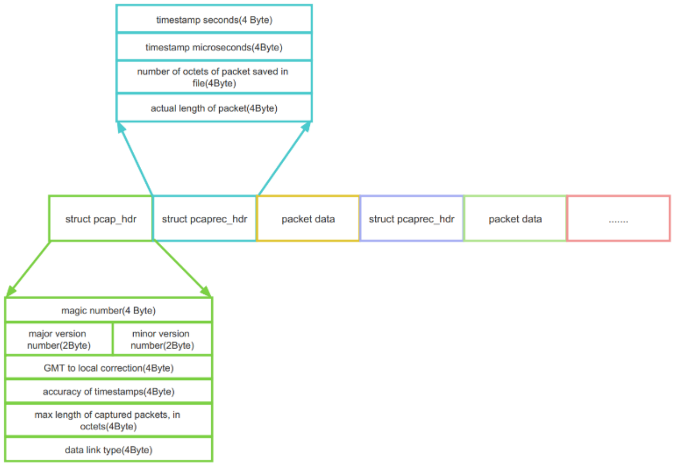
III. Methods

This section provides an overview of the dataset utilized in this paper, the data processing methodology, the construction of the model, and the parameter configuration within the model.

A. Data Preprocessing

The dataset utilized in this work consists of capture files, with each file corresponding to a distinct program, traffic type, and encryption method. These capture files are stored in the PCAP format. The initial 24 bits of a PCAP packet contain crucial data information, including a 4-byte file magic number, a 2-byte major version number, a 2-byte minor version number, a 4-byte local timezone, a 4-byte timestamp, a 4-byte maximum storage, and a 4-byte link type. Subsequently, each file consists of a combination of packet headers and packet data. The packet header is composed of four 4-byte fields, namely the high-order timestamp, low-order timestamp, current packet length, and offline data length. The data structure is visually depicted in Fig. 3.



timestamp seconds(4 Byte)
timestamp microseconds(4Byte)
number of octets of packet saved in file(4Byte)
actual length of packet(4Byte)
struct pcap_hdr
struct pcaprec_hdr
packet data
struct pcaprec_hdr
packet data
....
magic number(4 Byte)
major version number(2Byte)
minor version number(2Byte)
GMT to local correction(4Byte)
accuracy of timestamps(4Byte)
max length of captured packets, in octets(4Byte)
data link type(4Byte)

Fig. 3. Structure of pcap file.

In the data cleaning section, this paper undertakes the removal of IP addresses and port information from the source data. This step is crucial to prevent the model from relying on these details and making incorrect judgments, thereby eliminating biases associated with IP addresses and ports. Additionally, as the data remains in the PCAP format even after being divided into flows, the PCAP header also needs to be eliminated during the data cleaning process.

This work utilizes the five-tuple {source IP, source port, destination IP, destination port, protocol} to divide each PCAP file into numerous unidirectional flows. Subsequently, the data undergoes transformation into images through the following key steps:

1) Data refinement: Duplicate or blank data can significantly impact the training of deep learning models, introducing biases in learning features and reducing classification accuracy. Hence, it is imperative to remove any duplicate or blank content present in certain packets.

2) Privacy processing: In order to diminish the model's reliance on IP addresses within the data, this paper employs zero-padding on the IP-related information by filling them with zeros.

3) Data trimming: Based on data analysis, to comprehensively capture feature information of network traffic and achieve more accurate network traffic classification, this paper trims the payload data to a fixed length of 576 bytes. If the file size exceeds 576 bytes, the excess portion is deleted. Conversely, if the length is less than 576 bytes, zeros are added at the end.

4) Data transformation: Each data segment with a length of 576 bytes is transformed into a 24x24 image to facilitate processing by the model.

The aforementioned steps ensure the cleanliness, privacy protection, and appropriate formatting of the data, enabling effective analysis and classification of network traffic. By applying the above processing methods, 24x24 images of each category will be obtained, and some of the images are shown in Fig. 4.

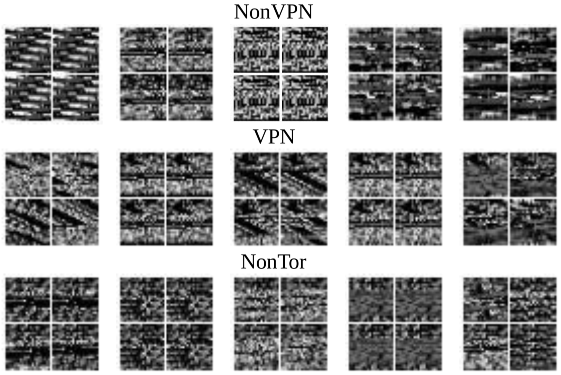


Fig. 4. Partial preprocessed images.

B. Model Structure

The primary model utilized in this paper is ConvNeXt-Tiny, selected for its lower parameter count and enhanced feature extraction capabilities, thereby reducing hardware requirements during training. In the task of traffic classification, the information content of the split pcap files is limited. To maximize the inclusion of information, the length of the traffic is truncated to 576 based on an analysis of the length feature of the original data flow. Subsequently, it is transformed into a 24x24 image.

1) ConvNeXt model incorporating attention mechanism: The network structure of ConvNeXt comprises four different kinds of blocks, each with a different number of channels. Each block type undergoes a specific number of cycles: the first kind goes through three times, resulting in a feature map with 96 dimensions, the second kind goes through three times, resulting in a feature map with 192 dimensions; the third kind goes through three times, resulting in a feature map with 384 dimensions, and the fourth kind goes through three times, resulting in a feature map with 192 dimensions768. Before each block, the feature map is subjected to a downsampling procedure, which decreases the final output size (W, H) by half compared to the original size, while simultaneously increasing the output dimension by convolution. Adding weight values to channels is crucial in this scenario.

Precise localization of the target is crucial in tasks that involve fine-grained categorization, as it enables successful feature extraction. In order to enhance the network's capacity to learn particular target features during training, we provide two methods called Embedded Block Attention (EBA) and Sequential Block Attention (SBA), both of which rely on embedded locations. The ConvNeXt-Tiny network incorporates the attention mechanism into each block, enabling the attention mechanism to be integrated into the internal loop of each block type. The term used to describe this integration is EBA. The feature maps of inverted residuals are subjected to attention weights, and attention parameters within each block are periodically trained. This process results in the formation of a feature map with attention weights for each block's cyclic object. This method allows for the iterative training of attention settings. To obtain a comprehensive depiction of the altered structure of the ConvNeXt Block, refer to Fig. 5.

$$\boldsymbol{F_{a1}} = \sigma(\mathrm{Con\,v}(\mathrm{GeL\,U}(\mathrm{L\,N}(\mathrm{Con\,v}(\mathrm{Conca\,t}(\mathrm{Avgpoo\,l}(\boldsymbol{F}), \mathrm{Maxpoo\,l}(\boldsymbol{F}))))))) = \sigma(\boldsymbol{W_1}(\mathrm{GeLU}(\mathrm{LN}(\boldsymbol{W_0}(\mathrm{Concat}(\boldsymbol{F^c_{avg}}, \boldsymbol{F^c}_{\max})))))) \quad (1)$$

In contrast to EBA, the integration of the attention mechanism through SBA in ConvNeXt-Tiny does not disrupt the cyclic process of the blocks. Instead, it applies the attention mechanism to the feature maps after the cyclic process of each type of block. This allows the training of attention weights to take into account the entire cyclic feature map, rather than individual blocks. As a result, the number of training iterations required for attention parameters is reduced. Additionally, to address challenges such as degradation, gradient explosion, and gradient vanishing in deep networks, residual shortcuts are employed to add the downsampled feature maps to the output of the attention module based on channels. For a more detailed illustration of the specific structures, (see Fig. 6).

When incorporating the attention mechanism using SBA, it is crucial to observe that the remaining connections of attention, except for the third kind of block, are removed (see Fig. 6). The rationale behind this decision stems from the observation that the third kind of block present in all iterations of ConvNeXt experiences the greatest extensive amount of iterations, specifically nine cycles in the Tiny version. Introducing external residual connections would result in the inclusion of a significant amount of untreated and superficial semantic information into the attention feature map. The integration would ultimately diminish the network's overall ability to extract features and learn.

2) Bilinear attention mechanism: Convolutional Block Attention Module (CBAM)[23] is enhanced in this paper, and a new attention mechanism is proposed to improve the accuracy of ConvNeXt. The attention mechanism also allocates feature weights in ConvNeXt-Tiny. This section offers a comprehensive overview of the planned CBAM enhancement.

This paper proposes a Bilinear CBAM (BLCBAM) by enhancing the CBAM utilizing the bilinear method, building upon the concept of bilinear CNN. Moreover, the Channel Attention Module (CAM) of CBAM incorporates the feature information from both the channel and spatial dimensions to boost its performance. In order to enhance the algorithm described in this research, it is important to take into account the bilinear nature of BCNN. The first max pooling and average pooling processes are kept concurrent to retain the preservation of feature information from the original maps to the maximum degree feasible. Subsequently, the output results are combined together according to the channel. The fully connected layer in the original architecture is substituted with a 1x1 convolutional layer, and batch data processing is conducted using layer normalization. ConvNeXt employs the Gaussian Error Linear Unit (GeLU) activation function, which is identical to the one used in the Swin Transformer. CBAM replaces the ReLU activation function with GeLU, which includes stochastic regularity. The proposed CBAM configuration is shown in Fig. 7.

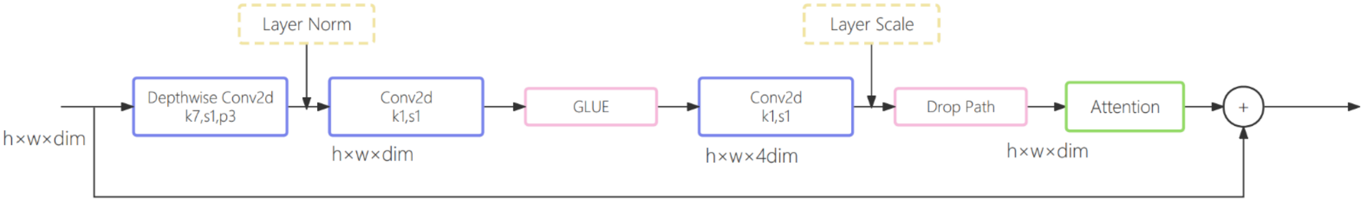

Fig. 5. Structure chart of EBA.

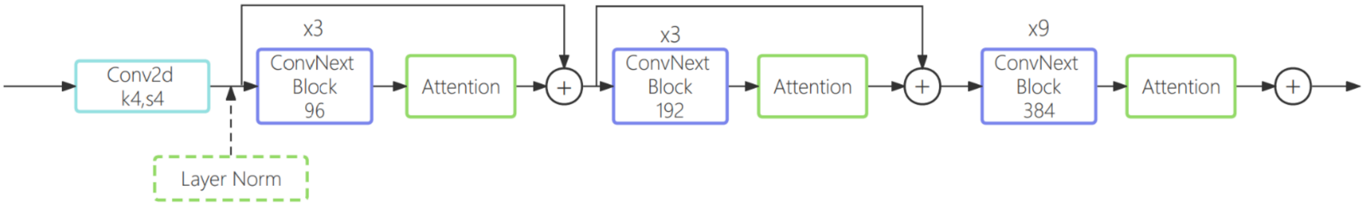

Fig. 6. Structure chart of SBA.

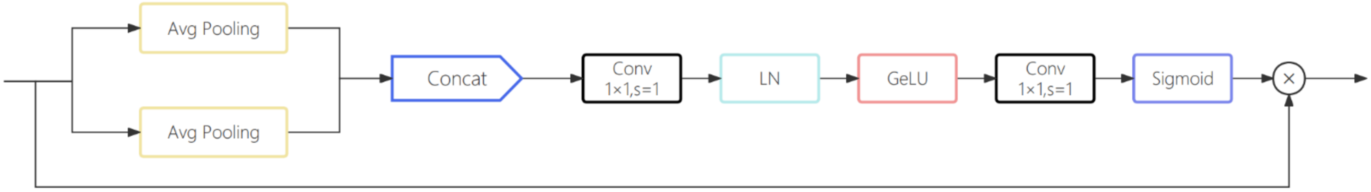

Fig. 7. Enhanced CAM structure.

Eq. (1) depicts the manner in which the network processes input data. The symbol F_{a1} denotes the map of feature generated by Enhanced CAM structure. Conv refers to the convolution operation and GeLU refers to Gaussian Error Linear Units, which are a type of activation functions. Once GeLU function applies, F becomes a tensor of shape $F \in \mathbb{R}^{(B,2C/r,W,H)}$. Upon the application of the function of sigmoid activation, F becomes a tensor of shape $F \in \mathbb{R}^{(B,C,W,H)}$. Avgpool is an abbreviation for average pooling, while Maxpool is an abbreviation for maximal pooling.

Subsequently, we incorporate bilinearity into the SAM. This work presents a new technique for extracting spatial attention, building upon existing methods. Firstly, we perform 1x1 and 3x3 convolution operations separately on the input feature maps. This allows model to obtain spatial features at different scales. Then apply layer normalization and the $GeLU$ activation function mapping to these two sets of features. Subsequently, individual channels are reduced in size using a convolution of 1 x 1. The two individual data channels are combined to generate spatial attention features at many scales. To create feature maps that combine spatial and channel weight features, features are multiplied by the feature map of channel attention weights. The data is then subjected to batch processing, and layer normalization is employed for two reasons. Firstly, we leverage the research findings of ConvNeXt, which utilizes layer normalization for batch processing in Transformer models. By applying layer normalization to the attention information in this paper, we align with the data processing method of ConvNeXt. Secondly, while batch normalization is widely used in CNNs and yields better results with larger batch sizes, Nevertheless, the hardware imposes a constraint on the batch size, which is independent of the layer normalization. When choosing the convolution kernel size, we opt for 1x1 and 3x3 convolutions. The 1x1 convolution not only allows us to obtain spatial features at different scales but also reduces the complexity and computational cost comprising the full network. Additionally, most of GPUs have implemented optimized algorithms for performing 3x3 convolutions, further improving efficiency. Based on the considerations mentioned above, we have optimized and modified the SAM structure accordingly. The improved SAM structure is illustrated in Fig. 8. The network structure's handling of input data is outlined in Eq. (2) to Eq. (4).

$$\boldsymbol{F_{a2}} = Sigmoid(\boldsymbol{F_1} \otimes \boldsymbol{F_2}) \quad (2)$$

$$\boldsymbol{F_1} = Conv_{1\times1}(GeLU(LN(Conv_{1\times1}(\boldsymbol{F})))) \quad (3)$$

$$\boldsymbol{F_2} = Conv_{1\times1}(GeLU(LN(Conv_{3\times3}(\boldsymbol{F})))) \quad (4)$$

F_{a2} refer to the map of feature generated by the structure of SAM. $Conv_{1\times1}$ refers to convolution using a 1 × 1 kernel. $Conv_{3\times3}$ refers to convolution using a 3 × 3 kernel. Once the $GeLU$ activation function applies, F has dimensions of $F \in \mathbb{R}^{(B,C/r,W,H)}$. Upon the application of the sigmoid activation function, F has dimensions of $F \in \mathbb{R}^{(B,1,W,H)}$.

In previous studies, attention mechanisms were primarily utilized to allocate weights solely between channel attentions, neglecting the consideration of spatial attention. This paper introduces a new and unique bilinear attention mechanism that consists of two separate branches. The first branch is tasked with supplying channel weights, and the secondary branch is dedicated to producing spatial weights. The initial CBAM process utilized a sequential processing approach. However, as we sought to enhance the algorithm's performance for fine-grained classification tasks, it became crucial for the network to accurately extract attention features. Consequently, we replaced the sequential processing with parallel processing to simultaneously train both channel and spatial attention. This approach ensures that multi-scale features of the target are obtained while preserving sufficient semantic information. For a detailed illustration of the specific attention network structure, please refer to Fig. 9.

The network indicated above demonstrates the processing of input data as depicted in Eq. (5):

$$F_{\text{out}} = (F_{a1} \otimes F_{\text{in}}) \otimes F_{a2} \oplus F_{\text{in}} \quad (5)$$

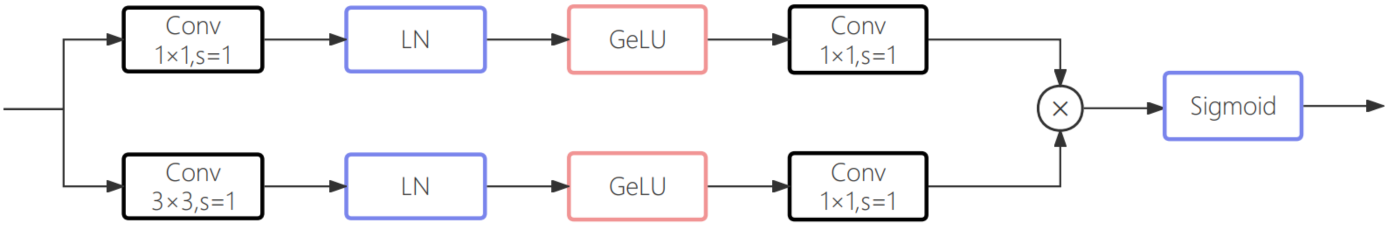

Fig. 8. Enhanced SAM structure.

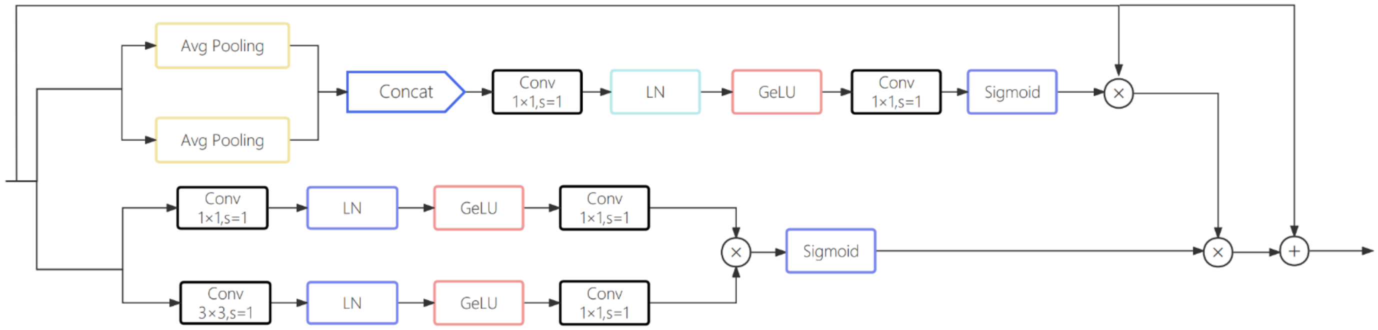

Fig. 9. Enhanced CAM structure.

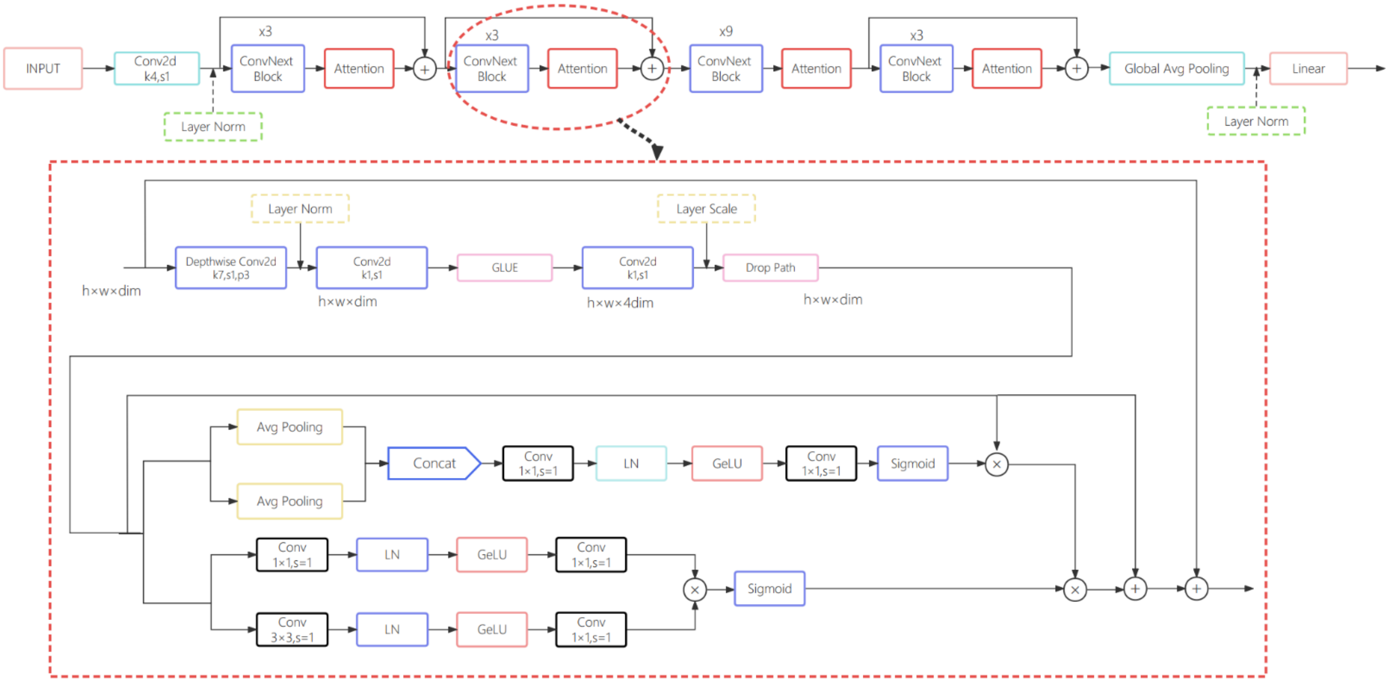

Fig. 10. ConvNeXt with BLCBAM model structure.

F_{a1} refer to the map of feature produced by CAM, F_{a2} refer to the map of feature produced by SAM, F_{in} refer to the input of BLCBAM map of feature, and F_{out} refer to the output of BLCBAM map of feature.

3) ConvNeXt Based on multiscale bilinear attention mechanism: Utilizing the proposed EBA, SBA, and multi-perspective attention framework, this paper presents a ConvNeXt model framework that incorporates bilinear attention. Through the training process, we not only extract multi-scale attention features from the feature maps iteratively but also effectively capture the fine-grained characteristics of the target.

Although ConvNeXt-Tiny already employs minimal parameters, the downsampling layers in its structure can still result in significant information loss after the conversion to images. Hence, each downsampling layer in the model is removed to preserve more information. This step enhances the information extraction ability of the embedded attention mechanism. Furthermore, considering that two-dimensional convolution can increase the dimensions of the data but may lead to information loss during convolution, the initial convolution stride in the relevant convolution modules of the original model is set to 1. This effectively strengthens the convolutional neural network's perception of the data.

Fig. 10 showcases how the proposed model structure seamlessly integrates the aforementioned components into the ConvNeXt network. As the network size and depth increase, the addition of attention modules theoretically enhances the accuracy of fine-grained classification.

IV. Implementation

In this section, the paper primarily introduces the experimental setup and implementation of the dataset, as well as presents the experimental results.

A. Dataset

To ascertain the viability of the model proposed in this paper, we conducted validation using meticulously labeled datasets obtained from the University of New Brunswick (UNB).

The datasets consist of the "ISCX VPN-nonVPN traffic dataset" (ISCX-VPN) and the "ISCX Tor-nonTor dataset" (ISCX-Tor). The primary data categorization of this dataset is displayed in Table I.

TABLE I. THE ORIGINAL DATA TYPES OF THE DATASET

Traffic Class	Application
Chat	ICQ,AIM,Skype,Facebook,Hangouts
Email	SMPT,POP3,IMAP
File transfer	Skype,FTPS,SFTP
VOIP	Facebook,Skype,Hangouts,Voipbuster
P2P	Torrent
Streaming	Viemo,Youtube,Netfilx,Spotify
VPN-Chat	ICQ,AIM,Skype,Facebook,Hangouts
VPN-Email	SMPT,POP3,IMAP
VPN-File	Transfer Skype,FTPS,SFTP
VPN-VOIP	Facebook,Skype,Hangouts,Voipbuster
VPN-P2P	Bittorrent
VPN-Streaming	Viemo,Youtube,Netfilx,Spotify

B. Data Classification Setting

After data processing, a comprehensive dataset containing all the classes was obtained for analysis in this paper. However, careful observation revealed an inherent imbalance within the dataset, which could potentially impede the overall classification performance. To address this concern, we undertook the task of reclassifying the data labels and subsequently created a balanced dataset. This was achieved by implementing the random undersampling method, which aims to maintain an equitable distribution of initial samples across each category.

The random undersampling technique functions by reducing the number of samples in the majority class, thereby rectifying the imbalance. Specifically, for the samples belonging to the majority class, random undersampling randomly selects a subset of them, ensuring that the sample size of the majority class approximates or equals that of the minority class. By adopting this approach, the model is prevented from exhibitingan excessive bias towards the majority class, consequently improving the overall classification performance. The utilization of random undersampling as a means to address the imbalanced dataset is an effective strategy that has been widely employed in various studies. Its application in this paper serves to mitigate the potential pitfalls associated with imbalanced data, ultimately enhancing the model's classification capabilities. The data classification after filtering is shown in Table II.

This paper encompasses the design of two distinct multi-class classification problems, each serving a specific purpose within the research framework:

Traffic category recognition: The primary objective of this task is to accurately identify and classify traffic based on three encryption techniques: nonVPN, VPN, and Tor. To facilitate this, the paper generated three multi-class datasets utilizing the processed data.

Application recognition: In order to assess the model's generalization capabilities, a dedicated application dataset was devised. The model underwent training on this dataset using transfer learning techniques, followed by fine-tuning using a limited amount of data from other protocols. This particular method sought to assess the model's competence in identifying various applications.

As previously mentioned, meticulous efforts were made to create filtered and balanced datasets for each sub-problem. Subsequently, the data was divided into a 90% training set and a 10% test set ratio, ensuring a robust evaluation of the model's performance.

C. Evaluation Metrics

In this paper, the evaluation of model performance is based on two key metrics: accuracy and recall. Accuracy is defined as the ratio of correctly predicted samples to the total number of predicted samples. It provides an overall measure of the model's correctness in predicting the class labels. On the other hand, recall assesses the model's ability to accurately identify positive samples. It quantifies the proportion of true positive samples correctly identified by the model. The formal definitions are as follows:

$$\text{Accuracy } = \frac{\sum_{i\in \text{ classes}} TP_i}{\sum_{i\in \text{ classes}} (TP_i+FP_i)} \tag{6}$$

$$\text{Recall } = \frac{TP}{TP+FN} \tag{7}$$

These evaluation metrics provide valuable insights into the model's overall accuracy and its ability to correctly identify positive samples. They are crucial in assessing the model's performance across different classification tasks.

D. Experimental

In this section, we have made necessary adaptations to the original model to address the specific requirements posed by smaller datasets. The original base structure, designed for classification tasks on larger datasets, needed adjustments to accommodate the significantly smaller data provided in this paper. Modifications were made to the initial convolutional parameters, and a stacking times ratio of 1:1:3:1 was implemented to prevent overfitting and safeguard the integrity of experimental accuracy.

Furthermore, to augment the model's perceptual prowess and maximize the retention of vital image information, while simultaneously safeguarding essential details, we made adjustments to the convolutional parameters and downsampling layers, as explicated in the preceding sections.

The primary objective of these adaptations is to make the model more adept at handling smaller datasets while improving its ability to perceive and interpret images. By doing so, we aim to enhance the model’s overall classification performance and ensure its suitability for the task at hand.

This paper presents a performance comparison between the improved structure and the original structure, as shown in Table III. The improved structure exhibits significant improvements in both accuracy and recall on non-VPN and VPN data. Particularly, the improved structure shows a more pronounced improvement on encrypted data compared to non-encrypted data. The average improvement rate of the improved structure is 14.75%.

For the adjusted model structure, the BLCBAM attention module is incorporated and used for classifying both encrypted and non-encrypted traffic. The traffic data is processed and transformed into images, which are then fed into the model for classification. The specific experimental results can be seen in Table IV.

TABLE IV. PERFORMANCE IMPROVEMENT AFTER ADAPTATION

	Non-VPN		VPN	
	Ac(%)	Re(%)	Ac(%)	Re(%)
Original version	78.53	77.95	82.35	81.32
Improved version.	94.35	94.67	95.14	95.3
promotion	15.8	16.7	12.6	13.9

The results in Table IV demonstrate that this paper achieves a recognition accuracy of 98.62% for non-VPN traffic, 97.43% for encrypted VPN traffic, and 98.33% for Tor traffic on this dataset. Compared to previous studies, the improved model in this paper shows a 5% improvement relative to the model proposed by Draper-Gil et al. [24] that uses CAE and CNN. Furthermore, compared to the model proposed by He H Y et al. [26] that combines Transformer and transfer learning, the model in this paper exhibits more accurate performance.

TABLE V. ADAPTATION RESULTS FOR SINGLE APPLICATION RECOGNITION

Classification	Accuracy (%)			
Chat	Training/Test	Non-VPN	VPN	Non-Tor
	Non-VPN	98.6	82.9	-
	VPN	75.7	96.4	-
	Non-Tor	-	-	-
Email	Training/Test	Non-VPN	VPN	Non-Tor
	Non-VPN	96.2	89.2	-
	VPN	69.7	98.2	-
	Non-Tor	-	-	-
File Transfer	Training/Test	Non-VPN	VPN	Non-Tor
	Non-VPN	98.8	73.9	81.6
	VPN	60.1	96.9	67.3
	Non-Tor	79.2	65.8	97.6
Streaming	Training/Test	Non-VPN	VPN	Non-Tor
	Non-VPN	99.8	71.9	70.6
	VPN	72.1	96.8	54.5
	Non-Tor	83.1	92.8	94.8
VoIP	Training/Test	Non-VPN	VPN	Non-Tor
	Non-VPN	95.6	69.4	85.2
	VPN	67.8	98.1	80.4
	Non-Tor	89.1	83.8	93.3

The comparison of traffic classification using different algorithms has been presented in the Table VI. The C4.5 machine learning algorithm exhibited suboptimal performance in accurately identifying both VPN and non-VPN data streams, with a precision value below 85%. Our proposed strategy in the domain of deep learning has exhibited a substantial enhancement in accuracy. Compared to algorithms utilizing a single model, the approach presented in this paper achieved an approximately 5% enhancement in VPN accuracy and a substantial 12% improvement in Non-VPN accuracy. Regarding the composite model approach, the method proposed in this paper exhibits similar performance in the VPN domain, while achieving an approximately 10% improvement in the Non-VPN domain. It is evident that, in comparison to prior research, the proposed method in this paper has achieved noteworthy advancements in traffic classification.

In certain real-world scenarios, it is necessary to identify whether specific protocols or applications exist within a large volume of network traffic. This paper conducts experiments specifically for this situation and trains the model using different encryption techniques to identify specific traffic categories. Transfer learning is employed using a small amount of data for the target protocols to improve the model's transferability. The results of the experiment are displayed in the Table V.

TABLE VI. OVERALL RESULT ON VARIOUS ALGORITHMS

Method	**VPN**		**Non-VPN**	
	Accuracy(%)	**Recall(%)**	**Accuracy(%)**	**Recall(%)**
C4.5 [27]	78.2	81.3	84.3	79.3
ID CNN [17]	92	95.2	85.8	85.9
SAE+1DCNN [28]	97.8	96.3	86.7	88.8
This Paper	97.4	98.2	98.6	98.9

By taking the average of the results for each encryption technique and considering only the cases where the test set has the same traffic category and encryption technique as the training set, the average accuracy obtained in this paper is as follows: 97.8% for non-VPN traffic, 97.28% for VPN traffic, and 94.9% for Tor traffic. Considering the overall average accuracy based on the above values, the overall average accuracy obtained in this paper is 96.66%. This paper has achieved significant success in describing and identifying internet traffic categories transmitted through different encryption techniques.

V. CONCLUSION

This paper presents a novel approach for traffic classification, employing ConvNeXt and a bilinear attention mechanism, with the goal of automatically extracting and analyzing traffic features to achieve accurate traffic characterization and application classification. The proposed method entails the conversion of data traffic into image representations, followed by the utilization of the ConvNeXt framework model, coupled with the bilinear attention mechanism, to enhance the model's perception of image features and optimize classification accuracy. Through extensive experimentation on various meticulously designed datasets, this paper thoroughly examines the performance of the proposed method and conclusively demonstrates its remarkable efficacy in accurately classifying diverse internet traffic categories.

Information Engineering College, Wuhan Design Engineering College, Wuhan 430000, Hubei, China[2]

Abstract—**The Internet of Things (IoT) significantly impacts communication systems' efficiency and the requirements for applications in our daily lives. Among the major challenges involved in data transmission over IoT networks is the development of an energy-efficient clustering mechanism. Recent methods are challenged by long transmission delays, imbalanced load distribution, and limited network lifespan. This paper suggests a new cluster-based routing method combining Tabu Search (TS) and Ant Colony Optimization (ACO) algorithms. The TS algorithm overcomes the disadvantage of ACO, in which ants move randomly throughout the colony in search of food sources. In the process of solving optimization problems, the ACO algorithm traps ants, resulting in a considerable increase in the time required for local searches. TS can be used to overcome these drawbacks. In fact, the TS algorithm eliminates the problem of getting stuck in local optima due to the randomness of the search process. Experimental results indicate that the proposed hybrid algorithm outperforms ACO, LEACH, and genetic algorithms regarding energy consumption and network lifetime.**

Keywords—Internet of things; clustering; data transmission; energy efficiency; ant colony optimization algorithm

I. Introduction

The Internet of Things (IoT) envisions the seamless integration of smart devices. The IoT enables smart objects to interact among themselves, aggregate information within a network, and combine digital and physical objects to create unique experiences that meet certain end-user requirements [1, 2]. Communication takes place between people and things and between things themselves. A broad range of real-world applications has been supported by data aggregation in terms of reducing energy consumption by Wireless Sensor Networks (WSNs). For example, when it is necessary to monitor an area for a particular purpose continuously, multiple sensor nodes may be placed in the area [3, 4]. The information collected from the sensors is gathered, summarized, and transmitted to the base station to address specific questions. When the surrounding environment remains relatively stable, individual sensor data may show a high level of temporal correlation, indicating that two successive values are unlikely to differ significantly. Due to the high energy consumption of such an application, it becomes necessary to minimize transmission sensor data with no changes [5].

The field of Artificial Intelligence (AI) has been rapidly advancing in recent years, with applications in various domains such as finance, healthcare, and the IoT. One area of interest is the use of deep learning-based models for stock price prediction, as discussed in research [6]. Another area of research is the design of efficient data collection methods for IoT networks, such as the use of unequal sized cells based on cross shapes proposed by Taami, et al. [7]. In the healthcare domain, Soleimani and Lobaton [8] proposed a phase-based interpretability and multi-task learning approach to enhance inference on physiological and kinematic periodic signals. In the energy sector, Bagheri, et al. [9] developed a data conditioning and forecasting methodology using machine learning for production data on a well pad. In the field of wireless communications, Webber, et al. [10] proposed a probabilistic neural network for predicting idle slot availability in WLANs, while in other studies, they explored the use of machine learning for human activity recognition [11], vaccine candidate prediction [12], network slicing [13], and green smart cities [14]. These studies demonstrate the potential of AI and machine learning techniques to address various challenges and opportunities in different domains.

In many cases, IoT devices operate on short-life and non-rechargeable batteries. These batteries need to be replaced periodically, which can be costly and time-consuming [15]. Furthermore, these batteries can potentially be a source of pollution if not disposed of properly. Recharging or replacing these batteries can be difficult and expensive [16, 17]. As a result, it is important to design IoT devices with energy-efficient components that can run on minimal power for extended periods. The ability to process, aggregate, and transmit data in an energy-efficient manner plays a vital role in IoT applications. By using low-power components, such as sensors and microprocessors, IoT devices can operate efficiently and cost-effectively [18]. This allows these devices to run on minimal power and, in turn, prolongs their lifespan. Wireless communications consume more energy than processing in internet-based systems. Thus, achieving a mechanism for transmitting data between sources and destinations is an important challenge in IoT. Clustering in IoT is crucial to the appropriate transmission of data. This process involves grouping devices into clusters and assigning them cluster heads to enhance resource utilization [19, 20].

In the clustering process in IoT-based, sensor nodes are initially deployed in a network. The system performance is improved by forming a cluster of nodes. The optimal CH is determined for each cluster under different performance metrics. The CHs collect data packets from non-Ch nodes and forward them to the IoT base station. A cloud server will be used to store the data obtained from the base station. During the data processing step, various analytics approaches are employed to eliminate noisy and inconsistent data. The outcome will be available to the end users upon completion of the process. Cluster head selection objectives include monitoring and managing network lifetimes, energy consumption, node failures, load balancing, and network resources. Various clustering mechanisms have been proposed in the literature, including heuristics, metaheuristics, and fuzzy-based approaches. A majority of heuristic algorithms are designed to minimize the number of clusters. In meta-heuristic clustering algorithms, the distance between devices and the remaining energy is considered key performance indicators, whereas data volume and the number of one-hop neighbors are not considered. Moreover, fuzzy-based algorithms rely on assumptions, and validation and verification need extensive tests.

In this paper, we propose a novel approach to CH selection by combining ACO and TS algorithms. Our method integrates the strengths of both algorithms synergistically. Specifically, it leverages the TS algorithm's robust search capabilities and rapid convergence to effectively address local optima issues commonly encountered with ACO. This fusion of ACO and TS enhances the efficiency and effectiveness of CH selection in IoT networks, ultimately contributing to the overarching goal of improving network performance while conserving energy and extending the network's lifespan. Through this research, we aim to provide a practical and innovative solution to the challenges associated with CH selection in IoT, offering a promising avenue for optimizing IoT network operation and sustainability.

II. Related Work

Mohseni, et al. [19] proposed a cluster-based routing strategy called CEDAR by combining the fuzzy logic system with the Capuchin search algorithm. Clustering is applied to both intra-cluster and extra-cluster routing. In this strategy, nodes in the network are clustered to reduce energy consumption, which is a significant benefit to IoT devices. Packets are routed between nodes within each cluster. Nodes can adapt to changing network conditions with the fuzzy logic system, and packets are routed efficiently with the Capuchin search algorithm. CEDAR performed better than comparative approaches in terms of energy consumption, network delay, and network lifetime based on simulation results. Based on the Sailfish optimization algorithm, Sankar, et al. [21] proposed a new method for selecting CHs and forming clusters. NS2 simulator is used for the simulation. This study compares the efficacy of SOA with hierarchical clustering-based, optimized particle swarm optimization, and improved ACO. In the simulation, it was demonstrated that the proposed SOA increases network life and reduces node-to-sink delays.

A new clustering method has been proposed by Yarinezhad and Sabaei [22] for balancing traffic loads in IoT-enabled WSNs. A 1.2 approximation algorithm is employed in the proposed clustering method. A new energy-aware routing algorithm is introduced to enable data packets to be transmitted from the CHs to their destinations. This algorithm allows data packets to be distributed among several nodes in the vicinity of the destination by segmenting the area properly. According to test results, the proposed clustering algorithm is not only suitable for large-scale IoT-enabled WSNs but also demonstrates superior performance over other algorithms of a similar nature. Senthil, et al. [23] proposed a new clustering method based on the particle swarm optimization (PSO) algorithm. Particles in the PSO represent candidate solutions and tend to move through their solution space at varying speeds (in several directions). Experimental results demonstrate that the proposed method optimizes the clustering process and achieves energy efficiency. In addition to reducing end-to-end delays and packet loss rates, the lifespan network and cluster count have been improved.

Maheswar, et al. [24] presented a cluster-based backpressure routing (CBPR) scheme to extend network lifetime and improve data transmission reliability through energy load balancing. Depending on the energy level and distance to the sink node, the CBPR scheme decides which cluster head to elect for each cluster of the sensor node. Additionally, the proposed CBPR routing scheme utilizes a highly robust data aggregation algorithm to prevent redundant data packets from circulating throughout the network. For data packet queuing and route selection, the backpressure scheduling machine is utilized, allowing it to determine the next-hop sensor node based on the queue lengths of sensor nodes. CBPR routing scheme has been evaluated extensively through extensive simulations, compared with those of other well-known routing schemes, including Information Fusion Based Role Assignment and Data Routing for In-Network Aggregation, in terms of throughput, energy consumption, and packet delivery.

Aravind and Maddikunta [25] introduced a cluster-based routing protocol for IoT based on a Self-Adaptive Dingo Optimizer with Brownian Motion (SDO-BM) algorithm to select optimum CHs under parameters including QoS, trust, overhead, delay, distance, and energy. The proposed protocol showed promising results in terms of energy consumption, latency, and packet delivery rate. It also had the ability to self-adapt to changing network conditions, making it a reliable and efficient routing protocol for IoT networks. This approach effectively uses an alternative CH, thus reducing the impact of a node failure. Additionally, it also helps conserve energy since it avoids the need to re-elect a new CH. By using this protocol, networks can become more reliable and efficient.

Energy-efficient clustering in the IoT networks faces several notable challenges. One significant challenge is the issue of long transmission delays. Many existing clustering algorithms struggle to strike a balance between data transmission efficiency and the need to conserve energy. As a result, data packets often experience delays, hindering real-time applications critical in IoT, such as remote monitoring and control. Another challenge lies in load distribution. Current approaches often suffer from imbalanced load distribution among CHs in the network. This imbalance can lead to premature energy depletion of some CHs, leaving parts of the network vulnerable and causing network degradation. Ensuring a fair and efficient distribution of responsibilities among CHs is a complex problem that needs to be addressed effectively. Furthermore, limited network lifespan remains a persistent challenge. The energy resources of IoT devices are inherently constrained, making it crucial to maximize network longevity. Many existing algorithms do not adequately optimize energy consumption, leading to shortened network lifespans. As IoT deployments continue to grow, addressing this issue becomes paramount to sustainability and cost-effectiveness.

Current approaches in energy-efficient clustering for IoT networks exhibit several limitations that hinder their effectiveness. One common limitation is the tendency to converge to local optima. Many clustering algorithms face challenges in escaping local optima due to their exploration-exploitation trade-off. This limitation can prevent the algorithms from discovering more energy-efficient solutions. Additionally, current approaches often lack adaptability to dynamic network conditions. IoT environments are dynamic, with nodes joining and leaving the network regularly. Many clustering algorithms struggle to adapt to these changes, resulting in suboptimal performance and the need for manual adjustments. Moreover, the scalability of current methods is a concern. As IoT networks grow in size and complexity, existing algorithms may struggle to handle the increased computational demands, potentially leading to performance degradation. Furthermore, the lack of a unified evaluation framework makes it challenging to compare the performance of different clustering algorithms objectively. This fragmentation hinders the identification of the most suitable algorithm for specific IoT deployment scenarios, limiting the practical applicability of current approaches. Addressing these limitations is essential to advance the field and provide more robust and adaptable clustering solutions for IoT networks.

III. Proposed Method

IoT networks consist of numerous nodes with varying capabilities in terms of power, processing, and storage. Sensor nodes continuously sense the network's data and relay it to the base station. Since the base station is overloaded for the aforementioned reasons, IoT sensor nodes may fail, redundant data may be generated, and temperature levels may increase. As a solution to these issues, existing nodes are grouped into clusters, with a CH chosen for each cluster based on its optimal performance. CHs are selected according to several factors, including the distance between the base station and the CH, the delay in passing the nodes to the base station, the network load, and the temperature and energy of the nodes. By selecting a suitable CH, the lifetime of the IoT network will be extended.

Traditionally, WSNs are characterized by terms such as distance, delay, and energy. Nevertheless, when choosing a CH for IoT, the load of the network and the temperature are also taken into account in addition to the above criteria. Consequently, a node with maximum energy, a minimum proximity to the base station, a minimum delay, a minimum load, and a low temperature is selected as a CH to optimize network performance. An optimal fitness function is illustrated in Eq. (1) to enhance the efficiency and stability of a network.

$$\mathrm{F} = \mathrm{a1} \times \mathrm{Load} + \mathrm{a2} \times \mathrm{Temp} + \mathrm{a3} \times (1 - \mathrm{Delay}) + \mathrm{a4} \times (1 - \mathrm{Distance}) + \mathrm{a5} \times \mathrm{Energy} \quad (1)$$

where, a1, a2, a3, a4, and a5 represent weighted parameters, and their sum equals one.

A. Load and Temperature

Choosing the optimal CH requires minimal load and temperature on sensor nodes. The Xively IoT platform monitors the performance of the nodes by collecting load and temperature data. As a Google IoT platform, Xively [26] connects, manages, and engages products in milliseconds across millions of connections. Scalability and performance are two of Xively's key features. Environmental monitoring, home automation systems, remote control systems, and building management systems are some application scenarios that can be considered. Data pertaining to the load and temperature of the sensor nodes are fed into Xively, and then the simulation's performance is evaluated. Load and temperature data are transmitted using the MQTT protocol.

B. Delay

An increase in network efficiency can be achieved by transmitting data packets in a limited period. In order to measure the delay in packet transmission to the destination, two factors are taken into account: transmission delay (Tt) and propagation delay (Tp). Tt is the time taken to send the data packet from the source to the destination. Tp is the time taken for the packet to travel from the source to the destination. Both delays must be considered when measuring network efficiency. In Eq. (2), the objective function for measuring the latency time for packets to be transferred from the CH to the base station is shown.

$$\mathrm{Delay} = \frac{\mathrm{Max} \sum_{\mathrm{t}=1}^{\mathrm{TCL}} \mathrm{CL}_{\mathrm{t}}}{\mathrm{A}} \quad (2)$$

C. Distance

The objective function for the distance between the sensor node and CH and BS is expressed in Eq. (3). In the case of trivial distances from the node to the BS, the optimal CH is chosen.

$$\mathrm{Distance} = \sum_{\mathrm{x}=1}^{\mathrm{X}} \sum_{\mathrm{t}=1}^{\mathrm{TCL}} \frac{\|\mathrm{Dis}_{\mathrm{S}}^{\mathrm{x}} - \mathrm{Dis}_{\mathrm{CL}}^{\mathrm{t}}\| + \|\mathrm{Dis}_{\mathrm{CL}}^{\mathrm{t}} - \mathrm{Dis}_{\mathrm{BS}}\|}{\mathrm{M} \times \mathrm{M}} \quad (3)$$

$\|\mathrm{Dis}_{\mathrm{S}}^{\mathrm{x}} - \mathrm{Dis}_{\mathrm{CL}}^{\mathrm{t}}\|$ indicates the distance between the xth sensor node and the corresponding tth cluster head. $\|\mathrm{Dis}_{\mathrm{CL}}^{\mathrm{t}} - \mathrm{Dis}_{\mathrm{BS}}\|$ denotes the distance between the tth cluster head and the BS, while M refers to the area of sensing in meters.

D. Energy Consumption

A network's lifetime and performance are greatly influenced by residual energy. An optimal CH should be selected when node energy is at a high level. Upon transmission and reception of the data packets, CH and normal nodes' energies are revised. In Eq. (4), the actual energy of a sensor node can be determined once the packets have been passed to the cluster head. Eq. (5) shows the remaining energy available in CH. Data can be transferred to CH until the node's energy reaches zero. The energy fitness function is represented in Eq. (6). In Eq. (4), $E_{X+1}(C_S^x)$ represents energy dissipation in the regular node upon transmission to the cluster head, $E_X(C_S^x)$ represents energy dissipation in the xth node. In Eq. (5), $E_{X+1}(C_{CL}^t)$ represents the energy available in CH following the transfer of data packets from the normal node, $E(C_{CL}^t)$ indicates the energy dissipated by tth cluster head.

$$E_{X+1}(C_S^x) = E_X(C_S^x) - E(C_S^x) \tag{4}$$

$$E_{X+1}(C_{CL}^t) = E_X(C_{C:}^t) - E(C_{CL}^t) \tag{5}$$

$$\text{Energy} = \frac{1}{A}\{\textstyle\sum_{x=1}^{A} E(C_S^x)\} + \frac{1}{TCL}\{\textstyle\sum_{t=1}^{CL} E(E_{CL}^t)\} \tag{6}$$

The ACO algorithm originated from the behavior of real ants in their search for the shortest route to food. A number of cycles (iterations) are involved in the construction of the solution. A number of ants construct complete solutions in each iteration based on heuristic information and previous groups' experiences. An important aspect of the ACO algorithm is the transition of ants and pheromone updates. In order to find food, ants establish the shortest paths to reach the food source. The ACO algorithm constructs solutions given the problem data and is capable of solving discrete optimization problems. As a general rule, ants search for food sources in a random manner. When an ant finds a food source, it returns some food to its colony. During their travels along the path, they leave behind chemical substances known as pheromones.

Consequently, shorter paths are likely to contain a greater concentration of pheromone trails. Pheromone trails function as a communication mechanism between ants. The intensity of pheromone trails present on the ground is determined by the quality of the solution (food source) found on the ground. Shorter paths accumulate pheromone trails with multiple ants, leading to a higher density than longer paths. This increases the appeal of shorter paths. An evaporation rate reduces all pheromone trails over time. Meanwhile, evaporation presents an opportunity for exploration and minimizes local stalling [27, 28].

$$P_{ij}^k = \begin{cases} \dfrac{(\tau_{ij})^a(\eta_{ij})^\beta}{\sum_{m\in N_i^k}(\tau_{im})^a(\eta_{im})^\beta} & j \in N_i^k \\ 0 & \text{otherwise} \end{cases} \tag{7}$$

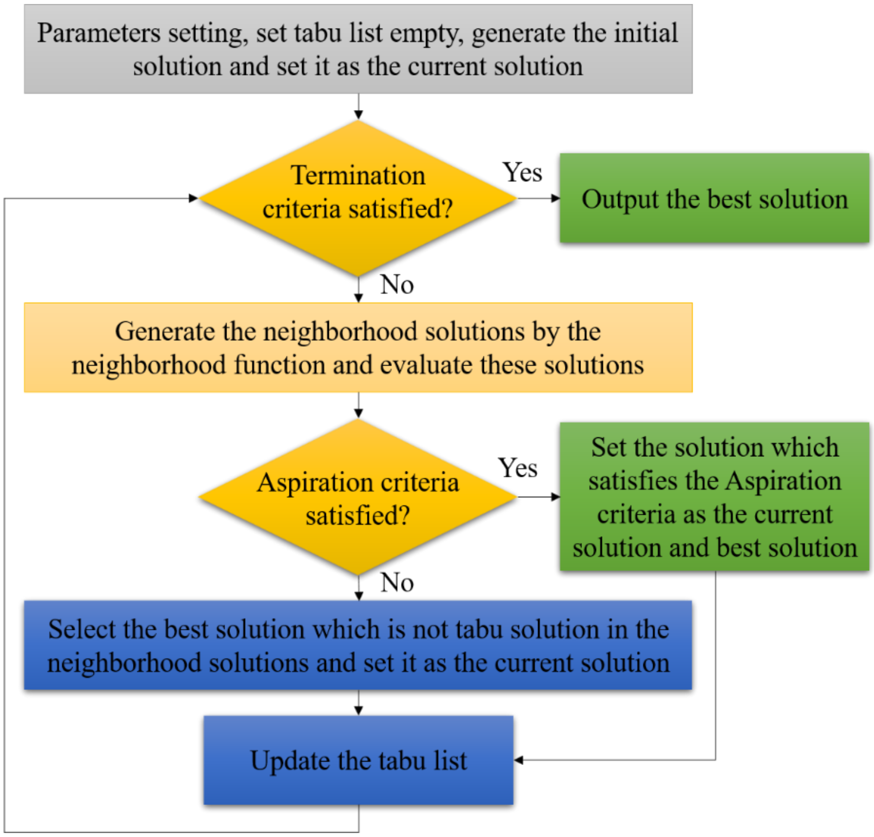
where, P_{ij}^k represents the probability of an ant k moving from node i to node j. Pheromone levels and heuristic information are important factors in this decision. α and β refer to the relative importance of heuristic information and pheromone concentration. τ_{ij} represents the pheromone concentration on edges i and j, η_{ij} refers to the heuristic function, and N_i^k denotes an unexplored neighborhood set. Pheromone updates can be expressed in the following manner:

$$\tau_{ij} \leftarrow \tau_{ij} + \Delta\tau_{ij}^k \tag{8}$$

Evaporation updates are provided by:

$$\tau_{ij} \leftarrow (1 - \rho)\tau_{ij} \tag{9}$$

$\Delta\tau_{ij}^k$ refers to the cost of the solution provided by ant k and ρ denotes a constant factor reduction of all pheromones.



Parameters setting, set tabu list empty, generate the initial solution and set it as the current solution
Termination criteria satisfied?
Yes
Output the best solution
No
Generate the neighborhood solutions by the neighborhood function and evaluate these solutions
Aspiration criteria satisfied?
Yes
Set the solution which satisfies the Aspiration criteria as the current solution and best solution
No
Select the best solution which is not tabu solution in the neighborhood solutions and set it as the current solution
Update the tabu list

Fig. 1. Flowchart of TS.

As a meta-heuristic method, Tabu Search (TS) can be used to solve a wide range of combinatorial optimization problems. It utilizes a sequence of operators to explore the search space and generate better solutions, and it is known for its simplicity, low computational cost, and good results. Additionally, TS is a powerful tool for tackling complex problems, as it can easily be adapted to different scenarios. The final solution generally results from tracking the actions taken to transition from one solution to another. It contains a number of components, including a tabu list, neighborhood structure, move attributes, aspiration criteria, and termination conditions. TS have become recognized as a highly effective local search strategy. Fig. 1 illustrates the basic workflow of TS [29].

The disadvantage of the ACO algorithm is overcome by the TS algorithm, in which the ants move randomly in search of food sources throughout the colony. Chemical substances known as pheromones are released along the path. In the process of solving optimization problems, the ACO algorithm traps ants, which in turn results in a considerable increase in the time required for local searches. TS can be used to overcome these drawbacks. In fact, the TS algorithm eliminates the problem of getting stuck in local optima due to the randomness of the search process. This allows the ants to explore the environment better and find the best solution. The ACO algorithm uses TS to perform local searches. One of the main advantages of using the TS is that distinct parameters are used apart from the population size. ACO constitutes the core of the proposed method; however, in order to find the best solution, it employs the TS strategy when developing new solutions for every starting problem. By using distinct parameters, the TS strategy is able to generate multiple solutions to the same problem. This allows the ACO algorithm to compare and evaluate each solution, giving it the ability to determine which solution is the best one. This process is repeated until the ACO algorithm finds the optimum solution. Once the best solution is determined, the ACO algorithm terminates, and the solution is presented.

IV. Experimental Results

In this section, we present the experimental results of our proposed algorithm and compare its performance with previous algorithms, namely GA, LEACH, and ACO. The experiments were conducted using a MATLAB simulator, and the simulation data are presented in Table I. Energy consumption and network lifetime diagrams were used to illustrate the testing results and comparisons. Fig. 2 compares the algorithms in terms of energy consumption and network lifetime. Our algorithm outperforms LEACH, GA, and ACO in terms of dissipated energy, with reductions of 70%, 34%, and 17.5%, respectively, for 100 nodes. For 500 nodes, our algorithm reduces energy dissipation by 70%, 37%, and 15%, respectively, compared to LEACH, GA, and ACO. With 1000 nodes, the dissipated energy is reduced by 67%, 38.7%, and 18.3%, respectively, compared to LEACH, GA, and ACO.

Fig. 3 illustrates the comparison of the number of rounds until the last node dies versus the network size for the proposed algorithm, ACO, GA, and LEACH algorithms. Our algorithm outperforms LEACH, GA, and ACO by 15.4%, 2.3%, and 2.1%, respectively, for 100 nodes. For 500 nodes, our algorithm outperforms LEACH, GA, and ACO by 4.7%, 2.7%, and 2.6%, respectively. For 1000 nodes, our algorithm is superior to LEACH, GA, and ACO by 9.5%, 3.6%, and 1.3%, respectively. Fig. 4 compares the number of rounds until the first node drains its energy versus different network sizes. Our algorithm outperforms LEACH, GA, and ACO algorithms by 157%, 33%, and 25.3%, respectively, for 100 nodes. For 500 nodes, our algorithm is superior to LEACH, GA, and ACO algorithms by 155%, 33.8%, and 7.5%, respectively. With 1000 nodes, the proposed algorithm exceeds the performance of LEACH, GA, and ACO algorithms by 155%, 3.7%, and 6.6%, respectively.

Our proposed algorithm has been compared with several other relevant research studies in the field, and the results show that it outperforms most of them in terms of energy consumption, network lifetime, and the number of rounds until the last node dies or the first node drains its energy. One of the significant strengths of our approach is that it uses a distributed algorithm that does not require a central controller, which reduces the communication overhead and energy consumption. Additionally, our algorithm uses a dynamic threshold that adapts to the network conditions, which improves the accuracy of the algorithm and reduces the false alarms. In comparison to existing methods, our algorithm has several advantages. For example, it outperforms the LEACH algorithm in terms of network lifetime and energy consumption. The LEACH algorithm uses a fixed threshold that does not adapt to the network conditions, which results in a high false alarm rate and reduces the network lifetime. Our algorithm, on the other hand, uses a dynamic threshold that adapts to the network conditions, which reduces the false alarm rate and prolongs the network lifetime. However, our approach also has some limitations. One of the weaknesses of our algorithm is that it requires a higher computational overhead than some of the other algorithms. This is because our algorithm uses a more complex decision-making process that involves multiple parameters. Additionally, our algorithm may not be suitable for all types of wireless sensor networks, as it is designed specifically for networks with a large number of nodes and a high data rate.

TABLE I. Simulation Variables

Variable	Value
Number of nodes	100-1000
Control packet length	100 b
Data packet length	5000 b
Circuit loss	50 nJ/b
Amplification coefficient of the free space model	10 pJ/b
The initial energy of each node	0.50 J
The maximum transmission power of each node	0.005 w

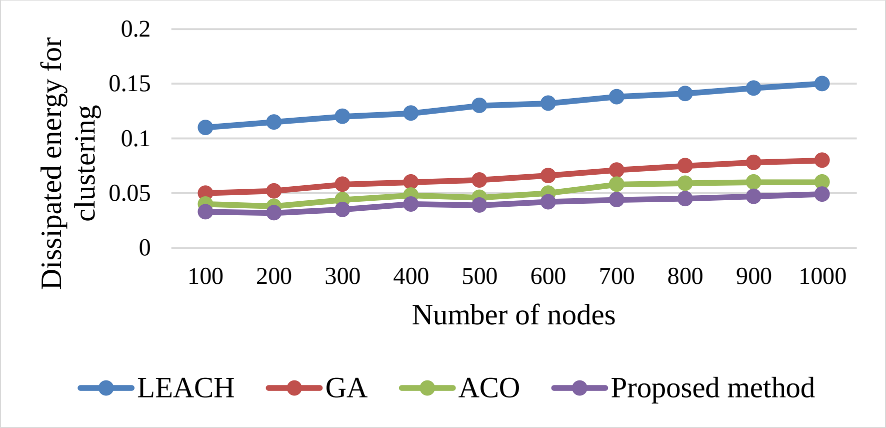


Fig. 2. Energy consumption comparison.

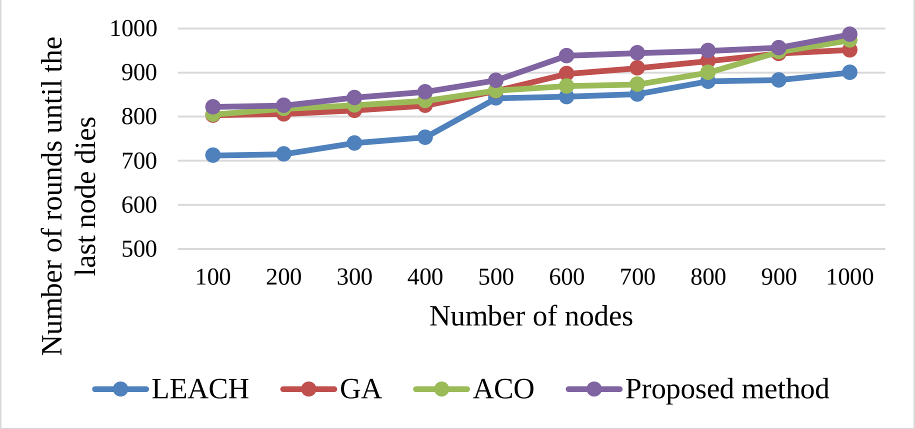

Fig. 3. Number of rounds until the last node dies.

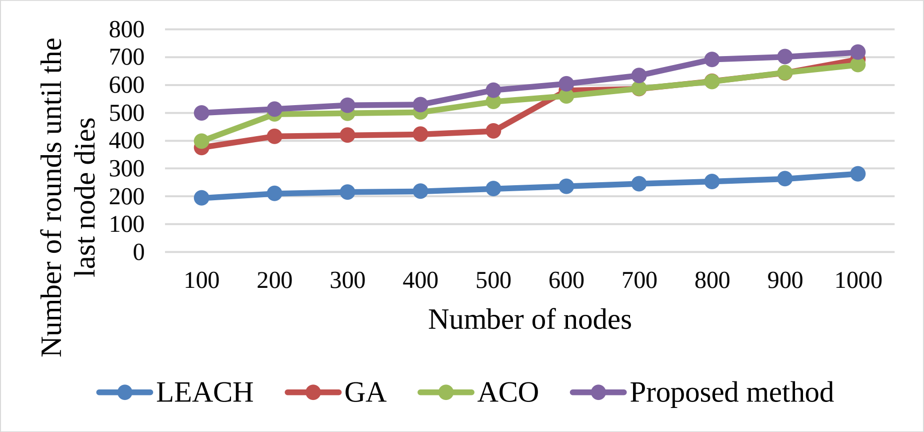

Fig. 4. Number of rounds until the first node dies.

V. Conclusion

Large-scale IoT networks collect data through sensor nodes, and the aggregated information is then sent to the next level of IoT to be processed. Considering the relatively low energy capacity of the sensor devices, IoT networks are often characterized by short battery life, resulting in a short lifespan of the network. Thus, it becomes imperative to prolong the lifespan of sensors. With clustering, collisions, interference, network redundancy, and energy consumption are reduced, and data aggregation, scalability, and network lifetime are improved. A new cluster-based routing method combining ACO and TS algorithms is presented in this paper. Using the TS algorithm, the adverse characteristics of ACO are overcome, such as the random movement of ants to find food sources in the colony. The ACO algorithm traps ants as it solves optimization problems, leading to a significant increase in the time required for local searches. TS is employed to overcome these drawbacks. Due to the randomness of the search process, the TS algorithm avoids getting stuck in local optima. Experiments have shown that the proposed hybrid algorithm performs better than ACO, LEACH, and genetic algorithms regarding energy consumption and network lifetime. There are several areas that can be explored to further improve the performance of our proposed algorithm. One possible direction is to investigate the impact of different network topologies on the performance of the algorithm. Another direction is to explore the use of machine learning techniques to optimize the parameters of the algorithm and improve its accuracy. Additionally, it may be beneficial to investigate the use of multiple thresholds to further reduce the false alarm rate and improve the network lifetime. Finally, it may be interesting to explore the use of our algorithm in other applications, such as environmental monitoring or industrial automation, to evaluate its performance in different scenarios.

Machine Learning-based Secure 5G Network Slicing: A Systematic Literature Review

Meshari Huwaytim Alanazi
Department of Computer Science, Northern Border University, Arar, Saudi Arabia

***Abstract*—As the fifth-generation (5G) wireless networks continue to advance, the concept of network slicing has gained significant attention for enabling the provisioning of diverse services tailored to specific application requirements. However, the security concerns associated with network slicing pose significant challenges that demand comprehensive exploration and analysis. In this paper, we present a systematic literature review that critically examines the existing body of research on machine learning techniques for securing 5G network slicing. Through an extensive analysis of a wide range of scholarly articles selected from specific search databases, we identify and classify the key machine learning approaches proposed for enhancing the security of network slicing in the 5G environment. We investigate these techniques based on their effectiveness in addressing various security threats and vulnerabilities while considering factors such as accuracy, scalability, and efficiency. Our review reveals that machine learning techniques, including deep learning algorithms, have been proposed for anomaly detection, intrusion detection, and authentication in 5G network slicing. However, we observe that these techniques face challenges related to accuracy under dynamic and heterogeneous network conditions, scalability when dealing with a large number of network slices, and efficiency in terms of computational complexity and resource utilization. To overcome these challenges, our experimentation shows that the integration of reinforcement learning techniques with CNNs, multi-agent reinforcement learning, and distributed SVM frameworks emerged as potential solutions with improved accuracy and scalability in network slicing. Furthermore, we identify promising research directions, including the exploration of hybrid machine learning models, the adoption of explainable AI techniques, and the investigation of privacy-preserving mechanisms.**

***Keywords*—5G; accuracy; deep learning; efficiency; security; machine learning; network slicing; scalability**

I. Introduction

5G networks represent the fifth generation of mobile communication networks and offer advanced features such as high-speed connectivity, ultra-low latency, and extensive machine-type communication capabilities. These networks have become crucial infrastructure for various industries due to the increasing demand for high-speed data transmission and real-time applications like autonomous vehicles, smart cities, and Industry 4.0. However, ensuring the security of 5G networks is a significant concern due to the utilization of new technologies and protocols, the complexity of the network architecture, and the potential for new attack vectors [1]. Network slicing is a crucial element of 5G networks, enabling the establishment of multiple virtual networks on a shared physical infrastructure. This technology empowers the customization of each network slice to cater to the unique demands of diverse applications and services. However, this also introduces new security challenges, including unauthorized access, data breaches, and denial of service attacks [2]. Conventional security measures such as firewalls, intrusion detection systems (IDS), and access control mechanisms may prove inadequate in effectively mitigating these threats.

Given the critical importance of 5G networks and the growing security risks, it is imperative to develop effective security mechanisms for network slicing. Machine learning-based intrusion detection systems (IDS) have emerged as a promising approach to enhance the security of 5G networks. These systems analyze network traffic, behavior patterns, and anomalies in real-time to detect and respond to security threats promptly [3]. Nevertheless, despite the potential that machine learning-based solutions hold for enhancing the security of 5G network slicing, there remains a dearth of comprehensive and methodical research in this particular domain. Therefore, the objective of this study is to conduct a thorough literature review of the current state-of-the-art in this field. The findings of this study will provide valuable insights to researchers and practitioners, helping them understand the current research trends, identify research gaps, and develop effective security solutions for 5G networks. Ultimately, this research endeavor aims to contribute to the development of secure and reliable 5G networks, which are crucial for the success of various industries and the digital economy.

This SLR is a significant contribution in the area of machine learning-based security mechanisms for 5G network slicing. The focus of this review is to analyze the security challenges through advanced machine learning and deep learning techniques, evaluating their effectiveness in the context of 5G networks slicing security, and identifying potential solutions for scalability and efficiency issues. This study analyzes various machine learning techniques for securing 5G network slicing in the subsequent sections beginning with the background in Section II. Section III details the concept of network slicing in 5G networks, explaining its implementation, business model, and significance. Section IV focuses on the security aspects of network slicing in 5G networks, addressing various security issues and challenges. Section V describes the methodology used for the systematic literature review, including data sources, search strategies, and article selection processes. Section VI presents the analysis of the findings from the literature review, discussing the advanced machine learning techniques employed for security in 5G network slicing, and highlighting the challenges and potential solutions. Section VII concludes and summarizes the key findings of the study and suggests directions for future research.

II. Background

The swift progression of technological innovations such as the Internet of Things (IoT), augmented reality (AR), and communication systems such as vehicle-to-vehicle (V2V) and vehicle-to-everything (V2X) have created a pressing demand for substantial enhancements in network and communication infrastructure [1][4]. As a response, 5G networks have gained prominence in meeting the growing consumer demands. The introduction of 5G technology has not only opened up opportunities for innovation but has also provided enhanced reliability for both service providers and consumers, resulting in a shift towards virtualization and widespread adoption of 5G. The benefits of 5G technology include exceptional data rates that are 10 to 100 times faster, widespread coverage, heightened reliability, minimal latency, enhanced quality of service (QoS), and cost-efficient service offerings. With the continuous expansion of these services and opportunities, service providers and network operators are engaged in fierce competition to deploy 5G networks and implement network slicing within the physical network.

The 5G technology consists of three distinct services, namely enhanced mobile broadband (eMBB), massive machine type communication (mMTC), and ultra-reliable low-latency communication (URLLC).eMBB offers peak data rates ranging from 10 to 100 Gbps and achieves high mobility support up to 500 km/h while ensuring reduced power consumption through the utilization of both macro and small cells. mMTC offers long-range connectivity with minimal data rates spanning from 1 to 100 Kbps, facilitating cost-effective machine-to-machine (M2M) communication. Conversely, URLLC provides highly responsive connections across multiple devices, achieving less than 1 ms latency and an end-to-end latency of 5 ms between mobile devices and base stations. URLLC also ensures moderate data rates ranging from approximately 50 Kbps to 10 Mbps, accompanied by an exceptionally high service availability of 99.9999%, establishing it as an exceptionally dependable service. [2]. The deployment of 5G networks is poised to act as a catalyst for market expansion. As of 2020, there were already 92 commercial networks operating across 38 countries, with China accounting for 150 million 5G subscribers and South Korea having eight million. Projections from Ericsson suggest that the United States alone will witness a subscriber base of 320 million by 2025 [11]. The emergence of 5G technology compels communication service providers (CSPs) to go beyond their conventional subscriber-centric business models and position themselves as digital service providers (DSPs). This transformation enables them to fuel innovation, enhance safety, and drive productivity on a global level. Recognizing the transformative potential of 5G, the World Economic Forum identifies it as a driving force behind the fourth industrial revolution. Numerous multinational companies including Huawei, Samsung, Qualcomm, LG, Ericsson, ZTE Corp, Nokia, AT&T, NEC Corp, Cisco Systems, Verizon, and Orange are actively engaged in research and development efforts related to 5G [4] [5]. Notably, AT&T, headquartered in Dallas, covers approximately 16% of the United States, while Verizon, based in New Jersey, has successfully expanded its ultra wideband network to 31 states [6]. Qualcomm predicts that by 2035, 5G will generate a staggering USD 13 trillion in value for goods and service industries worldwide [7]. Given the connectivity capabilities of 5G, which facilitate faster data rates and connect millions of devices, transitioning to 5G is imperative to meet market demands and expectations. Numerous ongoing initiatives are harnessing the potential of 5G technology to transform various industries including robotics, healthcare, automotive, agriculture, mining, media, and fashion. These projects encompass applications such as untethered industrial robots, robotic systems for agricultural purposes, AI-assisted medical diagnosis, virtual reality (VR) for palliative care, telesurgery enabling virtual patient operations, and augmented reality (AR) smart glasses for enhanced safety [8].

Delivering the aforementioned services on conventional 4G or other legacy networks presents significant challenges. To overcome these challenges and provide network services efficiently with limited resources and minimal costs for network service providers, network slicing has emerged as a promising solution. Network slicing is a key feature of 5G technology that involves partitioning the physical network into multiple logical networks, each capable of delivering customized services based on specific applications and their requirements [9]. By leveraging the progress of virtualization in cloud computing, the physical network resources are partitioned into numerous logical or virtual networks known as "slices" in the 5G context. Each network slice functions as an autonomous virtual network with dedicated resources, traffic flows, security measures, topology, and clearly defined quality of service (QoS) parameters. These slices are isolated from each other and serve the distinct service requirements of individual subscribers. [10]. Network slicing offers flexibility and scalability by allowing various services to coexist on a shared physical network. It could adapt to evolving subscriber needs, facilitate seamless end-to-end communication, support a multi-service environment, provide on-demand network services, and incorporate multi-tenancy capabilities within the 5G ecosystem. [11][12].

III. Network Slicing

The advancement and swift development of wireless communication systems have created a need for a wide array of services, applications, and scenarios tailored to meet the specific demands of enhanced mobile broadband (eMBB), ultra-reliable and low-latency communication (uRLLC), and massive machine type communication (mMTC).For instance, eMBB applications, such as virtual reality and video streaming, demand high throughput, while uRLLC services, including autonomous driving, require low latency and minimal errors. mMTC services, catering to sensing and monitoring applications, call for high connectivity. However, the existing network architecture is inadequate to meet the diverse needs of these services.

In response to this obstacle, 5G networks employ network slicing, an approach that enables the provisioning of customized services with distinct requirements over a unified network infrastructure. Network slicing includes the partitioning of the network into distinct slices, including access, transport, and core network slices. The network slicing framework is depicted in Fig. 1, illustrating this concept [14]. The core network slice consists of both the control plane and user plane, supporting shared or dedicated functions like session management, mobility management, user plane, and policy control for various slices. Notably, industry players like Ericsson and Nokia have developed their own network slicing systems tailored to their respective sectors [19]. In the current wireless communication environment, a wide range of services with different requirements in terms of security, reliability, data rate, latency, resources, and cost have emerged. Network slicing has emerged as a solution to enable resource sharing among services, customers, and providers. It requires the establishment of multiple logical networks on a shared physical infrastructure, enabling the provision of services with distinct characteristics that can concurrently support multiple technologies. Each service is allocated dedicated resources aligned with its specific requirements, thereby enhancing overall network performance. The management of network slicing involves coordinating virtual and physical resource management components, including Network Function Virtualization (NFV), Software-Defined Networking (SDN) controllers, and orchestrators [15]. NFVs (Network Function Virtualization), which refer to cloud-based functions, specify the requirements and attributes of network slices. Meanwhile, SDN (Software-Defined Networking) controllers establish instances of network slices by connecting virtual functions through SDN networks. [16][17]. Orchestrators automate the management and configuration of resources across different domains and slices, simplifying the process of creating, deploying, and monitoring services in an automated manner. Fundamentally, network slicing entails the establishment of logical networks on top of shared physical infrastructures, partitioning them into multiple virtual networks with independent control and management capabilities. Two types of orchestrators, Service Orchestrators (SOs) and Resource Orchestrators (ROs), play a crucial role in creating and managing multiple services. Several open-source network slicing orchestrators have been developed, such as openMANO, OSM, openNFV, openFV, openBaton, ZooM, ONAP, SliMANO, OpenBaton, cloudNFV, JOX, FlexRAN and Cloudify, to efficiently manage resources in access, core, and transport networks [15][18]. Notably, Huawei has developed an end-to-end (E2E) network slicing orchestrator that effectively allocates resources across the three network domains. Its performance has been validated through real hardware implementation, demonstrating reliable resource isolation per slice [19].

The business model related to network slicing comprises several integral components and entities vital to its functioning. These include the network slicing instance (NSI), network slicing subnet instance (NSSI), logical network, network subslice (NSS), network slicing template (NST), network segment, Network Function Virtualization (NFV), Software-Defined Networking (SDN), network slicing manager, communication service manager, resource slice, network slicing provider, network slicing terminal, network slicing tenant, network slicing repository, slice border control, slice selection function, infrastructure owner, infrastructure slice, infrastructure slice provider, and infrastructure slice tenant [20][21]. Each of these elements has specific roles and capabilities in managing the life cycle of a network slice. As an example, the NSI denotes a group of comprehensive logical networks that provide various services tailored to specific requirements, encompassing multiple sub-slice instances. Conversely, the NSSI represents the localized logical network within a network slice, which can be shared among multiple NSIs. Logical networks are virtual instances of network functions established on a single physical network.

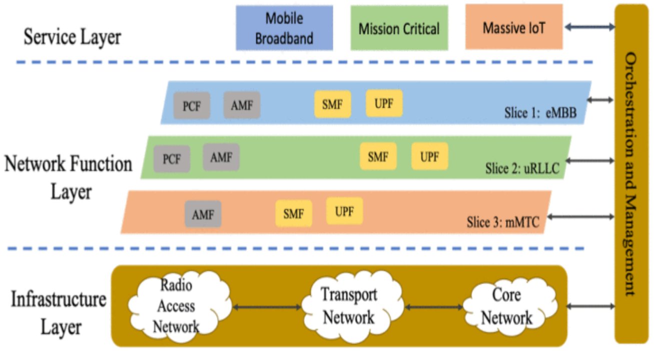

Fig. 1. Network slicing for 5g networks, adopted from [13].

The network slicing manager plays a pivotal role in overseeing the complete lifecycle of each slice or sub-slice by performing various management functions. These include the communication service management function (CSMF), network slice management function (NSMF), and network slice subnet management function (NSSMF). CSMFs are responsible for managing, communicating, and updating the requirements of the slice to support service requests through the communication service manager. NSMFs handle the management of NSIs based on the notifications received from CSMFs, while NSSMFs manage the NSSIs according to the requirements specified by NSMFs. The network slicing requirements encompass various aspects such as network type, network capacity, quality of service (QoS), latency, security level, device count, and throughput. The resource slice refers to the combination of physical and virtual resources necessary for the functioning of network slices. The network slicing provider is the entity responsible for owning the physical infrastructure where multiple slices are created, whereas the network slicing tenant refers to the users of the NSI who deliver specific services requested by customers. The infrastructure owner denotes the entity that owns the physical infrastructure, On the other hand, the infrastructure slice provider is the entity that owns the infrastructure and leases it to host a variety of services via network slicing. The infrastructure slice tenants are the users of the infrastructure slice itself [13].

IV. Security in Network Slicing

Ensuring security is of utmost importance during the implementation of network slicing, which enables the support of diverse services with varying security requirements [22]. The utilization of network slicing in multi-domain infrastructures, serving multiple customers, can introduce complex security challenges. This is especially evident when resources are shared among slices that adhere to distinct security policies established by various verticals and operators. To effectively address security issues both within and among slices, it is crucial to consider security coordination and protocols during the resource allocation and design stages. Neglecting these aspects may result in the emergence of new and advanced security vulnerabilities in 5G systems and beyond [23]. Each slice is created with isolation constraints in order to prevent the propagation of attack impacts across slices and allow for independent security solutions [24]. It is essential to ensure adherence to fundamental security principles such as confidentiality, authentication, availability, integrity, and authorization within each slice [25]. Confidentiality safeguards against unauthorized data disclosure, authentication verifies the identities of parties involved in interactions, availability ensures the accessibility of slices and applications, integrity guarantees that slice owners maintain control over functionalities and configurations, and authorization determines the permissible capabilities for each network element. Availability refers to the ability of the system to meet the requirements of service level agreements by ensuring that slices and applications can be accessed as needed, while Network Slice Manager (NSM) and Network Functions (NFs) remain consistently accessible. On the other hand, integrity ensures that only slice owners possess the authority to modify or replace the functionality and configuration of their respective slices [26]. Authorization defines the permitted functionalities for each network element, where slice owners are responsible for managing and controlling their respective slices, end-users engage exclusively with authorized slices, infrastructure providers oversee the network slice management (NSM), NSM governs the network slice instances (NSIs) and network functions, and network functions exercise control over resources. These elements consist of slice owners, end-users, service providers, infrastructure providers, network slice management (NSM), and Network Function Virtualization (NFV). The security of network slicing requires each slice and its owners to independently fulfill these requirements in order to mitigate the potential exploitation of network slicing features by attackers, which could lead to system failures [13].

A. Security Issues Introduced by Network Slicing

Network Slicing is distinguished by its crucial attribute of isolation, which has a direct impact on the dependability of the slicing solution. Attaining a high level of isolation is essential to achieve optimal outcomes. Merely supporting a single slice in a slicing system would essentially replicate a conventional non-sliced network, which is already extensively studied. Hence, the coexistence of multiple slices becomes a necessary prerequisite for network slicing, wherein these slices share the same underlying infrastructure. The ability to coexist without interference hinges on establishing the minimum requirements for each slice. By meeting these requirements, interference can be avoided, thereby ensuring effective isolation. Ensuring security in network slicing involves precisely defining the boundaries of interference for each slice, specifying the minimum requirements, and enforcing compliance with these requirements [27].

The significance of identifying isolation characteristics, implementing an abstraction layer for achieving end-to-end isolation at an appropriate level, and establishing appropriate security policies was emphasized in a study [28]. This survey highlighted the lack of a standardized description for isolation capabilities that can be employed for automated deployment. Hence, it is crucial to define the desired initial level of isolation, especially concerning security, and devise dynamic isolation mechanisms capable of enforcing the required level of isolation for each specific service. To tackle the security concerns associated with network slicing in the context of 5G, several organizations, such as the Next Generation Mobile Networks (NGMN), have released guidelines [29]. These recommendations assist in identifying potential security risks in the general packet core. Additionally, technology guidelines, such as ETSI's recommendations for Network Function Virtualization (NFV), provide further guidance in addressing security concerns. [30], have been taken into account. ETSI's guidelines encompass security considerations throughout the lifecycle of virtual network functions.

B. More Security Challenges to Network Slicing

Network slicing implementation in the telecommunications industry presents challenges, particularly concerning security and the deployment of the radio access network (RAN). These challenges have been extensively discussed by researchers like Kotulski et al. [32]. Security concerns arise with the introduction of network slicing. One significant risk is the potential for denial-of-service (DoS) attacks and resource depletion [32], which can disrupt network availability and performance. Other threats include monitoring, traffic injection, and impersonation attacks [27], jeopardizing data integrity and network efficiency. Moreover, the use of diverse systems from different vendors in network slicing creates a security vulnerability due to the absence of standardized security measures [32]. Exploiting vulnerabilities in these systems, attackers can successfully target network slices. Additionally, specific weaknesses in the isolation and protection mechanisms designed for network slices may enable unauthorized access to resources and sensitive data. To address these security threats and vulnerabilities, robust security measures are necessary. These can involve implementing intrusion detection and prevention systems, enforcing access control policies, and establishing comprehensive security monitoring. Furthermore, integrating security considerations into the design of network slicing systems and protocols ensures a secure-by-default approach. Standardized security practices enhance overall network slicing security and promote interoperability among different vendor systems [31] [32]. The physical realization of the RAN poses challenges in implementing network slicing. Ensuring resource, traffic, and user isolation within radio network elements is a significant obstacle. One suggested approach involves the utilization of millimeter waves for covering small cells, leveraging the cell size to achieve isolation. Nevertheless, current technologies like cognitive radio and non-orthogonal multiple access fall short in delivering the necessary levels of isolation and slicing required to meet the desired standards. Thus, further research and development are essential to overcome the physical implementation challenges of network slicing in the RAN [31].

The challenges pertaining to security and access management in network slicing originate from the varying security and privacy requirements [27] of different network slices in 5G networks. Network slicing is dependent on the implementation of software-defined networking (SDN) and network function virtualization (NFV). [33], which virtualize network functions as software components. However, ensuring secure inter-slice access and end-to-end network slicing security becomes more complex in 5G due to its comprehensive slicing approach. Securing the management of network slicing encompasses various tasks, including establishing secure access between the radio access network and core network resources, ensuring secure connections between user equipment (UE) and network slice instances, and effectively managing shared resources among different network slices. Neglecting these challenges can lead to security risks, including compromised controllers or orchestrators, isolation failures, insider threats, compromised NFV instances, and unauthorized data access [34][35]. The centralized slice manager also presents security considerations, including the security of network slice templates, concerns regarding unauthorized access, and issues related to trust [36]. Additionally, in multi-domain infrastructures or multi-tenant environments, network slicing may encounter additional security and privacy challenges. To mitigate these concerns, it is essential to adhere to established security principles, including but not limited to confidentiality, integrity, authenticity, availability, and authorization [37][38]. In the context of network function virtualization (NFV), maintaining confidentiality is vital to mitigate potential threats. For example, a compromised slice manager can lead to unauthorized monitoring of traffic through both northbound and southbound interfaces, potentially exposing sensitive slice configurations. Similarly, vulnerabilities in the application programming interface (API) used during configuration can enable malicious actors to interfere with slice installation, configuration, or activation. Thus, ensuring the confidentiality of inter-slice communications is crucial for establishing a secure environment [39][40][41]. Proactive measures like implementing secure communication protocols, enforcing access controls, and conducting regular security policy reviews are necessary to mitigate these threats effectively.

V. Methodology

This section provides an overview of the methodology employed to conduct a Systematic Literature Review (SLR) on the subject of Machine Learning-based secure 5G network slicing, following the recommended guidelines outlined in [42]. The process of formulating research questions is discussed, along with the motivating factors behind these questions. Various data sources were used to select relevant articles, and a specific search strategy was employed to obtain articles in the domain. Inclusion and exclusion criteria were applied to select articles for review. In order to present a comprehensive overview of the current state-of-the-art in Machine Learning-based 5G network slicing, Table I illustrates the research questions along with their respective motivations.

TABLE I. Research Questions and Motivation

	Question	Motivation
RQ1	What are the most advanced machine learning techniques currently employed for ensuring the security of 5G network slicing?	It aims to identify and analyze existing machine learning-based techniques for securing 5G network slicing to develop more effective and efficient security solutions.
RQ2	What are the main obstacles and constraints faced by these techniques in terms of accuracy, scalability, and efficiency?	It aims to identify the potential issues that may arise when implementing machine learning-based techniques for securing 5G network slicing, and to develop strategies to overcome these challenges and limitations.
RQ3	What are the potential solutions to address these challenges and limitations?	It aims to identify and propose possible solutions/recommendations to overcome the challenges and limitations of machine learning-based techniques for securing 5G network slicing.
RQ4	What are the future research directions and opportunities in this area?	It aims to explore the integration of explainable AI and federated learning, investigate the transferability of models across different network architectures and scenarios, and design new evaluation metrics and methodologies for machine learning-based solutions.

A. Data Sources

Table II displays the reputable publishers such as IEEE, Science Direct, Springer, ACM Digital Library, Wiley, Sage, MDPI and Google Scholar, from which the articles were selected for review.

TABLE II. Database Sources

Publisher	URL
IEEE	https://www.ieee.org
Science Direct	https://www.sciencedirect.com
Springer	https://link.springer.com
ACM Digital Library	https://www.acm.org
Wiley	https://onlinelibrary.wiley.com
Sage	https://journals.sagepub.com
MDPI	https://www.mdpi.com
Google Scholar	https://scholar.google.com/

B. Search Strategy

Due to limited research in this area initially, articles considered for review in this study were limited to those published from the year 2018 onwards. The initial stage in constructing the search query involved identifying appropriate keywords aligned with the theme and the research questions put forth. Primary keywords including "network slicing," "5G," "security," and "machine learning" were identified, and logical operators such as "AND" and "OR" were used to link these keywords appropriately. After conducting several tests, the researchers arrived at a search string that produced a sufficient number of related research articles. The keywords used in the search string are listed in Table III.

TABLE III. SEARCH STRING

String	Batch1	Batch2	Batch3	Batch4
String1	Network Slicing	5G	Security	Machine Learning
String2	Network-Slicing			Machine-Learning
String3				ML

C. Article Selection Process

The methodology employed for selecting articles commenced with formulating research questions that guided the creation of a search query for article retrieval. Only articles published in the English language were taken into account. The PRISMA flow diagram was utilized to visualize the article selection process [43] to ensure a systematic and transparent approach to article selection, as illustrated in Fig. 2. Once the pertinent literature was identified, a comprehensive review of load balancing techniques in software-defined networks was performed. The review process concluded with a meticulous categorization of the load balancing techniques to ensure thoroughness. Many articles were excluded during the screening process due to their titles not meeting the inclusion criteria or abstracts not being relevant for the survey.

Search String: (([Batch1, String1] OR [Batch1, String2]) AND ([Batch2, String1]) AND ([Batch3, String1]) AND ([Batch4, String1] OR [Batch4, String2] OR [Batch4, String3])).

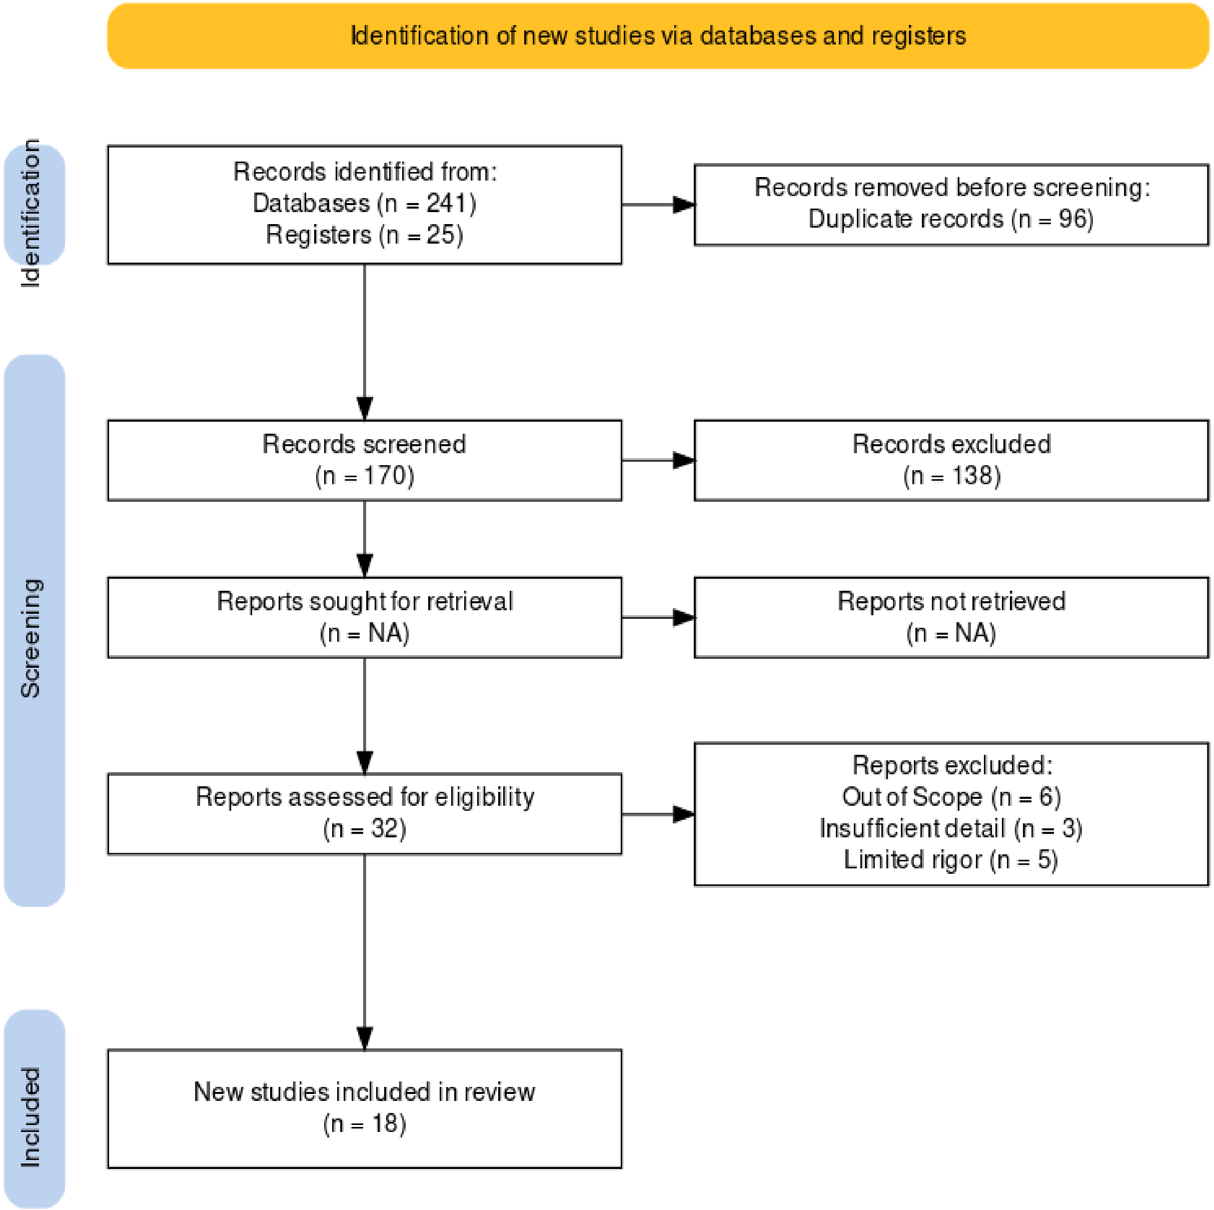

Fig. 2. PRISMA flow diagram.

D. Data Extraction

The research methodology utilized in this study encompassed an extensive exploration to collect relevant literature pertaining to the subject of secure 5G network slicing utilizing machine learning. The primary objective was to identify and select articles that provide valuable insights into this field of study. The research process consisted of several distinct phases, including a targeted search, application of inclusion and exclusion criteria, and comprehensive evaluation of selected articles. The initial step in the research process involved performing a targeted search using specific keywords. This search was conducted across reputable publishers and covered the period between 2018 and 2023. Fig. 3 shows the year-wise number of articles that were published by these publishers. The list of sources used to perform this survey is provided in Table II. The aim was to gather a comprehensive collection of articles related to the subject matter. As a result of this search, a total of 241 articles were identified and retrieved.

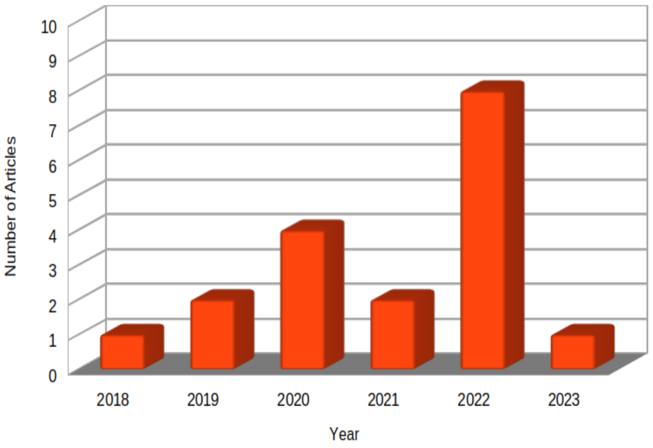

Fig. 3. Year-wise categorization of articles.

E. Inclusion and Exclusion Criteria

To refine the selection and focus on significant research, inclusion and exclusion criteria were established. These criteria were specifically designed to guarantee the inclusion of only articles that directly relate to the research topic. Table IV presents a comprehensive breakdown of the inclusion and exclusion criteria implemented during this process. By applying these criteria, the initial pool of 241 articles was reduced to 170, thereby eliminating articles that did not meet the predefined criteria. The subsequent phase of the research involved a detailed examination of the remaining 170 articles. During this phase, the titles and abstracts of the articles underwent a thorough examination to further refine the selection process. The purpose of this review was to identify articles that aligned closely with the research focus on machine learning-based secure 5G network slicing. As a result of this review, 32 articles were selected for further evaluation.

The selected 32 articles underwent a comprehensive evaluation based on their content to ensure a close match with the objectives and scope of the current research. This evaluation involved an in-depth analysis of the full texts of the articles, including an examination of the methodology, findings, and discussions presented. The aim of this evaluation was to identify articles that provide valuable insights and contribute directly to the research topic. Following this rigorous evaluation process, a final set of 18 articles was identified as the most relevant to the research topic. The selection of these 18 essential research articles was conducted meticulously, taking into account the alignment between the titles, abstracts, and comprehensive content of the articles. The selected articles were recognized as valuable sources of insights into machine learning-based secure 5G network slicing, and their inclusion in the study was deemed essential for the progression of the current research endeavor.

TABLE IV. INCLUSION AND EXCLUSION CRITERIA

Inclusion	Exclusion
The study focuses on Machine Learning-based secure 5G network slicing	The study that focuses on areas other than Machine Learning-based secure 5G network slicing
Only the articles written in English language are considered	Articles written in non-English language are not considered
Articles published by the publishers listed in Table II	Unpublished articles and those that are not peer-reviewed, are not considered
Articles published in well-reputed and high impact factor journals are considered	White papers, editorials, keynote speeches, and articles from predatory journals are not considered

VI. DISCUSSION

In this systematic literature review, we investigated the current state of research on machine learning-based solutions for secure 5G network slicing. Our review identified a total of 18 relevant articles that met our inclusion criteria. From our analysis of these articles, several key themes emerged. Firstly, machine learning techniques are widely used for various security-related tasks in network slicing, including anomaly detection, intrusion detection, and malware detection. Secondly, while there is a broad consensus on the potential benefits of machine learning-based solutions for securing 5G network slicing, there is also a lack of standardization and interoperability among different solutions. Finally, the use of machine learning in network slicing introduces several challenges related to data privacy, explainability, and scalability. In this discussion section, we will elaborate on these themes while answering the research questions and provide recommendations for future research in this area.

Q1. What is the most advanced machine learning techniques currently employed for ensuring the security of 5G network slicing?

Network slicing is a vital component of 5G and future generation networks since it enables the creation of customized logical networks with diverse functionalities, dependability, and security properties. Scholars have proposed multiple types of Machine Learning (ML) and Deep Learning (DL) approaches to increase the security and reliability of network slicing. Table V summarizes the state-of-the-art ML/DL algorithms used in the scientific literature for secure 5G network slicing. This discussion examines the strategies for secure 5G network slicing presented in the selected articles. Fig. 4 illustrates the performance of various machine learning algorithms concerning the security of 5G network slicing. Each algorithm is evaluated based on three key criteria: accuracy, scalability, and efficiency. Accuracy reflects the algorithm's ability to provide precise and reliable security measures. Scalability measures its capacity to handle an increasing number of network slices efficiently, accounting for complex dependencies. Efficiency assesses how well the algorithm utilizes resources during security processes. The chart clearly distinguishes the strengths and weaknesses of different algorithms. For instance, algorithms like RL (Reinforcement Learning) and DQN (Deep Q-Network) demonstrate high scores in all three categories, making them robust choices for secure 5G network slicing. On the other hand, algorithms like LSTM (Long Short-Term Memory) and DBN (Deep Belief Networks) show comparatively lower scores, suggesting room for improvement in their application.

TABLE V. STATE-OF-THE-ART ML TECHNIQUES, CHALLENGES AND POTENTIAL SOLUTIONS

Ref.	Algorithm	Challenges			Potential Solutions
		Accuracy	Scalability	Efficiency	
[45][49][51][52][61]	CNN (Convolutional Neural Networks)	Lack of accuracy in network slice orchestration and optimization and deep learning-based DDoS attack detection for network slicing.	Scalability challenges in securing multiple network slices simultaneously	Inefficient resource utilization during attack mitigation	Integrating reinforcement learning techniques with CNNs can address accuracy, scalability, and resource utilization challenges in secure 5G network slicing, including network slice orchestration, DDoS attack detection, and simultaneous protection of multiple network slices.
[44][55][56][62]	RL (Reinforcement Learning)	Limited accuracy in intelligent resource allocation	Difficulty in scaling up network slices due to complex dependencies	Inefficient resource utilization during IP shuffling processes	Multi-agent RL for accurate, scalable, and efficient secure 5G network slicing for intelligent resource allocation, complex dependencies, and IP shuffling processes.
[46][52][54][66]	SVM (Support Vector Machine)	Challenges in achieving accurate end-to-end security in network slices	Scalability challenges in managing security across numerous network slices	Inefficient utilization of security resources	Distributed and scalable SVM frameworks can address accuracy and scalability challenges in securing network slices, optimizing resource utilization in 5G network slicing.
[50][57][60][68]	DQN (Deep Q-Network)	Accuracy challenges in context-aware authentication handover for secure network slicing	Scalability concerns in managing authentication handover across numerous network slices	Inefficient resource allocation for authentication handover processes	Application of advanced deep reinforcement learning techniques, such as hierarchical or multi-agent DQN, to improve accuracy, scalability, and resource allocation for context-aware authentication handover in secure 5G network slicing.
[45][49][69]	LSTM (Long Short-Term Memory)	Lack of accuracy in network slice orchestration and optimization	Scalability issues in managing a large number of network slices	Inefficient resource allocation and utilization	Advanced LSTM-based deep learning with RL/attention improves accuracy, scalability, and resource allocation in secure 5G network slice orchestration.
[58][59]	FL (Federated Learning)	Limited local data in network slices hampers model performance and accuracy.	Limited computational resources in network slices hinder scalability, impacting Federated Learning.	Sub-optimal resource allocation and usage can impact system efficiency and performance	Improve model performance with data augmentation and transfer learning, optimize resource allocation for scalability, and employ efficient scheduling techniques to enhance system efficiency in secure 5G network slicing.
[48]	K-means clustering, Naive Bayes classifier	Accuracy issues in automated machine learning for network slice automation	Scalability concerns in managing and orchestrating a large number of network slices	Inefficient utilization of automated processes	Improving accuracy of automated machine learning models; Scalable orchestration frameworks; Efficient utilization of automated processes through optimization
[53]	GAN (Generative Adversarial Networks)	Accuracy challenges in adversarial machine learning for flooding attacks in network slicing	Scalability issues in detecting and mitigating flooding attacks across multiple network slices	Inefficient resource utilization during attack mitigation	Improving accuracy of adversarial machine learning models; Scalable flooding attack detection mechanisms; Efficient utilization of resources during attack mitigation
[54]	DBN (Deep Belief Networks)	Accuracy issues due to complex network slices, limited labeled data, and difficulty capturing intricate patterns.	Scalability issues in managing numerous slices efficiently and handling increased computational and communication overhead.	Inefficient resource utilization, communication overhead, and synchronization processes.	Data augmentation, transfer learning, efficient parallelization, optimized resource allocation, and adaptive strategies to improve accuracy, scalability, and resource utilization.

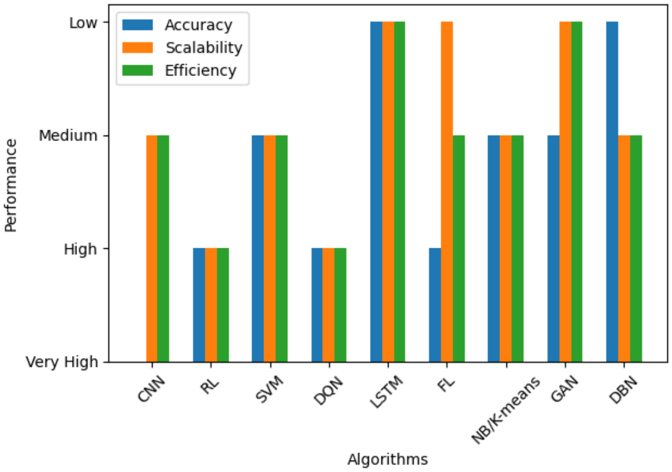

Fig. 4. Algorithm performance for secure 5G network slicing.

Jiang et al. [44] proposed a "Intelligence Slicing" framework combining network slicing and AI for improved intelligence, security, and flexibility. To maximize the efficiency of network slicing and to ensure end-to-end security, the framework employs AI techniques such as reinforcement learning, transfer learning, and deep learning. Deep neural networks are used in [45] to predict resource requirements for different slices, and a clustering technique is used to group analogous slices. The goal is to eliminate wastage of resources while maintaining network stability. Liu et al. [46] suggested a learning-assisted secure end-to-end network slicing technique for cyber-physical systems (CPS). For efficient resource allocation among similar CPSs, ML approaches such as k-means clustering and k-nearest neighbors are used. To maintain slice confidentiality and integrity, a secure key exchange mechanism is used. Sedjelmaci [47] presented a cooperative attack detection system based on AI, applying machine learning techniques such as random forest and decision trees to identify any type of malicious activity and differentiate between legitimate and malicious traffic. This method improves network slicing security by detecting and mitigating threats more effectively. Kafle et al. [48] developed an ML-based network slicing automation strategy based on a multi-agent reinforcement learning technique. To provide end-to-end security, the approach learns from previous slicing events to make accurate slicing decisions while optimizing resource allocation and restricting the attack surface. Secure5G is a DL-based architecture for secure network slicing that was introduced in [49]. It makes use of deep neural networks to estimate slice resource requirements and efficient resource allocation. The framework consists of a security module that detects and mitigates network attacks using a deep belief network. A reinforcement learning-based technique for attacking and defending 5G radio access network slicing is proposed in [50]. It learns optimal attack and defense techniques through deep reinforcement learning, enabling network administrators to identify and mitigate vulnerabilities. The DeepSecure technique introduced in [51] analyzes traffic patterns and detects distributed denial-of-service (DDOS) attacks on 5G network slicing, using convolutional neural networks. It enhances reliability and security by effectively detecting and mitigating such attacks. A hybrid DL-based approach for wireless network slicing is proposed in [52]. This approach combines deep neural networks for network traffic prediction and a reinforcement learning algorithm for resource allocation optimization. It aims to improve the reliability and accuracy of network slicing while ensuring end-to-end security. In [53], an adversarial ML approach is proposed to detect and mitigate flooding attacks on 5G radio access network slicing. It enhances security by effectively identifying and mitigating such attacks. Benzaid et al. [54] propose an AI-based autonomic security management architecture for secure network slicing in B5G networks, focusing on effective security management leveraging AI techniques. Another approach proposed in [56] introduces a learning augmented optimization approach to safeguard network slicing in 5G. It presents a mathematical model and optimization algorithm that utilizes machine learning to adapt to network environment changes, minimizing network cost while ensuring secure slices meeting quality of service requirements. [57] presents SliceBlock, a secure network slicing scheme utilizing a DAG-blockchain to authenticate handover requests between network slices in edge-assisted SDN/NFV-6G environments. It integrates DAG-blockchain technology with SDN/NFV and edge computing, providing a secure and reliable network slicing service. Federated learning, proposed in [59], aims to improve security in network slicing by aggregating training data from multiple slices to detect anomalies and security threats across the entire network. Simulation experiments demonstrate its effectiveness in enhancing security threat detection accuracy. Lastly, [60] proposes a reinforcement learning approach for attacking and defending NextG radio access network slicing. It utilizes multi-agent reinforcement learning to train agents capable of launching attacks and defending against them in network slicing scenarios.

Q2. What are the main obstacles and constraints faced by these techniques in terms of accuracy, scalability, and efficiency?

Network slicing has become a pivotal concept within 5G networks, enabling operators to divide their networks into virtualized networks that are customized to meet the distinct needs of various applications and services. Integrating machine learning (ML) and deep learning (DL) techniques presents a promising avenue for enhancing the security of network slicing. This integration facilitates the detection and prevention of security threats in real-time, offering an effective approach to safeguarding network slicing. However, leveraging ML and DL in secure network slicing poses various challenges, including the need for labeled data, complexity of models, and ensuring data confidentiality and privacy. Subsequent sections will delve into a comprehensive examination of these challenges, providing a detailed analysis, and presenting potential solutions to address them.

Jiang et al. [44] propose a comprehensive framework named "Intelligence slicing" that combines artificial intelligence (AI) with 5G networks. However, they do not discuss the limitations in terms of accuracy and scalability associated with their framework. Thantharate et al. [45] propose "DeepSlice," an approach based on deep learning (DL) for achieving efficient and dependable network slicing in

5G networks. The authors recognize the challenges associated with handling large volumes of training data and the need for substantial computational resources, which could potentially impede scalability and efficiency. Liu et al. [46] introduce the concept of "Learning-assisted secure end-to-end network slicing" for cyber-physical systems. They emphasize the issue of explainability in machine learning-based security approaches, underscoring its potential impact on trust and the acceptance of such methods. Sedjelmaci [47] puts forward a cooperative attack detection system based on artificial intelligence (AI) for 5G networks. The authors highlight the drawbacks of conventional rule-based systems and emphasize the potential advantages of AI-based systems, but they do not explicitly address the specific limitations associated with such approaches. Kafle et al. [48] suggest the automation of 5G network slicing through the utilization of machine learning techniques. The authors recognize the challenges brought about by the complexity of the network and the requirement for substantial amounts of training data. Thantharate et al. [49] introduce "Secure5G," a DL framework for secure network slicing in 5G and future networks. However, they recognize the challenge of developing DL models capable of detecting and defending against new and unknown attacks. The research in [50] presents a reinforcement learning approach for attacking and defending 5G radio access network slicing, but does not delve into the accuracy or scalability limitations of the approach. Kuadey et al. [51] introduce "DeepSecure," which is a deep learning-based approach for detecting distributed denial-of-service (DDoS) attacks in 5G network slicing. The authors acknowledge the difficulty of developing accurate models while minimizing false positives. The study presented in [52] proposes a hybrid deep learning approach for achieving high accuracy and reliability in wireless network slicing within the context of 5G. However, the study does not delve into the limitations of this approach. Shi and Sagduyu the approach proposed in [53] is based on adversarial machine learning and aims to address flooding attacks on 5G radio access network slicing. However, the study does not explicitly discuss the challenge of developing robust models that are resilient to adversarial attacks. Benzaid et al, [54] introduces an AI-based autonomic and scalable security management architecture for secure network slicing in B5G. However, they do not specifically discuss the limitations related to developing models capable of handling the dynamic and heterogeneous nature of B5G networks.. Yoon et al. [55] presents a technique called "Moving target defense for in-vehicle software-defined networking" that utilizes IP shuffling in network slicing, combined with multi-agent deep reinforcement learning. They address the challenges associated with accurate attack detection and mitigation in dynamic and mobile environments. Cheng et al. [56] suggests a method called "Safeguard network slicing in 5G" that employs a learning-augmented optimization approach. They acknowledge the challenge of managing the complexity and dynamics inherent in 5G networks. Abdulqadder and Zhou [57] present "SliceBlock," a solution that combines context-aware authentication handover and secure network slicing using DAG-blockchain in edge-assisted SDN/NFV-6G environments. However, the study does not delve into the specific limitations associated with their proposed models. In their paper [58], Bandara et al. introduces a federated learning platform for network slicing that incorporates blockchain and zero trust security mechanisms. However, the proposed platform encounters challenges in terms of ensuring high accuracy and scalability. Similarly, Wijethilaka and Liyanage [59] suggest a federated learning approach to enhance security in network slicing. However, the approach faces challenges in terms of scalability and efficiency. On the other hand, Shi et al. [60] utilize reinforcement learning for attacking and defending NextG radio access network slicing. However, their proposed approach encounters limitations in terms of scalability and accuracy. Lastly, Chowdhury et al. [61] introduce AUTODEEPSLICE, a data-driven technique for network slicing that employs automatic deep learning. However, they face challenges in achieving accurate results due to the inherent complexity of network slicing.

Q3. What are the potential solutions to address these challenges and limitations?

1) Solutions presented in the literature: One possible solution to tackle the challenges and limitations discussed in the papers involves developing and implementing intelligent slicing frameworks that integrate artificial intelligence (AI) into 5G networks [44]. This strategy capitalizes on machine learning algorithms to optimize and automate network slicing processes [48], enhancing the reliability of network slicing [52], and fortifying the security of 5G networks against cyber-attacks [46][49][51]. An alternative strategy is to utilize reinforcement learning to protect against flooding attacks in 5G radio access network slicing [53][60][63][64][65]. Furthermore, a context-aware authentication handover and secure network slicing that incorporates a DAG-blockchain in edge-assisted SDN/NFV-6G environments can enhance the security of network slicing [57]. Federated learning can also be deployed to bolster the security of network slicing [59]. By incorporating the Skunk-A Blockchain and Zero Trust Security Enabled Federated Learning Platform, the security of 5G/6G network slicing is significantly enhanced. [58]. Finally, data-driven network slicing techniques utilizing automatic deep learning can be employed to enhance network slicing in 5G networks [61].

2) Recommended solutions: The integration of Convolutional Neural Networks (CNNs) with reinforcement learning techniques offers a promising solution to tackle challenges related to accuracy, scalability, and resource utilization in secure 5G network slicing effectively. This integration can be applied to various aspects, including network slice orchestration, DDoS attack detection, and simultaneous protection of multiple network slices.

a) Markov Decision Process (MDP): Consider the problem of network slice orchestration as a Markov Decision Process (MDP) [63], defined by the tuple (S, A, P, R, γ). Here, S is the state space, A is the action space, P represents the transition probabilities, R is the reward function, and γ is the discount factor. The objective is to find an optimal policy π that maximizes the expected cumulative reward:

$$\pi^* = argmax_\pi E_\pi[\sum_{t=0}^{\infty} \quad \gamma^t R(s_t, a_t)] \tag{1}$$

Where, π^* represents the optimal policy that provides the best actions a_t in each state s_t, taking into account the long-term cumulative reward. The MDP formulation considers network slice orchestration as a sequential decision-making problem. By optimizing the policy π, it ensures that actions taken in each state lead to the maximum cumulative reward, which is vital for efficient network resource allocation.

b) Bayesian reinforcement learning: To improve DDoS attack detection, we can model it as a Bayesian Reinforcement Learning problem [64], where we need to infer the optimal policy π given a sequence of observations O and actions A. We seek to maximize the posterior probability of the policy given the data:

$$P(\pi|O,A) \propto P(O|\pi,A)P(\pi|A) \qquad (2)$$

Where, $P(\pi|O,A)$ is the posterior policy probability, $P(O|\pi,A)$ is the likelihood of observations given the policy, and $P(\pi|A)$ is the prior policy probability. The Bayesian RL formulation models DDoS attack detection as a probabilistic learning problem. It estimates the posterior policy π given observed data, enabling improved detection accuracy through probabilistic reasoning.

c) Multi-objective optimization: For simultaneous protection of multiple network slices, we can formulate it as a Multi-Objective Optimization problem [65]. Let $F = [f_1(x), f_2(x), \ldots, f_k(x)]$ represent a vector of k objective functions, and $X = [x_1, x_2, \ldots, x_n]$ denote the vector of decision variables. Additionally, $G = [g_1(x), g_2(x), \ldots, g_m(x)]$ represents a vector of m inequality constraints. The goal is to find a vector of decision variables X^* that optimizes multiple objectives while satisfying constraints:

$$X^* = arg\ min_x F(X) = [f_1(X), f_2(X), \ldots, f_k(X)] \qquad (3)$$

Subject to:

$$g_i(X) \leq 0, for\ i = 1,2,\ldots,m$$

The multi-objective optimization approach provides a rigorous framework to balance multiple objectives while considering constraints. It ensures that resources are efficiently allocated to protect multiple network slices.

d) Multi-agent reinforcement learning: In the context of secure 5G network slicing, multi-agent reinforcement learning [66] demonstrates potential for addressing accuracy, scalability, and resource utilization challenges. Specifically, it can enable intelligent resource allocation by considering complex dependencies and facilitating IP shuffling processes. We performed an experiment using python to demonstrate a custom reinforcement learning environment, termed NetworkSlicingEnv, designed to emulate a 5G network slicing scenario, where an agent makes resource allocation decisions with the goal of optimizing the allocation of resources based on dependencies among actions. The experiment utilizes the Proximal Policy Optimization (PPO) algorithm, a cutting-edge reinforcement learning method. The agent's training process includes learning to optimize resource allocation while considering dependencies among actions, contributing to the achievement of optimal resource utilization and scalability in 5G network slicing.

We define the ‘NetworkSlicingEnv’ environment and then train a PPO model to optimize resource allocation within the environment. After training, we evaluate the model's performance by calculating the mean reward over a specified number of episodes, denoted by ‘n_episodes’. This mean reward serves as an indicator of the model's resource allocation capabilities in the secure 5G network slicing scenario. The algorithm presented below depicts the scenario:

```
Algorithm:
Inputs:
    'n_episodes': Number of episodes for evaluation
Outputs:
    'mean_reward': Mean reward over the evaluation episodes
Initialize:
  1. Define the environment class 'NetworkSlicingEnv':
     a. Initialize the action space with 10 discrete resource allocation options.
     b. Initialize the observation space with a 5-dimensional state observation.
Procedure 'TrainModel' (Total Timesteps: 10,000):
  1. Create a multi-agent environment instance 'env'.
  2. Define a PPO model with a multi-layer perceptron policy ('MlpPolicy') for policy optimization.
  3. Train the model with the 'learn' method using 'total_timesteps=10,000'.
Procedure 'EvaluateModel' (Number of Episodes: 'n_episodes'):
  1. Initialize 'mean_reward' to 0.
  2. For each episode in the range 'n_episodes', do the following:
     a. Reset the environment ('env') and obtain the initial state.
     b. For each time step:
        i. Predict an action using the trained model ('model') based on the current state.
        ii. Simulate the environment's response and receive the reward.
        iii. Accumulate the reward.
        iv. Check if the episode is done. If done, break the loop.
  3. Calculate the 'mean_reward' as the sum of rewards over 'n_episodes' divided by 'n_episodes'.
Output 'mean_reward'.
End
```

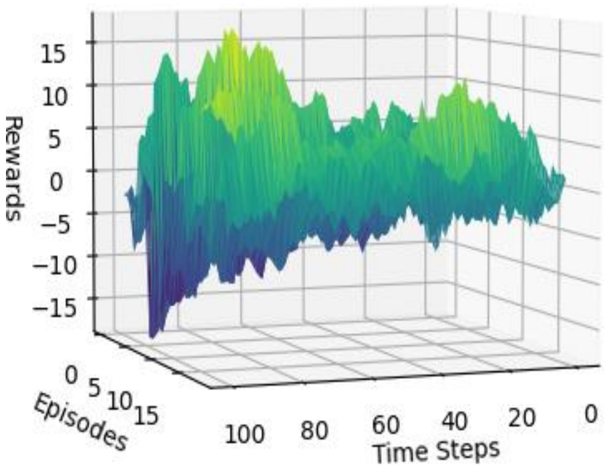

Fig. 5. Multi-Agent reinforcement learning training rewards over time.

The experimental results reveal the agent's learning progress, represented through a 3D plot showcasing the cumulative reward over training steps as shown in Fig. 5. The positive rewards indicate that the agent is learning to make resource allocation decisions that result in outcomes deemed favorable. This implies that the agent is successfully adapting its behavior over time to maximize the cumulative rewards. The learning dynamics suggest that the agent is gradually improving its understanding of the environment and making better choices in allocating resources. As the training progresses, the agent becomes more proficient in resource allocation. The positive rewards show that the agent is making decisions that lead to efficient resource utilization. This can be seen as an indication of improved performance in managing network resources for 5G network slicing. The 3D plot visualizes how the agent's rewards change over the course of training. Gradually, the agent should learn to make resource allocation decisions that result in higher cumulative rewards, which signifies an improved understanding of the environment and more effective decision-making. The mean reward, calculated at the end of training, provides a summary of the agent's performance. A higher mean reward suggests that the agent has improved its decision-making skills regarding resource allocation, which is a critical aspect of network slicing in 5G environments. The positive rewards demonstrate that the agent's learning dynamics are effective in improving its performance in resource allocation decision-making. The agent gradually learns to allocate resources more efficiently, resulting in higher cumulative rewards and, by extension, better performance for secure 5G network slicing.

e) Support Vector Machine (SVM): For securing network slices in a scalable manner, distributed and scalable Support Vector Machine (SVM) [67] frameworks can be employed. These frameworks contribute to improving both accuracy and scalability while optimizing resource utilization within the 5G network slicing environment. In the experiment conducted, a synthetic dataset was generated for binary classification, simulating a scenario in which SVM-based classification is employed. The code utilizes the Scikit-Learn library to create a two-dimensional dataset with 1000 samples. The algorithm presented below depicts the scenario:

```
Algorithm:
Input:
        • Training data: $(X_{train}, y_{train})$
        • Testing data: $(X_{test}, y_{test})$
Initialization:
    a. Initialize SVM model: $SVM_{model}$.
Data Preparation:
    a. Split the data into training and testing sets:
        • $X_{train}, y_{train}$ for training.
        • $X_{test}, y_{test}$ for testing.
Accuracy Optimization:
    a. Train the SVM model on the training data:
        • $SVM_{model}.fit(X_{train}, y_{train})$.
    b. Make predictions on the test data:
        • $y_{pred} = SVM_{model}.predict(X_{test})$.
    c. Calculate accuracy ($A$) using the ground truth and predictions:
        • $A = \frac{Number\ of\ correct\ predictions}{Total\ number\ of\ predictions}$.
Scalability Optimization:
    a. In SVM, the margin is automatically maximized during training to improve scalability ($S$).
Resource Utilization:
    a. SVMs automatically select a subset of support vectors for decision function, which reduces resource utilization ($R$).
Output:
    a. Return:
        • Trained SVM model: $SVM_{model}$.
        • Accuracy ($A$).
        • Scalability ($S$).
        • Resource Utilization ($R$).
End
```

The data is divided into training and testing sets to evaluate the SVM model's performance. The SVM model employs a linear kernel for classification and is trained on the training data. The decision boundary is plotted along with the data points, with a color scale indicating the accuracy level of 0.88 in this case. The visualization demonstrates how SVM, as a scalable framework, can effectively classify data while maintaining a high level of accuracy as depicted in Fig. 6. This technique proves to be an optimal solution for ensuring network slice security and efficient resource allocation within the complex 5G environment, making this experiment a valuable illustration of SVM's capabilities in a network slicing context.

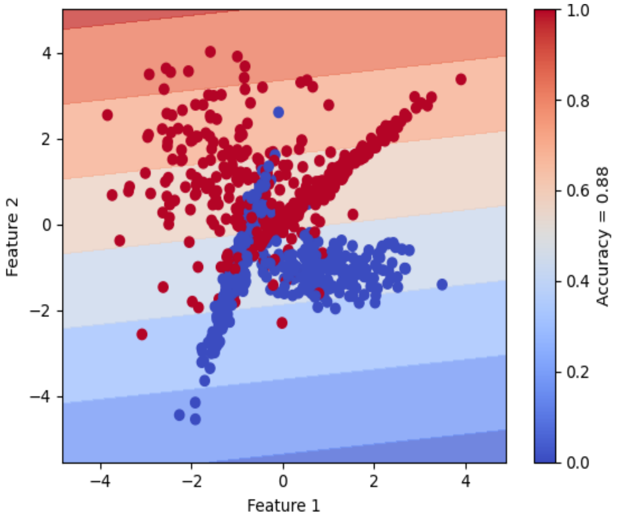

Fig. 6. Secure network slice classification: SVM decision boundary with 88% accuracy.

f) Deep learning: By leveraging sophisticated deep reinforcement learning methods like hierarchical or Multi-Agent Deep Q-Networks (MADQN) [68], it is possible to improve accuracy, scalability, and resource allocation in the context of context-aware authentication handover within secure 5G network slicing. We used TensorFlow library to demonstrate the concept of rewards over a series of episodes, environments, which is a critical aspect of evaluating the performance of Multi-Agent Deep Q-Networks (MADQN) in context-aware authentication handover within 5G network slicing environments. These rewards are indicative of the efficiency and learning progress of a group of agents working collaboratively to make decisions. The rewards represent various factors, including the success of authentication handover processes, the minimization of resource utilization, and the overall optimization of network slicing. By examining the rewards over episodes, we gain valuable insights into how well the MADQN is adapting and learning within this environment as shown in Fig. 7. Consistent, positive rewards indicate that the MADQN is effectively enhancing the authentication handover process and resource allocation, contributing to scalability and the overall security of 5G network slicing.

```
Algorithm:
Input:
    ● State size (‘state_size’)
    ● Action size (‘action_size’)
    ● Number of agents (‘num_agents’)
    ● Total training episodes (‘episodes’)
Initialization:
    ● Initialize ‘state_size’, ‘action_size’, ‘num_agents’, and
      ‘episodes’.
    ● Initialize the multi-agent environment (‘env’) with
      given parameters.
Agent Creation:
    ● For each agent (‘i = 1’ to ‘num_agents’):
        a. Create a DQNAgent (‘agent[i]’) with
           ‘state_size’ and ‘action_size’.
        b. Build a neural network model for ‘agent[i]’ with
           three dense layers.
Training Loop:
    ● For each episode (‘e = 1’ to ‘episodes’):
        a. Generate random initial states for each agent and
           store in states.
        b. For each step in the episode:
            i. Query each agent for actions based on their current
               state.
            ii. Implement the logic to take actions and receive new
                states, rewards, and 'done' flags.
            iii. Update each agent's Q-network based on their
                 experiences.
            iv. If all agents are done (all 'done' flags are True), exit
                the loop.
Output:
    ● Trained MADQN agents.
End
```

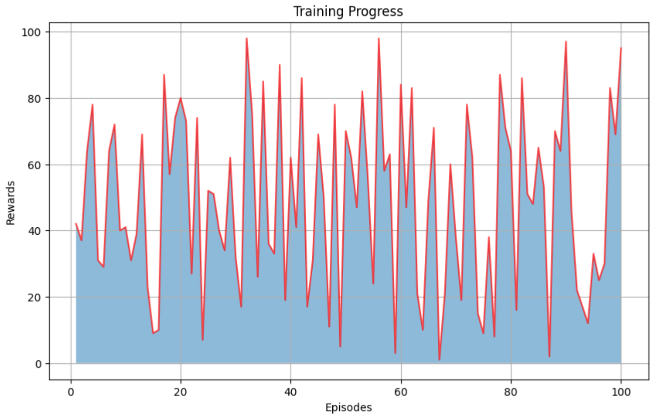

Fig. 7. Multi-Agent Deep Q-Networks (MADQN) episode rewards over time.

Furthermore, the utilization of advanced Long Short-Term Memory (LSTM)-based deep learning architectures [69], integrated with reinforcement learning or attention mechanisms, shows promise in improving accuracy, scalability, and resource allocation for secure 5G network slice orchestration.

g) Other potential solutions: To further improve the performance of secure 5G network slicing, data augmentation and transfer learning techniques can enhance model performance, while optimized resource allocation ensures scalability. Efficient scheduling techniques contribute to enhancing system efficiency within the secure 5G network slicing context. Moreover, potential solutions for improving the accuracy of automated machine learning models, scalable orchestration frameworks, and efficient utilization of automated processes through optimization are essential considerations. Additionally, addressing the accuracy of adversarial machine learning models, deploying scalable flooding attack detection mechanisms, and efficiently utilizing resources during attack mitigation are crucial aspects to enhance the security and performance of secure 5G network slicing. Overall, employing techniques such as data augmentation, transfer learning, efficient parallelization, optimized resource allocation, and adaptive strategies holds promise for enhancing accuracy, scalability, and resource utilization in the secure 5G network slicing domain.

Fig. 8. Word cloud visualization of potential solutions for secure 5G network slicing

The word cloud depicted in Fig. 8 is a visual representation of potential solutions for enhancing secure 5G network slicing, as discussed in the literature. The above word cloud was generated using python. This visualization method succinctly conveys the key strategies and concepts described in the literature by assigning word sizes based on their frequency of occurrence. Larger and bolder words indicate the prominence and importance of specific terms within the text. Notably, terms such as "security," "reinforcement learning," "slicing frameworks," "resource utilization," and "scalability" are the most prominent in the word cloud. These words represent the primary solutions put forward in the literature for addressing the challenges and limitations related to secure 5G network slicing. The word cloud effectively distills the essence of the text, providing an at-a-glance overview of the critical ideas and strategies to enhance accuracy, scalability, and resource utilization in the secure 5G network slicing domain. Scientists and researchers can quickly grasp the core themes and solutions discussed in the paper, making it a valuable addition to the scientific discourse for understanding complex topics with enhanced clarity.

Q4. What are the future research directions and opportunities in this area?

1) Future directions as discussed in the literature: The papers surveyed in this study present several potential future research directions in the domain of secure 5G network slicing. One promising avenue is the integration of reinforcement learning techniques with convolutional neural networks (CNNs) to address challenges related to accuracy, scalability, and resource utilization. This approach has shown promise in enhancing network slice orchestration, enabling DDoS attack detection, and facilitating simultaneous protection of multiple network slices [44]. Another area of interest is multi-agent reinforcement learning, which can be explored to tackle accuracy, scalability, and resource utilization challenges in secure 5G network slicing. By leveraging intelligent resource allocation and effectively managing complex dependencies, multi-agent reinforcement learning offers the potential for more efficient and effective network slicing [45].

Furthermore, the literature suggests the exploration of distributed and scalable frameworks such as support vector machines (SVM) to address accuracy and scalability challenges in securing network slices and optimizing resource utilization in 5G network slicing [46]. Additionally, advanced deep reinforcement learning techniques, including hierarchical or multi-agent deep Q-networks (DQN), can be applied to improve accuracy, scalability, and resource allocation in context-aware authentication handover for secure 5G network slicing [52][68]. The use of advanced LSTM-based deep learning architectures, coupled with reinforcement learning or attention mechanisms, also holds promise for enhancing accuracy, scalability, and resource allocation in secure 5G network slice orchestration [69].

2) Recommended future directions

a) Ensemble learning techniques: Ensemble learning (stacking or boosting for accuracy and robustness enhancement) involves combining multiple individual models to create a stronger and more accurate predictive model. Stacking and boosting are two common ensemble techniques. Stacking combines the predictions of multiple models using another model, often referred to as a meta-learner. Boosting, on the other hand, assigns more weight to instances that are misclassified by the previous models in the ensemble, thereby focusing on improving the accuracy of these instances. The application of ensemble techniques in secure 5G network slicing aims to enhance prediction accuracy and overall robustness by leveraging the strengths of multiple models.

b) Integration of explainable AI: Explainable AI techniques (for transparency and trust) aim to provide understandable and interpretable explanations for the decisions made by machine learning models. In the context of secure 5G network slicing, incorporating explainable AI methods allows users to understand the rationale behind decisions made by the network slicing system. This transparency enhances trust and accountability, particularly in critical applications where the ability to explain decisions is essential. By enabling stakeholders to comprehend how decisions are reached, explainable AI techniques contribute to increased confidence and acceptance of the system's outcomes.

c) Federated learning: Federated learning (for data privacy and security) is a decentralized machine learning approach that enables model training across multiple devices or nodes while keeping data localized. This approach prioritizes data privacy and security by not requiring data to be centralized for training. In the context of secure 5G network slicing, federated learning offers a solution to challenges related to sharing sensitive data across different slices. It allows models to be trained collaboratively without sharing raw data, thus ensuring privacy while still improving the performance of network slicing algorithms.

d) Edge computing: Utilization of edge computing and edge intelligence for localized decision-making involves processing data closer to the data source, reducing communication overhead and latency. Incorporating edge intelligence in network slicing enables localized decision-making at the edge nodes, which can lead to quicker responses and efficient resource utilization. By processing data and making decisions closer to where it is generated, edge computing optimizes the performance of network slicing and enhances its responsiveness.

e) Energy efficiency: Energy efficiency through algorithmic development and resource allocation is a critical concern in any network infrastructure. In the context of secure 5G network slicing, developing energy-efficient algorithms and resource allocation strategies is essential to minimize power consumption while maintaining optimal performance. By optimizing the allocation of resources based on workload and demand, energy-efficient network slicing can contribute to reducing operational costs and improving overall sustainability.

f) Generative adversarial networks: Generative Adversarial Networks (GANs) are a type of machine learning model used in tasks such as image generation and data synthesis. In the context of secure 5G network slicing, GANs can be employed to generate realistic adversarial examples that simulate potential attacks on the network slicing algorithms. By testing the robustness of these algorithms against such simulated attacks, GANs can help identify vulnerabilities and weaknesses in the system's security measures, thereby enhancing its overall security posture.

VII. Conclusion

This literature survey presented a comprehensive overview of the research conducted in the domain of secure 5G network slicing. The reviewed papers highlighted the challenges related to accuracy, scalability, and resource utilization in network slicing and proposed various techniques to address these issues. The experimental results show that the integration of reinforcement learning techniques with CNNs, multi-agent reinforcement learning, and distributed SVM frameworks emerged as potential solutions to improve accuracy and scalability in network slicing. Advanced deep reinforcement learning architectures, such as hierarchical or multi-agent DQN, and LSTM-based models with reinforcement learning or attention mechanisms were identified as effective approaches for enhancing accuracy, scalability, and resource allocation in network slice orchestration. Furthermore, data augmentation, transfer learning, efficient parallelization, optimized resource allocation, and adaptive strategies were suggested as methods to improve model performance, scalability, and resource utilization. The surveyed literature also shed light on the importance of securing network slices against cyber threats, with studies exploring the detection and mitigation of DDoS attacks, cooperative attacks, and adversarial machine learning models. Additionally, considerations for privacy, explainability, edge computing, energy efficiency, and the application of emerging techniques like Ensemble Learning, Federated learning, GANs, etc. were highlighted as potential future research directions. By exploring these avenues, this review has laid a foundation for researchers to contribute to the advancement of secure 5G network slicing, addressing the challenges and ensuring the reliability, efficiency, and security of future network infrastructures.

This review explored the significant advancements and challenges in the integration of 5G networks with security, network slicing, and machine learning techniques. The findings reveal that 5G networks offer immense potential for delivering high accuracy, scalability, and efficiency in various applications. Network slicing emerges as a crucial mechanism for resource allocation and management in 5G networks, enabling efficient utilization of network resources for different services. Moreover, machine learning and deep learning algorithms demonstrate promising capabilities in enhancing network performance and security by enabling intelligent decision-making and anomaly detection. However, the integration of these technologies also presents notable challenges, such as ensuring robust security measures, optimizing network slicing algorithms, and addressing scalability issues. Further research and development efforts are required to overcome these challenges and fully exploit the potential of 5G networks with security, network slicing, and machine learning for various domains and applications.

Information System, Universitas Kristen Duta Wacana, Yogyakarta, Indonesia[3]

***Abstract*—Stroke is a critical medical condition requiring prompt intervention due to its multifaceted symptoms and causes influenced by various factors, including psychological aspects and the patient's lifestyle or daily habits that impact risk factors. The recovery process involves consistent medical care and lifestyle adjustments tailored to the individual case. Expert Systems, a scientific field focused on studying and developing diagnostic systems, can employ the Case-based Reasoning method to identify the type of stroke based on similarities with prior patient cases, considering specific causes and symptoms. This study utilizes the Weighted Cosine, Jaccard Coefficient, and Minkowski Distance methods to assess the similarity of stroke cases. The evaluation is based on input data such as patient causes or symptoms and risk factors from medical records. The analysis of case similarity and solutions involves applying the Weighted Cosine, Jaccard Coefficient, and Minkowski Distance methods, with a defined threshold value. The highest similarity values from previous patient cases are selected for each method. The test outcomes suggest that employing the Minkowski Distance method with a threshold value of 75 and an r value of three or four yields the highest levels of accuracy, recall, and precision. The Minkowski Distance achieves an accuracy and recall rate of more than 88 percent with 100 percent precision.**

Keywords—Expert system; stroke; case-based reasoning; Minkowski Distance; jaccard coefficient; weighted cosine; threshold; accuracy; diagnosis

I. INTRODUCTION

Stroke is an emergency disease that must be treated immediately to minimize brain damage due to lack of oxygen and nutrients. Stroke can cause paralysis and death for patients. According to [1], stroke is an non-communicable condition arising from blockage, constriction, or hemorrhage within the brain's blood vessels, resulting in a diminished blood flow to the brain.

The development of information technology specifically for intelligent systems or artificial intelligence (AI) has had a positive impact on progress in the field of medicine and health. One of the applications of intelligent systems to support disease diagnosis is the development of an Expert System. According to reference [2][3], the expert system is a system based on knowledge that utilizes expert knowledge to address a particular issue. The essential components required for constructing the expert system include a knowledge base, inference engine, working memory, and user. There has been a number of systems developed in the medical field including [4] [5] [6] [7] [8] [9] [10] [11].

The utilization of techniques in creating the expert system is highly varied, with one example being the Case-Based Reasoning (CBR) approach. CBR involves retrieving cases from past occurrences, subsequently reusing and adapting them in new situations. [12] [13].

In the academic realm, expert systems play a crucial role in the learning process, especially in the field of stroke-related studies. The medical histories of individuals who have experienced strokes can be employed as a point of reference when diagnosing new cases, utilizing the Case-Based Reasoning (CBR) method. In this CBR process, successfully resolved issues are archived for potential use in future problem-solving scenarios. Conversely, if a problem persists without resolution, the case is identified and stored to prevent similar errors in the future [14]. The CBR method comprises four key stages of problem-solving: retrieve, reuse, revise, and retain.

Retrieve is taking back cases most similar or relevant to the new case [15]. Meanwhile, reuse is the process of reusing information and knowledge from old cases as solutions for new cases. The old case, which has a similarity value above the threshold value and which has the highest value, is reused as a solution to solve the new case. Revise is the revision process that involves reviewing and revising the proposed solution. In this process, information is re-evaluated to address problems that arise in new cases. After that, the system will generate a solution for the new problem [16], and retaining is the process of storing new cases that have been successfully resolved and have found solutions to the database so that they can be reused as solutions for new cases in the future.

There has been many fields that apply CBR to solve problems. In the geographical field, Dou, et al. [17] conducted research to detect landslides using CBR. Tempola and colleagues [18] conducted a study investigating the use of Case-Based Reasoning (CBR) to assess the qualification of students for scholarship awards.

In the CBR system, the calculation of case similarity at the retrieve phase becomes a very important part. This calculation is the basis for determining the level of document similarity. There are several similarity calculation metrics, such as Minkowski Distance similarity and weighted cosine similarity.

The Minkowski Distance represents a generalized version of the Euclidean Distance and Manhattan Distance approaches. [19]. The main difference lies in the value of r, which is a power constant in the *Minkowski Distance* method. Meanwhile, *Weighted Cosine Similarity* calculates the similarity between two objects based on the size of the cosine angle [20]. The primary objective of this study is to assess and compare the effectiveness of the Minkowski Distance Similarity and Weighted Cosine Similarity methods in achieving the highest accuracy for the stroke diagnosis system.

Another research was conducted by Adawiyah [21] regarding the use of the *Minkowski Distance* for the system to detect premature baby birth. A system accuracy testing was carried out using 20 test data, seven data with a normal diagnosis and 13 data with a premature diagnosis. From the test, there was two data obtained whose results are not appropriate because the value is below the *threshold*, which is ≤ 60%. The accuracy of the system is 90% in detecting premature births.

In 2022, Mubarak, et al. conducted a research on CBR for the diagnosis of malaria using the *Minkowski Distance Similarity* method where testing was carried out with 25 test data and 58 training data which showed a system accuracy value of 92% with a *threshold* of 80% [22].

A research on case-based reasoning to diagnose malnutrition in children aged 0 - 5 years by applying the Cosine Similarity method [23] was conducted by Soinbala, et al. in 2019. The system's accuracy and validity were evaluated through testing with 40 new cases, comparing the system's diagnostic results with those provided by experts. The test outcomes reveal an 80% accuracy rate when employing an 80% threshold.

Zainuddin and colleagues conducted a study in 2016 [24], concentrating on Case-Based Reasoning (CBR) for diagnosing strokes. They employed the K-Nearest Neighbor algorithm with an 80% threshold value. The research, based on 15 test cases, reported a system accuracy of 93.3%, consistent with expert diagnoses. In a separate study, Warman and team [25] investigated the use of expert systems in identifying diseases in rice plants. They utilized CBR with the K-Nearest Neighbor method for distance calculation. The evaluation of system sensitivity and accuracy involved 52 test data points with a threshold value of 70%. The findings indicated a system sensitivity of 100% and an accuracy rate of 82.69%.

This study represents a continuation of the research conducted by Nelson et al. in 2018. In their investigation, Nelson et al. developed an expert system for diagnosing strokes using a Case-Based Reasoning (CBR) approach. The system employs the Jaccard Coefficient method for calculating case similarity. The research utilized the Siriraj score as a distinguishing factor between ischemic and hemorrhagic types of strokes, incorporating dense indexing for enhanced efficiency [26]. The system underwent testing with 45 cases as test data and utilized 135 cases as a case base. The findings revealed that a threshold value of 0.7 resulted in superior sensitivity and accuracy compared to threshold values of 0.8, 0.9, and 1. The system demonstrated a sensitivity level of 89.88% and accuracy of 81.67% with indexing and 84.44% without indexing. Further research was carried out using the same dataset with the Minkowski Distance similarity calculation method [27]. The research results show that Minkowski Distance provides a better accuracy rate of 88.89% compared to the Jaccard Coefficient method.

The research carried out is a continuation of research [26] [27]. The focus of this research is to compare the level of similarity test between the Minkowski Distance Similarity and Weighted Cosine Similarity methods in the diagnosis of stroke patients. This research wants to find out whether Weighted Cosine Similarity can increase the accuracy of the system in diagnosing stroke. This research contributes to increasing the effectiveness of expert systems in diagnosing stroke.

II. Method

The process of developing the system involves several stages, commencing with needs analysis, followed by system design, program code implementation, and culminating in system testing, as depicted in Fig. 1.

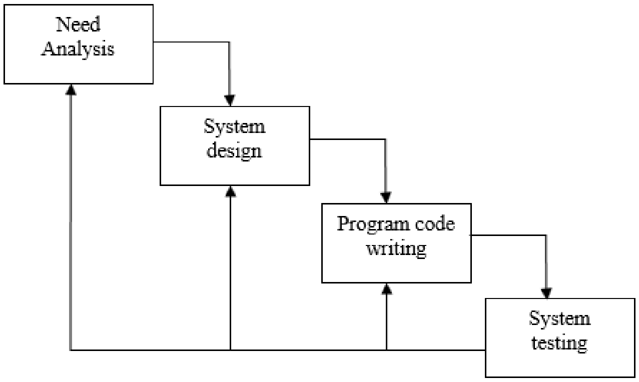

Fig. 1. The system development stages.

A. Data

The data used in this study was sourced from Nelson et al.'s 2018 research [26], specifically the study titled "Case-Based Reasoning for Stroke Diseases Diagnosis." It encompasses medical records extracted from patients who had experienced strokes and were treated at Dr. Soetarto DKT Hospital in Yogyakarta during the period of 2015-2016. The data were categorized into four types of stroke based on both the cause and anatomical pathology, namely embolic stroke, thrombotic stroke, subarachnoid hemorrhage stroke, and intracerebral hemorrhage stroke. We have limitations in terms of test data and future work has the opportunity to carry out better and more complete tests.

B. System Planning

The expert system is developed utilizing the Case-Based Reasoning (CBR) method, integrating the Minkowski Distance similarity method to evaluate similarities between newly entered cases and existing ones. Users input information in the form of the patient's personal data, symptoms, and risk factors. Subsequently, the system calculates local and global similarity values between the newly entered case data (user-provided data) and the cases stored in the case base. The case exhibiting the highest similarity, surpassing a predetermined threshold, is applied as the solution for new cases. In instances where the similarity value falls below the threshold, the case is retained in the case base for expert review. Conversely, if the similarity exceeds the threshold, the system generates an output indicating the type of stroke affecting the patient. The use case diagram for stroke diagnosis in the expert system is depicted in Fig. 2.

The goal of similarity measurement is to evaluate how closely two objects resemble each other. The determination of the similarity value involves calculating two values: the local similarity value and the global similarity value.

1) Local similarity: The aim of similarity measurement is to quantify how much two objects resemble each other. Calculations for local similarity are conducted to obtain similarity values by comparing the attributes of a problem with those of a case. The local similarity is determined based on the characteristics of the data and its features [28].

- Numeric data type

$$f(s,t) = 1 - \frac{|s-t|}{R} \tag{1}$$

Here, *s* and *t* represent the values of the features under comparison, and *R* denotes the range of values associated with these features.

- Boolean data type

$$f(s,t) = \begin{cases} 1, if\ s = t \\ 0, if\ s \neq t \end{cases} \tag{2}$$

where s, t {true, false}

2) Global similarity: Global similarity is utilized for assessing the similarity between problems and cases on a case base. This study will compare the accuracy of systems using Minkowski Distance Similarity and Weighted Cosine Similarity.

- Minkowski distance simmilarity [29]

$$E(C_i, C_j) = \left[\frac{\sum_{k=1}^{n} w_k^r * |d_k(C_{ik}, C_{jk})|^r}{\sum_{k=1}^{n} w_k^r}\right]^{1/r} * T(C_j) * \frac{n(C_i, C_j)}{n(C_i)} \tag{3}$$

Here, $E(C_i, C_j)$ is the global similarity between target case (C_i) and source case (C_j), meanwhile w_k is the weight value of attribute k; $d_k(C_{ik}, C_{jk})$ is the local similarity value between target case attribute to k and source case attribute to k, and r is a Minkowski factor (positive integer); $T(C_j)$ is The confidence level of the case in the case base, $n(C_i, C_j)$ is the total attributes of the target case (C_i) that appear in the source case (C_j), and $n(C_i)$ is the total number of attributes in the target case (C_i)

- Weighted Cosine Similarity

$$\text{Weighted Cosine Similarity} = \frac{\sum_{i=1}^{n} w_i x_i y_i}{\sqrt{\sum_{i=1}^{n} w_i {x_i}^2}\ \sqrt{\sum_{i=1}^{n} w_i {y_i}^2}} \tag{4}$$

Here, w_i is the weight value of attribute i, x_i is the value of local similarity for the first object (*target case*), and y_i is the local similarity value of the second object (*source case*)

C. Implementation

The system will be developed as web-based software using Hypertext Markup Language (HTML)/Cascading Style Sheets (CSS) and Hypertext Preprocessor (PHP), with Apache serving as the webserver and MySQL handling the database.

D. Test Design

During system testing, the confusion matrix method is utilized to produce accuracy, recall (sensitivity), and precision values. The confusion matrix [30] acts as a concise result table, presenting the counts of true and false test data. This matrix facilitates a comparison between the actual values and the predicted results, allowing for the calculation of accuracy, prediction, and recall values, as depicted in Table I.

TABLE I. SYSTEM TESTING MATRIC

Predicted Values	Actual Values		
		Positive	Negative
	Positive	TP-True Positive	FP-False Negative
	Negative	FN-False Negative	TN-True Negative

The formula for calculating accuracy, precision, and recall [30] can be seen in equations five to seven.

- Accuracy: The extent of accuracy exhibited by the model in accurately performing the classification.

$$accuracy = \frac{TP+TN}{Total} \tag{5}$$

Precision: The degree of accuracy between the requested data and the predicted results from the model.

$$precision = \frac{TP}{TP+FP} \tag{6}$$

- Recall: The system's effectiveness in retrieving information.

$$recall = \frac{TP}{TP+FN} \quad (7)$$

The test uses data from a research [31] in the form of medical record data from stroke patients during 2015-2016 at Dr Soetarto DKT Hospital, Yogyakarta consisting of 180 cases, where 30% of the cases, namely 54 cases, will be used as test data. The system underwent testing with various threshold values, specifically from 0.6 to 0.95. To find the highest accuracy value, the system will be tested using two different distance calculation methods, such as Minkowski Distance Similarity and Weighted Cosine Similarity methods. In a system that implements Minkowski Distance Similarity, a test is carried out on the Minkowski rank (r) to get the most optimal r value using different r values, started with r = 1 and continuing to increase by 1 until the resulting accuracy value does not show a significant difference.

III. Results

A. Stroke Diagnosis System

Research produces a system that can be used to diagnose stroke. The system has several interfaces, including an interface for carrying out diagnosis (see Fig. 3), an interface for displaying diagnosis results (see Fig. 4), and an interface for the system revision process (see Fig. 5).

Diagnose Result:

Number	Case	Deases	Similarity
1	K00055	Thrombosis Stroke	82.44%
2	K00002	Embolism Stroke	73.38%
3	K00041	Thrombosis Stroke	72.83%
4	K00096	Thrombosis Stroke	69.5%
5	K00157	Thrombosis Stroke	68.44%
6	K00050	Embolism Stroke	66.2%
7	K00086	Thrombosis Stroke	64.7%
8	K00024	Embolism Stroke	63.34%

Diagnose Result:

Thrombosis Stroke

Explanation:

Thrombotic stroke caused by inadequate blood flow to parts of the brain due to blocked arteries. There are certain factors that put a person at greater risk of developing atherosclerosis and suffering from thrombotic stroke.

Risk Factors:
- High Cholesterol
- Hypertension
- Smoking or using tobacco products
- Diabetes
- Obesity
- Lack of exercise
- The risk is also higher if there is a family history of thrombotic stroke.

On the diagnosis page, the user enters the symptoms experienced by a patient. This page is the input page for the system. Based on input from the user, the system calculates the similarity of the user input with the case dataset that the system already has. Instances of case representation are illustrated in Table II. When the system identifies similar cases (with similarity exceeding the threshold value), it will present a diagnosis results page. In the absence of cases resembling the symptoms entered by the user, the system will store the case data, and experts can review new cases through the system's revision page.

C. System Testing Results

System testing involves the calculation of accuracy, precision, and recall using Eq. (5), (6), and (7). The testing process utilizes 30% of the case data as test data, consisting of 54 cases. To enhance efficiency, an automation script is employed. This script logs into the system, automatically inputs patient data, symptoms, and risk factors based on the test data, and records the system results.

The test outcomes for the system utilizing the Minkowski Distance Similarity method, along with the Confusion Matrix, are detailed in Table III. This table depicts different levels of accuracy, sensitivity, and recall corresponding to each threshold value and *r* value. The peak accuracy is achieved with a threshold value of 75 and *r* values of three and four, resulting in an accuracy rate of 88.89%.

Table IV displays the outcomes of system testing utilizing the Weighted Cosine Similarity method and the confusion matrix. The highest accuracy is achieved with threshold values of 75 and 80, yielding an accuracy percentage of 83.33%. The accuracy value signifies the system's ability to diagnose correctly, with higher accuracy indicating more precise diagnosis results or solutions provided by the system.

TABLE III. MINKOWSKI DISTANCE SIMILARITY SYSTEM TEST RESULTS

Threshold	Nilai R	Accuracy (%)	Recall (%)	Precision (%)

65	79,63	82	95,35
70	81,48	82	97,62
75	83,33	82	100
80	83,33	82	100
85	81,48	80	100
90	44,44	40	100
95	24,07	18	100

IV. DISCUSSION

Accuracy calculates all actual predicted values without specificity for each label, so a higher accuracy doesn't necessarily indicate good performance in predicting specific labels. Therefore, recall and precision values are crucial. Recall assesses the system's success in retrieving information, with higher values indicating better identification of positive cases.

Fig. 6 depicts the system's recall rate at a threshold of more than or equal 75 using the Minkowski Distance method, which surpasses the recall rates of the system using the Jaccard Coefficient method without indexing and the Weighted Cosine method. The Minkowski Distance method achieves the highest recall value at 88%. Precision, a metric measuring the accuracy of positive predictions, is highest in the Minkowski Distance method when applying a threshold value of more than or equal 50, reaching 100% (see Fig. 7).

Across the three tested methods, the Minkowski Distance approach with a threshold value of 75 and *r* values of three or four consistently produces the highest levels of accuracy, recall, and precision. In a system designed to detect high-risk diseases such as stroke, recall is particularly crucial, as a low recall value implies misdiagnosing some patients with stroke as healthy, leading to serious risks. Therefore, the optimal configuration for the expert system for stroke diagnosis is the Minkowski Distance Similarity method with a threshold value of 75 at r = 3 or r = 4, achieving a system accuracy rate of 88.89%, a recall of 88%, and a precision of 100%.

	65	70	75	80	85	90	95
Minkowski Distance	84	86	88	76	60	34	32
Weighted Cosine	82	82	82	82	80	40	18

Fig. 6. Graph of comparison of system recall rates between Minkowski Distance, Weighted Cosine and Jaccard Coefficient.

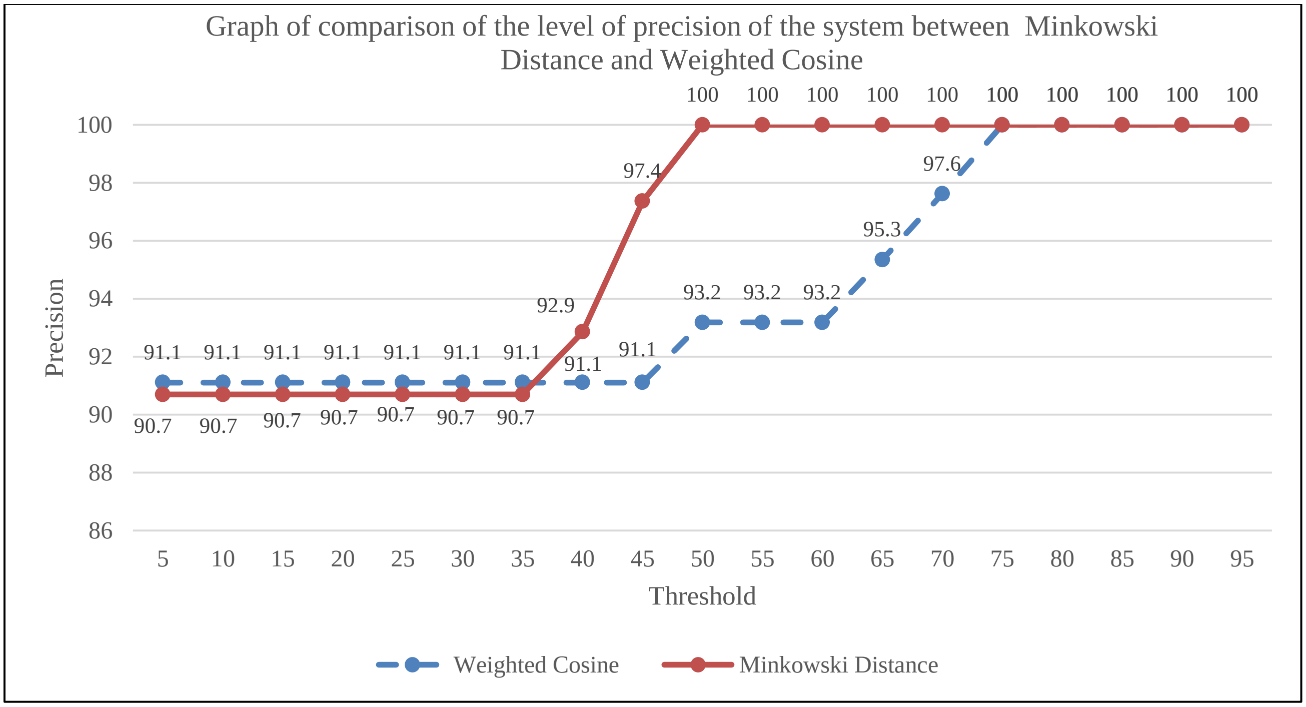

Fig. 7. Graph of comparison of the level of precision of the system between Minkowski Distance and Weighted Cosine.

A. Limitation

This research is a follow-up research that uses the same dataset from the work of Nelson and the team [26]. This study has not added a dataset with the latest cases for stroke diagnosis. Further research can be carried out by collecting and adding a dataset of cases in the last five years.

V. CONCLUSION

This research is a follow-up study that uses a dataset of stroke cases. Research focuses on the effectiveness of algorithms for stroke diagnosis. The system developed is an expert system with a CBR approach. The study focuses on finding the most effective algorithm for diagnosing stroke. In previous research, the Jaccard Coefficient algorithm was applied with an accuracy level of 81.67%, and Minkowski Distance Similarity was applied with an accuracy of 88.89%. In this research, the Weighted Cosine algorithm was applied, resulting in an accuracy of 83.33%. Through the comparison of the applications of the three algorithms, it becomes apparent that the Minkowski Distance Similarity algorithm exhibits a superior level of accuracy and sensitivity (or recall) in contrast to systems utilizing the Jaccard Coefficient method and the Weighted Cosine method. When the threshold is set at 75 or above, the system attains an accuracy rate of 88.89%, along with a recall of 88%. In comparison to the Weighted Cosine method alone, the precision level is 100%.

Further research is being carried out to develop a rule generator to automate the formation of a knowledge base in a rule-based system format. The anticipated outcome of this research is an enhancement in the efficiency of tracking case times for decision-making. Apart from this, updates to the stroke case dataset must also be carried out to enrich the case data

ACKNOWLEDGMENT

We express our gratitude to the Faculty of Information Technology and the Institute for Research and Community Service (LPPM) at Duta Wacana Christian University for providing the funding for both the research and its publication.

***Abstract*—The development of Wireless Sensor Network (WSN) has gained significant attention for smart systems due to their potential use in a wide range of areas. WSN consists of tiny, independently arranged sensor nodes that run on batteries. The resources and energy usage for sensor nodes are the major factors. Particularly, the unbalanced nodes' raises the energy use and reduces the network life-span. Energy efficiency in WSN cluster head selection remains a challenging task. The best method has been developed for reducing node energy consumption is clustering. However, the current clustering strategy failed to properly allocate the energy needs of the nodes without considering energy features, node quantity, as well as adaptability. Hence, there is need for advanced clustering process with new optimization tactics, and accordingly, a new cluster-head selection model in WSN is proposed in this work. Initially, the clustering process is done by the k-means algorithm. The Cluster Head (CH) selection is the subsequent progress under the consideration of node's energy, distances, delays, and risks as well. A novel CIOO (Chimp Integrated Osprey Optimization) algorithm combining the Osprey and Chimp optimization algorithm is proposed for Cluster Head Selection (CHS). Finally, the performance of proposed model is evaluated over the conventional methods.**

Keywords—Wireless sensor network; clustering; cluster head; cluster head selection; chimp optimization; osprey optimization

I. Introduction

In recent years, a wide range of application domains, including military operations, medical care, smart cities, renewable electric power and energy, with monitoring the environment, have benefited significantly from the technological innovation and research carried out on WSNs. WSN is made up of BS and many sensor nodes [1, 2]. These are tiny independent devices with many limitations, including battery life, low processing power, and short communication distance [3]. To detect or sense variations in environmental factors like temperatures, movement, stress, moisture, vibration, noise, etc., these nodes are scattered geographically over a vast region. Nodes are effective enough to speed up data transfer via wireless networks. One of the fundamental technologies of substantial WSN, data collecting has attracted major academic interest [4, 5]. The data is sent to a data sinks or BS after collection. Sensor nodes are periodically placed in dangerous locations; and in these situations, replacing the batteries is not feasible. The sensor nodes use more energy since they constantly transmit and receive data. When nodes consume too much energy, they fail and can no longer be repaired or recharged with another battery source [6]. Therefore, balancing the nodes energy is the main issue in WSN [7, 8]. In order to increase the longevity and efficiency of the network, it is essential to allocate node energy correctly and optimize node energy consumption. Networking solutions related to sustainability and efficacy are being explored for energy concerns through hierarchical clustering algorithms [9, 10]. A familiar cluster-based routing methods like Low Energy Adaptive Clustering Hierarchy (LEACH) [11], Centralized-LEACH, and Improved-LEACH significantly aids in optimizing node energy towards the network longevity [12, 13]. However, such protocols are constrained as they choose an arbitrary applicant for the CH without taking energy variables into account, and not succeed to accomplish optimal formation of clusters and CH. This resulting in exhibiting greater communication costs, route by a single hop, and consume a greater amount of energy [14, 15] leading to network lifetime extension. Also, more optimization algorithms do involve in this CHS since from its evaluation, however, few existing optimization techniques struggle to preserve the level of investigation and extraction of choosing CH since they concentrate on particular search domains. Hence, proposing advanced optimization algorithms for optimal clustering is needed, and accordingly, this paper intends to prepare a new cluster-based routing model. The main contribution of the proposed model is given below:

- Proposing a new CIOO algorithm that combines both osprey optimization algorithm and chimp optimization algorithm for the CH selection, and also determining an improved trust evaluation as the constraint for routing.
- The proposed algorithm is subjected for evaluation with the conventional algorithms to emphasis its effectiveness.

The remaining part of this research paper is structured as below. Literature review is shown in Section II. The proposed cluster head selection method is illustrated in Section III. The results and discussion are highlighted in Section IV. Conclusion and future scope of the recommended model is provided in Section V.

II. Literature Review

The latest advancements in cluster head selection in WSN are examined in this section. The authors in [16] stated that one of the most important techniques used to extended the lifespan of WSNs operated by batteries was clustering routing. However, the majority of currently used clustering techniques fail to make use of the node redundancies in WSNs, resulting in significant energy waste. The authors in [17] introduced a technique for cluster head selection in multilevel topological control that makes use of fuzzy grouping pre-processing and optimization of particle swarms. The authors in [18] created a distributed CH selection approach whereby distances among sensors and a base station were taken into account to ensure continuous optimization of energy usage among the sensors. Authors in [19] introduced a brand-new technique termed clustering-based Cluster-Head Selection Scheme with Power Control (CHESS-PC) in PSN. Authors in [20] explored the Dynamic Cluster Head Selection Methods (DCHSM) for WSN to address the problems of unreasonable cluster leader selection, which in turn results in imbalanced consumption of energy and inconsistent coverage in the cluster communications.

Authors in [21] presented an approach called LEACH to control the unpredictability that occurs in clustering algorithms. With this strategy, the cluster head count was stabilized. Authors in [22] proposed a Hausdorff clustering technique, a new static kind of cluster approach based on the arrangement of sensor nodes that also improves network interaction and effectiveness. Authors in [23] proposed the Cluster Head Selection by Randomness with Data Recovery (CHSRDR) approach, which was a new way for WSN to select the cluster head with recovered data and maintained inside the cluster. Authors in [24] created a Firefly algorithm for choosing the cluster head in a manner which was sufficiently near to the base station as well as the sensor nodes. As a result, the period of delay was significantly compact, increasing the information packets' transmission speed. Authors in [25] introduced a Particle Swarm Optimization (PSO) technique for creating energy-aware clusters by selecting the best cluster heads. The PSO has ultimately reduced the expenditure of determining the perfect place for the CH nodes.

Authors in [26] created a Fuzzy Based Balanced Cost CH Selection Algorithm (FBECS) that takes into consideration the remaining energy, distance toward the sink, and population of the node in the area as inputs to the fuzzy decision-making method. Authors in [27] introduced Hyper Exponential Reliability Factor Based Cluster Head Election (HRFCHE), an integrated prediction technique for energy and trust evaluation for extending the network's lifespan. By extending the network lifetime and decreasing consumption of energy by 28% and 34%, respectively, compared to cluster head selection systems used as a benchmark, the outcomes of HRFCHE have implied greater efficiency. Authors in [28] concentrated on the effective operation of WSN applications, proving that the energy-efficient operation of the sensors became an important framework for extending the lifespan of the network. Authors in [29] implemented a Fuzzy-TOPSIS method in Select CH effectively and efficiently in order to optimize the WSN lifetime.

Even though the literature survey deals with efficient cluster head selection methods, there is still scope to improve the overall lifetime of the network and increase the number of alive nodes. These gaps can be addressed by developing new multi-constraint-based optimal cluster head selection methods.

III. Proposed Chimp Integrated Osprey Optimization Algorithm for Optimal Cluster Head Selection in WSN

The two main obstacles in wireless sensor networks are selecting the right cluster head and energy-related constraints. In order to overcome these obstacles and extend the network's lifespan, optimized algorithms are crucial. Clustering is the most critical process for increasing network longevity in WSNs. Sensor nodes are organized into clusters, and each cluster is assigned a CH. The CHs take data from the nodes in each cluster and forward it to the base station. Choosing the suitable CH in WSNs is a major challenge. Four criteria's energy, delay, distance, and security are used to establish a novel cluster head selection framework in our proposed model. The suggested model is summarized as follows:

- Initially, the clustering procedure groups the sensor nodes together. The k-means clustering algorithm is used in our suggested work to perform the clustering procedure.
- After the cluster's development, the cluster head is selected by CIOO algorithm which combines both osprey optimization algorithm and chimp optimization algorithm.
- The new CIOO algorithm is executed with four parameters like energy, distance, delay, risk.

A. *Clustering via k-means Clustering*

The research community has focused heavily on clustered to address the energy, scalability and lifetime problems of WSNs. Clustering algorithms restrict connection to a local area and utilized forwarding nodes to send the essential data to the reaming nodes of the network. Generally, the cluster members do interact with the CH, and the CH collects and combines the information gathered to save the energy. Here, the cluster heads can additionally create an additional layer of clusters between them. The k-means procedure [30], which offers straightforward, extremely dependable, fast-convergent repetitions & re-clustering throughout failure conditions, is a well-liked centralized as well as spread probabilistic partitional clustering method. The clustering process in the k-means algorithm is largely dependent on Euclidian distances. The procedure for k means algorithm is explained in step-by-step procedure given below.

- Group the nodes into 'k' clusters, take 'k' centroids and arrange them initially at random locations.
- Calculate the nearest centroid by calculating the Euclidian distance among every node as well as the entire center. Initial clusters are created by this process, 'k'.
- Recalculating the locations of centroids in every cluster and any changes to be checked from the prior calculation.

- If any changes in the centroid position, then proceed to Step 2; else the clustering process is complete and finalized the clusters.

This involves grouping the nodes into 'k' clusters, and selecting the CHs for every cluster is by the hybrid optimization technique like CIOO technique, which is explained in the subsequent section.

B. Optimal Cluster Head Selection via CIOO Algorithm

After the clustering process, optimal cluster head is selected depends on the consideration of nodes energy, distance like inter-cluster and intra cluster distances, delay and Risk factors by using CIOO algorithm. The calculation of distance, delay and risk of the clustering nodes are explained as follows. Fig. 1 shows the architecture of CH selection via CIOO algorithm.

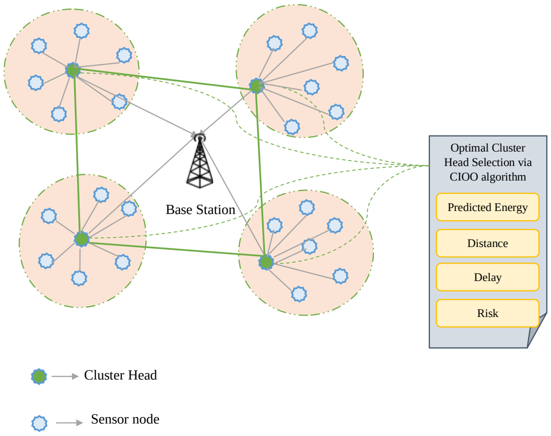

Fig. 1. CH selection framework by CIOO algorithm.

1) Distance (Δ_{CH})*:* The spacing among nodes in identical and separate clusters is measured by distance (Δ_{CH}). Here, Inter-cluster distance and intra-cluster distance are the two forms of distance that are computed. The Euclidean, Manhattan, and Chebychev distance formulas are utilized for the calculation of the distance among the cluster's nodes. Let R, S be the clusters, and their distance of each node in the cluster be $|R|$ and$|S|$, respectively. There are two distances determined by inter-cluster and intra-cluster distances are Average Linkage Distance and Complete Diameter Distance, respectively.

a) Average Linkage Distance (Inter cluster distance): Eq. (1) defines the calculation of averaged linkage distance that is the average distance between all of the nodes in two distinct clusters, where X represents the node in cluster, R and Y indicates the nodes in cluster S.

$$\Delta(R,S) = \frac{1}{|R||S|} \sum_{\substack{x \in R \\ y \in S}} d(\mathrm{x},\mathrm{y}) \tag{1}$$

b) Complete Diameter Distance (Intra cluster distance): Using Eq. (2), the whole diameter separation is determined as the spacing between two nodes in the same cluster (CH and Sensor node) which are located the furthest apart from each other.

$$\Delta(R) = \max\{d(x,y)\} \tag{2}$$

2) Delay (D_{CH})*:* When there do not exist accessible node for delaying the data, a delay constraint in a WSN is defined as the time interval between the dispersed data of one-time unit and another. As a result, the delay is more closely related to the delay of the probabilistic transmitting system. The mathematical computation of delay, which is the ratio of distance and speed, is shown in Eq. (3), where D' denotes the distance and S' denotes the speed.

$$Delay\ (D_{CH}) = \frac{D'}{S'} \tag{3}$$

3) Risk (f_{risk})*:* The various elements of security methods such as risky mode, the γ-risky mode and the security mode [31] that are explained below.

a) Risky mode: This strategy selects a present CH and accepts all risks to promote an ideal CHS. As a result, choosing CH is regarded as choosing an aggressive mode.

b) γ *-risky mode:* The setting of the Cluster Head which can handle the maximum of γ-risk level is selected based on the "γ-risky mode." Therefore, a likelihood metrics having a value between 0 and 1 of 100% that shows the secure and risky modes is represented by the symbol γ.

c) Security mode: This option supports the CH, which fulfills with security standards in security mode. The variables R^{sd} and R^{sr} indicates the security demand and the security rank pertaining to CH selection. The node is considered to be CH if $R^{sd} \leq R^{sr}$. Security constraints is determined as shown in (4). Additionally, "the risk should be 50% below if the chosen CH achieves the stated $R^{sd} < R^{sr}$. If the condition $0 < R^{sd} - R^{sr} \leq 1$ is true, the selecting process would proceed as planned rather than being delay in $1 < R^{sd} - R^{sr} \leq 2$. The state $2 < R^{sd} - R^{sr} \leq 5$ continues carrying out the related function as the CHS process unable to be completed.

$$f_{risk} = \begin{cases} 0 & \text{, if } R^{sd} - R^{sr} \leq 0 \\ 1 - e^{\frac{\left(R^{sd} - R^{r}\right)}{2}} & \text{if } 0 < R^{sd} - R^{sr} \leq 1 \\ 1 - e^{\frac{3\left(R^{dd} - R^{r}\right)}{2}} & \text{, if } 1 < R^{sd} - R^{sr} \leq 2 \\ 1 & \text{,if } 2 < R^{sd} - R^{sr} \leq 5 \end{cases} \tag{4}$$

C. Objective Function for CH Selection

The objective function for CH selection is calculated depends on the minimum fitness function of constraints like nodes energy, Delay, Distance and Risk. In the proposed work, two objective functions are considered, the first objective function is based on the consideration of Risk, Distance, Delay and the second objective function is based on the consideration of Energy. The fitness and the first objective function $f_1'$of Risk, Delay and Distance for CH selection is evaluated in Eq. (5) and Eq. (6), which obtained the minimum value of Risk, Distance and Delay, where,w_1, $w_2$and w_3 indicates the weight of Risk, Distance and Delay respectively. The summation of the total weight is represented as $\sum w_i = 1$. Then the second objective function f_2' of cluster head selection under the consideration of nodes energy is determined as per Eq. (7)

and Eq. (8). Here, w_4 denotes the weight of energy, which obtain maximum in energy consumption.

$$\text{Fit}= \text{Minimum}\left(w_1 * f_{\text{risk}} + w_2 * \Delta_{CH} + w_3 * D_{CH}\right) \quad (5)$$

$$\text{obj}(f_1') = \text{Minimum}(\text{ Fit }) \quad (6)$$

$$\text{Fit } = \text{Minimum}(w_4 * (1 - E)) \quad (7)$$

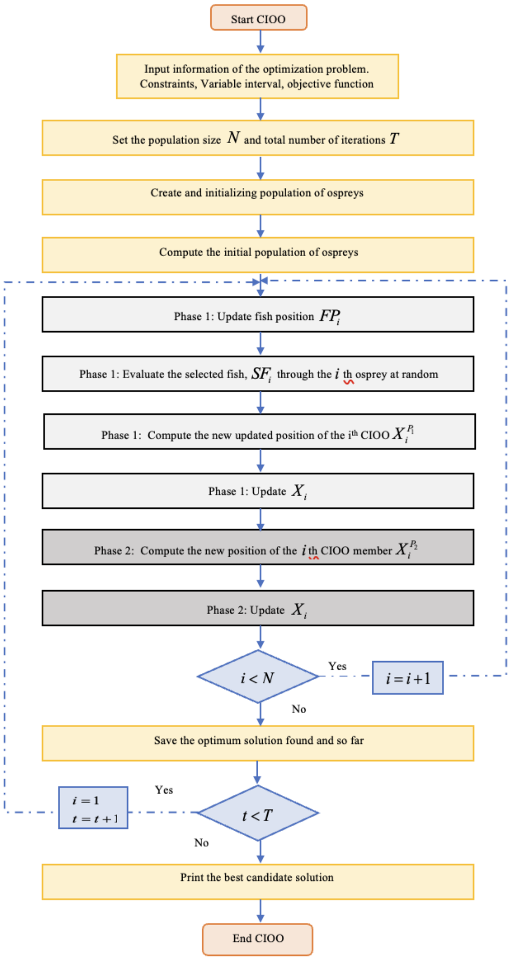
$$\text{obj}(f_2') = \text{Minimum}(\text{ Fit }) \quad (8)$$

Finally, combined the objective function is mathematically defined in Eq. (9), where, m denotes the parameter in the range of [0, 1], f_1' denotes the overall objective function for the CH selection, $f_1'$and f_2' are the two objective functions.

$$F' = m * f_1' + (1 - m) * f_2'; \;\; 0 < m < 1 \quad (9)$$

D. Solution Encoding for CH Selection

The Solution given to the CIOO algorithms are nodes. The lower bound value is fixed as 1 and the upper bound value is n, where, n denotes the number of sensor nodes. Here, the population size is allocated as 10. The flowchart in Fig. 2 shows the CIOO algorithm implementation processes.



Start CIOO
Input information of the optimization problem. Constraints, Variable interval, objective function
Set the population size N and total number of iterations T
Create and initializing population of ospreys
Compute the initial population of ospreys
Phase 1: Update fish position FP_i
Phase 1: Evaluate the selected fish, SF_i through the i th osprey at random
Phase 1: Compute the new updated position of the i^th CIOO $X_i^{P_1}$
Phase 1: Update X_i
Phase 2: Compute the new position of the i th CIOO member $X_i^{P_2}$
Phase 2: Update X_i
$i < N$
Yes
$i = i + 1$
No
Save the optimum solution found and so far
$i = 1$
$t = t + 1$
Yes
$t < T$
No
Print the best candidate solution
End CIOO

Fig. 2. Flowchart of CIOO algorithm.

IV. Results and Discussion

A. Simulation Procedure

The simulation of the proposed cluster-based routing in Wireless Sensor Networks (WSN) was conducted using MATLAB, with the MATLAB version being "Matlab R2018a."Further, the processor utilized was "Intel(IR) Core(TM) i5-1035G1 CPU @1.00GHz 1.19 GHZ" and the system had a total installed RAM size of "20.0GB," with "19.7GB" of it being usable.

B. Performance Analysis

Additionally, the performance of both the CIOO and conventional approaches was evaluated across various metrics, including Distance, Total Packets Transmitted to the Base Station (BS), Residual Energy, Delay, Alive Nodes, and Risk. Furthermore, the CIOO method was compared with state-of-the-art approaches such as DMOSC-MHRS [32] and PSO [33]. Additionally, a comparative analysis was conducted between the CIOO method and traditional algorithms, including GOA [34], SMO [35], BOA [36], COA [37], and OOA [38]. The network setup and energy model were illustrated in Fig. 3.

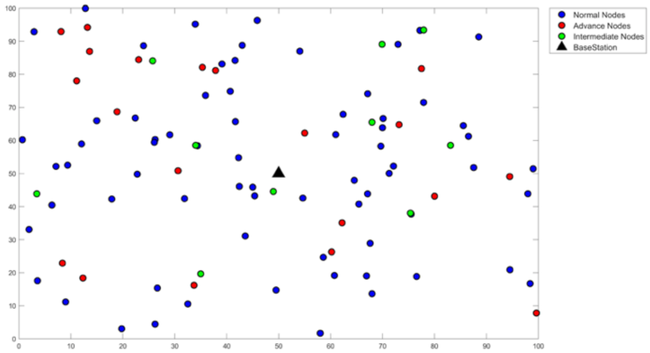


Fig. 3. Network setup.

C. Analysis on Delay and Distance

Fig. 4 and Fig. 5 provide an explanation of the delay and distance evaluation in comparison to PSO [33], DMOSC-MHRS [32], GOA [34], SMO [35], BOA [36], COA [37], and OOA [38] for the optimal selection of cluster heads. Additionally, this analysis is conducted while varying the number of rounds (500, 1000, 1500, and 2000). The objective for achieving optimal cluster head selection is to minimize both delay and distance ratings. Interestingly, at the 1000th round, the CIOO method exhibited the highest delay and distance values. However, as the number of rounds increased beyond 1000, there was a noticeable decrease in both delay and distance rates. Mainly, at the round 2000, the CIOO method achieved an impressively low delay value of 2134s. In contrast, traditional schemes recorded notably higher delay values, such as, PSO [33] =2856s, DMOSC-MHRS [32] =2150s, GOA [34] =2598s, SMO [35] =2342s, BOA [36] =2831s, COA [37] =2797s, and OOA [38] =2782s, respectively. In addition, the distance rate attained by the CIOO scheme is 8.732×104 at the round 1500, whereas the PSO [33], DMOSC-MHRS [32], GOA [34], SMO [35], BOA [36], COA [37] and OOA [38] resulted in greater distance ratings. As a result, the CIOO method employs a hybrid optimization strategy that combines

OOA [38] and COA [37] to achieve optimal cluster head selection in WSN. This method consistently achieves dependable results by efficiently decreasing both delay and distance metrics.

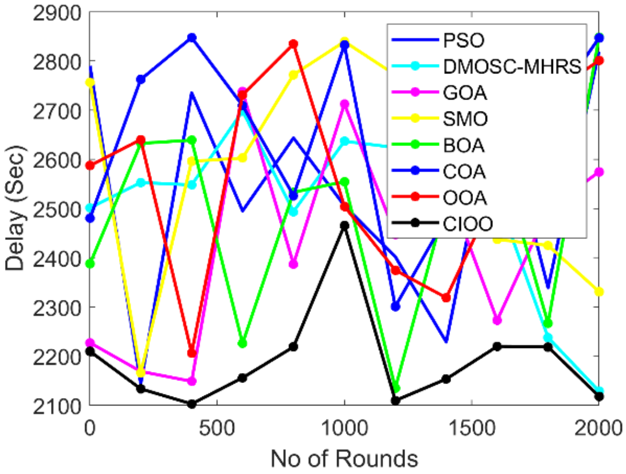

Fig. 4. Delay validation of CIOO with conventional algorithms.

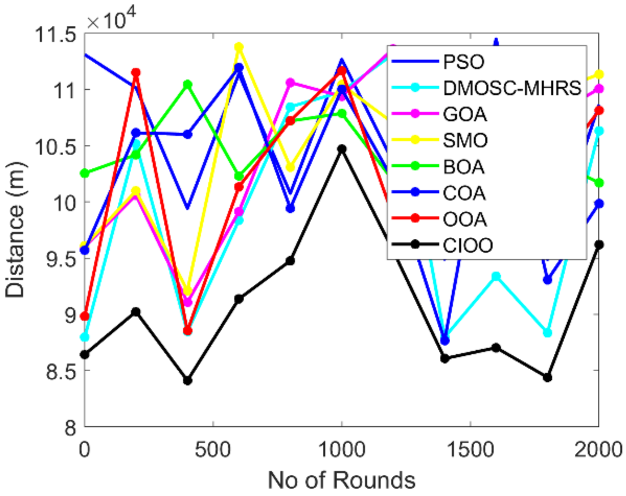

Fig. 5. Distance validation of CIOO with conventional algorithms.

D. Analysis on Alive Nodes

Fig. 6 presents a comparative analysis of the number of alive nodes in the CIOO approach versus PSO [33], DMOSC-MHRS [32], GOA [34], SMO [35], BOA [36], COA [37], and OOA [38] for cluster-based routing in WSN. In the pursuit of achieving optimal cluster-based routing in WSN, the primary goal is to maximize the number of nodes that remain active or "alive." During the initial round, both the CIOO and conventional approaches achieved the highest number of alive nodes. Nevertheless, as subsequent rounds progressed, the number of surviving nodes declined. Nevertheless, it's worth noting that the CIOO method consistently outperformed the conventional approaches by maintaining a higher number of active nodes. Significantly, the CIOO method achieved the highest number of active nodes, reaching 42 at round 2000. This count is notably superior to the numbers achieved by PSO [33], DMOSC-MHRS [32], GOA [34], SMO [35], BOA [36], COA [37], and OOA [38].

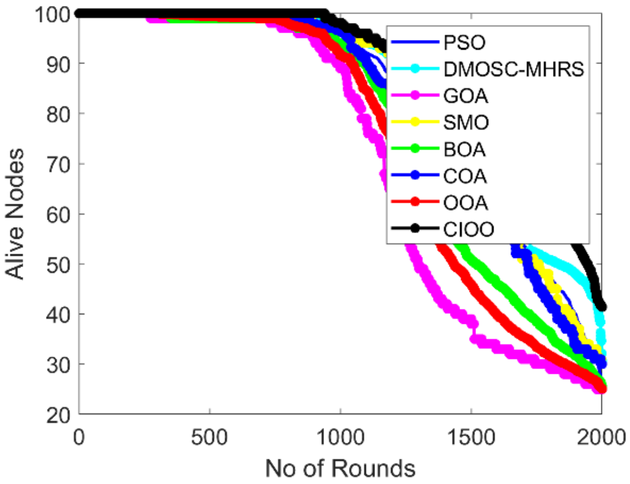

Fig. 6. Validation of CIOO with conventional algorithms on alive nodes.

E. Analysis on Risk and Total Packets Transmitted to Base Station

Fig. 7 depicts the assessment of risk associated with the CIOO method in comparison to PSO [33], DMOSC-MHRS [32], GOA [34], SMO [35], BOA [36], COA [37], and OOA [38] for the purpose of optimal cluster head selection. It is imperative to reduce the risk rate when aiming for the optimal selection of cluster heads. In this regard, the CIOO approach consistently demonstrated the lowest level of risk when compared to the conventional schemes throughout all rounds. Mainly, round=1000, the CIOO method achieved the lowest risk level of 0.012, while PSO [33], DMOSC-MHRS [32], GOA [34], SMO [35], BOA [36], COA [37], and OOA [38] exhibited higher risk ratings.

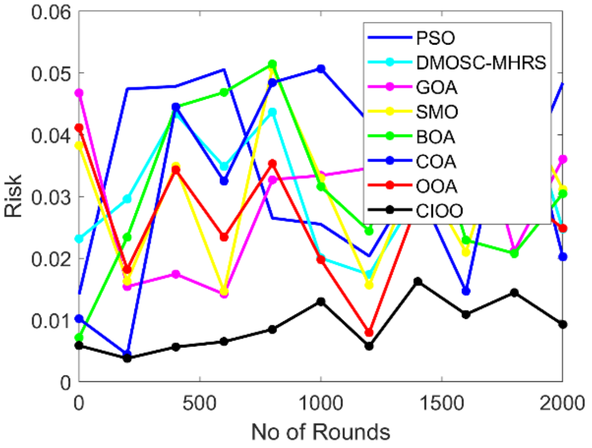

Fig. 7. Risk factor analysis of CIOO with conventional algorithms

The CIOO and conventional strategies is analyzed in terms of total packets transmitted to BS for cluster-based routing in WSN. The results of this analysis are presented in Fig. 8. Furthermore, this analysis is conducted with a network of 100 nodes, aiming to achieve the highest possible number of packets transmitted for optimal cluster-based routing. Primarily, the CIOO transmitted a larger number of packets to the BS compared to PSO [33], DMOSC-MHRS [32], GOA [34], SMO [35], BOA [36], COA [37], and OOA [38]. Hence, the CIOO approach consistently reduced risk ratings while increasing the overall number of packets sent to the BS when compared to conventional methods. In conclusion, the CIOO methodology demonstrates superior performance compared to previous approaches.

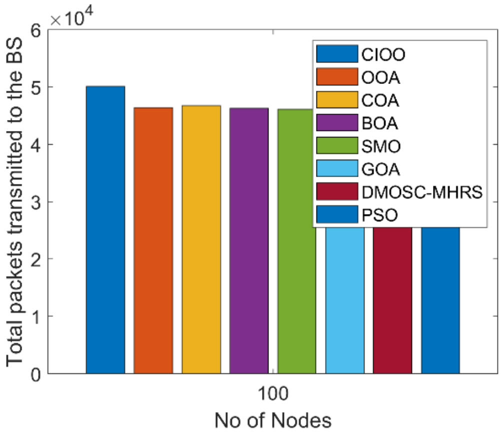

Fig. 8. Validation of CIOO and conventional schemes on total packets transmitted to base station.

F. Friedman Test Analysis

The Friedman test assessment on CIOO is compared with PSO [33], DMOSC-MHRS [32], GOA [34], SMO [35], BOA [36], COA [37] and OOA [38] for cluster-based routing in WSN is summarized in Table I. The Friedman test is a statistical hypothesis test designed for evaluating whether there exist statistically significant distinctions among various groups when analyzing correlated, non-parametric data. This test is commonly employed when dealing with multiple treatments or conditions, aiming to determine if there are overall differences in their effects. The procedure entails assigning rankings to the data within each group and subsequently assessing whether these rankings display significant variations among the groups. The presence of such variations indicates significant differences between the groups. Here, the CIOO attained the minimal value of 1, whereas the PSO [33] (5.900), DMOSC-MHRS [32] (3.500), GOA [34] (5.00), SMO [35] (6.500), BOA [36] (4.500), COA [37] (6.900) and OOA [38] (2.700), respectively.

TABLE I. ANALYSIS ON FRIEDMAN TEST

Methods	Values
PSO [33]	5.900
DMOSC-MHRS [32]	3.500
GOA [34]	5.000
SMO [35]	6.500

CIOO	1

V. CONCLUSION AND FUTURE SCOPE

This investigation proposes a new optimal cluster head selection model for WSNs based on multi constraints like delay distance security and risk. For cluster head selection, a brand new CIOO (Chimp Integrated Osprey Optimization) method has been developed. The proposed work could be evaluated with the conventional methods in terms of delay, distance, the number of alive nodes, residual energy, risk, total packets transmitted to the BS. And it is stated that the proposed CIOO method consistently outperforms against the conventional methods. These results suggest that CIOO is an effective and efficient approach for cluster-head selection in WSN, providing better network performance and energy efficiency while minimizing delay, distance and risk.

The proposed algorithm is better suited for higher-level applications where energy efficiency and the number of alive nodes are of critical concern. It may be possible to create sophisticated optimization algorithms to solve real-world problems like healthcare. Node failure detection may be an interesting security concern in the future.

Deep Learning-based Pothole Detection for Intelligent Transportation: A YOLOv5 Approach

Qian Li*, Yanjuan Shi, Qing Liu, Gang Liu
College of Vehicle and Transportation Engineering, Henan Institute of Technology, Xinxiang 453000, Henan, China

***Abstract*—Pothole detection plays a crucial role in intelligent transportation systems, ensuring road safety and efficient infrastructure management. Extensive research in the literature has explored various methods for pothole detection. Among these approaches, deep learning-based methods have emerged as highly accurate alternatives, surpassing other techniques. The widespread adoption of deep learning in pothole detection can be justified by its ability to learn discriminative features, leading to improved detection performance automatically. Nevertheless, the present research challenge lies in achieving high accuracy rates while maintaining non-destructiveness and real-time processing. In this study, we propose a deep learning model according to the YOLOv5 architecture to address this challenge. Our method includes generating a custom dataset and conducting training, validation, and testing processes. Experimental outcomes and performance evaluations show the suggested method's efficacy, showcasing its accurate detection capabilities.**

Keywords—Pothole detection; deep learning; intelligent transportation systems; YOLOv5

I. Introduction

Modern cities are witnessing a rapid transformation with the integration of advanced technologies, giving rise to the concept of smart cities [1]. These cities leverage cutting-edge infrastructure, digital connectivity, and intelligent systems to enhance the quality of life for their residents [2, 3]. The deployment of smart city facilities enables efficient management of resources, optimized transportation systems, and improved public services [4, 5]. However, amidst these advancements, the issue of deteriorating road conditions, particularly potholes, remains a persistent challenge. Potholes not only pose a threat to the safety of road users but also result in increased maintenance costs and traffic disruptions [6]. Therefore, the development of effective pothole detection methods has become crucial in modern cities.

Detecting and monitoring potholes in real-time is of paramount importance for maintaining the infrastructure and ensuring the safety of road users. Traditional manual inspection methods are time-consuming, expensive, and often inefficient for large-scale monitoring [7]. As a result, there is a growing interest in leveraging automated technologies for pothole detection. By employing advanced sensors, data analytics, and machine learning algorithms, cities can detect and address potholes promptly, thereby minimizing the associated risks and reducing repair costs.

In recent years, several technologies and methodologies have been proposed for pothole detection. Vision-based methods have gained a lot of attention because of their non-destructive nature and real-time applicability [4, 8, 9]. Vision-based techniques utilize cameras and image processing algorithms to analyze road surface images and identify potential potholes [10, 11]. These methods offer advantages such as cost-effectiveness, simplicity, and compatibility with existing surveillance infrastructure. Furthermore, with recent advances in deep learning techniques, vision-based pothole detection has witnessed substantial improvements in accuracy and robustness. Fig. 1 demonstrates a scheme of vision-based pothole detection system.

Previous studies have explored various vision-based and deep learning-based methods for pothole detection. Deep learning, in particular, has attracted significant interest from researchers due to its ability to learn discriminative features from large-scale datasets automatically. Convolutional neural networks (CNNs), one type of deep learning model, have displayed remarkable performance in a variety of computer vision tasks [13-15]. Consequently, researchers have investigated deep learning-based approaches for pothole detection, aiming to overcome the limitations of traditional methods and achieve higher accuracy.

However, despite the advancements in deep learning-based pothole detection, there are still research challenges and limitations that need to be addressed. Achieving high accuracy, non-destructiveness, and real-time processing capabilities remains demanding. To overcome these challenges, further studies are necessary to develop innovative approaches that meet the requirements of modern cities and their infrastructure management systems.

This investigation suggests a deep learning-based method for pothole detection using video analysis. By adopting a deep learning approach, we aim to tackle the aforementioned research challenges as well as satisfy the needs of high accuracy, non-destructiveness, and real-time processing. To train our model, we generate a custom dataset specifically designed for the pothole detection challenge. This dataset encompasses diverse road conditions and a wide range of pothole instances. Through training, validation, and testing processes, we demonstrate the effectiveness of our suggested method.

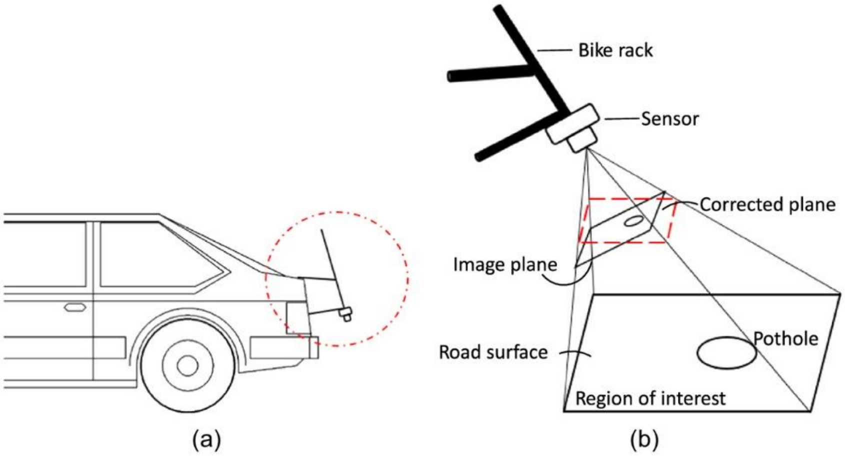

Fig. 1. A scheme of vision-based pothole detection [12].

The significance of this study lies in its pioneering approach to pothole detection through video analysis and the implementation of cutting-edge deep learning techniques, particularly the YOLOv5 algorithm. By addressing the challenges associated with pothole detection, such as high accuracy requirements, non-destructiveness, and real-time processing, our research contributes to the advancement of intelligent transportation systems.

The contributions of this research can be summarized as follows. Firstly, we generated a custom dataset tailored for the pothole detection challenge, providing a comprehensive benchmark for future studies. Secondly, we propose an efficient deep learning method that demonstrates superior performance in pothole detection compared to existing approaches. Lastly, we carry out extensive experiments and performance evaluations to verify the efficacy and viability of our approach, thereby contributing to the body of knowledge in this field.

The rest of this paper is as follows, Section II review previous studies. Section III discusses the methodology. Section IV presents experimental results. Finally, conclusion presents in Section V.

II. Related Works

Ping et al. [16] developed a deep learning-based method for street pothole detection. The proposed approach utilizes video analysis to identify and locate potholes in real-time accurately. The method employs a custom dataset specifically designed for the pothole detection challenge, ensuring diverse road conditions and pothole instances. Through extensive training, validation, and testing processes, the deep learning model demonstrates superior performance compared to existing approaches. However, the study acknowledges the limitation of demanding high accuracy, non-destructiveness, and real-time requirements, which pose research challenges. Further investigation is needed to address these limitations and develop innovative solutions to meet the needs of modern cities and infrastructure management systems. As a result, this research contributes by providing a comprehensive benchmark dataset, proposing an efficient deep-learning method, and conducting extensive performance evaluations for street pothole detection.

Pandey et al. [2] focused on pothole detection of critical road infrastructure using convolutional neural networks (CNNs). The method employs CNNs to analyze road surface images and accurately identify potholes. The study demonstrates the effectiveness of the proposed approach through extensive experiments and evaluations. However, the limitation of the method lies in its dependence on high-quality images and the need for sufficient training data. Further research is required to address these limitations and enhance the method's performance for real-world applications. In summary, this research contributes by utilizing CNNs for pothole detection, highlighting the method's potential, and identifying areas for future improvement.

Ahmed in study [17] presented a smart pothole detection method based on deep learning using dilated convolution. The proposed approach leverages dilated convolutional neural networks (DCNNs) to analyze road surface images and accurately detect potholes. The method takes advantage of the dilation technique to capture both local and global contextual information, enhancing the detection performance. Extensive experiments are conducted to validate the effectiveness of the proposed approach. However, the limitation of the method lies in its reliance on high-quality and well-segmented images, which may pose challenges in real-world scenarios with varying lighting conditions and road surface textures. Further research is needed to address these limitations and improve the method's robustness and generalizability. Therefore, this research contributes by introducing a deep learning-based approach with dilated convolution for smart pothole detection and highlighting the potential of this technique in enhancing road infrastructure management systems.

In research [18], a real-time pothole detection method was proposed using the YOLOv5 algorithm, aiming to enhance intelligent transportation systems. The approach utilizes the YOLOv5 architecture, which is a state-of-the-art object detection algorithm, to detect potholes in road images accurately. The method focuses on achieving real-time processing capabilities, enabling prompt identification and response to potholes. The study validates the feasibility of the approach through experiments and evaluations. However, one limitation of the method is its reliance on high-quality and well-annotated training data, which may pose challenges in real-world scenarios with diverse road conditions and variations in pothole appearances. Further research is necessary to address these limitations and improve the method's performance in challenging environments.

III. Methodology

In our study, a YOLOv5 model was generated for pothole detection on a custom dataset. The architecture of YOLOv5 is shown in Fig. 2 [19]. The dataset was annotated, meaning that each image was manually labeled to indicate the location and extent of potholes. This annotation process involved carefully marking the boundaries of potholes to create bounding box annotations. Additionally, class labels were assigned to differentiate potholes from other objects in the images.

To enhance the dataset and improve model performance, data augmentation techniques were applied. These techniques involved transforming the original images to create additional variations. In our study, data augmentation was performed to cover a broader range of scenarios and appearance variations. Various transformations, such as rotation, scaling, flipping, and changes in lighting conditions, were applied to the images. By augmenting the dataset, we aimed to increase its diversity and enable the model to generalize better and handle different real-world scenarios.

Subsequently, the dataset was split into three subsets: training, validation, and testing sets. The split was performed using an 80%, 13%, and 7% ratio, respectively. The training set, comprising 80% of the dataset, was utilized to train the YOLOv5 model. During the training phase, the model learns from the annotated images, optimizing its parameters to improve pothole detection accuracy. The validation set, accounting for 13% of the dataset, was utilized to appraise the model's performance during training. It helps in monitoring the model's progress, identifying potential overfitting, and making necessary adjustments to improve accuracy. Lastly, the testing set, consisting of 7% of the dataset, was utilized to assess the final performance of the trained YOLOv5 model. It provides an unbiased evaluation of the model's ability to detect potholes in unseen data.

After preparing the annotated and augmented dataset, we split it into three subsets: training, validation, and testing sets. The split was based on a specific ratio, with 80% of the dataset allocated to the training set, 13% to the validation set, and 7% to the testing set.
