Table VI shows the comparative results of other related work. In [35], the FFT method is used to reduce a certain amount of computational complexity, but still uses 16 bits long-data for computation. Due to the high computational complexity brought by long-bit-width data operations, in the case of limited DSP resources, it limits the computational parallelism. But multiple types of PEs are used in our paper which is suitable for different types of low-bit-width data operations to avoid low computational efficiency of a single long-bit-width PE structure. Therefore, compared with this method, our paper shortens the time by 89.3 times and reduces power consumption by 21.8 times. In addition, our paper reasonably allocates bit-widths for each layer of the CNN to improve its accuracy by 0.43%. In [36], they deploy a binary Resnet20 using an Application Specific Integrated Circuit (ASIC), and all network parameters are quantized to 1 bit. This method reduces computational complexity to the minimum via ultra low bit-widths, achieves higher frequency of operations and lower power consumption as shown in Table VI. However, this ultra low bit-width quantization method also produces a large precision error, which greatly affects the performance of the CNN. But the mixed precision quantization method and retraining the quantized model in our paper achieve a higher accuracy rate of 9.88% than that. In terms of computational speed, by efficiently utilizing the development board resources and increasing the parallelism of convolution calculation through multiplication circuits built with LUTs, it has achieved lower computational latency. In [37], the Winograd algorithm is used to reduce the computational load, but 16-bit data operation limits the overall performance, the mix precision low bit-width CNN in our work is more effective.

TABLE VI. PERFORMANCE COMPARISON

Work	Experiment Platform	Frequency (MHz)	Bit-Width (bits)	Latency (ms)	Throughput (GOP/S)	Energy (mJ)	Accuracy

[36]	ASIC 65nm	1000	1	0.98	/	3.8	81.8
[37]	ZynqZ7035	150	16	/	43.5	/	/
our	Kintex 7	100	6-8MP	0.47	179	6.26	91.68

V. CONCLUSIONS AND FUTURE WORK

In this paper, we propose a high-performance CNN design method tailored for edge computing. Employing quantization methods and a strategy search algorithm in the software algorithm mitigated the significant accuracy loss associated with quantizing CNN models. In the FPGA accelerator design, we implemented a reuse structure based on a streaming processing architecture. This involved designing different Processing Elements (PEs) according to the characteristics of the CNN model structure and quantization bit-width. Notably, different network layers could share the same PE, optimizing resource utilization. For efficient data transmission, we adopted a strategy of packing quantized low-bit-width data into long words. This approach fully leveraged high-bandwidth data transfer, utilizing a register set as a buffer and employing a data reuse method to achieve synchronous data reading and computing. The validation of our method using Resnet20 on the CIFAR-10 dataset demonstrated its effectiveness. Comparative analysis with other computational platforms and related works revealed that our CNN accelerator outperformed a unified 16-bit FPGA accelerator design, achieving an 89-fold increase in computing speed with lower power consumption. Specifically, our CNN accelerator exhibited a computing speed 3.72 times faster than the GPU (RTX 2070 SUPER), while consuming only 6.2% of its power. In conclusion, our research presents a novel approach to high-performance CNN design for edge computing, showcasing substantial improvements in computing speed and power efficiency compared to existing methods. As part of future work, we plan to explore further optimizations and scalability of our approach, addressing potential challenges and extending its applicability to broader CNN architectures and datasets.

Combining Unsupervised and Supervised Learning to Predict Poverty Households in Sakon Nakhon, Thailand

Sutisa Songleknok, Suthasinee Kuptabut*
Department of Computer, Sakon Nakhon Rajabhat University, Sakon Nakhon, Thailand

***Abstract*—Poverty is a problem that various government agencies are attempting to address accurately and precisely. This solution relies on data and analysis of features affecting poverty. Machine Learning is a technique to analyze and focus on poverty features encompassing five livelihood capitals: human, physical, economic, natural, and social capital to understand the household context and environment. The dataset contains 1,598 poverty households from Kut Bak district, Sakon Nakhon, Thailand. K-prototype was used to group categorical and numerical dataset into four clusters and labelled as Destitute, Extreme poor, Moderate poor, and Vulnerable non-poor. The performances of the Decision tree classifier with feature selection algorithms, including MI, ReliefF, RFE, and SFS, are compared. The best performance is SFS with F-measure, precision, and recall at 74.6%, 74.8%, and 74.7%, respectively. The result is the decision tree rules to predict the poverty level of households, enabling the establishment of guidelines for resolving household issues, and addressing broader problems within the areas.**

Keywords—K-prototype; decision tree; feature selection; Sakon Nakhon poverty households; unsupervised learning; supervised learning

I. INTRODUCTION

Poverty alleviation policy holds a significant role in every nation, with each country tailoring its poverty criteria to evaluate household poverty accordingly. Specifically, many of these countries utilize the poverty line measurement, a criterion established by the United Nations [1], to gauge household poverty levels. Subsequent poverty-related issues arise from various factors, extending beyond just income. Pandemic mitigating investments have largely not rectified issues such as poor health, lack of quality agricultural resources, and production quantity. These factors have further contributed to household poverty, making them multidimensional poor.

Thailand has established an information system dedicated to poor households. Responsible organizations, namely the Community Development Department [2] under the Health Board of Quality of Public Life Development (HBL), oversee data collection, database management, and information display through official online platforms. This organization collects basic minimum needs data at a household level in Thailand. This data demonstrates household members' fundamental status across various aspects of life quality, adhering to minimum standards.

In collaboration with the Office of the National Economics and Social Development Council (NESDC) and the National Electronics and Computer Technology Center (NECTEC), the Thai People Map and Analytics Platform (TPMAP) [3], was developed. This platform is designed to identify individuals in impoverished households who meet the criteria for basic minimum needs across five dimensions of poverty: health, living conditions, education, income, and access to public services. In addition, the Program Management Unit on Area-Based Development (PMUA) has developed a system called Practical Poverty Provincial Connext (PPPConnext) [4] to collect data on impoverished households within 20 provinces, which rank lowest in the nation's Human Achievement Index (HAI) regarding income. This data collection focuses on five dimensions of livelihood assets: human capital, economic capital, natural capital, physical capital, and social capital. These dimensions are utilized to develop appropriate solutions that match the specific needs of these households.

Most studies on poverty primarily focus on the target group at a household level, employing various research methodologies, including qualitative, quantitative, and Machine learning techniques. The poverty data were analyzed using two techniques: 1) Supervised Learning: This approach involves formulating the poverty level or target class. For instance, the research in [5], a study on factors affecting poverty, in [6], the prediction of households exhibiting characteristics at risk of poverty, and in [7] the development of prediction models for depression levels among the elderly in low-income households. This model utilizes techniques, such as Decision tree, Logistic regression, Neural networks, and Random forest. 2) Unsupervised Learning: This approach involves processing data without predetermined poverty level formulations, such as the research in [8, 9] that used clustering techniques to categorize impoverished households. Poverty alleviation programs should be prioritized in household clusters based on the poor conditions identified within each cluster. The research in [10] analyzes the factors affecting the sustainable livelihoods of poverty households. Both techniques contribute to predicting the relationship between factors and poverty, shaping policy guidelines and effective solutions to alleviate poverty.

The objectives of this paper are 1) to cluster the poverty households, 2) to compare the performance of feature selection techniques using a Decision tree classifier, and 3) to create rules to predict poverty status households. We utilized data from impoverished households collected through PPPConnext, and applied data mining techniques to comprehend the characteristics associated with poverty. The identified features are analyzed using both unsupervised learning and supervised learning models. Unsupervised learning, specifically the K-prototype algorithm, is employed to cluster the households based on their living capital aspects. Supervised learning, including Mutual information (MI), ReliefF, Recursive feature elimination (RFE), and Sequential forward selection (SFS) are utilized to reduce the information sizes. A Decision tree is utilized to construct a comparative model, select appropriate features, explain household characteristics, and predict the poverty level of households effectively.

The paper is structured as follows: Section II provides a comprehensive review of the related works; Section III outlines the proposed framework, detailing both clustering and classification steps, and Section IV presents the obtained results. Section V and Section VI wrap up the paper with a discussion and conclusion, respectively.

II. Related Work

A. Multidimensional Poverty

Poverty can be defined from different perspectives. Organizations, such as NESDC use the “poverty line” to establish standards for basic minimum food needs and essential goods, quantified in Baht per person per month. The poverty line has changed accordingly over the years. Individuals earning less than this threshold are classified as “poor.” This categorization is determined by comparing monthly income against the poverty line [11, 12]. Poverty has a relationship with the households’ economic status. The measurement of poverty in general uses the poverty line criteria as the condition for classifying poverty and non-poverty of households, which is widely used at provincial, national, and global levels. Nevertheless, extensive global research revealed that household poverty can be attributed to either insufficient income or various other contributing factors.

The UNDP and the Oxford Poverty and Human Development Initiative (OPHI) [11] have jointly created the Multidimensional Poverty Index (MPI) comprising 10 dimensions: nutrition, child mortality, and years in schooling, school attendance, cooking fuel, sanitation, drinking water, electricity, housing, and asset ownership. A lower MPI value for a country signifies reduced poverty, whereas a high MPI suggests significant multidimensional challenges, related to inequalities in areas like gender, ethnicity, and infrastructure.

B. Feature Selection

Feature selection (FS) involves the process of selecting, removing, and reducing duplication of the relevant features. There are three approaches to feature selection: Filter, Wrapper, and Embedded [13 - 15].

1) Filter approach. Filters evaluate the relevance of features based on intrinsic characteristics. The popular filter approaches include MI and ReliefF.

2) Wrapper approach. The wrapper approach constructs prediction models considering the feature interactions. The well-known wrapper approaches are REF and SFS.

3) Embedded approach. In feature selection, three main approaches are employed: Filter, Wrapper, and Embedded. Embedded approaches like LASSO (L1-Regularization) and RIDGE (L2-Regularization) combine aspects of both filters and wrappers.

In this paper, feature selection was implemented using the Filter approach (MI and ReliefF) and the Wrapper approach (REF and SFS).

C. Unsupervised Learning

The clustering technique, an unsupervised learning approach, is used for categorizing data based on similarities in their characteristics. In the analysis of poverty, this technique segregates impoverished households according to dataset features. The parameter k (number of clusters) can be determined either through predefined business rules, or varied techniques to determine an appropriate value for “k”.

When employing the clustering technique with the numeric dataset, the utilization of K-means clustering is required. For instance, the study in [8] applied the K-means algorithm to assess poverty status and categorize it into three levels: low, medium, and high poverty. This method was implemented in households in Hulu Sungai Tengah Regency, Indonesia. The study’s findings would be utilized to develop policies tailored to individual households to achieve specific goals. The study in [9] analyzes poverty conditions within a community in the Philippines, and groups households into three clusters: stable, critical, and at-risk. Each cluster offers valuable insights into poverty conditions, guiding the community’s planning and program implementation.

In study [16], the utilization of the clustering technique to group poverty households of Lagangilang, Abra, Philippines was divided into three clusters: non-poor, near poor, and poor. Each group describes different characteristics of households following health and nutrition, education, income, and livelihood to formulate appropriate poverty reduction programs. In cases [10] involving both numerical and categorical data, the K-prototype algorithm was employed. For example, this approach was utilized to analyze factors influencing the sustainable livelihoods of impoverished households, using data mining from poor households in Kut Bak district in Sakon Nakhon province, Thailand. The dataset classified poor households into four clusters: extreme, high, moderate, and low poverty levels.

D. Supervised Learning

Classification, a supervised machine learning method, involves constructing models to predict data labels in a given dataset. For example [17], poverty prediction was carried out using three techniques: Softmax classification, Random forest classification, and Multi-layer perception classifier. In predicting impoverished household data from the Cambodia DHS dataset, two types of predictive outcomes are considered: three-class classification (poor, middle, rich), and five-class classification (poorest, poorer, middle, richer, richest). The study revealed that the three-class classification achieved a higher accuracy of 87%, compared to the five-class classification.

Another research in [18] focused on identifying the causes of old-age poverty in South Korea, the decision tree algorithm was applied using 13 variables, with old-aged poverty as the target. The study revealed that earned income was the most significant factor influencing elderly poverty. In another research [19] conducted in Malaysia, Naive Bayes, Decision tree, and K-nearest neighbors' classifiers were employed to predict the bottom 40 percent of poverty households. Among these models, the decision tree model achieved the highest performance. Additionally, in [20] the decision tree model was utilized to predict household poverty based on health status using the Cuatro Santos health and demographic surveillance databases in Nicaragua. The key indicators of poverty, such as the presence of piped water with a meter, the highest education level in households, and ownership of a refrigerator.

This paper employed the Decision tree algorithm to generate a tree-like structure to represent classification rules. In this structure, internal nodes represent dataset features, branches represent decision rules, and each leaf node represents a specific class label.

III. METHODOLOGY

We acknowledge the importance of outlining the reasons behind our selection of the "proposed framework" in addressing the specific problems at hand. Here are the reasons that make the proposed framework appropriate for addressing such problems. Collectively, these facets enable comprehensive analysis, feature emphasis, and effective model evaluation, making the framework apt for addressing the problem. The proposed framework follows a systematic four-phase structure, ensuring methodical handling from data preprocessing to model evaluation. It sources the poverty dataset from a reliable source (PPPConnext) and employs K-prototype clustering for grouping similar data elements, aiding focused analysis. Automatic labelling of poverty households within clusters streamlines interpretation. Multiple feature selection techniques (MI, ReliefF, REF, and SFS) enhance model efficiency by emphasizing impactful attributes. Evaluation via Decision tree classifier comparing feature sets based on F-measure, precision, and recall ensures a robust model selection.

The studies as mentioned earlier used either unsupervised or supervised learning techniques. However, our framework utilized both unsupervised and supervised learning. Unsupervised learning was used to determine the poverty status of households, while supervised learning selected suitable feature datasets to generate rules using a decision tree model for predicting poverty status.

The limitations of the existing framework that may hinder its suitability for the current problems include the dependency on specific datasets restricting adaptability to new data structures, the clustering method may struggle to effectively group elements in different data types, limited feature selection techniques hindering the identification of crucial attributes, rigid evaluation metrics might not align with the problem domain, and inflexibility in model selection might limit adaptability to diverse data demands.

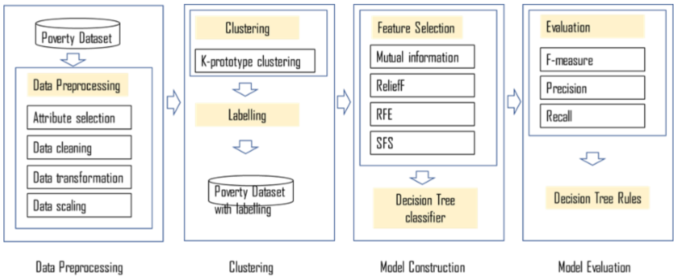

Fig. 1. Conceptual framework.

The conceptual framework shown in Fig. 1 outlines a four-phase process: Data preprocessing, Clustering, Model construction, and Model evaluation. In the data preprocessing phase, the poverty dataset was sourced from the PPPConnext database and underwent preparation for analysis. Utilizing K-prototype clustering, data objects with similar characteristics were grouped into clusters; ensuring data with differing characteristics were placed in distinct clusters. The poverty households cluster was then automatically labelled. Following this, feature selection techniques, MI, ReliefF, REF, and SFS, were applied to identify relevant features. The study then evaluated the performance of the Decision tree classifier by comparing various feature sets, selecting the one with the best performance based on F-measure, precision, and recall.

A. Data Set

The dataset utilized in this study originates from the PPPConnext database, focusing on poor households situated in Kut Bak district, Sakon Nakhon province, Thailand. Sakon Nakhon province ranked 71st out of 78 provinces in terms of income index in 2019. Within this province, Kut Bak district had a poverty rate reaching TPMAP in 2019 at the highest level. This district also held the distinction of having the lowest income level in Sakon Nakhon province. The dataset consists of five types of livelihood assets (human capital, physical capital, economic capital, natural capital, and social capital) to explain the asset limitations of poverty and power within the households. In total, the dataset contains responses from 1,598 households with 76 features (58 categorical features and 18 numerical features). These features are described in detail in Table I.

TABLE I. DETAILED DESCRIPTION OF FEATURES

capitals	**Attributes**	**Explanation**	**Value**
Economic capital (24 features)	income_remitted (N)	monthly remittances	Mean:909.57
	income_farming (N)	monthly income from farming	Mean:3,074.45
	income_non_farming (N)	monthly non-farming income	Mean:6,074.45
	income_welfare (N)	monthly income from state welfare	Mean:893.93
	expenses (N)	monthly household expenses	Mean: 6,951.47
	rice_farming (C)	rice farming households	0=No (14.02%) 1=Yes (85.98%)
	livestock (C)	livestock raising households	0=No (97.43%) 1=Yes (2.57%)

capitals	Attributes	Explanation	Value
	fishing (C)	freshwater fishery households	0=No (79.91%) 1=Yes (20.09%)
	industrial_crop (C)	industrial crop farming households	0=No (86.92%) 1=Yes (13.08%)
	poultry (C)	poultry farming household	0=No (94.62%) 1=Yes (5.38%)
	pig (C)	pig farming household	0=No (99.12%) 1=Yes (0.88%)
	cattle (C)	cattle farming households	0=No (72.03%) 1=Yes (27.97%)
	loan_cousin (C)	a loan from cousins with no collection of interest	0=No (98.56%) 1=Yes (1.44%)
	loan_cousin_ interest (C)	a loan from cousins with a collection of interest	0=No (95.24%) 1=Yes (4.76%)
	loan_community (C)	a loan from the financial savings community-based organizations	0=No (78.85%) 1=Yes (21.15%)
	loan_state (C)	a loan from state-support financial savings	0=No (78.29%) 1=Yes (21.71%)
	loan_BAAC (C)	a loan from the Bank for Agriculture and Agricultural Cooperatives	0=No (82.67%) 1=Yes (17.33%)
	loan_savings_ bank (C)	a loan from the Government Savings Bank	0=No (97.62%) 1=Yes (2.38%)
	loan_commercial _bank (C)	a loan from the Thai Commercial Bank	0=No (98.81%) 1=Yes (1.19%)
	loan_private (C)	a loan from Private AMC	0=No (98.87%) 1=Yes (1.13%)
	loan_creadit_shop (C)	households with credit accessibility from consumer goods shops and production factors	0=No (99.50%) 1=Yes (0.50%)
	loan_informal_ debt (C)	a loan from informal debt	0=No (99.50%) 1=Yes (0.50%)
	student_loan (C)	a loan from a student loan fund	0=No (98.62%) 1=Yes (1.38%)
	savings (C)	households with savings	0=No (45.74%) 1=Yes (54.26%)
Physical capital (31 features)	water_resources (C)	farming using water from water resources, such as rivers, brooks, and ditches	0=No (65.71%) 1=Yes (34.29%)
	reservoirs (C)	farming using water from reservoirs, and village ponds	0=No (93.43%) 1=Yes (6.57%)
	groundwater (C)	farming using water from under groundwater, surface water, artesian aquifer	0=No (85.61%) 1=Yes (14.39%)
	rainwater (C)	farming using rainwater	0=No (40.05%) 1=Yes (59.95%)
	irrigation_canals (C)	farming using irrigation canals	0=No (97.93%) 1=Yes (2.07%)
	ownership_rights (C)	households with issuing legal land rights documents, such as Title Deed	0=No (66.83%) 1=Yes (33.17%)
	ownership_rights _rai (N)	number of arable lands issuing legal land rights documents of ownership (Rai)	
	government_lease (C)	households with land title documents, such as ALRO, S.K.1	0=No (36.55%) 1=Yes (63.45%)
	government_lease _rai (N)	number of arable issuing land title documents (Rai)	
	no_title_arable_ land (C)	households with no land tile documents for arable lands in forest-protected areas or national parks	0=No (90.68%) 1=Yes (9.32%)
	no_title_arable_ land _rai (N)	number of arable lands within forest-protected areas or national parks (Rai)	
	others_rent_free (C)	households farm on others' arable lands rent-free	0=No (84.29%) 1=Yes (15.71%)
	others_rent_ free _rai (N)	number of households farm on others' arable lands rent-free	

capitals	Attributes	Explanation	Value
	others_rent (C)	households farm on others' arable lands with rent payment	0=No (99.50%) 1=Yes (0.50%)
	others_rent_rai (N)	number of arable lands from others with payment (Rai)	
	no_access_water (C)	arable lands with water resources inaccessible for cultivation	0=No (60.76%) 1=Yes (39.24%)
	fertile_soil (C)	number of arable lands with fertile agricultural land	0=No (86.55%) 1=Yes (13.45%)
	risk_area (C)	arable lands in areas with natural disaster risks, such as floods	0=No (98.62%) 1=Yes (1.38%)
	home_ownership (C)	households owning their own homes	1 = Staying with others (0.63%) 2 = Renting a house (0%) 3 = Building houses on others' lands (6.51%) 4 = Owning their houses (92.87%)
	house_condition (C)	house conditions	1 = Need urgent repair (3.32%) 2 = Need remedial action. (38.05%) 3 = No repair needed. (58.64%)
	house__cleanlines s (C)	cleanliness and organizing belongings of households	0= Messy (7.57%) 1= Not messy (92.43%)
	indoor_sewage (C)	households with an indoor sewage system	0=No (16.90%) 1=Yes (83.10%)
	toilet_sanitation (C)	toilets in households with healthy and sanitation conditions	0=No (5.82%) 1=Yes (94.18%)
	waste_separation (C)	households with waste separation	0=No (9.89%) 1=Yes (90.11%)
	electricity_house (C)	households with electricity	0=No (0.75%) 1=Electricity supplied from another house. (1.56%) 2=Yes (97.68%)
	tap_water (C)	households with water supply	0=No (72.09%) 1=Yes (27.91%)
	drinking_water (C)	households buying drinking water	0=No (21.53%) 1=Yes (78.47%)
	mobile_phone (C)	households having mobile phones	0=No (13.33%) 1=Yes (86.67%)
	computer_ ownership (C)	households with computers	0=No (90.30%) 1=Yes (9.70%)
	IT_welfare (C)	households utilizing technology to access state welfare services	0=No (37.23%) 1=Yes (62.77%)
	IT_income (C)	utilizing technology to increase household incomes	0=No (57.81%) 1=Yes (48.19%)
Human capital (18 features)	member_below_ 15 (N)	households with members' ages ranging over 15 years old	Max:7 Min:0 Mean:0.75
	skills_number (N)	number of household members having diverse skills in professions	Max:2 Min:0 Mean:1.16
	education_level (C)	households having individuals with the highest level of education	0 = No schooling education/non-completion of primary level (4.51%) 1 = Elementary school level (37.30%) 2 = Lower secondary school level (22.47%) 3= Secondary school

capitals	Attributes	Explanation	Value
			level or vocational certificate (23.59%) 4 = Diploma or higher vocational degree (3.82%) 5= Bachelor's degree (7.13%) 6 = Higher than a bachelor's degree (1.19%)
	employed_number (N)	working age in the household (15-59 years)	Max:7 Min:0 Mean:1.99
	farming (C)	farming households	0=No (26.47%) 1=Yes (73.53%)
	general_hired (C)	households with general hired occupation	0=No (77.60%) 1=Yes (22.40%)
	agriculture_ employ (C)	households' employment in the agriculture sector	0=No (91.36%) 1=Yes (8.64%)
	self_employed (C)	households with self-employed	0=No (93.55%) 1=Yes (6.45%)
	fishery (C)	households with fishery	0=No (98.87%) 1=Yes (1.13%)
	civil_services (C)	households with civil services	0=No (94.24%) 1=Yes (5.76%)
	contract_employee _in_government_ sector (C)	household members working as government employees	0=No (96.75%) 1=Yes (3.25%)
	private_employee (C)	household members working in private sectors	0=No (86.11%) 1=Yes (13.89%)
	disabled_number (N)	householders with disabled members with self-reliance	Max:2 Min:0 Mean:0.06
	bedridden_number (N)	household members with bedridden old adults and disabled adults with no self-reliance	Max:2 Min:0 Mean:0.02
	chronic_number (N)	household members with chronic illnesses	Max:4 Min:0 Mean:0.22
	healthy_number (N)	households with healthy members	Max:10 Min:0 Mean:2.96
	welfare_card (C)	households' members possessing public welfare card	0=No (10.95%) 1=Yes (89.05%)
	elderly_number (N)	elderly household members aged over 60 years old	Max:3 Min:0 Mean:0.64
Natural capital (2 features)	natural_living (C)	households using natural resources for livelihood, such as mushrooms, firewood, forest plants, edible insects	0=No (16.08%) 1=Yes (83.92%)
	natural_income (C)	households using natural resources to earn income such as honey, herbs, mushrooms	0=No (32.17%) 1=Yes (67.83%)
Social capital	join_community_ group (C)	households joining a community, such as occupational groups, finance groups, social welfare groups	0=No (2.25%) 1=Yes (97.75%)

Data type: N = numerical; C = categorical

B. Data Preprocessing

Data preprocessing is a crucial phase, aimed at simplifying data complexity and enhancing data quality before applying data mining algorithms. This phase encompasses four activities: attribute selection, data cleaning, data transformation, and data scaling.

1) Attribute selection: The dataset contains numerous attributes, some of which are irrelevant. This phase focuses on reducing the dataset size by eliminating irrelevant attributes. For example, features related to social capital that describe community characteristics and non-significant attributes, such as those indicating households without relevant information, were removed.

2) Data cleaning: Data cleaning involves filling in missing values and enhancing the data process of cleaning by filling in missing values. Numeric features are imputed with the average value from the same group, while categorical features are replaced with constant values. For example, if the land size of ownership rights is null, the null values are filled with the average value of the land size of all ownership rights or adjusted welfare allowance for the elderly on age brackets: individuals aged 60-69 received 600 Baht/month, those aged 70-79 received 700 Baht/month, those aged 80-89 received 800 Baht/month, and individuals aged 90 and above received 1,000 Baht/month.

3) Data transformation: Data transformation is used to convert textual information into numerical values for analysis. For example, "farmer" is represented as 1, while "non-farmer" represents 0, the highest education level of all household members, the count of elderly individuals aged 60 and above, as well as the count of working-age individuals between 15 and 59, are calculated.

4) Data scaling: Min-max normalization [21] is a scaling technique in which value rescaled data in a range of 0 to 1 using the formula in (1). The technique is applied to specific numerical attributes, such as the number of households, income, and expenses.

$$X' = (X - X_{min})/(X_{max} - X_{min}) \qquad (1)$$

where, X_{max} and X_{min} are the maximum and the minimum values of a feature, respectively.

C. Clustering

Clustering is the process of grouping data with similar characteristics, where clusters exhibit higher similarity within and differ from other clusters. In this paper, the K-prototype is applied to dealing with both numerical and categorical data. This algorithm combines numerical and categorical data to form clusters. The clusters represent 4 categories of poverty, ranging from the most impoverished to the less poor: Destitute, Extreme poor, Moderate poor, and Vulnerable non-poor, according to the PMUA classification. Poverty household status is labelled on each record and defined as a target attribute for creating a model. The resulting cluster offers valuable insights for community planning and implementation.

D. Model Construction

The feature selection process aims to reduce data dimensionality by removing irrelevant features. The algorithm, MI, ReliefF, REF, and SFS are used to select features from the dataset for classification. Relevant features or predictive features are selected by removing the irrelevant features. After selecting the features, the Decision tree classifier builds the model based on several predictive features.

1) Feature selection techniques: The goal of feature selection is to find the optimal feature subset. By eliminating irrelevant features, the number of features can be reduced, the accuracy of the model can be improved, and the running time can be reduced [22].

a) MI: MI is used as a measure of the relationship between a feature and the target output. The higher the value, the more strongly relevant between a feature and the target, which suggests that the feature is selected. If the score is 0 or very low, then a feature and the target are weakly relevant [23].

b) ReliefF: ReliefF is a filter method of the feature selection algorithm. It finds the weights of features in the case where y is a multiclass categorical variable. According to the correlations between features and targets, different weights are assigned to each feature, and the feature with a slighter weight greater than a certain threshold will be removed [24].

c) RFE: RFE is an algorithm to select features in a training set that are more relevant in predicting the target output and removing weak features. The RFE works by searching for a set of features by starting with all features in the training dataset and selecting the most significant features by finding a high correlation between features and target output. Such recursion works until the number of remaining features reaches the desired number [25].

d) SFS: SFS is an algorithm that selects features from the set of features and evaluates them for a model iterate number between the different sets by reducing and improving the number of features so that the model can find the optimal performance and results. The SFS starts with one feature and adds more iteratively [26].

2) Classification: A Decision tree is a technique to build a predictive model through two phases: the training phase builds a model from a training set with a labelled target output, and the testing phase finds the quality of the trained model from the testing set without labelled target output. The model is like a tree structure. The nodes represent the features, the branches represent the decision rules, and the leaf node represents a poverty household status.

E. Model Evaluation

The performance is evaluated based on the calculation of F-measure, precision, and recall using the confusion matrix. It consists of four elements: true positive (TP), false positive (FP), false negative (FN), and true negative (TN) [27].

TP is a condition when the observations coming from positive classes are predicted to be positive. TN is a condition when observations from negative classes are predicted to be negative. FP is a condition when the actual observation comes from negative classes but is predicted to be positive. FN is a condition when the actual observation comes from a positive but in a positive-negative predicted class.

The performance of the experiments is represented using precision, recall, and F-measure that are evaluated using Eq. (2) to Eq. (4), respectively.

$$Precision = TP/(TP+FP) \tag{2}$$

$$Recall = TP/(TP+FN) \tag{3}$$

$$\text{F-measure} = (2*\text{precision}*\text{recall}) / (\text{precision}+\text{recall}) \quad (4).$$

IV. Results

A. Clustering

The clustering algorithm divided the households into 4 clusters. Table II summarizes the cluster based on the important attributes. Cluster 4 constitutes the largest group containing 31.9%. While, the smallest cluster is Cluster 3, making up 19.1% of the entire cluster. The distinct characteristics of each group (four groups) according to the features to formulate the label were addressed below.

TABLE II. The Cluster of Poverty Households

Cluster	Instance	Percentage	Cluster name
1	397	24.8	Vulnerable non-poor
2	387	24.2	Extreme poor
3	305	19.1	Moderate poor
4	509	31.9	Destitute
Total	**1,598**	**100.0**	

The PMUA labels are assigned post-clustering, and their validity hinges on the methodology employed for the assignment. We used a procedure considering inherent cluster characteristics and, when available, external domain knowledge for labeling. To validate these labels, we cross-referenced them with established poverty classification criteria and assessed alignment with expected poverty attributes. Additionally, we ensured label consistency within clusters by employing quality assessment metrics, aiming to uphold the accuracy and reliability of the assigned PMUA labels.

Group classification using a clustering algorithm resulted in four clusters as shown in Fig. 2.

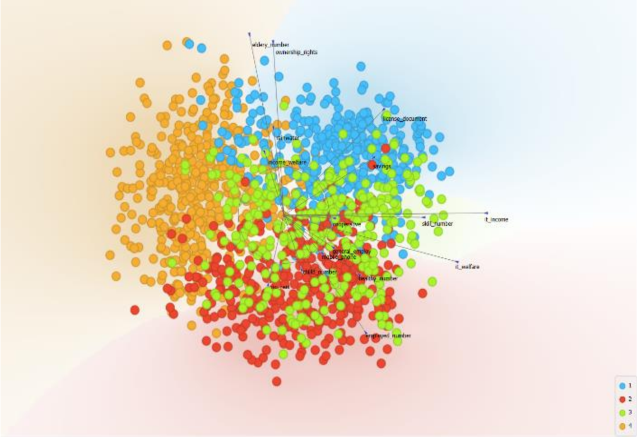

Fig. 2. Freeviz visualization.

Fig. 2 from orange software is used to show the characteristics of four different classes in different colors. Each class describes different characteristics of households. Each axis corresponds to different features; the length of each axis corresponds to the importance of the feature. Cluster 1 is grouped within a blue cluster that is characterized by government lease, savings, and rainwater. Cluster 2 is grouped within a red cluster that is characterized by employed_number, others_rent_free, member_below_15, mobile_phone, general_hired, and healthy_number. Cluster 3 is grouped within a green cluster that is IT_welfare, IT_income, and skills_number, while Cluster 4 is grouped within an orange cluster that is the elderly_number, income_welfare, and ownership_rights. The distribution of instances in Fig. 2 revealed that the instance of Cluster 3 (green area) had fewer colored areas, compared to other clusters. Some instances were mixed up in other clusters and many more were mixed up in Cluster 2 and Cluster 1.

The cluster of the data group divided into four clusters in TABLE II revealed that Cluster 4 had instances more than other clusters. Cluster 1 and 2 had similar cluster stances. Cluster 3 had the least instances. The remaining clusters exhibited similarity in the instance of all clusters, indicating that all householders included members of labor force age, school-age children, elderly, patients with chronic illness, bedridden patients, and disabled members with no self-reliance, disabled members. Most households owned mobile phones. The specific characteristics of each cluster are shown in Fig. 3 as follows:

Cluster 1 included 397 households that were the groups obtaining income from remittances and state welfare programs at the highest mean score, which was more than other clusters. These households also had an average monthly income at the second ranking. The income shows no difference, compared to the cluster with the highest income. The number of elderly and disabled members was at the highest level. The sizes of arable lands with legal land rights documents for ownership, and the legal land rights documents were more than other clusters. Most households completed their education at the elementary school level. The households exhibit the highest savings and use rainwater the most. However, those with features closely aligned to Cluster 3 are referred to as the “Vulnerable non-poor group”.

Cluster 2 included 387 households with an average income from off-farming sectors at the highest level. The average household income from farming sectors and state welfare programs was at the lowest level. The average household expenses ranked second; the labor force age members were at the second-ranking. The arable land sizes were at the lowest rank. Most arable lands had legal rights documents. Most household members completed lower secondary education or vocational certificate education. The households have the highest number of mobile phones, with a quantity similar to Cluster 3. The households have a high number of members under 15 years old, which is also close to that of Cluster 3. This group is referred to as the “Extreme poor group”.

Cluster 3 included 305 households with the average income at the highest level. The average income earned from farming sectors was at the highest level. The income from off-farming sectors was ranked second. Diverse skills in professions were at the highest level. The average number of labor force age and patients with chronic illness were at the highest level. The arable lands of all types were ranked second. Most household members completed their lower secondary education. The households use technology for state welfare applications and income generation, with proximity similar to Cluster 2. This group is referred to as the “Moderate poor group”.

Cluster 4 included 509 households with the average income at the lowest level. The income from off-farming sectors was at the lowest level. The healthy members and the labor force age members were both at the lowest level. The number of elderly was higher than young age members. The diverse skills for professions were at the lowest level. Most household members completed the elementary education level. The average expenses were at the lowest level. The average number of bedridden patients was more than in other clusters but equal to Cluster 1. The average number of chronically ill patients was at the second rank. The average number of disabled members was ranked second to Cluster 1, and the arable lands had the legal land rights documents for ownership. This group is referred to as the “Destitute group”.

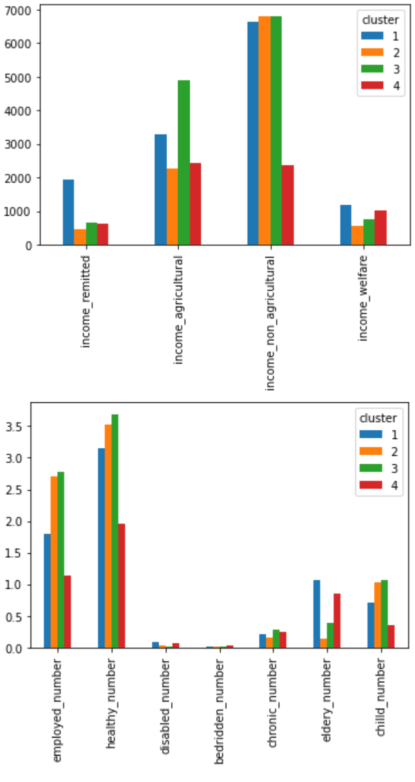

Fig. 3. Data comparison among clusters based on specific characteristics.

B. Feature Selection

The poverty household dataset was classified into four poverty statuses, namely Destitute, Extreme poor, Moderate poor, and Vulnerable non-poor. The values were stored in a column named “target”. Feature selection has been implemented using MI, ReliefF, RFE, and SFS algorithms. These algorithms were implemented in the Scikit-learn library for the selection of optimal features. The number of employed features by the MI algorithm was a high value. The top 20 features were selected to predict the model, shown in Table III. ReliefF calculates a feature score for each feature which can then be applied to rank and select the top 20 scoring features for feature selection, as shown in Table III.

TABLE III. THE SELECTED FEATURES BY EACH ALGORITHM

Features	MI	ReliefF	RFE	SFS	Common

The implementation of the RFE algorithm using the Decision tree classifier on the training set and five cross-validations was performed. The algorithm determined the optimal number of features, and 19 features were selected, indicating the importance of these features on the poverty dataset. The implementation of the SFS algorithm using the Decision tree classifier on the training set and five cross-validations was performed. The algorithm found the best score of 21 features.

Table III shows the selected features that have the most effect on the poverty level. The selected features were considered relevant by at least two selection algorithms. All algorithms selected eight features, and seven features were selected by three algorithms. The five features were selected by 2 algorithms and the other features were selected by only one algorithm. The set of features consists of 20 features, called common features.

C. Model

In this paper, the experiments were divided into 6 experiments that employed different feature selection techniques on a dataset of 1,598 impoverished households.

The selected features gained from the feature selection phase are used to train the Decision tree classifier. The number of features selected by the several types of feature selection algorithms is presented in Table IV. In the processing model, 10-fold cross-validation is applied. Nine folds were used for training and the remaining fold was used for testing. The process was repeated 10 times. The performance metrics such as F-measure, precision, and recall are measured to demonstrate the results and comparative analysis of the feature selection algorithms. The metrics consider the entire features, common features, and the feature set obtained by applying the feature selection techniques. Performance evaluation is given in Table IV.

From Table IV, the performance results varied significantly based on the size of selected features and characteristics attributes. The particular data characteristics associated with SFS using 12 features differed from those of other techniques, thus yielding diverse performance outcomes.

The SFS algorithm has achieved the best performance with F-measure, precision, and recall at 74.6%, 74.8%, and 74.7%, respectively. Thus, the SFS algorithm performed better than other feature techniques. Besides in Table V, a confusion matrix presented the performance of the Decision tree classifier with selected features by SFS algorithm.

TABLE IV. PERFORMANCE OF DECISION TREE CLASSIFIER

Feature selection techniques	No.of features	F-measure	Precision	Recall
All	76	72.0	72.0	72.2
MI	20	71.4	71.5	71.6
ReliefF	20	71.4	71.5	71.6
REF	19	73.6	73.7	73.6
SFS	21	74.6	74.8	74.7
Common features	20	58.9	59.2	58.9

TABLE V. CONFUSION MATRIX OF THE RESULTS OBTAINED BY THE DECISION TREE CLASSIFIER WITH SFS ALGORITHM

Actual	***Predicted***			
	Vulnerable non-poor	***Extreme poor***	***Moderate poor***	***Destitute***
Vulnerable non-poor	74.2%	5.2%	7.8%	6.6%
Extreme poor	6.7%	73.1%	9.8%	7.5%
Moderate poor	8.5%	8.5%	69.5%	6.2%
Destitute	10.6%	13.2%	12.9%	79.7%

From the decision tree model, the total number of trees is 587 nodes, which interprets 293 rules, and the depth is 16. The example tree model showed depths of trees, represented in Fig. 4. The most important feature, is whether using technology to request state welfare benefits is or not (IT_welfare), classified into nodes for with (IT_welfare=1) and without (IT_welfare=0) using technology. The left node shows the high education level of members in the household (education_level), the next level is arable lands with the legal land rights documents (ownership_rights), and the number of older people (elderly_number). The model from the Decision tree classifier can be interpreted and understood in the decision tree rules format. Table VI shows the example of decision tree rules. The relationship rules were able to describe the rule and class.

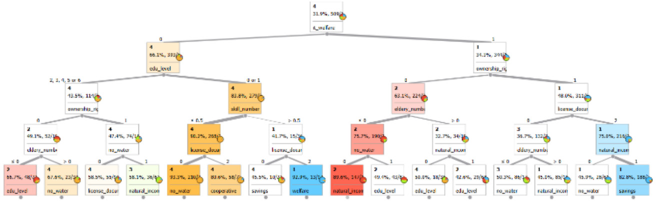

Fig. 4. Decision tree model with 5-level depth.

TABLE VI. DECISION TREE RULES MODEL APPLYING RESULTS

Rules	**Condition (If)**	**Class**	**Description**
1	IT_welfare = 1 and ownership_rights = 1 and government_lease = 0 and elderly_number > 0 and natural_income = 1 and skills_number > 0 and no_access_water = 1 and loan_savings_bank = 0 and education_level in (1,3,4,6) and reservoir = 0	Vulnerable non-poor	IF households utilize technology for requesting the state welfare programs AND have aroma lands with legal land rights documents of ownership AND have aroma lands without legal land rights documents AND have elderly members AND utilize natural resources to earn income AND have skills for professions AND have arable lands with no access to water supply AND no loan from the Savings Banks AND have their highest level of education lower than bachelor's degree AND have access to water supply from reservoirs for farming
2	IT_welfare = 1 and ownership_rights = 0 and elderly_number <= 0 and no_access_water = 0 and natural_income = 1 and education_level in (0,3,4,5,6)	Extremely poor	IF households utilize technology for requesting state welfare programs AND have aroma lands with legal land rights documents of ownership AND no elderly members AND no access to water supply for farming AND utilize natural resources to earn income AND have their highest level of education lower than bachelor's degree
3	IT_welfare = 0 and education_level in (2,3,4,5,6) and ownership_rights = 1 and no_access_water = 1 and natural_income = 0 and savings = 1 and elderly_number <= 0.33	Moderate poor	IF households utilize no technology for requesting the state welfare programs AND have their highest level of education lower than a bachelor's degree AND have aroma lands with legal land rights documents of ownership AND no access to water supply for farming AND no utilizing natural resources to earn income AND have savings AND have at least one elderly member
4	IT_welfare = 0 and ownership_rights = 1 and no_access_water = 0 and government_lease = 0 and savings = 0 and self_employed =0 and education_level = 2	Destitute	IF households utilize no technology for requesting the state welfare programs AND have aroma lands with legal land rights documents of ownership AND no access to water supply for farming AND having no aroma lands with legal land rights documents AND having no savings AND no self-employed business AND have their highest level of education at lower secondary education

V. DISCUSSION

Upon analyzing the factors affecting the classification of poverty levels based on livelihood capital, aiming to construct poverty indicators for classifying poverty levels, it was found that factors derived from the SFS technique and Decision tree classifier yielded the highest F-measure. These factors comprised five factors within human capital, seven factors within physical capital, six factors within economic capital, and 1 factor within natural capital. Nevertheless, there were no factors identified within the social capital category.

Features affecting the predicting of the poverty level, such as education_level, and skills_number, which were features related to the competencies of household members. The study in [28] suggests that the factors influencing poverty in Thailand are linked to the rise in per capita income and education, both showing statistical significance at the 0.10 level. The household members who completed at a basic education level or higher than the basic education level had abilities to earn more income and were able to scaffold knowledge to increasingly improve skills. These could reduce poverty in households.

The feature called IT_welfare for receiving welfare resources from government sectors of Thailand. Some welfare allowances were able to be accessed through the online register, receiving state welfare resources through applications, household members having technological skills and mobile phones. Thus, the household members were able to access state welfare resources and received assistance from the government sectors following the established conditions. The study referenced in [29] shows that the Internet has a significant impact on alleviating the vulnerability to poverty among rural households.

The features, ownership_rights, and government_lease, were related to arable lands of poor households because the land is a critical asset, the primary for generating a livelihood, and a main vehicle for investing, especially for the poor as it provides a means of livelihood through the production and sale of crops and other products. The studies in [30, 31] suggest that land can serve as collateral for credit to invest in the land or be exchanged for capital to start up another income-generating activity. The study in [32] suggests that the absence of land ownership may contribute to a high fertility rate, low capital investment, and consequently lower living standards.

The feature called no_access_water was related to water supply for farming was limited. Most farmers use rainwater as a major waste resource for agriculture. Some areas have water resources close to their arable lands, such as canals, and ponds. Thus, the increasing amount of water for farming areas is important for farmers to be able to farm yearly.

The elderly, children aged from 0-14 years of age, chronically ill, and bedridden patients living in households are vulnerable groups, who are key features affecting poverty because many households, while not currently in poverty, recognize that they are vulnerable to events - a bad harvest, a lost job, an illness, and unexpected expenses, an economic downturn - that could easily push them into poverty [33]. A vulnerability group is a group with no income or few incomes that rely on family members or households with members in the labor force, but rely on the state welfare system, such as the subsidy support budget program for newborn babies to six years old, the subsistence allowance provision for disabled persons. These support household expenses and alleviate poverty for vulnerable groups [34] or households would afford health care if the households had members with inpatients, households with members aged over 65 years, and households with disabilities [35].

VI. Conclusion

The conclusion concisely outlined our key findings, insights, and results, demonstrating the importance and implications of our work in addressing the issue.

The research employed both supervised and unsupervised learning techniques to analyze data on poor households. Initially, unsupervised learning divided the data into four clusters representing different poverty levels: Destitute, Extreme poor, Moderate poor, and Vulnerable non-poor groups. Using supervised learning, the study identified key features influencing poverty levels, employing algorithms like MI, ReliefF, RFE, and SFS. The decision tree model using the SFS algorithm proved most effective, achieving 74.6% F-measure, 74.8% precision, and 74.7% recall in predicting poverty levels. The study then summarized the characteristics of each poverty level in the Kut Bak district:

Destitute Households: These households earn an average monthly income of 6,426 Baht; heavily rely on state welfare due to limited development opportunities, with elderly members, minimal education levels, poor health, and reliance on government services.

Extreme Poor Households: With monthly income averaging around 10,088 Baht, these households mostly derive earnings from non-agricultural sources due to limited arable lands, facing excessive expenses with minimal savings, but possessing skills to access welfare resources.

Moderate Poor Households: These households earn an average income of 13,100 Baht monthly from both farming and off-farming sectors, facing substantial expenses on healthcare, but managing some savings. Lack of water access impacts household development.

Vulnerable Non-Poor Households: This group earns an average of 13,030 Baht monthly, primarily from agricultural sources and remittances, owning considerable arable lands, providing opportunities for an improved quality of life compared to other clusters.

In future work, we will create applications to predict households of poverty in four levels with the conditions drawn from the decision tree and using the class of poor households in the area of Kut Bak district. The leader of the community was a person who selected households following the characteristics of four clusters. After entering the data through the applications for predicting poor households to determine the accuracy between humans and machines and create the acceptance of the results from the predicting with the relevant organization in the areas to apply it for actual practices.

Acknowledgment

This research is part of the “Precision Poverty Alleviation in Sakon Nakhon Province” awarded as a research scholarship from the Program Management Unit on Area Based Development (PMUA) in 2022. Thank you to all households in Kut Bak district, Sakon Nakhon for collecting data.

Ethical Consideration

The data was collected from households in Kut Bak district in Sakon Nakhon located in the northeastern region of Thailand in 2022. Ethics approval for the fieldwork was obtained through the Human Research Ethics Committee at Sakon Nakhon Rajabhat University. Guarantee No. HE 65-095.

***Abstract*—With the development of computer technology, computer-aided instruction is being used more and more widely in the field of education. Based on speech recognition technology and deep neural network, this paper proposes an online oral English teaching system. Firstly, the speech recognition technology is introduced and its feature extraction is elaborated in detail. Then, three basic problems and three basic algorithms that need to be solved in speech recognition system using Markov model are discussed. The application of HMM technology in speech recognition system is studied, and some algorithms are optimized. The logarithmic processing of Viterbi algorithm, compared with the traditional algorithm, greatly reduces the amount of computation and solves the overflow problem in the operation process. By combining deep network with HMM, continuous speech signal modeling is realized. According to the characteristics of the DNN-HMM model, it is proposed that the model cannot model the long-term dependence of speech signals and train complex problems. Based on Kaldi, the model training comparison experiments of monophonon model, triphonon model and adding feature transformation technology are carried out to continuously improve the model performance. Finally, through simulation experiments, it is found that the recognition rate of the optimized DNN-HMM mixed model proposed in this paper is the highest, reaching 97.5%, followed by the HMM model, which is 95.4%, and the lowest recognition rate is the PNN model, which is 90.1%.**

Keywords—Deep neural network; Markov model; voice design technology; Viterbi algorithm; oral English teaching

I. INTRODUCTION

With the evolution of computer science and technology, computer-aided instruction is being used more and more widely in the field of education. Nowadays, with the help of computer-aided instruction, people can learn languages more conveniently [1]. The rich graphics and sound processing functions of the computer effectively promote the language learning effect of people. At present, research hotspots in this field focus on exploring effective language learning methods that combine speech recognition technology with multimedia technology [2]. The development of software for teaching spoken English with speech identification has emerged as a hot topic in this type of language teaching.

For the time being, given the cutting-edge lookup development of monosyllabic recognition, Zhang Jing et al. first added the algorithm primarily based on finite country vector quantization and the lookup consequences of its expanded algorithm in monosyllabic recognition, then added the algorithm based totally on the implicit Markov model, and special brought the lookup consequences of syllable attention combining hidden Markov mannequin with different administration strategies [3]. Yang et al. introduced the Fisher criterion and L2 regularization constraint to ensure the minimization of parameter errors in the stage of backpropagation adjustment of parameters, the dispersion of samples between classes and the concentration of intra-class distributions after classification, and the proper order of magnitude of network weights to effectively alleviate the overfitting problem [4]. Sun et al. utilized the end-to-end technological know-how primarily based on hyperlink timing classification to Japanese speech recognition. Considering the traits of Hiragana, katakana, and kanji in more than one writing type in Japanese, they explored the effect of special modeling gadgets on awareness overall performance via experiments on Japanese records units [5]. Huang et al. proposed a finite local weight shared convolutional neural network (CNN) speech recognition based on the Meir spectral coefficient (MFSC) feature to address the problem of unsatisfactory recognition effect in traditional speech recognition applications [6]. Hou Yimin et al. mainly analyzed and summarized several current representative deep learning models, introduced their applications in speech identification for speech feature extraction and acoustic modeling, and finally summarized the problems faced before and the development direction [7].

Compared with the traditional single model for speech classification, this paper innovatively proposes to optimize the deep neural network and fuse it with the Markov model, and the recognition rate of the DNN-HMM fusion model is greatly improved. The application of HMM technology in speech recognition system is studied, and some algorithms are optimized. The logarithmic processing of Viterbi algorithm, compared with the traditional algorithm, greatly reduces the amount of computation and solves the overflow problem in the operation process. By combining deep network with HMM, continuous speech signal modeling is realized. According to the characteristics of the DNN-HMM model, it is proposed that the model cannot model the long-term dependence of speech signals and train complex problems.

II. Speech Recognition Technology

A. Speech Recognition Technology and Feature Extraction

Speech attention means the ability to transform voice symbols into corresponding textual content [8]. Fig. 1 shows the shape of conventional voice attention and it consists in most cases of five parts: feature extraction, acoustic modeling, pronunciation lexicon, language modeling, and decoding search.

The mathematical description of this process is shown in Eq. (1):

$$\hat{W} = \arg\max_{W} P(W|\ O) \tag{1}$$

W is the candidate word sequence.

From Bayes' formula, Eq. (1) could be further written as:

$$\hat{W} = \arg\max_{W} P(W|\ O) = \arg\max_{W} \frac{P(W)P(O|\ W)}{P(O)} \tag{2}$$

P(W) stands for language model and represents the probability of occurrence of word sequence W; P(O|W) stands for acoustic model, which represents the probability of generating feature sequence O given word sequence W; P(O) represents the likelihood of watching the acoustic characteristic O, whose price has no impact on the closing cognizance result and could be overlooked [9]. So, system in Eq. (2) can be written as below:

$$\hat{W} = \arg\max_{W} P(W)P(O|\ W) \tag{3}$$

The speech signal is a kind of non-stationary signal, so it cannot use the traditional signal processing method. It is found that the characteristics of speech signals remain relatively stable in a short period (10~30ms). Therefore, it is necessary to do some processing before feature extraction, that is, pre-emphasis, frame, and window.

The speech signal is attenuated by 12dB/ octave after it is emitted from the glottis and by 6dB/ octave after it is radiated through the mouth. Therefore, in the speech spectrum generated after short-time FFT, the components of the high-frequency part are smaller, and the entire spectrum becomes steeper [10]. To flatten the signal spectrum, a pre-weighting process is generally required to improve the high-frequency portion at a rate of 6 dB per octave. This is usually accomplished using a first-order high-pass numerical filter:

$$H(z) = 1 - \mu z^{-1} \tag{4}$$

Frame processing is primarily used to enable the extraction of acoustic features and is predicated on the short-term stability of speech signals. The technique of overlapping segmentation is used to carry out frame segmentation, allowing for a seamless transition between different voice frames to guarantee their temporal continuity [11]. In the realm of digital signal processing, the most often utilized window functions are the rectangular window and the Hamming window, among others. In particular, the most popular window for voice recognition is the Hamming window, which may significantly reduce the spectrum leakage brought on by the truncation effect [12]. It has the following window functions:

$$w(n) = \begin{cases} 0.54 - 0.46\cos\left(\dfrac{2\pi n}{N-1}\right) & 0 \le n \le N-1 \\ 0 & \text{others} \end{cases} \tag{5}$$

The human ear perceives different frequency components of speech signals to different degrees, in which it is more sensitive to the low-frequency part and less distinguishable from the high-frequency part. MFCC is designed primarily based on this auditory grasp attribute of the human ear. Fig. 1 suggests the ordinary method of extracting MFCC features:

1) The enter voice sign is preprocessed to attain the time-domain sign after including the window.

2) Due to the challenging nature of analyzing the features of speech symbols in the temporal region, they are usually transformed into the spectral domain for evaluation [13]. The linear spectrum of the time-domain symbols is obtained by a short-time FFT transform:

$$S(k) = \sum_{n=0}^{N-1} s_w(n) e^{-j\frac{2\pi nk}{N}} \quad (0 < k < N) \tag{6}$$

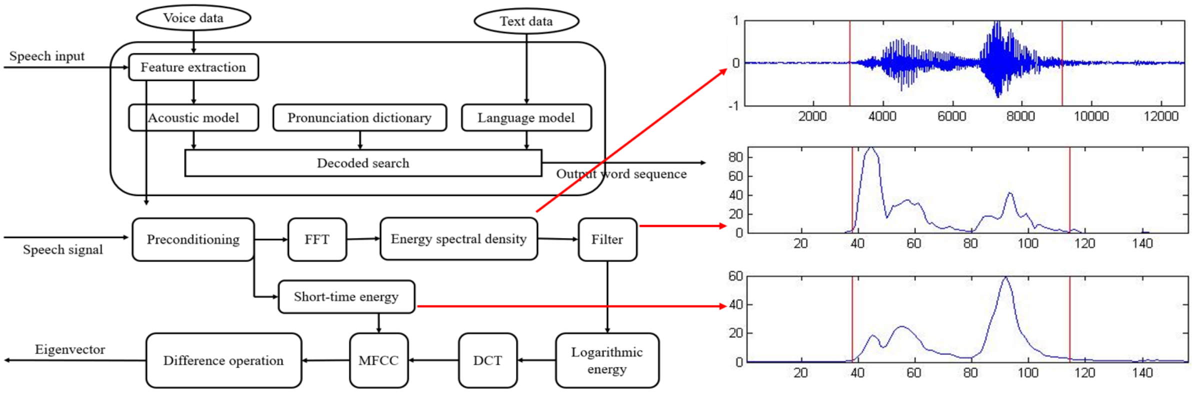

Fig. 1. Speech recognition architecture diagram.

After FFT transformation, the short-time emission profile can be obtained directly:

$$P(k) = S(k)S^*(k) = | S(k) |^2 \tag{7}$$

3) The MFCC features are constructed based on the auditory perception of the human ear, and the Mel frequency corresponds to the perceived frequency of the human ear. Therefore, to convert the linearity spectrum to Mel frequency, it is mainly realized by a set of delta strip bandpass filters uniformly distributed on the Mel frequency ruler [14].

The expression for this set of delta band pass factors is shown in Eq. (8):

$$H_m(k) = \begin{cases} \frac{k - f(m-1)}{f(m) - f(m-1)}, f(m-1) \le k \le f(m) \\ \frac{f(m+1) - k}{f(m+1) - f(m)}, f(m) \le k \le f(m+1) \\ 0, \text{ others} \end{cases} \tag{8}$$

The conversion formula from linear frequency to Mel frequency is as follows:

$$Mel(f) = 1125 \times \ln\left(1 + \frac{f}{700}\right) \tag{9}$$

Or:

$$Mel(f) = 2595 \times \log_{10}\left(1 + \frac{f}{700}\right) \tag{10}$$

In this case, the triangle bandpass filter bank serves the following purposes: it may minimize the quantity of feature data and make calculations easier; it can smooth the spectrum and remove the effects of harmonics.

4) Determine the subband energies at the Mel scaling, or the logarithmic quantities of the energies of each factor in the channel bank, and perform a discharge cosine shift on them.

$$E_m = \ln\left(\sum_{k=0}^{N-1} P(k) H_m(k)\right) \tag{11}$$

$$C_d = \sum_{m=0}^{M-1} E_m \cos\left[m\left(k - \frac{1}{2}\right)\frac{\pi}{M}\right], d = 0,1,\ldots,D-1 < M \tag{12}$$

After a series of operation steps, a frame of speech signal can be represented by a multi-dimensional MFCC vector. For Fbank features, its extraction method is very similar to that of MFCC, except that DCT transformation is not required, so the correlation information between various dimensions is completely retained [15].

Short-time average zero crossing rate applications that can play the following roles in endpoint detection applications:

Distinguish between voiceless and voiceless sounds by the cost of the zero-crossing rate. The corresponding speech section with a greater zero crossing charge is voiceless, whilst the corresponding speech phase with a decreased zero crossing price is dulled [16]; Judging the beginning of speech by the price of the zero-crossing rate, the usage of the zero-crossing charge can be aware of that that is the noise, that is the actual beginning factor of speech; The zero-crossing rate combined with short-time energy can also be used as a basis for judging whether there is speech generation.

B. *Linking Temporal Classification Algorithm*

Both GMM-HMM and DNN-HMM belong to the mixed model in which a variety of models work together. There are many problems in this mixed modeling method. For example, in terms of model training, the process of fully training a hybrid modeling system is very complicated, and the relatively independent training of each module will make it difficult for the system to carry out overall optimization. Moreover, before training the DNN-HMM system, it is necessary to train a GMM-HMM to obtain the frame-level correspondence between speech data and labels, which leads to the final recognition accuracy of the system to a certain extent depending on whether the GMM-HMM model alignment is accurate [17]. In terms of the structural characteristics of the model itself, to obtain a high recognition rate in continuous speech recognition tasks with a large vocabulary, only the modeling units below the word can be selected, such as mono phonemes, tri phonemes, etc., which need to be escaped by pronunciation dictionaries. In addition, the HMM model used to model speech sequence information fails to take into account the contextual correlation between speech frames.

Proposed by Alex Graves in 2006, the linked time sequence classification method is a key technology for end-to-end speech recognition. Neural networks alone complete the entire process of continuous speech recognition, which belongs to an integrated modeling method [18]. The final text sequence can be generated directly, which solves the problems of traditional methods such as forced alignment, cumbersome recognition process, and non-consistent optimization.

Assuming that the conditions between the output symbols of each speech frame are independent, for a single sample (O, W), the final optimization goal of CTC can be described as minimizing the negative logarithm of the posterior probability of the output symbol sequence:

$$L_{CTC} = -\ln P(\mathbf{W} | \mathrm{O}) = -\ln \sum_{\pi \in B^{-1}(\mathbf{W})} \prod_{t=1}^{T} p\left(\pi_t | \mathbf{o}_t\right) \tag{13}$$

From Eq. (13), it can be seen that if the CTC loss function is computed directly, it is necessary to obtain a summation of the conditional probabilities of all possible symbol orders capable of yielding the output character sequence W. Therefore, similar to the forward-backward algorithm in HMM calculation, dynamic programming is usually used to calculate the loss of CTC in practice. By combining the symbol sequence that can get the same output character sequence in the same time step, the calculation amount is reduced and the double calculation is avoided.

$$\alpha(s,t)=\sum_{\pi_{1.t}\in B^{-1}(\mathbf{W}_{1s/2}),\pi_t=w_s'}\prod_{i}^{t}P\left(\pi_i\middle|\ x_i\right) \tag{14}$$

$$\alpha(1,1)=P\left(\varphi\middle|\ o_1\right) \tag{15}$$

$$\alpha(1,2)=P\left(w_1\middle|\ o_1\right) \tag{16}$$

$$\alpha(1,s)=0,\quad \forall s>2 \tag{17}$$

According to the introduction of the neural network, after establishing the neural network, it is necessary to reduce the mistake between the forecasting result of the neural network and the actual sample labeling as much as possible, i.e., to reduce the loss function as much as possible. By analyzing the damage factor of CTC and the calculation method of the loss function, it can be found that the output probability of each time step is microscopic. Therefore, the backpropagation algorithm can be used to update each parameter value of the neural network using the CTC method and minimize the loss function to realize the classification of time series. The following describes the reverse derivation of the CTC loss function on the output of the neural network.

Assume that the number of neurons in the output level of the neural network is |U '|, SoftMax is used as the activation function, and each neuron outputs a posterior probability of a specific symbol on the time step. Then, for a single sample, the bias of the posterior probability of the output character label sequence as a whole to the output of a single neuron of the neural network is:

$$\frac{\partial P(\mathbf{W}|\ \mathbf{O})}{\partial P\left(q\middle|\ o_t\right)}=-\frac{1}{P\left(q\middle|\ o_t\right)^2}\sum_{s\in lab(\mathbf{W},q)}\alpha(s,t)\beta(s,t) \tag{18}$$

Then, the derivative of the CTC loss function to the output of the neural network is:

$$\frac{\partial L_{CTC}}{\partial P\left(q\middle|\ o_t\right)}=\frac{1}{P(\mathbf{W}|\ \mathbf{O})P\left(q\middle|\ o_t\right)^2}\sum_{s\in lab(\mathbf{W},q)}\alpha(s,t)\beta(s,t) \tag{19}$$

III. Markov Model

A. Basic Problem and its Structure

Given the remark sequence and HMM model, if the kingdom transition sequence is known, the chance that the HMM mannequin produces the output remark sequence is:

$$P(O|\ q)=b_{q_1}\left(O_1\right)b_{q_2}\left(O_2\right)\ldots b_{q_T}\left(O_T\right) \tag{20}$$

The probable gas output sequence q of the HMM model is:

$$P(q|\ \lambda)=\pi_{q_1}a_{q_1q_2}a_{q_2q_3}\ldots a_{q_{T-1}q_T} \tag{21}$$

For all possible state transition sequences q, the model outputs the probability of observing sequence O:

$$\begin{aligned}P(O|\ \lambda)&=\sum_{\forall\ q}P(O|\ q,\lambda)P(q|\ \lambda)\\&=\sum_{q_1,q_2,\ldots,q_T}\pi_{q_1}b_{q_1}\left(O_1\right)a_{q_1q_2}b_{q_2}\left(O_2\right)\ldots a_{q_{T-1}-q_T}b_{q_T}\left(O_T\right)\end{aligned} \tag{22}$$

In practice, this amount of computation cannot be borne, so forward algorithm and backward algorithm are adopted to reduce the amount of computation [19].

Define the forward probability as:

$$\alpha_t(i)=P\left(O_1O_2\ldots O_T,q_t=S_i\middle|\ \lambda\right) \tag{23}$$

The forward probability may be computed using the recursion formula that follows:

Starting Point:

$$\alpha_1(i)=\pi_ib_i\left(O_1\right)\quad 1\le i\le N \tag{24}$$

Iteration:

$$\alpha_{t+1}(j)=\left[\sum_{i=1}^{N}\alpha_t(i)a_{ij}\right]b_j\left(O_{t+1}\right),\quad 1\le t\le T-1,1\le j\le N \tag{25}$$

Terminate:

$$P(O|\ \lambda)=\sum_{i=1}^{N}\alpha_T(i) \tag{26}$$

The first step is to set the forward probability to the combined probe of the state and the first observable. The main component of the algorithm is the second step. If the phantom is in any of the N potential ones at moment t, it will transfer to the state at moment t+1 with a specific probability. Step 3 The sum of all aT(i) is P(O|λ) according to the definition of forward probability.

Corresponding to the forward probability, the backward probability is defined as:

$$\beta_t(i)=P\left(O_{t+1}O_{t+2}\ldots O_T\middle|\ q_t=S_i,\lambda\right) \tag{27}$$

Initialization:

$$\beta_T(i)=1,\quad 1\le i\le N \tag{28}$$

Iteration:

$$\beta_t(i)=\sum_{j=1}^{N}a_{ij}b_j\left(O_{t+1}\right)\beta_{t+1}(j),\quad 1\le t\le T-1,1\le j\le N \tag{29}$$

Terminate:

$$P(O|\ \lambda)=\sum_{i=1}^{N}\beta_1(i) \tag{30}$$

By using forward and backward probabilities, the likely output of the entire observational series to the HMM model can be divided into the product of the probabilities of the two observational series. By using the corresponding recurrence formula, the following output probability calculation formula can be obtained:

$$P(O|\ \lambda)=\sum_{i=1}^{N}\alpha_t(i)\beta_t(i)=\sum_{i=1}^{N}\sum_{j=1}^{N}\alpha_t(i)a_{ij}b_j\left(O_{t+1}\right)\beta_{t+1}(j),\quad 1\le t\le T-1 \tag{31}$$

The Viterbi algorithm is usually used, which is a dynamical engineering-based approach for searching for a singularly best sequence of states [20]. The problem to be solved by the Viterbi algorithm is to determine a sequence of states that maximizes the probability of the outcome given a given sequence of observations and a module, i.e., the problem of identification.

$$\delta_t(i)=\max_{q_1,q_2,\ldots,q_{t-1}}P\left(q_1,q_2,\ldots,q_t,q_t=S_i,O_1,O_2,\ldots O_t|\ \lambda\right) \tag{32}$$

If the state of the system at point t is Si, the optimal path is traced back to time T-1 along the optimal route, and a state labeling of the system is introduced, then the process of searching for the optimal succession of states is as follows:

Initialization:

$$\begin{gathered}\delta_1(i)=\pi_i b_i\left(O_1\right),1\le i\le N\\ \psi_1(i)=0\end{gathered} \tag{33}$$

Iterative calculation:

$$\begin{gathered}\delta_t(j)=\max_{1\le i\le N}\left|\delta_{t-1}(i)a_{ij}\right|b_j\left(O_t\right),\quad 2\le t\le T,1\le j\le N\\ \psi_t(j)=\arg\max_{1\le i\le N}\left|\delta_{t-1}(i)a_{ij}\right|,\quad 2\le t\le T,1\le j\le N\end{gathered} \tag{34}$$

Termination calculation:

$$\begin{gathered}p^*=\max_{1\le i\le N}\delta_T(i)\\ q_T^*=\arg\max_{1\le i\le N}\delta_T(i)\end{gathered} \tag{35}$$

Path backtracking:

$$q_t^*=\psi_{t+1}(i)\left(q_{t+1}^*\right),\quad t=T-1,T-2,\ldots,1 \tag{36}$$

A statistical model of voice signals' time series structure, known in mathematics as a double stochastic process, is called the hidden Markov model.

Two methods are available for simulating the change in the statistical properties of the speech signal: an implicit random process that employs a Markov chain with a finite number of states, and a random process that utilizes the observation sequence linked to each stage of the Markov chain. Although the latter expresses the previous, the former's actual boundaries are incalculable.

For voice recognition, there are four pattern-matching steps: feature extraction, template training, template classification, and judgment. Fig. 2 illustrates its fundamental framework:

Voice identification using HMM is essentially a probabilistic operation. After calculating the model parameters based on the training set dataset, it is also required to calculate the conditional probability (Viterbi's algorithm) of each model separately based on the test set data, and the model with the largest likelihood is the recognition result [21].

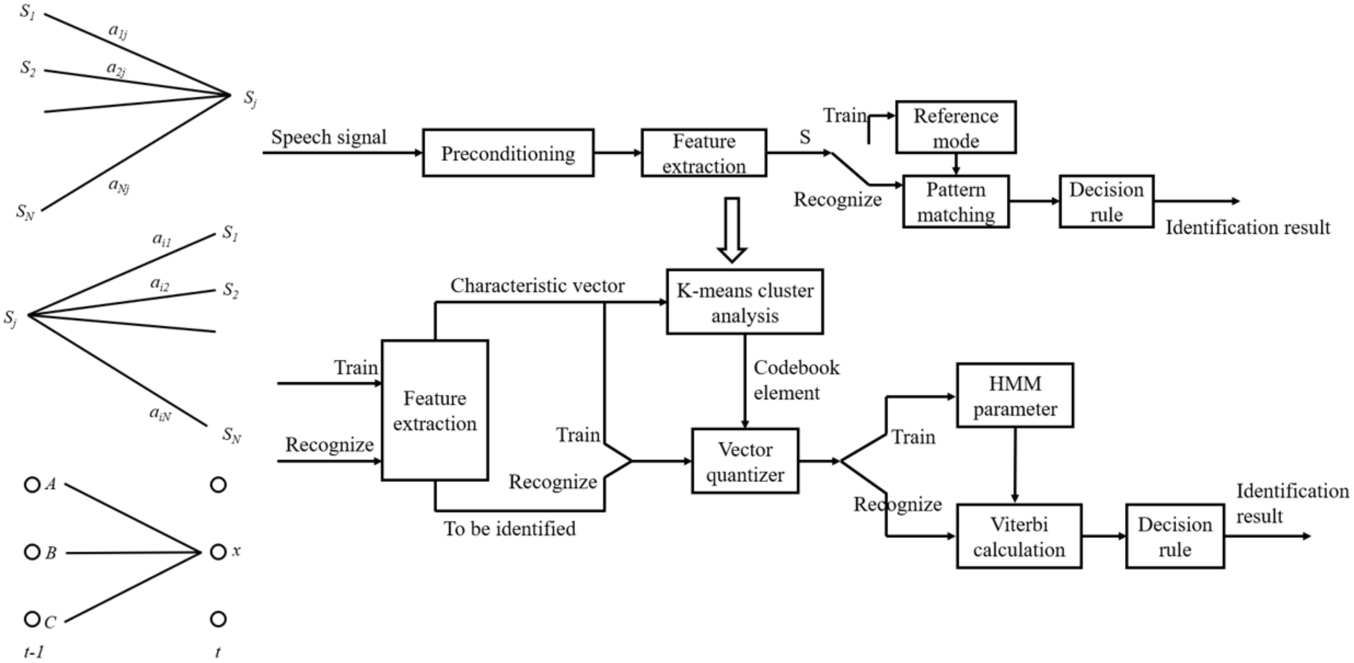

Fig. 2. Hidden markov model architecture.

Model parameter estimation is the process of training the pattern parameters, i.e., the series of known observations, and the output probability can be maximized by adjusting the model parameters. The specific steps are as follows: first, initialize the model parameters, then use some algorithm to input the same sequence of observations as the sequence of training samples, and repeatedly correct the sequence of observations, so that the pattern parameter with the maximum output potential becomes the final trained model parameter [22]. Since the Baum-Welch method is based on the maximum likelihood criterion, it has the advantages of fast convergence speed and monotonous growth of likelihood value, so the Baum-Welch method is usually used for parameter re-estimation.

The Baum-Welch algorithm uses the maximum likelihood criterion to obtain a fresh pair of variables by replacing the observed values and the initial model parameters. In other words, the results computed from multiple substitutions according to the re-estimation formula are more representative of the observed series than the original inputs. This process is repeated until convergence, which is the desired model parameter.

$$\xi_t(i,j) = p\left(q_t = i, q_{t+1} = j \middle| \; O, \lambda\right) \tag{37}$$

According to the forward-backward algorithm, we can get:

$$\xi_t(i,j) = \frac{p\left(q_t = i, q_{t+1} = j, O \middle| \; \lambda\right)}{P(O/\lambda)} = \frac{\alpha_t(i) a_{ij} b_j\left(O_{t+1}\right)\beta_{t+1}(j)}{\sum_{i=1}^{N}\alpha_t(i)\beta_t(i)} \tag{38}$$

Then, the odds that the observed sequence is in a certain condition at time t:

$$\gamma_t(i) = \sum_{j=1}^{N}\xi_t(i,j) = \frac{\alpha_t(i)\beta_t(i)}{\sum_{i=1}^{N}\alpha_t(i)\beta_t(i)} \tag{39}$$

The flowchart of the Baum-Welch algorithm is below in Fig. 3.

B. *Application of the HHM Model in Speech Recognition*

The choice of state type is the first problem to be considered when HMM is applied to speech recognition. There are two kinds of HMM model structure: each state traversal and left to right. The HMM model of state traversal can be applied to speaker recognition, language recognition, and so on. According to the characteristics of the human pronunciation process, the HMM of the right and left models is generally selected in speech recognition. In this paper, no span left-right model is adopted. There is no clear regulation on the number of states, which needs to be clarified through experiments and experience [23]. In English isolated word recognition technology, generally, the number of states between 4-8 is sufficient to achieve better results. Through the analysis of the test results, the amount of states N=4 is selected.

In addition to the number of states, the Gaussian mixture number of observed probability density functions also determines the final recognition rate. Through the analysis of subsequent experimental simulation results, the Gaussian mixture model number selected in this paper is M=3.

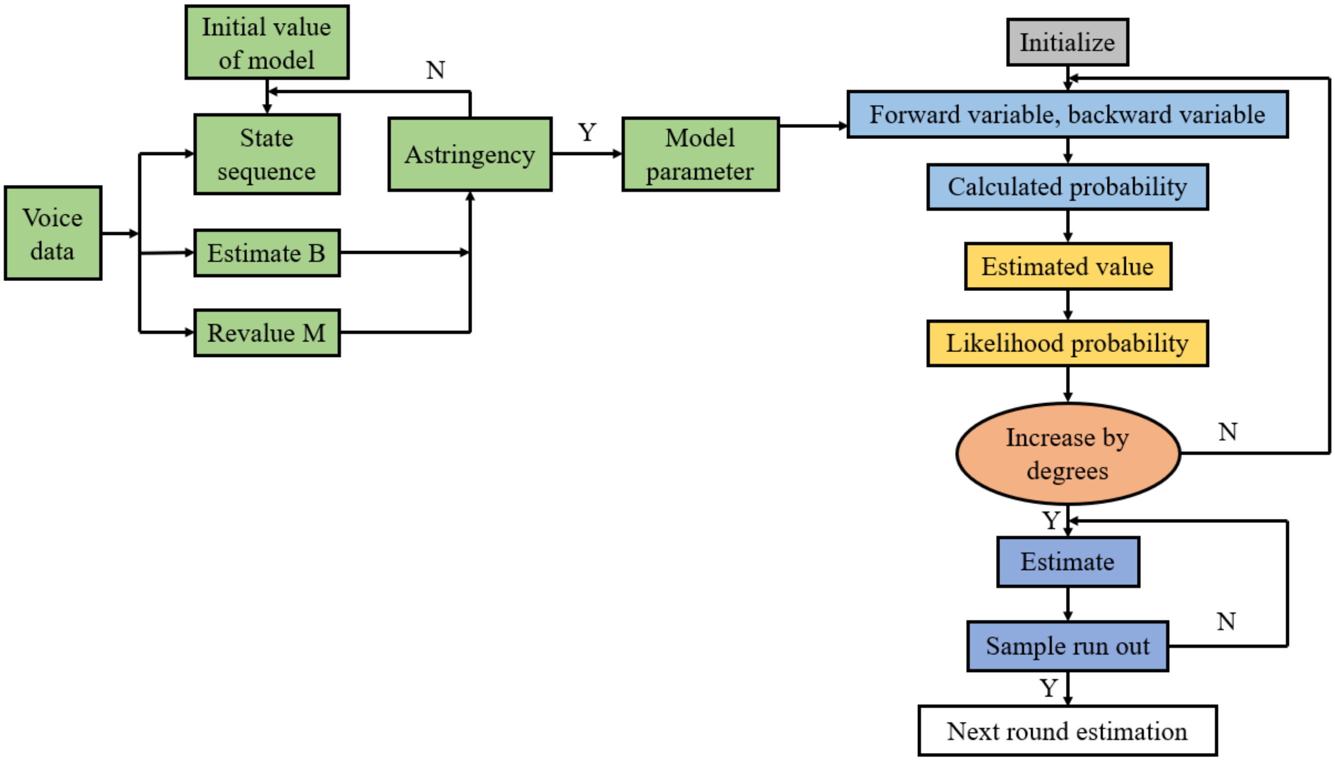

Fig. 3. Flowchart of Baum-Welch algorithm.

When applying the Baum-Welch algorithm to the parameter training of HMM models, how to correctly determine the initial parameters of the HMM to keep the partial maximization value as close as feasible to the global optimum is the focus of research [24]. In addition, a good choice of initial values can also reduce the number of iterations required for convergence, i.e., improve the computational efficiency. According to experience, the selection of the internal probability and initial value of the state transformation matrix does not have much influence on the recognition rate, and non-zero random numbers or uniform values can be used. Therefore, the initial probability of the state transition matrix and the choice of the initial value of the state transition matrix do not have much influence on the recognition rate, and non-zero random numbers or uniform values can be used. Based on this consideration, this paper adopts a composite clustering algorithm that combines the piecewise K-means algorithm, Viterbi algebras, and Baum-Welch algebras.

The basic idea of the method is as below:

1) Establish the initial parameters of the HMM model.

2) According to λ, use the Viterbi method to classify the input training speech database into the most probable state sequences.

3) Re-estimation of the input B using the "segmented K-means" method for the continuous HMM assumption using a hybrid Gaussian density function with M number of mixtures. The speech parameters corresponding to a particular state are pooled together and a K-means clustering operation is performed to classify the trained state speech clusters into M classes [25]. Then the meaning and covariance of the speech parameters of the same class are computed as the meaning vector and variance covariance mosaic of the class, thus obtaining the M normally distributed parameters of the M classes. Finally, the mixture weights of the class density functions are obtained by taking the number of speech frames included in each class and dividing it by the number of all speech in that state. This gives a new B, and thus a new set of initial values.

4) The λ obtained in step (3) is used as the initial value for the BW parameter re-estimation method to perform parameter re-estimation on the HMM module, thus obtaining the new module variables.

5) If the difference is less than the preset min value, it indicates that the model parameters have converged, there is no need to re-estimate, and λ is the final parameter output. Otherwise, λ continues the iteration as the new initial argument.

Since the segmented K-means algorithm is the idea of state optimization to carry out the maximum likelihood criterion, it can greatly accelerate the training speed of the model by realizing the initial parameter re-estimation.

IV. Optimize the DNN-HMM Model and its Analysis

A. Deep Neural Network

A neural network is also composed of neurons as shown in Fig. 4, which is a simple nervous web. The net is composed of an input level, a hidden level, and an output level. The nodes directly connected between layers are fully connected. This network model can fit simple nonlinear transformations.

When the amount of input data increases, it is necessary to fit complex nonlinear transformations, which can be achieved by adding the number of neurons in the hidden layer or the number of layers in the hidden layer. As shown in Fig. 4, the number of neurons and the number of hidden layers in a deep Neural Web increases accordingly.

The network can be trained using the error backpropagation algorithm, which can accommodate more complex functions. To meet the large increase in the amount of data, the number of layers of the deep neural network needs to be increased. At this point, the amount of network layers increases, the parameters surge, and training becomes more difficult, and the results are often difficult to converge.

The activation function in neurons is nonlinear, and the input is digital information, through which certain mathematical operations can be performed [26]. According to different excitation forms, there are different activation functions:

Sigmoid activation function:

$$f(x) = \frac{1}{1+\exp(-x)} \tag{40}$$

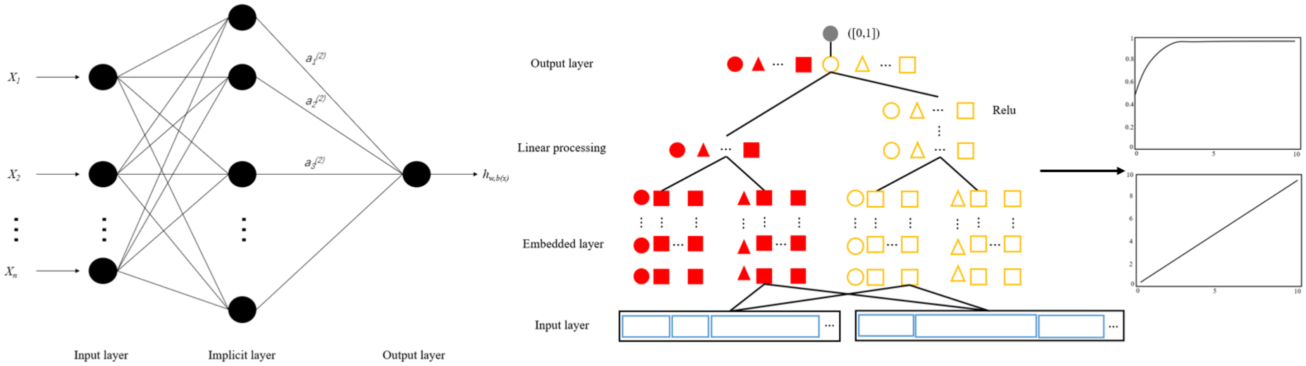

Fig. 4. Deep neural network model.

Tanh activity feature:

$$f(x) = \tanh(x) \quad (41)$$

ReLU activity feature:

$$f(x) = \max(x, 0) \quad (42)$$

The featured graph of the Tanh function compensates the output value between [-1, 1] and suffers from the same saturation problem as the sigmoid feature, but its output is zero-centered. Therefore, in practice, the Tanh nonlinear function is widely used.

Compared with the sigmoid and tanh functions, the ReLU function has a great acceleration effect on the convergence of stochastic gradient descent.

B. Optimization of DNN-HMM Model

The DNN-HMM model in speech recognition combines HMM and DNN, each performing its duties and sharing different tasks. HMM models speech timing signals. DNN models the posterior probability distribution of the input sample.

The input of DNN is the feature vector extracted from each frame of a speech signal after it is divided into frames. However, the output vector is the probability of the corresponding HMM state, so its dimension is equal to the number of states in the HMM. But since this is a supervised learning task, the input-to-output mapping must be found. Although the speech information and its corresponding text information of each sample can be known from the training sample, it seems that this is the mapping relationship between the input speech and the output text, but the DNN-HMM does not directly model the whole speech, but the model of each frame signal. Therefore, it is necessary to obtain the HMM state label corresponding to each input vector in the DNN, and then use this label to train a DNN model. In order to obtain the HMM state labels corresponding to each utterance, a traditional GMM-HMM model is usually trained in advance. GMM-HMM is used to force align the training samples. Each signal in the observed sequence is aligned with the state of its corresponding HMM. After alignment, DNN can be used instead of GMM to calculate the observation probability in HMM for training.

The input to the model is the feature of successive frames, that is, in addition to the current frame, the information of previous and subsequent frames is included. In general, if the current frame time is t, the input feature also includes all information from time T-4 to time t+4. The combination of 9 consecutive features to represent the current situation effectively utilizes contextual information, which is one of the reasons that DNN is superior to GMM. However, for continuous speech recognition tasks, it is not enough to only use the context information of the frame to model the speech. It is necessary to take into account the long-term dependence of the speech signal in time. The model works better if it can model the long-term dependence of the speech signal using its historical information. However, DNN-HMM based on a feedforward neural network cannot do this.

TDNN also belongs to the feed forward neural network, and its network structure is shown in Fig. 5. Different from DNN, it is not fully connected between layers, but the connection is controlled by the delay parameter. For example, [-2,2] in hidden layer 1 represents that the current frame is taken as the basis, and the two frames before and after each frame are a total of five as the input of the network, and each neuron in the time domain connects with the previous layer according to this rule. The architecture of the hidden levels is the same, so the income of each hidden level in TDNN is not just the output of the preceding level at the present moment, but also the outcome of the preceding level at t moments around the previous level. This allows each hidden layer to extend the time domain, especially deeper into the network, which contains more information from the input layer.

From a local point of view, the same layer of TDNN can be divided into many repeated network structures. For example, the first hidden layer can be split into substructures as shown in Fig. 5.

C. Neural Network Model Training under Kaldi

DNN-HMM model training is supervised training, which means that alignment information is obtained by the GMM-HMM model before training. The regularity of input features is conducive to the training of model parameters, so the input features are transformed in different stages of the GMM-HMM model training. The total transformation process is shown in Fig. 6.

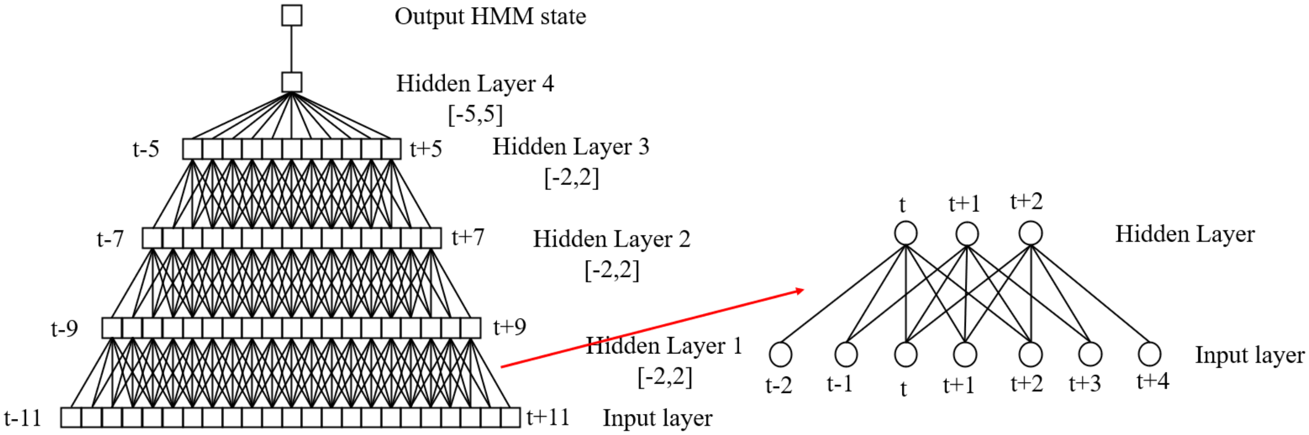

Fig. 5. TDNN structure diagram.

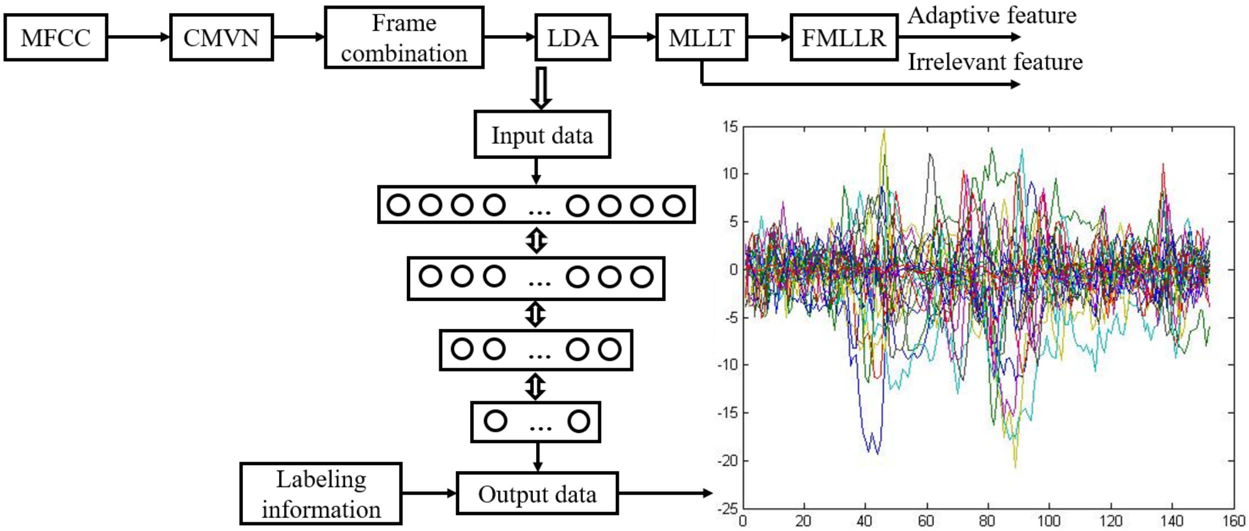

Fig. 6. DNN-HMM training process.

The GMM input feature has not been normalized after a series of processing, so another normalization process is needed. Based on this, several frames of data are spliced together forward and backward in the time domain to augment the modeling capability of the neural net, and the feature data need to be normalized and de-correlated again. Because the feature dimensions of time domain splicing are strongly correlated, it is not conducive to the training of neural networks. In this paper, CMVN is used to normalize the mean and variance of each dimension to achieve the purpose of de-correlation.

where, each element of the weight matrix specifies the weight of the edge between the concealed level cell and the visual level cell, with a bias for each visible level cell and a bias for each concealed level cell. Depending on the distribution of the random variables, the "energy" of the RBM is defined in two ways:

$$E(v,h) = -\sum_i a_i v_i - \sum_j b_j h_j - \sum_i \sum_j h_j w_{i,j} v_i \tag{43}$$

$$E(v,h) = \sum_i \left(a_i - v_i\right)^2 - \sum_j b_j h_j - \sum_i \sum_j h_j w_{i,j} v_i \tag{44}$$

Eq. (43) represents the equivalent energy function for the Bernoulli distribution and Eq. (44) represents the equivalent energy function for the Gaussian distribution. According to the Gibbs distribution, the probability of RBM in the current state is given by Eq. (45).

$$P(v,h) = \frac{1}{Z} e^{-E(v,h)} \tag{45}$$

$$Z = \sum_v \sum_h e^{-E(v,h)} \tag{46}$$

This probability can be considered as a joint probability distribution of the deep-level state and the hidden-level state, which is obtained by the RBM energy of the current state being normalized by the RBM energy of all possible states according to the exponential rule, where, Z is the partition function, which is a regular term that takes into account the energy of RBM in all states. Therefore, the edge distribution of the state vector of the display layer could be derived from the above joint distribution.

$$P(v) = \frac{1}{Z} \sum_h e^{-E(v,h)} \tag{47}$$

After Kaldi calls steps/net/pre-train dbn. sh for pre-training, it is time to train the neural network. The Truncated BPTT algorithm is usually used, that is, BPTT is carried out in a data block, which can contain a sentence or a fragment of fixed length. In Kaldi, steps/nnet/train.sh is called for training, the number of input layer units is set to 40, the number of hidden layers is fixed to 4, and the number of units in each level is set to 1024. the initial studying ratio is defined to be 0.008. the results obtained from the model's alignment will be used for the subsequent discriminative training.

D. Result and Discussion

According to the implementation method of the HMM model, PNN model, and DNN-HMM mixed model, MATLAB programming is carried out for the three models, and the three recognition systems are tested and analyzed with the help of the MATLAB simulation experiment platform.

All experiments were programmed using MATLAB for the three models, and the recognition system model program was split into two parts: the speech trainer and the speech recognition program. The speech test samples were 10 place names, namely Beijing, Shanghai, Guangzhou, Tianjin, Chongqing, Wuhan, Shenyang, Dalian, Changchun, and Harbin. The speakers were five men and five women, each pronouncing each word five times. The top 250 samples were taken as test samples and the bottom 250 samples were taken as training samples. The speech training program first builds a reference model library for these 10 words, and then the speech recognition program recognizes the results by comparing the input parameters with the reference model library. To validate the anti-jamming performance of the DNN-HMM mixture module, the HMM model and the PNN module are compared in a pure speech environment and a signal-to-noise environment, respectively. Table I displays the word recognition rate compared between the models in the pure speech environment. The first digit in the table is the number of correctly recognized words, and the last digit is the overall number of recognized letters. 24/25 means that 25 samples are input to be recognized, and the number of correctly recognized words is 24.

According to the speech recognition rate data in the above table, the test of this model in Beijing, Tianjin, Wuhan, Changchun and Harbin has reached 100%, while the test of this model in other regions is also close to 98%. The recognition rate of the optimized DNN-HMM mixed model is the highest, reaching 97.5%, followed by the HMM model with 95.4%, and the PNN model with 90.1% is the lowest. The data comparison shows that the hybrid model has better recognition performance than the single model, and the recognition rate is improved, which achieves the expected effect. There is little difference between the HMM and the optimized DNN-HMM modules in terms of recognition rate. To further illustrate the benefits and performance of hybrid models in speech recognition, we analyzed the anti-interference performance of each model. Table II displays a comparative identification ratio after adding different signal-to-noise ratios to each model.

From Tables I and II, it can be observed that as the SNR gradually decreases, the identification rate of the speech identification system continues to decrease, and the identification rates of the HMM model and the PNN model decrease obviously, however, the identification rate of the hybrid module decreases less obviously than that of the single model. The optimized DNN-HMM hybrid module incorporates the strong sequential handling capability of the HMM model and the excellent classifying capability of the probabilistic neural net. This combined ability can characterize the linguistic content of voice in a more comprehensive and detailed way, and improve the recognition rate, anti-interference performance, and ruggedness of the speech recognition system.

TABLE I. COMPARISON OF RECOGNITION RATES OF DIFFERENT RECOGNITION MODELS

Model ***Recognizer***	***HMM model***	***PNN model***	***Optimized DNN-HMM***
Peking	24/25	22/25	25/25
Shanghai	24/25	21/25	24/25

25db	89.8	89.3	94.7
30db	93.6	90.4	96.7

V. CONCLUSION

In this paper, a web-based oral English teaching system is proposed by combining speech recognition technology with a deep neural network-Markov model. The continuous speech signal is modeled by combining DNN and HMM. To solve the long-term dependence problem of DNN, TDNN is used to reconstruct the acoustic model, its structure and implementation principle are introduced, and the neural network model is built and trained by Kaldi. Specific conclusions are as follows:

First, this paper takes the technical principles of speech identification as the theoretical basis for a thorough study and research. Speech identification system according to the Hidden Markov Model. In speech processing, MFCC is used as the feature principle of speech, and the Hidden Markov Model is utilized for training and recognition, to produce a speech recognition system.

Second, because GMM-HMM does not utilize the context information of frames, DNN is introduced to construct a new acoustic model DNN-HMM, and its structure and training algorithm are introduced. However, DNN does not take into account the long-term dependence on the time of speech signals, so TDNN is used to reconstruct the acoustic model to introduce its structure and advantages, build and train the neural network based on Kaldi, and apply the DT method to train the neural network model to continuously improve the performance of the acoustic model.

Third, the simulation results show that in terms of speech identification rate, the optimized DNM-HMM hybrid model has the highest recognition rate of 97.5%, followed by the HMM model with 95.4%, and the PNN model has the lowest identification rate of 90.1%. The optimized DNN-HMM hybrid model achieves a high recognition rate of 96.7% when the signal-to-noise ratio is 30db. It incorporates the strong sequential processing capability of the HMM model and the excellent categorization capability of the probabilistic neural network, which can characterize the semantic meaning of speech in a more comprehensive and detailed way.

Chinese Pediatrics, First Affiliated Hospital, Heilongjiang University of Chinese Medicine, Harbin 150040, China[2]

***Abstract*—In response to the frequent recurrence and readmission of patients with chronic obstructive pulmonary disease, a machine learning based recurrence risk prediction and risk classification model for patients with chronic obstructive pulmonary disease is studied and constructed. Approach: This model first utilizes the optimized long short-term memory network to recognize named entities in patient electronic medical records and extract entity features. Then, XGBoost is used to predict the probability of patient relapse and readmission, and its risk is classified. Results: These results confirm that the optimized bidirectional long short-term memory network has the best performance with an accuracy of 84.36% in electronic medical record named entity recognition. The accuracy of XGBoost is the highest on both the training and testing sets, with values of 0.8827 and 0.8514, respectively. XGBoost has the best predictive ability and effectiveness. By using k-means for layering, the workload of manual evaluation was reduced by 91%, and the overall simulation accuracy of the model was as high as 97.3% and 96.4%. Conclusions: These indicate that this method can be used to balance high-risk patients between risk, cost, and resources.**

I. Introduction

Chronic Obstructive Pulmonary Disease (COPD) is a type of lung disease characterized by airflow restriction, which is a long-term, irreversible, and progressive chronic respiratory disease [1]. COPD is a common disease with a high incidence rate, which poses a heavy burden on the physical health and disease burden of the people [2]. It has become an important public health problem that restricts China's economic and social development [3]. Due to factors such as medical quality, hygiene effectiveness, and economy, some patients may relapse and be hospitalized within a month due to the same reasons, which has become a major challenge facing the world [4-5]. Predicting preventable frequent relapse hospitalization and understanding the causes of relapse hospitalization are currently important topics of widespread concern [6]. Machine Learning (ML) is a scientific method that enables prediction, identification, and decision-making of environmental changes without human intervention [7]. ML has achieved rapid development in medicine, especially in early warning of diseases, providing convenient and fast decision support for people [8]. Currently, ML and data mining have become methods that can potentially improve the predictive ability of relapse admission risk prediction models [9]. How to use ML technology to predict the recurrence of COPD patients and classify their risk is the main problem of this study. Currently, research on recurrence prediction and risk classification for COPD patients mainly relies on the experience and professional knowledge of clinical doctors, lacking objective and systematic prediction models. Therefore, the research on using ML technology for predicting the recurrence and risk classification of COPD patients still needs to be improved. The main objective of this study is to use ML technology to establish a model that can accurately predict the recurrence of COPD patients and classify their risk, improve the management and treatment level of COPD patients, reduce the risk of recurrence, and improve their quality of life. The innovation of this study lies in the full utilization of electronic medical record text information, while also ensuring the personal information of patients.

The article consists of four sections. In Section I, there is a literature review that introduces the relevant research content of different scholars. Section II outlines the related works. Section III is the research method, which mainly introduces the Named Entity Recognition (NER) of electronic medical records of COPD patients, as well as the prediction and risk classification of relapse and readmission of COPD patients. Section IV is the result analysis, which explains the electronic medical record NER of COPD patients under different ML algorithms, as well as the results of predicting relapse, readmission, and risk classification of COPD patients. Discussion is presented in Section V. Finally, Section VI is the conclusion that summarizes the results of recurrence prediction and risk classification for COPD patients and points out the shortcomings of the research.

II. Related Works

The Bidirectional Long Short-Term Memory Network (BiLSTM) is widely used in NER and predictive analysis, and many scholars have achieved good research results. To improve the NER efficiency of product review, researchers such as Postiche H proposed a product review NER method based on BiLSTM. These experiments confirm that the research method is more efficient in identifying named entities in product reviews compared to current methods. Benali B A et al. proposed a multi-head self-attention mechanism based on structures such as BiLSTM to improve the accuracy of NER in natural language texts, to perform NER on natural language in social media. These experiments confirm that this method can combine characters and words in the embedding layer, resulting in significantly better recognition results than current naming recognition methods [10]. Long R and other scholars proposed a disease diagnosis depth framework that integrated BiLSTM to enhance the analysis of electronic medical record data. These experiments confirm that the framework can significantly improve the performance of disease diagnosis [11]. Puh K et al. designed a deep learning model based on BiLSTM to predict the emotions in tourist comments in the tourism industry to extract and rate the emotions in tourist comments. These experiments confirm that this deep learning model has more efficient work efficiency and more accurate prediction results compared to other models [12].

ML has become an emerging and effective method for predicting the risk of disease recurrence. Matheson A M and other researchers proposed an ML-based prediction method to address the high risk of COPD recurrence. These experiments confirm that this method's predicting accuracy is superior to traditional regression analysis methods, which is beneficial for the prevention of COPD recurrence [13]. AL khadar and other scholars designed a recurrence prediction model based on decision tree classifier to enhance the prediction efficiency of recurrence and survival rate in oral cancer patients. These experiments confirm that the research method has the best predictive performance compared to other traditional ML models [14]. To compare the predictive performance of ML algorithm for early biochemical recurrence after prostatectomy, Wong NC et al. selected three supervised ML algorithms to construct models for prediction and compared them with traditional regression analysis. These experiments confirm that these three ML models have high accuracy in predicting biochemical recurrence [15]. Paredes AZ and other scholars proposed a fusion ML index prediction method to address the issue of high postoperative recurrence rates in patients with liver metastasis from colorectal cancer. This method combines resampling method with multivariate mixing effect to construct a prediction model. These experiments confirm that this method has a high accuracy in predicting indicators, which is beneficial for clinical analysis of postoperative recurrence risk [16].

In summary, BiLSTM can improve the accuracy of NER, and ML outperforms traditional analysis methods in predicting the risk of disease recurrence. However, the above studies lack the application of NER in predicting the recurrence risk of disease patients. There are few studies that combine these two and use ML to predict the risk of disease recurrence based on NER of electronic medical records. Therefore, to predict and classify the risk of recurrence in COPD patients, this study uses ML to perform NER on the patient's electronic medical record and predicts the re-admission of recurrence, providing a certain scientific basis for medical institutions.

III. ML Based Recurrence Prediction and Risk Classification Model for COPD Patients

A recurrence prediction and risk classification model for COPD patients is constructed for the prediction of recurrence. Firstly, BiLSTM-CRF is used to perform NER on electronic medical records. Then, XGBoost is used to predict the recurrence and readmission of COPD patients. Finally, k-means is used to classify the recurrence risk of COPD patients, as well as early prevention and effective intervention.

A. Electronic Medical Record NER for COPD Patients Based on Optimized BiLSTM

The electronic medical record collects rich diagnosis and treatment information from patients, including detailed historical data of patients seeking medical treatment and treatment in the hospital. It is the foundation and core of medical and health big data. There are various forms of electronic medical record storage, including structured and textual data. If people only focus on easily processed structured data and ignore textual data, it will lead to the inability to obtain certain characteristics of patient real data [17]. When designing a method for predicting the recurrence and readmission of COPD patients, it is first necessary to extract medical entities with more features from text data in electronic medical records and structurally process them. Fig. 1 shows the NER of an electronic medical record.

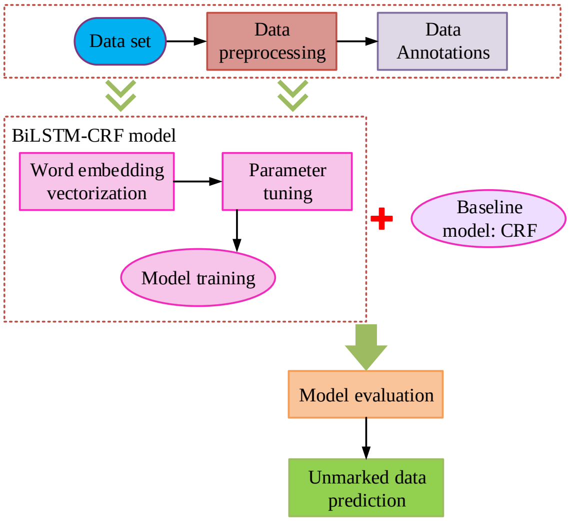

Fig. 1. The recognition process of named entities in electronic medical records.

According to Fig. 1, in electronic medical records' NER, it should first obtain data, and then preprocess and annotate the data. In the experiment, an electronic medical record NER method based on BiLSTM-CRF is designed, followed by word embedding vectorization, parameter tuning, and model training. Due to the fact that CRF is a commonly used method superior to other methods, it is used as a baseline method for method evaluation and prediction of unlabeled data.

The electronic medical record data in this study are sourced from the hospitalization records of patients in a tertiary hospital in Zaozhuang City. COPD patients who were hospitalized in the hospital from January 2020 to January 2021 were selected. With consent, the researchers logged into hospital's patient information management system and searched for target patient information. And it was deprivileged to obtain the inpatient information table and inpatient case text. Among them, textual information written by doctors, such as admission and exit records, can promote the design of predictive methods for patient relapse and readmission, and needs to be processed using the NER method based on ML. Before performing NER on inpatient electronic medical records, it is necessary to standardize the electronic medical records, including desensitization of patient data, detection and processing of sick sentences, and removal of irrelevant symbols [18]. Useful entity information was extracted for predicting the recurrence and readmission of COPD patients, mainly divided into comorbidities, examination indicators, indicator values, disease course, past physical fitness, and lifestyle habits. Afterwards, the data entities were annotated to construct the entity annotation dataset for the training model.

When designing the NER method based on BiLSTM, it is necessary to first perform word vector embedding transformation. Word embedding can solve the problem of vector encoded word similarity by converting text into numerical values. On this basis, the BiLSTM-CRF system is used to identify entities defined in the electronic medical records of hospitalized COPD patients. This system mainly includes two parts: BiLSTM layer and CRF loss layer. The former is essentially a traditional recurrent neural network. Due to its risk of gradient vanishing or exploding, it utilizes Long and Short-Term Memory (LSTM) for long-distance dependency capture [19]. Since LSTM cannot encode information from back to front, it is optimized to obtain BiLSTM to capture bidirectional semantic dependencies. The outputs of BiLSTM are all independently selected markers with higher scores, and there is no significant correlation between each marker. CRF can extract a certain number of constraint rules from samples and adjust them at the syntactic level. Therefore, this can enhance the constraints on samples, reduce the possibility of illegal sequences appearing, improve the prediction accuracy of labeled sequences, and ensure the generation of globally optimal labeled sequences. A BiLSTM-CRF system was constructed by combining BiLSTM and CRF. BiLSTM was used to learn features in the training set, including sub embedding and other features. After feedback to CRF layer, the tag sequence with the highest score was output. For a certain input sentence $[x]_1^T$, $[f\theta]i,t$ means the score of the i-th tag at time t. $[A]_{i,j}$ represents the probability of the ij-th position in the transition probability matrix of CRF, that is, the probability of transitioning from state i to state j. So for a certain input sentence and its label sequence $[i]_1^T$, Eq. (1) is the final score.

$$S\left([x]_1^T,[i]_1^T,\theta\right)=\sum_{t=1}^{T}\left([A]_{[i]_{t-1},[i]_t}+[f\theta]_{[i]_t,t}\right) \tag{1}$$

In Eq. (1), S represents the final score. A BiLSTM-CRF system has been successfully constructed to recognize entity information in electronic medical record texts. This model mainly consists of a word vector, BiLSTM, and CRF layers in Fig. 2.

Through Fig. 2, the system takes the text sequence of medical records as input and the relevant entities in the medical records as output. In the implementation of the system, each character input is first converted into a vector form through Word2Vec, which is used as the input of BiLSTM to extract contextual features. The output feature vector is used as the input of the CRF layer, and the input is normalized and the final label sequence is output. BiLSTM can provide users with more complete contextual information, thereby better understanding contextual dependencies. On this basis, an additional CRF layer has been added to further improve the existing BiLSTM system. By comprehensively optimizing the recognition results at the sentence level, the shortcomings of BiLSTM system are compensated.

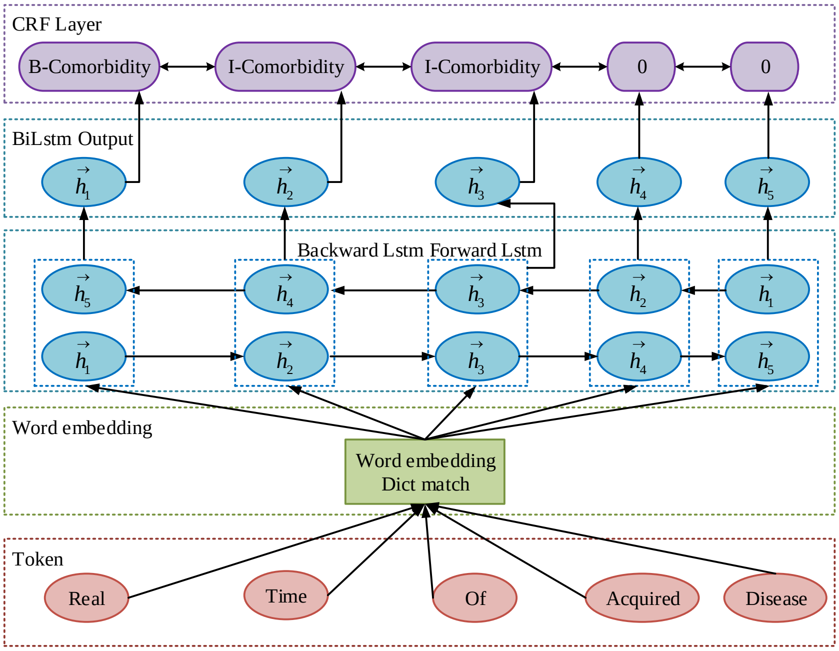

Fig. 2. BiLSTM-CRF network architecture.

B. Prediction of Recurrence in COPD Patients Based on XGBoost

This model's second layer is the prediction of relapse and readmission. That is, based on the medical information generated by the patient during hospitalization, it determines whether they will relapse and be re-admitted due to their physical condition for a period of time after discharge. 30 days are usually the most commonly used readmission threshold. Therefore, in this study, the readmission threshold is set to 30 days when predicting the recurrence and readmission of COPD patients [20]. With medical big data accumulating and ML progressing continuously, the prediction and prediction technology for relapse and readmission can effectively identify potential risk factors, providing a basis for the diagnosis and treatment of relapse and readmission patients. Fig. 3 shows the ML-based prediction of relapse and readmission in COPD patients.

According to Fig. 3, in the ML-based prediction of relapse and readmission of COPD patients, it is necessary to first integrate geometric features and then clean the data. Afterwards, a recurrence and readmission prediction system for COPD patients is designed and evaluated. Based on the previous section of NER, the extracted entity information and features are preserved. Due to the presence of noise and missing raw data, it is necessary to preprocess it to carry out predictions and obtain accurate prediction results. Fig. 4 shows the preprocessing content.

According to Fig. 4, preprocessing includes feature processing for comorbidities, assignment of discrete features, handling of outliers and missing values, descriptive statistics of variables, and handling of classification imbalance. Using ML algorithm to construct a relapse readmission prediction system for COPD patients, considering the system applicability, it should find the optimal classification method to achieve the best prediction effect. XGBoost is similar to a decision tree, in which each tree is divided by a special interval in its columns. On each tree shape, special attention should be paid to the sample with the highest error rate on the previous tree shape, so that there will be more optimization samples on the next tree shape. Finally, the results of each tree are combined and the weighted average method is generally used to obtain the results of each tree [21]. When adjusting XGBoost parameters, it should first adjust the learning rate of the system, followed by the total number of estimators used, the depth of each estimator, and finally the L1 and L2 regularization parameters [22]. To evaluate the classification performance, it should use five indicators: accuracy, accuracy, recall, F1 value, and ROC. Eq. (2) represents the accuracy.

$$ACC = \frac{TP + TN}{TP + TN + FP + FN} \tag{2}$$

In Eq. (2), ACC represents accuracy. TP, FN, TN, and FP represent positive cases that are correctly classified, positive cases that are misclassified as negative cases, negative cases that are correctly classified, and negative cases that are misclassified as positive cases, respectively. Eq. (3) represents the precision.

$$P = \frac{TP}{TP + FP} \tag{3}$$

In Eq. (3), P represents precision. Eq. (4) represents the recall rate.

$$R = \frac{TP}{TP + FN} \tag{4}$$

Fig. 4. Preprocessing content.

In Eq. (4), R represents the recall rate. Eq. (5) is the expression for F1.

$$F1 = \frac{2P*R}{P+R} \tag{5}$$

Eq. (6) is the calculation of ROC.

$$FPR = \frac{FP}{FP+TN} \tag{6}$$

In Eq. (6), FPR represents the ROC value. To further explain the output results of the system, this study will use Shapley addition to explain the output results of the prediction system. As a visualization tool, it calculates each feature and explains the system's prediction results by contributing to the prediction. Eq. (7) is the calculation of the Shapley value.

$$y_i = y_{base} + f\left(x_{i1}\right) + f\left(x_{i2}\right) + \ldots + f\left(x_{ik}\right) \tag{7}$$

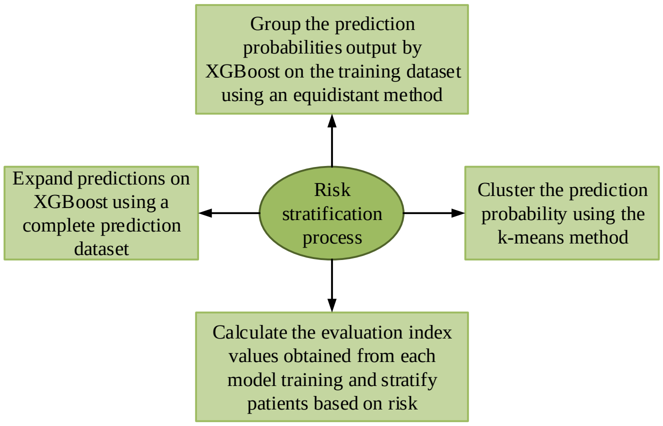
In Eq. (7), x_{ik} represents the k -the feature of the i -the sample. The system baseline is y_{base}. The predicted value of the system for this sample is y_i. $f\left(x_{ik}\right)$ represents the Shapley value of x_{ik} [23]. Generally speaking, $f\left(x_{ik}\right)$ is the contribution of x_{ik} to the final predicted value y_i. When $f\left(x_{ik}\right) > 0$, it indicates that the feature can improve the predicted value and has a positive effect. On the contrary, it indicates that the feature value leads to a decrease in the predicted value, which has a reverse effect. This value can reflect the influence and positive and negative shapes of sample features and has a powerful data visualization function, which is conducive to visually displaying the prediction results.

C. Recurrence Risk Classification of COPD Patients Based on K-means

The last layer of the model is the classification of recurrence risk for COPD patients. After selecting the best recurrence and readmission prediction method XGBoost, the selected method can be arranged and used. And combined with the predicted recurrence and readmission results of the patient, the discharge decision was obtained together. On this basis, a risk scoring system is constructed to divide recurrent COPD patients into different risk groups based on the obtained risk scores, providing decision support for doctors. The probability of XGBoost output on the test dataset was stratified using k-means and the results were validated in Fig. 5.

According to Fig. 5, the risk stratification process requires first using a complete prediction dataset to perform predictions on XGBoost. Then, the prediction probabilities output by XGBoost on the training dataset are grouped according to the equidistant method, and samples that do not meet the required probabilities are discarded. Then, the retained samples are input into XGBoost, and the prediction probability is clustered according to k-means. Samples that do not meet the required probability are eliminated, and samples that meet the probability continue to be predicted in XGBoost [24-25]. Finally, the evaluation index values obtained from each method training are calculated, and patients are stratified according to risk. In the k-means clustering, a dataset with d dimensions, whose number is n, is divided into k clusters. The purpose is to minimize the sum of squares of the distances between each observation in the same cluster and the center of the cluster to which it belongs in Eq. (8).

$$J\left(c,u\right) = \sum_{i=1}^{M} \left\| x_i - u_{ci} \right\|^2 \tag{8}$$



Group the prediction probabilities output by XGBoost on the training dataset using an equidistant method
Expand predictions on XGBoost using a complete prediction dataset
Risk stratification process
Cluster the prediction probability using the k-means method
Calculate the evaluation index values obtained from each model training and stratify patients based on risk

Fig. 5. Risk stratification process.

In Eq. (8), x_i represents the i -the sample. c_i is the cluster to which x_i belongs. u_{ci} represents the center point of the cluster pair. M is the total number of samples [26]. By using the k in the initial conditions, multiple different choices are made for k class, and the optimal clustering is obtained.

D. Methodology

In this study, the design of data collection and analysis programs is crucial. Data are collected from hospitals or medical databases, including electronic health records and clinical trial data. Information is collected from various aspects such as medical history, lifestyle, treatment response, and laboratory test results. The data types include patient basic information, clinical data, lifestyle data, and treatment information. Patients' basic information features include age, gender, weight, etc. Clinical data features include lung function test results, blood gas analysis, imaging examination results, etc. Treatment information features include drug treatment, non-drug treatment, etc. Lifestyle data features include smoking history, dietary habits, activity levels, etc.

Then the data are preprocessed and cleaned, including handling missing values and outliers. Standardization processing, such as normalizing numerical data, is conducted. Feature engineering, such as selecting features with high relevance, is performed. Statistical analysis of basic characteristics, such as age distribution and gender ratio, is carried out. The recurrence of COPD is analyzed, including frequency, severity, etc.

The first step of analyzing the program is to select a suitable ML model based on the characteristics of the data. The second step is to train and validate the model, dividing the dataset into training and testing sets. The model is trained on the training set and its performance is verified on the testing set. The model parameters are optimized using methods such as cross validation. The third step is to conduct feature importance analysis, analyzing the impact of each feature on predicting COPD recurrence and determining the most influential risk factors. The fourth step is to carry out risk classification, classify patients according to the predicted results, and set clinical decision guidelines corresponding to different risk levels. These steps need to be carried out in compliance with relevant data protection regulations and ethical standards.

IV. Result Analysis of Recurrence Prediction and Risk Classification Model for COPD Patients

The results of the ML-based recurrence prediction and risk classification model for COPD patients were analyzed, thereby promoting the improvement of medical structure and the utilization of medical resources. These results include the NER results of COPD patient electronic medical records based on optimized BiLSTM, the recurrence prediction results of COPD patients based on XGBoost, and the recurrence risk classification of COPD patients based on k-means.

A. NER Results of Electronic Medical Records for COPD Patients Based on Optimized BiLSTM

A suitable programming language was selected to implement the BiLSTM-CRF system and conduct the experiment. Appropriate development tools and libraries were installed to support system development. Electronic medical record data were preprocessed, including word segmentation, feature extraction, and label format conversion. It was ensured that the data format met the model input requirements and useful features were extracted for system training. When setting up the experimental environment, it ensures that all development tools, libraries, and data can be installed and configured correctly, enabling it to run smoothly. The BiLSTM-CRF system is built, and Table I shows the experimental environment settings.

Statistical analysis was conducted on the results of three recognition methods, BiLSTM, CRF, and BiLSTM-CRF, on the test set. All data are the average obtained from a 10-fold cross test. The overall experimental results were calculated in Table II.

According to Table II among these three methods, BiLSTM-CRF has the highest accuracy, regression rate, and F1 value, followed by BiLSTM and CRF. Overall, the accuracy rates of the three recognition methods BiLSTM, CRF, and BiLSTM-CRF are 84.36%, 83.67%, and 87.40%, respectively. Among these three methods, BiLSTM-CRF has the best performance. Subsequently, the recognition performance of different types of entities using the BiLSTM-CRF method was analyzed in Fig. 6.

According to Fig. 6, there is no significant difference in P and R values between these six entities naming recognition results. BiLSTM-CRF has the best recognition effect for both "comorbidities" and "examination indicators", with F1 greater than 90%. For F1, "lifestyle habit" is 74.00% and "course of disease" is 74.39%, indicating the difficulty in distinguishing between these two types. Based on the analysis of experimental results and annotated corpora, the effectiveness of entity recognition is closely related to the number of annotations and the degree of differentiation between different types of entities.

B. *Prediction of Recurrence in COPD Patients Based on XGBoost*

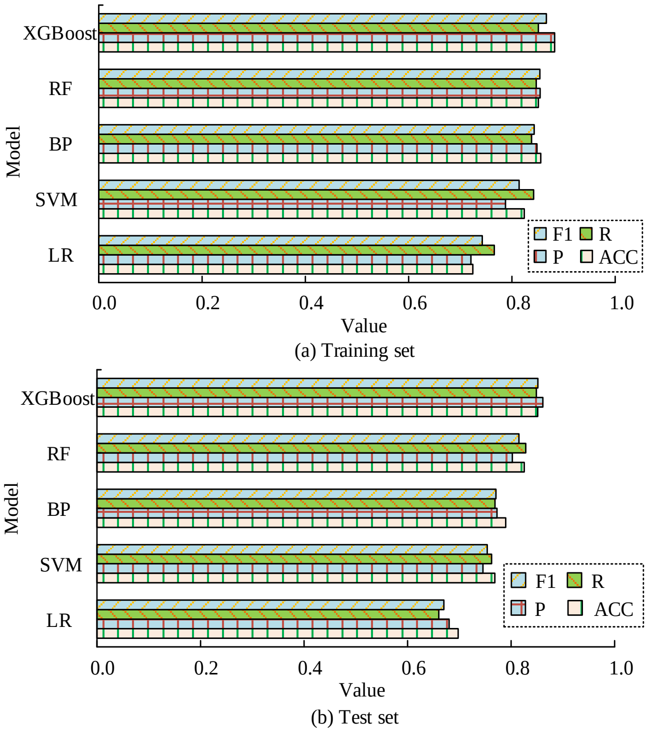
The experimental data are divided into training and testing sets, with a ratio of 7:3. The performance of individual patterns in the training set was evaluated using a grid search method with 10-fold cross validation. On this basis, the optimal hyperparameter combination for each method was selected, corresponding hyperparameter combinations were established, and fitting was conducted on a complete training dataset. Finally, the method was validated through independent experimental data. Due to the fact that this method is not affected by the experimental set during parameter adjustment and learning, the experimental set is only used for final evaluation. A comparison was made between five common ML constructed prediction systems: Logistic Regression (LR), Support Vector Machine (SVM), BP neural network, Random Forest (RF), and XGBoost in Fig. 7.

Fig. 7(a) and Fig. 7(b) show the predictive performance results of the five systems on the training and test sets, respectively. According to Fig. 7, five systems' accuracy on the training set is XGBoost, BP, RF, SVM, and LR, in descending order, with values of 0.8827, 0.8559, 0.8512, 0.8239, and 0.7244, respectively. The accuracy of these five systems on the test set is in descending order of XGBoost, RF, BP, SVM, and LR, with values of 0.8514, 0.8254, 0.7896, 0.7687, and 0.6978, respectively. Among these five systems, XGBoost has the best performance in terms of prediction accuracy, recall, and F1 value. Subsequently, the ROCs of five systems were analyzed in Fig. 8.

According to Fig. 8, the areas under the ROC of these five systems are XGBoost, RF, BP, SVM, and LR in descending order, with AUC values of 0.9173, 0.8256, 0.8252, 0.7682, and 0.6993, respectively. XGBoost has the best predictive ability and effectiveness, verifying its efficiency as a classification method for predicting the recurrence and readmission of COPD patients.

C. *Classification of Recurrence Risk in COPD Patients Based on K-means*

On the basis of XGBoost-based patient relapse readmission prediction system, k-means was selected for risk classification. To verify the superiority of this method, equidistant partitioning was used for comparative analysis. Firstly, patients are divided into five risk groups, namely low risk high reliability, low risk medium reliability, low risk or high-risk low reliability, high risk medium reliability, and high-risk high reliability. Among them, for patients with a lower risk of relapse and higher credibility, the classification probability tends to be closer to zero. For patients with high reliability and high risk of relapse and readmission, the classification probability tends to be closer to 1. Table III shows the results.



(a) Training set

(b) Test set

Fig. 7. Performance results of five common machine learning prediction system.

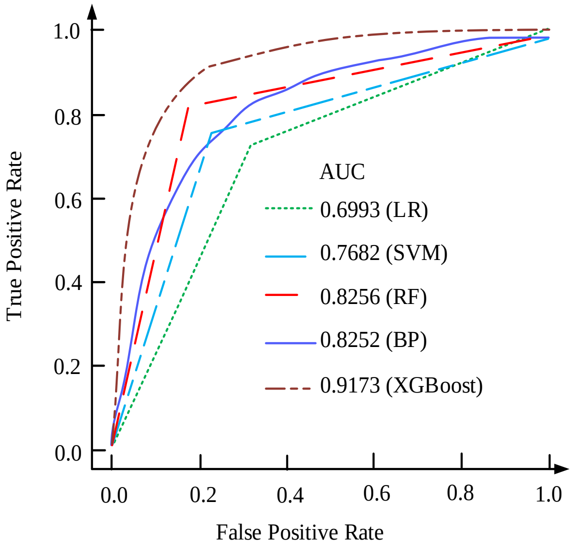


Fig. 8. ROC curves of 5 systems.

According to Table III, in equidistant stratification, only 17% of patients were classified into the low confidence group, which meant that the workload of manual evaluation was reduced by 83%. Among patients stratified using k-means, only 9% were classified into the low confidence group, which meant that the workload of manual evaluation was reduced by 91%. Compared with equidistant layering methods, k-means stratification required less manual evaluation workload. Therefore, k-means was selected as an evaluation indicator for the risk of relapse and readmission. In the current situation, if the balance point between different risk types is determined as a low risk or high-risk patient layer with a prediction probability of [0.286, 0.507] and low reliability, decision-makers only need to spend their limited resources to study these cases. That is, only 9% of the total cases need to be further manually evaluated. Through this approach, high-risk patients can achieve a balance between risk, cost, and resources.

Experimental validation confirms that among the three layers of the overall model for predicting recurrence and risk classification in COPD patients, each layer has the best performance. These three layers were integrated, and simulation analysis was conducted on the recurrence prediction and risk classification of COPD patients to verify the overall model's prediction and classification results in Fig. 9.

Fig. 9(a) and Fig. 9(b) show the fitting of the overall model for patient recurrence prediction and risk classification, respectively. According to Fig. 9, the simulation accuracy of the overall model for predicting patient recurrence and risk classification is 97.3% and 96.4%, respectively. This model can accurately predict the recurrence probability and risk classification of COPD patients, which is beneficial for providing decision-making assistance suggestions for hospitals.

TABLE III. PREDICTED RESULTS OF RISK GROUP FOR RECURRENT READMISSION PATIENTS

Method	Confidence level	Probability	Discard data (%)	Retained data	Accuracy (%)	Sensitivity (%)	Specificity (%)	Class I error	Class II error
Equidistant partition	All	All	0	1335	85.09	71.39	90.03	82	121
	Low	<0.4,>0.6	4	1287	83.92	71.82	91.63	70	115
	Medium	<0.3,>0.7	16	1110	86.48	73.24	94.75	46	103

V. Discussion

Through the analysis of the results, the BiLSTM-CRF model performs the best in entity recognition tasks, followed by BiLSTM, and CRF performs the weakest. The BiLSTM-CRF model combines BiLSTM with CRF, the former can capture long-range dependent features of data, and the latter can consider constraints between labels in sequence prediction problems. This combination enables the model to perform well in entity recognition tasks with strong dependencies. Although BiLSTM performs well in capturing the contextual information of data, the lack of CRF layers makes it unable to utilize global information in label sequence prediction, resulting in weaker performance than the BiLSTM-CRF model. The simple CRF model only considers the relationship between labels and ignores contextual information, so its performance is the weakest. Entity recognition shows good recognition performance for "comorbidities" and "examination indicators", which may be due to the standardized expression of these entity types in the text. Entities such as "lifestyle habits" and "disease course" have poor recognition performance due to their diverse or vague expressions. The effectiveness of entity recognition is closely related to the quantity and quality of annotations, and more annotated samples and high-quality annotations can improve the accuracy of entity recognition.

The XGBoost model performs the best in predicting recurrence in COPD patients. XGBoost is an efficient gradient boosting algorithm that enhances model performance by continuously reducing errors during iterations. The high or low AUC value also reveals XGBoost's classification ability. In terms of risk classification, the k-means clustering algorithm reduces the workload of manual evaluation compared to equidistant partitioning, indicating that k-means can more effectively classify patients into different risk groups. This method supports hospitals to allocate resources more accurately, focusing on patients with moderate recurrence risk and lower credibility. Finally, the accuracy of the overall three-layer model in predicting recurrence and risk classification of COPD patients is verified through simulation analysis. This indicates that combining different analytical methods can comprehensively evaluate and predict the recurrence risk of patients, thereby providing more accurate support for hospital decision-making.

The entity recognition results indicate that the quantity and quality of annotated samples can significantly affect the accuracy of recognition. In the recurrence prediction model, XGBoost performs excellently with its efficient iterative performance. The selection of risk classification methods has a significant impact on reducing the workload of manual assessment, and the k-means method has shown advantages. Combining different methods can improve the accuracy of predictions and help hospitals make more precise decisions in resource allocation and decision support.

VI. Conclusion

Predicting the recurrence and hospitalization of frequent COPD patients that can be prevented, as well as understanding the reasons for recurrence and hospitalization, are important tasks to ensure the health of the people. This study uses ML to predict the recurrence probability of COPD patients and classify their risks, providing a scientific basis for medical institutions. These studies have confirmed that the accuracy rates of these three recognition methods BiLSTM, CRF, and BiLSTM-CRF are 84.36%, 83.67%, and 87.40%, respectively. BiLSTM-CRF has the best recognition effect for "comorbidities" and "examination indicators", with F1 greater than 90%. For F1, the "lifestyle habit" is 74.00% and the "course of disease" is 74.39%, indicating the difficulty in distinguishing between these two types. In the prediction of recurrence, the accuracy rates of XGBoost, BP, RF, SVM, and LR on the training set are 0.8827, 0.8559, 0.8512, 0.8239, and 0.7244, respectively. Their accuracy rates on the test set are 0.8514, 0.8254, 0.7896, 0.7687, and 0.6978, respectively. Among patients stratified using k-means, only 9% are classified into the low confidence group, which means that the workload of manual evaluation is reduced by 91%. Compared with the equidistant stratification method, the k-means stratification requires less manual evaluation workload, and the overall model has a more accurate fit for predicting recurrence and risk classification of COPD patients. There are still many shortcomings in this study, such as insufficient data scale and lack of data diversity. Future work will expand the dataset size to include more data from COPD patients to improve the model's generalization ability. And the diversity of data should be increased to ensure that patient data cover different geographical regions, races, genders, and age groups to enhance the comprehensiveness and adaptability of the model.

Supply Chain Disturbance Management Scheduling Model Based on HPSO Algorithm

Ling Wang*
Nanjing University of Finance & Economics Hongshan College, Nanjing, 210003, China

Abstract*—The continuous expansion of business has led to the development of enterprises from vertical integration to horizontal integration, and the interlocking of the supply chain system, but the influence of anti-production behavior factors and the frequent occurrence of disruption events lead to difficulties in supply chain scheduling, which affects the development of enterprises. To address the above problems, the study analyzes the factors influencing counterproductive behavior based on system dynamics, constructs a supply chain disruption management scheduling model on this basis, and solves the supply chain disruption management scheduling model using Hybrid Particle Swarm Optimization algorithm. The findings indicate that the number of non-inferior solutions, uniformity of distribution of non-inferior solutions, dominance ratio of non-inferior solutions, average distance between non-inferior solutions and optimal Pareto, maximum distance, dispersion of non-inferior solutions and coverage of non-inferior solutions of the hybrid particle swarm algorithm are 12.3, 5.283, 0.264, 0.611, 4.474, 4.627, 601.300, respectively in the A condition, 601.300. The number of non-inferior solutions, uniformity of non-inferior solution distribution, dominance ratio of non-inferior solutions, average distance between non-inferior solutions and optimal Pareto, maximum distance, dispersion of non-inferior solutions and coverage of non-inferior solutions for the hybrid particle swarm algorithm under B condition are 12.3, 5.283, 0.264, 0.611, 4.474, In summary, the proposed algorithm has excellent performance and can effectively reduce the impact of interference events, thereby improving the level of supply chain interference management and scheduling, and promoting the sustainable development of this field.

Keywords*—*HPSO algorithm; disturbance management; supply chain; system dynamics; anti-production behavior

I. Introduction

With the popularization of computer technology and the development of market economy, enterprises are shifting their focus from themselves to supply chain, and supply chain management is particularly important for enterprise management [1-2]. Supply chain management is a management mode that effectively organizes suppliers, manufacturers and distributors to jointly complete product production, transportation and distribution on the premise of minimizing the cost of the entire supply chain [3-4]. However, the supply chain system itself is a complex and dynamic network, which is faced with many challenges from uncontrollable factors both internally and externally, such as resource shortage, equipment failure, and market demand fluctuations. These factors increase the uncertainty and dynamics of the supply chain, making it difficult for traditional supply chain management methods to effectively cope with [5]. At present, how to accurately identify and quantify the influencing factors of employee Counterproductive Work Behavior (CWB) in the supply chain environment and its impact on supply chain performance is a relatively difficult problem [6-7]. In order to better deal with the deterioration effect of CWB and the scheduling deviation of SCM disturbance, in this study, the influence factors of CWB are deeply analyzed, and the corresponding mathematical model is established by using the theory of System Dynamics (SD) to quantify the impact of CWB on supply chain performance. In addition, the research also aims to solve the hybrid model using HPSO algorithm to verify the validity and practicability of the model and provide decision support for enterprises in the face of supply chain disturbance events. Finally, through empirical research, the effect of the proposed model and algorithm in practical application is verified, which provides theoretical basis and practical guidance for the supply chain management of enterprises. This study will integrate SD theory and HPSO algorithm, enrich the research methods and technical means in the field of supply chain management, and provide new perspectives and ideas for the development of supply chain management theory. In addition, this study will provide decision support and practical guidance for enterprises to deal with supply chain disturbance events in actual operations. By optimizing the supply chain scheduling strategy, enterprises will be able to improve the stability and efficiency of the supply chain, reduce operating costs, improve customer satisfaction, and thus enhance the market competitiveness of enterprises. Finally, the research on employee CWB will help enterprises to understand the impact of employee behavior on supply chain performance more comprehensively, and then take targeted management measures to reduce potential losses.

This research is mainly divided into four sections, Section II is a review of relevant research results, Section III is the use of HPSO algorithm to solve the SCIMC model, Section IV is to verify the effectiveness of the HPSO algorithm proposed by the research, and Section V and Section VI is discussion and summary of the research respectively.

II. Related Work

The traditional SC optimization research is mostly focused on transportation and distribution, but rarely involves production optimization algorithm. The findings indicate that the algorithm can effectively reduce the time for computation [8]. Li et al. reduce the maximum time for completion by establishing a task pool and employing a genetic forbidden search algorithm for the production and transportation integration scheduling problem in a hybrid flow shop.

Experimental results confirm that the method can successfully address the scheduling problem for production and transportation integration [9]. Goli et al. employ a cycle duration and integer multiplier technique to coordinate the replenishment cycle of the SC and developed a simulated annealing algorithm to solve the economic lot size and delivery scheduling problems of a multi-stage SC. Simulation experiments demonstrated that the method can reduce the production cost of the SC [10]. Solina et al. proposed a quantitative approach to production and distribution to minimize production and distribution costs with reference to real-life food companies. The findings indicate that the method can significantly improve the performance and sustainability of the SC [11]. Du et al. explored the importance of dynamic optimal production scheduling with demand fluctuations and uncertainties. The study developed a multi-objective genetic algorithm for precast manufacturing based on a dynamic flow shop scheduling model, and simulation studies demonstrated that the method can cope effectively with demand changes [12].

Disruption management is also needed to solve the stochastic disturbance problem because of the real-life uncontrollable factors and SC systems are often affected by many disruptive events that delay production schedules and increase production costs. Lee J et al. designed a joint reactive and proactive airline disruption management method to cope with air traffic disruptions that lead to flight delays, cancellations, and missed passenger connections. The method can predict the probability of future disruptions by estimating the system delays at hub airports. The research data showed that the method can effectively reduce the expected recovery cost of airlines [13]. Jiang et al. constructed an attitude based disruption management model for handling delivery delays to minimize the negative impact of sudden disruptions in the distribution phase of the SC, and designed a heuristic algorithm, and the simulation results verified the effectiveness of the method [14]. Ning et al. addressed the flexible job shop in a comparison experiment with the traditional rescheduling method, the interruption management method improves the stability of the production and processing system under the deterioration effect [15]. Pandi et al. developed a GPU-based adaptive large-neighborhood search technique to address the issue of fleet interruption due to vehicle failure. Simulation experiments indicate that the algorithm can reduce the idle time and operating cost of the fleet under normal operation [16]. Malik A I et al. present a production disruption model for a multi-product single-stage production inventory system to handle the problem of unforeseen disturbances disrupting the entire manufacturing schedule. The data suggest that the effectiveness and superiority of the performance of this production disruption model [17].

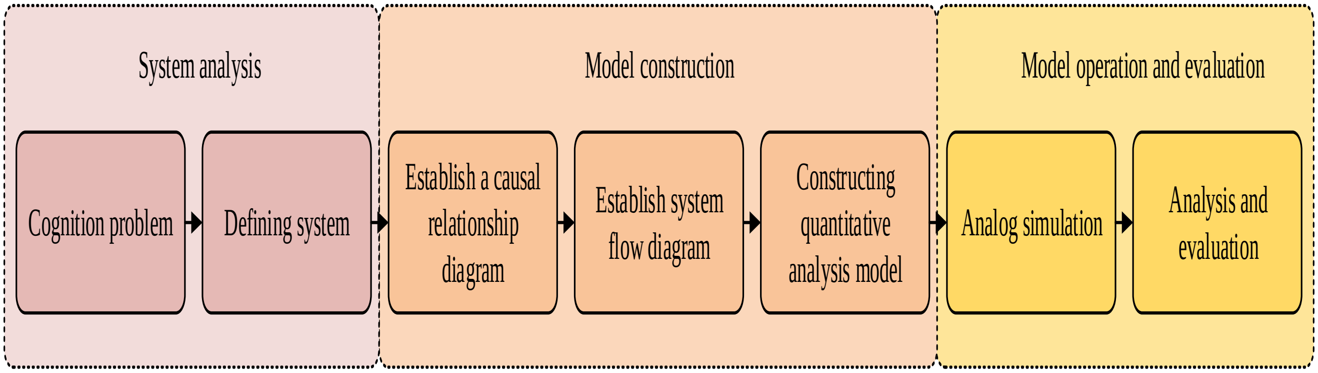
In summary, there are many research results about interference management in the field of SC production scheduling, but the majority of the research findings center on the reasonable distribution of negotiated benefits and the optimization of the overall benefits of the SC, ignoring the impact of interference events and CWB of employees, which leads to difficulties in SC scheduling. To address the problem that SC scheduling is easily affected by disruptive events and CWB, this paper analyzes the influencing factors of CWB based on SD theory and establishes SCIMC model, and solves the model by HPSO algorithm.

III. Construction of SCIMC Model based on HPSO Algorithm

The analysis of CWB influencing factors based on SD theory is the premise of SCIMC model construction. Since the SCIMC problem has multi-objective and non-linear characteristics, the study introduces the HPSO algorithm to solve it, and this chapter focuses on the analysis of CWB influence factors based on SD theory and the design of the HPSO algorithm.

A. Analysis of the Factors Influencing Employee CWB Based on SD Theory

SD theory is an effective tool that combines cybernetics, systems theory and information theory and uses computer simulation techniques to study the feedback structure and behavior of systems. It mainly studies the dynamic development law of the system through modeling, simulation and comprehensive reasoning according to the feedback characteristics that the internal components of the system are causal [18]. The main steps of SD theory are shown in Fig. 1.



System analysis
Model construction
Model operation and evaluation
Cognition problem
Defining system
Establish a causal relationship diagram
Establish system flow diagram
Constructing quantitative analysis model
Analog simulation
Analysis and evaluation

Fig. 1. The main steps of SD theory.

The SD theory in Fig. 1 is mainly composed of three steps: system analysis, model construction, model operation and evaluation. The presence of CWB frequently disrupts the normal running of the production line [19]. To dynamically describe the nonlinear mechanism of CWB, the study uses the SD method as an entry point to explore the influencing factors of CWB. the influencing factors of CWB include job satisfaction A1, sense of organizational justice A2, supervision level A3, team atmosphere positivity A4, group normative level A5, organizational culture building A6, and organizational concern A7. The causal relationship of each influencing factor of CWB is shown in Fig. 2.

Fig. 2 depicts the CWB feedback relationship, which is separated into six major sections. In the first step, which functions as positive feedback, higher job satisfaction lowers the likelihood of CWB incidence, which causes the amount of group norms to rise, and a corresponding decrease in the level of job boredom as an important component of job satisfaction, which further increases job satisfaction. The second part is a negative feedback process, where an increase in organizational justice causes an increase in employee job satisfaction, which decreases the chance of CWB occurrence and leads to an increase in the level of employee burnout, which decreases organizational justice and concern. The third part is the negative feedback process, with the improvement of the organizational supervision mechanism, the team atmosphere positivity and the number of behavior correction is increasing, accompanied by a decrease in the sense of organizational justice and attention, which will bring negative impact on the level of organizational supervision. The fourth part is the positive feedback process, the higher the team climate positivity, the lower the level of group regulation will be, accompanied by employee alienation and increasing job conflict will also lead to a decrease in job satisfaction, which will increase the chances of CWB, further improving the level of organizational regulation and thus increasing the team climate positivity. The fifth part is the positive feedback process, where the increase in the level of group norms makes CWB less likely to occur, thus reducing the level of organizational attention and supervision, making the team gradually looser and further increasing the level of organizational norms. The sixth part is a negative feedback process. The improvement of organizational culture also increases the motivation of the team atmosphere, so the chance of CWB decreases, but the decrease of CWB makes the organization slack, which further reduces the level of attention and organizational culture. The study adds the corresponding state variables, rate variables and auxiliary variables based on the feedback relationship of CWB-related influencing factors, and draw the CWB-SD model flow diagram using Vensim simulation software.

$$\begin{cases} Z_{A1} = 2 + \int_{t0}^{t} \left(H_1 - H_2\right) dt \\ Z_{A2} = 1 + \int_{t0}^{t} \left(H_3 - H_4\right) dt \\ Z_{A3} = Z_{A2} \times B_1 + Z_{A6} \times B_2 + Z_{A8} \times B_3 + Z_{A9} \times B_4 \\ Z_{A4,5} = 1.5 + \int_{t0}^{t} \left(H_5 - H_6\right) dt \\ Z_{A6} = 2 + \int_{t0}^{t} H_9 dt \end{cases} \tag{1}$$

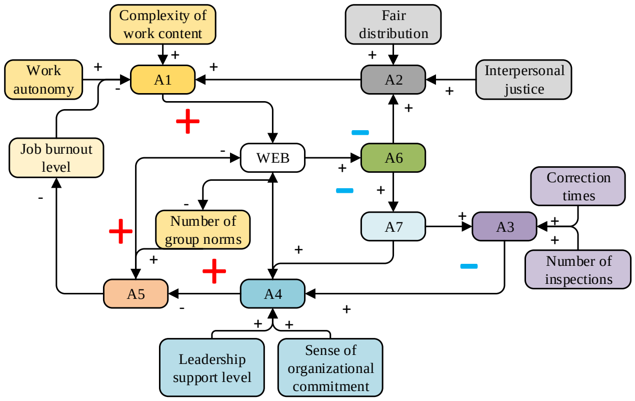


Fig. 2. Feedback relationship between CWB influencing factors.

In Eq. (1), Z_{A1} to Z_{A6} represent job satisfaction, organizational justice, organizational supervision level, team atmosphere motivation, group norm level, and organizational culture building level, respectively. B_i H_1 and H_2 represent rates of satisfaction growth and decline, H_3 and H_4 represent the fairness's growth and decline rates, and H_5 and H_6 represent the increase and decrease rates of organizational culture building. The expressions of the number of behavioral corrections Z_{A8} and the monitoring and improvement mechanism Z_{A9} are shown in Eq. (2).

$$\begin{cases} Z_{A8} = 2 + \int_{t0}^{t} H_{10} dt \\ Z_{A9} = 2 + \int_{t0}^{t} H_{11} dt \end{cases} \tag{2}$$

In Eq. (2), H_9 , H_{10} refer to the rate of increase in the level of organizational culture building and the rate of increase in behavior modification, respectively. The expression of CWB can be obtained from Eq. (1) and Eq. (2), see Eq. (3).

$$Z_{CWB} = Z_1 \times G_1 + Z_2 \times G_2 + Z_3 \times G_3 + Z_4 \times G_4 + Z_5 \times G_5 + Z_6 \times G_6 \tag{3}$$

In Eq. (3) G_i denotes the influence coefficient of each state variable. Human behavior influences the operation and state of the system, and employees' dissatisfaction with their jobs directly leads to an increased chance of CWB and thus negativity. To portray the effect of subjective human behavior on CWB, the study uses employee dissatisfaction to describe the deterioration rate and thus measure the processing time after disturbance, and the dissatisfaction value $Q\left(R_i\right)$ is expressed in the range of $x_i < 0$ as shown in Eq. (4) [20].

$$Q(R_i) = \chi (R_i - O_i)^{\beta} \tag{4}$$

In Eq. (4), O_i denotes the initial scheduling scheme and χ is the risk aversion factor. β It refers to the degree of concavity of the value curve, and its value range is $(-\infty, 1)$. When $Q(R_i) = 1$, $R_i = O_i + \left(\frac{1}{\chi}\right)^{\frac{1}{\beta}}$, the dissatisfaction function $Q(x_i)$ see Eq. (5).

$$Q(x_i) = \begin{cases} 1, x_i \geq R_i \\ \chi (x_i - O_i)^{\beta}, O_i \leq x_i \leq R_i, i = 1, 2, 3, \cdots, n \\ 0, 0 \leq x_i \leq O_i \end{cases} \tag{5}$$

The occurrence of a disturbance event causes O_i to be no longer optimal, and the repair scheduling solution derived according to the specified constraint affects the change in machining position of the corresponding workpiece. The size of the measured disturbance can be expressed in terms of the amount of machining position change, and the dissatisfaction function of the amount of position disturbance $Q(s_j)$ is shown in Eq. (6).

$$Q(s_j) = \begin{cases} 1, s_j \geq R_1 \\ \chi_1 s_j^{\beta_1}, 0 \leq s_j < R_1 \end{cases} \tag{6}$$

In Eq. (6) s_j denotes relative position perturbation, $R_1 = \left(\chi_1^{-1}\right)^{\beta_1^{-1}}$ denotes the upper limit of dissatisfaction tolerance, and employee dissatisfaction Q is shown in Eq. (7).

$$Q = \sum_{j=1}^{n} Q(s_j) \Big/ n \tag{7}$$

Employee psychological dissatisfaction brings about defiance, which lengthens the operation's processing time and subsequently affects the deterioration rate. The deterioration rate function $\theta(s_j)$ is shown in Eq. (8).

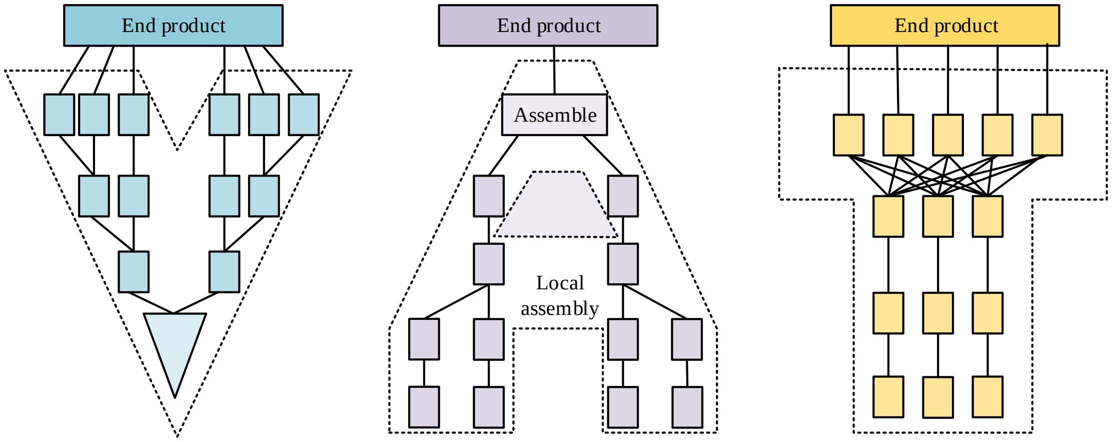
$$\theta(s_j) = \begin{cases} 1, s_j > R_1 \Box R_2 \cap s_j > R_1 \\ \chi_2 s_j^{\beta_2}, 0 \leq s_j < R_1 \Box R_2 \cap 0 \leq s_j < R_1 \end{cases} \tag{8}$$

In Eq. (8) $R_2 = \left(\chi_2^{-1}\right)^{\beta_2^{-1}}$, then the deterioration rate of operation time θ is shown in Eq. (9).

$$\theta = \sum_{j=1}^{n} \theta(s_j) \Big/ n \tag{9}$$

B. SCIMC Model Construction Based on HPSO Algorithm

Each node enterprise in SC rotates around the core enterprise, forming a fully functional network chain, through regulating the flow of information and cash from acquiring raw resources to producing finished goods, and finally delivering products to consumers through the sales network. According to the different products and manufacturing processes, the SC is split into V-type, T-type and A-type, and the basic structure of the SC is shown in Fig. 3 [21].



(a) Basic structure of V-type supply chain

(b) Basic structure of a-type supply chain

(c) Basic structure of t-type supply chain

Fig. 3. Basic structure of SC.

Fig. 3(a) shows the basic structure of V-type SC, which is the most basic structure in the SC mesh. The success of V-type SC depends on the reasonable arrangement of the critical internal capacity bottlenecks. Fig. 4(b) depicts the basic structure of A-type SC, the overall form of this SC is expressed as convergence type, and A-type SC is generally driven by orders and customers. No market forecast is taken. Fig. 4(c) shows the basic structure of T-type SC, which is a hybrid SC structure that mainly determines the manufacturing standardization of common parts to reduce the complexity. In a two-stage SC with a single manufacturer and supplier, both need to share the task of a batch of orders from customers, the supplier processes the relevant spare parts according to customer demand, and the manufacturer produces according to the spare parts delivered by the supplier, in which the supplier is in a dominant position and the supplier should be satisfied by the manufacturer on each requirement of the order. To increase production effectiveness, the study constructs the SCIMC model, which mainly consists of three parts: initial scheduling, interference management, and cooperation gain, and the initial scheduling is shown in Eq. (10).

$$\min\left\{ f\left(\pi_0{}^s\right)=\sum\nolimits_{j=1}^{n} w_j \cdot C_j,\ f\left(\pi_0{}^m\right)=\sum\nolimits_{j=1}^{n} w'_j \cdot C'_j \right\} \tag{10}$$

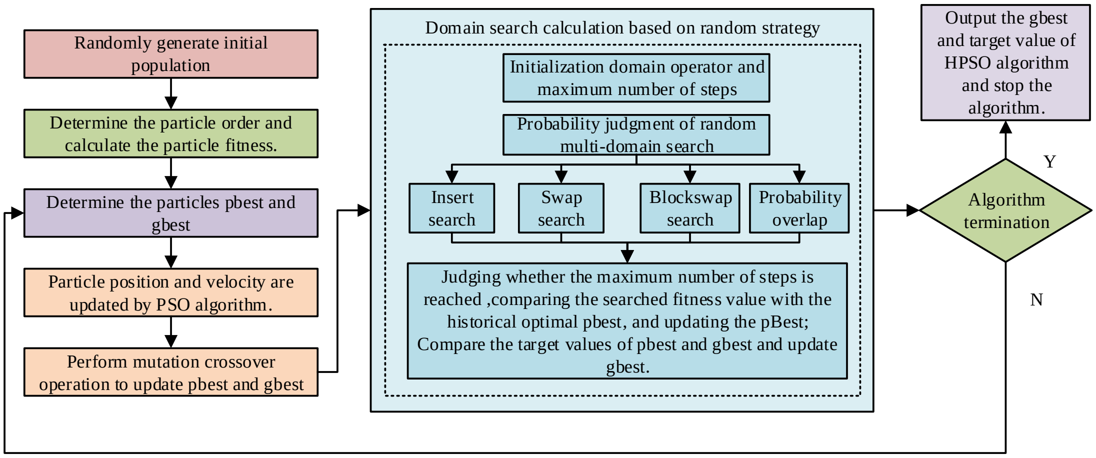
Eq. (10) is the optimisation goal for initial scheduling, $\pi_0{}^s$ and $\pi_0{}^m$ refer to the initial scheduling time of suppliers and manufacturers, respectively, w_j and C_j refer to the weighting factor and completion time of suppliers, respectively, and w'_j and C' refer to the weighting factor and completion time of manufacturers, respectively. The expression of interference management is shown in Eq. (11).

$$\min\left\{ f_1\left(\pi'\right)=\sum\nolimits_{j=1}^{n} w'_j \cdot C'_j,\ f_2\left(\pi'\right)=\sum\nolimits_{j=1}^{n} w'_j \cdot \bar{\Delta} t'_0 \right\} \tag{11}$$

Eq. (11) is the optimization objective of disturbance management scheduling when the machine is disturbed. $f_1\left(\pi'\right)$ denotes the optimization objective of the manufacturer's balanced disturbance repair solution and initial scheduling solution, and $f_2\left(\pi'\right)$ denotes the minimization objective, where $\bar{\Delta} t'_0=\max\left\{C'_j-\bar{C}'_j,0\right\}$, $\bar{C}'_j$ are the completion times of the manufacturer's artifacts J_j in the initial scheduling solution. The expression of the cooperative gain is shown in Eq. (12).

$$\min\left\{ f_3\left(\pi'\right)=-V_m \cdot V_s \right\} \tag{12}$$

Eq. (12) is the revenue maximization objective of supplier-manufacturer cooperation, and V_m and V_s denote the revenue of the manufacturer and supplier after the perturbation, respectively. The supplier's processing artifacts arrive before the manufacturer can start production, and the expression is $D_j^s \le S_j^m$, where D_j^s denotes the supplier's delivery time and S_j^m is the manufacturer's processing start time. In a product's processing system, neither the supplier nor the manufacturer is allowed to start both workpieces at the same time, see $\left(S_j \ge C_k\right) \vee \left(S_k \ge C_j\right), \forall j,k \in J$. During the time window when the disturbance occurs, the supplier cannot schedule the disturbed workpiece for processing, as expressed in the formula at $S_j^s, C_j^s \notin \left[t_1,t_2\right], \left(j \in list\right)$, where S_j^s and C_j^s denote the supplier's processing time and completion time, respectively. To efficiently optimize the SCIMC model, the study selects the HPSO for solving. Based on the PSO algorithm's great global fast search capability, the HPSO combines the strengths of the variable domain search algorithm's strong local fine search capability, and incorporates the heuristic algorithm obtained from the variational crossover theory related to the genetic algorithm. the HPSO algorithm flow is shown in Fig. 4 [22].



Randomly generate initial population
Determine the particle order and calculate the particle fitness.
Determine the particles pbest and gbest
Particle position and velocity are updated by PSO algorithm.
Perform mutation crossover operation to update pbest and gbest
Domain search calculation based on random strategy
Initialization domain operator and maximum number of steps
Probability judgment of random multi-domain search
Insert search
Swap search
Blockswap search
Probability overlap
Judging whether the maximum number of steps is reached ,comparing the searched fitness value with the historical optimal pbest, and updating the pBest; Compare the target values of pbest and gbest and update gbest.
Algorithm termination
Y
N
Output the gbest and target value of HPSO algorithm and stop the algorithm.

Fig. 4. HPSO algorithm flow.

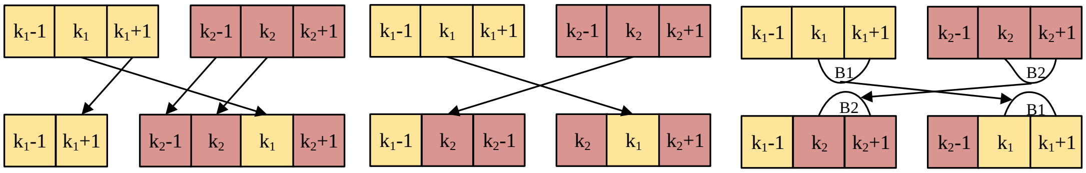
The HPSO algorithm in Fig. 4 consists of the basic PSO algorithm, variational operations, crossover operations and random field structures. The PSO algorithm first requires particle initialization and particle position initialization, where a particle represents a processing ordering and the particle initialization is to ensure that the processing of a workpiece is unique at the same time. Eq. (13) displays the iterative equation for a particle's velocity at the instant of $t+1$.

$$v_{i,j}(t+1)=wv_{i,j}(t)+c_1r_1\left[p_{i,j}-x_{i,j}(t)\right]+c_2r_2\left[p_{g,j}-x_{i,j}(t)\right] \tag{13}$$

In Eq. (13), w denotes the inertia factor, c_1,c_2 is the learning factor, r_1,r_2 is the arbitrary number generated between $(0,1)$, $p_{i,j}$ and $p_{g,j}$ denote the current and the global optimal position of the particle in the j dimension, respectively, so the iterative formula for the position of the particle at the moment of $t+1$ is Eq. (14)

$$x_{i,j}(t+1)=x_{i,j}(t)+\left|v_{i,j}(t+1)\right|, j\in 1,2,\cdots,n \tag{14}$$

After the initialization of the particle positions, the study also needs to form two new particles by mutating the particle's own best position $pbest$ and the population's best position $gbest$, and the mutated particles are used as the parents to perform the crossover operator based on the process encoding. The PSO algorithm after mutation crossover improves the capability of global search, but the capacity for local search still needs to be improved. To solve this problem, the study introduces a local search strategy with a random domain structure. The stochastic domain structure mainly consists of insertion domain, exchange domain and block exchange domain structure, and its structure is shown in Fig. 5.



(a) Insert domain structure

(b) Swap domain structure

(c) Blockswap domain structure

Fig. 5. Schematic diagram of domain structure.

Fig. 5(a) shows the insertion field structure, randomly inserting the artifact l before the artifact l_1 , where l_1 is any position in the arrangement π before l_1 . Fig. 6(b) shows the swap field structure, where the positions of the workpieces l_1 and in the arrangement l_2 π are randomly swapped. Fig. 6(c) shows the block swapping domain structure, randomly swapping the positions of the B_1 and B_2 blocks in the arrangement π . The local search strategy based on the random domain structure is to perform the domain operation with random probability c_{pm} and the random probability c_{pm} is shown in Eq. (15).

$$c_{pm}=\begin{cases}(\alpha_1\le r_1\le\beta_1)\Rightarrow insert\\(\alpha_2\le r_2\le\beta_2)\Rightarrow swap\\(\alpha_3\le r_3\le\beta_3)\Rightarrow blockswap\end{cases} \tag{15}$$

The probability interval overlap is defined in Eq. (15) as $COM<I,S,BS>$, then the priority levels of the domain operations are, in order, the insertion domain, the insertion domain and the block exchange domain.

IV. Performance Analysis of HPSO Algorithm in SCIMC Model

To evaluate how well the HPSO performs in the SCIMC model, the study first requires an analysis of the degree of variation of the WBB under different influencing factors, the experimental software is Visual and the time parameter is set to 20 in months.

Fig. 6 displays the CWB outcomes in various affecting circumstances. From the figure, the CWB changes with time and the degree of CWB change varies under different influencing factors. At the beginning of the simulation, CWB shows an increasing trend with time and reaches saturation at the 7th month, and then decreases rapidly after seven months, and the decreasing trend slows down at the 14th month. Job satisfaction has the greatest impact on CWB, and the level of organizational culture building has the least impact. To optimize the SCIMC model, the study conducted 20 independent numerical experiments on the HPSO algorithm, GA-TOM algorithm, basic PSO algorithm, and ACO algorithm, respectively. The HPSO algorithm's parameters were set with 100 iterations as follows, $w=0.2$, $c_1=c_2=2$, and $c_{pm}=\left\{[0,0.75],[0.55,0.95],[0.8,0.1]\right\}$

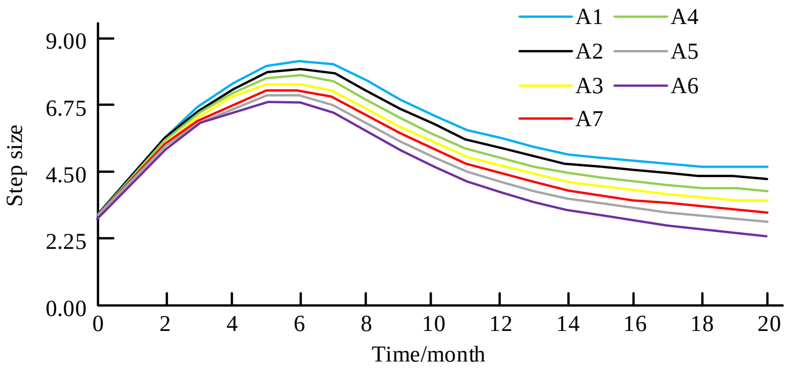


Fig. 6. Comparative analysis of CWB under different influencing factors.

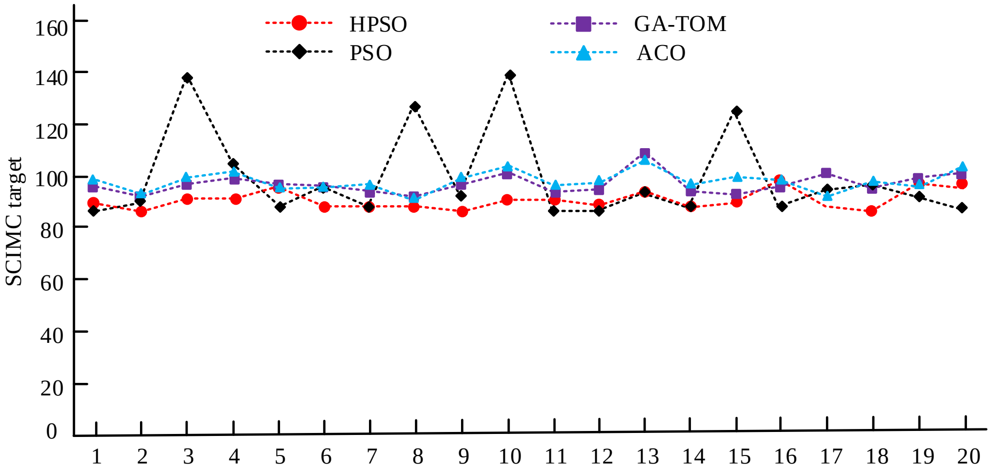

Fig. 7. SCIMC index change curves of four algorithms.

Fig. 7 shows the change curve of SCIMC index of different algorithms. The lower the SCIMC calculation result of the algorithm, the more robust its performance. As can be seen from Fig. 7, the HPSO has a maximum value (MV) of 95.81, a minimum value (IV) of 85.19, and an average value of 89.53. PSO, ACO, and GA-TOM algorithms have MVs of 136.77, 105.45, and 101.37, respectively, the IVs are 86.28, 85.37, and 85.24, respectively, and the average values are 99.09, 90.45, and 89.78, respectively. In summary, the outcomes of the HPSO and the GA-TOM differ less, and the calculation results of HPSO and GA-TOM are lower than the basic PSO and ACO, which proves that HPSO and GA-TOM have better performance in these four algorithms are superior in performance. To compare the performance of HPSO in SCIMC model more scientifically, the study set the machine interference time windows of A $[100,125]$ and B $[125,150]$ respectively, and conducted 10 simulation experiments using GA-TOM algorithm as the control group. Performance indicators include the Number Of Non-inferior Solutions (NONS), uniformity of non-inferior solution distribution, UNSD), dominant proportion of non-inferior solution (DPNS), average distance between non-inferior solution and optimal Pareto (DPNS), ADNSOP), maximum distance between non-inferior solution and optimal Pareto (MDNSOP), Noninferior Solution Dispersion, NSD) and Noninferior solution coverage (NSC), in which the larger the values of NONS, DPNS and NSC, the better the performance, and the smaller the values of UNSD, ADNSOP, MDNSOP and NSD, the better the performance.

Fig. 8 illustrates the experimental results of NONS and UNSD for the two algorithms under a working condition. Fig. 8(a) illustrates the NONS results of the two algorithms, the MV of HPSO algorithm is 14, the IV is 10, and the average is 12.3. The GA-TOM algorithm's MV is 12, the IV is 10, and 10.7 is the average. Fig. 8(b) illustrates the UNSD results of the two algorithms, the MV of HPSO algorithm is 9.700, the IV is 1.454, and the average is 5.283; it is higher than the MV of 4.970, the IV of 1.367, and the average of 2.435 for the GA-TOM algorithm.

The NONS and UNSD variation curves of the two algorithms under B working condition are presented in Fig. 9. The NONS variation curves for the two algorithms are displayed in Fig. 9(a). The maximum, minimum and average values of the HPSO algorithm are 12, 9 and 10.4, respectively, and the values of the GA-TOM algorithm are 11, 8 and 9.3, respectively. Fig. 8(b) shows the UNSD variation curves of the two algorithms, the MV of the HPSO algorithm is 10.500, the IV is 2.526 and the average is 6.132, The MV of GA-TOM algorithm is 12.26, the IV is 1.769, and the average is 5.936. Combining the results of Fig. 8 and Fig. 9, HPSO algorithm is marginally superior to GA-TOM algorithm in terms of the number of non-inferior solutions.

The CM, Dav and Dmax experimental results of the two algorithms under working conditions A and B are shown in Table I. As can be seen from Table I, the experimental results of DPNS, ADNSOP and MDNSOP for the two algorithms under A and B working conditions are presented in Fig. 1. The average of DPNS for the HPSO algorithm is 0.264 and that for the GA-TOM algorithm is 0.069. The average of ADNSOP for the HPSO algorithm is 4.474 and that for the GA-TOM algorithm is 4.485. The average value of MDNSOP for the HPSO algorithm is 4.627 and that for the GA-TOM algorithm is 4.638. The average values of DPNS, ADNSOP, and MDNSOP for the HPSO algorithm are 0.114, 3.104, and 3.189, respectively, for the B condition, and the average values of DPNS, ADNSOP, and MDNSOP for the GA-TOM algorithm are 0.066, 3.110, and 3.193, respectively. In terms of the link between the non-inferior solution set dominance and the separation of non-inferior solutions from the ideal Pareto front, the HPSO method surpasses the GA-TOM.

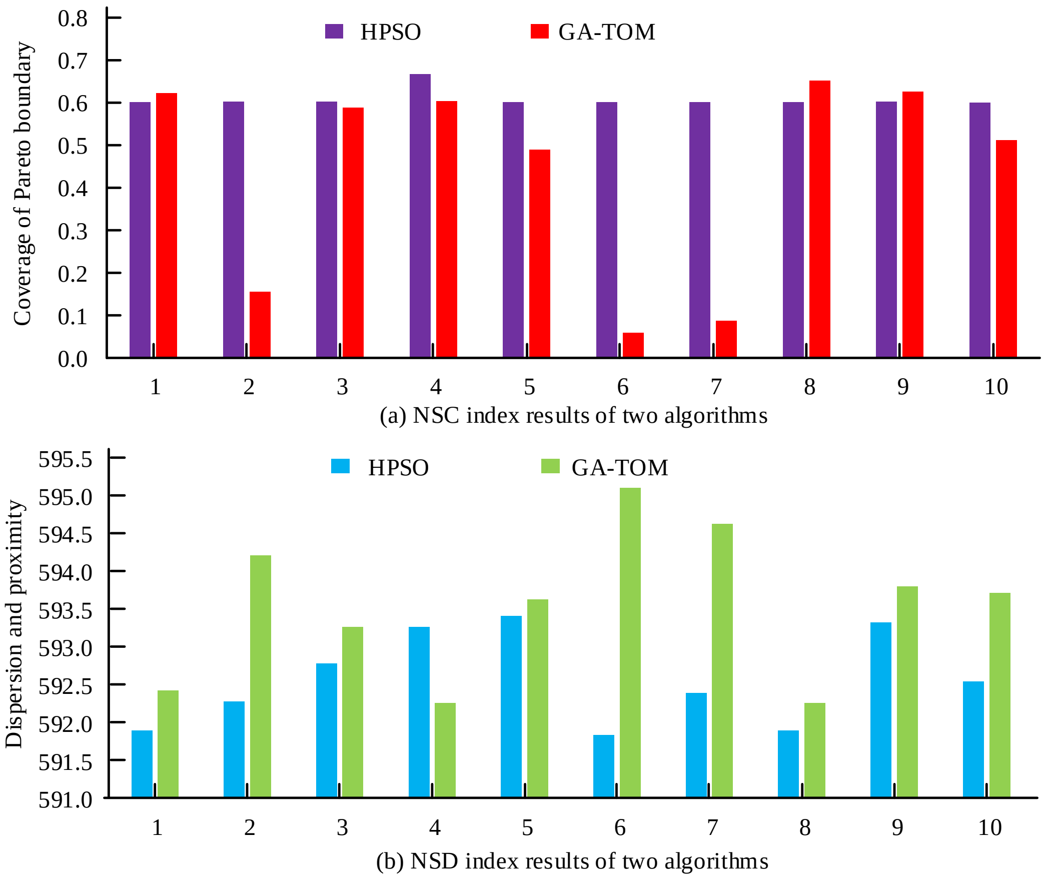
(b) NSD index results of two algorithms

Fig. 10. NSC and NSD results of two algorithms under ‘A’ working condition.

Fig. 10 shows the experimental results of NSC and NSD for both algorithms under ‘A’ working condition. Fig. 10(a) shows the NSC results of both algorithms, the MV of HPSO algorithm is 0.638, the IV is 0.570, and the average is 0.611. The MV of GA-TOM algorithm is 0.511, the IV is 0.124, and the average is 0.298, The IV is 600.581 and the average is 601.300; it is lower than the MV of 602.753, the IV of 600.849 and the average of 601.961 of GA-TOM algorithm.



(a) NSC index results of two algorithms

(b) NSD index results of two algorithms

Fig. 11. NSC and NSD results of two algorithms under 'B' working condition.

TABLE II. COMPARES THE RESULTS OF EACH INDEX OF THE PROPOSED ALGORITHM AND THE TRADITIONAL ALGORITHM IN THE ACTUAL SUPPLY CHAIN INTERFERENCE MANAGEMENT SCHEDULING PROCESS

Evaluation index	Traditional algorithm	Research and propose algorithms
Response time	48 hours	24 hours
Cost saving	5%	12%
Customer satisfaction	75%	88%
Robustness	Intermediate	High
Expandability	Finitude	Good
Innovativeness	There is no	There are

The NSC and NSD variation curves of the two algorithms under B working condition are presented in Fig. 11. The NSC variation curves for both techniques are demonstrated in Fig. 11(a), the maximum, minimum and average values of HPSO algorithm are 0.667, 0.600 and 0.611, respectively. The values of GA-TOM algorithm are 0.652, 0.059 and 0.440, respectively. Fig. 11(b) demonstrates the NSD variation curves of both algorithms, the MV of HPSO algorithm is The MV of the HPSO algorithm is 593.407, the IV is 591.833, and the average is 592.54. The MV of the GA-TOM algorithm is 595.101, the IV is 592.251, and the average is 593.524. Combining the Fig. 10 and Fig. 11, the HPSO algorithm outperforms the GA-TOM algorithm in terms of non-inferior solution coverage, dispersion, and approximation. Finally, in order to carry out the practical application effect of the proposed algorithm, it is applied to the actual supply chain interference management scheduling process. In order to comprehensively evaluate the application effect of the proposed algorithm in the actual supply chain interference management and scheduling process, this study adopts response time, cost saving, customer satisfaction, robustness, scalability and innovation as evaluation indicators. The results of each indicator of the proposed algorithm and the traditional algorithm in the actual supply chain interference management and scheduling process are shown in Table II.

It can be clearly seen from Table II that the proposed algorithm has significant advantages compared with traditional algorithms in the actual supply chain interference management scheduling process. First, in terms of response time, the new algorithm is able to react within 24 hours, while the traditional algorithm takes 48 hours, which indicates that the new algorithm has a faster reaction speed. Secondly, in terms of cost savings, the new algorithm achieved a cost savings of 12%, much higher than the traditional algorithm of 5%, showing higher economic benefits. In addition, the new algorithm also showed a significant improvement in customer satisfaction, reaching 88 percent compared to 75 percent for the traditional algorithm, indicating that the new algorithm was better able to meet customer needs. In addition, the proposed algorithm also shows strong advantages in robustness, scalability and innovation, and has high stability and adaptability. Therefore, it can be concluded that the proposed algorithm has excellent performance and wide application prospects in the actual supply chain interference management scheduling process.

V. Discussion

With the deepening of globalization and networking, supply chain has become the core component of modern enterprise operation. The complexity, dynamics and uncertainty of supply chain bring unprecedented challenges to enterprises. Especially in recent years, due to the global epidemic, trade war, natural disasters and other multiple factors, the stability of the supply chain has been seriously threatened, resulting in a series of problems such as rising enterprise costs, delayed delivery, and decreased customer satisfaction. In order to cope with these challenges, supply chain interference management has gradually attracted the attention of enterprises and academia. SCDM aims to ensure supply chain continuity and stability by identifying, assessing, preventing and responding to disruptive events in the supply chain. However, the traditional supply chain optimization methods are often powerless in the face of complex and dynamic interference events. Therefore, how to effectively manage and dispatch the interference events in the supply chain has become an urgent problem in the field of supply chain management. This study aims to build an efficient and flexible supply chain interference management scheduling model by introducing HPSO algorithm. HPSO algorithm combines the advantages of particle swarm optimization algorithm and other optimization techniques, and can achieve global optimization and fast convergence in complex and dynamic environments. By applying HPSO algorithm, this study is expected to provide a new solution and method for supply chain interference management, help enterprises improve the stability and efficiency of supply chain, reduce operating costs, and enhance customer satisfaction.

The performance of HPSO algorithm in SCIMC model is analyzed and verified by experiments. Firstly, the variation degree of CWB under different influencing factors was analyzed. The results show that job satisfaction is the most influential factor on CWB, while the influence of organizational culture building level is relatively small. This finding is similar to the research results obtained by Bilandi's team in 2021, and this result provides a valuable reference for optimizing SCIMC model, suggesting that more attention should be paid to improving job satisfaction in practical applications [23]. Secondly, through independent numerical experiments on HPSO algorithm, GA-TOM algorithm, basic PSO algorithm and ACO algorithm, it is found that the results of HPSO algorithm and GA-TOM algorithm have little difference, and are better than the basic PSO algorithm and ACO algorithm. This shows that HPSO algorithm and GA-TOM algorithm have higher stability and efficiency in solving SCIMC model. The above results coincide with the research results of XX et al. on HPSO algorithm in 2022 [24]. In order to investigate the performance of HPSO algorithm more scientifically, the research also sets up the machine interference time window in A condition and B condition, and carries out the simulation experiment. The experimental results show that HPSO algorithm is slightly better than GA-TOM algorithm in terms of the number of non-inferior solutions. HPSO algorithm also shows some advantages in the dominant relation of the non-inferior solution set and the distance of the non-inferior solution from the optimal Pareto front. The research results are similar to the performance test results of the improved HPSO algorithm conducted by Zhang's team in 2020 [25].

In summary, the experimental results of this study verify the superior performance of HPSO algorithm in multiple performance indicators, providing strong support for the optimization of non-inferior solution coverage, dispersion and approximation, etc., and the conclusions obtained in this study are also consistent with the conclusions of the latest research. In future research, it is necessary to further explore the application potential of HPSO algorithm in other optimization problems, and constantly improve and improve the algorithm to improve its solving efficiency and stability. At the same time, we will also pay attention to the influence mechanism of key factors such as job satisfaction on the degree of CWB change, with a view to providing more targeted suggestions and guidance for solving practical problems.

VI. Conclusion

With the increasing growth of the economy, the market competition model has undergone a new change, and the traditional competition of enterprise units has been converted into the competition of SC units. Effective SC management can bring more economic benefits to enterprises, but since the SC itself is a dynamic and complex system, its internal is susceptible to disruptive events and the deterioration effect brought by CWB, which leads to hindering the production operation of enterprises. To address this difficulty, the study uses the HPSO algorithm to solve the behavior-based SCIMC model. The experimental results show that the HPSO algorithm for SCIMC objective calculates the MV of 95.81, the IV of 85.19, and the average value of 89.53, which is less difficult than the GA-TOM algorithm with the MV of 101.37, the IV of 85.24, and the average of 89.78. The average of NONS, DPNS, and NSC for the HPSO algorithm under ‘A’ working condition are 12.3, 0.264 The average of ADNSOP, MDNSOP, and NSD for the HPSO algorithm are 4.474, 4.627, and 601.300, which are lower than those of 4.485, 4.638, and 601.961 for the GA-TOM algorithm. The average of ADNSOP, MDNSOP, and NSD of HPSO algorithm are 3.104, 3.189, and 592.54, which are lower than 3.110, 3.193, and 593.524 of GA-TOM algorithm. In summary, the HPSO algorithm proposed in this study has robust performance, can effectively solve SCIMC problems, and promote the development of supply chain scheduling. However, the research still needs to be deepened, especially in considering the multi-benefit objectives of each node enterprise and the complex and changeable negotiation scheduling process. Looking forward to the future, the research in this field can be expanded in the aspects of multi-objective optimization, dynamic scheduling, application of game theory, integration of big data and artificial intelligence, and practical application verification, so as to reveal the internal law of supply chain interference management scheduling more comprehensively, and provide enterprises with more targeted and practical supply chain management strategies. Through these forward-looking discussions and practices, it is expected to promote the research of supply chain interference management scheduling to a new height.

Presentation of a New Method for Intrusion Detection by using Deep Learning in Network

Hui MA*
Modern Educational and Technological Center, Henan Quality Institute Pingdingshan, Henan, 467000, China

*Abstract***—Intrusion detection in cyberspace is an important field for today's research on the scope of the security of computer networks. The purpose of designing and implementing the systems of intrusion detection is to accurately categorize the virtual users, the hackers and the network intruders based on their normal or abnormal behavior. Due to the significant increase in the volume of the exchanged data in cyberspace, the identification and the reduction of inappropriate data characteristics will play a significant role in the increment of accuracy and speed of intrusion detection systems. The most advanced systems for intrusion detection are designed for the detection of an attack with the inspection of the full data of an attack. It means that a system of detection will be able to recognize the attack only after the execution of the attack on the attacked computer. In this paper, a system for end-to-end early intrusion detection is presented for the prevention of attacks on the network before these attacks cause further detriment to the system. The proposed method uses a classifier based on the network of the deep neural for the detection of an attack. The proposed network on a supervised method is trained for the exploitation of the related features by the raw data of the traffic of the network. Experimentally, the proposed approach has been evaluated on the dataset of NSL-KDD. The extensive experiments show that the presented approach performs better than the advanced approaches based on the accuracy, the rate of detection and the rate of the false positive, and also, the proposed system betters the rate of detection for the classes of the minority.**

Keywords—Attack; security on cyberspace; classification; intrusion detection; deep learning

I. Introduction

The ever-increasing expansion of the Internet, in terms of infrastructure and in terms of software, has caused an increment in the number of network users' number and their applications [1]. Today, many public sector services and many private sector services are virtually done on the Internet. The development of this virtual space has caused the detection of intrusion to become the most important subject in the scope of the security of computer networks. The systems for intrusion detection try to classify the activity of the made connections by the users into two categories: the normal and the abnormal [2]. In more advanced systems, sometimes, the type of abnormal behavior, which is also called an attack, is specified. Each connection in the network is described based on the collection of features, which these features can be used for the determine of the normal connection or the abnormal connection [3], [4].

The accuracy of the detection for the systems of intrusion detection is the most important indicator of the efficiency of these systems. The increment of the accuracy in the systems of the detection of the intrusion prevents the result of more attacks in the system. The attack neutralization will play a decisive role in the reduction of the costs caused by the attacks on valuable network resources [5]. The attacks of the Denial of Service (DoS) are the most popular kind of attacks that are constantly sent to servers by different IP addresses and prevent the serving of the servers or shut down of the servers [6]. Usually, the attacker varies the address of the IP to carry out an attack on the victim's computer. Although the network firewall that first responds to the attack performs the process of filtering the attack, unfortunately, today, this amount of security is not enough. Then, the attacks that can elapse the firewall are sent through an intermediate router into the deep learning-based approach to the detection of the intrusion. Here, the multitude of variant classes of new attacks can be identified. If an unusual position is observed, it is immediately related to the center of the management of the system. Usually, this center informs the system officers about this situation via SMS or email, and then it automatically blocks this attack [7], [8].

It is essential to provide a more precise method of the detection of attack for the detection of novel attacks in the servers and the networks. The detection methods do not use the programming of the unequivocal according to problem complexity [9]. Usually, they use the methods of machine learning, which can be remarkably prosperous on the problems of decision-making as long as the features of the sufficient are presented on problem [9], [10]. In deep learning, incumbent features are also exploited by training certain layers like Recurrent Neural Networks (RNNs) or Convolutional neural networks (CNNs). The achievement of an extended network of deep learning strongly appertains the kind of layers of feature extraction. Also, it depends on sufficiently large training dataset. In addition, the preprocessing and organization of input data may have an important result in achievement [11]. Thus, hunt for superior methods in different fields is a topic that is studied by researchers. In current paper, a system for end-to-end early intrusion detection is presented for prevention of attacks on network before these attacks cause further detriment to the system. The proposed method uses a classifier based on the network of the deep neural for the detection of an attack. The proposed network on a supervised method is trained for the exploitation of the related features by the raw data of the traffic of the network.

In summary, the contributions and the reasons for choosing the methods of this paper are as follows: 1) A basic network intrusion detection method is presented. If more data is available, the proposed approach can make a more informed decision about the class label of a given network traffic data, but it delays the decision. Therefore, in this work, the focus is on optimizing the attack detection accuracy with minimum delay. 2) The proposed approach extracts relevant features from raw network traffic data end-to-end instead of relying on manual feature engineering process. Therefore, the proposed approach is domain-independent and does not require domain-specific data preprocessing steps. 3) A new metric is introduced to evaluate how early the proposed approach can detect attacks.

The continuation of this article is as follows: Section II provides a review of the research literature. Section III the proposed method, which uses the model of deep learning, is presented. In Section IV, the dataset used in the designed experiments details and the outcomes of these experiments are presented. In Section V, the general conclusions and the prospects for future research are presented.

II. Review of Literature

The system of intrusion detection in the network is applied for the monitoring of the network traffic to protect the system from network threats. This system tries to find the destructive acting like the attacks of DoS, the attacks that monitor the network traffic, and the port scanning attacks [12]. In general, two methods are used to detect the intrusion on the network:

A. Detection of Anomaly

It is when the observed behavior of the user does not follow an expected behavior [12]–[14]. In network anomaly detection, the normal system activities such as the network bandwidth, the ports, the rules and the device communication are examined. The detection of the anomaly of the intrusion is a hard problem with several proofs. First, the use of the system and user behavior is constantly evolving. Therefore, the intrusion detector must also evolve. Without the permission for these changes in the behavior, the network administrator will soon be inundated with false alarms, and it will rapidly affect the trust in the system. A second important factor in the detection of the anomaly is that an alert of the behavior of the abnormal may not furnish any specific beneficial data for the administrator of the network. The ambiguous alert about which the system may be beneath the attack makes it hard to catch the firm's measured action. Also, sometimes, the known attack may not be recognized by the system of the detection of the anomaly. This is the fundamental problem [12]– [14].

B. Signature-based Detection

It is when the observed behavior indicates an intention for the misuse of the network computing resources. The benefits of the detection based on the signature consist of simpleness and effectiveness, and it has a great ability for detecting the attacks of the known. The other important profit is that the alert that is published is a certain alert because it reconciles the signature of the pattern of a certain attack. By a special alert, the administrator of the network can rapidly assess whether the attack of the doubtful is a wrong alert or real. I.e., if it is detected as real, the network administrator can adopt an appropriate response. Another advantage of this approach is the ability to produce accurate results and reduce false alarms. However, a disadvantage of the system of detection based on signature is that the signature file must be updated. Also, with the increment of the number of signatures, the efficiency of the system is decreased. On the other hand, the system will be able to recognize the attacks of the known. The smallest change in the known attacks causes the possible loss of the attack detection by the system [15]–[17].

In the literature, there are different researches for IDS with the use of the methods of machine learning. Here, the latest articles based on the deep learning are presented. In [18], the authors have presented a hybrid method based on the networks of the deep belief and the networks of the probabilistic neural. The authors deal with the imbalance of the class in the NSL-KDD dataset with the use of SMOTE about the increment of the classes of the minority and with the use of NCL about the classes of the majority of the under-sampling. In [19], the authors have presented a technique for the extraction of the feature with the use of the sparse auto-encoder. Their presented system is contrasted to the prior methods of the extraction of the feature. The process of the classification is speeded up, and a superior process for the learning is acceded. An impressive practical model has been developed for use in the systems of the detection of intrusion.

In study [20], the authors have proposed a revision of the literature on machine learning and the applications of deep learning in the detection of intrusion on the network. Also, the authors have appraised the different databases, the different approaches and the different problems with the detection of the intrusion. In research [21], the authors have provided the models based on the optimization of the particle swarm for the selection of the feature and for the meta-parameter selection. They have evaluated the different models of deep learning, like the Long Short-Term Memory (LSTM) and the Deep belief network (DBN). In study [22], the researchers have provided a review of research about deep learning for the IDS. They have also reviewed the light research and the directions for the future. The authors provide an approach for the architectures of deep learning for the kinds of IDS and for the databases. In research [23], the authors have proposed the categorization of the models of deep learning for the systems of the detection of intrusion. Also, they have presented the literature review in their research. The training and the test have been performed on the various databases with the use of $four$ methods of deep learning. Their test outcomes are compared by articles in the literature. Also, the assessments for the latter research about the systems of the detection of the intrusion, which are based on deep learning, are provided.

The authors have provided an approach to the detection of the attack based on deep learning about the attacks of Distrubed Denial of Service (DDOS). Their presented approach has been evaluated in the dataset of CICIDS. Also, it has been simulated the traffic of the DDOS. It is expressed that the presented approach outperforms the several prior approaches for the detection of the attacks of the DDOS [24]. In [25], the authors have provided an asymmetric deep auto-encoder classification method for the unsupervised learning of the features. Their proposed method is evaluated on GPU with the use of the dataset of KDD-CUP99 and the dataset of NSL-KDD. The obtained outcomes have been contrasted by the research on literature. In study [26], the researchers have extended a model of the deep network, which consists of the

RNNs with the units of the recurrent of the gated, the Multi Layer Perceprton (MLP) and the modules of the softmax for an increment of the efficiency of the systems of the detection of the intrusion. Their experiments on the presented model have been performed in the dataset of KDD-99 and the dataset of NSL-KDD. The outcomes of the experiments have displayed that the GRU has superior outcomes over LSTM in the systems of the detection of intrusion. In study [27], the authors have extended an IDS basis on self-learning according to the framework of STL to propose the superior security of the network over the standard technologies for the defense of the network. The experiments in the dataset of NSL-KDD incur accuracy of the classification of binary and the accuracy of the five-class classification. Also, their experiments reduce the time of the training and the time of the test.

In research [28], the authors have provided an approach based on the cloud for the detection of the intrusion in the network in real-time with the use of the binomial deep learning models and the models of the 5-class deep learning along with the framework of H2O. In case of an attack, the models can dispatch a notification to the mobile to the model authorities with the help of a web page on the architecture basis on the cloud, which the authors are planning. In study [29], the authors have proposed a model of IDS based on the improved DBN by the algorithms of the genetic for IoTs. The structure of the network of the optimal with GA is characterized by the use of numerous iterations. In study [30], the researchers have investigated a model of DNN by the different layers. Also, authors have used the NSL-KDD dataset, the UNSW-NB15 dataset, the Kyoto dataset, the WSN-DS dataset and the CICIDS 2017 dataset for NIDS and HIDS. Due to the done tests, this approach can be scouted on the time of the real, and it has superior outcomes over the traditional algorithms of machine learning. In research [31], the researchers have extended an approach based on DBN by a layer of the classification with four-layer and Support Vector Machine (SVM). These authors have done the experiments using different kernels like Radial Basis Function (RBF), the linear, the sigmoid and the polynomial. Due to the empirical outcomes in the dataset of NSL-KDD, authors have obtained the foremost outcomes with the use of the kernel of RBF.

III. The Presented Method

In the current section, the proposed system for the detection of intrusion and the detection of network attacks is presented. The primary purpose of the presented method is the monitoring of the traffic of the network on the time of the real, the extraction of the automatic features from the raw data of the traffic of the network, the prevention of the time-consuming task of the feature extraction using the traditional methods and the accurate detection of the attacks in the network. The presented method can be intersected into two general stages. The overview of the presented method is displayed in Fig. 1. In the first step, the proposed flow classifier is trained and then evaluated using a dataset that has the labeled flows of the network and the related packets of the network into these flows. In the second step, the trained classifier of the flow is used for the prediction of whether a given flow from the network is destructive or the usual. The flow of the network is the two-way trail of the packets, which is swapped among two endpoints in a specified interval of time by several joint features of the flow [9], such as the addresses of the IP of the source, the addresses of the IP of the destination, the numbers of the port of the source, the numbers of the port of the destination and the protocol kind. In the proposed method, a flow of the network is defined as a trail from the regular packets T. In it, T displays the longitude of a full flow. The given flow is shown as follows:

$$F_T = \{P_1.P_2.\cdots.P_T\}\ \forall P_i \in \mathbb{R}^d \wedge 1 \leq i \leq T \tag{1}$$

d is the packet length. Two main steps of the proposed method use a flow processing approach, which this approach includes three modules: the filtering of the packet, the identification of the flow and the preprocessing of the packet. The module of the filtering of the packet takes the packets of the network and then sends them into the latter modules if these packets meet certain criteria. The next modules convert the packets, and then these modules categorize them in the flows of the network. When a flow of the network is updated by a novel packet, then the classifier of the flow is used for the updation of the related prediction to the flow.

A. *Approach of the Processing of the Flow*

In the current section, the modules of the approach of the designed flow processing are introduced. As mentioned in the previous section, in this approach, three modules are used, which are as follows:

1) *Filtering of packet:* The traffic of the raw of the network among the unreliable network and the attacked system is monitored. Just the packets from the network are selected that are relevant to the kind of attacks that have to recognize them. For instance, if the goal is the detection of web attacks [10], then we only capture the packets of HTTP.

2) *Identification of flow:* With the reception of a novel packet, the model checks the packet features, like the addresses of the IP of the source and the addresses of the IP of the destination, for the identification of a flow of the appropriate activity for it. The flow of the active displays a session of communication between two endpoints of the network. Also, if no active flow is found that matches the features of the packet, then a novel flow is created. A flow of the network is presumed to be inactive or terminated. After that, the connection is lost or the time at which the flow has not embraced a novel packet on a specified time period. The value of the timeout of the flow can be set due to the kind of protocol of the traffic of the network, which is adapted for the detection of attacks.

3) *Preprocessing of packet:* When the suitable flow of the novel packets is identified, then every packet is sent via the below preprocessing stages to truncate the unfavorable data and to convert it to the byte vector with a uniform size: the truncation step and the transformation step. The primary goal of the mentioned stages is the confidence that the classifier must rely on the related features to classify the flow. The details of these steps are as follows:

a) *Truncation step:* The packets of the raw received consist of the header of Ethernet. This header contains the data about the link of the physical. However, this information is worthless for the detection of an attack insomuch it can be faked as easily. Therefore, the header of Ethernet is deleted from the packet. Also, the header of the IP on the packets contains data like the perfect longitude of the packet, the version of the protocol, the addresses of the IP of the source and the addresses of the IP of the destination. The mentioned data is essential for the routing of the packets on the network. This data is considered disjointed for the classifier because it is possible that the classifier starts to emphasize the IP information for the detection of the flows of the attack. Thus, it is deleted from the packets. It permits the classifier to operate consistently if the node's address on the network has varied. Also, it allows the classifier to popularize the learned information from an environment of the network to another environment.

b) Transformation step: At the time of the usage of the neural network for the classification operation, an input with a fixed size is required. In order to uniform the header longitude of the layer of the transport and in order to uniform the payload of the packets, these packets with the zeros to a fixed length are cutted. It should be noted that if the packet's longitude on a flow is limited, then, the flow longitude is not limited, unlike the other proposed methods like the presented approaches [11].

B. *Flow Classification*

An essential aspect of proper forecasting is the prediction of the attack with enough time to implement the true reaction to the attack as rapidly as possible before it causes further damage to the attacked system. Therefore, to minimize the time of the prediction, a DNN is used as a classifier of the flow insomuch with an increment of the model size, the prediction time is increased because more computations are required. The key problem is that the decrement of the size of the model usually makes the finite power and the little accuracy [32], [33]. To alleviate the mentioned problem, instead of the training of a model of the large complex for the classification of all kinds of attacks, a set from the naive models is trained which in it, every model is trained for the classification with just a subset of the classes of the attack. Several ensemble strategies, like the voting of the majority and the ranking, have been proposed in the literature for the employment of multiple models and the combination of their predictions [34]. However, the discussion of the ensemble strategies is beyond the domain of the current article.

In the current article, the networks of the neural convolutional as one-dimensional [35] are used for the extraction of a good representation of the internal flows of the network and the presentation of it as the input of a network of the fully-connected or the network of the dense. A layer of the softmax [36] is used as the layer of the final of the network for the calculation of the distribution of the probability for the classes of the target. CNNs are used for the extraction of the related features by the data of the input of the network, like the images and the trails. These networks are able to model the dependencies of the spatial and the dependencies of the temporal on the data with the learning of the corresponding filters of the convolution. A convolution layer consists of several convolution filters, and each filter is used for the extraction of a feature of the specific from the data of the input. Therefore, the output of the layer of the convolution is named the map of the feature.

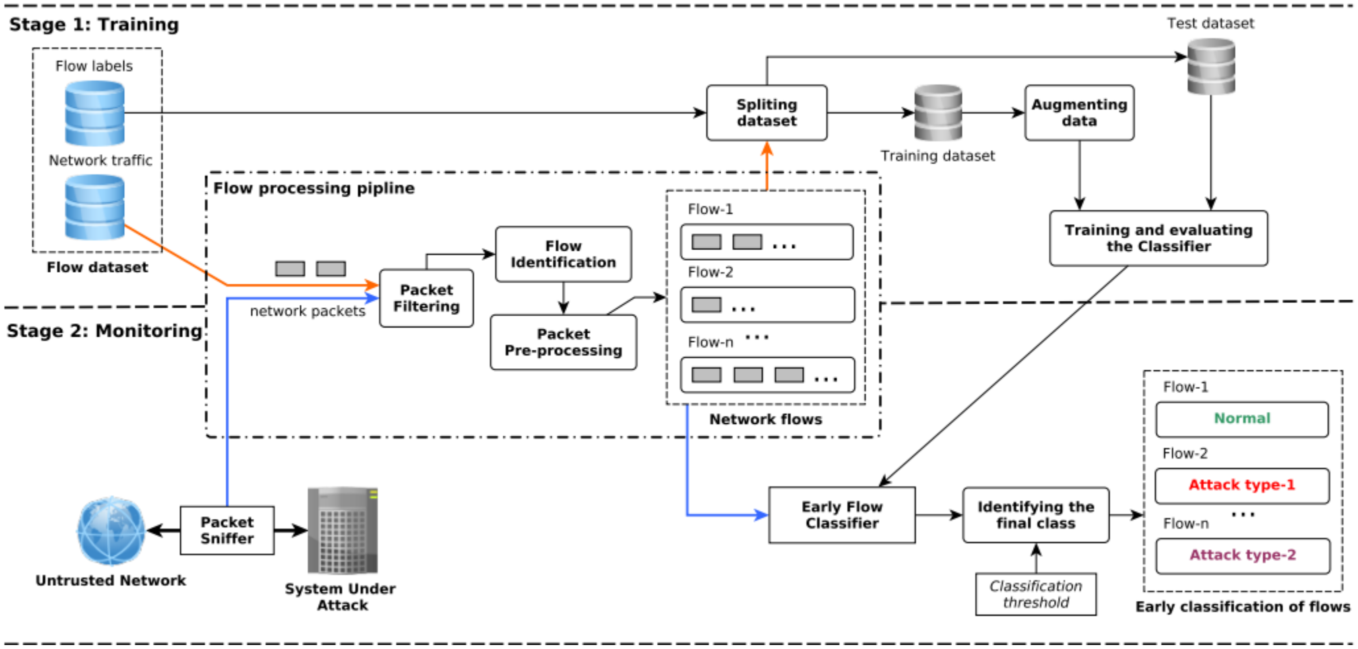

Fig. 1. An overview of the steps of the presented model for network intrusion detection.

The data of the input of ID-CNN has two dimensions. 1-th dimension determines the trail of the circumstances. In contrast, 2 -th dimension is related to the features of the individual from a circumstance. ReLU [37] is used as a function of the activation of the nonlinear in each neuron on the layer of the convolution. Usually, every layer of the convolution is coupled with a layer of the pooling [36] to get the translation-invariance from the returned output with the layer of the convolution. The mentioned layer decreases the size of the time of the output by replacing every partition with the static size by a statistic of the summary from the adjacent elements. CNNs have fewer trainable parameters than the other kinds of ANNs [35]. Therefore, they have fewer possibilities for the overfitting of the data of the training versus the networks of the fully connected. After the convolution operations and the operations of the pooling, a flow of the network with the changeable longitude is displayed with a series of maps of the feature with the changeable longitude. A global layer of the pooling [38] is used for the transformation of the series to a vector with the changeable longitude, and this vector is presented as the input of the layers of the fully connected to obtain the vector of the feature. Finally, a layer of the softmax is applied to the vector of the feature to achieve a distribution of the probability for every class. Based on the distribution of the probability and the basis of the threshold of the classification, the predictions of the final are made.

C. Training

The classifier is trained before its use for the detection of early intrusion online. The system's purpose is to learn automatically the features of the spatial-temporal from the flows of the raw of the network, and then, this system uses these learned features for the reliable identification of the attack flows as quickly as possible. a dataset of the flow labeled is needed for the training of the supervised, which dataset includes the normal flows and the flows of the attack. Moreover, the flows of the labeled and the dataset must contain the corresponding packets of the network with flows. Most of the datasets that are used to train IDSs suffer from the imbalance of the class [2]. That is, the sample number between the various classes in the dataset is not the same. The trained classifier on an unbalanced dataset usually shows the bad efficiency basis the accuracy of the prediction. Thus, in the current article, to correct the effect of the imbalance of the class, the used classifier is trained by the weighting of the sample, which this weighting performs as a factor for the value of the computed loss in every sample among the process of the training. The weight of every sample is based on the related class. Inversely, it is computed with the frequencies of the class in the data of the training of the proportional. The goal is that the classifier must pay further attention to the examples which belong to the classes of the down-represented.

The dataset of the training is prepared with the processing of each packet into flows with the use of the mentioned method above. A dataset of the flow is displayed as $= \{(F_T^{(i)}.y_j)\}$ $1 \leq j \leq N$. In it, N is the flow number F_T and y shows their labels. As regards the goal, it is the training of a classifier that can reliably detect an attack flow after the view of the first packets from a certain flow. Thus, the dataset is extended with the creation of a stack of the short fragments of a flow with the variable longitudes. The expanding process of the dataset of the training with the generation of more data than the existing data is named the augmentation of the data [39]. The process start with the creation of the smallest fragment from a certain flow that contains just the first packet from the flow. Subsequently, by cumulatively adding more packets, more fragments per flow are created, according to the predefined fragmentation rate s_r such that $0 < s_r < 1$. The fragmentation rate s_r is a meta-parameter which is used for the calculation of the fragment size $s_z = [s_r * T]$ in a certain flow, which in it, T is the flow longitude. The value of this parameter reins the number of the produced fragments in every flow. For example, with the decrement of the value of s_r, the more fragments are generated in each flow.

Presume that a flow is given as $F_T^{(j)} = \{P_1.P_2.\cdots.P_T\}$, the fragments set of this flow is as below:

$$\left\{F^{(j)}_{t=k*s_z}\right| k = 1.2.\cdots.\left\lfloor\frac{T-1}{s_z}\right\rfloor \qquad (2)$$

All fragments have the label of a similar y_j which the main flow is needed. For instance, suppose 3 flows by the various longitudes: $F_6^{(1)}$, $F_{15}^{(2)}$, and $F_{70}^{(3)}$. The fragmentation rate s_r is set with 0.25. The fragment sizes s_z for $F_6^{(1)}$, $F_{15}^{(2)}$ and $F_{70}^{(3)}$ are determined $2, 4$ and 18. Table 1 catalogs the fragments from the generated flows with the process of the augmentation of the data.

TABLE I. THE FRAGMENTS FROM THE GENERATED FLOWS BY THE DATA AUGMENTATION PROCESS FOR THE MENTIONED EXAMPLE

No.	Flows	Flow Segments
1	$F_6^{(1)} = \{P_1.P_2.\cdots.P_6\}$	$\{P_1.P_2\}$
2		$\{P_1.P_2.\cdots.P_4\}$
3	$F_{15}^{(2)} = \{P_1.P_2.\cdots.P_{15}\}$	$\{P_1.P_2.\cdots.P_4\}$
4		$\{P_1.P_2.\cdots.P_8\}$
5		$\{P_1.P_2.\cdots.P_{12}\}$
6	$F_{70}^{(3)} = \{P_1.P_2.\cdots.P_{70}\}$	$\{P_1.P_2.\cdots.P_{18}\}$
7		$\{P_1.P_2.\cdots.P_{36}\}$
8		$\{P_1.P_2.\cdots.P_{54}\}$

The data augmentation is applied only to the flows of the dataset of the training. This dataset is expanded with the inclusion of the created flow fragments. Table I shows the fragments from the generated flows by the data augmentation process. The proposed classifier is trained for the learning of the map function $H: F_t^{(j)} \rightarrow y_j$ (where $t \leq T$). Namely, the classifier must be able to predict the label of the class y_j from a certain flow $F_t^{(j)}$ by just the first packets t. In the proposed method, the function of the loss of the cross-entropy and the optimizer of Adam [40] have been used for the training of the proposed classifier.

D. Monitoring

Real-time monitoring on high-speed networks is challenging work because of the great rates of the packet. In the proposed method, the mentioned point is the main reason that only process the packets of the network that are relevant to the attack's kind, which want to recognize. The module of the sniffer of the packet is responsible for the monitoring of the traffic of the network on the time of the real. As shown in Fig. 1, it captures and then forwards the incoming network packets and the outgoing packets of the network to the approach of the processing of the flow. The mentioned module, with the use of the library of libpcap is implemented, which furnishes an interface of the programming for the capturing of the packets which are passed via the interfaces of the network. Also, this library asserts the filters that can be configured to take just the specific packets. These filters, which usually are supported by the kernel of the system of the operating, cure the efficiency with the reduction of the overhead of the process of the filtering of the packet.

Also, a roster of the flows of the active and the prognostications about these flows are holded, which are done by the classifier of the flow. As shown in Fig. 2, while the flow of the network is updated by a novel packet, the classifier of the flow is used for the obtention of a prediction. The class of the final of a flow is the class that has the greater probability over the other classes, and classification threshold $\in [0.1)$. Whenever none of the probabilities of the class is greater than the certain threshold, then the proposed method returns Unknown as the class of the final. If the threshold of the classification is increased, then the rate of false positives is reduced, which improves the classification accuracy. The thresholds are presented by the administrator of the network, who sees the traffic of the network, and this person is responsible for the reaction to the attacks.

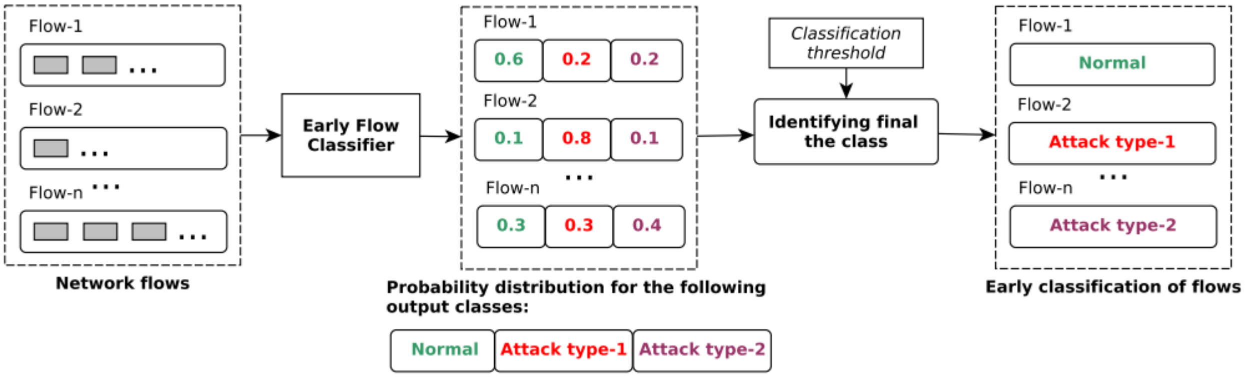

Fig. 2. The flow classification process.

IV. Experiments and Evaluation of Results

In the current part, the used dataset, the performed experiments and the obtained results are presented. The presented method is implemented on the computer by Core (TM) i7 CPU 3.0 GHz Intel(R) and 8G RAM. The efficiency of the presented approach is tested in the dataset of NSL-KDD. The data distribution of this dataset is shown in Fig. 3. It should be noted that the distribution of the data is unbalanced. The efficiency is displayed with the performing of the comparisons by the other deep learning models for the verification of the performance of the various components.

A. The Evaluation Criteria and the Parameter Setting

In the designed experiments, the strategy of K -Fold Stratified cross-validation is used for the test and for the training to ensure a good ratio of the training test. The optimizer of Adam [40] is applied as an optimizer for the optimization of weights for the training. The proposed model is trained in 150 iterations on the architecture of the basic. The rate of learning is adjusted to 0.001. Also, the exponential rate of the decay for the estimation of the first moment is adjusted to 0.9, and the estimation of the second moment is adjusted to 0.999. The tests are done with the use of Keras. Then, the proposed approach is appraised, due to three criteria: FPR, ACC and DR. ACC evaluates the ability of the model to predict the traffic of the normal and the traffic of the attack, while DR measures its ability for the detect of the attack traffic. A higher DR indicates that this approach is susceptible to the attacks of the network and that it aids in the persons to act the precautions on time. FPR is applied for evaluation of the misclassification of the traffic of the normal. DR and FPR should be presumed as common since a great DR can be overshadowed by a great FPR. The above criteria definitions are as follows:

$$ACC = \frac{TN + TP}{FP + FN + TP + TN} \tag{3}$$

$$DR = \frac{TP}{FN + TP} \tag{4}$$

$$FPR = \frac{FP}{TN + FP} \tag{5}$$

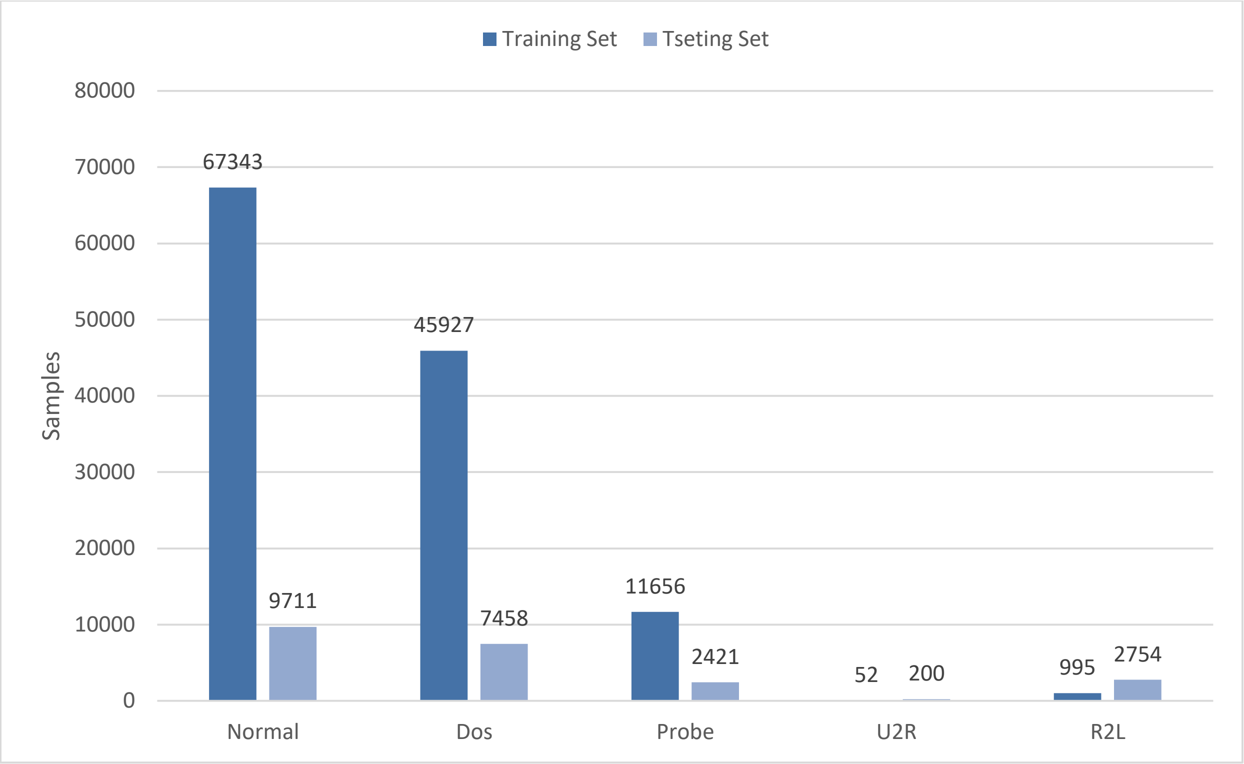

Fig. 3. The data distribution in the dataset of NSL-KDD.

TN and TP display the number of the traffic of the normal and the number of attacks that are properly classified, respectively. FP display the number of the records of the real normal that are misclassified as attacks. Also, FN display the number of attacks that are misclassified as the traffic of the normal.

B. The Acquired Results

To display the performance of the presented approach, two scenarios are considered: 1) the binary classification where the proposed method judges whether an instance is an attack or the traffic of the normal. 2) the classification of the multi-class where the proposed approach forecasts whether an instance is a class from the given attacks on the dataset or the normal.

1) The classification of the Binary: Table II displays the outcomes of the classification of the binary with the K-Fold Stratified cross-validation, where k is in the range of 2-10. For the dataset of NSL-KDD, the mean ACC is equal to 99.71%, the mean DR is equal to 99.75%, and the mean FPR is equal to 0.28%. In Fig. 4, it is clear that the presented method has the great DR and the great ACC. Also, it has a little FPR. With analysis of Fig. 4, it can be seen that the foremost outcomes become visible at K equal to 10. Because with an increment of the folds number, there will be more examples from every class of the attack/normal that the approach can be trained with them. Thus, the approach can classify them as superior. The outcomes show that the proposed method has the powerful ability to discern between the traffic of the normal and the traffic of the attack.

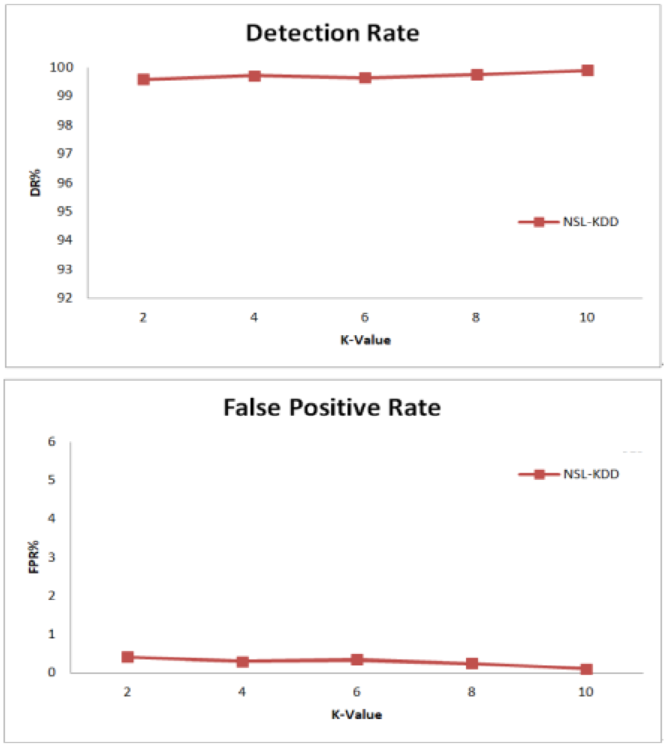

Fig. 4. The comparison of DR and FPR in the binary classification mode

TABLE II. THE OUTCOMES OF THE PRESENTED APPROACH ON THE BINARY CLASSIFICATION MODE

K	ACC	DR	FPR
2	99.62	99.63	0.40
4	99.66	99.73	0.27
6	99.62	99.67	0.36
8	99.81	99.79	0.25
10	99.83	99.93	0.11
Average	99.71	99.75	0.28

2) The classification of the multi-class: The outcomes of the classification of the multi-class are presented in Table III. For the dataset of NSL-KDD, the mean ACC is equal to 99.71%, the mean DR is equal to 99.73%, and the mean FPR is equal to 0.32%. Fig. 5 displays DR of the classes for the five-classes classification in the dataset of NSL-KDD. As it is clear from Fig. 5, the proposed method shows excellent performance in the detection of malicious attacks. To display the outcomes of the detection of the approach directly, a matrix of the confusion is used for the representation of the outcomes of the test. Fig. 6 displays the matrix of the confusion in the dataset of NSL-KDD for the classification of the multi-class. According to Fig. 6, it is shown which most instances are focused on the matrix diameter, and this point shows that the total efficiency of the detection is great.

TABLE III. THE OUTCOMES OF THE PRESENTED APPROACH ON THE MULTI-CLASS CLASSIFICATION MODE

K	ACC	DR	FPR
2	99.58	99.46	0.33
4	99.72	99.85	0.40
6	99.69	99.77	0.37
8	99.81	99.78	0.20
10	99.74	99.80	0.31
Average	99.71	99.73	0.32

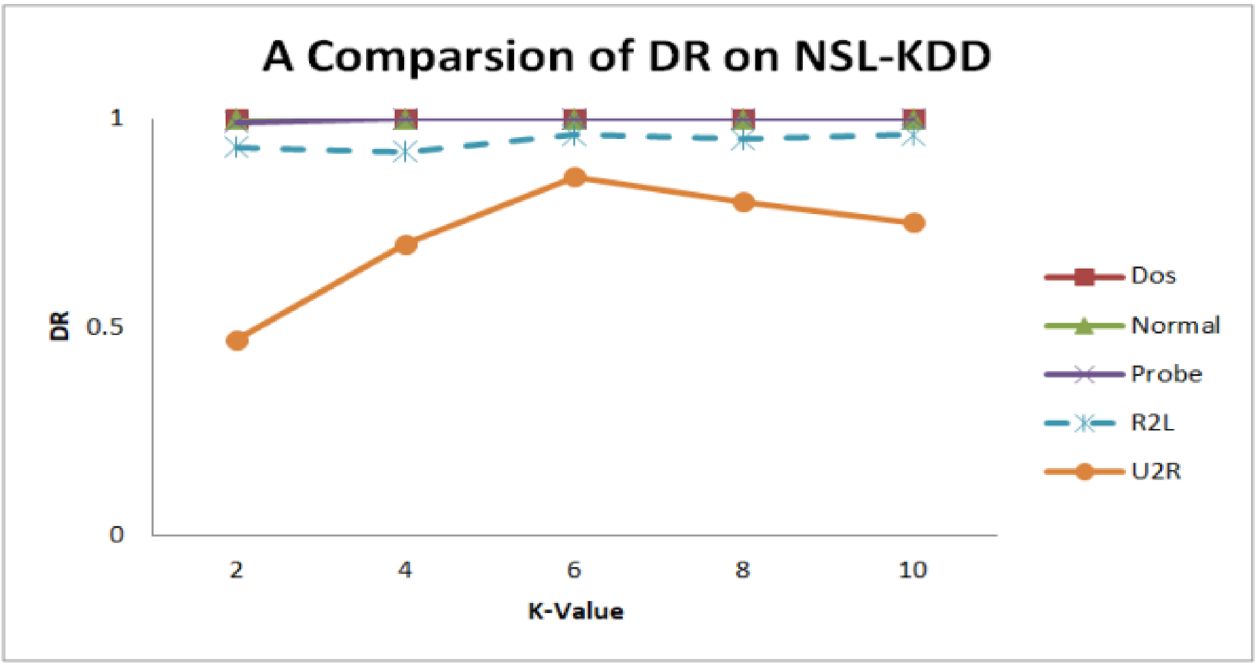

Fig. 5. The DR results of all classes in the dataset of NSL-KDD.

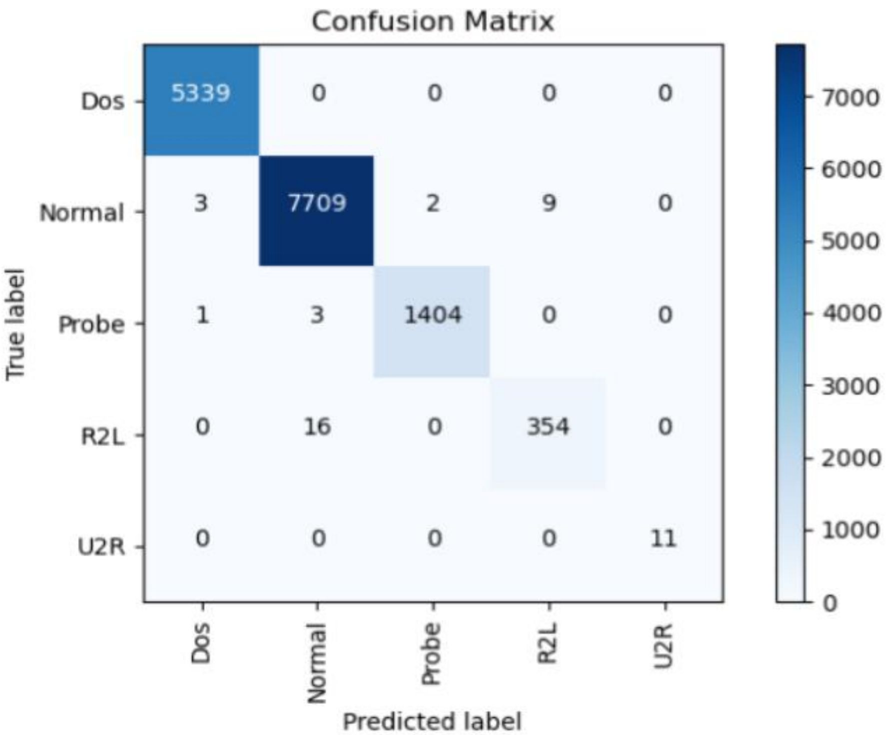

Fig. 6. Confusion matrix for the dataset of NSL-KDD.

TABLE IV. THE COMPARISON OF OUR PRESENTED APPROACH WITH SIMILAR METHODS

Model	ACC	DR	FPR
SVM [41]	69.52	70.23	1.03
RF [42]	69.84	68.79	1.16
AdaBoost [43]	71.98	72.36	0.99
HAST-IDS [44]	93.27	95.85	0.52
CNN-BiLSTM [45]	99.22	98.88	0.43
LuNet [46]	99.14	99.02	0.61
Pelican[48]	99.21	99.13	0.65
Proposed Method	99.81	99.80	0.20

To prove the strong efficiency of the presented approach, the proposed approach of this paper is compared with seven advanced models. These methods are: SVM in [41], RF in [42], AdaBoost in [43], HAST-IDS in [44], CNN-BiLSTM in [45], LuNet in [46] and Pelican in [47]. These methods are trained and tested with a similar data partition and, with the strategy of the cross-validation with k equal to 10. The outcomes of the proposed approach are provided in the best case. Table IV shows the outcomes of the multi-class comparison of the proposed method with seven advanced models. It is clear that the proposed model outperforms the other models on all evaluation criteria. The outcomes display that the presented model betters the detection rate. Also, it maintains a low false positive rate. This point shows the greater effectiveness of the model for network intrusion detection.

C. Discussion

Despite the good performance of the proposed method, there are limitations to the presented work, which are discussed in this section. The main threat to the validity of the proposed method is that only one dataset was used in the evaluation. Therefore, the test results may be different for other datasets that have different types of attack classes. To the best of the authors' knowledge, most publicly available datasets, with the exception of NSL-KDD, are outdated and/or lack raw network traffic data. The proposed approach can extract relevant features from raw network traffic data instead of relying on manual feature selection process. Therefore, it can be easily applied to other datasets. Future work could be to conduct additional experiments by using different datasets such as CSE-CIC-IDS2018 to mitigate this threat.

Another threat to the validity of the proposed method is that the evaluation may appear subjective. Another threat to the proposed work is that only three attack classes are considered. As mentioned, a simple DNN model (ie, a model with a relatively small number of trainable parameters) is trained to detect only certain types of attacks to achieve good accuracy and reasonable prediction time.

V. Conclusion

In the current article, a system of the early detection of the intrusion, which is based on the end-to-end, has been presented for the prevention of real-time network attacks before they cause further detriment to the system of the attack. A classifier basis on CNN is used, to detect the attack. The model is trained as a method of the supervised extraction of the related features by the data of the raw traffic of the network rather than relying on the process of the manual selection of the feature, which is applied to the most relevant methods. The designed experiments have been evaluated in the dataset of NSL-KDD, and the obtained results display that the presented approach improves the overall results (especially the rate of detection and the rate of false positives). The presented approach in the current paper is competitive. It obtains the lower overhead of the computational, which is essential for practical network intrusion detection.

Further analysis has shown that the proposed method has gaps for the betterment of the discerning among the groups by similar features, and the future work will be reviewed here. Furthermore, in the latter task, the researchers can aim to evaluate the proposed approach in the different datasets. Also, the various architectures of the network of the neural can be investigated to check the comparative efficiency in the early detection of the attack.

***Abstract*—Extensive global research aims to improve digital marketing profits through pricing decision-making and optimization. A dual word-of-mouth diffusion pricing model is developed for cross-border e-commerce, addressing word-of-mouth accumulation and information diffusion effects. The traditional artificial bee colony algorithm is optimized with security domain search and information diffusion profiles, enhancing global search capabilities. Performance tests reveal that word-of-mouth scale significantly influences cross-border e-commerce profits, increasing with scale coefficient, consumer conversions, and optimal profits. The proposed algorithms demonstrate high efficiency and convergence rates, surpassing common iterations and benefits in the clothing pricing problem. The comprehensive imitation effect is -0.14, and the word-of-mouth scale effect is 1.34. Pre-sale and sales prices for clothing are set at 347.49 and 641.393, respectively. Similarly, in pricing cross-border e-commerce electronic products, the algorithm achieves optimal profits after 230 iterations, surpassing other algorithms. Overall, the proposed model exhibits superior computational performance in cross-border e-commerce pricing decision-making compared to conventional approaches.**

I. INTRODUCTION

With the year-on-year increase in Internet users, e-commerce, especially cross-border e-commerce (CBEC), has developed rapidly in the context of the normalisation of the new crown epidemic. The spread of the epidemic and the preventive and control measures of various countries have had a serious impact on international trade activities. The existing supply chain and industrial chain have been obstructed. The game between China and the United States and the changes in the international political situation have made the international market economically volatile. However, the development of e-commerce has brought prosperity to China's CBEC business, which has become an important force in stabilising foreign trade and played an important role in stabilising global supply [1-3]. CBEC has become increasingly competitive, with international companies such as Amazon and Ebay, as well as domestic companies such as Jingdong and Tmall, entering the field [4-5]. In CBEC digital marketing, the application of cognitive decision-making (CDM) algorithms is of great value. Li et al. designed a hierarchical product classification and retrieval system suitable for CBEC shopping websites based on the analysis of image retrieval algorithms. The classification decision layer was used to determine the category of product images, and then the corresponding product image features were accurately retrieved. The recommendation results were highly accurate [6]. This algorithm is based on modeling the decision-making of individuals and exploring the theory and methods of how individuals make decisions under uncertainty. The study aims to explore the application of CDM algorithms in CBEC digital marketing to improve marketing effectiveness and economic efficiency. The study includes an introduction to CBEC digital marketing and CDM algorithms, a study of the pricing strategy problem in CBEC digital marketing, a test and analysis of the performance of the models and algorithms, as well as a summary and exposition of the study. The main contribution of the research is the application of CDM algorithms to CBEC digital marketing, which provides a new perspective in the field of international trade to improve marketing effectiveness and economic efficiency.

II. RELATED WORKS

CBEC and digital marketing have been hot topics in the economic field in recent years, and a large number of scholars have conducted research on them. Setkute et al. conducted research on digital marketing inapplicability in B2B small and medium-sized enterprises, and used qualitative research methods to investigate background factors of small B2B companies. They analyzed the obstacles that affect digital marketing practices, and the results showed that the “one size fits all” digital marketing mindset is not suitable for B2B small and medium-sized enterprises [7].

Yan et al. analyzed the impact of performance management systems on employee productivity in Chinese CBEC enterprises by using quantitative methods. Descriptive statistics were used as a data analysis tool to analyze the statistical data of 400 employees of the surveyed e-commerce enterprises using percentages and frequencies [8]. Li et al. conducted research on the impact of environmental regulation on CBEC exports of agricultural products. Based on the certification process of agricultural products under the influence of environmental regulation, they established an agricultural products output equation under the influence of environmental regulation, and analyzed how environmental regulation intensity affects the quality of agricultural products exported through CBEC and the competitiveness of agricultural products exporting enterprises [9]. CDM algorithms are based on modeling the decision-making process of individuals and exploring the theories and methods of how individuals make decisions under uncertainty. They are widely used in various fields. Ezaleden et al. used the NPSO algorithm to learn the importance of relationship types between concepts to complete a simulated recommendation system based on the highest ranking for dynamic learners. They studied the CLM and ECLM concept models, and the simulation results showed that ECLM performed better than other existing methods, with a mean reciprocity rate value of 0.780 [10].

Cao et al., to achieve intelligent recognition of surface Electromyography (sEMG) gesture signals in human-computer interaction, proposed a sEMG gesture recognition intelligent model combined with feature extraction, genetic algorithm (GA) and SVM model, and proposed adaptive mutation particle swarm optimization (AMPSO) algorithm to optimize SVM parameters. Research outcomes denoted that AMPSO-SVM could effectively recognize low-frequency sEMG signals of different gestures, with good performance [11]. Stojanovic Blaza et al. applied intelligent optimization algorithms to stability control of multi machine power systems. The stability of this method in system dynamic stability control has been demonstrated through comparative experiments of simulation results [12]. Jarndal et al. applied PSO and GA intelligence optimization algorithms to the efficient electrothermal large signal GaN HEMT modeling. Experiments have shown that the model also exhibited accurate simulation of nonlinear power amplifiers, with excellent computational speed and convergence [13]. Song et al. coupled the temperature and structure of the braking system using finite element method, and used GA parameter optimization and sensitivity analysis. Experiments have shown that this method can optimize the thermal stress and deformation problems of fan openings in high-temperature environments [14].

In summary, although researchers have conducted extensive research on various aspects of CBEC and digital marketing, research in digital marketing decision-making is still very scarce, which is highly related to CBEC profits. Using CDM algorithms to conduct due research on it has high potential application value.

III. Design of CBEC Digital Marketing Pricing Decision Model

With digital marketing as the support, the digital marketing manages the production, logistics, distribution, publicity and a series of enterprise marketing activities that run through the product cycle online and offline. The marketing channel tends to be flat, and the direct communication between enterprises and consumers will cost business operations. Product pricing is the basic point of digital marketing and the main factor for scholars to analyze enterprise marketing decisions. At present, the research on product pricing decisions focuses on the two-stage sales model of “pre-sale+sales”, and the research will also study the digital marketing pricing under this sales model.

A. Design of Product Pricing Model for the Diffusion Benefits of Cross-border e-commerce Digital Marketing

The research on product pricing focuses on the game and equilibrium between consumer behaviour and enterprises' pricing. In the two-stage sales model of “pre-sale+sales”, it is mainly the impact of enterprises' pricing diffusion on the demand of the later market. The pattern of this diffusion event is shown in Fig. 1.

TABLE I. VARIABLE SYMBOLS

Symbol	Meaning; implication; sense; import; meanings
c	The production cost for each product sold
p_1	Pre-sale price
p_2	Sales period price
N	Number of consumers receiving product information (i =1,2)
u	Utility values obtained per unit of product
θ	Strategic consumers in the pre-sale period of the proportion (0< θ <1)
Δ	Utility values obtained by product diffusion
Q	Order quantity of products
m	Regret utility
δ	The possibility that consumers will buy a product during the normal sales period
D_1	Product demand during the pre-sale period
D_2	Crystal production demand during the sales period
Π_1	Product profit during the pre-sale period
Π_2	Crystalline production profit during the sales period.
β_1	The effect coefficient of the innovation effect, ($\beta_1 > 0$)
β_2	The influence coefficient of the imitation effect, ($\beta_2 < 0$)
β_w	Integrated imitation effect coefficient
η	Scale effect coefficient
$F(.)$	The probability of consumers buying a product during the pre-sale period.
N_{D1}	The number of consumers attracted by the product diffusion effect
g_r	Out of stock cost of unit product due to out of stock
$k(.)$	The impact of crystal production diffusion on retailers' normal sales period demand
φ	The percentage of negative word of mouth

In the pre-sale stage of products, CBEC publishes information such as pre-sale and normal sales prices, and quantities on e-commerce platforms. To attract consumers to purchase, CBEC sets pre-sale prices lower than normal sales prices. However, due to the limitations of information dissemination on e-commerce platforms, it is not possible for all consumers to receive pre-sale related information. Only some well-informed consumers can successfully receive product pre-sale information, while consumers who have not received product pre-sale information are classified as message blocking consumers. Informed consumers judge the effectiveness of products based on product information, measure prices and demand, and make decisions. Consumers who purchase products publish their usage experiences on the internet, and over time, their word-of-mouth (WoM) accumulates or decreases, leading to the diffusion of product information. This diffusion effect affects the number of consumers attracted during the normal sales phase [15-16]. The diffusion model of Base is shown in Fig. 2.

The process of converting potential purchasing groups is influenced by two aspects: innovation and imitation effects. Innovation effect mainly refers to the influence of external factors such as advertising, marketing, and price on shopping behavior, while imitation effect is influenced by WoM to cause potential groups to follow the buying behavior. When product diffusion events occur, CBEC enterprises make decisions on product supply based on factors such as reputation and the number of pre-sale consumers in the product diffusion effect, to minimize cross-border logistics storage costs and achieve max profits. Because the product diffusion effect will affect the actual demand in the pre-sale+sales period, the optimal pricing decisions for enterprises to obtain max profits are divided into pre-sale and sales price decisions. The variable symbols used in the decision model are displayed in Table I.

Under the diffusion effect, the optimal selling price decision of a product can be expressed as Eq. (1).

$$p_2^* = \begin{cases} \dfrac{\lambda + \theta\lambda\bar{F}(p_2) + N_{D1}}{\theta\lambda f(p_2)}, & N_{D1} \le Q - 2\lambda \\ \dfrac{Q - (1-\theta)\lambda - \theta\lambda F(p_2)}{\theta\lambda f(p_2)}, & N_{D1} > Q - 2\lambda \end{cases} \tag{1}$$

In Eq. (1), $\bar{F}(p_2) = 1 - F(p_2)$ denotes the proportion of consumers who purchase products during the sales period. It should be noted that there is a situation where $\min(Q - (1-\theta)\lambda - \theta\lambda F(p_2), \theta\lambda\bar{F}(p_2) + \lambda + N_{D1})$ is taken. When supply exceeds demand, i.e. $N_{D1} \le Q - 2\lambda$, the sales profit of CBEC is as expressed in Eq. (2).

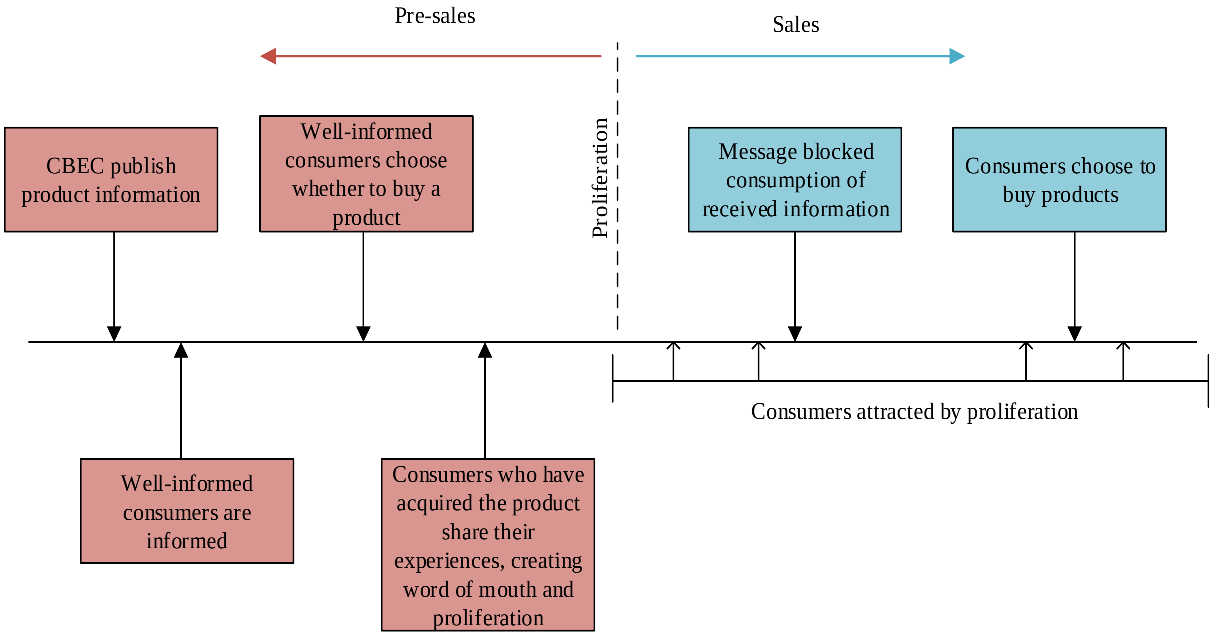
$$\begin{aligned} E(\Pi_2) = {} & p_2(\lambda + \theta\lambda\bar{F}(p_2) + N_{D1}) \\ & -c(Q - (1-\theta)\lambda - \theta\lambda f(p_2)) \end{aligned} \tag{2}$$

If the second-order derivative is less than 0, then the profit function has an optimal sales period price. When demand exceeds supply, there is $N_{D1} > Q - 2\lambda$. Since $\bar{F}(p_2) = 1 - F(p_2)$ is a decreasing function of p_2, the optimal sales period price relationship is shown in Eq. (3).

$$\begin{aligned} E(\Pi_2') = {} & (p_2 - c)(Q - (1-\theta)\lambda - \theta\lambda F(p_2)) \\ & -g_r(2\lambda + N_{D1} - Q) \end{aligned} \tag{3}$$

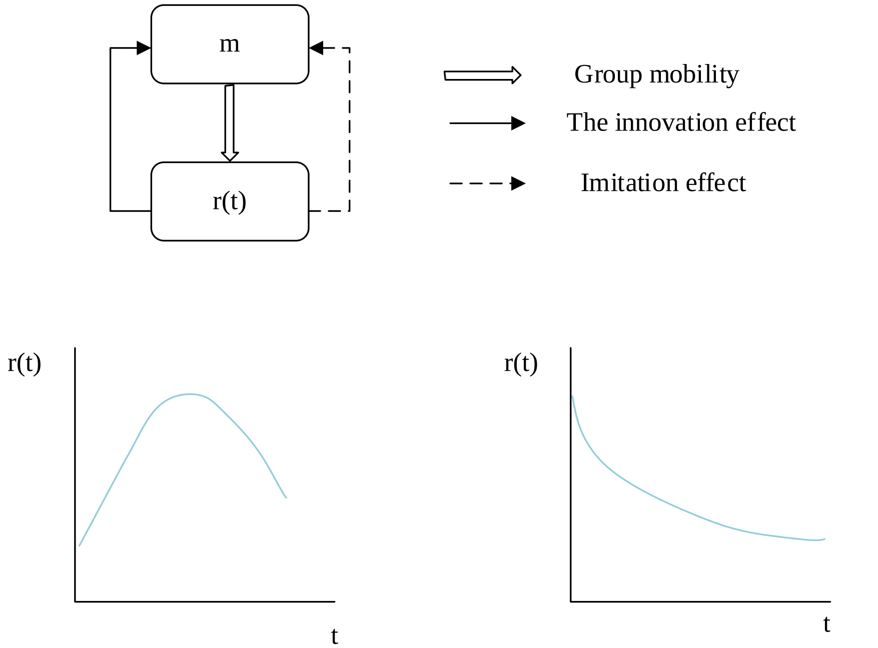
From Eq. (3), it is easy to obtain that its second-order derivative is less than 0, and the function has the optimal sales period price. From the above analysis, the product price decision during the sales period of CBEC mainly depends on the impact of diffusion effects on consumer demand. When the impact is small, there is still surplus in the product, and the sales price will increase with the increase of diffusion. On the contrary, if the product supply is insufficient, the setting of sales prices can temporarily ignore the diffusion effect of the product during the pre-sale period. The expression for the optimal pre-sale price of a product under the diffusion effect is shown in Eq. (4).

$$\begin{aligned} p_1^* &= u - (u - p_2^* + \Delta)\delta + m(1-\delta) \\ &= (1-\delta)(u+m) + (p_2^* - \Delta) \end{aligned} \tag{4}$$



Pre-sales
Sales
CBEC publish product information
Well-informed consumers choose whether to buy a product
Proliferation
Message blocked consumption of received information
Consumers choose to buy products
Consumers attracted by proliferation
Well-informed consumers are informed
Consumers who have acquired the product share their experiences, creating word of mouth and proliferation

Fig. 1. Event diffusion model.



(a) The imitation factor is greater than the innovation factor

(b) The innovation factor is greater than the imitation factor

Fig. 2. Base diffusion model.

The pre-sale pricing of CBEC is influenced by the sales period price. As the diffusion effect increases on consumer demand, when supply exceeds demand, the sales price increases accordingly. The pre-sale price is higher, but when supply is less than demand, it has little impact on the pre-sale price. The scale effect of WoM refers to the impact of WoM generated by the sale of a product on the purchasing intention of potential consumers, increasing (or decreasing) the inflow of intended consumers, and the potential consumers who form the scale effect of WoM are ηN_2. Consumers who purchase products will be divided into positive and negative WoM groups, which is known as the WoM ratio effect. A product pricing model that combines the scale and proportion of WoM to form a dual WoM diffusion effect. The impact of product diffusion on the normal sales period demand of CBEC in the model is shown in Eq. (5).

$$\begin{aligned} k(D_1) = \beta_1 + \beta_2 + \frac{\varphi((1-\theta)N_1 + \theta\lambda F(p_2))}{\eta N_2} \\ -\beta_2 - \frac{\varphi((1-\varphi)(1-\theta)N_1 + \theta N_1 F(p_2))}{\eta N_2} \end{aligned} \tag{5}$$

In Eq. (5), β_1 and β_2 denote the coefficients of innovation and imitation effects, respectively. The coefficient of innovation effect refers to the coefficient of external factors other than WoM that affect consumer shopping behavior. The coefficient of imitation effect stands for the coefficient of shopping behavior affected by WoM transmission, which is divided into positive WoM imitation effect coefficient β_{2+} and negative WoM imitation effect coefficient β_{2-}. The comprehensive imitation effect coefficient of the two is denoted in Eq. (6).

$$\beta_w = (1-\varphi)\beta_{2+} - \varphi\beta_{2-} \tag{6}$$

Under the dual WoM diffusion effect, the impact of WoM diffusion on customer demand during CBEC sales is shown in Eq. (7).

$$k(D_1) = \beta_1 + \beta_w \frac{(1-\theta+\theta F(p_2))}{\eta} \tag{7}$$

The dual effects of WoM and diffusion effects jointly constitute the consideration factors for CBEC pricing decisions, considering multiple supply and demand relationships. Under the influence of the dual WoM diffusion effect, the sales price can be calculated as expressed in Eq. (8).

$$p_2^{**} = \begin{cases} \dfrac{(1+\theta+\beta_1) + \dfrac{\beta_w}{\eta}(1-\theta)(1+F(p_2)) + c\theta f(p_2)}{\theta f(p_2) - \dfrac{\beta_w}{\eta}\theta f(p_2)}, \\ \dfrac{Q}{\lambda} - 2 \geq \beta_1 + \dfrac{\beta_w}{\eta}(1-\theta+\theta F(p_2)) \\ \quad \dfrac{Q-(1-\theta)\lambda - \theta\lambda F(p_2)}{\theta\lambda f(p_2)} + c + g_r(1-\dfrac{\beta_w}{\eta}), \\ \quad \dfrac{Q}{\lambda} - 2 < \beta_1 + \dfrac{\beta_w}{\eta}(1-\theta+\theta F(p_2)) \end{cases} \tag{8}$$

According to Eq. (8), when supply exceeds demand, p_2^{**} is positively correlated with β_1, and is influenced by β_w and η. That is, the higher the external influence of WoM on consumers, the greater the diffusion effect. At this point, a high pricing decision can be chosen. When supply and demand are not met, the sales price is highly correlated with the existing reputation of the product. Therefore, the premise for the optimal pricing of CBEC is as Eq. (9).

$$p > c + g_r(1 - \frac{\beta_w}{\eta}) \tag{9}$$

Under the dual WoM diffusion effect, the pre-sale price of the product is set as shown in Eq. (10).

$$p_1^{**} = u - (u - p_2^{**} + \Delta)\delta + m(1-\delta) \tag{10}$$

In summary, the pricing of products during the pre-sale period of CBEC is influenced by the dual WoM diffusion effect. When the supply is sufficient, the increase in innovation effect has a significant impact on potential consumers, and the pre-sale price is higher. The product diffusion effect is influenced by comprehensive WoM, which also affects product pricing. When supply does not meet demand, pricing is only related to WoM.

B. *CD-ABC Algorithm Design Based on Security Domain Search Strategy and Information Diffusion Statistical Model*

The products and markets in CBEC activities are relatively complex, requiring a deep understanding of consumer behavior and preferences to make better decisions. There is a high demand for the global optimization ability of CDM algorithms. Therefore, an artificial bee colony (ABC) algorithm with strong global optimization ability, high solving accuracy, and few control parameters is selected to solve the pricing decision problem. The ABC algorithm is derived from human observation of the information exchange process during bee foraging. Karaboga proposed the ABC algorithm based on this process, dividing individuals searching for the target space into three roles: picking bees, observing bees, and reconnaissance bees. These three roles switch to each other as needed. Picking bees search for new foraging locations based on known information and share it with observing bees. Reconnaissance bees are responsible for randomly searching for new honey sources near the hive. In the ABC algorithm, the dimension of the solution to the optimization problem is D dimension, and one solution of the problem is the coordinate corresponding to a honey. The amount of honey is the fitness of the solution, and the number of honey and bees collected or observed is equal, set as SN. The process of searching for the next honey position is as shown in Eq. (11) when the bees reach one honey position [17-20].

$$x_{id} = x_{id} + \varphi_{id}(x_{id} - x_{kd}) \tag{11}$$

In Eq. (11), $i = 1, 2, \cdots, SN$, $d = 1, 2, \cdots, D$, and φ_{id} are random numbers of [-1.1], and $k \neq i$. After picking bees to find new honey, it compares the new honey position with the original honey position, and retains the position with the highest amount of honey. If the new honey quantity is lower than the old honey, the information is transmitted to the observing bee [21]. It observes the bees and calculates the probability of the next honey occurrence position based on Eq. (12).

$$p_i = \frac{fit_i}{\sum_{j=1}^{SN} fit_j} \tag{12}$$

Picking and observing bees will traverse the honey in the current domain. If the fitness value of the honey does not improve before reaching the limited number of iterations, the honey will be discarded. At the same time, the bees in this position will be transformed into reconnaissance bees, and the fit_i in the equation represents the fitness value of the solution. After the process is completed, the reconnaissance bee will search for the next honey in the solution space, as shown in Eq. (13).

$$x_{id} = x_d^{\min} + r(x_d^{\max} - x_d^{\min}) \tag{13}$$

In Eq. (13), $x_d^{\max}$ and $x_d^{\min}$ denote the upper and lower limits of the D-dimensional solution space, and r means a random number in the interval [0,1]. The reconnaissance bee searches in the solution space by randomly selecting a number in the D-dimensional solution space to obtain a location. The ABC algorithm flow is shown in Fig. 3.

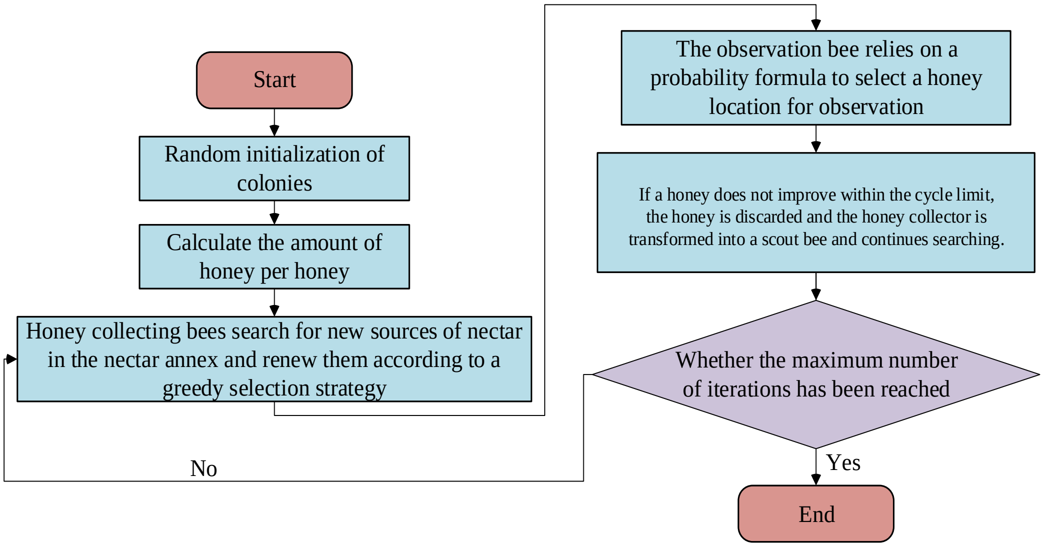
The ABC algorithm starts by randomly initializing the bee colony, calculating the amount of honey at the location where the bees are collected, and then the bees start searching for the next honey to update the honey location. At the same time, the bees select the honey location for observation. To ensure that bees are not attacked (interfered) by other groups when searching for new honey sources, a security domain search strategy is studied, as shown in Eq. (14).

$$v_{id} = x_{id} + r(x_{id} - x_{kd}) + r(SP_d - x_{id}) \tag{14}$$

In Eq. (14), SP_d indicates the safe location of the d honey source. Obviously, v_{id} is randomly guided from multiple directions and approaches the safe location. The safe location in the group is expressed in Fig. 4.

In a bee colony, the area where the proportion of bees to the population is greater than μ is considered a safe area. The triangle in the figure represents bees, and the circle centered around the safe position C_d is considered a safe area. The maximum safe distance of the $C_j = SP = (SP_1, SP_2, \cdots, SP_D)$ safe area is the radius MSD of SP. In the observing bee search stage, it conducts probability selection according to the honey source information transmitted by the picking bee to find the optimal location for mining. However, this method is uncertain and blind, and cannot ensure that good honey sources are more attractive to observing bees than poor honey sources. The statistical model of information diffusion is introduced to adjust the selection strategy of the picking bee, as shown in Eq. (15).

$$p(x_i) = \frac{1}{(N-1)\sqrt{2\pi}} e^{\frac{-(fit(x_i) - fit_{\max})^2}{2h^2}} \tag{15}$$



Start
Random initialization of colonies
Calculate the amount of honey per honey
Honey collecting bees search for new sources of nectar in the nectar annex and renew them according to a greedy selection strategy
The observation bee relies on a probability formula to select a honey location for observation
If a honey does not improve within the cycle limit, the honey is discarded and the honey collector is transformed into a scout bee and continues searching.
Whether the maximum number of iterations has been reached
No
Yes
End

Fig. 3. ABC algorithm flowchart.

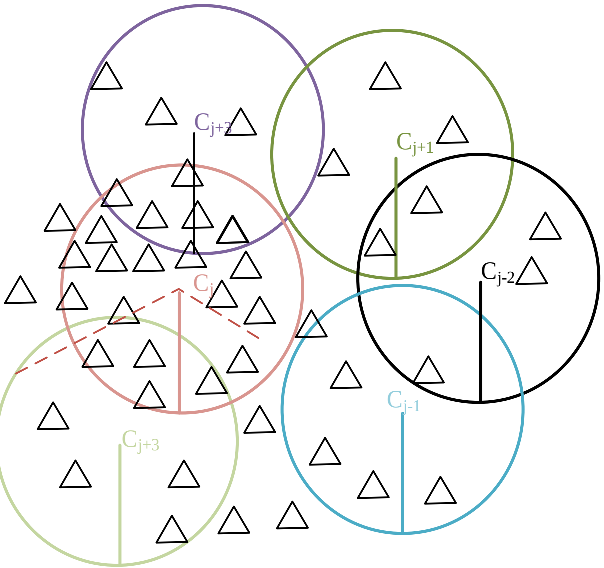


Fig. 4. Safe location in a group.

In Eq. (15), $p(x_i)$ refers to the probability of observing bees selecting honey source i, and h stands for the information diffusion coefficient.

IV. Performance Test of CBEC Digital Marketing Pricing Decision Model

Based on research on CBEC products, a clothing product of a certain CBEC enterprise was selected as an example for model performance testing. First, the relationship between innovation effect coefficient and pre-sale pricing under different WoM propagation of product pricing model, and the relationship between comprehensive imitation coefficient and CBEC pricing under different word of mouth scale were analyzed. The impact of product diffusion effect and comprehensive imitation effect on CBEC profits was investigated. The results are shown in Fig. 5.

As shown in Fig. 5, Fig. 5(a) and Fig. 5(b) show the impact of product diffusion effect and comprehensive imitation coefficient on CBEC profits, respectively. Fig. 5(a) shows that the impact of WoM communication has increased, and the profits obtained by CBEC have increased. At the same time, as the product diffusion effect increased, the profits obtained by CBEC continued to increase. Observing the diffusion effect coefficient of products, as the effect coefficient increased, supply exceeded demand, sales decision prices increased, and pre-sale prices were higher. At this time, CBEC profits increased. When supply did not meet demand, the increase in diffusion effect only increased the gap in goods, leading to a decrease in CBEC profits. Fig. 5(b) shows the impact of WoM scale effect on CBEC profits under the dual WoM diffusion effect. As the WoM scale coefficient increased, the amount of potential consumer conversions increased, and the optimal profits obtained by CBEC increased. As the comprehensive imitation coefficient increased, the diffusion effect of products increased and CBEC profits increased due to the influence of WoM scale effect. The rationality of the model was verified. Based on this, the CD-ABC algorithm's wide area search capability and resource utilization capability were tested to verify the excellent performance of the algorithm. The C-ABC algorithm (secure neighborhood search ABC algorithm), D-ABC algorithm (information diffusion ABC algorithm) and ABC algorithm were used as comparison objects. Twenty tests were conducted on 22 benchmark functions (D=30). The population setting was 30, $\lim it = 200$, and the maximum number of iterations was 100000. The test results are shown in Fig. 6.

By comparing Fig. 6 as a whole, the D-ABC, C-ABC, and CD-ABC algorithms generally outperformed the ABC algorithm in most functions. In most functions, the convergence degree of the D-ABC and C-ABC algorithms was better than that of ABC, indicating that compared to traditional ABC algorithms, the two improved methods proposed in the study had good performance optimization. CD-ABC algorithm had better performance than C-ABC and D-ABC algorithms in most functions, and its rate of convergence was significantly faster than D-ABC and C-ABC, indicating the effectiveness of the improved CD-ABC algorithm. To further illustrate the advantages of information diffusion probability over ABC probability, a test was conducted on the impact of bees on the honey source search probability for the same initial population. The results are shown in Fig. 7.

Fig. 7. Individual evolution frequency test.

As shown in Fig. 7, representative unimodal functions SumSquare, uncertainty function Roserock, and multimodal function Ackley were selected for experiments to test the ABC algorithm's concept. Comparing Fig. 7 as a whole, there was no significant difference in the individual evolution frequency of the ABC algorithm, indicating that it was unable to detect the superiority of honey sources. However, in D-ABC, some individuals exhibited higher evolution frequencies, indicating that the information diffusion probability could detect the superiority of honey sources and convey it to the observation bees, so that the excellent and beautiful honey sources received more attention. This indicated that the information diffusion probability could detect the value of hidden honey sources in ABC, improving ABC's deep mining ability. Based on the above test results, the CD-ABC algorithm was compared and tested with other ABC variant algorithms with excellent improvement effects. The parameter settings and algorithm are displayed in Table II.

to conduct a fair comparison test on the above improved algorithms, the same parameter settings were used for the experiment. The results of the algorithm rate of convergence comparison test are shown in Fig. 8.

When D is set to 30, the CD-ABC algorithm outperformed GABC, MABC, qABC, and dABC in 14 functions. Fig. 8 shows the convergence curves of the above algorithms on some functions. CD-ABC showed high efficiency and Rate of convergence in most functions. Based on the above verification of the efficient performance of CD-ABC, its performance in solving practical pricing problems was tested. The product pricing model with dual WoM diffusion effect proposed in the study was used for solution analysis, and compared with particle swarm optimization (PSO), whale optimization algorithm (WOA), GA, ABC and WOA-GA algorithms. The experimental object was the pricing of clothing products in CBEC, as shown in Fig. 9.

TABLE II. ALGORITHM COMPARISON TEST PARAMETER SETTINGS

Improved algorithms	Parameter settings		
	N	limit	C/P/r/u
GABC	50	200	1.5
MABC	50	200	0.7
dABC	50	200	/
qABC	50	200	1.5
CD-ABC	50	200	0.3

(a)Elliptic

Fig. 8. Comparison test results of algorithm rate of convergence.

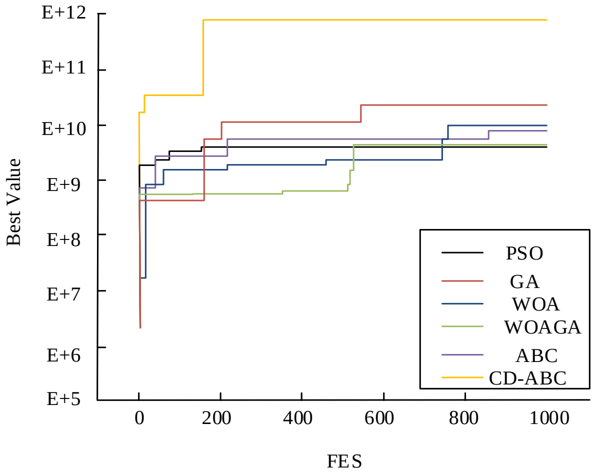

Fig. 9. Iterative curves for solving clothing pricing problems using different algorithms.

Fig. 9 shows the iteration curve of each algorithm to solve the CBEC clothing pricing problem under the dual WoM diffusion effect model. The CD-ABC algorithm obtained the optimal pricing decision, and its rate of convergence was fast. After 200 iterations, the convergence was completed, and the number of iterations was far lower than the common decision solving algorithm. And the pricing optimization decision obtained by the algorithm resulted in CBEC gained much higher profits than other algorithms, ultimately benefiting 7.95e+11. The comprehensive imitation effect calculated by the CD-ABC algorithm in 200 iterations was -0.14, the reputation scale effect was 1.34, the pre-sale price was finally set at 347.49, and the sales price was 641.393, which indicated that the pricing obtained by the CD-ABC algorithm was closer to life and could provide a reference for enterprises to make pricing decisions. To demonstrate the applicability of the CD-ABC algorithm in solving pricing decision-making problems in various application scenarios, a CBEC enterprise's electronic product was selected as a case for comparative testing. The test results are shown in Fig. 10.

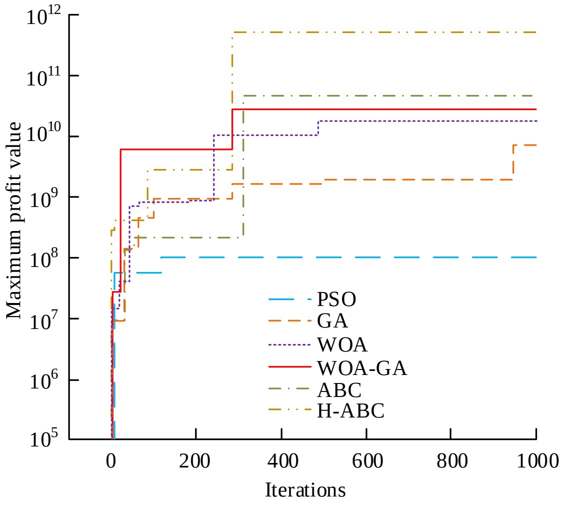

Fig. 10. Iterative curve for solving the pricing problem of cross border e-commerce electronic products.

Fig. 10 shows the iteration curve of each algorithm to solve the pricing problem of CBEC electronic products under the dual WoM diffusion product pricing model. The CD-ABC algorithm obtained the maximum profit. After 230 iterations, the optimal profit decision reached 5.31e+11, which was far higher than the results of other algorithms. However, its rate of convergence was worse than that of GA, and its global optimization ability was weak. However, overall, it still had high performance in solving CBEC pricing problems, which could provide a certain basis for CBEC pricing decisions.

V. Conclusion

To optimize CBEC marketing strategies and improve competitiveness, the research focused on the pricing throughout the whole e-commerce marketing, built a dual WoM diffusion product pricing model suitable for CBEC product pricing, and optimized the traditional ABC algorithm to enable it to have excellent performance in solving the dual WoM diffusion product pricing model strategy. The performance test outcomes of the model indicated that the impact of WoM communication increased, and the profits obtained by CBEC increased. At the same time, as the product diffusion effect increased, the profits obtained by CBEC continued to increase. Under the dual WoM diffusion effect, the impact of WoM scale effect on CBEC profits increased with the coefficient of WoM scale, the number of potential consumer conversions, and the optimal profits obtained by CBEC. Using the C-ABC, D-ABC and ABC algorithms as comparison objects, the test results of 22 benchmark functions showed that the D-ABC, C-ABC and CD-ABC algorithms generally outperformed ABC algorithm in most functions, and the convergence degree of D-ABC and C-ABC algorithms was better than ABC algorithm. This is because the C-ABC and D-ABC algorithms introduced security-specific domain search strategies and information diffusion probabilistic model optimisation mechanisms that are more suitable for dealing with complex non-linear problems in solving the dual WoM diffusion product pricing problem. In particular, the CD-ABC algorithm, by combining the advantages of C-ABC and D-ABC, was able to adjust the search strategy more quickly, avoid premature convergence, and maintain a balance between exploration and exploitation. This allowed the algorithm to find solutions closer to the global optimum even when faced with the interaction of multiple factors in a changing market environment. For the same initial population, the test results of observing the influence of bees on the honey source search probability showed that some individuals in D-ABC had a high evolutionary frequency. When D was set to 30, the CD-ABC algorithm performed better than GABC, MABC, qABC, and dABC in 14 functions. In most functions, the CD-ABC showed efficient solution efficiency and rate of convergence. This is due to the efficient evolutionary strategy of the CD-ABC algorithm in dealing with the colony's search behaviour for nectar sources. In the D-ABC algorithm, individuals exhibited different evolutionary frequencies, and this differentiated evolutionary strategy provided more diverse search paths for the probabilistic model of information diffusion. When the evolution frequency parameter was set to 30, the CD-ABC algorithm was able to adjust its search strategy more accurately, which ensured excellent performance on various test functions, especially in comparison with other state-of-the-art algorithms such as GABC and MABC. This diversified search path not only accelerated the convergence speed but also improved the solution efficiency, enabling the CD-ABC algorithm to efficiently approximate the global optimal solution in complex optimisation problems, especially when simulating market decisions in real-world dynamic environments. The actual strategy solution findings showed that in the CBEC clothing pricing problem, the CD-ABC algorithm converged after 200 iterations, with lower iterations than common decision solving algorithms and much higher benefits than common algorithms, reaching 7.95e+11. The comprehensive imitation effect was -0.14, the WoM scale effect was 1.34, the pre-sale price was ultimately set at 347.49, and the sales price was 641.393. When solving the pricing problem of CBEC electronic products, after 230 iterations to reach convergence, the optimal profit decision obtained reached 5.31e+11, which was much higher than the results obtained by other algorithms. The research proposed a dual WoM diffusion product pricing model and the CD-ABC algorithm, which had better computational performance compared to common models in CBEC pricing decision-making problems. However, their lack of consideration for the background of the interaction of multiple factors in practical problems is also an area for further research to improve.

Planning and Expansion of the Transmission Network in the Presence of Wind Power Plants

Hui Sun*
Department of Automotive Engineering, Hebei Vocational University of Industry and Technology, Hebei 050091, China

***Abstract*—The proliferation of renewable energy sources, particularly wind farms, is rapidly gaining momentum owing to their numerous benefits. Consequently, it is imperative to account for the impact of wind farms on transmission expansion planning (TEP), which is a crucial aspect of power system planning. This article presents a multi-objective optimization model that utilizes DC load flow to address the TEP challenge while also incorporating wind farm uncertainties into the model. The present study aims to optimize the expansion and planning of the TEP in the power system by considering investment and maintenance costs as objective functions. To achieve this, a multi-objective approach utilizing the shuffled frog leaping algorithm (SFLA) is proposed and implemented. The proposed objectives are simulated on the RTS-IEEE 24-bus test network. The results obtained from the proposed algorithm are compared with those of the Genetic Algorithm (GA) to assess and validate the proposed approach.**

Keywords*—Wind farms; Transmission Expansion Planning (TEP); multi-objective optimization model; Shuffled Frog Leaping Algorithm (SFLA)

NOMENCLATURE

Abbreviations	
TEP	Transmission expansion planning
SFLA	Shuffled frog leaping algorithm
Parameters and variables	
Cij	The cost of new lines among buses i and j
Nij	The number of new lines among buses i and j
N0ij	The initial lines between buses i and j
lij	The length of new lines between buses i and j
CM, CO	The maintenance and operation costs
S	Intersection matrix for buses
f	Power flow vector
r	Resistance of lines
gij	Vector of the power generation
d	Load demand vector
fij	Power flow between lines in buses i and j
θi	Voltage angle in bus i

I. INTRODUCTION

A. Aims and Related Research

During the past few decades, problems have existed in the electric power generation sector in a traditional system, such as high production costs, environmental effects, high losses and low reliability [1]**.** Hence, distributed generation systems have been used in such systems, which are installed in the vicinity of consumption centers and have lower power, loss, and cost, as well as more reliability than traditional forms of electric energy generation. Wind energy is one of the energy sources that have received a lot of attention [2]. Investigating the effects of wind energy resources on power networks from various aspects, such as uncertainty and uncontrollability of generation power compared to conventional sources of energy production, has been studied as one of the important challenges in this field [3]. In addition to these cases, the distance from demand centers and the strong dependence of wind turbine production capacity on wind speed should be added as the biggest obstacles to the use of this energy [4]. The objectives of transmission expansion planning (TEP) in the power system are twofold: to plan power systems that ensure a dependable energy supply to customers and to identify optimal locations and methods for investing in new transmission lines that will facilitate reliable energy supply to customers. Additionally, TEP involves the operation of load growth based on demand forecasting [5]. Hence, to implement of reliable energy supply the increase the generation share of wind farms compared to the total generation of electric energy in the traditional systems [6], [7], it is necessary to have a reliable supply of energy in order to maintain customer satisfaction in the power system planning with regard to uncertainties [8], [9].

The research of the power systems considering different areas like power plants, transmission and distribution grids are assessed in this subsection. In research [10], energy optimization with TEP considering power generation of renewable energies such as solar power and wind turbines is proposed. Authors in study [11] installed and sized the solar panels and storage systems in the transmission lines with consideration of the power loss reduction reported. The operation of the generation units in the power plants by using the unit commitment approach is proposed in [12]. In (Moreira et al., 2017), the economic dispatch approach for energy scheduling in the power plants is used. The planning and operation modeling in the power grids with maximizing reliability is studied in [13]. The article in [14] presents an economic approach to power flow analysis, taking into account factors such as fuel costs in power plants and the operation of units during peak demand. Meanwhile, [15] models power flow with a focus on the cost of transmission lines and incorporates the use of Flexible AC Transmission Systems (FACTS) to enhance voltage index. The modeling economic of the microgrids for TEP and power grids for covering the uncertainty of renewable energy is studied in [16].

B. Contributions

This paper presents a multi-objective optimization model for TEP in the power system, taking into account the operation of wind farms. The objective functions based on investment and maintenance costs are modeled for implementing TEP in the power systems. The shuffled frog leaping algorithm (SFLA) is proposed for solving the optimization approach. The expansion of the wind farms in the TEP is modeled based uncertainty approach. The DC power flow is considered for TEP with wind farm operations. Hence, the contributions of this paper can be summarized as follows:

1) Proposing multi-objective modeling for TEP in the power system considering wind farm participation.

2) Implementing TEP by investment and maintenance costs.

3) Utilizing shuffled frog leaping algorithm (SFLA) for solving problems.

4) Modeling wind farm based on uncertainty approach.

II. TEP FORMULATION

The inability to accurately predict the load due to the uncertainty of power generation, such as wind energy, leads to the introduction of new technologies in electrical energy generation. Hence, wind farms, due to the randomness of the generation power in their generation, cannot be ignored. Therefore, the modeling of these uncertainties in the planning of power systems will lead to the creation of stronger planning that can meet different conditions [17]. It should be noted that the uncertainties of the network structure make the decision-making process difficult. In traditional planning, the main goal is to minimize investment costs [18]. However, in modern planning, several different goals are optimized simultaneously, and traditional methods are not able to provide acceptable solutions [19].

A. Wind power modeling

The amount of power produced by wind farms is contingent upon the speed of the wind. As a result, the power output of a wind turbine differs significantly from that of a conventional energy generation unit [20]. Hence, modeling wind power is formulated by the "power-speed" curve in Fig. 1 and other parameters of the turbine. Also, modeling wind turbines is formulated by Eq. (1) [20].

$$P_{WT}(v)=\begin{cases} 0 & if \quad v \le V_{cin} \\ P_{N,WT}\times\left(\dfrac{v-V_{cin}}{V_r-V_{cin}}\right) & if \quad V_{cin}\le v\le V_r \\ P_{N,WT} & if \quad V_r\le v\le V_{co} \\ 0 & if \quad V_{co}\le v \end{cases} \tag{1}$$

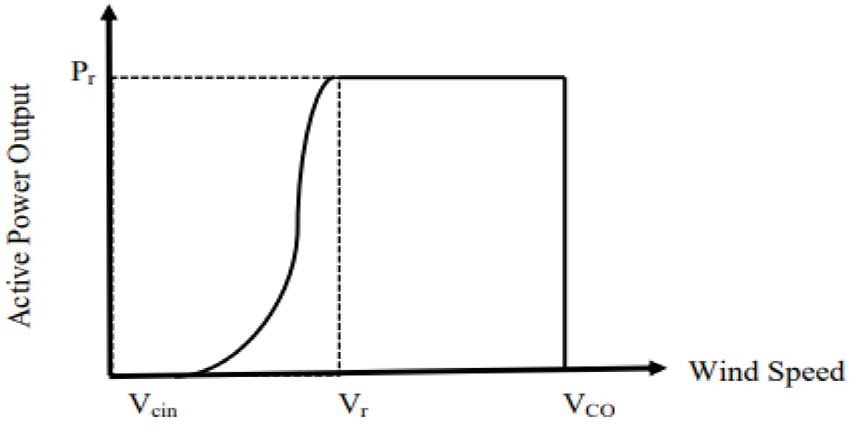

Fig. 1. Wind turbine "power-speed" characteristic.

B. Objective functions formulation

The objective functions, such as investment and maintenance costs, are minimized to TEP in this section. The modeling of the objectives is as follows:

1) Cost of investment: The modeling investment considering constraints for this objective is as follows:

$$\min f_{IC}=\sum_{i,j=1}^{n} C_{ij}\times l_{ij}\times N_{ij} \tag{2}$$

Subject to:

$$Sf+g=d \tag{3}$$

$$f_{ij}-r(N_{ij}^{0}+N_{ij})(\theta_i-\theta_j)=0 \qquad \forall i,j,n \tag{4}$$

$$\left|f_{ij}\right|\le(N_{ij}^{0}+N_{ij})f_{ij}^{\max} \qquad \forall i,j,n \tag{5}$$

$$0\le N_{ij}\le N_{ij}^{\max} \qquad \forall i,j,n \tag{6}$$

$$0\le g_{ij}\le g_{ij}^{\max} \qquad \forall i,j,n \tag{7}$$

Where constraints in Eq. (3) and Eq. (4) are power flow balance and power flow in branches *i* and *j*, respectively, the constraints in Eq. (5) and Eq. (6) limit the power flow and limit of the number lines *i* and *j*, respectively. Constraint in Eq. (7) is active power generation by units in buses *i* and *j*.

2) Maintenance and operation costs: The second objective is to minimize the maintenance and operation costs of the TEP:

$$\min f_2 = \sum_{i,j=1}^{n} C_M N_{ij} + C_O N_{ij} \tag{8}$$

In objective function in Eq. (8) first and second terms are maintenance and operation costs, respectively.

III. Optimization Method

This study uses SFLA as an optimization method to solve the objective functions. SFLA is modeled based on the population of frog groups or memeplexes to find food. This method addresses the creation of frog populations as part of local and global strategies and objective functional changes based on the replacement of existing frogs. SFLA can be done by following these steps [21], [22]:

1) Population generation: Randomly generates a population "p", considering each frog's position and search space.

2) Creation of the memeplexes: The frogs must be evenly distributed in the memeplexes, taking into account their fitness function, where the population of frogs as m memeplexes with n frogs is p = [m × n].

3) Update frog location: Frogs in memeplexes are updated based on their best and worst locations from local search. Then the worst frog (Ωw) is updated with the best frog (Ωb) in each memeplex and the whole memeplex with the best frog (Ωgb):

$$\Omega_w^{new} = \Omega_w + rand \times (\Omega_b - \Omega_w) \tag{9}$$

$$\Omega_w^{new} = \Omega_w + rand \times (\Omega_{gb} - \Omega_w) \tag{10}$$

Here, 0 ≤rand ≤1 is a random number. With (9), the worst frog Ω_w can be upgraded by placing the best frog Ω_b. In this step, if Ω_w^{new} is better than Ωw, Ωw is replaced by Ω_w^{new}; otherwise, Ωw can be replaced with Eq. (10) by the best frog in the Ω_{gb} memeplex. To find the optimal solution of SFLA, this process is performed for all iterations and memeplexes. The process of the SFLA is presented by Algorithm 1.

Algorithm 1: Process of the SFLA.

Algorithm 1 pseudocode of the SFLA

```
1. Start
2. Create population of P frogs, randomly;
    3. Calculate fitness function of the i frog;
    4. Sort the frogs based on their fitness;
    5. Distribution of the frogs by m memeplexe and n frog ($P = m×n$);
       In each memeplex;
      Determine $X_B$ and $X_W$;
          Improve the $X_W$ position using Eqs. (11) and (12);
      Repeat for number of iterations;
      Stopping critical satisfied?
      Yes
      End
      Else=go to step 2
```

taSince objectives are optimized in this study simultaneously. The frontier solutions will be obtained. The energy operator must determine the optimal solution for objectives in the frontier solutions as a decision maker. Hence, the max-min fuzzy method is proposed for a determined optimal solution as follows [23], [24]:

$$\Gamma\left(f_z(\vartheta)\right) = \begin{cases} 0 & otherwise \\ \dfrac{f_z^{\max} - f_z(\vartheta)}{f_z^{\max} - f_z^{\min}} & f_z^{\min} \le f_z(\vartheta) \le f_z^{\max} \\ 1 & f_z^{\min} \ge f_z(\vartheta) \end{cases} \tag{11}$$

$$\max\left\{\min \Gamma\left(f_z(\vartheta)\right)\right\} \tag{12}$$

Here, *Γ (f* —

Here, *Γ (f_z (ϑ))* and *$f_z(\vartheta)$* are membership functions or solutions in *zth* objective and value of objective at ϑth frontier solutions, respectively. Also, to determine the optimal solution in frontier solutions maximum and minimum procedure is presented in Eq. (11). In Eq. (12), a high rate of minimum solution is introduced as the optimal solution.

IV. Numerical Simulation

In this section, TEP studies have been carried out using the proposed algorithm in the MATLAB software environment in a system with a 4 GHz CPU and 6 GB RAM using DC load flow. The RTS-IEEE 24-bus test network is used for implementing TEP considering wind farm installation. In Fig. 2, the RTS-IEEE 24-bus test network with wind farms is shown. The wind speed based on average value is shown in Fig. 3. As should be mentioned, the TEP time study is considered for ten years. The average wind speed is considered in the simulation, and data from the wind farm is presented in Table I. The two wind farms have the same data. Also, load demand data is listed in Table II. Information on the generator units and test network are extracted from study [25]–[27].

TABLE I. Wind Farm Data

Parameters	Value
PN, WT	10 MW

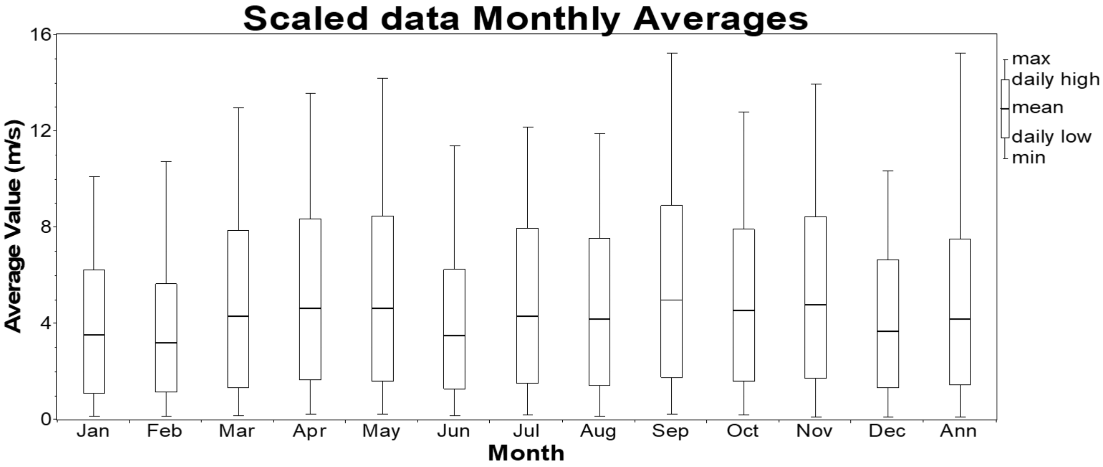

Fig. 3. Wind speed in test network.

A. *Results Analyse*

To examine the impact of various conditions on the outcomes of resolving the TEP issue utilizing the suggested algorithm, the ensuing scenarios were analyzed and executed on the 24-bus RTS-IEEE test system. The scenarios are as follows:

Scenario A) Implementing TEP without wind farms.

Scenario B) Implementing TEP with wind farms.

Also, in this study, the proposed optimization approach is compared with the Genetic Algorithm (GA) for verification and confirmation of the SFLA. In Fig. 4 and 5, frontier solutions of the objective functions for scenarios A and B by comparing SFLA with GA are shown, respectively. The obtained optimal solution by fuzzy method for the first and second objectives by SFLA in scenario A are equal to

$11996.3 and $768.6, respectively. The optimal solution generated by GA yields a first objective amount of $12453.3 and a second objective amount of $796.4. These results of the SFLA represented more convergence of the optimization for TEP in scenario A than GA. The value of the optimal solutions in scenario A, by the fuzzy method for SFLA and GA, is equal to 0.46 and 0.43, respectively.

On the other side, with implementing TEP with wind farms, the results of the objective functions in Fig. 5 are more optimizer than scenario. In scenario B, the SFLA algorithm has yielded optimal solutions of $11153.4 and $750.6 for the first and second objective functions, respectively. It's visible with the installation of the wind farms; expansion of the transmission lines for supply load demand is optimized than scenario A. Furthermore, the utilization of GA in scenario B results in a decrease in the values of both the first and second objective functions. These reductions of the objective functions in scenario B are due to more generation capacities, dropping power flow in lines, and increasing line capacities in meeting load demand.

Fig. 6 and Fig. 7 depict TEP implementation in scenarios A and B using SFLA and GA in the RTS-IEEE 24-bus test network. The orange lines represent optimal TEP solutions to meet load demand while considering economic power generation from the units. The implementation of the TEP by SFLA in both scenarios leads to reduce investment costs and maintenance and operation costs in comparison with GA.

V. Conclusion

As a result of the escalating load growth and the integration of renewable resources into the power system, TEP has become an unavoidable issue. This article addresses the TEP problem as a multi-objective optimization problem, taking into account the presence of wind farms. Specifically, the study investigates the effectiveness of the SFLA on the modified RTS-IEEE 24-bus network. The proposed method aims to minimize investment and maintenance costs. Comparative analysis between SFLA and GA demonstrates the superiority of the former in achieving the desired objectives.

In comparison to other models, a significant advantage of this particular model lies in its investment and maintenance costs, which align with the fundamental objectives of TEP. Consequently, it is imperative to incorporate the cost of investment and maintenance as a component of fixed costs, given their crucial role in the planning process of power systems. Furthermore, the inclusion of wind farms in TEP-related matters will progressively enhance the performance of power networks in accordance with the load demand rate.

Abstract*—Cross-Project Defect Prediction (CPDP) based on domain adaptation aims to achieve defect prediction tasks in an unlabeled target software project by borrowing the defect knowledge extracted from well-annotated source software projects. Most existing CPDP approaches enhance transferability between projects but struggle with misalignments due to limited exploration of class-specific features and inability to preserve original local relationships in transformed features. In order to tackle these challenges, The article introduces a novel Cross-Project Defect Prediction (CPDP) approach called Local Preserving and Distribution Alignment (LPDA). This approach addresses the challenge of misalignments in CPDP due to limited exploration of discriminative feature representations and the failure to preserve original local relationship consistency. LPDA combines transferability and discriminability for CPDP tasks. It uses locality-preserving projection to maintain module consistency and distribution alignment, which includes transferable and discriminant distribution alignment. The former narrows the distributions of both source and target projects, while the latter increases the discrepancy between different classes across projects. The effectiveness of LPDA was tested through 118 cross-project prediction tasks involving 22 software projects from four distinct repositories. The results showed that LPDA outperforms baseline CPDP methods by efficiently learning representations that integrate transferability and discriminability while preserving local geometry to optimize distances within and between categories.

Keywords*—*Cross project defect prediction; discriminative distribution alignment; local preserving; domain adaption

I. Introduction

As software grows in size and complexity, defects inevitably arise, compromising quality and security [1], [2]. Ensuring software quality is therefore crucial before its release [3]. Software Defect Prediction (SDP) is a key technique to improve reliability by identifying potential defects in software modules, allowing for better allocation of testing resources. This technique uses historical data, like past source code and defect reports, to build models that can predict defects in new modules. Common methods for creating these models include neural networks [4], Naive Bayes [5], and support vector machines [6]. When prediction models are based on data from the same project, it's known as Within Project Defect Prediction (WPDP) [7], [8]. However, not all companies maintain historical defect data, and for those scenarios, Cross Project Defect Prediction (CPDP) uses data from external projects to build prediction models [9], [10].

CPDP aims to achieve defect prediction tasks in an unlabeled target project by learning the defect knowledge obtained from a source software project [11], [12]. However, Defect prediction for a target project is challenging due to differences from the source project, such as coding languages and developer expertise, which prevent direct knowledge transfer [13]. Domain adaptation is used to bridge the gap between projects, allowing defect knowledge to be transferred by adjusting features or instances in CPDP methods [14]. Various transfer learning algorithms from the literature [15], [16], [17], [18] are used to narrow marginal and/or conditional distribution difference between two projects. The CPDP approaches based on instance level select or reweight appropriate instances to decline the unfortunate impact from irrelevant cross-project data. For example, Ma et al. [19] proposed the Transfer Naive Bayes (TNB), introducing data gravitation that reweights instances of the source project. Moreover, software defect data often exhibits class-imbalance, with a significantly larger number of non-defective instances compared to defective instances. Class-imbalance has been broadly investigated both in WPDP [20], [21] and CPDP [22], [23], [24]. The impact of imbalanced datasets on the ranking of the approaches is also assessed [25], which addresses both class-imbalance and distribution mismatching. Tong et al. [11] introduced KSETE (Kernel Spectral Embedding Transfer Ensemble) to tackle class-imbalance in both homogeneous cross-project and heterogeneous cross-project scenarios.

Existing CPDP methods effectively reduce the gap between source and target projects, yet they overlook class distinction and disrupt local instance relationships. This can blur the decision boundary and misplace instances in the feature space, making accurate predictions difficult. Integrating locality-preserving techniques with domain adaptation could improve performance by maintaining the original data structure. Locality preserving projection is a typical approach based on manifold learning [26] that allows for learning a favourable feature space where the local consistency in the raw feature space can be effectively retained. The perfect performance will be obtained by integrating locality preserving projection and domain adaptation [27], [28], [29], but Locality-preserving objectives have not received thorough exploration within the CPDP domain.

To overcome the aforementioned limitations, this article introduces a new CPDP method called Local Preserving and Distribution Alignment (LPDA), which focuses on maintaining class distinctions and local data relationships. It aligns distributions globally and locally while keeping instances of the same class close and separating different classes. Additionally, new representations are generated in a low-dimensional subspace where instances instances from the same class remain closely, while instances from different classes are positioned farther apart. Extensive CPDP tasks on 22 open-source projects from four software repositories validate the effectiveness of the proposed approaches. The evaluation metrics used included F-measure, Balance, MCC, and AUC. The Wilcoxon signed rank test and Scott-Knott ESD test were adopted to statistical significance test. The contributions of this article can be summarised as follows:

1) Our proposed CPDP method, unlike previous ones, enhances transferability by reducing distribution discrepancies and also focuses on discriminability between different classes in the projects..
2) In CPDP, using locality-preserving projection maintains local consistency within classes, keeping similar instances closer and distinctly separating different categories.
3) The extensive experiments on 22 software projects from four software repositories demonstrate that the proposed LPDA approach is superior to several state-of-the-art CPDP approaches in terms of four performance indicators.

The article is organized as follows. Section II reviews prior works on CPDP and subspace alignment-based domain adaptation. Section III introduces the technical specification of our LPDA approach. Section IV covers the experiment configuration, encompassing aspects like open datasets, statistical tests, evaluation criteria, and research questions. In Section V, Extensive experiments along with analysis under CPDP scenarios are presented in detail.

II. Related Work

In this section, we will provide a concise overview of previous research in the domains of cross-project defect prediction and domain adaptation based on feature alignment.

A. Cross Project Defect Prediction

CPDP aims to seek instances with a high likelihood of defects in an unlabeled target software project using a predictive model trained on other well-labeled software projects[30]. In earlier research, Zimmermann et al. [31] investigated different factors that might influence the cross-project prediction performance for the first time. They have found that a few tasks (only 3.4% of the cross-project tasks) could achieve adequate prediction results and CPDP tasks between the projects are not symmetrical. The current CPDP approaches can be broadly categorized into two groups: homogeneous cross-project and heterogeneous cross-project, based on the similarity of software metrics (features) [11], [32]. In the context of homogeneous cross-project, the source and target projects share the same feature space, whereas in heterogeneous cross-project, the features of source and target projects differ. The CPDP approach employed in this paper falls under the category of homogeneous cross-project.

According to the theory of knowledge transfer, the current CPDP approaches can be mainly divided into instance transferring and feature transferring. The CPDP approaches based on instance transferring seek to select or reweight relevant instances from the source project data, which can be advantageous for the target task. The CPDP approaches based on feature transferring pay attention to learning shared feature representations for the two projects so as to narrow the distribution discrepancy between them. The former either chooses or adjusts the training data to mitigate the influence of detrimental information. The latter ensures that the source and the target projects exhibit a comparable distribution within the newly created feature subspace.

To the best of our knowledge, Turhan et al. [33] presented the CPDP approach that focus on instance transferring named Nearest Neighbor filter (NN-filter). They used KNN to gather close instances together to construct a similar training dataset.

In greater detail, for every instance of target project, NN-filter method picks the ten nearest instances from the source project and subsequently incorporates them into the training dataset. Building upon the NN-filter, Peters et al. [34] presented the Peter-filter approach, which selected instances using the k-means clustering algorithm. Using different clustering algorithms to select instances, Kanwata et al. [35] and Bhat et al. [36] presented two different CPDP approaches. Lately, Hosseini et al. [37] presented a search-based genetic instance selection approach, using genetic algorithm to select training data. These CPDP approaches based on instance selecting led to the source project wasting some data or a few available instances. To solve these problems, Ma et al. [19] proposed TNB, using the concept of data gravity, the transfer weights from the source projects is computed. These weights could strengthen the instances with significant correlations and weaken the impact of ineffective instances.

Drawn from transfers component analysis (TCA) [38], a classical transferring learning algorithm, Nam et al. [17] proposed the TCA+. This method adds normalization rules to process source and target data before distribution alignment. Liu et al. [39] detected that the prediction performance of TCA+ is erratic. Thus, they proposed two-phase transfer learning (TPTL) approach to m the issue of instability. TCA+ and TPTL only narrow the disparity in marginal distribution between the source and target projects. Simultaneously considering both the marginal and conditional distributions, Qiu et al.[15] and Xu et al. [18] proposed joint distribution matching (JDM) and balanced distribution adaptation (BDA), respectively.

Since deep learning has become capable of automatically extracting semantic features from ASTs of software program, many researchers have used it in the research SDP. Wang et al. [40] claimed that only used traditional software metrics were far from enough and represented the relationship between semantic features and software programs by abstract syntax tree (AST). Then they applied a deep belief network (DBN) to obtain software code semantic features from ASTs. Subsequently, Li et al. [41] constructed a extracting feature approach based on CNN to extract semantic features, and then integrated this features and traditional software metrics to address the absence of semantic information. However, these shallow learning and deep learning CPDP approaches consider only the transferability between source and target projects but ignore discriminability between classes.

B. Feature Alignment-based Domain Adaptation

Feature alignment-based domain adaptation approaches aim to learn a low-dimensional feature subspace where the disparity in distribution between the source and target data is explicitly narrowed. As a pioneer, Pan et al. [38] proposed to map both source and target data into a shared feature subspace via TCA, which aligns the marginal distributions between the source and target domains while maximizing the data variance in adaptation process. However, focusing only on aligning marginal distributions is insufficient for better learning purposes. Therefore, Long et al. [42] proposed to align both marginal and conditional distributions between two domains via joint distribution analysis (JDA). Similarly, Wang et al. [43] proposed a balanced domain adaptation (BDA), which simultaneously aligns the marginal and conditional distribution discrepancy and exploits a balance factor to adjust their importance degrees. JDA and BDA employ the classifier trained on source domain data to generate pseudo labels for the unlabeled target domain. After that, many variants will emerge. For example, Wang et al. [44] further proposed manifold embedded distribution alignment (MEDA) to dynamically adjust the relative importance of these two distributions. Zhao et al. [45] proposed discriminative joint probability MMD (DJP-MMD), which not only minimizes the divergence in joint distribution between two domains, but also maximizes the divergence in joint probability distribution between distinct classes in different domains to learn discriminative feature representation.

III. Research Methodology

In this section, we will present the LPDA approach for CPDP in more details. After describing the descriptions of notations used in this article.

A. Notations

$\mathcal{D}_s = \{\mathbf{x}_i^s, y_i^s\}_{i=1}^{n_s}$ and $\mathcal{D}_t = \left\{\mathbf{x}_j^t\right\}_{j=1}^{n_t}$ respectively represent the source project and the target project under the assumptions that both marginal distributions and conditional distributions of source and target projects are inequality($P\left(\mathbf{x}^s\right) \neq P\left(\mathbf{x}^t\right)$ and $Q\left(y^s \mid \mathbf{x}^s\right) \neq Q\left(y^t \mid \mathbf{x}^t\right)$). Let $\mathbf{X}_s \in \mathbb{R}^{d \times n_s}$ ($\mathbf{X}_t \in \mathbb{R}^{d \times n_t}$) is the source project data matrix (target project data matrix) containing $n_s(n_t)$ instance with d-dimension. $\mathbf{X}^c$ denotes a set of instances with label c. $\mathbf{x}_i^s \in \mathbf{X}_s$ and $\mathbf{x}_j^t \in \mathbf{X}_t$ are the $i-th$, $j-th$ instances in the source project and target project, respectively. The proposed CPDP approach aims to learn a transformation matrix $\mathbf{A}$ to transform the instances from the original feature space into a low-dimensional subspace where the distributions can be aligned and the important properties of the original data can be preserved. M_{mar} and M_{con} denote the distribution matching of marginal and the conditional distributions, respectively.

B. Overall Framework of LPDA

The previous CPDP approaches, such as JDM [15], TCA+ [17], TPTL [39] and BDA [18], learn global feature representation to narrow the distribution gap between different projects for the purpose of higher transferability, but disregard the discriminability between different classes. Additionally, these CPDP approaches cannot well preserve original local relationship consistency instances of shared the same label after transforming the features. To address these problems, this article proposes a novel CPDP approaches called Locality Preserving and Distribution Alignment (LPDA). Peculiarly, LPDA tries to fulfill three complementary objectives as follows. (1)

1) It aims at the characteristics of cross-project significant variations and draws from the idea of domain adaptation to reduce the global inter-project difference and the local intra-class discrepancy for to increaser transferability.
2) For discriminability between defective and non-defective classes, LPDA leverages class-wise MMD to enlarge the distance of different classes.
3) LPDA introduces the reward graph and penalty graph to maximize preserve the geometric structure of project instances.

The overall objective function of LPDA is follows:

$$\begin{aligned}\underset{\mathbf{A}}{\mathcal{L}} = \arg\min_{\mathbf{A}} & \underbrace{\mathcal{M}_t\left(\mathbf{X}_s, \mathbf{X}_t, \mathbf{A}\right)}_{\text{transferability}} - \mu \underbrace{\mathcal{M}_d\left(\mathbf{X}_s, \mathbf{X}_t, \mathbf{A}\right)}_{\text{discriminability}} \\ & + \eta \underbrace{\mathcal{G}\left(\mathbf{X}_s, \mathbf{X}_t, \mathbf{A}\right)}_{\text{geometric structure}} + \lambda \underbrace{\Omega(\mathbf{A})}_{\text{regularization}} .\end{aligned} \tag{1}$$

In Eq. (1), $\mathcal{M}_t$ is distribution difference in both marginal and conditional distributions across two project. $\mathcal{M}_d$ implies the distribution difference of different class between different projects. $\mathcal{G}$ represents the term of manifold regularization. Ω is the term structural risk. In addition μ, η and λ are the trade-off parameters.

C. Transferability in LPDA

Drawing on previous literatures [15], [18], we adopt maximum mean discrepancy (MMD) [38] to measure both the marginal distributions and conditional distribution distances between source and target projects. The marginal distributions distance can be achieved as follows:

$$\begin{aligned} M_{\text{mar}}\left(\mathbf{X}_s, \mathbf{X}_t\right) = & \left\| \frac{1}{n_s} \sum_{i=1}^{n_s} \phi(\mathbf{x}_i^s) - \frac{1}{n_t} \sum_{j=1}^{n_t} \phi(\mathbf{x}_j^t) \right\|_{\mathcal{H}}^2 \\ & = \operatorname{tr}(\mathbf{A}^\top \mathbf{K} \mathbf{M}_0 \mathbf{K}^\top \mathbf{A}), \end{aligned} \tag{2}$$

where, $\mathbf{X} = [\mathbf{X}_s, \mathbf{X}_t]$. $\mathbf{M}_0$ is the marginal distribution MMD matrix and it is computed as

$$(\mathbf{M}_0)_{ij} = \begin{cases} \frac{1}{n_s^2}, & \text{if} \quad \mathbf{x}_j, \mathbf{x}_i \in \mathbf{X}_s, \\ \frac{1}{n_s^2}, & \text{if} \quad \mathbf{x}_j, \mathbf{x}_i \in \mathbf{X}_t, \\ \frac{-1}{n_s n_t}, & \quad \text{otherwise.} \end{cases} \tag{3}$$

Pseudo-labels in the target project are annotated by a classifier trained on the source project to represent conditional distribution. The conditional distributions distance can be achieved as follows:

$$M_{\mathrm{con}}\left(\mathbf{X}_s, \mathbf{X}_t\right) = \sum_{c=1}^{C} \left\| \frac{1}{n_{s,c}} \sum_{i=1}^{n_{s,c}} \phi(\mathbf{x}_i^{s,c}) - \frac{1}{n_{t,c}} \sum_{j=1}^{n_{t,c}} \phi(\mathbf{x}_j^{t,c}) \right\|_{\mathcal{H}}^2 = \mathrm{tr}(\mathbf{A}^\top \mathbf{K} \sum_{c=1}^{C} \mathbf{M}_c \mathbf{K}^\top \mathbf{A}), \tag{4}$$

where, $n_{s,c}$ and $n_{s,t}$ refer to the numbers of the c class instances of source and target projects, respectively. $\mathbf{M}_c$ is the conditional distribution MMD matrix with the label c, and it is computed as

$$(\mathbf{M}_c)_{ij} = \begin{cases} \frac{1}{n_{s,c}^2}, & \text{if} \quad \mathbf{x}_i, \mathbf{x}_j \in \mathbf{X}_s^c, \\ \frac{1}{n_{t,c}^2}, & \text{if} \quad \mathbf{x}_i, \mathbf{x}_j \in \mathbf{X}_t^c, \\ \frac{-1}{n_{s,c} n_{t,c}}, & \text{if} \left\{ \begin{array}{l} \mathbf{x}_i \in \mathbf{X}_s^c, \mathbf{x}_j \in \mathbf{X}_t^c, \\ \mathbf{x}_i \in \mathbf{X}_t^c, \mathbf{x}_j \in \mathbf{X}_s^c, \end{array} \right. \\ 0, & \text{otherwise.} \end{cases} \tag{5}$$

Here, M_{mar} plus M_{con} is rewritten as the follows:

$$\mathcal{M}_t\left(\mathbf{X}_s, \mathbf{X}_t, \mathbf{A}\right) = M_{\mathrm{mar}} + M_{\mathrm{con}} = \mathrm{tr}(\mathbf{A}^\top \mathbf{X} \sum_{c=0}^{C} \mathbf{M}_c \mathbf{X}^\top \mathbf{A}). \tag{6}$$

This section considers the transferability between different projects from both marginal and conditional distributions perspectives. However, only considering the transferability might not be sufficient for better prediction performance.

D. Discriminability in LPDA

In this section, we explore the discriminability between defective and no-defective classes by leveraging class-wise MMD to augment the distribution distance between different class, which can be achieved as follows:

$$\mathcal{M}_d\left(\mathbf{X}_s, \mathbf{X}_t, \mathbf{A}\right) = \sum_{c=1}^{C} \sum_{\widehat{c} \neq c} \left\| \frac{1}{n_{s,c}} \sum_{i=1}^{n_{s,c}} \phi(\mathbf{x}_i^{s,c}) - \frac{1}{n_{t,\widehat{c}}} \sum_{j=1}^{n_{t,\widehat{c}}} \phi(\mathbf{x}_j^{t,\widehat{c}}) \right\|_{\mathcal{H}}^2. \tag{7}$$

In order to facilitate the calculation, we introduce a one-hot coding label matrix to calculate the class-wise MMD based on the literature [45]. In particular, the source project and target project one-hot coding label matrices are written as $\mathbf{Y}_s = [c_{s,1}, ..., c_{s,n_s}]$ and $\widehat{\mathbf{Y}}_t = [c_{s,1}, ..., c_{s,n_s}]$. Two matrices are defined as follows

$$\mathbf{U}_s = \frac{1}{n_s} \left[\mathbf{Y}_s(:,1) \bullet (C-1), \ldots, \mathbf{Y}_s(:,C) \bullet (C-1)\right],$$
$$\mathbf{U}_t = \frac{1}{n_t} \left[\widehat{\mathbf{Y}}_t(:,1:C)_{\hat{c}\neq 1}, \ldots, \widehat{\mathbf{Y}}_t(:,1:C)_{\hat{c}\neq C}\right],$$

where, $\mathbf{Y}_s$ and $\widehat{\mathbf{Y}}_t$ denote the $c-th$ column of $\mathbf{Y}_s$ and $\widehat{\mathbf{Y}}_t$, respectively. $\mathbf{Y}_s(:,c) \bullet (C-1)$ denotes that $\mathbf{Y}_s(:,c)$ is repeated $C-1$ times. The Eq. (7) can be further expressed to matrix form as the follows:

$$\mathcal{M}_d\left(\mathbf{X}_s, \mathbf{X}_t, \mathbf{A}\right) = \mathrm{tr}(\mathbf{A}^\top \mathbf{X} \mathbf{U} \mathbf{X}^\top \mathbf{A}), \tag{8}$$

where,

$$\mathbf{U} = \left[\begin{array}{cc} \mathbf{U}_s \mathbf{U}_s^\top & -\mathbf{U}_s \mathbf{U}_t^\top \\ -\mathbf{U}_t \mathbf{U}_s^\top & \mathbf{U}_t \mathbf{U}_t^\top \end{array} \right]. \tag{9}$$

In this article, $\mathcal{M}_t$ and $\mathcal{M}_s$ are integrated and defined as discriminant distribution distance as

$$D(\mathbf{X}_s, \mathbf{X}_t) = \mathcal{M}_t\left(\mathbf{X}_s, \mathbf{X}_t, \mathbf{A}\right) - \mu \mathcal{M}_d\left(\mathbf{X}_s, \mathbf{K}_t, \mathbf{A}\right) = \mathrm{tr}\left(\mathbf{A}^\top \mathbf{X} \left(\sum_{c=0}^{C} \mathbf{M}_c - \mu \mathbf{U}\right) \mathbf{X}^\top \mathbf{A}\right). \tag{10}$$

Discriminant distribution alignment strategy is used to enhance perdition performance by Eq. (10) can to improve the transferability and discriminability.

E. Local Structure Preserving

From a geometric perspective, if two instances in intra-class are close in the intrinsic geometry of the data distribution, then their transforming should also be close [46]. However, the transformed features cannot well preserve original local relationship consistency. For example, the distance between two instances in intra-class but from the different projects may be expanded after feature transformation, resulting in this distance being longer than the distance between two instances in different classes but from the same projects. In an attempt to solve these problems, we ensure that instances in intra-class stay close after feature transformation and keep instances in inter-class far from each other. To preserve the local structure in the transforming subspace, we have defined two embedding graphs (reward graph penalty graph)as expressed as below.

Reward Graph: $\mathbf{x}_i^c$ is connected with $\mathbf{x}_j^c$, where $\mathbf{x}_j^c$ is one of the k nearest neighbors of $\mathbf{x}_i^c$, $\mathbf{x}_i^c \in \mathbf{X}^c$ and $\mathbf{x}_j^c \in \mathbf{X}^c$.

Penalty Graph: $\mathbf{x}_i^c$ is connected with $\mathbf{x}_j^{\widehat{c}}$, where $\mathbf{x}_j^{\widehat{c}}$ is one of the k nearest neighbors of $\mathbf{x}_i^c$, $\mathbf{x}_i^c \in \mathbf{X}^c$ and $\mathbf{x}_j^{\widehat{c}} \notin \mathbf{X}^c$ $(c \neq \widehat{c})$.

The connection edges between the nodes of the two graph are assigned weights

$$\mathbf{W}_{ij} = \begin{cases} \exp\left(\frac{-\|\mathbf{x}_i - \mathbf{x}_j\|^2}{2}\right), & \text{if } \mathbf{x}_i \text{ and } \mathbf{x}_j \text{ are conencted} \\ 0, & \text{otherwise.} \end{cases}$$

We denote the pre-defined reward and penalty weight matrices as $\mathbf{W}^r$ and $\mathbf{W}^p$, respectively. The intra-class and inter-class scatter matrices are respectively defined as follows ($\mathbf{S}_b$ denotes the inter-class scatter matrix, and $\mathbf{S}_w$ denotes the intra-class scatter matrix):

$$\mathbf{S}_w = \frac{1}{2} \sum_{i=1}^{n_c} \sum_{j=1}^{n_c} W_{ij}^r \left\| \mathbf{x}_i^c - \mathbf{x}_j^c \right\|^2 = \mathrm{tr}(\mathbf{A}^\top \mathbf{X} \mathbf{L}^r \mathbf{X}^\top \mathbf{A}), \tag{11}$$

$$\mathbf{S}_b = \frac{1}{2} \sum_{i=1}^{n_c} \sum_{j=1}^{n-n_c} W_{ij}^p \left\| \mathbf{x}_i^c - \mathbf{x}_j^{\widehat{c}} \right\|^2 = \mathrm{tr}(\mathbf{A}^\top \mathbf{X} \mathbf{L}^p \mathbf{X}^\top \mathbf{A}), \tag{12}$$

where, $\mathbf{L}^r$ and $\mathbf{L}^p$ respectively represent the reward Laplacian graph and the penalty Laplacian graph. ($\mathbf{L}^r = \mathbf{D}^r - \mathbf{W}^r$, $\mathbf{L}^p = \mathbf{D}^p - \mathbf{W}^p$). $\mathbf{D}_r$ and $\mathbf{D}_p$ are diagonal matrices whose each diagonal entry is $D_{ii}^r = \sum_j W_{ij}^r$ and $D_{ii}^p = \sum_j W_{ij}^p$, respectively. The geometric structure regularization can be expressed as follows:

$$\mathcal{G}\left(\mathbf{X}_s, \mathbf{X}_t, \mathbf{A}\right) = \mathbf{S}_w - \mathbf{S}_b = \mathrm{tr}(\mathbf{A}^\top \mathbf{X} (\mathbf{L}^r - \mathbf{L}^p) \mathbf{X}^\top \mathbf{A}). \tag{13}$$

F. Subspace Learning

Finally, the objective function in Eq. (1) can be reformulated byto maximize preserve the geometric structure of project instances.

$$\underset{\mathbf{A},\Phi}{\mathcal{L}} = \min \operatorname{tr}\left(\mathbf{A}^\top \mathbf{X}\left(\sum_{c=0}^{C} \mathbf{M}_c - \mu \mathbf{U} + \eta(\mathbf{L}^r - \mathbf{L}^p)\right)\mathbf{X}^\top \mathbf{A}\right) + \lambda \|\mathbf{A}\|_F^2, \tag{14}$$

$$\text{s.t.} \quad \mathbf{A}^\top \mathbf{X}\mathbf{H}\mathbf{X}^\top \mathbf{A} = \mathbf{I},$$

where, $\mathbf{H} = \mathbf{I} - \frac{1}{n}\mathbf{1}$ is the centering matrix to avoid trivial solutions, and $\mathbf{I} \in \mathbb{R}^{n\times n}$ is the identity matrix. According to the constrained optimization, deriving the Lagrange function finds solution of problem Eq. (14). The Lagrange function is:

$$\underset{\mathbf{A},\Phi}{\mathcal{L}} = \min \quad \operatorname{tr}\left(\mathbf{A}^\top\left(\mathbf{X}\left(\sum_{c=0}^{C} \mathbf{M}_c - \mu \mathbf{U} + \eta(\mathbf{L}^r - \mathbf{L}^p)\right)\mathbf{X}^\top + \lambda \mathbf{I}\right)\mathbf{A}\right) + \operatorname{tr}\left(\left(\mathbf{I} - \mathbf{A}^\top \mathbf{X}\mathbf{H}\mathbf{X}^\top \mathbf{A}\right)\Phi\right), \tag{15}$$

where, $\Phi = diag(\phi_1, ..., \phi_d)$ is a diagonal matrix with the Lagrange multipliers. By setting the derivative of Eq. (15) $\frac{\partial \mathcal{L}}{\partial \mathbf{A}} = 0$, the optimization can be solved as a eigen-decomposition problem displayed as follows:

$$\left(\mathbf{X}\left(\sum_{c=0}^{C} \mathbf{M}_c - \mu \mathbf{U} + \eta(\mathbf{L}^r - \mathbf{L}^p)\right)\mathbf{X}^\top + \lambda \mathbf{I}\right)\mathbf{A} = \mathbf{X}\mathbf{H}\mathbf{X}^\top \mathbf{A}\Phi. \tag{16}$$

By taking the first d_0 smallest eigenvectors, the optimal solution of transformation matrix $\mathbf{A}$ is obtained. We can acquire the new representation $\mathbf{Z}_s = \mathbf{A}^\top \mathbf{X}_s$ and $\mathbf{Z}_t = \mathbf{A}^\top \mathbf{X}_t$. In summary, Algorithm 1 presents the pseudo code of the proposed LPDA approach.

Algorithm 1 Locality Preserving and Distribution Alignment (LPDA)

```
Input: Labeled source project: $\mathcal{D}_s = \{\mathbf{X}_s, \mathbf{Y}_s\}$; Unlabeled target project: $\mathcal{D}_t = \{\mathbf{X}_t\}$; Subspace dimension $d_0$; The number of iterations $T$; Number of nearest neighbors $k$; The trade-off hyper-parameters $\mu$, $\eta$ and $\lambda$.
Initialize pseudo labels $\widehat{\mathbf{Y}}_t$ of target project by using the classification model trained the source project.
Let $\mathbf{X} = [\mathbf{X}_s, \mathbf{X}_t]$;
for $z$=1:$T$ do
    Construct MDD matrices $\mathbf{M}_0$ and $\mathbf{M}_c$ by Eq. (3) and Eq. (5);
    Construct discriminability matrix $\mathbf{U}$ by Eq. (9);
    Construct the reward Laplacian graph $\mathbf{L}^r$ and penalty Laplacian graph: $\mathbf{L}^p$;
    Solve Eq. (16) and take the $d_0$ smallest eigenvectors to construct $\mathbf{A}$;
    Obtain the source feature presentations $\mathbf{Z}_s = \mathbf{A}^\top \mathbf{X}_s$;
    Obtain the source feature presentations $\mathbf{Z}_t = \mathbf{A}^\top \mathbf{X}_t$;
    Train a classifier $f(\cdot)$ by using the source features presentations $\mathbf{Z}_s$ and labels $\mathbf{Y}_s$;
    Update the target pseudo labels $\widehat{\mathbf{Y}}_t$ by using the classifier $f(\cdot)$.
Output: The transformation matrix $\mathbf{A}$.
```

G. Computational Complexity

In this subsection, we present an analysis to time complexity of the proposed approach in Algorithm 1. The computational cost of solving eigen-decomposition problem is $O(T \times d_0 \times d^2)$, of constructing the MMD matrices, Laplacian graphs and the two discriminability matrix is $O(T \times C \times n^2)$, and of all other steps is $O(T \times d \times n)$. Thus, the overall computational complexity is $O(T \times d_0 \times d^2 + 3 \times T \times C \times n^2 + T \times d \ \times n)$.

IV. EXPERIMENTAL SETUP

A. Benchmark Datasets

To assess the put forward method, a total of 22 publicly software projects from four different software repositories, including AEEEM [47], NASA [48], Relink [49] and PROMISE are applied in our experiments. Table I offers comprehensive information about these projects.

AEEEM includes five software project [47]. Software module (instance) granularity is classified in AEEEM. Each instance includes 61 metrics (features), among them five entropy-of-change metrics, 17 code metrics, five previous-defect metrics, 17 entropy-of-code metrics and 17 churn-of-code metrics.

NASA is the most popular software defect data in previous studies. Each project signifies a software system, encompassing static code metrics along with associated defect labels. The static code metrics encompass attributes like McCabe, Halstead, lines of code, among others, and are valuable for predicting software quality and defects. The static code metrics encompass McCabe complexity, Halstead intricacy, code line count, and similar factors. These measurements offer valuable insights into software quality and predicting defects. In the research, we selected five projects that shared common feature spaces and merged them to create 20 cross-project predictive tasks. *Promise* is collected by Jureczko and Madeyski [50] and , comprises 20 class-level metrics, including CK metrics and QMOOD metrics. In the article, we selected 10 open projects and then used these projects to combine 90 cross-project prediction tasks.

ReLink is denoted by Wu et al. containing three open projects (i.e Apache, Safe and ZXing) They can be combined into cross-project prediction six tasks.

B. Performance Indicators

In this article, applying the four performance indicators, including F-measure, Balance, MCC and AUC evaluate our method and comparison methods. A software defect task typically yields one of four typical output results:

True Positive (TP): Correctly predicted defective instances.

True Negative (TN): Correctly predicted non-defective instances.

False Positive (FP): Incorrectly predicted defective instances.

False Negative (FN): Incorrectly predicted non-defective instances.

PD (aka. *recall or sensitivity*) determines the defective instances correctly predicted. The higher PD, the lower the cost generated by type II mis-classifications. *PF*(aka. *false positive rate*) is the ratio of non-defective instances that are incorrectly predicted.*Precision* is the ratio of correctly predicted instances that are defective They are denoted as the follows.

$$PD = \mathit{Recall} = \frac{\mathrm{TP}}{\mathrm{TP}+\mathrm{FN}};$$
$$PF = \frac{\mathrm{FP}}{\mathrm{TN}+\mathrm{FP}};$$
$$Precision = \frac{\mathrm{TP}}{\mathrm{TP}+\mathrm{FP}}.$$

F-measure is a harmonic mean of *Precision* and *Recall*, which is denoted as

$$\textit{F-measure} = \frac{(1+\theta^2)\times \mathit{Recall} \times \mathit{Precision}}{\mathit{Recall} + \theta^2 \times \mathit{Precision}}.$$

where, θerves as a bias parameter that determines the relative significance of *Recall* and *Precision*. There are three F-measure variants, i.e., $\mathbf{F_1}$ ($\theta = 1$) treats precision and recall equally, $\mathbf{F_{0.5}}$ ($\theta = 0.5$) prefers precision, and $\mathbf{F_2}$ ($\theta = 2$) prefers recall. There are two types of error in defect prediction. The first type of misclassification is the prediction of non-defect instances as defect instances. The second type of misclassification is when a defect instance is predicted to be a non-defect instance. The cost of the latter error is higher than that of the former error. Defect prediction mainly concerns finding as many defective instances as possible, which is consistent with the evaluation of performance measurement bias to recall. Thus, defect prediction more emphasize that Recall is more important than Precision(θ is set as 2).

Balance is the normalized Euclidean distance from the ideal point (1,0) to the actual point (*PD, PF*) in the ROC curve[51], [52], which is denoted as

$$\mathit{Balance} = 1 - \frac{\sqrt{(1-PD)^2 + (0-PF)^2}}{\sqrt{2}}.$$

MCC (Matthews Correlation Coefficient) is to measure the correlation coefficient between the actual and predicted outputs, which is denoted as:

$$MCC = \frac{\mathrm{TP}\times\mathrm{TN} - \mathrm{FP}\times\mathrm{FN}}{(\mathrm{TP}+\mathrm{FP})(\mathrm{TP}+\mathrm{FN})(\mathrm{TN}+\mathrm{FP})(\mathrm{TN}+\mathrm{FN})}.$$

AUC(Area Under the Curve) The Area Under the Curve (AUC) refers to the area under the receiver operating characteristic curve (ROC). AUC is a comprehensive metric that effectively captures the trade-off and provides a better reflection of the overall performance of a prediction model.

C. Research Questions

To assess the predictive performance of the proposed LPDA, we delve into three research questions, in depth.

RQ1: Does LPDA perform better than the instances-based CPDP approaches?

As baselines for addressing this question, we employed five instance transfer approaches, which include ALL, NN-Filter, TNB, Peter-Filter, and DTB. Among these, TNB and DTB involve the reweighting of instances to mitigate the adverse influence of irrelevant cross-project data. In contrast, NN-Filter and Peter-Filter focus on filtering instances from the source project that are similar to the target project. These methods do not change the original feature space. Unlike these methods, the proposed method transfers the feature spaces while exploiting all the instances in the training step to avoid information loss. This research question is designed to investigate whether LPDA is superior to the instances-based CPDP methods in terms of CPDP performance improvement.

RQ2: Is LPDA more effective than the domain adaptation based CPDP methods?

We attempted to improve the CPDP performance from two aspects: the transferability between projects and the discriminability between class. Typically, domain adaptation-based CPDP methods investigate transferability by assuming that the source and target projects share a common distinguishing boundary. However, although the distribution gap between the two projects is narrowed after feature transformation, the instances from different classes are too close to be classified accurately near the decision boundary. The proposed LPDA method simultaneously explores the transferability and discriminability for CPDP tasks. This research question is designed to investigate whether the method considering both the transferability and discriminability is better able to improve the CPDP performance compared with other transfer learning methods.

RQ3: How do LPDA components have affect the prediction performance?

Since locality-preserving projection and distribution alignment are used in the proposed method, this research question is designed to investigate whether the components (i.e. transferable distribution alignment, discriminant distribution alignment and locality-preserving projection) can affect the prediction performance.

D. Statistical Testing

To better illustrate the effectiveness of the proposed method, we employ two statistical testing methods, namely the Wilcoxon signed-rank test and the Scott-Knott ESD test.

The Wilcoxon signed-rank test used to determine whether a significant difference exists between our method and each baseline for each cross-project task. Data distributions are identical without the assumption that they follow the normal distribution. Additionally, we employ the Win/Tie/Lose (W/T/L for brevity) evaluation to assess how many cross-project tasks our method can enhance in comparison to each baseline. Each entry's W/T/L implies that our method outperforms W cross-project tasks, ties on T cross-project tasks, and loses on L cross-project tasks.

The Scott-Knott ESD test is an expansion of the statistical methodology developed by Scott-Knott, which employs hierarchical cluster analysis to categorize a set of evaluation metrics into distinct, non-overlapping groups with statistically significant differences. This test consists of two stages: (1) the identification of a partition that maximizes the mean between different groups, and (2) either the separation into two distinct groups or the merging of any two groups with statistically significant differences and a negligible effect size into a single group. For a comprehensive explanation of the Scott-Knott ESD test, please refer to [53].

E. Experimental Settings

A total of 23 projects from four different repositories including AEEEM (5 projects), NASA (5 projects), ReLink (3 projects) and Promise (9 projects) are used in the paper. We we first identify all cross-project tasks in NASA, AEEEM, Relink and Promise. One project is selected as the target project, and the other projects from the same repository as the source. For example, when EQ is selected as the target project, the other projects separately are use as the source project. There are four cross-project tasks: JDT⇒EQ, LC ⇒EQ, ML⇒EQ, and PDE⇒ EQ. In total, there are 118 (9× 8+5×4 +5×4+3×2) cross-project tasks. We repeat each cross-project task 30 times and report the average values, each time we randomly select 90% of instances the source projects as the training set to train the model and all instances from the target project as test set, since a random selection of 90% of instances ensure that the training data are not consistently identical. In the article, Logistic Regression (LR) is selected as the foundational classifier. Due to its simplicity and effective performance in contrast to more intricate modeling methods, LR (Logistic Regression) has been a common choice in previous SDP research[18].

V. Experimental Results

A. Results for RQ1

To investigate the question, we apply some CPDP based-instance transferring methods as the baselines, including ALL, NN-Fifter, Petter-Fifter, TNB and DTB. ALL means that all the instances from the source project are used to train the prediction model without any instance filter and reweight process.

TABLE II. Average Values of Four Indicators for LPDA and Five Instance based CPDP Methods on the Different Dataset

Dataset	indicators	ALL	NN-Filter	Peter-Filter	TNB	DTB	LPDA

According to the data presented in Table II, the proposed LPDA consistently outperforms the five baseline methods across various indicators on all datasets. For instance, on the AEEEM dataset, LPDA achieves an average F-measure value of 0.542, which represents a substantial improvement, ranging from 1.87% (in comparison to TNB) to a remarkable 34.06% (in comparison to ALL), with an average enhancement of 21.6%. In terms of the average Balance score (0.696) achieved by LPDA, improvements range from 15.77% (in comparison to TNB) to 21.68% (in comparison to ALL), with an average boost of 18.01%. Moreover, the average MCC value (0.376) obtained with LPDA demonstrates significant improvements, varying from 36.81% (in comparison to DTB) to an impressive 85.59% (in comparison to ALL), with an average enhancement of 59.04%. The average AUC value (0.748) also shows positive trends, with improvements ranging from 4.47% (in comparison to TNB) to 22.38% (in comparison to NN-Filter), averaging a substantial 12.85% improvement when contrasted with the five instance-based CPDP methods. Concerning the 20 cross-project pairs on the AEEEM dataset, data from Table III reveal that LPDA exhibits a statistically significant superiority in at least 13 of these cross-project pairs across all indicators. Conversely, it may perform less favorably on most of the four cross-project pairs. Fig. 1 demonstrates that the median values of all four indicators by LPDA higher than the five baseline methods. In particular, the median F-measure, Balance and AUC of the Relink dataset by LPDA are similar or even better than to the maximum value achieved by the five baseline methods.

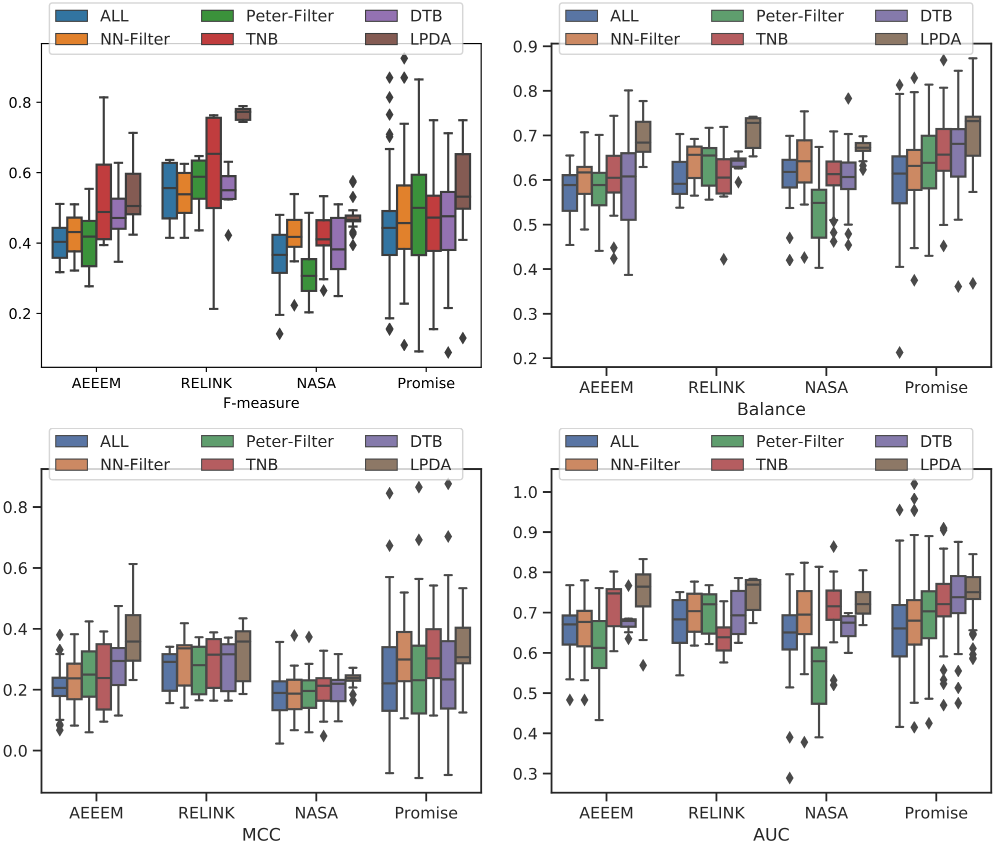

Fig. 1. Boxplots of f-measure, balance MCC, and AUC across all datasets for LPDA and the five instance-based CPDP methods.

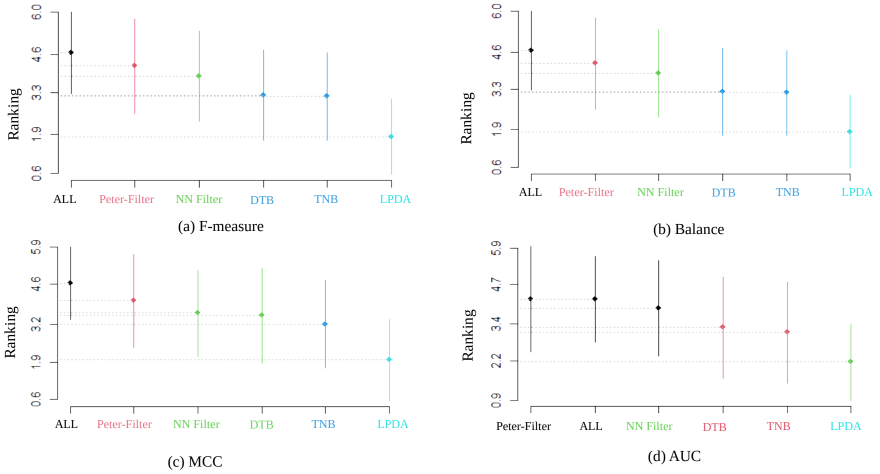
On NASA dataset, the average F-measure value (0.474) by LPDA yields improvements between 13.40% (for TNB) and 49.45% (for Peter-Filter) with an average improvement of 25.92%, the average Balance value (0.670) by LPDA gains improvements between 5.77% (for NN Filter) and 24.89% (for Peter-Filter) with an average improvement of 12.65%, the average MCC value (0.233)by LPDA achieves improvements between 13.37% (for DTB) and 30.41%(for ALL) with an average improvement of 21.07%, and the average AUC value (0.724) gets improvements between 2.14% (for DTB) and 28.61% (for Pete-Filter) with an average improvement of 12.23% compared against the five instances-based CPDP methods. Three are also 20 cross-project pairs on NASA dataset. From Table III, the result shows that LPDA is significantly more accurate at least on 14 cross-project pairs and significantly less accurate at most on five cross-project pairs in terms of F-measure, Balance and MCC indicators. LPDA almost equal TNB (eight wins and seven losses) in terms of AUC. Compared to other the four baseline methods, LPDA is almost complete victory (at least 12 wins and at most 5 losses).

On the RELINE dataset, LPDA achieves an average F-measure value of 0.767, resulting in improvements ranging from 30.76% (compared to TNB) to 43.36% (compared to Peter-Filter), with an average improvement of 38.25%. The average Balance value, at 0.708 by LPDA, shows enhancements ranging from 10.64% (compared to NN-filter) to 18.98% (compared to TNB), with an average improvement of 13.66%. Furthermore, the average MCC value of 0.320 by LPDA demonstrates improvements ranging from 9.75% (compared to NN-filter) to 22.50% (compared to ALL), with an average improvement of 15.33%. The average AUC value of 0.745 also shows enhancements ranging from 6.16% (compared to Peter-Filter) to 16.16% (compared to DTB), with an average improvement of 9.27% when compared to the five instances-based CPDP methods. It is evident from Table III that LPDA outperforms the five baseline methods in terms of these four indicators, albeit it falls slightly short of them in certain aspects.

On Promise dataset, the average F-measure value (0.563) by LPDA yields improvements between 13.06% (for Peter-Filter) and 27.25% (for ALL) with an average improvement of 20.56%, the average Balance value (0.702) by LPDA gains improvements between 6.05% (for DTB) and 17.73% (for ALL) with an average improvement of 10.46%, the average MCC value (0.338) by LPDA achieves improvements between 4.84% (for TNB) and 34.90% (for ALL) with an average improvement of 21.84%, and the average AUC value (0.746) gets improvements between 2.08% (for DTB) and 12.72% (for ALL) with an average improvement of 7.07% compared against the five instances-based CPDP methods.

Table III shows the results of Wilcoxon signed-rank statistical test for each baseline method. By using the “W/T/L” evaluation, we can investigate 118 cross-project pairs in which LPDA can outperform other comparing method. As shown in the table, it is obvious that LPDA can achieve more positive



(a) F-measure

(b) Balance

(c) MCC

(d) AUC

Fig. 2. The results of scott-knott ESD test in f-measure, balance MCC, and AUC across all datasets for LPDA and other instance-based methods. The smaller ranking, the better performance.

results in terms of F-measure,Balance, MCC and AUC measure indicators when compared with other competing methods. For example, LPDA has significant superiorities to TNB on 81/118 (81 out of 118 cross-project pairs) in F-measure, and 83, 79 and 71 in Balance, MCC, and AUC, respectively. Fig. 2(a)-(d) present the results of Scott-Knott ESD test for the proposed LPDA and five baseline methods in terms of F-measure, Balance,MCC, and AUC, respectively. The x-axis and y-axis represent the method and ranking, respectively. The smaller the ranking, the better the performance. Each method corresponds to a bar denoting the range of ranking of this method on all cross-project pair tasks. The dot in the bar indicates the average ranking value. Different colors denote different groups with statistically significant differences. From these figures, we can see that LDPA obtains the smallest average ranking and thus is categorized into the top group which do not include any baseline method in terms of the four indicators.

B. Results for RQ2

In order to address this question, we have chosen five domain adaptation-based methods. A concise overview of these baseline methods is provided below:

1) *TCA*: This method aims to match marginal distribution between two projects [38] .
2) *TCA+*: An TCA variation improved in previous research [17] add customized normalization rules before distribution matching.
3) *JDM*: This method matches the marginal and conditional distributions simultaneously [15].
4) *BDA*: BDA [18] takes into account both the marginal and conditional distributions and dynamically assigns varying weights to them.
5) *TPTL*: TPTL [39] selects the benefits of source project selection and use transfer learning to construct a SDP model.

Table IV presents the mean values of the four metrics for both LPDA and the five domain adaptation-based methods across the four datasets. Fig. 3 illustrates box-plots representing the four metrics for all six methods across the entire set of datasets.

TABLE IV. Average Values of Four Indicators for LPDA and Five Domain Adaptation based CPDP Methods on the Different Dataset

Dataset	indicator	TCA	TCA+	JDM	BDA	TPTL	PLDA
AEEEM	F-measure	0.468	0.487	0.505	0.533	0.510	**0.542**
	Balance	0.671	0.645	0.674	0.689	0.647	**0.696**
	MCC	0.217	0.244	0.253	0.258	0.290	**0.378**
	AUC	0.701	0.716	0.725	0.703	0.729	**0.748**
NASA	F-measure	0.391	0.382	0.456	**0.484**	0.456	0.474
	Balance	0.651	0.572	0.646	0.666	0.660	**0.670**

RELINK	F-measure	0.636	0.639	0.632	0.643	0.703	**0.767**
	Balance	0.630	0.487	0.599	0.639	0.640	**0.708**
	MCC	0.271	0.306	0.282	0.306	0.295	**0.320**
	AUC	0.611	0.621	0.645	0.665	0.733	**0.745**

According to the data in Table IV, LPDA outperforms the five domain adaptation-based methods in all metrics when it comes to the AEEEM dataset, with higher average values.More specifically, LPDA compared with the five domain adaptation based methods achieves improvements of 1.55%–15.75% in F-measure , 0.92%–7.8% in Balance, 30.40%–74.42% in MCC, 2.26%–6.68% in AUC.

On the NASA dataset, the proposed LPDA achieves the best average values in terms of Balance and MCC, while BDA and TPTL achieve the best average values in terms of F-measure and AUC, respectively. More specifically, compared with the five baseline methods, LPDA achieves improvements ranging from 0.58% to 17.11% on Balance, and 5.92% to 22.99% on MCC, respectively. However, the average F-measure and AUC of LPDA are 1.95% and 0.2% lower than TNB and DTB, respectively. The results presented in Table IV show that average values in four evaluation indicators by

	MCC	6/0/0	5/1/0	6/0/0	5/0/1	5/1/0
	AUC	6/0/0	6/0/0	6/0/0	6/0/0	3/2/1
Total	F-measure	90/10/18	84/8/26	71/8/39	71/18/29	72/13/33
	Balance	79/20/19	80/12/26	71/16/31	53/27/38	63/16/39
	MCC	93/9/16	82/21/15	87/13/18	69/29/20	69/17/32
	AUC	95/11/12	85/13/20	82/16/20	76/15/27	67/17/34

the proposed LPDA are the best average values on the Relink dataset. More specifically, compared with the five baseline methods, average value by LPDA gains the improvement of 9.17%-21.34% in terms of F-measure, of 10.53%–45.47% in terms Balance, of 4.61%–18.04% in terms MCC, and of 1.61%–21.82% in terms AUC. On the Promise dataset, the proposed LPDA achieves the best average values in terms of F-measure, MCC and AUC, while TPTL achieves the best average values in terms of Balance. To be specific, compared with the five baseline methods, LPDA achieves improvements ranging from 4.69% to 25.56% on F-measure, 6.97% to 36.79% on MCC, and 5.83% to 11.69% on AUC, respectively. However, the average value by LPDA is 0.58% lower than the best average value (for TPTL) among the five baseline methods in terms of Balance. From Table V, It is obvious that LPDA has more than 53 wins over Wilcoxon signed-rank test in any evaluation indicator. Taking TCA+ as an example, the "W/T/L" results show that LDPA has statistically significant improvements of 84/118 (84 out of 118 cross-project pair prediction), 80/118, 82/118 and 85/118 in F-measure, Balance MCC and AUC, respectively.

Fig. 3 depicts the boxplots of four indicators for the six methods on four datasets. This figure illustrates that the median values of all four indicators achieved by LPDA surpass those obtained by the five baseline methods on both the AEEEM and Relink datasets. On the NASA dataset, the median values of all four indicators by LPDA are not superior to these by the TPTL. On the Promise dataset, the values of Balance indicators

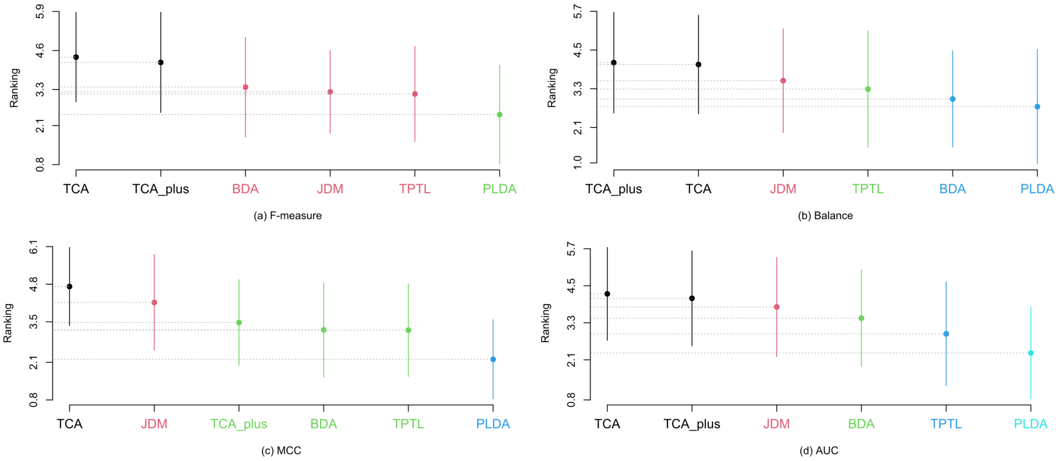

Fig. 4. The results of scott-knott ESD test in f-measure, balance MCC, and AUC across all datasets for LPDA and the five domain adaptation based CPDP methods.

by LPDA are slightly weaker than that by the TPTL.

Moreover, in Fig. 4(a)-(c), the outcomes of the Scott–Knott ESD test are presented for LPDA and the five domain adaptation-based methods across 118 cross-project pairs, considering F-measure, Balance, MCC, and AUC. The figures reveal that LPDA consistently achieves the lowest average ranking and is clearly separated into a distinct group concerning the four evaluation metrics. This indicates that LPDA significantly outperforms domain adaptation-based CPDP methods.

C. Results for RQ3

TABLE VI. Average Values of Four Indicators for LPDA and It's Variants on the Different Dataset

Dataset	indicator	LPDA_TA	LPDA_DA	LPDA_noDA	LPDA_noLP	PLDA

LPDA has three key components, including locality preserving, transferable distribution transferable distribution alignment and discriminant distribution alignment. To investigate whether the proposed LPDA approach is more effective than other combinations of these three components, we specially conduct experiments to study the design of these components. We separately conduct LPDA_TA with only transferable distribution alignment (without locality preserving and discriminant distribution alignment), which is referred to as LPDA_TA, LPDA without discriminant distribution alignment, which is referred to as LPDA_noDA and LPDA without locality preserving, which is referred to as LPDA_noLP and LPDA with only discriminant distribution alignment which is referred to as LPDA_DA.

TABLE VII. Wilcoxon Signed-rank Test Results of LPDA Against Each Variant Method

Dataset	Against(W/T/L)				
	indicators	LPDA_TA	LPDA_DA	LPDA_noDA	LPDA_noLP

Table VI shows the average values of F-measure, Balance, MCC and AUC on four different datasets of LPDA_TA, LPDA_DA, LPDA_noDA, PLDA_noLS and LPDA on Relink dataset, AEEEM dataset, NASA dataset and Promise dataset. In these table, the best values in each row are in bold. Fig. 5 depicts the boxplots of four indicators for the five methods. Table VII shows the results of Wilcoxon signed-rank statistical test. We present the following findings in Table VI, Table VII and Fig. 5. The results on the AEEEM dataset show that the proposed LDPA performs better than its four variants. To be specific, the improvement of LPDA over LPDA_TA, LPDA_DA, LPDA_noDA and PLDA_noLS on average is at least by 8.83%, 4.13%, 4.21%, 2.72% and at most by 14.38%, 8.87%, 12.48%, 8.86% in terms of F-measure, Balance, MCC and AUC, respectively. The results of Wilcoxon signed-rank statistical test shows that LPDA achieves more than 12 improvements with reference to Balance and F-measure , more than 10 improvements with reference to MCC, and more than nine improvements with reference to AUC, respectively.

On NASA dataset, the improvement of LPDA over LPDA_TA, LPDA_DA, LPDA_noDA and PLDA_noLS on average is at least by 14.69%, 2.38%, 2.26% , 2.27% and at most by 21.95%, 10.19%, 10.18%, 2.56% with regard to F-measure, Balance, MCC, and AUC, respectively. The results

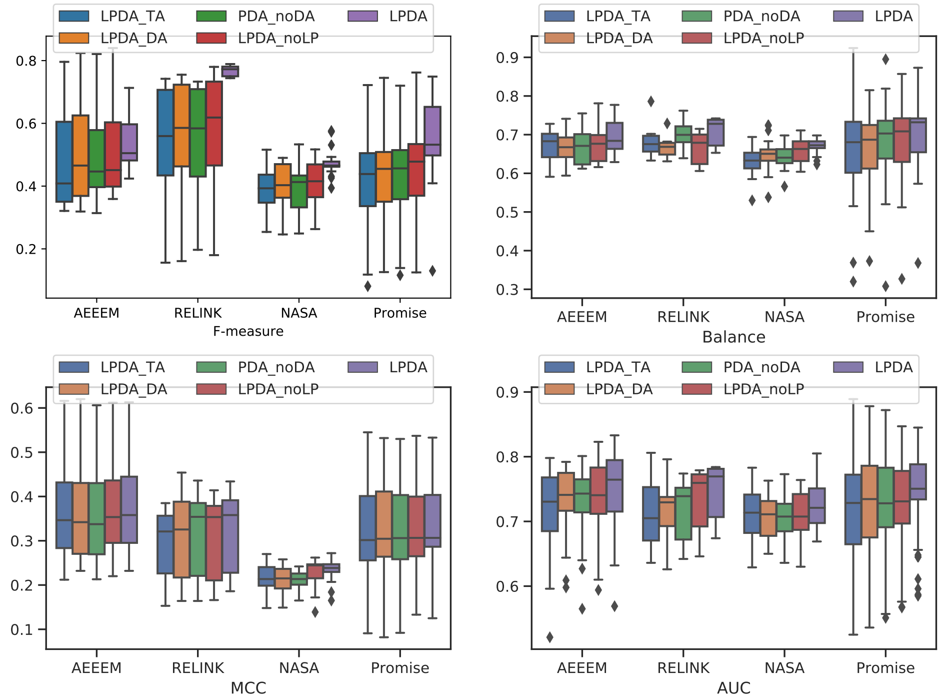

Fig. 5. Boxplots of f-measure, balance MCC, and AUC across all datasets for LPDA and it’s variant methods.

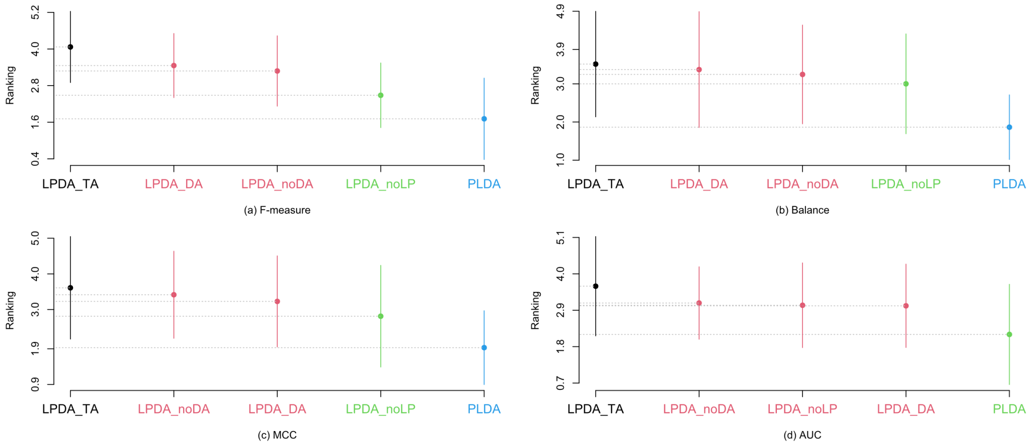

Fig. 6. The results of scott-knott ESD test in f-measure, balance MCC, and AUC across all datasets for LPDA and it’s variant methods. The smaller ranking, the better performance.

of Wilcoxon signed-rank statistical test shows that LPDA achieves more than 10 improvements with reference to Balance and MCC , more than 14 improvements with reference to F-measure, and more than 11 improvements with reference to AUC respectively.

On Relink dataset, the improvement of our method over LPDA_TA, LPDA_DA, LPDA_noDA and PLDA_noLS on average is at least by 36.11%, 1.04%, 2.33% , 1.76% and at most by 45.51%, 6.38%, 10.28%, 4.9% with regard to F-measure, Balance, MCC, and AUC, respectively. The results of Wilcoxon signed-rank statistical test shows that LPDA achieves more than four improvements with reference to Balance, AUC and F-measure. However, MCC of LPDA only wins on two cross-project pairs and ties on three cross-project pairs compared with LPDA_noDA.

On Promise dataset, the improvement of our method over LPDA_TA, LPDA_DA, LPDA_noDA and PLDA_noLS on average is at least by 23.44%, 2.55%, 2.28% , 3.32% and at most by 34.37%, 5.68%, 5.45%, 3.66% with regard to F-measure, Balance, MCC, and AUC, respectively. The results of Wilcoxon signed-rank statistical test shows that LPDA achieves more than 50 improvements with reference to F-measure, more than 32 improvements with reference to Balance, more than 35 improvements with reference to MCC and more than 43 improvements with reference to AUC respectively. As can be seen from the results shown in TableVII

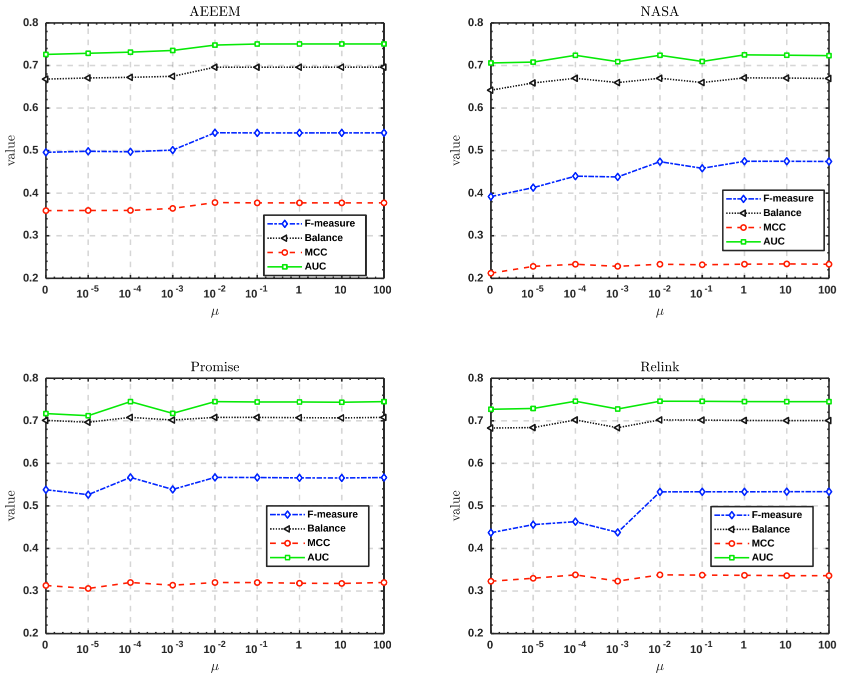

Fig. 7. Average f-measure, balance, MCC and AUC of LPDA on different datasets using differ trade-off parameter μ.

that LPDA attains more than 85 improvements in term of F-measure , more than 70 improvements with reference to Balance, more than 63 improvements with reference to MCC , and more than 68 improvements with reference to AUC, respectively.

VI. Discussion

A. Parameters Sensitivity

We explored the parameter sensitivity of LPDA to confirm that a diverse range of parameter values can be utilized to achieve a satisfactory level of performance. There are three parameters in LPDA, including the regularization parameter λ, the trade-off parameters μ and η. We change the values of these parameters in the range of $\{0, 0.00001, 0001, 0.001, 0.01, 0.1, 1, 10,1000\}$ to report the overall average F-measure, Balance, AUC, and MCC on different datasets at 30 random points of times. It is worth noticing when μ=0,LPDA becomes LPDA_noDA, which is without discriminant term, when η=0, LDPA becomes LDPA_noLP, which is without locality preserving term, and when μ=0 and η=0, LDPA becomes LPDA_TA.

Fig. 7 presents the aggregate average value of F-measure, Balance, MCC, and AUC for LPDA across various datasets, influenced by varying the trade-off parameter μ. This figure suggests that indicates that lower emphasis on discriminant distribution alignment (reflected by a smaller μ value) leads to less accurate LPDA predictions. Additionally, the g-measure exhibits steady fluctuation within the μ, parameter range of [0.01, 100]. We plotted the overall average F-measure, Balance, MCC and AUC of LPDA with different trade-off parameter η on four different datasets which are shown in Fig. 8. We find that LPDA is sensitive to η and robust to η in [0.001, 10].

We plotted the overall average F-measure, Balance, MCC and AUC of LPDA with different trade-off parameter λ on four different datasets which are shown in Fig. 9. We find LPDA is sensitive to λ and the robust results of λ on different datasets are different. We observe that $\lambda \in [0.001, 1]$ is the robust prediction result for AEEEM and NASA datasets. $\lambda \in [0.01, 1]$ and $\lambda \in [0.1, 100]$ are the robust parameter values for Promise and Relink datasets, respectively.

VII. Threats to Validity

A. Internal Validity

The primary challenges to internal validity stem from unmanaged variables affecting the experimental procedure. An instance of this is the emergence of defects during the reimplementation of baseline methods, which may occur during the coding phase. To mitigate these issues, especially for baselines with openly accessible source code (e.g., TCA and TPTL methods), we utilize the provided source code to minimize potential discrepancies. For baselines without accessible source code, we make every effort to ensure precise implementation by meticulously adhering to the instructions outlined in relevant research studies.

B. External Validity

External validity mainly concerns that our research can be generalized to other software projects. Twenty-two software projects are employed in our experiment. We evaluated our methods against ten CPDP approaches using five performance evaluation metrics. Additionally, we employed both the Wilcoxon signed-rank test and the Scott Knott-ESD test for further analysis. However, we still cannot guarantee the consistence of our method on other software projects not covered

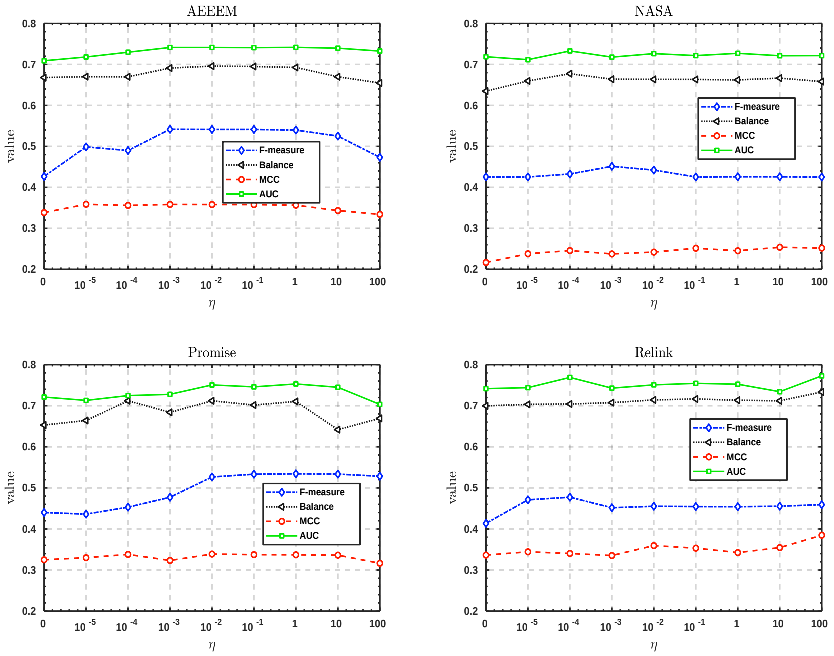

Fig. 8. Average f-measure, balance, MCC and AUC of LPDA on different datasets using differ trade-off parameter η.

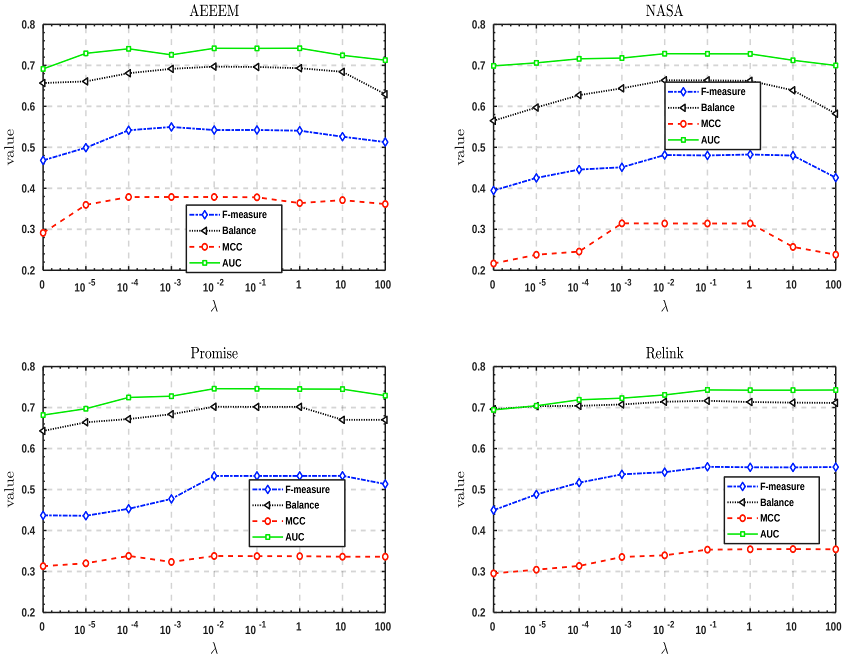

Fig. 9. Average f-measure, balance, MCC and AUC of LPDA on different datasets using differ trade-off parameter λ.

in this article. Further investigations on the applications of our research to commercial projects are needed.

VIII. Conclusion

In this paper, we propose a novel representation learning method LPDA for CPDP, which efficiently learned representations: 1) achieving transferability between two projects, and 2) preserving the local geometry to achieve discriminability between different categories. The local geometry is preserved by minimizing the distances between instances and their nearest neighbors within the same categories and maximizing the distances between instances and their neighbors in the different categories. The performance of LPDA is evaluated by five well-known evaluation indicators, including *Balance*, *F-measure*, *MCC* and *AUC*. We select ten state-of-the-art CPDP methods as baselines. We compare LPDA with ten baselines using the Wilcoxon signed-rank test and Scott-Knott ESD test (see Fig. 6). The experimental results on 22 software projects from four software repositories have shown that LPDA method is significantly superior to ten other CPDP methods. However, the proposed LPDA still has some limitations. LPDA does not consider important practical issues regarding the acquirement of useful knowledge from multiple external software projects and the application to projects. Moreover, LPDA method only considers traditional metric features and ignores effective high-level context features of source code. In our future work, we will further explore the potentials of LPDA.

Exploiting Deepfakes by Analyzing Temporal Feature Inconsistency

Junlin Gu, Yihan Xu, Juan Sun, Weiwei Liu
Jiangsu Vocational College of Electronics and Information,
China

Abstract—**In recent years, the rapid advancement of image generation technology has facilitated the creation of counterfeit images and videos, posing significant challenges for content authenticity verification. Malefactors can easily extract videos from social networks and generate their own deceptive renditions using state-of-the-art techniques. The latest Deepfake face forgery videos have reached an unprecedented level of sophistication, making it exceptionally difficult to discern signs of manipulation. While several methods have been proposed for detecting fraudulent media, they often target specific aspects, and as new attack methods emerge, these approaches tend to become obsolete. This paper presents a novel detection approach that combines Convolutional Neural Networks (CNN) and Long Short-Term Memory Networks (LSTM). Initially, CNN is employed to extract image features from each frame of the input facial video, capturing subtle alterations and irregularities in manipulated content. Subsequently, the extracted feature sequence is used to train the LSTM network, mimicking the temporal consistency of human visual perception and enhancing the effectiveness of counterfeit video detection. To validate this methodology, a comprehensive evaluation is conducted using the FaceForensic++ dataset, affirming its proficiency in identifying Deepfake counterfeit videos.**

Keywords*—*Face forgery detection; Convolutional Neural Network; Long Short-Term Memory Network; time consistency

I. Introduction

The rapid and remarkable progress in machine learning technology has elevated the capabilities of video modification and production to an unprecedented level. A pivotal development in this arena is the widespread adoption of Generative Adversarial Networks (GANs), which have revolutionized the automatic generation of images and video synthesis through network model training [1]. Notably, the advent of Deepfake technology, a derivative of GANs, has enabled the seamless replacement of facial features in videos. After post-processing, these videos attain an exceptional degree of realism. However, this rapid technological advancement has brought forth a slew of significant societal challenges [2]. The proliferation of Deepfake technology raises concerns about privacy violations, and its misuse can potentially lead to legal liabilities. Despite diligent efforts by network oversight bodies, the digital landscape remains inundated with a vast volume of synthetic, manipulated videos. It is, therefore, imperative to expeditiously develop effective methods for detecting forged videos to address this burgeoning issue.

As Deepfake technology continues to evolve, the field of detection methods has made substantial progress. Researchers have delved deeply into deep learning models, including spatial domain methods [3], [4], [5] and temporal domain methods [6], [7], in a comprehensive effort to identify irregularities and inconsistencies inherent in Deepfake videos. These models autonomously extract and categorize features, thereby enhancing the accuracy of forged content detection. Moreover, the development and utilization of extensive datasets have played a pivotal role in advancing research on deep forgery detection. Datasets such as FaceForensics++ [8], Deeperforensics [9] have provided a wealth of real and fake video examples, serving as invaluable resources for researchers in this field. The adoption of multi-modal detection approaches, which combine visual data with audio, voice, and other sources of information, has significantly improved the precision and effectiveness of detection methods. Nevertheless, the field of deep forgery detection continues to grapple with an array of challenges. Adversaries consistently refine their Deepfake techniques, making detection increasingly intricate. Consequently, researchers are compelled to continually enhance detection methodologies to bolster their robustness and real-time performance, effectively responding to evolving forgery threats.

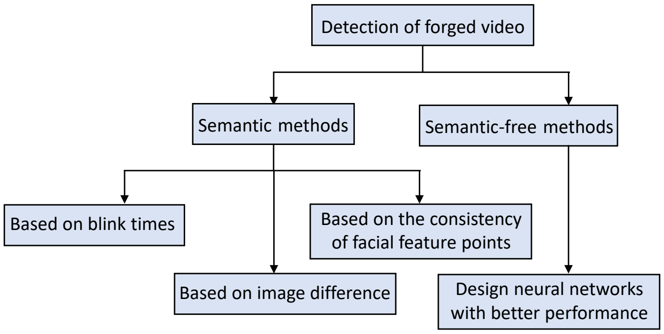
In alignment with these advancements, this paper introduces a temporal feature inconsistency analyzing method to enhance the accuracy of Deepfake forgery detection. Specifically, the proposed approach integrates a deep convolutional neural network for image feature extraction and incorporates an LSTM network to analyze correlations between feature sequences. Empirical findings substantiate the efficacy of this methodology, affirming its capacity to facilitate efficient and reliable deep forgery video detection. The main contributions of this paper are as follows:

1) We propose a deepfake detection framework based on the extraction of temporal inconsistencies, combining the feature extraction capabilities of CNN and the temporal feature analysis abilities of LSTM to achieve accurate detection of deepfakes.
2) We tested the algorithm's detection accuracy on video sequences of various lengths using the FaceForensics++ dataset. The experimental results indicate that our algorithm ensures both detection accuracy and computational efficiency when applied to video sequences of 40 frames in length.

This paper focuses on detecting deepfake videos using temporal continuity. Section II provides an overview of recent advancements in deepfake detection research. Section III details the proposed methodology, while Section IV validates its effectiveness through experiments measuring detection accuracy, computational efficiency, and related metrics. Finally, the Section V concludes the paper by summarizing our proposed scheme.

II. Related Work

Currently, research in the field of image forgery detection has made notable advancements. However, there is still a compelling need for further exploration, particularly in the context of real-world scenarios. The domain of forged video detection is predominantly categorized into two main classes: semantic detection and non-semantic detection. The specific detection methods within these categories are systematically organized and illustrated in Fig. 1.



Detection of forged video
Semantic methods
Semantic-free methods
Based on blink times
Based on the consistency of facial feature points
Based on image difference
Design neural networks with better performance

Fig. 1. Classification of forgery video detection methods.

A. Semantic-based Detection Method

1) Classification using the number of blinks in the video: Blinking, denoting the swift opening and closing of eyelids, constitutes a notable behavioral trait. The generation of counterfeit videos through GAN models relies on extensive training data sourced from facial images. As a consequence, many genuine photos do not capture subjects with their eyes closed, leading to a distinctive lack of blink in the generated fake videos. From this vantage point, the absence of blinking emerges as a conspicuous discrepancy between counterfeit and authentic videos.

In the realm of computer vision, blink detection has garnered attention for diverse applications such as fatigue detection [10], [11], [12] and face spoofing detection [13]. Various approaches have been explored in this context. Sukno et al. [14] employed an active shape model in conjunction with optimal invariant features to delineate the eye contour, subsequently assessing eye state based on vertical eye displacement. Torricelli et al. [15] analyzed eye states through the comparison of consecutive frames. Divjak et al. [16] harnessed optical flow to capture eye motion, subsequently extracting the principal eye motion for analysis. Yang et al. [17] deployed parameterized parabolic curves to model eye shapes and fitted the model to individual frames for eyelid tracking.

Drutarovsky et al. [18] delved into the variance of vertical eye area movement as detected by the Viola-Jones algorithm. They further utilized a group of KLT trackers within the eye area, dividing each eye region into 3x3 subregions to calculate the average motion within each. Notably, the most recent development in forged video detection with a focus on blink motion is attributed to Li et al. [19]. Their approach discerns blink occurrences through a combination of Convolutional Neural Networks (CNN) and Long Short-Term Memory Neural Networks (LSTM), ultimately rendering judgments regarding video authenticity based on blink frequencies.

However, this technology primarily hinges on the quantification of blink incidents. Crucially, GAN models employed for the generation of counterfeit videos are trained on a substantial corpus of facial images. In the event that malicious actors augment the training data with closed-eye facial images, the resultant Deepfake counterfeit videos will exhibit plausible blink occurrences, effectively undermining the blink-based detection mechanism.

2) Using the difference between the head pose of the person in the generated video and the head pose of the original video to classify: The face exchange algorithm is designed to generate faces of different individuals while preserving the original facial expressions. However, it is essential to note that the facial feature points of these two faces may not align. The positions of these feature points on the human face are intrinsically linked to crucial structures such as the eyes and mouth. Given that neural network synthesis algorithms cannot guarantee the exact replication of facial features between the original human face and the synthesized face, Yang et al. [20] introduced a novel approach to assess the head pose by comparing estimations derived from all facial feature points with those calculated solely from the central region.

This method is grounded in the observation of errors stemming from the integration of the synthesized face region into the original image. These errors become evident when attempting to estimate the three-dimensional head pose from the facial image. The authors empirically validated this phenomenon through a series of experiments and subsequently devised a classification method based on these observations. It's noteworthy, however, that this approach has yet to be evaluated using the latest Deepfake forged face datasets. Consequently, the question of whether it can effectively detect the most recent Deepfake videos remains an open challenge.

3) Classification by comparing the differences between the face area and the surrounding area: In the realm of image and video detection, recent strides have been taken towards identifying content generated by Generative Adversarial Networks (GANs). Notably, in the context of face exchange, where the original face image from one video is transposed onto the face image of another video, even after a series of fuzzy optimization processes, disparities inevitably emerge between the facial image and its surrounding context.

Li et al. [21] introduced a novel approach that leverages a Convolutional Neural Network (CNN) model to discern discrepancies between the facial region and its neighboring context, thereby facilitating the detection of forged faces. To simulate a broader spectrum of affine distorted faces across different resolutions, the authors trained four CNN models, namely VGG16 [22], ResNet50, ResNet101, and ResNet152 [23]. Subsequently, these models were evaluated by testing them on several synthetic videos sourced from YouTube, affirming the effectiveness of this method for detecting Deepfake forged videos.

B. Non-semantic Detection Method

In recent years, the field of digital image forensics has witnessed a notable integration of deep learning techniques. Rao and Ni [24] introduced a network dedicated to detecting image stitching, while Rahmouni et al. [25] demonstrated the capacity of deep learning to discriminate between computer-generated and photographic images. These developments underscore the robust performance of deep learning in the domain of digital forensics.

Indeed, traditional microscopic analysis relying on image noise becomes inapplicable within the constraints of compressed video environments, where image noise is often significantly denoised. Similarly, differentiating forged face images at a higher semantic level poses a considerable challenge for the human eye. To address these issues, Darius and Vincent et al. [26] proposed an intermediary approach, employing a deep neural network with a streamlined architecture for image detection. They presented two network structures tailored for detecting forged videos, achieving commendable detection results with a minimal computational overhead. Experimental results showcase an average detection accuracy of 98% for Deepfake counterfeit videos. To further validate the efficacy of this solution, considerable effort was devoted to visualizing the designed network layers and filters.

Another pioneering contribution in the realm of deepfake video detection was presented by Huy et al. [27], who harnessed capsule networks for detecting counterfeit videos across diverse scenarios. This work marked a significant advancement, as it was among the first to explore the application of capsule networks in the field of detection. Capsule networks, initially devised to address issues in digital forensics, were thoroughly examined. The authors conducted a comprehensive analysis and comparison against four mainstream datasets, affirming the superior performance of their method.

However, challenges still persist in the domain of Deepfake video detection, including issues related to the representativeness of datasets and the limited scope of detection. To address these concerns, this paper employs a combination of Convolutional Neural Networks for feature extraction and Long Short-Term Memory networks for analyzing temporal inconsistencies.

III. Problem Analysis and Proposed Method

A. Problems in Deepfake Generation Methods

This section briefly introduces the process of Deepfake generation, and analyzes the problems existing in Deepfake generation method according to its production process.

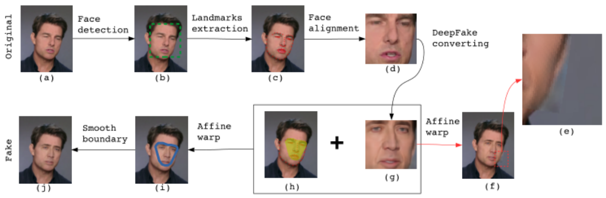


Fig. 2. Forged face generation process diagram.

As illustrated in Fig. 2, the process of generating a forged frame image within a video is detailed. Initially, the original image (a) undergoes face detection to delineate the facial region, depicted as the bounding box in (b). Subsequently, the facial feature points are extracted, and these extracted points are visualized in (c). These feature points convey essential facial characteristics, including facial orientation. Following necessary adjustments, the result in (d) is obtained, which then serves as input to a Generative Adversarial Network (GAN) to produce (g). The subsequent task involves seamlessly integrating (g) with the original image. Two distinct methods are employed for this integration. The first method entails directly replacing (g) with the original image (a) via an affine transformation, generating an image such as (f). However, it becomes evident from (e) that the replaced area does not seamlessly blend with the original image, resulting in noticeable discrepancies. The second approach involves initially identifying the region to be replaced based on the feature points detected in (c), as depicted in (h). This replacement region predominantly corresponds to the central area of the face. Subsequently, (g) is replaced in this region via an affine transformation. Finally, the boundary of the replacement region is softened and smoothed to enhance the image's overall realism. Totally, the problems of Deepfake generation technology are as follows:

1) Intra-frame: When introducing a new face into the target frame image, even with subsequent blurring and smoothing of the boundary, the central facial region tends to exhibit disparities in terms of color, brightness, and resolution when compared to the other areas within the target frame image.

2) Inter-frame: In the context of video face forgery, each image frame undergoes processing, and the GAN employed to generate facial images lacks the ability to retain knowledge of previous frames. In essence, the GAN lacks information about the facial content in the preceding frames, making it challenging to capture the temporal consistency between adjacent frames. Consequently, the facial expressions in consecutive frames may exhibit significant divergence, whereas genuine video sequences tend to maintain a higher degree of consistency in the facial expressions between adjacent frames.

B. The Proposed Method

Building upon David's approach [28], this paper leverages the incongruities present in intra-frame and inter-frame Deepfake video content for detection purposes. In addressing intra-frame disparities, Convolutional Neural Networks are harnessed to extract image features, with the objective of obtaining discriminative features capable of distinguishing genuine from fabricated videos. To address the issue of temporal continuity between frames, this paper adopts the Long Short-Term Memory network (LSTM) for detection. LSTM is a network well-suited for processing sequential data, allowing for the analysis and processing of features that exhibit temporal coherence.

Consequently, this experiment capitalizes on the inconsistency within the image content of Deepfake forged videos and the lack of continuity between adjacent frame images. The process commences with feature extraction performed on each frame within the video, and the resulting feature sequence is subsequently input into the LSTM network. The LSTM network is meticulously trained to identify Deepfake forged videos. The workflow of this solution is visually represented in Fig. 3.

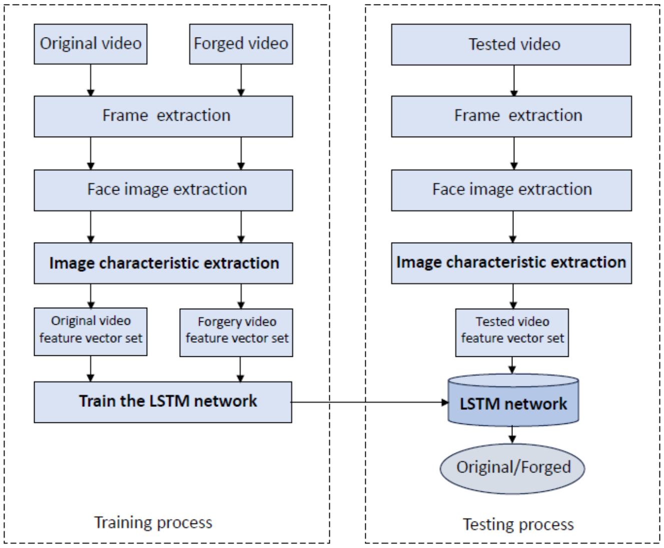

Fig. 3. The workflow of the solution.

1) Video frame extract: Before proceeding with spatial feature extraction, the initial step involves extracting individual frame images from the video footage. To comprehensively evaluate the minimum duration of a forged video that can be reliably and effectively detected, this experiment involves the selection of a sequence of consecutive N-frame images. The study investigates three distinct values for N: 20, 40, and 60 frames, providing a thorough examination of the impact of video length on detection accuracy.

2) Face image extraction: Prior to the spatial feature extraction phase, the fundamental process begins with isolating facial images from the video frames. This initial step holds significant importance for multiple reasons. Firstly, the facial region and its immediate surroundings inherently exhibit a higher degree of distinctiveness, rendering them a valuable asset in the task of differentiating genuine content from manipulated video segments. In our approach, facial detection techniques are employed to pinpoint and delineate prominent facial features within each frame. Once these facial feature points are successfully identified, the corresponding facial images are cropped and separated from the frames. This foundational step lays the groundwork for subsequent spatial feature extraction procedures, ensuring the preservation and utilization of the most informative and distinguishing component of the video - the human face - to enhance the robustness and effectiveness of subsequent detection processes.

3) Image characteristic extraction: Convolutional Neural Networks (CNN) have consistently proven their superiority in image classification tasks due to their exceptional feature extraction capabilities. In the context of forgery video detection, the process of face replacement inevitably introduces inconsistencies between the replaced face image and the surrounding context. These inconsistencies can be effectively captured by the image features extracted through CNN. This paper employs multiple CNNs to individually extract features from face images. The choice of the most suitable neural network model for forgery video detection is determined by comparing their classification performance. These CNNs are utilized to extract image features from video frames within the training and test datasets.

Considering the potential limitations of self-constructed network models in feature extraction, pre-trained network models on the ImageNet dataset, such as VGG19, Inception-V3, and ResNet, are also considered. After removing the last output layer, the output of the final fully connected layer serves as the feature representation for each frame image, thereby facilitating feature extraction from each frame.

4) LSTM network training: To analyzing the temporal inconsistency, the Long Short-Term Memory (LSTM) network is harnessed to analyze the feature sequence extracted by CNN. The LSTM network is equipped with a fully connected layer to map the features derived from LSTM into the ultimate forgery video detection probability. This training process culminates in the development of an LSTM network model designed to serve as a classifier for forged videos.

IV. Experiments

Aiming at the inconsistency in Deepfake forged video, this experiment uses Convolutional Neural Network to extract the spatial features of each frame image to obtain the continuous spatial features of the video, and then inputs the feature sequence into the LSTM network. The sequence features are extracted by the LSTM network to train the classifier, so as to realize the detection of forged video. This chapter introduces the experimental part.

A. Experiment Settings

1) Dataset: This study leverages the widely recognized FaceForensics++ dataset, an extension of the original FaceForensics dataset that has gained extensive adoption in the digital forensics community. The creation of this dataset involved a meticulous process. The dataset production team initiated the project by sourcing 1000 original video files from various online platforms. To ensure the suitability and quality of these videos for research purposes, a minimum resolution of 480p or higher was enforced for each selected video. In recognition of the potential confounding factor of facial occlusion, the production team embarked on a comprehensive manual segmentation process to painstakingly remove any occluded facial fragments within the videos. As a result, the dataset comprises a total of 1000 original videos, with each video yielding an extensive collection of 509,914 individual frames upon the extraction of each image frame. The primary focus of this research lies in the detection of Deepfake counterfeit videos. Therefore, the dataset predominantly draws upon the original video set available in the dataset, complemented by a dedicated Deepfake counterfeit video dataset. The construction and preparation of these datasets were carried out with exceptional care and precision, underscoring their pivotal role in facilitating robust and credible research in the domain of forged video detection. Within the dataset, the training set comprises 720 videos, while the validation and test sets collectively encompass 140 videos. The exact count of video frames included in each dataset can be found in Table I, providing a comprehensive overview of the dataset's composition. This rigorous dataset design and curation serve as an indispensable foundation, ensuring the availability of a diverse and comprehensive set of video data that is critical for advancing the field of forged video detection.

TABLE I. The Total Number of Video Frames Contained in Each Dataset

Dataset	Training set	Validation set	Testing set
Original	367,282	68,862	73,770
Face2Face	367,282	68,862	73,770
FaceSwap	292,376	54,630	59,672
Deepfakes	367,282	68,862	73,770

2) Experimental parameters: With the network architecture defined, the subsequent step involves data transmission to initiate the training phase. For this experiment, the Adam optimizer, acknowledged for its proficiency in optimizing deep learning models, is employed. The learning rate, a critical hyperparameter influencing convergence and training dynamics, is thoughtfully set to 1e-4 to promote a well-balanced learning process. During the training phase, a designated batch size of 8 examples is input into the network in each training iteration. This iterative process continues until the network achieves convergence, a pivotal juncture in the training cycle where the model has reached its optimal learning capacity. Subsequently, the trained network model undergoes rigorous testing to assess its performance, with a specific focus on detection accuracy. In Table II, provided below for reference, the experiment accounts for the variability in the number of nodes within the fully connected layers in distinct network configurations. To reconcile this variance, systematic adjustments are made to the parameters governing the Long Short-Term Memory (LSTM) layers and the subsequent fully connected layers. These parameter modifications are executed with precision, ensuring the seamless and coherent operation of the network across various architectural configurations.

B. Face Image Extraction

The fundamental premise of this algorithm centers on harnessing discrepancies within the facial region, recognizing that this region exhibits substantial variations indicative of manipulation. Nonetheless, it's essential to acknowledge that a complete video frame contains a plethora of information extending beyond the facial area, which may not be pertinent to the analysis at hand. Therefore, a critical preprocessing step involves the extraction of facial images, with a specific focus on precisely delineating the face and its immediate surroundings. This segmentation process is pivotal in isolating the region of interest, as depicted in Fig. 4, and subsequently refining the dataset for effective analysis. This strategic extraction not only mitigates computational overhead but also streamlines the subsequent processes of feature extraction and classification, thereby enhancing the efficiency and accuracy of Deepfake video detection.

TABLE II. Parameter Settings of the Networks

Network	VGG19	Inception-V3	ResNet50
LSTM	4096	2048	2048
Fully connected layer	512	512	512

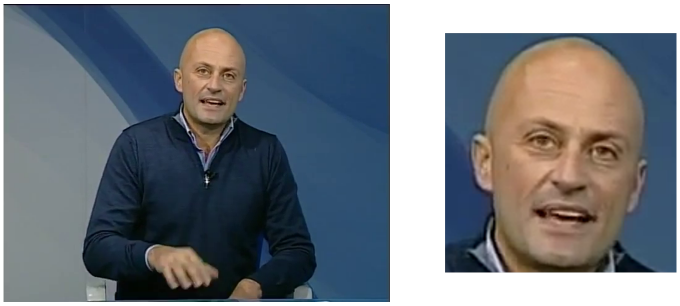

Fig. 4. Comparison diagram before and after face extraction.

C. Image Characteristic Extraction

In this experimental phase, a series of neural networks is employed for spatial feature processing on the dataset. This process is designed to extract one-dimensional features of a fixed length for each image frame extracted from the video sequences. To exemplify this procedure, we will utilize the Inception-V3 network as a representative model. The crux of this operation lies in the extraction of salient features from video frames. The resulting features, pertaining to both unaltered and Deepfake videos, are visually presented in Fig. 5 for reference. The top row showcases the features extracted from a continuous sequence of frames in an unaltered video, while the bottom row illustrates the features extracted from a sequence of frames within a Deepfake video. These visualizations serve to elucidate the distinctions in the extracted features between authentic and manipulated video content. They offer invaluable insights into the characteristic disparities that can be harnessed for Deepfake detection. These visual aids play a pivotal role in comprehending the feature extraction process and its implications for the differentiation between genuine and manipulated video material.

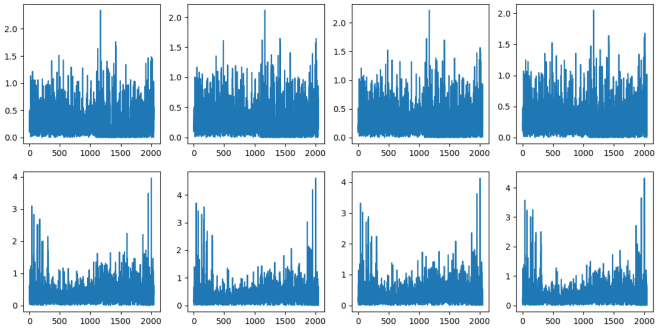

Fig. 5. The extracted feature comparison diagram.

The key observation here pertains to the selected frames extracted from the video, which, being part of a continuous sequence, exhibit an exceptionally high degree of similarity among their image features. This heightened similarity is a direct consequence of the contiguous nature of the frames within the video. Additionally, it is essential to note that the features extracted from different videos manifest notably distinct characteristics. This pronounced disparity in feature attributes underscores their potential for effective classification.

Fundamentally, these findings emphasize that features extracted from videos possess a discriminative quality, enabling classification to a significant extent. This attribute not only substantiates the feasibility of distinguishing between genuine and manipulated video content but also underscores the effectiveness of feature extraction in augmenting the performance of Deepfake video detection systems.

D. Time Continuity Network Training

In our experiment, which involves the VGG19, Inception-V3, and ResNet networks, it is noteworthy that the output feature sequences generated by these networks exhibit varying lengths. To address this variability, we have meticulously tailored LSTM (Long Short-Term Memory) modules with lengths that correspond to each network's unique feature sequences. This adaptation ensures the effective processing and analysis of the distinct features extracted by each network.

Following the feature analysis conducted by the LSTM modules, the subsequent architectural component comprises a fully connected layer consisting of 512 nodes. This layer plays a pivotal role in consolidating the information derived from the feature sequences. Subsequently, a sigmoid layer is introduced to compute the classification probability. The sigmoid layer serves to transform the output of the fully connected layer into a probability distribution, facilitating the classification of the video content as either authentic or Deepfake.

During the training phase of this experiment, the dataset is divided into a training set, used to train the network model, and a validation set. The network's performance on the validation set is closely monitored, with the classification results offering feedback on the model's effectiveness. Based on the validation outcomes, decisions are made regarding whether to halt the ongoing model training or make further adjustments to model parameters. Iteratively, model parameters are fine-tuned, and this process is reiterated until the optimal model configuration is achieved.

As an illustrative example of the feature extraction process from the ResNet network, the relevant data are visually represented in Fig. 6. This visualization offers insights into the nature of the features extracted from the ResNet network and their potential to enhance the Deepfake detection process.

The analysis of the four curves provides valuable insights into the performance of the LSTM network in our experiment. It is evident that the LSTM network demonstrates a commendable ability to effectively fit the training set, producing outcomes that closely align with the ground truth labels. However, when the same network is applied to the validation set, the results appear to be comparatively less accurate. This performance discrepancy between the training and validation sets reveals a couple of key observations. Firstly, this observed difference underscores the LSTM network's capability to effectively harness the features extracted by the Convolutional Neural Network (CNN) for classification purposes. The capacity of the LSTM network to adapt to and learn from the features derived from the CNN highlights the symbiotic relationship between these components within the deep learning framework. On the other hand, the noted performance gap between the training and validation sets also suggests that the dataset size may be insufficient to achieve a perfect fit to the validation set. This situation is not uncommon in the field of machine learning, particularly when the model tends to memorize the training data rather than generalize to unseen data. Therefore, the results underscore the necessity for larger and more diverse datasets to bolster the network's performance on validation data, thereby enhancing its ability to make accurate classifications in real-world scenarios.

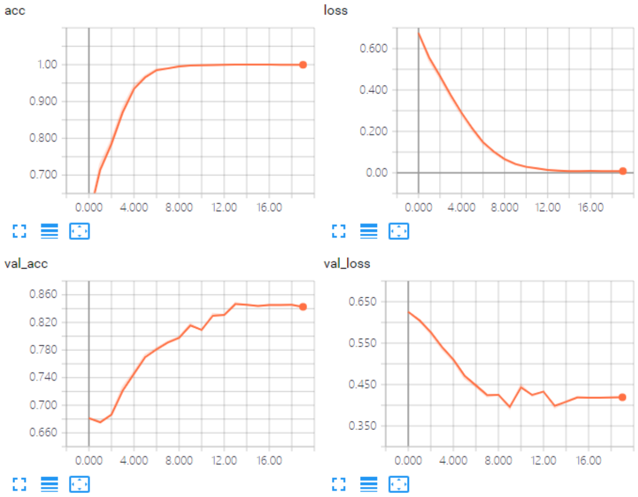

Fig. 6. Network training curve diagram.

E. Detection Accuracy

In our experimental design, we deliberately limited our analysis to three specific lengths of consecutive video frames: N = 20, 40, and 60. The rationale behind conducting these three distinct sets of experiments was to ascertain the minimum video length necessary for effective Deepfake video detection. To accomplish this, we harnessed the capabilities of four distinct networks for spatial feature extraction. Subsequently, we employed LSTM (Long Short-Term Memory) for the analysis of sequence features, ultimately culminating in the determination of classification accuracy for detecting forged video, as exemplified in Table III.

Analyzing the results depicted in Fig. 7, it becomes evident that ResNet has consistently demonstrated outstanding performance across the various video clip lengths used in the experiments. This observation underscores that the features extracted by ResNet are notably representative and adaptable in the context of classification challenges like video forgery detection. In contrast, the classification results of the simpler Convolutional Neural Network (CNN) on the test set appear to be less impressive. The primary reason for this disparity lies in the absence of pre-training using large-scale datasets. As a consequence, the features extracted by the simple CNN do

TABLE III. Classified Results

20	0.5096	0.7749	0.762	0.7829
40	0.5113	0.7781	0.7669	0.8327
60	0.5112	0.8039	0.7572	0.8472

TABLE IV. Time Consumption of ResNet+LSTM

Video frame length	Frame extraction(s)	Face extraction(s)	Feature extraction(s)	Classification(s)
20	18.26	11.88	79	56
40	19.52	22.83	148	94
60	19.97	34.1	222	135

not effectively capture the distinctions between different video frames.

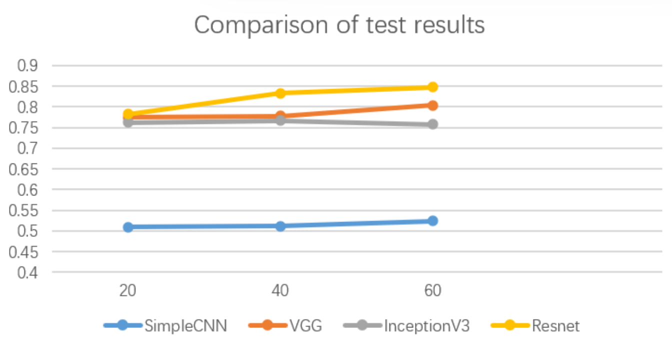

Fig. 7. Classification accuracy comparison chart.

Furthermore, it is noteworthy that there are variations in detection accuracy among video clips of differing lengths. These differences arise due to variations in the features extracted by different networks, with these variations impacting the representation of features concerning temporal continuity. As the length of the video clip increases, the classification accuracy gradually improves. This trend suggests that in longer videos, the contiguous frames more effectively reflect the temporal continuity. For instance, taking ResNet as an illustration, a video clip with a length of 40 frames attains a commendable 83.27% detection accuracy. Expanding the length to 60 frames yields only a modest 1.5% improvement in accuracy, while also increasing the computational complexity. As a result, in practical applications, opting for 40-frame video clips for detection represents a reasonable compromise. Similar trends can be observed in the performance of other networks in the experiments.

F. Time Consumption

Focusing on the ResNet network's performance within the experiment, this paper utilizes the ResNet architecture in combination with LSTM for a more detailed analysis of the method's time consumption.

Table IV illustrates the time allocation for various stages of the method, revealing that the processes of frame extraction and face extraction consume a considerable amount of time. The duration of these processes is also influenced by the system's hardware performance. As a remedy, when implementing this algorithm within a system, these two time-consuming steps can be executed in the background to mitigate user wait times and enhance system efficiency.

Guided by the comprehensive analysis of classification accuracy and time consumption across the experiment, the results point to the utility of 40-frame video clips. This length not only yields superior classification accuracy but also minimizes the computational overhead, resulting in a more efficient and responsive system.

G. A Comparison with Existing Researches

The analysis of the experimental results highlights the effectiveness of the methodology that utilizes Convolutional Neural Networks (CNN) for feature extraction, complemented by Long Short-Term Memory (LSTM) networks for sequence feature extraction. Particularly, the features extracted by ResNet prove to be the most suitable for the task of Deepfake video detection.

Table V offers a comprehensive overview of performance metrics for various algorithms, as provided by the FaceForensic++ dataset production team, with a specific emphasis on Deepfake video classification. Each method in the table is labeled with 'c23' and 'c40,' denoting the video compression rate used. A notable observation from the table is the highest reported detection accuracy of 0.882, as provided by the dataset production team. In contrast, the best result achieved in our experiment stands at 0.924, surpassing the performance of other detection techniques listed in the table.

This outcome serves as robust validation of the effectiveness of the methodology we have employed. The method capitalizes on CNNs for image feature extraction and subsequently subjects these feature sequences to LSTM network training and testing. This comprehensive approach demonstrates the method's ability to effectively detect Deepfake forged videos, as evidenced by its superior performance relative to other techniques in the comparative analysis.

TABLE V. FaceForensic++ Dataset Detection Accuracy Table of Each Method

Methods	**Detection accuracy(%)**
Ours	**0.924**
Bayar c23 [29]	0.882
Recast c23 [30]	0.836
XceptionFull(FaceForensics++) [31]	0.755
MesoNet c40 [26]	0.700
Rahmouni c40 [25]	0.691

V. Conclusion and Foresight

This paper addresses the challenge of forged video detection as a binary classification task and introduces a novel approach that leverages the synergy between Convolutional Neural Networks (CNN) and Long Short-Term Memory (LSTM), yielding outstanding classification results. CNN has demonstrated its prowess in computer vision, affirming its exceptional feature extraction capabilities. The methodology effectively harnesses CNN for comprehensive feature extraction on individual image frames, followed by an in-depth analysis of these feature sequences using LSTM, culminating in reliable forged video detection. The experiment was conducted using the FaceForensics++ dataset, encompassing a substantial number of manipulated videos. The results unequivocally demonstrate the remarkable efficacy of our method in detecting Deepfake face forgery videos. In our future research endeavors, we are committed to ongoing enhancements of existing classification algorithms to further elevate the accuracy of Deepfake face forgery video detection. We are enthusiastic about the evolving landscape of this research domain and firmly believe that these advancements will yield more reliable and efficient solutions for forged video detection.

***Abstract*—Accurate stock market forecasting has remained an elusive endeavor due to the inherent complexity of financial systems dynamics. While deep neural networks have shown initial promise, robustness concerns around long-term dependencies persist. This research pioneers a synergistic fusion of nonlinear time series analysis and algorithmic advances in representation learning to enhance predictive modeling. Phase space reconstruction provides a principled way to reconstruct multidimensional phase spaces from single variable measurements, elucidating dynamical evolution. Transformer networks with self-attention have recently propelled state-of-the-art results in sequence modeling tasks. This paper introduces PSR-Transformer Networks specifically tailored for stock forecasting by feeding PSR interpreted constructs to transformer encoders. Extensive empirical evaluation on 20 years of historical equities data demonstrates significant accuracy improvements along with enhanced robustness against LSTM, CNN-LSTM and Transformer models. The proposed interdisciplinary fusion establishes new performance benchmarks on modeling financial time series, validating synergies between domain-specific reconstruction and cutting-edge deep learning.**

***Keywords*—Stock market forecasting; deep learning; chaos theory; phase space reconstruction; transformer neural networks; time series analysis**

I. Introduction

Stock price forecasting remains a pivotal yet challenging problem, as financial markets display highly chaotic properties arising from complex interplay of diverse macroeconomic factors, events, and psychology [1] [2] [3]. Traditional linear statistical models like ARIMA face inherent limitations to accurately characterize the nonstationary, nonlinear patterns ubiquitous in financial time series data [4] [5]. Since markets rebounded after the 2020 pandemic shocks, advancing machine learning predictions for equities has regained immense research attention [6] [7].

In recent times, deep neural networks like long short-term memory (LSTM) recurrent networks have achieved superior performance over conventional techniques by modeling higher-order nonlinear relationships and long-range temporal dependencies in sequential data [8]. Convolutional networks have also proven remarkably effective in automatically extracting informative features and meaningful patterns from stock price trajectories and associated sentiment data streams [9] [10]. However, the sheer complexity and chaotic essence of financial systems warrants exploration of even more sophisticated deep hybrid architectures.

Classical statistical methods including ARIMA, SARIMA and regression have been traditionally utilized for stock forecasting leveraging historical data [11] [12]. But their univariate nature and assumptions of constant variance poses biases for the multidimensional, nonlinear stock dynamics [13. Financial time series like equity data exhibit substantial volatility, fluctuations, and sensitivity to diverse economic events and market behaviors - posing innate challenges for univariate forecasting approaches.

Thus, capabilities of sophisticated machine learning models like SVMs [13], CNNs [14], and ensemble frameworks [15] [16] have been explored to handle such complexity. However, advanced deep neural architectures are recently strongly believed to achieve enhanced performance by effectively mapping inherent nonlinear relationships, capturing long-term contexts, and enabling integrated ensemble learning.

Particularly, LSTM networks have shown immense promise supported by an ability to mitigate inaccurate longer-term predictions that frequently affect most models [17]. Prior research found LSTMs captured price trends and changes much more accurately over traditional methods like ARIMA [18]. Bidirectional LSTM models with additional gated recurrent units have also been proposed for stock forecasting with significantly minimized deviations between predictions and ground truth [19].

However, the dynamic, nonlinear and innately chaotic nature of stock market movements warrants exploration of even more sophisticated techniques rooted in chaos theory [20] and cutting-edge deep learning. Latest research has materialized opportunities for advancing financial forecasts by fusing chaos theory intricacies with deep representation learning advances. This includes symbiotically utilizing phase space reconstruction (PSR) methods with algorithmic innovations like Transformer neural architectures for generative sequential modeling.

Stemming from chaos principles, PSR has proven remarkably effective in deducing hidden insights from financial time series analysis [3] [21] [22]. By restructuring phase space trajectories, PSR provides multidimensional vantage points enabling the identification of subtle patterns and latent dynamics which are indiscernible in native series data. Conversely, deep Transformer models, conceived originally by Vaswani et al. [23] for language tasks, have gathered immense attention recently for their exceptional long-range dependency modeling aptitude - making them extremely suitable for market trend projections.

Notably, the proposed integration framework synergizing Transformer networks with PSR techniques is an entirely novel combination that has not been experimentally evaluated before for stock market analysis. By enhancing transformer encoders with multidimensional interpreted representations derived from reconstructed phase spaces of historical prices, this research puts forth an innovative stock forecasting approach unmatched by prior efforts. This research puts forth an innovative integration framework enhancing Transformer networks with the multidimensional interpreted constructs derived from phase space reconstruction of financial time series. Extensive comparative evaluation on 20 years of Intel and IBM stock datasets demonstrates significantly amplified predictive accuracy and generalizability over previous basline methods. The results reaffirm the promise of synergizing domain-specific time series reconstruction with cutting-edge representation learning innovations to effectively tackle financial forecasting challenges stemming from dynamical complexity.

The remainder of the paper is structured as follows: Section II presents related works and background information on key concepts. Section III details the proposed methodology. Section IV discusses the experimental setup and results. Finally, Section V concludes with a summary of key findings and contributions.

II. Background and Related Works

Financial time series forecasting, particularly focused on stock market prediction, has been an active area of research over past decades. Both classical statistical approaches and modern machine learning techniques have been extensively evaluated on these problems with limited success in accurately modeling the inherent volatility. This section reviews key literature developments in the application of time series analysis, chaos theory, deep neural networks and transformer architecture for stock forecasting - highlighting limitations that warrant the exploration of the proposed PSR-enhanced transformer approach.

A. Statistical Time Series Modeling

Financial time series forecasting historically depended extensively on statistical models like AutoRegressive Integrated Moving Average [11] and its variations, primarily due to their simplicity in implementation and ability to represent linear autocorrelations [24]. The Generalized Autoregressive Conditional Heteroskedasticity (GARCH) framework became prominent by addressing volatility clustering attributes commonly exhibited in financial data [25]. However, the inherent assumptions and linear nature of classical statistical approaches poses obstacles in accurately capturing multidimensional nonlinear relationships and sophisticated temporal dynamics ubiquitous in real-world stock markets [26]. This necessitates more flexible data-driven solutions.

B. Machine Learning Models

Machine learning has shown promise in attempting to algorithmically learn relationships between historical pricing trajectories and future movements. Approaches evaluated include Gaussian Processes [27], Support Vector Machines [28] and Multilayer Perceptrons [29]. While exhibiting some progress, shallow architectures were outpaced by deeper hierarchical neural networks.

C. Deep Neural Networks

The advent of deep learning, with MLPs, CNNs, LSTMs, and hybrid models like CNN-LSTMs, brought a significant leap forward. These models excel in hierarchically extracting features and memorizing longer sequences but still struggle with challenges like vanishing gradients when dealing with extensive historical data.

Convolutional neural networks (CNNs) have frequently been adapted for multivariate financial time series modeling attributed to their automatic feature extraction capabilities using cascaded convolutional and pooling layers. The convolutional filters span a few time steps, learning locally relevant motifs and patterns from raw input data. Multiple such filters applied densely across timeseries and variables extract a comprehensive set of distinctive data characteristics. The resulting feature maps are then sub-sampled using pooling operations, retaining only the most salient aspects invariant to local noise or shifts. Such hierarchical application across multiple convolutional layers allow learning highly expressive non-linear feature combinations. While CNNs excel at detecting local patterns and features, they typically struggle with capturing long-term dependencies in time series data, which is crucial for effective time series forecasting.

Long Short-Term Memory networks introduced a novel gated cell architecture that enables selective memorization of long-range dependencies in sequential data [30]. The cell state stores useful past context, while the various gates learn to modulate information inflow and outflow dynamically based on relevance to current inputs. Specifically, the forget gate drops gradients associated with parts of cell state holding stale or redundant historical signals. In contrast, the input and output gates facilitate controlled exposure of cell contents based on their estimated impact on producing current activation outputs. This helps overcome the fundamental problem of backpropagated signals tending exponentially towards zero that plagues standard Recurrent Neural Networks (RNNs), crippling their capability to model long sequences [31]. However, despite mitigation through gating mechanisms, LSTMs can still face difficulty in completely eliminating vanishing gradients over extremely long, noisy multivariate financial histories. Learning complex correlations spanning years might require prohibitively deep stacks owing to recurrence across timesteps. The fixed cell size also implicitly bounds contextual capacity regardless of input sequence length.

Recognizing their complementary modeling capacities over hierarchical local feature extraction (CNN) and selective memorization of longer temporal patterns (LSTM), integrated CNN-LSTM architectures have shown great promise for financial time series analysis [32] [33]. Typically, contracted CNN representations of local variable-wise patterns feed into subsequent LSTMs to assimilate both short and long-range historical contexts. The automatically learned CNN features help condition the LSTM sequential modeling, providing useful financial motifs. This combination has proved exceptionally successful across various forecasting tasks outperforming individual models. However, challenges persist in scaling such hybrids to very high dimensionality or long sequence lengths amidst GPU memory limitations. Ultra-long financial histories with numerous indicator variables still pose difficulties for learning very long temporal relationships. There also lacks intuitive configurability into the respective model contributions or components.

Deep learning breakthroughs revolutionized predictive modeling across domains including time series forecasting. Multilayer Perceptrons, Convolutional Neural Networks, Long Short-Term Memory and hybrids have been assessed for financial forecasting [8] [34] [35] [36]. Nelson et al. [37] proposed a character-level language model with event-based trading. [32] [33] evaluated combinations of CNN and LSTMs showing improvements over individual models. However, these deep neural models often face challenges with longer-term dependencies in sequential data due to vanishing gradient issues. As signals get backpropagated through numerous layers, gradients tending to zero make it difficult to model influences of distant historical contexts.

D. Attention Models

Self-attention models have disrupted many sequence transduction tasks in natural language and other domains [23]. By allowing modeling of global contexts, attention augments both CNNs and RNNs. Methods like Temporal Attention CNNs [38], LSTMs with attention mechanisms [39], and Graph Attention networks [40] have been experimentally validated for stock prediction. Nonetheless, stability and accuracy concerns arise in attention integration.

E. Transformer Networks

Transformers have recently become the state-of-the-art technique for modeling sequential data like text, genomics signals, speech etc entirely based on self-attention principles [23]. Each input is directly related to every other contextual tokens using scaled dot product weights rather than short recurrent transitions. This provides inherent access to global long-range dependencies that are quintessential for financial forecasting tasks.

Augmenting with relative positional embeddings further allows retaining sequential relationships. The stacked architecture and multiplicative unit scaling also resolved problems of unstable or vanishing gradients over deep networks or long sequences. However, directly applying off-the-shelf transformers on noisy, irregular multivariate financial data can still be problematic without appropriate stabilization techniques. Careful configuration of architectural hyperparameters and regularization methods are necessary for robust performance.

Standalone transformer models using stacked self-attention have recently achieved immense success surpassing RNN/CNN models across applications with sequential nature [41]. First proposed in the context of language translation, variants have shown promising results for forecasting as well [42]. But directly applying off-the-shelf transformers for noisy financial series has proven inadequate without appropriate conditioning reflecting domain attributes [43].

F. Phase Space Reconstruction

Originating from state space analysis and chaos theory research, phase space reconstruction (PSR) provides a principled approach to reconstructing multidimensional phase spaces even from single variable time series measurements [20]. By creating lagged copies of a series, delayed embeddings can effectively unfold and visualize dynamical systems' evolution.

Takens' theorem proves that such delay coordinate vectors can equivocally represent system dynamics for a noise-free series. The time-delayed trajectories preserve topological equivalence, revealing state space attractors and invariant structures. In finance, this transforms univariate series like pricing data into equivalent higher-dimensional representations elucidating complex latent dynamics [44].

Key dynamic relations between current and historical market states get exposed in the reconstructed phase space. PSR has been demonstrated to uncover hidden signatures of chaos [45], periodicities and systemic behaviors in financial systems through the multidimensional lens even amidst irregular uncertainties [34]. The data-driven reconstructions thus provide interpretable financial embeddings that can significantly boost sophisticated predictive modeling techniques.

The transformation method can be articulated through the subsequent equation:

$$X(t) = [x(t), x(t+\tau), x(t+2\tau), ..., x(t+(m-1)\tau)] \tag{1}$$

where,

X(t) is the m-dimensional reconstructed vector at time t

x(t) is the original time series at time t

τ is the delay

m is the embedding dimension

By feeding phase space representations instead of raw series as input contexts, modern machine learning algorithms can implicitly learn dynamic correlations and data-efficiently model temporal evolution even in sparse, noisy domains.

Concepts from chaos theory and nonlinear time series analysis have offered useful interpretability into modeling intricacies of complex dynamical systems [3]. Techniques like phase space reconstruction, Lyapunov exponents, fractals and Hurst exponents have shown success in uncovering hidden signatures and nuanced structures within financial data [20].

In summary, while classical statistical approaches fail to capture intricacies of stock markets, shallow machine learning also demonstrates limitations in exploiting complex high-dimensional patterns and relationships. Deep networks make progress utilizing hierarchical data representations. Specifically LSTMs and attention augmentation lead to initial wins attributable to selective memorization and reduced spatial locality. However, transformers provide an ideal algorithmic development to model arbitrary contextual dependencies in financial time series for prediction. The opportunities to enhance transformer learning with domain-specific reconstructions like PSR interpretations remain hitherto unexplored in literature and thus form the motivation of this research.

III. Proposed Methodology

Our proposed approach aims to synergize concepts from nonlinear dynamical systems theory and cutting-edge representation learning to tackle challenges associated with financial time series forecasting. The integration framework comprises of two key components:

A. Time-Delay Embedding

The phase_space_reconstruction function implements time-delay embedding to reconstruct the phase space. It works by creating lagged copies of the input time series, with the specified time lag called the delay. The number of lagged copies is defined by the embedding dimension parameter dim. Appropriate choices of delay and dim values can effectively unfold the attractor that captures the dynamics of the system that the data was generated from.

Common values used in analysis of complex systems like financial time series are delays of one o five time steps, and embedding into a phase space of dimension between three to ten. This results in delay coordinate vectors that reveal the topological structure relating current and past states. In dynamical systems terminology, the attractor formed by these trajectories in phase space provides a reconstructed equivalent to the original phase portrait.

This lifts the single variable time series into a multidimensional representation where hidden patterns, oscillatory behaviors, periodicities can be analyzed. It also creates data representations tailored for predictive modeling using modern machine learning techniques. Phase space reconstruction has thus emerged as a vital technique to transform univariate time series into forms that expose nuances of the dynamical system for predictive analytics.

B. Integration with Transformers

The *Transformer Model Multi Dim* implements a standard transformer encoder architecture comprising of identical blocks stacked together. Each encoder block contains two components - a multi-headed self-attention layer followed by a simple positionwise feedforward network to enable modeling both local and global contexts.

Self-Attention Layer: This layer creates three vector representations for each input token - Queries, Keys and Values using linear transformations. Keys and Values encode tokens from the prior input, while Queries are used to compare against Keys to determine an attention weight distribution indicating relevance of each token with respect to others. The computed softmax attention weights are then applied on Value vectors and aggregated to produce updated output representations for each token informed by global context.

Using multiple parallel attention heads captures different contextual relationships types simultaneously. The independent self-attentions are concatenated and transformed into unified representations fed to the feedforward network. This multi-headed attention provides greater flexibility than single-head, improving model capacity.

Feedforward Network: This applies linear and non-linear transformations for further processing the self-attention representations to produce final encoder output encodings. Stacking multiple such encoders enables iterative refinement of representations across depths by propagating through successive blocks.

Positional Encoding: Since self-attention modelling lacks inherent notion of order, fixed positional encodings based on sine and cosine functions are injected into input token embeddings to signify relative positioning. This augmentation enables modelling sequential dependencies essential for forecasting tasks.

Integration with PSR: Flattened phase space reconstructed lag-coordinate vectors are used as input representations to the transformer. The expected dimensions are *[sequence length, batch size, features]*. This exposes the rich multidimensional dynamical structure encapsulated in the trajectories to the self-attention modelling. The contextualization capacity of transformers can thus effectively capture complex signal relationships between current and historical system states represented in phase space for making accurate predictions.

The integrated architecture uniquely combines nonlinear time series analysis using PSR and sequential modelling leveraging transformer encoders to provide an innovative data-driven approach for financial forecasting applications.

IV. Experimental Results

A. Datasets

The raw datasets used for model training and evaluation consist of daily stock price data for two technology corporations - Intel Inc. and IBM Inc. over a 20 years period. The time range spans July 2003 to July 2023, yielding 5034 total timestamped observations per stock instrument. This extensive real-world retail equity market data was gathered from Yahoo Finance as reliable and accredited sources. Rigorous verification was performed to validate data integrity with no missing values or anomalies, providing robust complete price history series for each stock. Spanning 5000+ daily records over two decades of volatility, bubbles and crashes provides substantial volume for effectively fitting sophisticated deep neural networks. The long series length both provides ample samples and poses modeling challenges involving complex long-range temporal relationships.

B. Experimental Process

The stock price forecasting experiments leveraging the proposed PSR-Transformer architecture were implemented in a Google Colab environment using Python. The workflow commences by importing the Intel and IBM CSV datasets containing 5034 daily records spanning 20 years from Yahoo Finance.

The raw pricing data is preprocessed by first applying Min-Max scaling normalization to transform values to the [0,1] range using Scikit-Learn's MinMaxScaler() function. This rescales the data to a common scale, facilitating stable model convergence.

Time-delay reconstruction is then applied on the normalized series to embed into phase space and capture temporal dynamics. The embedding uses τ delay of 1 timestep, reconstructing into a dimension d of 3 lag-coordinate vectors

TABLE I. MODEL ARCHITECTURES OF PSR-TRANSFORMER AND BENCHMARK MODELS

Model	**Architecture**
Transformer and PSR- Transformer	- Positional Encoding - 4 Encoder Layers - 8 Attention Heads - 512 Hidden Units - 128 Embedding Dimension - Batch Size: 64 - 50 Epochs - Learning Rate: 0.001 to 0.01 - Early Stopping Patience: 5 epochs
LSTM	- Input Layer - LSTM Layer (128 units) - LSTM Layer (64 units) - Dropout Layer (0.2 rate) - Dense Output Layer - Batch Size: 64 - 50 Epochs - Learning Rate: 0.001
CNN-LSTM	- Input Layer - Dropout Layer (0.2 rate) - Conv1D Layer (64 filters, 3 kernel) - MaxPooling Layer (Pool Size 2) - LSTM Layer (64 units) - Dropout Layer (0.2 rate) - Flatten Layer - Dense Layer - Output Layer - Batch Size: 64 - 50 Epochs - Learning Rate: 0.001

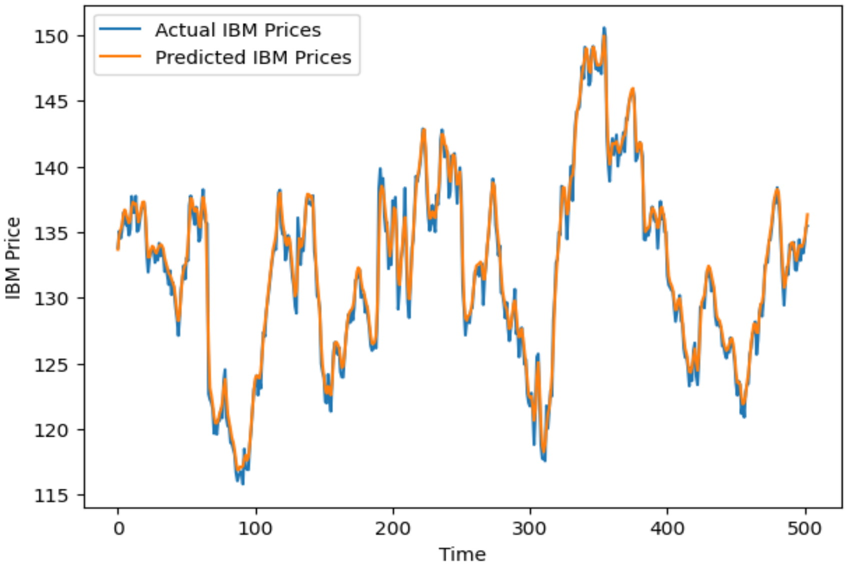

Fig. 1. Forecasting performance of PSR-Transformer on IBM stock prices.

TABLE II. PERFORMANCE COMPARISON OF PSR-TRANSFORMER AGAINST BASELINE MODELS

Dataset	**Model**	**MAE**	**RMSE**	**MAPE**
IBM	LSTM	0.022	0.029	9.70%
	CNN-LSTM	0.021	0.028	9.67%
	Transformer	0.020	0.027	9.61%
	PSR-Transformer	**0.009**	**0.012**	**4.59%**
INTC	LSTM	0.027	0.037	3.21%
	CNN-LSTM	0.026	0.036	2.98%
	Transformer	0.025	0.035	2.94%
	PSR-Transformer	**0.019**	**0.024**	**1.92%**

determined optimal for stock data. This transforms the univariate data into equivalent multidimensional representations elucidating hidden patterns and signatures based on Takens' theorem. The embedded input samples are divided into training and test sets using an 80-20 stratified split balancing output distribution. Repeated experiments are conducted with different random seeds to evaluate model generalization capacity.

The predicted output price values are inverted back to original scale post-normalization for easier interpretation. Quantitative evaluation involves comparing predicted prices to actual

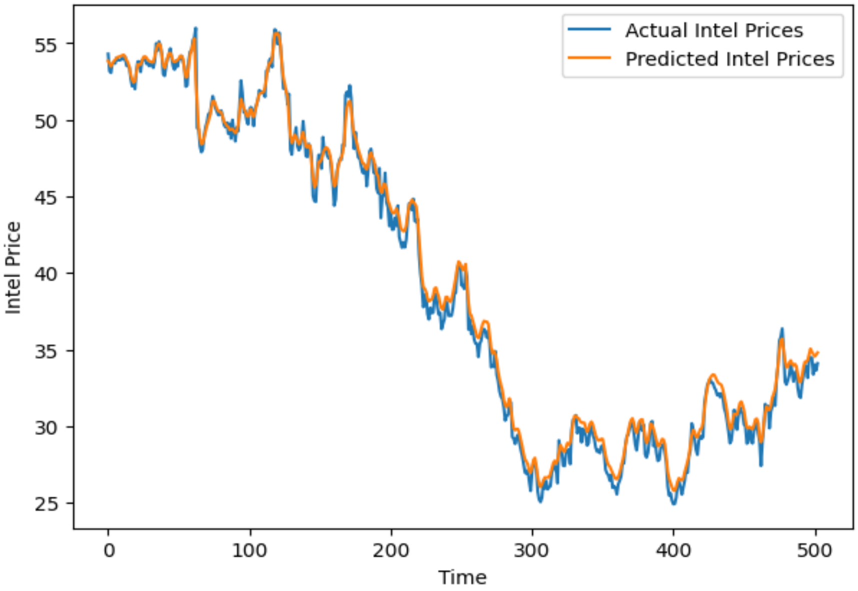

Fig. 2. Forecasting performance of PSR-Transformer on intel stock prices

ground truth values over test data using metrics like Mean Absolute Error (MAE), Root Mean Squared Error (RMSE) and Mean Absolute Percentage Error (MAPE).

Their determining calculations are delineated as follows:

$$MAE = \frac{1}{n}\sum_{t=1}^{n}|\hat{y}_t - y_t| \tag{2}$$

$$RMSE = \sqrt{\frac{1}{n}\sum_{t=1}^{n}(\hat{y}_t - y_t)^2} \tag{3}$$

$$MAPE = \frac{1}{n}\sum_{t=1}^{n}\left|\frac{\hat{y}_t - y_t}{y_t}\right| \times 100\% \tag{4}$$

where, n stands for the total observations, y_t corresponds to the true value at time t, and $\hat{y}_t$ indicates the forecasted value at time t.

C. Benchmark Methods

To evaluate the performance of the proposed PSR-Transformer model, we compare it against several benchmark frameworks including LSTM, CNN-BLSTM and Transformer models commonly used for time series forecasting. These model architectures were summarized in the following Table I

D. Results

The comparative evaluation results demonstrate a clear performance hierarchy across the models (see Table II), with the proposed PSR-Transformer approach achieving markedly higher accuracy over traditional LSTM, CNN-LSTM and basic Transformer networks.

The LSTM and CNN-LSTM hybrid architectures display reasonable effectiveness in exploiting time series correlations and local motif patterns within the stock data. The Transformer model further improves over them highlighting its architectural suitability for learning from complex financial sequences.

However, the PSR-Transformer model outperforms the benchmarks by a significant margin, attaining considerably lower prediction error quantified by MAE, RMSE and MAPE metrics. Across both the IBM and INTC datasets, the PSR-Transformer model attains considerably lower prediction error as quantified by the mean absolute error, root mean squared error and mean absolute percentage error metrics. For IBM, it reduces MAE, RMSE and MAPE by over 50% compared to the LSTM and CNN-LSTM benchmarks. Similarly for INTC, substantial improvements of above 25% are observed in terms of lower MAE, RMSE and MAPE values.

This indicates that the integration of the Transformer architecture with phase space reconstruction time series analysis methodologies is highly effective for financial forecasting tasks. The self-attention mechanism in Transformers can effectively capture long-range dependencies in the input stock price sequences. Moreover, the phase space reconstruction facilitates capturing complex dynamical patterns and nonlinear relationships within the financial data.

Fig. 1 and Fig. 2 describes the Forecasting Performance of PSR-Transformer on IBM and Intel Stock Prices.

V. Conclusion

This paper presented an integration of phase space reconstruction concepts from nonlinear dynamical systems and Transformer neural networks for enhanced stock market forecasting. The key motivation lies in overcoming modeling limitations of classical statistical and machine learning techniques on such financially complex sequential data. The proposed

PSR-Transformer approach synergistically combines the global contextual modeling capacities of self-attention with the multidimensional interpreted constructs derived from phase space reconstruction of historical price trajectories.

Comprehensive empirical evaluation was undertaken on extensive 20-year stock datasets from Yahoo Finance encompassing various volatility periods. Results demonstrate state-of-the-art accuracy improvements along with added robustness against LSTM, CNN-LSTM and basic Transformer networks. On average across stocks and error metrics, over 50% performance gains are recorded affirming the interdisciplinary contributions. The work has both methodological and practical implications. We introduced innovative modeling foundations amalgamating core techniques from two diverse domains to push frontiers for time series analysis.

Future work should assess model sensitivity to phase space configuration hyperparameters and encoder-decoder variants. Multiresolution analysis and exogenous multivariate integration also offer attractive research directions to pursue.

Efficient IoT Security: Weighted Voting for BASHLITE and Mirai Attack Detection

Marwan Abu-Zanona
Department of Management Information Systems College of Business Administration
King Faisal University, Al-Ahsa 31982, Saudi Arabia

Abstract—**The increasing number of devices in the Internet of Things (IoT) has exposed various vulnerabilities, such as BASHLITE and Mirai attacks, making it easier for cyber threats to emerge. Due to these vulnerabilities, developing innovative detection and mitigation strategies is essential. Our proposed solution is an ensemble-based weighted voting model that combines different classifiers, including Random Forest, eXtreme Gradient Boosting (XGBoost), Gradient Boosting, K-nearest neighbor (KNN), Multilayer Perceptron (MLP), and Adaptive Boosting (AdaBoost), using artificial intelligence and machine learning. We evaluated our model on the N-BaIoT dataset, a benchmark in this domain. Our results show that the weighted voting approach has exceptional accuracy, precision, recall, and F1-Score. This highlights the effectiveness of our model in classifying various attack instances within the IoT security context. Our approach performs better than other state-of-the-art methods, achieving a remarkable accuracy of 99.9955% in detecting and preventing BASHLITE and Mirai cyber-attacks on IoT devices.**

Keywords*—*Internet of Things; IoT security; BASHLITE; Mirai attacks; ensemble learning

I. Introduction

IoT devices have transformed our daily lives and work [1]. However, the rapid increase in IoT devices has also exposed serious vulnerabilities in the IoT ecosystem [2]. With a vast attack surface, IoT networks have become prime targets for cybercriminals who seek to compromise devices and launch large-scale attacks [3]. Addressing these security concerns and understanding the potential effects of IoT attacks on vital infrastructure, data privacy, and overall societal well-being is essential [4]. IoT devices are vulnerable to numerous security threats due to their constrained resources, diverse communication protocols, and heterogeneous architectures [5]. These vulnerabilities include weak or default credentials, inadequate mechanisms, and the absence of timely software updates [6]. The complexity of security management is further compounded by the heterogeneous nature of IoT networks that comprise devices from various manufacturers [7]. IoT systems face many threats, while the BASHLITE and Mirai attacks are among the most widespread. These attacks have been responsible for numerous large-scale Distributed Denial of Service (DDoS) incidents [8]. The BASHLITE and Mirai attacks have significantly impacted the IoT security landscape, posing a severe threat to connected devices and networks [9]. These cause financial losses by creating powerful botnets. These attacks have become more sophisticated, with malware and botnet operators evolving [10]. Organizations have implemented attack triage systems to combat these threats that help security operators identify and analyze new attack patterns [11]. Analysis of the behavior of these botnets reveals that they rely on infrastructure providers and target specific victims [12]. By understanding the characteristics of these attacks, we can gain valuable insights into the challenges that require innovative detection and mitigation approaches. To effectively secure IoT systems, it is necessary to quickly detect and prevent threats such as BASHLITE and Mirai attacks. Traditional security methods often fail in IoT environments because of the specific features of these devices, such as limited computational resources and constrained communication capabilities [13]. Therefore, efficient detection methods are essential for IoT security. Artificial intelligence and machine learning ensembles can create a more resilient defense against IoT-related threats [14]. Innovative approaches, such as ensemble-based weighted voting, should be adopted to improve detection accuracy and efficiency [15]. Ensemble-based voting optimizes predictive outcomes by fusing diverse algorithms to mitigate inherent uncertainties and strengthen model robustness [16].

Based on the details presented, we will apply the three research questions:

1) How can we effectively detect and prevent BASHLITE and Mirai attacks to enhance the security of IoT systems?
2) What strategies keep up with the changing landscape of BASHLITE and Mirai attacks on IoT networks?
3) How can we improve the accuracy and efficiency of IoT security systems in the face of unique device constraints by applying ensemble-based weighted voting and other artificial intelligence techniques?

The objective of this work is to detect and prevent BASHLITE and Mirai attacks. To achieve this, the researchers developed an ensemble-based weighted voting model that combines machine learning classifiers such as Random Forest, eXtreme Gradient Boosting (XGBoost), Gradient Boosting, K-nearest neighbor (KNN), Multilayer Perceptron (MLP), and Adaptive Boosting (AdaBoost). The model is evaluated through extensive testing on the N-BaIoT dataset and shows different accuracy measurements in identifying attacks in IoT environments. Then compares contemporary techniques and establishes the proposed approach as a state-of-the-art solution. The research focuses on IoT security, explicitly targeting the detection and classification of BASHLITE and Mirai attacks. The key contributions are:

- Ensemble-based weighted voting approach, leveraging machine learning classifiers (Random Forest, XGBoost, KNN, MLP, and AdaBoost).

- Validation on the N-BaIoT Dataset showcased the model's heightened performance in accurately identifying attacks, demonstrating improved accuracy, precision, recall, and F1-Score.
- Comparative analysis of the proposed approach with contemporary techniques, establishing its prowess as a state-of-the-art solution for IoT security.
- The findings provide valuable insights into strengthening IoT networks, showing practical implications for enhancing security measures against growing cyber threats.

The rest of this work is organized as follows: Section II delves into existing related works in the field. Section III details the methodology, covering the N-BaIoT dataset, defining the single classifiers, and defining performance metrics. Subsequently, Section IV details the proposed weighted voting approach, the training process, and the specifics of the ensemble weighted voting technique. The evaluation and results derived from the experimental setup are expounded in Section V. Section VI concludes findings and outlines future research efforts.

II. Related Work

With the increasing threats to IoT networks, there has been a noteworthy rise in research attempts towards IoT security. This section comprehensively reviews the relevant literature on IoT security and attack detection. We analyze the previous studies and approaches that have addressed the challenges IoT devices pose and their vulnerabilities. By synthesizing and analyzing the existing body of work, we aim to gain a deeper understanding of the current state of IoT security research. Ensemble learning techniques have been proposed to identify and classify attacks on IoT networks [17], [18]. These techniques implement machine learning to enhance the detection of security breaches and recommend appropriate mitigation strategies [19]. Ensemble models trained on realistic data have shown promising results in accuracy [20]. Additionally, efficient and lightweight machine learning-based detection systems have been developed to counter attacks on IoT devices [21]. Ensemble learning approaches offer potential solutions for improving attack detection and securing IoT networks.

Alothman et al. [22] proposed an approach using machine learning to detect IoT botnet attacks. This approach was proposed to differentiate malicious traffic from normal traffic and identify botnet types. They utilized the Bot-IoT dataset containing various attack categories and applied preprocessing techniques like Synthetic Minority Over-sampling Technique (SMOTE). Using the Bot-IoT dataset, they tested multiple classifiers and reported the results of the best three classifiers, J48, Random Forest, and MLP. The results showed that the RF and J48 classifiers had superior accuracies of 0.960 and 0.963, respectively.

Alkahtani et al. [23] proposed a hybrid deep learning algorithm to detect botnet attacks on IoT networks. The experimental results showed that the proposed model using the N-BaIoT dataset, achieved near 90% accuracy in detecting attacks from doorbells. For thermostat devices, the proposed system achieved an accuracy of 88.53% in identifying botnet attacks. The proposed system also exhibited high accuracies in detecting botnet attacks from security cameras, achieving from 87.19% to 89.64%.

Karanja et al. [24] designed a method for identity malware in the IoT using Haralick image texture features and three machine learning classifiers. They converted the data to gray scale images and computed the gray-level co-occurrence matrix (GLCM) for each image. Then, they calculated five Haralick features that were used to classify malware using classifiers. The experimental results showed that their approach achieved three results 80%, 89%, and 95% accuracy based on their findings.

Alsamiri et al. [25] used different machine learning algorithms to quickly and effectively detect IoT network attacks. They utilized the Bot-IoT dataset for the evaluation process. During the implementation phase, several algorithms were applied, and most achieved high performance. Additionally, new features were extracted from the Bot-IoT dataset which resulted in better results. Based on the experimental results, the KNN algorithm was found to be the most effective with 99% accuracy.

A research study [26] produced a MedBIoT dataset containing both typical and botnet traffic in the IoT network. The dataset includes data from the primal phase of botnet preparation and features real botnet malware such as Mirai, BASHLITE, and Torii. Machine learning models, both supervised and unsupervised, were built using the data to demonstrate the effectiveness of machine learning-based botnet classification and intrusion detection systems. The experimental results showed that the RF algorithm was the most effective, with an accuracy of 96.17%. The collected dataset has proven suitable and reliable for botnet detection using machine learning techniques.

In [27], the authors proposed new algorithms designed to encrypt data streams in an efficient IoT environment that meets the security requirements of 5G networks. They demonstrated that their algorithms resist various types of attacks, including quantum attacks, eavesdropping, plaintext attacks, chosen ciphertext attacks, and public critical attacks. The authors compared their proposed algorithm with leading post-quantum (PQ) cryptography algorithms such as LWE, LIZARD, and NTRU. According to their findings, the symmetric algorithm they proposed is 70 times faster than the aforementioned symmetric algorithms, and their asymmetric algorithm is ten times faster than the above-stated asymmetric algorithms. Additionally, both the proposed algorithms require 6000 times less memory.

When it comes to IoT devices, we face a challenge: they tend to need more energy and power. Post-quantum cryptography is usually more computationally intensive than the current cryptographic standards. In study [28], authors used the post-quantum digital signature scheme CRYSTALS-Dilithium to authenticate Message Queue Telemetry Transport (MQTT) and measure CPU, memory, and disk usage. They also explored using a key encapsulation mechanism (KEM) trick suggested in 2020 for transport-level security (TLS), which can save up to 90% of CPU cycles. They utilized the post-quantum KEM scheme CRYSTALS-KYBER to compare the resulting CPU, memory, and disk usage with traditional authentication. The study found that using KEM for authentication resulted in a 25 ms speed increase and a 71% savings. Although there were some additional costs for memory, they were minimal enough to be acceptable for most IoT devices.

Some maintain the trade-offs among cost, performance, and security, especially when considering resource-constrained IoT devices. The authors in [29] discussed various S-boxes used in the popular LWC algorithms by their input–output bit-sizes and highlighted their strengths and limitations. Then, it focuses on the proposed 5-bit S-box design. The novel design uses a chaotic mapping theory to offer a random behavior of the element in the proposed S-box. The experimental results from ASIC implementation reveal two essential characteristics of the proposed S-box, cost and performance, and further compare it with 4/5-bit competitors. It demonstrates the security strength of the proposed 5-bit S-box through cryptanalyses such as bijective, nonlinearity, linearity, differential cryptanalysis, differential style boomerang attack, avalanche effect, bit and independence criterion. Also, a comparison is carried out to exhibit the superiority of the proposed 5-bit S-box over its 5-bit competitors.

The article in [1] presented an efficient design method for PSCA-resistant ciphers implemented in hardware using high-level synthesis. The focus is on lightweight block ciphers that use addition, rotation, and XOR-based permutations. They also studied the effects of threshold implementation, which is a secure countermeasure against power side-channel attacks, on the behavioral descriptions of ciphers, along with changes in high-level synthesis scheduling. The proposed method successfully improves the resistance against power side-channel attacks for all addition/rotation/XOR-based ciphers used as benchmarks, as demonstrated by the results obtained using Welch's t-test.

III. Methodology

A. The N-BaIoT Dataset

The N-BaIoT dataset, introduced by Meidan et al. [30], comprises 115 attributes obtained through port mirroring of IoT devices. It includes benign data captured immediately after network setup, featuring two types of packet sizes, packet counts, and jitters. These data samples are categorized based on source IP, source MAC-IP, channel, socket, and total, with attributes such as packet, packet count, and time between packet arrivals. Statistical measures like mean, variance, integer values, magnitude, radius, covariance, and correlation coefficient are covered across 23 features for each of the five-time windows. The dataset incorporates injected BASHLITE and Mirai attacks into various IoT devices, each associated with specific device types and model names. BASHLITE, also known as gafgyt, is a botnet for DDoS attacks on Linux-based IoT devices, employing flooding attacks like UDP and TCP attacks. In contrast, Mirai, developed by Paras, executes large-scale attacks on IoT devices by scanning for vulnerabilities and launching flooding attacks. This dataset offers a comprehensive understanding of IoT device behavior under benign and malicious conditions, providing insights into the impact of different attacks on various device types.

B. Single Classifiers

Our ensemble model leverages the unique features of each classifier. Each classifier has a distinct architecture, hyperparameters, and beneficial features for IoT security. Our approach employs various machine learning models, including the Random Forest Classifier, XGBoost, Gradient Boosting Classifier, KNN Classifier, MLP Classifier, and AdaBoost Classifier, to classify attacks and anomalies in the proposed data. Every model plays an essential role in our approach to enhancing attack detection in IoT ecosystems.

1) Random Forest Classifier: The Random Forest Classifier is a machine learning algorithm for classification and regression tasks [31]. It is a reliable and robust technique that enhances predictive accuracy by utilizing multiple decision trees while minimizing overfitting. The algorithm creates a collection of decision trees using bootstrapping to build each tree from a subset of the dataset. During the creation of each tree, a random subset of features is considered for splitting at each node. This diversity is necessary to ensure that the forest is not overly dependent on a particular set of features, promoting robustness and flexibility in the predictive system [32]. The prediction process involves aggregating the outputs of individual trees, where each tree casts a vote for the class label. Overall, the Random Forest Classifier is a powerful tool for machine learning tasks that require high accuracy and flexibility. Let T denote the set of decision trees in the forest, and $h_i(\mathbf{x})$ represent the prediction of the i-th tree for input vector $\mathbf{x}$. The final prediction $\hat{y}$ is determined by a majority vote:

$$\hat{y} = \underset{y}{\operatorname{argmax}} \left(\sum_{i=1}^{|T|} \mathbb{I}\{h_i(\mathbf{x}) = y\} \right) \tag{1}$$

where, $\mathbb{I}\{\cdot\}$ is the indicator function, and $|T|$ signifies the total number of trees in the Random Forest. This approach allows Random Forest to make accurate predictions by combining decisions from multiple trees, improving adaptability, and reducing overfitting.

2) Gradient Boosting Classifier: The Gradient Boosting Classifier is an advanced machine learning algorithm that constructs predictive models sequentially [33]. It achieves this by addressing the errors of its predecessors, which refine the model's accuracy and make it particularly effective for classification tasks. The core idea behind this algorithm is to combine the outputs of multiple weak learners, usually decision trees, in a weighted manner [34]. Each tree is trained to rectify the mistakes of the preceding ones, optimizing the overall predictive performance. The algorithm employs a scheme that minimizes a composite objective function. It contains a loss term that quantifies prediction errors and regularization terms for controlling model complexity. Through gradient descent, the classifier adjusts the parameters of each weak learner to improve its predictive capabilities. This approach enables Gradient Boosting to excel at capturing intricate patterns within data, making it a valuable tool for various real-world applications. In the Gradient Boosting Classifier, the prediction is formulated as an additive ensemble of weak learners, typically decision trees. The overall prediction $F(x)$ is a weighted sum of these weak learners, given by the equation:

$$F(x) = \sum_{t=1}^{T} \alpha_t f_t(x) \tag{2}$$

where, T represents the total number of weak learners in the ensemble, α_t denotes the weight assigned to the t-th weak learner, and $f_t(x)$ is the prediction made by the t-th weak learner. Gradient boosting works by adding weak learners sequentially. Each new learner addresses the residuals (errors) of the combined model from the previous iterations. This approach helps in improving the overall model accuracy gradually by focusing on the previously misclassified instances. During the training process, the weights (α_t) are determined, which depend on the contribution of each weak learner to minimizing the overall loss function.

3) XGBoost Classifier: XGBoost is a highly efficient and versatile ensemble learning algorithm that is widely used for predictive modeling [35]. It is a gradient boosting method that builds a series of weak learners, such as decision trees, and adaptively improves their predictive performance. XGBoost includes regularization terms in its objective function, which promotes model simplicity and reduces overfitting [36]. XGBoost optimizes predictive accuracy with its innovative approach to tree construction and parallel processing. The XGBoost classifier algorithm aims to improve the predictive capabilities of an ensemble of weak learners, typically decision trees. It does this by minimizing the objective function through an iterative boosting process that adjusts the parameters of each weak learner. The final prediction is determined by aggregating the weighted contributions of individual learners, where weights reflect the influence of each learner on the overall model. The success of XGBoost in achieving superior performance across diverse classification scenarios is due to its gradient descent optimization and regularization. The XGBoost classifier is defined as:

$$\hat{y}_i = \phi(\mathbf{x}_i) = \sum_{k=1}^{K} f_k(\mathbf{x}_i) \tag{3}$$

While, $\hat{y}_i$ represents the predicted output for the i-th instance, $\mathbf{x}_i$ denotes the feature vector, K is the total number of weak learners, and $f_k(\mathbf{x}_i)$ represents the output of the k-th weak learner. The ensemble prediction is obtained by summing the outputs of all weak learners, and $\phi(\mathbf{x}_i)$ produces the final predicted value. The parameters of the weak learners are adaptively updated during the iterative training process, allowing the model to learn complex relationships in the data.

4) K-Nearest Neighbors (KNN): The KNN classifier is a type of machine learning algorithm used for classification and regression tasks that does not require any pre-defined parameters [37]. It works by determining the classification of a data point based on the majority class of its KNNs in the feature space. The algorithm often uses Euclidean distance as a metric to measure similarity between data points. The consensus of the classes within the neighborhood of a point forms the decision boundary. The KNN algorithm is versatile and can adapt to different data and decision boundaries. However, choosing the appropriate value for k is essential since a small value of k can increase sensitivity to noise, while a high value of k may smooth out local patterns. Despite its simplicity, KNN has proven effective in various applications, especially when decision boundaries are intricate and non-linear [38]. The KNN classifier predicts the class label of a data point by considering the majority class among its k-nearest neighbors in the feature space [39]. Let x be the data point for which we want to make a prediction, and let $N(x)$ denote the set of its k-nearest neighbors based on a specified distance metric. The predicted class label, $\hat{y}$, is determined by the majority class among these neighbors. It is presented in the equation:

$$\hat{y} = \arg\max_{y} \left(\sum_{i=1}^{k} \mathbb{I}\{y_i = y\} \right) \tag{4}$$

where, y_i represents the class labels of the k-nearest neighbors. The decision is made by selecting the class y that maximizes the count of its occurrences among the neighbors. This formulation captures the essence of the KNN algorithm, emphasizing the reliance on local neighborhood information for classification decisions. The choice of the distance metric and the parameter k significantly influences the algorithm's performance and its adaptability to different datasets.

5) Multi-Layer Perceptron (MLP): The MLP classifier is an artificial neural network comprising several layers of interconnected nodes, each serving as a processing unit [40]. It is a versatile and powerful model that can be used for both classification and regression tasks. In classification, the MLP classifier uses a feed-forward architecture, where information moves from the input layer through hidden layers to the output layer. The hidden layers have nodes that use non-linear activation functions, enabling the model to capture complex relationships in the data. Overall, the MLP classifier is a reliable tool for handling complex datasets [41]. Let $\mathbf{x}$ represent the input vector, and W and b denote the weight matrix and bias vector, respectively, for each layer. The output of the MLP is obtained through a series of transformations and activation functions. The prediction $\hat{y}$ is calculated as:

$$\hat{y} = \sigma(W_{\text{out}} \cdot \sigma(W_{\text{hidden}} \cdot \sigma(W_{\text{input}} \cdot \mathbf{x} + b_{\text{input}}) + b_{\text{hidden}}) + b_{\text{out}} \tag{5}$$

σ denotes the activation function, such as the Rectified Linear Unit (ReLU) or hyperbolic tangent (tanh). During training, the weights and biases of MLPs are optimized using back propagation and gradient descent algorithms. The flexibility of these models enables them to learn complex patterns and relationships present in the data, which makes them an excellent fit for a wide range of machine learning applications.

C. Performance Metrics

This section establishes a set of evaluation metrics to assess the performance of our ensemble model and its components quantitatively. We have chosen metrics that help evaluate accuracy, precision, recall, and F1-score. These metrics provide objective benchmarks for comparing our approach with existing detection methods. Additionally, we discuss our methodology for conducting experiments and collecting results. Selecting and interpreting evaluation metrics is essential to ensure a comprehensive and informative assessment of our research outcomes. We use several standard evaluation metrics for accuracy, precision, recall, and F1-score.

- **Accuracy (ACC):** Accuracy is a metric that measures the ratio of correctly predicted instances to the total instances in the dataset. ACC is calculated as,

$$\text{ACC} = \frac{\text{True Positives} + \text{True Negatives}}{\text{Total Instances}} \tag{6}$$

- **Precision (P):** Precision measures the model's ability to identify true positives accurately. P is calculated as,
$$\text{P} = \frac{\text{True Positives}}{\text{True Positives} + \text{False Positives}} \tag{7}$$
- **Recall (R):** Recall is a metric that indicates the percentage of actual positive cases that the model correctly predicted. R is calculated as,
$$\text{R} = \frac{\text{True Positives}}{\text{True Positives} + \text{False Negatives}} \tag{8}$$
- **F1-Score (F1):** The F1-score provides a balance between precision and recall. F1 is calculated as,
$$\text{F1} = \frac{2 \cdot \text{P} \cdot \text{R}}{\text{P} + \text{R}} \tag{9}$$

These metrics are essential to objectively evaluate the performance of our ensemble model in detecting BASHLITE and Mirai attacks. They enable comparisons with other detection methods and offer a comprehensive assessment of our research outcomes.

IV. Proposed Weighted Voting Approach

A. Proposed Approach Overview

The proposed approach involves a weighted voting strategy using an ensemble of five single classifiers (as described in Section III-B). These classifiers are trained with a prepared dataset and their predictions are assigned weights based on their performance and confidence. Fig. 1 provides a clear overview of our proposed approach.

B. Preprocessing

In this step, we will discuss data collection, and preprocessing procedures, namely feature encoding and scaling. Feature encoding involves transforming categorical variables into a numerical format, which helps machine learning algorithms to understand and represent categorical data accurately. Feature scaling is an essential technique that plays a pivotal role in normalizing the range of numerical features. The process helps to prevent any feature from disproportionately influencing the learning process. Feature scaling is an essential technique in machine learning, and the Standard Scaler is one of the most commonly used methods [42]. Its primary purpose is to normalize the range of numerical features within a dataset. This helps to prevent any feature from having an outsized impact on the learning process. By transforming the data distribution to have a mean of 0 and a standard deviation of 1, the Standard Scaler ensures all features are brought to a common scale. For each feature x_i in the dataset, the Standard Scaler computes the z-score by subtracting the mean (μ) of the feature and dividing it by its standard deviation (σ), as expressed in the equation:
$$z = \frac{(x_i - \mu)}{\sigma} \tag{10}$$
Here, z means the standardised set of the characteristic x_i. This process ensures the stability and effectiveness of the training process in interpreting and utilizing numerical features. By meticulously scaling our features, we can improve the performance and reliability of our model in the later stages of our research.

C. Training Machine Learning Classifiers

The training data included labels that explained whether a particular output had an anticipated associated class. The main goal is to train the learning model to perceive the correct position of the unseen data by matching it to the sample data. However, in many cases, we found that a single learning model could have produced the best results or the minimum errors. Therefore, we adopted an ensemble learning technique that involved constructing multiple assumptions on the training data and incorporating them to recognize the correct position of the sample. This method combined the decisions from several models and enhanced the overall efficiency of the model, resulting in more accurate results. Moreover, this approach led to a stable and more robust model than individual models.

To prepare our ensemble model, we meticulously execute the training process for each machine learning classifier making up our ensemble. The classifiers as described in Section III-B, include the Random Forest, XGBoost, Gradient Boosting, KNN, MLP, and AdaBoost Classifiers. Each classifier's diverse architectures, hyperparameters, and unique capabilities contribute to the comprehensive learning process. Subsequently, these trained classifiers collectively form the basis learned for the ensemble approach, paving the way for the ensemble's ultimate strength through Weighted Voting in detecting malicious activities within IoT environments.

D. Ensemble Weighted Voting

The proposed approach relies on the Weighted Voting strategy, which allows us to use the unique strengths of individual models within the ensemble [43]. It delves into the intricacies of Weighted Voting, explaining how it assigns weights to predictions from base trained models based on their performance and confidence [44]. This approach aims to optimize the accuracy of our ensemble system, enabling it to adapt to varying degrees of model reliability. Leveraging these weighted predictions is essential in improving the detection of BASHLITE and Mirai attacks in IoT networks. Let C_i represent the i-th base classifier, where i ranges from 1 to n (n = 5). Each base classifier provides a prediction denoted as P_i, and these predictions collectively form the set $\{P_1, P_2, ..., P_n\}$. Next, individual weights are assigned to these predictions based on the performance or reliability of each base classifier. Let W_i denote the weight assigned to the prediction of classifier C_i. The assignment of weights can be influenced by various factors, such as the accuracy or precision of each base classifier on a validation set. The weighted sum, denoted as S, is computed by summing the product of each prediction and its corresponding weight:
$$S = \sum_{i=1}^{n} W_i \cdot P_i \tag{11}$$
In ensemble learning, the final prediction output is the sum of the five predictions made by all the base classifiers. Each base classifier's prediction has a weight assigned to it, and the final output is a combination of all these weighted predictions. To ensure that the weights form a proper distribution, they are often normalized. This means that each weight is divided by

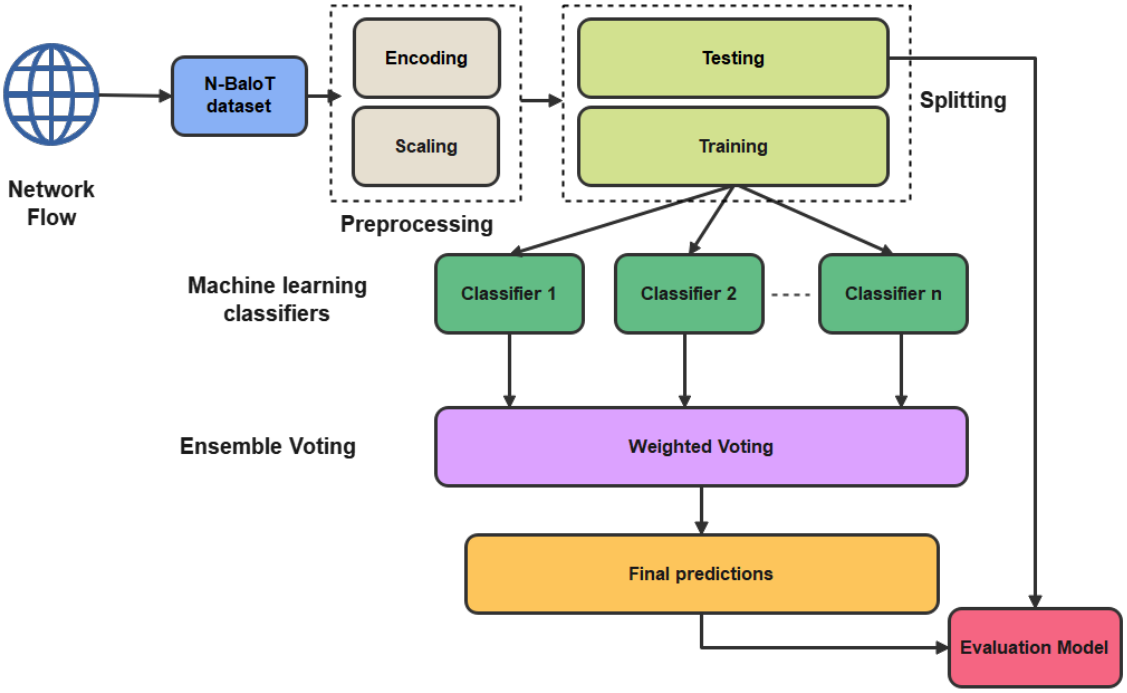

Fig. 1. Flow diagram of the proposed weighted voting attack detection approach.

the sum of all the weights:

$$\text{Normalized Weight, } \bar{W}_i = \frac{W_i}{\sum_{j=1}^{n} W_j} \tag{12}$$

This normalization guarantees that the weights collectively sum to 1, maintaining the integrity of the weighted voting process. The Weighted Voting mechanism ensures that the final prediction is a well-informed combination of individual base classifier predictions. Each contribution is appropriately weighted to enhance the overall accuracy of the ensemble. The mechanism's effectiveness lies in its ability to assign weights adaptively based on the reliability of each classifier. This helps to improve the predictive accuracy of the ensemble.

V. Evaluation and Results

In this section, we thoroughly evaluate and present the results of our proposed ensemble approach for detecting BASHLITE and Mirai attacks from the N-BaIoT dataset in IoT networks. Our experimental evaluation meticulously analyzes the model's performance using key metrics such as accuracy, precision, recall, and F1-score. We provide insightful analyses of the experimental setup and the obtained results and then conduct a comparative assessment with other existing detection methods. This comprehensive evaluation presents a detailed perspective on the strengths of our ensemble model and potential enhancements in IoT security.

A. Experimental Setup

TABLE I. Parameters and Methods for the Machine Learning Models

Model	**The parameters used for the model experiments.**
Random Forest	- **Number of Trees :** 100. - **Criterion for Splitting (criterion):** 'gini'. Methods:'entropy'.
Gradient Boosting	- **Number of Boosting Stages (n_estimators):** 100. Methods: Tune based on the trade-off between performance and computational cost. - **Loss Function (loss):** 'deviance'. Methods:'exponential'. - **Learning Rate:** 0.1.
K Nearst Neighbors	- **Number of Neighbors (n_neighbors):** 5. Methods: Square root of the number of samples. - **Weight Function (weights):** 'uniform'.
MLP	- **Number of Neurons in Hidden Layers (hidden_layer_sizes):** 100.- **Activation Function (activation):** 'relu'. Methods: 'tanh'.
AdaBoost	- **Number of Weak Learners (n_estimators):** 50. - **Learning Rate (learning_rate):** 1.0.
XGBoost	- **Number of Trees (n_estimators):** 100.

In this section, we explain the experimental settings of our contribution designed for the detection of BASHLITE and Mirai attacks in IoT networks. We provide a detailed account of the implementation steps and propose solutions aimed at validating the effectiveness of our approach in enhancing the security of IoT environments. A critical aspect of the validation process involves the assessment of the N-BaIoT dataset, underscoring its significance in evaluating any proposed solution for IoT security improvement. Table I summarizes parameters and methods employed for various machine learning models, explaining the comprehensive experimental setup to strengthen IoT security. We split the N-BaIoT dataset into two sets-training and testing, with 80% for training and 20% for model evaluation. This helped balance model learning and validation, measuring our ensemble model's real-world performance while minimizing overfitting.

B. Experimental Results

The study employed Python on Google Colab GPU for multiclass classification [45]. To detect BASHLITE and Mirai attacks, we employed five machine learning techniques (Random Forest, XGBoost, Gradient Boosting, KNN, MLP, and AdaBoost). The results were combined using a weighted voting technique. The ensemble approach and the five classifiers were evaluated using performance evaluation measures such as accuracy, precision, recall, and F1-score. The performance of different machine learning classifiers was compared, including the Ensemble Weighted Voting approach and individual classifiers. The results presented in Tables II, and III, show the weighted and macro average performance metrics.

TABLE II. WEIGHTED AVERAGED FOR DIFFERENT METRICS ACROSS MODELS (IN %)

Model	Accuracy	Precision	Recall	F1-Score
Ensemble Weighted Voting	99.9955	99.9955	99.9913	99.9955
XGBoosting	99.9796	99.9796	99.9624	99.9796
KNN	99.9087	99.9087	99.8669	99.9087
Random Forest	99.9909	99.9909	99.9847	99.9909
MLP	99.9781	99.9781	99.9663	99.9781
AdaBoost	69.13	65.14	59.33	65.14

TABLE III. MACRO AVERAGED METRICS FOR DIFFERENT MODELS (IN %)

Model	Precision	Recall	F1-Score
Ensemble Weighted Voting	99.99	99.99	99.99
XGBoosting	99.97	99.96	99.96
KNN	99.87	99.86	99.87
Random Forest	99.98	99.98	99.98
MLP	99.97	99.96	99.97
AdaBoost	66.20	66.20	66.20

The Ensemble Weighted Voting model outperformed the individual classifiers across various metrics such as accuracy, precision, recall, and F1-score. The Ensemble Weighted Voting model has shown exceptional accuracy in the Weighted Averaged metrics, achieving a score of 99.9955%. This is higher than all other classifiers, including XGBoosting, KNN, Random Forest, MLP, and AdaBoost. Additionally, the model's precision, recall, and F1-Score are consistently superior, reaching 99.9955%, 99.9913%, and 99.9955%, respectively. Its higher precision and recall values indicate a better ability to correctly identify and classify instances of attacks, leading to a high F1-score. In the macro-averaged metrics, which measure the average performance across different classes, the Ensemble Weighted Voting model outperforms its competitors with precision, recall, and F1-Score values of 99.99%, 99.99%, and 99.99%, respectively. On the other hand, the individual classifiers, including AdaBoost, exhibited lower precision, recall, and F1-score performance. The ensemble's weighted average results highlight its effectiveness in combining diverse models, emphasizing the importance of ensemble learning in achieving improved detection capabilities in IoT security applications. This indicates that the model is robust and reliable, with a superior ability to detect various classes within the IoT security context.

C. Discussion

This section discusses the implications of the study's findings and the recent techniques used to detect and prevent BASHLITE and Mirai cyber-attacks on IoT devices based on evaluating the N-BaIoT dataset. Our proposed solution focused on an ensemble-based weighted voting model, representing a comprehensive IoT security approach. This model combines various classifiers, including Random Forest, XGBoost, Gradient Boosting, KNN, MLP, and AdaBoost, utilizing artificial intelligence and machine learning techniques. The evaluation of the N-BaIoT dataset, a recognized benchmark in the domain, demonstrates the exceptional performance of the weighted voting approach. The model achieves outstanding accuracy, precision, recall, and F1-Score, surpassing state-of-the-art methods. Notably, the accuracy of 99.9955% in detecting and preventing BASHLITE and Mirai cyber-attacks on IoT devices is a remarkable highlight. Comparing our approach with recent works, as summarized in Table IV, affirms the superiority of the proposed model. Abu Al-Haija and Al-Dala'ien [46] used different machine learning techniques AdaBoosted, RUSBoosted, and bagged, achieving a detection accuracy of 99.6% for botnet attacks.

TABLE IV. COMPARISON BETWEEN MOST RECENT WORKS AND THE PROPOSED APPROACH WITH RESULTS FINDINGS

Authors	Dataset	Results in %
Ours	N-BaIoT	99.9955
Abu Al-Haija and Al-Dala'ien [46]	N-BaIoT	99.6
Okur et al. [47]	N-BaIoT	99.92
Sakthipriya et al. [48]	N-BaIoT	95.02
Abbasi et al. [49]	N-BaIoT	above 90
Hezam et al. [50]	N-BaIoT	89.75

Okur et al. [47] reported a 99.92% accuracy detection rate using Random Forest in the N-BaIoT dataset. These results provide a context for understanding the competitive edge of our ensemble-based approach. Furthermore, examining alternative methods, Sakthipriya et al. [48] focused on dimensionality reduction, with auto-encoder outperforming PCA with an accuracy of 95.02%. Abbasi et al. [49] proposed logistic regression for intrusion detection, achieving above 90% classification accuracy, while Hezam et al. [50] explored deep learning algorithms, with RNN achieving the highest accuracy of 89.75%. The comparison presented in Table IV highlights the superior accuracy of our proposed model compared to recent uses the N-BaIoT dataset. Our model's performance was a comprehensive ensemble of classifiers used to prevent IoT security issues with robustness and effectiveness. The evaluation process was meticulous, ensuring the accuracy of the results.

VI. CONCLUSION AND FUTURE SCOPE

The increasing number of devices in the IoT has also led to an increase in security risks, such as BASHLITE and Mirai attacks. To address these vulnerabilities, we need innovative detection and mitigation strategies. In this study, we present a new solution based on an ensemble-based weighted voting model that uses a variety of classifiers, including Random Forest, XGBoost, Gradient Boosting, KNN, MLP, and AdaBoosting, powered by artificial intelligence and machine learning. We rigorously evaluated the model's effectiveness on the N-BaIoT dataset, a benchmark in the IoT security domain. Our results indicate that the proposed weighted voting approach achieves exceptional accuracy, precision, recall, and F1-Score in accurately classifying various attack instances in the IoT security context, outperforming other state-of-the-art methods. Notably, the model demonstrates an outstanding accuracy rate of 99.9955% in detecting and preventing BASHLITE and Mirai cyber-attacks on IoT devices. The proposed ensemble-based weighted voting model is designed to overcome the challenges posed by BASHLITE and Mirai attacks and provides valuable insights into IoT networks. Combining different machine learning classifiers, the model shows superior performance metrics to individual classifiers, making it adaptable to changing attack patterns. This study aims to protect against current IoT security threats, providing a robust defense model.

In the future, we can explore how attack methods evolve and test more machine learning classifiers to see how well the proposed ensemble-based approach adapts. We can also study how well the model performs in real-world IoT environments, and we can improve its practical usefulness by testing how it handles larger datasets. Continuously improving and expanding the model using different artificial intelligence techniques and cybersecurity advancements ensure its effectiveness in the ever-changing landscape of IoT security.

Acknowledgment

The researcher extends his sincere thanks and appreciation to the administration of King Faisal University in the Kingdom of Saudi Arabia for providing all forms of support to the university's faculty members, especially in the field of scientific research. We extend our sincere thanks to the Deanship of Scientific Research at the university for agreeing to support this scientific research with GRANT number 5,290.

Sentiment Analysis on Banking Feedback and News Data using Synonyms and Antonyms

Aniruddha Mohanty, Ravindranath C. Cherukuri
Department of Computer Science and Engineering
CHRIST (DEEMED TO BE UNIVERSITY)
Bangalore, India 560074

***Abstract*—Sentiment analysis is crucial for deciphering customers' enthusiasm, frustration, and the market mood within the banking sector. This importance arises from financial data's specialized and sensitive nature, enabling a deeper understanding of customer sentiments. In today's digital and social marketing landscape within the banking and financial sector, sentiment analysis is significant in shaping customer insights, product development, brand reputation management, risk management, customer service improvement, fraud detection, market research, compliance regulations, etc. This paper introduces a novel approach to sentiment analysis in the banking sector, emphasizing integrating diverse text features to enable dynamic analysis. This proposed approach aims to assess the sentiment score of distinct words used within a document and classify them as positive, negative, or neutral. After rephrasing sentences using synonyms and antonyms of unique words, the system calculates sentence similarity using a distance control mechanism. Then, the system updates the dataset with the positive, negative, and neutral labels. Ultimately, the ELECTRA model utilizes the self-trained sentiment-scored data dictionary, and the newly created dataset is processed using the SoftMax activation function in combination with a customized ADAM optimizer. The approach's effectiveness is confirmed through the analysis of post-bank customer feedback and the phrase bank dataset, yielding accuracy scores of 92.15% and 93.47%, respectively. This study stands out due to its unique approach, which centers on evaluating customer satisfaction and market sentiment by utilizing sentiment scores of words and assessing sentence similarities.**

Keywords*—*ELECTRA; Synonyms and antonyms; sentiment analysis; datasets; sentiment score; control distance

I. Introduction

Enhanced comprehension of customer perceptions regarding various banking products and services entails evaluating customers' sentiments, opinions, and attitudes [1]. In the age of digitalization and advanced data analytics, the analysis of social media feedback data has become prevalent. The Banking, Financial Services, and Insurance (BFSI) sector utilizes Customer Relationship Management (CRM) to make informed business decisions based on customer feedback received daily. Nowadays, this feedback data is accessible on social media platforms, significantly aiding in analyzing customer sentiments [2]. Organizations are investing significant resources in research to create tools and strategies for analyzing customer feedback data and aligning products with current market trends [3]. Likewise, banking news reflects the general atmosphere or attitude conveyed in articles, reports, and discussions rooted in economic sentiment. Researchers increasingly favor text-based economic activities [4] due to their advantages over surveys in terms of cost, scope, and timeline.

Constraints imposed and integrity issues associated with text-based sources like news, microblogs, and organizational product disclosures have limited research in this field when analyzing their impacts on various market aspects [5]. Sentiment analysis represents a distinctive feature within the financial sector, enabling sentiment analysis that gauges customer confidence in banking products and services. Banks can pinpoint recurring issues or concerns raised by customers and promptly address them, thus enhancing customer satisfaction and loyalty. Utilizing feedback data allows for enhancing existing products and developing new services tailored to customer preferences while bolstering the organization's reputation and competitive offerings. Identifying unusual patterns and sentiments also serves the purpose of detecting fraud and can be harnessed for customer awareness [6]. Similarly, favorable banking news increases investor confidence, contributes to an upward market trend, and enhances an organization's reputation. Conversely, negative information can have the opposite effect [4]. Public sentiment regarding regulations and policies can sway lawmakers and regulators, shaping the formulation of crisis management strategies.

Contextual comprehension significantly influences sentiments; for instance, 'interest' typically evokes positive sentiment, while 'loans' often yield negative sentiments. Challenges arise in sentiment analysis due to sarcasm, subjectivity, and multilingual nuances in language. Within financial institutions, data often holds sensitive information, making balancing privacy regulations vital when handling customer feedback, reviews, and media releases. Leveraging the integration of machine learning and Natural Language Processing (NLP) [7] techniques proves instrumental in mitigating these challenges.

In this paper, various sources known for their integrity gather the data. After pre-processing and clustering the data, the system computes sentiment scores. The analysis system ensures the integrity of the document's content, focusing on preserving form rather than just content. This approach helps to prevent different classes resulting from the synonyms and antonyms in the text document. The conservation block compares the normalized sentences of the analysis system with newly generated sentences containing synonyms and antonyms, utilizing a control distance mechanism. This process results in an updated dataset for the experiment. The analysis system provides the updated dataset as input to the ELECTRA, a self-supervised language representation learning model for classifying responses within the context of the proposed customer-based banking analysis system.

The rest of the paper includes Section II, which elaborates on banking products and services. Section III presents related work on sentiment analysis, focusing on customer feedback and news from diverse sources. Section IV delves into the proposed system model and its architecture. The research methodology of the model is discussed in Section V, followed by result analysis and discussion of the proposed hypothesis with novelty, strength, and implication in Section VI. Finally, Section VII summarizes the paper, providing conclusions and future scope prospects.

II. Banking Products and Services

The market offers a variety of banking products, each differing from one organization to another. These products and services undergo regular updates and enhancements. The banking system has two primary categories: retail banking and corporate banking. Table I provides an overview of the products and associated services offered by retail and corporate banking sectors.

TABLE I. Products of Retail and Corporate Banking

Retail Banking	Corporate Banking
Checking and saving account, Certificates of deposit, Mortgage, Automobile financing, Credit cards, Lines of credit (Home equity lines of credit and personal credit products), Foreign currency and remittance services, Stock brokerage, Insurance, Wealth management, Private banking.	Loans and other credit products, Treasury and cash management services, Equipment lending, Commercial real estate, Trade financing, Employer service.

III. Related Work

Sentiment analysis assesses customers' responses to products, services, and situations by analyzing texts, posts, reviews, news, and other digital content. This analysis aids business leaders in comprehending customer attitudes and market perceptions over time.

A. Sentiment Analysis on Banking Data

The bank ontology facilitates extracting text feedback data features from websites like Mouthshut.com and myBankTracker.com. The experiment then applies sentiment classification to this data [8]. Rule-based classifier helps to analyze the sentiments of Russian review texts to classify sentiments [9]. The Vader Aware Dictionary and Sentiment Reasoner (VADER) [10] is a lexicon and rule-based sentiment analysis tool specifically crafted to discern sentiments within social media data related to UniCredit bank's European region. Retail banks in South Africa employ both lexicon-based and machine learning-based methods [11] to assess customer feedback sentiments. The results from a fine-tuned DistilBERT model are fed into machine learning classifiers such as Random Forest, Decision Tree, Logistic Regression, and Linear Support Vector Classifier (SVC) [12] to categorize sentiments in news related to Indian banking, governmental, and global topics. Nine classifiers, including Naïve Bayes, Logistic Regression, K-Nearest Neighbours, Support Vector Machines, Random Forest, Decision Tree, Adaptive Boosting, eXtreme Gradient Boosting, and Light Gradient Boosting Mechanism [13], have been employed to detect customer satisfaction levels within Indonesian banks, such as Jenius, Jago, and Blu. The BERTopic architecture utilizes a combination of Kernel Principal Component Analysis (KernelPCA) and K-means Clustering to generate coherent topics, similar to the Latent Dirichlet Allocation (LDA) [14] approach. This method calculates coherence scores for Nigerian bank data, facilitating sentiment analysis. Word representation has evolved by integrating static and contextual words to handle language ambiguity, encompassing semantics, and syntax within a given context. These word representations are fed into a Convolutional Neural Network (CNN) [15] to capture sentiments within financial news contexts.

B. Sentiment Analysis Approach on Text Data

The RCNN [16] analyzes each word's context in the document and then applies the max-pooling layer to identify the text's crucial elements for classification, along with the SoftMax layer. Clustering techniques, such as the K-means-type algorithm [17], exhibit improved performance when applied to balanced data, whereas the designed weighting model delivers exceptional results for both balanced and unbalanced datasets. The word embedding layer [18] converts sentences into words, preserving the contextual information of each word, and then applies a CNN for sentiment analysis. Support Vector Machine (SVM), Deep Learning (DL), and Naïve Bayes (NB) [19] classifiers utilize sentiment scores and the associated weights of hashtags to classify sentiments within social media data. The classification of sentiments [20] involves employing the Bidirectional Long Short-Term Memory (BiLSTM) layer, a global pooling mechanism, and a sigmoid layer. The Collaborative and Bidirectional Gated Recurrent Unit (BiGRU) can also adopt this approach to assess performance. Hierarchical Attention Networks (HAN) [21] enable the identification of sentiment polarity in customer communications, thereby enhancing the efficiency of Customer Relationship Management (CRM) operators in terms of response time. The integration of the BERT model with Bidirectional Long Short-Term Memory (BiLSTM) and Bidirectional Gated Recurrent Unit (BiGRU) algorithms [22] facilitates the analysis of positive, negative, and neutral sentiments.

The literature analysis above demonstrates various modelling approaches employed in sentiment analysis of banking text data, incorporating different types of text data and data corpora. Examining synonyms and antonyms within a data corpus is instrumental in simplifying the identification of customer sentiments toward financial organizations in diverse regions. Further research is necessary to develop a more efficient approach capable of swiftly discerning customers' intent, serving as a driving force to create a more streamlined sentiment analysis context for optimizing banking business strategies.

IV. System Model

The proposed sentiment analysis approach comprises two key components, as illustrated in Fig. 1. The initial phase involves collecting banking data from various sources, including customer service teams, visual feedback tools, review sites, net promoter sources, online surveys, social media, and news media facilitated by banking organizations. These data are then gathered and stored in a database. A "Stop-word" data cloud developed helps to preprocess the dataset documents.

The filtered and pre-processed text data identifies the sentiment scores for unique words. The subsequent step involves determining synonyms and antonyms for these unique words and their corresponding sentiment scores. Replacing each unique word with synonyms and antonyms forms new sentences, as depicted in Fig. 1. This process allows considering a maximum of three synonyms and antonyms for each identified word during replacement.

The experiment employs the Control Distance approach to assess the similarity between the original and newly generated sentences by rephrasing with synonyms and antonyms. Based on their degree of similarity, the experiment uses the resulting similarity score to categorize sentences as positive, negative, or neutral.

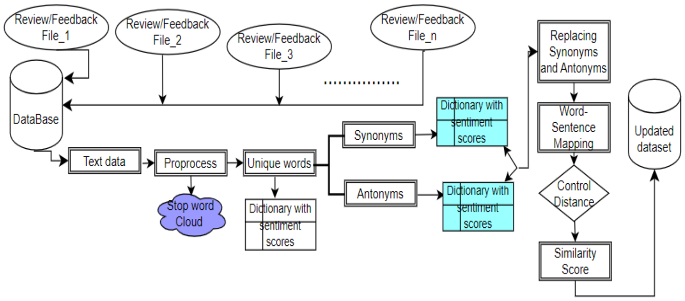

Fig. 1. System model to create an updated dataset.

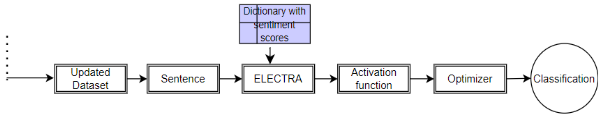

Fig. 2. System model to identify sentiment.

A self-supervised language representation learning model, ELECTRA, trains itself using all words from the data dictionary with sentiment scores. This model is then applied to the updated dataset, as Fig. 2 illustrates. Subsequently, individual sentences are classified and identified for sentiment, enhancing the efficiency of the Sentiment Analysis framework. ELECTRA operates efficiently on sample words, making it faster and requiring fewer resources. The following provides a summary of the detailed implementation:

- The initial step involves gathering datasets from a variety of banking data sources.
- Design and develop the 'Stop-word' word cloud that does not impact sentiments.
- Then, pre-processed the text data using the specially designed 'Stop-word' word cloud.
- Create a data dictionary by identifying unique words and their corresponding sentiment scores.
- The positive, negative, and neutral sentiment scores determine synonyms and antonyms of unique words and establish a distinct data dictionary for these synonyms and antonyms.
- A control distance approach, as proposed, assists in measuring the similarity score between the original and updated sentences. The resulting dataset encompasses positive, negative, and neutral sentiments.
- The ELECTRA model is self-trained and then applied to the updated dataset by merging the data dictionary containing synonyms, antonyms, unique words, and their sentiment scores. SoftMax activation and a modified Adam optimizer help to identify the sentiment for each feedback statement.

V. Research Methodology

This section delves into the analysis of sentiments from banking feedback and media data, encompassing a discussion of the experiments and the results obtained. Firstly, it covers the specifics of the dataset employed for training, cross-validation, and testing, followed by a detailed examination of the approach's implementation. Following this, the analysis delves into the experiment results, revealing the sentiments and information patterns present within the datasets. The study evaluates the effectiveness and performance of the proposed approach by comparing it with other established methods. Furthermore, the analysis includes applying the predefined approach to the post banking customer feedback and phrase banking datasets to determine the accuracy score, given their absence of prior implementation using the ELECTRA model.

A. *Dataset Collection*

Central banks worldwide gather customer feedback on banking services, encompassing satisfaction levels, complaints, and insights on product usability. The sources of post bank customer data [23] are from the Russian finance website "www.banki.ru" spanning 2013 to 2019. Reviews are rated from one to five, with one denoting negativity and five indicating positivity. The "responses_header" column comprises feedback messages from 16,659 customers.

The phase bank dataset [24] includes positive, negative, and neutral sentiments of 5,000 customers about companies listed in OMX Helsinki. The data originates from the LexisNexis database, including 10,000 randomly selected articles from limited financial and economic resources. Analyzing these sentiments assists the marketing team in improvising the banking products and services. The details of collected datasets are shown in Table II and saved in CSV files to calculate the sentiment content of each text sentence. These datasets are divided into 65% for training, 15% for cross-validation, and 20% for testing.

TABLE II. The Datasets in the Experiment

sl#	Dataset	Provided Ratings
1	Post Bank Customer Review	Positive: 2160
2		Negative: 2472
3		Neutral: 1391
4	Phrase Banking	Positive: 1853
5		Negative: 861
6		Neutral: 3131

B. Text Data

Each dataset includes a variety of text messages shared by different banking customers and media sources, extracting subjective information from the shared data. The goal is to discern the attitude, emotional tone, market sentiment, and expressions within a text, allowing for the analysis of overall sentiments from individual feedback and media statements. Various methods, such as rule-based, machine learning, and deep learning techniques, are employed to assess these sentiments.

The article employs a rule-based approach to measure the sentiment scores of unique words in the dataset file. It creates data dictionaries that assign sentiment scores to unique words, synonyms, and antonyms. These dictionaries help to determine the overall sentiment scores of sentences or paragraphs.

C. Pre-processing the Text Data

Text pre-processing involves cleaning text data by eliminating irrelevant information like URLs, numbers, and punctuation marks. This step ensures the availability of more pertinent texts for conducting sentiment analysis activities. Then, the process [25] involves tokenizing, normalizing, removing stop words, stemming, and lemmatization.

In this implementation, aside from general stop words, specific banking-related stop words such as currency names (Rupee, dollar, etc.), Roman numerals (I, II, III, etc.), and auditing firms (KPMG, Deloitte, etc.) are utilized. These stop words significantly impact sentiment determination and play a significant role in determining sentiment. They are used to generate the word cloud, which, in the process, assists in removing these words from the dataset files, as shown in Fig. 3. In pre-processing and stop word removal, the process extracts unique words, facilitating the identification of context and reducing words to their root form. Identifying distinct words in a dataset facilitates the analysis of individual words for information retrieval purposes. The extraction of unique words serves several functions, including:

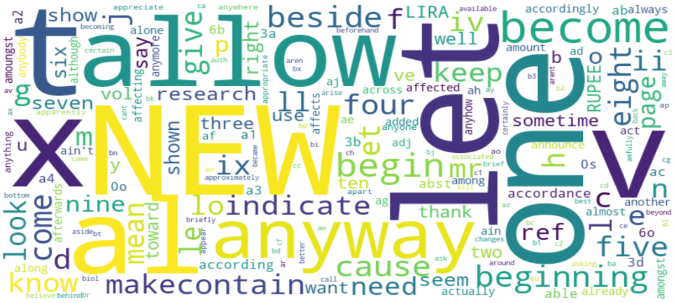

Fig. 3. Generated word cloud for stop words.

- Analyzing the richness of vocabulary in the data corpus.
- Constructing a data dictionary.
- Accessing the diversity and complexity in the written content.

WordNet, a computational lexical database with linguistic and physiological features [26], identifies English verbs, nouns, adjectives, and adverbs through part-of-speech tagging. Table III illustrates some unique words extracted from the data corpus.

TABLE III. Few Unique Words from the Data Corpus

solutions	powerful	multimedia	company	relevant
sales	search	technology	moved	doubled
turnover	platform	location	leverage	strengthened
content	communities	domestic	profit	loss
period	project	recorded	ownership	generated

D. Sentiment Score and Data Dictionary

Determining the significance of specific words within a group of relevant words is vital in determining the sentiment scores. The newly proposed approach calculates this importance by assigning sentiment scores, following the formulation, as depicted in Eq. (1).

$$SC = WP * \log(n/N) \tag{1}$$

where, SC is the sentiment score, WP is the word presence, n is the frequency of the unique word W_i, and N is the number of words present in the document. As $\log()$ is used in the formulation, SC value will be less and vice versa if the frequency of the word is more. WP takes the value as 0 or 1 for the presence or absence of the words in the document.

It can be challenging to obtain unique words and their corresponding sentiment scores for the next step. Therefore, a metadata repository, termed a data dictionary, is established to store words and their associated sentiment scores (SC). This data dictionary elucidates each word's context, offering crucial information for future reference without the need for in-depth analysis of the raw data. The SC value categorizes words as positive, negative, or neutral based on predefined threshold values, denoted as L_{value} and H_{value} in Eq. (2).

$$\begin{cases} positive & \text{if } SC \leq L_{value} \\ negative & \text{if } L_{value} < SC > H_{value} \\ neutral & \text{if } SC \geq H_{value} \end{cases} \tag{2}$$

The final step involves clustering the banking data document's positive, negative, and neutral words to serve as input for the subsequent phase.

In this implementation, words with a threshold value below and equal to 0.003 are classified as "positive," while words between 0.003 and 0.007 are considered "negative," and words exceeding the threshold of 0.007 are "neutral." These values are pivotal in creating a new dataset sorting statements into positive, negative, and neutral categories and establishing a data dictionary for positive, negative, and neutral categories containing unique words and their corresponding sentiment scores. Table IV presents a selection of unique words with their sentiment scores.

TABLE IV. UNIQUE WORDS WITH SENTIMENT SCORES

Sl#	Unique words	Sentiment Score
1	profit	0.0021
2	search	0.0014
3	relevant	0.0043
4	multimedia	0.0055
5	platform	0.0081

E. Synonyms and Antonyms with Sentiment Scores

Synonyms are words or phrases sharing identical meanings, allowing their replacement in a specific context without altering the meaning. Antonyms represent words with opposite meanings, conveying contrasting ideas in specific contexts. Comprehending synonyms and antonyms is vital for language and communication, fostering a diverse vocabulary and enhancing effective expression. This knowledge equips writers and speakers to convey messages precisely, highlighting contrasts and differences between ideas and concepts. WordNet [27] discerns connections between word meanings, identifying relationships such as synonyms and antonyms. For instance, “move, drive, impel” are synonymous words, while “stay, stop, discourage” are antonyms.

In this implementation, the process extracts synonyms and antonyms from unique words. It then allocates positive sentiment scores to synonyms, retains the same scores for unique words, and assigns antonyms a negative sentiment score with an identical value. Table V presents a selection of synonyms and antonyms with their sentiment scores corresponding to unique words.

TABLE V. SYNONYMS AND ANTONYMS WORDS WITH SENTIMENT SCORES

Sl#	Unique words	Synonyms	SC	Antonyms	SC
1	profit	financial gain	0.0021	loss	-0.0021
2	search	explore	0.0014	ignore	-0.0014
3	relevant	pertinent	0.0043	irrelevant	-0.0043
4	multimedia	multimodal	0.0055	monomodal	-0.0055
5	platform	podium	0.0081	ground	-0.0081

F. Sentence Similarity and Updated Dataset

Substituting synonyms and antonyms results in an updated dataset derived from the existing one. The newly proposed method, Control Distance, calculates sentence similarity after rephrasing these words, as depicted in Fig. 4.

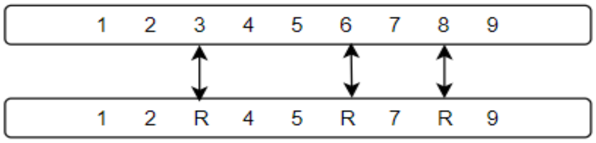

Fig. 4. Replaced words on original statement.

1) Control Distance: Calculating the sentence similarity between two strings involves determining the minimum number of edits (insertions, deletions, or substitutions) necessary to transform one string into another. This method also handles topographical inconsistencies in string data. In this implementation, the proposed expression assesses the similarity or dissimilarity between the original sentence and the sentences with substituted synonyms and antonyms.

$$SS_v = n * \frac{\sum_{i=1}^{n} SC_i}{N} \tag{3}$$

Here, SS_v is the Sentence similarity, and n is the words substituted in a sentence or a paragraph. N is the sum of the words present in a sentence or a paragraph. SC_i is the sentiment score of the substituted words.

After determining the Sentence Similarity (SS_v) between the original sentence and the sentences substituted with synonyms and antonyms, the SS_v is utilized to classify the sentences as similar or dissimilar by applying a standard threshold value, T_v.

$$Similarity = \begin{cases} Similar & SS_v \geq T_v \\ Dissimilar & SS_v < T_v \end{cases} \tag{4}$$

The similarity of the sentences determines the corresponding positive, negative, and neutral sentiments assigned to the original sentences.

Standard threshold values help measure sentences’ positive, negative, and neutral sentiments. Sentences with similarity values ranging from 0 to 3.0 are classified as positive, while those with similarity scores between 0 and -3.0 are negative. The remaining sentences with different similarity scores are considered neutral. Table VI presents a few of the sentence similarity scores.

TABLE VI. SIMILAR AND DISSIMILAR SENTENCES

Sl#	Statement	Similarity Score	Sentiment
1	L&G still paying price for dividend cut during crisis, chief says	Nill	Positive
2	L&G still rewarding price for dividend cut during emergency, chief says	2.26	Positive
3	L&G still remunerating price for dividend cut during disaster, chief says	1.93	Positive
4	L&G still compensating price for dividend cut during hardship, chief says	2.67	Positive
5	L&G still forgiving price for dividend cut during normalcy, chief says	-1.63	Negative
6	L&G still withholding price for dividend cut during certainty, chief says	-0.98	Negative
7	L&G still deferring price for dividend cut during harmony, chief says	-2.16	Negative

G. Model Implementation with Optimizer

ELECTRA (Efficiently Learning an Encoder that Classifies Token Replacements Accurately) [28] stands as a self-supervised language representation learning model. Its pretraining objective resembles the traditional Masked Language Model (MLM) but incorporates binary classification objectives. ELECTRA is a binary classifier during pretraining but can help adapt for multiclass classification tasks through finetuning.

ELECTRA operates through a Discriminator (D) designed to differentiate between “real” and “forged” tokens within a sentence. Additionally, it includes a Generator (G) network that substitutes certain input tokens with incorrect ones. Both the generators and discriminators are composed of transformer encoder layers, following the formulation below.

- Masked token replacement with sentiment score: The sequence token $T = [t_1, t_2, t_3, t_4, ..., t_i, ..., t_n]$ with associated sentiment score $SC = [SC_1, SC_2, SC_3, SC_4, ..., SC_i, ..., SC_n]$ where t_i represents the i^{th} token with corresponding sentiment score SC_i. The process of generating masked token operates as follows: for token t_i, it is replaced by a mask token $[MASK]$ with sentiment score SC_i.

- Generator (G): The generator (G) attempts to predict original token t_i from the $[MASKED]$ token, and its output is a probabilistic distribution over the vocabulary of each position i. Generator Loss (L_G) is calculated as

$$L_G = \sum_{i=1}^{n} SC_i * \sum_{j=1}^{V} t_i \log G([MASK], t_{connect}) \quad (5)$$

Here, V represents the vocabulary size, $G([MASK], t_{connect})$ signifies the output probabilities of the generator for masked taken $[MASK]$ given the context $t_{connect}$.

$$L_D = \sum_{i=1}^{n} SC_i * t_i \log D(t_i, t_{connect}) + (1 - t_i) \log(1 - D([MASK], t_{connect}))) \quad (6)$$

Here, $D(t_i, t_{connect})$ represents discriminator prediction for the token t_i with given context $t_{connect}$. Both the generator and discriminator are trained to minimize their respective loss based on the Sentiment scores.

To produce a probabilistic distribution over masked token, the SoftMax Function [29] is employed in the generator component. The function converts raw score denoted as $[S_1, S_2, S_3, S_4, ..., S_i, ..., S_v]$ into probabilities $[P_1, P_2, P_3, P_4, ..., P_i, ..., P_v]$ using below formula

$$SoftMax(P_i) = \frac{e^{S_v}}{\sum_{j=1}^{V} e^{S_j}} \quad (7)$$

The raw score generated by the ELECTRA generator is passed through the SoftMax function to obtain the probability of each token being the correct replacement for the masked token.

An optimizer is a crucial algorithm employed to fine-tune neural network attributes, such as learning rates and weights, to minimize loss during training. Its main purpose is to identify the optimal parameters that minimize the disparity between predicted and actual values. In this particular implementation, using the Adaptive Moment Estimation (ADAM) optimizer [30] proves invaluable for obtaining optimal results from the ELECTRA model. Additionally, integrating the L2 regularizer [31] into the modified Adam optimizer enhances convergence, addresses sparse gradient issues, prevents computation in local minima, and handles imbalanced data effectively.

H. Sentiments

Banking customers convey feelings about specific media data, brands, products, or services, encompassing attitudes, opinions, and emotions. Analysts examine sentiments based on written or voice feedback provided by customers and the mass media data, typically classifying them into three categories: positive, negative, and neutral [17], reflecting different emotional tone.

- **Positive:** Expresses satisfaction, joy, love, excitement, etc.

- **Negative:** Conveys feelings of sadness, anger, disappointment, displeasure, etc.

- **Neutral:** Lacks strong positive or negative emotions, presenting factual text without any specific emotional tone.

An automated sentiment analysis approach that identifies these emotions in feedback and media text documents offers valuable insights into the emotional content, proving particularly useful in banking data analysis.

I. Algorithm for Sentiment Analysis

The suggested approach for analyzing sentiment from textual data involves four distinct phases. Algorithm 1 addresses text data pre-processing. Algorithm 2 outlines the identification of Synonyms and Antonyms associated with individual words and their respective Sentiment Scores. Algorithm 3 illustrates the generation of an enhanced Dataset. Lastly, Algorithm 4 demonstrates sentiment classification utilizing the ELECTRA model on the updated dataset.

VI. Results and discussion

The Sentiment Analysis model uses Python, relying on various frameworks and machine learning libraries for implementation. Python (specifically Python 3.6.3$rc1$) and the NLTK 3.0 library are used for text data processing, providing a range of built-in functions. The Seaborn and Matplotlib libraries for statistical data analysis and visualization help plot the graph. Additionally, the experiment utilizes machine

Algorithm 2 Extracting Synonyms and Antonyms from Unique words with Sentiment Score

```

learning libraries such as Keras (version 2.6.0), TensorFlow (version 2.6.0), and Scikit-learn.

A. Results

In this setup, the assessment of the model's validation performance uses various metrics from the confusion matrix, including accuracy, recall, precision, and F-score. A rigorous $10 - fold$ cross-validation approach helps to evaluate the sentiment scores. Multiple scenarios, including the original dataset, datasets with synonyms replaced, datasets with antonyms replaced, and combinations help to estimate the model's performance. As a constraint, the implementation includes only three synonyms and antonyms words. Table VII displays the model performance on the Postbank dataset, as well as datasets containing synonyms and antonyms rephrased sentences.

Fig. 5 illustrates a graphical representation of negative, neutral, and positive sentiments. The basis of this representation is on performance measures such as False Positive Rate (FPR) and False Negative Rate (FNR) values. The analysis includes the post-bank dataset, datasets with replaced synonyms and antonyms. The analysis of the post-bank dataset involves a combination of sentences with rephrased synonyms and antonyms, along with the original sentences. Table VIII presents the performance metrics for the post-bank dataset, including sentences with rephrased synonyms and antonyms.

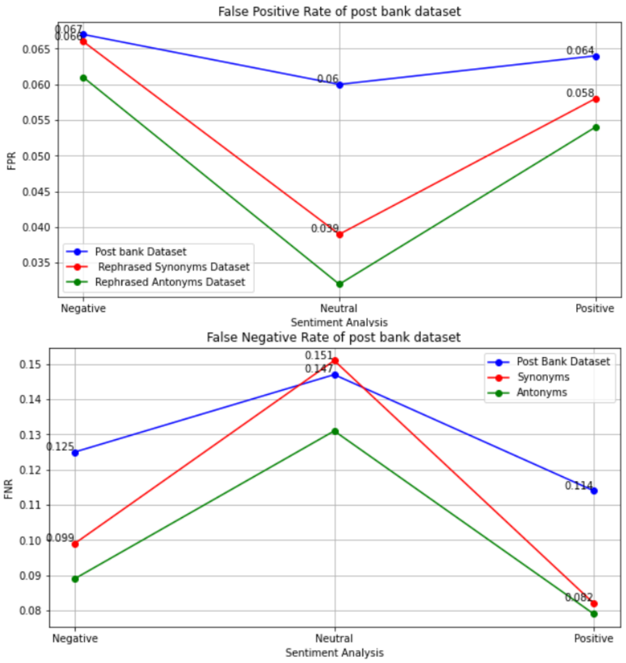

Fig. 5. FPR and FNR values for post bank, rephrase synonyms and antonyms dataset.

Regarding the performance metrics, neutral sentiments are exhibiting lower performance compared to other sentiments. Similarly, the assessment of the performance of the Phrase bank dataset includes sentences with rephrased synonyms and antonyms. Table IX displays the model performance on the Phrase bank dataset, as well as datasets containing synonyms and antonyms rephrased sentences.

TABLE VII. PERFORMANCE METRICS OF POST BANK, SYNONYMS AND ANTONYMS DATASETS

Sl#	Parameters	Original Dataset			Synonym Dataset			Antonym Dataset		
		negative	neutral	positive	negative	neutral	positive	negative	neutral	positive
1	Precision	87.26	84.80	88.98	87.16	90.41	89.81	88.23	92.01	90.50
2	Recall	87.40	85.22	88.50	90.05	84.83	91.72	91.07	86.81	92.07

Fig. 6 depicts a graphical representation of negative, neutral, and positive sentiments based on performance metrics such as False Positive Rate (FPR) and False Negative Rate (FNR) values. The analysis of the Phrase bank dataset involves a combination of sentences with rephrased synonyms and antonyms, along with the original sentences. Table X presents the performance metrics for the Phrase bank dataset. The proposed model analyzes both the Post bank customer data and Phrase bank datasets. These datasets contain statements with rephrased synonyms and antonyms alongside original statements or paragraphs. The analysis utilizes the modified ADAM optimizer. Fig. 7 illustrates the overall performance of the proposed model for both datasets.

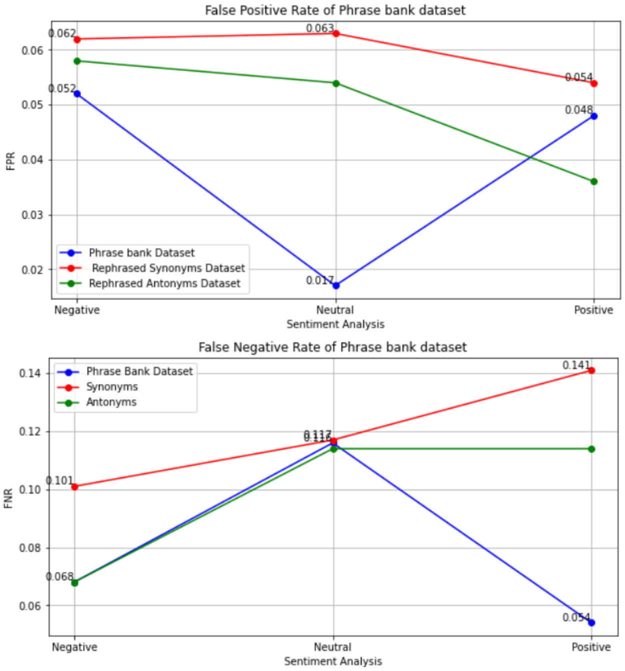

Fig. 6. FPR and FNR values for phrase bank, rephrase synonyms and antonyms dataset on testing data.

The implementation is validated using the ADAM optimizer and the modified Adam optimizer, incorporating L2 regularization. The modified Adam optimizer outperforms the standard Adam optimizer significantly. Table XI shows the comparative performance results.

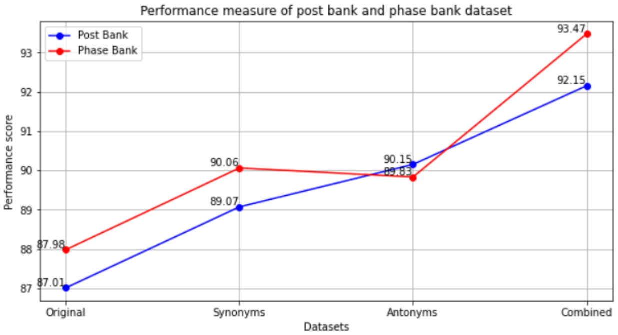

Fig. 7. Overall performance of the post bank and phrase bank dataset on testing data.

B. Performance Comparison

Utilizing the banking dataset in the proposed model yields superior results to conventional datasets such as general English sources (Wikipedia and BooksCorpus) and banking datasets like Phrase Bank.

The Name Entity Recognition (NER) task employs the financial language model based on ELECTRA [32]. In NER, a knowledge graph assists in comprehending the connections among various financial entities, such as individuals, organizations, and locations. The FLANG model achieves 82% accuracy in NER when applied to general English datasets like Wikipedia and BooksCorpus. However, the NER and FLANG concepts are also applied to the post-bank dataset, resulting in an accuracy of 82.9%.

The proposed approach is applied to analyze sentiments in the financial Phrase Bank dataset and financial tweets [33] utilizing the FinBERT model. Incorporating the CLS token, a special marker used for sequencing classification task representations, the model achieves an accuracy of 87.1%. Implementing the Phrase bank dataset [24] involves applying the ELECTRA model with Self-Attention and prediction layers, resulting in an accuracy of 83.87%, as shown in Table XII. This experiment represents the initial utilization of the Phrase bank dataset with ELECTRA and CLS tokens. Before this, ELECTRA had not incorporated the Phrase bank dataset.

C. Strength and Implication

The implementation results have numerous practical and theoretical implications. Theoretically, this research activity enhances our understanding of the sentiments conveyed by individual words in a sentence. It sheds light on market

sentiments and aids in comprehending the spread of misinformation within the Banking domain. This concept offers valuable insights into the psychological and social factors that influence the dissemination and reception of misinformation, informing the design of marketing strategies.

In practical terms, the suggested approach for evaluating sentiment scores assists in discerning the sentiments of individual meaningful words. Using synonyms and antonyms enhances the system's efficiency, enabling it to identify sentiments across a broader spectrum of arguments. Additionally, the control distance approach aids in recognizing similarities between sentences and their rephrased counterparts.

D. Novelty and Scope

The study centers on extracting sentiments from banking text data, including feedback and media reports. Previous literature has covered various studies on sentiment analysis. This research is purpose-built for improved efficiency and reduced latency. The paper's novelty can be summarized as follows:

- Proposed a sentiment-scoring approach for individual words, synonyms, and antonyms. Assign sentiment scores (positive, negative, and neutral) to synonyms and antonyms.
- Devised a Control Distance approach to validate the similarity score between the original sentence and the synonyms and antonyms used in sentences.
- Subsequently, design a self-trained model for the ELECTRA model, incorporating words with sentiment scores from the designed data dictionary.
- The implementation assessed performance using the ADAM optimizer and the modified ADAM optimizer, incorporating the L2 regularizer.

VII. Conclusion and Future Scope

The study presents a comprehensive sentiment analysis, identifying positive, negative, and neutral sentiments within customer feedback, financial, and economic texts. This analysis aids in combating misinformation in the market and informs marketing strategies. The article employed several methodologies, including text data preprocessing, sentiment identification for each word, synthesizing synonyms and antonyms for unique words, labeling individual sentences or paragraphs, and modeling. The dataset also labeled using sentiment scores for individual words and the control distance technique, providing meaningful sentiment analysis for individual sentences, thereby enhancing the overall implementation.

The implementation aims for a profound understanding of sentiments across a diverse dataset. A normalized threshold range of sentiment scores facilitates categorizing unique words into positive, negative, and neutral labels. Synonyms and antonyms are assigned similar sentiment scores, distinguished by positive and negative signs, respectively. The control distance approach verifies the sentiment scores of individual words in a sentence, evaluating positive, negative, and neutral statements. Subsequently, the ELECTRA model is self-trained using words with sentiment scores to classify sentiments. The implementation evaluates the model's output using both Adam and modified Adam optimizers for comparison.

The implemented approach demonstrates exceptional performance compared to FLANG_ELECTRA with NER model and the FinBERT model, using both Post banking customer data and Phrase banking data. The performance improvement compared to traditional models is substantial.

This article summarizes exploring the sentiments expressed in banking and financial-related data from customer feedback and financial news. The findings provide valuable insights for policymakers in the banking and financial sectors, aiding in developing strategies for customer feedback analysis, brand monitoring, product and service evaluation, fraud detection, market research, and competitor analysis. Additionally, the research holds practical significance by informing the design of automated tools for identifying sentiments within banking and financial text data.

Implementation of the proposed approach focuses on capturing sentiment scores within the documents. However, future work can broaden the scope. Currently, this implementation uses only three synonyms and antonyms. Exploring more synonyms and antonyms for word replacement opens avenues for further research.

Moreover, incorporating diverse deep learning, machine learning, and other models can enhance sentiment accuracy. Despite these options, this approach is the foundation for future investigations involving banking datasets. Researchers can also explore different banking-related datasets for in-depth analysis.

Iterative Learning Control for High Relative Degree Discrete-Time Systems with Random Initial Shifts

Dongjie Chen, Tiantian Lu, Zhenjie Yin*
Basic Courses Department, Zhejiang Police College, Hangzhou, Zhejiang 310053, China

***Abstract*—In this paper, an iterative learning control (ILC) strategy under compression mapping framework is presented for high relative degree discrete-time systems with random initial shifts. Firstly, utilizing the high relative degree of the system and difference term, a control law is designed and a p-order non-homogeneous linear difference equation is established. The appropriate control gain is selected according to the characteristics of solution of the difference equation and the initial shifts, so as to ensure that the high relative degree discrete-time system can reach a steady-state deviation output at a fixed time. Subsequently, a PD-type control law is employed to correct the fixed deviation of the system. Theoretical analysis indicates that this ILC strategy can ensure that the high relative degree systems achieve accurate tracking after the predefined time. Finally, the simulation experiments are conducted on a linear discrete-time Multiple-Input Multiple-Output(MIMO) system with relative degree 1 and a Multiple-Input Single-Output(MISO) system with relative degree 2, respectively, and the results verify the effectiveness of the algorithm.**

***Keywords*—Relative degree; iterative learning control; random initial shifts; difference equation; discrete-time system**

I. Introduction

For the control systems in the field of repetitive operations, iterative learning control (ILC) is a commonly used intelligent control strategy. Drawing from prior batch tracking errors and inputs to update the current batch's control inputs, ILC enables the repetitively operated system to follow the desired trajectory to a high degree of precision over a finite interval. Notably, ILC's lack of reliance on the knowledge of system dynamics, coupled with its superior adaptability, renders it an ideal fit for complex control systems. ILC is widely used in robot control systems [1]-[3], medical rehabilitation [4], [5], multi-agent formation [6], [7], batch processes [8], [9], train automatic control [10], [11]and so on.

The relative degree is utilized to express the extent to which a system control input directly feeds back the system output. In mathematical terms, the relative degree is defined as the lowest order derivative of system output with respect to time, which can be directly fed back by the control inputs. In the discrete-time dynamic systems, the relative degree is manifested as the time delay between the input and output of system, which is inherent in many practical applications. In many engineering practices, the system relative degree is larger than 1. The widespread presence of high relative degree dynamic systems has incited considerable interest in their ILC research within the control community in recent years.

For the high relative degree nonlinear continuous systems, under strict conditions of zero initial error, [12] adopted an antagonistic ILC method to enable system convergence; [13] designed a class of ILC algorithms based on data sampling; [14] proposed ILC laws which using error derivatives with the order less than the system relative degree. [15] presented a first-order D-type ILC based on the dummy model, which does not require the relative degree to be known. When there is a fixed initial shift, the control law proposed in [16] achieved consistent tracking over a specified interval by incorporating an initial correction behavior. This correction strategy had also been used in [17], [18] for high relative degree nonlinear discrete-time systems with fixed initial states.

For the high relative degree linear continuous systems, when the initial error is 0, [19] proposed a linear matrix inequality(LMI) design method based on the bounded real lemma(BRL). The research in [20] presented a unified 2-D analysis method for both continuous and discrete-time systems by defining similar symbols for continuous and discrete operators, but the model can only achieve asymptotic tracking for systems with initial shifts. The study in [21] proposed a PD-type control law for the fixed initial shifts, which guarantees convergence of the system within a finite interval, and the convergence speed is uniform. For uncertain systems with fixed initial shifts, [22] proposed an adaptive ILC algorithm. For the high relative degree linear multi-variable discrete-time systems, [23] proposed an iterative learning controller with an H_∞-based approach to suppress the random iteration-varying perturbations; when the system has a fixed iteration initial error, a P-type ILC algorithm is presented in [24] can achieve asymptotic tracking.

Regarding the initial value problem of ILC, most of the studies require that the initial shift is zero or fixed [25]-[27]. However, in many practical situations, the system will always inevitably exist initial shifts at each iteration, and due to the limitation of the actual repeat localization accuracy, the study of ILC with arbitrary initial shifts is of great significance. For nonlinear systems with varying initial iteration errors and tracking trajectories, the study in [28] proposed two adaptive ILC laws to achieve a complete reference trajectory tracking. The study in [29] presented a ILC method with a time-varying sliding mode, which enables random initial state errors to converge to zero beyond a initial time interval. This strategy achieves complete tracking for second-order nonlinear systems. An adaptive ILC algorithm based on filtering error correction is proposed in [30] to achieve precise tracking for non-parametric uncertain systems with random initial shifts and unknown input dead zones. For linear discrete time-delay systems, [31] proposed an ILC strategy with correction of initial state deviation to solve the trajectory tracking problem. The research in [32] adopted a phased ILC strategy, which first corrected arbitrary initial deviation to fixed deviation, and then corrected the fixed deviation, to achieve complete tracking for second-order continuous systems.

Despite these remarkable advances on ILC for arbitrary initial value problems, the study of high relative degree systems with arbitrary initial shifts is still relatively scarce. For the linear continuous MIMO systems with vector relative degree, the study in [33] proposed a control strategy based on an iteratively moving average operator, which make the system converge under a fixed initial error condition. Under an arbitrary initial error condition, this algorithm only made the system converge to a bounded range. For high relative degree SISO continuous systems, the presented ILC algorithm in [34] is based on the high relative degree, which utilized a form of multi-pulse compensation to suppress arbitrary initial shifts. For high relative degree linear discrete-time MIMO systems, [35] presented three ILC algorithms based on average operator to achieve complete tracking under the condition that the initial state vibrate slightly near a fixed point.

In this paper, an ILC algorithm based on compression mapping are presented to solve the random initial shift problem for high relative degree linear discrete-time systems. This algorithm draws on the phased correction strategy in [32] to deal with the random initial deviation problem. The random initial shifts are transformed into a fixed shift using a difference controller, and then the fixed shift is corrected by a PD-type controller to make the system converge at a predefined time. Finally, the validity of the proposed algorithm is demonstrated by simulation of two examples with different relative degrees. The conclusions are presented.

II. Problem Formulation

Consider a linear discrete-time system operating in the interval $[0, T]$:

$$\begin{aligned} x_k(t+1) &= Ax_k(t) + Bu_k(t) \\ y_k(t) &= Cx_k(t) \end{aligned} \tag{1}$$

where, $k = 1, 2, \cdots$ denotes the number of iterations; $x_k(t) \in \mathbb{R}^n$, $u_k(t) \in \mathbb{R}^n$, $y_k(t) \in \mathbb{R}^n$ denote the state variable, input and output of the system, respectively. A,B,C are system parameter matrices, which B is right invertible and C is left invertible.

$y_d(t)$ is the given desired output, $x_d(t)$ is the corresponding desired state. The system output error is defined as follows:

$$e_k(t) = y_d(t) - y_k(t) \tag{2}$$

Definition 1: [35] For the linear discrete-time system (1), if the Markov parameters satisfy

$$\left\{ \begin{array}{ll} CA^iB = 0, & 0 \leq i \leq p-2 \\ CA^{p-1}B \neq 0. & \end{array} \right. \tag{3}$$

The system relative degree of system is p.

Assumption 1: The initial state $x_k(0) \neq x_d(0)$ varies only arbitrarily within a certain range, i.e., $x_k(0)$ is a neighborhood of $x_d(0)$.

$$D = \{x_k(0) | \mid x_k(0) - x_d(0) \mid \leq \tfrac{\Lambda}{2}, x_k(0) \neq x_d(0)\}$$

where, $\frac{\Lambda}{2}$ is the radius of the neighborhood D.

III. Controller Design

In order to correct the random initial shifts of system (1), the controller is designed as follows:

$$\begin{aligned} & u_{k+1}(t) \\ = \; & u_k(t) + \textstyle\sum_{i=0}^{p-1} K_i(e_{k+1}(t-i) - e_k(t-i)) + r_k(t) \end{aligned} \tag{4}$$

where, K_i are control gains that can be set manually. $r_k(t)$ is a undetermined function.

Considering $x_{k+1}(t+p) - x_k(t+p)$, there is

$$\begin{aligned} & x_{k+1}(t+p) - x_k(t+p) \\ = \; & A(x_{k+1}(t+p-1) - x_k(t+p-1)) \\ & +B(u_{k+1}(t+p-1) - u_k(t+p-1)) \end{aligned} \tag{5}$$

Combining the control law (4) and Eq. (5), there is

$$\begin{aligned} & x_{k+1}(t+p) - x_k(t+p) \\ = \; & A(x_{k+1}(t+p-1) - x_k(t+p-1)) \\ & +B \textstyle\sum_{i=0}^{p-1} K_i(e_{k+1}(t+p-1-i) - e_k(t+p-1-i)) \\ & +Br_k(t+p-1) \\ = \; & A(x_{k+1}(t+p-1) - x_k(t+p-1)) \\ & -B \textstyle\sum_{i=0}^{p-1} K_iC(x_{k+1}(t+p-1-i) - x_k(t+p-1-i)) \\ & +Br_k(t+p-1) \end{aligned}$$

Setting $\eta_k(t) = x_{k+1}(t) - x_k(t)$, there is

$$\begin{aligned} & \eta_k(t+p) + (BK_0C - A)\eta_k(t+p-1) \\ & +B \textstyle\sum_{i=1}^{p-1} K_iC\eta_k(t+p-1-i) \\ = \; & Br_k(t+p-1) \end{aligned} \tag{6}$$

Eq. (6) is a p-order linear non homogeneous difference equation with constant coefficients. The corresponding homogeneous difference equation is

$$\begin{aligned} & \eta_k(t+p) + (BK_0C - A)\eta_k(t+p-1) \\ & +B \textstyle\sum_{i=1}^{p-1} K_iC\eta_k(t+p-1-i) = 0 \end{aligned} \tag{7}$$

Let its general solution be as follows:

$$\eta_k(t) = \varphi_k(t) + \varphi_k^*(t)$$

where $\varphi_k(t)$ is the general solution of Eq. (7) and $\varphi_k^*(t)$ is a particular solution of Eq. (6). One can set $\varphi_k(t) = \sum_{j=1}^{p} C_j\lambda_j^t$. λ_j are the p characteristic roots of the characteristic Eq. $\lambda^p + (BK_0C - A)\lambda^{p-1} + B\sum_{i=1}^{p-1} K_iC\lambda^{p-1-i} = 0$; C_j are arbitrary constant matrices.

Let characteristic equation have only one root λ, there is

$$\lambda = \lambda_j = \tfrac{A - BK_0C}{p} \tag{8}$$

The control gains K_i $(i = 1, 2, \cdots, p-1)$ can be obtained as follows:

$$K_i = B^{-1}C_p^{i+1}(-\lambda)^{i+1}C^{-1} = \tfrac{B^{-1}p!(-\lambda)^{i+1}C^{-1}}{(p-i-1)!(i+1)!} \tag{9}$$

Then $\varphi_k(t)$ can be written as:

$$\varphi_k(t) = \textstyle\sum_{s=0}^{p-1} C_st^s\lambda^t$$

For convenience, one can set $r_k(t+p-1) = Q\lambda^t$, where Q is an undetermined constant matrix. There is $r_k(t) = Q\lambda^{t-p+1}$. There is

$$\varphi_k^*(t) = qt^p\lambda^t$$

where q is an undetermined constant matrix.

Substituting the particular solution $\varphi_k^*(t)$ and Eq. (9) into Eq. (5), there is

$$\begin{array}{rl} & BQ\lambda^t \\ = & q(t+p)^p\lambda^{t+p} + (BK_0C - A)q(t+p-1)^p\lambda^{t+p-1} \\ & +B\sum_{i=1}^{p-1} K_iC(t+p-i-1)^p q\lambda^{t+p-i-1} \\ = & ((t+p)^p - p(t+p-1)^p \\ & +\sum_{i=1}^{p-1} C_p^{i+1}(-1)^{i+1}(t+p-i-1)^p)q\lambda^{t+p} \\ = & \sum_{j=0}^{p} C_p^j(-1)^j(t+p-j)^p q\lambda^{t+p} \\ = & \sum_{j=0}^{p} C_p^j(-1)^j(-j)^p q\lambda^{t+p} \end{array} \tag{10}$$

Thus

$$Q = B^{-1}\sum_{j=0}^{p} C_p^j(-1)^j(-j)^p q\lambda^p \tag{11}$$

$\eta_k(t)$ can be represented as

$$\begin{array}{rl} & \eta_k(t) = \sum_{s=0}^{p-1} C_s t^s\lambda^t + qt^p\lambda^t \\ = & \sum_{s=0}^{p} C_s t^s\lambda^t \end{array} \tag{12}$$

where $C_p = q$.

When $t \in [0, p-1]$, there are

$$\begin{cases} \eta_k(0) = C_0 \\ \eta_k(1) = \sum_{s=0}^{p} C_s\lambda \\ \eta_k(2) = \sum_{s=0}^{p} C_s 2^s\lambda^2 \\ \vdots \\ \eta_k(p-1) = \sum_{s=0}^{p} C_s(p-1)^s\lambda^{p-1} \end{cases} \tag{13}$$

If at a certain time $t = h$, there is $\eta_k(h) \to 0$, thus

$$\eta_k(h) = \sum_{s=0}^{p} C_s h^s\lambda^h = 0 \tag{14}$$

From (13) and (14), the coefficients C_s in (12) can be obtained as follows.

$$\begin{pmatrix} C_0 \\ C_1 \\ C_2 \\ \vdots \\ C_{p-1} \\ C_p \end{pmatrix} = \Upsilon \begin{pmatrix} \eta_k(0) \\ \eta_k(1) \\ \eta_k(2) \\ \vdots \\ \eta_k(p-1) \\ 0 \end{pmatrix} \tag{15}$$

where,

$$\Upsilon = \begin{pmatrix} I & \mathbf{0} & \mathbf{0} & \cdots & \mathbf{0} & \mathbf{0} \\ \lambda & \lambda & \lambda & \cdots & \lambda & \lambda \\ \lambda^2 & 2\lambda^2 & 2^2\lambda^2 & \cdots & 2^{p-1}\lambda^2 & 2^p\lambda^2 \\ \vdots & \vdots & \vdots & \ddots & \vdots & \vdots \\ \lambda^{p-2} & (p-2)\lambda^{p-2} & (p-2)^2\lambda^{p-2} & \cdots & (p-2)^{p-1}\lambda^{p-2} & (p-2)^p\lambda^{p-2} \\ \lambda^{p-1} & (p-1)\lambda^{p-1} & (p-1)^2\lambda^{p-1} & \cdots & (p-1)^{p-1}\lambda^{p-1} & (p-1)^p\lambda^{p-1} \\ \lambda^h & h\lambda^h & h^2\lambda^h & \cdots & h^{p-1}\lambda^h & h^p\lambda^h \end{pmatrix}^{-1}$$

When $t = h \ (h > p)$ and $\eta_k(h) \to 0$, there are $x_{k+1}(h) \to x_k(h)$, $x_k(h) \to x_{k-1}(h)$, $\cdots$, $x_3(h) \to x_2(h)$,. That is, when $t = h$, the system output $y_{k+1}(h)$ tends to a certain steady value, but not necessarily $y_d(h)$.

In order to converge the output error to zero, the controller is modified as follows:

$$u_{k+1}(t) = \begin{cases} u_k(t) + \sum_{i=0}^{p-1} K_i(e_{k+1}(t-i) - e_k(t-i)) & \\ +r_k(t) & t \in [0,h] \\ u_k(t) + K_d(e_{k+1}(t) - e_k(t)) & \\ +\Gamma e_k(t+p) & t \in (h,T] \end{cases} \tag{16}$$

where K_d and Γ are control gains that can be set manually.

IV. Convergence Analysis

This section focuses on he convergence analysis of the system (1) after applying the control law (16). In this section, $||\cdot||$ is defined to be a certain norm for vectors or matrices.

Theorem 1: When the initial shifts satisfies **Assumption 1**, and the control gain Γ satisfies

$$||I - B\Gamma CA^{p-1}|| < 1 \tag{17}$$

Then the correction control law (16) can make the system (1) achieve complete tracking,that is $\lim_{k\to\infty}||e_{k+1}(t)|| = 0$.

Proof: According to the **Definition 1**, when $t \in [0,h]$, $CA^{i-1}B = 0$, one has

$$\begin{array}{rl} & y_k(t+i) \\ = & Cx_k(t+i) \\ = & CAx_k(t+i-1) + CBu_k(t+i-1) \\ = & CA^2x_k(t+i-2) + CABu_k(t+i-2) \\ & +CBu_k(t+i-1) \\ = & CA^ix_k(t) + \sum_{j=1}^{i} CA^{j-1}Bu_k(t+i-j) \\ = & CA^ix_k(t) \end{array} \tag{18}$$

In the analysis of the previous section, through the correction of the control law (16), the output error of the system (1) is stabilized at a fixed value when $t = h$.

When $t > h$, one has

$$\begin{array}{rl} & x_{k+1}(t) - x_k(t) \\ = & A(x_{k+1}(t-1) - x_k(t-1)) \\ & +BK_d(e_{k+1}(t-1) - e_k(t-1)) \\ & +B\Gamma e_k(t+p-1) \end{array} \tag{19}$$

From the Eq. (18), there is

$$e_k(t+p-1) = CA^{p-1}(x_d(t) - x_k(t)) \tag{20}$$

Setting $\Delta x_k(t) = x_d(t) - x_k(t)$. Substituting $\Delta x_k(t)$ into (19), one has

$$\begin{array}{rl} & \Delta x_k(t) - \Delta x_{k+1}(t) \\ = & (A - BK_dC)(\Delta x_k(t-1) - \Delta x_{k+1}(t-1)) \\ & +B\Gamma CA^{p-1}\Delta x_k(t) \end{array} \tag{21}$$

When $t = h+1$, according to $x_k(h) = x_{k+1}(h)$ and (21), there is

$$\Delta x_{k+1}(h+1) = (I - B\Gamma CA^{p-1})\Delta x_k(h+1)$$

Therefore, when $||I - B\Gamma CA^{p-1}|| < 1$, there is

$$\lim_{k\to\infty} ||\Delta x_{k+1}(h+1)|| = 0 \tag{22}$$

So

$$\begin{aligned} & \lim_{k\to\infty} ||e_{k+1}(h+1)|| \\ = \; & C\lim_{k\to\infty} ||\Delta x_{k+1}(h+1)|| \\ = \; & 0 \end{aligned}$$

Similarly, when $t \in (h+1, T]$, there is

$$\lim_{k\to\infty} ||e_{k+1}(t)|| = 0$$

V. Numerical Simulations

To verify the above conclusion, this paper conducts simulation experiments on two systems with relative degree 1 and 2, respectively. And compared it with the algorithm proposed in [24].

A. Linear Discrete-time MIMO System with Relative Degree 1

Considering the following MIMO system:

$$\begin{aligned} x_k(t+1) &= \begin{bmatrix} 0.6 & 0.25 \\ 0 & 0.65 \end{bmatrix} x_k(t) + \begin{bmatrix} 1 & 0.05 \\ 0.1 & 1.7 \end{bmatrix} u_k(t) \\ y_k(t) &= \begin{bmatrix} 0.8 & -0.13 \\ 0.1 & 0.5 \end{bmatrix} x_k(t) \end{aligned} \tag{23}$$

From $CB \neq 0$, the system relative degree is $p = 1$. Let the control gains of (16) be

$$K_0 = 1.2, \qquad K_d = 0.9, \qquad \Gamma = \begin{bmatrix} 0.27 & 0.14 \\ 0.03 & 0.31 \end{bmatrix}$$

It is easy to verify that $||I - B\Gamma CA^{p-1}|| < 1$, which satisfies the condition of **Definition 1**. $r_k(t)$ is determined according to Eq. (11) and (15). The system reference trajectory is as follows:

$$y_d(t) = \begin{bmatrix} y_{1,d}(t) \\ y_{2,d}(t) \end{bmatrix} = \begin{bmatrix} 0.0008(t-50)^2 - 1 \\ sin(0.02\pi t) \end{bmatrix} \tag{24}$$

The system initial state is $x_k(0) = [rand + 0.5 \;\; rand - 0.5]^T$(where $rand$ generates a random value between 0 and 1). Let the system operating interval be $[0, 100]$, and the preset time $h = 15$. The simulation results are shown in Fig. $1-3$, where simulation is implemented for 50 iterations.

Fig. 1 shows the results of system outputs $y_{1,k}(t)$ and $y_{2,k}(t)$ tracking the reference trajectories $y_{1,d}(t)$ and $y_{2,d}(t)$ after different number of iterations, respectively. Fig. 2 shows the results of tracking errors $e_{1,k}(t)$ and $e_{2,k}(t)$. Fig. 3 shows the variations of system inputs $u_{1,k}(t)$ and $u_{2,k}(t)$. From Fig. $1-3$, it is obvious that when $t = 15$, the system outputs $y_{1,k}(t)$ and $y_{2,k}(t)$ tend to be fixed values, and when $t = 16$, both the system tracking errors are zero, the system achieves accurate tracking.

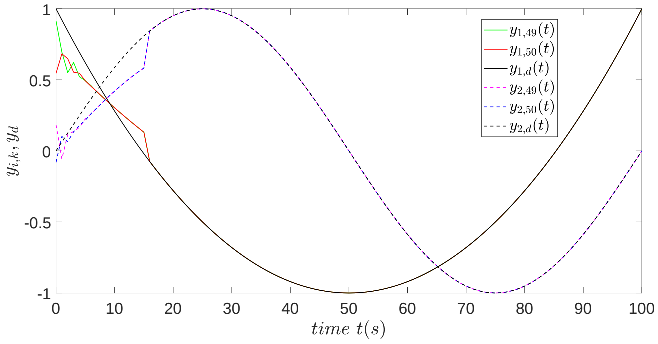

Fig. 1. Outputs $y_{i,k}(t)$ and reference trajectories $y_{i,d}(t)$.

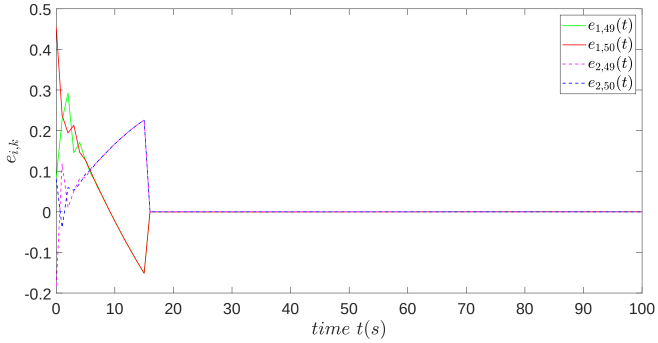

Fig. 2. Errors $e_{1,k}(t)e_{2,k}(t)$.

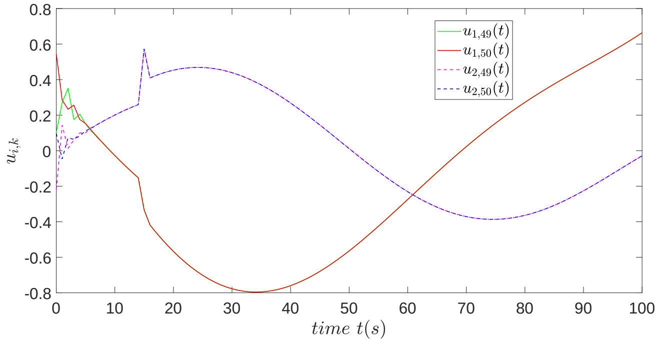

Fig. 3. Inputs $u_{1,k}(t)u_{2,k}(t)$.

B. Linear Discrete-time MISO System with Relative Degree 2

Considering the following MISO system:

$$\begin{cases} x_k(t+1) &= \begin{bmatrix} 0.8 & 0.1 \\ -0.25 & -0.33 \end{bmatrix} x_k(t) + \begin{bmatrix} 0 \\ 1.1 \end{bmatrix} u_k(t) \\ y_k(t) &= \begin{bmatrix} 1.7 & 0 \end{bmatrix} x_k(t) \end{cases} \tag{25}$$

From $CB = 0$ and $CAB \neq 0$, the system relative degree is $p = 2$. Let the control gains in the control law (16) be $K_0 = 1.8, K_d = 1.1, \Gamma = 2.9$. According to the relative degree $p = 2$ and Eq. (9), there exists $K_1 = -0.0052$. $r_k(t)$ is determined according to Eq. (11) and (15). It is also easy to verify that $||I - B\Gamma CA^{p-1}|| < 1$. Let the system operating interval be $[0, 100]$, and the preset time $h = 20$. The system desired trajectory is as follows:

$$y_d(t) = cos(0.02\pi t) \qquad t \in [1, 100]$$

The system initial state is $x_k(0) = [rand \quad rand]^T$. The simulation results are shown in Fig. $4-6$, where simulation is implemented for 50 iterations. Fig. 4 shows the result of the system output $y_k(t)$ tracking the desired trajectory $y_d(t)$ with the number of iterations. Fig. $5-6$ shows the variations of tracking error $e_k(t)$ and system input $u_k(t)$ after different number of iterations, respectively.

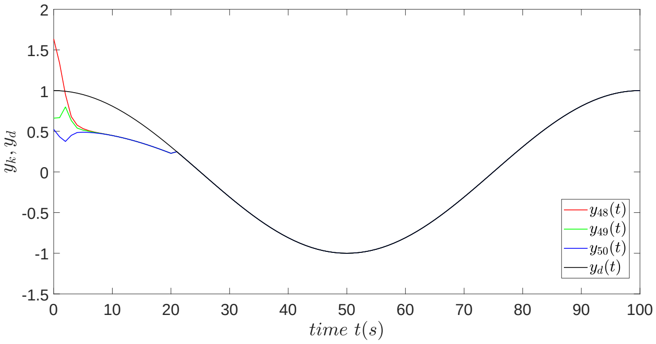

Fig. 4. $y_k(t)$ and $y_d(t)$.

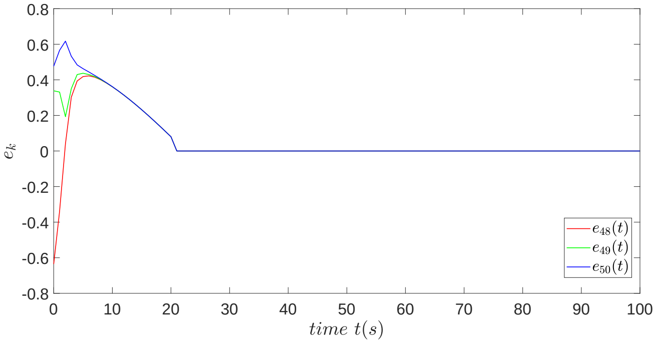

Fig. 5. Errors $e_k(t)$.

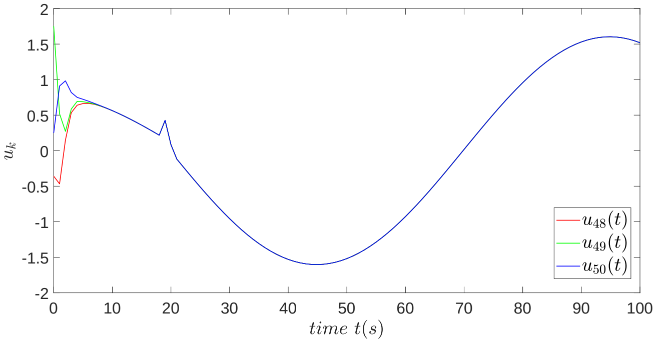

Fig. 6. Inputs $u_k(t)$.

From Fig. $4-6$, it is obvious that when $t = 20$, the system output tends to a fixed value. When $t = 21$, the system tracking error is 0, and the system achieves accurate tracking.

C. Comparison of Different Algorithms

For high relative degree linear discrete-time systems, the current research mainly focuses on the systems with fixed initial shifts, which is not applicable to the ones with random initial shifts. The ILC law (16) is compared with the algorithm proposed in [24] to demonstrate the effectiveness of the algorithm presented in this paper. Under the same conditions, the system (25) is simulated by using these two algorithms separately, and the results are shown in Fig. 7. The blue lines denote the outputs of the algorithm proposed in [24] after 48, 49, and 50 iterations respectively, and the black solid line denotes the desired trajectory, the red lines denote the outputs of the algorithm proposed in this paper. It is obvious that our algorithm can make the system converge, while the algorithm in [24] is unable to do.

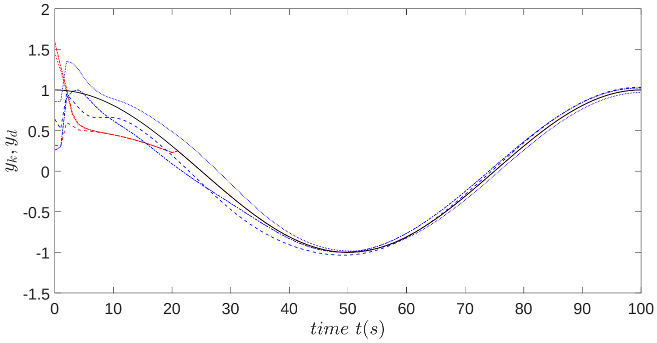

Fig. 7. $y_k(t)$ and $y_d(t)$.

VI. Conclusion

The ILC problem for high relative degree linear discrete-time systems with random initial shifts is discussed in this paper, and a control strategy with deviation correction is proposed. Theoretical analysis indicates that the presented algorithm can quickly correct the system initial state error and make the system converge after the predefined time. Finally, simulations were conducted using two discrete-time systems with relative degree 1 and 2, respectively, and the results proved the effectiveness of the algorithm. In the future, the effectiveness of this ILC strategy on discrete time-delay systems will be discussed.

***Abstract*—The collaboration between distribution companies is gaining a great interest in the last years due to the benefit provided to reduce the cost of deliveries. In this work we study the centralized two-echelon collaborative multi-center multi-periodic vehicle routing problem with a specific constraints. In which each distribution center conserves its VIP customers, and each partner keep their delivery scheduling unchangeable. The problem is modelled as a MILP, and to solve it a hybrid algorithm is proposed. This algorithm combines a multi-population memetic algorithm (MPMA) and a variable neighbourhood search algorithm that integrates a tabu search list (VNS-T). The results obtained are compared with those obtained by CPLEX solver and the best known solution of the multi-depot vehicle routing problem (MDVRP).**

***Keywords*—Collaborative vehicle routing problem; two-echelon networks; memetic algorithm; Variable neighbourhood serach**

I. Introduction

The significant growth in the delivery of small volumes of goods generated by the increase in e-commerce sales [1] and domestic freight, particularly during the Covid-19 pandemic [2], creates major challenges for distribution companies operating in the urban sector. It's well known that the urban transport faces a major problem of empty runs with more than 40% of unloaded trips. The empty running of trucks generates multiple challenges like higher delivery costs [3], congestion of distribution networks [4], and increased CO2 emissions [5]. To face these challenges, distribution companies are driven to explore new distribution strategies.

Recently, centralized collaborative strategies have been gaining considerable attention due to their positive impact on the reduction of distribution costs. These strategies generate coalitions involving multiple independent members, in which the organization of the collaborative process can be outsourced to a third-party (TP). This collaboration is often described by the collaborative multi-center vehicle routing problem (CMCVRP) [6]. The maximum performance of a collaborative process is obtained through total information sharing between its members [7]. Nonetheless, the formation of new coalitions faces several challenges [8], especially in establishing the necessary level of trust between partners. The most common problem resides in the lack of background in the field of collaborative practices as well as an incomplete legislative framework [9]. Moreover, Companies are not willing to risk losing their Very Important (VIP) customers in favour of other coalition members. On the other hand, to prevent a possible deterioration of their service quality, companies try to keep their delivery schedules unchangeable.

To the best of our knowledge, there are no studies that tackle the centralized CMCVRP where the information related to VIP customers is concealed and the delivery schedule of each member of the coalition is kept unchanged. To fill this gap, this paper studies a new extension of the two-echelon collaborative multi-center vehicle routing problem (2E-CMCVRP) by considering constraints of VIP customers and inflexible delivery schedules [10]. The problem is formulated as a MILP, and a multi-phase solving approach (MPSA) is proposed to solve it. The MPSA integrates a multi-population memetic algorithm (MPMA) and a modified VNS algorithm.
The remainder of this paper is organized as follows. In Section II, the literature is reviewed. Then in Section III, we describe the problem and we formulate its corresponding mathematical model. In Section IV, a detailed description of the proposed multi-phase solving approach is presented. The numerical results are presented in the Section V. Finally, the conclusions and future research suggestions are presented in the Section VI.

II. Literature Review

A. Collaborative Two-echelon Periodic MCVRP

The underlying problem of this paper (CMCVRP) is an extension of the MDVRP. Several approaches to solve the MDVRP have been examined in the literature. In 2012 Vidal et al. proposed a hybrid genetic algorithm with an adaptive diversity control metaheuristic to solve the periodic MDVRP [11]. In 2015, Rahimi et al. introduced a new modular heuristic algorithm (MHA) to manage the periodic MDVRP with capacity, duration, and maximum budget constraints [12]. Recently, an extensive review of different formulations and solving approaches for the MDVRP was published by Ramos, Shara et al. [13], [14].

To deal with the different challenges, distribution companies are constrained to treat their competitors differently by introducing new forms of interaction. Therefore, various forms of collaboration are emerging in this sector that show an important potential benefits [15], [16], [17], [18], [19]. Moreover, different variants of the routing problem in a collaborative setting have been explored. In [20] the authors developed an adaptive large neighborhood search iterative algorithm to solve a pickup and delivery problem with time window (PDPTW) that considers the outsourcing and exchange of requests between collaborators in a centralized collaborative configuration. In 2016, Soysal et al. studied the impact of horizontal collaboration on perishable products, logistics costs, and CO2 emissions for the inventory routing problem (IRP) [21].

Generally, the urban distribution is a periodic VRP (PVRP) for which several studies focused on implementing collaborative scenarios are presented. In [22] an empirical study is conducted to evaluate the influence of three companies' characteristics (e.g., the number of orders to transport, the order size and the ability of a company to delay its orders) which operate in a periodic scenario on the total profit. In 2017, Smilowitz et al. developed an adaptive large neighborhood search algorithm to solve the periodic location routing problem in the collaborative recycling sector [23]. They concluded that increasing the flexibility of delivery schedules impacts positively the reduction of expenses, especially when the maximum capacity constraint is very stringent.

The two-echelon vehicle routing problem (2E-VRP) is a variant of the multi-echelon vehicle routing problem (MEVRP) where the delivery of goods to customers is done by various intermediate plants. The urban distribution is one of the sectors where the 2E-VRP is often implemented [24]. In [25] Wang et al. introduced the two-echelon collaborative multi-center vehicle routing problem (2E-CMCVRP) as a combination of a multi-center VRP (MCVRP) and a profit allocation problem. The authors evaluated the economic and environmental impact of such collaboration and they proposed a two-phase algorithm based on a clustering method and a non-dominated sorting genetic algorithm to solve it.

In 2020, Wang et al. [26] proposed a collaborative and resource-sharing strategy to solve the multi-depot multi-period vehicle routing problem with pickup and delivery (MD-PVRPPD). The authors concluded that combining collaborative and resource-sharing mechanisms improve the multi-depot multi-period logistics network with pickup and delivery.

B. Information Sharing in Decentralized and Centralized Collaboration Configurations

The development of the collaborative process involving different partners requires certain level of information sharing. Generally, there are two information sharing strategies: partial sharing in decentralized collaborative configurations and total sharing in centralized configurations [27]. In both strategies, a third-party (A logistics service provider, online platform...etc) it's responsible for organizing the collaboration.

The decentralized collaborative VRP has been the focus of several studies that considered different mechanisms of information sharing. In [28] the authors suggested a request exchange mechanism based on the auction of a single request with limited information. In 2017, Huang et al. [29] developed an efficient auction-based mechanism for the carrier collaboration problem with bilateral exchange (CCPBE) where the carriers can only offer requests with the highest marginal costs and can bid on a bundle of lanes. Under this mechanism, the shared lanes' information is available to all carriers. In [30], the authors evaluated the impact of providing information about requests to the auction pool in an auction-based carrier collaboration problem where the requests are shared in an aggregated form. The aggregates are generated through grids that cover the geographical area of the requests.

Different types of central authorities have been considered in studies investigating the centralized collaborative VRP. The dynamic collaborative pickup and delivery problem which relies on a peer-to-peer platform that matches ad hoc drivers or backup vehicles to deliver tasks in real time is introduced in [1]. In [17], Maneengam et al. developed the centralized collaborative bidirectional multi-period vehicle routing problem under profit-sharing agreements, where the collection and integration of information and resources are done by a control tower. The tower establishes a collaborative transport planning respecting the profit-sharing agreements. The integration of tactical collaborative decisions has been raised in [32], in which the authors evaluated the economic and environmental impact of two collaborative scenarios in a centralized configuration: semi-cooperative and fully cooperative. In the first scenario, collaboration takes place at the operational level where all the customers and vehicle capacity information are shared to build the routing plan. In the second scenario, the collaboration occurs not only on an operational level but also tactical one. In this scenario, the routing and facility location decisions are taken jointly.

III. The Two-echelon Collaborative Multi-center Multi-periodic Vehicle Routing Problem

A. Problem Description and Assumptions

The 2E-CMCPVRP with VIP customers and inflexible delivery schedules is a distribution network with several independent distribution centers (DC), in which we suppose that one of the centers has the needed infrastructure to play the role of a logistics center (LC). Each center i serves a set of customers according to a specific schedule w_i of several periods t with a fleet of K_i vehicles, some of these customers can be shared with other centers except its VIP customers. Furthermore, we consider that a neutral third-party is in charge of the organization of the centralized collaborative process whose objective is to establish a collaborative network by a possible reassignment of non-VIP customers. The volumes of goods corresponding to the reassigned customers are initially stored in the LC. The presence of a LC transforms the initially independent distribution network into a collaborative two-echelon system where the routes between the LC and the DCs are covered by semi-trailers. The major assumptions of this study are:

- The LC has enough additional storage space,
- Each center DC has enough storage space to accommodate the reassigned goods from other centers,
- The customer's demand is deterministic and is known a priori,
- Each customer is visited only once during the consolidated delivery schedule,
- The fleet of vehicles is homogenous and each DC has a limited number of vehicles,

- Each vehicle starts and ends its route at the center in which it is parked within a limited time,
- The semitrailer starts and ends its route at the LC,
- The average speed of the roads (arcs) may differ from one road to another,
- The maintenance, leasing, and fuel costs of the vehicles may differ from one vehicle to another.
- Model formulation

The proposed MILP model for the 2E-CMCPVRP-VCIS is formulated as a two-echelon collaborative periodic VRP model. The objective is to minimize the total distribution costs considering the VIP customers' constraints and the inflexible delivery schedules. The parameters and related notations used in the 2E-CMCPVRP-VCIS model are detailed in the next section.

B. Parameters and Notations

The parameters and notations used in this work are presented in Table I, Table II and Table III. The best values of the parameters are obtained by testing various values of each parameter.

TABLE I. Data Sets in the 2E-CMCPVRP-VCIS

Set	Definition
I	Set of centers (DC and LC)
J	Set of customers
K	Set of vehicles
T	Set of periods in w
K^i	Set of vehicles belonging to the center i, i∈ I
J^i	Set of customers initially assigned to center i, i∈ I

C. Modeling

a) Objective function: The objective function is defined as follows:

$$T_{total} = T_1 + T_2 + T_3 \tag{1}$$

where,T1 defines the sum of costs related to the semi-trailer's, T_2 is the sum of the dispatching, maintenance, leasing, and fixed costs and T_3 is the sum of delivery costs related to the fuel consumption during a consolidated delivery schedule.

$$T_1 = \sum_{t \in T} (T_{11}^t + T_{12}^t) \tag{2}$$

where, T_{11}^t and T_{12}^t are respectively the sum of the fuel costs and maintenance costs of the semi-trailer over a period *t* given by the Eq. (3) and Eq. (4).

$$T_{11}^t = \sum_{i,h \in I, h \neq i} H_{se} \times \rho \times d_{ih} \times o_{ih}^t \tag{3}$$

$$T_{12}^t = \sum_{(i,h \in I, h \neq i)} \frac{M \times o_{ih}^t \times d_{ih}}{K_a} \tag{4}$$

TABLE II. Input Parameters in the 2E-CMCPVRP-VCIS

Parameter	Definition
u_j^t	Equals 1 if the customer must be visited on period t, j∈J,t∈T
ρ	Fuel price
N_i	Number of vehicles belonging to the center i,i∈I
N_s	Number of semi-trailers
H_{se}	Average fuel consumption of the semi-trailer per 100km
h_k	Average fuel consumption of the vehicle k,k∈K per 100km
F	Average annual vehicle maintenance costs
L	Average annual vehicle rent or leasing costs
Q_{max}	Maximum capacity of a vehicle
N_{Tot}	Total number of available vehicles
K_a	Average annual distance covered by a semi-trailer (Km)
B	The capacity of the semi-trailer
T_{max}	Maximum working time per period
q_j	The demand of the customer j,j∈ J
M	Average annual semi-trailer maintenance costs
G_i	Fixed costs of center i per period. The third-party (TP) covers the fixed costs when the centre i agrees to cooperate, i∈I
P_i	CA's service costs for center i per period when cooperation is achieved, i∈I
τ	Number of consolidated delivery schedules per year
w_i	Delivery schedule of center i,i∈I
w	Consolidated delivery schedule of the coalition with $w = \cup_{i \in I} w_i$
d_{ij}	The distance between centers i and j, i,j∈ $J \cup I$
y_i	Coefficient of variable costs of center i, i∈I
vip_{ij}	If the customer j is a VIP customer of centre i, $vip_{ij} = 1$ else $vip_{ij} = 0$,j∈J, i∈I
v_{ij}	Average road speed between nodes i and j, (j,i)∈ $J \cup I$
V_{ik}	Assignment of a vehicle to a specific center, i∈I,k∈K
y_i	y_i=1 if centre i collaborates else y_i= 0, i∈I

TABLE III. Decision Variables

Variable	Definition
x_{ij}^{kt}	Equals 1 if vehicle k travels directly from i to j during the period t otherwise is equal to 0, (i,j)∈I∪J,k∈K,t∈T
o_{ij}^t	If the semi-trailer travels directly from center i to centre j on period t, $o_{ij}^t = 1$ else $o_{ij}^t = 0$, i,j∈I,t∈T
ϕ_{ik}	A variable used for the elimination of sub-turns in the second echelon. It is always positive, i∈I,k∈K
δ_{ik}	A variable used for the elimination of the sub-turns in the first echelon. It is always positive, i∈I,k∈K

T_2 gives the sum of the dispatching, maintenance, leasing, and fixed costs as in the Eq. (5).

$$T_2 = T_{21} + \sum_{t \in T} T_{22}^t. \tag{5}$$

where T_{21} Gives the total service costs required by the third-party plus the maintenance and leasing costs of the fleet, and T_{22}^t is the dispatching costs of the quantities delivered during a period *t*. where:

$$T_{21} = \sum_{i \in I} [(1 - y_i)G_i + y_i P_i + (T_{23} \times (\frac{F + L}{\tau}))] \tag{6}$$

where T_{23} gives the needed number of vehicles to cover the customers' demands over the consolidated delivery schedule; it is equal to the highest number of vehicles used by all centers during a period *t*.

$$T_{22}^t = \sum_{i \in I} \sum_{k \in K^i} \sum_{p \in I \cup J} \sum_{j \in J} x_{ij}^{kt} \times u_j^t \times q_j \times \gamma_i. \tag{7}$$

T_3 is the sum of delivery costs related to the fuel consumption during a consolidated delivery schedule as in Eq. (8)

$$T_3 = \sum_{t \in T} \sum_{i,j \in I \cup J} \sum_{k \in K} \frac{d_{ij} \times x_{ij}^{kt} \times u_j^t \times \rho \times h_k}{100}. \quad (8)$$

First echelon constraints:

$$\sum_{j \in J, j \neq i} o_{ji}^t = 1, i \in I, t \in T (i = 1 \text{ corresponds to LC}) \quad (9)$$

$$\sum_{i \in J, j \neq i} o_{ij}^t = 1, j \in I, t \in T (j = 1 \text{ corresponds to LC}) \quad (10)$$

$$\sum_{j \in I} o_{ij}^t - \sum_{j \in I} o_{ji}^t = 0, i \in I, i \neq, t \in T \quad (11)$$

$$\sum_{i \in I} \sum_{k \in K_i} \sum_{l \in I \cup J, p \in J \setminus J^i, l \neq i)} x_{ij}^{kt} \times u_j^t \times q_p \leq B, t \in T \quad (12)$$

$$\phi_i - \phi_j + N_s \times o_{ij}^t \leq (N_s - 1), i, j \in I, i \neq 1, t \in T \quad (13)$$

$$\phi_i \geq 0, i \in I, i \neq 1 \quad (14)$$

Second echlon constraints:

$$\sum_{t \in T} \sum_{k \in K} \sum_{i \in I \cup J, i \neq j} x_{ij}^{kt} \times u_j^t = 1, j \in J \ (15)$$

$$\sum_{j \in J} (q_j \times \sum_{i \in I \cup J} x_{ij}^{kt}) \leq Q_{max}, k \in K, t \in T \ (16)$$

$$\delta_{ik} - \delta_{jk} + N_v \times x_{ij}^{kt} \leq N_{Tot} - 1, k \in K, i, j \in J, t \in T \ (17)$$

$$\delta_{ik} \geq 0, k \in K, i \in J \ (18)$$

$$\sum_{j \in I \cup J} x_{ij}^{kt} - \sum_{j \in I \cup J} x_{ji}^{kt} = 0, k \in K, i \in I \cup J, t \in T \ (19)$$

$$\sum_{i,j \in I \cup J} x_{ij}^{kt} \times \frac{d_{ij}}{v_{ij}} \leq T_{max}, k \in K, t \in T \ (20)$$

$$\sum_{t \in T} \sum_{K^p} \sum_{i \in I \cup J} x_{ij}^{kt} \geq vip_i j, p \in I, j \in J \ (21)$$

$$\sum_{k \in K} \sum_{j \in J} x_{ij}^{kt} \leq N_i, i \in I, t \in T \ (22)$$

$$\sum_{J \in J} x_{ij}^{kt} - V_{ik} = 0, i \in I, k \in K, t \in T \ (23)$$

$$T_{23} \geq \sum_{k \in K} \sum_{i \in I, p \in J} x_{ij}^{kt} \ (24)$$

$$x_{ij}^{kt} \in \{0, 1\}, i \in I \cup J, j \in J, k \in K, t \in T \ (25)$$

$$\theta_{ij}^t \in \{0, 1\}, i \in I, j \in J, t \in T \ (26)$$

Constraints (15) ensure that each customer must be visited only once during the consolidated delivery schedule. Constraints (16) concern the vehicle's capacity. Constraints (17) and (18) are used for the vehicle's sub-tours elimination. Constraints (19) guarantee the flow conservation from/to each customer. Constraints (20) limit the vehicle travel time. Constraints (21) state that if j is a VIP customer it can be served only if there is a vehicle starting from its original center, otherwise, if it is not a VIP customer, it can be served by any available vehicle. Constraints (22) limit the number of vehicles starting from a center to the number of vehicles belonging to this center. Constraints (23) guarantee that any vehicle that starts from a center must belong to this center. Constraints (24) ensure that the number of vehicles to cover all the customer requests throughout the consolidated delivery schedule equals the sum of the maximum of vehicles used by each center in the busiest period. Constraints (25) and (26) ensure that the decision variables are binary.

IV. Multi-phase Solution Approach

The main objective of this approach is to determine the optimal coalition that minimizes the distribution cost and assures the best individual profit for its members. The approach is divided into two phases. In the first phase, we optimize the second echelon routes using a multi-population memetic algorithm (MPMA). And, in the second phase, to optimize the semi-trailer's routes we propose a variable neighbourhood search (VNS) algorithm that integrates a tabu list mechanism. These two phases are performed for each period of the delivery schedule.

Memetic algorithms are a hybridization of a genetic algorithm (GA) with local search heuristics. They are widely adopted in the resolution of routing problems [33], [34]. In the proposed MPMA, the chromosomes are encoded as a giant tour as presented in sub-section IV-A. The solutions are firstly evaluated using the clustering algorithm detailed in sub-section IV-B, and secondly by an improved splitting algorithm given by the pseudo-code 2. The MPMA uses three same-sized populations to avoid premature convergence [35]. Two populations are relaxed and may contain infeasible solutions P_{relax1} and P_{relax2} while the third one contains only feasible solutions$P_{feasible}$. To build the initial populations a clustering method is used as described in sub-section IV-C.

In P_{relax1} the fleet size N_i is relaxed according to the following equation $N_i = CR_v \times N_i, i \in I, CR_v \geq 1$ while in P_{relax2}, the maximum working time T_{max} and the maximum capacity Q_v are relaxed as follows $T_{max} = CR_t \times T_{max}$ and $Q_v = CR_l \times Q_v, CR_t \geq 1, CR_l \geq 1$ where CR_v is the vehicles number relaxation coefficient, CR_t is the maximum route duration relaxation coefficient and CR_l is the maximum load relaxation coefficient. During the search process, the populations remain sorted in ascending order according to their solutions' fitness values. In each generation, the algorithm selects two parent solutions from each population and then performs the crossover procedure presented in sub-section IV-D. The resulting offspring solutions are then evaluated using the modified Beasley-Bellman algorithm described in sub-section IV-G. If the new solution is feasible it is inserted in $P_{feasible}$ if it verifies the insertion conditions. Otherwise, the new solution will be inserted in one of the corresponding unfeasible populations if it checks the insertion conditions. The insertion conditions are: (1) the new solution should be different from all the existing solutions in the population and (2) the new solution should outperform the worst one in this population. To intensify the search around the newly generated solutions, a local search procedure, as presented in sub-section (e), is performed after each $n = Freq_{loc}$ generations. The algorithm then calculates the second echelon costs T_3 and based on the best feasible solution it calculates T_{22}. Then, the first echelon route optimization is performed as detailed in sub-section (g). When all the periods are processed the MPMA calculates T_{23} and T_{21}. Finally, the sub-coalition total cost is computed.

The pseudo-code of MPMA is shown in Algorithm 1.

A. Chromosome encoding

The chromosome encoding is defined by a giant tour divided into routes by delimiters representing the center from which each route starts. The node numbering $(0, \ldots, i-1)$ represents the centres and the following numbers $(i, \ldots, n+i-1)$ represent the set of n customers. During the crossover, the route delimiters are removed and then reinserted later using the splitting algorithm as shown in Fig. 1.

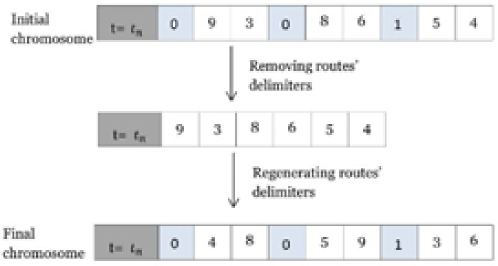

Fig. 1. Chromosome encoding in the MPMA.

B. Chromosome Evaluation

To build the solution corresponding to each chromosome, we apply the splitting procedure described in Algorithm 2. This algorithm is inspired by Vidal's adapted version of the Beasley-Bellman method [36] and integrates specific constraints of our model. During the splitting process, we perform an extraction of intermediate solutions while updating the set of the needed vehicles for each centre. The feasible sub-sequences of customers $T_{ts} = (T_t, \ldots, T_s), t \in [0, n], s \in [t+1, n]$ are evaluated using two nested loops as shown in Algorithm 2. The duration of the route $(dc, \sigma T_{ts}, dc)$, where σT_{ts} is a circular permutation of T_{ts}, is calculated by choosing the dc having available free vehicles and offering minimal service time. If among the customers belonging to sub-sequence Tts there is a VIP customer of a centre i then this centre must be the starting and ending node of the route.

C. Generation of Initial Population

To generate the initial population, we use the Split Middle Line Clustering (SMLC) method, which is a variant of the route-first cluster-second method. The SMLC method takes into consideration the collaborative and periodic aspects of the problem.

a) Step1: Initial clustering: This procedure creates a giant tour or a cluster cl_{it} for each pair center-period (i, t), which includes the centers' VIP customers and closest customers as shown in Fig. 2(b). After that, it creates shared zones between each pair of clusters cl_{it} and cl_{jt} which include non-VIP customers for whom the distance to the nearest customers belonging to the other cluster is smaller than the distance to the nearest customers of their own cluster (see Fig. 2(b)).

b) Step2: Route splitting: The splitting procedure divides the giant tour into routes, respecting the problem's constraints, by assigning customers from the center's giant tour and shared areas to the routes as follows:

- Place the center dc_i as the first element of each route r_i^m starting from dc_i where m is the index of the route and i is the number of the centre.
- Add the closest node n_i to dc_i as the second element of r_i^m and determine the barycentre z of (dc_i, n_i).
- Add the closest node n_2 to the barycentre and determine the new barycentre of (dc_i, n_1, n_2). Repeat this

```

operation until reaching the parametrized number of nodes $N_{initial}$.These nodes are used to determine the first slope of the line connecting dc_i to the barycentre z of $(dc_i, n_{1,2} ..., n_{N_i nitial})$.

- Determine the slope $\Delta_c = \frac{y_2 - y_1}{x_2 - x_1}$ of the line connecting the center dc_i to z where (y_1, y_2) are the coordinates of dc_i and (x_1, x_2) are the coordinates of z.
- Add the node p which minimizes the value of D. Given the new slope Δ_t and the length l_p of the arc $N_{(initial,p)}$: $D = w_f |(\Delta_t - \Delta_c)/\Delta_c| + w_d \times l_p$. Where w_f= *shape weight*, w_d= *distance weight*, with $|\frac{\Delta_t - \Delta_c)}{\Delta_c}| \leq Max_{deviation}$
- Add the following nodes according to the same principle while respecting the non-relaxed constraints. If the deviation of the resulting slope Δ_c engendered by adding the node p' to the route is greater than $Max_{deviation}$, then the node p' will not be considered.
- Place the center dc_i as the last node of the route.
- Merge the routes of not fully loaded vehicles if the non-relaxed constraints allow it.

c) Step3: Route sequencing:

- Project the nodes coordinates of each route on a plane and divide it into two sub-routes by a split middle line (SML).
- Project the nodes of the first sub-route on the SML and reorder them in ascending order according to the resulting coordinates as shown in (see Fig. 2(a)).
- Project the nodes of the second sub-route on the SML and reorder them in descending order according to the resulting coordinates as shown in (see Fig. 2(a)).
- Reconstruct the route by connecting the two sub-routes considering dc_i as the starting and ending node of the route (see Fig. 2(a)).

d) Step4: Initial improvement:

- Perform inter-route improvement using a $swap(n1, n2)$ move by exchanging $n1$ successive customers of one route with $n2$ successive customers of another route while respecting the route's constraints.
- Perform intra-route improvement using an iterative $swap(1, 1)$ move.

The three populations $p_{feasible}$, p_{relax1} and p_{relax2} are filled using the intermediate solutions generated in Step 4.

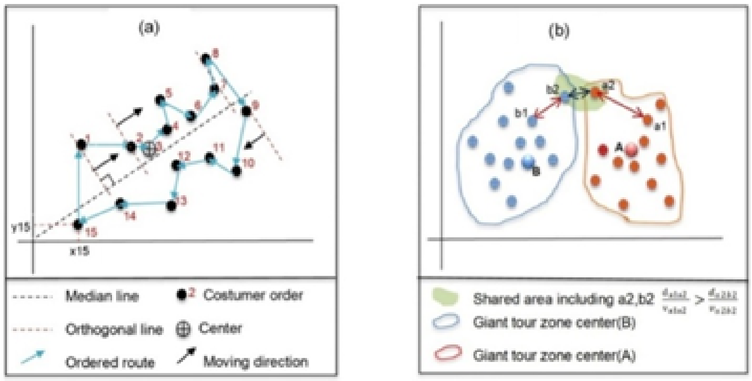

Fig. 2. (a) Route splitting and (b) The initial clustering

D. Selection and Crossover Mutation

In the selection procedure, the first parent is randomly selected from the first half of the population which is always sorted according to the fitness value, and the second parent is randomly chosen from the other half of the population. The proposed genetic operator performs three types of transpositions with different frequencies. To perform the crossover, two cutting points are defined randomly as shown in Fig. 3:

- A typical crossover consists of placing the genes between the cutting point of the second parent in the same position in the first offspring and the rest of its genes are copied from the first parent circularly. The same operation is performed for the second offspring by changing the roles of parents 1 and 2 as shown in (see Fig. 3).

- A transposition similar to the first one, but in this case the exchanged portions are partially or fully rotated (see Fig. 4).
- A transposition with position shifting in which the position of the exchanged portions is shifted when placed in the offspring chromosomes (see Fig. 5).

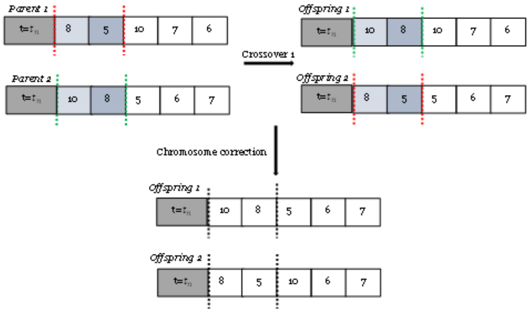

Fig. 3. First transposition method of the genetic operator.

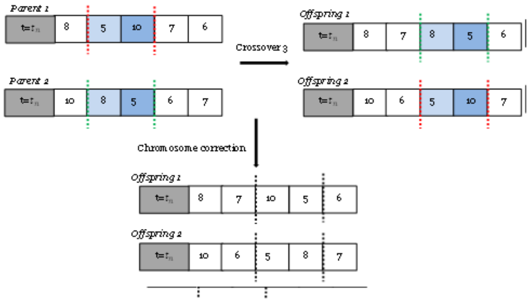

Fig. 4. Second transposition method of the genetic operator.

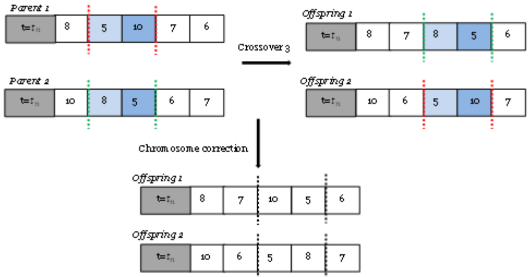

Fig. 5. Third transposition method of the genetic operator.

E. Local Variable Neighbourhood Tabu Search

The proposed VNS-Tabu algorithm (VNS-T) is a modified version of the Skewed Variable Neighbourhood Search algorithm proposed by Hansen et al. in 2020 [36], [37], it integrates a Tabu list and a variable acceptance margin α. The VNS-Tabu algorithm uses a list of neighbourhoods $k = (k_1, k_2, \ldots, k_n)$ corresponding to a sequence of intra-route and inter-route swap moves and shift moves applied on a current solution s. The local search (*LocalImprovement*) performs 2-opt and 3-opt heuristics moves. A new solution $S_i^{'}$ is accepted only if the cost quotient $\frac{f(s_i^{'})}{f(s)}$ is inferior to $1+\alpha$ where $\alpha = \beta \times \frac{i}{Maxreps}$ and β is a scale parameter. To avoid a local optimum, a *Tabulist* that stores the solution s and the move k_j performed on it is used. This list is emptied for each new value of α. The pseudo-code of **VNS-T** is presented in Algorithm 3.

Algorithm 3 : VNS-Tabu algorithm

```
$S_{best} \leftarrow$ Splitted chromosome
s$\leftarrow S_{best}$
$k = (k_1, k_2, ..., k_n) \leftarrow$ Set of neighbourhoods
j$\leftarrow$ 1
I$\leftarrow$1
$\alpha \leftarrow$0
while $i \leq Maxreps$ do
    while $j \leq n$ do
        if $(s, k_j) \notin Tabulist$ then
            $s^{'} \leftarrow$ Shake(s,$k_j$)
            $s^{''} \leftarrow LocalImprovements^{'}$
            if $\frac{f(s")}{f(s)} \leq (1+\alpha)$ then
                Tabulist.Add(s,$k_j$)
            end if
            if f(s")$\leq$ f(s) then
                $S_{best} \rightarrow s"$
                $s \leftarrow s''$
            else
                $j \leftarrow j+1$
            end if
        else$j \leftarrow j+1$
        end if
    end while
    Tabulist.Empty()
    $i \leftarrow i+1$
    $\alpha \leftarrow \beta \times \frac{1}{Maxreps}$
end while
Return
```

a) No results found by CPLEX within the time limit. b) The time limit for the small and medium sized instances was set to 3600s. For the large-scale instances (≥150 customers) the time limit is 7200s.

F. Results of the MPMA for the MDVRP Instances

To measure the efficiency of the MPMA, a comparative study is performed between the results of Vidal's HGA [31] and Juan's ILS [12] and those obtained by our algorithm with the best-known solutions (BKS) in the literature for 20 MDVRP instances of Cordeaux & al. Table V shows that the solutions obtained by the MPMA are close to the BKS with an average gap of 0.33%. Also, we observe that our method outperforms the ILS algorithm. Furthermore, MPMA was able to match 13 BKS within relatively small processing times. These experiments prove the efficiency of the proposed algorithm and its adaptability to solve the MDVR problem.

G. Fitness Evaluation

In the second echelon, the fitness evaluation for a given period t and a given population is based on the objective sub-function $T_3^t = \sum_{i,j \in I \cup J_t} \sum_{k \in K} \frac{d_{ij} \times x_{ij}^{kt} \times u_j^t \times \rho \times h_k}{100}$. For $p_{feasible}$, the fitness is equal to T_3^t. For p_{relax1} and p_{relax2}, the fitness is equal to $\frac{T_3^t}{Cf_v} \times Cf_l \times Cf_t$ where Cf_v is the percentage of centres respecting the fleet constraint,Cf_t is the percentage of routes respecting the duration constraint and Cf_l is the percentage of routes respecting the load constraint. For the first echelon, we use the objective function T_{total}.

H. First Echelon Optimization using the Local Variable Neighbourhood Tabu Search Algorithm

The first phase of the MPMA generates the second echelon routes for each period t, then based on the best second echelon feasible solution S_{best}, the demands of the reassigned customers are calculated. These demands represent the quantities of goods to be delivered by the LC to each DC each period t. Additionally, the algorithm optimizes the semi-trailer route by performing the above-mentioned VNS-T algorithm.

V. Numerical Results

In this section, we present the results obtained by MPMA by solving 19 new instances built for the 2E-CMCPVRP-VCIS with IBM Ilog CPLEX Optimization Studio 20.1. After that, we compare the efficiency of our MPMA with Vidal's HGA and Juan's ILS based on Cordeaux's MDVRP benchmark instances. Three different scenarios are considered: non-collaborative, collaborative with VIP customers, and collaborative without VIP customers.

A. Description of Data Instances

19 new instances of different sizes and complexity are considered by adapting Cordeaux's MDVRP benchmark instances. For each instance, we add the following information related to the first and second echelon: semi-trailer's fuel consumption and annual maintenance costs, vehicles assignment to the centers, maintenance, annual leasing costs of each vehicle, centers' fixed and variable costs, the variable cost coefficient, customers' initial assignment to the centers, centers' delivery schedules, centers' VIP customers and third-party service costs. In these instances, the number of customers (Cst.) varies between 20 and 498, the number of centers (Dc) ranges from 2 to 6, the number of periods varies between 2 and 4, and the average speed of the arcs ranges between 70km/h and 110km/h. Moreover, the input parameter settings are: $H_{se} = 98l/100$km, H_{sl}=410l/100km,$h_(k)$ ∈[19,25]l/100km, F_v ∈[123 800,138000],L_v ∈[216000,288000], K_a = 190720km, M = 380000, B =2000, $\rho = 9.8$, $G_i \in [586, 645]$, P_i ∈[605,935], $y_i = 1.5$.

B. Parameter tuning

To tune the parameters of the proposed algorithm, multiple iterative computational treatments are performed on a set of MDVRP benchmark instances following an experimental methodology inspired by the design of experiments (DOE) approach. Firstly, we determine the three parameters that most significantly impact the performance of our MPMA and their levels through extensive testing. The parameters that obtained, and their respective levels are: $Maxreps \in \{10, 20, 40\}$, $Freq_{loc} \in \{2, 7, 14\}$, $P_{feasible} \in \{30, 50, 100\}$. In the second phase, 10 runs of the algorithm are performed on the instances set for each of the following twenty-seven parameter configurations: $\{10, 20, 40\} \times \{2, 7, 14\} \times \{30, 50, 100\}$. Then, the average of all the iterations' results for each instance is compared to the corresponding BKS. Next; the average gap and the standard deviation for each configuration is computed. The experiments indicate that the optimal parameter settings are: $maxreps = 40, freq_{loc} = 7, P_{feasible} = 30$.

C. Results of the MILP and MPMA for the 2E-CMCPVRP-VCIS Instances

The comparison between the MILP and MPMA results based on the values of the fitness function T_{total} are presented in Table IV. In the first four columns, the parameters of the 2E-CMCPVRP-VCIS instances are described in the following order: name of the instance, number of customers, number of centers, and number of periods. The second part of Table IV, from column 5 to column 9, summarizes the MILP results obtained by the CPLEX solver. BI refers to the best integer solution found by CPLEX, LB refers to the lower bound and column Stat describes the CPLEX status (Opt: CPLEX found

TABLE V. MPMA RESULTS VS BEST KNOWNS SOLUTIONS OF THE MDVRP

the optimal solution, OM: CPLEX goes out of memory, Int: The best solution was found by CPLEX within the time limit). The results obtained show that CPLEX was able to find an optimal solution only for the small-sized instance C-PVip-2 within 336 seconds. For sixteen instances, CPLEX was able to find a feasible solution within the set time limit and with an average gap between BI and LB of 7.7%. For two instances, the solver found a feasible solution but went out of memory before the time limit. For the large-scale instances, CPLEX went out of memory before finding any solution or LB. The third-party of Table IV, from columns 10 to 13, presents the average results of the MPMA on 10 runs for each one of the 19 instances, the computational time of the MPMA and the gaps between the MPMA results and the LB and BI respectively. The results revealed that the MPMA was able to find good quality solutions for all the instances with an average gap of 2.01% with the LB and -6.59% with the BI and within a relatively short average computational time of 43.23 seconds. Moreover, the gap between the MPMA and CPLEX for the instance C-PVip-2 for which the MILP optimal solution was found is negligible. The computational results validate the MILP model and prove the efficiency of the MPMA.

VI. CONCLUSION

In this paper, we have introduced the two-echelon collaborative multi-center multi-periodic vehicle routing problem with VIP customers and inflexible delivery schedules (2E-CMCPVRP-VCIS). To solve the proposed model, an efficient multi-phase solving approach (MPSA) based on a multi-population memetic algorithm (MPMA) and a variable neighborhood search method is proposed. The performance of the MPSA is evaluated on benchmark MDVRP instances as well as newly created instances for our case of study. The numerical results on the benchmark instances show that the MPMA outperforms Juan's ILS and can find high-quality solutions with an average gap of 0.33% to the BKS. Furthermore, the results on the new instances prove the performance of our algorithm and its superiority compared to the upper bounds obtained by solving the MILP model on CPLEX. This research underscores the effectiveness of the proposed MPSA in tackling the 2E-CMCPVRP-VCIS.

***Abstract*—Speech is considered the most natural way to communicate with people. The purpose of speech recognition technology is to allow machines to recognize and understand human speech, enabling them to take action based on the spoken words. Speech recognition is especially useful in educational fields, as it can provide powerful automatic correction for language learning purposes. In the context of learning the Quran, it is essential for every Muslim to recite it correctly. Traditionally, this involves an expert *gari* who listens to the student's recitation, identifies any mistakes, and provides appropriate corrections. While effective, this method is time-consuming. To address this challenge, apps that help students fix their recitation of the Holy Quran are becoming increasingly popular. However, these apps require a robust and error-free speech recognition model. While recent advancements in speech recognition have produced highly accurate results for written and spoken Arabic and non-Arabic speech recognition, the field of Holy Quran speech recognition is still in its early stages. Therefore, this paper aims to provide a comprehensive literature review of the existing research in the field of Holy Quran speech recognition. Its goal is to identify the limitations of current works, determine future research directions, and highlight important research in the fields of spoken and written languages.**

***Keywords*—Speech recognition; acoustic models; language model; neural network; deep learning; quran recitation**

I. Introduction

Speech is the most natural way to communicate with people [7]. Designing a machine that mimics human behavior, including speaking naturally and responding correctly to spoken language, has puzzled engineers and scientists for centuries [51]. Automatic speech recognition (ASR) refers to the computational process of transforming acoustic speech signals into written words or other linguistic units through dedicated algorithms [28], [7]. The goal of ASR is to enable machines to interpret and respond to spoken language [4]. ASR involves the capability of a machine to accurately recognize speech, convert it into text, and take appropriate actions based on human instructions [7]. In particular, speech recognition is useful in educational fields as it allows for the building of powerful automatic correctors for language learning purposes. As [41], they build a model of English pronunciation learning for Chinese learners.

The researchers have made significant contributions to speech processing in various languages spoken worldwide. There are three classes in Arabic, which has approximately 420 million speakers [47]. The primary class taught in schools is Modern Standard Arabic (MSA), which adheres to the grammatical rules of the Arabic language. The second class is Arabic Dialect (AD), which represents the everyday spoken language of native Arabic speakers, varying across countries and regions. The third class is classical Arabic (CA), the language used in the Holy Quran, which has been renowned globally for centuries. CA is known for its extensive grammar and vocabulary, as well as its unique recitation guidelines [15], [24].

Recently, the use of speech recognition in the Quranic recitation field has emerged as an important research direction. Indeed, there are more than two billion Muslims in the world [2]. Muslims generally strive to learn the precise recitation of CA and adhere to certain rules known as *Tajweed* in order to recite the Holy Quran accurately. Learning these rules is very important for all Muslims to master the recitation of the Holy Quran [15]. Consequently, building accurate Holy Quran Speech Recognition (HQSR) models represents a significant research outcome for all Muslims.

Teaching the correct recitation of the Quran is essential for every Muslim. Learning Quran recitation usually depends on an expert, also known as *gari*, who listens to the student's recitation, determines recitation mistakes, and instructs the student with the appropriate correction. This way of learning is very effective, but it's time-consuming because the teacher needs to correct the errors of every student independently. For this reason, the apps that help students fix their recitation of the Holy Quran are beneficial and essential, but these apps need a robust and error-free speech recognition model. Despite conducting several research studies in this area, researchers have not yet achieved the optimal solution for recognizing speech in the Holy Quran. Though recent models have been applied to written and spoken Arabic and non-Arabic speech recognition and produced highly accurate results, Quran speech recognition is still in its early stages. Therefore, this paper aims to propose a comprehensive literature review of the works in the field of Holy Quran speech recognition and shed light on some important research in the field of spoken and written languages.

The main motivation for our research is as follows:

1) Though the Holy Quran represents an essential book for all Muslims, current models for Holy Quran speech recognition have low accuracy or do not cover all chapters (i.e., rely on small datasets).
2) Some people find it difficult to attend Quran learning courses or retrieve their memorization in front of the teacher. Many individuals struggle to retain the Quran due to fear. Thus, building a professional app for Quran learning is important to help them retain the Quran in their home.
3) Quran memorization requires a continuous review process, which is time-consuming. Thus, it is hard for Quran teachers to listen and validate long recitations for many students.
4) Some people prefer reading what they memorize, especially in night prayer (i.e., without reading from the *Mushaf* to not lose their submission in prayer). However, they can easily make mistakes. An automatic corrector can assist Muslims in their prayers.
5) Some non-Arabic countries, mainly those with a minority of Muslims, do not have enough qualified teachers to teach the Holy Quran.

However, research in the field of HQSR is still in its early stages. Indeed, recognizing individual words is easy, but the challenge is recognizing continuous recitation [7] and detecting erroneous recitation and violations of tajweed rules. In the realm of speech recognition systems (see Fig. 1), various factors, such as speaker dependency, vocabulary size, and noisy environments, can significantly impact their performance. Recognition performance increases with limited vocabulary and reciter-dependent conditions while using broad vocabulary and reciter-independent scenarios; performance can decrease significantly [7]. Besides, most research developments focus on one or a few chapters or a few tajweed rules. Also, existing works in HQSR suffer from the lack of large datasets used. Finally, current works use traditional techniques and do not investigate end-to-end learning.

The critical objective of this research is to use machine learning for Holy Quran recitation. Our main contributions are to provide a thorough literature review to find the most important issues that need more investigation in the field of Holy Quran speech recognition. Moreover, our study summarizes some important and informative papers in the Arabic and non-Arabic languages fields and recent papers in the HQSR field and provides a taxonomy for speech recognition and HQSR.

Various machine learning algorithms could be used in speech recognition, including Dynamic Time Warping (DTW), Hidden Markov Models (HMM), and Artificial Neural Networks (ANN) [51].

In the context of Arabic ASR, many algorithms were used, such as recurrent neural networks (RNN), long short-term memory (LSTM), which is a particular case of RNN, and connectionist temporal classification (CTC) [4].

The remaining parts of this paper are structured in the following way: Section II discusses some important research in written and spoken languages speech recognition. Section III discusses the recent papers in the field of Holy Quran Speech Recognition. Next, Section IV discusses some of the research directions in the field of Holy Quran Speech Recognition. Finally, Section V concludes the paper.

II. Speech Recognition for Written & Spoken Languages

In this section, we highlight some speech recognition solutions that produced impressive results in Arabic and non-Arabic languages. These solutions may be categorized as traditional speech recognition (either with deep learning architecture or without deep learning) or as an end-to-end-based speech recognition solution.

A. Traditional Models

Fig. 2 shows that traditional ASR systems are made up of three separate parts: the acoustic model, the pronunciation model, and the language model [54]. The Acoustic Model (AM) assesses the likelihood of acoustic units such as phonemes, graphemes, or sub-word units [13]. In contrast, the Language Model (LM) evaluates the likelihood of word sequences. By integrating linguistic knowledge derived from extensive text collections, language models improve the precision of acoustic models. These models use the acquired syntactic and semantic rules to re-evaluate the hypotheses generated by the acoustic model. The process of mapping a series of phonemes to words is done by the Pronunciation Dictionary (PD), and it aligns the phonetic transcriptions produced by the AM system with the unprocessed text used in language models. The training of these three components is done individually, and then they are merged together to form a search graph by utilizing finite-state transducers (FSTs). Feature Extraction (FE) takes input speech as input, produces the essential features, and then sends these features to the decoder. Following that, the decoder produces lattices, which are then evaluated and ordered to generate the desired sequences of words.

The acoustic model can be modeled using HMMs [32] and Gaussian Mixture Models (GMMs) [61]. It is worth noting that recent ASR models have replaced the use of GMMs in the acoustic model with deep neural networks (DNNs) [30]. These are referred to as hybrid HMM-DNN and are widely used as competitive ASR models. Also, some research replaced GMMs with Bidirectional Long-Short Term Memory (BLSTM) [50], while some other studies replaced HMM with another classification method such as Support Vector Machine (SVM) [12], [36], Linear Discriminant Analysis (LDA) combined with Quadratic Discriminant Analysis (QDA) [33], Convolutional Neural Networks (CNNs) and SVM [40], and Hidden Semi-Markov Model (HSMM) [34], etc.

Some research has been suggested to address speech recognition for Arabic and non-Arabic languages.

Arabic Language. In their study, [39] introduced a novel approach that combines three distinct training systems for speech recognition. Four-gram language model re-scoring, system combination with minimum Bayes risk decoding, and lattice-free maximum mutual information are a few of these groups. They achieved significant progress, with a word error rate of 42.25% on the Multi-Genre Broadcast (MGB-3) Arabic

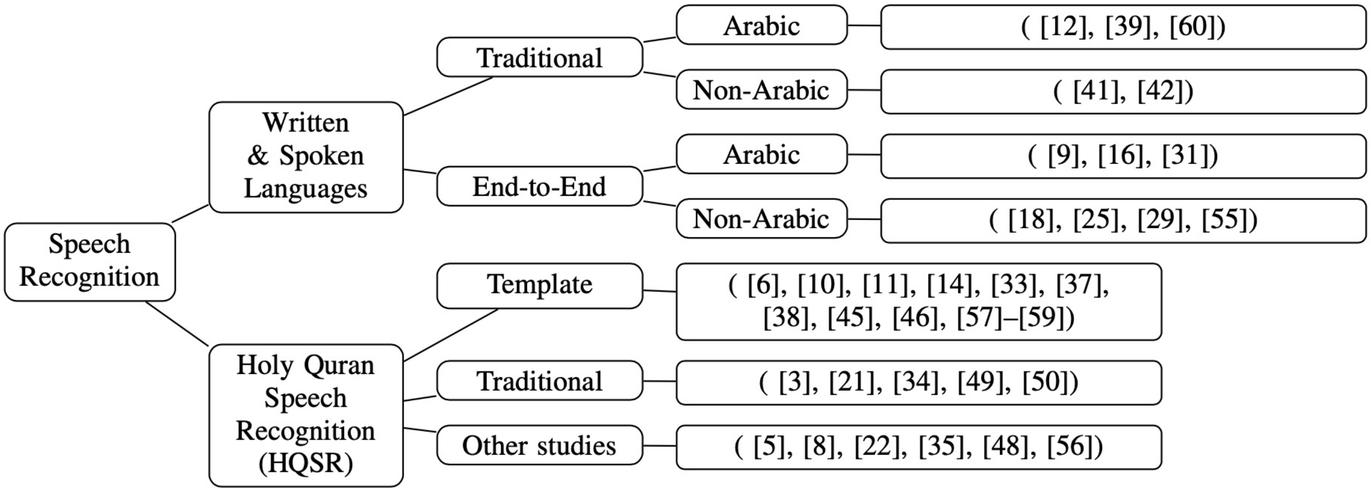

Fig. 1. Speech recognition taxonomy.

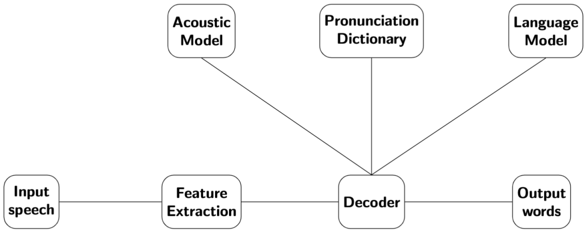

Fig. 2. Traditional ASR Pipeline ([54]).

development set. They got this result by using a 4-gram rescoring strategy for a chain BLSTM system. This system did better than a DNN system that had a word error rate of 65.44%.

In [60], the authors presented a comprehensive framework for Arabic speech recognition. To turn sequences of Mel Frequency Cepstral Coefficients (MFCC) and Filter Bank (FB) features into fixed-size vectors, they used recurrent LSTM or GRU architectures. They then fed these vectors into a multi-layer perceptron network (MLP) to perform classification and recognition tasks. The researchers evaluated their system using two different databases: one for spoken-digit recognition and another for spoken TV commands. However, a limitation of their work is the absence of datasets that incorporate recorded speech signals in noisy, realistic environments.

In [12], they presented a speech recognition system for the Arabic language. The system aimed to evaluate three feature extraction algorithms: MFCC, Power Normalized Cepstral Coefficients (PNCC), and Modified Group Delay Function (ModGDF). We performed the classification process using an SVM. The results indicated that PNCC was the most effective algorithm, while ModGDF achieved moderate accuracy. PNCC and ModGDF outperformed MFCC in terms of precision. PNCC achieved an accuracy rate of 93% to 97%, ModGDF achieved 90%, and MFCC achieved 88%.

Non-Arabic languages. The authors of [42] presented the design of Kaldi, a speech recognition toolkit that is freely available and open-source. The highly permissive Apache License v2.0, under which Kaldi is released, enables extensive usage. Kaldi provides a robust speech recognition system that utilizes finite-state transducers and is built on the OpenFst library. The toolkit provides comprehensive documentation and scripts that make it easier to build comprehensive recognition systems. Kaldi is coded in C++, and its core library offers a range of functionalities, including phonetic-context modeling, acoustic modeling using subspace Gaussian mixture models (SGMM), standard Gaussian mixture models, and linear and affine transforms.

A speech-learning system for the English language was developed and implemented by [41]. It utilized a speech recognition technique based on HMM to decode speech using the Viterbi algorithm and determine the recognition score through posterior probability. The system achieved an average recognition rate of 94%. Its purpose was to help English learners assess pronunciation accuracy during verbal practice and identify different types of errors. By engaging in systematic practice with this system, users can significantly enhance their listening and speaking skills. The system provides real-time feedback on oral pronunciation accuracy, error correction reports, and allows for repeated practice to facilitate effective training.

Table I summarizes traditional speech recognition techniques for Arabic and non-Arabic languages.

B. End-to-End-based Speech Recognition Models

The purpose of the end-to-end (E2E) system is to directly transform a series of acoustic features into a corresponding series of graphemes or words. This approach greatly simplifies traditional speech recognition methods by eliminating the need for manual labeling of information in the neural network. Instead, the E2E system automatically learns language and pronunciation information, as depicted in Fig. 3.

End-to-end speech recognition systems typically rely on an encoder-decoder framework. According to studies [17], [13], this architecture takes an audio file as input and processes it through a series of convolution layers to generate a condensed

vector. The decoder then uses this vector to generate a character sequence. Researchers can use different objective functions, such as CTC [23], ASG [20], LF-MMI [25], sequence-to-sequence [18], transduction [44], and differentiable decoding [19], to optimize the end-to-end ASR [13]. Researchers have also explored different neural network architectures, including ResNet [27], TDS [26], and Transformer [52]. Additionally, integrating an external language model has been shown to improve the overall performance of the system.

Recently, some research has been suggested for both Arabic and non-Arabic speech recognition using end-to-end models. In what follows, we discuss and summarize these solutions.

Arabic Language. In [9], the researchers introduced the first comprehensive approach to building an Arabic speech-to-text transcription system. They utilized lexicon-free RNNs and the CTC objective function to achieve this. The system consisted of three main components: a BDRNN acoustic model, a language model, and a character-based decoder. Unlike word-level decoders, their decoder did not rely on a lexicon during the transcription process. The RNN acoustic and language model successfully distinguished between characters with the same accent but different writing styles. The researchers evaluated the model using a 1200-hour corpus of Aljazeera multi-genre broadcast programs, resulting in a 12.03% word error rate for non-overlapped speech. It is important to note that deep learning techniques were only used in the feature extraction phase.

In [16], the authors proposed a robust diacritized ASR system using both traditional ASR and end-to-end ASR techniques. They trained and tested their models on the Standard Arabic Single Speaker Corpus (SASSC) with diacritized text data, using MFCCs and FB for feature extraction. The ASR speech recognition system incorporated a total of eight models, comprising four GMM models, two SGMM models, and two DNN models. We constructed these models using the KALDI toolkit and performed language modeling using CMU-CLMTK. The best achieved word error rate (WER) among these models was 33.72% using DNN-MPE. Additionally, the authors proposed an end-to-end approach for diacritized Arabic ASR, employing joint CTC-attention and CNN-LSTM attention methods. The CNN-LSTM with attention method outperformed the others, achieving a character error rate (CER) of 5.66% and a WER of 28.48%. This method resulted in a significant reduction in WER compared to both the traditional ASR and joint CTC-attention method, by 5.24% and 2.62%, respectively.

Researchers conducted a comprehensive comparison on Arabic language and its dialects using different ASR approaches in [31]. The researchers collected a new evaluation set comprising news reports, conversational speech, and various datasets to ensure unbiased analysis. They extensively analyzed the errors and compared the ASR system's performance with that of expert linguists and native speakers. While the machine ASR system showed better performance than the native speaker, there was still an average WER gap of 3.5% compared to expert linguists in raw Arabic transcription. The proposed end-to-end transformer model outperformed prior state-of-the-art systems on MGB2, MGB3, and MGB5 datasets, achieving new state-of-the-art performances of 12.5%, 27.5%, and 33.8%, respectively.

Non-Arabic Languages. Researchers introduced ESPnet, a novel open-source platform for end-to-end speech processing, in [55]. ESPnet leverages dynamic neural network toolkits like Chainer and PyTorch, serving as the primary deep learning engine. This platform simplifies the training and recognition processes of the entire ASR pipeline. The ESPnet uses the same feature extraction/format, data processing, and scheme style as the Kaldi ASR toolkit. This gives researchers a complete way to test speech recognition and other speech processing techniques. The test results show that ESPnet does a good job with ASR and is about as efficient as the most advanced HMM/DNN systems that use traditional setups. Notably, ESPnet has made significant advancements, including the incorporation of multi-GPU functionality (up to 5 GPUs). In just 26 hours, ESPnet successfully completed the training of 581 hours of the CSJ task.

In [25], the authors described a simple HMM-based end-to-end method for ASR and tested how well it worked on well-known large-vocabulary speech recognition tasks, specifically the Switchboard and Wall Street Journal (WSJ) corpora. The authors trained the acoustic model used in this approach without the need for initial alignments, prior training, pre-estimation, or transition training, making it entirely neural except for the decoding/LM part. The proposed method surpassed other end-to-end methods in similar setups, particularly when dealing with small databases. By employing a comprehensive biphone modeling approach, the researchers achieved results almost comparable to regular LF-MMI training.

In [18], the researchers introduced a new attention-based model called Listen, Attend, and Spell (LAS) for sequence-to-sequence speech recognition. LAS combines the sound, pronunciation, and language model parts of regular ASR systems into a single neural network, so there's no need for a separate dictionary or text normalization. The researchers compared LAS with a hybrid HMM-LSTM system and found that LAS achieved a WER of 5.6%, outperforming the hybrid system's WER of 6.7%. In a dictation task, LAS achieved a WER of 4.1%, while the hybrid system achieved a WER of 5%.

The study [29] introduced a new strategy to address multilingual ASR speech recognition, specifically in the context of code-switching speech. The researchers employed three techniques to achieve this. The researchers decoded the speech by utilizing a global language model constructed from multilingual text. Their system used a multigraph approach along with weighted finite-state transducers (WFST), which let them switch between languages while decoding by using a closure operation. The output of this process was a bilingual or multilingual text based on the input audio. Secondly, they employed a robust transformer system for speech decoding. They found that WFST decoding was particularly suitable for inter-sentential code-switching datasets among the techniques used.

Table II summarizes end-to-end speech recognition techniques for Arabic and non-Arabic languages.

In the following, we compare the end-to-end architecture mentioned in the previous works with the baseline traditional techniques on the same datasets as indicated in the previous reviewed studies. As we see in Table III, the end-to-end architecture outperforms the hybrid architecture in all the studies mentioned in the table, except [25].

III. Holy Quran Speech Recognition (HQSR)

This section summarizes the recent studies that concern the HQSR. It also presents the used techniques and the performance of the proposed solutions. Moreover, it determines the gap and limitations in the current research on the HQSR. We classified the current studies of HQSR into three categories: template-based speech recognition, traditional-based speech recognition, and other HQSR studies.

A. Template Based Speech Recognition

This section summarizes the papers that follow template-based speech recognition, which is an old style of speech recognition that relied only on FE, classification, and matching techniques (i.e., it didn't have acoustic, lexical, or language models).

In [46], the authors provide a deep learning model utilizing a dataset of seven famous reciters and CNNs. They employ MFCCs to extract and assess data from audio sources. Their provided model achieved 99.66% accuracy.

In [6], the authors highlight the key distinctions between a basic ASR system and an ASR-based language tutor specifically designed for Quran memorization. They demonstrate that ASR techniques alone are not sufficient for an intelligent Quran tutor and propose modifications to enhance its capabilities. To support their claims, the researchers utilize data from Sūrat Al-Nass. However, one of the major obstacles to developing a Quran tutor is the absence of a comprehensive dataset containing both correct and incorrect recitations, which is necessary for conducting meaningful experiments in this domain.

In [37], researchers proposed an online verification system for Quran verses to ensure the integrity and authenticity of the Quran. They gathered data from ten expert Qari who recited Surat Al-Nass ten times correctly and ten times with various types of mistakes (e.g., Tajweed, Makhraj, missing words). Unlike modern techniques, this study did not utilize acoustic, lexical, or language models. Instead, it relied on MFCC for feature extraction and HMMs for recognition and matching. However, the study did not provide any testing results.

In [14], the authors center on the examination and identification of classical Arabic vocal phonemes, specifically vowels, through the utilization of HMM. They aim to tackle the issue of semantic changes that can occur due to variations in vowel durations (short or long) in Arabic. To investigate this, they examine three chapters (Alfateha, Albaqarah, and Alshuraa) from the Holy Quran. Their findings demonstrate an impressive overall accuracy rate of 87.60% without the utilization of a specified language model.

In [58], researchers developed a speech recognition system that utilizes MFCC for feature extraction and HMM for classification. The system focuses on recognizing and identifying the rules of Iqlab on Qira'at of Warsh. It uses a database of expert teachers' rules to compare and report any mismatches in the iqlab rules for specific verses. The system achieved a 70% accuracy in correctly spelling words with the correct rules from the database, a 50% accuracy for words with incorrect rules from the database, and a 40% accuracy for new words not included in the training database.

In [57], the researchers presented an interactive Tajweed system that assists in verifying the appropriate Imaalah Checking rule for Warsh recitation. This system utilizes an auto-

matic speech recognition system with MFCC as the feature extraction technique and HMM as the classification method. The researchers conducted experiments using fifteen speech samples. The results showed that the system achieved a 60% accuracy rate for identifying the Imaalah rule based on the Warsh narration in the training data.

Researchers developed a system in [10] that identifies the Ahkam Al-Tajweed in a specific audio recording of Quranic recitation. The study focused on eight rules: “EdgamMeem” (one rule), “EkhfaaMeem” (one rule), “Ahkam Lam” in ‘Allah’ Term (two rules), and “Edgam Noon” (four rules). The classification problem involved 16 classes, covering the entire Holy Quran for verses that contained the eight rules. The system utilized various feature extraction techniques, including traditional methods like MFCC and LPC as well as newer methods like CDBN. Classifiers such as SVM and RF were employed, with the best accuracy of 96.4% achieved using SVM for classification and features extracted through MFCC, WPD, HMM-SPL, and CDBN.

In [59], authors developed a speech recognition system that can accurately differentiate between different types of Madd (elongated tone) and Qira’at (method of recitation) related to Madd. The system utilized MFCC as a feature extraction technique and HMM as a classification method. The focus of the study was on two specific types of Madd: greater connective prolongation and exchange prolongation rules for Hafss and Warsh. We collected a total of sixty data samples for analysis. The results showed that the accuracy of identifying the exchange prolongation rule was 60% for Warsh and 50% for Hafss. Additionally, the accuracy for identifying the greater connective prolongation rule was 40% for Warsh and 70% for Hafss.

Researchers developed an automated self-learning system in [33] to support the traditional method of teaching and learning Quran. The system aimed to classify the characteristics of Quranic letters. The study collected audio data from 30 participants, including 19 males and 11 females. The participants recited each sukoon alphabet once without repetition. The system used the Sukoon alphabet from the Quran to provide a description of the Makhraj (point of articulation) and Sifaat (characteristics) of each letter. The study successfully identified and classified the characteristic features of the alphabet, specifically in terms of learning (Al-Inhiraf) and repetition (Al-Takrir). The results showed that using QDA with all 19 features achieved the highest accuracy, with 82.1% for leaning (Al-Inhiraf) and 95.8% for repetition (Al-Takrir) characteristics.

The researchers conducted the study with the aim of creating a comprehensive system that accurately recognizes and determines the correct pronunciation of different Tajweed rules in audio. To achieve this, the researchers employed 70 filter banks as a feature extraction technique and utilized SVM as the classification method. The study focused on four specific rules, namely Ekhfaa Meem, Edgham Meem, Takhfeef Lam, and Tarqeeq Lam. The study utilized a dataset of 80 records, comprising a total of 657 recordings, encompassing both correct and incorrect recitations for each rule. They tested the models in the system against 30% of the recorded data and achieved a validation accuracy of 99%. [38] developed a recognition model to identify the “Qira’ah” from the corresponding Holy Quran acoustic wave. The study utilized MFCC as the feature extraction technique and SVM as the classification method. With a dataset of 258 wave files for 10 “Qira’ah” and including various reciters, the SVM accuracy achieved approximately 96%, while the accuracy of the ANN was 62%.

In another study, [45] proposed a system that automates the process of checking Tajweed for children who are learning the Quran. The system used the MFCC algorithm to extract the input speech signal and the HMM algorithm to compare children’s recitation with the recitation stored in the database. However, this project focused solely on Surah Al-Fatihah and did not provide any testing results.

Table IV summarizes the previous studies of template-based speech recognition in the HQSR field.

B. Traditional Based Speech Recognition

This section summarizes the papers that follow traditional speech recognition as described in Section II-A.

The researchers aimed to develop a precise Arabic recognizer for educational purposes in the study conducted by [34]. They implemented an HSMM model with the primary objective of improving the durational behavior of the traditional HMM model. To achieve this, they utilized a corpus consisting of recordings from 10 reciters, totaling over 487 minutes of speech. They meticulously segmented the corpus at three levels: phoneme, allophone, and words, with precise time boundaries. They obtained the recordings by reciting the Holy Quran, covering all the essential Arabic sounds. As a result of their work, the recognition accuracy saw an improvement of approximately 1.5%.

The researchers constructed an acoustic model using the Carnegie Melon University (CMU) Sphinx trainer [21]. The CMU Sphinx trainer utilized recordings from 39 different reciters and 49 chapters (surah) to build a robust framework for continuous speech recognition. The acoustic model achieved an impressive WER of approximately 15%, showcasing its accuracy and effectiveness.

In their research, [50] utilized data from everyayah.com, a website that provides open-access Quran recitations by numerous professional reciters, including Sheikh [1]. They adopted a deep learning approach to train an acoustic model for Quranic speech recognition. The study focused on 13 different reciters and concluded that the hybrid HMM-BLSTM method outperformed the HMM-GMM method in terms of speech recognition accuracy. The baseline models (HMM-GMM) achieved an average WER of 18.39%. In contrast, the acoustic model using Hybrid HMM-BLSTM achieved significantly better results, with an average WER of 4.63% in the same testing scenario.

The researchers utilized the KALDI toolkit to create and assess a speaker-independent continuous speech recognizer specifically designed for Holy Quran recitations in a study [49]. The researchers successfully developed a large-vocabulary system capable of recognizing and analyzing Quranic recitations. They use 32 recitations for Chapter 20 (Sūrat Taha), according to Hafs from the A’asim narration. The most effective experimental configuration involves utilizing Time Delay Neural Networks (TDNN) with a sub-sampling

TABLE IV. SUMMARY OF HQSR TEMPLATE-BASED SPEECH RECOGNITION

Ref#	Main Idea	Dataset	FE	ML algo.	Pros	Cons
[45]	Automated tajweed Checking System for Children.	Surah Al-Fatihah. Ten respondents' recitation for testing purposes. One audio of correct recitation is used for comparison with the respondents' audio	MFCC	HMM	-	very small data set & no testing result
[46]	The objective of this research was to differentiate between reliable and unethical Qur'anic reciters.	Seven well-known Qur'anic reciters have been gathered into a dataset. On an audio file, each reciter recited the Quran's surahs for eighty minutes.	MFCC	CNN	The proposed system stages are well-organized and easily understandable.	-
[38]	A recognition model for the "Qira'ah" from the corresponding Holy Quran acoustic wave.	The corpus contains 258 wave files labeled based on the "Qira'ah" (they consider 10 "Qira'ah") .	MFCC	SVM	good accuracy (96.12 %)	-
[11]	A system for recognizing/correcting the different rules of Tajweed in an audio.	Almost 80 records for each rule name and type, a total of 657 recordings of 4 different rules.	FBs	SVM	Good process for data collection.	Consider only 4 rules
[33]	Features identification and classification of alphabet (ro) in Leaning (Al-Inhiraf) and Repetition (AlTakrir) characteristics.	30 reciters(19 males and 11 females).	PSD & MFCC	LDA & QDA	Used multiple features extraction and classification methods	Not determined the used dataset
[59]	recognize, identify, and highlight discrepancies between two specific types of Madd rules: the greater connective prolongation and the exchange prolongation rules. This system focuses on verses that contain both rules and aims to point out the mismatches and differences between the rules for Hafss and Warsh recitation styles.	Reciter's database selected from Internet (60 data samples).	MFCC	HMM	-	few data samples
[10]	A system that determines which tajweed rule is used in a specific audio recording of a Quranic recitation (8 tajweed rules).	3,071 audio files collected from ten different expert reciters (5 males and 5 females). Each file contains a recording of one of the 8 rules considered (in either the correct or the incorrect usage).	Traditional (MFCC, LPC, WPD, HMM-SPL) & Non-traditional (CBDN)	KNN, SVM, ANN, RF, multiclass classifier, bagging.	Use of multiple feature extraction algorithms.	-
[57]	A system for distinguishing, recognizing, and correcting the pronunciation of tajweed rules for Warsh narration type).	15 speech simples. 5 verses recited by 3 Warsh .	MFCC	HMM	-	Few data samples
[58]	A system for recognizing, identifying and pointing out the mismatch of the iqlab rules for the verses containing the rules.	6 verses recited by 4 reciters with Qira'at of Warsh. Hence. The total is 24 of speech simples.	MFCC	HMM	-	Few data samples
[14]	differentiate between short and long vowels in Arabic. This distinction is crucial as it plays a significant role in altering the meaning of words.	MFCCs, deltas coefficients, deltas-deltas coefficients and the cepstral pseudoenergy	HMM	have a good accuracy	-	
[37]	A model to identify errors in the Quranic audio files and subsequently distinguish incorrect recitation from the correct recitation.	Ten of expert Qari each of them recite surat Al-Nnass ten times correct and ten times with mistakes.	MFCC	HMM and DTW	-	Covers only one sura
[6]	A system implemented using ASR technique.	Alnass, 20 utterances recited by only a one speaker with and without errors in recitation.	MFCC	ANN	-	Covers only one sura

technique. This setup achieved a WER ranging from 0.27% to 6.31% and a sentence error rate (SER) ranging from 0.4% to 17.39%.

The researchers of [3] used MFCC for the purpose of feature extraction. The researchers adjusted these features using the minimal phone error (MPE) as a discriminative model. The researchers utilized the deep neural network (DNN) model to construct the acoustic model. Here, they introduce an n-gram LM. The dataset utilized for training and assessing the proposed model comprises 10 hours of.wav recitations conducted by 60 reciters. The experimental results demonstrated that the proposed DNN model attained a remarkably low CER of 4.09% and a WER of 8.46%.

Table V summarizes the previous studies of traditional-based speech recognition in the HQSR field.

C. Other HQSR Studies

This section summarizes papers that follow other HQSR techniques, such as using the Google Speech API, Genetic Algorithm (GA), and MFCC.

The authors in [56] used MFCC to detect and recognize sounds for simple IDHAR tajweed without providing any testing results for this study.

Researchers proposed a solution in [22] to facilitate the memorization and learning of the Holy Quran. They employed the Fisher-Yates Shuffle algorithm to randomize the letters of the Quran, aiding in the memorization of verses. In addition, they employed the Jaro-Winkler algorithm for text matching and utilized the Google Speech API for speech recognition. The study focused on data from Juz 30. The achieved accuracy was approximately 91%, with an average matching time of 1.9 ms. However, the study revealed that it was still not possible to distinguish certain Arabic letters with similar pronunciations in Quranic verses in detail.

In [8], the authors produce a new speech segmentation algorithm for the Arabic language. Developing robust algorithms to accurately segment speech signals into fundamental units, rather than just frames, is a crucial preprocessing step in speech recognition systems. They focus on the precise segmentation of Quran recitation using multiple features (entropy, crossings, zero, and energy) and a GA-based optimization scheme. The results of the testing demonstrate a significant enhancement in segmentation performance, with an approximate 20% improvement compared to conventional segmentation techniques based on a single feature.

In [5], the authors implement an Android-based application called TeBook and provide a method for the assessment of the Holy Quran's recitation without the involvement of a third party by taking advantage of the use of speech recognition and an online Holy Quran search engine. There is no testing result present for this study. The limitation of this application is its reliance on multiple online services, which renders it unusable if the services are down.

The authors in [35] suggested a brand-new method called Samee'a to make it easier to memorize any form of literature, including speeches, poetry, and the entire Holy Qur'an. Samee's system utilizes the Jaro Winkler Distance technique to calculate the degree of similarity between the original and transformed texts, and employs the Google Cloud Speech Recognition API to translate Arabic speech to text. Seventy gathered files, ranging in length from twelve to four hundred words, together with a few chapters from the Holy Qur'an, were used to test the system. For the 70 files, the average similarity was 83.33%, while for the chosen chapters of the Holy Qur'an, it was 69%. Preprocessing operations on the text files and the Holy Qur'an improved these results to 91.33% and 95.66%, respectively.

In [48], the authors focus on the digital transformation of Quranic voice signals and the identification of Tajweed-based recitation faults in Harakaat as the primary research objective. They wanted to look into how to process speech using Quranic Recitation Speech Signals (QRSS) in the best digital format possible, using Al-Quran syllables and a design for feature extraction. The objective was to identify similarities or differences in recitation (based on Al-Quran syllables) between experts and students. We employ the DTW approach as a Short Time Frequency Transform (STFT) to quantify the Harakaat of QRSS syllable features. The research presents a method that utilizes human-guidance threshold classification to assess Harakaat, focusing on the syllables of the Qur'an. The categorization performance achieved for Harakaat exceeds 80% in both the training and testing phases.

Table VI summarizes the previously discussed studies of the other techniques used in the HQSR field.

D. HQSR Taxonomy

This section classifies the previously mentioned works of HQSR based on feature extraction methods and classification techniques. It is worth noting that most work done uses MFCCs as feature extraction techniques and the HMM as a classifier (e.g., [37], [14], [58], [57], [59], [45]). Fig. 4 illustrates the techniques of feature extraction and classification used in current HQSR research.

Researchers improved an Arabic recognizer by incorporating a HSMM instead of the traditional HMM [34]. Another approach, mentioned in [6], replaced HMM with ANN. Similarly, Nahar et al. [38] opted for SVM instead of HMM, and in [46] they use CNNs. Furthermore, researchers also explored various feature extraction techniques. For instance, [11] utilized FB for feature extraction and SVM for classification. [33] also used different methods, such as Formant Analysis, Power Spectral Density (PSD), and MFCC, along with LDA and QDA for sorting.

In [10], two categories of feature extraction techniques were employed: traditional and non-traditional. The traditional approach involved the utilization of MFCC, LPC, multi-signal WPD, and HMM-SPL. As for the non-traditional type, they use CDBN. They use K-Nearest Neighbors (KNN), SVM, ANN, Random Forest (RF), multiclass classifiers, and bagging for classification. [50] used MFCC for feature extraction, BLSTM as one of the deep learning topologies, and combined it with HMM as a hybrid system. The entire speech recognition system was built using the Kaldi toolkit [43], starting with feature extraction, acoustic modeling, and model testing. [49] used the deep learning approach in the KALDI toolkit to design, develop, and evaluate an ASR engine for the Holy

TABLE V. SUMMARY OF HQSR TRADITIONAL-BASED SPEECH RECOGNITION

Ref#	Main Idea	Dataset	FE	AM	LM	Pros	Cons
[49]	create a speech recognition engine that is independent of speaker and capable of handling continuous speech. Additionally, a written corpus that accurately represents the script of The Holy Quran is developed. To aid in the recognition process, a phonetic dictionary for The Holy Quran recitations is also be constructed.	32 recitations for Sūrat Taha according to Hafs from A'asim narration.	MFCC	KALDI toolkit to train the acoustic model (traditional and DNN approaches)	n-gram	Best research of current HQSR researches	Used only one sura
[50]	The acoustic model for Quran speech recognition was trained using a deep learning approach. In addition, the model was built to analyze the effect of Quran recitation styles (Maqam) on speech recognition.	The dataset is from everyayah.com [1].	MFCC	Hybrid HMM-BLSTM	3-grams	First work that used BLSTM in HQSR	no preprocessing method to eliminate noise and echo and not specified the used dataset
[21]	Used CMU Sphinx which is a robust framework for speaker-independent continuous speech recognition to train accurate acoustic models.	49 chapters were used: From chapter 067 to chapter 114 in addition to the chapter 001 and the supplication that is recited before the Holy Quran (Isti'adah).	CMU Sphinx framework			Get WER around 15% of trained acoustic model.	-
[34]	Presented the results of an enhanced Arabic recognizer by implementing an HSMM model instead of the standard one utilized in the baseline recognizer.	Arabic database utilized consists of 5935 waveform files for 10 reciters.	MFCC	HSMM	flat LM	Get enhancement by around 1.5% in the accuracy	-
[3]	Suggested the traditional method to recognizing Qur'an verses using a dataset of Qur'an verses.	A total duration of 10 hours of MP3 recordings containing recitations of Qur'an verses by 60 reciters.	MFCC	DNN	n-gram	Well-structured and clear article.	-

TABLE VI. SUMMARY OF OTHER HQSR STUDIES

Ref#	Main Idea	Dataset	Used Algorithms	Pros	Cons
[5]	Allow learners to learn how to memorize without the constraints of being in a fixed place and outside the classroom.	Everyayah.com Recitation Audio, Surah.my Translation	Alfanous JOS2 API, Android Speech Recognition	-	Relied heavily on online services and not specified the used dataset
[8]	A novel speech segmentation algorithm for Arabic language with a focus on the accurate segmentation of Quran recitation. Starting with a set of initial segmentations, three basic speech features: zero crossings, entropy, and energy are used.	They used the comprehensive KACST dataset with manually labelled Quran syllable structures.	feature fusion and Genetic Algoritms.	First segmentation on Quran recitation.	-
[22]	A solution to memorize and learn the Holy Quran easily.	juz 30	Fisher-Yates Shuffle Jaro-Winkler	-	Relies on Google Speech API which not trained on Quran verses
[56]	Emphasize idhar, which had a distinct and unambiguous pronunciation. The chosen hijaiyah letters comprised six possibilities, with only nun sukun and tanwin, making it effortless to identify them.	-	MFCC, FFT	-	Not specifying dataset, no testing result, and the poor organization of the content.
[35]	This article introduces a novel system called Samee'a, which aims to enhance the process of memorizing various types of texts, including poems, speeches, and the Holy Qur'an.	The system completed testing utilizing a dataset of 70 files, with word counts ranging from 12 to 400, including selected chapters from the Holy Qur'an.	Google Cloud Speech Recognition API and Jaro Winkler Distance algorithm	A comprehensive and informative paper	-
[48]	This study focuses on the digital transformation of Quranic voice signals and the identification of Tajweed-based recitation faults of Harakaat as its main research objective.	-	Dynamic Time Warping (DTW)	-	Not specifying dataset

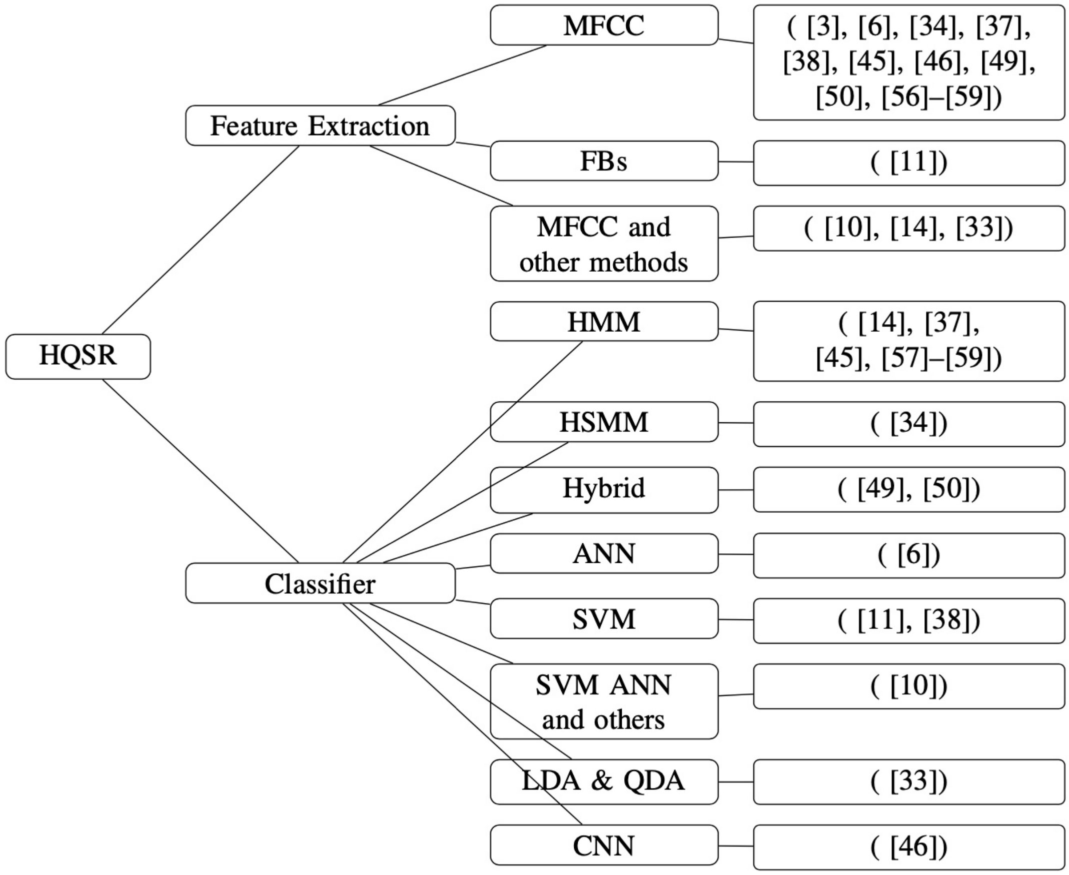

Fig. 4. HQSR Taxonomy of Used Technique

Quran recitations. The best experimental setup was achieved using TDNN with sub-sampling technique.

In [21], the CMU Sphinx trainer [53] was employed to train the acoustic model specifically for the Holy Quran. In a similar vein, a study by [22] utilized the Jaro-Winkler algorithm for text matching and relied on the Google Speech API to establish a framework for speech recognition.

The solution of [5] uses Android speech recognition and depends heavily on third-party online services. In [8], they developed a robust hybrid speech segmentation system based on multiple features (entropy, zero crossings, and energy) and a GA-based optimization scheme to obtain accurate segment units specially adapted for Quran recitation.

IV. Discussion and Future Research Directions

Recent research in the field of HQSR has suggested numerous works. We provide in Table VII a comparative analysis of current research works based on the dataset characteristics and the suggested methodology:

- Dataset characteristics:
  1) #verses: This refers to the total number of verses used in the study: L (number of verses between 1-100), M (number of verses between 101-200), H (number of verses greater than 200), and N (number of verses not determined in the paper).
  2) #sura: This refers to the total number of suras used in the study.
  3) #reciters: This shows the number of reciters who participate in this study.
- Proposed methodology:
  1) DL-based: This criteria shows if the study used deep learning in any stage of the study.
  2) LM: This shows if the study used a language model in their solution or not.
  3) AM: This shows if the study used an acoustic model in their solution or not.
  4) Reciter Independent: This shows if the output model of this study is reciter independent or not.
  5) Speaker Adaptation: This shows if this study used any techniques of speaker adaptation or not.

As we can see in Table VII, there is a significant gap in the current work of HQSR. First, most of the works in HQSR follow template-based speech recognition, which is an old style of speech recognition. This style extracts features of raw audio and feeds these features into a classifier to classify and match with stored templates without using acoustic, lexical (pronunciation), or language models [58]. Examples of these works are ([45], [38], [11], [33], [59], [57], [58], [14], [6], and [37]) as shown in Table VII. Few works suggest the use of deep learning. However, they still rely on an old-style design. For instance, [10] used a deep learning architecture with the old style (i.e., it didn't use acoustic, lexical, and language models but deep learning in the feature extraction phase only). In addition, the authors in [5], [22] employed the Google Speech API for their solution. However, this approach had limitations as the API was unable to accurately differentiate between the seven letters that share similar pronunciations in the verses of the Quran.

Second, only a few studies follow traditional speech recognition, as explained in Fig. 2, either with a deep learning architecture like [49], [50], [3] or without, such as [34], [21]. It is worth noting that more work investigating deep learning architecture should be conducted to improve the accuracy of Arabic speech recognition in general and the Holy Quran in particular.

Third, we can observe in Table VII that the used data set is too small for most of the work (number of verses, suras, and reciters). while an extensive dataset helps produce a robust and generalized speech recognition system.

Finally, no research on HQSR used end-to-end deep learning architecture, while this architecture shows outstanding results with Arabic and non-Arabic languages, as previously discussed in Section II-B (see Table III, which presents a comparison between some end-to-end based speech recognition architecture and traditional techniques in Arabic and non-Arabic languages).

To sum up, many challenges still need to be considered in future work. Indeed, in recognition of speech, recognizing individual words is easy, but the challenge is recognizing continuous speech [7]. Multiple conditions, including speaker dependency, vocabulary size, and noisy environments, can affect the performance of speech recognition systems. Recognition performance increases with limited vocabulary and speaker-dependent conditions while using broad vocabulary and speaker-independent scenarios; performance can decrease significantly [7]. Moreover, Arabic is a morphologically complex language that contains a high degree of affixation and derivation, resulting in a massive increase in word forms [31]. Furthermore, speech recognition of the Holy Quran has additional difficulties compared with written and spoken languages for the following reasons:

- Lack of a comprehensive dataset that contains recitations of women, children, and native and non-native Arabic speakers with both the correct and incorrect recitation of the Holy Quran.
- Mistakes are not acceptable when reading the Quran because an error in reciting only one letter may change the meaning.
- The diversity of narrations in reading the Qur'an makes it difficult for the model to recognize different narrations.
- The diversity of *Magam* in Quran Recitation, such as (*bayat*, *Ajam*, *Nahawand*, *Hijaz*, *Rost*, *Sika*, etc.), adds more difficulty for the model when recognizing the recitation.
- The length of prolongation (*Madd*) varies when reciting the Quran. In Hafs An Asim narration, reciters can recite some types of the madd with 2, 4, or 5 *Harakat*.
- Recitation of the Holy Quran must follow the rules of "tajweed" and correctly pronounce Makhraj (point of articulations) and the Sifaat (characteristics) of each alphabet.

TABLE VII. COMPARING HQSR SOLUTIONS

Ref#	Dataset			Methodology				
	#verses	#sura	#reciters	DL-based	LM	AM	Reciter Independent	Speaker Adaptation
[45]	L	1	1

V. CONCLUSION

This paper surveys Holy Quran Speech Recognition (HQSR) works. It summarizes some studies of speech recognition in written and spoken languages and the most recent work in the HQSR field. It provides a general taxonomy of speech recognition and a specific one dedicated to HQSR studies that illustrates the techniques of feature extraction and classification used in current HQSR research. We compared the current solutions and clarified the limitations of the current studies. The main challenges of the HQSR field are the lack of a comprehensive dataset, minimizing mistakes that are not acceptable when reading the Quran, diversity of narrations, diversity of Magam in Quran recitation, and diversity of prolongation (Madd) length when reciting the Quran. The field of HQSR needs a lot of work to improve the current speech recognition models of the Holy Quran by using better techniques that already show good results with written and spoken languages but haven't been used with HQSR yet.

***Abstract*—Airplane mode of transportation is statistically the most secure means of travel. This is due to the fact that flights require several conditions and precautions because aviation accidents are most of the time fatal and have disastrous consequences. For this purpose, in this paper, the mean goal is to study the different levels of fatality of airplane accidents using machine learning models. The study rely on airplane accident severity dataset to implement three machine learning models: KNN, Decision Tree and Random Forest. This study began with implementing two features selection and extraction methods, PCA and RFE in order to reduce dataset dimensionality and complexity of models and reduce training time by implementing machine learning models on dataset and measuring their performance. Results show that KNN and Decision Tree demonstrates high levels of performances by achieving 100% of accuracy and f1-score metrics; while Random Forest achieves its best performances after application of PCA when it reaches an accuracy equal to 97.83% and f1-score equal to 97.82%.**

Keywords*—Airplane accident; severity; flights safety; machine learning; KNN; Random Forest (RF); Decision Tree (DT)

I. Introduction

It is well known that the plane is the safest mode of transportation. In 2022, there have been only two fatal plane crashes without counting small and helicopter crashes [1]. In 2007, The National Transportation Safety Board known as NTSB, claimed that 24 million hours of plane travels had occurred, only 6.84 of every 100.000 flights hours had a plane accident and 1.19 of every 100.000 plane flights are fatal crashes. The aviation industry contribute significantly to the national economic of each country if they have robust and strong aviation policies and technologies. Thousands of incomes in this field can be reached every year; for this purpose, this industry is well developed and controlled by international standards. Among the most important requirements in aviation industry is safety. That is why different measures of security are taken into consideration before and after any flight. These requirements include:

- A strict safety requirements based of international standards in order to establish a base to rate degree of safety in any flight.
- Collecting data in order to perform data analytics to find out any shortcoming and to perform safety improvements.
- Continuous extensive training for pilots to update their knowledge and skills.
- Safety Management System (SMS) should be implemented in any plane in order to have synchronous state of the plane.
- Auditing safety measures by investigating incidents, analysing performances indicators, etc.

The most important requirement for us in this study is the use of data in order to perform safety audit, prevent accidents and rectify any breaches of policies or technologies misconfigurations or malfunctions. As we can say, safety requirements are very hard and complex to implement because any small error or misconfigurations may lead to fatal consequences. According to [13] airplane accidents can be caused by so many factors including: Pilot error due to miscommunication, distraction, exhaustion, drainage, etc. mechanical error, bad weather conditions, sabotage and human errors. So many scientific contributions had tried to implement data0based approaches using machine learning (ML) models to deal with these safety issues specially in the context of our study which is the prediction of severity of airplane incidents. [4,6,7,12,13] propose ML-based models, deep learning are used and implemented on complex dataset that need deep models such as in [11,14]. Authors using machines learning (ML) models achieved promising results but there is always some data and implementations constraints including limited resources and information about fatal accidents because there are very rare to occur; that is why it is difficult to collect enough data to establish meaningful statistical analysis. The factors that control the operations of an airplane are numerous and complex; they include environmental factors, techniques, human resources factors. Data may be biased toward the condition and purposes so it can misrepresent some conditions and important factors. Mathematical representation of severity may be very difficult for modelisation using classical approaches such as text mining [2]. Hence the need for machine learning solutions. Emre Kuşkapan et al. [8] propose an approach for aviation accidents classification using data mining algorithms. They collect data worldwide from 2000 to 2019. They implement J48, Naïve Bayes and Sequential Minimal Optimization methods. J48 outperforms all methods based on Precision, Recall, F-measure and ROC Area. L. J. Raikar et al. [3] implement SVM, KNN, Adaboost, XGboost to analyse airplane crash. They include feature selection and scaling methods in order to reduce dimensionality of data by removing unnecessary characteristics. In this study, we will implement machine learning models on airplane accident severity dataset to predict severity of airplane accidents. Before that, we established a robust phase of feature selection and extraction in order to get the most relevant and important features. These features will be the focus of future work. We get interesting results. Some ML models reached 100% of accuracy using KNN and Decision Tree. The rest of this paper is organised as follows: In Section 2, we will discuss the related work, in Section 3, we will present the background of this study and the followed methodology. In Section 4, we will present our results, discuss and criticise them and finally a conclusion where we will mention the relevant results, limits of this study and its perspectives in future work.

II. Related Work

R. A. Burnett et al. [6] implement machine learning models in order to predict the injuries and fatalities in aviation accidents. They face so many problems in data processing. First of all, they needed to deal with redundant fields, missing values, lack of generalisation which means that there are lot of changes of conditions over years, so implementing machine learning models on old statistics may lead to misrepresent the results. Another raised problem is that they needed to deal with it is imbalanced data which is a very complex task in machine learning context. They used six Federal Aviation Administration Aviation Incidents and accidents records in range from 1975-2002. They Implement KNN, SVM and KNN models to predict the rate of aviation accidents. Results show that ANN gives a promising results and its obvious because ANN models can generalise and analyse internal relationships between features in order to extract pattern more better than regular machine learning models.

It is well know that in any information system, the human being is the most vulnerable asset. Human factor contribute to approximatively 75% of aircraft accidents and incidents [5]. In the paper by M. Bagarzan et al. [7], they conducted an interesting study in order to analyse the impact of the age, experience and gender of pilots on aviation accidents. They specify six categories of age: “less than 20”, “20-29”, “30-39”, “40-49”, “50-59” and “more than 60”. “Experience” in this study is based on the number of hours for each pilot involved in an accident. the records belong to the NTSB database. They implement chi-square and logistic regression models in their study in order to figure out if there is any relationships between pilot characteristics and how much these characteristics can contribute in causing aviation accident that lead to serious consequences. Results show that the gender had no great impact of the pilot error but females make fatal errors less than men. Pilots that are older than 60 years old can make pilot error. Experienced pilots can easily get involved in fatal accidents because due to their experiences they can fly in conditions that non experienced pilots cannot do but these experienced pilots are less likely to make pilot errors. Authors suggest that there are environment conditions that can affect the performances of a pilot and they suggest to maintain training for pilots and improve performances of technologies used in this mode of transportation.

In the study by N. Pande et al. [13], they conducted a study about the prediction of fatal aviation accidents. They used Random Forest, XGBoost, Neural Network, multiple Linear Regression, chi-square, linear regression, ensemble model that combine so many machine learning models and logistic regression. This study is based on a data that is collected since 1908. 4700 data points of it were used in this study. What is interesting about this study is that it is based on simple classical machine learning models like RF, XGBoost and complex machine learning models that refers to the combination of different machine learning models in order to predict the dependant feature. The evaluation metrics in this study include minimum error, maximum error, mean absolute error, linear correlation and standard deviation. Results show that Neural Network model outperform all of the implemented models reaching an accuracy equal to 90.6% which is the case for [13].

We can say that machine learning models are widely used in the field of severity and fatalities of flights accidents. The usefulness of machine learning models in this field are related to the complexity of data. In order words, same conditions of weather and other plane characteristics that we can gather using sensors, the same data can lead to different results. We can never be sure of these characteristics because even a bird strike [9] can cause fatal damage.

III. Theoretical Background

In order to implement our ML models, we will rely on two models for data processing: PCA for feature extraction and RFE for features selection. Then we will implement our ML models that are: RF, DT and KNN.

A. Feature Extraction: PCA

It is an abbreviation for Principal Component Analysis [19]. It is an unsupervised ML model that is used to reduce data dimensionality based on statistical measurements, and generates new components to contain the most significant feature data by capturing a large amount of variance[20]. PCA is used to transform a large set of data into a small one but keeping relevant information about data. The principal components of PCA are orthogonal. PCA is useful to reduce the noise in data, to compress data and helps in visualising data with high dimensions and to detect any relationships between features mainly correlation and other relationships in order to gather correlated features with each others. Given a dataset X with n observations and p variables, we can perform PCA by following these steps:

Center the data by subtracting the mean $\bar{x}$ from each variable:

$$\tilde{x}ij = xij - \bar{x}j \tag{1}$$

where $\tilde{x}ij$ is the centered value of variable j in observation i.

Calculate the sample covariance matrix S:

$$S = \frac{1}{n-1}\sum_{i=1}^{n} \tilde{x}_i \tilde{x}_i^T \tag{2}$$

where $\tilde{x}_i$ is the centered vector of observation i.

Compute the eigenvectors $v_1, v_2, ..., v_p$ and corresponding eigenvalues $\lambda_1, \lambda_2, ..., \lambda_p$ of S.

Select the k eigenvectors with the highest eigenvalues, where k is the number of dimensions in the reduced feature space.

Project the centered data onto the k selected eigenvectors to obtain the reduced feature space:

$$Y = XV_k \tag{3}$$

where V_k is a matrix containing the top k eigenvectors as columns.

The final output Y will have dimensions $n \times k$, where each row represents an observation and each column represents a principal component.

B. Feature Selection: RFE

Recursive Feature Elimination is a feature selection method used to get the most important features that contribute to improve ML models performances. RFE is a recursive method that removes in each iteration the worst features. We first provide RFE with all features, RFE run on ML models on the dataset for instance Random Forest. After training the model -ML model- RFE measures the contribution and importance of each feature. Less relevant features will be removed and re-run the model until we get the best number of features that contribute the most to the model. The process of Recursive Feature Elimination (RFE) involves assigning weights to different features in order to identify which ones contribute the most towards predicting the target variable. This is done by ranking the features based on their relative importance [21], which will help to decrease complexity of the model, minimising time of training and increasing model performances. The RFE algorithm can be mathematically represented as follows: Let X be the feature matrix and y be the target vector. Let n be the total number of features and k be the desired number of features.

1) Initialize $X_{\text{RFE}} = X$ and $k_{\text{RFE}} = n$.
2) Train a model on X_{RFE} and y to obtain coefficients or feature importance.
3) Calculate the importance of each feature
4) Remove the least important feature from X_{RFE} to obtain X'_{RFE} and decrement k_{RFE}.
5) we repeat the same steps until $k_{\text{RFE}} = k$.

C. Decision Tree

It is a supervised ML model used for classification and regression.DT are not only highly useful in various applications but also renowned for their interpretability and resilience [16] . DT split the data based on features with most importance. These features importance is measured using Gini index or Entropy. The final structure of a DT model is a tree, where nodes represent features and leafs represent the dependant feature. The process of a DT model is as follow: The dataset went through DT from input node to the leafs where each leaf refer to a value of the dependant feature. Unlike RF, DT may have bad performances in front of high dimensionality datasets or noisy datasets.

To construct a Decision Tree, the ID3[15] algorithm is utilized, which involves several steps. The initial stage involves computing the entropy or Gini impurity of the target class in order to assess the data's impurity.

$$Gini(S) = 1 - \sum_{i=1}^{k} p_i^2 \tag{4}$$

Where k represents the total number of classes, while p_i denotes the proportion of instances that belong to the i-th class.

Afterward, we calculate the Gini gain for each attribute in our dataset and select the attribute that provides the greatest value and create a node for that attribute. The formula used to calculate the Gini gain for each attribute is:

$$Gini\_Gain(S, A) = Gini(S) - \sum_{v \in values(A)} \frac{|S_v|}{|S|} Gini(S_v) \tag{5}$$

Where A represents an attribute, while S refers to the dataset. S_v represents the subset of instances in S where attribute A has a value of v. Repeat steps 2 recursively for every subset of data generated by the split until all instances within a subset are categorized under the same class or there are no remaining attributes left to split the data.

D. Random Forest

Random forest [17] is a supervised machine learning model used for many purposes including classification and regression. It is based on building Decision trees on subset of the samples and features. RF contains n DT. The choice of n depends on the task. Each DT is trained on a random part of the data using random partitions that helps to decrease the model's complexity and to prevent it from overfitting. Each DT makes a prediction and then the majority vote will be considered for prediction. RF gives best results on large data of high dimensions and RF is very useful in case of noisy data.

E. KNN

Abbreviation of K-Nearest Neighbors. It is a non-parametric supervised machine learning model [18], mainly used for classification and regression tasks. The purpose of KNN is to find the K nearest data points of data in order to make a prediction. KNN measures the distance between data points using Euclidean distance:

$$d\left(X, Y\right) = \sqrt{\sum_{i=1}^{n} \left(X_i - Y_i\right)^2} \tag{6}$$

Or Manhattan distance:

$$d\left(X, Y\right) = \sum_{i=1}^{n} |X_i - Y_i| \tag{7}$$

These distances are used to group subsets of data in order to measure the dependant variable in the training phase. In case of large datasets, KNN may need additional computational resources. The choice of the k is not trivial, choosing a wrong k will lead to performances degradation.

F. Accuracy

Accuracy is a commonly used metric in machine learning to evaluate the performance of a model. It involves counting the number of true positive (TP) and true negative (TN) samples in a given dataset, and dividing it by the total number of samples including false positive (FP) and false negative (FN) samples. In other words, accuracy measures how many samples are correctly predicted out of all samples in the dataset.

$$Accuracy = \frac{TP + TN}{TP + TF + FP + FN)} \tag{8}$$

G. F1-Score

The F1-score is a metric used to measure the classification performance of machine learning models. It combines two different metrics, precision and recall, to provide a single score that reflects the overall performance of the model. A good F1-score requires good results for both precision and recall, or high results for one metric if the other metric has low results, in order to balance the results.

$$F1 - Score = 2 * \frac{Precision * Recall}{Precision + Recall} \tag{9}$$

IV. Results and Discussion

Table I shows the results of KNN, DT and Random Forest using all features. Results show that KNN and DT reached 100% of performances for both metrics: accuracy and f1-score. RF reaches an accuracy equal to 95.48% and f1-score equal to 95.49%.

TABLE I. KNN, DT and RF ML Models Performances using All Features based on Accuracy and F1-score

	Accuracy	F1-Score
Random Forest	95.48%	95.49%
Decision Tree	100%	100%
KNN	100%	100%

In order to reduce the dimensionality of the dataset, we used PCA with Principal Components equal to 8. Results in Table II show that results remain the same for KNN and DT, which means that PCA preserved relevant inertia of original dataset while reducing complexity of the models and training time. For RF model, we find out that RF performances increase by 2.35% to reach 97.83% of accuracy. Same remark for f1-score metric, it increase by 2.33% to reach 97.82%.

TABLE II. KNN, DT and RF ML Models Performances after Applying PCA based on Accuracy and F1-score

	Accuracy	F1-Score
Random Forest	97.83%%	97.83%
Decision Tree	100%	100%
KNN	100%	100%

Table III shows the performances of ML models after selecting the most important features based on RFE feature selection metric. As for PCA metric, the performances of KNN and DT remain the same (100% of accuracy and f1-score for both models). For RF model, accuracy decreased by 0.71% to become 94.77%. Same behaviour for f1-score, it decreased by 0.73% to become 94.76%.

TABLE III. KNN, DT and RF ML Models Performances after Applying RFE based on Accuracy and F1-score

	Accuracy	F1-Score
Random Forest	94.77%	94.76%
Decision Tree	100%	100%
KNN	100%	100%

Fig. 1 shows the confusion matrix of RF model using all features of the dataset. It shows that the accuracy of multi-classification is in the range [94%-97%]. Fig. 2 and Fig. 3 show respectively the multi-classification for both KNN and DT, each class from 0 to 3 are well classified which means that these two models can be a good choice to deploy them as real classifiers for predicting severity of aviation accidents.

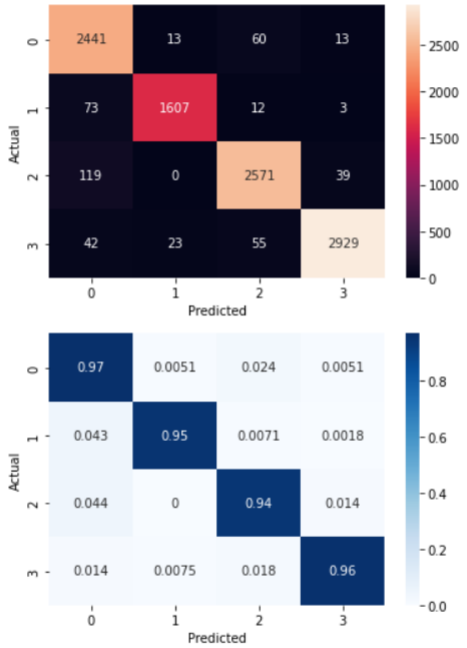

Fig. 1. Multi-classification results of RF model using all features.

Fig. 4 shows the multi-classification performances of RF after application of PCA. We can remark that the range of accuracy for the four classes is [97%-99%]. We also remark that comparing with results using all features, we can say that accuracy augmented for all classes after applying PCA by 2%, 4%, 3% and 1% for respectively class 0, class 1, class 2 and class 3.

Fig. 5 and Fig. 6 show the performance of both KNN and DT. Results remain the same, each class reach 100% of accuracy for the four classes for both KNN and DT; results same the same comparing them with results obtained after application of PCA. Fig. 7 shows the performances of RF model after application of RFE feature selection based method. Results show a decrease of performances by 1%, 1%, 1% for respectively class 0, class 1 and class 2, while the accuracy of class 3 remain the same. Fig. 8 and Fig. 9 show performances of both KNN and DT after application of RFE. Results remain the same such in the two cases (after application of PCA & using all features).

After discussing all these results, we can say that RF,

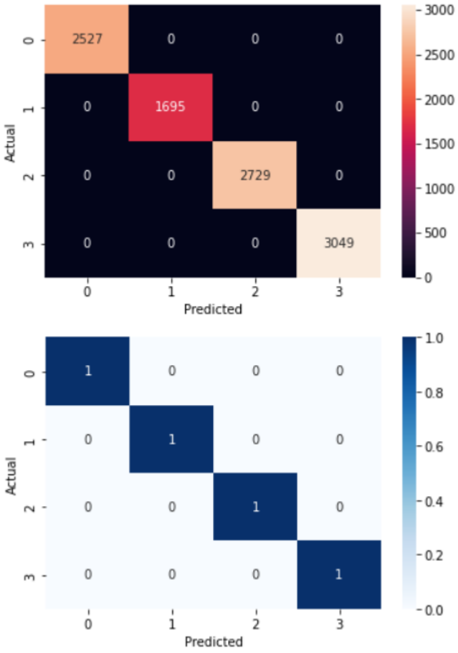

Fig. 2. Multi-classification results of KNN model using all features.

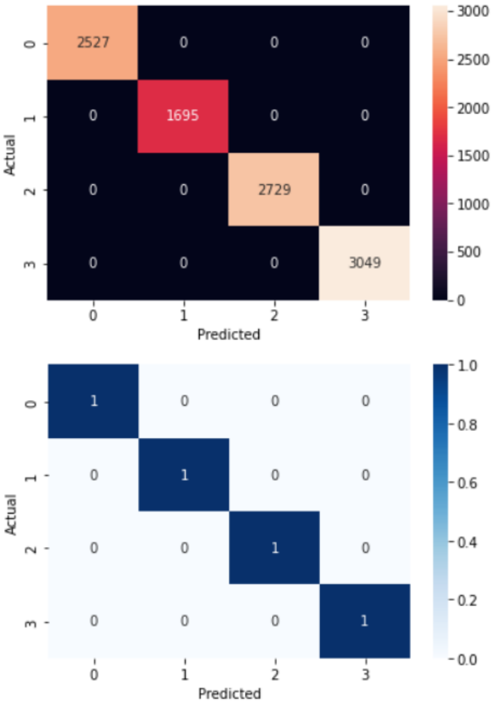

Fig. 3. Multi-classification results of DT model using all features.

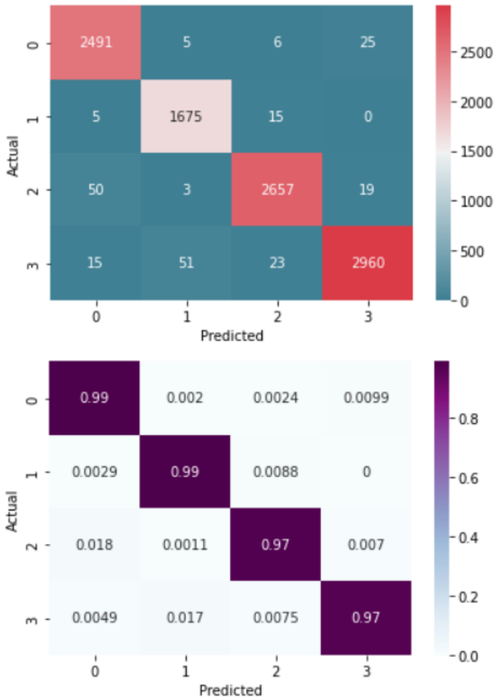

Fig. 4. Multi-classification results of RF model after application of PCA.

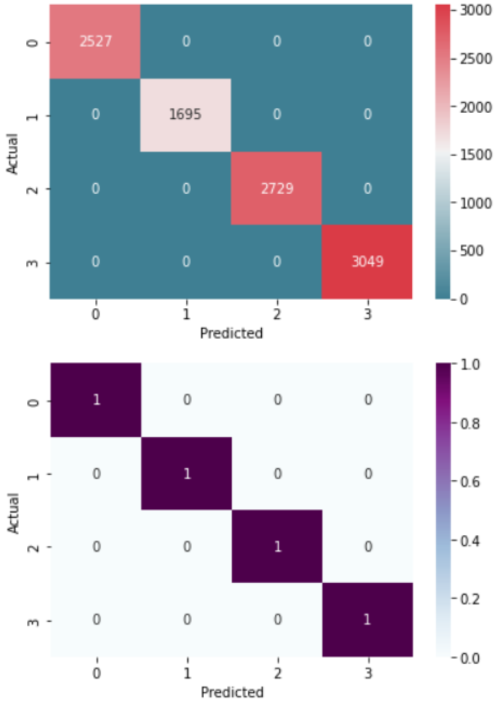

Fig. 5. Multi-classification results of KNN model after application of PCA.

KNN and DT are promising models that can deployed in real situations for predicting severity of aviation accidents. KNN and DT give an accuracy and f1-score equal to 100% which means that all classes of severity have been adequately classified so we can say that intelligent solutions based on ML or Deep Learning models can be relevant alternatives to overcome the limits of classical solutions such as statistical analysis, solutions based on expertise, solutions that require sometimes advanced mathematical modelisation that are complex and may lead sometimes to misrepresent real conditions in the phase of abstraction.

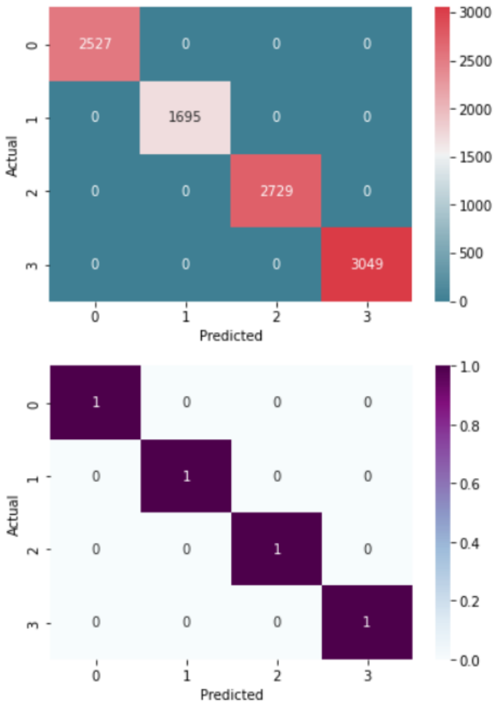

Fig. 6. Multi-classification results of DT model after application of PCA.

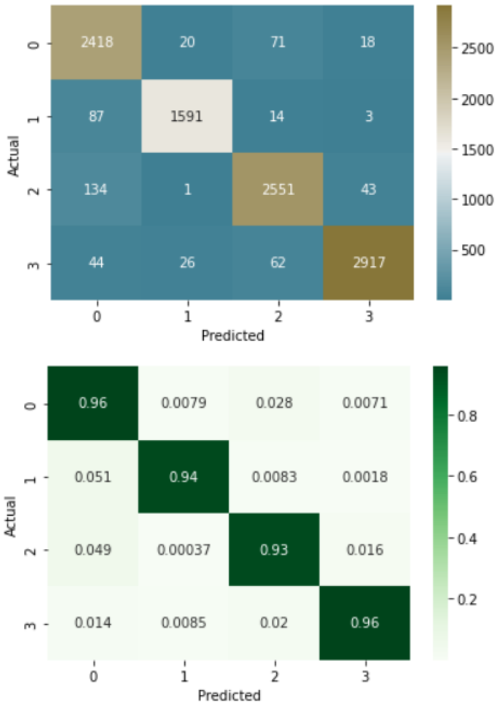

Fig. 7. Multi-classification results of RF model after application of RFE.

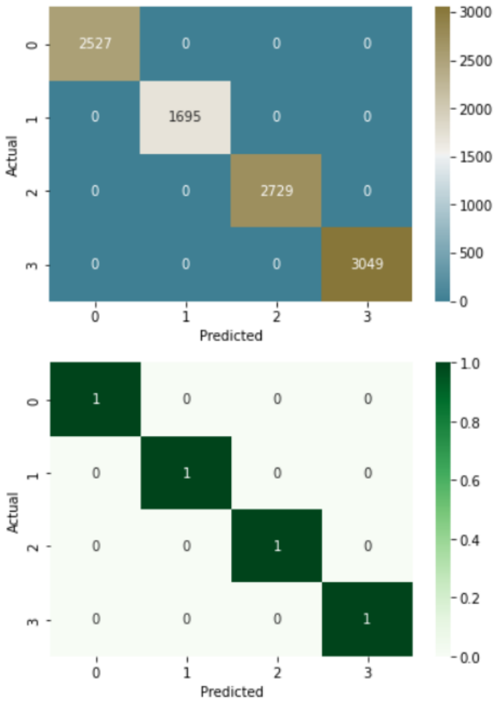

Fig. 8. Multi-classification results of KNN model after application of RFE.

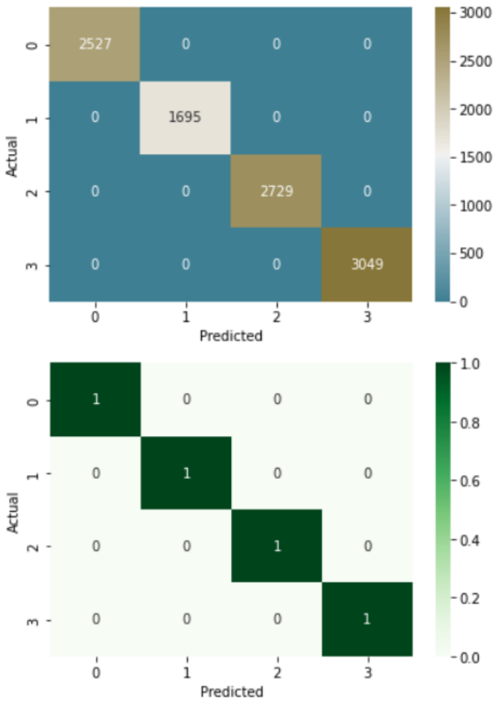

Fig. 9. Multi-classification results of DT model after application of RFE.

V. Conclusion and Future Work

This paper shows the robustness of machine learning models for predicting severity of aviation accidents. KNN and DT achieved high level of performances based on accuracy and f1-score metrics while RF gives respectful results but never achieved 100% of accuracy or f1-score but we should pay attention that these models should be tested in real situations to test its stability. Furthermore, as we had discussed earlier, Neural Network and Deep Learning models can be a good alternatives of the models we had implemented in this study.

This proposition must be the perspective of this data and test our models on other datasets that contain different information and then different conditions. Predictions models in field of aviation are a very complex tasks that require gathering the maximum possible of information about environment plane, human, technologies, etc. in order to improve intelligent solutions like ML and DL models to overcome limits of classical solutions.

Enhancing Safety and Multifaceted Preferences to Optimise Cycling Routes for Cyclist-Centric Urban Mobility

Mohammed Alatiyyah
Department of Computer Science, College of Sciences and Humanities-Aflaj,
Prince Sattam Bin Abdulaziz University, Al-Kharj, Saudi Arabia

***Abstract*—In order to optimise bicycle routes across a variety of multiple parameters, including safety, efficiency and subtle rider preferences, this work explores the difficult domain of the Bike Routing Problem (BRP) using a sophisticated Simulated Annealing approach. In this innovative structure, a wide range of limitations and inclinations are combined and carefully calibrated to create routes that skillfully meet the varied and changing needs of cyclists. Extensive testing on a dataset representing a range of rider preferences demonstrates the effectiveness of this novel approach, resulting in significant improvements in route selection. This research is a significant resource for urban planners and politicians. Its data-driven solutions and strategic recommendations will help them strengthen bicycle infrastructure, even beyond its immediate applicability in resolving the BRP.**

***Keywords*—Bike routing; dynamic vehicle routing inventory routing; approximate dynamic programming**

I. Introduction

When compared to driving, biking is an affordable, environmentally friendly, energy-efficient, and health-conscious alternative to other forms of transportation [1]. It goes beyond simple transportation, providing a means of regular physical activity, encouraging wholesome living, and reducing car emissions. Even with the growing number of towns attempting to develop networks of bicycle lanes, a significant percentage of trips within rideable distances are still made by automobile [2]. Promoting a mentality that embraces riding for recreational and everyday transportation purposes is still a critical obstacle to creating genuinely bike-friendly urban settings.

The key to solving this problem is to carefully hone the bike-path network's functionality and architecture. Riding a bicycle is one of the most effective ways to use energy and promote public health. It is also one of the most important forms of active transportation to reduce traffic congestion and avoid emissions from vehicles. Because walking and cycling are accessible and don't require any specific equipment or expertise, they are suitable for people of all ages and allow them to customise the amount of physical effort they want to put in. But if walking is more suitable for shorter distances, cycling is a better choice for longer ones. However, the belief that riding a bicycle is a dangerous activity endures, mostly because of things like heavy traffic, congested roads, and a lack of designated bike lanes. There are several obstacles that prevent cycling from becoming widely accepted, including worries about comfort, safety, and accessibility [3]. Safety barriers are significant difficulties that arise from concerns about criminal activity, road accidents, or personal injury. Cycling enthusiasts frequently view themselves as vulnerable users of a space designed primarily for motor vehicles. The selection of bike routes is a significantly more complex procedure than the selection of driving routes. Whereas motorists focus on distance and travel time [4], cyclists consider a variety of factors, such as the condition of the bike lanes that are available [5][6] and avoiding hilly terrain and particularly unsettling intersections like roundabouts [7]. Bicyclists' preferred routes are greatly influenced by their closeness to motorised vehicles, especially on high-speed main roads [6]. In order to avoid heavily trafficked or densely populated bike regions, cyclists frequently choose longer but supposedly safer routes [8][9]. This paper introduces a novel approach to the Bike Route Problem (BRP), with a focus on cycling route optimisation to improve safety, efficiency, and compatibility with a range of rider preferences. The new framework synthesises a wide range of limitations and preferences, allowing bicycle routes to be customised to meet the diverse needs of different riders. Our study provides empirical confirmation of the suggested method's effectiveness using a dataset that encompasses a wide range of rider preferences. The flexibility of the Simulated Annealing method demonstrates its ability to create customised routes that meet the various needs of cyclists.

The Bike Route Problem is explained in Section III, while the following sections outline the state of relevant research in Section II. Section IV presents our suggested options for solving the problem, followed by an in-depth analysis of the findings. In the end, Section V summarizes the findings and suggests possible avenues for more research and development.

II. Related Work

Bicycle routing is a problem that has been extensively studied in a number of research paradigms, both directly and indirectly. The multi-objective routing problem was first tackled by Martins et al. [10], who defined the problem in terms of several objective functions and developed a multi-criteria label-setting algorithm for its solution. Later research, like that of Song et al. [11], explored the use of multi-label correction algorithms to find Pareto routes and included hierarchical clustering techniques to expedite the selection procedure. Even with recent improvements in label-setting algorithms, real-time applications are still hindered by the processing timescales these techniques demand.

Routing difficulties have seen the use of evolutionary approaches, most notably genetic algorithms. Genetic algorithms were used in conjunction with High-performance Clusters (HPC) by Arunadevi et al. [12] to address routing issues. Comparably, Kang et al. [13] used evolutionary algorithms to compute segment-specific cost functions in networks of cyclists, taking perceived risk and distance into account. Nevertheless, the multi-objective landscape of bicycle routing was not explored in these research, which mostly concentrated on single-objective optimisation. Several studies have used various criteria to build bicycle routes, frequently maximising each criterion on its own. Using ArcGIS Server and specific Google APIs, Hochmair et al. [14] developed an online cycling route planner. Hrncir et al. [15] used a cost vector that included several parameters such as trip time, comfort, quietness, and levelness with the A-Star algorithm. Chen et al. [16] investigated the use of artificial neural networks to generate routing algorithm heuristic functions. Contraction hierarchies were combined with OpenStreetMap data by Luxen et al. [17] to determine the most straightforward graph-based pathways. Methods for solving the multi-objective bike routing problem have been developed recently, and their effectiveness has been demonstrated in real-world network scenarios. Bike routing algorithms were improved by Hrncir et al. [18] and Hrnvcivr et al. [19], who presented a heuristic-driven Dijkstra algorithm that included a multi-criteria viewpoint. Notable platforms have surfaced in the world of bicycle-specific internet route planners. Though it is available in some areas, Google Maps does not provide much personalization. Using routing techniques like the A* algorithm and contraction hierarchies, OpenTripPlanner incorporates a bicycle planning option that allows users to balance preferences like speed and terrain flatness. Popular in the United Kingdom, Cyclestreets offers a range of route alternatives depending on balance, speed, and tranquilly. Berlin, Germany-based BBBike takes into account variables including the kind of route and the presence of lights. Still, there isn't much written about this topic in the literature. A few studies—Robert et al. [20] and Su et al. [21], for example—introduced computerised cycling route planners customised for certain areas, while Hochmair et al. [14] offered a bicycle route planner for Broward County, Florida, taking into account a variety of factors influenced by cyclist preferences. A route planner for electric bicycles was presented by Tal et al. [22], with an emphasis on weather and energy efficiency.

Although bike routing has progressed, there is still a significant gap in the field of multi-objective methods that balance optimising complicated objectives with computing feasibility. In order to close this gap, this work presents a novel approach that uses genetic algorithms to approximate the optimal Pareto set. It also investigates the possibility of using genetic algorithms to solve multi-objective problems in a reasonable amount of computational time.

III. Bike Routing Problem (BRP)

We define the BRP as follows: let $G = \{V, E\}$ be a undirected weighted graph where, $i \in V$ and $i = 1, 2, \dots, |V|$ be a set of nodes, and E be a set of edges between nodes where E_{ij} be the edge between V_i and V_j. In addition, each edge has a set attributes denotes A where $a \in A$ and $a = 1, 2, \dots, |A|$. The starting node is s and the terminal node is e where $s = 1$ and $e = |V|$. However, cyclists have number of constraints. Mandatory Constraints (MC) be denoted MC; $mc \in MC$, where $mc = 1, 2, \dots, |MC|$. Optional Constraints (OC) be denoted OC; $oc \in OC$, where $oc = 1, 2, \dots, |OC|$. The total number of constraints $|MC| + |OC| \leq |A|$. In addition, each constraints (MC or OC) be applied in each edge and be denoted MC_{ij}^{mc} or OC_{ij}^{oc} where MC or $OC \subseteq A$.

$$Max \sum_{i=1}^{|V|} \sum_{j=1}^{|V|} A_{ij} \times X_{ij} \tag{1}$$

$$\Big(|MC| + |OC|\Big) \leq |A| \tag{2}$$

$$\sum_{i=1}^{|V|} X_{si} = 1 \tag{3}$$

$$\sum_{i=1}^{|V|} X_{ie} = 1 \tag{4}$$

$$X_{ij} \in \{1, 0\}; \forall i, j = 1, 2, \dots, |V| \tag{5}$$

$$\sum_{n=1}^{|V|-1} X_{nr} = \sum_{n=2}^{|V|} X_{ru} = 1 \tag{6}$$

$\forall r = 2, \dots, |V| - 1$

$$2 \leq I_n \leq |V| \tag{7}$$

$\forall n = 2, \dots, |V|$

$$I_n - I_u + 1 \leq (|V| - 1) \times (1 - X_{nu}) \tag{8}$$

$\forall n, u = 2, \dots, |V|$

Eq. 1 presents the objective function of BRP where X_{ij} denotes the decision variable moving from node i to node j and the the value of X_{ij} is 0 or 1 (see Eq. (5)). Eq. 3 and 4 represent a constraint to ensure the path starts from s and ends at e. Eq. 6 is a constraint to ensure that the path is connected and each vertex is visited once at most. Eq. 7, I_n denotes the position of node n in the path, and the combination of Eq. 7 and Eq. 8 prevents sub roues.

$$MC_{ij} = \prod_{mc=1}^{|MC|} MC_{ij}^{mc} \tag{9}$$

$$_{ij}^{mc} \in \{1, 0\} \tag{10}$$

$$\forall i, j = 1, 2, \dots, |V| \text{ and } \forall mc = 1, 2, \dots, |MC|$$

As have been mentioned above that there are numbers of MCs which is donated in Eq. 9. Mainly, MC_{ij}^{mc} denotes the MC (mc) from node i and j where MC_{ij}^{mc} has one value if the constraint is satisfied, the value is equal 1 otherwise equal 0 (see Eq. (10)).

TABLE I. INSTANCE TEST SCENARIO CATEGORIES

Scenario	Description	Details
S1	Commuter Cyclist	Using bike for work commuting
S2	Fitness Enthusiast	Cycling for exercise and fitness
S3	Urban Explorer	Exploring the city and its surroundings
S4	Nature Lover	Cycling in natural landscapes and parks
S5	Daily Commuter	Regular commuting for work and daily activities
S6	Adventurous Cyclist	Exploring challenging terrains and trails
S7	Family Outings	Cycling with family for recreational activities
S8	Bike Commuters	Using bike for work commuting in a busy city
S9	Night Rider	Cycling during nighttime for relaxation
S10	Touring Cyclist	Long-distance touring and exploration

TABLE II. INSTANCE TEST SCENARIO IN MORE DETAILS

Scenario	Attributes				
	Safety	Bike Lanes	Traffic Volume	Scenery	Elevation
S1	MC	OC	OC (M)	OC	OC (Low)
S2	OC	OC	OC (L)	MC	MC
S3	OC	OC	OC (M)	MC	OC (Low)
S4	MC	OC	OC (L)	MC	OC (Low)
S5	MC	MC	OC (L)	OC	OC (Low)
S6	OC	OC	OC (L)	OC	OC (High)
S7	MC	OC	OC (L)	OC	OC (Low)
S8	OC	OC	MC	OC	OC (Low)
S9	OC	OC	OC (L)	OC	OC (Low)
S10	MC	OC	OC (L)	OC	OC (High)

$$OC_{ij} = \frac{\sum_{oc=1}^{|OC|} OC_{ij}^{oc}}{|OC|} \tag{11}$$

$$0 \leq OC_{ij}^{oc} \leq 1 \tag{12}$$

$$\forall i, j = 1, 2, \ldots, |N| \text{ and } \forall oc = 1, 2, \ldots, |OC|$$

In contrast, a OC indicates a specific level of satisfaction and meeting it is optional. Numbers of OCs which is donated in Eq. 11, where OC_{ij}^{oc} one value between 0 to 1 (see Eq. (12)). In additional, Eq. 13 presents the calculation of MC and OC from i to j.

$$A_{ij} = MC_{ij} \times OC_{ij} \tag{13}$$

IV. SOLUTION APPROACHES

In this section, we elaborate on our heuristic-driven Simulated Annealing method designed for solving the BRP. Our approach integrates a data model for constraints and Simulated Annealing techniques to address the Bike Route Problem. The fundamental concept involves simplifying the complexity of the problem by consolidating constraints into a single value that encapsulates the attributes sought by riders.

A. Benchmark Instances

To the best author knowledge there is not any dataset for bike routing problem, so A set of benchmark instances were created to analyze how the propose model performs through numerical experiment results. Random problem instances were generated so as to maintain the properties of one of ten general scenario categories as defined in Table I. In each scenario, it has been generated different circumstances where difference constraints and preferences are applied. Each instance was randomly generated assuming a grid of 40 by 40 miles based on an area similar in size Newcastle upon Tyne, UK. Table II shows the details of each scenario, and in the dataset has been created five attributes for each of edges.

Table II delineates a variety of constraints and preferences. The Optional Constraints (OC) column details the preferences of the riders, while the Mandatory Constraints (MC) column lists the constraints that are requisite. Furthermore, the Traffic Volume attribute accommodates varying preferences: certain riders opt for routes with low traffic, whereas others may favor routes with moderate traffic levels. Additionally, the Elevation attribute reflects diverse inclinations regarding physical exertion; some riders seek routes with minimal elevation to reduce effort, while others pursue routes with significant elevation for a more challenging ride.

TABLE III. INSTANCE SCENARIO WITH START AND END LOCATION

Instance	Start location	End location
I1	121	165
I2	77	351
I3	462	145
I4	282	393
I5	25	115
I6	80	476
I7	323	342
I8	109	464
I9	491	171
I10	31	375

The ten benchmark sets under consideration encompass a total of 100 instances, with each set comprising 10 instances characterized by a node count of 500. While each benchmark (scenario) shares identical start and end points, they are differentiated by their unique constraints and preferences. Table III details the start and end points for each instance, providing a clear reference for the scenarios tested.

Algorithm 1 Bike Routing Problem

```
$SenarioData \leftarrow ReadingDataFiles()$
$Edges \leftarrow ReadingEdges()$
while $i <= SenarioData.lenth()$ do
    while $j <= Edges.lenth()$ do
        $InitialRoute \leftarrow CreateInitialRoute()$
        $InitialTemperature = 1000$
        $CoolingRate = 0.995$
        $BestRoute = SimulatedAnnealing()$
        $j \leftarrow j + 1$
    end while
    $i \leftarrow i + 1$
end while
```

B. Simulated Annealing

Simulated Annealing (SA) is a powerful optimization algorithm inspired by the annealing process in metallurgy. Initially introduced by Kirkpatrick, Gelatt, and Vecchi in the 1980s [23], SA mimics the annealing of materials, where a solid is heated to high temperatures and then gradually cooled to minimize its energy state. This process allows the algorithm to escape local optima and explore the solution space more effectively. The key idea behind SA is to accept worse solutions

Algorithm 2 $SimulatedAnnealing$ Algorithm

```
while $temperature > 0.1$ do
    while $ReplacedNode$ do
        $SwapIndex \leftarrow random(1, Route.length())$
        $NewNode \leftarrow FindReplacedNode()$
        if $NewNode! = Null$ then
            $Route[SwapIndex] \leftarrow NewNode$
            $Update =$
        else
            $ReplacedNode \leftarrow False$
        end if
    end while
end while
```

with a certain probability, enabling the algorithm to explore the solution space broadly before converging towards the optimal solution [23][24]. This approach has proven to be highly effective in solving complex optimization problems where the objective function is not explicitly defined and can only be evaluated through computationally expensive simulations [24]. SA's ability to balance exploration and exploitation makes it a popular choice in various real-world applications, ranging from engineering and logistics to machine learning and artificial intelligence [24]. Its widespread applicability and efficiency in tackling challenging optimization problems have solidified its position as a prominent metaheuristic algorithm in the field of computational optimization.

V. Computational Results

In this section, we provide the outcomes of our numerical experiments. Initially, we assess the efficiency of our BRP formulation as well as the Constraints formulation coupled with Simulated Annealing. Subsequently, we analyze the performance of our proposed Simulated Annealing algorithm. All experiments were carried out on a computer with an Intel i7-2.10 GHz processor and 64 GB RAM, running on the Windows 11-x64 operating system.

The study examined the effectiveness of BRP in uneven situations. Results from the tenth series of tests were analyzed in comparison with outcomes obtained using Simulated Annealing methods. Tables IV - XIII summarize the computational results for each instance, respectively. In these tables, the three columns display the scenario name, total scores based on the edges are visited, and the path. The total scores values are evaluated based in Eq. 1. Please note that, the computation times of these heuristics are less than 1s.

Table IV reports the results obtained from the test problem in instance-1 which representing a scenario of transporting from Node-121 to Node-165. As it can be seen, the results can be categorized into five categories: (1) Scenario 1, 5, and 8, (2) Scenario 2 and 3, (3) Scenario 4 and 6, (4) Scenario 7 and 10, and (5) Scenario 9; each one of these category has the same result.

Table V presents the results of the instance-2 which presents the problem of moving from Node-77 to Node-351. In addition, Table XII presents the results of the instance-9 which presents the problem of moving from Node-491 to Node-171. Surprisingly, all results from different scenarios has the same result (path); In instance-2 the result is [77, 422, 351], and the instance-9 the result is [491, 218, 171].

Table VI shows the results of the instance-3 which presents the problem of moving from Node-462 to Node-145. In this experiment, All scenarios shows the same results (path) except the scenario-3.

Table VII presents the results of the instance-3 which presents the problem of moving from Node-282 to Node-393. The results can be seen in four categories: (1) Scenario 2, 5, 7, 8, and 10, (2) Scenario 3 and 4, (3) Scenario 6 and 9, and (4) Scenario 1.

Table VIII presents the results of the instance-2 which presents the problem of moving from Node-25 to Node-115. There are six scenarios have different result completely which

TABLE VIII. The Result for Instance 5

Instance	Total Scores	Path
Scenario-1	[25, 240, 184, 115]	0.56
Scenario-2	[25, 18, 108, 115]	1.00
Scenario-3	[25, 497, 131, 115]	0.47

are Scenario 3, 4, 6, 7, 9, and 10. However, Scenarios 1 and 8 are the same, and the Scenario 2 and 5 are the same.

Table IX shows the results of the instance-6 which presents the problem of moving from Node-80 to Node-476. In this experiment, All scenarios shows the same results (path) except the scenario-7. Moreover, Table X shows the results of the instance-7 which presents the problem of moving from Node-323 to Node-342. Also, ins this experiment, All scenarios shows the same results (path) except the scenario-6.

Table XI shows the results of the instance-8 which presents the problem of moving from Node-109 to Node-464. Surprisingly, all results are different for each scenario.

Table XIII presents the results of the instance-10 which presents the problem of moving from Node-31 to Node-375. The results can be seen in two categories: (1) Scenario 1, 2, 3, 4, 6, 7, 8 and 10, and (2) Scenario 5 and 9.

VI. Conclusions and Future Work

The study successfully applied a heuristic-driven Simulated Annealing algorithm to the BRP, demonstrating its efficacy in processing and optimizing complex routing problems within reasonable computational times. The results confirmed that the proposed method could handle a variety of scenarios by accommodating diverse constraints and preferences, thus offering a flexible and robust solution to the BRP. The findings suggest that the method is not only applicable in the context of cycling but may also extend to other forms of transportation where route optimization is essential. The research contributes to the field by providing a systematic approach to addressing BRP and paving the way for more sustainable urban transport systems. Future research directions include scaling the proposed solution to larger datasets and urban areas with more complex networks. There is also scope for integrating real-time data, such as traffic updates and weather conditions, to enhance the dynamicity and responsiveness of the route planning process. Another avenue for exploration is the application of the Simulated Annealing approach to different types of multi-objective routing problems beyond cycling, such as pedestrian pathfinding and electric vehicle charging station routes. Further studies could also investigate the integration of machine learning techniques to predict and adapt to cyclists' preferences more accurately.

Recognition and Translation of Ancient South Arabian Musnad Inscriptions

Afnan Altalhi, Atheer Alwethinani, Bashaer Alghamdi, Jumanah Mutahhar, Wojood Almatrafi, Seereen Noorwali
College of Computers and Information System, Umm AlQura University
Makkah, Saudi Arabia

***Abstract*—Inscriptions play an important role in preserving historical information. As such, conservation of these inscriptions provides valuable insights into the history and cultural heritage of the region. *Musnad* inscriptions are considered one of the earliest forms of writing from the Arabian Peninsula, preceding the modern Arabic font; however, most Musnad inscriptions remain unread and untranslated, signifying a substantial loss of historical information. In response, this paper represents a significant contribution to the field by proposing a successful approach to interpreting Musnad inscriptions. To do so, a dataset was prepared from the Saudi Arabian Ministry of Culture and subjected to preprocessing for optimal recognition, a step that entailed several experiments to enhance image quality and preparedness for recognition. The dataset was then trained and tested with 29 classes using three different convolutional neural network (CNN) architectures: Visual Geometry Group 16 (VGG16), Residual Network 50 (ResNet50) and MobileNetV2. Thereafter, the performance of each architecture was evaluated based on its accuracy in recognising Musnad inscriptions. The results demonstrate that VGG16 achieved the highest accuracy of 93.81%, followed by ResNet50 at 89.39% and MobileNetV2 at 80.02%.**

***Keywords*—Musnad inscriptions; text recognition; deep learning; VGG16; ResNet-50; MobileNetV2**

I. Introduction

The ancient writings and inscriptions found in the Arabian Peninsula hold great significance in the modern era, as they serve as a source for historians and researchers studying ancient history and civilisations. Within the Kingdom of Saudi Arabia, numerous archaeological sites are covered with inscriptions and ancient texts written in the form of Musnad inscriptions, which represent a rich cultural heritage and hold great historical value.

The Musnad inscriptions, originating in the southern region of the Arabian Peninsula, predates the current Arabic font, with Musnad inscriptions discovered on diverse surfaces, from forts and mountainsides to smaller stone fragments and statue bases [1]. These inscriptions provide invaluable insights into the lives of the individuals who created them, including their lifestyle, beliefs, political climate and relationships with neighbouring nations. In addition, Musnad inscriptions were utilised in daily interactions, further highlighting their importance [2] [3].

The Musnad inscriptions is comprised of 29 characters, and the writing direction is right to left. Unlike Arabic font, the characters in Musnad are separate and unconnected in a word. This means the shape of each character remains the same, regardless of its position in the word. As well, words are separated by a vertical line (|). Furthermore, Musnad does not include any punctuation or diacritical marks [2].

In Fig. 1, an example of a Musnad inscription from Al-Faw village is depicted. To translate these inscriptions, each Musnad character is converted into its corresponding counterpart in Standard Arabic, as shown in Fig. 2, where the translation considers the vertical line that separates each word. It is important to note that the translated words belong to an old Arabic dialect, but they are all Arabic [4].

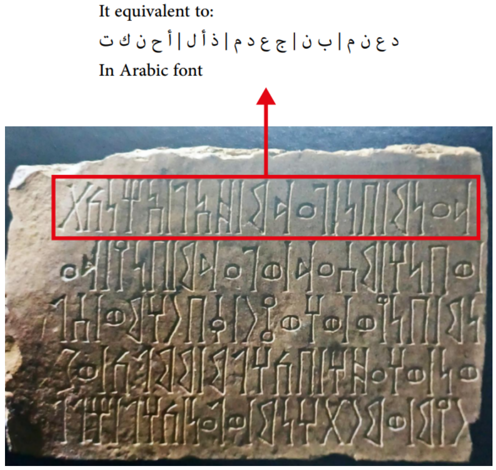

Fig. 1. One of the musnad inscriptions in the village of Al-Faw.

Motivated by the limitations of existing translation methods, such as the time-consuming nature of manual techniques and the dependence on expert availability, this research presents the first attempt to automate the recognition and translation of Musnad inscriptions into Arabic using image processing and deep learning. Consequently, it seeks to enhance the experience of reading Musnad inscriptions, making them more accessible and effortless to understand. Thus, the contributions of this work can be summarised as follows:

- Creation of a dataset for the Musnad inscriptions.
- Application of an optimal image processing technique to improve recognition accuracy.
- Comparison of the performances of three deep learning models (ResNet50, MobileNetv2 and VGG16) to determine which has the highest accuracy.

The remainder of the paper is structured as follows: Section II presents a literature review, Section III provides a detailed description of the Musnad inscription dataset, Section IV outlines the proposed methodology, Section V presents the

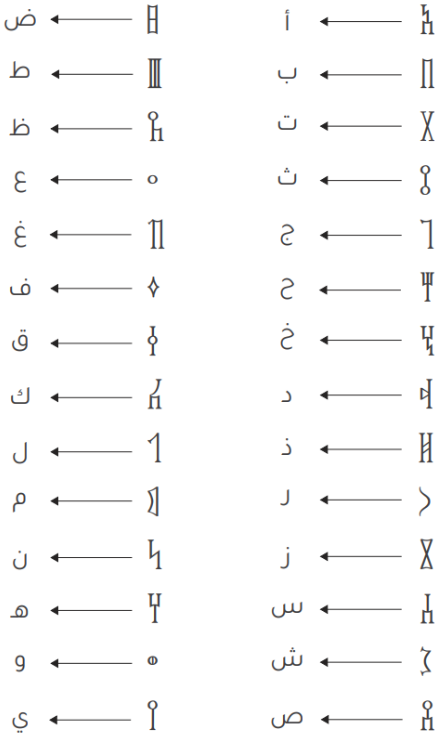

Fig. 2. Musnad alphabet.

results and discussions and Section VI concludes the paper and suggests future directions for research.

II. Literature Review

Scientific research has adopted different approaches to implementing detection and recognition, depending on the inscriptions, ancient characters and language itself. This section will thus provide an overview of related works in our field.

According to previous research, you only look once (YOLO) object detection methods are used in [5], [6], which implements the CNN architecture. YOLOv3-tiny was able to recognise the Kawi character on copper inscriptions due to its high detection accuracy (average of 97.93% in [5] and high detection speed. Meanwhile, the Oracle Bone inscriptions (OBIs) were recognised using two deep learning models in [6]: first, YOLOv3-tiny was used to detect and recognise OBIs, and second, MobileNet was used to detect undetected OBIs, as YOLOv3-tiny's limitations prevent all OBIs from being correctly recognised. Thus, MobileNet had the best performance in training accuracy and validation accuracy (99.30% and 98.89%, respectively).

Further, [7] analysed and identified four different algorithms for adapting the OCR process to recognise Tamil scripts, and support vector machines (SVM) was identified as the best option. Meanwhile [8] a method called advanced maximally stable extremal regions (AMSER) to improve the accuracy of identifying Tamil characters in images by detecting the extremal region and characteristic function, the accuracy of recognition of which was 95.59%. This method was introduced because of the low accuracy of inscriptions images using OCR. In addition, [9] suggested a k number of clusters (k-means clustering) for an ancient Kannada text using scale-invariant Fourier transform (SIFT) and speeded up robust features (SURF). Moreover, in [10], OCR was used to identify ancient Tamil inscriptions on stone using a feature extracted with the SIFT algorithm.

According to [11], who employed the Siamese network in few-shot learning (FSL),the local feature extraction of Chinese characters performs better using the VGG16 network as the backbone feature extraction network, achieving a recognition accuracy of 82.67%. Meanwhile, [12] the efficient and accurate scene text (EAST) detection model and the feature extractor VGG16 to extract painting inscriptions by combining the characteristics of Chinese paintings, achieving a high accuracy of 89%. In addition, in [13], Sundanese writing inscribed on palm leaves was recognised using a three-layer CNN with a 73% recognition accuracy. Next, in [14], was employed for recognition, and Tesseract training was performed using a deep neural network architect. Then, CNN long–short-term memory (LSTM) networks were configured and trained for the language model of the Tamizhi script, leading to an OCR accuracy of 91.21%. Furthermore, [15] used a CNN to extract and translate information from each character into Modern Tamil, achieving an accuracy of 94.6%.

CNNs are used as feature extractors, as well as classifiers, for their ability to recognise 33 classes of basic characters from Devanagari ancient manuscripts, as in [16], reaching a recognition accuracy of 93.73%. Further, the historical Kannada handwritten characters are recognised using the line segmentation approach with LBP features in [17], and the SVM classifier achieved a good performance, with an accuracy of 96.4%. In [18], a CNN was used with dropout to recognise Brahmi words, with a 92.47% accuracy. As well, [19] designed and developed an automatic recognition tool for variant characters to assess tablet inscriptions, leading to an accuracy of the trained model ResNet50-18 of 90%. In addition, [20] utilised CNN and MobileNet to detect Tamil-Brahmi script, achieving an accuracy of 68.3%, but MobileNet outperformed all other models employed. In [21], a CNN was used to classify and recognise Brahmi characters, as well as broken part of these characters, and VGG16 models provided results with the best accuracy, at 93.33%.

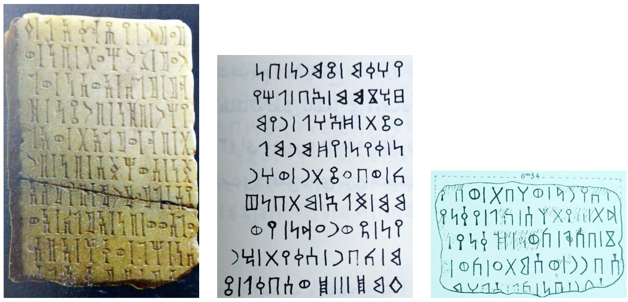
Through this literature review, various approaches, such as SIFT, ResNet18 and VGG16, for feature extraction and classification techniques, including CNN, were explored. The results reported in these papers vary depending on such factors as the condition of the inscriptions and the techniques employed. Despite an extensive review, it is noteworthy that no research paper was identified that specifically addresses the recognition and translation of inscriptions in the ancient Southern Arabic Musnad font.

III. Dataset

A. Dataset Collection and Description

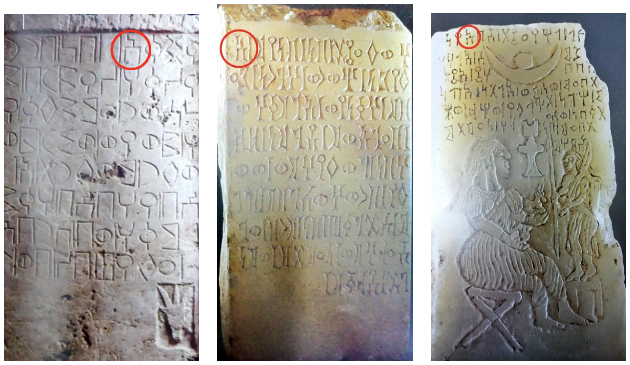
A request was made to the Ministry of Culture to provide a collection of images for use as a dataset in this work, and they did so with a collection of images from the Heritage Commission of the Ministry of Culture. The dataset contained images of the Musnad inscriptions in Lahyani form. And contained images of the Musnad from Qaryat al-Faw, Yemen and Al-Ula, totalling 293 inscriptions, which were divided into three categories: real, written and anointed, as shown in Fig. 3.

As the Musnad inscriptions span consecutive historical stages, researchers divided them into three types: ones that take on a geometric look, as in Fig. 4(b); ones that tend to bend, as in Fig. 4(c); and ones that appear exaggerated in decoration, as in Fig. 4(a) [2][22]. Further, the dataset comprises all feasible images sourced from the Ministry of Culture, ensuring the highest quality.



(a) Real (b) Written (c) Anointed

Fig. 3. The three categories of the dataset.



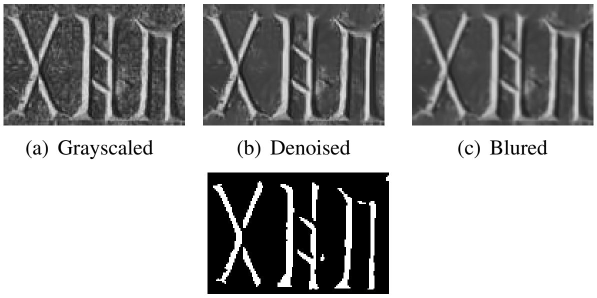
(a) Decorated (b) Geometric (c) Bend

Fig. 4. Three periods of the musnad inscriptions.

B. Image Preprocessing

The preprocessing experiments aimed to improve the recognition efficiency and accuracy of the dataset [15]. Of the several experiments conducted, only two produced good results, one for natural scene images and one for anointed and written images, as described below:

1) Preprocessing for natural scene images: In the first experiment, four processes were carried out using natural scene images. After first converting the input image from RGB to grayscale, as shown in Fig. 5(a), the grayscale image was then denoised using the cv2.fastNlMeansDenoising function, and the result of the denoising is shown in Fig. 5(b). The denoised grayscale image is then smoothed with the cv2.GaussianBlur function, as shown in Fig. 5(c). Finally, the smoothed grayscale image is then binarised using the cv2.threshold function with a threshold of 130, as shown in Fig. 5(d).



(a) Grayscaled (b) Denoised (c) Blured

(d) Binarized

Fig. 5. Preprocessing for natural scene images.

2) Preprocessing for anointed and written images: In the second experiment, five processes were carried out using the anointed and written images, starting by converting the input image from RGB to grayscale, as shown in Fig. 6(a).

Then, the cv2.medianBlur function was used to remove noise from the grayscale image, as shown in Fig. 6(b), after which the median filter result was smoothed using the cv2.GaussianBlur function with a kernel size of 5, as shown in Fig. 6(c). Thereafter, the Gaussian blur result was further denoised using the cv2.fastNlMeansDenoising function, as shown in Fig. 6(d). Finally, the denoised result was binarised using the cv2.adaptiveThreshold function with a Gaussian method and the inverse binary thresholding method with a threshold value of 255, as shown in Fig. 6(e).

C. Segmentation and Augmentation

Roboflow Datasets is a comprehensive computer vision tool that offers a range of functionalities, including dataset upload, organization, collaboration, labeling, augmentation, and processing [23]. The selection of the Roboflow Datasets tool is based on its notable ease of use, particularly in scenarios where characters appear too close to each other or when certain images exhibit characters that have been damaged. In Fig. 7, the labeling process is illustrated, followed by the implementation of a data augmentation technique involving a rotation of 10 degrees in both clockwise and counterclockwise directions. This technique was chosen for its recognized capacity to diversify the dataset, introducing variations in orientation that enhance recognition accuracy.

Subsequently, the dataset was divided into two sections, with 80% allocated for training and 20% for testing. The training set consisted of 11,103 images, while the test set comprised 2,763 images. Fig. 8 illustrates the distribution of the dataset across 29 classes. To ensure consistency, all images in the dataset were standardized to a size of 224 x 224 pixels.

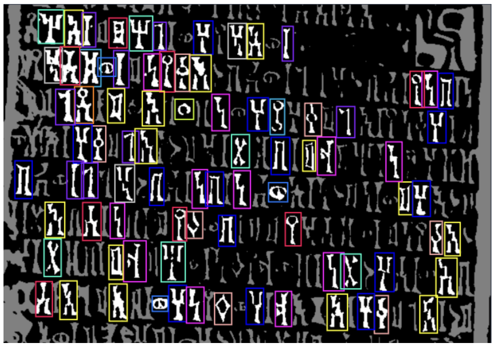

Fig. 7. Segmentation result.

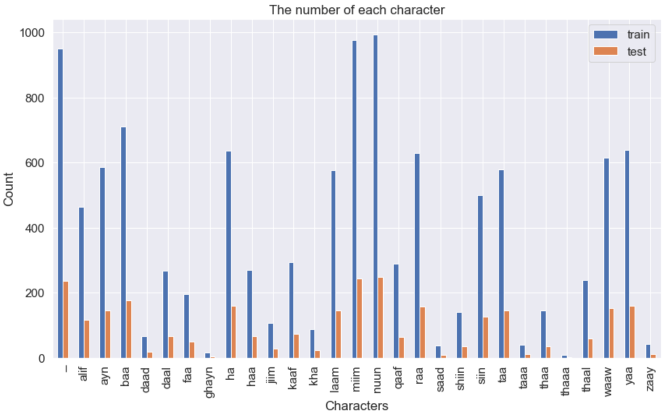

Fig. 8. Musnad characters classes.

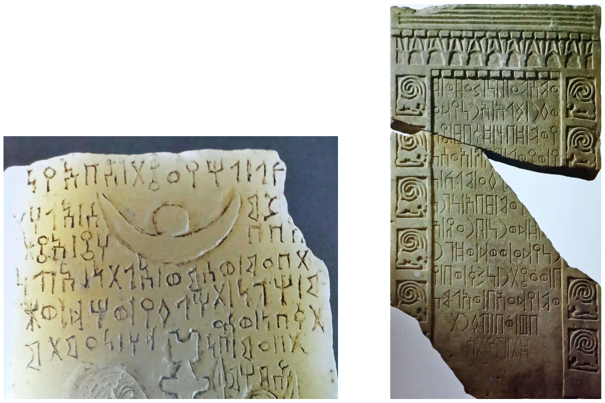
D. Challenges and Limitations

Recognising the Musnad font involves challenges for several reasons. First, the segmentation process requires manual intervention, as it becomes difficult due to complex structures, as several images contain illustrations, as shown in Fig. 9(a). Further, some characters were too close to each other, some were not on the same line and some were cut off due to broken backgrounds, as shown in Fig. 9(b). Furthermore, Fig. 10(b) displays the results of preprocessing, where certain characters lack clarity due to varied surface conditions, as depicted in Fig. 10(a).

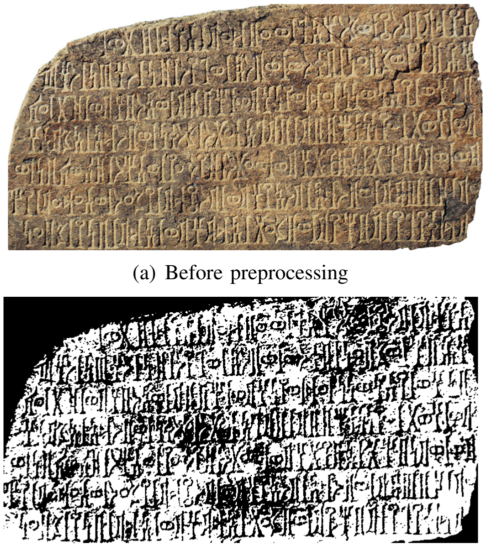
IV. Methodology

Here, the key steps and techniques implemented in the work to accomplish the desired outcomes. First, an image is captured and uploaded, after which the system implements image preprocessing. Third, the system detects and recognises the correct Musnad characters, and finally, the Musnad characters are translated into Arabic characters. For reference, Fig. 11 shows the proposed workflow of the system. In subsequent sections, each of these processes will be discussed in detail, providing a comprehensive understanding of the methodology employed.



(a) Inscription containing illustrations (b) Inscription with a broken background

Fig. 9. Dataset sample.



(a) Before preprocessing

(b) After preprocessing

Fig. 10. Surface condition: before and after preprocessing.

A. Image Preprocessing

The process for preprocessing natural scene images mentioned in III-B1 will be applied to the input image, with the addition of a new dilation process by utilising the cv2.dilated function.

B. Text Detection and Recognition

1) Contour Detection: Contour detection is a method often used in computer vision and image processing to detect and

find the outlines of objects in an image [24]. Unfortunately, the project's pretrained recognition models were only capable of correctly identifying one character, as they treated the image as containing only one character, presneting an obstacle in the recognition process. This project used a method for dealing with this problem by utilising the OpenCV function, which provides two functions: findContours and drawContours. The contouring process utilised herein is findContours, which detects the contours of the inscription to recognise all the characters of the Musnad inscriptions [25].

The findContours function requires three arguments: IMAGE, RETR_EXTERNAL and CHAIN_APPROX_SIMPLE, all of which were carefully chosen to optimise the contour detection process. By applying this method, the Musnad inscriptions in the image were successfully outlined, as demonstrated in Fig. 12.

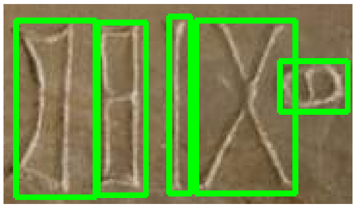

Fig. 12. Contour detection example.

2) *Deep Learning Models:* CNN is a highly efficient technique for image classification, and it is widely used in many recognition problems. CNN can perform both feature extraction and classification [26]. However, deep learning algorithms typically require more time and data than conventional machine learning systems offer to achieve an optimal performance [27]. As such, transfer learning is a technique that leverages a model pretrained on a specific dataset and that adjusts its parameters to suit new datasets. This approach is more efficient than creating a new CNN model from scratch [27], but one challenge that can arise is overfitting. In this case, the model becomes too specialised and cannot be adapted to new data [27]. To overcome this issue in this paper, early stopping and dropout techniques have been employed. Thus, this section presents how to employ the concept of transfer learning using feature extraction with VGG16, ResNet-50 and MoileNetV2, which were chosen due to their proven effectiveness in identifying ancient inscriptions [21], [6], [19].

VGG16: VGG16 is a CNN model for image classification developed by the Visual Geometry Group (VGG), comprising 16 layers in total, including 13 convolutional layers and three fully connected layers, using only 3×3 convolutional layers stacked atop each other [28]. The VGG16 model in this project is composed of two parts: a pretrained VGG16 model and additional custom layers added atop the pretrained model. Further, the VGG16 model is loaded as a pretrained model with the input shape set to (224,224,3), the top layer set to 'false' and the weights set to 'none'. By setting the top layer to false, the VGG16 model's fully connected layers are not included, allowing the model to be used as a feature extractor. After loading the pretrained model, a new sequential model is created, and the pretrained model is added as the first layer. The output of the pretrained VGG16 model is flattened using a flattened layer, after which the model has two fully connected Dense layers with 256 and 512 neurons, respectively. Batch normalisation is then applied after each Dense layer, followed by the rectified linear unit (ReLU) activation function. Dropout with a rate of 0.25 was applied after each activation function, producing an output Dense layer with 29 classes and a softmax activation function.

ResNet50: ResNet50: ResNet-50 is a CNN model with 50 convolutional layers that contain residual blocks, as well as approximately 25.6 million parameters [29]. Both the ResNet-50 and VGG16 models underwent the same modification to their fully connected layer (FCL) architecture, utilising the same parameter values.

MobileNetv2: MobileNetV2 is a CNN model designed to be fast and efficient to reduce the large network size and to minimise the cost of network computing [30]. The MobileNetV2 has undergone the same modifications as the VGG16 and Resnet-50 models, but they resulted in an underwhelming performance. Therefore, to improve the results, we altered the FCL modifications to differ from those applied to the VGG16 and ResNet-50 models to enhance its effectiveness.

The MobileNetV2 model is comprised of two parts: a pre-trained MobileNetV2 model and additional custom layers added atop the pre-trained model. In addition, the pre-trained MobileNetV2 model is loaded with ImageNet weights, and the input shape is set to (224,224,3) with the top layer set to ‘false’. A new sequential model is created, with the pretrained MobileNetV2 model being added as the first layer. Then, the output from the MobileNetV2 model is processed through a GlobalAveragePooling2D layer, after which it is flattened using a Flatten layer. It is then fed into three Dense FCLs with 256 neurons and a ReLU activation function, followed by a Dropout layer with a rate of 0.25. Finally, the output layer is a Dense layer with 29 classes and a softmax activation function.

Experimental Setup and Conditions: The experiments were performed on a computer system equipped with the Windows 11 Pro operating system, an Intel Core i5 11400 central processing unit (CPU) and an Intel(R) UHD Graphics processing unit (GPU). In addition, the machine learning framework used was Keras 2.11.0, which was run using Python 3.9.12 in Spyder Anaconda.

C. Evaluation Metrics

Evaluation metrics are used to measure the performance of a classifier with a dataset, providing a way of measuring the model’s performance in making correct predictions. The confusion matrix provides information about a predictive model’s performance, and various metrics can be derived therefrom to gain deeper insights. These metrics include accuracy, precision, recall, F1 score and the confusion matrix itself [31]. Below are the evaluation metrics used to evaluate the models herein:

Confusion matrix: Compares predictions made by the trained classifier to the true labels in the test set. Correctly detected results are shown in diagonal cells, while incorrect predictions are shown in the remaining cells [32].

Accuracy: This metric establishes the model’s accuracy in making predictions, as follows:

$$Accuracy = \frac{TP + TN}{TP + FP + TN + FN} \tag{1}$$

Precision: Indicates the proportion of correctly positive predictions of all positive predictions. This metric establishes the reliability of the predictive model in making accurate predictions, as follows:

$$Precision = \frac{TP}{TP + FP} \tag{2}$$

Recall (also known as Sensitivity or True Positive Rate): Applies the same principle as precision, but instead of focusing on false positives, it focuses on false negatives.

$$Recall = \frac{TP}{TP + FN} \tag{3}$$

F1-Score: This metric assesses the accuracy with which the predictive model can predict positive values while accounting for both FN and FP. It provides a balance between the two measures by taking the harmonic mean of precision and recall [31].

$$F = \frac{2TP}{2TP + FP + FN} \tag{4}$$

V. Result and Discussion

We evaluated the performance of pretrained models, namely VGG16, ResNet50 and MobileNetV2, in recognising Musnad inscription characters. The VGG16 model underwent training for 63 epochs with early stopping enabled, which took approximately 12.42 hours to complete. Similarly, the ResNet50 model was trained for 78 epochs, which required approximately 8.08 hours of training time. Finally, the MobileNetV2 model underwent training for 149 epochs, which required approximately 5.38 hours to train. For all models, the learning parameters remained consistent, including a learning rate of 0.00001, 150 epochs with early stopping and a batch size of 32.

The model evaluations were based on various metrics, as mentioned in IV-C, and the results are summarised in Table I. The VGG16 model demonstrated the best performance among the tested models, achieving an average accuracy recognition rate of 93.81% across 29 character classes. Both the ResNet50 and MobileNetV2 models also showed excellent accuracy results, although they were slightly lesser compared to the VGG16 model.

Fig. 13 demonstrates the convergence and effectiveness of the VGG16 model by illustrating its loss and accuracy during the training and testing phases, providing valuable insights into the model’s performance. Likewise, Fig. 14 and Fig. 15 display the loss and accuracy trends of the ResNet50 and MobileNetV2 models, respectively, highlighting their training progress and overall performance and contributing a comprehensive view of how these models perform over time. Moreover, Fig. 16 presents the confusion matrix for all three models, providing an insightful visualisation of their classification performance.

These findings suggest VGG16 can effectively recognise Musnad inscription characters with high accuracy. As such, the results demonstrate the potential of this model in the field of character recognition and provide valuable insights for further improvements and applications.

VI. Conclusion

This paper automated the recognition and translation of Musnad inscriptions, making a unique contribution to ancient text recognition and translation by creating a Musnad inscription dataset, developing a recognition and translation system and comparing three CNN models (VGG16, MobileNetv2 and ResNet-50). The paper's findings indicate that real-scene images of the language's inscriptions can form a useful dataset, that the optimal sequence of image processing techniques to improve recognition accuracy and that the VGG16 deep learning model provides the highest accuracy, with a recognition rate of 93.81%. Further, ResNet-50 achieved a recognition rate of 89.39% and MobileNetV2 a rate of 80.02%. In the future, the objective will be to enhance the recognition method for practical use in real-world scenarios. As such, the focus will eventually shift towards addressing broken inscriptions and recognising old drawings, ensuring the effectiveness of techniques in challenging scenarios and with unseen or difficult-to-read inscriptions, including those with varying levels of degradation, different lighting conditions or unconventional surfaces. This enhancement will be achieved by enlarging the datasets for model training, improving image processing to generate a high-quality dataset and using NLP to determine the Arabic meanings of the words in the Musnad inscriptions.

Acknowledgment

We would like to thank the Saudi Ministry of Culture for providing us with the Musnad inscription images, which have been essential to creating our dataset. As well, we deeply appreciate the Ministry's support in preserving and sharing these valuable resources.

***Abstract*—The emergence of many face forgery technologies has led to the widespread of forgery faces on the Internet, causing a series of serious social impacts, thus face forgery detection technology has attracted increasing attention. While many face forgery detection algorithms have demonstrated impressive performance against known manipulation methods, their efficacy tends to diminish severely when applied to unknown forgeries. Previous research commonly viewed face forgery detection as a binary classification problem, disregarding the crucial distinction between real and forged faces, thereby limiting the generalizability of detection algorithms. To overcome this issue, this paper proposes a novel face forgery detection method that utilizes a trainable metric to learn local similarity between local features of facial images, achieving a more generalized detection result. What's more, it incorporate cross-level features to accurately locate forgery regions. After conducting extensive experiments on FaceForensics++, Celeb-DF-v2, and DFD, which demonstrate that the effectiveness of the proposed method is comparable to state-of-the-art detection algorithms.**

Keywords*—*Face forgery detection; local similarity; forgery localization; generalized detection

I. Introduction

With the advancements in computer vision and deep learning technology, face forgery technologies have become a growing concern for society. These technologies have matured significantly in recent years, producing counterfeit faces that are indistinguishable to the human eye [1], [2], [3], [4]. Criminal misuse of these technologies can pose severe societal consequences, including pornographic featuring public figures, the spread of political misinformation, and fraudulence that jeopardizes personal and property rights. In response to this challenge, many researchers have developed studies on face forgery detection approaches [5], [6], [7]. Though these approaches perform well in specific scenarios, they are often inadequate when it comes to detecting forgeries unseen in the training data, known as the generalization problem.

Early research considered face forgery detection a binary classification task, employing convolutional neural networks (CNN) to distinguish real and forged faces. While such approaches have shown impressive performances in in-domain settings where training data and testing data are forged by the same algorithm, they cannot be easily applied to unknown domains given that the unknown forgery algorithms have different forgery features. Consequently, some face forgery detection approaches have been proposed to mine generalizable artifact traces [8], [9], [10]. These approaches rely on identifying discrepancies in image features such as brightness, color, and texture to distinguish forged faces. However, they can be affected by the quality of the images and thus may not be suitable for real-world scenarios. To address this issue, emerging approaches centered around data augmentation are being employed [11], [12]. By using various forgery algorithms, these techniques aim to expand the training data, to improve generalization capability. However, it's worth noting that training data depending on forgery detection approaches may become ineffective in light of the continuous advancements in forgery algorithms. On the other hand, some researchers concentrate on the identification details of forged faces, discover identity discrepancies to identify forged faces, and have achieved remarkable success with face replacement [13], [14]. Nevertheless, this type of method cannot detect face images with unchanged identity information. As face forgery algorithms continue to advance, the forgery traces have become increasingly subtle and difficult to detect using previous approaches. Thus, some researchers start paying attention to identifying fine-grained local feature inconsistencies [15], [16], [17].

In this paper, we focus on face forgery detection approach that does not rely on data augmentation but extracts essential features of real and forged faces. Our solution is based on the observation that real faces typically exhibit evenly distributed features and local region similarities [15], whereas forged faces usually exhibit local abnormalities resulting from the blending between real and forged regions. Inspired by this, we propose a novel generalized forgery face detection approach. Our approach improves generalization by leveraging auxiliary constraints between local features of real and forged faces. Unlike existing methods that rely on metrics such as cosine similarity [17], we utilize a learnable network to measure the similarities between local features, which makes the similarity measurement better suited to aligning features extracted by CNN backbones. We also introduce a cross-level forgery localization module that integrates various features across different levels with a lightweight attention module. Our approach enables accurate forgery localization and forged face recognition with strong generalizability. In brief, our contributions are summarized as follows:

- We propose to learn the dense fine-grained similarity between real and forged local features, which greatly improves the generalization of face forgery detection approach.
- We propose a Y-shaped network that achieved accurate face forgery detection and localization with the proposed cross-level attentional feature fusion module.

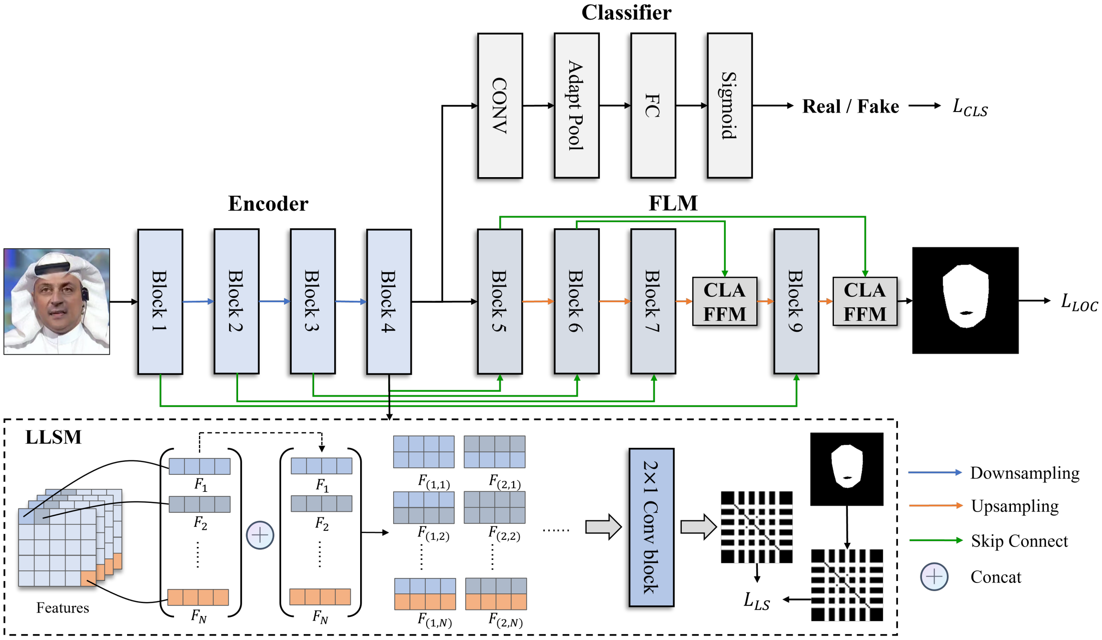

Fig. 1. The overall architecture of the proposed approach.

- Extensive experiments validate the superior detection performance and impressive generalization ability of our approach.

II. Related Work

A. Face Forgery Algorithms

Face forgery technology has advanced quickly in recent years. It can be categorized into three categories: face swap, face editing, and face generation, based on the forgery objects. Early face swap algorithms are mostly accomplished using graphics techniques [18], which are complex and challenging. With the rapid development of deep learning, several novel face swap algorithms have emerged, significantly reducing the difficulty of face swapping [3], [4]. The advance of Generative Adversarial Networks (GAN) has further improved the realism of the forged faces [1], [2].

B. Face Forgery Detection Algorithms

Early face forgery algorithms were not very mature, resulting in flawed faces with obvious artifacts. Therefore, early detection algorithms depend mostly on CNN to catch these probable artificial traces, such as color artifacts [8], blink rate [19], head position [14], synthetic artifacts [9], and so on. However, with the advance of face forgery algorithms, these problems have largely been resolved, forcing researchers to develop new detection methods capable of identifying generic forgery clues.

On the one hand, the researchers discovered that forgery faces have invariable forgery patterns in the frequency domain, giving rise to frequency-aware forgery detection approaches. Qian *et al.* [20] proposed a two-stream collaborative learning framework that leverages frequency-aware image decomposition and local frequency statistics to extract forgery patterns. Meanwhile, Chen *et al.* [21] tackled face forgery detection through local relational learning, integrating RGB and frequency information using an attention module to improve generalization. On the other hand, temporal inconsistencies of forged videos have become a significant clue for forgery detection. Time-aware models that extract temporal features from numerous single-frame inputs have been introduced to detect the authenticity of face videos. Güera *et al.* [22] used Long Short-Term Memory (LSTM) to extract temporal features from numerous single-frame. Gu *et al.* [23] detected local dynamic inconsistencies induced by tiny movements in forged videos. In addition, approaches based on advanced semantic information are proposed. Haliassos *et al.* [24] suggested detecting forgery videos by analyzing differences in lip movements between real and forgery videos, while Dong *et al.* [13] developed an identity consistency transformer to safeguard celebrities by detecting identity inconsistencies between inner and outer faces. However, approaches based on common forgery clues may not be suitable for real-world scenarios with unknown forgery clues, and approaches based on temporal inconsistency may be limited by video quality.

Due to the flaws in splicing, blending, and editing procedures present in the majority of available face forgery algorithms, forged faces may contain features from multiple sources, leading to local inconsistencies. Shang *et al.* [15] proposed to capture pixel-level and region-level differences for face forgery detection. Zhao *et al.* [16] proposed pairwise self-consistency learning of local features, which achieved excellent performance in generalization. Sun *et al.* [25] enhanced the generalization by creating positive and negative sample pairings and contrastively learning real and forged regions. The studies mentioned above highlight the importance of local inconsistency in improving the generalization of face forgery detection. They mainly use fixed metric measures when calcu-

lating consistency or similarity, which may result in feature misalignment issues. For example, when using normalized cosine similarity to measure the similarity of local features, it directly transforms the feature onto a unit hypersphere. However, the most generalizable features extracted from the backbone network may not satisfy the similarity requirement measured by the cosine similarity metric.

In this paper, we propose a plug-and-play learnable local similarity module that densely imposes fine-grained similarity constraints on the features extracted from the backbone network. Unlike existing approaches, the similarities are not directly *calculated* but learned using ConvNets, and we turn the optimization target into binary classification between features.

III. Methodology

A. Overview

The proposed approach is shown in Fig. 1. It is a Y-shape network with an encoder, a decoder, and a classifier head, where a learnable local similarity module works in collaboration with the encoder, a cross-level attention feature fusion model connects the encoder and decoder that performs pixel-level forgery localization. The classifier head implements image-level binary classification of authenticity (real/fake) for the input faces.

B. Learnable Local Similarity Module

Deepfake faces contain subtle artifacts or feature conflicts from several sources, this difference is frequently displayed at the fine-grained feature level and is difficult to detect. Therefore, we build a specific fine-grained local feature similarity map to mine fine-grained feature inconsistencies by computing its feature similarity with all locations based on local features. We constructed a learnable local similarity module for the augmented model to further enhance the model's capacity for generalization by mining fine-grained local differences.

The learnable local similarity module (LLSM) is a plug-and-play module that takes as input the deep features extracted by the backbone and calculates the similarity between local features. Given a face image I, we first pass through the encoder to obtain its middle layer feature $F \in R^{H \times W \times C}$ where C, H, and W represent channel, length, and width respectively. The middle layer feature F is then fed into LLSM, which predicts a single-channel local similarity map. As shown in Fig. 2, the 3-d tensor F is first unfold into a 2-d matrix of shape $\mathbb{R}^{(H \times W) \times C}$, $F_{(i,j)}$ $(0 \leq i < H, 0 \leq j < W)$ denote the local feature, where i and j are the spatial index. A shallow ConvNet with a single kernel of size $2 \times 1 \times C$, denoted by f then perform convolution operation on each local feature pairs. For $\forall i, m \in [1, H], \forall j, n \in [1, W]$, to predict the local similarity map, we use the following equation to calculate the similarity of any local features on the feature F:

$$M_{i*H+j,m*H+n} = \sigma(f(F_{(i,j)}, F_{(m,n)})), \tag{1}$$

where M is the predicted 2-d map of size $\mathbb{R}^{(H \times W) \times (H \times W)}$. That means each local feature is compared with all local features including itself by f, which outputs a binary prediction on the similarity of arbitrary two local features. After all the local features are calculated and arranged according to the corresponding positions, we can obtain a feature inconsistency map M^F with the shape of $(HW) \times (HW)$. On the optimization strategy for the feature inconsistency map, we calculating the ground truth local similarity map are as follows: First, downsample the mask until its dimensions match those of the middle layer feature map. Then expand the mask map into a one-dimensional tensor $m^{'}$, calculate the Cartesian product of all positional features, and return the local similarity map of $(HW) \times (HW) \times 2$ after adjusting the shape. After that, it is divided into two identically sized feature maps m_1,m_2 based on the third dimension, and the ultimate ground truth local similarity map M^{GT} is obtained by binarizing the two after an absolute value difference. We adopt the following BCE loss to supervise the training:

$$M^F = LSC\left(F\right), \tag{2}$$

$$m_1, m_2 = split\left(Cartesia\_prod\left(m^{'}, m^{'}\right)\right), \tag{3}$$

$$M^{GT} = binary\left(\left|m_1 - m_2\right|\right), \tag{4}$$

$$L_{LS} = \frac{1}{N}\sum_{i=1}^{N} BCE\left(M_i^F, M_i^{GT}\right), \tag{5}$$

where LSC stands for the method of predicting the local similarity map, *split* means split features by dimension, *Cartesia_prod* means Cartesian product operation, and *binary* means binarization operation.

C. Forgery Localization Module with Multi-level Feature Fusion

Previously, the forgery localization module usually had a single structure or could not adequately integrate the feature

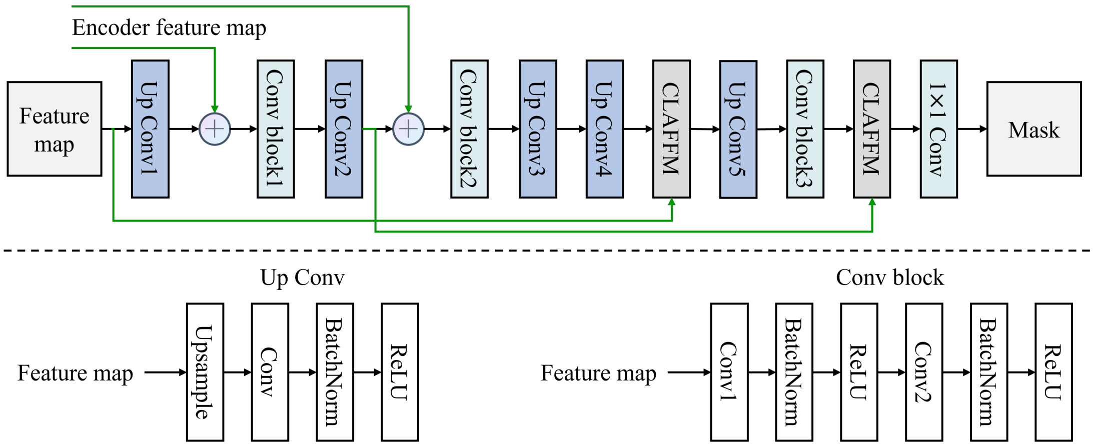

Fig. 4. The detailed architecture of the proposed forgery localization module (FLM).

information of each level, resulting in unsatisfactory outcomes in the forgery region localization task. Therefore, we propose a forgery localization module based on multi-level feature fusion, which made full use of the feature extractor and the feature information of each level of the forgery locator itself, resulting in improved forgery localization effect and detector generality. As shown in Fig. 4, our forgery localization module with multi-level feature fusion receives as input the feature f_i of various block layers of the encoder. Following the up-sampling stage of the forgery locator, the features from different layers of the encoder are coupled with the current features via channels, and more convolution operations are conducted on them to feed into the next up-sampling block. We obtain the forgery localization mask $M^{prd} \in R^{1 \times H \times W}$ for the final output prediction after several layers of upsampling.

Skip connection is a commonly used feature fusion technique in neural networks which can aggregate different levels of semantic information. In addition to combining semantic features at various levels in the feature extractor, we additionally introduce a novel attentional fusion module for combining localization feature information at various levels in the forged localization module. Specifically, our proposed cross-level attentional feature fusion module does not only aggregate features. It is able to obtain a set of adaptive learning weights by adaptively learning the attention of low-level semantic features on the channel. These weights are subsequently utilized to highlight the channel attention of high-level semantic features. This attention technique strengthens the robust local similarity information learned by high-level semantic features while still preserving the local similarity details that low-level semantic features value. Its structure is shown in Fig. 3. For feature A, get previous feature B, first adopt adaptive pooling processing, then perform 4×4 convolution operation and activate it. After that, perform a 1×1 convolution, Sigmoid activate to obtain the attention weight of the same number of channels as the current feature A and output a new feature after multiplying with the feature A. With a very tiny amount of calculation, this module may bring the previous feature's attention information to the present feature and increase the positioning accuracy of the fusion feature based on the channel attention level. The forgery localization loss is defined as follows:

$$L_{LOC} = \frac{1}{N} \sum_{i=1}^{N} BCE \left(M_i^{prd}, M_i \right), \tag{6}$$

where M^{prd} is the prediction mask output by the multi-level forgery localization module, and M is the ground-truth mask.

D. Classifier

In addition to the modules mentioned above, we must additionally include a classifier to receive feature input and verify the image's authenticity. Specifically, the features that the decoder outputs are average pooled and input to a fully connected network classifier for classification. For classifier predictions, we use BCE loss for supervised training:

$$L_{CLS} = \frac{1}{N} \sum_{i=1}^{N} BCE \left(y_i^{'}, y_i \right), \tag{7}$$

where $y^{'} \in [0,1]$ denotes the label of the input image, $y \in \{0,1\}$ denotes the prediction of the classifier. The overall loss

function is as follows:

$$L = L_{CLS} + \alpha L_{LS} + \beta L_{LOC}, \tag{8}$$

where α and β are loss weights and range between [0, 1].

IV. Experiments

A. Experimental Settings

1) Datasets: We conduct experiments on several face forery datasets FaceForensics++ (FF++), Celeb-DF-V2, and Deepfake Detection Dataset (DFD) [46]. FF++ is a large-scale public face forgery dataset that contains 1,000 real videos and 4,000 forged videos created using 4 forgery algorithms, including Deepfakes (DF), Face2Face (F2F), FaceSwap (FS), and NeuralTextures (NT). Additionally, FF++ has three compression levels: original version (Raw), high-quality (C23), and low-quality (C40). CelebDF-V2 is a more challenging dataset consists of 569 original videos and 5,639 forged videos. DFD is a large dataset containing 363 real videos and 3,068 forged videos in various scenarios.

2) Implementation details: All faces are detected, cropped, normalized and resized to 224×224 pixels. We use pre-trained Xception as the backbone. All experiments use Adam optimizer with the learning rate set to 1e-4. The batch size is 32, and each epoch has 200 iterations. For the metrics, we utilize binary classification accuracy (Acc.) and area under the curve (AUC.) as the metrics to evaluate model performances.

B. Evaluations

1) In-dataset evaluations: We first evaluate the in-dataset effectiveness of our approach on the FF++, where the network is trained and tested on the same dataset. We only use C23 and C40 versions of FF++ since detecting compressed forged faces is more challenging. We also compare with some state-of-the-art (SOTA) approaches. The results are presented in Table II. We can observe that the proposed approach has promising performances compared to the SOTA approaches when faced with highly compressed forgery faces. The AUC on C23 is close to SOTA [44], while the AUC on C40 exceeds SOTA [45] by 1.49%. This result indicates our method has excellent detection potential. Our proposed method is distinct

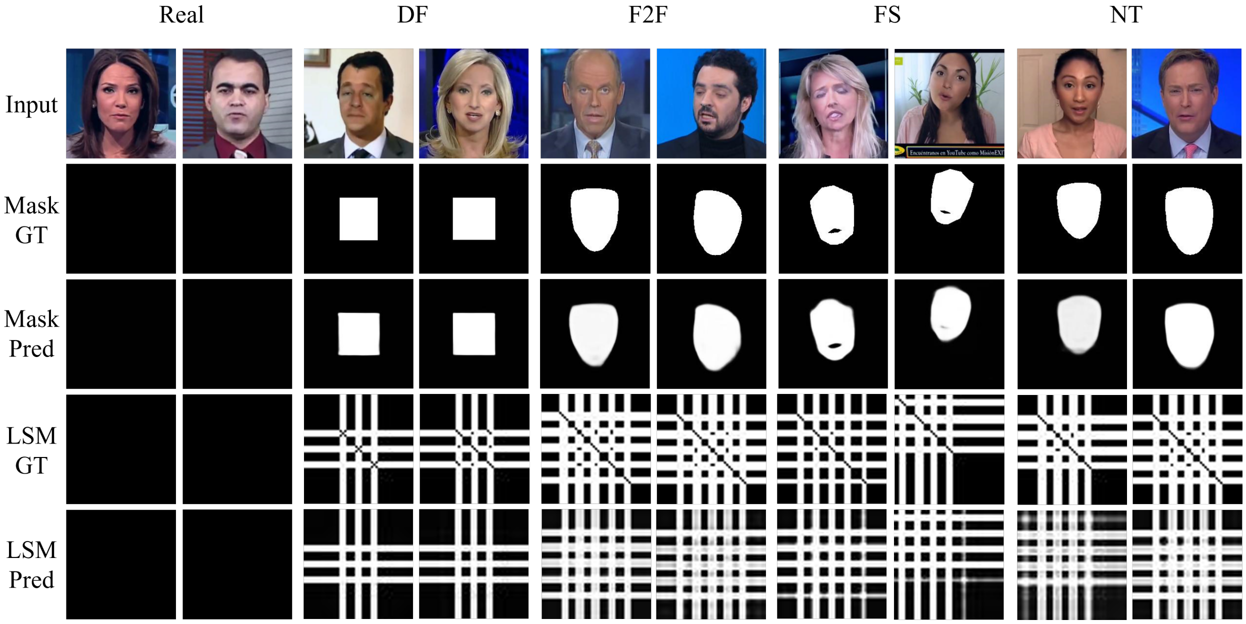

Fig. 5. Visualization of our approach on the FF++. From top to bottom are the original faces, ground-truth of pixel-level mask (Mask GT), predictions of face forgery localization (Mask Pred), ground-truth of local similarity map (LSM GT), and predictions of local similarity map (LSM pred).

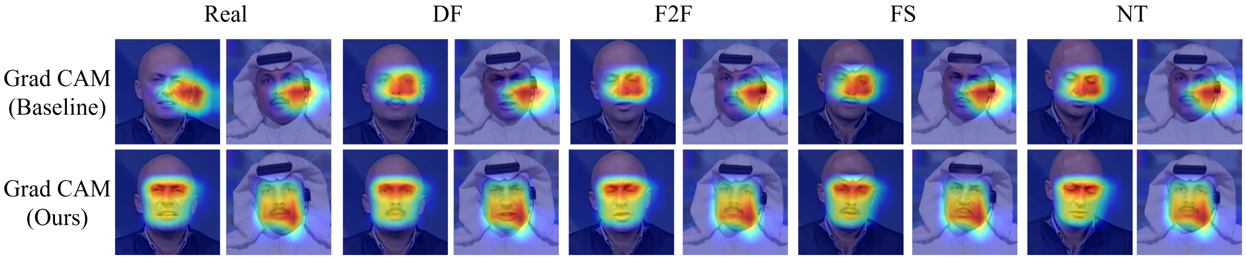

Fig. 6. Visualization of the heatmaps extracted by grad CAM.

from the prior deep learning detection method since it focuses on the fine-grained inconsistency that is shared by various forgery faces rather than just learning the distribution of real and forgery faces, which can effectively improve detection accuracy.

Although we do not achieve the best performance in each setting, we have a clear advantage in high compression scenario (C40) measured by AUC. Moreover, we achieve the best averaged AUC when facing both levels of compression.

2) Cross-dataset evaluations: As we all know, there are countless face manipulation techniques in real scenes, but the face manipulation techniques contained in the samples for training detection models are limited. Therefore, the generalization of detection models based on different manipulation methods is of great practical significance. Cross-dataset evaluations directly reflect the generalization of detectors. Table III presents the cross-dataset evaluation results on FF++(C23). We use only one subset of FF++ for training while the remaining 3 subsets for testing. Our approach achieves the highest average AUC across the three training scenarios. We further evaluate the generalizability of our approach on other datasets. As shown in Table I, we train the model on FF++ (C23) and test it on Celeb-DF and DFD. We can observe that our approach can outperform most recent SOTAs by 2% to 10.00% in terms of AUC while maintaining a promising in-dataset performance, with a gap of less than 1.00% on FF++(C23) compared with SOTAs. On DFD, our approach achieves 96.01% AUC which is 4.35% higher than [25] and nearly 10% better than other approaches on average. The results demonstrate that the proposed learnable local similarity can significantly improve generalization capabilities across different forgeries.

TABLE IV. ABALATION STUDIES ON LLSM AND FLM. THE MODEL IS TRAINED ON FF++(C23) AND EVALUATED ON CELEB-DF (AUC)

Baseline	LLSM	FLM	Celeb-DF
✓			72.15
✓	✓		75.11
✓		✓	76.67
✓	✓	✓	**80.56**

C. Ablation Study

To demonstrate the effectiveness of each module of our approach, we conduct the following ablation studies: 1) Baseline (Xception) without any of the proposed modules; 2) Baseline with the proposed learnable local similarity module; 3) Baseline for the proposed forgery localization module with multi-level feature fusion; 4) The complete network. We present the cross-dataset results trained on FF++ (C23) in Table IV. We can observe that the utilization of LLSM leads to a 2.96% improvement in the performance on Celeb-DF, which confirms the effectiveness of local similarity learning in enhancing generalization. The proposed framework, when incorporated with FLM, demonstrated a 4.52% improvement in performance, affirming its superiority. It is noteworthy that the combined use of FLM and LLSM results in a remarkable performance improvement.

D. Visualization

To provide further evidence of our approach's effectiveness, we evaluate the visualization results using the FF++. As shown in Fig. 5, we compare the forgery localization results and pixel level ground-truth of four different forgery types. The results demonstrate that our approach is capable of performing high-precision forgery localization. Additionally, we present the predictions of LLSM and the corresponding ground-truth similarity map. For real faces, given that the local features share the same source, the similarity maps do not exhibit any abnormal patterns. However, the similarity map of the forged face reveals clear abnormal patterns, which differ depending on the forged region. The LLSM can also achieve accurate predictions on the local similarity patterns. This provides further evidence of the effectiveness of our proposed approach.

We also visualize the heatmaps extracted using Grad CAM [47] to demonstrate the effectiveness of the proposed approach. In these attention maps, the warmer color indicates the areas more significant for predictions or localization. As shown in Fig. 6, we observe that the baseline model is not accurate in identifying the manipulated region, whereas our approach successfully directs the network's attention to the forged facial region.

V. Conclusion

In this paper, we propose a dual-task approach that achieves generalized face forgery detection and accurate forgery localization. Our approach takes advantage of the feature similarity between the internal parts of the forged image. The learnable local similarity module successfully enhances the difference traces between real and forged features and improves the generalization of the model. Furthermore, from a multi-tasking learning view, we present a forgery localization module with cross-level attentional feature fusion strategy, which improves the detection capability even further. We conduct extensive experiments, and the results fully demonstrate the effectiveness of our approach. However, our suggested learnable local similarity module relies on fine-grained local feature calculation, which requires more computational overhead and has feature size restrictions. Moreover, our approach has limited robustness for very low-quality faces. In further studies, we will consider calculating local Inconsistencies for a few local features instead of the entire feature to reduce computational overhead. Additionally, we will design novel image enhancement algorithms to improve the robustness of the detection model.

In the future, exploring the connections between local inconsistencies, identity inconsistencies, and inter-frame inconsistencies may further improve forged face detection performance.

CLFM: Contrastive Learning and Filter-attention Mechanism for Joint Relation Extraction

Zhiyuan Wang, Chuyuan Wei*, Jinzhe Li, Lei Zhang, Cheng Lv
School of Electrical and Information Engineering,
Beijing University of Civil Engineering and Architecture
Beijing 100044 China

Abstract—**Relation extraction is a fundamental task in natural language processing, which involves extracting structured information from textual data. Despite the success of joint methods in recent years, most of them still have the propagation of cascade errors. Specifically, the error in former step will be accumulated into the final combined triples. Meanwhile, these methods also encounter another challenges related to insufficient interaction between subtasks. To alleviate these issues, this paper proposes a novel joint relation extraction model that integrates a contrastive learning approach and a filter-attention mechanism. The proposed model incorporates a potential relation decoder that utilizes contrastive learning to reduce error propagation and enhance the accuracy of relation classification, particularly in scenarios involving multiple relationships. It also includes a relation-specific sequence tagging decoder that employs a filter-attention mechanism to highlight more informative features, alongside an auxiliary matrix that amalgamates information related to entity pairs. Extensive experiments are conducted on two public datasets and the results demonstrate that this approach outperforms other models with the same structure in recall and F1. Moreover, experiments show that both the contrastive learning strategy and the proposed filter-attention mechanism work well.**

Keywords—Natural language processing; relation extraction; attention mechanism; contrastive learning; multi-task learning

I. Introduction

Relation extraction intend to extract pairs of entity and correlative relations in the form of $< subject, relation, object >$ from the given unstructured texts. The extracted information provides a supplement to many natural language processing(NLP) tasks, such as text summarization [1] knowledge graph construction [2] and question answering [3].

Conventionally, existing methods mainly include pipeline methods and joint methods. Pipeline works [4], [5], [6], [7] traditionally treat the task as two independent subtasks: named entity recognition (NER) and relation extraction (RE). While these approaches are straightforward and adaptable, they overlook the inherent connection between NER and RE, making them prone to error propagation due to the conventional order of subtasks. For this reason, most recent studies focus on joint methods [8], [9], [10]. Current joint models, as evidenced by the work of Cabot et al. in REBEL [11] and Zheng et al. in PRGC [12], have demonstrated remarkable efficiency while achieving outstanding performance. However, most of them first identify entities then find corresponding relationships from all predefined relationships, which faces the problem of relational redundancy and cause unnecessary calculations. Fig. 1 shows the difference between entity first and relation first methods. The entity first method always recognizes possible entity pairs and then matches them against all predefined relationships, which causes redundancy in relationships and introduces unnecessary computation into the model. In contrast, the relation first approach avoids this problem well by first recognizing the relations present in the sentence. Another problem is that some methods only perform simple interactive behaviors between sequence and potential relation representations like concatenating. The operation could carry information unrelated to the task and cannot fully utilize useful mutual information. In addition to this, most of the models suffer from General issue of error propagation. The error in former step will be accumulated in the final triplets.

To alleviate error propagation issue and enhance the interaction between two subtasks, this work makes use of a contrastive learning strategy and proposes a filter-attention mechanism for RE and relation-specific NER(CLFM), respectively. Specifically, the contrastive learning employ the R-drop [13] idea, which has been used in supervised image classification for computer vision tasks. The contrastive learning strategy brings a new constraint to the part of potential relation classification rather than just relying on cross-entropy loss. This can lead to more accurate classification results, especially in scenarios with multiple relationships. The potential relation classification module employs the R-drop idea, which has been used in supervised image classification for computer vision tasks. This strategy brings a new constraint to the part of potential relation classification rather than just relying on cross-entropy loss. This can lead to more accurate classification results, especially in scenarios with multiple relationships, thus the problem of error propagation can be mitigated. For the relation-specific NER task, a novel filter-attention mechanism based on the attention mechanism [14] is proposed. Unlike prior works that simply concatenate or add sentence and relation representations, task interaction in this method is achieved in two ways: Initially, attention scores are computed for sentence and relation representations to signify the token relevance concerning the current relation. Next, low scores indicating weak correlations within the score matrix are removed, followed by the concatenation of particular representations to form the input for the relation-specific Named Entity Recognition (NER) task. Regarding NER, it is perceived as a conventional sequence tagging task for acquiring potential entity pairs. This process strengthens the interaction between

*Corresponding authors

the two subtasks and eliminates inconsequential information across distinct relationships. While executing the relation classification task, simultaneous computation of the auxiliary matrix occurs, which is subsequently utilized to determine the final triplets.

CLFM is mainly composed of three parts: All possible relations in the input sentence are identified in the first part; The second part is the identification of all possible head entities and tail entities under the specific relationships that have been extracted earlier; Finally, the model uses an auxiliary matrix called subject-object alignment step to help select the final triplets from extracted entity pairs and relationships. Since the order of the subtasks, the proposed end-to-end method can also solve the problem of redundant relationships.

The approach has been tested on two widely-used public datasets, namely, NYT [15] and WebNLG [16]. Experimental results indicate the model's performance is on par with state-of-the-art methods on these benchmark datasets. In summary, the paper's key contributions are as follows:

1. A relation first end-to-end framework is introduced by this work, along with the design of three components pertaining to the subtasks. These components effectively tackle issues related to redundant relations and enhance the interaction between subtasks.

2. This work incorporates a contrastive learning strategy into relation classification to introduce a new constraint that enhances classification accuracy and mitigates error propagation.

3. An innovative filter-attention mechanism is presented in this work, with the objective of fostering deeper interaction between the two subtasks by proficiently filtering out irrelevant task-specific information. Extensive experimentation on various public benchmarks demonstrates results that exhibit performance comparable to the baseline, especially in scenarios involving multiple relationships.

This paper is structured as follows: Section II is related work of recent years in relation extraction; Section III are detailed description of the each model part; Section IV are experimental results compared to other baseline methods and ablation experiments; Section V are conclusion and future work.

II. Related Work

The traditional incipient relational triplet extraction methods, such as those proposed by Zelenko et al. [4] and Chan et al. [5], adopted a pipeline framework that divided the entire task into two separate subtasks: entity identification and relation classification. However, these approaches were prone to error propagation problems and ignored the fact that these subtasks are interactive. Therefore, later works began to extract entities and relations jointly using a single model, such as feature-based models [17], [18], [19]. These models rely on various external NLP tools and complicated manual operations, making them heavily dependent on the accuracy of these external tools. Although these models are very representative, they have limitations in terms of scalability and efficiency. In the past few years, joint methods based on neural networks have become a major research focus. This section is presented in three subsections: entity first methods, relation first methods and other methods.

A. Entity First

Zheng et al. [20] first proposed a novel joint model based on a tagging scheme, which transformed the relation extraction task into a sequence labeling task and applied Long Short-Term Memory network to learn long-term dependencies. However, the model has no ability to extract overlapping triplets. To address the overlapping issue, Yu et al. [21] proposed a method that extracts head entities in the first step, followed by all correlative tail entities and relations using decoding strategies. In addition, A unified joint extraction annotation framework was designed by Wei et al. [22], capable of achieving single-stage joint extraction while addressing exposure bias and the intricate issue of overlapping. In the work by Wang et al. [23], a one-stage approach was presented to simultaneously extract entities and overlapping relations. This approach effectively narrows the discrepancy between training and inference stages. Specifically, they formulated joint extraction as a token pair linking problem and introduced a novel handshaking tagging scheme that aligns the boundary tokens of entity pairs under each relation type. Shang et al. [24] first generated candidate entities by enumerating sequences of tokens in a sentence, and they converted the extraction task into a linking problem on a head-to-tail bipartite graph that could directly extract all triplets in a single step. Nayak et al. [25] proposed a pointer network-based decoding approach where an entire tuple is generated at every time step and achieved significantly higher F1 scores

B. Relation First

All of the approaches mentioned, regardless of being single-stage or not, suffer from relational redundancy issue [20], [22], [23]. As a result, a new model structure for extracting sequences has emerged. These methods typically involve performing relation classification first, which only preserves related relations and not all redundant relations in the input sentence. However, Yuan et al. [8] proposed a gating mechanism to obtain relation-specific sentence representation, which can be used for sequence tagging tasks and can provide a fine-grained representation. Nevertheless, this mechanism is unable to address the problem of subject-object overlapping. To address this issue, Ma et al. [26] proposed a cascade dual-decoder approach to extract overlapping relational triples. This approach utilizes relevant information of relations and subjects as auxiliary information for subjects and objects recognition, respectively. However, the approach still has poor generalization due to insufficient interaction and a span-based extraction strategy. Zheng et al. [12] decomposed the entire task into three subtasks: relation judgement, entity extraction, and subject-object alignment. They designed a low complexity global correspondence matrix to align the subject and object. Despite achieving success, this approach lacks deep interaction between relation classification and entity recognition.

C. Other Method

Shang et al. [27] proposed a one-step and one-module model that consists of a scoring-based classifier and a relation-specific horns tagging strategy. Zhao et al. [28] tackled the task of relation extraction using heterogeneous graph neural networks. Their approach involves modeling relations and words as nodes on a graph and iteratively fusing the two types of semantic nodes using a message passing mechanism to obtain node representation. This approach leverages the graph structure and takes into account the contextual information of both relations and words. Ning et al. [29] considered the extraction task based on the table-filling method as a target detection task and proposed a single-stage target detection framework, which combined with the auxiliary global relational triplets region detection to ensure the region information can be fully utilized. Ye et al. [30] employed the different strategies for NER and RE by using solid and levitated markers of neighboring spans inside the same sample.

III. Proposed Method

A. Problem Formulation

Given the input sentence $S = \{x_1, x_2, \ldots, x_n\}$ with n tokens, the task goal is to extract all possible relational triplets such as $\{T = (s, r, o) \mid s, o \in E, r \in R\}$, where E and R are entity and relation sets respectively, a triplet T represents a pair of entity and a relation between them contained in sentence S.

As shown in Fig. 2, given an input sentence S, the encoder starts modeling its text semantics. The potential relation decoder, with a contrastive learning strategy, detects all possible relations $r \in R$ based on the text semantics. For each detected relation r, the filter-attention mechanism computes and filters the low weights of each input token to get relation-specific sentence representation as the input of NER. The relation-specific entity decoder extracts the corresponding head and tail entities by using a sequence tagging scheme. Finally, the model obtains the final triplets T with the aid of an auxiliary matrix M which were generated at the same stage as the potential relation prediction.

B. Model Encoder

This approach employs a pre-trained language model called BERT [31] for a fair comparison, which is widely used to encode sentences and capture the semantics of text. The output of the model encoder is $H_{enc} = \{h_1, h_2, \ldots, h_n \mid h_i \in \mathbb{R}^{d\times 1}\}$, where n is the number of tokens, and d is the dimension of the embedding. It can also use other pre-trained language models, such as RoBERTa [32] and so on.

C. Relation Classification

The relation classification component is illustrated in Fig. 2. It is important to note that not all sentences contain all predefined relations. Therefore, CLFM starts by identifying potential relations, which helps to reduce redundant relationships in the current text. To complete the operation, average pooling and a fully connected layer are employed. Given the embedding $\mathbf{h} \in \mathbb{R}^{n\times d}$ of the input sentence, where n is the number of tokens, each element of the relation classification component is obtained as follows:

$$\begin{aligned} h^{pool} &= \varphi(\mathbf{h}) \in \mathbb{R}^{d\times 1} \\ P^{pot} &= \sigma(W_r h^{pool} + b_r) \end{aligned} \tag{1}$$

Where φ denotes the average pooling operation [33] and σ is the sigmoid activation function, $W_r \in \mathbb{R}^{d\times 1}$ is a trainable weight and b_r is a parameter.

Unlike previous works [21], [26], [12], which treat relation classification as a simple binary classification task, this approach incorporates a contrastive learning strategy to add a new constraint to the result of the relation classification task. Inspired by [13], CLFM employs the idea of R-drop to impose a new constraint on the result of the potential relation classification task. Specifically, it computes the Kullback-Leibler divergence of the classification results as a part of the relational loss by running the sentence embedding $\mathbf{h}$ through the sentence classifier twice. Since the classifier contains a dropout operation, two results for the same input may be different, which can increase the robustness of the classifier by continuous training. For classification results, if the probability exceeds a threshold λ_1, model allocates the corresponding relation a tag of 1; otherwise, model assigns a tag of 0. The detailed contrastive learning component and potential relation loss are as follows:

$$L_{cl} = \frac{1}{2}(D_{KL}(P_1^{pot} \parallel P_2^{pot}) + D_{KL}(P_2^{pot} \parallel P_1^{pot})) \tag{2}$$

$$\mathcal{L}_{rc} = -\frac{1}{n_r}\sum_{i=1}^{n_r}(y_i \log P^{pot} + (1-y_i)\log\left(1-P^{pot}\right)) \tag{3}$$

$$L_{rel} = \alpha L_{rc} + \beta L_{cl} \tag{4}$$

Where P_1^{pot} and P_2^{pot} are transformed into a predefined relational representation by P^{pot}, $D_{KL}(\|)$ denotes Kullback-Leibler divergence and n_r is the size of predefined relation set. α and β are weights of each sub-loss. Performance might be better by carefully tuning the weight of each sub-loss. The reason why this work takes the average of the two calculations as the result is that Kullback-Leibler divergence is asymmetric. After adding the new constraint, CLFM can better handle of datasets with more relationships.

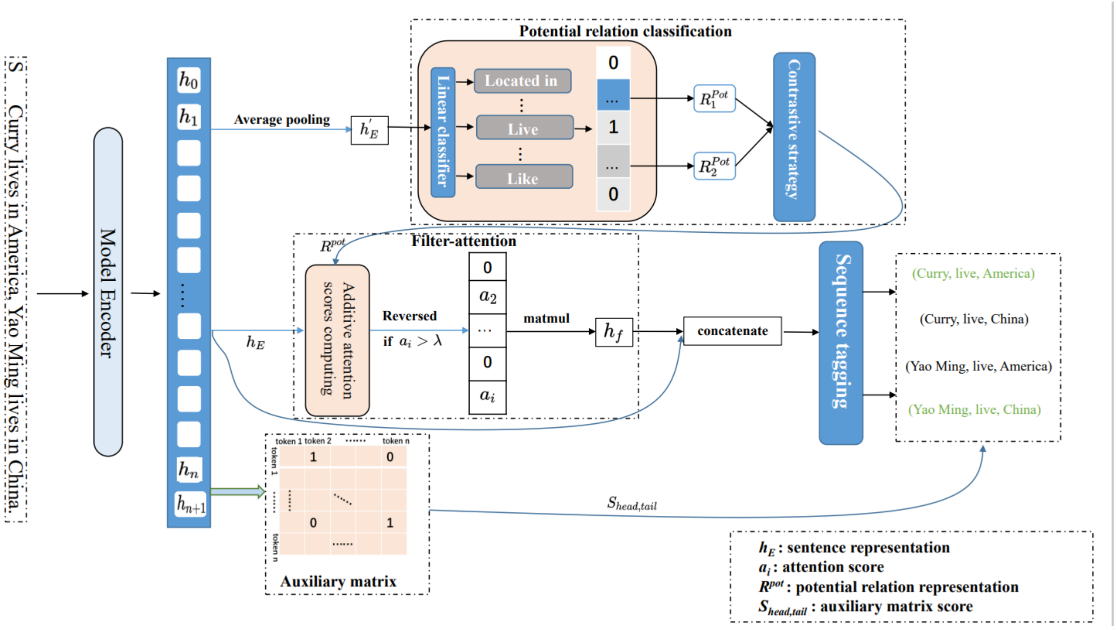

Fig. 2. The overall structure of CLFM. It combines three parts: potential relation classification, sequence labeling and auxiliary matrix.

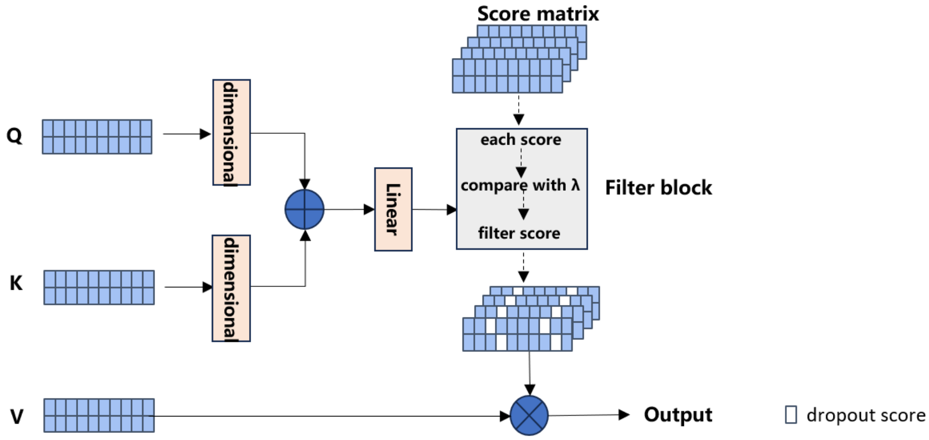

Fig. 3. The process of filter-attention.

D. Filter-attention Mechanism

After obtaining all potential relationships in the current sentence, previous works typically concatenate sentence and relation embeddings or design complex gating mechanism. However, concatenation can lead to the introduction of useless information. Compared to than gating mechanism, attention mechanism is more intuitive and easier to understand and the elements are more closely related. Therefore, this paper designs an attention mechanism with a filtering function based on attention mechanism [14] to retain useful mutual information. Fig. 3 shows the details of filter-attention mechanism. Before starting relation-specific NER, sentence embedding and relation embedding are fed into filter-attention. It utilizes additive attention to capture diverse semantic information across various relationships, as it aligns better with the encoder-decoder structure. After computing attention scores, filter module selects higher scores for retention to obtain a more accurate representation of the input containing information about the current relationship. The filter-attention mechanism component is as follows:

$$\begin{aligned} &S(\mathbf{h}, h_r) = W_v\theta(W_q\mathbf{h} + W_k h_r) \\ &S_{filter}(\mathbf{h}, h_r) = F(Softmax(S(\mathbf{h}, h_r))) \\ &\mu = S_{filter}(\mathbf{h}, h_r) \cdot h_r \end{aligned} \tag{5}$$

Where W_q, $W_k \in \mathbb{R}^{d\times d}$ and $W_v \in \mathbb{R}^{d\times 1}$ are trainable weights, h_r is transformed into a predefined relation representation by P^{pot}. $\theta(\cdot)$ is tanh activation function and $F(\cdot)$ is the filter operation. A threshold λ_{att} is established for the filter mechanism. When scores exceed λ_{att}, the scores in the original matrix are retained; otherwise, they are discarded. After conducting thorough experiments, λ_{att} is assigned a value of 5e-3. The ultimate representation that undergoes the filter-attention mechanism is denoted as $u \in \mathbb{R}^{d\times 1}$.

E. Relation-specific NER

As shown in Fig.2, the model starts the relation-specific entity recognition task after completing the filter-attention operation. CLFM model it as a sequence tagging task because the generalization of span-based extraction methods is poor. To solve common overlapping triplet issues, it perform separate sequence tagging for head entity and tail entity. This strategy can handle issues including EntityPairOverlap (EPO) and SingleEntityOverlap (SEO). The sequence tag set for the head entity is $\{B\text{-}H, I\text{-}H, O\}$, and the sequence tag set for the tail entity is $\{B\text{-}T, I\text{-}T, O\}$. CLFM employ the traditional LSTM-CRF[10] network for sequence tagging, and the detailed formula descriptions are as follows:

$$\begin{aligned} o_{i,j} &= \left[\overrightarrow{\mathrm{LSTM}}\left(h_i;\mu_j\right); \overleftarrow{\mathrm{LSTM}}\left(h_i;\mu_j\right)\right] \\ P_{i,j}^{head} &= \mathrm{CRF}\left(o_{i,j}\right) \end{aligned} \tag{6}$$

Where $(;)$ denotes concatenating operation, h_i is $i\text{-}th$ token representation of sentence S and μ_j is $j\text{-}th$ relation representation after going through filter-attention component. $\mathrm{CRF}(\cdot)$ is Conditional Random Field approach. The head entity formula is only given, tail entity formula is the same as Eq. (6). The loss of whole entity recognition is Eq. (7):

$$\mathcal{L}_{seq} = -\frac{1}{2 \times n \times n_r^{pot}} \sum_{t \in \{head,tail\}} \sum_{j=1}^{n_r^{pot}} \sum_{i=1}^{n} y_{i,j}^{t} \log P_{i,j}^{t} \tag{7}$$

Where n_r^{pot} is the size of potential relation set of sentence S.

F. Auxiliary Matrix and Training Strategy

After all the above operations, CLFM gets all possible head and tail entities that correspond to specific relations. However, if the model directly outputs the outcome, there will be a high probability of obtaining inaccurate triplets. To avoid this situation, following [12], the model computes an auxiliary matrix $M \in \mathbb{R}^{n \times n}$ for the given sentence S with n tokens to denote whether a relationship exists between tokens. This is similar to a pruning operation that increases the limits and make the final triplets more accurate. The value of each element in the matrix is computed as follows:

$$P_{i_{head},j_{tail}} = \sigma\left(W_g\left[h_i^{\text{head}}; h_j^{\text{tail}}\right] + b_g\right) \tag{8}$$

Where h_i^{head} , $h_j^{\text{tail}} \in \mathbb{R}^{d \times 1}$ are the encoded representation of the $i\text{-}th$ token and $j\text{-}th$ token in the input sentence forming a potential pair of head and tail entities. W_g is a trainable weight.

Matrix loss is as follows:

$$\begin{aligned} \mathcal{L}_{\text{matrix}} = -\frac{1}{n^2} \sum_{i=1}^{n} \sum_{j=1}^{n} (y_{i,j} \log P_{i_{\text{head}},j_{\text{tail}}} \\ + \left(1 - y_{i,j}\right) \log\left(1 - P_{i_{\text{head}},j_{\text{tail}}}\right)) \end{aligned} \tag{9}$$

The total loss is the sum of these three parts:

$$\mathcal{L}_{totalloss} = \gamma_1 L_{rel} + \gamma_2 L_{seq} + \gamma_3 L_{matrix} \tag{10}$$

where $\gamma_1, \gamma_2, \gamma_3$ are adjustable loss weights.

IV. Experiment

A. Datasets and Evaluation Metric

For fair and comprehensive comparison, this work follow [22], [9], and [21] to evaluate CLFM on two widely used public datasets: NYT and WebNLG. The NYT dataset is generated by aligning the relations in Freebase with the New York Times (NYT) corpus and is widely used for remotely supervised relational extraction tasks. It contains 24 relation types. The WebNLG dataset, originally employed for natural language generation tasks, includes 246 relation types. It is worth noting that both datasets have another version: NYT* and WebNLG*, which annotate the last word of entities. Table I shows the statistics for the above datasets.

Two evaluation metrics are employed for expensive experimental studies: Partial Match for NYT* and WebNLG*, where an extracted triple (s, r, o) is regarded as correct only if its relation and the last word of the head entity name and the tail entity name are correct; Exact Match for NYT and WebNLG, where a predicted triple (s, r, o) is regarded as correct only if its relation and the full names of its head and tail entities are all correct.

TABLE I. The Statistics of Datasets

Datasets	Train	Valid	Test	Relations
NYT	56196	5000	5000	24
WebNLG	5019	500	703	171
NYT*	56195	4999	5000	24
WebNLG*	5019	500	703	216

B. Implementation Details

As presented in Fig. 2, CLFM encoder employs the PyToREh version of $BERT_{base}\,(cased)$ English. To ensure equitable comparison, the input sentence length is standardized to a fixed size of 100, and the Adam optimizer [34] is employed with a batch size of 32/6 for the NYT/WebNLG datasets. The learning rate for the BERT encoder is set to 5e-5, while the decoder learning rate is set to 1e-3 to achieve fast convergence. Moreover, the utilization of weight decay [35] at a rate of 0.01 is incorporated. The potential relation decoder threshold and filter-attention threshold are set as 0.5 and 5e-3, respectively.

The experiments are conducted on a server equipped with Intel(R) Xeon(R) Silver 4215 CPU @ 2.50GHz and an NVIDIA Tesla V100 GPU.

C. Baseline Methods

A selection of nine baseline methods has been made for the purpose of comparison. This assortment comprises representative models as well as models featuring analogous structures. CLFM is compared with the following strong baseline models on the NYT and WebNLG datasets. The top six models are representative methods, while the last three have similar structures to CLFM: (1) CasRel[22] (2) TPLinker[23] (3)WDec[25](4) CGT[36] (5) StereoRel[37] (6) RIFRE[28] (7)PRGC[12] (8) RSAN[8] (9) Cascade dual-decoder[26].

TABLE II. PERFORMANCE OF CLFM AND EIGHT COMPARED BASELINES ON NYT AND WEBNLG

Model	NYT			WebNLG			NYT*			WebNLG*		
	Pre.	Rec.	F1	Pre.	Rec.	F1	Pre.	Rec.	F1	Pre.	Rec.	F1

D. Experimental Results

This section presents experimental results and compares them with other baseline models. It also conduct an in-depth analysis of the results to gain a better understanding of the performance of CLFM in relation to the other methods. Through a comprehensive analysis of the outcomes, valuable insights into the workings of CLFM can be acquired.

1) Overall Results: Table II presents an overall comparison of CLFM with other baselines. CLFM outperforms all of the baselines in terms of F1 scores, and for most cases, precision and recall are also superior. Notably, CLFM exhibits better robustness and generalization on the WebNlG dataset, where a wide range of relations are involved. This success can be attributed to the incorporation of the introduced contrastive learning strategy, which significantly enhances the accuracy of the relation classification decoder. Although RSAN[8] also employs attention calculations through a gate mechanism, CLFM achieves superior performance (with at least an 8% improvement over RSAN) due to its simplicity and commonality. Additionally, the model achieve a 0.6% improvement on the WebNLG dataset compared to PRGC. Regarding the NYT dataset, although CLFM achieves similar performance as PRGC, it is believe that the limited number of relations in the dataset and the already high-quality results may have contributed to the lack of significant improvement.

2) Result Analysis on Different Sentence Types : Following previous works [26], we conduct extensive experiments to verify that our method makes effective in the scenario of overlapping triples on NYT and WebNLG datasets. Table III shows the detailed results on the three overlapping patterns, where Normal is the easiest pattern while EPO and SEO are more difficult to be handled. The experimental findings reveal a consistent and superior performance exhibited by our proposed model across all three overlapping patterns. Noteworthy is the model's exceptional efficacy in handling intricate patterns such as EPO and SEO, where it consistently outperforms the established baseline, PRGC. This substantiates the robust capabilities of our model in effectively addressing the intricate challenges posed by overlapping triplets.

Furthermore, an extensive examination was conducted to extract triples from sentences featuring varying numbers of triplets. The sentences were categorized into five subclasses, each encompassing texts with 1, 2, 3, 4, or $\geq$ 5 triples. The comparative results of the five methods across the different triple categories are depicted in Fig. 4. The figure illustrates that our model consistently achieves the highest F1 scores across most cases in the two datasets, exhibiting remarkable stability as the number of triples increases. Particularly noteworthy is the superior performance of our model in comparison to the leading baseline, PRGC, in the most challenging class ($\geq$ 5) on NYT and WebNLG. This suggests that our model demonstrates enhanced resilience in handling intricate scenarios involving a substantial number of triples.Moreover, our model outperforms others in nearly every subset, irrespective of the number of triples. In summary, these additional experiments substantiate the advantageous features of our model, particularly in complex scenarios, highlighting its robustness and superior performance over existing methods.

TABLE III. F1-SCORE OF SENTENCES WITH DIFFERENT OVERLAPPING TRIPLETS ON NYT AND WEBNLG

Model	NYT			WebNLG		
	Normal	SEO	EPO	Normal	SEO	EPO
WDec	80.3	81.4	86.7	75.5	63.3	67.0
CasRel	84.2	83.0	83.6	86.9	80.6	83.7
PRGC	88.6	93.6	94.1	86.8	89.0	89.8
Cascade dual-decoder	88.2	92.8	92.9	86.2	88.9	88.5
CLFM	**90.9**	**94.4**	**94.7**	**87.6**	**89.6**	**94.1**

3) Explore for Filter Threads: The performance of the filter-attention mechanism is highly influenced by the threshold λ_{att}. To study the impact of threshold changes and find the appropriate value, A series of experiments are carried out. Table IV shows the results of these experiments. Variations were introduced to the threshold within a predefined range, revealing that further enhancements in the experimental outcomes could be achieved by implementing additional threshold adjustments. Based on the current results, A threshold value of 5e-3 was chosen for the filter-attention mechanism. Nevertheless, it is important to highlight that the optimal threshold might exhibit variability contingent on the specific dataset or task. As a consequence, undertaking additional experiments and meticulous refinement of the threshold could be imperative

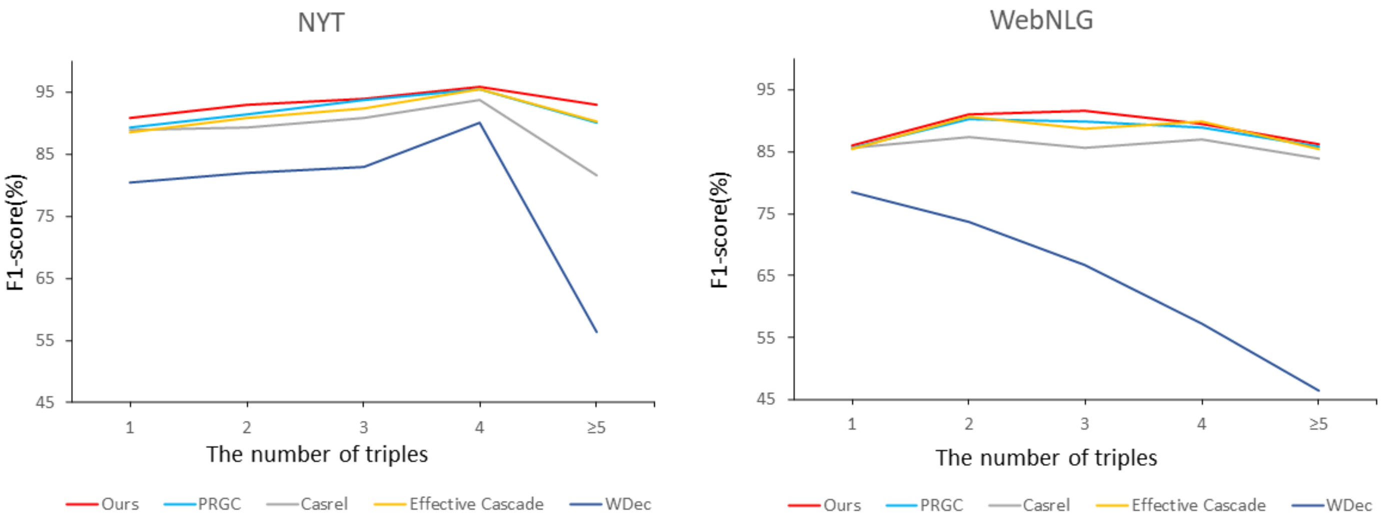

Fig. 4. Results of different sentence types on NYT and WebNLG.

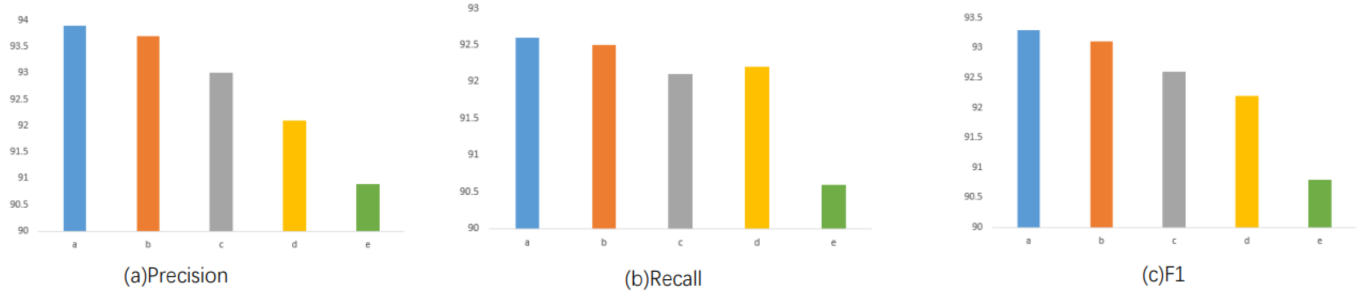

Fig. 5. The results of different combination approaches.

for attaining superior results.

TABLE IV. The Experimental Results of Different Threads on WebNLG*

Thread	F1(WebNLG*)
1e-3	92.8
3e-3	92.4
4e-3	92.0
5e-3	**93.3**
7e-3	92.0

4) Ways of Filter-attention: Furthermore, diverse methodologies for amalgamating the representations acquired via the filter-attention mechanism with the sentence embeddings are explored. To facilitate discourse, the nomenclature adopted encompasses the relation embeddings procured via the filter-attention mechanism, denoted as filter-relation, the sentence embeddings acquired through the filter-attention mechanism, termed as filter-sequence, and the sentence embeddings generated by the BERT encoder, identified as sentence-output. Concatenation function is represented by the $(\cdot, \cdot)$ notation. As illustrated in Fig. 5, five distinct strategies for amalgamating the embeddings are subjected to experimentation on the WebNLG* dataset, namely, (a) sequence-output, filter-relation, (b) filter-sequence, (c) sequence-output, filter-relation + filter-sequence, (d) sequence-output, filter-sequence, (e) filter-sequence, filter-relation. Precision, recall, and F1 score are used to evaluate the performance of each approach. The experiment results demonstrate that the first Combination method, (sequence-output, filter-relation), outperforms the other four combinations and is currently the best approach. Additionally, this validation substantiates the rationale behind the inception of the filter-attention mechanism.

5) Ablation Study: This section examines the contributions of different modules components in CLFM, using the best performing model on the WebNLG* dataset. Initially, the contrastive learning component is removed. Subsequently, an exploration is conducted into the influence of the filter-attention mechanism. This entails retaining the attention mechanism while discarding the filter function, as well as removing both components. Table V shows the results. It can observe that contrastive strategy and filter-attention mechanism can improve the performance of the model. The results demonstrate that contrastive learning can enhance the accuracy of the relation decoder when dealing with multiple relations, while filter-attention can improve the quality of the interactive representations between two subtasks.

TABLE V. ABLATION STUDY RESULTS ON WEBNLG* TEST SET

Method	Pre.	Rec.	F1
CLFM	**93.9**	**92.6**	**93.3**
-contrastive learning	93.5	92.3	92.9
-filter	93.4	92.2	92.8
-filter-attention	93.4	92.0	92.7

V. CONCLUSION

In this paper, a novel approach is presented for relational triplet extraction, emphasizing a relation-first perspective. This work incorporates a contrastive strategy and a filter-attention mechanism to effectively address the challenges posed by redundant relations and the accurate classification of relations within a diverse range. The proposed model also enhances the synergy between subtasks and effectively filters out extraneous information during sequence tagging. Empirical evaluations conducted on publicly available datasets showcase the remarkable performance of CLFM. In the subsequent research endeavors, the exploration of more intricate filter-attention mechanism is on the horizon to elevate the overall quality of representations.

Enhancing Airborne Disease Prediction: Integrating Deep Infomax and Self-Organizing Maps for Risk Factor Identification

Bhakti S. Pimpale, Dr. Anala A. Pandit
Department of Computer Application
Veermata Jijabai Technological Institute (V.J.T.I)
Mumbai, India

***Abstract*—Asthma poses a significant global public health concern, particularly in urban centers where environmental pollutants and variable weather patterns contribute to heightened prevalence and symptom exacerbation. The Deonar dumping ground, one of Mumbai's largest landfills, releases a complex mix of particulate matter and hazardous gases, posing a serious threat to local respiratory health. Despite the urgency for comprehensive research integrating patient-specific data with localized weather and air quality metrics, such studies remain limited. This study addresses the critical research gap by investigating asthma risk factors near the Deonar dumping ground. Integrating detailed patient records with precise local weather and air quality measurements, our research aims to unravel the intricate relationship between environmental exposure and respiratory health outcomes. The findings provide crucial insights into the specific risk factors influencing asthma incidence and severity in this region, informing the development of targeted interventions and mitigation strategies. Employing a novel ensemble Deep Info Max - Self-Organizing Map (DIM-SOM) technique, our study compares its performance with various clustering algorithms, including SOM, K-Means, Bisecting K-Means, DBSCAN, and others. The novel ensemble DIM-SOM demonstrated superior performance, achieving a significantly higher Silhouette Score of 0.9234, a lower Davies-Bouldin Score of 0.1276, and a more favorable Calinski-Harabasz Score of 389723.6225 compared to other algorithms. These findings underscore the efficacy of the novel ensemble DIM-SOM approach in generating dense, well-separated, and meaningful clusters, emphasizing its potential to enhance clustering performance compared to traditional algorithms. The study further emphasizes the need for proactive mitigation measures and tailored healthcare interventions based on the identified environmental risk factors.**

***Keywords*—Asthma; deepinfomax; self organizing map; risk factors; air pollution**

I. Introduction

Asthma, a chronic respiratory condition marked by airway inflammation and hyper-responsiveness, has been a focal point of global health concerns. Urban environments, characterized by a dynamic interplay of environmental pollutants and ever-changing weather patterns, witness a rising prevalence of asthma and an escalation of related symptoms [1] [2] [3] [4]. Mumbai, home to over 20 million residents, grapples with the intricate relationships between air pollution, meteorological factors, and public health. The Deonar dumping ground, among India's largest landfills, stands as a substantial contributor to air pollution, raising pertinent concerns about potential health risks, particularly respiratory ailments such as asthma.

In light of the advancements and challenges faced in this domain, this study seeks to contribute to the existing body of knowledge by investigating the risk factors associated with asthma in the vicinity of the Deonar dumping ground. Existing literature as discussed in Section II highlights the complexities of understanding the intricate relationship between environmental exposure and respiratory health outcomes. Despite a growing body of research, there remains a critical gap in studies that integrate patient-specific data with localized weather and air pollution metrics. This research endeavors to bridge this gap.

The importance of this study lies in its potential to offer crucial insights into the specific risk factors contributing to the incidence and severity of asthma in the specified region. By merging detailed patient records with precise measurements of local weather patterns and air quality indices, this research aims to unravel complex relationships, providing a nuanced understanding of the environmental determinants of respiratory health. The novelty of this approach is underscored by the proposed ensemble Deep Info Max - Self-Organizing Map (DIM-SOM) technique, offering a sophisticated methodology for asthma risk factor analysis.

While existing studies provide valuable information, this research distinguishes itself through its comprehensive integration of patient-specific data and localized environmental metrics, emphasizing the specificity of the Deonar dumping ground's impact on respiratory health. By shedding light on the complex interplay between environmental exposure and asthma outcomes, this study aims to provide actionable insights for local authorities and healthcare providers. Although such insights are essential for the development of targeted interventions, mitigation strategies, and informed healthcare protocols.

The subsequent sections of this paper provide a structured approach to the study. Section I introduces the significance of the study, emphasizing the global health concern posed by asthma, particularly in urban areas with high environmental pollutant levels. Section II offers a comprehensive overview of existing literature, summarizing related work in the field. Section III details the dataset used, incorporating patient-specific data, localized weather patterns, and air quality metrics. In Section IV, the proposed ensemble Deep Info Max - Self-Organizing Map (DIM-SOM) technique is introduced, outlining the methodology for asthma risk factor analysis. Section V describes the experimental setting, including environmental setup and machine setup. Following this, Section VI presents the results obtained from the clustering approach and initiates a comprehensive discussion on their implications. In the concluding Section VII, key findings are summarized, conclusions are drawn, and avenues for future research are suggested.

II. Related Work

Asthma's global prevalence and its association with urban environments, air pollution, and complex weather patterns have been extensively studied [5] [6] [7] [8]. The Deonar dumping ground's impact on the respiratory health of Mumbai's inhabitants highlights the critical need for an in-depth exploration of the specific risks involved in this context. Understanding the interplay of environmental factors and respiratory health outcomes in this setting is essential for the development of effective intervention strategies.

The study conducted in Helsinki [9] on the inhabitants of blockhouses built on a former dump area shed light on the potential health risks associated with landfill exposure. The findings suggested a slightly increased incidence of cancer, particularly in males following prolonged residence on the dump site. Moreover, the relative risk of chronic diseases, including asthma and chronic pancreatitis, exhibited a notable elevation. The implications of these results led to the subsequent demolition of the affected houses by the Helsinki City Council.

In a research report published by Shally Awasthi, Priya Tripathi, and Rajendra Prasad, [10] the authors aimed to identify asthma risk factors, including environmental exposures like motor vehicle air pollution, industrial smoke, active and passive smoking, and exposure to environmental tobacco smoke (ETS). The analysis, conducted according to Global Initiative for Asthma guidelines, categorized participants into two age groups, revealing significant associations between the studied environmental factors and asthma. The results indicated that motor vehicle air pollution, industrial smoke, and exposure to ETS were associated with asthma in participants aged 1–15 years. Additionally, the study highlighted the role of hospitalization in asthma severity.

Nonhlanhla Tlotleng, et al from Johannesburg [11] highlighted the health risks faced by waste recyclers, emphasizing the prevalence of acute respiratory symptoms in the population. Findings revealed that exposure to waste containing chemical residues significantly increased the likelihood of respiratory symptoms. Moreover, discrepancies in symptom prevalence were observed across different landfill sites, underscoring the need for improved occupational health and safety measures. Recommendations included providing appropriate protective gear and promoting hygiene practices to mitigate health hazards associated with waste sorting among informal workers.

ShriKant Singh, Praveen Chokhandre, Pradeep S. Salve, Rahul Rajak [12] aimed to evaluate the health effects of a dumping site on the nearby community, emphasizing potential risk factors associated with solid waste management. Utilizing a case comparison design, the research identified a notable increase in respiratory illnesses, eye irritation, and stomach problems among the exposed group in comparison to the non-exposed group. The findings underscore the significant impact of exposure to the dumping site on the prevalence of respiratory illness and eye infections, as highlighted by both the Propensity Score Matching (PSM) method and multivariate analysis. Furthermore, the assessment of air-quality-index indicated concerning levels of PM10 and PM2.5 during a fire outbreak at the Deonar dumping site, reinforcing the urgency for effective waste management strategies.

The study conducted by Seung-Woo Shin et al. [13] delves into the impact of air pollution levels on the severity of asthma exacerbations. Over a ten-year period, the research collected data from 143 adult asthmatics who experienced 618 exacerbation episodes, analyzing the influence of air pollutants such as O3, SO2, and NO2. The findings reveal significant associations between asthma exacerbations and increased pollutant levels during summer and winter, emphasizing similar relative risks for moderate and severe exacerbations. These results underscore the potential risks posed by specific air pollutants on asthma severity, particularly during distinct seasons, contributing valuable insights to the field of respiratory health. The study initiated by Kebalepile MM, Dzikiti LN, Voyi K. [14] investigated acute respiratory outcomes, particularly asthma, in relation to environmental exposures using self-organizing maps (SOM), a computational intelligence paradigm of artificial neural networks (ANNs). Utilizing air quality data such as nitrogen dioxide, sulphur dioxide, and particulate matter, along with clinical and socio-demographic information, the SOM effectively classified asthma outcomes. Notably, age emerged as a significant factor, with older patients exhibiting a higher likelihood of asthma. The study highlighted the importance of SO2 as a critical pollutant requiring attention. The SOM model demonstrated a low quantization error, suggesting its efficacy in studying asthma outcomes with multidimensional data. The overall accuracy of the model was found to be 59%.

In this study [15], the authors address the existing gap in mHealth applications for asthma self-management by proposing an optimized Deep Neural Network Regression (DNNR) model. Integrating weather, demography, and asthma tracking, the model demonstrates significant potential, achieving a score of 0.83 with Mean Absolute Error (MAE) of 1.44 and Mean Squared Error (MSE) of 3.62. The authors further enhance the model's accuracy through an optimization process, resulting in a remarkable 94% accuracy rate with MAE of 0.20 and MSE of 0.09.

Based on the literature review, it is evident that existing studies have explored the relationship between environmental factors and asthma prevalence and severity. However, there is a distinct gap in research that delves into personalized risk factor identification. While prior studies have provided valuable insights into the general associations between air pollution, climatic conditions, and asthma, this research seeks to address this gap by focusing on personalized risk, thus providing a more targeted approach to asthma management and prevention. This study's approach holds promise for identifying individualized risk factors and tailoring interventions for patients facing air pollution-induced asthma exacerbations.

III. Dataset

The data for this research was collected from multiple sources to facilitate a comprehensive analysis of the risk factors

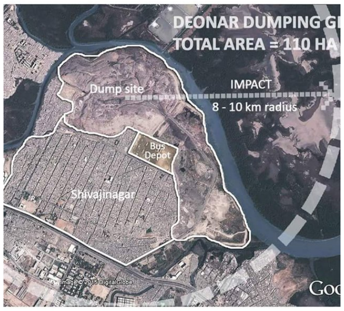

Fig. 1. Location of deonar dumping ground.

associated with asthma in the vicinity of Mumbai's Deonar dumping ground as shown in Fig. 1. The most affected areas near dumping ground are Bainganwadi, Deonar village, Govandi village, Shivajinagar, KamalaRamannagar, Rafiqnagar, Sanjaynagar and Shantinagar. Patients' data, air pollution and weather data is mainly collected from above selected areas.

A. Data Collection

1) Patient Data: Patient data, crucial for understanding the health profiles and medical histories of individuals, was obtained from Shatabdi Hospital, a government healthcare facility situated in Govandi, Mumbai. The patient data, comprising a comprehensive set of health metrics and demographic details, including Date of Visit, Age, Gender, Location, Smoking Status, Blood pressure, Body temperature, Height, Weight, Allergy status, and Symptoms of asthma (like cough intensity, sputum colour, wheezing, rales, rhonchus, etc.), spans the period from Jan 2015 to March 2020, encompassing a total of 46158 patients of asthma. The dataset contains total 76 features including physical characteristics and symptoms as discussed above. This dataset forms the basis for the study's examination of asthma incidence, symptomatology, and individual risk factors, enabling a detailed analysis of the interplay between air pollution and patient health.

2) Air Pollution Data: Air pollution data was sourced from the Copernicus Atmosphere Monitoring Service (CAMS) via the CAMS Global Reanalysis EAC4 dataset [16]. This dataset offers detailed information on air quality and atmospheric conditions. The collection period extends from Jan 2015 to March 2020, encompassing various pollutants and their concentrations, which are pivotal to assessing their impact on respiratory health in the study area. The dataset includes various key pollutants such as SO2, NO2, PM10, PM2.5, CO, O3, CH4, NH3, and dust aerosols, all of which were measured in kilograms per kilogram (kg/kg).

3) Weather Data: To understand the influence of meteorological factors on asthma risk, weather data was gathered from the NASA's Power Data Access Viewer [17]. The dataset provides a comprehensive overview of weather variables including temperature, humidity, Uv index, wind speed, dew point and rainfall etc. Data collection for weather variables aligns with the time-frame from Jan 2015 to March 2020, ensuring a holistic examination of weather patterns in the study region.

From Table I, it is clear that several parameters in the dataset display a positively skewed distribution, indicating a prevalence of higher values, while others exhibit a symmetrical skew, highlighting a more balanced distribution of values. The positively skewed parameters, including SO2, CO, NO2, O3, PM10, PM2.5, NH3, Dust Aerosol concentrations, UV index, wind speed, dew point, rainfall, and maximum temperature, exhibit a distribution where the tail of the data points extends towards higher values. This skewness indicates that, most of these parameters have relatively lower values, while a small number of data points have significantly higher values. Understanding the skewness of these parameters is crucial for assessing their impact on asthma exacerbation, as it suggests that elevated levels of these pollutants might be associated with more severe asthma symptoms. In contrast, parameters such as CH4 (methane), temperature, relative humidity, and minimum temperature demonstrate a more symmetrical distribution, where the data is relatively evenly distributed around the mean. This symmetric distribution implies that the values of these parameters do not have a strong skew towards higher or lower values. For these parameters, it is essential to explore their impact on asthma exacerbation by considering their overall levels rather than the skewness of their distribution.

B. Data Pre-processing

Prior to the analysis, a series of data pre-processing steps were applied to ensure the quality and integrity of the dataset.

1) Missing values: All the datasets were first examined for missing values. In the case of the air pollution dataset, missing values were handled using the KNN Imputer [18], which imputes missing values based on the values of the nearest neighbors in the feature space. This approach enabled to account for the complex interdependencies among the pollutant variables, ensuring a more accurate representation of the air quality indicators. Air pollution data contains only 73 missing values in UV index column shown in Fig. 2. A customized function was developed, to fill the missing values

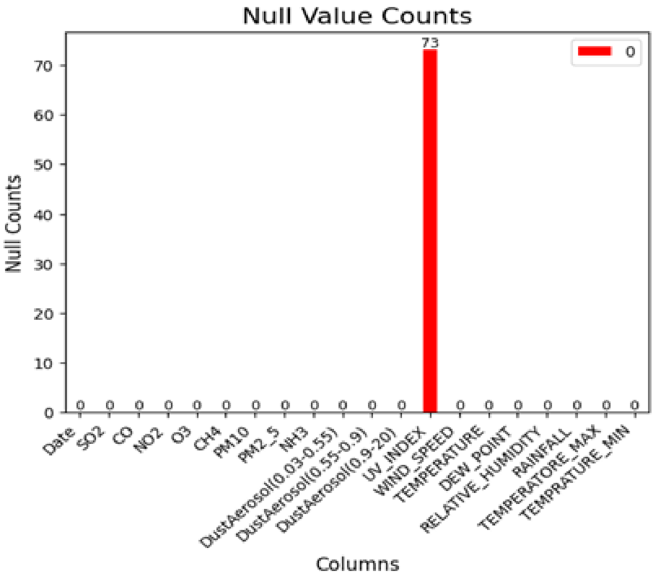

Fig. 2. Null value count of air pollution and weather data.

TABLE I. Statistical Representation of Air Pollution and Weather Data

of blood pressure and temperature in the patients' dataset. The function utilizes age-specific ranges for blood pressure and temperature, using linear interpolation to estimate missing values within the normal ranges. This approach ensures that the filled values remain within the expected physiological limits for each patient, minimizing potential data inaccuracies. Table II shows the missing value count in patients' dataset.

TABLE II. Missing Values in Patients' Data

Column	Null Count
Date	0
Diastolic Blood Pressure	3304
Systolic Blood Pressure	3320
Temperature	10141
.	.
.	.
Disease	0

2) Label encoding: To facilitate the integration of the Body Mass Index (BMI) information into the analysis, a categorical BMI variable was derived from the patients' body weight and height measurements. The BMI values were categorized into distinct groups, namely 'Underweight,' 'Normal,' and 'Overweight,' based on predefined threshold values. To incorporate this categorical information into the dataset, a one-hot encoding technique was applied. This process involved transforming the categorical variable into a set of binary variables, with each representing a specific BMI category.

3) Data normalization: To ensure consistent scaling in the dataset, an extensive analysis of various scaling methods was conducted. Initially, several known standardization techniques were explored, including the standard scaler and normalization, along with the application of the MinMaxScaler for assessing its efficacy in preserving data distribution within a specific range. However, after thorough experimentation and evaluation, the MaxAbsScaler [19] technique emerged as the most suitable choice. Results of all normalization techniques shown in Table V.

The MaxAbsScaler normalization method was selected for its remarkable ability to retain the data's inherent sparsity and preserve the relative relationships among the features. By rescaling each feature based on its maximum absolute value, the method ensured that the range of each feature fell within the [-1, 1] range. This approach not only maintained the dataset's unique characteristics but also enabled a fair comparison and interpretation of the features. Consequently, the adoption of the MaxAbsScaler technique not only provided a balanced and optimal scaling approach but also contributed to the robustness and reliability of subsequent analyses.

4) Data integration: The integration of the patient data and air pollution data involved a merging procedure based on the 'Date of Visit' and 'Date' variables from the respective datasets. This operation facilitated the alignment of the patients' symptomatology records with the corresponding air pollution data, providing insights into the potential associations between symptom onset and ambient air quality. A unified dataset was created, laying the groundwork for a detailed analysis of the interdependencies between air pollution exposure and asthma incidence.

5) Data correlation: The heatmap shown in Fig. 3 revealed several notable correlations within the dataset. Parameters such as runny nose, high cough, chest tightness, throat irritation, itchy eyes, and watery eyes exhibited a positive correlation with CO, O3, PM10, and PM2.5, indicative of potential associations between these respiratory symptoms and elevated levels of air pollutants. Conversely, these symptoms demonstrated a negative correlation with minimum temperature and Dew Point. The negative correlation indicate that cooler and more humid weather conditions could be linked to an increase in the severity of the mentioned respiratory issues.

IV. Proposed Model

In the initial stages of the study, the consolidated dataset, which included the merged information from air pollution, weather, and patient health records, underwent an extensive application of various clustering algorithms. K-means [20] [21], Self-Organizing Maps (SOM) [22], Mini-Batch K-means [23],FuzzyCmeans [24], Birch clustering [25], DBSCAN clustering [26], Agglomerative clustering [27], Spectral Clustering, Bisecting Kmeans clustering and Gaussian Mixture models [28] were each individually applied across lag 2 to 15, encompassing a comprehensive analysis of the dataset at different time intervals. Despite these efforts, the outcomes did not meet the predetermined benchmarks, indicating a need for an alternative approach. DeepInfomax algorithm [29], a deep learning

technique was implemented. Although it was mainly used for images. This algorithm is capable of extracting intricate features and uncovering latent patterns within complex dataset. In the case of DIM, the model is trained to predict certain parts of the input data from other parts, without requiring explicit supervision from labeled data.

Using the power of the DeepInfomax technique, intricate associations and previously unnoticed patterns within the combined dataset numeric in nature were observed. This helps to better understand the complex relationships within the dataset, which traditional clustering techniques couldn't capture well.

Later the Self-Organizing Map (SOM) technique was used to further refine the clustering outcomes and establish distinct clusters and associated labels within the dataset. This combined methodology yielded a notable enhancement in the evaluation metric. This integrated approach not only improved the precision of the clustering process but also facilitated a holistic understanding of the multifaceted factors contributing to the incidence and patterns of asthma in relation to the interconnected influences of air pollution and weather conditions over the specified lag. Fig. 4 shows the proposed model with three different stages like data integration, pattern recognition and clustering followed by risk factor analysis.

V. Experimental Settings

The experiments were performed on an Intel Core i5 @ 1.19 GHz and 8 GB of memory. Python software was used for model creation and prototyping because it includes publicly accessible library sets for machine learning and statistical methods like Scikit-learn, and Matplotlib. Modeling tests were run to confirm the efficacy of the proposed model. Data and results were plotted using the Python 2D graphing tool included in the Matplotlib. The effectiveness of the model was examined using Sklearns cluster metrics, a Python module for performance measurements of machine learning models. All experiments were also conducted using Google Colab, a cloud-based Jupyter notebook environment that enabled seamless integration with Google Drive and provided access to high-performance computing resources. Validated our results using earlier method.

VI. Result and Discussion

The aim of this study was to identify clusters that could analyze the impact of air pollution on patients living near a dumping ground along with the associated risk factors. To accomplish this, determining the precise time-frame between disease onset and patient treatment was crucial. Multiple methods were utilized to determine the most efficient approach, and the results were documented and are presented in Table III and Table IV for further analysis.

However, the results obtained from these different methods did not reveal clear or meaningful patterns in the data. This unexpected outcome posed a challenge in selecting the appropriate lag for subsequent analysis. Therefore, identifying the best lag remains a crucial aspect of the research, prompting to explore alternative approaches to address this issue.

To determine the optimal lag, the novel technique of creating an ensemble using the Deep Info Max (DIM) initially, followed by the application of the self-organizing map (SOM) was implemented. The choice of the SOM algorithm was based on its ability to maintain the topological characteristics of the data, thereby uncovering the fundamental structure and interrelationships among data points. This capability becomes particularly pertinent when dealing with intricate, high-dimensional datasets, where preserving the original data structure is paramount. Unlike the K-Means algorithm, SOM excels in capturing non-linear associations within the data, proving invaluable for datasets where clusters may lack clear boundaries or exhibit complex configurations. Additionally, SOM demonstrates greater resilience to outliers and noise, thereby minimizing the influence of such irregularities on the clustering outcomes. Moreover, SOM can function as a dimensionality reduction technique during the clustering process, which proves especially advantageous when dealing with datasets featuring numerous dimensions(in this case 97 features). This reduction can simplify data exploration and comprehension, facilitating a more accessible understanding of the data's underlying patterns and relationships. Architecture of DIM is shown in Fig. 5 The DIM neural network architecture comprises an input layer designed to accommodate data

instances of 97 features. This is followed by a sequence of four densely connected layers, namely, ‘dense’, ‘dense1’, ‘dense2’, and ‘dense3’, responsible for hierarchically processing the input data. These layers utilize various mathematical operations, including weighted summation and activation functions, to extract and transform the input data into meaningful representations. Furthermore, the inclusion of a custom ‘InfoNCELoss’ layer underscores the network’s reliance on the Information Noise-Contrastive Estimation (InfoNCE) loss function. By leveraging this tailored layer, the model is adept at maximizing the agreement between representations of related instances while minimizing the agreement between representations of unrelated instances. This approach, commonly associated with self-supervised learning, facilitates the acquisition of effective data representations, consequently enabling the model to find intricate patterns and relationships within the dataset.

Fig. 5. Architecture of DIM.

Let $\mathbf{X}$ denote the input data with dimensions $(N, 97)$, where N represents the batch size. The neural network architecture can be symbolically represented as follows:

$$\text{Input Layer:} \quad \mathbf{X} \in \mathbf{R}^{N\times 97} \tag{1}$$

$$\text{Dense Layer 1:} \quad \mathbf{H}^{(1)} = \sigma(\mathbf{X}\cdot\mathbf{W}^{(1)} + \mathbf{b}^{(1)}) \tag{2}$$

$$\text{Dense Layer 2:} \quad \mathbf{H}^{(2)} = \sigma(\mathbf{H}^{(1)}\cdot\mathbf{W}^{(2)} + \mathbf{b}^{(2)}) \tag{3}$$

$$\text{Dense Layer 3:} \quad \mathbf{H}^{(3)} = \sigma(\mathbf{H}^{(2)}\cdot\mathbf{W}^{(3)} + \mathbf{b}^{(3)}) \tag{4}$$

$$\text{Dense Layer 4:} \quad \mathbf{H}^{(4)} = \sigma(\mathbf{H}^{(3)}\cdot\mathbf{W}^{(4)} + \mathbf{b}^{(4)}) \tag{5}$$

$$\text{InfoNCELoss Layer:} \quad \text{Custom layer utilizing InfoNCE} \tag{6}$$

In the above representation, σ denotes the activation function, such as the LeakyReLU function, which introduces non-linearities into the network. $W^{(i)}$ represents the weight matrix and $b^{(i)}$ denotes the bias vector for the ith dense layer.

The results of the novel ensemble Deep Info Max - Self-Organizing Map (DIM-SOM) technique, presented in Table VI, reflect the evaluation based on prominent clustering metrics, including the Silhouette Score [30], Calinski Harabasz Score [31], and Davies Bouldin Score [32]. The findings illustrate the complex dynamics involved in choosing the ideal lag value.

Among the considered lag values, the analysis spotlights lag 12 as a prominent contender with an impressive Silhouette Score of 0.9234, indicating distinct and well-defined clusters within the dataset. Moreover, the notably high Calinski-Harabasz Score of 389723.6225 for lag 12 further signifies the presence of dense and well-separated clusters, in producing meaningful clustering outcomes. Complementing these findings, the relatively low Davies-Bouldin Score of 0.1276 for lag 12 underlines the improved cluster separation compared to other lag values. Hence novel ensemble DIM-SOM technique, emphasizing its potential to generate compact, well-separated, and distinct clusters was established.

Further insight into the clustering performance was gained through a comparison of the self-organizing map (SOM) and the novel ensemble DIM-SOM. Table VII illustrates the comparison, highlighting the superior performance of the novel ensemble DIM-SOM over the standard SOM algorithm. Specifically, the novel ensemble DIM-SOM algorithm attained a significantly higher Silhouette Score of 0.9234, a lower Davies-Bouldin Score of 0.1276, and a more favorable Calinski-Harabasz Score of 389723.6225, surpassing the respective metrics achieved by the SOM algorithm (Silhouette Score: 0.2619, Davies-Bouldin Score: 1.6610, Calinski-Harabasz Score: 3040.4192). These findings underscore the efficacy of the novel ensemble DIM-SOM approach in generating dense, well-separated, and meaningful clusters, further emphasizing its potential to enhance clustering performance in comparison to the traditional SOM algorithm.

Risk factor analysis The role of environmental factors in exacerbating asthma symptoms remains a critical area of investigation. The analysis focused on exploring the influence of air pollution, meteorological conditions, and obesity on two distinct clusters of asthma patients. The feature importance analysis is shown in Fig. 7 which notably indicate the varying impact of these factors on the identified clusters, describing important insights into the complex interactions between health outcomes and environmental conditions. The visualization from Fig. 6 clearly indicates the division of the data into two distinct clusters. Subsequent analysis enabled the classification of these clusters as “Asthma Aggravated by Air Pollution” and “Asthma Not Significantly Affected by Air Pollution”.

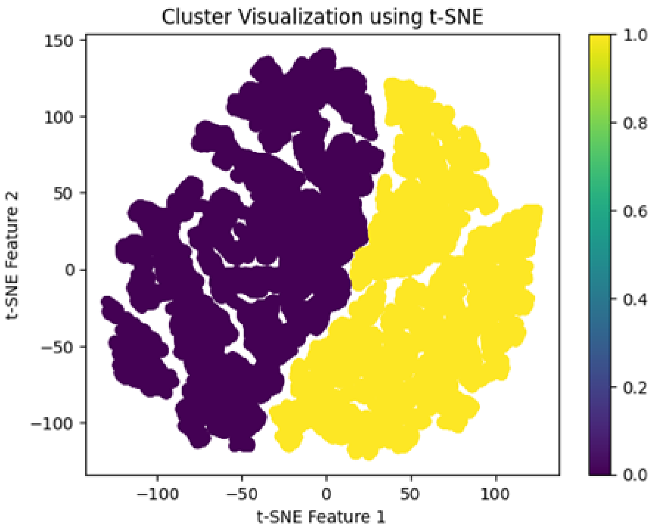

Fig. 6. Cluster visualization.

Asthma Aggravated by Air Pollution Cluster: The analysis revealed a significant association between air pollution and the severity of asthma symptoms in this cluster. The feature importance analysis highlighted the substantial impact of various pollutants, including average SO2, average CO, average NO2, average O3, average CH4, average PM10, and average PM2.5. Additionally, meteorological factors such as average TEMPERATURE, average DEW POINT, and average RELATIVE HUMIDITY exhibited a relationship with air pollutants, amplifying the adverse effects on asthma exacerbation. Asthma Not Significantly Affected by Air Pollution Cluster: In this cluster, the influence of air pollution on asthma symptoms appeared notably milder compared to the first cluster. Nevertheless, specific pollutants, particularly average PM10 and average PM2.5, still demonstrated a discernible impact, albeit to a very lesser extent. Moreover, meteorological parameters, including average TEMPERATURE, average WIND SPEED, and average RELATIVE HUMIDITY, played a prominent role, indicating their potential contribution to the manifestation of asthma symptoms. Obesity has long been recognized as a risk factor for various health conditions, including asthma. The feature importance analysis in both clusters elucidated the noteworthy impact of different BMI categories, emphasizing the crucial role of weight status in the severity and exacerbation of asthma symptoms. The analysis revealed the following insights: In both clusters, the feature importance values for both BMI Category Overweight and BMI Category Underweight suggested a similar negative impact, indicating that being either underweight or overweight may contribute to the aggravation of asthma symptoms (Table VIII).

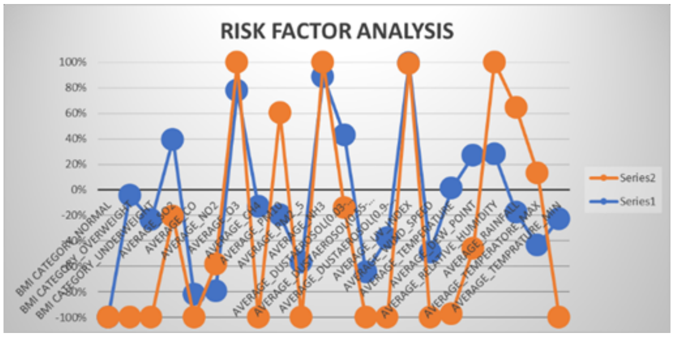

Fig. 7. Risk factor analysis.

TABLE VIII. COMPARISON OF STUDIES AND PROPOSED MODEL

Study	Focus	Key Findings	Results
Helsinki[9]	Landfill Exposure	Increased cancer incidence; elevated relative risk of chronic diseases, including asthma.	High correlation of air pollutants and pulmonary diseases.
Awasthi et al.[10]	Asthma Risk Factors	Significant associations between motor vehicle air pollution, industrial smoke, and asthma in participants aged 1–15 years.	Children are more vulnerable to the adverse effects of high air pollution.
Tlotleng et al.[11]	Waste Recyclers' Health	Increased respiratory symptoms in waste recyclers due to exposure to waste containing chemical residues.	Noticable correlation of respiratory symptoms and air pollution in the vicinity of dumping ground.
Singh et al.[12]	Dumping Site Impact	Notable increase in respiratory illnesses, eye irritation, and stomach problems among the exposed group as compared to controlled group.	High correlation of symptoms and air pollution.
Shin et al.[13]	Air Pollution and Asthma	Significant associations between asthma exacerbations and increased pollutant levels during summer and winter.	High correlation of air pollutants and weather parameters with asthma symptoms.
Kebalepile et al.[14]	SOM for Asthma Outcomes	SOM classified asthma outcomes based on air quality data and socio-demographic information. Age was a significant factor.	Classification Accuracy: 59%
Model for regression[15]	mHealth Application	Optimized DNNR model for asthma self-management.	Achieved 94% accuracy.
Proposed Model DIM-SOM	**Clustering Performance,for Asthma risk factor analysis**	**Higher Silhouette Score, lower Davies-Bouldin Score, and favorable Calinski-Harabasz Score for DIM-SOM.**	**Silhouette Score:0.92, Davies-Bouldin Score:0.12, Calinski-Harabasz Score:389723.62**

VII. CONCLUSION

This study has undertaken a comprehensive exploration of the intricate interplay between environmental factors and their impact on respiratory health, particularly in the context of the Deonar dumping ground in Mumbai. By employing a sophisticated novel ensemble model, which combines patient-specific data, localized weather patterns, air quality metrics, and the innovative ensemble Deep Info Max - Self-Organizing Map (DIM-SOM) technique, the multifaceted risk factors contributing to the incidence of asthma within this region were identified. The findings have unveiled the pivotal role played by environmental pollutants and meteorological variations in exacerbating(synonym) respiratory ailments, highlighting the heightened vulnerability of the local population to asthma. The novel ensemble DIM-SOM algorithm, introduced in this literature has demonstrated its efficacy in generating meaningful clusters, signifying its potential for accurate and interpretable insights into the complex relationship between environmental exposure and respiratory health. In the wake of these insights, this research calls for the implementation of proactive mitigation measures and tailored healthcare interventions to address the specific challenges posed by the Deonar dumping ground. By incorporating the results into policy planning and public health initiatives, local authorities and healthcare stakeholders can design effective strategies to alleviate the impact of environmental hazards on respiratory well-being in the affected communities.

Moreover, this study offers the potential for developing sustainable, evidence-based interventions that can safeguard public health in regions confronted with similar environmental challenges, further reinforcing the importance of ensemble methodologies in complex data analysis and pattern recognition within the context of public health.

While this study provides crucial insights into the complex interplay between environmental factors and respiratory health in the Deonar dumping ground area, it is important to acknowledge certain limitations. The reliance on retrospective data poses constraints on the establishment of causal relationships, warranting further longitudinal investigations to ascertain the temporality and directionality of the identified associations. Additionally, the study's focus on a specific geographical location necessitates caution in generalizing the findings to broader populations, emphasizing the need for multi-site studies to enhance the external validity of the results.

In terms of future scope, the incorporation of genetic and epigenetic data in conjunction with environmental factors could offer a more nuanced understanding of the individual susceptibility to asthma in polluted environments. Moreover, creating specific plans to help the community get involved and actively participate could be very effective in dealing with the many challenges caused by the environmental issues and respiratory health in similar areas.

ACKNOWLEDGMENT

We would like to express our sincere gratitude to Dr. Priyanka Kulkarni BAMS, MD - Ayurveda, and, Dr. Sonali Renushe BAMS, MD - Ayurveda for their essential guidance and support in assisting us to comprehend the medical component of our research work. Our research has been substantially enhanced by their insights into it.

***Abstract*—This study conducts a thorough assessment of ensemble machine learning methods, specifically focusing on the identification of Assamese words. This task is crucial for improving Content-Based Image Retrieval systems and safeguarding the digital heritage of Assamese culture. We analyze the efficacy of different algorithms, such as CatBoost, XGBoost, Gradient Boosting, Random Forest, Bagging, AdaBoost, Stacking, and Histogram-Based Gradient Boosting, by thoroughly examining their performance in terms of accuracy, precision, recall, Kappa, F1-score, Matthews Correlation Coefficient, and AUC. The CatBoost algorithm stands out as the top performer, achieving an accuracy rate of 97.7%, precision rate of 95%, and recall rate of 96%. XGBoost is also acknowledged for its substantial effectiveness. This comparative analysis emphasizes CatBoost's superiority in terms of precision and recall. Additionally, it underscores the strong ability of ensemble classifiers to enhance assistive technologies, promote social inclusivity, and seamlessly integrate the Assamese language into technological applications.**

I. Introduction

Assamese, predominantly spoken in the state of Assam and various other regions in Northeast India, holds a significant position as one of the primary languages in India [1]. Hence, the development of a precise Assamese automatic word recognition system holds the potential to safeguard the cultural heritage of India. The recognition of Assamese words is of utmost importance in the preservation and promotion of the Assamese language. An accurate recognition system has the potential to address numerous domains, including digital resource management, the creation of educational tools, and the preservation of digital languages [2]. The ability to accurately recognize words enhances the accessibility of information for individuals who speak Assamese. The utilization of this technology enables the advancement of various technological applications, including content based image retrieval (CBIR), natural language processing (NLP), and information retrieval systems that are specifically tailored for the Assamese language. This facilitates the utilization of digital content, retrieval of pertinent information, and engagement in online platforms by Assamese speakers in their mother tongue.

The Assamese language exhibits dialectal variations, accents, and regional distinctions, which may pose difficulties in word recognition. Ensemble techniques refer to the automated process of effectively identifying and accurately interpreting word images [3]. This is achieved by integrating multiple models or classifiers, thereby leveraging their respective strengths and weaknesses. Ensemble methods have the ability to utilize the combined knowledge and expertise of individual models in order to generate results that are more accurate [4]. The task at hand pertains to the development of computational models, algorithms, and systems with the capability to effectively identify and comprehend Assamese words. In contrast to state-of-the-art methods, ensemble methods exhibit greater accuracy and robustness due to their utilization of multiple models trained on distinct subsets of the data or employing diverse feature representations. In order to facilitate the preservation and expansion of the Assamese language, as well as its integration into society, numerous researchers have employed various methodologies.

A. Distinctive Contribution

This study encompasses the completion of three primary objectives:

1) Identification of handcrafted features for Assamese Word Recognition.
2) Implementation of Ensemble Classification using the handcrafted features.

*Corresponding authors

3) Evaluation of performance to determine the optimal ensemble classification method for classification analysis.

The schematic depicted in Fig. 1 offers a graphical illustration of the sequence of tasks involved in this work.

This work is organised in the following format . Section II entails a thorough examination of relevant studies to establish the essential context and background for the research. Section III, entitled “Materials and Methods”, offers a thorough elucidation of the process by which the dataset was generated and the precise methodologies employed for feature engineering. Section IV, of the research paper discusses various ensemble models, while Section V, provides comprehensive details on the performance metrics employed to assess these models. Section VI, presents a comprehensive analysis of the findings, offering a comparative assessment of the effectiveness of the models. In Section VII, the paper concludes by presenting a succinct overview of the primary discoveries and contributions. Section VIII subsequently provides a delineation of prospective paths for future research. In addition, a comprehensive compilation of references is provided to support and validate the research.

II. Related Studies

The authors of [5] used feature extraction techniques such as zoning, chain code, and Fourier descriptors to recognize Assamese handwritten numerals. Table I presents a compilation of the relevant literature pertaining to ensemble methods. The extracted features could be used for word recognition. The study explores a deep learning-based approach for Assamese text recognition [6]. The results show that preprocessing can help a convolutional neural network (CNN) architecture recognize words accurately. Several studies have examined Assamese handwriting recognition issues. An ensemble system uses deep learning models like CNNs and LSTMs to improve recognition accuracy [7]. Ensemble techniques can improve Assamese handwriting recognition and social inclusion, according to this study. The paper proposes an adaptive approach for handwritten Assamese word recognition [8]. The horizontal, vertical, and gradient profiles of word images are used to extract features. The system uses a hybrid classifier that combines SVM and ANN benefits. This study contributes to inclusive word recognition by focusing on Assamese handwriting recognition challenges. This paper focuses on recognizing characters in offline Assamese handwriting [5]. The CNN architecture presented in this study is designed for Assamese character recognition. Word recognition systems require precise character identification, and this study improves Assamese word recognition. This study proposes a Hidden Markov Model (HMM) and Support Vector Machine (SVM) approach for Assamese online character recognition [9]. These models are also compared for efficacy. According to [10], an OCR system for handwritten Assamese characters uses Artificial Neural Networks (ANN) for character segmentation. Character segmentation is done using horizontal and vertical projection on handwritten text. In [11], researchers examine Academic literature proposes algorithms for online handwriting and machine-printed Assamese language text recognition. The Assamese language has more cursive writing than English and others. Feature selection (FS) extracts many features from simple to complex data.

Bagging and AdaBoost classifiers are popular ensemble learning methods for handwritten character recognition. Using different subsets of training data, many researchers have trained decision trees, support vector machines, and neural networks. The authors of [12] show that Bagging and AdaBoost Classifiers enhance devnagari document recognition accuracy. Researchers in [13] proved that statistical features can accurately classify handwritten Assamese language. Several studies have shown that deep learning techniques like CNNs, RNNs, and Deep Boltzmann Machines can effectively recognize handwritten text [14]. The above Assamese word recognition papers offer significant contributions and methods. They demonstrate the ongoing effort to improve social inclusivity by creating accurate and reliable recognition systems. Table IV presents a concise overview of the ensemble learning techniques employed in different scripts.

TABLE I. The Literature Concerning Ensemble Learning Methods Applied to Scripts

Year	Author	Technique	Dataset	Advantages
2007	Sarma[5]	Feature extraction (zoning, chain code, Fourier descriptors)	Handwritten Assamese numerals	Potential for word recognition
2007	Sarma (Character Recognition) [5]	CNN architecture for character recognition	Offline Assamese handwriting	Specific to characters
2013	Sarma[9]	HMM and SVM models	Assamese online characters	Utilizes multiple models
2015	Singh[8]	Hybrid classifier (SVMs, ANNs)	Handwritten Assamese words	Focuses on difficulties
2018	Jangid[14]	Deep learning techniques (CNNs, RNNs, etc.)	Handwritten text	Utilizes deep learning
2019	Alvear[6]	CNN architecture with preprocessing	Assamese text	Utilizes deep learning
2019	Narang[12]	Bagging and AdaBoost Classifiers	Devanagari documents	Ensemble learning
2019	Narang[13]	Statistical features	Handwritten Assamese language	Utilizes statistical features
2021	Choudhury [7]	Ensemble system (CNNs, LSTMs)	Handwritten Assamese text	Societal inclusion
2019	Chourasia [10]	ANN for character segmentation	Handwritten Assamese characters	Specific to character recognition
2022	Ghosh[11]	Various algorithms	Online handwriting and machine-printed Assamese text	Explores various algorithms

TABLE II. Summary of Instance Counts for Each Class Label

Sl. No.	Class Label	Instance Count
1	Burhi_aair_xadhu	2040
2	Bezbaruahr Rasanawali (Vol 2)	2065
3	Kirttana_and_Ghosha	2050
4	Gauburha	2062
5	Jilikoni	2057
	Total	10274

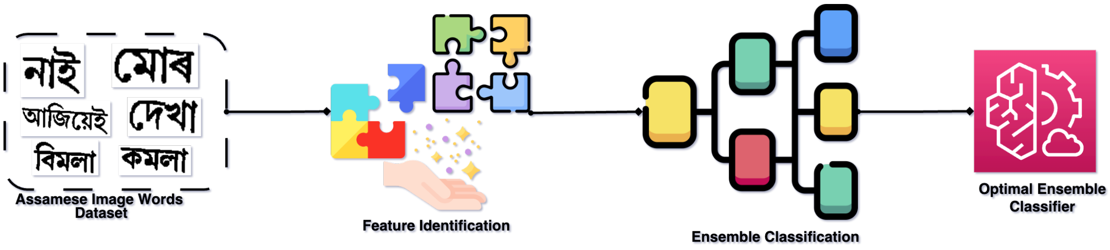

Fig. 1. The workflow of the methodology.

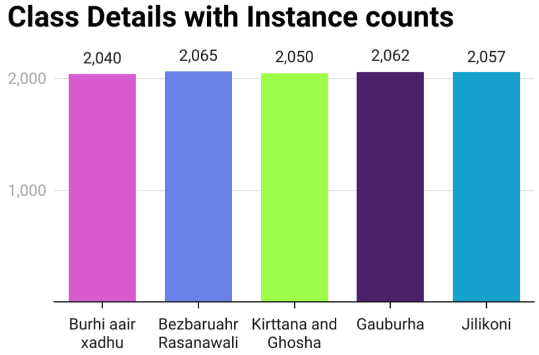

Fig. 2. Class details with instance counts.

III. Materials and Methods

A. Dataset Creation

The dataset curation approach for the experiments entailed a rigorous manual technique. The visual representations were created utilizing publicly accessible web resources related to the Jonaki and Shankari literary periods in Assamese literature. Access to the dataset can be provided upon a formal request, taking into account its potential significance.

The dataset used in this research was carefully chosen and organized. It consisted of photographs obtained from freely available online publications that were related to the Jonaki and Shankari periods in Assamese literature. The importance of studying these literary periods is in their contribution to the cultural heritage of Assam. The collection notably features images from five specific novels, namely, “Burhi Aair Xadhu”, “Bezbaruahr Rasanawali (Vol 2)”, “Kirttana and Ghosha”, “Gauburha”, and “Jilikoni”. The dataset, comprising images extracted from particular books, is presented in Table II, and Fig. 2 displays the specific information regarding the classes and the corresponding number of instances in our dataset.

Borah et al. offer a thorough and complete explanation of a detailed segmentation process [15]. The experimental phase utilized a dataset consisting of 10,274 photographs, which were classified into five unique categories, as detailed in Table II and Fig. 2.

B. Feature Engineering

Table III presents a comprehensive compilation of 1523 distinct characteristics used in the image dataset. These characteristics encompass a wide range of diverse attributes. Every attribute contributes to the creation of a comprehensive representation of handwritten word images. Significant metrics in this context encompass CHA (Convex Hull Area) and CHP (Convex Hull Perimeter), which provide valuable information about the geometric attributes of words. SPLBP (Spatial Layout Binary Pattern) provides valuable information regarding spatial layout attributes, including position, orientation, and scale. The analysis is improved by integrating features such as PHOG (Pyramid of Histograms of Oriented Gradients) and EHD (Edge Histogram Descriptors), which offer insights into texture, structure, and shape. The local shape properties are understood by considering additional characteristics such as kurtosis, rectangularity, volume, compactness, and HuMoments. The recognition system requires a wide variety of features in order to accurately distinguish and categorize handwritten Assamese words. This will improve the accuracy and robustness of ensemble classification methods. Additionally, [16] offers a comprehensive examination of various shape-based features utilized in CBIR.

TABLE III. Features Implemented on the Image Dataset

Feature Name	Count	Description
CHA	1	Area of smallest convex polygon containing the object.
CHP	1	Perimeter of smallest convex polygon containing the object.
Compactness	1	Measure of object’s packing density.
Contlength	1	Length of object contour or boundary.
EHD	80	Edge Histogram descriptors for shape analysis.
HuMoments	7	Moments computed from central moments for shape description.
Kurtosis	1	Measure of distribution’s “peakedness” or “flatness”.
MaAL	1	Length of object’s major axis.
MiAL	1	Length of object’s minor axis.
Num_corners	1	Number of corners or vertices in the object’s contour.
Num_holes	1	Number of holes or voids in the object.
Perimeter	1	Length of the object’s contour.
Rectangularity	1	Ratio of object area to minimum bounding rectangle area.
ShapeIndex	36	Scalar value characterizing local shape based on curvature.
Skewness	1	Measure of object’s distribution asymmetry.
Solidity	1	Ratio of object’s area to its convex hull area.
SPLBP	756	Features describing spatial layout: position, orientation, scale.
Volume	1	Volume or space occupied by the object.
PHOG	630	Pyramid of Histograms of Oriented Gradients
Total	1523	

C. Ensemble Classification

Ensemble classification is a commonly employed technique in the domain of machine learning that leverages the combined power of multiple models to enhance the precision of predictions [17]. In order to create an ensemble model that is more reliable and accurate, the proposed methodology integrates forecasts made by numerous base classifiers, also referred to as “weak learners”. Ensemble methods, including bagging, boosting, and stacking, are employed to introduce diversity among individual models and collectively mitigate their respective limitations. An illustration of a technique employed in the field of machine learning is bagging, wherein multiple instances of base models are generated on bootstrapped samples. This particular methodology successfully decreases variance and addresses the potential problem of overfitting. By giving weights to samples that were wrongly classified, the boosting algorithm makes it possible for the model's performance to be improved over and over again. The stacking technique entails the amalgamation of multiple models through the utilization of a meta-learner, with the aim of capitalizing on their respective strengths. Ensemble classification is extensively employed across diverse domains, including image recognition, natural language processing, and financial forecasting, with the primary aim of achieving enhanced predictive accuracy. The methodology employed in our study is depicted in Fig. 1, outlining the step-by-step process of improving Assamese word recognition.

1) Gradient Boosting (GB): The technique of Gradient Boosting is employed to optimize a loss function through the sequential addition of weak learners, typically in the form of decision trees [18]. The ultimate forecast is computed by aggregating the individual predictions of the learners using a weighted sum.

Mathematically, in each iteration, we update the model as follows:

$$F_t(x) = F_{t-1}(x) + \arg\min_h \left(\sum_{i=1}^{N} L(y_i, F_{t-1}(x_i) + h(x_i)) \right) \tag{1}$$

Definitions:

1. $F_t(x)$: The ensemble's prediction at iteration t. 2. $h(x)$: The weak learner's prediction. 3. $L(y_i, F(x_i))$: The loss function, typically squared error for regression or cross-entropy for classification.

2) CatBoost (CB): In order to enhance the training procedure, CatBoost employs the ordered boosting technique, which takes into account the ordering of categorical variables [19]. This methodology facilitates the preservation of the inherent hierarchy of categorical attributes, which can prove advantageous in a multitude of contexts including recommendation and ranking systems. By integrating the natural order of categorical variables, CatBoost has the capability to augment the model's predictive performance.

CatBoost, apart from employing ordered boosting, incorporates a statistical technique to mitigate the risk of overfitting in the context of categorical data. Overfitting occurs when a model learns an excessive amount of the training data, including any noise or random fluctuations, which can result in inadequate generalization to new data. CatBoost implements a regularization technique to mitigate the risk of overfitting, specifically in the context of categorical features.

From a mathematical standpoint, it can be observed that this approach optimizes the identical loss function as gradient boosting. However, it distinguishes itself by employing distinct methods to handle categorical features.

$$\text{CB} = \sum_{i=1}^{N} L(y_i, F(x_i)) + \sum_{j=1}^{J} \Omega(C_j) \tag{2}$$

Where: - $L(y_i, F(x_i))$ is the loss function that measures the difference between the predicted values and the true labels.
- $F(x_i)$ represents the model's prediction for the i-th data point.
- C_j represents categorical features and $\Omega(C_j)$ is a regularization term applied specifically to categorical features.
- J is the total number of categorical features.

3) Random Forest (RF): Random Forest is a machine learning algorithm that operates by aggregating multiple decision trees. As such, it does not possess a singular equation that fully encompasses its functionality. The RF algorithm creates a collection of decision trees and aggregates their predictions using either voting (for classification [20], [21]) or averaging (for regression [22]).

4) XGBoost: XGBoost effectively optimizes the given objective function in order to construct an ensemble of decision trees, rendering it a robust and efficient algorithm that is extensively employed in machine learning competitions.

$$\text{XGBoost} = \sum_{i=1}^{N} L(y_i, F(x_i)) + \sum_{k=1}^{K} \Omega(f_k) \tag{3}$$

Where:
-L(y_i, F(x_i)) & is the loss function.
-Omega(f_k) & is the regularization term for each tree.

5) Bagging: Bagging improves decision tree-based predictive models' accuracy and resilience. Original model is a “weak learner”, usually a decision tree. Bootstrap samples create multiple instances by training the base model on different training data subsets. This subset is created by random sampling with replacement. Academic literature calls these subsets “bootstrap samples”. Multiple base models trained on bootstrap samples are exposed to slightly different dataset variations. Predicting future events. Model predictions are aggregated. Regression aggregation averages predictions, while classification determines majority vote. Bagging reduces variance, overfitting, and generalization by using trained model heterogeneity. Thus, it enhances prediction.

The Bagging prediction can be represented as:

$$\text{Bagging Prediction} = \frac{1}{N} \sum_{i=1}^{N} f_i(x) \tag{4}$$

Where: - Bagging Prediction is the final prediction made by Bagging. - N is the number of base models (often decision trees) created through bootstrapped samples. - $f_i(x)$ represents the prediction of the i-th base model on input data x.

6) AdaBoost: AdaBoost, also known as Adaptive Boosting, is a machine learning algorithm that employs the technique of ensemble learning to construct a robust model by aggregating multiple weak learners [23]. The algorithm employs an iterative process whereby distinct weights are assigned to each weak learner in accordance with their respective performance. The primary objective is to rectify the errors made by preceding models. The ultimate forecast is derived by calculating a weighted sum of the prognostications made by these inferior learners.

The AdaBoost algorithm can be mathematically summarized as follows:

1) **Initialization:** Start by initializing the sample weights w_i uniformly, where i ranges from 1 to the number of training samples.
2) **Iteration t:**
   a) Train a weak learner, denoted as $h_t(x)$, on the training data with the current sample weights w_i.
   b) Compute the weighted error ϵ_t of $h_t(x)$ on the training data:
   $$\epsilon_t = \sum_{i=1}^{N} w_i \cdot I(y_i \neq h_t(x_i)) \tag{5}$$
   where N is the number of training samples, y_i is the true label, x_i is the input data, and I is the indicator function.
   c) Compute the importance weight of $h_t(x)$:
   $$\alpha_t = \frac{1}{2} \cdot \ln\left(\frac{1-\epsilon_t}{\epsilon_t}\right) \tag{6}$$
   d) Update the sample weights for the next iteration:
   $$w_{i,t+1} = w_i \cdot \exp\left(-\alpha_t \cdot y_i \cdot h_t(x_i)\right) \tag{7}$$
   Normalize the weights so that they sum up to 1:
   $$w_{i,t+1} = \frac{w_{i,t+1}}{\sum_{i=1}^{N} w_{i,t+1}} \tag{8}$$
3) Repeat the above steps for a predefined number of iterations or until a stopping criterion is met.
4) The final prediction $F(x)$ is obtained by combining the predictions of weak learners with their importance weights:
$$F(x) = \sum_{t=1}^{T} \alpha_t \cdot h_t(x) \tag{9}$$

7) Stacking: Stacking combines multiple base models by training a meta-model on their predictions. The meta-model learns to weigh the predictions of the base models optimally [25].

Mathematically, stacking can be represented as follows:

$$\hat{y} = g(f_1(x), f_2(x), \ldots, f_k(x)) \tag{10}$$

Where:

$\hat{y}$ is the final prediction.

$f_i(x)$ are the predictions of individual base models.

g is the meta-model, which can be a LR, DT etc.

8) Histogram-based Gradient Boosting: Histogram-Based Gradient Boosting uses histograms to speed up training [24]. It optimizes the same loss function as traditional gradient boosting but employs histogram-based techniques for better efficiency.

The mathematical details of HistGradientBoosting involve optimizing the loss function similar to gradient boosting but with histogram-specific optimizations.

The optimization objective of Histogram-Based Gradient Boosting (HistGradientBoosting) can be summarized as follows:

$$\min_{F(x)} \sum_{i=1}^{N} L(y_i, F(x_i)) + \sum_{j=1}^{J} \Omega(C_j) \tag{11}$$

Where: - $\min_{F(x)}$ denotes the minimization of the objective with respect to the ensemble model $F(x)$. - N is the number of training samples. - $L(y_i, F(x_i))$ is the loss function that measures the difference between the true labels y_i and the predictions $F(x_i)$. - J represents the categorical features, and $\Omega(C_j)$ is a regularization term specific to categorical features.

This equation provides a simplified representation of the optimization objective in HistGradientBoosting, highlighting the key components involved in gradient boosting with histogram-based techniques.

TABLE IV. SUMMARY OF ENSEMBLE MODELS ASSAMESE WORD RECOGNITION

Model	Description
Gradient Boosting (GB)	Gradient Boosting is an ensemble learning method that builds multiple decision trees sequentially. Each tree corrects the errors of the previous one. It's a powerful model for classification and regression tasks, known for its high predictive accuracy.
CatBoost (CB)	CatBoost is a gradient boosting algorithm that is particularly effective for categorical feature handling. It automatically handles categorical data, reducing the need for preprocessing, and can work well with both numerical and categorical features.
Random Forest (RF)	Random Forest is an ensemble of decision trees. It builds multiple trees and combines their predictions through voting (classification) or averaging (regression). It's robust, handles high-dimensional data well, and is less prone to overfitting.
XGBoost	XGBoost (Extreme Gradient Boosting) is an efficient gradient boosting algorithm known for its speed and performance. It's highly customizable and widely used in machine learning competitions due to its predictive power.
Bagging	Bagging stands for Bootstrap Aggregating. It's an ensemble method that builds multiple instances of a base model (usually decision trees) on bootstrapped samples of the data. It reduces variance and helps in avoiding overfitting.
AdaBoost	AdaBoost (Adaptive Boosting) is another boosting algorithm that focuses on the weaknesses of the base model. It assigns weights to misclassified samples and combines multiple weak learners to create a strong ensemble model.
Stacking	Stacking, or Stacked Generalization, combines multiple base models by training a meta-model on their predictions. It leverages the strengths of different models, potentially improving overall performance.
HistGradientBoosting	Histogram-Based Gradient Boosting is an efficient variant of gradient boosting that uses histograms to speed up training. It's particularly useful for large datasets and high-dimensional data.

IV. PERFORMANCE METRICS

In the domain of machine learning evaluation, a variety of fundamental performance metrics are frequently utilized to

TABLE V. PERFORMANCE METRICS FOR VARIOUS MACHINE LEARNING MODELS

Model	Accuracy	Precision	Recall	Kappa	F1-score	MCC	Build Time (s)	Run Time (s)	AUC

evaluate the efficacy of classification models. These metrics offer significant insights into the predictive capabilities and overall quality of a model. In this section, we present a concise summary of several key performance metrics.

A. Accuracy

Accuracy is a crucial metric that quantifies the ratio of accurately classified instances to the total number of instances in the dataset. The aforementioned statement offers a comprehensive evaluation of the accuracy of the model's predictions on a global scale.

B. Precision

Precision is a metric that quantifies the ratio of correctly predicted positive instances to the total number of positive predictions made by the model. The evaluation assesses the model's capacity to minimize the occurrence of false positive predictions.

C. Recall

The term "recall", which is also referred to as sensitivity or true positive rate, is a metric used to measure the proportion of true positive predictions in relation to all the actual positive instances. The evaluation measures the model's capacity to accurately identify and include all pertinent positive instances.

D. Kappa

The Cohen's Kappa statistic serves as a quantitative measure to assess the level of agreement between the predictions generated by a model and the observed outcomes. The method takes into consideration the potential occurrence of coincidental agreement and offers an indication of the model's efficacy beyond what would be expected by random chance.

E. F1-score

The F1-score can be defined as the mathematical average of precision and recall, specifically calculated using the harmonic mean. The provided analysis presents a comprehensive evaluation of the model's capacity to effectively balance precision and recall, making it particularly advantageous in scenarios involving imbalanced datasets.

F. Matthews Correlation Coefficient (MCC)

The Matthews Correlation Coefficient (MCC) is a metric used to evaluate the degree of correlation between the predictions made by a model and the actual labels assigned to the data. It takes into account all four categories: true positives, true negatives, false positives, and false negatives. The aforementioned metric offers a thorough evaluation of the performance of the model.

G. Build Time (s) and Run Time (s)

The term "Build Time" denotes the duration, measured in seconds, necessary for the training or construction of a machine learning model. The metric of Run Time quantifies the duration, expressed in seconds, required for generating predictions on novel and unobserved data. The metrics presented in this context serve as indicators of the computational efficiency of the model.

H. AUC Area Under the ROC Curve (AUC)

The quantification of a model's ability to differentiate between positive and negative classes is accomplished by the Area Under the Receiver Operating Characteristic (ROC) Curve (AUC). A greater Area Under the Curve (AUC) value signifies an enhanced capacity to differentiate between different classes.

Performance metrics play a crucial role in the assessment and comparison of the efficacy of machine learning models in classification tasks.

I. Training, Testing and Validation Details

The dataset was divided into training and testing sets using a 70-30 split, allowing for a comprehensive evaluation of ensemble classification techniques for identifying Assamese words. More precisely, 70% of the data was allocated for training and denoted by the variables X_{train} and y_{train}. The remaining 30% of the data, referred to as X_{test} and y_{test}, was used for testing. The division was performed using the `train_test_split` function, with the `test_size` parameter set to 0.3. In addition, an additional 20% of the training set was allocated for validation purposes. The validation subset played a vital role in optimizing and validating the models. It enabled the adjustment of parameters and the prevention of overfitting, ensuring the best possible performance of the model on new, unseen data. The results were greatly impacted by the implementation of the data segmentation strategy, which offered a thorough approach for training and evaluating the model. This, in turn, improved the reliability and accuracy of the findings.

J. Experimental Environment Details

The study was conducted on a computational system in the experimental environment, which had the following specifications. The system utilized Python version 3.8.17 and functioned on the Darwin operating system with Kernel Version 23.2.0. The system architecture was 64-bit, with a RAM capacity of 32.00 GB. The CPU was equipped with a configuration consisting of 10 cores and 10 threads. The hardware and software specifications enhance the transparency and reproducibility of the experimental setup, guaranteeing a strong basis for the study's results.

V. Results

The present study provides a comprehensive evaluation of various machine learning models within the framework of a classification task. Each model is assessed using a variety of performance metrics, including accuracy, precision, recall, Kappa, F1-score, MCC (Matthews Correlation Coefficient), build time, run time, and AUC (Area Under the ROC Curve). Testing how well a model works involves checking how well it correctly labels instances, how well it balances precision and recall, how well it matches real-world results, and how quickly it can do the calculations (see Table V). It is noteworthy to mention that specific models, such as CatBoost (CB) and XGBoost, demonstrate a significant degree of accuracy and AUC values, indicating their strong discriminatory abilities. In contrast, AdaBoost demonstrates reduced accuracy and Matthews Correlation Coefficient (MCC) values, suggesting the existence of potential areas for improvement as seen in Fig. 3 and 4a. The table serves as a valuable instrument for selecting the most suitable machine learning model based on specific classification requirements, considering both predictive accuracy and computational efficiency. Fig. 3 illustrates the performance of the classifiers on our dataset, specifically emphasizing accuracy and precision and Fig. 4a and 4b provides a performance analysis of the models, showcasing their ROC values and computational efficiency.

VI. Discussion

This study offers a comprehensive assessment of machine learning models in the context of a classification task. This analysis yields significant insights of note.

The CatBoost (**CB**) model demonstrates superior performance across various metrics, establishing its dominance in the field. The model demonstrates exceptional performance in terms of accuracy (97.7%), precision, and recall, highlighting its proficiency in making precise predictions and effectively capturing positive instances.

The competence of Gradient Boosting (**GB**) is notable, as it consistently demonstrates high accuracy (96.0%) and performs competitively across multiple metrics. It is a highly suitable option for precise classification tasks.

The achievement of high F1-scores, which effectively balance precision and recall, is notable in the performance of **CB** and **XGBoost**. This particular attribute holds significant value when addressing datasets that exhibit imbalances.

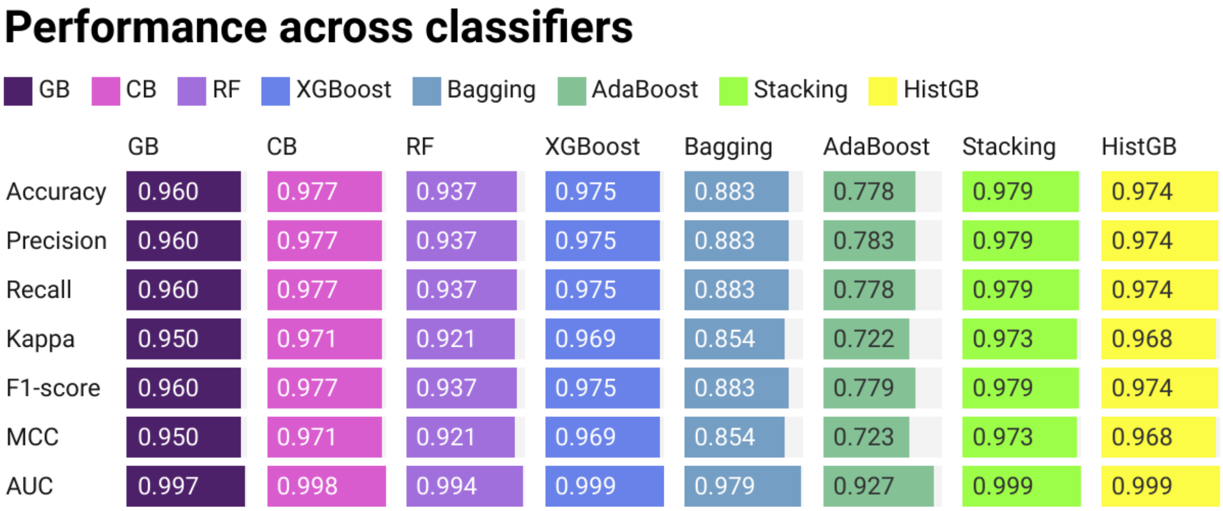
The observed Kappa values for **CB** and **Stacking** indicate a significant level of agreement that surpasses what would be expected by chance alone. This suggests their credibility in generating forecasts that surpass mere chance concurrence.

The discriminatory power of all models is exceptional, as evidenced by their AUC values that approach 1. This suggests their proficiency in effectively discerning between positive and negative classes.

Computational efficiency is a crucial aspect to consider when evaluating the performance of algorithms such as **CB** and **XGBoost**. Although these algorithms exhibit exceptional performance, it is important to note that they necessitate a greater allocation of computational resources. In contrast, **AdaBoost** and **Random Forest** algorithms provide expedited construction and execution durations, rendering them appropriate for situations where computational efficiency is of paramount importance.

A. Perfomance with Reference to other Script based Works

The data as seen in Table VI is a comparative analysis of the limited number of techniques utilized in the field of document recognition and analysis across a variety of scripts. The methodologies being evaluated are attributed to distinguished researchers who have implemented unique approaches for the extraction and categorization of features. The comparative analysis in question examines a wide range of scripts, which comprise Assamese, Devanagari, Hindi, Gurumukhi, and Bangla.



Performance across classifiers

🟪 GB 🟪 CB 🟪 RF 🟦 XGBoost 🟦 Bagging 🟩 AdaBoost 🟩 Stacking 🟨 HistGB

	GB	CB	RF	XGBoost	Bagging	AdaBoost	Stacking	HistGB

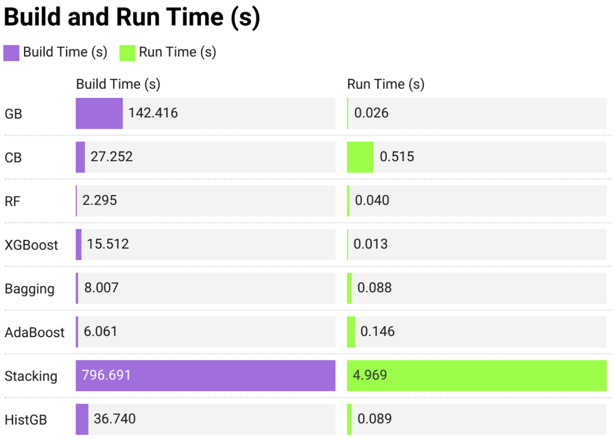
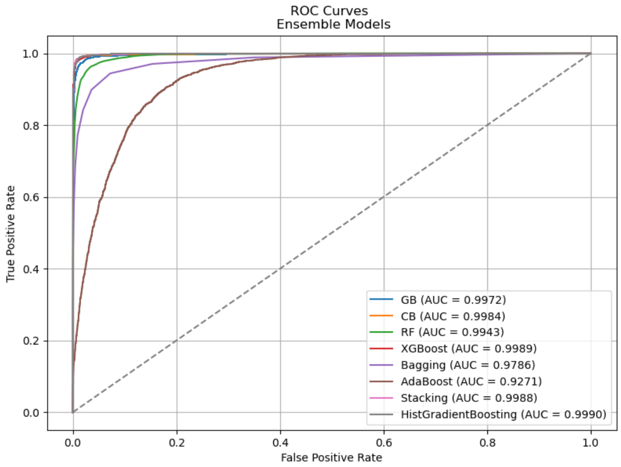
Fig. 3. The performance of several classifiers on the dataset.



(a) Build and run times of several classifiers.



(b) ROC values for classifiers.

Fig. 4. Performance analysis of models.

The methods described herein employ datasets with substantial variation in word count, which spans from 3,142 to 40,000. This discrepancy is indicative of the vast and varied scale of the document corpora under investigation. Prominent feature extraction methodologies include modified spatial co-occurrence functions (SCF), stroke-based techniques, curvelet transforms, combinations of zoning and centroid features, low-level features, zoning features, and gradient features. Moreover, the integration of ensemble techniques, exemplified by the proposed method, encompasses a multitude of low-level characteristics, including those based on shape, region, and descriptors.

Hidden Markov Models (HMM), Support Vector Machines (SVM), k-Nearest Neighbors (KNN), gradient-boosted decision trees, Multi-Layer Perceptrons (MLP), XGBoost, and CatBoost are among the classifiers utilized in the assessed methodologies. The aforementioned classifiers demonstrate an extensive array of algorithmic methodologies, which accurately represents the intricate demands of document analysis across various scripts.

One crucial metric for evaluating the effectiveness of the suggested methodologies is accuracy. The range of obtained accuracy values is between 85.6% and 97.7%. The performance of the proposed method, which employs a feature-based ensemble approach for Assamese script recognition, is noteworthy. By attaining an accuracy of 97.7% with CatBoost and 96.0% with XGBoost, this ensemble method solidifies its position as a formidable competitor within the realm of script recognition methodologies.

VII. Conclusion

The investigation of Assamese word recognition demonstrated superior performance in terms of F1-scores, accuracy, precision, and recall. This was achieved by utilizing ensemble methods and feature extraction techniques, with a specific focus on the effectiveness of CatBoost and XGBoost.

The research inquiry has emphasized the findings regarding the efficacy of different ensemble methods, particularly in the identification of Assamese words. Furthermore, it is emphasized that although AdaBoost and Random Forest can be effective alternatives, especially in scenarios with limited computational resources, they demonstrate slightly lower performance metrics compared to CatBoost and XGBoost.

The methodology's resilience and practicality are showcased by employing a comprehensive dataset comprising 10,000 words and diverse feature extraction methodologies.

A significant advancement in the field of computational linguistics has been achieved by successfully developing a method for recognizing Assamese words. This has resulted in the promotion of technological diversity across different languages.

VIII. Future Work

This study presents various opportunities for future research. An important focus is the incorporation of deep learning methods to improve the process of extracting distinctive characteristics and accurately categorizing Assamese words. Investigating recurrent neural networks and convolutional neural networks has the potential to yield substantial enhancements. Moreover, augmenting the dataset to encompass a wider range of handwriting styles and integrating multi-script recognition systems would significantly bolster the model's resilience. Finally, exploring the practical and influential application of these models in real-time on mobile devices and web applications would be a worthwhile direction.

IX. Conflict of Interest

The authors declare that there is no conflict of interest.

***Abstract*—In the era of Microblogging and the rapid growth of online platforms, an exponential rise is shown in the volume of data generated by internet users across various domains. Additionally, the creation of digital or textual data is expanding significantly. This is because consumers respond to comments made on social media platforms regarding events or products based on their personal experiences. Sentiment analysis is usually used to accomplish this kind of classification on a large scale. It is described as the process of going through all user reviews and comments that are discovered in product reviews, events, or similar sources in order to look for unstructured text comments. Our study examines how deep learning models like LSTM, GRU, CNN, and hybrid models (LSTM+CNN, LSTM+GRU, GRU+CNN) capture complex sentiment patterns in text data. Additionally, we study integrating BOW and TF-IDF as complementing features to improve model predictive power. CNN with RNNs consistently improves outcomes, demonstrating the synergy between convolutional and recurrent neural network architectures in recognizing nuanced emotion subtleties.In addition, TF-IDF typically outperforms BOW in enhancing deep learning model sentiment analysis accuracy.**

Keywords*—*Sentiment analysis; LSTM; GRU; Convolutional Neural Networks (CNNs); BOW; TF-IDF

I. Introduction

Using accurate and reliable methods, sentiment analysis aims to automatically determine a text's sentiment and extract meaningful information. Various methodologies, tactics, algorithms, and approaches are investigated in sentiment analysis to understand textual emotions [1]. Its main purpose is to automatically classify text into neutral, joyful, furious, sad, and other emotions in addition to positive and negative ones. Sentiment analysis is essential for evaluating consumer evaluations of products and services since it reveals customer sentiment. The system uses advanced natural language processing algorithms to categorize customer evaluations, comments, and ratings as favorable, negative, or neutral (see Fig. 1). This enables organizations swiftly assess client opinion of their products.

Sentiment analysis also examines feedback to find traits that elicit positive or negative responses. Text-based movie reviews may be automatically analyzed and classified using sophisticated computational approaches for sentiment analysis [2]. Filmmakers and consumers may better communicate and enjoy film via movie reviews. Sentiment analysis algorithms evaluate reviews' language, tone, and context to determine positive, negative, or neutral sentiment [3]. This strategy helps filmmakers and spectators understand crowd responses. Sentiment analysis gives filmmakers vital audience feedback. Positive comments help filmmakers identify their talents by highlighting audience preferences. Conversely, negative feelings indicate places for progress. This helps improve storyline, character development, and cinematography in future projects. Sentiment analysis helps viewers choose movies [4]. Potential viewers may determine whether a film suits them by reading reviews.

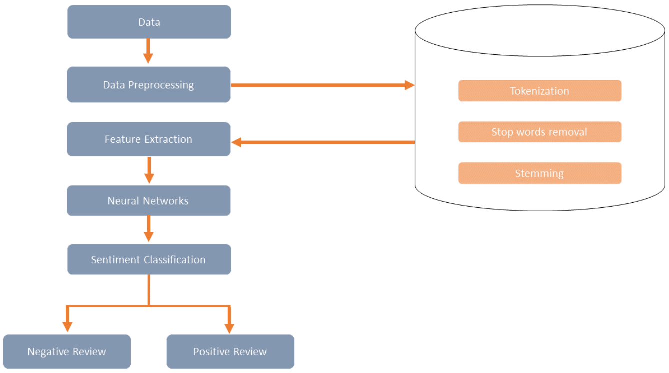

Fig. 1. Processing of DL algorithms.

An element of sentiment analysis employed in Coursera evaluations is the computerized evaluation of the emotion represented by students in their course remarks. Using ML or DL models trained on the labeled dataset, the sentiment analysis system learns to discover patterns that connect particular linguistic cues to particular sentiments [5]. The main motivation of this work is to analyze people's opinions by collecting reviews in the form of text and predicting the outcome, i.e., positive or negative reviews. Additionally, the goal is to assess the efficiency of deep learning models compared to machine learning techniques. When fresh Coursera reviews are fed into the algorithm, it forecasts the mood of each review, giving information about how students feel about the platform, instructors, course material, and more. This information can guide course improvements, influence instructional strategies, and offer valuable feedback to instructors, helping them refine their teaching methods based on learner sentiments.

The following sections offer a concise overview of pertinent details. In Section II, we examine prior research related to sentiment analysis, seeking to establish connections between existing knowledge and recent discoveries. Section III delves into the methodologies employed for this analysis, while Section IV is dedicated to detailing the dataset utilized in this paper. The conclusion of our work, along with the presentation of results, will bring this paper to a close.

A. Applications

1) Social media monitoring and brand management: Businesses use sentiment analysis to track mentions of their goods, providers of services, and brands on social media. By analyzing the sentiment of these mentions, you can gauge public perceptions, identify potential problems, and engage with your customers more effectively [6], [7].
2) Customer Opinion or Reviews: E-commerce platforms, restaurants, hotels, and other businesses use sentiment analysis to automatically process customer reviews. This helps us understand customer satisfaction, identify opportunities for improvement, and respond quickly to negative feedback [8], [9].
3) Movie and TV show review : Sentiment analysis is used to measure audience reactions to movies and TV shows, which aids in marketing and content creation [10], [11].
4) Product Development: Companies use sentiment analysis to analyze feedback and reviews of existing products, guiding improvements, and informing the development of new products that align with customer preferences [12], [13].

II. Related and Recent Work

In the recent past, the field of Machine Learning, Deep Learning, and Natural language processing (NLP) has witnessed a notable rise in sentiment analysis. With the huge expansion of textual information on the web, there is a growing need for automated tools that can accurately identify sentiment and emotional nuances within text. This increased focus on sentiment analysis has spurred the development of various novel methods and techniques that make use of deep learning models' capabilities to extract intricate sentiment insights from text data. These advances allow many applications, from social media sentiment analysis to corporate customer sentiment analysis. Here, we shall explain the recent contributions that have had a major influence on this subject and their relevance.

The work by Vateekul [14] used LSTM and DCNN deep learning algorithms on a Thai Twitter dataset. Deep learning outperformed several classic machine learning methods, according to their results. A reduced feature set and dimensionality reduction approaches were used in Akmal et al.'s clustering algorithm for emotional analysis [15]. The authors used deep learning to analyze sentiment in COVID-19 reviews [16], [17]. Their method uses an LSTM-RNN network and attention layers to improve features.For aspect extraction and emotion classification. A multitask learning technique was proposed by Akhtar et al. [18]. The extraction and sentiment categorization of aspects are seen to be separate activities. CNNs and BI-LSTMs execute the duties. The BI-LSTM layer infers Beginning and interior tags for each word using word embeddings to identify aspect keywords in a review sentence. Use a masking layer to remove non-aspect words from a text.

To extract sentiments from consumer evaluations about various characteristics of items, Pham and Le [19] used a multilayer architecture based on recurrent neural networks (RNNs). Their approach was used to examine 174,615 reviews relating to 1,768 hotels on tripadvisor.com. The results show that their technique has a lot of potential for sentiment analysis and hotel rating prediction. In this domain, Hassan and Mahmood used a hybrid technique that blends CNN and RNN architectures. They begin by training word embeddings with an unsupervised NLP model that has previously been fine-tuned on a large dataset. Following that, they use the capabilities of CNN for feature extraction and RNN for capturing interdependencies to detect sentiments in a variety of datasets [20].

We previously covered sentiment analysis using machine learning techniques [21] on similar datasets, as well as data cleaning and feature extraction, and this project serves as an expansion, digging into sentiment analysis using deep learning. Our findings reveal that machine learning models like Random Forest models demonstrate competitive performance, especially in scenarios with limited data. However, deep learning models, outperform Random Forest as the dataset size increases. We discuss the trade-offs between interpretability and performance, as Random Forest provides explicit feature importance, while deep learning models offer superior representation learning capabilities.

III. Methodology

This section offers a detailed overview of the approach employed for Sentimental Analysis using the neural networks.

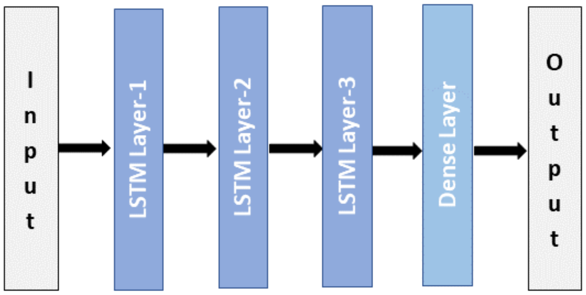

Fig. 2. LSTM Architecture.

A. LSTM

Long Short-Term Memory (LSTM) is a type of sophisticated recurrent neural network (RNN) crafted for proficient sequence modeling and prediction, mitigating the challenges of vanishing gradients in extended sequences [22]. In our model, first, we take input and pass it to LSTM Layers. Fig. 2 illustrates the three LSTM layers in our model. The first layer of the LSTM, Layer 1, has 32 units and returns sequences, passing on its output sequences to the subsequent layer. Layer 2, on the other hand, has 64 units and likewise returns sequences. Layer 3, on the other hand, has 128 units and does not return sequences, resulting in a fixed-size output. Data is eventually passed to a dense layer with 64 units and the ReLU activation function since it was an output layer for binary classification [23]. The output layer additionally has one neuron with a sigmoid activation function.

B. GRU

One type of specialised recurrent neural network (RNN) is the gated recurrent unit (GRU). The unique way that a GRU manages the temporal flow of information sets it apart from other RNN designs, such the Long Short-Term Memory (LSTM) network. The two gates that GRU uses to regulate information flow within the network are an update gate and a reset gate. This architectural simplicity of the GRU contributes to its ease of training and reduced susceptibility to overfitting, particularly in scenarios characterized by limited data [24]. The model that we used, contains three GRU layers as illustrated in Fig. 3. The first and second layer contains 32 and 64 units as well as return sequences, whereas the third layer contains 128 units with no return sequences. Subsequently, it is forwarded to a dense layer comprising 64 units, employing the ReLU activation function. The final layer is made up of a single neuron that has sigmoid activity, serving as the output layer for binary classification.

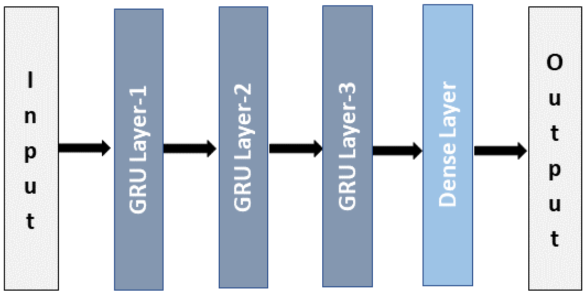

Fig. 3. GRU Architecture.

C. CNN

Convolutional neural networks, or CNNs for short, are a kind of Deep Learning neural network design that is frequently used in sentiment analysis, picture categorization, and other related applications. Convolutional neural networks, or CNNs, are known to be composed of several layers, including the input, convolutional, pooling, and dense layers. While the Pooling layer reduces the dimensions to lessen computational overhead, the Convolutional layer uses filters to extract features from the input. Ultimately, the fully connected layer is responsible for generating the final prediction [25]. In our model, the first layer is input layer which processes data with given shape and serves as entry point for review. Convolutional Layer 1, the next layer, has 32 filters, a 3×3 kernel, and ReLU activation. Using this, we then employed pooling. This pooling helps to reduce the size. Average and max poolings are the two main categories of pooling. Since max pooling performs better than average pooling and aids in the extraction of more significant features, we employed it with the default size. This process is repeated with Convolutional Layer 2, which has 64 filters, and then with an additional Convolutional Layer 3 using 128 filters. Convolutional layers extract various layers of information from the input. The main reason of using activation function as ReLU over other activation functions, i.e., Sigmoid, tanH and Softmax is that it does not activate all neurons at the same time. The output will be sent to the dense layer once the text has been processed via all of the pooling and convolutional layers. Since the dense layer requires input in the form of a 1-D array, we are unable to pass the convolutional layer's multi-dimensional output straight to it. To overcome this, we used the Flatten method between the dense layer and the convolutional layer. Finally, we used a dense layer to classify sentiment from convolutional layers as shown in Fig. 4. In our model, Since the output layer was intended for binary classification, it has one neuron with sigmoid activation function.

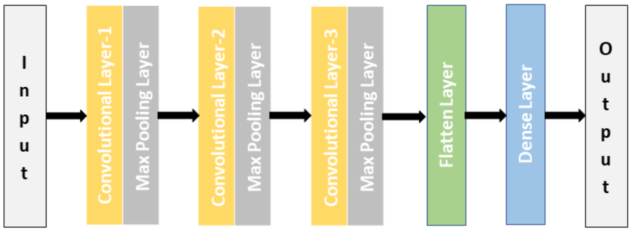

Fig. 4. CNN Architecture.

D. GRU+LSTM

As widely acknowledged, the Gated Recurrent Unit (GRU) is considered a highly promising algorithm within the realm of Recurrent Neural Networks (RNNs). In terms of functionality, both GRU and LSTM share similarities, However, GRU unifies the forget gate and input gate into a single update gate, using a single hidden state. Moreover, GRU creates a single state by merging the concealed state with the cell state. This efficient approach has led to GRU being recognized as a simplified variant of LSTM [26]. The model we have employed incorporates an initial layer with a single GRU layer containing 32 units and a return sequence. The subsequent layer features an LSTM layer with 64 units, also with a return sequence. We have added layer with a GRU and 128 filters the result then uses the ReLU activation algorithm to advance to a dense layer with 64 units. The final layer remains consistent with other hybrid models as depicted in Fig. 5.

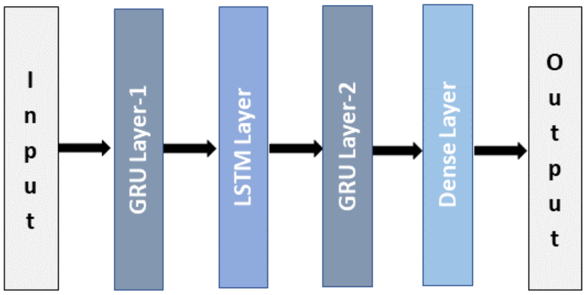

Fig. 5. GRU+LSTM Architecture.

E. CNN+LSTM

A Convolutional Neural Network (CNN) operates on sequential data by employing sliding convolutional filters over the input, enabling it to capture features from both spatial and temporal dimensions. In contrast, an LSTM network processes sequential data by iterative processing time steps, capturing long-term dependencies between them. A CNN-LSTM network combines convolutional and LSTM layers to effectively extract insights from training data [27]. In our model, The initial layer serves as the input layer, processing data with a specified shape. Following this, The first Convolutional Layer is then presented; it has 32 filters and uses a 3×3 kernel with activation as ReLU. After this operation, we apply pooling. This sequence is then replicated with Convolutional Layer 2, which incorporates 64 filters, and subsequently with an additional Convolutional Layer 3, utilizing 128 filters. Following the passage through the pooling and convolutional layers, the data is directed to the LSTM Layer, housing 64 units with a specific activation function. Subsequently, the output moves on to a 64-unit dense layer, employing the ReLU activation function. The final layer is composed of a 1 neuron utilizing a sigmoid activation function as illustrated in Fig. 6, which is ideal for binary classification, serving as the output layer.

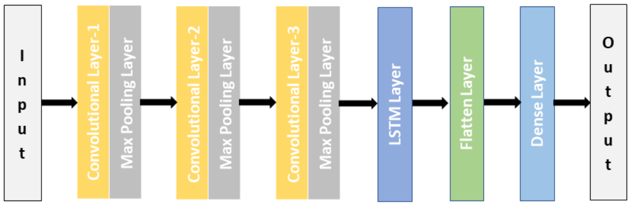

Fig. 6. CNN+LSTM Architecture.

F. GRU+CNN

The combination of CNN and Gated Recurrent Unit (GRU) components is our next hybrid model. The predictive performance of this dual-architecture method is enhanced. It also lessens the chance of overfitting and it is a novel work for the four different datasets in the context of sentimental analysis. The model we utilized, which is seen in Fig. 7, starts with a GRU (Gated Recurrent Unit) layer with 32 units and return sequences. Next, we add convolutional operations to the network by incorporating a Conv1D layer, which has 64 filters and a kernel size of 3. We next add another 128-unit GRU layer to the sequence, which is followed by a 64-unit dense layer with a ReLU activation function. Last but not least, we include a single-unit output layer and use a sigmoid activation function for binary classification.

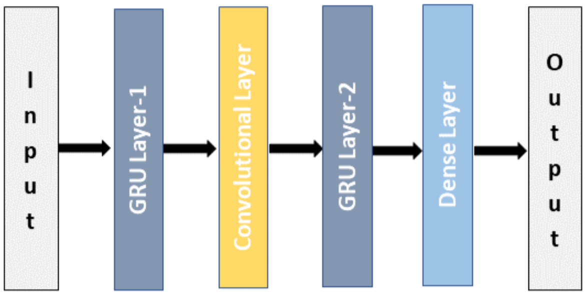

Fig. 7. GRU+CNN Architecture.

IV. Dataset Statistics

In our study, we harnessed a diverse array of four datasets to embark on comprehensive sentiment analysis. These datasets were meticulously selected for their relevance and diversity, thereby encompassing a broad spectrum of reviews from various domains. To elucidate further, the initial dataset centered around Movie Reviews and contained $34,000$ entries. Our second dataset, Coursera Reviews, proved to be expansive, comprising a total of $107,018$ reviews. Additionally, the Google Play Store Reviews dataset, our third one, provided valuable insights into the realm of mobile applications with its $12,485$ reviews. Lastly, the fourth dataset, Flipkart Reviews, encompassed a total of $9,976$ reviews, revealing a distinct polarity in emotional sentiment. This carefully curated assortment of datasets serves to ensure that our sentiment analysis model receives training from a diverse collection of linguistic expressions and contextual subtleties. There are $16,993$ instances of 0s and $17,007$ instances of 1s in the Movie Reviews data collection. There are $102,298$ occurrences of 0s and $4,720$ occurrences of 1s in the Coursera Reviews data set. There are $7,635$ instances of 0s and $4,850$ instances of 1s in Google Play Store Reviews. Finally, there are $8,975$ instances of 0s and $1,001$ instances of 1s in the Flipkart Reviews data set. Within their individual data sets, these binary values most likely indicate specific features or emotion labels connected with each review.

Formally, within a provided training dataset of reviews and their associated sentiment labels, a sentiment score of $'1'$ signifies a negative review, while a score of $'0'$ designates a positive one. We aim to characterize the feelings included within the supplied text collection appropriately.

A. Steps to Perform

In our research, we followed a structured process to prepare and preprocess our dataset [28].

- Data Cleaning: Special Character Removal: In this step, you remove special characters such as symbols, emojis, or any characters that don't contribute significantly to the text's meaning. This can be done using libraries like NLTK (Natural Language Toolkit) or regular expressions. Punctuation Removal: Similar to special characters, punctuation marks like periods, commas, and exclamation marks are often removed as they can add noise to the text.

- Tokenization: Dividing each sentence into individual words or tokens. For the majority of natural language processing (NLP) activities, this is a fundamental step.

- Stemming: The process of reducing words to their root or basic form is known as stemming. For instance, the terms “running,” “ran,” and “runs” may all have the same root, “run”. This can increase processing efficiency and aid in lowering the dimensionality of the text data.

- Feature Extraction: After that, we used Bag of Words and TF-idf (Term Frequency-Inverse Document Frequency) feature extraction methods to quantitatively represent text data for deep learning or machine learning models. TF-idf weighted words by importance in documents, while Bag of Words employed word counts to vectorize the text. Our data was better after these pretreatment stages and suitable for study analysis and modeling.

Bag-of-Words (BoW) characteristics were an important text analysis tool. BoW includes accumulating words to extract traits from text materials. For model training, a thorough vocabulary of different concepts from all training dataset records is needed. To facilitate text mining and information extraction, we used TF-IDF as a text data weight analysis approach. The significance of each word in a document is measured by TF-IDF. It normalizes word frequency according to text length, making it suitable for diverse document sizes. Additionally, TF-IDF rates each word's importance in a publication. Since it examines term frequency and normalizes it by text length, it works for a variety of document sizes. Furthermore, when determining the frequency with which a term appears in a particular text, TF (Term Frequency) accounts for changes in document lengths. On the other hand, IDF compares a word's meaning throughout the corpus to common, meaningless phrases like "that," "of," and "is". We may eliminate extraneous terms and concentrate on the most pertinent ones thanks to this strategy.

V. Results

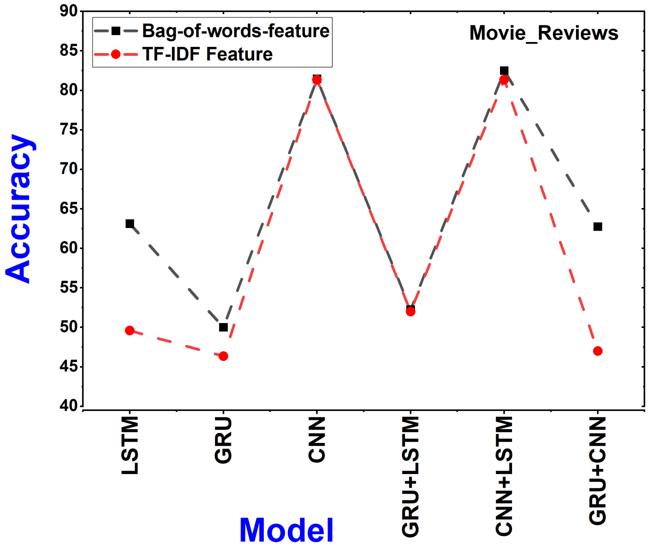

Fig. 8. Using six different DL algorithms with TF-IDF and Bag of Words, the accuracy score for movie reviews.

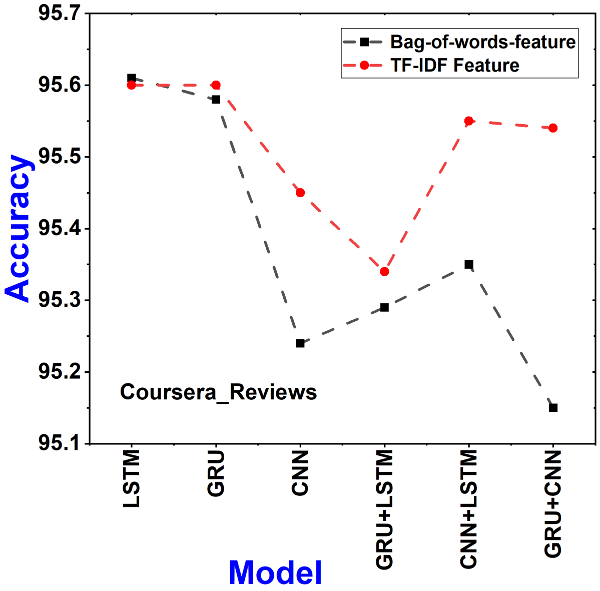

Fig. 9. Accuracy score for coursera reviews using six DL algorithms with TF-IDF and bag of words.

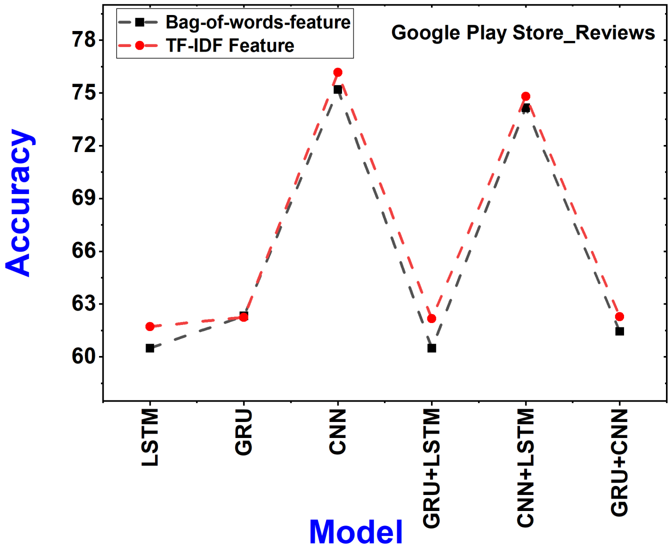

Fig. 10. Six DL algorithms with TF-IDF and bag of words were used to calculate the accuracy score for reviews on the google play store.

In this section, following the training of six distinct deep learning models (LSTM, GRU, CNN, LSTM+GRU, CNN+LSTM, and CNN+GRU), it became evident that the CNN+LSTM model consistently achieved higher accuracy scores across all the datasets, i.e., Movie, Coursera, Google Play Store, and Flipkart reviews compared to other deep learning models. The outcomes are displayed in Fig. 8, 9, 10, 11. Accuracy utilizing deep learning methods for different data sets is shown in Table I. We also observed that when the data set contains more reviews, deep learning models are more accurate in predicting compared to machine learning models. While CNNs on their own are typically not anticipated to surpass LSTM or GRU in terms of sentiment analysis performance due to their limited capacity to capture sequential dependencies, the combination of CNNs with RNNs, like CNN+LSTM often proves to be more effective than standalone models, shown in the Fig. 8, 9, 10, 11. Because these models can leverage the strength of CNNs in capturing local patterns and combine it with the sequential modeling capabilities of LSTMs. The

TABLE I. Accuracy Utilizing Deep Learning Methods for Different Data Sets

Model	Features	Movie	Coursera	Google Play Store	Flipkart
LSTM	Bag-of-words-feature	63.12	95.61	60.49	89.38
	TF-IDF Feature	49.59	95.60	61.72	89.94
GRU	Bag-of-words-feature	50.00	95.58	62.33	87.35
	TF-IDF Feature	46.34	95.60	62.25	88.91
CNN	Bag-of-words-feature	81.46	95.24	75.20	92.18
	TF-IDF Feature	81.34	95.45	76.16	93.08
GRU + LSTM	Bag-of-words-feature	52.25	94.29	60.49	82.42
	TF-IDF Feature	52.0	95.34	62.17	87.88
CNN + LSTM	Bag-of-words-feature	82.50	95.35	74.16	92.25
	TF-IDF Feature	81.36	95.55	74.80	93.45
GRU + CNN	Bag-of-words-feature	62.75	95.15	61.45	89.38
	TF-IDF Feature	47.00	95.54	62.28	89.97

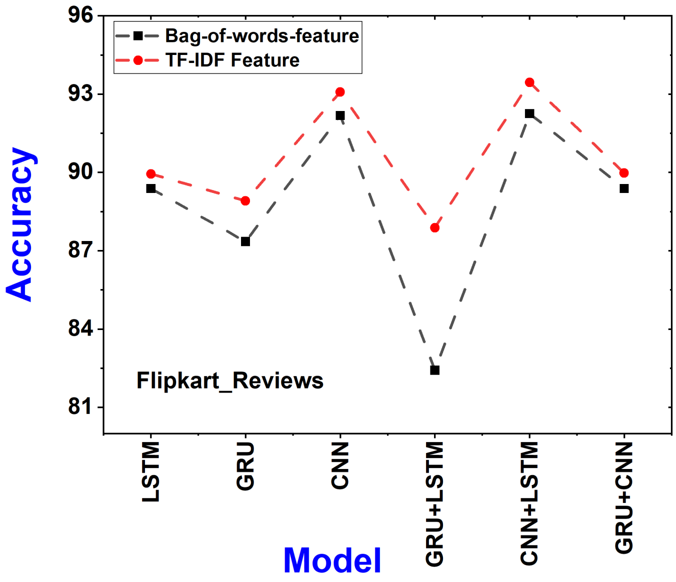

Fig. 11. The accuracy score for flipkart reviews is based on six DL algorithms, including bag of words and TF-IDF.

CNN component is capable of extracting high-level textual features, whereas the LSTM excels at capturing long-term dependencies. We also observed that the Combination of CNN with LSTM performs better than the combination of CNN with GRU. Also, we observed the combination of GRU+ LSTM will not lead good results compared to other deep learning models. This is due to a combination of both GRU and LSTM, which are similar in their functioning, and combining them does not introduce a significantly new perspective for sentiment analysis. Also, we can say that when CNNs are used for text-based tasks, they are typically employed in combination with RNNs or as part of more complex architectures, such as the Attention-based models, Transformers, or BERT-based models. These designs have performed admirably in a variety of NLP tasks, including sentiment analysis, by capturing both local and global patterns in text data. Ultimately, it was observed that Deep Learning models (LSTM, GRU, CNN, LSTM+GRU, CNN+LSTM, and CNN+GRU) outperform machine learning techniques (Logistic Regression, KNN Classifier, Bernoulli Naive Bayes, Multinomial Naive Bayes, XGBoost, Decision Tree, Random Forest Classifier) in the prediction of sentiment analysis. We also notice that these models yield improved results when utilizing the TF-IDF feature extraction technique.

In addition to the previously mentioned findings, it is noteworthy to highlight the quantitative performance of the proposed CNN+LSTM and CNN+GRU models in comparison to other state-of-the-art deep learning algorithms across diverse datasets, namely Movie, Coursera, Google Play Store, and Flipkart. The assessment was conducted using both bag-of-words and TF-IDF features to comprehensively evaluate the models' capabilities.

The CNN+LSTM model, leveraging bag-of-words features, exhibited commendable accuracy scores of 82.50, 95.35, 74.16, and 92.25 across the respective datasets. Employing TF-IDF features, the CNN+LSTM model demonstrated consistently high accuracy scores of 81.36, 95.55, 74.80, and 93.45, except in the Movie review dataset, where TF-IDF slightly outperformed bag-of-words. Notably, in the Movie review dataset, bag-of-words not only outperformed TF-IDF for the CNN+LSTM model but also surpassed the other five algorithms in accuracy.

In stark contrast, the GRU+LSTM model, when utilizing bag-of-words features, showed lower accuracy scores of 52.25, 94.29, 60.49, and 82.42 across the Movie, Coursera, Google Play Store, and Flipkart datasets, respectively. Similarly, with TF-IDF features, the GRU+LSTM model exhibited accuracy scores of 52.0, 95.34, 62.17, and 87.88. It is noteworthy that, compared to the other 5 DL models, the performance of the GRU+LSTM model is relatively poor.

VI. Conclusions

This article compares and contrasts sentimental categorization and analysis using several Deep-learning techniques that are currently available. Finally, several significant insights are shown by Table I of model accuracies based on different features and datasets. TF-IDF features are superior to Bag-of-Words features in capturing the nuances of the text data, as demonstrated by the consistently superior performance of the models that used them. The GRU with TF-IDF features and the CNN with TF-IDF features demonstrated the highest accuracies across the separate models across several datasets, demonstrating their efficacy in sentiment analysis tasks. In the realm of sentiment analysis, deep learning models exhibit superior performance when contrasted with traditional machine learning models across various domains, including reviews on Coursera, Flipkart, movies, and the Google Play Store. It's important to remember, though, that the model's performance varied greatly based on the dataset that was employed.

The majority of the models in the data from the Coursera and Google Play Store had consistently excellent accuracy scores, whereas the Movie dataset had lower accuracy ratings. Additionally, Flipkart data showed that different models performed differently, with some doing remarkably well and others having difficulty. The performance of the combination models, like CNN + LSTM and GRU + CNN, was frequently good, demonstrating the advantages of integrating several neural network architectures for improved sentiment analysis. In actuality, the model and feature representation used should be based on the needs of the particular dataset and application. Even if TF-IDF features work well most of the time, they might not be the ideal option every time. Deep learning excels in sentiment analysis by automatically learning intricate patterns, capturing contextual dependencies, and enabling end-to-end feature extraction. Hierarchical feature learning and adaptability to diverse data types make deep learning models like CNNs and LSTMs effective, the unique properties of the data should be taken into account while deciding between combination models and individual models. Future work should explore enhancing the interpretability of deep learning models in sentiment analysis, addressing its nature through methods like attention mechanisms. Investigating efficient training strategies, and data-efficient approaches, and applying novel architectures, including transformer-based models, will contribute to advancing the field and making deep learning more accessible for sentiment analysis tasks.

Predictive Modeling of Landslide Susceptibility in Soft Soil Canal Regions: A Focus on Early Warning Systems

Dang Tram Anh, Luong Vinh Quoc Danh, Chi-Ngon Nguyen*
Can Tho University, Can Tho City, Vietnam

***Abstract*—The Mekong Delta (MD) has suffered significant losses in land resources, economic damage, and human and property casualties due to recent landslides. An early warning system for landslides is a valuable tool for identifying the effectiveness and timely detection of changes in the soil to promptly determine solutions and minimize damage caused by landslides in an area. In this study, we apply a machine learning approach based on the Long Short-Term Memory (LSTM) algorithm to experiment with early warning of landslide events on soft soil in the MD. Horizontal pressure, the change in inclination angles of the sensor pile due to the soil mass sliding in both the x and y directions, and the warning levels are determined based on the deformation and displacement of the soil along the riverbank, considered candidate factors for inputs in the model. Data from the established sensor system is used to train the model, creating a training and testing dataset of 374,415 samples. The accuracy of the detection and classification threshold of the system is proposed to be measured using the average F1 score derived from precision and recall values. The optimal prediction results are gleaned from an observational window of 4 minutes and 30 seconds to project roughly 2 hours into the future. The validation process resulted in recall, precision, and F1-score stands at 0.8232 with a remarkably low standard deviation of about 1%. The successful application of this research can help identify abnormal events leading to riverbank landslides due to loading, thereby creating conditions for developing a reliable information system to provide managers with the ability to suggest timely solutions to protect the lives, property of residents and infrastructures.**

Keywords*—Landslide early warning; soft soil; Mekong Delta; long short-term memory

I. Introduction

Landslides represent a formidable global challenge, exerting a profound toll on economies, depleting natural resources, and tragically affecting human lives [1], [2]. Despite their localized occurrence, the ramifications of landslides extend far beyond their immediate vicinity, resulting in significant devastation to vital infrastructure elements such as roads, bridges, and power lines. This, in turn, leads to the distressing loss of land, homes, and, most tragically, human lives [3]. Vietnam in Southeast Asia bears witness to a history marked by a succession of natural disasters, including but not limited to floods, the encroaching threat of rising sea levels, shifts in climate patterns, coastal erosion, and the peril of landslides. Among the vulnerable regions, the Mekong Delta stands out, situated in the southern expanse of the country, densely populated yet perilously exposed to the caprices of nature. Its topographical identity is characterized by extensive low-lying stretches, intricately interlaced with an intricate network of rivers, canals, and verdant wetland areas, rendering it particularly susceptible to the forces of erosion and inundation.

The Mekong Delta region experiences a notable uptick in landslide occurrences, a trend that tends to peak during the rainy months. This phenomenon is intricately linked to the seasonal patterns of precipitation and the unique geological characteristics of the area. As moisture-laden rains saturate the soil and increase the weight and pressure on slopes, the propensity for landslides escalates. This heightened vulnerability underscores the need for vigilant monitoring and proactive mitigation measures to safeguard the natural landscape and its communities. According to the statistical data provided by the National Steering Committee for National Disaster Prevention and Control - Vietnam [4], until September 2023, there have been 558 locations of riverbank landslide within the area, resulting in a total affected and lost land length of over 740 km. Among these are 81 hazardous landslide sites and 137 high-risk landslide sites, causing damage to over 200 houses, residents' properties, and infrastructure worth thousands of billions of Vietnamese dong (VND).

Throughout the initial nine months of 2023, Can Tho City, situated among the thirteen provinces in the Mekong Delta region, bore the brunt of an alarming surge in landslides. This period witnessed an unsettling total of over 30 landslide incidents. These events led to injuries sustained by two individuals, the complete submersion of eight houses into the river, partial collapses, and grave impacts on 19 other residences. The cumulative length of the riverbank affected by these events totaled 1976 meters. Furthermore, the region has grappled with an escalating frequency of landslides in recent years, a trend partly attributed to the transformative impact of human activities and urban development encroaching upon riverine areas, thereby altering the natural landscape [5]. This surge in landslide occurrences has had far-reaching consequences, significantly and adversely affecting the lives of local residents and impeding the region's broader socio-economic development.

A preliminary assessment by domestic experts on the causes of erosion and instability of riverbanks and coastlines in the Mekong Delta region indicates that erosion at the base of the slope, saturated slopes after prolonged heavy rains or floods, and variations in groundwater levels are the primary factors contributing to slope instability along the riverbank [6], [7]. In addition to these long-term causes, the load of the structure, particularly the dynamic load induced by traffic,

*Corresponding authors.

can act as triggering factors for landslides [8], [9]. The complex relationships between landslide disasters and the factors that trigger them remain unclear. This complexity makes it challenging to analyze these mechanisms of landslides using simple algebraic equations [10]. Hence, predicting the ground's stress behavior and the soil mass's displacement along the riverbank becomes crucial and challenging.

The exploration of landslide risk assessment commenced in the 1970s [11]. Since then, propelled by advancements in modern statistical science and the advent of machine learning techniques, deep learning has become a vital tool in landslide research, particularly for landslide detection [12], [13], [14], [15]. While conventional approaches often treat landslide displacement prediction as a static regression problem, it is imperative to acknowledge that landslides are dynamic systems. The influencing factors and displacement conditions at one moment profoundly influence the subsequent moment. Thus, an effective landslide displacement prediction model should integrate susceptibility modeling, which considers the accumulation of variables over time.

The primary objective of this research is to present a predictive model for landslides utilizing advanced deep learning. The approach is rooted in the integration of input data, which encompasses variables such as soil pressure, incline in the x and y directions, alongside temporal factors. By harnessing machine learning algorithms, the primary aim of this work is to unravel the intricate interplay between these input parameters and their consequential impact on riverbank landslides. In the context of this study, a specialized form of recurrent neural network known as LSTM neural network was utilized to predict the progression of landslide events, extracting profound insights from time series data. This architectural framework excels in capturing complex patterns and temporal relationships in sequential data, providing favorable conditions for the development of a robust reduction framework. To facilitate the landslide prediction experiments, this study deployed a data collection system based on sensors. Through training on the gathered dataset, the model has demonstrated effective predicting capabilities for early warning of landslide phenomenon through training on the gathered dataset.

The underlying objective of the research is to study the performance of deep learning neural networks like LSTM to devise an early warning landslide system. The model is evaluated in term of accuracy on the dataset collected from the various experiments along the riverbank. In Section II we have discussed the related work. Section III explains the sources of collected dataset, the adopted methodology, the evaluation method and discusses the results in the study. Section IV is the conclusion of study.

II. Related Works

Recent machine learning and neural network breakthroughs have prompted extensive research, with CNNs being favored for their effectiveness in diverse applications. By utilizing neural networks, many researchers have developed landslide susceptibility maps and spatial modeling of landslides in highly prone mountainous areas using artificial neural networks [12], [16], [17], [18], [19], [20], [21]. Applying machine learning techniques along with GIS information [15], nonlinear spatial models have been created [22]. Neural Networks [23], [24], [25], [26], Boosted Regression Trees [27], [28], the Wavelet Transform model [29], [30] and Random Forest [31], [32], [33] are among the AI algorithms applied to tackle the intricate problems of landslide assessment. The Random Subspace Space Fuzzy Rule-based Classifier (RSSCE) is utilized to predict landslide occurrences based on the analysis of rainfall data triggered by heavy rainfalls in hilly areas [34], [35].

Research on landslide displacement prediction has indicated that utilizing deep learning on time series data, specifically the Long Short-Term Memory (LSTM) model, offers accurate forecasts [36]. LSTM's ability to capture historical information reduces the complexity of triggering factors, making it suitable for predicting landslide trends. Its performance in identifying these factors based on spatiotemporal sensor data demonstrates its superiority over other algorithms [37]. By extracting precise correlations between temporal and spatial data, LSTM has captured intricate time-dependent dependencies, outperforming traditional mechanical models [38]. The study in the Three Gorges Reservoir area, based on experimental mode decomposition and LSTM, has demonstrated superior accuracy compared to other static models in landslide displacement prediction [39]. Besides, [40] also proposes a novel coupled method using LSTM neural networks and support vector regression (SVR) algorithm, focusing on decomposing cumulative displacement into trend and periodic terms. The author introduces ensemble models based on SVR to optimize the combination of LSTM and SVR results, aiming for better accuracy in landslide predictions. The research on the mechanisms of damage and long short-term memory model for landslide prediction aims to address surface degradation phenomena, focusing on short-term impacts. The study emphasizes the effectiveness of LSTM in predicting landslide behavior and assessing damage based on joint distribution characteristics in building disaster prediction models [41]. These studies have applied the LSTM model based on various data such as rainfall, reservoir level, change in reservoir level, humidity, elevation, and displacement. The prediction results have observed that the prediction performance of the LSTM model is suitable and superior to static models like SVR, BP, SVM, ARMA, and even the dynamic Elman model.

Besides, combined models have been highly successful in fields such as flooding [42], [43] and drought [44], which has led researchers to explore ensemble modeling in landslide prediction as well. Risk analysis and forecast of landslide hazards using LSTM-RNN and DBA-LSTM models based on rainfall changes and water level variations have shown high accuracy [45], [46]. Researchers have used the original sequence of landslide displacement as input for combined machine learning models to predict the movement of landslides in steep slopes [47], [48], [49], [50]. The prediction of landslide movement in the major branches of the Three Gorges Dam area in China is carried out through combined models such as LSTM-TAR VMDstacked, LSTM-FC models, and LSTM models combined with Weighted Moving Average (WMA) using rainfall and reservoir water level data in each cycle with high accuracy [50], [51]. A prediction model for slope displacement based on the LSTM neural network and the Singular Spectrum Analysis (SSA) algorithm, using survey and geotechnical monitoring data, has significantly improved the model's performance in the dataset for predicting displacement within the next 24 hours

[52]. Landslides are likely to occur more frequently, along with climate change and the increasing surface loads caused by human activities.

In general, the conducted studies have been carried out in mountainous areas with a geological structure of loose rock. The primary factors causing landslide movements are mainly related to the permeability of the surface soil layer on the slope due to rainfall. In contrast to the riverbank landslides in the Mekong Delta, where the substrate is composed of alluvial deposits, young deltaic sediment, and riverbank soil with a predominantly geological structure of clayey soil, which is soft and weak. Additionally, factors contributing to riverbank landslides can arise from various causes: the inherently weak and saturated soil substrate with poor load-bearing capacity, subsurface erosion, changes in groundwater levels along the riverbank resulting in seepage flow, and human activities (such as construction and traffic), depicted in Fig. 2a. The studies on data collection systems based on modern sensor technologies or remote sensing techniques to generate databases for training landslide prediction models are presented in Table I and Table II. Thus, the need for early warning to assess the stability of slopes is becoming imperative [53]. Despite the extensive use of LSTM algorithms for landslide prediction in mountainous terrains with rocky geological structures, they have not been applied to predict riverbank landslides occurring in soft soil formations.

In this study, a new method to predict riverbank landslides using deep learning combined with data collected from sensors was proposed. To facilitate this, an Internet of Things (IoTs) - based sensor data collection and monitoring system have been implemented at the experiment sites along the riverbank within the Mekong Delta region. The collected data is used for training the LSTM machine learning algorithm to predict the possibility of riverbank slope instability for the purpose of early warning of riverbank landslides.

III. Methods

A. System Architecture for Predicting Landslides

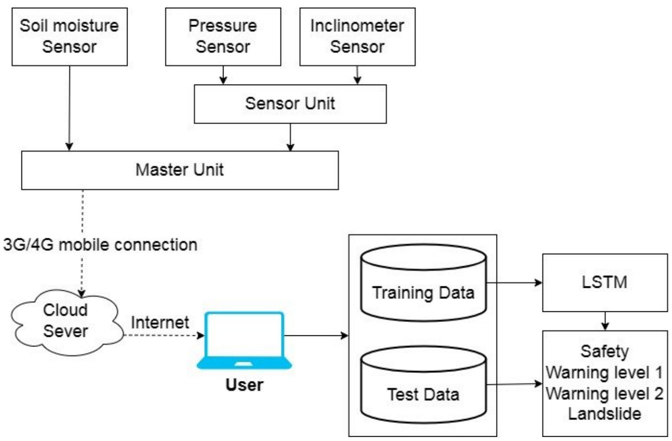

Fig. 1. System architecture for predicting landslides.

The architecture of the landslide prediction system is presented in Fig. 1. Our endeavor revolves around establishing a cutting-edge data collection framework focused on a diverse array of sensor devices. These instruments encompass a range of measurements, from monitoring soil moisture and inclination to gauging soil pressure. Central to this intricate setup is the Master Unit, a pivotal component acting as the central hub where these distinct sensors seamlessly converge to facilitate the precise acquisition of data. The Master Unit is a testament to seamless integration, meticulously designed to aggregate data from various sources with exceptional precision and efficiency.

In our commitment to ensure the accessibility and continuous availability of this data, we have dedicated substantial effort to engineer a robust data transmission mechanism. This designed system leverages the high-speed capabilities of 3G and 4G connectivity, enabling the collected data to be transferred from the Master Unit to our designated server. This data transmission process is characterized by its exceptional reliability and speed, forming an essential bridge that connects the physical realm of sensor data with the digital domain and ensures that this critical information is delivered promptly and with utmost accuracy.

The collected dataset undergoes a data preprocessing phase. This phase involves a blend of data cleansing, transformation, and normalization, all working in concert to ensure the data's integrity and suitability for subsequent analysis. A grid search method is employed on the training dataset to determine the appropriate number of layers of the LSTM method. The training dataset is split into two parts that comprise 80% and 20% of the dataset. The first part is used for training the model, and the second part is used to test the model's predictive ability. The crux of our methodology resides in utilizing deep learning architectures: LSTM. Our predictive framework relies on this algorithm model, which is predictable in time series within sequential data. The primary objective of this study is to forecast the warning level and landslide probability at time t, utilizing current time series data. This proactive approach significantly enhances the effectiveness of relocation efforts and minimizes potential damage in the aftermath of a landslide.

B. Experimental Setup for Data Collection System

In this work, to ensure consistency with the geological reality of the study, we excavated a channel (measuring $25m \times 3m$, with a slope ratio of $H = 0.5, V = 2$ on the banks of the Cai Sau channel in Can Tho city and tested the proposed system (Fig. 3). The geology at the research location is determined to be soft soil with the following physico-mechanical parameters: soil cohesion $C = 8.1kPa$, internal friction angle $\phi = 316'$, bulk weight $w = 1.571g/cm^3$, void ratio $e = 1.808$ and its initial water contents was 67%. The sensor pile is fixed at a distance of $0.1m$ from the channel bank edge (Fig. 4). The sensor node is composed of one Master unit and a Sensor unit. The soil pressure transducer is fixed on the sensor pile and inserted at a depth of 0.2 to 0.4 meters from the ground surface. The inclination sensor is compact (5 to $8mm$ in width and $10mm$ in length), installed in a waterproof plastic tube, and fixed on the sensor pile. The inclination sensor and soil pressure transducer are connected to the Sensor unit. The other item to be measured is soil moisture using a soil moisture sensor. This type of sensor is easy to use, plugged into the soil at a depth of $0.2m$ to observe and maintain the moisture of the canal bank slope in a saturated state throughout the

testing process. Then, the Sensor unit and Soil moisture sensor are connected to the Master unit. Measurement data will be transmitted to the Cloud server via 3G/4G mobile networks by the Master unit every 60 seconds. Solar power is used to provide energy for the sensor node.

The applied load is in the form of a strip load, simulating the load of the structure along the riverbank. The pressure exerted on the canal bank is created by sandbags placed on a steel plate with an area of 0.6m x 1.4m, arranged around the sensor pile with a distance of $0.2m$ as shown in Fig. 3. The canal bank in the experimental area was saturated with artificial continuous rainfall of 15mm/h. After filling the canal with water, the canal's water level was changed in combination with waves generated (by wave generators) to create a scour hole at the base of the slope as in Fig. 2. The strip load was gradually increased until the landslide occurred. Each load level was 3.5 kPa. Data on soil pressure, pile tilt angle, and soil moisture were recorded during the experiment.

Measurement data of inclination angle and soil pressure during the destructive deformation of the ground at the pile position are shown in Fig. 5, respectively. It can be observed that the landslide occurs in a relatively short time, only a few minutes since the mechanism of landslide is sudden deformation. Values of the inclination angle in the two directions, x y, differ in magnitude and time because the sensor pile moves along with the sliding ground mass.

C. Dataset

We performed testing at 45 sites. Each experiment lasted approximately seven days. The loading and data recording started 24 hours after embedding the sensor piles into the riverbank soil mass, with the load level increasing from 3.0 kPa to 4.5 kPa at each level. Each loading level was applied for continuous 11-hour intervals. An illustrative example of a measured data set is the horizontal soil pressure recorded during the second loading phase, which was 1.16 kPa. The X and Y tilt angles showed minor variations in the first 3 hours due to soil structure consolidating pressure, increasing soil compactness at the measurement site. Loading gradually increased at specified intervals until signs of soil failure became apparent. Such data recorded at 12:35:58 on December 19, 2022, as shown in Fig. 5, indicated a horizontal soil pressure of 1.9 kPa under an applied total load of 13.5 kPa. At 22:13:28 on

TABLE II. Research on Landslides in the Mekong Delta

Research	Method	Results
Initial assessment on the causes of riverbank instability in Chau Thanh district, Hau Giang province [6].	Google Earth remote sensing images from 2006 to 2019 were used to assess the current status of riverside construction and erosion. The Analytic Hierarchy Process (AHP) was used to determine the impact levels of factors that cause riverbank instability. Using the AHP method and field survey can be extended to other areas in the Mekong Delta to analyze riverbank stability.	The survey and analysis results show that geology is the most affecting factor among the factors, and in combination with the encroaching construction of riversides to protection buffer areas, it creates the surcharge load reducing the stability coefficient of the riverbank. Besides, the curvature and flow velocity are also the causes of riverbed erosion and deformation, leading to an increase in the stiff slope which affects riverbank stability.
Analysis of factors affecting riverbank stability: case study at Cha Va river section, Vinh Long province [61].	Satellite images were loaded from Google Earth to analyze the current erosion of the river banks and the urbanization process along the river banks.	The integrated effects of soft soil, water level fluctuation, wave load, and surcharge loads is found to be the cause of instability of the Chavas river bank.
Assessment of the situation of landslides and sedimentation in the coastal area of Ca Mau and Bac Lieu province from 1995-2010 using remote sensing and GIS technology [62].	Research using remote sensing images Landsat	Assess shoreline changes erosion or deposition processes
Monitoring developments in Cu Lao Dung's coastline using remote sensing image analysis technology [63].	Multispectral Landsat images were utilizad for the analysis	Analyze erosion and deposition locations with specific values
Monitoring erosion and accretion situation in the coastal zone at Kien Giang province [64].	The study applied Normalized Difference Water Index (MNWI) method and water level extraction using LANDSAT imagery from 1975 to 2015 for highlight the shoreline.	Analysis was identified erosion and accretion areas based on shoreline changes and land use influenced by landslides and deposition

the same day, the horizontal soil pressure measured was 2.11 kPa and showed a decreasing trend. Subsequently, continuous changes in soil pressure and sensor pile tilt were observed, accompanied by the appearance of cracks on the canal bank, as shown in Fig. 4 (small cracks visible). This indicated that the soil had reached its ultimate limit state. By 23:34:58 on December 19, 2022, when the horizontal soil pressure reached 2.13 kPa, an additional loading level was applied, raising the total load to 18 kPa. The horizontal soil pressure and tilt angle remained relatively stable for about 1 hour and 30 minutes, while monitoring revealed the gradual expansion of cracks. Simultaneously, the soil pressure data showed a rapid decrease, and the tilt angle of the sensor pile experienced a sudden significant change. Finally, the canal bank slope completely slid after the horizontal soil pressure reached its peak value of 2.5 kPa. Data measured from sensors will be saved as data files on the memory card. Then, the Master device will scan the memory card and transmit the data files to the Cloud server. Users can download the measured data for analysis and real-time observation through the Web server. First, the dataset "landslide monitoring.csv" was downloaded. The monitoring dataset includes date and time, soil pressure, soil moisture, and inclination angles due to soil movement and landslides. Data was collected at one-second intervals throughout the loading experiment until the landslide occurred. We can use this data to address the prediction issue for the next two hours based on changes in ground pressure and soil displacement in the preceding hours. Next, the data was labeled and categorized according to warning levels. Then, the data was transformed into a supervised learning problem. We normalized the data for model training using a 30-second sliding window approach. After reprocessing, we obtained 374,415 samples, split into a training set comprising 70% (262,090 samples) and a test set comprising 30% (112,325 samples). The soil moisture content in the experimental conditions was always saturated; thus, this value was not included in the input dataset. There were three input variables: ground pressure (p), X-axis inclination angle (x angle), Y-axis inclination angle (y angle), warning level, and warning label arranged in 5 columns in the input data table.

D. Warning Thresholds

The calculated ultimate bearing capacity of the soil foundation using the finite element method based on geological parameters at the experimental site was determined to be 20.61 kPa. The analysis results of the finite element model under external loading show: (1) when the soil stress is below 40 percent of the ultimate bearing capacity, the soil remains in a safe state; (2) when the soil stress reaches a ratio below 70 percent of the ultimate bearing capacity, the soil starts deforming and consolidating; (3) similarly, when the ratio increases to 80 percent, the soil shows significant deformation and displacement; (4) finally, when this ratio exceeds 80

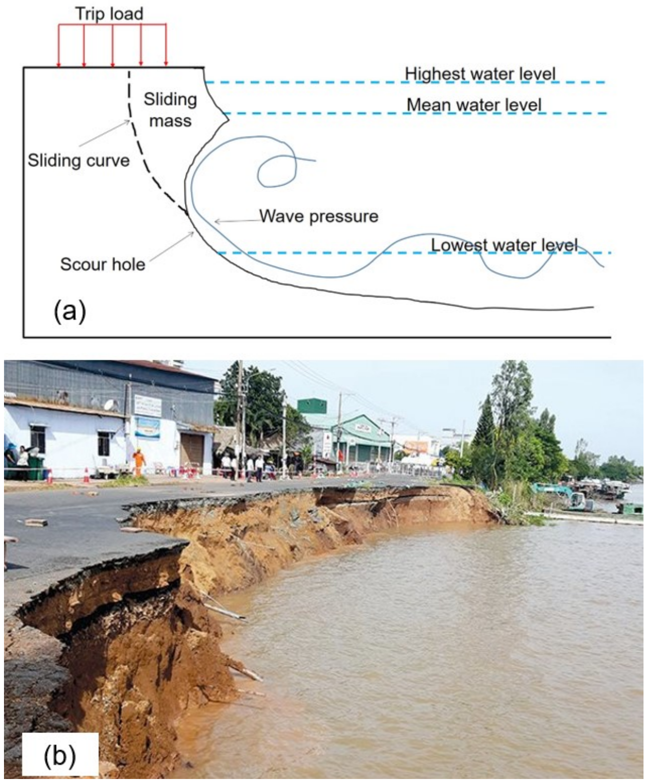

Fig. 2. Riverbank landslide: (a) Diagram of the main factors contributing to slope deformation; (b) Landslide submerges a section of national highway 91 into the hau river in an Giang province, Vietnam [65].

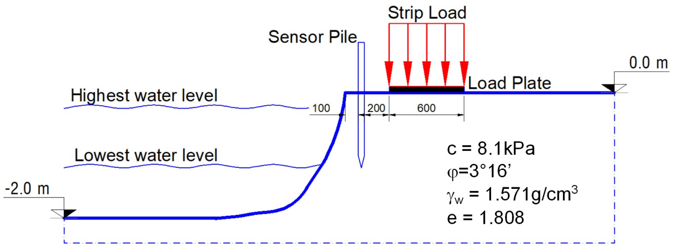

Fig. 3. Dimensions of the experimental canal.

percent, the analysis results indicate complete deformation and destruction of the soil. The analysis results using the numerical method extracted from Plaxis software are presented in Fig. 6, 7, 8, 9 with the surveyed load levels of 30%, 63%, 82.5% and 99.5% of the ultimate bearing capacity, respectively. Fig. 9 clearly shows the sliding curve of the riverbank soil mass (highlighted in orange) and the failure strain area (highlighted in red). The results of soil pressure values in the horizontal direction and displacement obtained from the measurement system showed similarities in pressure ratios with the model analysis results. Therefore, we have proposed pressure ratio values to determine the warning thresholds as shown in Table III below, where q_{ult} is the ultimate bearing capacity of the ground.

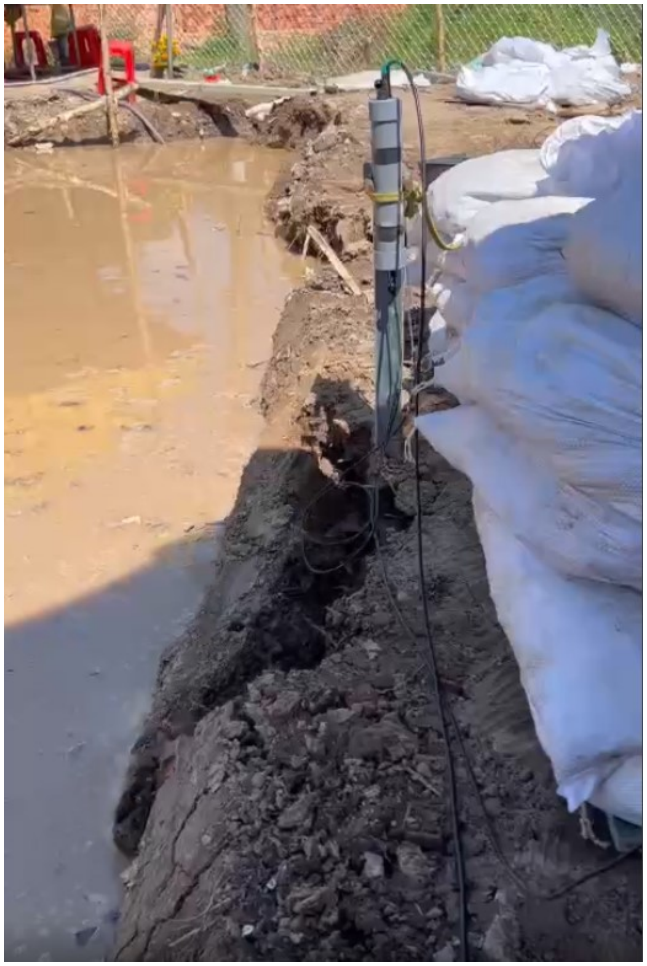

Fig. 4. Photo taken at the experimental site.

TABLE III. Pressure Ratio Values to Determine the Warning Thresholds

Soil pressure factor	Displacement	Level of warning
k $\leq$ 40%.qult	-	Safety
40%.qult <k $\leq$ 70%.qult	Narrow oscillation angle	Warning level 1
70%.qult <k $\leq$ 80%.qult	The oscillation angle gradually widens	Warning level 2
k >80%.qult	Sudden fluctuation in the oscillation angle	Landslide

E. Long Short-Term Memory

The architecture of an LSTM neural network is explicitly designed to handle sequential data, making it a powerful tool for tasks like time series prediction, natural language processing, and more. At its core, an LSTM network comprises individual LSTM cells that work together in a chain-like structure (see Fig. 11). Each LSTM cell (see Fig. 10) contains three main gates: the Forget Gate, the Input Gate, and the Output Gate, along with a Candidate Gate. These gates, implemented using a combination of activation functions and weights, control the flow of information through the cell. The Forget Gate determines what information to discard from the previous cell state. The Input Gate decides what new information to store in the cell state, and the Output Gate regulates what information to expose to the output. This ar-

chitectural design enables LSTMs to effectively capture long-term dependencies in sequential data, addressing the issue of vanishing or exploding gradients often encountered in standard RNNs.

The approach with LSTM models for landslide prediction represents a significant stride in harnessing advanced technology for geohazard mitigation. LSTM, a specialized form of recurrent neural network (RNN), excels in handling sequential data, making it particularly well-suited for predicting time-dependent variables associated with landslides. This is paramount in regions prone to geological instability, where timely warnings are crucial for safeguarding lives and infrastructure. One critical strength of LSTM models is their ability to capture intricate temporal dependencies and patterns within time series data. By incorporating memory cells that can retain and update information over time, LSTMs excel in modeling sequences characterized by long-term dependencies. This dynamic memory retention mechanism empowers the model to discern subtle shifts in environmental factors leading to a potential landslide event. Consequently, LSTM-based predictive models stand at the forefront of cutting-edge geotechnical research, offering a promising avenue for enhancing early warning systems and ultimately minimizing the impact of landslides on vulnerable communities.

The equations for an LSTM cell are as follows. In these equations, x_t represents the input at time t, h_t represents the hidden state at time t, c_t represents the cell state at time t, and f_t, i_t, g_t, and o_t represent the forget gate, input gate, cell gate, and output gate respectively.

1) Forget Gate:

$$f_t = \sigma(W_f \cdot [h_{t-1}, x_t] + b_f)$$

2) Input Gate:

$$i_t = \sigma(W_i \cdot [h_{t-1}, x_t] + b_i)$$

3) Candidate Cell State:

$$g_t = \tanh(W_c \cdot [h_{t-1}, x_t] + b_c)$$

4) Update Cell State:

$$c_t = f_t \cdot c_{t-1} + i_t \cdot g_t$$

5) Output Gate:

$$o_t = \sigma(W_o \cdot [h_{t-1}, x_t] + b_o)$$

6) Hidden State:

$$h_t = o_t \cdot \tanh(c_t)$$

Here,

- σ represents the sigmoid activation function.
- $\tanh$ represents the hyperbolic tangent activation function.
- W_f, W_i, W_c, and W_o are weight matrices specific to the forget gate, input gate, cell gate, and output gate, respectively.
- b_f, b_i, b_c, and b_o are bias vectors associated with the respective gates.

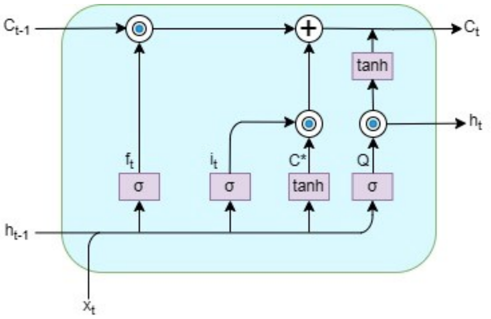

Fig. 10. The LSTM cell operation.

F. Landslide Prediction with LSTM

LSTM networks resolve the vanishing gradient issue that hinders traditional RNN training by utilizing a memory cell capable of retaining information over extended durations. This quality makes them highly effective for modeling time series sequences, a crucial aspect in predicting landslides due to their complex temporal nature influenced by various factors.

The dataset gathered from 45 experimental points is vital for implementing the LSTM algorithm in predicting landslide warning levels. This extensive time series monitoring dataset captures a multitude of critical attributes, including ground pressure (p), the X-axis inclination angle (x angle), the Y-axis inclination angle (y angle), and the respective warning levels recorded at various experimental sites situated along the banks of Rach Cai Deep River. It's important to note that this dataset was meticulously collected at 30-second intervals, a frequency maintained throughout the loading test, persisting until a landslide event occurred. To formulate the predictive challenge effectively, we have stratified it into four levels: safety, warning level 1, warning level 2, and landslide. The very essence of this endeavor is rooted in the comprehensive time series data collected in the context of six scenarios. The particulars of these six distinct experimental scenarios are elucidated in depth in the experimental results section.

Furthermore, our experiments extend beyond mere data collection, encompassing the proactive prediction of landslide levels. This predictive process spans specific time intervals, specifically after 2 hours, 2.5 hours, 2.7 hours, 4.3 hours, 4.8 hours, and 5.5 hours post-initiation. This time horizon is of particular significance, representing a window during which strategic asset relocation can effectively mitigate the potential loss of valuable assets and infrastructure. For training and evaluating the LSTM model, the entire dataset is thoughtfully partitioned into two subsets. A substantial 70% of the data is designated for training, with the remaining 30% preserved for testing and validation. This partitioning strategy ensures the robustness and accuracy of the model's performance, affirming its capacity to effectively predict landslide warning levels under diverse temporal and environmental conditions.

G. Evaluation Method

In multiclass classification, the performance of a classification model is typically evaluated using various metrics to assess its accuracy and effectiveness in classifying data into multiple classes. The evaluation metrics used include accuracy, precision, and recall [66]. The F1 score is the harmonic mean of precision and recall, representing a balanced average between accuracy and recall [19], [67]. It ranges between 1 and 0. The highest possible value of F1 is 1.0, and an F1 score approaching 1 signifies perfect precision and recall, indicating high confidence and reliability of the algorithm in predicting landslide warning levels [68]. Detailing the indices presented in the documents [69], [70]. Common evaluation metrics include:

$$\text{Accuracy} = \frac{\text{Number of Correct Predictions}}{\text{Total Number of Predictions}} \tag{1}$$

$$\text{Precision} = \frac{\text{True Positives}}{\text{True Positives + False Positives}} \tag{2}$$

$$\text{Recall (Sensitivity)} = \frac{\text{True Positives}}{\text{True Positives + False Negatives}} \quad (3)$$

$$\text{F1-Score} = \frac{2 \cdot \text{Precision} \cdot \text{Recall}}{\text{Precision} + \text{Recall}} \quad (4)$$

H. Experimental Results for Predicting Landslide

The LSTM model under study boasts a tri-layered structure, with each layer densely populated by 512 neurons. Despite its apparent complexity, the architecture remains streamlined and efficient, designed expressly for seamless operation on low-performance laptop hardware. The training of this model employs the AdamW optimizer, set at a learning rate of 0.0001. To ensure robustness and repeatability in our results, we conducted each experiment three times, then averaged the F1-scores, noting their standard deviation. Although the training was set for a potential maximum of 100 epochs, early stopping was incorporated with a patience of 8 epochs. Remarkably, most experiments converged to their optima around the 50 epochs. The model uses the CrossEntropyLoss function for optimization. Despite its depth and intricacy, the model remains relatively lightweight with 5.3 million trainable parameters, resulting in an estimated total model size of 21 MB. The forecast performance is depicted in Table IV.

TABLE IV. The Forecast Performance of our Model

Observed window	Forecast at	F1-score
30min	330min (∼5.5h)	0.8088 ± 0.0380
22min	292min (∼4.8h)	0.7688 ± 0.0136
22min	262min (∼4.3h)	0.7879 ± 0.0053
14min 30sec	164min 30sec (∼2.7h)	0.7927 ± 0.0319
04min 30sec	154min 30sec (∼2.5h)	0.7756 ± 0.0107
04min 30sec	124min 30sec (∼2h)	0.8232 ± 0.0122

In this research framework, the forecasting setup is delineated: The 'observed window' denotes the uninterrupted period during which data is observed. Data acquisition involved procuring three distinct time series, e.g., pressure, x-angle, and y-angle, from sensors strategically positioned on the experimental pole. The positioning strategy is squarely within the ambit of multivariate time-series forecasting [71], [72]. The forecasting objective seeks to predict events in the vicinity of the pole for a specified future time point. For example, if it monitors the three-time series for 4 minutes and 30 seconds, the predictive model aims to forecast events at the 124-minute and 30-second mark—roughly a 2-hour projection into the future.

I. Remark and Discussion

Fig. 4 illustrates the appearance of cracks on the ground, gradual soil mass horizontal displacement, and the tilted state of the sensor pile. The canal bank is progressively damaged, starting with the scour hole at the base of the slope. The canal bank is saturated after the rains and the increasing applied load. By monitoring the gradual expansion of cracks along the canal banks and around the sensor pile, the measured soil pressure data and observing the tilting behavior of the sensor pile before the soil mass ultimately failure took place over more than 12 hours. This is also identified as shown in Fig. 5 from the time the Level 1 warning signs appeared for the second time, then progressed to Level 2 warning until the soil mass slid into the canal, it took place from 21:00:00 on December 19, 2022, to 12:00:00 on December 20, 2022, equivalent to approximately 15 hours. Such behavior could be used as a signal for early warning. It should be noted that the pressure values and the behavior of tilting before failure vary case-by-case. Thus, the criteria for issuing warnings should be carefully determined.

From a research standpoint, while the F1-score demonstrates commendable performance at the 330-minute forecast time point, it is imperative to note a relatively higher standard deviation, approximately 3.8%. Our optimal prediction results are gleaned from an observational window of 4 minutes and 30 seconds to project roughly 2 hours into the future. For instance, the F1-score stands at 0.8232 with a notably low standard deviation of about 1%. However, by conducting experiments over various observational windows, we intend to establish a reliable database to provide in-depth insights for managers to implement appropriate solutions to protect the lives of residents and infrastructure.

IV. Conclusion

In this work, we have presented the establishment of an experimental model for monitoring the landslide of riverbank soil in the Mekong Delta region. The data collected from the experiment show good agreement with finite element method calculations. We propose warning thresholds based on soil pressure, deformation, and displacement data under saturated soil conditions. The results of this study contribute to the establishment of a system to predict the likelihood of extreme events at a specific time in the future based on 374,415 samples and three input parameters, including soil pressure, inclination of the sensor pile in directions towards and along the riverbank, warning level, and warning label, using the LSTM method. The experiment with an observation window of 4 minutes and 30 seconds indicates that the optimal result for predicting warning events is around 2 hours in the future. Through experimental results, the LSTM model effectively predicts early warning landslides for riverbanks with soft soil characteristics under external loading. The findings of this research can be applied in developing early warning systems for riverbank landslides in the Mekong Delta region.

Transformative Learning Through Augmented Reality Empowered by Machine Learning for Primary School Pupils: A Real-Time Data Analysis

Abinaya M, Vadivu G
Department of Data Science and Business Systems
SRM Institute of Science and Technology
Kattankulathur, Chennai

***Abstract*—Academic performance and student engagement are constant challenges in the field of modern education. When it comes to engaging students, traditional teaching methods frequently fall short, so creative solutions are needed. The Transformative potential of Augmented Reality (AR) technology as a cutting-edge teaching strategy is examined in this study. AR presents a dynamic, immersive learning environment that has the potential to completely transform conventional classrooms. By incorporating AR into the curriculum, our research transforms pedagogical paradigms, closes the engagement gap, and raises academic performance through an adaptive learning system. The study reveals the complex dynamics of AR-enhanced education through thorough analysis, powerful visualizations, and significant ANOVA results (p-value=0.03). It challenges accepted educational theories and provides insights into the complex effects on learning outcomes and student engagement. This study highlights the significance of AR in educational settings and promotes its incorporation as a transformative instrument that can establish dynamic and captivating learning environments, encourage critical thinking, creativity, and early field exploration through Artificial Intelligence (AI), and ultimately mould future leaders who can succeed.**

Keywords*—*Artificial intelligence; augmented reality; adaptive learning; machine learning; transformative learning

I. Introduction

A new era of education has begun as a result of the convergence of cutting-edge technologies and traditional teaching methods in the rapidly changing environment of modern education [1]. Augmented reality (AR), which provides educational experiences that are both immersive and interactive, is at the forefront of this revolution. These experiences are designed to captivate the minds of young learners [2]. In this digital age, when students exhibit a variety of learning styles and preferences, there has never been a greater need for personalized and adaptive learning approaches [3].The research investigates the potentially revolutionary field of augmented learning by investigating how the combination of AR and advanced machine learning algorithms has the potential to radically alter the dynamic of conventional classroom settings [4]. When it comes to education, the traditional "one-size-fits-all" approach frequently falls short of adequately addressing the specific requirements of individual students [5]. By incorporating AR technology, personalized engagement goes from being a possibility to becoming a reality [6] allowing educational experiences to be tailored to match the preferred learning pace and style of each individual student. The research is based on the conviction that AR is more than just a word [7], [8]; rather, it is the key that unlocks educational opportunities that are without parallel [9], [10].

The current particular study takes a systematic approach to analyze the effects that AR had on students both before and after it was introduced into classrooms. It seeks to highlight the transformative potential of AR by conducting research into the shifts that occur in levels of academic performance, levels of knowledge retention, and levels of engagement. The process of education is given a boost in terms of its potential to be both dynamic and interactive to AR. The purpose of the study is to shed light on the significant changes that were observed in students after they engaged with educational content that incorporated AR, thereby highlighting how important it is for education to embrace technological innovations like these. As we embark on this transformative journey, our goal is to unveil innovative strategies that will empower educators, captivate students, and pave the way for a future in which education will not simply be informative but will instead be truly immersive, engaging, and profoundly enriching.

The objective of the research is

1) To carefully evaluate how AR-enhanced learning experiences affect student's levels of engagement and retention.
2) To show, through comparison with traditional teaching methods, how much better AR-enhanced learning is at meeting the needs and styles of a diverse student body.
3) To provide verifiable data and evidence-based solutions to real-world challenges in integrating AR and ML in classrooms.
4) To give legislators, tech developers, and educators intelligent information that will shape education's use of cutting-edge technologies in the future.

II. Literature Review

Augmented reality (AR) has the capacity to transform STEM education in higher learning institutions by offering immersive and interactive learning encounters. A comprehensive literature review of 45 articles revealed that AR has been employed as an instructional tool for various STEM disciplines. However, the majority of studies have concentrated on the application of AR in laboratory-based environments, with particular emphasis on biology and chemistry. Further investigation is required to create and assess AR applications for a broader array of STEM disciplines and educational settings, focusing on aspects such as design, user involvement, and cost-effectiveness [11]. AR has the potential to revolutionize education by offering immersive and interactive experiences that promote transformative learning. Machine learning (ML) has the ability to improve AR-based learning by customizing instruction, adjusting to individual student requirements, and creating fresh educational material. AR and machine learning have the potential to revolutionize education by creating personalized and transformative learning experiences that cater to the unique needs of every student [12]. According to [13], AR has the ability to bring about significant changes and improvements in education and training. AR facilitates immersive learning experiences by enhancing the visualization of intricate concepts, promoting individualized and cooperative learning. despite the obstacles posed by expenses, the declining cost of AR devices and the demand for top-notch applications suggest a bright future for the integration of AR in education. This compels researchers and practitioners to delve into its various applications.

The author in [14] highlight the significant impact that AR can have on education, emphasizing its ability to bring about profound changes. They mention several advantages of AR in education, including heightened involvement, enhanced comprehension, increased creativity, and improved collaboration. Nevertheless, they express concerns regarding issues such as expenses, the requirement for top-notch applications, and possible diversions. Educators should thoroughly investigate AR options, carefully choose appropriate applications, and strategically design integration plans in order to effectively utilize its potential for improving student learning and engagement. According to [15], AR and virtual reality (VR) have the capacity to transform education by improving engagement, comprehension, creativity, and collaboration. Nevertheless, it is imperative to tackle obstacles such as the expenses associated with devices, the requirement for outstanding applications, and the possibility of distractions. Teachers should investigate the potential of AR and VR applications, recognizing their advantages while strategically incorporating them into the curriculum to foster captivating and interactive educational experiences for students. The author in [16], emphasises the significant impact that AR can have on Education 4.0, particularly in terms of creating immersive and interactive learning experiences. The idea they have includes AR applications such as virtual laboratories, improved field trips, collaborative environments, and customised learning experiences. Despite obstacles such as the high expenses of devices and the varying quality of applications, educators are strongly encouraged to investigate the potential uses of AR, conduct thorough research on the available technology, and carefully incorporate AR into their teaching methods to improve student involvement and learning in the era of Industry 4.0. The prevalence of AR in science education (62%), according to Fidan and Tuncel's (2018) content analysis of AR in education between 2012 and 2017. The most common type of AR was marker-based (67%), with achievement (54) and attitude (46%). In 67% of the studies, there was a positive impact on student achievement. The findings highlight the potential of AR in education, particularly in science, urging educators to investigate appropriate AR types and variables while acknowledging the need for additional research across diverse subjects. AR implemented with care can significantly improve student engagement and learning experiences.

The author in [17] analysis of AR in education (2012-2017) underscores its potential, especially in science education (62%). Marker-based AR was predominant (67%), focusing on achievement (54%) and attitude (46%). While positive impacts on student achievement were common (67%), attitudes towards AR varied. Educators are encouraged to explore AR types, consider relevant variables, and integrate high-quality applications to enhance student engagement across subjects, emphasizing the need for thoughtful planning and implementation in educational contexts [18] highlight AR potential to improve education through increased engagement, comprehension, creativity, and collaboration. Despite challenges such as device costs and application quality, educators are encouraged to investigate the benefits of augmented reality, research appropriate technologies, and integrate high-quality applications. AR can revolutionise education by creating more engaging, effective, and personalised learning experiences for all students with careful planning and implementation [19] advocate AR in medical education for immersive learning experiences, improved understanding, enhanced practical skills, and reduced costs. Despite challenges like expenses and distractions, AR offers engaging, effective, and affordable learning opportunities. Medical schools should integrate AR thoughtfully, raise faculty awareness, and conduct ongoing research to maximize its benefits for students' education.

In their paper, [20] argue that AR can transform education by improving engagement, effectiveness, and accessibility. They highlight AR's immersive, interactive learning experiences and personalised feedback and support. However, device costs, high-quality app development, and teacher training must be addressed. Teachers should investigate AR's benefits, research relevant technologies, and carefully plan integration. Safety, access, and assessment methods should be considered to maximise AR's impact on student learning. Careful planning and implementation can make AR a powerful educational tool.With the potential to provide students with immersive and interactive learning experiences that surpass the constraints of conventional teaching methods, augmented reality (AR) has the potential to revolutionise the primary school education system. The author in [21], [22] are just two of the many studies that have shown how AR improves student learning outcomes. discovered that AR-based virtual reality walkthroughs can effectively reduce motion sickness and improve learning outcomes. Furthermore, it has been demonstrated that AR-based instructional digital mo. AR technology has also been used to produce interesting experiences, such as AR-based mobile applications that assist learning in kids with learning disabilities and AR-enabled sports games that increase student motivation for physical activity [23]. AR is essential to transformative learning because it challenges students' preconceived notions and presumptions. Augmented reality (AR) provides first-hand experiences that help students develop a more nuanced worldview and a deeper understanding of history by submerging them in virtual simulations of historical events [24]. Moreover, augmented reality fosters global perspectives and tolerance in students by facilitating the exploration of various cultures and viewpoints.There are significant ramifications for elementary schools. AR has the potential to completely transform education by giving students interactive experiences that improve their comprehension of difficult concepts and by adjusting instruction to meet each student's needs [25]. AR can be used by primary school teachers to support individualised learning programmes, interactive scientific experiments, virtual field trips, and educational games. Access to AR devices, top-notch applications, and careful planning to match AR activities with the curriculum are necessary for a successful integration, though [26], [27]. AR is a potent tool that can improve learning outcomes and student engagement in elementary schools when used strategically.

A. Overcoming the Limitations of Previous Research

For a more thorough and influential study, the constraints of the previous work on AR in education are tackled in the current study. The main limitation of the previous studies are, there is a distinct focus on AR applications in science education, namely in the fields of biology and chemistry, this provide the research gap for the investigation of AR in a wider range of STEM disciplines and educational contexts. Furthermore, although the revolutionary potential of augmented reality (AR) is acknowledged in the previous study, there is a shortage of thorough investigation into the cost effectiveness, involvement of users, and design of AR applications. In order to get beyond these restrictions, the study ought to expand its scope to cover a wider variety of STEM fields and educational settings, guaranteeing a thorough assessment of AR's suitability. Along with providing useful answers to these problems, the study must also carry out a thorough investigation into the potential difficulties brought on by expenses, device costs, and application quality. In order to offer a comprehensive understanding of AR adoption in education, the study also ought to investigate the design features of AR applications, taking user involvement and cost-effectiveness into account. In order to effectively shape the future of education, educators, legislators, and tech developers access the verifiable data, evidence-based solutions, and intelligent information. By addressing these limitations, the study can provide a more delicate and practical perspective on the integration of AR in education.

TABLE I. No. of Participants Detail in the Study

GRADE	BOYS	GIRLS
GRADE 2	32	31
GRADE 3	31	33
TOTAL	63	64

III. Methods

A. Data Gathering

Grade 2 and 3 students at Little Scholars Matriculation Higher Secondary School (LSMS) in Thanjavur District, Tamil Nadu, India were selected to participate. The study included a total of 127 students, with 63 boys and 64 girls. Table I shows the grade breakdown of the participants. A variety of data points were methodically gathered and organized to guarantee thorough insight into the AR learning experience. Fig. 1 depicts the Grade 2 Children saw the Marker based AR scene in a Mobile Phone.

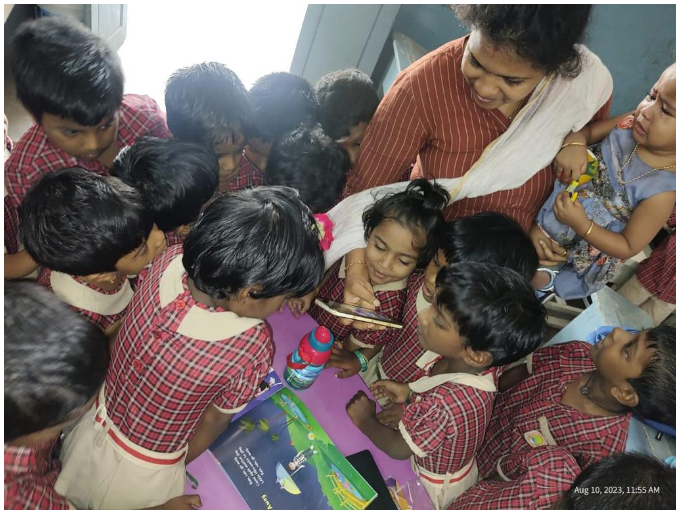

Fig. 1. Grade 2 children viewing the augmented reality scene in mobile phone.

1) Pre- and Post-Assessment: The first round of test scores was collected from the student's permanent files to reveal their knowledge levels at the outset. Before participating in the AR interventions, students underwent a pre-assessment test to evaluate their initial understanding. Students were given a starting point in the form of these pre-test scores. Subsequently, students engaged in a series of five AR-based activities designed to enhance their understanding of the subject matter. A post-task evaluation was given after participants had finished these exercises. Scores on assessments given after AR treatments were implemented were used to draw comparisons. Using this method, we were able to compare students' pre- and post-assessment scores representing their prior knowledge and the impact of AR-based learning activities, respectively to determine how much growth each student had made.

2) No. of Augmented Reality Activities: Student participants in the study used five different AR applications designed to facilitate interactive learning about fruits, animals, careers, rhymes, and the solar system. These exercises were carefully designed to stimulate deeper thought and greater participation from students. Time spent in each AR app by each student was meticulously recorded during each AR session. A built-in timer within the augmented reality applications tracked how long students spent on each activity. The information was instrumental in determining how long students were fully engaged in their studies. It also revealed important information about the level of interest that students had in the material being taught.

3) Educator Engagement and Ethics in Augmented Reality: All participant's rights and safety were protected throughout our study's entire data collection process, which was conducted in accordance with the highest ethical standards. Informed consent was diligently obtained from both the students and their guardians, signifying their voluntary agreement to participate in the AR learning activities. Our research would not have been possible without this open and ethical methodology, which emphasized the value of informed consent and personal autonomy.

An attentive teacher was there to help every step of the way, which greatly boosted the effectiveness of the AR lessons. The teacher's presence was essential to the success of the activities and contributed to a positive and encouraging classroom climate. Students benefited greatly from this direction because it made them feel safe and encouraged them to fully immerse themselves in the augmented environment.

4) Consent from Institution: Prior to the start of the study, parents received detailed consent forms outlining the nature of augmented reality activities, their benefits, and the potential educational outcomes. Only children whose parents agreed to participate in the study were included

5) Assent from Student: Students were briefed on the activities and given the option to participate if they desired. Getting people's Permission to take part in AR sessions was a precondition for doing the activity.

B. Augmented Reality Implementation

AR requires a deliberate and immersive approach in order to be integrated into the educational framework. The creation and incorporation of AR content were carefully planned to meet the goals of the curriculum and provide young students with an enjoyable learning environment.

1) AR Content Development and Integration: We took a forward-thinking approach to creating AR content with the intention of giving students access to engaging and thought-provoking educational opportunities. Our AR content's marker-based interface was both easy to use and straightforward. ThE technology made it easy for students to interact with the material, creating a stimulating classroom atmosphere. The AR modules we've developed feature vibrant 3D models, captivating animations, and enveloping auditory cues, all of which were thoughtfully developed. Students' interest and understanding of the material were both boosted by the incorporation of these interactive features. Modules about fruits, vegetables, careers, the solar system, and rhymes were developed. Each AR module was created with a distinct set of pedagogical goals in mind. For instance, fruits and vegetables taught students not only about agriculture and nutrition but also about the value of caring for one's body and the environment. the Professions AR content encouraged early exploration and understanding of a variety of professions by introducing children to them. Students' minds were blown by the solar system modules, which took them on a fascinating journey through space. The rhymes unit also made use of visual aids, which helped to develop both vocabulary and imagination.

2) AR Software and Platforms: The merging of Unity, an advanced game development engine, and Vuforia, an innovative AR platform, has resulted in a revolutionary era of interactive learning. The ground-breaking collaboration gave rise to Marker-based AR, which completely altered the educational landscape. Unlike conventional markers or triggers, this technology can instantly identify physical books and printed materials, triggering digital overlays within the AR app with ease. The app's intuitive design makes it suitable for elementary school students, and its AR content is accessible to even the youngest students. Integrating five separate educational activities studying fruits and vegetables, animals, careers, nursery rhymes, and the solar system improves participation and memorization. Through the use of school issued tablets and our own mobile devices, students are able to access these enlightening modules outside of the confines of the classroom.

C. Algorithm

1. Collect the pre assessment score of students
2. Analysis of Augmented Reality Interactions with post assessment score, time of interactions and the no of activities completed and the improvement score
3. Preprocess the collected Data
4. Selection of Features
5. Machine Learning in Statistical Analysis
6. Analyse the statistical analysis results
7. Use graphs and charts to visually represent findings

IV. Results

AR technology has brought in a new era of immersive learning at LSMS School, as seen in the Fig. 1 interesting photo of students participating in an AR-enhanced lesson. Their reactions, full of wonder and teamwork, reflect the fresh energy that AR has brought to their academic pursuits. Fig. 2, a Box Plot showing before and after AR scores, vividly illustrates how this excitement translated into remarkable academic progress. Students' impressive progress after adopting AR-based learning experiences is effectively demonstrated by this visual representation.

A visualization that captures how AR has transformed student performance. The correlation between AR enhanced learning experiences and subsequent improvements in students' scores is clearly displayed by the graph. Our box plot, which displays a compelling comparison of pre and post-augmented reality scores, is a testament to the thorough analysis carried out. The distinct division between the two stages highlights the noteworthy advancements that students achieved following the incorporation of augmented reality-based educational opportunities. The impactful, precise data representation reveals the various ways in which students reacted to AR interventions by highlighting not only the mean scores but also their distribution and spread. The Violin Plot in the Fig. 3 provides a more comprehensive look at how AR activities correlate with assessment results. Its graceful arcs and peaks represent the wide range of reactions from students at different engagement levels. Like individual notes in an educational piece, each activity tally represents a distinct educational opportunity. Increases in the violin's dynamic range signify collective growth wherein agreed-upon tasks significantly advance shared goals. Numerous differences denote unique learning paths, necessitating a pliable instructional strategy analogous to a skilled conductor leading a meticulously prepared band. This complex web of relationships exemplifies the individualised nature of education that caters to different approaches to learning.

Incorporating AR into educational practices is effective, as evidenced by the observed increase in improvement scores and

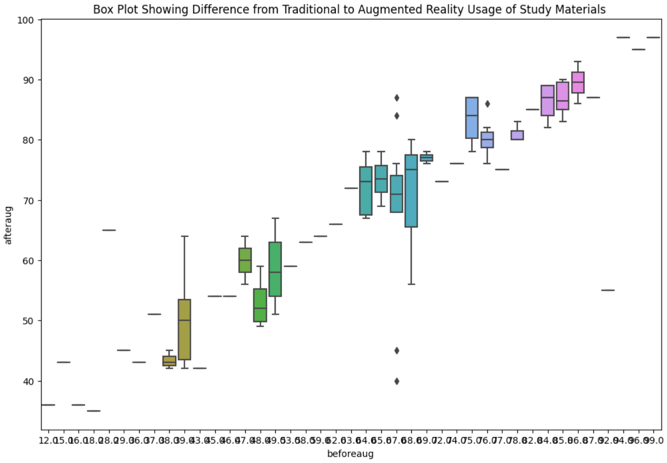

Fig. 2. Box plot shows the pre and post marks of the students after using augmented Reality in to their curriculum activity.

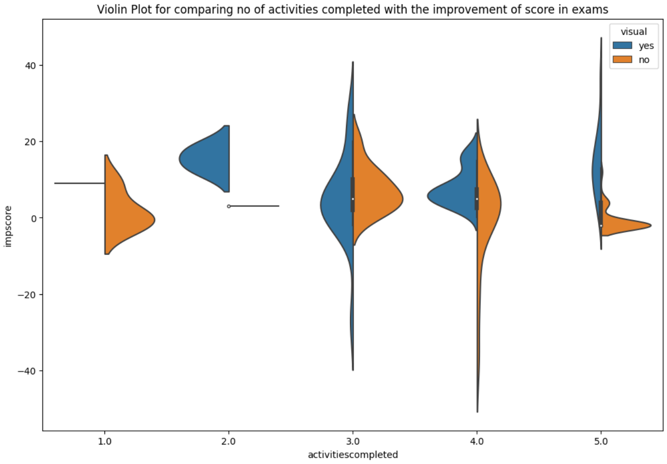

Fig. 3. Violin plot shows the no.of activities in augmented reality increases the marks in exam.

the significant p-value of 0.03 from ANOVA analysis when compared with the pre- and post-assessment scores of the students. The result confirms that AR not only improves understanding and interest, but also facilitates unique educational paths. The findings point to a future where technology and education work hand in hand to provide each student with a stimulating and individualised education. the integration of AR tools with conventional classroom practices has revolutionised education. Students, once confined by conventional boundaries, now explore a spectrum of knowledge, fostering a harmonious blend of technology and education. These results not only prove that AR interventions work, but also stress the importance of using flexible methods of instruction to maximise the benefits of this new paradigm in education.

The scatter plot in the Fig. 4 results clearly shows the complex relationship between students' improvement scores and their augmented reality experiences. Plotting the individual student data points reveals an interesting pattern that highlights the beneficial effects of augmented reality on academic advancement. The values that are systematically extracted from

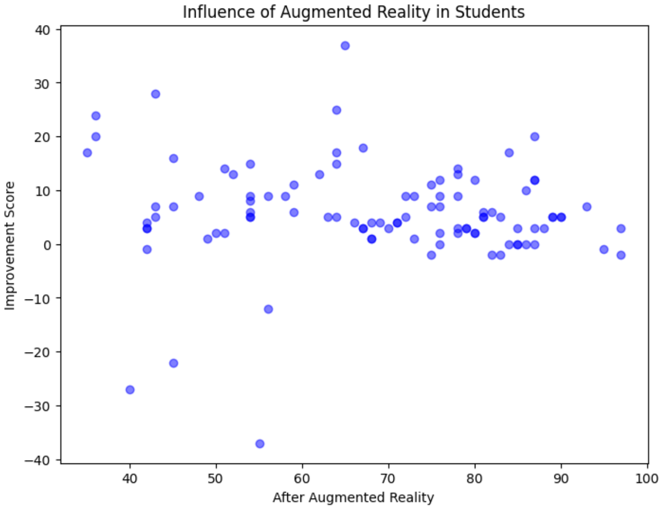

Fig. 4. Scatter plot to visualize the improvement of marks in students after using augmented reality.

the augmented reality interventions and improvement scores provide an inspiring tale that highlights the revolutionary potential of cutting-edge educational technologies.

V. Discussion

Fig. 1 effectively captures the immersive quality of augmented reality, where traditional barriers to education vanish and interactive, hands-on learning becomes possible. Pupils can be seen examining virtual objects and even reaching out to touch and interact with them. Their obvious excitement reflects a deeper level of engagement made possible by augmented reality technology. This dynamic interaction turns abstract ideas into real, memorable experiences that go beyond the pages of textbooks.Beyond the technical marvel, the picture emphasises how AR fosters a collaborative spirit. In the augmented environment, students are seen collaborating to solve problems, sharing insights, and highlighting discoveries. In addition to improving their comprehension, this cooperative learning environment helps them develop critical thinking, communication, and teamwork skills.This graphic insight highlights the critical role that augmented reality plays in boosting student engagement and encouraging collaborative learning experiences. The excitement that the students displayed is consistent with the favourable results that our study showed, confirming AR's potential as a revolutionary teaching tool.

the determination, curiosity, and participation of the pupils. It represents an evolution in the learning process rather than just an improvement in scores. With AR, education becomes more than just a teaching tool; it becomes a shared experience in which teachers and students work together in a dynamic, immersive learning environment. Upon considering the effects of this Fig. 5, it is evident that AR is more than a superficial trend; rather, it is a revolutionary force influencing the course of education. It has the infinite capacity to captivate, motivate, and enhance educational experiences. In a larger sense, this visual witness questions established educational theories and calls on establishments to adopt cutting-edge technologies and reconsider the definition of a classroom.

The plot also presents the idea of outliers, or students whose performance increased after AR was implemented. These outliers are more than just statistics; in which augmented reality served as a catalyst to enable remarkable academic achievements. These anomalies cast doubt on accepted ideas about learning paths, highlighting the revolutionary potential of immersive learning technologies. There are significant consequences to be taken from this box plot. It highlights that AR is acustomized experience that accommodates a range of learning styles and speeds rather than an inflexible tool. This necessitates a change in our pedagogical paradigms as educators—from standardized instruction to individualized, AR-enhanced learning. It calls for the development of flexible, responsive curricula that value each student's uniqueness and promote an atmosphere in which unusual growth is not only welcomed but encouraged.

Unexpectedly, the plot also presents the idea of outliers, or students whose performance increased after AR was implemented. These outliers are more than just statistics; in which AR served as a catalyst to enable remarkable academic achievements. These anomalies cast doubt on accepted ideas about learning paths, highlighting the revolutionary potential of immersive learning technologies. The ANOVA test yielded a significant p-value of 0.03 that is highly significant. According to statistics, there is less than a 5 per cent chance that the observed differences in improvement scores between traditional and augmented reality methods are the result of random fluctuations if the p-value is less than the conventional threshold of 0.05. Because of this low p-value, the idea that augmented reality is a key component enhancing learning outcomes is strongly supported.

A strong degree of confidence in the observed results is indicated by the 0.03 p-value, which supports the finding that augmented reality is significantly linked to higher student test scores. This statistical result emphasises the validity and reliability of the study's findings and is consistent with our qualitative observations and analyses.

This confirmation strengthens the case for the use of AR technologies in teaching methods, as does the accompanying picture that shows student participation and visual proof.

The compelling picture, showcasing students' increased enthusiasm and active participation in AR classes, is a perfect visual representation of our study's striking findings. This deeper involvement with the material explains why students are performing better in school, underscoring the significant effect AR has on education. AR's interactive nature enables immersive and individualised learning, meeting the needs of students with a wide range of learning styles. We believe that students' increased flexibility is a major factor in the positive impact on their academic growth that we have observed. The visually impressive documentation supports the centrality of AR in education, which is emphasised by our analysis. The classroom environment is improved and students learn more when technology is used in the classroom. We believe that AR can be a game-changer in the classroom by creating more interactive and collaborative learning spaces. Our AR content has been highly commended for its ability to foster critical thinking, creativity, and early exploration across a wide range of disciplines. This cutting-edge method guarantees that students not only learn new information but also develop crucial skills necessary for their future success.

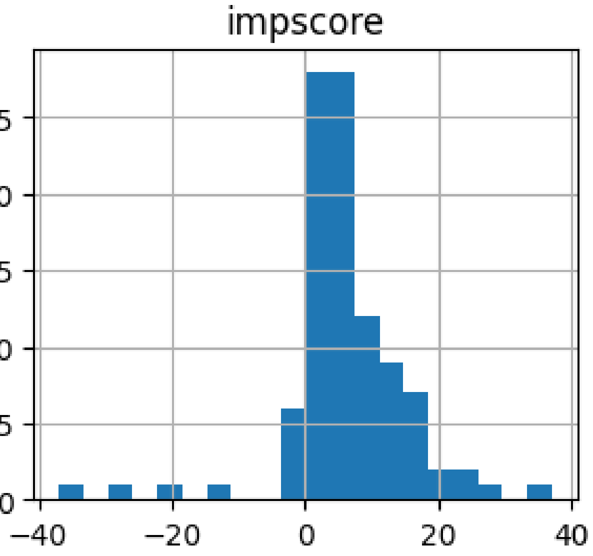

Fig. 5. Statstical representation of overall improvement score of the students.

VI. Conclusion

As an outcome, the statistical evaluation highlights the effect of AR on the academic achievement of learners, as evidenced by a significant ANOVA result with a p-value of 0.03. The result validated the usefulness of AR in educational settings by showing that the variation in improvement scores between traditional and AR methods .AR is crucial to improve learning outcomes was supported by the sample data collected from the school, which includes powerful diagrams comparing pre- and post-augmented reality scores. The box plot, which clearly contrasts the use of AR with traditional methods, offers a clear visual depiction of the improvement in student performance. The positive correlation between interactive learning experiences and academic progress is further supported by the violin plot, which correlates the number of activities with improvement scores. our study explored the practical implications of augmented reality in addition to establishing its statistical significance. The image, which shows students' enthusiastic participation and active engagement during augmented reality sessions, is a potent illustration of how this technology has revolutionised the classroom and the results demonstrate that augmented reality is an initiator for a pedagogical revolution and not simply a technical development. Adopting cutting-edge technologies like AR is essential as education changes because it allows teachers to design dynamic, personalized, and interactive learning environments. It is recommended that educational institutions and instructors incorporate augmented reality into their pedagogical approaches, capitalizing on its capacity to enhance the learning experience and equip learners for a technologically and knowledge-driven future.

VII. Future Gap

Our research sheds light on important developments in the field of AR-enhanced education, but there are still many questions that need to be answered. Long-term research into effects is an exciting avenue to explore. The longer the study runs, the more insight we'll have into the long-term effects of AR on students' learning trajectories and retention rates. Exploring AR's utility and efficacy in a variety of subject areas and with students of varying ages could shed light on the technology's potential in the classroom as a whole. Furthermore, investigating how best to combine AR with other pedagogical approaches like gamification or individualized learning could lead to novel and complementary learning strategies. Ethnographic studies could provide detailed insights into students' experiences, shedding light on the emotional and social dimensions of augmented reality-enhanced learning. In the final analysis foremost, addressing the current gaps in technology access by investing in the development of low-cost and easily accessible augmented reality tools for resource-constrained educational settings would guarantee an inclusive educational landscape. By filling these future gaps, we can improve AR's use in the classroom and create more engaging, effective, and equitable learning environments for all students.

Computer Science Department-School of Computer Science, Bina Nusantara University, Jakarta, Indonesia 11480[4]

Abstract—**Twitter is a social media platform that has a large amount of unstructured natural language text. The content of Twitter can be utilized to capture human behavior via emphasized emotions located in tweets. In their tweets, people commonly express emotions to show their feelings. Hence, it is crucial to recognize the text's underlined emotions to understand the message's meaning. Feature engineering is the process of improving raw data into often overlooked features. This research explores feature engineering techniques to find the best features for building an emotion recognition model on the Indonesian Twitter dataset. Two different text data representations were used, namely, TF-IDF and word embedding. This research proposed 12 feature engineering configurations in TF-IDF by combining data stemming, data augmentation, and machine learning classifiers. Moreover, this research proposed 27 feature engineering configurations in word embedding by combining three-word embedding models, three pooling techniques, and three machine-learning classifiers. In total, there are 39 feature engineering combinations. The configuration with the best F_1 score is TF-IDF with logistic regression, stemmed dataset, and augmented dataset. The model achieved 65.27% accuracy and 66.09% F_1 score. The detailed characteristics from the top seven models in TF-IDF also follow the same feature engineering configuration. Lastly, this work improves performance from the previous research by 1.44% and 2.01% on the word2vec and fastText approaches, respectively.**

Keywords*—*Text classification; feature engineering; emotion recognition; Indonesian tweet; natural language processing

I. Introduction

Twitter is a social media platform that provides services to share ideas and opinions. The popularity of Twitter leads to millions of users sending data in the form of tweets, i.e. a short message from Twitter users [1]. As a result, Twitter has a large amount of unstructured natural language text. Researchers have used the content of Twitter to predict economic trends, e.g., financial market prediction [2]. Furthermore, Twitter data can also be utilized to capture human behavior via emphasized emotions located in tweets.

Based on Shaver's theory, emotions can be categorized into five basic classes, i.e., anger, fear, happiness, love, and sadness [3]. On Twitter, people commonly express emotions to show their feelings toward something, e.g., political party, sexual abuse, or simply a bitter experience in their life. Thus, it is crucial to recognize the text's underlined emotion to understand the message's meaning [4]. The underlined emotions can be identified directly via emotion words, e.g., *dukacita* (grief) for sadness, and *kesal* (annoyed) for anger. However, Twitter users can also implicitly display emotions in their tweets, making them hard to identify.

The ability to recognize emotions automatically is essential for various applications. In politics, emotion recognition can predict the polarity of the sentiment in the Presidential election based on social media data [5]. Emotion recognition can also be utilized for games with emotion-based dynamic difficulty adjustment [6]. Furthermore, emotion recognition can also be utilized to build a recommendation system for culinary and food [7]. Lastly, the emotion model can be used to build an emotionally aware chatbot capable of recognizing and interpreting human emotions [8].

There are several challenges to building an automatic emotion recognition model. First, the natural language text in Twitter data is unstructured and uncontrolled, e.g., the length of tweets might be too short or too long, the texts contain typos, and the texts contain misused terms. Second, Twitter datasets for emotion recognition tasks are primarily available for the English language [9], [10]. Datasets for Indonesian emotion recognition from previous studies are not available publicly [11], [12]. Fortunately, Saputri et al. share their Indonesian Twitter dataset for emotion classification task [13].

Inspired by the work of [13], the authors explore feature engineering to build an emotion recognition model on the Indonesian Twitter dataset. This work extends the work of [13] by further exploring feature engineering techniques to find the best features for identifying emotion in Indonesian Tweet. It combines various data preprocessing techniques, word embedding models, different pooling techniques, and machine learning classifiers. The limitation of this work is it does not include an experiment using a combination of features. Specifically, this work focuses on basic features, namely, Bag-of-Words (BOW), Word2Vec (WV), and FastText (FT).

In total, 39 feature engineering configurations are proposed and compared. This work compares the best feature engineering configurations based on the F_1 score metric for evaluation. The best F_1 score achieved was 66.09% from the TF-IDF approach with logistic regression, stemmed dataset, and augmented dataset. The experiment results have shown that the TF-IDF text representation is better than word embedding. On average, the stemming process increases the accuracy performance by 0.11%. Nevertheless, it decreases the F_1 score by 0.06%. Moreover, the dataset augmentation reduces both accuracy and F_1 score by 0.45% and 0.67%, respectively. These results contribute to comprehensively exploring feature engineering techniques to identify the best features for building emotion recognition models on the Indonesian Twitter dataset [13]. It also has potential practical implications for developing an emotionally aware chatbot capable of recognizing human emotions.

The structure of this paper is as follows: related works are presented in Section II. The system architecture of this work is described in Section III. The results and discussions are presented in Section IV and Section V, respectively. Lastly, the conclusion and future work of this work are discussed in Section VI.

II. Related Works

A. Emotion Recognition

Emotion recognition is an attempt to recognize and classify people's emotions. The basic pipeline of emotion recognition is data preprocessing, data representation, training model, and model evaluation. There are two superior-level categories of emotions: positive and negative [3]. Two major basic level categories in the positive category were love and happiness. The three major basic level categories in the negative category were anger, fear, and sadness. Emotion recognition tasks can be performed in various modalities, such as textual [13], audio [14], speech [15], and brain activity [16]. Furthermore, it can also be performed in a multimodal dataset [4].

B. Dataset of Emotion Recognition

Several datasets can be utilized to train the emotional recognition model. The ISEAR [17], the Tales [18], and the AffectiveText [19] are known datasets that are available in the English language. The ISEAR consists of 7,665 sentences labeled with a specific emotion, i.e., joy, fear, anger, sadness, disgust, shame, and guilt [17]. The Tales consists of 15,302 sentences from 176 stories by three different authors [18]. It utilizes Ekman's six basic emotions theory [20], merging anger and disgust. The AffectiveText consists of 1,250 instances from news headlines and has six basic emotions models of Ekman complemented by its valence [19]. Furthermore, the emotions recognition dataset is also available in the Indonesian language, i.e. the Indonesian Twitter Emotion Dataset [13]. It consists of 4,403 Indonesian tweets with general topics. The emotions model is labeled using Shaver's five basic emotions: love, anger, sadness, and fear [3]. The summary of the emotion recognition dataset is listed in Table I.

The study of [13] has performed feature engineering using various text features: lexicon-based, Bag-of-Words, word embeddings, orthography, and Part-of-Speech (POS) tags. In the experiment, [13] has represented word embeddings with several dimensional variations. However, the research has not focused on exploring feature engineering with various word embedding pooling techniques. This paper addresses that issue by exploring various feature engineering configurations, including using various word embedding pooling techniques, to build an Indonesian emotion recognition model.

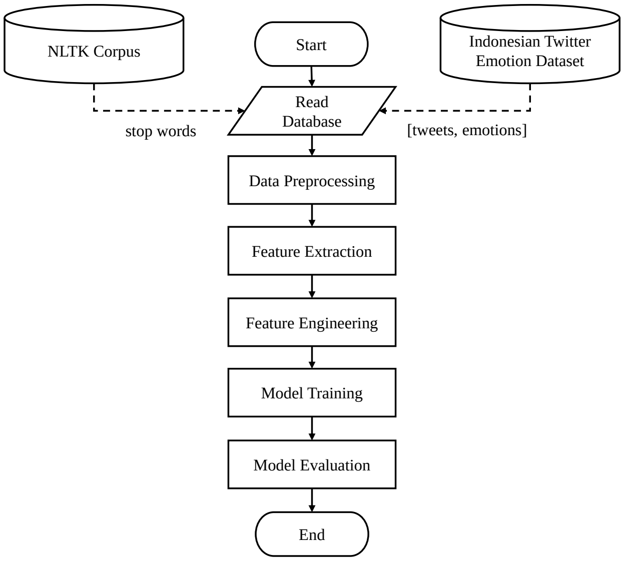

Fig. 1. The system architecture of Indonesian twitter emotions recognition using feature engineering.

III. System Architecture

This work uses feature engineering to present a system architecture for Indonesian Twitter emotion recognition (see Fig. 1). There are two sources of the dataset: NLTK Corpus[1] for a list of Indonesian stop words and Indonesian Twitter Emotions Dataset [13] for model training.

The arrow in the system architecture shows the direction of the process. Furthermore, the dashed arrow shows the data flow. The details of each step in building our model are explained in the following sections:

A. NLTK Corpus

In data preprocessing, the system removes stop words from text inputs. Stops words are low-value words that generally do not contain helpful sentence meanings. The library of NLTK Corpus contains approximately 750 Indonesian stop words. Examples of stop words are *adalah* (is), *agak* (somewhat), and *ke* (to).

B. Indonesian Twitter Emotion Dataset

This work utilizes the Indonesian Twitter emotion dataset from [13] for model training. Saputri et al. collected 4,403 Indonesian tweets using Twitter Streaming API for two weeks. The Twitter metadata, namely, username, hyperlink, and phone number in the sentences, are converted into special tags (i.e., [USERNAME], [URL], and [SENSITIVE-NO]). Then, they annotated the collected dataset with Shaver's emotions model [3]. The emotion distribution of the dataset is shown in Fig. 2.

[1] https://www.nltk.org/api/nltk.corpus.html

TABLE I. PUBLICLY AVAILABLE EMOTION RECOGNITION DATASET

No	Dataset Name	Size	Granularity	Language
1	ISEAR [17]	7,665	descriptions	English
2	Tales [18]	15,302	sentences	English
3	AffectiveText [19]	1,250	headlines	English
4	Indonesian Twitter Emotion Dataset [13]	4,403	tweets	Indonesian

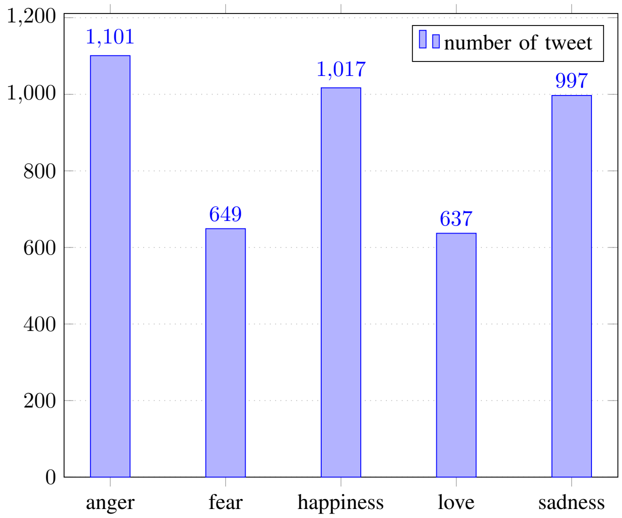

Fig. 2. The class distribution of Indonesian twitter emotion dataset.

C. Read Database

This section explains the process of reading and utilizing data from the data sources. The NLTK corpus was utilized to get Indonesian stop words. Then, the list of stop words was used in the data preprocessing step. The Indonesian Twitter emotion dataset is stored in Pandas DataFrame. Then, the data were preprocessed and converted to features for the model training.

D. Data Preprocessing

Data is the training material for the emotions recognition model. The quality of the model depends on the readiness of the data. Hence, the data preprocessing prepares data for the model training by performing several improvement steps. The case-folding converts all sentences to lowercase to avoid counting the same words as different information. Irrelevant information (i.e. username, URL, sensitive number) is removed because it is unrelated to the emotion recognition task. Then, the inputs were standardized using regular expressions to keep only the alphabet a – z. The stemming algorithm converts words to their roots. For this task, the Sastrawi python library was applied, utilizing the algorithm of Nazief and Adriani [21]. The stemming process was executed in approximately 25 minutes on 17,903 tokens. Lastly, stop words were removed to focus on important words. As a result, the data preprocessing reduces the tokens to 13,521. The algorithm illustration for the data preprocessing is shown in Algorithm 1.

Algorithm 1 Algorithm for data preprocessing

```
$corpus = [\ ]$
$i \leftarrow 0$
$N \leftarrow len(tweets)$
while $i < N$ do
    $tweet \leftarrow tweets[i]$                                   ▷ take a single tweet
    $tweet = tweet.lower()$                                        ▷ case folding
    $tweet = tweet.removeIrrelevantInformation()$
    $tweet = re.sub('[\hat{}a\text{-}z]+', ' ', tweet)$            ▷ standardization
    $tweet = stemmer.stem(tweet)$                                  ▷ stemming
    $tweet = tweet.removeStopWords()$
    $corpus.append(tweet)$                                         ▷ combine tweet
end while
```

E. Feature Extraction

This work utilizes two types of word representation for text analysis: TF-IDF and word embedding. The TF-IDF represents a document as a vector. On the other hand, word embedding represents a word as a vector. Furthermore, the length of array word embedding has a fixed array length, i.e., 300 dimensions. In the TF-IDF, the array's length depends on the size of the bag-of-words (BoW).

Three models of word embedding are utilized in this work. First, word2vec consists of 129,390 vocabulary sizes with 400 sizes of vector [13]. Second, fastText consists of 69,465 sizes of vocabulary with 100 sizes of vector [13]. Lastly, the neural network language modeling (NNLM) architecture from Google has 128 vector sizes[2]. It is trained on the Indonesian Google News 3B corpus.

In the word embedding approach, each word vector from a tweet is pooled into one vector. This work utilizes three techniques: mean pooling, sum pooling, and min-max pooling. The sum pooling sums up all vectors into the pooled vector. The mean pooling sums up all vectors and then finds their average value as the pooled vector. Lastly, the min-max pooling combines the minimum vector with the maximum vector. The result of min-max pooling is double the size of a vector. The word embedding vectorization and the pooling technique are presented in Fig. 3.

F. Feature Engineering

This research performs and combines several text-processing techniques to extract features from texts for model training. Two different text data representations were used, namely, TF-IDF and word embedding. The dataset was split into a train set (80%) and a test set (20%). This work uses a stratified train-test method to ensure both sets have a proportioned class distribution. Furthermore, a random seed '88' was used to ensure reproducible results.

SMOTE was used to perform data augmentation, i.e., over-sampling the data for model training [22]. The synthetic data were created at the vector level. The data was sampled by using a maximum sampling strategy. Moreover, a fixed random seed, i.e., '88', was used consistently to get the same sampling

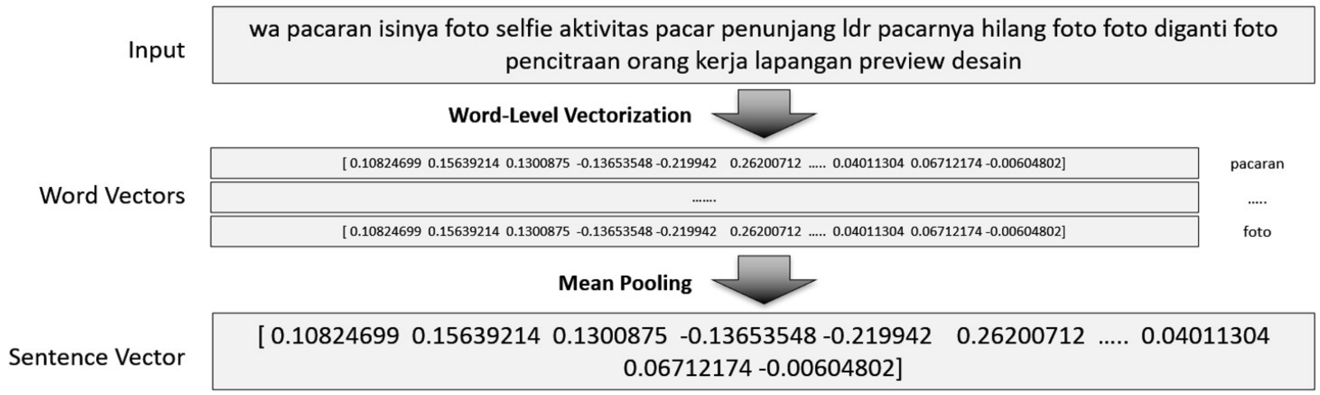

Fig. 3. The illustration of word embedding and pooling process.

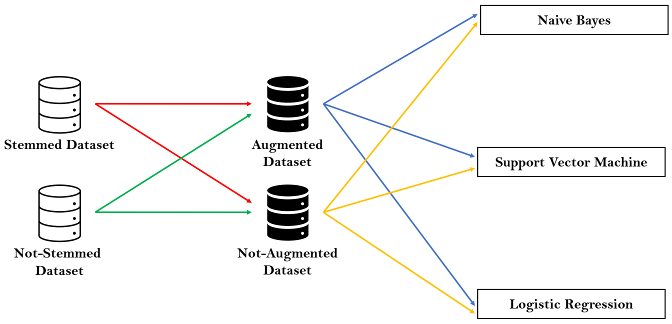

Fig. 4. Feature engineering configurations in TF-IDF.

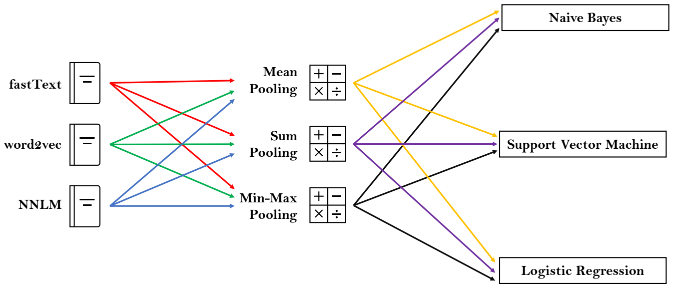

Fig. 5. Feature engineering configurations in word embedding.

result. Different machine learning classifiers were utilized for training the emotion recognition model. Based on the preliminary research, the recommended classifiers are Naive Bayes (NB), Logistic Regression (LR), and Support Vector Machine (SVM).

This research proposes twelve feature engineering configurations in TF-IDF by mixing data stemming, data augmentation, and machine learning classifiers. Fig. 4 shows the feature engineering configuration illustration for TF-IDF. The red line symbolizes the data flow of the stemmed dataset, and the green line symbolizes the data flow of the not-stemmed dataset. Then, those data were passed to the data augmentation process. The blue lines symbolize the data flow of the augmented dataset, and the yellow line symbolizes the data flow of the not-augmented dataset. Finally, those data were passed to three different classifiers.

This research proposes 27 feature engineering configurations in word embedding by mixing three-word embedding models, three pooling techniques, and three machine-learning classifiers. Fig. 5 shows the feature engineering configuration illustration for word embedding. The red, green, and blue lines symbolize feature extraction using fastText, word2vec, and NNLM, respectively. Then, the word embedding results were combined into sentence embedding with three different pooling techniques. The yellow, purple, and black lines symbolize the pooling technique using mean pooling, sum pooling, and min-max pooling, respectively. Finally, the data were passed to three different classifiers.

This work creates a naming scheme to differentiate the configurations. For example, the configuration of TF-IDF with SVM, not-stemmed database, and augmented is “TFIDF_SVM_notstem_aug”. Moreover, the configuration of word embedding with Naive Bayes, fastText, and sum pooling is “WE_NB_ft_sum”. The detail of the naming scheme is as follows:

- **TF-IDF**: TFIDF_name of classifier technique_status of dataset stemming_status of dataset augmentation.
- **Word Embedding**: WE_classifier technique_word embedding model_pooling technique.

G. Model Training

The emotion recognition model was trained using Google Colab[3]. The model training uses ’88’ as the random seed. Furthermore, the model training was performed using Python v3.7.13, NLTK v3.7, scikit-learn v1.0.2, and various text processing libraries (e.g., *re* for regular expression operations).

H. Model Evaluation

The emotion recognition model is evaluated using accuracy and macro F_1 score. The accuracy score is calculated by dividing the number of correct predictions by the number of total data. The equation of accuracy metric is presented in Equation (1).

[3] http://colab.research.google.com/

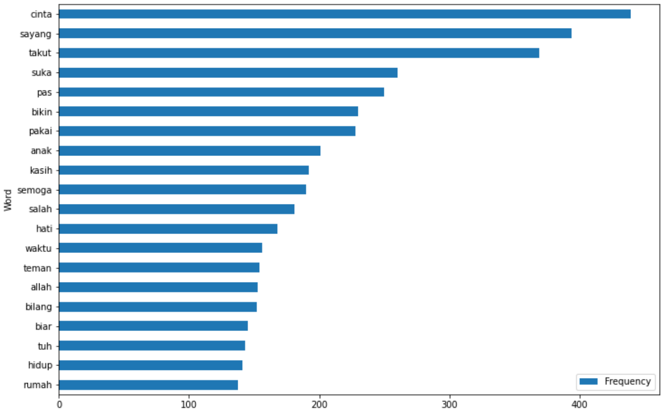

Fig. 6. Word frequency analysis of top 20 common words (excluding stop words).

$$accuracy = \frac{TP + TN}{TP + TN + FP + FN} \tag{1}$$

In machine learning, TP means true positive, TN means true negative, FP means false positive, and FN means false negative.

$$F_1 = \frac{2 * TP}{2 * TP + FP + FN} \tag{2}$$

The F_1 metric combines precision and recall to calculate the harmonic mean of the two metrics. The equation of F_1 metric is presented in Equation (2).

IV. Results

This section discusses the result of exploring the Indonesian Twitter emotion dataset. Furthermore, the result of the experiment is divided into two subsections, namely TF-IDF and Word Embedding. The full results of the experiment can be viewed on the GitHub page[4].

A. Dataset Exploration

Fig. 6 shows the word frequency analysis of the top 20 common words in the Indonesian Twitter emotion dataset. The result has excluded stop words that are valueless for model training. It shows the words "*cinta*" (love), "*sayang*" (darling), "*takut*" (afraid), and "*suka*" (like) are the most commonly occurring word frequencies.

Moreover, the frequent use of words is also shown as a word cloud. The diagram below includes all words from the dataset. It can be seen in Fig. 7 that the most common words are dominated by stop words, e.g., "*saya* (I)," "*yang* (which)," and "*kamu* (you)."

B. TF-IDF

This work explored 12 feature engineering configurations of TF-IDF by combining data stemming, data augmentation, and machine learning classifiers. The F_1 score results for every configuration with TF-IDF are presented in Fig. 8.

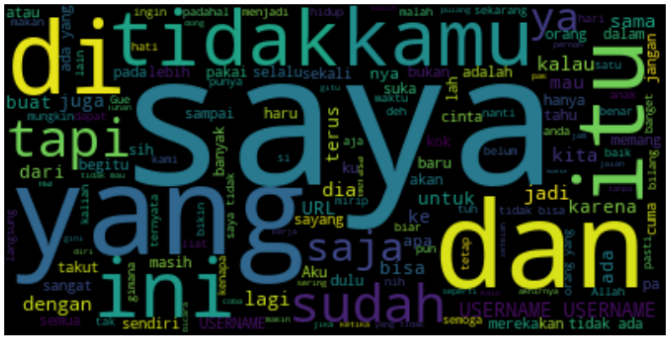

Fig. 7. Word cloud plot of Indonesian twitter emotion dataset (including all words).

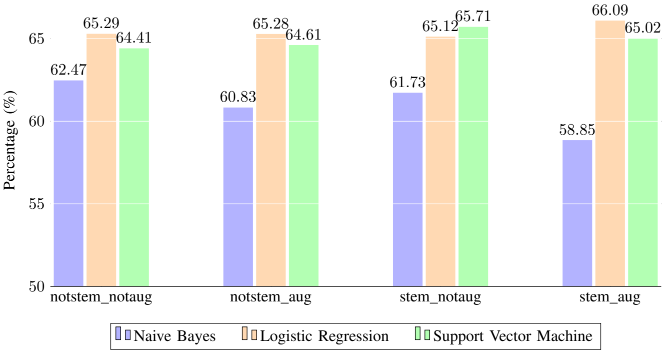

Fig. 8. The F_1 score results with TF-IDF configurations

(notstem: not-stemmed, stem: stemmed, notaug: not-augmented, aug: augmented)

The best configuration in the TF-IDF approach is "TFIDF_LR_stem_aug," i.e., the combination of logistic regression (LR), stemmed dataset (stem), and augmented dataset (aug). The model achieved 65.27% accuracy and 66.09% F_1 score. Furthermore, the worst configuration in the TF-IDF approach is from "TFIDF_NB_stem_aug" with 59.59% accuracy and 58.85% F_1 score. The experimental results show that different machine learning classifiers greatly impact the same preprocessed dataset, i.e., stemmed dataset (stem) and augmented dataset (aug). Moreover, the performance of the Naive Bayes classifier is inferior to the others.

From the machine learning classifier perspective, the logistic regression provides the best performance across all configurations, i.e., 64.42% average accuracy and 65.45% average F_1 score. From the data preprocessing perspective, using the stemming process increases the overall accuracy by 0.11% compared to not using it. However, it reduces the overall F_1 score by 0.06%. Finally, the augmentation process reduces average accuracy and average F_1 score by 0.45% and 0.67%, respectively.

Fig. 9 shows the confusion matrix result of the TF-IDF model, i.e., "TFIDF_LR_stem_aug". The most accurate prediction is anger (18.39%), and the least accurate prediction

[4] https://github.com/rhiosutoyo/emotion-recognition-model

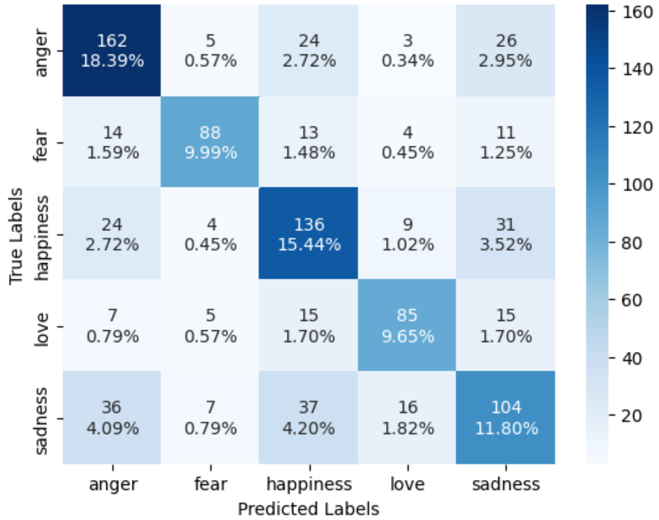

Fig. 9. The confusion matrix from the best TF-IDF model (TFIDF_LR_stem_aug).

is love (9.65%). The result is unsurprising because anger has the highest label than the other emotions. Furthermore, love has the lowest label than the other emotions. The confusion matrix result shows that anger tends to be misinterpreted as sadness. Moreover, fear tends to be misinterpreted as anger. Happiness tends to be misinterpreted as sadness. Love tends to be misinterpreted as happiness or sadness. Lastly, sadness tends to be misinterpreted as happiness.

Based on the experiment results, implementing data augmentation to increase the training data does not yield a positive outcome. In theory, the augmentation process is supposed to increase the model performance. However, the performance of using augmentation techniques is lower than that of not using them. This work argues that the original dataset has performed well because the Indonesian Twitter dataset is quite balanced. Thus, the augmented dataset is having trouble outperforming the performance of the not-augmented dataset.

C. Word Embedding

This work explored 27 feature engineering configurations of word embedding (WE) by combining three-word embedding models, three pooling techniques, and three machine-learning classifiers. The F_1 score results for every configuration with word embedding are presented in Fig. 10.

The best configuration in the word embedding approach is from the combination of support vector machine (SVM), fastText (ft), and sum pooling (sum), or “WE_SVM_ft_sum.” The model achieved 65.27% accuracy and 64.50% F_1 score. Furthermore, the worst configuration in the word embedding approach is from “WE_NB_w2v_sum” with 38.59% accuracy and 36.86% F_1 score.

From the machine learning classifier perspective, the SVM performs best across all configurations, i.e., 58.17% average accuracy and 57.89% average F_1 score. From the word embedding model’s perspective, the fastText model provides the best performance across all configurations, i.e., 56.26% average accuracy and 55.68% average F_1 score. The fastText’s average F_1 score is 3.52% higher than Google’s NNLM and 3.7% higher than the word2vec model. The word2vec incapability to handle out-of-vocabulary tokens might be the reason for the poor performance. Lastly, the pooling technique with the best average performance across all configurations is mean pooling, i.e., 57.28% average accuracy and 56.83% average F_1 score. The mean pooling’s average F_1 score is 7.12% higher than the min-max pool and 2.49% higher than the sum pool. The min-max pooling technique that discards features from the input might be the reason for the poor performance.

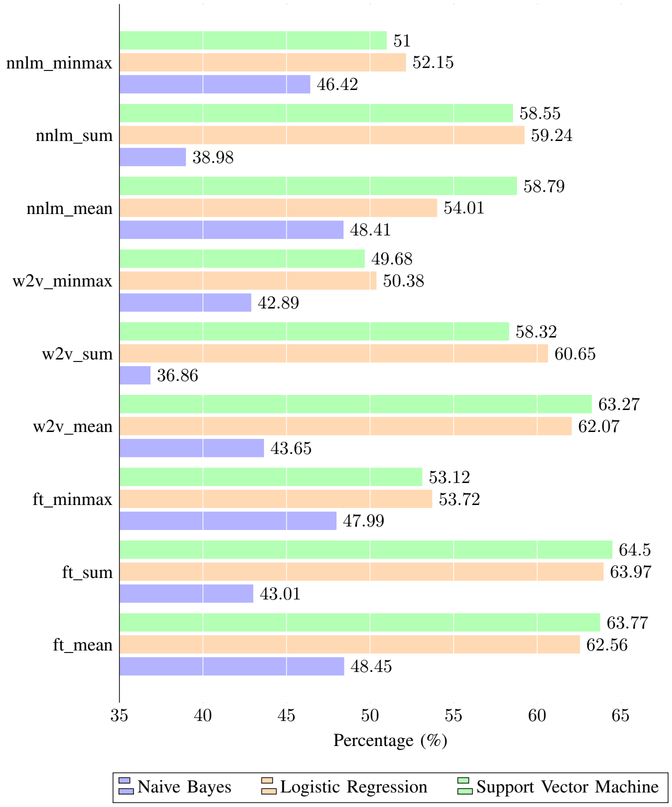

Fig. 10. The F_1 score results with word embedding configurations.

(nnlm: neural network language model, w2v: word2vec, ft: fastText)

Fig. 11 shows the confusion matrix result of the word embedding model, i.e., “WE_SVM_ft_sum”. The most accurate prediction is anger (21.11%), and the least accurate is sadness (8.29%). Emotion with the highest result from word embedding is the same as the TF-IDF approach,i.e., anger. Emotion with the lowest result from word embedding differs from the TF-IDF approach, i.e., love. The confusion matrix result shows that anger tends to be misinterpreted as happiness. Furthermore, fear tends to be misinterpreted as anger. Happiness tends to be misinterpreted as anger. Love tends to be misinterpreted as happiness. This is normal because both emotions share similar characteristics. Lastly, sadness tends to be misinterpreted as anger.

Unlike the TF-IDF, the confusion matrix result of word embedding shows that the prediction results do not align with the sum of the label quantities in the dataset. Based on the sum

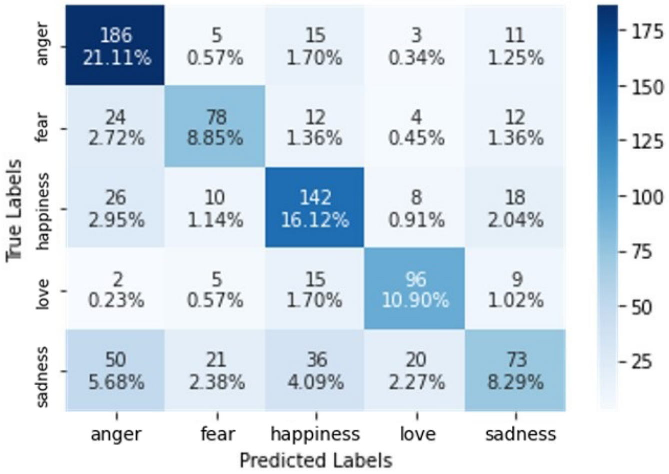

Fig. 11. The confusion matrix from the best word embedding model (WE_SVM_ft_sum).

TABLE II. The Configuration Detail of the Top Seven Models in TF-IDF

Configuration Component	Measurement	Frequency	%
Data Stemming	Stemmed	4	57%
	Not-Stemmed	3	43%
	Total	7	100%
Data Augmentation	Augmented	4	57%
	Not-Augmented	3	43%
	Total	7	100%
Machine Learning Classifier	Logistic Regression	4	57%
	Support Vector Machine	3	43%
	Naive Bayes	0	0%
	Total	7	100%

of the label quantities in the dataset, the order of emotions is anger, happiness, sadness, fear, and love (see Fig. 2). Based on the confusion matrix performance, the emotions are anger, happiness, love, fear, and sadness (see Fig. 11).

V. Discussions

A. Configuration Detail of the Top Seven Models

This work proposed 39 feature engineering configurations, i.e., 12 with TF-IDF and 27 with word embedding. This section shows the configuration detail of the top seven models from both word representation techniques.

The configuration detail of the top seven models in TF-IDF is shown in Table II. The experiment shows that the top-performance model has the following component configurations: logistic regression, stemmed dataset, and augmented dataset. The result matches the top model on TF-IDF, which is "TFIDF_LR_stem_aug."

Moreover, the configuration detail of the top seven models in word embedding is shown in Table III. The experiment shows that the top-performance model has the following component configurations: logistic regression, fastText, and mean pooling. The result does not match the top word embedding model, "WE_SVM_ft_sum."

TABLE III. The Configuration Detail of the Top Seven Models in Word Embedding

Configuration Component	Measurement	Frequency	%
Word Embedding Model	fastText	4	57%
	word2vec	3	43%
	NNLM	0	0%
	Total	7	100%
Pooling Technique	Mean Pooling	4	57%
	Sum Pooling	3	43%
	Min-Max Pooling	0	0%
	Total	7	100%
Machine Learning Classifier	Logistic Regression	4	57%
	Support Vector Machine	3	43%
	Naive Bayes	0	0%
	Total	7	100%

TABLE IV. Average F_1 Score of TF-IDF and Word Embedding from the Top Seven Model Configurations

Word Representation	F_1 Score
TF-IDF	65.30%
Word Embedding	62.97%

The top seven model configurations of TF-IDF and word embedding produce an F_1 score of more than 60%. On average, the top seven models of TF-IDF perform better than word embedding. The results are shown in Table IV.

B. TF-IDF vs. Word Embedding

Based on the experiment, the F_1 score from the best model of the word embedding technique (64.5%) is lower than the TF-IDF technique (66.09%). Hence, the best feature engineering configuration for the emotion recognition model is the TF-IDF approach from the combination of logistic regression (LR), stemmed dataset (stem), and augmented dataset (aug).

In theory, the word embedding technique should be able to produce a higher performance result because it has dense information packed in fixed-size arrays. Nevertheless, other research also shows that the performance of word embedding is lower than TF-IDF [23], [24]. In their research [23], Piskorski and Jacquet argue that features from word embedding might be great for deep learning but not for machine learning. Furthermore, specific features make the dataset biased in favor of traditional machine-learning approaches. These features appear exclusively for some categories (e.g., unique keywords). Thus, the classical machine learning algorithms can perform the classification with high precision because of the feature vector built using the TF-IDF technique.

C. Performance Comparison

The previous work from [13] does not provide codes and test splits. Hence, this study repartitioned the Indonesian Twitter emotion dataset by using several random seed values to perform the experiments. Ultimately, the random seed "88" was chosen because it achieved the best result.

The experiment resulted in a slightly better performance than the previous study [13] from the perspective of basic features, i.e., Word2Vec (WV) and FastText (FT). The Word2Vec (WV) F_1 score is increased by 1.44% by using mean pooling and SVM. Moreover, the FastText (FT) F_1 score is increased by 2.01% by using sum pooling and SVM.

In general, the quality of features can be increased by utilizing different pooling methods. Moreover, SVM produces better results than logistic regression.

VI. Conclusions and Future Work

This research explored feature engineering to build an emotion recognition model on the Indonesian Twitter dataset. Two different text data representations were used, namely TF-IDF and word embedding. This research proposes 12 feature engineering configurations in TF-IDF by mixing data stemming, data augmentation, and machine learning classifiers. Furthermore, this research proposes 27 feature engineering configurations in word embedding by mixing three-word embedding models, three pooling techniques, and three machine-learning classifiers. Moreover, this research analyzed the top seven models of both data representation techniques to find the recommended configuration component. Finally, performance comparisons were conducted to evaluate the models further.

The best performance configuration of TF-IDF is achieved by "TFIDF_LR_stem_aug," i.e., logistic regression (LR), stemmed dataset (stem), and augmented dataset (aug). The model achieved 65.27% accuracy and 66.09% F_1 score. The best performance configuration of word embedding is achieved by "WE_SVM_ft_sum," i.e., support vector machine (SVM), fastText (ft), and sum pooling (sum). The model achieved 65.27% accuracy and 64.50% F_1 score. The detailed characteristics from the top seven models show the recommended component configurations in TF-IDF: logistic regression, stemmed dataset, and augmented dataset. The recommended component configurations in word embedding are logistic regression, fastText, and mean pooling.

Furthermore, the experiment shows a slightly better performance than the previous study from the perspective of a single basic feature, i.e., word embedding. This work improved the word2vec F_1 score by 1.44% by using mean pooling and SVM. Moreover, the fastText F_1 score is increased by 2.01% by using sum pooling and SVM. Based on the results, the quality of text features in word embedding can be enhanced by utilizing different pooling methods. The recommended configuration element in word2vec is mean pooling; in fastText, it is sum pooling.

Lastly, the experiment shows that word embedding performs lower than TF-IDF. Thus, further exploration of utilizing word embedding in deep learning with a more significant number of examples can become the focus of future work.

***Abstract*—Extreme learning machines (ELM) have recently attracted considerable attention because of its fast learning rate, simple model structure, and good generalization ability. However, classical ELM with least squares loss function is prone to overfitting and lack robustness in dealing with datasets containing noise and outliers in the real world. In this paper, inspired by the maximum correntropy criterion, an exponential squared loss function is introduced, which is nonconvex and insensitive to noise and outliers. A robust ELM with exponential squared loss (RESELM) is presented to overcome the overfitting problem. The proposed model with nonconvexity is difficult to be directly optimized. Considering the superior performance of difference of convex functions (DC) programming in solving nonconvex problems, this paper optimizes the model by expressing the objective function as a DC function and employing DC algorithm (DCA). To examine the effectiveness of the proposed algorithm in noisy environment, different levels of outliers are added to the training samples in the experiments. Experimental results on benchmark data sets with different outliers levels illustrate that the proposed RESELM achieves significant advantages in generalization performance and robustness, especially in higher outliers levels.**

Keywords*—Extreme learning machine; exponential squared loss; DC programming; DCA; robust regression

I. Introduction

To improve the slow learning rate of single hidden layer feedforward neural networks (SLFNs), Huang and his team proposed extreme learning machine (ELM) in 2004 [1], [2], [3]. Traditional algorithms for feedforward neural networks require iterative adjustment of all parameters in the whole network. However, the experiments in [4], [5] illustrate that input weights and hidden layer bias of SLFNs may not need to be adjusted. The hidden layer input weights and biases of ELM are determined by random generation, which reduces the number of parameters to be solved in the network by a large part. ELM can be regarded as a simple linear system with only the output weights to be solved. ELM is widely used in various real-world problems relying on its fast learning rate, simple model structure, and good generalization ability [6], [7], [8].

However, samples in real-world problems are different from the clean and uncontaminated samples used in the laboratory, which is potentially polluted in the process of both generation and acquisition [9]. Training ELM with samples containing outliers can exacerbate the discrepancy between the true and predicted values, leading to longer learning time and poorer model prediction accuracy [10], [11]. The loss function plays a crucial role in ELM training. Classical ELM employs the least squares loss function, which is easy to be solved and can improve the learning rate of the model. However, its squared effect leads to more sensitivity to outliers. When the outliers are larger, the empirical risk of the model becomes higher, which eventually affects the accuracy of the model [12].

In order to minimize the disturbance of outliers, researchers have turned to finding alternative loss functions to obtain a more robust algorithm [13], [14]. Deng et al. proposed an improved ELM based on a weighted 2-norm loss function (WELM) [15], which assigned weights to the samples depending on the residuals, improved the model's generalization. Zhang et al. developed outlier robust ELM (ORELM) by applying the 1-norm loss function to ELM [16]. The 1-norm loss function grows slower than the 2-norm loss function as the residuals increase, thus obtaining a better accuracy than ELM. Chen et al. constructed a robust ELM that can use four loss functions (1-norm, Huber, Bisquare, Welsch) [17]. The experiment's optimal accuracy was obtained by the model that used Bisquare or Welsch loss functions, both of which are nonconvex loss functions. The 1-norm and Huber loss functions are both convex loss functions and has a linear relationship with residuals, which is still not robust. When the residuals are enormous, the penalty imposed on the sample by the convex loss function can also be very large. Models usually treat outliers as normal values to reduce the large value's loss caused by outliers in empirical risk at the cost of sacrificing the model's generalization, and nonconvex loss functions can compensate for this deficiency [18].

The nonconvex loss function has a strong learning capability in terms of both generalization and robustness. The capped type of nonconvex loss functions can directly limit the maximum penalty value caused by noise and outliers and explicitly suppress the negative impact of such samples on the decision hyperplane to build models with excellent robustness [18], [19]. Different capped 2-norm loss functions are constructed in [20] and [21], respectively, which have shown stronger robustness and generalization. In recent years, with the development of information theory, Liu et al. proposed correntropy in 2007 [22], which is a measure of similarity of two sets of random variables and widely used in robust learning. Xing et al. proposed a robust ELM model based on the regularized correntropy criterion [23], which showed that the proposed model has better robustness and can effectively handle scenes with outlier interference.

This paper proposes a nonconvex exponential squared loss function inspired by the above literature and the maximum correntropy criterion. This loss function is applied to ELM, which leads to a new robust ELM. RESELM can sufficiently suppress the negative impact of outliers on the robustness of the model and effectively improve the model's generalization. However, nonconvexity makes the model difficult to optimize. Considering the advantages of DCA [24] in solving nonconvex problems, this paper converts the objective function into DC programming [25] and then uses DCA to obtain the optimal output nodes.

The main contributions of this paper can be summarized as follows:

(1) A new loss function is constructed based on the maximum correntropy criterion, called the exponential squared loss function, which is nonconvex and can deal with training samples with noise and outliers.

(2) Robust ELM with the exponential squared loss function (RESELM) is developed. The nonconvexity of the proposed model makes it difficult to optimize directly by classical convex optimization algorithms. Therefore, it is transformed into a DC programming, and solved by DCA.

(3) The RESELM is tested in the case with 0%-20% lower outliers levels and with 25%-40% higher outliers levels, respectively. The experimental results show that RESELM improves the robustness and has excellent generalization ability, especially in the case of higher outliers levels.

The remainder of the paper is organized as follows. Section II briefly reviews the ELM. In Section III, the proposed model of this paper and the process of optimization by adopting DC programming are elaborated in detail. In Section IV, the experimental results of RESELM with different outliers levels are shown and analyzed. In the fifth part, the work of this paper is summarized.

II. Related Works

For N arbitrary samples $\{(\mathbf{x}_i, y_i)\}_{i=1}^N$, where $\mathbf{x}_i \in R^d$ is the input variable and $y_i \in R$ is the corresponding target in regression estimation, the output of ELM with L hidden nodes can be described as follows:

$$f(\mathbf{x}) = \sum_{j=1}^{L} h_j(\mathbf{x})\boldsymbol{\beta_j} = \mathbf{h}(\mathbf{x})\boldsymbol{\beta} \tag{1}$$

where $\boldsymbol{\beta} = [\beta_1, \beta_2, ..., \beta_L]^T$ is the output weights vector that connects the hidden layer to the output node, and $\mathbf{h}(\mathbf{x}) = [h_1(\mathbf{x}), h_2(\mathbf{x}), ..., h_L(\mathbf{x})]$ is the output of the hidden layer and $h_j(\mathbf{x})$ is the activation function. The formulation of regularized ELM [26] can be expressed as the following optimization:

$$\underset{\boldsymbol{\beta}}{min} \quad \frac{1}{2}\|\boldsymbol{\beta}\|^2 + \frac{C}{2}\sum_{i=1}^{N} e_i^2 \tag{2}$$

$$s.t. \quad \mathbf{h}(\mathbf{x}_i)\boldsymbol{\beta} = y_i - e_i, i = 1, ..., N, \tag{3}$$

where e_i denotes the error of training sample $\mathbf{x}_i$, and C is the regularization parameter. The optimal solution $\boldsymbol{\beta}$ of (2)-(3) is given by [26]

$$\boldsymbol{\beta} = \begin{cases} (\mathbf{H}^T\mathbf{H} + \dfrac{\mathbf{I}}{C})^{-1}\mathbf{H}^T\mathbf{y}, & N \geq L, \\ \mathbf{H}^T(\mathbf{H}\mathbf{H}^T + \dfrac{\mathbf{I}}{C})^{-1}\mathbf{y}, & N < L. \end{cases} \tag{4}$$

where $\mathbf{y} = [y_1, y_2, ..., y_N]^T$ and

$$\mathbf{H} = \begin{bmatrix} \mathbf{h}(\mathbf{x}_1) \\ \mathbf{h}(\mathbf{x}_2) \\ . \\ . \\ . \\ \mathbf{h}(\mathbf{x}_N) \end{bmatrix} = \begin{bmatrix} h_1(\mathbf{x}_1) & h_2(\mathbf{x}_1) & ... & h_L(\mathbf{x}_1) \\ h_1(\mathbf{x}_2) & h_2(\mathbf{x}_2) & ... & h_L(\mathbf{x}_2) \\ . & . & . & . \\ . & . & . & . \\ . & . & . & . \\ h_1(\mathbf{x}_N) & h_2(\mathbf{x}_N) & ... & h_L(\mathbf{x}_N) \end{bmatrix} \tag{5}$$

is the output matrix of the hidden layer.

In Regularized ELM (2)-(3), the least squares loss function may result in poor performance of ELM in dealing with the training samples containing noise and outliers. The reason for this is that least squares loss function assumes that the training samples obey a normal error distribution [12]. However, it can not guaranteed in the real world, which mistakenly considers the role of outliers with large residuals. This paper will focus on suppressing the effect of outliers by introducing a new exponential squared loss function for the ELM.

III. Research Methodology

A. Exponential Squared Loss Function

In information theory, the maximum correntropy criterion [22] is used to deal with the analysis of signals affected by various noises, which can effectively improve the robustness of signal analysis, and it is defined as follows:

$$V_\sigma(A, B) = E[k_\sigma(A - B)], \tag{6}$$

where $k_\sigma(\cdot)$ is a kernel function and $E[\cdot]$ is the mathematic expectation. In general, the joint probability distribution between variables A and B is unknown, so the average value is used to estimate the mathematical expectation. Then the maximum correntropy criterion is expressed as

$$V_\sigma(A, B) = \frac{1}{m}\sum_{i=1}^{m} k_\sigma(A_i, B_i), \tag{7}$$

where $k_\sigma(A_i, B_i) = \exp\left(-\frac{\|A_i - B_i\|^2}{\sigma^2}\right)$ is Gaussian kernel function.

In order to overcome the drawback of the least squares loss function, this paper constructs the exponential squared loss function based on the correntropy,

$$\ell_\sigma(z) = \sigma^2\left[1 - \exp\left(-\frac{z^2}{\sigma^2}\right)\right], \tag{8}$$

where σ^2 is the upper bound of the exponential squared loss function. Fig. 1 demonstrates the different curves of exponential squared loss with respect to the different of σ^2. As shown in Fig. 1, the proposed loss function is bounded.

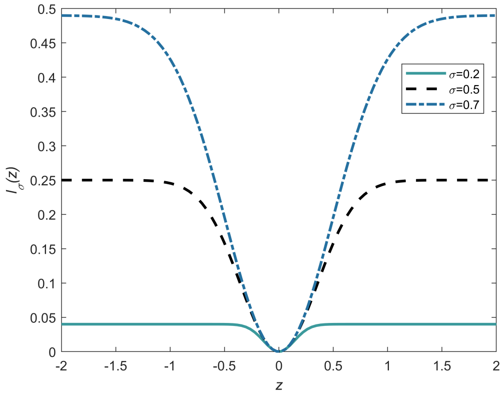

Fig. 1. Exponential squared loss function with different σ.

B. Robust ELM with Exponential Squared Loss Function

In this subsection, a robust ELM with exponential squared loss function is developed to improve the robustness of ELM, and the corresponding optimization problem can be obtained as

$$\min_{\boldsymbol{\beta}} \quad \frac{1}{2}\|\boldsymbol{\beta}\|^2 + \frac{C}{2}\sum_{i=1}^{N} \ell_\sigma(z_i) \tag{9}$$

where training error $z_i = y_i - \mathbf{h}(\mathbf{x}_i)\boldsymbol{\beta}$ and $\ell_\sigma(z_i)$ is the exponential squared loss function. The expression (8) can be written in the following equivalent form.

$$\ell_\sigma(z) = \ell_1(z) - \ell_2(z) \tag{10}$$

where $\ell_1(z) = z^2$, $\ell_2(z) = z^2 - \sigma^2\left[1 - \exp\left(-\frac{z^2}{\sigma^2}\right)\right]$. Substituting $\ell_1(z)$ and $\ell_2(z)$ into the optimization problem (9) can be derived as follows:

$$\min_{\boldsymbol{\beta}} \quad \frac{1}{2}\|\boldsymbol{\beta}\|^2 + \frac{C}{2}\sum_{i=1}^{N} \ell_1(z_i) - \frac{C}{2}\sum_{i=1}^{N} \ell_2(z_i) \tag{11}$$

Mark $L_1(\boldsymbol{\beta}) = \frac{1}{2}\|\boldsymbol{\beta}\| + \frac{C}{2}\sum_{i=1}^{N}\ell_1(z_i)$, $L_2(\boldsymbol{\beta}) = \frac{C}{2}\sum_{i=1}^{N}\ell_2(z_i)$. According to the DCA, the optimal solution of the optimization problem (11) is obtained by solving the following iterations:

$$\boldsymbol{\beta}^{(t+1)} = \arg\min_{\boldsymbol{\beta}} \left\{ L_1(\boldsymbol{\beta}) - L_2^{'}(\boldsymbol{\beta}^{(t)}) \cdot \boldsymbol{\beta} \right\} \tag{12}$$

where $L_2^{'}(\boldsymbol{\beta}^{(t)})$ represents the derivative of $L_2(\boldsymbol{\beta})$ at $\boldsymbol{\beta}^{(t)}$. For a certain $\boldsymbol{\beta}$, the derivative expression is as follows:

$$L_2^{'}(\boldsymbol{\beta}) = \frac{C}{2}\sum_{i=1}^{N} \frac{\partial \ell_2(z_i)}{\partial z_i} \cdot \frac{\partial z_i}{\partial \boldsymbol{\beta}} = \frac{C}{2}\sum_{i=1}^{N} \left(\frac{\partial \ell_2(z_i)}{\partial z_i}\right) \cdot \left(-\mathbf{h}^T(\mathbf{x}_i)\right) \tag{13}$$

Denote $s_i = \frac{C}{2} \cdot \frac{\partial \ell_2(z_i)}{\partial z_i}$, and then define

$$s_i = C z_i \left[1 - \exp\left(-\frac{z_i^2}{\sigma^2}\right)\right] \tag{14}$$

From (13) and (14),

$$\begin{aligned} -L_2^{'}\left(\boldsymbol{\beta}^{(t)}\right) \cdot \boldsymbol{\beta} &= \sum_{i=1}^{N} s_i^{(t)} \cdot \mathbf{h}\left(\mathbf{x}_i\right)\boldsymbol{\beta} \\ &= \mathbf{s}^T \mathbf{H}\boldsymbol{\beta} \end{aligned} \tag{15}$$

where $\mathbf{s} = [s_1, s_2, ..., s_N]^T$, then (12) can be transformed into solving the following optimization problem

$$\boldsymbol{\beta}^{(t+1)} = \arg\min \left\{ \frac{1}{2}\|\boldsymbol{\beta}\|^2 + \frac{C}{2}\|\mathbf{y} - \mathbf{H}\boldsymbol{\beta}\|^2 + \mathbf{s}^T\mathbf{H}\boldsymbol{\beta} \right\} \tag{16}$$

Following the line [26], the optimal solution of (12) in the (t+1) iteration is obtained

$$\boldsymbol{\beta} = \begin{cases} \left(\frac{\mathbf{I}}{C} + \mathbf{H}^T\mathbf{H}\right)^{-1} \mathbf{H}^T \left(\mathbf{y} - \frac{\mathbf{s}}{C}\right) & N > L, \\ \mathbf{H}^T \left(\frac{\mathbf{I}}{C} + \mathbf{H}\mathbf{H}^T\right)^{-1} \left(\mathbf{y} - \frac{\mathbf{s}}{C}\right) & N \le L. \end{cases} \tag{17}$$

Next is the step to solve RESELM by DC algorithm

Algorithm 1 RESELM

```
Input: $\{(\mathbf{x}_i, y_i)\}_{i=1}^N$, set $t$=0 and choose an initial point $\mathbf{s}^{(0)}$,
  $L$, $C$, $t_{max}$ and $\varepsilon > 0$ is a sufficient small number
Output: $\boldsymbol{\beta}$
  repeat
    Compute $s_i^{(t)}$ by (14) and $\mathbf{s}$.
    Calculate (17) to obtain $\boldsymbol{\beta}^{(t+1)}$.
    Let $t$=$t$+1.
  until $\left\|\boldsymbol{\beta}^{(t)} - \boldsymbol{\beta}^{(t+1)}\right\| \le \varepsilon$ or $t > t_{max}$
```

IV. Results and Discussion

To validate the efficacy of RESELM, it is compared with four related methods, regularized ELM [26], weighted ELM (WELM) [15], outlier robust ELM (ORELM) [16] and iteratively reweighted ELM (IRWELM) [27] on 18 benchmark data sets. In the first part, to simulate the samples in real world, different outliers levels are added to each of the 18 benchmark data sets, which can better reflect the robustness. of each algorithm. In the second part, the effects of the number of hidden nodes L and the parameter σ on the performance of the algorithms are studied. The root mean squares error (RMSE) [28] is used to measure the performance of the five regression algorithms. In the experiments, three parameters should be selected, L, C, σ. The maximum number of iteration t_{max} = 20, and the number of hidden nodes L=200. C is chosen from $\left\{2^{-19}, 2^{-18}, 2^{-17}, ..., 2^{18}, 2^{19}, 2^{20}\right\}$, and the width parameter of exponential squared loss function in RESELM is chosen from $\{0.05, 0.1, 0.15, 0.2, ..., 0.95, 1\}$.

A. Experimental Results on Benchmark Data Sets

This section shows the accuracy of the five algorithms on the benchmark data sets with different outliers levels. Table 1 demonstrates the algorithms' RMSE on 10 benchmark data sets with different outliers levels (0%, 5%, ...,35%, 40%). Fig. 2 adopts a line chart to intuitively exhibit the accuracy variation

of the five algorithms on 8 benchmark data sets with 0% to 40% outliers levels.

In the experiments, each data set is randomly divided into training set and test set. Then different proportions of outliers are added to the training set, which is determined by the targets of the training set. The experiment select different proportions of outliers from $[y_{min},\ y_{max}]$ and add these outliers to the training samples randomly. The test set does not take any operation. The 10-fold cross-validation is applied on benchmark data sets, and taking the average RMSE of these ten independent experiments as the final result.

Observing the results in Table I, RESELM performs the best in the case of no outliers and achieves the optimal RMSE on four data sets. The accuracy on the other data sets is similar to the optimal RMSE. The worst performer is ELM, which achieves the optimum only on the Concrete data set. The performance of ORELM and IRWELM is close to each other. On the data set with 5% outliers level, the accuracy of ELM decreases most significantly, with a larger RMSE than the other algorithms on each data set. The accuracy of IRWELM is better than it would have been in the case of no outliers. RESELM obtains more comparable robustness, and its accuracy is optimal on most of the data sets. When the outliers level rises to 10%, the accuracy of ELM is still not very competitive, and the RMSE of WELM is better than that of the ELM. RESELM maintains its advantage in robustness, obtaining the optimal RMSE on eight data sets. The accuracy of the IRWELM is next to that of the RESELM in most cases. In the case of 15% and 20% outliers levels, the accuracy of RESELM obtains the best RMSE on most of the data sets. At the same time, ELM fails to obtain the optimal accuracy on any of data sets and has the worst RMSE of the five algorithms in most cases.

In the lower outliers levels (0%-20%), the optimal RMSEs are obtained for ELM only on Concrete. The most optimal RMSEs is RESELM with 34 times, and RESELM ranks second in accuracy for most other cases. It can be seen that ELM, WELM and ORELM are most negatively affected as the outliers increase. In comparison, RESELM is hardly affected, which shows that RESELM can effectively suppress the effect of outliers.

This paper focuses on the improvement of RESELM in terms of robustness. In the case of lower outliers levels, the robustness of RESELM improves but does not achieve the optimal RMSE on all data sets, such as on the data sets Body-fat, which is mainly determined by the loss function, where the difference between the true value and the predicted value is larger, the bigger the corresponding loss function value. Researchers have proposed various loss functions in order to reduce the effect of outliers so that the robustness of the model will be better [18], [19]. As shown in Table I, the loss function of RESELM does not have a significant advantage in the lower outliers levels, so experiments with higher outliers levels are conducted to investigate the robustness of the proposed algorithm.

From Table I, it can be seen that the robustness of ELM remains uncompetitive in the case of higher outlier levels, and its RMSE increases with the outliers level. ELM applies a least squares loss function, and when the residuals are small, the least squares loss function does not differ significantly from the exponential squared loss function. Therefore, ELM can produce more accurate results when there are no outliers. However, this loss function increases infinitely with the growth of the residuals and is growing exponentially, so it cannot effectively constrain the effect of outliers, which makes the ELM less robust.

In the case of 25%-40% outliers levels, WELM does not obtain the optimal RMSE, but it has better accuracy than ELM. A weighted 2-norm loss function is proposed in WELM, which assigns different weights according to the value of the residuals to improve the robustness. However, the algorithm of WELM relies too much on the initial accuracy of the model, and the results obtained are not satisfactory.

ORELM has a better increase in accuracy than the lower outliers levels, and has the smallest difference from the optimal RMSE in most cases. ORELM uses the 1-norm loss function, which has a larger function value than the others when the residuals are small, and therefore has poorer accuracy. However, after the residuals increase, it has an advantage over the least squares loss function and the weighted 2-norm loss function. This is the reason that why ORELM is worse than IRWELM in most cases in the lower outliers levels but has better RMSEs than IRWELM in the cases of 25% to 40% outliers levels.

Fig. 2. The performance of ELM, WELM, ORELM, IRWELM and RESELM on data sets with different outliers levels.

IRWELM is the opposite of ORELM. The accuracy of IRWELM ranks second 25 times in the lower outliers levels, and its ability to suppress outliers is worse than ORELM when the outliers level increases. IRWELM and WELM apply the same loss function, but IRWELM is more robust than WELM because IRWELM's solution method is an iterative reweighting algorithm. Compared with WELM which solves the output nodes directly, the iterative approach of IRWELM makes it obtain more accurate output nodes than those of WELM.

In the higher outliers levels, the RESELM has a significant advantage. The optimal RMSE is achieved 37 times due to the insensitive nature of the exponential squared loss function to higher outliers, it does not grow indefinitely, and the optimization problem is solved using an iterative approach in RESELM. Therefore, RESELM can effectively suppress outliers and has excellent generalizability.

Compared with ELM, WELM, ORELM, and IRWELM, RESELM obtains better accuracy than them in most cases. The RMSE is usually used in the study of improved models for ELM to illustrate the performance of the model in terms of accuracy, and experiments are conducted in [15], [16], [27] to verify the ability of the model to suppress outliers. The experiments in this paper show that the RMSE of RESELM is smaller than the other four models, so the proposed method effectively improves the robustness of ELM and has excellent generalization.

In Fig. 2, 8 benchmark data sets are chosen to show the variation of RMSE with the increasing outliers level for the five algorithms by line chart. It is more intuitive to observe the outliers level's effect on the algorithms' accuracy by the line chart. The line of ELM is almost always at the top of the axis and is most obvious on the Cooling, Yacht, Space, and Heating data sets, which have higher fold line from 0% outlier level to 40% outliers level than the other algorithms. WELM and IRWELM sometimes have worse RMSE than ELM in the higher outliers levels, as seen on the NO2, Airfoil, Abalone, and MG data sets. The fold line of ORELM are in the middle of ELM and RESELM on all data sets except the MG data set, which illustrates that the robustness of ORELM has improved somewhat compared to ELM but still suffer some effect in the higher outlier level compared to RESELM. The fold line of RESELM is always below all the folds except on the MG data set. Its accuracy is least affected by outliers, which means it has the best robustness.

B. Parameter Influence

Different parameters have an effect on the performance of the model. Next, the effect of hidden layer nodes L and the upper bound parameter σ of the exponential squared loss function on the performance of RESELM is examined. The experiments are conducted on four data sets without outliers, Cooling, Yacht, Airfoil, and Heating. In the experiments, the optimal parameters are selected for all parameters except the ones to be studied. The experiments reflect the effects of the parameters by RMSE.

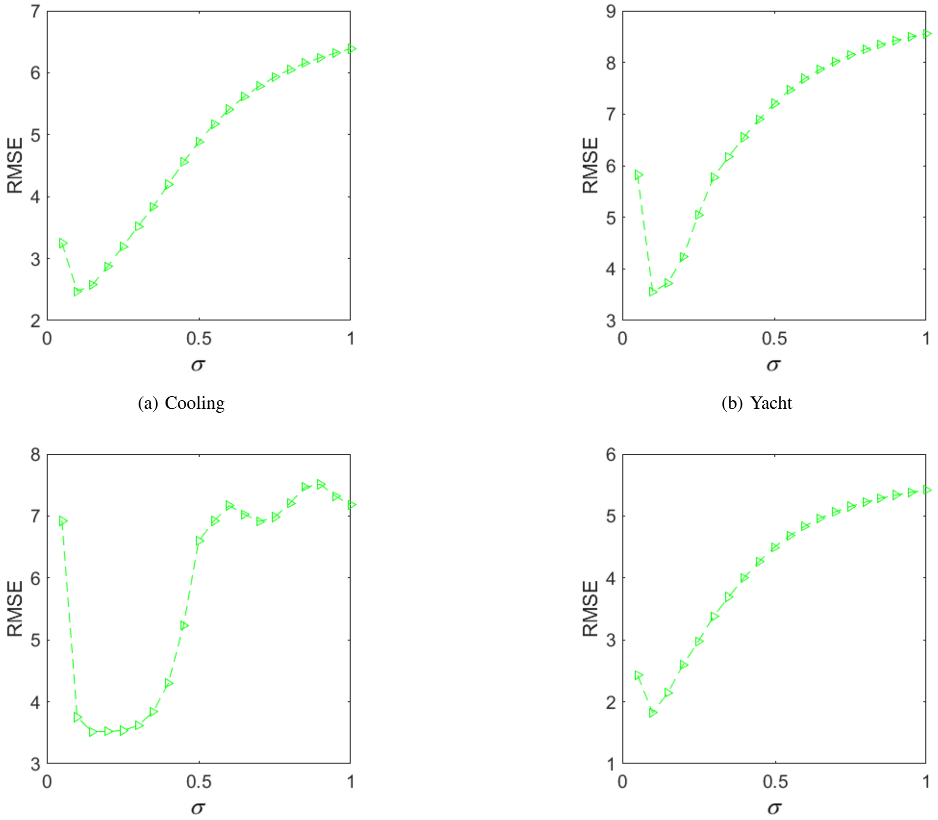
(b) Yacht

(c) Airfoil

(d) Heating

Fig. 3. The effect of L on RMSE.



(a) Cooling

(b) Yacht

(c) Airfoil

(d) Heating

Fig. 4. The effect of σ on RMSE.

There is no exact method to determine the number of hidden layer nodes L in ELM, and in practice previous experience or experimental methods within a certain range are usually used, but the number of L can affect the model's accuracy. When the L is too small, the model may have difficulty dealing with more complex problems. When L is too large, some nodes will not be meaningful to the model performance, which makes the model training time longer without improving the model accuracy. Therefore, the appropriate L is significant for the model's performance.

The effect of L on the model's accuracy is shown in Fig. 3, with L taking values from $\{100, 200, 300, 400, 500, 600, 700, 800, 900, 1000\}$. The figure visualizes the effect of L. In Fig. 3(a) and (d), the curves of RMSE show a decreasing trend. The RMSE at L=1000 is the smallest, indicating that a minimum value is achieved in the given range. In Fig. 3(b) and (c), the RMSE decreases and then increases, and the optimal L is found in [300, 500]. The curves on four data sets are not smooth, which indicates that RESELM is a little sensitive to the network size. Therefore, when conducting experiments, choosing a more appropriate number of hidden layer nodes has an essential impact on the performance of RESELM.

To investigate the effect of σ on accuracy, experiments are conducted on four data sets using different σ chosen from the range [0, 1] with an interval of 0.05. In Fig. 4, the curves on the four data sets demonstrate that the RMSE first decreases and then continues to increase as σ increases. The global optimum is found in [0,0.5]. Although slightly different on the Airfoil data set, the global optimum is still in [0, 0.5]. The optimal RMSE can be obtained when the σ is small. By observing Fig. 1, it can be observed when the σ is small, the upper bound of the loss function also becomes smaller. When the residuals are larger, the value of the proposed loss function is also smaller for smaller σ, and the robustness of the model is better.

V. Conclusion

This paper proposes a robust ELM based on the exponential squared loss function (RESELM) for training samples contaminated with noise and outliers. The loss function used in the model is obtained based on correntropy. The nonconvexity of the exponential squared loss function enables RESELM to control the effect of outliers effectively. However, the nonconvexity also makes the model difficult to optimize. The proposed model is solved by formulating it as a DC programming and then adopting DCA. Experiments were conducted to verify the performance of RESELM on benchmark data sets with different outliers levels. The experimental results demonstrated that RESELM is non-sensitive to outliers and can obtain better robustness with a significant advantage in accuracy, especially in the case of 25% to 40% outliers levels. This paper discusses offline ELM, but in real-world problems, online learning is usually required, so future work considers extending RESELM to online sequential learning for better application to real-world problems.

Abstract—**The Internet of Things (IoT) data is the main component for finding the basis that allows decisions to be made intelligently and enables other services to be explored and used. Data originates from smart things that have the capabilities to connect and share data enormously with other things in the IoT ecosystem. However, the level of intelligence obtained and the type of services provided, all depend on whether the data is trusted or not. High-quality data is the most trusted;, it can be used to extract meaningful insights from an event and can also be used to provide good services to humans. Therefore, decisions based on high-quality and trusted data could be good, whereas those based on low-quality or untrusted data are not only bad but could also have severe consequences. The term Quality of Data (QoD) is used to represent data trustworthiness and is used throughout this paper. To the best of our knowledge, this work is the first to coin the term QoD. The problems that hinder QoD are identified and discussed. One if it is an outlier, it is a major feature of the data that degrades its overall quality. Several machine-learning techniques that detect outliers have been studied and presented, with few data-cleaning techniques. This paper aims to present the elements necessary to ensure QoD by presenting the overview of the IoT state-of-the-art. Then, data quality, data in IoT, and outliers are studied, and some quality assurance techniques that maintain data quality is presented. A comprehensive taxonomy is shown to provide state-of-the-art data in IoT. Open issues and future directions were suggested at the end of the paper.**

Keywords*—*Quality of Data (QoD); Internet of Things (IoT); RFID; WSN; Taxonomy; trustworthiness; outlier; anomaly; confusion matrix; QoD assurance technique

I. Introduction

The Internet of Things (IoT) has emerged as the new evolution of internet connecting different entities, things and objects from different sources around the globe, thereby generating enormous amounts of data every time, every second. The amount of data generated by the IoT is used and consumed by the objects with which it communicates than by humans. The number of servers needed to hold information for access by users is very large, giving an insight into the number of devices that connect to the internet. Then the number of IoT-connected things and devices is ten times the number of those internet PCs [**?**].

The tremendous amount of data generated by different things brings out the realization of big data problems, intelligent decision-making, and the development of many IoT applications. To start with the big data problem, when these things generate all the data and share, exchange, and store it in the cloud, the cloud centers need to provide enough storage to handle this data and also enough services to manage the data. Providing these two becomes a challenge for the cloud centers [**?**]. Advances in the technology have exploited many capabilities of these data from the things, thereby encouraging the continuous flow of data. Thus, IoT has become a major catalyst for big data problems.

For example, the scale of IoT is continuously expanding; reports show that by the end of the year 2025, the number of IoT connections could reach 24.6 billion, with a compound annual growth rate of 13% [**?**]. According to the International Data Corporation (IDC), there will be more than 38 billion linked things in 2025 and reach about 50 billion by 2030. Another projection by [**?**] reports that connections to IoT could be about 41 billion by 2025, which could generate approximately 79 zettabytes of data. According to [**?**], approximately 50 billion device connections exist today, with an estimated 75.44 billion device connections by 2025.

Intelligent decision-making is achieved when enough data is obtained from things covering enough scenarios and events to compare, deduce, and reach a conclusion. However, the IoT can perform all these based on the type and quality of data received; if the data is of good quality, decisions are likely to be good, but if the data lacks quality, decisions derived would also be bad [**?**]. Therefore, for a reliable, trusted, and intelligent decision, the data must be trustworthy.

Users and vendors found a lot of opportunities in the prevalence of IoT. New applications are being developed for the ease and comfort of the user. Some researchers are also working on AI applications that incorporate IoT, such as smart homes, smart cities, efficient energy management and distribution, and so on. To achieve optimality in IoT applications for both driven applications and network optimization, research has used meta-heuristic and heuristic algorithms to simulate physical and biological phenomena [**?**].

Examples of IoT applications in smart homes includes the adjustment of blinds according to temperature and environmental changes, the opening of doors for authorized vehicles, and the ordering of medical services when there is an emergency. In the traditional home, home devices are part of existing Internet expansion, but when IoT arrives, the migration of smart things begins to the IoT network [**?**]. When devices get corrupted, the consequences are severe. For example, when smart locks are hacked, anyone can access the home; when baby monitors are compromised. The homeowner can be scared; and when microwaves are hacked, it can cause fire. If the security of smart devices cannot to achieved, then smart homeowners may not want to live in their smart homes. On the contrary, they can expect to improve home safety by using intelligent surveillance services [**?**]. In addition, the privacy of smart homeowners must be preserved. However, the continuous incoming of data from smart devices can reveal the secrets of house owners. And this can pose serious threats to their privacy.

Some widely adopted applications include smart homes, smart cities, smart grids and smart transportation. IoT technologies have drastically changed our way of life [**?**]. The widespread interconnection of intelligent IoT objects distributed physically extends computational operation and communication costs to IoT objects with different specifications. These devices' sensor capabilities enable them to collect real-time data from the physical world. The analysis of such data enables us to build an intelligent world and make better decisions for its management. If these security concerns are not adequately addressed, the wide adoption of IoT applications will be severely hampered. Consider the two typical IoT application areas, Smart Home and Smart Health, where system-sensitive information and critical assets require high protection [**?**].

IoT will continue to affect our lives in many ways, both in our homes, offices, healthcare, cities, etc. IoT in our society can represent a symbolic capital of power [**?**]. The way to deal with this enormous amount of data has changed from manually entered data to autonomous devices such as RFID readers, sensor nodes, etc. Our common appliances could have embedded components to allow them to communicate and become more intelligent to ease our lives. Examples are the light bulb that warns you of its remaining life, a toaster that toasts bread and provides a weather forecast, a refrigerator, a television, a video camera, and a solar panel roof, which might all be IoT devices. Despite the comforts we enjoy when these appliances generate such data, it has posed a challenge to the servers to manage and process such a huge amount of data from around the globe, which leads to big data problems.

During the last decade, we have worried about computer protection. Last five years, we have been worried about our smartphones' protection, now we are worried about car protection; home appliances, wearables, and many other IoT devices. According to Hewlett-Packard, in 2014, 70% of the most common IoT devices were infected with serious vulnerabilities. The authors of [**?**] discussed various current security challenges: interoperability, resource constraints, the protection of privacy on the Internet of Things Security 297, and scalability. Thus, the security of IoT is currently the main concern and requires research attention.

IoT devices collect large amounts of data and transmit it to the network. There are many personal data in these data, such as blood pressure, pulse, electrocardiograms, place environment data, area humidity, room temperature, etc. Another authentication scenario is to consider the types of entities involved in the remote client and server scenarios [**?**]. Clients want to access servers' services. After the first registration, the client can have a mutual authentication with the server. After the authentication, the two can create a shared key, and the client can use this key to access the server's service. A server can provide its clients with different types of services. Servers have the responsibility to perform registration and password changes. Before these services can be provided to the client, the server must verify whether the client is registered or not [**?**].

We researched the quality of the data in this work and coined the term Quality (QoD), and to the best of our search and knowledge, we are the first to coin the term QoD. However, many factors contribute to the data inefficiency and lack of QoD. The first problems associated with the data and IoT devices include constraint capabilities, intermittent loss of connection, and deployment hazards [**?**]. Other problems come from smart things, such as node failure, faulty nodes, data loss, network congestion, architectural flaws, and so on [**?**]. A third-world problem is one created by humans and launched into the deployment field to gain some benefit; examples are side-channel attacks, node capture attacks, sensor impersonation, stolen verifier attacks, Sybil attacks, etc. For IoT to gain wide acceptance and embrace more deployment, the QoD needs to be ensured.

This survey first investigated the nature of the QoD, or data trustworthiness, in an IoT ecosystem. The data in IoT is explored further, from the data lifecycle to its characteristics and quality considerations in IoT, then the technology of RFID that allows the data to be shared is studied, and then down to the factors that affect the QoD in IoT. Some of the reliable techniques to ensure QoD are studied, and the techniques are presented in tabular form for ease of comparison. Data outliers, is the main component that compromises QoD, are researched, and the types and impacts of the outliers are presented for prevention and measurement. A comprehensive taxonomy that shows all the forms of data that can be used is designed for ease of understanding. Some IoT application domains, open issues, and future directions are presented as well.

The remainder of this article is presented as follows: after the introduction in Section 1, data in IoT is presented in Section II. Section III is the QoD assurance techniques and data outliers made in Section IV. A comprehensive data taxonomy is shown in Section V while some of the most common IoT application domains are made in Section VI. Open issues in QoD are presented in Section VII, and then, lastly, future directions and conclusion are in Section VIII. The paper has eight sections in all.

II. Overview of Data In IoT

Data is an important component that makes up the IoT paradigm and is the source of information and means of communication. Furthermore, QoD, or trustworthiness, is an essential requirement for any IoT ecosystem (i.e., IoT services). In the following sub-sections, we present the data life cycle in the context of the IoT. We also discuss the characteristics of IoT data. In addition, we discuss QoD in IoT. Moreover, we looked at RFID as the first technology on which the IoT is built, which allows data sharing among IoT devices. And then some of the factors that affect data quality in IoT were also discussed.

Since data is considered a valuable asset because of the insights gained about a phenomenon, it is used to provide intelligence in our daily lives dealings. Researchers, therefore, exploit the insights and intelligence in the data using different mining techniques and algorithms [?]. Data trustworthiness is essential in QoD to have a reliable handling of the data from the data itself, data interpretation, simulation results, and any other form of data representation. Data is characterized by losing its quality when some factors, such as things constrained resources, large-scale deployment, and intermittent connections are not obtained [?].

Some of these problems can be measured from the data quality dimensions that arise as a result of hazardous elements. One way to ensure that data quality is compromised is the identification of data outliers [?]. However, some outliers appear only to describe errors, while others describe rare events, e.g. unusually high temperature in a warehouse, maybe as a result of a fire. In IoT, QoD problems need to be solved. QoD is an essential requirement for any data user (things, entities, IoT services, and IoT user applications).

A. Data Lifecycle

In the original landscape setting of the internet, data primarily originates from users using their computers, surfing the web, engaging on social media networks, and generally being utilized to offer services to these users. In contrast, the IoT sees a paradigm shift where the majority of data is generated by interconnected devices, serving both as the source and primary recipient to deliver services to individuals. The Machine-to-Machine (M2M) is a precursor to IoT, which emphasizes data as the primary communication channel [?], facilitating autonomous collaboration among IoT objects to offer innovative services. Data holds significant value in the IoT, serving as a crucial asset that provides insights into various phenomena, individuals, or entities. These insights are leveraged by applications to deliver intelligent services ubiquitously. The accuracy of data is paramount, as any inaccuracies may compromise the reliability of extracted knowledge and subsequent actions based on it. Fig. 1 presents data life cycle stages.

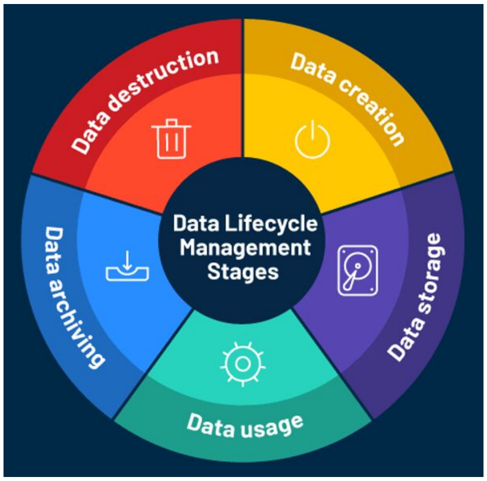

Fig. 1. Data life cycle stages.

B. Characteristics of IoT Data

The IoT device is embedded with a chip that can sense the environment and collect and share data with similar devices. The IoT devices are deployed mostly in hazardous environments, making them susceptible to natural effects such as earthquakes, rain, erosion, wind, etc. They can also be vulnerable to physical attacks and forced alteration by humans. These IoT sensors can be designed to measure variables of interest such as temperature, pressure, humidity, sleep habits, slope of a pipe, fitness level, movement positions, light intensity, and many more. However, some of the IoT characteristics are considered omnipresent, that is, erroneous, uncertain, noisy, distributed, voluminous, etc., while other characteristics can be considered dependent on the measured phenomenon, that is, continuous, smooth variation, periodicity, correlation, and Markovian behavior [?]. Some of these characteristics are:

1) Uncertain, noisy and erroneous data: uncertainty in QoD can make the data either incomplete, ignorant, ambiguous or imprecision caused by the constraint nature of the IoT nodes. Any factor that could make the data uncertain or put noise in the data, or make the data entirely wrong and have some wrong elements in it will compromise the QoD. And this can easily occur in any IoT ecosystem where the data is generated from volatile devices [?].

2) Voluminous and distributed data: In the IoT ecosystem, sensors can be deployed at any place to measure the parameters of interest. These sensors are densely deployed everywhere to gather enough data for decision-making and data management. The heterogeneous nature of IoT devices generates enormous amounts of data that are nearly impossible to manage and have challenges to manage. There is no standard IoT architecture to manage the total amount of data generated by its devices [?].

3) Smooth variation: in a continuous setting of data flow, such as the time stamp or time series, data is flown continuously at some interval. The collection and processing of such data requires some technique (like a machine learning technique) to collect the data and process it accordingly. An example is watering a tomato garden at some regular intervals [?].

4) Continuous data: The data here is similar to the smooth variation characteristic, but not necessarily that the data comes at a regular interval. The data can be random and have different patterns of arrival e.g., batch, stream, or real time. An example is to report any incident of traffic violation [?].

5) Correlation: The correlation feature exists in the IoT data set because of the heterogeneous nature of the IoT network. It consists of different sensors that measure different parameters. The data can have two correlations: spatial and temporal. When the data is correlated spatially according to the positions of the sensors, the processing of the data can give the best results in information form for certain phenomena. Whereas when the data is correlated temporally, the data might depend on its timestamp. For example, when the temperature values for the future are to be predicted, then the current temperature values can be used to make the prediction. It is also possible for the data set to have both types of correlations; the data can either be spatial (as related to memory space), temporal (as related to the time of its arrival), or both spatial and temporal [?].

6) Periodicity: This can be defined as the accuracy or age of specific data or the difference between the previous time stamp and the current time stamp as the item's punctuality or the data being sufficiently up to date for a task. Data sets that are related to scenarios may have inherently periodic patterns where the same values may occur at specific intervals [?].

7) Markovain behavior: An IoT sensor can be a function of a previous sensor, at a given time stamp of the previous sensor denoted by ti–1 [?].

C. Quality of Data in IoT

Quality of Data (QoD) in IoT can be seen as the possibility to ascertain the integrity of the data provided from its origin or the probability of the accuracy of the data [?]. Data must be clean, sensitized, and free from errors before it is transferred from a lower layer to an upper layer in the architectural stack. In other words, data must be reliable and trustworthy before it can be transmitted to preceding layers or peers for further processing. To compute trust in IoT ecosystem, it starts with the reliability of the sensors. Data from a reliable sensor could be considered trustworthy whereas data from a non-reliable sensor must be evaluated further to ascertain its correctness. However, the deployment nature of the IoT nodes in an unprotected environment makes the sensor vulnerable to attacks and unreliable [?].

Mechanisms have been developed to measure the trustworthiness in the WSN and the traditional internet; however, these mechanisms may not be suitable to ascertain the correctness of data in an IoT ecosystem due to the heterogeneous nature of the IoT, which is not the same as in WSN and the internet [?], [?]. Therefore, different mechanisms suitable for measuring QoD need to be developed, assessed, and implemented. Data is gathered massed from smart things providing ubiquitous services to users. For QoD to be ensured, the technologies used to allow the generation and sharing of the data should be addressed.

The first technologies used to allow things to connect and communicate were RFID, then WSN, which continues to evolve into other technologies up to the most widely used today, the internet (802.11 and its families). [?] assessed the quality of the data considering five dimensions, which include confidence, accuracy, timeliness, volume, and completeness. The new arising IoT applications rely on distributed and heterogeneous data for proper functioning; thereby, integration into IoT data is necessary [?]. However, maintaining such data becomes challenging due to the different sources it comes from [?], [?].

Data integrity is an essential asset in the authentication process of IoT devices. It ensures that node credentials are correct and unaltered. To ensure data integrity in an IoT distributed architecture, the MQTT protocol requires more attention because, when a connection is established between the nodes it has to transmit data to the destination, the credentials must be mutually verified to ensure that they have not been altered [?].

Assuming that the issuer ”P1” connects to the broker ”B1” directly, where the subscriber ”S1” connects to the broker ”B2” directly, the data is transferred from ”P1” to ”B1”, and also to ”B2” before it reaches the destination ”S1”. During this data transfer, the credentials of the data sender and the data recipient must be verified mutually. A common method of cryptography to ensure data integrity is the hash function (such as SHA-1 and SHA-2) [?].

However, ensuring QoD presumes fulfilling the criteria of accuracy, timeliness, precision, completeness, and reliability [?], [?], [?]. The authors of [?] define “timeliness as the data being current. That is, the most updated data in the most recent time”. While [?], sees timeliness from two different perspectives, i.e., “an error recovery of the data and its age item, this distinguishes the recorded timestamp from current system time while the regularity of the data is with respect to its application context”. Again, [?] defines “timeliness as the mean age value of the data in a source”. According to [?], timeliness is defined as “the extent to which data are sufficiently up-to-date for a task”.

D. Quality of Data in RFID

The first technology to be embraced by communicating entities is Radio Frequency Identification (RFID) [?]. The RFID system for authentication comprises three important tangible components: tags, readers, and data centers. The reader scans the tag to collect the necessary information and stores it in the data center. RFID can be seen as a transmitter microchip that is similar to an adhesive sticker. Active receives batteries that always emit data signals, while passive gets activated only when they are activated. The concept of radio technology was developed from RFID, where the chip does not have to view the reader in physical vision before it can communicate with it. While barcode technology requires the physical view of the reader to communicate with it [?]. RFID is also an actuator that stimulates events, an action a barcode could not do. WSN is a multi-strip wireless network connected to a dispersed sensor field that measures a specific data collection device's speed, humidity & temperature, whose values are transmitted to processing equipment. RFID is a short-range communication technology that is termed asymmetric, whereas WSN technology has a relatively long range and communication ability in a peer-to-peer fashion.

Since IoT's idea is to allow automatic connection and sharing of data among entities and any object with the ability to sense, process, transmit, and store information via the internet, it has made the network heterogeneous due to the different backgrounds of the objects. The early technologies start with RFID, then WSN, then Bluetooth, then wireless local area networks (WLANs), then wireless metropolitan area networks (WMANs), then cellular networks (LTE, 2G, 3G, 4G, 5G, and now 6G) [?], [?]. The IoT's vision is to [?] enable people and things or entities to communicate to anyone, at any time, anywhere through some sort of medium such as the internet [?]. With the rapid development of RFID technologies, Bluetooth, sensors, and smartphones, the applications and usage of IoT have increased tremendously, which directly affects daily life [?].

RFID automatically identifies entities, objects, and people. RFID's operation comes in three frequency ranges: the first is low frequency (LF), the second is high frequency (HF) and the third is ultra-high frequency (UHF). RFID devices can be separated into two groups: active and passive [?]. Active RFID requires an energy source, while passive RFID does not require any energy to power it. The encryption levels in RFID are: the first encryption mode with no traffic encryption, the second encryption mode with the Data Encryption Standard (DES), and the third encryption mode with AES-128 bits [?]. RFID uses radio waves to communicate with data in electronic devices to identify and sense the location around them.

In recent years, WSN and RFID have gained tremendous attention in the field of IoT applications. Both technologies have different capabilities and are used in different scenarios depending on their needs [?]. RFIDs provide reading content that is used to detect and identify objects they are associated with. WSNs provide dynamic content based on the environment in which they are installed [?]. However, these technologies are used as connectors between devices and local networks or even the wider Internet. This technology is necessary to identify devices, share information with each other, verify each other's identities, and broadcast other useful information to the network. In Table I, a list of some technologies used in the WSN and the internet are presented.

E. Factors Affecting Quality of Data

Data in the IoT is itself the weakest point due to many factors that affect its quality. When data lacks quality, it cannot represent the actual scenario it is being assigned to monitor, and it could have other negative effects both on the decision being made and the operational levels of any business or organization [?]. In order to have a phenomenon of interest, some potential problems in the IoT need to be addressed. Some of the issues facing the maintenance of QoD in the IoT include but are not limited to:

1) Resource constraints: Since their inception, IoT devices have been characterized as being resource constraints in nature. Because of the limited memory available in it, the small power consumption, and the lower computational ability of the IoT devices, it becomes difficult to trust all the data that comes from them especially if the data is more than what the device can hold, and naturally, more and more data keeps coming from these devices. The IoT devices are mostly battery-powered, and resources are scarce, data collection policies and trade-offs are inherently utilized to improve the quality and cleanliness of data [?].

2) Scalability: IoT is today being deployed on a global scale, starting from organizations to homes to cities and now to the globe. Any setting of the IoT deployment generates large amounts of data, and merging any setting or integrating any application makes the data even larger, thereby increasing the chances of error occurrence in the data [?].

3) Heterogeneity: IoT devices are heterogeneous in nature, they come from different settings and backgrounds the same way their data differs from the background it comes from. It is always more challenging to manage data of the same kind with data of different kind. IoT devices can only achieve functional optimality if they integrate heterogeneous data. Therefore, the issue of heterogeneity needs to be addressed perfectly [?].

4) Sensors: When sensors are deployed, they may suffer from a lack of accuracy in reporting their readings or from a loss of calibration. Some sensors may become faulty and then report incorrect data. This is a challenge that makes it mostly difficult to find the faulty sensor, especially in a large deployment setting [?].

5) Environment: The deployment is mostly in an unprotected surrounding affected by hazards and natural effects such as rain, earthquake, erosion, the mountain's summit, wind, or the intended attack by humans [?].

6) Network: The connection often gets lost and regained again due to limited resources, bad weather, infrastructural interference, and a bad signal. IoT is an IP network with a constrained higher loss of packets than the conventional network [?].

7) Vandalism: The environment is mostly unprotected and therefore suffers from physical attacks that include damage, stealing, altering, and forceful extraction of data from it. The vandalism also extends to animals whose aim is to search for food or scatter in any setting they come across. Therefore, this factor affects the QoD [?].

8) Dead node: It often happens in many circumstances that a node is dead, but data is continuously received from the node. This has made the quality of the data untrustworthy [?].

9) Privacy: This is a major part of the acceptance of IoT globally. People's data is not guaranteed to be secure, and when data is breached (like a patient's data), the damage is too high [?].

10)Data stream: Data from the smart IoT device is received and sent continuously in the back-end pervasive applications that use them [?].

Other problems include sleeplessness habits of some nodes, unauthorized access, altering the source code & attributes, incompleteness, etc. In the the memory devices could neither send large packets nor report events frequently due to constraints; therefore, only small-sized messages could be sent, which is insufficient to report all events. Also, the scarcity of resources will cause things to go into sleep mode to save energy. However, Internet Protocols (IP) maintain the backbone of IoT connectivity and are unsuitable for sleep modes so it requires the smart things to be operational at all times, unreliable readings, multi-source data inconsistencies & alignment, data duplication, data leakage, etc.

III. Data Outliers

A data outlier is an uncertainty in an event or scenario; it is a deviation from the normal distribution setting, resulting in problems in the data set and incorrect results in the model. Outliers are the major manifestations of QoD problems. Data outliers can also be defined as phenomena with extremely small chances of occurrence. It is again defined as points in a data set that is highly unlikely to happen in a given model [?].

In other words, anomalies are defined as patterns in data that do not conform to a well-defined notion of normal behavior [?]. Data outliers belong to a class of unreliable sets or groups; they fall outside of the normal status. In most machine learning models, they are considered the unusual points in a given data set [?]. Although these points have few chances

TABLE I. THE USE OF RFID & WSN TECHNOLOGY IN IOT, PROS AND CONS

N0	AUTHORS	DOMAIN	TECHNOLOGY	OBJECTIVE	PROS	CONS
1	[?]	WSN	RFID	To provide ultra-lightweight authentication by exploiting the RFID cache reader	It achieves reduced computational cost especially when authenticating a large number of tags, It achieves security	However, it needs to provide or expand storage space for a large number of tags
2	[?]	Big Data	RFID	To provide lightweight authentication based on simpler authentication protocols	The scheme combines multiple authentication protocols and runs well	Availability is guaranteed
3	[?]	WSN	WLAN	To develop a protocol needed to incorporate the TEPANOM solution and its architecture with the EAP infrastructure	This EAP supports many authentication mechanisms by introducing lower communication overhead compared to others, it does not require any global infrastructure, thus it is scalable	It cannot integrate closely the TEPANOM solution and its architecture with the EAP infrastructure
4	[?]	Smart Grid	6LowPAN, CoaP, IEEE, 802.15.4	To provide a lightweight authentication in the smart grid application	It maintains message integrity	The scheme is only tested and proved on a small scenario field nodes
5	[?]	WSN	GWN	To introduce a novel authentication and key agreement using bio hashing to eliminate false accept rate and false reject rate	Bio hashing has some functional advantages over biometrics such as high secure operation of imposter populations and genuine zero equal error rate level	The design is inefficient with limitations to support forward secrecy and unlinkability in two factor authentication. Also lack a dynamic identity mechanism to involve nonpublic key
6	[?]	WSN	GWN SN	To develop a lightweight biometric scheme to authenticate remote users and key agreement scheme for secure IoT services	User is authenticated remotely and offline	Memory requirements need to be found in the testbed and the lightweight feature extends to real IoT devices
7	[?]	IIoT	WSN	To design a lightweight computational biometric user authentication and key agreement scheme	The protocol is lightweight and less complex authentication is achieved. Authentication, availability, and integrity of data packets are guaranteed and the protocol needs further investigation	
8	[?]	WSN	WLAN	To design a light Weight node-to-node and node-to-node authentication protocols continuously	It authenticates each data transmitted between two nodes within a pre-defined time period in the IoT ecosystem	A more accurate model needs to be designed to minimize use of battery energy consumption and to discover more dynamic device features is challenging
9	[?]	NFC	RFID	To develop an Ultralight Weight Mutual Authentication Protocol to achieve forward security by using sub key and sub index number into its key update	Computational wise, the scheme is lightweight and proved to protect against synchronization attack	The NFC authentication needs to improve performance and function while still considering the security and privacy of the system
10	[?]	NFC	NFC	To develop a novel lightweight NFC identity authentication protocol for mobile NFC IoT networks	It has three working modes in the NFC mobile phone that it can work in the tag as the card, the reader, and support peer-to-peer file sharing	Its application electronic financial services still need privacy for public trust

to occur in the whole data set, but they often occur. Another formal metric-based outlier is the distance-based outlier (DB) [?]. It is defined when an object, let's say, 'x' in a given data set 'T', and the fraction of 'x' is higher than the distance 'D' within the context of 'DB', is considered an outlier. Fig. 2 shows an example of an outlier.

A. Types of Outliers

Data outliers as defined, are anomalies that do not conform with the normal behavior of the remaining data in the data set. Sometimes an outlier may represent an error, sometimes it may represent an incompatible element in a cluster, and sometimes it may even represent useful information. There are different types of data outliers in a model, but the most common ones are as follows:

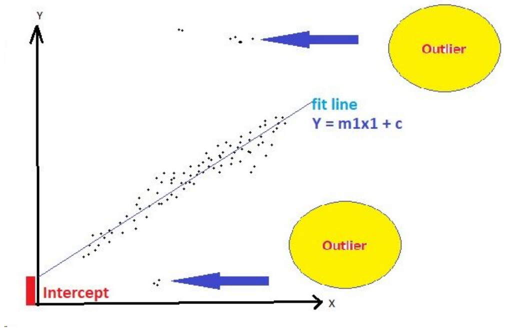

Fig. 2. Data outliers.

1) Error: This is any value generated as a result of node failure or node malfunction. When the node's battery is drained and is not replaced and the node continues to send data to the user's access point, it is very likely that the data is wrong or that repetitive data is sent. Sometimes the node may be altered by an attacker and forced to send the wrong data [**?**]. Attackers often try to extract some useful information from a captured node while trying to let it continue to send information to the base station. This process has already altered the normal process, so therefore, wrong data may be sent. It can also be affected by some natural effects, such as wind displacement, i.e., when a node is deployed in an environment and configured to measure a parameter of interest within a given ratio and the node is displaced outside that ratio, then the readings sent will not represent that area of interest [**?**].

2) Event: This is any scenario with an associated value generated due to a change in a certain setting or phenomenon. This can be demonstrated by a natural effect of event occurrence; for example, if in a hazardous environment, there is an accident or any natural phenomenon that changes the setting of the environment suddenly, then definitely the reading from the node at that particular time follows any sudden change as well, thereby not giving the expected outcome [**?**].

3) Point anomaly: This is the deviated data, a group of similar data that differ in value, behavior, and attributes. When usual data occurs in a given data set, deviating from the normal distribution pattern of the remaining data and the difference is huge enough to believe that it is out of context, then that outlier is considered a point anomaly [**?**]. For example; a model records the card withdrawals of an employee in Asia to occur once every day and then there appears to be a withdrawal transaction in Europe three hours from the last transaction in Asia, this translates into an impossible scenario; therefore, the data point of the transaction in Europe is classified as a clear point anomaly [**?**].

4) Contextual anomaly: This represents a value that could be an anomaly, but it does not depend on the context. Sometimes a deviation may occur, and still, the data may not be an outlier due to the context of the data set it belongs to [**?**]. Many scenarios happen where unusual data becomes an outlier in one context while being considered normal in another context. For example, given two data sets A and B, where data set A is a small data set in size, let's say with 100 rows, and data set B is large let's say it has 1000 rows. The calculation of its 'variance' using the same data point may become an outlier in data set A while proving normal in data set B [**?**].

5) Collective anomaly: represents a set of collected values that differs largely from other values in the data set. When more than one anomaly, let's say a group of anomalies appears in the data set, forming another cluster of anomalies, then it is referred to as a collective anomaly. This type of outlier is mostly identified in clustering algorithms such as the K-means algorithm, the Naive Bayes algorithm, the Decision Tree, etc. [**?**]. Fig. 3 gives examples of some of these outliers.

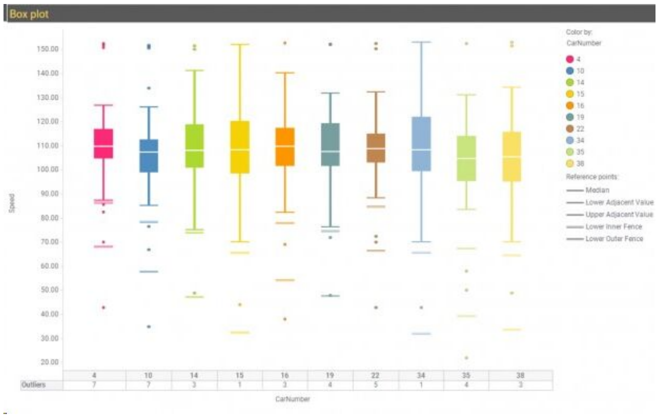

Fig. 3. Types of outliers.

B. An Outlier from the Confusion Matrix

A machine learning model is a powerful technique widely used to detect an outlier in a data set [**?**]. Today, there is seamless integration between the IoT domain and machine learning models. Many machine learning models are designed to solve IoT problems. One technique used to solve an IoT problem is the identification of an outlier by a model called the confusion matrix. This model has two true classes and two negative classes that are passed to the machine mode. An output is given by the model based on what it has learned. The four classes are described as follows:

1) True positive: when a true instance is passed to the model, the machine model computes the prediction and gives an output based on the data it learned. If the prediction corresponds to the actual or real event, then it is considered True Positive. For example, when it rains, the event is passed to the model, and the outcome is confirmed to be 'rain' or 'it rains'.

2) True negative: When the model receives the actual event and predicts wrongly giving an output that does not correspond to the expected outcome, then the scenario is considered True Negative. An example is when, in reality, it rains, the event is passed to the model, and the model predicts 'not to rain' or 'not raining'.

3) False positive: The other way around is to supply the model with the wrong event and expect it to learn and produce an output based on what it learns. When the outcome produced reveals the actual scenario that occurred while it was fed with the wrong event, then it is considered a False Positive. For example, when the status of an impregnated woman is passed to the model and it gives the output that the woman is pregnant then it is considered a False Positive.

4) False negative: But when the event passed to the model is the wrong event and the algorithm learns and predicts that the event is the wrong one, then it is called a False Negative. For example, if the model is fed with the woman's status as not being pregnant and produces the output as 'not pregnant'. Fig. 4 illustrates the confusion matrix in a diagram.

C. Impact of Outliers in the IOT

In IoT, environment data is obtained from the sensor as a result of measurement of parameters of interest, such as temperature, pressure, humidity, etc. and serves as an input to mine data so as to gain insights about a monitored phenomenon (e.g home, environment, health, etc. [**?**]. Based on these

		CONDITION determined by "Gold Standard"			
	TOTAL POPULATION	CONDITION POS	CONDITION NEG	PREVALENCE $\frac{\text{CONDITION POS}}{\text{TOTAL POPULATION}}$

		Miss Rate False Neg Rate FNR FNR = $\frac{\text{FN}}{\text{CONDITION POS}}$	*Specificity (SPC)* True Neg Rate TNR TNR = $\frac{\text{TN}}{\text{CONDITION NEG}}$	Neg Likelihood Ratio LR - LR - = $\frac{\text{TNR}}{\text{FNR}}$	

Fig. 4. The confusion matrix.

insights, decisions can be made from different angles. It is clear that the conclusions reached from an erroneous data will produce bad and unsound decisions. For example, a model giving out too many false positives and false negatives such as a scenario of a campus fire alarm, the alarm system rings many times every week while in reality there is no cause for the panic [?].

Another scenario involves monitoring forest fires to respond quickly and take appropriate measures. In addition to component monitoring applications, the data on the state of the components should be reported accurately in order to protect expensive systems and avoid damage. An inability to provide accurate data can cause damage to whole systems or even the lives of people [?]. Other examples include forest fire alerting system that requires quick action, earthquake that requires quick evacuation to safe zones, etc.

The importance of accurate and reliable data is paramount, consider the examples above and imagine if any of the system do not alert about the occurrence of the dangers happening or the model reports otherwise about the danger, the consequences will be very severe and the lives of the people and entities is as high risk. When these nodes report actual data and the model predicts right and the system alarms correct, it will help and save lives and properties while if the nodes report faulty data, the model may easily predict wrong and the whole system may not function well to give the correct outcome, this is jeopardizing lives and properties.

The trustworthiness of the data is essential to the engagement of users and to the acceptance of IoT services and is therefore important to the success of the large-scale implementation of the IoT domain [?]. Data as a component of a holistic approach to managing IoT trust collection, reliability, and accuracy are the main concerns of data perception reliability.

As experiments and simulations are a good way to demonstrate and understand IoT systems likewise machine learning models are a good way to identify and prevent outliers in any given dataset. Many IoT experimentation test beds, such as the FIT-Equipex exist [?]. the authors of [?] examined several other existing testbeds (public and private). However, in order to study more on the impact of data anomalies. There are two real-world cases that examine the impact of QoD problems on the field of electronic health applications.

The first case study by [?] examines the effect of QoD problems on electronic health monitoring applications. This work identifies QoD issues that affect QoD criteria (e.g. accuracy, precision, timeliness, accessibility, and consistency) that are critical to providing appropriate help to the patient. There are three levels of data management defined to monitor cardiac scenarios: Data Acquisition, Data Processing, and Data Discovery. For example, at the level of data collection, the problems relate mainly to the performance of body sensors, the amount of data processed, and the quality of communications [?].

The second reported case study by [?] examines the poor impact of QoD on Ambient Assisted Living systems (AAL) systems, which results from the convergence of ambient intelligence and assisted living technologies. AAL supports monitoring applications (i.e. monitoring of health and well-being) to people in their homes. This paper argues that poor QoD alters the representation of events that occur, which hinders the system from giving appropriate support to users and causes incorrect reports on the health of patients, inefficient management of environmental conditions at home, etc. [?]. The application of e-health is one of the most important IoT applications taking into account the factors affecting human life and therefore tolerating uncertainty in the QoD.

IV. Quality of Data Assurance Techniques

In conventional programming, a common rule states: "Never trust user input," while in IoT the rule can be stated as: "Never trust things". This is proven as a result of uncertainties and inconsistencies in sensor data. In order to reduce the expensive effects of low QoD, a technique is needed to prepare data and improve its quality [?]. The following are five main techniques that could promise QoD in an IoT paradigm:

A. *Outlier detection*

This is to find the elements that differ from the normal distribution setting or deviate from the normal behavior of the data. The ultimate goal is to highlight outliers [?]. Identifying outlier detection in a model increases its overall reliability and efficiency. In addition, detecting outliers is the first step needed to handle all the events of inconsistencies. The next is the accuracy and reliability of data processing. If these are handled, then QoD will be ensured and better decisions will be made. Note that individual data element accuracy at the level itself does not increase because it relates only to the source of data generation and processing and cannot be improved [?]. The parameters used to detect outliers pay attention to highlighting data value differences to find out the outliers (for example, values that are not consistent with an established model) [?]. However, the QoD dimension values used to evaluate data are seen as insufficient, for example, the accuracy extracted from the measurement precision class of the sensor specified by the manufacturer. When the sensor fails to clean due to any cause, the accuracy becomes unreliable and irrelevant.

B. *Interpolation*

Interpolation is defined as a data generation method that can hence improve the QoD dimension of the data size (i.e., add the available data elements). However, interpolation is the opposite of completeness in effect, i.e., the ratio of the available data to non-interpolated items (i.e., both interpolated and non-interpolated) in the stream window in question. This scenario can be explained as an optimization effect to find the best compromise between these two dimensions, but nonetheless, is limited to satisfying user-defined QoD requirements [?]. Furthermore, when selecting interpolation techniques, it is important to consider the accuracy of the interpolation value [?], which is expected to meet user requirements. This technique involves the use of missing values based on a dataset. Data flows are described as missing data flow attributes or tuples (from sensor malfunctions and loss of connection) [?]. The missing data points represent gaps in the dataset that is available for a particular entity or a topic of interest. A model knowledge-generating processing of such a dataset, including those missing gaps in it would have incomplete knowledge and hence reduce QoD.

C. Data Integration

All the heterogeneous data from different landscapes must be integrated to overcome structural differences and inconsistencies and really benefit the universal service. Frameworks for Data Quality (DQ) techniques such as Resource Description Framework (RDF) and Web Ontology Language (OWL, 2009) provide standard mechanisms for data description to perform search, retrieval, and processing tasks more directly [?]. Also, linked data is a reliable approach to trigger data retrieval and integration in the IoT ecosystem. Another framework proposed by [?] integrates semantic data that uses the principles of Linked Data and semantic web technologies. The authors of [?] proposed an architectural model to integrate and incorporate all intelligent features into the smart application. Again, a Service Architecture Paradigm (SOA) model that extracts heterogeneity in intelligent objects and improves interoperability in the context of e-health applications is developed.

D. Data Deduplication

is a technique for the compression of data designed to lessen the volume of data stored by deleting duplicate data elements and replacing them with unique data references that remain unchanged. Data deduplication is a process of duplicating redundant data elements. It decreases the amount of data and affects the QoD of the data volume. [?] proposed a video duplication technique with considerations for privacy protection. The authors of [?] specify the deduplication technology for cloud-storage encrypted data. While [?] proposed a model for exploiting the deduplication capabilities together with the Hadoop framework.

E. Data Cleaning

The cleaning of data defines the life cycle of data; it starts with the selection of errors and goes down to the correction of identified errors and the identification of potential errors. It is also defined that the detection of anomalies is limited to the identification of anomalies, while data cleaning goes further to suppress the elements discovered. It has become a widely adopted technique for enterprise data management in data warehouses [?]. Data cleaning is a widespread topic of research in big data analysis [?]. It consists of three main stages: (i) determining the type of error; (ii) identifying potential errors; and (iii) correcting identified errors. It is also very common to manage enterprise data in the context of data storage. Fig. 5 presents some QoD techniques.

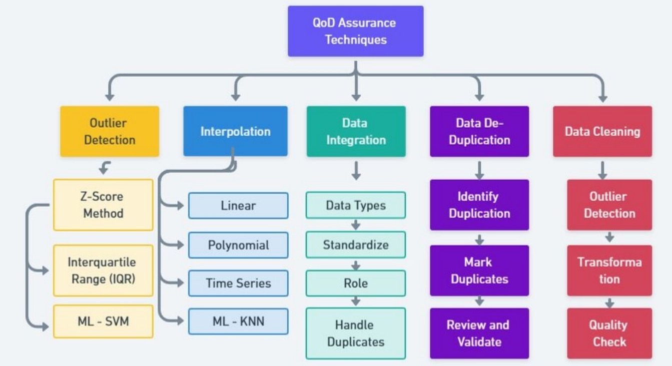

Fig. 5. QoD Assurance techniques.

V. Taxonomy for Quality of Data in IOT

The IoT and other similar domains such as WSN, have a set of attributes, features, characteristics, protocols, and technologies that are suited for their deployment and implementation. With a taxonomy, it can be seen what techniques have been used to measure data trustworthiness, what are the most important parameters to consider in ensuring QoD, what domains are integrated in the IoT data trustworthiness ecosystem, and what has been done and what needs to be done in the area.

A. Data Source

The data comes from one or more sources, and the source of the data determines whether the data can be trusted or not. Data could come from a sensor configured to provide the readings of an event, which is the source of the data, or from humans directly, especially in situations where interactive information is required by the model or the environment [?].

B. Data Processing

The first form is called stream or batch where data is usually sent at some specific time interval. The data in the same batch is mostly similar or has the same attributes. Data from the sensor could be sent in batch for processing, the data is first gathered and stored in the temporary memory of the device and then sent across the network to the server, or any base station provided. An example of batch processing can be any event whose action is not urgent [?]. Real-time processing is when the data is sensitive and needs to be processed immediately after it is obtained. In real-time, events such as fast decision-making making, banking transactions are examples of such scenarios. Another form of processing the data is computed in the near time, where the history of data is referred before making any computation. The processing of such data is not immediate, but time is also to be considered.

C. Data Type

The data obtained from the sensor could be presented to the user in the form of either Numeric, Alpha, Alpha Numeric, or even Symbols. The type of the data depends on the parameter measured and result representation [?].

D. Trust Type

The type of trust can be either direct or indirect. When data is gotten directly from a sensor it is considered as direct trust, likewise when the data is obtained from other sensors passing it to neighboring nodes, the quality of the data might degrade or the data may be intercepted and altered by natural phenomena, so therefore, the data is considered as indirect trust [?].

E. Trust Computation Location

The location of the node can be computed to determine the trustworthiness of the node. The computation can either be distributed or centralized. A cluster-based wireless sensor architecture can have the cluster head to compute the trustworthiness of the sensor node in the network, which is below a certain assigned value, where the actual data is sent to the gateway and then to the application layer. This considered as a centralized computation. Whereas in distributed trust computation, the node assesses the trustworthiness itself and send actual data to the cluster and gateway [?]

F. Trust Aggregation Method

is used to summarize trust evidence that has been gathered via nearby sensor node feedback or self-observations [?]. The majority of the literature's work use the following methods:

1) Weighted sum: This is the simplest model for aggregating trust scores. The method can summarise several factors that contribute to trust scores, the factors are multiplied by the specified weight, then adds up all results that contribute to a product that represents the trust score. Therefore, it is a commonly used technique for calculating trust score [?].

2) Bayesian inference: Due to its simplicity and solid statistical foundation, Bayesian inference is a popular confidence calculation model. This method considers trust as a random variable that follows a distribution of probability and which parameters are updated with new results.

3) Belief theory: The theory of belief, also known as the theory of evidence or Dempster-Shafer Theory (DST) provides a method for summarising confidence values from different pieces of evidence using Dempster's Rule of Combination. The rule assumes that this evidence is independent. Evidence is the confidence values computed by different sensor nodes in the network [?].

4) Regression analysis: Regression analysis is a method of aggregating confidence scores by calculating the relationships between data. The scores are calculated based on estimating the relationships of the trust factors and a number of other variables that affect the trust.

5) Fuzzy logic: This is a method that deals with estimation rather than fixed and exact conclusions, fuzzy logic also provides rules for reasoning. The confidence value determined with fuzzy logic can have a value between 0 and 1 with fuzzy measures [?].

6) Game theory: This involves making decisions between two or more decision-makers involved in certain conflicts or competitions. Game theory can be used to predict competitive rules of action with certainty. An example of using game theory models to ensure data reliability is the work of [19], which develops a defense strategy that ensures that sensor nodes are protected against attacks so that the difference between the value accepted by the sink and the true sense value is below a certain assigned value.

G. Trust Establishment

This refers to how to end a trust score from multiple properties. There are two aspects of the establishment of trust, namely single trust and multi-trust. A single trust implies that only one trust property is taken into account in the calculation of the total trust rating. On the contrary, multi-trust is a combination of trust and trust. Establishments use several trust factors to calculate the total data trust. Many proposed techniques utilize multi-trust factors to calculate trust scores, with two factors chosen on average. Among the factors used were communication, nodes' familiarity, energy, and nodes' reliability [?].

H. Trust Results

These are also called Trust Decisions, and are considered as an element of data trust calculation that deals with how the results are presented to the requestor or user. There are two options for representing the results either in binary or in a range of values or judgments. Binary represents the results as either trust or non-trust only. From this point of view, users or application layers can simply choose trusted data to process further. In terms of range, this means that the data reliability value calculated can fall within any range of possible degrees of trust. This is similar to the Likert scale, but the trust values can be determined by more than two options. As such, the requestor or user and application layers can decide accordingly on the basis of their decision logic [?].

I. Data QoS

The summation of all the packets involved in the transmission having the maximum delay (i.e., 400ms standard) and a regular jitter interval between its consecutive packets (i.e., 1ms interval) should then be able to produce the maximum number of packets received [?].

J. Node Quality

This is of two types: a resistant node which is able to prevent itself against side-channel attack and unclonability and any form of memory extraction. Most of such nodes have multiple ICs designed over one another to make it harder for an attack to recover anything from it. An unresistant node is one that is unable to protect itself from the attack mentioned [?].

K. Node State

A node can either be in a passive state where it remains ideal until it is triggered to send data, this node performs better in such a state since its battery will last longer while an active node is the one that is continuously measuring and sending data, the problem associated with this type of node is called sleep deprivation attack [?].

L. Measurable Parameters

These nodes are deployed to measure some readings called parameters. The parameters include but are not limited to the volume of an object, the temperature of a room or place, the pressure of equipment, humidity of a place, slope position of ground, fitness level of things, sleep habits in pipelines, state of the area, movement positions of liquids, etc. [?].

M. Data Accuracy

The data from the node is considered accurate as long as it is precise, correct, and reliable. The basis for having a sound decision is from accurate data while bad data produces a severe decision that comes with consequences. When data is accurate it is said to represent the actual scenario of an event [?].

N. Data Consistency

For the data to be consistent, it should satisfy standards and integrity, and the codes with which it is burned to the device must also be consistent in producing the actual result any time it is being run.

O. Data Completeness

Data is said to be complete if its record in the database is complete, the field data is complete and the single Unique Identifier is complete [?].

P. Data Timeliness

The timeliness or the regularity of the data is measured from its time stamp as well as its real-time updates [?].

Q. Data Relevance

Data is relevant according to the user requirements it satisfies and the contextual relevance of the data.

R. Data Robustness

When data is robust it should be able to accommodate fault tolerance by being resilient as well as quality monitoring [?].

S. Data Security

There are many forms to protect the data but for the sake of this research the most commonly practiced are access control mechanisms, encryption (symmetric and asymmetric), and data masking [?].

T. Metadata Quality

Metadata is the data from which data is made up or simply some supporting data that helps in the execution of the actual data. In Fig. 6, a comprehensive taxonomy for QoD in IoT is shown.

VI. IOT APPLICATION DOMAINS

- Smart Home: Smart homes have the vision to integrate intelligence into everyday objects such as appliances, door locks, surveillance cameras, garage doors, etc., and to communicate with existing cyber infrastructure [?]. Adding intelligence to physical objects is beneficial for improving people's lives, such as improving their comfort, convenience, security, and effective use of natural resources. For example, a smart home can adjust the blinds according to environmental changes, open garage doors automatically when an authorized vehicle approaches, or order medical services when there is an emergency. In smart homes, traditional home devices are part of existing Internet expansion. When devices are damaged, the consequences can be serious. For example, successfully hacking smart locks allows strangers to enter the house; compromising baby monitors can scare visitors away from the baby; hacking microwaves can cause a fire at home [?]. Smart homeowners may not want to live in smart homes if security is not guaranteed. On the contrary, they can expect to improve home safety by using intelligent surveillance services. In addition, the privacy of smart homeowners must be preserved. However, the continuous collection of data from smart home devices can reveal the private activities of house owners, as indicated in [?]. It poses serious threats to the privacy of owners.

- Another typical IoT application is the creation of smart networks, Smart grids are designed and implemented to improve the reliability, cost reduction, and efficiency of traditional power grid systems. It not only integrates green and renewable energy such as solar power, wind power, heat, etc. but also aims to improve the reliability and efficiency of traditional energy networks. Intelligent grid data communication networks connect many smart grid devices and play an essential role in achieving the above-mentioned objectives. It collects energy consumption data and monitors the state of smart grid systems. More applications can be developed based on smart and communication networks. For example, utilities can allocate and balance load more wisely based on energy use information collected. It can also help to design fair but scaled pricing models by taking into account unbalanced energy consumption in space and time. With a smart grid status monitoring application, you can identify faults in the grid system as quickly as possible and as well design new fault-tolerant mechanisms to better react to them. Many technologies, including Automatic Measurement Infrastructure (AMI), have been proposed to build smart network communication networks. Because so much data is moving around the mission-critical system, security is one of the most important concerns of such systems. Invading the smart grid [?] and cutting the supply of electricity to a large area can cause enormous physical and economic damage to society. Analyzing energy usage data can also reveal people's daily private activities.

- By embedding smart medical devices into the medical

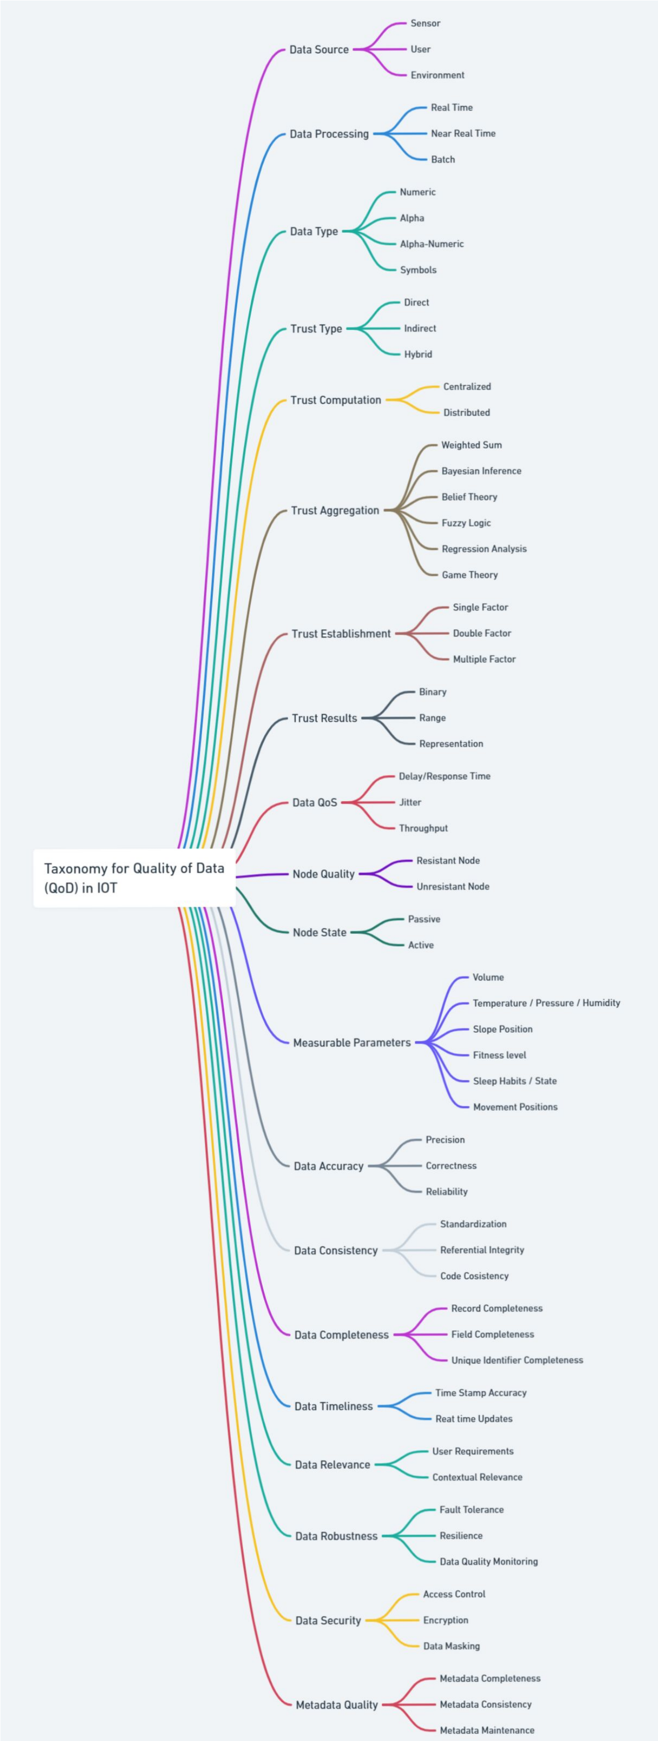

Fig. 6. Taxonomy of QoD in IOT.

infrastructure, health professionals can better monitor patients and use the data to determine those who need the most attention. In other words, healthcare professionals believe that prevention is more important and effective than treatment, so they can build proactive management systems based on collected data using the best of these networks of devices. Researchers also studied other possible techniques for implanting sensors into human bodies to monitor people's health status [?]. Using the collected data, health personnel can discover behavioral changes in the body of patients and medicines during treatment. Security is also an essential issue in Smart Connected Health. In network medical devices, data collection and monitoring of the status of the device is convenient, but there are also risks because instructions can be sent to terminate the device functions [?]. Stopping medical devices that are important to the patient's life such as heart injuries is extremely dangerous.

- Intelligent Transportation System (ITS) refers to the use of advanced technologies and data-based solutions to improve the efficiency, safety, and sustainability of transportation systems. Smart transportation uses technology and data to create more efficient, safer, and sustainable transportation systems that benefit individuals and communities. These systems play a key role in addressing urbanization, congestion, and environmental impacts in rapidly developing cities. In addition, IoT applications can manage passenger luggage at airports, and advise drivers about road conditions [?].
- The telecommunications industry includes a variety of technologies and services such as Global System for Mobile Communications (GSM) and Digital mobile network standards for voice and data communications on mobile phones and a few others. The Bluetooth technology is a short-range data exchange that is commonly used to connect headphones, speakers, and other peripheral devices. Wireless Local Area Network (WLAN): Wireless network technology allows devices to connect to the Internet or local network within a limited area. Wi-Fi called (wireless fidelity) is a service that allows voice calls and texts to be sent via Wi-Fi networks, providing coverage in areas with weak mobile signals [?]. Global Positioning System (GPS) is a satellite-based navigation system that provides accurate location information and is widely used in mobile phones, navigation devices, and vehicle tracking [?]. These technologies are essential to modern communication, connectivity, and location-based services.
- Logistics and Supply Chain Management: In logistics, RFID-embedded intelligent shelves enable real-time tracking of items, improving inventory visibility, accuracy, and efficiency [?]. This technology simplifies business, reduces errors, and helps companies optimize their supply chains to improve their performance and customer satisfaction. RFID-embedded smart shelves track items in real-time.
- Aerospace and Aviation Industry: In the aerospace and aviation industries, the Internet of Things (IoT) plays an essential role in enhancing safety, maintenance, and efficiency. Sensors and connected devices monitor aircraft components, collect performance data, allow real-time maintenance, improve reliability and safety, and reduce operational costs [?]. IoT has revolutionized the aerospace and aviation industries by providing real-time data and connectivity solutions to improve safety, reduce costs, improve passenger experience, and optimize the entire ecosystem, improve safety and security of elements.
- Automotive Industry: In the automotive industry, the IoT has changed the design, manufacture, operation, and maintenance of vehicles. It revolutionizes the automotive industry by making connected, autonomous, and safer vehicles, improving manufacturing processes, and improving consumer driving experiences. Sensors monitor and report vehicle parameters [?].

VII. Open Issues in Quality of Data for IOT

The following are a few issues that require additional research presented in four broad categories:

A. *Scalability*

The IoT can now be seen being deployed on a bigger scale, to say on an unprecedented scale that exceeds even the scale of the traditional Internet. Most of the solutions, however, are concentrated, and unlike distributed architectures, they do not provide sufficient flexibility and scaling for large-scale deployment [?].

B. *Heterogeneity of Data Sources*

The data generated in the IoT ecosystem comes from multiple types of objects, entities, sensors, RFID tags, etc. The architecture developed for IoT must be able to adapt to the heterogeneity of data origin. Furthermore, proposed technologies must be able to process different variables to meet the requirements of IoT applications. In order to meet the requirements of IoT applications, which may provide complex services based on multiple parameters such as user behavior, energy management, and home temperature relative to external temperature [?].

C. *Domain-agnostic/automated verification*

In IoT visions, things share data automatically with neighboring nodes based on their configuration. Domain-agnostic data cleaning methods confirm that data transmitted between "things" is uninterrupted, without human involvement, and with minimal human control, which is essential to the creation of a seamless IoT service [?].

D. *Distributed Architectures*

In addition to IoT scaling issues, distributed architectures also provide a platform that can adapt to faults and failure resilience. These functions are vital in the IoT perspective, because of the continuity and accessibility of data cleaning infrastructure, providing all-encompassing services even in the event of failures in ecosystems [?].

VIII. Conclusion and Future Directions

IoT offers great potential to connect millions of everyday objects and provide intelligent and ubiquitous services to help you live. The amount of data generated from the IoT infrastructure is very large. The collected data serves as the basis for obtaining insights that aid in decision-making, data management, and other services. QoD is an important interest in this scenario. Data security is linked to data quality, and the security of any model begins with data trustworthiness, which is essential to user participation and acceptance in the IoT paradigm. IoT is a promising domain, and there have been exciting results recorded in this field. In this context, QoD plays an important role. However, more research is needed to investigate how to improve QoD to ensure the widespread adoption and acceptance of IoT. Therefore, more work needs to be done to ensure effective and perfect decision-making, since data reliability is highly needed in IoT. The following are a few suggestions for future work to maintain QoD in IoT: Lightweight outlier detection Techniques, IoT network Traffic based Outlier Detection, Personalized QoD management platforms, QoD assessment-based outlier techniques, and QoD management middleware.

Acknowledgment

The authors would like to thank Yayasan Universiti Teknologi Petronas (YUTP) for providing the funding to carry out this research work. YUTP grant (015LC0-311) is granted by Universiti Teknologi PETRONAS (UTP).
