Improving QoS in Internet of Vehicles Integrating Swarm Intelligence Guided Topology Adaptive Routing and Service Differentiated Flow Control

Tanuja Kayarga¹, Ananda Kumar S^{2*}
SCOPE, Vellore Institute of Technology, Vellore, India^{1,2}

Abstract—Internet of Vehicles (IoV) is an evolution of vehicular adhoc network with concepts of internet of things (IOT). Each vehicle in IOV is an intelligent object with various capabilities like sensors, computation, storage, control etc. Vehicles can connect to any other entity in the network using various services like DSRC, C2C-CC etc. Ensuring QoS for vehicle to everything (V2X) communication is a major challenge in IoV. This work applies an integration of hybrid metaheuristics guided routing and service differentiated flow control to ensure QoS in Internet of Vehicles. Clustering based network topology is adopted with clustering based on hybrid metaheuristics integrating particle swarm optimization with firefly algorithm. Over the established clusters routing decision is done using swarm intelligence. Packet flows in the network are service differentiated and flow control is done at cluster heads to reduce the congestion in the network. High congestion in routes is mitigated with back up path satisfying the QoS constraints. Due to optimization in clustering, routing and data forwarding process, the proposed solution is able to achieve higher QoS. Through simulation analysis, the proposed solution is able to achieve 2% higher packet delivery ratio and 9.67% lower end to end packet latency compared to existing works.

Keywords—Particle swarm optimization (PSO); QoS; bio inspired technique

I. INTRODUCTION

Internet of Vehicles is seen as a most promising solution to address the challenges of modern transportation like improving road safety, mitigating traffic congestion, reduce fuel consumption etc[1]. Each vehicle is an intelligent object with sensing, computing, storing, control and communication facilities. Vehicles can connect to any entity within vehicular adhoc network (VANET) like Road Side Units (RSU), other vehicles and entities outside network like application servers, cloud etc. The connectivity is enabled using various mechanisms like dedicated short range communication (DSRC), car to car communication consortium (C2C-CC) etc. IoV is different from traditional IoT networks as it can generate information volume thousand times more than traditional IoT networks. IoV need to support messages of different categories like emergency messages, real time cooperative control messages, infotainment message etc with different delay and reliability constraints. Supporting wide variety of IoV applications with guaranteed quality of service (QoS) is a challenge in IoV networks. QoS requirements are in terms of packet delivery ratio, delay and jitter. Due to vehicle movement, network topology is dynamic and connectivity

between vehicles is on constant change. This affects the stability of the routes and in turn affects all the QoS parameters. Providing guaranteed QoS in highly dynamic IoV network is a very challenging multi constraint optimization problem [2]. The optimal solution to this problem can be found through hybrid metaheuristics.

In this work, an integrated solution combining hybrid metaheuristics for topology adaptive routing and service differentiated flow control is proposed to provide guaranteed QoS in IoV networks. The network is partitioned to clusters with efficient cluster head selection using hybrid metaheuristics based multi criteria optimization. Clustering is adaptive for a hybrid IoV with or without RSU availability. A QoS guaranteed routing using Ant colony optimization is proposed on the clustered topology. In addition it, packet flows in the network is differentiated and flow control is done at cluster heads to reduce the congestion and facilitate differential QoS for different services. In short, the proposed work is able to provide differential QoS guarantee for different services in IoV through three factors of topology control, topology adaptive routing and service differentiated flow control. Compared to earlier works addressing any one particular area of topology, routing or data forwarding optimization the proposed solution integrates optimization in all three areas of topology, routing and data forwarding. This integration has provided added advantage in achieving higher QoS in proposed solution.

The paper is organized as follows. Section II presents the existing works in VANET for ensuring higher QoS and their shortcomings. Section III presents the research gap. Section IV presents the proposed solution integrating clustering, routing and data forwarding optimizations to ensure higher QoS. Section V presents the novelties in the proposed solution. Section VI presents the results of the proposed solution and its comparison to existing works. Section VII presents the conclusion and scope of future work.

II. RELATED WORK

Authors in [3] proposed a QoS routing protocol for VANET. The protocol is designed specifically for high wayscenario. The network is clustered with cluster head selected based on the link expiration time of the neighbors. Artificial Bee Colony (ABC) algorithm is used to find the optimal path with higher QoS. This work enforces QoS requirements both during clustering and routing. The performance of solution was tested against different traffic

scenarios and the work was found to perform well for highway scenario where traffic density is normal. The performance degrades for higher urban traffic density. Authors in [4] proposed a QoS based clustering algorithm for mobile adhoc networks. The algorithm tries to create stable clusters and maintain stability during communications and link failure at the same time considers QoS requirements. Mobility metrics like velocity and distance are added to QoS functions to select stable clusters. The relay nodes for routing are selected using ant colony algorithm with requirement of satisfying mobility and stability constraints. A cheating prevention mechanism is also proposed in this work for fair and reliable relay selection. Direction of movement, load processed by MPR and packet flow categories are not considered in this work. A passive clustering aided routing protocol is proposed in [5] to improve the routing performance for one way multi-lane highway scenario. A multi metric distributed election strategy using metrics such as node degree, expected transmission count, and link lifetime is proposed for cluster head selection. The election strategy tries to maximize the stability of cluster structure. A weighted routing protocol based on metrics of expected transmission time, link life time and node degree is used for selecting the best relay cluster head. The work could not accommodate dynamic variation in speed and density. Authors in [6] proposed a QoS multicast routing protocol for VANET based on bee communication principle. The proposed protocol is able to find and maintain robust route between the source and multicast group members. The path is selected to maximize the average bandwidth and packet delivery ratio at same time minimizing the end to end delay and normalized overhead load. Failure of link cause due to vehicle dynamics is not considered for multicast tree reorganization in this work. A situation aware multi constrained routing protocol is proposed in [7] for VANET combining situational awareness and ant colony algorithm. From among multiple feasible routes between source and target vehicle, a best route satisfying multiple QoS constraints and reliability metrics is found. The reliability risks in the best route selected is mitigated using situation awareness and ant colony optimization by proactively predicting link failure and replacing them with backup links. The work predicts only movement based failures, but could have been extended for congestion based failures. Authors in [8] proposed a clustering algorithm for IoV network with nature inspired Moth flame optimizer. The cluster heads are selected in such a way that average of distance between cluster members to cluster head is minimal in the network. By minimizing the distance, the transmission energy is also reduced in the network. Clustering did not accommodate any QoS requirements in this work. A new stability based clustering algorithm is proposed for VANET is [9]. The algorithm has two stages: setup and maintenance. In setup stage, close proximity nodes are organized to clusters with selection of cluster head. In maintenance stage, a backup cluster head is selected and it becomes primary to maintain stability and reliability of cluster. The stability of cluster is measured in terms of velocity differences between the vehicles in the cluster and this difference is important criteria for clustering in this work. QoS requirements are not considered as criteria for clustering in this work. Authors in [10] proposed a hybrid of harmony search algorithm (HSA) and PSO algorithm

for cluster head selection in sensor networks. The cluster heads are selected to minimize the energy consumption in the network. With high search efficiency of HSA and dynamic capability of PSO, efficient clustering of network is done resulting in increased life time of the network. Authors in [11] used multi objective particle swarm optimization to optimize the number of clusters in adhoc network. Degree of nodes, transmission power, energy consumption of nodes and velocity of nodes and are the parameters considered for optimization. The goal of cluster head selection is to reduce the overall energy consumption in the network. Authors in [12] proposed a clustering algorithm for VANET using grey wolf optimization. Social behavior and hunting mechanism of grey wolfs are replicated to create efficient clusters. Stability of clusters is the optimization criteria for the fitness function in grey wolf optimization algorithm. Authors in [13] proposed two bio inspired evolutionary algorithms for clustering in VANET – comprehensive learning PSO and Multi objective PSO. Maximizing the number of cluster members without affecting the stability due to velocity of the vehicles is the optimization criteria used in both the evolutionary algorithms. Authors in [14] proposed a clustering algorithm using ant colony optimization for VANET. The variables considered for clustering are distance of neighboring nodes from cluster head, speed of vehicles, direction of cluster head and cluster nodes within a cluster. The algorithm tries to find the minimal number of clusters so that packet routing cost is minimized. Dragon fly optimization algorithm is used for clustering VANET in [15]. The approach also adapted the transmission rate dynamically based on the traffic density and mobility pattern. Dragon fly fitness function for cluster selection is based on speed, velocity and direction of the vehicles. A routing algorithm integrating ant colony optimization with Dynamic MANET (DYMO) on demand protocol is proposed for VANET in [16]. The path selection is based on two parameters of hop distance and path reliability. Path reliability is measured in terms of expected number of transmissions. Authors in [17] proposed an efficient clustering for flying adhoc networks. A variant of K-means density clustering algorithm is used for selection of cluster heads. Transmission power of nodes is adjusted based on their operational requirements. The approach works only for low mobility of nodes. Authors in [18] proposed a novel path planning algorithm for reliable and efficient routing in VANET. Congestion is managed by distributing load over alternate paths and splitting the larger packets to small packets. Routing is based on multiple QoS constraints of packet delivery ratio and energy. Authors in [19] proposed a novel, secure and reliable multi constrained QoS aware routing algorithm for VANETs. Ant colony optimization is used to compute feasible routes ensuring differential reliability for different traffic types. Authors in [20] proposed a novel moving zone based routing protocol. The moving zone is formed by clustering the vehicles with similar movement patterns and trajectories. A coordinator node is selected for each moving zone to assist in message dissemination. Authors in [21] used ant colony optimization for selection of routing paths with higher QoS in VANET. The factors considered for QoS improvement in this work were packet delivery ratio, delay and link connectivity. Routing to improve QoS based on vehicle orientation is proposed in [22]. The salient part of this

work is that it translated multi constraint QoS objectives to single constraint objectives using a cosine similarity scalarization model. Authors in [23] proposed an angle based clustering algorithm for VANET. The most stable vehicles that can act as cluster head are selected based on the angular position and direction of the vehicles. Each vehicle builds its neighborhood information using an angular technique. Clusters are created based on this neighborhood information. Authors in [24] used the concept of location aided routing to propose a reactive routing protocol for VANET. The protocol used multi objective particle swarm optimization for searching the route. Authors in [25] surveyed different QoS routing protocols in VANET. The study observed QoS cannot be guaranteed in VANET only with routing and it needs much more mechanisms like flow control, class differentiation etc. The solution proposed by us is in this direction of integrating flow control and class differentiation along with routing and topology control for guaranteed QoS in VANET.

III. RESEARCH GAP

- Following are some of important research gaps identified from the survey
- Most of the existing solutions consider ensuring QoS in IoV as topology control and routing problem without consideration of different services and their QoS needs. Better QoS management strategy must also consider service differentiation and flow control along with topology and routing management.
- Most of existing multi objective optimization based clustering works use limited parameters like velocity, direction etc, without consideration for their resource capability. Multi objective optimization based clustering methods must also include resource metrics affecting QoS, so that the QoS can be improved in the network.
- In this work, we address the above two open issues and design a swarm intelligence guided topology and routing management with multi objective QoS guarantee and integrating it with service differentiated flow control for better QoS management in IoV.

IV. PROPOSED SOLUTION

The proposed solution for improving QoS in IoV has following important functionalities

A. Multi Objective QoS Constrained Clustering

Multi objective QoS constrained clustering is implemented using particle swarm optimization (PSO). Each particle is the array of length N with each element in the array is the ID of the cluster head node. Each particle covers whole of the network and particle does not have any duplicate ID. The multi objective particle swarm optimization algorithm proposed in [11] is adapted. While the approach [11] is designed with goal of clustering for energy optimization, in this work, clustering is done for multi objective QoS optimization. A new multi constraint QoS objective function is introduced. The function considers following parameters

- Average Stability of cluster (S)

- Average effective hop count between clusters (h_c)
- Average Degree difference (D_d)
- Average uncovered vehicles on speed/direction variations. (U_c)

In [9], the objective values are measured for each cluster head in the particle and they are then summed up to provide the total objective value for the particle. Deviating from it, this work models selects the cluster heads as a multi objective optimization problem using hybrid metaheuristics. Compared to using single optimization algorithm, use of hybrid metaheuristics solves the problem of local minima. Combining algorithms with contrasting features of exploration and exploitation results in optimal solution avoiding the local minima. In this work Particle swarm optimization (PSO) with exploration capability is combined with firefly algorithm with exploitation capability to select the optimal cluster heads.

PSO is a swarm intelligence algorithm (Kennedy et al 1995) simulating the social behavior of swarm of organisms. This method is popular for solving optimization problems due to its simplicity, flexibility and versatility. Organisms move randomly with different velocities and use these velocities to update their individual position. Each candidate solution is a 'particle'. Each particle tries to attain its best velocity based on its own local best (p_{best}) value and its neighbor's global best (g_{best}). Each particle's next position depends on the current position, current velocity, distance from current position to p_{best} , distance from current position to g_{best} . The movement of particle in its search space depends on its velocity. For a particle X, its current position X_i and current velocity V_i is updated as

$$X_i(t+1) = X_i(t) + V_i(t+1) \quad (1)$$

$$V_i(t+1) = wV_i(t) + c_1r_1(p_{besti}(t) - X_i(t)) + c_2r_2(g_{besti}(t) - X_i(t)) \quad (2)$$

In the above equations, t is the iterative value. c_1 and c_2 are acceleration coefficients, r_1 and r_2 are random numbers, w is the inertia weight. The iteration is repeated till termination condition is met.

Firefly is swarm intelligence algorithm (Yang et al 2008) based on the behavior of fireflies in naturally occurring environment. Fireflies exhibit unique light flashes for various purposes like mating, warning about potential danger etc. Fireflies operation is guided by two parameters: light intensity and level of attractiveness. Light intensity (I) is inversely proportional to the distance between the emitting and observing firefly (r). It is given as

$$I = \frac{1}{r^2} \quad (3)$$

Level of attractiveness is proportional to the light intensity. It is calculated as

$$\beta(r) = \beta_0 e^{-\gamma r^2} \quad (4)$$

β_0 is the attractiveness at $r=0$ and γ is the light absorption coefficient. Euclidean distance formula is used for calculating r .

The movement of firefly (FX_i) governed by attraction from another firefly (FX_j) is calculated as

$$FX_i = FX_i + \beta_0 e^{-\gamma r^2} (FX_j - FX_i) + \alpha \epsilon_i \quad (5)$$

In the above equation α is the randomization parameter and ϵ_i is a random number.

The hybrid metaheuristics algorithm for clustering first invokes firefly algorithm to select the cluster heads with random cluster heads as input. PSO algorithm is then started with the cluster heads selected by firefly as input and the output of the PSO is the optimal cluster heads.

The fitness function for selection of optimal cluster heads is framed as

$$F_f = w_1 S + w_2 h_c + w_3 \frac{1}{d_d} + w_4 \frac{1}{u_c} \quad (6)$$

Firefly algorithm is started with K fireflies each firefly has N bit string with M (number of desired cluster head) out it is marked as 1 and rest marked as 0. Value of 1 represents, the corresponding node is cluster head. The initial N bit string is formed randomly. Firefly algorithm is run with fitness function defined in Eq. (6) on each iteration and the firefly with maximum value for F_f is selected as best and movement of other firefly is done based on best firefly. Once the maximum iteration is reached or error has reached minimum value firefly algorithm is stopped and N bit string of the best firefly is taken as the seed. From this seed, K particles are initialized with N bit string by toggling P random positions. The PSO algorithm is then started with this solution formed from firefly. At each iteration, the fitness function defined in Eq. (6) is calculated and the particle is maximum value for F_f is selected as globally best solution. Once the maximum iteration is reached or error has reached minimum value PSO algorithm is stopped and N bit string of the globally best particle is taken. The positions where 1 is marked in N bit string are taken and the corresponding nodes are made as cluster heads.

B. QoS based Routing

The proposed QoS based routing uses both two different routing modes: vehicle to cluster head and cluster head to cluster head. Vehicle to cluster head is through geographic routing. Cluster head to cluster head routing is using ant colony optimization algorithm.

The source vehicle which needs to send packet to destination vehicle sends routing request message to the source cluster head. The routing request message also carries the service identifier. Source cluster head initiates a group of forward ant in search of the destination vehicle cluster head. The service identifier is carried in the forward ant. When forward ant reaches any cluster head i, it records the cluster head ID and transmission delay, it makes a decision to choose the next cluster head based on the global pheromone (gp) and local pheromone (lp) stored at cluster head i. The probability of selecting the next cluster head j is given as

$$p_{ij} = \frac{gp_{ij}^\alpha lp_{ij}^\beta}{\sum_{m=1}^K gp_{im}^\alpha lp_{im}^\beta} \quad (7)$$

Where K is the number of next hop cluster heads to i. α, β are the weight values. Local pheromone (lp) and global pheromone (gp) is calculated in terms of QoS requirements as

$$lp_{ij} = w_1 C_p(e_{ij}) + w_2 pdr_p(e_{ij}) + w_3 d_p(e_{ij}) + w_4 j_p(e_{ij}) + w_5 L_p(e_{ij}) \quad (8)$$

Where w_x is the weight associated with each factor such a way that

$$\sum_{x=1}^5 w_x = 1 \quad (9)$$

e_{ij} is the link between cluster head i and j. C_p is the connection probability, pdr_p is the predicted packet delivery ratio, d_p is the predicted delay, j_p is the predicted jitter and L_p is the predicted link expiration time. For two cluster heads u and v positioned at (x_u, y_u) and (x_v, y_v) , moving with velocity v_u and v_v in direction of θ_u and θ_v , the link expiration time is calculated as

$$L(u, v) = \frac{\sqrt{d^2(a^2+c^2)-(ad-bc)^2-(ab+cd)}}{a^2+c^2} \quad (10)$$

Where

$$\begin{aligned} a &= v_u \cos \theta_u - v_v \cos \theta_v \\ b &= x_u - x_v \\ c &= v_u \sin \theta_u - v_v \sin \theta_v \\ d &= y_u - y_v \end{aligned}$$

In each link, the past values of delivery ratio, connectivity probability, delay and jitter are collected. Based on the previous history, prediction over new interval is done applying exponential moving average as

$$v(t+1) = \alpha * x + (1 - \alpha)v(t) \quad (11)$$

Where x is the current observed value and $v(t+1)$ is the predicted value. α is a constant.

When forward ant arrives at destination cluster head, it checks the delay value in the forward ant against the delay threshold set for the service. If the delay in the forward ant is less the delay threshold, the path passed by the ant is selected as a probable candidate route. The forward ants which arrive through candidate route are converted to backward ant. The backward ant traverses back to the source cluster head. As it traverses, its updates the global pheromone value as

$$\begin{aligned} gp_{ij} &= \\ (1 - \delta)gp_{ij} + \delta * \\ \text{best local phenome value over the path} \end{aligned} \quad (12)$$

Once all backward ants arrive at source cluster head, for each backward ant, a QoS fitness score fs is calculated for the route provided by the backward ant. The route having the highest value for fs is the path used for routing between source and destination cluster head. QoS fitness score fs is calculated as

$$fs(P_x) = w_1 C_p(P_x) + w_2 pdr_p(P_x) + w_3 d_p(P_x) + w_4 j_p(P_x) + w_5 L_p(P_x) \quad (13)$$

Where P_x is the path traversed by the backward ant.

The backward ant calculates the C_p of entire path as minimum value of connection probability of all links in the path. It calculates the pdr_p of entire path as minimum value of packet deliver ratio of all links in the path. It calculates the d_p of entire path as maximum value of delay of all the links in the path. It calculates the j_p of entire path as maximum value of jitter of all the links in the path. It calculates the L_p of entire path as minimum value of link expiration time of all links in the path.

C. Service Differentiation and Flow Control

The flows or sessions in the network are categorized based on the services to different priorities. At each of the cluster head, a differential flow control is done. Cluster head maintains multiple queues, each corresponding to a priority for queuing the incoming packets. Different from allocating processing slots based on priority alone, in this work, we use estimated traffic demand in each priorities, priority of the packet and estimated congestion on immediate forwarding links as the three parameters for allocating processing slots to the queues. The processing slots are grouped into time frames. The traffic demand for each priority queue is estimated as

$$DQ = \min(MA_i + D_i, T \times \Delta) \quad (14)$$

The exponential moving average of incoming traffic to queue MA is calculated with D as total packets in queue and physical transmission rate as T as

$$MA_i = \begin{cases} \alpha \cdot T + (1 - \alpha)MA_{i-1} & \text{if } T \neq 0 \\ (1 - \alpha)MA_{i-1}, & \text{otherwise} \end{cases} \quad (15)$$

From the estimated traffic demand the slots n_s for queue x is allocated out of N total slots as given below:

$$n_{S_x} = \frac{FD_x}{\sum_{x=1}^n FD_x} * \frac{P_x}{\sum_{x=1}^n P_x} * N \quad (16)$$

Where P is the priority of queue. The total slots N is not fixed and it should be adapted to congestion on immediate forwarding links. We model congestion in terms of predicted round trip time(RTT). RTT prediction is done as a probability mass function of past delay distribution. It is calculated as:

$$RTT = \begin{cases} \sum_{i=0}^{\infty} f_i(a) \cdot f_i(b), & x = 0 \\ \sum_{i=0}^{\infty} f_i(a) \cdot f_{2x+i}(b) + \sum_{i=0}^{\infty} f_i(b) \cdot f_{2x+i}(a), & x > 0 \end{cases} \quad (17)$$

The forward direction for packet travel is denoted as a. The backward direction for packet travel is denoted as b. The probability mass function of delay in direction v is denoted as f(v).

From the predicted RTT, the value of N is calculated as:

$$N = \frac{k}{RTT} \quad (18)$$

Where, k is the total number of messages that can be forwarded when RTT is at a best lower bound value. This value is configured by network administrator.

V. NOVELTY IN PROPOSED SOLUTION

Following are the novelties in the proposed solution

- Ensuring QoS in IoV is solved through an integrated solution combining QoS based topology control, QoS based routing and service differentiated flow control.
- Clustering using swarm intelligence considers multiple QoS metrics in addition to usual parameters of velocity, direction, etc.
- Multi class multi QoS optimization based ant colony optimization is done to find effective routes for different service flows.
- Adaptive service differentiated flow control based on network congestion feedback is proposed.

VI. RESULTS

NS2 simulator is used for measuring the effectiveness of the proposed solution. The vehicle traces are generated using SUMO and NS2 extension code implements the proposed solution on these traces.

The simulation was conducted against configuration parameters in Table I.

TABLE I. SIMULATION CONFIGURATION

Sl no.	Simulation Configuration	
	Parameter	Value
1	Road length	4Km
2	Road length	4Km
3	Road topology	Highway
4	Number of lanes	4
5	Vehicle density	25 to 200
	Vehicle speed	30 m/s
7	Transmission range	250 m
8	MAC protocol	IEEE 802.11 p
9	Data packet size	1000 bytes
10	Data rate	5 packet/second
11	Simulation time	1000 seconds

Four different traffic types are used for simulation. The traffic types and their priorities are given in Table II.

TABLE II. TRAFFIC CLASSES

Sl no.	Simulation Configuration	
	Traffic class	Priority
1	Bulk transfer	2
2	Audio	3
3	Video	3
4	General applications	5

The performance of the proposed solution is compared against CBQoS-Vanet [3] and SAMQ [7] in terms of following metrics:

- Packet delivery ratio
- Packet dropped ratio
- Normalized overhead load
- Average end to delay
- Throughput

Varying the number of vehicles, packet delivery ratio is measured and the results are given in Fig. 1.

Fig. 1. Packet delivery ratio.

From the Fig. 1, it can be seen that in both CBQoS-VANET and Proposed, as the vehicle density increases, the delivery ratio drops. But the delivery ratio in Proposed is much higher compared to SAMQ and CBQoS-VANET. The increase in delivery ratio in the proposed when compared to CBQoS-VANET is due to implementation of flow control in the proposed. On an average packet delivery in the proposed solution is 2.07 % more compared to CBQoS-VANET and 12.88% more compared to SAMQ.

The results of packet dropped ratio for different vehicle density is given in Fig. 2.

Fig. 2. Loss ratio.

From the Fig. 2, it can be seen that although the loss rate is within 2 to 6% in all the three protocols, best performance is achieved in proposed with average loss rate 70% lower compared to CBQoS-VANET and 53.15% lower compared to SAMQ. Congestion is controlled based on RTT feedback in the

proposed solution. Due to this, the loss rate is lower in the proposed solution.

Varying the vehicle density, normalized overhead is measured and the result is given in Fig. 3.

Fig. 3. Network overhead.

From the Fig. 3, the normalized overload in the proposed solution is on average is 16.52% lower compared to SAMQ and 23.47% lower compared to CBQoS-VANET. The overhead increases with higher vehicle density. The overhead is higher in proposed compared to SAMQ in lower vehicle density is due to clustering and routing finding process, but SAMQ overhead increased for higher vehicle density.

Varying the vehicle density, the average end to end delay for packet delivery is measured and the result is given in Fig. 4.

Fig. 4. Delay.

As seen from Fig. 4, delay increases with higher vehicle density. The average end to end delay in proposed solution is 9.67% lower compared to CBQoS-VANET and 19.35% lower compared to SAMQ. Service differentiation and flow control has reduced the average end to end delay in the proposed solution.

Varying the vehicle density, throughput is measured and the result is given in Fig. 5.

Fig. 5. Throughput.

As seen from Fig. 5, throughput reduces with higher vehicle density. The average throughput in proposed solution is 3.51% higher compared to CBQoS-VANET and 16.85% higher compared to SAMQ. The throughput has increased in proposed due to consideration of QoS constraints both during clustering and routing.

Varying the speed for 100 vehicles, the packet delivery ratio is measured and the results are given in Fig. 6.

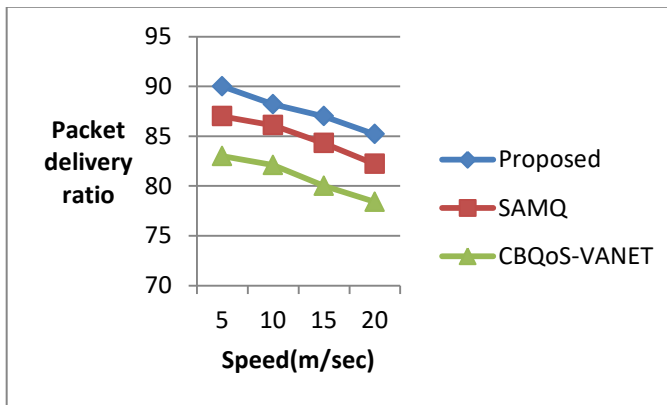

Fig. 6. Packet delivery ratio vs speed.

The packet delivery ratio is higher in proposed even as the speed increases. The average packet delivery in proposed solution is at least 3% higher compared to SAMQ and 7.6% higher compared to CBQoS-VANET. The higher packet delivery ratio in proposed solution is due to selection of more stable cluster head and effective routing path for forwarding the packet. In addition, the service differentiation based source rate control limits the packets during congestion and this helped to improve the packet delivery ratio even more in proposed solution.

Varying the speed for 100 vehicles, the packet delay is measured and the results are given in Fig. 7.

The delay is lower in proposed solution compared to existing works. It is on average 13% lower compared to SAMQ and 9.4% lower compared to CBQoS-VANET. The delay has reduced due to reduction of congestion and retransmissions due to congestion in the proposed solution.

This was achieved using service differentiated control of source rate of packets.

Fig. 7. Packet delay vs speed.

The optimization performance of the proposed hybrid metaheuristics is measured in terms of best value and worst value for the fitness function for six different network configurations (vehicle density). The performance is compared against PSO, Firefly and genetic algorithm and results are given in Tables III and IV.

TABLE III. BEST VALUES OF FITNESS FUNCTION

No of vehicles	Fitness Function			
	PSO+Firefly	PSO	Firefly	GA
50	4.72E+04	3.12E+08	1.86E+09	3.40E+06
60	2.62E+02	2.68E+10	7.11E+10	3.39E+06
70	3.04E+02	4.06E+04	3.79E+05	4.25E+02
80	4.00E+02	3.55E+03	1.09E+04	4.33E+02
90	6.06E+02	6.34E+02	6.44E+02	6.21E+02
100	7.00E+02	9.30E+02	1.56E+03	7.02E+02

TABLE IV. WORST VALUES FOR FITNESS FUNCTION

No of vehicles	Fitness Function			
	PSO+Firefly	PSO	Firefly	GA
50	1.62E+07	5.57E+08	5.27E+09	5.47E+07
60	1.55E+04	4.18E+10	1.14E+11	3.63E+06
70	1.01E+03	5.94E+04	1.60E+08	5.12E+04
80	5.80E+02	6.44E+03	3.30E+04	6.44E+02
90	6.17E+02	6.39E+02	6.53E+02	6.30E+02
100	7.01E+02	1.04E+03	2.01E+03	7.03E+02

In terms of best values and worst values, the proposed PSO+Firefly combination has better values compared to PSO, Firefly and GA algorithm. This is due to combination of both exploration and exploitation capability in the PSO+Firefly compared to their usage in separation.

A. Limitations

The proposed solution has following limitations:

- The solution was tested only for highway scenarios where directional mobility is not dynamic. The

applicability of solution for city scenarios with dynamic directional mobility is yet to be tested.

- The solution made assumption on ratio of traffic distributions and data generators. Testing for realistic scenarios like peak hour periods, etc. was not considered in this work.

VII. CONCLUSION

An integrated approach combining swarm intelligence guided clustering/routing with service differentiated flow control is proposed in this work. Clustering is done using multi optimization hybrid metaheuristics and routing paths are found using ant colony optimization. In both clustering and routing swarm intelligence algorithms, objective functions are designed with QoS constraints. The proposed solution is able to achieve 2% more packet delivery ratio, 9.67% lower end to end delay, 3.51% more throughput compared to existing solution. Extending the solution for city scenarios and realistic traffic distributions is in scope of future work.

Abstract—Mobile Ad Hoc Network (MANET) is a group of wireless mobile nodes that can connect with each other over a number of hops without the need for centralized management or pre-existing infrastructure. MANET has been used in several commercial areas such as intelligent shipping systems, ad hoc gaming, and clever agriculture, and non-commercial areas such as army applications, disaster rescue, and wildlife observing domains. One of the main challenges in MANET is routing mobility management which affects the performance of MANET seriously. The routing protocols have been functionally classified into proactive routing protocols, reactive routing protocols, and hybrid routing protocols. The objective of this paper is to create observations about the advantages and disadvantages of these protocols. Thus, the aim of this paper is to conduct a comparative analysis of the three groups of MANET routing protocols by comparing their features and methods in terms of routing overhead, scalability, delay, and other factors. It was shown that the proactive protocols guarantee the availability of the routes. However, it suffers from scalability and overhead. Whereas, reactive protocols initiate route discovery only when data needs to be sent. However, reactive protocols introduce an undesirable delay due to route establishment, which affects the network performance. Hybrid protocols, attempt to utilize the beneficial features of both reactive and proactive protocols, hybrid protocols are suitable for large networks and keep up-to-date information, but they increase operational complexity. It was concluded that MANET needs enhancement with regard to routing in order to meet the required performance.

Keywords—MANET; routing protocols; proactive protocols; reactive protocols; hybrid protocols; Ad Hoc Networks

I. INTRODUCTION

The routing process in MANET is responsible for discovering, establishing, and maintaining a route between two mobile nodes. Routing of packets can be performed using either a single-hop or a multi-hop paradigm [1]. In the single-hop paradigm, the destination node is assumed to be inside the communication range of the source node. Thus, the source node can connect with its destination directly. Within the multi-hop model, the source node can interact with its destination via intermediate nodes while the destination is outside the source node's communication range. MANET is regarded as a multi-hop network where mobile nodes in the network collaboratively help in forwarding the data or control packets between the source node and its destination. The

mobile nodes are involved in the discovery of routes, and once found, the intermediate mobile nodes on the routes would have key roles in maintaining the routes. There are some difficulties in establishing a route between source and destination nodes through intermediate nodes including low bandwidth, limited coverage and connectivity due to limited transmission range, higher error rate, high possibility of interference, power consumption, no centralized mechanism for routing, and frequent network topology changes due to mobility. Mobility makes routing a more complex task in MANET. Routing protocols should be capable of managing routing in MANET efficiently; therefore, it is important to investigate the advantages and disadvantages of the different protocols for MANET to identify the performance evaluation of each routing protocol as the applications of MANET are strongly dependent upon the underlying routing protocol which must be reliable and robust to accommodate frequent disruptions in the communication between mobile node pairs due to node mobility, interference, and lack of infrastructure. These routing protocols can be categorized functionally and structurally based on their routing processes and structures; therefore, the main goal of this work is to perform a comparison between the routing protocol categories with respect to the common parametric evaluation metrics.

The remainder of this paper is structured as follows: Section II describes the general issues and challenges in MANET, routing structure and protocols in MANET are covered in Section III, and Section IV briefly describes the functional classification of routing protocols which includes table-driven, on-demand, and hybrid routing protocols. The structural classification of routing protocols is covered in Section V. The routing protocols are discussed in Section VI with their limitations. The discussion and studies are presented in Section VII. Finally, the conclusion and future works are discussed in Section VIII.

II. GENERAL ISSUES AND CHALLENGES IN MANET

Routing and mobility management are the two key issues with MANET. Routing becomes more challenging due to mobility in MANET, which generally consists of a group of decentralized mobile nodes, that move randomly and frequently causing topology changes [2], [3], [4]. The following are the subsections that summarize the major challenges and issues in MANET.

A. Routing Traffic

Every node in MANET works as a source, a destination, or a router to send data to other nodes. Therefore, mobile nodes are equipped with a discovery function for their environment where a node can forward a message directly to nodes within range or to other unreachable nodes through the intermediate node(s) [5]. The main mechanism used to raise the whole network capacity and performance is multi-hopping. Thus, a node can send data to a specific destination on behalf of another node [6]. This means that even if a source is outside of the destination's radio range, the destination can still receive data from it. Packets travel through numerous wireless nodes to reach their destination. According to Minhas et al. [7], the multi-hopping mechanism helps in conserving energy resource conservation, interference reduction, and increasing the network throughput.

The network can stay operational by constructing new routes by flooding to deliver the data using a multi-hopping mechanism. In the flooding procedure, control packets are moving infinitely in the entire network. As a result, the flooding procedure consumes too much energy from the network resources when it is used for data transmission. Thus, controlling flooding is one of the major challenges to such networks.

B. Nodes Mobility Management

In normal conditions, any two neighboring nodes can exchange data between them (see Fig. 1). Nevertheless, their connection will vanish if any of them leaves the transmission range of the other. Thus, in MANET with high mobility nodes, the probability of a link breaking between any two network neighbors is considerable. This is another significant obstacle to such networks. Due to MANET's dynamic nature, the network topology frequently changes, which therefore results in frequent connection failures [8], [9], [10]. The network must create new routes, just as in the case of broken links, to assure data transmission [11], [12]. A dynamic routing system is required to maintain routes between a source and its destination because of the frequent topology changes.

Therefore, the reliability and success of MANET depend on the effectiveness of the routing protocol and the attribute and usefulness of the collected data [13].

C. Scalability and No Fixed Boundaries

MANET is subject to several challenges such as scalability and no fixed boundaries [14]. MANET is naturally dynamic where mobile nodes arrive and exit arbitrarily without control from a base station (BS) or other central points. Furthermore, as nodes in MANET join and leave arbitrarily, the number of nodes and the size of the network can grow erratically which introduces a heavy burden on the routing mechanism. Consequently, scalability becomes a major issue in MANET [15].

D. Node Density

The density of nodes in regions such as a national or urban park, where high density is presented, compared to highways where the density is varied from high to low depending on rush hour times, should be considered [16] Modeling the mobile

nodes and communication links is one of the problems in MANET. Such modeling can provide valuable information regarding the pattern or behaviors of the wireless transmission under different situations as wireless transmissions in a MANET functioning on a flat open environment can be different from such transmissions in an ad hoc network of nodes placed on a building [17].

The scatter or the distribution of nodes in a geographical area affects the efficiency of routing, especially when there are a lot of middle nodes between the source and the destination. In Fig. 2, where S and D denote the source node and the destination node correspondingly, the light gray area shows the potential flooding and the dark area shows the potential intermediate nodes involved in routing.

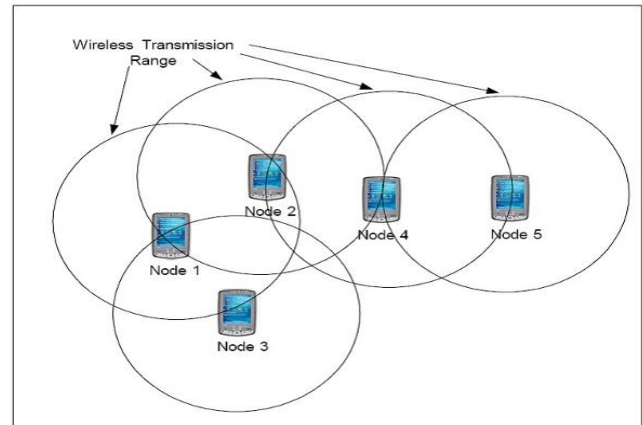

Fig. 1. Communications between adjacent mobile nodes.

Fig. 2. Big number of nodes between the source and destination.

E. Security Concerns

Besides the technical problems mentioned above, In MANET, where trust relationships must be established, security is a significant problem [18], [19]. It is crucial to note that using several hops can cause a problem because it enables unauthorized individuals to intercept data illegally. In addition, there is intentional electronic interference or unintentional interference occurring while many nodes share the same air interface domain. The major challenges and issues in MANET are shortened in Table I.

TABLE I. MAJOR CHALLENGES AND ISSUES IN MANET

Issue	Description
Routing Traffic	The flooding procedure used in the discovery of new routes consumes too much energy from the network resources
Nodes Mobility Management	Nodes mobility causes frequent link breakages
Scalability and No Fixed Boundaries	As nodes in MANET join and leave arbitrarily, the size of the network can grow erratically which introduces a heavy burden on the routing mechanism
Node Density	The scatter or the distribution of nodes in a geographical area affects the efficiency of routing
Security Concerns	The use of multiple hops can be problematic since it makes it easier for an unauthorized person to intercept data.

III. ROUTING STRUCTURE AND PROTOCOLS IN MANET

The routing process in MANET is responsible for discovering, establishing, and maintaining a route between two mobile nodes. Routing of packets can be performed using either a single-hop or a multi-hop paradigm. In a single-hop paradigm, the destination node is assumed to be within the communication range of the source node. Thus, the source can communicate with its destination directly. Within the multi-hop paradigm, the source node can communicate with its destination through intermediate nodes as the destination is out of the communication range of the source node [20]. MANET is considered a multi-hop network where mobile nodes in the network collaboratively help in forwarding the data or control packets between the source node and its destination. The mobile nodes are involved in the discovery of routes, and once found, the intermediate mobile nodes on the routes would have key roles in maintaining the routes. Therefore, routing protocols should be capable of managing routing in MANET efficiently. There are some difficulties in establishing a route between source and destination nodes through intermediate nodes including low bandwidth, limited coverage and connectivity due to limited transmission range, higher error rate, high possibility of interference, power consumption, no centralized mechanism for routing, and frequent network topology changes due to mobility.

A lot of protocols have been developed for routing in MANET. These routing protocols can be classified functionally and structurally according to their routing processes and structures.

IV. FUNCTIONAL CLASSIFICATION OF ROUTING PROTOCOLS

According to the methods that are used in discovering and maintaining routes, routing protocols in MANET are categorized into three groups; table-driven (proactive) routing protocols, on-demand (reactive) routing protocols, and hybrid routing protocols [4], [14], [21], [22].

A. Table Driven Routing Protocols

Tables-driven protocols also called proactive protocols are developed depending on link state and distance vector routing techniques that are traditionally used on the Internet. The main

characteristic of this type of protocol is that they are proactive in the sense that every mobile node maintains an updated routing table to any other node in the network. Therefore, each node should periodically communicate routing information with other nodes in order to maintain its routing table up-to-date on whether the routes are used or not [23], [24]. The frequency of updating the routing tables is crucial. Even though it can reflect the state of the network accurately, and the routing process would be robust to the dynamic changes in the network; however, the bandwidth usage for exchanging routing information will be high. This would leave not much bandwidth for delivering data packets, which affects throughput at the destination nodes considerably. Furthermore, it causes Broadcast Storm Problems (BSP) [25], [26], as the network will be flooded with routing information updates. Hence, the bandwidth for sending data packets will be reduced significantly; especially, in MANET with high node density. On the other hand, as table-driven protocols ensure that routes to destinations are always available, this would reduce the delay in sending data packets once required. In reaction to network topology changes, each proactive protocol reacts differently according to its routing structure, the size of the routing table, and the frequency of routing information updates.

B. On-demand Routing Protocols

On-demand routing protocols also called reactive routing protocols were developed to improve scalability and overhead problems presented by table-driven routing protocols. The aim is to save bandwidth by reducing the number of control messages sent across the network. Therefore, a route to a destination is only looked up when the higher protocol levels demand it, compared with the periodic search for routes and updating them as with proactive protocols. Subsequently, the routing overhead is decreased significantly, which makes it more suitable for mobile network environments [15]. There are two main processes in reactive routing; which are route detection and route maintenance. When a Source node (S) needs to forward data, it first searches its routing table to examine whether it has a route to the desired Destination (D). If there is no route found, a route detection procedure is generated in order to discover a route to the destination. In route detection, the source node floods the network by broadcasting Route Request (RREQ) packets as shown in Fig. 3 [27]. When the destination or an intermediate node that has an active path to the destination receives the RREQ packet, it broadcasts or unicasts a Route Reply (RREP) back to the source node.

Fig. 3. Route detection in conventional on-demand routing protocol.

The route maintenance process starts when the route that is used currently to transport data is disconnected. The node that detects the route failure may repair the route using its local repair process, or otherwise, forward a Route Error (RERR) packet to the source node which will initiate a new route discovery attempt. The main difference between proactive and reactive routing methods in MANET is revealed in Table II [28].

TABLE II. DIFFERENCE BETWEEN PROACTIVE AND REACTIVE ROUTING METHODS IN MANET

Parameter	Table Driven	On-Demand
Route availability	Constantly available	Calculated when needed
Periodic updates	Always required	Not required
Handling mobility	Updates happen at regular intervals	Use localized route discovery
Control traffic generated	Usually higher than on-demand	Growth with mobility of active routes
Storage requirements	Higher than on-demand	Depends on the number of routes maintained or needed
Scalability	Typically, up to 100 nodes	Frequently higher than table-driven

Reactive routing protocols can be classified into two classes; which are hop-by-hop and source-based routing protocols. Source-based routing methods convey the whole path to the destination, while, hop-by-hop routing protocols hold only the destination and next hop addresses in their data packets header.

C. Hybrid Routing Protocols

Hybrid routing is a combination of distance-vector routing and link-state routing. Thus, hybrid routing protocols share the properties and useful features of both reactive and proactive protocols. These protocols are developed to increase the scalability and improve routing in MANET by determining the optimal routes to a destination and reporting network topology when there is a change only [29]. In cases where connectivity to nearby nodes should be maintained, reactive routing is used, while proactive routing can be used if routes to remote nodes are required. This minimizes the periodic propagation of routing information and may provide accurate and reliable routes for transmitting data packets to their intended destination. Moreover, these protocols are able to reduce the number of rebroadcasting nodes in the network using different hierarchical strategies [30]. These strategies enable the nodes to organize themselves to provide effective routing where only selected nodes are used to perform route discovery. Nevertheless, the disadvantage of these protocols is that their efficiency depends on the number of nodes activated in the network. In addition, the gradient of traffic volume plays an important role in reacting to traffic demand. Compared to reactive or proactive protocols, hybrid routing protocols are naturally more complex and require a high computation level to investigate their performance in large MANET.

V. STRUCTURAL CLASSIFICATION OF ROUTING PROTOCOLS

Based on their routing structures, routing protocols in MANET can be classified into three categories; flat, hierarchical, and geographic position routing protocols [31]. Every protocol in these categories performs routing whether proactively or reactively or both. For example, flat routing protocols can be reactive such as AODV and DSR, or proactive such as DSDV and OLSR. In hierarchical routing protocols such as ZRP, nodes are grouped into zones (cluster-based) or trees that would help in limiting the flooding area during the route discovery process. In hierarchical routing, the group leader is responsible for routing management within its group which can reduce the global exchange of routing information (overhead) and the size of routing tables [32]. In addition, hierarchical routing protocols scale better than flat routing protocols in large MANET. Nonetheless, these protocols cause high overhead in highly dynamic MANET due to the frequent reconstruction of zones and cluster head election [33]. Geographic position routing protocols such as ZHLS require that each mobile node must be equipped with GPS in order to acquire their location information when needed. In geographic position routing protocols, data are sent to all mobile nodes in a particular region using geographical information and routing. Hence, the propagation of routing information to the whole network is obviated. The use of geographical information makes those protocols adjust themselves to topology changes quickly. However, high overhead is introduced due to the mapping of address to location procedure.

VI. LITERATURE REVIEW

This section discussed the previously mentioned routing methods along with their limitations in terms of the route discovery process.

Some of the table-driven routing protocols, like Optimized Link State Routing (OLSR) [34], [35], Mobility based OLSR (Mob-OLSR) [36], [37], and Fisheye State Routing (FSR) [38], [39], are developed based on link-state routing algorithm where nodes maintain link-state cost to their neighbouring nodes [40]. Other routing protocols in this category, such as Destination Sequenced Distance Vector (DSDV) [41] and Wireless Routing Protocol (WRP) [42] developed based on distance vector routing where the shortest paths to a destination are checked and maintained periodically by every node.

DSDV routing protocol [41], which is a table-driven routing mechanism based on the Bellman-Ford algorithm [43], was developed to overcome the routing loop problems based on the sequence number of each route stored in the routing table that is announced by the destination. Hence, the data packets are routed through the route with the most recent sequence number. DSDV requires a consistent update of the routing tables [44] which utilizes some of the bandwidth even when the network is not used, which leads to fast depletion of battery power. DSDV is not appropriate for a very dynamic or large-scale MANET [45] as it needs a new sequence number whenever the network topology changes.

Similar to DSDV, WRP [42] was developed to diminish route loops and confirm reliable message exchange based on

the Bellman-Ford algorithm. WRP preserves an up-to-date view of the network by using a set of tables. Maintaining multiple tables requires a significant amount of memory and greater processing power. As WRP uses hello messages to ensure connectivity with neighbours, in highly dynamic MANET, the control overhead involved in updating tables is high and more bandwidth and energy are consumed. Therefore, WRP is not suitable for large MANET since it suffers from limited scalability issues.

FSR [38], [39] is a link state-based routing protocol that controls the overhead by sending out information about mobile nodes that are within its range only. In FSR, a node maintains the link state for every destination in the network by periodically broadcasting update messages to its neighboring nodes. In addition, route updates related to closer nodes are propagated more frequently. FSR provides good packet delivery when mobility in a MANET is low. However, in highly dynamic MANET where the network topology changes repeatedly, FSR presents inaccurate routing information to the destination which makes it not suitable for large MANET.

OLSR [35], [46] is a proactive link-state routing protocol, which discovers and propagates information using Topology Control (TC) and hello messages. OLSR is a shortest-path first-based algorithm. OSPF (Optimize Shortest Path First) floods the topology data using a reliable algorithm that is not suitable for MANET nature. Accordingly, OLSR is considered an unreliable protocol for a highly dynamic MANET. Also, it does not sense the quality of the route; it just assumes that the route is active if some of the hello packets have been received properly. Furthermore, OLSR uses many network resources i.e., bandwidth and energy that are limited in MANET. It is the same for the enhanced version of OLSR where a new technique for node mobility measurement was proposed by [36].

The common on-demand routing protocols in practice are Dynamic Source Routing (DSR) [47], [48], Ad-hoc On-Demand Distance Vector (AODV) [49], [50], Dynamic MANET On-demand (DYMO) [51], [52], Location-Aided Routing (LAR) [53], and Temporally-ordered routing algorithm (TORA) [54].

DSR [47] is an on-demand reactive routing protocol that uses source routing rather than depending on the routing table information at each intermediate node. DSR has two main mechanisms; which are route discovery and route maintenance. Route discovery is initiated when a node requests a route to a specific destination. Route maintenance is triggered when a link between two nodes that are involved in the active route breaks down. DSR, like other on-demand routing protocols, floods the network with RREQ packets during the route discovery process. In determining the route to a destination, the addresses of the intermediate nodes between the source and destination are accumulated during the route discovery process where each node caches the route information. The learned route is used to transmit data packets that contain the address of each node along the path to the destination. DSR controls the bandwidth consumed by control packets, eliminating the periodic update messages required in proactive routing. Load balancing is achieved by using multiple routes which can

increase robustness as well DSR is beacon-less. Moreover, although DSR performs well in networks with low mobility, its performance degrades significantly in highly dynamic networks [55], [56], [57]. Furthermore, its route maintenance strategy does not locally repair a broken route. If routes in the cache are stale, it can cause incompatibility when the route is reconstructed. Also, the delay in establishing a connection is higher compared to that of table-driven protocols.

AODV [48], [58] is a hop-by-hop reactive routing protocol that broadcasts discovery packets only when needed. AODV applies destination sequence numbers to find the latest route to the destination, which also helps in avoiding the infinite loops problem. In addition to that, the delay of the connection establishment in AODV is lower. Overheads and contention are reduced since AODV maintains only active routes. However, having an old source sequence number in the intermediate nodes can lead to unreliable routes. Also, heavy control overhead can be caused by multiple RREP packets in response to a single RREQ and due to the use of periodic "HELLO" packets route maintenance. Furthermore, AODV uses periodic beaconing to keep routing tables updated, which results in unnecessary bandwidth consumption. Moreover, AODV shows better performance in terms of throughput and delay in small-size MANET with no node mobility; and in dense networks with minimum mobility [59]. However, the quality of its performance decreases as the node mobility increases. The mobility-aware approach was added to AODV [60] to improve the management of high mobility in MANET by avoiding the frequent link breakages associated with using unstable paths that contain high mobile nodes. This added feature has shown some enhancement compared to AODV [61].

DYMO (also known as AODVv2) [51] is designed for dynamic environments such as MANET where network topology changes frequently. DYMO shares many benefits of the operational structure of DSR and AODV. DYMO outperforms AODV and DSR protocols as it uses accumulative routing which reduces RREQs noticeably [62]. DYMO was improved by considering the energy and traffic parameters of the network and showed better performance compared to the original DYMO and AODV routing protocols [63].

LAR [53] is an on-demand routing protocol that uses geographical location information to limit the propagation of RREQ packets to a certain number of nodes rather than flooding the network, which in turn reduces the routing overhead considerably. The location of nodes is detected using Global Positioning System (GPS) information and defined in an area that is called a "Request Zone". Only nodes in this zone are required to forward RREQ packets. This can help in avoiding the broadcast storm [20]. However, connection and tracking problems may appear with the use of LAR. It is because when a source node has to find a route to a destination, it should first get the coordinates of the destination from an external location service. LAR has been enhanced further to improve the link ability during routing [64], and to control the overhead found in LAR [65].

TORA [54] is an adaptive routing protocol designed to restrict the propagation of control messages in the highly

dynamic context of mobile computing. In TORA, each node has to explicitly start a query when it needs to forward data to a specific destination. TORA tries to figure out what is known as a Directed Acyclic Graph (DAG) which is rooted at the destination. Even though TORA performs well in dense networks, it does not scale by any means. Several evaluation studies showed that DSR and AODV outperform TORA [66], [67]. It was enhanced to provide better packet delivery, and acceptable routing overhead and packet latency [66].

Location Update Routing Protocol (SLURP) [68], Zone Routing Protocol (ZRP) [40],[69] and Zone-based Hierarchical Link State (ZHL) [70],[71] routing protocols are among the common hybrid routing protocols served the base for the development of several protocols proposed later.

SLURP [68] uses GPS instead of a cluster head to manage the node location and coordinate the transmission of data packets. It utilizes the identification (ID) of the node and zone ID of the destination to perform routing. Therefore, SLURP shares the same advantages mentioned above. Moreover, it limits the need for flooding as the nodes within the zone maintain location information with each other. Thus, nodes know how to find an efficient route to destinations when required. SLURP limits the overhead of maintaining routing information further. This is achieved by restricting route discovery to the home region or specific zone assigned to each node in the network. The home region is determined by a static mapping function that is known to all nodes in the network. The drawback of SLURP is that it depends on a predefined static zone map.

ZRP [40], [69] was developed to speed up data delivery and reduce processing overhead. In ZRP, mobile nodes are clustered into zones where communications among nodes are performed according to their locations in the zone. ZRP maintains robust network connectivity within the routing zones using the reactive routing technique. Also, it reactively discovers remote routes faster. Nonetheless, ZRP behaves as a proactive protocol if the routing zone is too large. On the other hand, if the routing zone is too small, ZRP performs as a reactive protocol. Thus, it is important to set the value of the zone radius according to the density of nodes in the network.

In ZHLS [70], the nodes are divided into non-overlapping zones where each node is associated with two identifiers which are a node ID and a zone ID that is calculated using GPS. Traffic bottleneck is avoided in ZHLS as it does not require a cluster head to coordinate data transmission. Therefore, there is no processing overhead necessary for electing the cluster and restructuring the zone in case of a single point of failure. Hence, the communication overhead is reduced significantly, compared to the flooding method in reactive protocols. Furthermore, ZHLS can adapt to the changes in network topology faster as it only requires the node ID and the zone ID of the destination when routing data packets. However, in ZHLS, for a node to function, it should have a static zone map, which is not practicable in networks like MANET where the geographical boundary is dynamic.

VII. DISCUSSION AND STUDIES

This section discusses the advantages and disadvantages of the routing methods mentioned earlier and presents a comparison between different types of MANET routing protocols in terms of the common parametric evaluation metrics.

Proactive routing protocols have been evaluated theoretically and through simulation [23],[36],[44],[72],[73],[74],[75] and it was found that the main advantage of the proactive routing protocol is to ensure the availability of routes whenever needed with a minimum delay of data delivery, as every node should maintain routing information to every node in the network. The main disadvantages of this type of routing are the continuous discovery of routes and the broadcast of routing information which introduces high overhead and consumes high energy and bandwidth. Therefore, table-driven routing protocols are not appropriate for large and highly dynamic MANET since every node is required to maintain entries in the routing table about all nodes in the network. Because of the nature of MANET, a routing protocol designed for such networks should improve the scalability and decrease the routing overhead by restraining route computations to situations when a route is needed.

The evaluation of reactive routing protocols [17], [66],[76],[77] showed that reactive routing introduces lower overhead as loop free since routes are only constructed when required, which is a privilege of this type of the protocol compared to proactive routing. The disadvantages of reactive routing are that, due to the initial route discovery process, there is a critical delay between the time a source node requests a route for data transmission and the time when the actual transmission takes place. The source node must wait until a route is found then it can start transmitting its data. Rapid changes in a MANET topology due to mobility may break active routes and cause subsequent route discoveries which can substantially impact the network's performance. Additionally, the flooding technique utilized throughout the route discovery phase can result in a broadcast storm.

The performance evaluation of hybrid routing protocols [2],[29],[71],[78],[79] showed that, in comparison with reactive protocols, hybrid protocols can reduce the average length of the routes in terms of the number of nodes and the physical length of the route as well. It was found that the overhead cost in hybrid routing is tolerable in most of the evaluation scenarios. However, even though that hybrid protocols are suitable for large networks and make available up-to-date information, they increase operational complexity.

Table III [80] presents a methodological comparison between different categories of MANET routing protocols with respect to the corresponding parametric evaluation.

TABLE III. COMPARISON BETWEEN ROUTING PROTOCOLS CATEGORIES

Parameter	Reactive Routing Protocols	Proactive Routing Protocols	Hybrid Routing Protocols
Routing Structure	Flat	Flat, Hierarchical	Flat Hierarchical, Geographic

Routing Method	On-demand	Table driven	Both
Routing Overhead	Low	High	Medium
Delay	High-as a result of flooding	Low as a result of routing tables	Low inside the zone; high outside the zone
Scalability	Inappropriate for large-size MANET	Low	Suitable for large-size MANET
Route Availability	Required when needed	Always available in routing tables	Both
Periodic Updates	Not required	Required for updating on topology changes	Required inside the zone only
Storage	Low-depending on the routes number	The high-routing table can be large	High inside the zone
Mobility Management	Route maintenance	Periodic updates	Both

VIII. CONCLUSION AND FUTURE WORKS

This paper discusses that data packet routing is the main concern to improve the performance of MANET where nodes move arbitrarily with no central administration. This presents a heavy burden on the routing protocol in use. In regards to a functional classification of routing protocols discovering and maintaining routes are considered, the protocols have been classified into table-driven (proactive) routing protocols, on-demand (reactive) routing protocols, and hybrid routing protocols. It was shown that in proactive protocols, nodes should maintain a routing table for forwarding packets to any other node in the network. This enforces periodic exchange of information between mobile nodes to keep their routing table up-to-date. In this type of protocol, scalability and overhead become serious issues. Whereas, reactive protocols initiate route discovery only when there is data to send. However, it was recognized that such a process introduces an undesirable delay between the request for data transmission and the actual transmission of data before route establishment, which affects the network performance. Moreover, the flooding procedure used in the route discovery process can cause broadcast storms. Hybrid protocols, however, attempt to utilize the beneficial features of both reactive and proactive protocols to tackle these problems. Nonetheless, it was concluded that while hybrid protocols are suitable for large networks and keep up-to-date information, they increase operational complexity.

In this paper, in connection with the routing methods mentioned earlier, the routing protocols are also classified based on the structure of the network into flat, hierarchical, and geographical position routing protocols, along with a discussion on their performance in terms of some common evaluation metrics. It was concluded that MANET needs enhancement with regard to routing in order to satisfy the service quality requirements of the user applications with desirable performance. The insights gathered from this study will be useful to researchers, network designers, and professionals that work in this area as they design and optimize future MANETs. Future research should include recommendations for selecting the best routing protocol for various scenarios and conduct a comparative analysis of additional routing protocols, including their advantages and disadvantages. Furthermore, future research could be the

investigation on how routing protocols in MANETs can be improved using machine learning and artificial intelligence techniques.

Abstract—The field of agriculture and its specifics has been gaining more attention nowadays due to the limited present resources and the continuously increasing need for food. In fact, agriculture has benefited greatly from the advancements of artificial intelligence, namely, Machine Learning (ML). In order to make the most of a crop field, one must initially plan on what crop is best for planting in this particular field, and whether it will provide the necessary yield. Additionally, it's very important to constantly monitor the quality of soil and water for irrigation of the selected crop. In this paper, we are going to rely on Machine Learning and data analysis to decide the type of crop that we will use, and the quality of soil and water. To do so, certain parameters must be taken into consideration. For choosing the crop, parameters such as sun exposure, humidity, soil pH, and soil moisture will be taken into consideration. On the other hand, water pH, electric conductivity, content of minerals such as chloride, calcium, and magnesium are among the parameters taken into consideration for water quality classification. After acquiring datasets for crop and water potability, we implemented a deep learning model in order to predict these two features. Upon training, our neural network model achieved 97% accuracy for crop recommendation and 96% for water quality prediction. However, the SVM model achieves 96% for crop recommendation and 92% for water quality prediction.

Keywords—Deep learning; irrigation; artificial intelligence; soil moisture

I. INTRODUCTION

As humans became more advanced, they learned that plants do not only provide necessary food for both humans and animals, but it also plays a very important role in the fields of medicine, energy production, and the wellbeing of the entire planet. Agriculture is one of the most essential needs for humans to maintain a sustainable livelihood. Without agriculture, humans would not be getting the sufficient nutrients in their meals, and livestock will not have food to eat which means soon cows and sheep will no longer survive [1]. Thus, it is important to play close attention to crops and to constantly monitor their needs. One of the important needs is water, and not just any water. Irrigation water must have certain qualities in order to be used for planting the crops. So, a water quality assessment or classification system is necessary. In addition, it is essential to know which crops grow best in which environmental conditions, which means a crop prediction system becomes necessary as well.

In many fields such as aquaculture, livestock production, and food industry, water is a critical raw material. For this reason, not any kind of water can be used in any field. To illustrate, not all water is good enough for drinking, or watering plants, etc. [2]. Chatterjee described four different water qualities which are palatable water, infected water, potable water, and contaminated water. From these four types, only palatable and potable water are useable. The water can be classified based on several parameters that have different effects on the water quality.

Generally speaking, the water parameters can be divided into three categories: physical parameters, biological parameters, and chemical parameters as shown in Fig. 1. The physical parameters include total suspended solids (TSS), temperature, electric conductivity (EC), and turbidity. The biological parameters consider whether the water contains any microorganisms. On the other hand, the chemical parameters include Sulfate, pH, heavy metals, and total nitrogen [3].

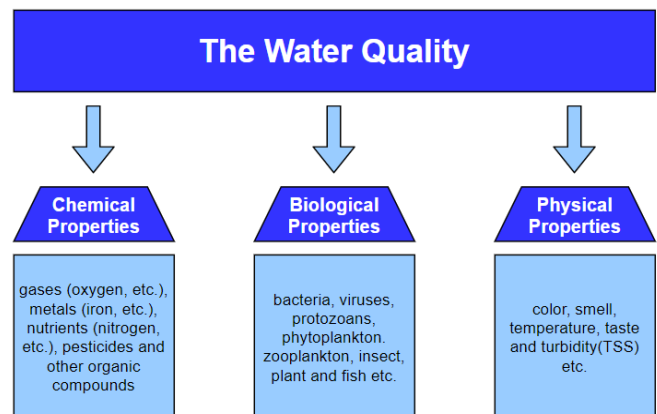

Fig. 1. Water quality parameters.

Predicting the crop is critical for sustainable intensification and efficient use of natural resources [4]. There are many factors that play a role and influence the yield production of crops including environmental conditions and management [5]. In Fig. 2, some of the factors are soil conditions such as pH and moisture play a role in determining the yield of a crop, in addition to weather conditions such as humidity, temperature, and rainfall. Furthermore, factors such as the genotype of the plant, the implemented water irrigation systems, and pesticide control also contribute greatly to how much yield a plant will produce [6].

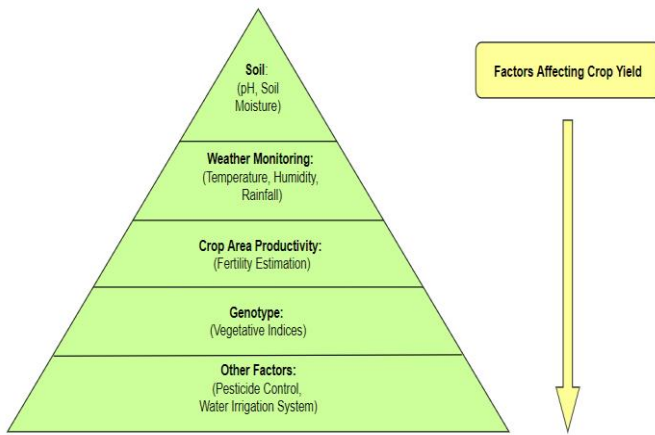

Fig. 2. Factors that influence the crop.

In order to achieve the objectives of the study, we first have to mention the problems that we are trying to address. As mentioned previously, two of the major issues or challenges in the proper maintenance of an agricultural field are the quality of irrigation water that is reaching the plants and that the plants need for proper growth, as well as the appropriate crop type since crops don't react and grow the same as each other in different climates and conditions. Thus, we propose a model that can attempt to solve the water quality analysis and crop recommendation problems at the same time. The contributions that we offer in our study can be summed as follows:

- We developed a system that can predict whether the available water is suitable for irrigation or not, and at the same time can perform crop recommendation based on crop prediction.
- Our model can provide reliable and accurate recommendations for farmers.
- The model that we propose is an inexpensive solution to solve the common problems that farmers face such as low crop.

In summary, this paper aims to address the challenges faced by farmers in selecting the appropriate crop type and evaluating the quality of irrigation water. We propose a model that utilizes deep learning and machine learning algorithms to predict the suitability of available water for irrigation and recommend the best crop type based on crop prediction. Our model offers a cost-effective solution to the common problems faced by farmers, providing reliable and accurate recommendations. The paper also includes a literature review on water quality studies and crop recommendation datasets, as well as a detailed description of the dataset used in our model. Additionally, we discuss the factors that influence crop growth and the contributions of our study.

II. LITERATURE REVIEW

Due to the importance of correctly selecting a crop type, and to continuously evaluate the quality of irrigation water, there's a huge pool of studies that revolve around these two topics.

A. Water Quality Studies

El Bilali et al. [7] designed and implemented a total of 8 Machine Learning models to statistically predict the irrigation water quality (IWQ) parameters that make water suitable for irrigation. Ten irrigation water quality parameters, namely Kelly ration (KR), sodium absorption ratio (SAR), adjusted SARA, Sodium percentage ($\text{Na}^+\%$), exchangeable sodium percentage (ESP), residual sodium carbonate (RSC), total dissolved solids (TDS), chloride (Cl^-), permeability index (PI), and magnesium absorption ratio (MAR) were measured by analysis of 264 samples that were gathered from the Bouregreg watershed, as well as 29 samples from Cherrate and 35 samples from Nfifikh watersheds in Morocco. As for the Machine Learning algorithms, the chosen ones were: multiple linear regression, artificial neural network (ANN), decision tree (DT), random forest (RF), K-nearest neighbor (KNN), support vector machine/regression (SVM/R), stochastic gradient descent (SGD), and adaptive boosting. Upon testing, the results show that all of the 8 models except for SVR and KNN, are capable of predicting only 8 IWQ parameters through the use of electrical conductivity and pH as input variables in Bouregreg watershed surface. To further confirm the results, the six validated ML models were generalized to the Cherrate and Nfifikh watersheds. The results of this generalization attempt revealed that the previous models can be generalized for three parameters in Cherrate watershed and 4 in Nfifikh watershed. Some of these models were not able to statistically predict the MAR and the PI, possibly because of the poor relationship between the EC and pH input variables and these two parameters. Additionally, it was revealed that the adaptive boosting model achieves better performance in comparison with other models in Bouregreg watershed. Thus, it is possible to confirm that ML models can help farmers to better manage the irrigation water quality through extensive analysis.

Ali Mokhtar et al. [8] purposed to study the quality index of the irrigation water of Bahr El-Baqr drain. The authors gathered data from the analysis of 105 water samples of 1L each at a depth of 1m collected from Bahr El-Baqr during the month of July in 2020, ten features were taken into consideration, including pH level, electrical conductivity, sodium concentration, potassium concentration, Ca^{2+} , Mg^{2+} , chloride, carbonate, bicarbonate and sulfate composition. These data were cleaned and modified in order to reach the best score and the most accurate prediction possible. Multiple regressions including principal component regression, stepwise regression, partial least squares regression and ordinary least squares regression, in addition to Machine Learning methods including random forest, extreme gradient boosting, and support vector machine were applied in order to go through the features and determine the features most responsible of identifying the quality index. After applying the root mean square error, the best performance was for the stepwise regression with the values of 0.21% and 0.03%. While after applying the scatter index, all models gave values less than 0.1% except RSC.

B. Crop Recommendation Studies

Bandara et al. [9] proposed a system that can be used for predicting what type of crop should be planted in a certain area within Sri Lanka with the help of artificial intelligence. The

system in fact is a recommendation system based on the collection of multiple environmental factors that directly impact the growth and yield of a certain crop. These factors are collected via sensors, namely temperature and humidity sensor, soil moisture sensor, pH sensor, and sunlight sensor, and are then communicated through Arduino microcontroller to the database for storage and analysis. The study relied on datasets collected by the authorities, as well agricultural books and websites. The collected data is preprocessed before being used by two algorithms which are the support vector machine (SVM) and naïve Bayes (NB) algorithms to perform a prediction based on the input data. The parameters are used to generate a PLU code related to each crop as an output. The added value of this study is that it offers an option for feedback by the users, from which the system will self-train accordingly as a response. Initially the model generated a 92% accuracy which can be enhanced to 95% upon constant use and feedback from farmers.

Priyadarshini et al. [10] purposed to help farmers finding the best crop to be grown in their lands by creating a recommendation system. The authors gathered data from government website and from Kaggle including the yield dataset which includes 16 major crops, the cost of cultivation dataset indicating the cost of each crop, the modal price of crops dataset which gives the market prices of crops among two months, the soil nutrient content dataset which includes five features which are order state, nitrogen content, phosphorous content, potassium content, and average pH. And the rainfall temperature dataset which includes crops, min and max rainfall, min and max temperature, and pH values. These data were cleaned and modified so that the null numbers are replaced by -1 in order not to affect the prediction process. Seven different methods were applied in order to go through the features in order to achieve accuracy and precision, these methods are the linear regression, the neural network, decision tree, K nearest neighbor, K nearest neighbor with cross validation, naïve Bayes and support vector machine. The best performance was for the neural network, with an accuracy of 89.88%.

Shilpa Mangesh Pande [11] and his colleagues in this paper proposed a prediction system in order to help farmers choose the most profitable crop with maximum yield and the best time for using fertilizers in order to reach the best results possible. The authors collected historical data for Maharashtra and Karnataka from different sources among which are indianwaterportal.com, data.gov.in and kaggle.com, while taking six features into consideration which are region, soil type, crop type, area, season, and year. These data were cleaned and modified so that the unavailable values are substituted with the mean values. Five different methods were applied in order to go through the features which are the support vector machine, artificial neural network, K nearest neighbor algorithms, random forest, and multivariate linear regression algorithms. The best performance was for the random forest algorithm with an accuracy of 95%.

Jadhav et al. [12] purposed to deal with the difficulties faced by farmers and find the best solutions and crops for farmers to grow in order to reach the best results possible. The authors gathered data from Kaggle while taking seven features

into consideration; the features selected are the ratio of nitrogen content in soil, the phosphorous ratio, the potassium ratio, the temperature, humidity, rainfall and pH value. While these data were cleaned and modified so that only important features are selected using bar charts, scatter plots, box plots etc., also a UI was built so that the farmer can enter his data in order to get immediate results and recommended crops to grow. Four different methods were applied in order to go through the features leading to the ones responsible of finding the most accurate and the best result of which crop to grow, these methods are random forest, decision tree, logistic regression and XGBoost. The best performance was for the random forest algorithm, reaching an accuracy of 98.9%.

In conclusion, the literature review has highlighted the importance of water quality assessment and crop prediction in agriculture. However, the studies have gaps such as the lack of a comprehensive model for both water quality assessment and crop recommendation, and underutilization of deep learning and machine learning algorithms. Our proposed model addresses these gaps by using these algorithms to predict water quality and recommend crop types. Additionally, our model provides a cost-effective solution to common farmer problems with reliable and accurate recommendations. The limitations across the four references on crop recommendation systems include the lack of information on datasets used, need for further validation in real-world scenarios, generalizability of the systems, and lack of comparison with existing systems. Our study contributes to the literature by providing an efficient model for water quality assessment and crop recommendation.

III. METHODOLOGY

A. Deep Learning Model

There are in the least millions of neurons in a human brain, that interaction among each other and communicate information. The neuronal interactions usually occur via electrochemical signals. The parts of the neurons that are responsible for connecting them to others are known as a Synapse, and they are the location of the passage of electrochemical signals. Neural networks resemble the functioning of the human central nervous system [13], since deep neural networks comprise a huge number of processing units that are connected to each other [14]. Deep neural networks are an important concept of Machine Learning as they can process large amounts of data, and then use them to come up with a pattern from which it can learn [15]. In the majority of cases, neural networks are used for classification tasks because they have a robust and efficient capability of processing the datasets [16]. There are three basic layers in the artificial neural network, which are the input layer, hidden layers, and output layer (Fig. 3).

1) *Input layer*: In the input layer, each input is assigned a vector where the attributes are represented. However, an output must also be given in order to be able to evaluate the model based on its accuracy.

2) *Hidden layer*: The hidden layers consist of weights and thresholds that improve the attributes. Two main processes take place in the hidden layers which are the multiplication of

weights and attributes, followed by sigmoid function that is used for output generation.

3) *Output layer*: The output layer is the level on which comparisons between the resultant output and the actual output take place. Depending on the similarities or differences, the feedback is given to the hidden layers. Additionally, permutation and combination of the weights and attributes occur in the output layer, to ensure better accuracy.

B. Forward propagation

In the case of forward propagation, the data flow is unidirectional in the sense of the output direction. In addition, no feedback is available which makes the accuracy measurements difficult as a way of evaluating the model [17].

C. Back propagation

Back propagation is different from forward propagation since it is constantly training itself by looping the comparisons between the actual and the desired outputs. The comparison is then propagated to the error function which alters the weights of the hidden layers in order to significantly reduce the differences between the actual and the desired outputs.

Fig. 3. Artificial neural network.

D. Activation Function

1) *Sigmoid function*: It can be used whenever the values are between 0 and 1. Where 0 represents the minimal probability of an event and 1 represents the maximum probability. Thus, for event predictions, the sigmoid function is very suitable. In addition, it is possible to find the derivative of the sigmoid function, being a curve between two points.

$$f(x) = \frac{1}{1+e^{-x}} \tag{1}$$

2) *SoftMax function*: It is similar to the sigmoid function, yet the output values in the SoftMax function are divided and can be summed up to a total of 1 [18]. Thus, it is like a probability distribution of the output values.

$$softmax(z_i) = \frac{exp(z_i)}{\sum_j exp(z_j)} \tag{2}$$

3) *Rectified linear unit (ReLU) function*: It is beginning to replace the sigmoid function. In this case, whenever the output

value is below zero, it will be rounded up so that the output is zero. The output and input values are considered equal when the input value is greater than zero.

$$RELU(x) = \begin{cases} 0 & \text{if } x < 0 \\ x & \text{if } x \geq 0 \end{cases} \tag{3}$$

E. Support Vector Machines

Support vector machines (SVM) is a supervised machine learning method that is commonly used for solving classification and regression problems. It was initially developed by Vapnik and Chervonenkis, and has its roots in Statistical Learning Theory. SVM is designed to learn structure from given data and can handle both continuous and categorical variables. The model represents different classes in a hyperplane within a multi-dimensional space, and its objective is to categorize a dataset into different classes by identifying the maximum marginal hyperplane (MMH) [19].

SVM employs kernel functions to transform input data into a desired form. For non-linear problems, the kernel trick technique is utilized in SVM with the aid of slack variables and additional dimensions, which transforms the data into a higher dimensional space. SVM utilizes several types of kernels, which are listed in Table I.

TABLE I. DESCRIPTION OF WATER QUALITY PARAMETERS

Kernel Type	Equation
Polynomial	$k(x, y) = (ax^T y + c)^2$
Linear	$k(x, y) = (ax^T y + c)$
Sigmoid	$k(x, y) = \tanh(ax^T y + c)$
Laplacian kernel	$k(x, y) = \exp\left(-\frac{\ x - y\ }{2\sigma}\right)$
Radial Basis Function (RBF)	$k(x, y) = \exp\left(-\frac{\ x - y\ ^2}{2\sigma^2}\right)$

F. Proposed System Workflow

The following figure describes the workflow of the overall system including the steps required in both of its subsystems.

Fig. 4. The proposed workflow of our proposed prediction system.

Fig. 4 describes the general process performed in order to create our proposed prediction model. Our overall model is concerned with two separate tasks which are crop recommendation, and water quality classification. Thus, we decided to divide the system into two subsystems: subsystem one for crop recommendation, and subsystem two for water quality.

Mainly, similar processes take place in both of the subsystems, which slight differences. Initially, two different datasets are used for the different subsystems. In subsystem one, a crop dataset is acquired from Kaggle, where data selection and preprocessing take place. After that, a deep learning algorithm, namely neural network is implemented to see the results it can achieve, while SVM machine learning algorithm is also used for the same purpose. The objective is to determine for the case of crop recommendation, which perform better: neural network or SVM? The answer to this question can be obtained by comparing their results and thus determining whose result will be taken into consideration when recommending crops.

In subsystem two, a water quality assessment dataset is used and subjected to preprocessing, where it is later fed to a neural network and an SVM algorithm, in order to compare which one of them performs better in terms of classifying the quality of water which will be used for irrigating the crops.

G. Dataset Description and Preprocessing

1) Dataset Description

a) *Crop recommendation dataset:* For subsystem one, we use a dataset comprising the soil-specific attributes which are collected from online sources [20]. The crops considered in our model include 'rice', 'maize', 'chickpea', 'kidney beans', 'pigeon peas', 'moth beans', 'moonbeam', 'blackgram', 'lentil', 'pomegranate', 'banana', 'mango', 'grapes', 'watermelon', 'muskmelon', 'apple', 'orange', 'papaya', 'coconut', 'cotton', 'jute', 'coffee'.

Fig. 5 illustrates the number of instances or repetitions of each crop available in the training dataset. These crops differ in the climate that they need to grow and have good yields. For instance, the rice crop requires a lot of water, thus it is suitable for planting in areas with a lot of rainfall. The coffee crop is suitable to be planted in tropical regions. Jute for example is a crop that requires rainfall but also special soil conditions, thus it only grows in specific regions around India. Black gram crop conversely requires hot and humid climate to grow well and provide the best yield. Therefore, the different crop types require different climate conditions for their prosperity.

The five different attributes or parameters that were considered in the crop yield prediction dataset can be visualized in Fig. 6. For instance, the majority of data about the Phosphorous content fall between 45 and 60 units, whereas the Potassium values are always below 50 units. The pH value falls almost always between 6 and 7, humidity is above 80% most of the times, and the rainfall is between 40 to 120 units in most cases.

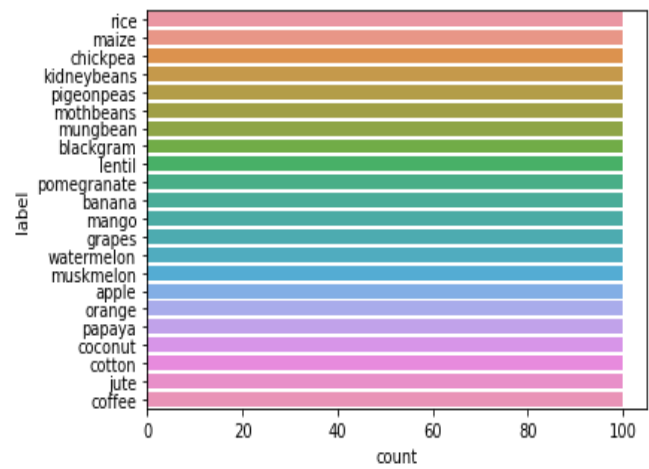

Fig. 5. Number of how many times each crop is present in the training dataset.

Fig. 6. Distribution of the crop prediction parameters.

b) *Water potability dataset:* The water quality dataset is acquired from Kaggle [21]. This dataset includes metrics for 3276 water bodies that differ in their water quality. This dataset is often used to determine the potability of the tested water. The parameters according to which the water is assessed are shown in Table II:

The nine different parameters that were considered in the water potability dataset are shown in Fig. 7. The ratio between the parameters being suitable or not is different and this difference in each of the features is used to predict the water quality. For instance, the difference between the values of turbidity being suitable for irrigation or unsuitable for irrigation determines if this parameter in particular classifies the tested water as suitable for irrigation or not.

TABLE II. DESCRIPTION OF WATER QUALITY PARAMETERS

Parameter	Description
<i>pH value</i>	representing the acid-base balance in the water, since this factor can be quite harmful to human or natural life if it were significantly off.
<i>Hardness</i>	representing the amount of calcium and magnesium salts present in water.
<i>Total dissolved solids</i>	representing the collection of organic and inorganic minerals that can be dissolved in water.
<i>Chloramines</i>	representing the measure of disinfectants that remain in the water after its treatment.
<i>Sulfate</i>	it is a mineral that can be found groundwater and its concentration varies depending on location.
<i>Conductivity</i>	representing the degree to which the water is capable of conducting electricity based on its minerals content.
<i>Organic carbon</i>	representing the organic matter that can be found in water as a result of decaying natural or synthetic matter.
<i>Trihalomethanes</i>	representing the chemicals that can be detected in water after chlorine treatment.
<i>Turbidity</i>	describing the light emitting properties of water depending on the amount of solid matter in its suspension.
<i>Potability</i>	describing the safety of water for human drinking.

Fig. 7. Water quality parameter distribution.

2) *Data preprocessing*: The acquired data are not always clean, in fact they often include missing values, null values, and noise which make the dataset unfit to be used in ML or DL algorithms. Thus, data preprocessing is performed to clean the data and prepare it to be a suitable input for the algorithms. Preprocessing includes many tasks such as the removal of outliers or flawed data, as well as replacing the missing values if present. There are two techniques that can be performed to resolve the missing data, among which is deletion. Deletion

means the removal of the entire row where the missing data reside. In the case of deletion, this might lead to significant reduction in the size of the dataset if it was already small. The other technique includes filling the missing spaces with the average or mean values of the attributes.

a) *Crop recommendation system data preprocessing*: The crop recommendation dataset did not contain any empty values. The data was entered to Standard Scaler in order to standardize the features since the input from the dataset have very different characteristics range. Feature standardization takes place through subtracting the mean and then scaling to unit variance, where unit variance is achieved by dividing all the values by the standard deviation.

b) *Water data preprocessing*: The water quality classification dataset contained some null values, thus these null value rows were dropped from the data so that the performance of the algorithms is not negatively affected by them. Just like the crop recommendation dataset, the data was entered to StandardScaler.

H. Experimental Set Up

In order to achieve the best results, the ML and DL algorithms must be trained and tested under a variety of scenarios. In this study, we trained models on the data so that it will predict the crop that can be grown based on various given parameters such as the soil nutrients and environmental factors. We give different set of input parameters and based on them we train the data to predict the exact crop to be grown. We fit the data to the X, Y training values and make predictions on the X test data. We trained the model for 100 epochs. The model with the lowest loss is considered as the best model and that model is used for evaluation and testing.

The DL model's performance is evaluated in the python environment. TensorFlow is a free deep-learning framework tool it offered by google. It provides a library of various models for data preprocessing, classification, clustering, forecasting, visualization, etc. The collab in which our experiments were conducted contains many powerful features that help the developer and researchers in the development and research process.

IV. RESULTS

A. Correlation for Water

Seaborn heat map function (fig. 8) was used to determine the correlations between the different factors. Each two factors affect each other to a certain degree, which is referred to as correlation.

The correlation matrix illustrates that each feature is strongly correlated to itself only (+1 score), and not to other features. In fact, the water potability/quality factors don't show any string correlations between each other, except for the two parameters pH and hardness, where a weak correlation exists (0.08).

These correlation results imply that dimension reduction is not possible in the water quality data due to the lack of correlation between its parameters.

Fig. 8. Correlation between different features.

In the water quality classification dataset, all of the parameters are regarded as independent features, whereas the water potability parameter is the only dependent factor.

B. Evaluation Metrics

There are several metrics that can be used to evaluate the performance of the models such as precision, recall, f1 score, and accuracy [see (4), (5), (6) and (7)]. Recall is another term used for sensitivity, which resembles the true positive value, which is also the portion of the correctly classified inputs as positive among the entire inputs that should have been classified as positive. Precision is the portion of the true positive classifications over the entirety of the positive results. F-measure is the harmonic mean of the precision and recall and sums up the predictive performance of a model.

$$Recall = TP / (TP + FN) \tag{4}$$

$$Precision = TP / (TP + FP) \tag{5}$$

$$F\text{-Measure} = 2 \cdot Precision \cdot Recall / (Precision + Recall) \tag{6}$$

$$Accuracy = (TN + TP) / (TN + TP + FN + FP) \tag{7}$$

Where, True positive is designated by TP. True negative is designated by TN. False positive is designated by FP. False negative is designated by FN. Area under curve AUC is also a beneficial metric, where the values must be between 0 and 1, such that the higher the AUC value, the better the performance. If the model can discriminate between the instances of two classes perfectly, then AUC would be 1. Conversely, if the model fails to distinguish between any instances, the AUC would be 0.

C. System Results Evaluation

The evaluation metrics were obtained for the proposed water quality and crop recommendation for irrigation system during the training phase. The subsystem was evaluated based on accuracy, precision, f1 score, recall, and loss.

For the crop recommendation system, both the DL and SVM models achieved high levels of accuracy, precision, recall, and F1 score, with only slight variations between the

two models. As shown in Fig. 9, the DL model achieved a slightly higher accuracy of 0.975, compared to the SVM model's accuracy of 0.968. Both models achieved high precision scores of 0.97 and high recall scores of 0.97 and 0.98, respectively. The F1 score was also high for both models, at 0.97. These results suggest that both the DL and SVM models were effective in predicting crop recommendations, with the DL model performing slightly better than the SVM model in terms of accuracy.

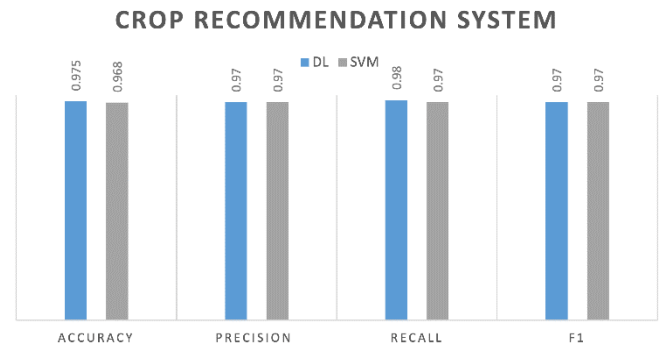

Fig. 9. Crop recommendation system.

As shown in Fig. 10, for the water classify system, the DL model achieved a higher level of accuracy (0.964) compared to the SVM model (0.927), as well as higher precision and recall scores (0.94 for both). The SVM model achieved a lower precision score of 0.914 and a lower recall score of 0.9. The F1 score for both models were relatively similar, with the DL model achieving 0.94 and the SVM model achieving 0.9. These results suggest that the DL model outperformed the SVM model in predicting water potability, with a higher accuracy, precision, and recall score. Overall, the DL model was more effective in classifying water samples as potable or non-potable compared to the SVM model.

Fig. 10. Water classify system.

As a result, the SVM algorithm was able to achieve the accuracy less than neural network model by scoring 97% for crop recommendation for DL as shown in Fig. 11, and 96% for SVM. On the other hand, the water classify subsystem achieve 96% accuracy for DL as shown in Fig. 12, and 92% for SVM.

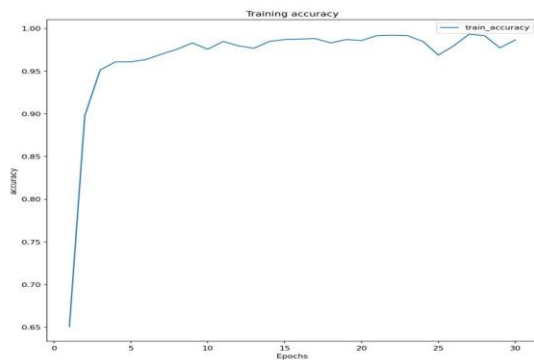

Fig. 11. Training accuracy for crop recommendation using DL.

Fig. 12. Training accuracy for water classify using DL.

Compared to the related works mentioned in the literature review, our work stands out for providing a solution for both crop recommendation and water potability prediction, while some of the studies focused on only one of these tasks. While our work and the related studies all utilize datasets for crop recommendation systems, our approach stands out due to the unique nature of our dataset. Our dataset consists of soil-specific attributes that were collected from online sources, providing a comprehensive and informative dataset for crop recommendations. In contrast, the datasets used in the related studies are either unspecified or contain a limited number of crops. For example, [10] only contains 16 crops. Furthermore, our dataset includes 23 crops, which is a more extensive and diverse selection compared to some of the other studies that do not mention the number or types of crops considered. Therefore, our dataset is more comprehensive and suitable for accurate crop recommendations.

Additionally, our work used a variety of parameters for prediction, such as sun exposure, humidity, soil pH, and soil moisture, as well as water pH, electric conductivity, and content of minerals such as chloride, calcium, and magnesium. Some of the references also used similar parameters, but the methods varied, including decision trees, random forests, and Naive Bayes classifiers. Results from the four references show that accuracy ranged from 90% to 96.7% using different machine learning algorithms. However, the proposed system in our work achieved a higher accuracy for both crop recommendation and water quality prediction, demonstrating the effectiveness of the proposed model.

V. CONCLUSION

Two of the major issues or challenges in the proper maintenance of an agricultural field are the quality of irrigation water that is reaching the plants and that the plants need for proper growth, as well as the appropriate crop type since crops don't react and grow the same as each other in different climates and conditions.

In conclusion, the study proposed a binary model based on deep learning to address the challenges of water quality analysis and crop recommendation. The model was divided into two subsystems that relied on data collected from separate sources for training and testing. The performance of the model was evaluated using various metrics, including a confusion matrix, accuracy, recall, and precision. The neural network achieved high accuracy rates of 97% and 96% for crop recommendation and water quality prediction, respectively, while SVM achieved 96% and 92% accuracy. The results suggested that the binary model had the potential to serve as an effective tool for addressing the complex issues of water quality analysis and crop recommendation simultaneously.

The crop recommendation dataset used in the study has some limitations, including missing or incomplete soil-specific attributes, reliance on online sources for data collection, and a limited number of crops. Meanwhile, the water potability dataset may be limited by a lack of representativeness in sampled water bodies and incomplete or missing data, which could affect the accuracy of water potability predictions.

In the future, we might add to our dataset a wider collection of crops that the system can choose from based on the selected parameters. Additionally, we can implement other algorithms in the future to check if the accuracy can be improved, or if tweaking the algorithms, a bit can add more efficiency. We can also integrate IoT systems in order to be able to collect more data from the field for both the water quality prediction and the crop recommendation features.

Context Aware Automatic Subjective and Objective Question Generation using Fast Text to Text Transfer Learning

Arpit Agrawal¹, Pragya Shukla²

Institute of Engineering and Technology, DAVV Indore, India^{1,2}

Abstract—Online learning has gained a tremendous popularity in the last decade due to the facility to learn anytime, anything, anywhere from the ocean of web resources available. Especially the lockdown all over the world due to the Covid-19 pandemic has brought an enormous attention towards the online learning for value addition and skills development not only for the school/college students, but also to the working professionals. This massive growth in online learning has made the task of assessment very tedious and demands training, experience and resources. Automatic Question generation (AQG) techniques have been introduced to resolve this problem by deriving a question bank from the text documents. However, the performance of conventional AQG techniques is subject to the availability of large labelled training dataset. The requirement of deep linguistic knowledge for the generation of heuristic and hand-crafted rules to transform declarative sentence into interrogative sentence makes the problem further complicated. This paper presents a transfer learning-based text to text transformation model to generate the subjective and objective questions automatically from the text document. The proposed AQG model utilizes the Text-to-Text-Transfer-Transformer (T5) which reframes natural language processing tasks into a unified text-to-text-format and augments it with word sense disambiguation (WSD), ConceptNet and domain adaptation framework to improve the meaningfulness of the questions. Fast T5 library with beam-search decoding algorithm has been used here to reduce the model size and increase the speed of the model through quantization of the whole model by Open Neural Network Exchange (ONNX) framework. The keywords extraction in the proposed framework is performed using the Multipartite graphs to enhance the context awareness. The qualitative and quantitative performance of the proposed AQG model is evaluated through a comprehensive experimental analysis over the publicly available Squad dataset.

Keywords—Automatic question generation; Text-to-Text-transfer-transformer (T5); natural language processing; word sense disambiguation (WSD); domain adaptation; multipartite graphs; beam-search decoding

I. INTRODUCTION

Assessment has always been a very crucial tool in the educational ecosystem to identify the attainment of the learning outcomes and the curriculum gaps. Various evaluation techniques and assessment methods have been proposed by the researchers and academicians to exploit various aspects of students' learning. Question-answer technique has found to be the most effective way of evaluating the students' knowledge as it serves various purposes simultaneously like offering the

opportunity to practice the retrieval of information from memory, identifying the misconceptions, reinforced learning through iterative core concepts, engagement in learning activities, etc. However, deriving these questions manually is a huge task as it requires the thorough knowledge, training and depth of understanding. The challenge increases many folds when the questions need to be replaced periodically to ensure the validity and value which reduces after few rounds of usage. The emergence of e-learning has added a new dimension over the last decade through the available massive open online courses (MOOCs) and adaptive learning. These tools require a large pool of questions to ensure their effectiveness [1-3].

Considering the amount of labor, time and cost associated with the process of generating questions manually, automatic question generation (AQG) has been introduced recently to automate the process. It produces the questions automatically through the structured or unstructured knowledge source and hence enables the educators to invest the time in some other instructional activities. A well-structured and customized question bank can also be created by controlling the difficulty and cognitive level to make the testing adaptive as per the students' requirements. The type of the questions may be subjective or objective. Subjective questions can be used to assess the depth and diversity of understanding of the students, while the binary mode of assessment in objective questions may be used to evaluate the logical understanding in a faster and reliable manner. The most popular varieties of objective questions include the multiple-choice questions (MCQs), fill in the blank questions, true or false questions or matching questions. Although the subjective question-based assessment has remained the most trusted tool in the traditional education systems so as to assess the writing skills and critical reasoning of the students, the recent growth in the e-learning paradigm has attracted many universities towards the objective questions. This is due to the reason that in computer-assisted examination, accurate assessment of numerous students through subjective questions will be a very tedious task. Automatic generation of semantically meaningful and well-formed questions (subjective and objective) has the potential to greatly enhance the learning and assessment experience [4-6].

Traditionally, the process of AQG is classified in two categories, rule-based approach and deep learning approach. Rule-based approach derives the questions on the basis of the hand-crafted rules which are derived through a high level of manual interference. However, the limitation of this approach is that the rules derived for one domain may not be suitable for

other domains. On the other hand, deep learning approach utilizes the natural language processing (NLP) techniques like text abstraction, text summarization, machine translation, etc to generate the questions automatically. Many question answer scenarios and various datasets have been presented over the last decade with different size of context, different formats of answers and sizes of training datasets [7,8]. However, the performance of the AQG model is greatly subject to the understanding and reasoning about the relationship between the sentences in the contextual data. The most important requirement from a machine learning model applied for NLP task is to process the text in a way which is acquiescent to downstream the learning through a general-purpose knowledge framework which understands the text.

Recently, transfer learning has emerged as a very powerful technique in NLP which utilizes the knowledge retrieved from one task to the other related task and therefore reduces the necessity of fine-tuning dataset and improves the performance. This feature of transfer learning technique is also known as domain adaptation which is achieved through the word vector mapping between the similar words and similar vectors. The general-purpose knowledge and abilities in transfer learning is achieved through the pre-training of the entire model over a data rich task. This knowledge is further been transferred to the downstream tasks afterwards. Generally, supervised learning on a large labeled dataset is used to pre-train the transfer learning model for computer vision applications and unsupervised learning on unlabeled data is utilized for the same in NLP applications. The enormous amount of text data available on internet may be used in transfer learning to train the network. Various transfer learning models have been proposed for the NLP applications like GPT, ELMo, BERT, XLNET, ALBERT, RoBERTa, etc. [9-12]. All of these models have shown promise for doing particular tasks, but when asked to fulfill a more comprehensive set of requirements, they fell short. The performance of these models differs from one task to the next due to the fact that even the procedures, practices, and processes that they use are not consistent. Therefore, in order to comprehend transfer learning more thoroughly, a methodology that is both consistent and methodical is essential.

Various unifying approaches like language modeling, span extraction, casting of all text as question answering, etc have been proposed by the researchers in last few years for NLP tasks. But, Text-to-Text-Transfer-Transformer (T5) has evolved as the most powerful unified framework which treats every text processing problem as a “text-to-text” problem [13]. It takes text as input, process or transforms it and generates text as output. The unification has made it possible to apply the same model, objectives, training and decoding procedure to any NLP task at hand like text abstraction, document summarization, question-answer generation, text classification, sentiment analysis from text, etc. The encoder-decoder model in T5 is pretrained on a multi-purpose blend of supervised and unsupervised tasks. The encoded input is fed through a cross-attention layer to generate the autoregressive decoded output using the scalar embedding. The training algorithm in T5 is teacher forcing and hence requires an input sequence and target sequence compulsorily.

However, due to the sequential nature of T5 model, the text-to-text transformation is naturally slow. The model speed even reduces for the larger T5 models and makes the implementation really difficult with limited resources. Augmenting the transformer model with WSD to generate the objective questions in terms of multiple choice, fill-in-the-blank, true/false or pair matching questions enhances the complexity further. This paper presents a fast automatic question generation model for objective and subjective questions by using the fastT5 model which is capable of inferencing faster than the conventional transformer for a reduced model size. The proposed model is run on the onnx runtime which quantizes the whole process and gives the model as output in a single line of code. The flexibility to customize the whole model as per the application has been achieved in this work through the PyTorch Lightning library. It is a lightweight, scalable and high-performance deep learning framework which provides a flexible interface for PyTorch which can easily work on distributed hardware while keeping the models hardware skeptical. The keywords extraction in the proposed framework is performed using the Multipartite graphs to enhance the context awareness. The speed of finding and replacing the keywords in objective questions generation is further improved by using the FlashText library.

The major contribution of the proposed work lies within the application of FastT5 transfer learning model for the subjective and objective question generation automatically. The augmentation of word sense disambiguation (WSD) and domain adaptation framework with the proposed model has improved the meaningfulness of the questions. As the model is required to understand and reason about the relationship between the sentences in the story, the context awareness in the proposed work is enhanced using the multipartite graph-based keyword extraction and FlashText library and the flexibility is achieved through the PyTorch Lightning library. The performance of the proposed technique is evaluated thoroughly through an experimental analysis over SQuAD dataset. Specifically, “teacher forcing” methodology has been used here to train the model with a maximum likelihood objective regardless of the task. Due to the quantized model over onnxruntime, the proposed system is lightweight and faster with good BLEU score.

Rest of the paper is organized as follows: Section II deals with the literature survey through the analysis of related work. The mathematical framework of the text-to-text transformer is given in Section III. The proposed automatic subjective and objective question generation using the proposed fastT5 model is discussed in Section IV. Effectiveness of the proposed strategy is illustrated through the experimental analysis in Section V while Section VI concludes the paper.

II. RELATED WORK

The potential of AQG to change the complete paradigm of online education system, information retrieval systems and interactive support systems has attracted a lot of researchers towards it. Rus et al. [14] has defined the problem of AQG as “the task of automatically generating questions from various inputs such as raw text, database, or semantic representation”. The increasing availability of the digital information on

internet and the amazing advancement in the field of NLP has driven the pace of research in the area of AQG. Conventionally, the problem of AQG is classified in two categories rule-based approaches and neural network approaches (also called neural approaches). In rule-based approaches, human designed syntactic rules are used to transform the declarative sentences in text to the interrogative sentences. It typically applies some lexical transformation around the main verb in the sentence. Heilman and Smith [15] presented a trained logistic model to generate the questions from a paragraph by deriving the transformation rules to produce multiple declarative sentences. These sentences are further converted into questions by syntactic and lexical transformations. Dhole and Manning [16] proposed a collection of semantic and syntactic rules-based heuristics model and named it Syn-QG. They addressed the problem of rule-based approach of generating the questions on Blooms Taxonomy level 1 like “what” and “yes or no”. The proposed Syn-QG model utilizes the VerbNet to generate a set of semantically richer questions. However, this approach requires extensive knowledge in linguistics and well-designed transformation rules to convert the declarative sentences into questions.

Wang et al. [17] proposed a parser based AQG model for medical knowledge evaluation. The medical terms in the articles are extracted and the unstructured entries are classified into different fields using the parsers. They formed more than 100 templates to match the parsed data entries to the question template. However, this method required an extensive labor and the respective templates are domain specific and cannot be applied to other applications. Fabbri et al. [18] developed a context-answer pair based syntactic dataset and used it for the training of deep learning model. The accuracy and effectiveness of this model was dependent on the quality of the dataset and was not generalized for any application. The generated questions were also monotonous.

RNN Encoder-decoder based framework was proposed by Zhou et al. [19] for AQG using attention mechanism for generating natural language questions. The network in the encoder is bidirectional Gated Recurrent Unit (GRU) and left-to-right GRU in the decoder. A multi-perspective context matching algorithm has been proposed by Song et.al. [20] in the sequence-to-sequence LSTM encoder-decoder framework with the copy mechanism for the AQG. Two sets of hidden vectors were generated by encoding the context passage and answer pair through two bi-directional LSTMs. Yuan et al. [21] proposed a combination of supervised learning and reinforcement learning to train a model for AQG. The proposed framework has trained the model first with an objective function of minimizing the cross-entropy loss and then maximized the reward function using the policy gradient method.

Kim et al. [22] derived an answer masking based AQG framework to encode the answers and the sentences separately where the answer text is replaced special tokens. The stack of attention layers with a dot-product based alignment score is used as attention module which cooperates with the answer encoder. The output gate of the LSTM network utilized retrieval style word generator to predict the token. Recently the

potential of transfer learning has been exploited by Mitkov et. al. [23] to generate the multi-choice questions answering. They have showed that the unsupervised transfer learning can be helpful in NLP based applications through iterative self-labeling technique. The transferability of knowledge in encoder and decoder has been explored by See et.al. [24] through a thorough experimental analysis with source question dataset and target dataset. They have used a sequence-to-sequence pointer-generator network over a smaller sized dataset and evaluated the performance over semi-supervised learning.

Most of the prior works in the field of AQG has assumed the access to the sufficiently large dataset for the training and validation. The time taken in the training of the existing models and transformers is also very large. The techniques proposed in the traditional techniques were mostly domain specific and were either suitable for subjective question generation (long answers and short answers) or for objective question generation. Motivated by these facts, our work aims to provide a general purpose, fast and more meaningful AQG model for subjective and objective questions generation using transfer learning.

III. T5 TRANSFORMER MODEL DESCRIPTION

Transfer learning has gained a lot of attention over the last years due to its potential to utilize the knowledge learned from one task for the inferential study of another task and thereby reducing the necessity of fine tuning the dataset. It typically reuses the learned weights of a base network which is trained with a large dataset to the target network by changing the training objectives over a smaller dataset. Typically, the objective of transfer learning is to enhance the learning characteristics through the target conditional probability distribution $P(Y_T|X_T)$ in a target domain D_T utilizing the knowledge attained from the source domain D_S and Source task T_S . **Text-to-Text Transfer Transformer (T5)** is an advance model based on transfer learning converts every problem of NLP like question answering, text classification, translation, question generation, etc. to a text-to-text problem [25]. The model takes text as input and gets trained with the input so as to generate some target text. It enables the model to use the same model, hyperparameters, loss function, activation function, etc. for any diverse set of NLP application. The typical structure of the transformer model is shown in Fig. 1 which is based on an encoder-decoder model. The input sequence of symbols represented by $X=(x_1, x_2, \dots, x_n)$ is mapped to a sequence of continuous representation $Z=(z_1, z_2, \dots, z_n)$ at the encoder. Taking the sequence z , decoder generates an output sequence of symbols $Y=(y_1, y_2, \dots, y_n)$ with one element at a time. The model works in autoregressive style to generate the next symbol by utilizing the previously generated symbols.

The encoder comprises of a sequentially connected stack of N identical encoder layers where the output of one layer is the input to the next layer. The input token sequences fed to the

encoder first concerted into vectors of size d_{model} by the token embedding layer and the position embedding layer. Each block of encoder layer is further comprising of two components; a multi-head self-attention layer and a fully connected feed-forward layer. A simplified layer normalization is applied to

the input of each sublayer where the activation function is rescaled without adding bias. Residual skip connection method is applied afterwards to map each sub-component's input to the output. Dropout is applied within the feed-forward network, on the skip connection, on the attention weights, and at the input and output of the entire stack. Self-attention mechanism plays a vital role in transformer model which relates different positions of a single sequence to compute the representation of the sequence. It typically utilizes the weighted average of the rest of the sequences to replace each element of a sequence. The process of multi-head self-attention mechanism can be represented as

$$MultiHeadAttn(\tilde{Q}, \tilde{K}, \tilde{V}) = [\phi_1; \phi_2; \phi_3; \dots; \phi_h] W^O \quad (1)$$

and

$$\phi_i = Attention(\tilde{Q}W_i^Q, \tilde{K}W_i^K, \tilde{V}W_i^V) = \text{softmax}\left(\frac{QK^T}{\sqrt{d}}\right)V \quad (2)$$

Fig. 1. Text-to-text-transformer model [25].

Similar to the encoder, the decoder structure also comprises of a stack of identical layers. However, each layer in decoder comprises of three sublayers. The third extra sub-layer in decoder is of the form of autoregressive or casual self-attention which performs the multi-head attention over the output of encoder stack and allows the model to attend to past outputs. The residual connections are employed around each sub-layer followed by layer normalization. The self-attention sub-layer is modified here to prevent the positions from attending to subsequent positions. The output of the final decoder block is given to the dense layer with 'softmax' output. The weights of this dense layer are further shared with the input embedding matrix. All attention mechanisms here are fragmented into independent "heads" whose outputs are concatenated before being further processed.

The computation complexity in case of convolutional neural network based like Extended Neural GPU, ByteNet and ConvS2S increases with the increase in the distance between the two arbitrary inputs or output positions [26-28]. It varies linearly for ConvS2S and logarithmically for ByteNet which

makes it extremely difficult to establish the learning among the dependencies between distant positions. This issue has been resolved in T5 transformer architecture by limiting the computation to a constant number by establishing a tradeoff with reduced resolution. Considering the fact that self-attention is an order independent operation, an explicit position is provided in the transformer architecture. Relative position embedding is used here instead of fixed embedding to provide the learned embedding with respect to the offset between the "key" and "query". A simplified form of position embedding is used in T5 model where the attention weights is computed by adding a scaler "embedding" to the corresponding logit. The model efficiency is further enhanced by sharing the position embedding parameters across all the layers. The major difference in the structure of T5 model with the conventional transformer model is that the layer normalization in T5 is placed outside the residual path. It also utilizes different position embedding scheme and removes the Layer norm bias as compared to the traditional model without affecting the performance considerably due to the orthogonal changes in the structure.

IV. PROPOSED METHODOLOGY

The proposed framework is designed for the automatic subjective and objective questions using the fast T5 Model as shown in Fig. 2.

Fig. 2. Proposed model for subjective and objective question generation.

The methodology used for both the cases is discussed here in two parts. Part 1 will discuss the AQG for Subjective question generation and part 2 will discuss the objective questions generation.

Part 1. AQG for Subjective questions: It comprises of four phases of processing namely problem formulation, data preprocessing, baseline model training and domain adaptation

A. Problem Formulation

Considering w_k as the word in the input sentence $S = \{w_k\}_{k=1}^L$ with length L^S , the problem is formulated as the generation of natural question Q with an objective of maximization of the conditional probability of the predicted question sequence Q given the input sentence S as

$$P(Q|S, \theta) = \prod_{t=1}^{L^Q} P(q_t | S, \{q_\tau\}_{\tau=1}^{t-1}, \theta) \quad (3)$$

where L^Q and q_t denote the length of the output question Q and words within Q respectively, θ represents the set of parameters of the prediction model. It is assumed here that the answer of the generated question is a consecutive segment in S so as to generate factual questions.

B. Data Preprocessing

The dataset comprises of three fields (C, Q, A) where C is the prefix which is a string indicating the task to perform, Q and A are the question (target text: The target sequence) and answer (input text: The input text sequence) from the context respectively. As mentioned earlier, our source data set, Squad [29], is a general-purpose QA dataset containing questions generated from Wikipedia pages that cover various topics. Preprocessing is performed to derive the pair of input sequence S and the corresponding question from the context. The larger paragraph is first of all transformed to the abstractive form through text abstraction process. The sentence which contains the answer A is extracted from the short paragraph C. Sentence-question (S,Q) pair is generated through this process which can be utilized for the training of the transformer model.

C. Baseline Model

The baseline model used in the proposed work is T5 model which converts every NLP problem into a text-to-text problem. The architecture of the model is discussed in earlier section. However, the sequential manner of text-to-text transformation is naturally slow and makes the implementation in real time challenging. The performance deteriorates further for larger models as the decoder in T5 model is utilized repeatedly for inference. To overcome this challenge, the conventional T5 Transformer model in this paper is augmented with fast T5 library which makes the inference of the conventional transformer faster. The high inference speed is achieved by running it on onnx runtime which quantize the whole model to decrease its size. FastT5 library converts the pretrained model to Open Neural Network Exchange (onnx) for quantization and generates a model as output which can run in a single line of code through a cross-platform inference framework, onnx runtime. It is a training machine-learning accelerator which offers compatibility among different hardware, drivers and operating systems to optimize the overall performance. The resultant quantized model is lightweight models which offer almost the same accuracy with low latency (due to graph optimization) as compared to the conventional transformer models.

The encoder and decoder are exported to the onnx model separately to reduce the computation complexity and the memory requirement considerably. It is also observed in the conventional transformer model that a constant number of inputs are given to the models, but first level of decoder does not take the previous key values. In contrast, the past key values are provided to the other layers of decoder. This uneven computation issue is addressed in fastT5 model by creating two different decoders; one for the first step without past key values and other for the other steps with past key values. The augmentation of word sense disambiguation (WSD) [30] and domain adaptation framework with the proposed model has improved the meaningfulness of the questions. As the model is required to understand and reason about the relationship

between the sentences in the story, the context awareness in the proposed work is enhanced using the multipartite graph-based keyword extraction and FlashText library and the flexibility is achieved through the PyTorch Lightning library. Beam search algorithm has been used in this model in the decoder which tracks the n (number of beams) most likely hypotheses (based on word probability) at each timestep and finally chooses the hypothesis with the highest overall probability. Teacher forcing has been used in the model as the error propagation-based learning strategy during the training phase of the T5 model where the inference of a new token is depending upon the previous predicted tokens and current hidden state. This strategy modifies the training process by using the true tokens partially instead of always using the generated tokens.

D. Domain Adaptation

Domain adaptation is the process to learn a predictive function F_t which can be used to map the knowledge attained from the source domain D_S for task T_S to the target domain D_T for task T_T . The transfer of knowledge is done in such a way that domain distribution discrepancy between D_S and D_T is reduced to a minimum possible value. Supervised domain adaptation has been used in this work where the best model M_b is selected on the basis of best model evaluation parameters over the validation dataset in target domain for a given number of epochs. The best model is further fine-tuned for the target domain.

Part 2. AQG for Objective questions: Automatic generation of objective questions comprises of three phases of processing namely problem formulation, data preprocessing, and baseline model and distractor generation

E. Problem Formulation

Considering $C = \{w_t^c\}_{t=1}^{t=L_c}$ as the contextual passage, $Q = \{w_t^q\}_{t=1}^{t=L_q}$ as the question and $A = \{w_t^a\}_{t=1}^{t=L_a}$ as the correct answer with lengths L_c, L_q and L_a respectively. The problem here is to design a transfer learning model M to generate a distractor $D = \{w_t^d\}_{t=1}^{t=L_d}$ about the question. The determination of best possible distractors \bar{D} is done in such a way that the conditional likelihood is maximized given by $\bar{D} = \arg \max_D \log \Pr(D|C, Q, A)$

F. Data Preprocessing

The preprocessing stage for objective questions generation is similar to that discussed earlier for subjective questions. The dataset comprising of three fields (C, Q, A) but the difference is that the field A will be a word or a phrase. The length of A as compared to subjective question generation scenario is very small instead. The dataset will be transformed to Sentence-question (S,Q) pair which can be utilized for the training of the transformer model.

G. Baseline Model

The baseline model for objective question generation is FastT5 model where the encoder and decoder are exported to the onnx model separately to achieve the faster speed and low complexity. However, the model is augmented with distractor

generating algorithm to generate other options which are similar to the correct answer but are wrong answers and are used to befuddle the examinee. The keywords extraction in the proposed framework is performed using the multipartite graphs to enhance the context awareness. An objective question, especially a multiple-choice question or fill in the blank question, comprises of three important parts; a question stem, a correct answer and distractors. Due to the limited scope of varying stem or answer, a right set of distractors can greatly control the level and relevance of the automatically generated questions. For MCQs, this task has been performed in this paper through the ConceptNet which is a freely available semantic framework designed to enable the computer understand the meaning of the commonly used words. Word embeddings has been created by ConceptNet [30] by representing the word meanings as vectors. These word embeddings are free, multilingual, aligned across languages, and designed to avoid representing harmful stereotypes. It is a graph knowledge base $G \subseteq C \times R \times C$ where C and R represent the natural language concepts and commonsense relations respectively. ConceptNet contains 32 million triplets where each triplet instance in the respective graph (c_1, r, c_2) represents a commonsense knowledge such as '(Commitment, Leadsto, Success)'. The words and relations for which the created MCQs are referred as seed words and seed relations, respectively. In the generated graph, the directed edge from node c to node p with relation r , p is referred as a parent of node c and c as a child of node p with relation r . The siblings of a node, with respect to a specific relation, are defined as all the children of its parent node, except for the node itself. The selection of distractors for objective questions is done on the basis of hypothesis that the distractors should not share any common property with correct answer. It has been ensured by finding non-overlapping graph communities within words. To attain these leading nodes of non-overlapping community, a one hop expansion is performed in that community and repeated words are removed. The community for each seed word along with its leading nodes is identified to derive the objective questions. Depending on the existence of path between the respective leading node and seed word, distractors from the same community can be chosen using the same seed relation. These generated distractors can be used to derive multiple choice questions, fill-in-the-blanks or True-false questions.

V. EXPERIMENT RESULTS AND DISCUSSION

An experimental analysis has been performed to evaluate the performance of the proposed AQG model. Stanford Question Answering Dataset (SQUAD) has been used in this work which comprises of a rich set of 107785 questions collected from the crowd workers on 536 Wikipedia articles. It is generated through the question-answer pairs from the paragraphs of Wikipedia articles. The selection of Squad in this paper is to derive the questions from a larger spectrum of fields. The available SQUAD dataset consists of two sets: a training set and development set which has been divided further for training, testing and validation. The dataset is having three fields namely context, question and answer. The part of the dataset which is accessible has 490 articles which is divided randomly as given in Table I.

TABLE I. STATISTICS OF DATA SPLIT

Data Split	Articles	Passage-answer pairs	Avg. passage tokens	Avg. question tokens
Train	442	75668	154.32	12.26
Validation	24	10566	159.61	12.58
Test	24	11877	133.64	12.55

The dataset has been used here for the subjective and objective questions generation. The data is first processed using the Wordpiece tokenizer which is a data-driven sub-word level method and consists of 30522 tokens trained from Google. Context selection has been implemented in this work by truncating the input tokens as per the need. The maximum limit of number of tokens in the tokenizer has been chosen 512 tokens as maximum limit so as to attain the optimal training speed and number of truncated data. The limit for number of question tokens has been set to 96 here. The context and answer are given as input to the proposed fast T5 model and question is the output of the transformer.

The proposed T5 model and its training procedures have been implemented using the PyTorch v1.5.0, Pytorch-Lightning frameworks along with the Transformersv3.0.2 from Hugging Face which is a python library providing various transformer architectures. Cross entropy loss and teacher training has been used here for the efficient training performance whereas GPT2 has been used in the decoder. The encoder and decoder of the transformer are exported to the onnx model separately to reduce the computation complexity and the memory requirement considerably. The reasoning and understanding between the sentences in the story to attain the context awareness is enhanced using the multipartite graph-based keyword extraction and FlashText library and the flexibility is achieved through the PyTorch Lightning library. The decoder has utilized the Beam search algorithm in this model so as to reduce the risk of hidden high probability word sequences by keeping the most likely number beams of hypotheses at each time step and help in choosing the hypothesis that has the overall highest probability.

The model training and the evaluation of the proposed framework is performed with Google Cloud Compute Engine. One virtual machine with one 16 GB NVIDIA Tesla T4 GPU has also been used. The sum of token embeddings, segment embeddings and position embedding are set to 0.1. The dropout probability of the self-attention layer and all fully connected layers is also kept 0.1 similar to the original transformer.

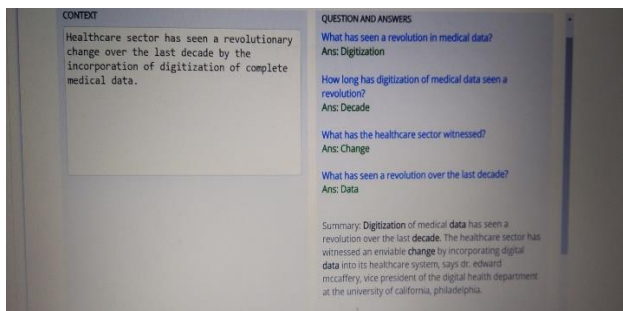

The initial learning rate is set to 5×10^{-5} for the training of the FastT5 model with Adam optimizer. The batch size for the model is kept 64 and is trained only with 2 epochs with equal number of iterations due to the GPU memory constraints. The quality of question generation has been evaluated by BLEU-4 score during the training process which is an automatic performance measuring parameter. It resembles to the 4-gram precision of the hypothesis against the corresponding reference. The performance of the proposed fastT5 model based AQG has also been compared with some conventional

models over BLEU-4 score with 2000 samples. The respective comparison has been shown in Table II.

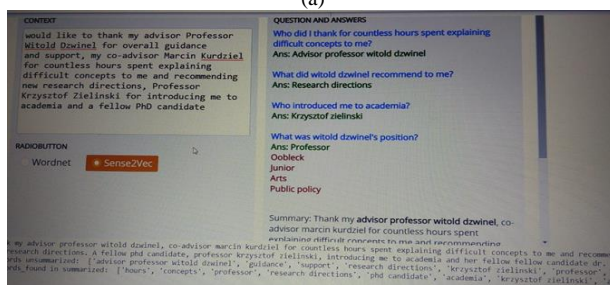

TABLE II. COMPARATIVE ANALYSIS OF THE PROPOSED WORK

Model	BLEU-4
NQG[31]	12.28
M2S+cp [32]	13.98
Ass2s [33]	16.20
S2S-a-at-mp-gsa [34]	16.38
Proposed model	20.28

A graphical user interface (GUI) has been designed in this work using Gradio to present a user-friendly interface to utilize the model as shown in Fig. 3(a) and 3(b). It creates customizable UI components quickly around your TensorFlow or PyTorch models. The GUI shows four fields, namely, context, RadioButton(corpus type), question and answer, and summary field. The user needs to enter the context in the context field and select the suitable corpus; the generated questions and the summary will be automatically displayed in the respective fields. The sense2vec is a powerful variation of word2vec which improves the performance of algorithms like syntactic dependency parsing while significantly reducing computational overhead for calculating the representations of word senses. It enables the model to be implemented for the specific and typical context as well.

VI. CONCLUSION

A challenging problem of automatic subjective and objective question generation with context awareness has been addressed in this work using unified text to text transfer learning. It presents a fastT5 based transformer model which reframes natural language processing tasks into a unified text-

to-text-format and augments it with word sense disambiguation (WSD), concept net and domain adaptation framework to improve the meaningfulness of the questions. The proposed T5 model and its training procedures have been implemented using the PyTorch v1.5.0, Pytorch-Lightning frameworks along with the Transformersv3.0.2 from Hugging Face which is a python library providing various transformer architectures. Beam-search decoding algorithm has been used here to reduce the model size and increase the speed of the model through quantization of the whole model by Open Neural Network Exchange (onnx) framework. The keywords extraction in the proposed framework is performed using the Multipartite graphs to enhance the context awareness. It can be used to derive multiple choice questions, fill-in-the-blanks or True-false questions. The qualitative and quantitative performance of the proposed AQG model is evaluated through a comprehensive experimental analysis over the publicly available SQuAD dataset. The research can further be extended in future with the more advance text transformers. The computation complexity can also be addressed in the future research work.

Multistage End-to-End Driver Drowsiness Alerting System

Sowmyashree P, Sangeetha J

Department of Computer Science and Engineering, M S Ramaiah Institute of Technology, MSR Nagar, Bangalore- 560 054, India

Abstract—Drowsiness in drivers is the major cause for these fatal road accidents. Hence detecting drowsiness in drivers and alerting them on time is very important to avoid accidents. Researchers have developed several techniques to detect drowsiness in driver and warn the driver. However, in the past there is no work done towards the end-to-end driver drowsiness alerting system. Therefore, in this proposed system, it will ensure that the driver is awake through its end-to-end multi-stage (i.e., three stage) alerting system. The proposed system, at first performs driver authentication. Next, it detects the driver's face and also checks whether he/she has consumed alcohol or not, in either case the car engine will not start, and a warning mail is sent. Then the system performs drowsiness detection. If the driver is found drowsy then a multi-stage alerting system (i.e., voice alert, seat vibration alert and physical alert) is performed to wake him/her. After the voice alert, the driver has to give his/her fingerprint as proof for not being drowsy. If the system fails to get a fingerprint it starts the vibration alert. Once again system asks for driver's fingerprint, without which the system starts physical alert through robot arm which is performed with three different frequencies (i.e., Low, Medium and High) and three questions are asked after each frequency to make sure the driver is alert. In the process, it creates a log file which contains the driver's drowsiness details, after analyzing which it gives rating to the driver and mail this rating to the concerned person. This rating can be used to choose the driver for a safe and comfortable journey. Thus, the system ensures that driver is alert and avoids road accidents.

I. INTRODUCTION

The Internet of Things (IoT) indicates billions of appliances worldwide connected to the internet, gathering and distributing data. IoT is a technology that has steadily gained momentum and is now quietly changing our future. The world around us is becoming more intelligent and receptive because of the Internet of Things, which is merging the digital and physical worlds. IoT technologies have a good range of applications in agriculture, health sector, homes, cities, environment, industry and transport system [1]. In the contemporary world, transportation plays a significant role. People rely on automobiles as their primary source of transportation. In 2021, 79.1 million vehicles were produced globally, which is 1.3 percent more than the year 2020 [2]. Although the automobile has changed how people live and made doing everyday activities easier, it also has a connection to a variety of negative effects, such as road accidents.

As reported in a survey by Foundation for Traffic safety [3], over 96 percent of motorists consider drowsy driving to be highly or extremely risky. Only significantly fewer than 40% of respondents believed that fatigued drivers ran the chance of being pulled over by the police. Approximately 27% of drivers acknowledged that they had driven while feeling so sleepy that it was difficult, at least once in the previous 30 days to keep their eyes open, despite high rates of perceived risk and personal/social disapproval surrounding drowsy driving. According to [4], in India there were nearly 4.49 lakh of road accidents in the year of 2019. Our nation has faced 4,69,418 number of serious injuries and 1,51,417 number of deaths in the year 2019. Each year sleepy driving has caused around 100,000 road mishaps and nearly 1,500 deaths in the United States [5]. Therefore, being drowsy poses a severe risk to road safety, resulting in serious injuries, fatalities, and financial losses. Therefore, it is essential to detect drowsiness in drivers and alert them in time.

Many researchers have implemented numerous techniques to identify driver drowsiness and alert him/her. These researchers have considered different parameters to detect drowsiness. Some of them have used parameters like facial expressions [6], head position [7], blink rate [8], eye closure rate [9, 10] and yawning [11]. Many other systems use driver's biological conditions such as heartbeat rate [12, 13], pulse rate [14], galvanic skin response [15] and also features like steering wheel angle [16, 17], vehicle lane [18], speed variation, etc. Some researchers have combined these parameters for attaining better results [19, 20]. Most of the researchers have considered eye as the region of interest to find drowsiness. Eye Aspect Ratio (EAR) [21], Percentage of Eye Closure (PERCLOS) [9], Template Matching [9, 16] are some of the algorithms used for detecting drowsiness. EAR and PERCLOS gives good accuracy among these algorithms. Many authors have also used different Machine learning algorithms. Classifiers used for classifying drowsy and non-drowsy are SVM [6, 14, 18, 20], CNN [7, 8, 13]. CNN gives good accuracy, but it is computationally intensive.

The authors in [21] have developed a real-time system, implemented using mobile application which detects drowsiness using Eye Closure Ratio (ECR) and Eye Aspect Ratio (EAR). They use Dilib library to detect facial characteristics like eye and eyelids. Then by using these features EAR output is computed and a threshold is set for this output which classifies driver as drowsy or non-drowsy. When the driver is found drowsy, he is given an alert using mobile alarm. In [22], the researchers have created a fatigue detection system depending on grayscale image scanning and

PERCLOS. The suggested system comprises of three sections. In the first section, it determines where the driver's face is generally located in grayscale photos and next it examines the eye locations using a mini template. In second section, it creates a fatigue model applying the information from the previous part and PERCLOS. Depending on the driver's unique sleep model, in the third section, the system continually assesses the driver's condition. When the driver is found drowsy, the system warns him/her using an alarm sound. A drowsiness detection system which detects drowsiness by observing the eye movements is proposed in [23]. By combining data from numerous successive video frames with machine learning models' capacity to recognize various eye behaviors, a temporal aspect is added to the system. EAR value and blink classification techniques are used for detecting drowsiness in drivers. Here each video frame contains a calculation and storage of the EAR values. The time dimension was added to the ML model by concatenating a certain number of consecutive EAR values. Previously known blink patterns are used to assess if a user is sleepy or not. When the driver is found sleepy, the system sends a caution message, and a voice is played to warn the driver. The suggested methodology also includes a user feedback process to modify models based on particular user's feedback to produce even better outcomes.

A drowsiness detection system to examine the potential of smart watches and other wrist-worn wearables for the identification of driver drowsiness across a range of age groups is suggested in [24]. The authors have organized two simulators for this study – a low-level simulator and a high-level simulator. Study with high-level simulator was undertaken with two age groups to more thoroughly validate the methodology. Estimation of the heart rate signal and driving status were taken in the first step. The gathered information was prepared for feature extraction in the subsequent step. The final phase involved creating data sets by labeling the features in accordance with the subject's detected state during the simulator drive. A variety of machine learning methods were then used to classify the labeled data. The findings showed that drowsiness varies by age group i.e., younger drivers are more likely to become sleepy than older drivers. Authors have not discussed about in what way they will alert the driver once he/she is found drowsy. The study in [25] discusses a deep learning network-based Electroencephalogram (EEG) categorization system for drowsiness detection. The device EmotivEPOC+ headset is used to collect EEG signals, which is then preprocessed. Data preparation, signals interpretation, and data amplification are the three main focuses of the preprocessing stage. In data preparation, noises are removed from the data. Signal interpretation is based on research into Alpha-Theta waves from the occipital and temporal areas, which are used to assess alertness and drowsiness, respectively. By multiplying the vectors at random intervals, segments were extended to a predetermined length in the data amplification. Then the proposed model is analyzed by using different CNN networks. The system achieved an accuracy of 90.14%.

From all these approaches, it can be seen that the way of warning the driver when he is found drowsy is not specified in many of the works. Many researchers have used simple

buzzers or alarms to alert the driver and there is no way provided to ensure that the driver is awake after the buzzer or alarm goes off. It is important to have a good system to alert the driver, because many people have the habit of sleeping off after the alarm stops. In a real scenario, when a person is in drowsy state, simple alarms or buzzers will not help him/her to be alert. Hence, the proposed system introduces a multi-stage alerting system to wake the driver when he/she is found drowsy.

The proposed system starts with driver authentication by detecting the driver's face and also checks whether he/she has consumed alcohol or not, in either case the car engine will not start, and a warning mail is delivered to the concerned person. Then the system performs drowsiness detection. If the driver is found drowsy then a multi-stage alerting system (i.e., voice alert, seat vibration alert and physical alert) is performed to wake him/her. After the voice alert, the driver has to give his/her fingerprint as proof for not being drowsy. If the system fails to get a fingerprint, it starts the vibration alert. Then again driver has to give his/her fingerprint, without which the system starts physical alert through robot arm which is performed with three different frequencies (i.e., Low, Medium and High) and three questions are asked after each frequency to make sure the driver is awake. If the driver is found alert after any of these multistage alerts, the system continues with detecting drowsiness. In the process, it creates a log file containing the driver's drowsiness details, by analyzing which it gives rating to the driver and mail the rating to the concerned person. This rating can be used by passengers while choosing drivers for their journey. Thus, the system ensures that driver is alert and avoids road accidents to save lives. This paper is separated into III principle segments. In segment II we discuss the methodology used in the proposed system. Result of the proposed system is discussed in segment III. The conclusion is given in the end.

II. METHODOLOGY

The proposed system has two modules – Driver Authentication and Driver Drowsiness Detection and Alerting. Driver authentication module checks for authorized driver and alerts the owner in case the driver is not authorized. Driver drowsiness detection alerting module detects drowsiness in driver and alerts him until he is awake with its multistage alerts. The Fig. 1 represents the flow chart of the suggested system.

A. Driver Authentication

The proposed system starts with driver authentication. As soon as the driver enters the car the system does a face recognition using Haar Cascade Classifier. If the face matching fails, a warning message is delivered to the possessor of the vehicle and the vehicle's engine will not start. After successful face recognition, the system does an alcohol test on the driver using alcohol sensor. If he/she has been detected positive, then the vehicle's engine will not start, and a warning message is sent to the concerned person. Hazards due to drunk driving can be prevented by this alcohol test. If no alcohol content is detected, the system moves to drowsiness detection and alerting module.

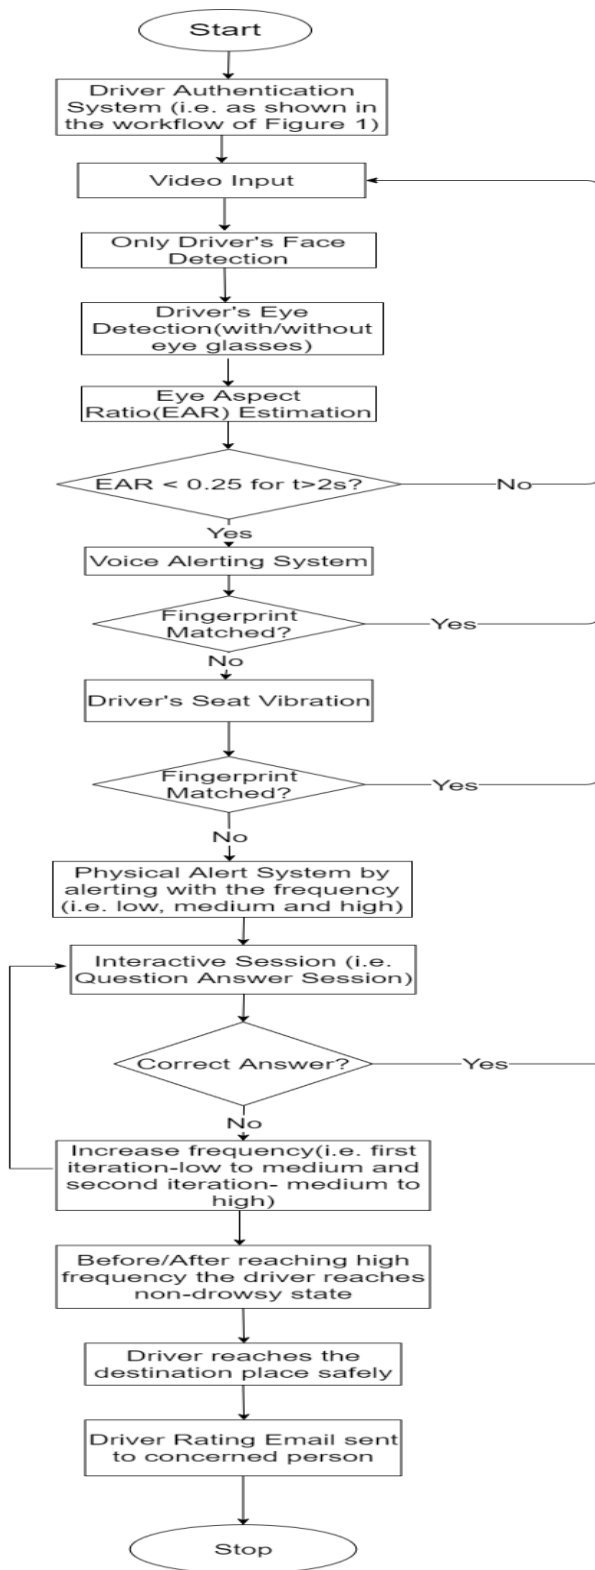

Fig. 1. Flowchart of the proposed system.

B. Driver Drowsiness Detection and Alerting

The system, as seen in Fig. 1 takes continuous video input of the vehicle driver's face and performs face detection and eye detection respectively. After the eye detection, the proposed

system performs EAR (Eye Aspect Ratio) estimation. If the estimated EAR is greater than threshold amount (i.e., 0.25) then the driver is not in sleepy state and hence the system again goes back to monitor the video input. If the estimated EAR is less than threshold amount for more than 2 seconds, then the driver is drowsy. Now, the system undergoes multi-stage alerting (i.e., voice alert, driver's seat vibration alert and physical alert).

1) *Voice alerting system*: When a sleepy driver is discovered, the voice alert is performed by telling the driver to be alert. Next the system asks for the fingerprint of the driver. If the system gets the fingerprint input, the driver is awake, and the system goes back to monitor the video input. If fingerprint input is not provided by the driver, then the system starts the second stage of alerting (i.e., Seat Vibration Alert).

2) *Driver's seat vibration alerting system*: In this stage, the system vibrates the driver's seat of the vehicle to awake him/her. After the car seat vibrates, the system again asks driver to provide his fingerprint, if it is given by the driver then he is awake, and the system goes back to video input monitoring. If the fingerprint is not obtained, then the system starts the third stage of alerting.

3) *Physically alerting the driver by using robot arm*: The proposed system physically alerts the driver by three measures of frequencies (i.e., low, medium and high frequency). After physically alerting the driver with low frequency, our proposed system asks the driver's name, father's name and place. If correct answer is provided by the driver, then the system continues to observe the video input of the driver (i.e., he/she is in non-drowsy state). If it receives wrong answer, then the system again starts physically alerting the driver with the medium frequency. Likewise, the physical alerting system alerts the driver with high frequency.

All the above stages of drowsy detection and alerting are recorded in the form of log file and using this file it gives rating to the driver as Excellent, Good, Average and Bad. This rating is then mailed to the concerned person. The system stops once the driver reaches the destination.

C. Haar Cascade Classifier

Haar cascade classifier suggested by Viola and Jones [26] is one among the few object identification algorithms. We use this algorithm in the proposed system for driver's face detection. For detecting a face, this technique uses four steps: Haar-like attribute, intrinsic image, AdaBoost learning, and The Attentional Cascade. The camera module captures driver's facial behaviour in the form of video. This video is divided into many image frames and these image frames are given as input to Haar Cascade Classifier.

1) *Haar-like Attribute*: Collecting Haar-like attributes on the input image frame is the first step in Haar Cascade Classifier. The crucial component of the Haar cascade classifier is the Haar-like attributes. These attributes make it simple to determine lines or borders and parts where there is a sudden change in the pixel brightness. These rectangular attributes are moved across the image, and the aggregate

number of pixels in the white and black parts is subtracted from one another. The darker portion has a pixel value of 1 and lighter portion has a pixel value of 0. We compute the aggregate of all the image pixels situated in the Haar attributes black and white areas respectively and then Haar value is calculated by taking the difference between them as shown in equation (1). If there is an edge in the image separating light pixels on the left from dark pixels on the right, the Haar value will be close to 1.

$$\text{Haar value} = (\text{Sum of dark pixels} / \text{Number of dark pixels}) - (\text{Sum of light pixels} / \text{Number of light pixels}) \quad (1)$$

The edge attribute is used to detect edges, is the difference between the sums of the pixels inside the two rectangular sections. The line feature determines the sum within two outer rectangles subtracted from the sum within a centre rectangle and is used mostly for line detection. The four-rectangle attribute calculates the difference between rectangle diagonal pairings.

2) *Intrinsic image*: Every pixel in an intrinsic image is calculated by using the primary image so that it is equivalent to the sum of all the pixels to its upper right and to its left. The amount at some point (m, n) is given by equation (2).

$$I(m, n) = \sum_{\substack{m' < m \\ n' < n}} i(m', n') \quad (2)$$

where $i(m, n)$ is the original image and $I(m, n)$ is the integral image. The value of the intrinsic image, $I(m, n)$, is derived by adding the preceding index values from left to right. Over the primary image, the integral image can be calculated in a single pass by applying the following equations (i.e., equation (3) and equation (4)).

$$s(m, n) = s(m, n - 1) + i(m, n) \quad (3)$$

$$I(m, n) = I(m - 1, n) + s(m, n) \quad (4)$$

The Intrinsic Image's endmost pixel in the bottom right corner will be equal to the aggregate of all the pixels in the Primary Image. For whatever attribute size, the Intrinsic Image demands only four continual value additions every time to calculate the Haar value. The total of $i(m, n)$ across the rectangle extended by A, B, C, and D is shown in equation (5).

$$\sum_{\substack{m_0 < m < m_1 \\ n_0 < n < n_1}} i(m, n) = I(D) + I(A) - I(B) - I(C) \quad (5)$$

Where $i(m, n)$ is the sum of pixel values of the rectangle ABCD and the values $I(A), I(B), I(C)$ and $I(D)$ are the pixel values at position A, B, C and D respectively.

3) *AdaBoost algorithm*: After finding Haar attributes in the input image, we have to make a classification function, which will classify the input image frames into two classifications (i.e., the input image that contains face and that does not contain face). To achieve this, we need a training data set which contains images with and without faces, and the Haar attribute set. In the selected Haar attributes, majority of them won't complement the face features nicely or will be unnecessary. Typically, a basic 24×24 image yields

approximately 1,60,000 attributes. Many of these Haar attributes will be irrelevant while performing face detection. So, in this case, a feature selection strategy is required to choose a subset of attributes from the vast set, which will not only choose attributes that perform better than the rest but will also eliminate the unnecessary ones. For this purpose, we use a boosting technique called AdaBoost which is an iterative machine learning process which will select subset of attributes and also train the classifier.

AdaBoost uses the combination of several weak classifiers generated using same set of training dataset which creates a strong classifier. Training data set contains many images with and without human face. At first, on the training set, a basic classifier is trained and predictions are made. Each sample is initially given the same weight. The weight will be decreased if the sample is correctly classified and increased otherwise. This will make the incorrectly classified sample stand out so that a new sample set may be created. Next, the weak classifier is created by training the new sample set and it makes predictions based on the training set, updates the weights, and so on. By overlapping these weak classifiers, the strong classifier will be created. At the end we will be left with most pertinent features needed for face detection. In this way, the number of features selected is reduced to 6000.

4) *The attentional cascade*: After selecting Haar attributes and training the classifier, now system detects face in the input image frame. The Attentional Cascade is an approach to building a cascade of classifiers that improves face detection performance while drastically cutting down on calculation time. AdaBoost-trained classifiers are used to build the stages of the cascade. Fig. 2 represents the architecture of the cascade classifier.

The Haar attributes selected after applying AdaBoost are run on the input image frames by using cascade classifier to detect the face. This is done with the presumption that not all the Haar attributes need to be run on every window. We can say that the face features are absent on a specific sub-window if one Haar attribute fails on that sub-window and hence we can move to next sub-window where there might be a facial feature present. The cascade classifier works as below:

1) The classifier divides the input image into smaller sections, or sub-windows.

2) We then make use of a cascade ordering of N detectors, each of which picks up a type of Haar attributes from the image frame it is fed with. After attribute extraction is finished, a confidence rating is given for each sub-window.

3) The sub-windows (or images) that have the high confidence rating are identified as faces and are submitted to the accumulator while the remaining images are rejected. The cascade then restores the succeeding frame or image, if any, and continues the process.

The process continues in the same manner and at the last stage driver's face is detected.

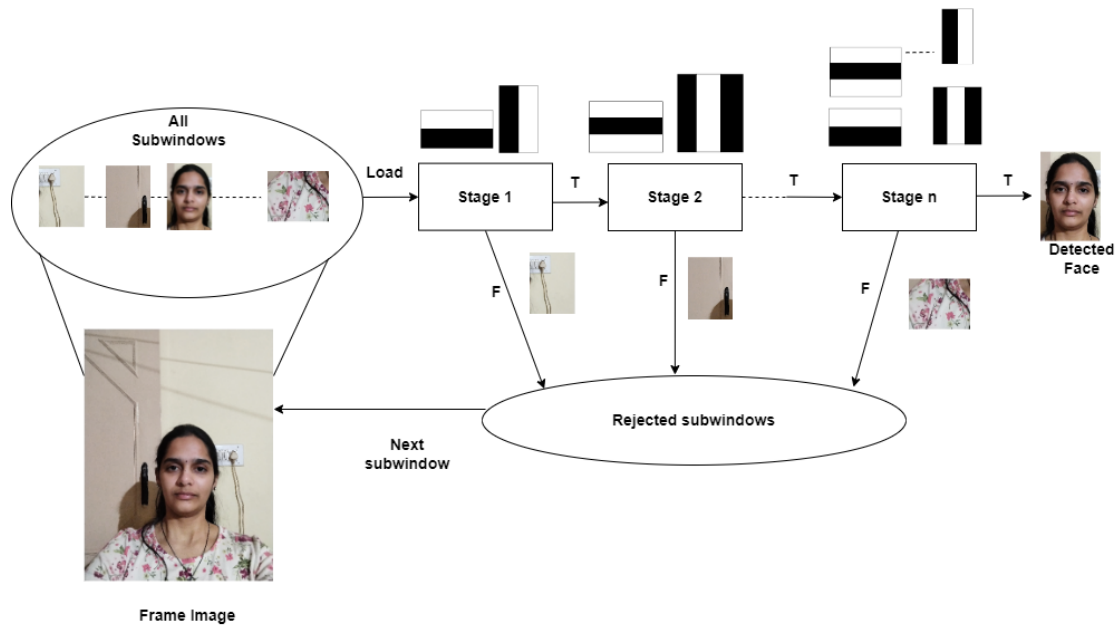

Fig. 2. Cascade classifier architecture.

D. Eye Aspect Ratio (EAR)

After the driver’s face is detected, face landmarks are detected using Dlib library. We use the Dlib library’s pre-trained model to initialize the face landmark detector. After detecting facial landmarks, the drowsiness is detected on the basis of eye blink rate. Eye Aspect Ratio (EAR) [27], detects eye blink. Suppose that the driver flickers his/her eyes repeatedly, it indicates that they are drowsy. In order to determine the eye blink frequency, it is important to precisely detect the eyes shape. Based on the eye landmarks detected previously using Dilib library, the EAR value is calculated and is used to assess the eye-opening state. For every video frame six landmark coordinates around the eyes are taken. Then equation (6) is applied to compute the eye aspect ratio.

$$EAR = \frac{||X2-X6||+||X3-X5||}{2||X1-X4||} \quad (6)$$

Where X1, X2, X3, X4, X5 and X6 are the 2D landmark positions. As indicated in Fig. 3(a), the X2, X3, X5, and X6 are utilized to compute height, whereas the X4 and X1 are utilized to compute eye width in meters (m). The EAR remains persistent when the eye is open, but as the eye gets closed, it rapidly goes to zero, as indicated in Fig. 3(b).

Fig. 3. Eye landmarks.

$$EAR = \begin{cases} y > 0; \text{eyes open} \\ y \cong 0; \text{eyes close} \end{cases} \quad (7)$$

Equation (7) illustrates the EAR value extent when the eyes are closed and open. When eyes are open, the EAR can be some integer value y that is larger than 0, but when they are closed, the EAR will be near to 0. A threshold amount of 0.25 is taken for deciding whether the person is drowsy or not, If the EAR value remains close to 0.25 or less for a time of 02 seconds or more, then the driver is considered to be sleepy [28].

III. RESULTS AND DISCUSSION

In this paper, we are proposing a Multistage End-to-End Driver Drowsiness Alerting System to detect drowsiness in drivers and alert them with multi-stage alerting system. The system detects drowsiness both in day and night condition, and also when the driver is wearing eye glasses. It is implemented using Raspberry Pi 3 Model B. Picamera has been utilized for recognizing and monitoring the driver’s face and Infrared (IR) Light Emitting Diode (LED) is used during night driving. The system starts with driver authentication by detecting driver’s face and recognizing it for an authorized driver. The Haar cascade classifier is applied for face recognition.

Fig. 4. Face authentication.

Fig. 4(a) displays the result of face authentication at daytime and Fig. 4(b) shows the outcome of face authentication at nighttime. Here the face is identified and recognized both at day and night conditions. A green box is

drawn around the identified face and his name is displayed on top of this box. The system then tests for alcohol consumption using alcohol sensor as shown in Fig. 5. If the driver is not authenticated or if he has consumed alcohol, then the system stops the vehicle engine, and an alert email is delivered to the vehicle owner. The alert mail is given in Fig. 6.

Fig. 5. Alcohol sensor.

Fig. 6. Alcohol detection warning email.

After driver authentication, the system starts detecting drowsiness. The system detects the shape of both left and right eye and estimates EAR to determine whether the eye is open or closed. A threshold value is taken to decide whether the eye is closed or open. If the EAR output remains less than threshold for greater than 2 seconds, the person is said to be drowsy. The system can detect drowsiness in both day and night condition and also when the driver is wearing eye glasses. The result of eye detection when the driver's eyes are open in day condition is shown in Fig. 7(a) and 7(b) show the result of eye detection when driver is drowsy.

a: Open Eye b: Drowsy Eye

Fig. 7. Eye detection at day condition.

Fig. 8(a) and 8(b) show the result of eye detection when the driver's eyes are open, and eyes closed in night condition respectively.

Fig. 8. Eye detection at night condition.

The result of eye detection while driver is wearing eye glasses in day time is shown in Fig. 9.

a: Open Eye b: Drowsy Eye

Fig. 9. Eye detection with eye glasses.

After performing drowsiness detection, if the driver is found drowsy then a multistage alerting system (i.e., voice alert, seat vibration alert and physical alert) is performed to wake him/her. The multistage driver drowsiness alerting system consists of:

A. Voice Alerting System

The system continuously monitors the driver's eye for drowsiness. It detects drowsiness by applying EAR algorithm. If the driver is found drowsy, as seen in Fig. 10, then the system starts the first stage alert, i.e. voice alert.

Fig. 10. Drowsy eyes.

Fig. 11 shows the voice alerting system. We use a Bluetooth speaker for providing voice alert to the driver. When the voice alert is initialized, a voice saying "wake up" is played thrice using the speaker, shown in Fig. 11(a). Fig. 11(b) shows respective output.

a: Bluetooth Speaker.

Fig. 11. Voice alerting system.

Once the speaker stops playing the voice, the system asks the driver to give his/her fingerprint as a proof for not being drowsy. Fig. 12(a) shows the fingerprint sensor used in the system and Fig. 12(b) shows the respective output. If the system reads a fingerprint and it is matched with driver's fingerprint, then it indicates that the driver is alert. The system continuously observes the driver's eyes for detecting drowsiness. If the driver is still in drowsy state and the system doesn't receive fingerprint, then it starts the next stage alert (i.e., Seat Vibration Alert).

B. Seat Vibration Alerting System

After voice alert, if the system does not receive the fingerprint, then the next stage of alerting system (i.e., seat vibration alert) is initialized. Here the driver's seat vibrates for one minute time to make him alert. Fig. 13(a) shows the DC motor we used to provide driver seat vibration alert and Fig. 13(b) shows the respective output. Once the seat vibration stops, the system asks for driver's fingerprint as shown in Fig. 14. If driver provides a fingerprint and it is matched, then the driver is alert and hence the system goes back to monitor driver's eye. Else, if no fingerprint is provided, the system starts next stage alert (i.e., Physical Alert).

C. Physical Alerting System

After seat vibration alert if the system does not receive the fingerprint, the system starts physical alert through robot arm which is performed with three different frequencies (i.e., Low, Medium and High Frequency). Fig. 15 shows the robot arm used to provide physical alert and respective output is shown in Fig. 16.

After low frequency physical alert, the system starts a question-and-answer session with the driver to make sure he is awake. The following are the questions asked:

- 1) What is your name?
- 2) What is your father's name?
- 3) Where are you from?

For all the above questions the driver has to answer correctly, even if one question is answered incorrectly then the system concludes the driver is drowsy and goes for next frequency physical alert (i.e., medium frequency). Fig. 17 shows the output of question-and-answer session.

Fig. 19. Log file.

By analyzing this log file, we rate the drivers as Excellent, Good, Average and Bad. The driver who gets alert by voice alerting system is rated as Excellent and the driver who gets alert by seat vibration is rated as Good. The drivers who get alert after low frequency or medium frequency physical alert are rated Average. A Bad rating is given to the drivers who get alert after high frequency physical alert. This rating is then mailed to the concerned person. Fig. 20 shows the mail that has been sent to the concerned person containing the driver's name and his rating for the journey. This rating can help peoples to choose a good driver for a safe and enjoyable journey. Thus, our proposed system provides multistage end-to-end driver drowsiness detection and alerting functionality. This system helps us to avoid road accidents and save people's lives.

Fig. 20. Driver rating email.

IV. CONCLUSION AND FUTURE WORK

In the literature, various researchers have developed techniques to check drowsiness of the driver. However, in the past, there is no work done towards ensuring that driver is awake after the alerting system goes off. Hence, we suggest a driver drowsiness detection system which ensures that driver is alert through its multi-stage alerting system. The system starts with driver authentication by face recognition and alcohol testing. Then it detects drowsiness in driver, and if he/she is found drowsy, multi-stage alerting system is started. In the first stage a voice alert is given. After the voice alert, the driver has to give his/her fingerprint as a proof for not being drowsy. If the system fails to get a fingerprint it starts the vibration alert. Then again driver has to give his fingerprint, without which the system starts physical alert through robot arm which is performed with three different frequencies (i.e. Low, Medium and High) and three questions are asked after each frequency to make sure the driver is alert. We create a log file containing the driver's drowsiness details, by analyzing which we rate the driver and mail the rating to the concerned person. This rating can be used while hiring the driver for a safe and comfortable journey by avoiding road accidents. Thus, the system ensures that driver is alert and avoids road accidents. Future work can be to detect drowsiness when the driver is wearing sunglasses.

ACKNOWLEDGMENT

This research work is filed for patent at the Indian patent office with Patent Number – 202241076823.

SJB Institute of Technology, Bangalore, India²

Abstract—With the increased social network usage, there is a rising concern about potential security and privacy risks related to digital information data. Although there have been numerous studies in this area, a summary is necessary to understand the effectiveness of existing security approaches. The ultimate goal is to provide valuable insights into the effectiveness of existing security schemes in the social network ecosystem. Therefore, the proposed paper discusses the existing research that has been done on authentication and data security measures, including methodologies, issues, benefits, and drawbacks. The inquiry further contributes to highlighting existing research trends and identifying the gap. The paper concludes by stating its learning results that help to open possible insights into the effectiveness of existing security schemes in the social network. Furthermore, blockchain is witnessed with increased interest in distributed security over large data. The paper's outcome states that blockchain-based authentication systems possess better scope if subjected to amending their inherent shortcomings. The findings of this paper emphasize the importance of continuous innovation in data security to ensure the safety and privacy of user data in an ever-evolving digital landscape. This paper offers a foundational aspect for future research toward developing more secure, privacy-preserving solutions for social network users.

Keywords—Social network; security threat; authentication; blockchain

I. INTRODUCTION

With an ongoing demand and trend of sharing information, social network has been creating breakthrough innovations in this perspective [1]. It is not only used for sharing information but also extensively used for constructing business opportunities too [2]. A social network can be more generalized, while its implication can be multi-formed based on usage. It can be represented or rather classified into a consumer review network (e.g., TripAdvisor, Yelp, etc.), a network with content curation (e.g., Flipboard, Pinterest, etc.), a forum for discussion (e.g., Quora, Reddit, etc.), the network for media sharing (YouTube, Snapchat, Instagram, etc.), for the social purpose (LinkedIn, Twitter, Facebook, etc.) [3]. This classification of social network usage will eventually state that volumes of information are involved in each application that is stored, shared, and accessed seamlessly and concurrently [4]. Although most social network offers a simplified design that the account owner can customize, a security breach cannot be fully stopped [5]. As social networks are formed by highly

interconnected networks over the internet, recognizing and comprehending harmful behavior and differentiating them from regular behavior is quite challenging [6]. The attacker intrudes on the network by hiding their identity as a regular node whose malicious intention cannot be guessed initially. Using various alternative means and tools, it is always possible for an attacker to gain access to the user's private information in the social network [7]. Various studies have reported different variants of intrusive activities in the social network [8]. There are also accomplished studies and ongoing research toward strengthening social network security [9]. However, due to their publicly exposed contents, no tool or program has yet been identified or benchmarked as offering full-proof security in social networks. At present, the blockchain-based approach over large data, along with integrated encryption, is highly in demand and is increasingly adopted for securing the contents to avoid falling into the hands of an attacker [10]. Encryption is another preferred technique for securing the contents to offer more data integrity and privacy [11].

However, blockchain and encryption have potential flaws irrespective of their known beneficial features for security. One of the significant problems in blockchain implementation is achieving performance scalability [12]. It also suffers from limiting the number of transactions a network with the block can process. A different arena of problems also exists for an encryption-based solution. Usually, the strong encryption algorithm is characterized by a higher size of keys and is iterative in its operation [13]. Aside from that, the encryption technique is also reliant on a precise set of resources to be fully executed. These shortcomings eventually offer a possible hindrance to a robust authentication method in social networks.

Therefore, the proposed paper discusses existing security approaches in social networks, specifically emphasizing data security and authentication. The contributions of the paper are i) reviewing existing data security approaches exercised in social networks, ii) highlighting a few prominent works using encryption, privacy preservation, learning approaches, and other miscellaneous methodologies towards data security in social network, iii) identifying advantages and shortcomings of various methodologies, iv) highlighting research trends towards publications and v) exploring prominent research gap. The paper is organized as follows: Section II discusses security insights into social networks and discusses existing data security approaches in Section III. Section IV discusses the

current contribution of authentication. At the same time, research trends are highlighted in Section V. Discussion of the research gap is presented in Section VI. Section VII presents the findings and discussions. Section VIII concludes with highlights of its learning outcomes of the proposed review work in social network security.

II. SECURITY INSIGHTS IN SOCIAL NETWORK

In the current era of social networks, it is noted that most social media applications are publicly disclosed, where it is feasible for the attacker to aggregate the data stealthily without letting the user know [7]. The next level of attackers is more interested in illegitimately gaining access to genuine users' accounts. However, the degree of threat in the social network depends on their planned motive. Attackers deploy various alternative techniques to understand the user in social media, thereby initiating malicious activities. Various forms of intrusive activities performed by attackers are briefed as follows:

- **Data Breach:** Using multiple alternative approaches, an attacker can steal a user's credentials and gain illegitimate access to their account. This led to a potential breach of users' private information at the hand of the attacker.
- **Malware propagation:** An attacker can easily divert users to visit their sites using various counterfeited portals. Once the user visits such sites, they are prompted to do simple activities which lead to the activation of malicious codes, and thereby malicious malware starts propagating.
- **Data Theft:** If an attacker can access any business account on the social network, they can also exfiltrate sensitive information channeled to their account. Hence, both data and account eventually get compromised.
- **Impersonation of the brand:** An attacker can construct a counterfeited account of a specific brand where prospective customers can be tricked in various ways, either by maliciously draining their finances or stealing confidential data.
- **Phishing:** Such an attack calls for forwarding a malicious link in messages to the user in various ways. When the user clicks, it directs them to various security threats, including account hijacking. It could also lead to latent stealing of personal information stored in the device.
- **Social Engineering:** In this form of threat, the attacker convinces or tricks the user of their genuine and trustworthy profile. The users are prompted to forward either a financial asset or high-profile information at their wish that is maliciously forwarded to the attacker's account.

All of the above-mentioned invasive actions are common, but a standard classification also explains their variations. Apart from the above-mentioned activities, other forms of attacks in social network are cyberbullying too which are used to intimidate and harass the user by posting objectional

comments and spreading counterfeited rumors. Fig.1 highlights further classification in the form of traditional adversaries, modern adversaries, and targeted adversaries. All these adversaries work with different techniques; hence, there is no fair possibility of developing a common solution to stop all these adversaries. Work is being carried out towards modeling lethal threats in the social network [8], yet it has a restricted security feature.

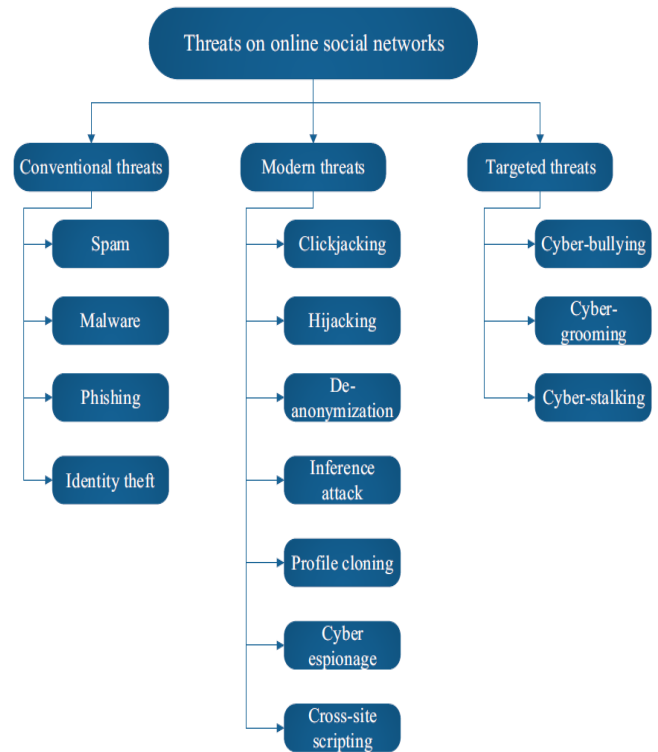

Fig. 1. Classification of adversaries in social networks [14].

Nevertheless, much research is being done to combat the risks spread through social networks. [8], there is also the evolution of smart solutions: cyberstalking, clickjacking, cyber grooming, cyberbullying detection, and phishing detection. From the commercial application viewpoint, the normal recommendation towards securing a social network is to adopt a strong credential, restrict location sharing, install threat detection software, understand and be aware of a third-party application, be vigilant towards sharing content, and review every new friend request [14]. However, from the research perspective, it is suggested to use a strong security protocol that uses potential data encryption, understanding the network connectivity, and vigilant towards usage of underlying threads in the device [15].

Unfortunately, the degree of attacks on social networks is consistently rising despite knowing the facts to be considered for security. It will eventually mean a potential tradeoff between actual security demand and existing effectiveness in security schemes. One of the most primitive intrusion points is via weak authentication in social networking applications [16][17]. Unfortunately, denser and more aggressive authentication protocol usage will also affect the actual motive of social networks, which is towards large-scale data sharing in

a multi-dimensional manner. Further social networking applications migrating to a cloud-based ecosystem offer some application-feature-based advantages but at the cost of security. Moreover, as one social network application is also connected to different applications, the level of threat propagation is quite excessive. Therefore, there is a potential demand to investigate better authentication with better data security. The next section discusses some of the contributions of existing schemes toward securing social networks.

III. DATA SECURITY APPROACHES IN SOCIAL NETWORK

The prior section noted various security threats in social network applications. There is also the evolution of various research techniques to circumvent such forms of threats due to different forms of threats. Due to a large chain of sophisticated networks, offering robust data security in the social network is challenging. Therefore, this section outlines the contribution of some of the identified essential techniques to offer data security.

A. Encryption-based Approaches

This approach is designed and implemented to encrypt the data propagated in social media. From the viewpoint of data, it is found that multimedia data is in circulation and shared in social networks along with the text. The recent work carried out by Ali, and Ali [18] has implemented an encryption strategy toward securing a color image by adopting a chaotic map. A non-linearity element is generated by amending the pixel values, which further results in a random sequence by diffusion. This operation is followed by mixing the encrypted image to generate a consistent distribution of randomness further. Huang et al. also investigated data encryption [19], where a re-encryption policy is applied based on the identity-based sharing of confidential data.

One of the significant advantages of this policy is that it only permits a re-encryption process for matched encrypted data, thereby offering better access control. The work by Qiu et al. [20] discussed a selective encryption system based on coding an embedded block. The investigation also uses optimized truncation to secure a selected part of bitstreams. The work by Zuo et al. [21] used homomorphic encryption to secure the graph operation in social networks associated with untrusted clouds. This investigation model offers effective data security and retains better privacy preservation. The beneficial point of adopting an encryption-based approach is its explicit resistivity towards a specific attack; however, its scope of applicability is limited to specific intruders and involves quite a sophisticated key computation that demands many computational resources.

B. Privacy Preservation-based Approaches

This type of security approach mainly concerns safeguarding all the necessary information that holds privacy details of the data and the user in the social network. A unique investigation formulated by Barni et al. [22] discussed security issues related to adopting biometrics in social media, specifically using iris. As a solution, the author has used a generative adversarial network to generate images with

eliminated biometric information in social networks. Another work by Chen et al. [23] used an integrated method of searchable encryption and blockchain to offer privacy. The presented mechanism is highly decentralized and uses public-key encryption to secure communication in a vehicular network. Li et al. [24] have provided a de-anonymization strategy for the heterogeneous social network in a different piece of work—the model claims to improve the detection system by using user profile and network structure information. Li et al. also presents a similar work form [25]. The investigation model assesses privacy factors associated with the behavioral attributes in social networks based on structural similarity.

The work carried out by Qu et al. [26] has addressed the solution to the gap between the utility of data and privacy customization. The investigation model customizes the level of protecting privacy by using the shortest distance between two nodes in the social network. The model has also adopted an improved version of the Laplacian method for noise modeling that is finally subjected to decoupling to prove its resistivity against collusion attack. Another unique work is carried out by Xu et al. [27] investigating the context behind the communication of anti-social elements using social networks. This investigation has presented a mechanism to retrieve data associated with privacy preservation which further performs a query on suspect communication. The method also securely implements classification and regression trees to resist privacy leakage. The work by Xu et al. [28] presented a selection technique of an optimal trajectory and adopted a heuristic method. The implemented technique also performs clustering operations for facilitating multiple forms of trajectories that finally assist in discovering the community. Assurance of privacy preservation was also discussed by Yin et al. [29] using deep learning approaches.

A hybrid scheme has been deployed using a Bayesian network, a federated learning approach, and a sparse differential gradient. This work aims to optimize the functional encryption operation to secure data sharing among social network multi-parties. A similar investigation was also carried out by Zhang et al. [30], where the data privacy factor is assessed by evaluating the sentence correlation using a convolution neural network and the firefly algorithm. This work aims to ensure secure privacy preservation for social users using large communication scenarios like Internet-of-Things (IoT). The investigation by Zhu et al. [31] presented a computational model for the propagation of privacy information for more in-depth identification of the malicious nature of social nodes. The benefit of adopting the privacy preservation model in securing social network communication is that it offers various techniques while offering higher coverage of security problems in the social network. However, the limiting factor associated with privacy preservation schemes of existing studies is related to their non-applicability in a different test environment.

C. Learning-based Approaches

Learning-based approaches are a part of artificial intelligence that can identify and solve complex problems facilitated by predictive outcomes. The algorithm written for

learning-based approaches offers an extensive capability of execution with a higher adaptation rate of intelligence. Adopting a learning approach facilitates evaluating the problems in social networks and further evolves with more accurate solutions.

The investigation carried out by Abbasi et al. [32] essentially focuses on implementing a learning approach toward identifying any drift factor associated with the concept of massive ranges of social data. The author uses ensemble learning for this purpose, where the idea is to perform an optimal classification of social data to identify the concept drift. The work carried out by Chen et al. [33] presented a model for evaluating multiple trusts for users of social networks considering discrete criteria as well as features, e.g., link, feedback, behavior, and profile. The investigation model implements multiple machine-learning approaches to evaluate its performance.

Another learning-based approach is implemented by Gao et al. [34] to confirm the presence of a Sybil attacker. The technique implements a convolution neural network for extracting low-end and high-end features by Long Short-Term Memory. Discussion towards the applicability of the deep learning approach to the social network security aspect has been carried out by Garg et al. [35]. The investigation has emphasized using Software Defined Networks (SDN) to improve social network security systems. The first module of the investigation uses a support vector machine with gradient descent for anomaly detection.

In contrast, the second module of the investigation implements SDN to ensure a better delivery system. Mei et al. [36] have presented a solution to inference attacks in social media by amending the existing deep learning approach. The work by Sansonetti et al. [37] has presented a technique for identifying the propagation of counterfeited news in social media. The learning-based technique is applied for this analysis in both online and offline modes.

Another learning-based approach is discussed by Shen et al. [38], where an encryption system and blockchain have been introduced to secure the classification operation. The presented investigation uses a support vector machine for performing training operations, while the scheme also assists in resisting any collusion of data involved in it. The adoption of an adversarial learning scheme has been presented by Zhang et al. [39], emphasizing privacy protection. The research helps defend against attacks that try to establish a connection between two nodes in graph embedding.

Consequently, the scheme minimizes the accuracy of the prediction of an attacker. The beneficial factor for adopting a learning-based approach is its effective modeling toward predictive computation considering complex security loopholes. However, a closer look into existing approaches exhibits the prevalence of using static use cases of adversaries, implying its applicability only to specific case studies. In

addition, the computational complexity linked to a higher number of repeats is still unaddressed by the current scheme.

D. Miscellaneous Approaches

Apart from the conventional security practices in social networks seen in prior sections, various off-beat mechanisms are introduced to address similar security problems. From the work presented by Song et al. [40], game theory has been increasingly adopted in modeling social networks. This article claims that game theory is used in behavioral analysis, community identification, and information dissemination to improve the security of social networks by improving access controls and formulating privacy policies. The adoption of game theory is seen in the work of Du et al. [41], where privacy protection is emphasized using the evolutionary game concept in the social network. The idea of this work is to investigate the selection strategy of a user toward privacy protection. The outcome of this investigation is analyzed concerning computational performance cost. Although blockchain is also reported to be used in securing social network communication and services, some studies enhance blockchain's usage towards more security. The work carried out by Fan et al. [42] has used blockchain to offer better non-repudiation in security services as well as to perform a better formulation of access policy using a secret sharing scheme.

Further information used for constructing access policy is hidden for enhanced security. The work carried out by Gao et al. [43] has developed a game-based framework to investigate the social reputation and its impact on controlling data access. A similar line of work is also carried out by Wang et al. [44] towards identifying and resisting counterfeited messages. Huang et al. also adopted a game-based framework [45] to construct an economic model. The core idea of this part of the implementation is to identify any alteration in the network concerning user income. The implementation also assists in developing a model for price decisions under a specific network condition.

The framework developed by Kong et al. [46] has constructed a security framework for strengthening the reputation system over the cloud ecosystem considering the use case of a large-scale healthcare system. The investigation has implemented a convolution neural network that categorizes textual data followed by applying a dynamic game model for constructing a strategy toward incentive allocation.

Su and Xu [47] have worked on allocating resources toward secure communication in social media using the game-based model. The primary agenda of this work is to carry out secure group-based communication for social networks followed by resource gain improvement. Sun et al. [48] have presented a key-based encryption strategy for securing social network data. Using a secure data-sharing scheme, the idea is to identify and protect against intrusion. Table I summarizes all the above data security approaches in the social network.

TABLE I. SUMMARY OF DATA SECURITY APPROACHES

Authors	Problems Addressed	Methodology Adopted	Advantage
Ali & Ali [18]	Image encryption	Chaotic Map	Efficient non-linearity in encryption
Huang et al.[19]	Secure Data Sharing and encryption	Identity-based Re-encryption	Better access control
Qiu et al. [20]	Data security	Selective encryption	Can secure text, image, and video file
Zuo et al. [21]	Data security	Homomorphic encryption	Ensure better data ownership
Barni et al. [22]	Privacy issues in biometrics	Generative adversarial network	Significantly control
Chen et al. [23]	Privacy in vehicular network	Searchable encryption	Satisfactory response time
Li et al. [24]	De-anonymization of user	Modeling using user profile and network structure	Maximize accuracy of detection
Li et al. [25]	Privacy measurement	Structural similarity model of behavior intimacy	Effectively reduces privacy leakage
Qu et al. [26]	Privacy preservation	Analytical model using the Laplacian method	Customization privacy
Xu et al. [27]	Sensing criminal communication in social network	Retrieval of data for privacy, classification & regression tree	Significantly less overhead
Xu et al. [28]	Discovering latent trajectory	Community discovery model using clustering	Offers higher accuracy
Yin et al. [29]	Data sharing in multi-party	Sparse differential gradient, functional encryption, federated learning	Enhance transmission efficiency
Zhang et al. [30]	Privacy preservation for social users in IoT	Convolution Neural Network, Firefly algorithm,	Optimize more usage of data in social network
Zhu et al. [31]	Privacy propagation	Empirical approach	Applicable for dynamic social network
Abbasi et al. [32]	Identification of concept drift	Ensemble learning	Satisfactory accuracy
Chen et al. [33]	Trust evaluation in social network	Multiple machine learning for feature selection	Better accuracy performance
Gao et al. [34]	Detection of Sybil attack	Long Short-Term Memory	Higher accuracy in detection
Garg et al. [35]	Anomaly detection	Support Vector Machine (Gradient Descent), SDN	Ensure secure flow routing
Mei et al. [36]	Inference attack in social network	Revised convolution neural network	Satisfactory accuracy performance
Sansonetti et al. [37]	Identification of counterfeited news in social media	Learning-based approach	Overall satisfactory accuracy performance
Zhang et al. [39]	Privacy preservation	Adversarial learning	Higher preservation performance
Song et al. [40]	Review of game theory	Reviewing existing approaches	Higher applicability
Du et al. [41]	Privacy protection	Evolutionary game	Offer consistency in privacy protection with increased network size.
Fan et al. [42]	Secure data sharing	Blockchain, secret sharing	Resistive against collusion attack
Gao et al. [43]	Impact on social reputation	Game-based framework	Improve the rate of cloud storage
Wang et al. [44]	Counterfeited Message	Game-based model	Increased probability of detection of malicious message
Huang et al. [45]	Issues in price decisions in cyber-physical system	Game-based model	Suitable for price adjustment
Kong et al. [46]	Data privacy for large network	Convolution neural network	Improve model reliability
Su and Xu [47]	Secure resource allocation	Coalition game model	Effective resource efficiency

IV. AUTHENTICATION APPROACHES IN SOCIAL NETWORK

Different authentication mechanisms have evolved with the increasing features of social network applications. However, such authentication mechanism differs strongly between commercially used applications and those reported in scientific papers. The commercially available applications use normal user identity-based credential mechanism that adopts user name and password. The authentication mechanism could be carried out in single execution and sometimes in multiple executions. However, almost all commercially available social network applications use a static form of security token to authenticate the user, where traces of authentications are stored

in mobile devices within its cache memory system. This is a highly vulnerable state for the user where their services and data are exposed to a potential threat. On the other hand, various recently developed protocols have been carried out to strengthen and evolve of authentication scheme.

The work by Alvarez et al. [49] has discussed different authentication system mechanisms for strengthening the associated privacy factors. The investigation suggests the usage of biometrics for this purpose. The majority of the social network application is investigated using a graphical concept. One such work by Jin et al. [50] emphasizes implementing a stochastic approach to authenticate such graphs. The technique

uses a supervised learning mechanism to identify such malicious activities in the social network. An authentication model discussed by Megouache et al. [51] has presented a unique scheme for privacy preservation in an environment with multi-clouds. The investigation uses an encryption approach toward data integrity as well as authentication. The work carried out by Park et al. [52] have presented distributed scheme of authentication considering multi-factor authentication based on trust score. Ruan et al. [53] have presented a work towards location privacy where replicated information is used to secure the user's privacy. At the same time, it controls all sorts of inference of activity track of use from the location server to keep it more secure. The work by Sinha et al. [54] used elliptical curve encryption and symmetric encryption to resist replay attacks and cryptanalysis attacks in the social network. The investigation model has implemented a key exchange mechanism to carry out authentication. Soni et al. [55] have presented a security scheme using fuzzy c-means algorithm. In contrast, it uses a series of encryption techniques (e.g., Rivest Shamir Algorithm (RSA), Advanced Encryption

Standard (AES), and Rivest Cipher 6 (RC6)) to cipher the data further. A recent investigation has also witnessed the adoption of blockchain to secure the trust factor in next-generation networks based on user behavior.

Tu et al. [56] carried out an investigation where a novel trust control modeling is based on user behavior. A unique authentication model is presented by Xu et al.[57] over the storage framework associated with the social network using blockchain. The authentication is provided by incorporating secure access control developed by integrating the Clark-Wilson model and blockchain technology. The adoption of homomorphic encryption was carried out by Zuo et al. [58], where a sub-graph matching mechanism was introduced to carry out authentication. The cloud carries out the query processing of the subgraph without any dependency on the secure and sensitive information of the user. The investigation model of authentication is claimed to offer data integrity too. Table II highlights the summarization of the existing authentication schemes.

TABLE II. SUMMARY OF AUTHENTICATION APPROACHES

Authors	Problems Addressed	Methodology Adopted	Advantage
Alvarez et al. [49]	Sensor-based authentication	Review work	Elaborated discussion of existing methods
Jin et al. [50]	Authentication of graph	Supervised learning, stochastic	84.4% of accuracy rate
Megouache et al. [51]	Authentication & Integrity	Encryption-based model	Stabilized system
Park et al.[52]	Cyber-security threat	Distributed authentication model	Reduced latency
Ruan et al. [53]	Privacy protection	Replicated identity construction	Lower communication and computation cost
Sinha et al. [54]	Replay attack on social network	Key exchange, Elliptical curve cryptography, symmetric encryption	Less processing time
Soni et al. [55]	Data security in the cloud	Fuzzy c-Means clustering, RSA, AES, RC6	Simplified technique
Tu et al. [56]	attacks in next-generation network	Blockchain-based trust model	Minimized network threats
Xu et al.[57]	Access Control on storage	Blockchain, Clark-Wilson Model	Offers data integrity
Zuo et al. [58]	Privacy preservation	Homomorphic encryption	Offers data privacy and integrity

V. RESEARCH TRENDS

To understand the existing research trend, data were collected from well-known publications, e.g., IEEE Xplore, Springer, ACM, Wiley, and Elsevier, ranging between the publication year of 2012-2022. It was noted that approximately 6538 conference papers and 1395 journals are being published towards discussing and evolving out of security models associated with social networks in IEEE alone [59]. After a complete evaluation of overall methodologies, it has been noted that there are different variants of techniques towards incorporating security, authentication-based approaches, blockchain technology, investigation towards data integrity, adoption of game theoretical framework, usage of different types of machine learning models, studies towards privacy preservation, and encryption-based approaches. All the studies mentioned above methodology are witnessed to address different forms of security problems arising in social media. From Fig. 2 it can be noted that more studies have been carried out to emphasize privacy preservation in social networks. The studies adopting blockchain-based and encryption-based mechanisms are also increasingly evolving. However, many of these approaches are very less than privacy preservation

approaches. Games and learning-based programs are still in the early stages of development.

Therefore, the inference obtained from the simplified analysis of the research trend of publication is as follows:

- The amount of research on protecting privacy on social networks is relatively higher. The scope of this outcome is that existing privacy preservation is carried out considering a set of adversaries that it can successfully resist [14],[16],[21]-[31],[39], [49]. Therefore, such a privacy preservation scheme is robust to act against specific attacks; however, the prime shortcoming is that there is a need to address dynamic attackers in the social network that are few to be reported. Similar problems are also applicable to data integrity schemes.
- From an implementation standpoint, research on authentication and encryption-based systems is closely related [11], [13], [18]-[20], [23]. There is an increasing trend toward using a symmetric key, elliptical curve cryptography, RSA, and many other approaches in public key encryption. Such encryption approaches introduce sophisticated techniques of private key

computation without considering encrypting default public keys. Apart from this, most authentication-based approaches using key-based mechanisms do not consider the device complexity used in social networks. Each social network application has a unique performance signature on different devices, which is not evaluated in existing research.

- Machine learning [16], [29],[32]-[35], [37], [39] and game theoretical models [40]-[47] are slowly gaining pace toward social network security. However, such approaches are yet to be addressed from their practical world implementation owing to their larger dependencies on additional information and data. The complex problems associated with them are yet to be researched.

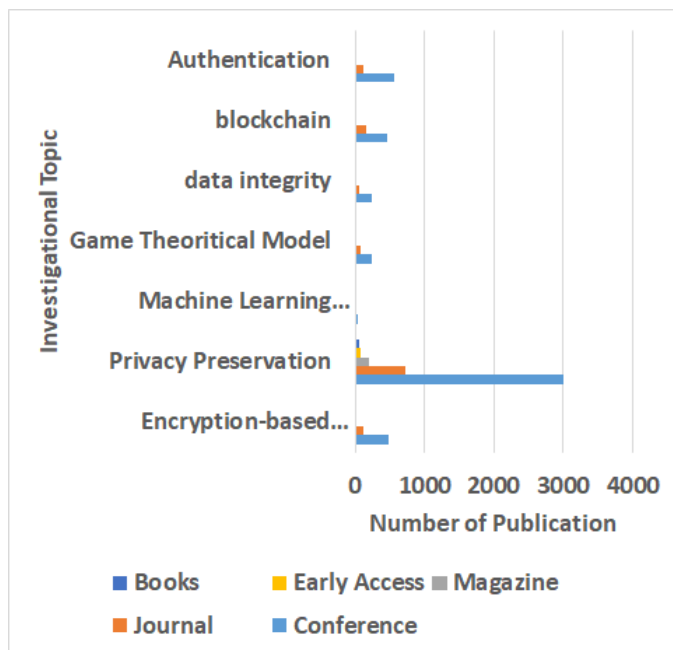

Fig. 2. Research trends of publication (2012-2022).

VI. GAP ANALYSIS

Undoubtedly, current research on secure social network applications has significantly contributed. With different classes of algorithms, various security solutions are available to resist potential threats. After reviewing various classes of existing schemes for securing communication in social networks, the following shortcomings have been witnessed in the form of a research gap:

- *Attack Specific Investigation:* There are variously reported adversaries present in the social network, e.g., cross-site scripting, clickjacking, SQL injection, whaling attack, malware propagation, spamming attack, etc., apart from various other conventional reported attacks. Different variants of methodologies presented to date have used only specific forms of attacks, and hence that solution is rendered inapplicable when exposed to a different set of attacks. The problem becomes more significant when the attacker introduces

malicious activities dynamically. Hence, there is a need to develop an adversarial model first which bears the maximum characteristics of existing attackers to prove the resiliency of security protocols.

- *Unbalance computational efficiency:* The primary stage of developing the social network is constructing a higher linked and inter-connected topology of the user (or nodes). As social networking application is run over user handheld device, hence, is predicted to support such resource constraint device. Applying a strong encryption algorithm will only negatively affect the system's performance, even if it can resist certain threats. Hence, introducing a simplified, lightweight encryption scheme can only ensure computational efficiency. Unfortunately, no reported work has presented evidence of consistency in the computational performance of security when confronted with large and heavy traffic on the social network.
- *Usage of Conventional Authentication Scheme:* From the viewpoint of practical deployment, existing social network applications still use static passwords. Adopting a key-management scheme induces maximized resource dependencies while using encryption sets introduces computational burden over the long run. Existing multi-factor schemes are executed without protecting the location where algorithms are executed and thereby introduce a tradeoff between security and computational demands.
- *Lack of integrated schemes:* As a social network is a large chain of nodes formed in a complex way, data leakage is also possible. Hence, the authentication mechanism should be studied alongside data privacy and integrity to offer maximum protection. Such integrated schemes are not yet found been introduced or benchmarked.

VII. FINDINGS AND DISCUSSION

There are mainly two core classes of research toward the direction of security in the existing system, i.e., data security and authentication approaches. More studies have been carried out on data security approaches compared to authentication approaches. The core approaches discussed in this paper are encryption-based, privacy preservation-based, machine learning-based, and game-based modeling to strengthen social network security.

Reviewing existing research trends showcase more concentrated work towards privacy preservation while very little research is towards learning and data integrity-based methods. It is, therefore, evident that current solutions do not provide comprehensive security services and can only provide data integrity, data privacy, or non-repudiation. A social network is a complex network exposed to multi-dimensional threats. Hence, it's predicted to offer maximum security services, which is not found reported in existing security schemes.

It has been also identified that the blockchain is one of the evolving solutions for security in the social network. However,

there are various pitfalls seen in implementation effectiveness. i) blockchain-based scheme demands a potential form of the secured and interconnected topology of nodes integrated with a service provider with resources to operate. Existing blockchain schemes don't address this fact, ii) adoption of blockchain approach is associated with complexity, especially if it's a large and heterogeneous network of complex user behavior; hence computational burden is inevitable in the blockchain. Hence, there is potential for improving these blockchain problems to harness their security strength. None of the existing solutions has discussed the essential type of content in the social network. Textual content is more extensively used than other forms, e.g., images, GIFs, video, and audio. Encryption algorithms are eventually a better alternative; however, achieving encryption performance with computation and service relaying performance in social networks is yet to be seen. Therefore, there is a need for an investigation that would emphasize securing the text contents from dynamic attackers in the social network.

VIII. CONCLUSION AND FUTURE WORK

This paper has presented a compact discussion of securing communication in the social network. It is noted that various classes of methodologies are being adopted towards improving the security aspect with claimed benefits; however, the paper has identified a shortcoming associated with it. Hence, based on the complete review, it can be said that multifold findings state that there is still a large open scope for improving the security aspect of the social network. Exploring the existing research literature followed by methodologies, challenges, benefits, and drawbacks has highlighted the need for continuous innovation and improvement to protect user data effectively. The paper also emphasizes the growing interest in blockchain technology as a promising distributed security and authentication solution. Ultimately, the findings of this paper underscore the importance of a collaborative and multidisciplinary approach to data security and authentication in social networks. In future work, the scope of this paper will be extended toward modeling computationally efficient and robust security approaches to address dynamic security and privacy issue in social networking applications.

A Novel Framework for Semi-supervised Multiple-label Image Classification using Multi-stage CNN and Visual Attention Mechanism

Joseph James S*, Lakshmi C

Department of Computational Intelligence, Faculty of Engineering and Technology, SRM Institute of Science and Technology, Kattankulathur, Chennai, Tamil Nadu, India

Abstract—To train deep neural networks effectively, a lot of labeled data is typically needed. However, real-time applications make it difficult and expensive to acquire high-quality labels for the data because it takes skill and knowledge to accurately annotate multiple label images. In order to enhance classification performance, it is also crucial to extract image features from all potential objects of various sizes as well as the relationships between labels of numerous label images. The current approaches fall short in their ability to map the label dependencies and effectively classify the labels. They also perform poor to label the unlabeled images when small amount of labeled images available for classification. In order to solve these issues, we suggest a new framework for semi-supervised multiple object label classification using multi-stage Convolutional neural networks with visual attention (MSCNN) and GCN for label co-occurrence embedding (LCE) (MSCNN-LCE-MIC), which combines GCN and attention mechanism to concurrently capture local and global label dependencies throughout the entire image classification process. Four main modules make up MSCNN-LCE-MIC: (1) improved multi-label propagation method for labeling largely available unlabeled image; (2) a feature extraction module using multi-stage CNN with visual attention mechanism that focuses on the connections between labels and target regions to extract accurate features from each input image; (3) a label co-existence learning that applies GCN to discover the associations between different items to create embeddings of label co-occurrence; and (4) an integrated multi-modal fusion module. Numerous tests on MS-COCO and PASCAL VOC2007 show that MSCNN-LCE-MIC significantly improves classification efficiency on mAP 84.3% and 95.8% respectively when compared to the most recent existing methods.

Keywords—Semi-supervised; visual attention; multi-label; image classification; label propagation

I. INTRODUCTION

Multiple labels image classification has lately sparked a lot of interest in areas such as human attribution recognition, music mood categorization, and multi-object recognition. Multi-label image categorization, as compared to single-label image recognition, turns into a useful and difficult job that necessitates a deeper comprehension of the image objects because images from real world application always encompass numerous objects that contain extensive semantic information. Numerous of noteworthy works have been suggested to investigate the semantic connections between different labels

and accomplish successful classification of multiple label images. There are two major groups into which these strategies fit. In contrast to the former which focuses on learning the regional correlations between target labels and true labels, the latter uses a (GCN) [1] to acquire the overall label relationships among different objects. This multi-label image, as seen in Fig. 1, is typical in real life and primarily includes three objects: "person," "tennis ball," and "tennis racket." Each of these objects is annotated based on the target regions that have been highlighted in the image rather than other areas of it.

Wang et al. [2] and others [3, 4, 5] coupled recurrent neural network (RNN) and convolution neural network (CNN) to mutually describe the image label significance and label relationships, but they failed to take into account of the geographic setting of images. The main limitation of these techniques is that they ignore the intricate topology structure that exists between objects. This encourages study into methods for identifying and examining the label dependency in different approaches.

To directly model label dependencies, some methods built around RNN [2] or stochastic graph models [6, 7] have been suggested. The first approach views the multiple label problem of classification as a systematic reasoning problem that might have scaling issues due to its high computational complexity. Another work uses attention mechanisms to tacitly model the label correlations [8]. The global associations between labels that must be derived from information drawn from visuals other than the one being studied are still being ignored. Instead, they consider correlations between observed areas of an image, also referred to as regional associations. To address this issue, Zhu et al. [9] propose the Spatial Regularization Network (SRN), which learns an attention map for each label by using image-level supervisions and focused on the associated image region for every label. To update the complete network, however, they employ a subpar multi-step training workflow. Despite the fact that these methods [10] analyze label relationships with mechanisms of attention, they only take into account a small amount of local association among various target regions that show in a single image and ignore association of the labels distribution on every one of the training images.

Fig. 1. Multiple label images.

Fig. 1 shows that if two things are semantically associated in the real world, they are more probable to appear together in an image compared to when they are not. The ML-GCN architecture developed by Chen et al. [11] records the global label correlations on all training examples by employing GCN to generate label relationship embedding using the label statistics. It has been suggested that A-GCN [12] represent the label correlations in reference to ML-GCN by developing a method for label network construction. However, these two approaches use the dot product (DP) to finish the fusion of label co-occurrence embeddings and image features, severely impeding model convergence and multiple label image categorization performance improvement. In this work, we suggest a new multi-staged CNN with a visual attention mechanism to extract features and produce better feature representations from the training images. This method captures the local and global label dependency and speeds up model convergence. We use a more effective label propagation technique to label the unlabeled images and multi modal factorized bilinear pooling (MFB) [13] as an element of fusion. Then, we suggest an innovative semi-supervised multiple label classification of images model with an attention mechanism in order to successfully integrate visual characteristics and label co-occurrence embeddings (referred to as MSCNN-LCE-MIC). MSCNN-LCE-MIC is composed of four fundamental modules: cross-modal fusing with MFB; learning by label co-occurrence embedding with GCN; and feature extraction with multi-staged CNN, attention mechanisms, and improved label propagation techniques.

In the first module, we use CNN inspired by VGG-16 to learn the features of the images by creating a feature map for each label with multi-stage CNN, a visual attention mechanism and an improved label propagation technique to obtain the labels for unlabelled images. All labels are transformed into word vectors in the second module before being used as inputs to GCN to produce label co-occurrence embedding. The MFB component is finally integrated into our task in the module of cross-modal fusion, where it helps us effectively combine label embeddings and image characteristics to allow a complete classification system. Widespread tests on MS-COCO [14] and PASCAL VOC2007 [15] show that MSCNN-LCE-MIC significantly improves convergence efficiency and outperforms existing methods in terms of classification outcomes. The following are the paper's main contributions:

1) By combining the multi-staged CNN with a visual attention process for effective extraction of features and GCN to simultaneously detect regional label relationships in an

image and universal label relationships among different items over the data distribution, we provide an innovative complete capable of training multi-label image categorization framework, MSCNN-LCE-MIC.

2) To effectively extract features of each object from an image, which will improve the performance of the classification model, we suggest a multi-staged CNN with a visual attention mechanism.

3) We incorporate an improved label propagation technique to add labels to the training data's unlabeled images, and we also incorporate the fusion component MFB into MSCNN-LCE-MIC to effectively combine features of image and embeddings of label co-occurrence. As a result, model convergence is considerably accelerated and classification performance is improved.

4) The proposed method, MSCNN-LCE-MIC, consistently outperforms earlier competing approaches and is simple to apply end-to-end. We put our approach to the test using benchmark datasets for multiple label image identification.

The remaining portions of the piece of writing are structured as follows: In Section II, we will review recent works related to the topic. Section III will cover the suggested framework for semi-supervised multiple label image classification, along with a comprehensive explanation of each component. Section IV will discuss the experimental design, the datasets used, the architecture, and analysis of the results obtained. Section V, reviews the findings and concludes the whole work with the proposal to future research options.

II. RELATED WORKS

A. MultipleLabel Image Classification

Due to the emergence of large-scale datasets like Image Net [16], MSCOCO [14], and PASCAL VOC [15], as well as the quick advancement of deep convolutional networks [3, 17], the efficiency of image categorization has seen a quick improvement. Extending deep CNNs for categorization of images with multiple labels has received a lot of attention. Image categorization using a single label techniques have advanced significantly with the quick creation of CNN-based models. Experts employed binary methods to classify images that have multiple labels through developing a binary classification algorithm for each label. To recognize multi-label photos, [18] apply pre-built features of ImageNet. Chatfield et al.'s [19] model success is improved by using the target dataset to create task-specific image characteristics. A deep network that excels on particular items is VeryDeep [4]. These methods, however, deal every object in the image separately and ignore the connections between various elements. To jointly describe the label significance and relationships, Wang et al. suggest CNN-RNN [2].

The SRN created by Zhu et al. [9] places an emphasis upon the associated image area associated with every label and uses image level oversights to obtain an attention map for each label. They are unable to finish end-to-end training because they update the entire network using a subpar multi-step training workflow. The study [20] suggests employing

GCAM to record the label relationships between diverse image transforms. Graph convolution network (GCN) is used by MLGCN [11] and AGCN [12] to produce label co-occurrence embedding for multiple label picture categorizations. Unfortunately, they use dot product (DP) to finish the process of fusing label co-occurrence embeddings and image features, substantially impeding system convergence and more effectively classify images with multiple labels.

B. Learning with Structured Graph

By utilizing graph propagation and reasoning, it is possible to model the relationships between labels in a useful fashion as well. In order to improve image categorization, [21] used neural networks to analyze data with a graph layout and provide a paradigm using GNNs to discover more characteristic relationships. In order to investigate the relationships between various labels of multiple label zero-shot learning, [22] used information graphs. For the study of graph-structured data, [1] introduced a GCN method, which utilized layer wise propagation to encode both graph data and node attributes. According to the aforementioned GCN, Semantic embeddings and classification associations were merged by Wang et al. [23] to predict the effectiveness of the visual classification for each group. Moreover, [11] provided a framework built on GCN that modeled the relationships between labels for multi-label categorization using a predefined graph.

C. Cross-modal Fusion

Recent years have seen a rise in interest in the disciplines of visual question and answering (VQA) [24, 25] and multi-modal counterfeit news discovery [26], which attempts to successfully combine vectors from several modules. These fields combine visual and linguistic representation derived from open, sizable linguistic or visual databases. Nevertheless, current techniques are unable to produce expressive image-text features or to comprehend the complex connections between these characteristics. The majority of available solutions merely integrate cross-modal embeddings using linear models such element-wise addition. It has been suggested that MCB and MLB significantly lower the calculation costs associated with the VQA fusion procedure to address this issue. However, there are two significant drawbacks: MLB requires too much iteration before it converges, while MCB can only produce good results if it collects multi-dimensional feature vectors. Additionally, [13] proposed MFB, which successfully combines image features and text embeddings while also noticeably accelerating model convergence. MFB first transforms vectors of high dimension into vectors of low dimension before combining the matching position element of cross modal vectors. By incorporating MFB to be trained on the multiple label picture characteristics, F-GCN [27] successfully addresses the cross-modal fusion problem, but it disregards each image's attention process.

The problems in the existing methods are lack of efficient feature extraction methods to handle morphological similarity

issues and label dependency that exists between objects of an image.

The proposed work presents an innovative semi-supervised framework called MSCNN-LCE-MIC that acquires label relationship and their interdependence with GCNs in order to enhance the accuracy of multiple object label image categorization. The aforementioned structure learning methods served as inspiration for this framework. Our MSCNN-LCE-MIC explicitly stacks numerous GCN layers to build universal models for exploring the feature representations, in contrast with earlier structure learning methods. The main difference between MSCNN-LCE-MIC and rival approaches is that the proposed work uses an end-to-end methodology during the training stage to concurrently record localized label correlations within an image along with universal label correlations across multiple items in the data distribution. The label encoding and structured representation of graphs techniques used in MSCNN-LCE-MIC are more efficient at addressing the over-smoothing and scaling problems that are brought on by the substantial depth of GCN-based architecture.

III. PROPOSED WORK

The general structure of our suggested framework, multi-stage CNN with label co-occurrence embedding and attention mechanism (MSCNN-LCE-MIC) for semi-supervised classification of multiple label images, is given away in Fig. 2. This framework includes (1) enhanced label propagation to obtain labels for unlabelled images, (2) a multi-stage CNN with visual attention to mine the each input image features, (2) a module for learning label co-occurrence embedding that is built on the GCN, and (3) a module for fusing the two cross modal vectors described above successfully. We describe our plan's workflow in more detail below.

A. Improved Label Propagation

The label propagation method (LPA) is a well-known clustering technique due to its popularity and freedom from parameter dependence. Label propagation is a technique for propagating labels from labeled to unlabeled picture data based on the association between the two object classes [28][29]. The similarity weights in conventional label propagation systems, on the other hand, may not be appropriate for subsequent label propagation because they distribute labels after a certain data graph generation process. This strategy offers benefits, but it also has some disadvantages. Another drawback of LPA is the unpredictability with which nodes are clustered, which increases instability and the creation of big communities. When nearby nodes are chosen at random from a list of fixed constant hops, a collection of disconnected nodes results. We suggest an LPA-based solution to overcome the problem of random community allocation and build better clusters. These variations improve the quality of communities that are found by taking advantage of node attribute values and link strength.

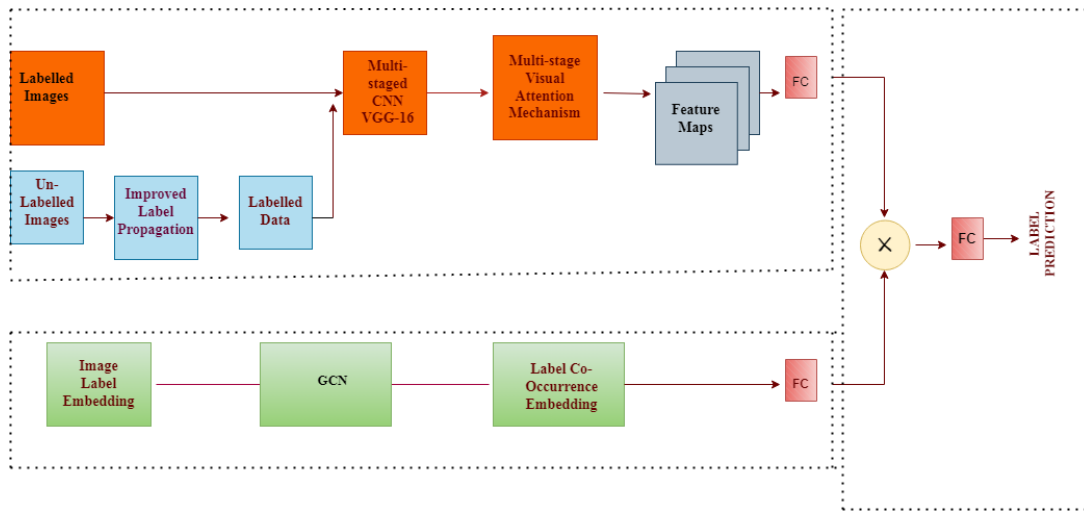

Fig. 2. Overall flow diagram of proposed method.

Using the feature data, a weighted graph is first created. The issue of random selection between nearest neighbors is then addressed via enhanced label propagation with dynamic connection strength metrics. The improved label propagation identifies the linked neighbors in the graph by using the heat kernel dispersion approach and its corresponding heat equation. The community arrangement of the node-attributed network is then returned by the program. In this form, the weighted common neighborhood (WCN) is employed as the link strength measure to award a community label (Murata & Moriyasu, 2007). The WCN value for each community label is then added together for the neighborhood. The system then chooses the community tag to apply to the selected node that has the highest total. The equation below describes how to measure the WCN connection strength.

$$Strength_{A,B} = \sum_{C \in \Gamma(A) \cap \Gamma(B)} w(A,C) + w(C,B) \quad (1)$$

The shared neighbors of nodes A and B are shown by the pair (A) (B). The edge weights that link the nodes A and B to their neighbor C are $w(A, C)$ and $w(C, B)$, respectively.

B. Multi-stage CNN

The projected model is based on an 18-layer CNN inspired by VGGNet [30]. However, as shown in Fig. 3, the proposed design classifies data by considering both high level and mid-level features. The second, third, and fourth network segments are used to extract these feature maps. The data from the first block is not directly used because it only contains minimal object label recognition filters. It is clear that the initial block's attributes made little of an impact. At this point, the networks can only understand and learn about simple textures, which is insufficient to define the essential traits required to differentiate objects.

Fig. 3. Proposed multi-stage CNN with attention mechanism.

Furthermore, although mid-level layers in the second and third blocks produce local features, high-level layers in the fourth and fifth blocks greatly contribute to tiny object recognition via global characteristics. In this study, we propose MS-CNNs that combine local and global features in a predetermined way to produce the global feature vector g . Our networks, in contrast to conventional CNNs, generate a large number of essential characteristics that make the system robust to fluctuations in image quality and object occlusion problems. Also, a few pointless feature extraction filters are present in the same block, which is consistent with the discovery made regarding mid-level features in the prior section is given in eq.2.

$$(F_1^1, F_2^1, \dots)^T \oplus (F_1^2, F_2^2, \dots)^T = (F_1^1, F_2^1, \dots, F_1^2, F_2^2, \dots)^T \quad (2)$$

where $(F_1^1, F_2^1, \dots)^T$ and $(F_1^2, F_2^2, \dots)^T$ feature vectors that came from different network tiers. If the input is the result of Convolutional layers, vectorization is required before employing this operator.

C. Attention Mechanism

Attention estimators have been inserted after layers 7, 10, and 13. The attention estimator receives the layer 7 output and generates a "attention mask" consisting of integers between 0 and 1, then multiplies by output of the layer 7 to produce " g_a1 ". Following layers 10 and 13, the attention estimators go through a similar process, producing, respectively, g_a2 and g_a3 . There was often another fully connected layer (FC) after the FC layer with the number "16," but it has been eliminated, leaving only the fully connected layer that comes after the dense layer at the network end to make the label classification. Instead, the three attention estimators' inputs are now handled by a new fully connected layer. The process of visual attention method for feature extraction is described as follows,

Step 1: The compatibility score C is calculated with use of the regional feature vector l and the universal feature vector g . The compatibility score is meant to be high when the local characteristics-defined image patch contains components of the dominating picture category. For instance, if the image contains a multiple objects, we assume that the global feature vector g adequately describes all possible object features. The patch that most closely resembles a particular object is also expected to produce local traits l that, when paired with g , will result in a high compatibility score.

$$C_i^s = \langle l_i^s, g \rangle, i \in \{1, \dots, n\} \quad (3)$$

The local feature vector l and the global feature vector g are simply added together. Be aware that while the local features l will change based on the convolutional layer (layers 7, 10, and 13), the global feature vector g will remain constant. Projecting g into l 's lower-dimensional space will make sense if l and g are not the same dimensions.

Step 2: Calculate the Attention Weights a_i from the Compatibility Scores C shown in eq(4). The outcome is referred to as "a", after that the compatibility scores C are compressed into the range of (0, 1) using a softmax.

$$a_i^s = \frac{\exp(C_i^s)}{\sum_j^n \exp(C_j^s)}, i \in \{1, \dots, n\} \quad (4)$$

Step 3: Determine Each Layer's Final Attention Mechanism Output using equation 5.

$$g_a^s = \sum_{i=1}^n a_i^s l_i^s \quad (5)$$

Here, we calculate the attention mechanism's (g_a) final output for a certain layer using a weighted combination of the l for that particular layer (s). The attention weights "a" that we recently found are the weights that we employ.

Step 4: Create a categorization forecast based on final outcome of the attention module. We now want to select a classification using the attention outputs g_a that we just gathered for layers 7, 10, and 13. To acquire intermediate predictions, feed each attention output into a separate, completely connected layer. The final projections are then calculated by averaging these intermediate guesses.

D. Label Dependency Learning with GCN

According to [1] and [11], the label co-existence learning (LCL) module uses GCN of two-layers, with each layer taking the output of the layer before it and producing a new graph representation. Fig.4 shows the LCL module with GCN. The semantic encoding vectors $X = \{X_i\}_{i=1}^C$ and the equivalent association graph G are fed into the LCL component for the initial GCN layer. The graph representation and node feature may be easily combined by the LCL module in the convolution. The LCL module, which serves as the central part of the proposed MSCNN-LCE-MIC, intends to be trained on a set of classifier score $W \in R^{s \times d}$ to recalibrate early values for every label received from the image feature embedding module. In order to satisfy the requirements of the broadcast method, it is important to address two crucial challenges, namely word embedding and graph representation (5).

1) *Word embedding*: To retrieve the word embeddings for each of the labels across these multiple label image datasets, we use the 300-dim GloVe [31] algorithm learned on the Wikipedia dataset. We demonstrate that it is evenly efficient when using the suggested LCL method as demonstrated in Sections 4(c). To acquire the global label interdependence on the training set, we build a GCN with two layers. We use GloVe [31][33] to create 300 dimensional vectors for each of the objects in order to create the label embeddings matrix $Z \in R^{C \times 300}$, following MLCGN [32].

Fig. 4. Label Co-occurrence embedding network with GCN.

2) *Graph representation*: It goes without saying that the correlation matrix A affects how the node representations propagate. Instead of starting from scratch, researchers have suggested a number of methods for building the predetermined correlation matrix (explicit graph representations). For instance, WordNet [34] was used by Lee et al. [22] to develop their structured knowledge network. String matching was employed by Gao et al. [35] to plot concepts to nodes available in concept Net [36]. To express relationships between labels, these methods rely solely on semantic embedding and do not explicitly include information about interdependencies. Instead, we concentrate on the label co-existence matrix based on the training images, which is then used to represent the organized network composed of label associations by combining the label relationship data from neighboring nodes into a singular association matrix.

The following is the production procedure:

1) The first component of the label co-existence matrix P for the training image, we count the times at which pairs labels (L_i, L_j) first emerge.

$$P = \{p_i\}_{i=1,j=0}^c \in \mathfrak{R}^{c \times c} \quad (6)$$

2) The initial label correlation matrix P' can be constructed using the matrix R^{c x c}.

$$P' = \{p_i / N_i\}_{i=1,j=0}^c \in \mathfrak{R}^{c \times c} \quad (7)$$

where N_i is the object label's ith number. As a result, the graph constructed from such an asymmetric matrix P' is directed.

$$M_{i,j} = \begin{cases} p_{i,j} < \phi \\ 0, & p_{i,j} \geq \phi \\ \lambda^* \frac{p_{i,j}}{\sum_{j=0}^c p_j + \theta} \end{cases} \quad (8)$$

In order to safeguard label partnerships' specifics as stated in eq. (8), this work presents a nonlinear method for preparing matrix P' which can reduce noise (7), where φ is the noise filtration cutoff, 1^{e-6}, and M is the label association matrix employed in every GCN layer.

E. Multi-Label Classification Loss

Both the MS-COCO and the PASCAL VOC-2007 datasets exhibit the issue of class imbalance, which usually manifests as an inequity in the amount of negative and positive data. The suggested weighted cross entropy loss is taken into account as the multiple label categorization loss employed in our MSCNN-LCE-MIC to tackle this issue, and is described as:

$$Loss(b_i, l_i) = -wt_p \sum_{l_i=1} \log(\sigma(b_i)) - wt_n \sum_{l_i=0} \log(1 - \sigma(b_i)) \quad (9)$$

Where, $wt_p = \frac{|po| + |Ne| + |1|}{|Po| + |1|}$ and $wt_n = \frac{|po| + |Ne| + |1|}{|Ne| + |1|}$, |Po| and |Ne| are The total amount of both positive and negative image labels in a batch, b_i is belief of each class label, σ is the sigmoid function.

Formally, for all i ∈ [1,C], we will fuse F and W_i to obtain Yⁱ, or the ith component of the predicted label Y ∈ R^C, where W_i indicates the ith row vector of W. This is done provided the Ith image feature vector F. First, using two f_C layers, W_i and F will be transformed into the corresponding m dimensional vectors M1 and M2. Additionally, M1 and M2 are cross-modal vectors that will be multiplied element-wise into an m-dimensional vector M1 M2 to enhance the interaction between these two embeddings. We further convert M1 ⊗ M2 into a m / g dimensional vector M via group sum-pooling to decrease parameter inflation and over-fitting, the elements in each group are represented by the letter g, to hasten convergence. The ith constituent of Y is then obtained by creating a f_C layer. As a result, we are able to produce the full anticipated labels Y following fusion of C number of times. In order to create an end-to-end classification model, we employ the multiple label loss function by updating the Loss given in eq. (9) between predicted labels Y and the actual labels Y' ∈ {0, 1 }^C of Ith image.

IV. EXPERIMENTAL SETUP

A. Specifications of Implementation

PyTorch is used to perform all experiments. Each input image is resized to 448x448 before passing it to feature extraction component. Using the GloVe [37] model, each object is transformed to become a 300-dimensional vector that includes words in the label association embedding module. We set g = 2 to perform the group sum-pooling procedure and m = 358 to perform the fusion of the vectors of features and label co-existence embedded data with reference to the FGCN. A batch size of 32 is used when updating our network during the training procedure. The proposed model uses stochastic gradient descent (SGD) with 0.9 momentum, 10⁻⁴ weight decay and initial learning rate of 0.001.

1) *Datasets*: We conducted in-depth tests to confirm the effectiveness of MSCNN-LCE-MIC on MS-COCO [14] and PASCAL-VOC2007 [15]. To separate the datasets, we use the similar settings of MLGCN and FGCN. For further information, consult the references [5, 24].

2) *Metrics for evaluation*: We employ the following assessment metrics in accordance with mainstream techniques [9, 11]: (P-C) precision per class, (R-C) recall per-class, (mAP) mean average precision, F1 per class (F1-C) and F1 overall (F1-O). For fair comparisons, we also catalog the investigational findings on the top-3 classes of the categorization scores.

B. Investigational Results and Discussions

The convergence effectiveness and classification outcomes of MSCNN-LCE-MIC are compared to those of cutting-edge image classification methods.

1) *Convergence efficiency*: We track how the number of training epochs changed the mAP on the examination set in this section. We execute this experiment using the same parameters as ML-GCN, including SGD, batch size, learning rate, datasets, loss function, etc., to allow for fair comparisons. MSCNN-LCE-MIC has, on MS-COCO and PASCAL VOC2007, converged at the 25th and 23th epochs, respectively, and it produces superior mAP of 84.3% and 95.8%. Instead, MLGCN has not yet converged, and its mAP values are 45.8% and 75.7% lower than MSCNN-LCE-MIC at this time. Moreover, it will take the MLGCN roughly 200 epochs (more than 10 times as long as MSCNN-LCE-MIC) to complete its learning process. These findings show that multi-stage CNN, visual attention and cross module fusion significantly quickens model convergence and enhances performance of classification model.

2) *Results comparisons with the existing models*

a) *Evaluation results on MS-COCO*: The most recent existing techniques are compared to MSCNN-LCE-MIC, including FGCN [27], AGCN [12], MLGCN [11], ResNet-101 [3], SRN [9], Order Free RNN [38], RNN with Attention [8], and CNN+RNN [2]. Fig. 5(a) and 5(b) shows the graphical representations of results obtained on MS-COCO dataset using proposed method. MSCNN-LCE-MIC nearly outperforms other options on all metrics which are shown in Table I and Table II. MSCNN-LCE-MIC significantly enhances the classification outcomes by 7% mAP in comparison to ResNet-101 baseline [3]. This occurrence shows that understanding the label dependency to produce more precise label features is greatly influenced by GCN. Also, as compared to those DP-based approaches, cross fusion module effectively completes the modal fusion to improve the efficiency of MSCNN-LCE-MIC. Additionally, based on the discrepancy between the earlier FGCN [27] and MLGCN [11], the multi-stage CNN with attention mechanism does in fact assist in extracting more precise image features, improving the effectiveness of categorization outcomes by 1.3% mAP.

b) *Evaluation results on VOC2007*: The state-of-the-art approaches are compared to MSCNN-LCE-MIC, including CNN+RNN [2], MLGCN [5], AGCN [6], ResNet-101 [8], Attention Reinforce [16], RNN with Attention [14], Very Deep [13], and FGCN [24]. The AP values and mAP values for each category are listed in Table III. With the exception of somewhat poorer performance on "bike", "bird" and "person" MSCNN-LCE-MIC outperforms other contenders overall in every category. The main cause is that the majority of earlier techniques ignored the local and global label dependencies, allowing them to solely focus on one or a few objects while ignoring the distribution of global labels. Our MSCNN-LCE-MIC, in contrast to existing approaches, considers both the regional label relationships in addition to the universal label relationships among diverse objects (multi-stage CNN with attention mechanism) within an image. MSCNN-LCE-MIC outperforms other methods for the remaining 17 objects. Although it appears that there is a trade-off between other

approaches and our MSCNN-LCE-MIC in this phenomenon, we think that this global viewpoint is essential for multi-label picture categorization. The MSCNN-LCE-MIC produces a superior mAP value of 1.8% when compared to the existing method FGCN [27], which shows that both the multi-stage CNN with attention mechanism and the cross fusion module are involved and help to provide more accurate classification results. In Table IV of Section IV C, we also discuss how these modules have an impact.

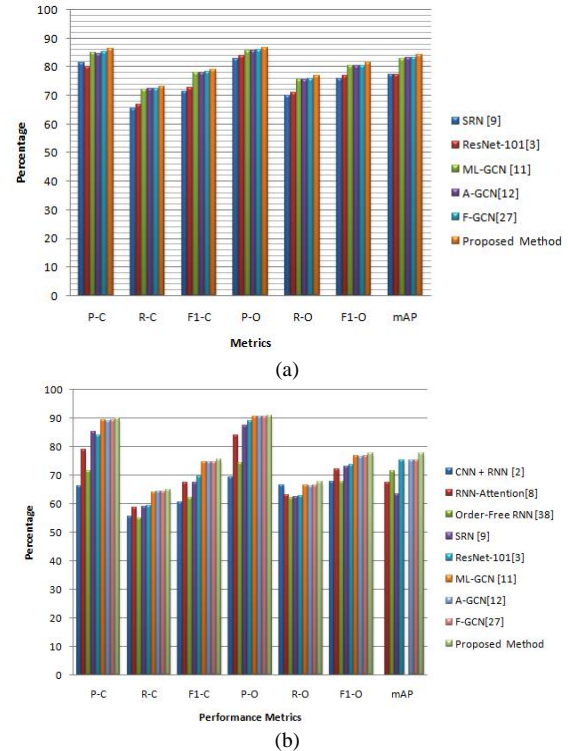

Fig. 5. Performance comparison of proposed method on MS-COCO dataset (a) Overall labels (b) top-3 class.

TABLE I. ACCURACY(%) OBTAINED ON MS-COCO IMAGE DATASET

C. Ablation Studies

We carry out ablation study to examine how important elements and parameter settings affect MSCNN-LCE-MIC.

1) *Classification performance of MSCNN-LCE-MIC with/without different modules:* In this section, we examine how five crucial modules—namely, Multi-stage CNN, the visual attention method, the GCN, label propagation and the cross modal fusion affect our proposed model. Cross-modal fusion won't work if our suggested paradigm is used without GCN. Table IV displays the mAP results for MS-COCO and PASCAL VOC2007 with different module combinations. As can be seen, MSCNN-LCE-MIC performs best when all four of these modules are used at once. The evaluation findings show that any one module can enhance our model's mAP output. By incorporating the label dependencies between objects in global level, GCN especially improves MS-COCO and PASCAL VOC2007 mAP by 5.9% and 4.1%, respectively. In addition, the visual attention method boosts the mAP value by 0.3% on these two datasets while taking into account the label dependencies within an image. Finally, MFB keeps improving the classification outcomes with respective mAP improvements of 0.4% and 0.5%. These outcomes attest to the potency of our strategy, which notably benefits from both local and global level label dependencies, also the cross-modal fusion to boost the accuracy of classification.

2) *GCN with different layers:* The change in performance is shown in Table V and Fig. 6 after designing two (1024-2048), three (1024-1024-2048), and four (1024-1024-1024-2048) GCN layers in this section. With MS-COCO, MSCNN-LCE-MIC achieves its best performance with two GCN layers (Fig. 6(a)), after which its performance on mAP would degrade as GCN layers are added. Similar to Fig. 6(b), MSCNN-LCE-MIC produced the best outcome (mAP) on PASCAL VOC2007 using a 2-layer GCN. The main reason is because adding more layers of GCN would have a major negative impact on the model's functionality by making it so that the output features of nodes are no longer recognizable during the propagation process. We therefore employ two

GCN layers in order to acquire the label-occurrence embeddings.

3) *Number of units g in group sum pooling:* By using group sum-pooling, we reduce each **m** dimensional vector to a manageable small **m / g** dimensional vector. Changing **g** from 1 to 64 allows us to track how performance changes and the outcomes are exposed in Table VI. As can be shown, **g = 2** improves the outcome on MS-COCO even though the improvement in mAP on PASCAL VOC2007 is less pronounced. We think that **g = 2** is more appropriate for minimizing the dimension and convey the semantic significance of the top phrase, despite the fact that various values of **g** have a comparable effect.

Fig. 6. Change in performance of proposed method with different GCN layers.

4) *Performance of improved label propagation:* The PASCAL VOC-2007 is a sizable multiple label standard dataset gathered for a number of computer vision tasks, including captioning, recognition and segmentation. The test collection contains 77,980 images, 24640 number of objects. There are about 2.4 object labels per picture, and there are 20 different classes in which the objects are divided. The 5K samples are used for testing, while the 20K samples are divided into 5 batches and used as training data. From each batch, we took 4k labeled samples at random and used the remaining 16K examples as unlabeled data. For each batch, this process is repeated five times. The end accuracy is the average of these trials. 32 mini-batch sizes were employed. Table VII and Table VIII display the outcomes of enhanced label propagation using various epochs. The proposed label propagation method achieves 3% less error than the existing label propagation method.

TABLE IV. CLASSIFICATION PERFORMANCE WITH / WITHOUT DIFFERENT MODULES

Improved label propagation	Multi-stage CNN	Visual Attention	GCN	MFB	mAP

V. CONCLUSION AND FUTURE WORK

This paper argues that most of the images in large scale datasets are unlabeled; the labels have dependency and morphological similarity issues. The existing methods using traditional convolution technique may fail to extract features efficiently and classify labels accurately due to large unlabeled data. We construct MSCNN-LCE-MIC, which combines multi-stage CNN with visual attention and GCN to concurrently collect global and regional level dependencies. A feature extraction component with multi-stage CNN and visual attention technique helps to create the most precise features of each image by concentrating on the relationships among labels and regions of target which solves the problem of morphological similarity issues exists between objects. MSCNN-LCE-MIC primarily consists of four key modules: improved label propagation technique to find labels of large volumes of unlabeled images available in real time applications; learning tool for label co-occurrence with GCN; and multi-stage CNN with attention mechanism. Comprehensive tests on MSCOCO and VOC2007 show that MSCNN-LCE-MIC significantly improves the effectiveness of our suggested framework and yields superior classification outcomes than the existing methods in the field. Experimental results demonstrate that the MSCNN-LCE-MIC method achieves higher mAP of 3.6% on MS-COCO dataset and 1.8% mAP on PASCALVOC-2007 dataset.

In the future, instead of using label propagation to train a neural network model, a generative adversarial network model could be used to get more labeled images from unlabeled image data and also reduce the time complexity due fusion of multiple components.

Abstract—With the onset of the COVID-19 pandemic, online education has become one of the most important options available to students around the world. Although online education has been widely accepted in recent years, the sudden shift from face-to-face education has resulted in several obstacles for students. This paper, aims to predict the level of adaptability that students have towards online education by using predictive machine learning (ML) models such as Random Forest (RF), K-Nearest-Neighbor (KNN), Support vector machine (SVM), Logistic Regression (LR) and XGBClassifier (XGB). The dataset used in this paper was obtained from Kaggle, which is composed of a population of 1205 high school to college students. Various stages in data analysis have been performed, including data understanding and cleaning, exploratory analysis, training, testing, and validation. Multiple parameters, such as accuracy, specificity, sensitivity, F1 count and precision, have been used to evaluate the performance of each model. The results have shown that all five models can provide optimal results in terms of prediction. For example, the RF and XGB models presented the best performance with an accuracy rate of 92%, outperforming the other models. In consequence, it is suggested to use these two models RF and XGB for prediction of students' adaptability level in online education due to their higher prediction efficiency. Also, KNN, SVM and LR models, achieved a performance of 85%, 76%, 67%, respectively. In conclusion, the results show that the RF and XGB models have a clear advantage in achieving higher prediction accuracy. These results are in line with other similar works that used ML techniques to predict adaptability levels.

Keywords—Machine learning; adaptability; students; online education; prediction; models

I. INTRODUCTION

In recent years, online education has experienced an unprecedented boom. The COVID-19 pandemic further accelerated this process, forcing millions of students and educators to adapt to a fully digital educational environment [1]. In response to the educational crisis caused by the COVID-19 pandemic, UNESCO has established partnerships with various international organizations, such as the International

Labour Organization (OIT), the United Nations High Commissioner for Refugees (UNHCR), the United Nations Children's Fund (UNICEF) and the World Health Organization (WHO) [2]. Companies such as Microsoft, Google, Facebook, and Coursera [3] also participate. With the aim of addressing the problems of connectivity, content through digital tools and seeking distance learning solutions for children, youth, and adults through innovation. Today, online education is not only a viable alternative to face-to-face education, but has become an indispensable tool for many students, professionals, and individuals around the world. This type of education is offered through online platforms and tools, such as websites, mobile applications, discussion forums, videoconferencing, among others [4], [5]. Since the advent of the COVID-19 pandemic, online education has been an indispensable alternative for students around the world [6]. However, the sudden transition from face-to-face to online education has posed many challenges to students, especially in terms of their ability to adapt to this new educational environment [7]. Adaptability is a fundamental skill that allows us to face new and unfamiliar situations with flexibility and creativity [8]. In the case of online education, adaptability refers to the ability of students to adjust to a new educational model [9], which requires different skills and tools than those used in face-to-face education [10]. However, not all students have the same ability to adapt to online education and some may have difficulty staying motivated and engaged [11]. Early identification of these students can be key to providing them with appropriate support and improving their online academic success [12]. For example, in Latin America and the Caribbean, Brazil has the highest rate of online students with 49%, Mexico with 15%, Colombia with 11%, Argentina with 8%, Chile with 6% and Peru with 5% [13] as shown in Fig. 1.

Fig. 1. Representation of online education in Latin America and the Caribbean.

Online education has revolutionized the world of teaching and learning, providing new opportunities to access education from anywhere in the world [14], [15]. In recent years, ML has started to play a very important role in online education, enhancing the learning experience and personalizing education for each student [16], [17]. ML is a discipline within the field of artificial intelligence (AI) that provides the ability for computers to learn and improve their performance on a specific task without being explicitly programmed. In the field of online education, ML is used to analyze student data and create personalized learning models [18], [19]. This work aims to predict the level of adaptability of students in online education for which we use the following models: RF, KNN, SVM, LR and XGB of ML. Furthermore, this work aims to provide a more in-depth understanding of how ML is transforming online education and how it can be used to improve education in the future. In addition, it will examine the challenges and limitations associated with the use of ML in online education. The predictive capacity of the models is also sought, for which the results of the trained models are compared.

This document is structured as follows: Section II presents the related works. Section III explains the materials and methods used, as well as the process of data collection and understanding. Section IV presents the results obtained after model processing and training. Section V discusses the analysis and discussion of the results, as well as the performance of the models. Finally, Section VI presents the conclusions drawn from the study and proposes future work.

II. RELATED WORKS

Predicting the level of student adoptability in online education has become an important issue. In this context, researchers and academics have carried out work related to ML

models for the analysis of distance education and student adaptability, these methods involve the use of algorithms that allow the analysis of large volumes of data and the extraction of significant patterns. For example, in [20] they developed a study on the role of student adaptability in virtual education during the COVID-19 pandemic, in this work they used a population of 1548 students. The findings showed that adaptability is a crucial personal resource that can help students in their online learning process. Similarly, in [21] The authors conducted an investigation to estimate the level of student adaptability in virtual education using ML techniques, where they explored the gap between virtual and face-to-face education from a Bangladeshi context. They found that 8.3% of the students adapted with high ease to online education, they also identified factors that make it difficult for them to adapt, such as Internet connectivity, lack of knowledge in the use of digital tools, problems of access to electricity, among others. Also, in [22] they presented the results of a survey conducted in June 2022 to beginning teachers, analyzing factors such as technology, Internet accessibility, teachers' competencies, pedagogical knowledge and learning opportunities. The results showed that for teachers to adapt easily to online education, they must have certain digital competencies, such as the adoption of information and communication technologies. Similarly, in the following work [23] they proposed an adaptive system to predict an educational path by applying different data mining algorithms to extract relevant features and build a personalized model. The results showed that ML algorithms are efficient in their performance and accuracy. Similarly, [24] made use of ML algorithms to predict student performance in online education. For which they used deep neural network algorithms and SVM and decision tree (DT) classifiers. As a result, they concluded that the SVM classifier is the one that obtains the best results in its accuracy and performance. Furthermore, in [25] examined the prospects, advantages, and problems of artificial intelligence (AI) in online education. They used ML algorithms to classify the level of adaptability of the students. As a result, an accuracy level of 93% was obtained, RF models and neural networks proved to be the most efficient. Similarly, the authors in [26] developed a study to determine the influence of IA on students' social adaptability. They used a population of 1328 students. They used ML algorithm to determine the influence on student adaptability, using variables such as: teacher-student, parents and society, age, connectivity, technological competencies, among others. The results showed that IA has a positive influence on adaptability in online education. Neural network classifiers are contributing significantly to learning prediction. For example, in the work [27] they developed a paper that seeks to associate learning styles with distance education student behavior, in which they applied linear regression models. The results of the study indicated that no significant relationship was found between learning styles and student performance in distance education. Furthermore, in the article [28], a study was conducted on the performance of students in online education using the deep learning short- and long-term memory (LSTM) technique, in which a total of 22437 students participated. As a result, an accuracy of 0.8457, precision of 0.8224 and F1-Score of 0.7943 were obtained using the LSTM technique.

III. METHODOLOGY

The purpose of this section is to present the methodology used in this work, which is divided into two parts: A) description of the ML models (RF, KNN, SVM, LR and XGB); B) the development of the case study. Within the case development process, the following stages are followed: 1) data set collection; 2) data set processing and exploratory data analysis; 3) training and validation of the ML models.

A. Description of the ML Models

ML is composed of a set of algorithms for regression, classification, reduction, clustering, among other types of algorithms. However, for this work that aims to predict the adaptability of online students, five classification algorithms have been chosen, such as: RF, KNN, SVM, LR and XGBC.

1) *Random forest*: The supervised learning (SL) algorithm known as RF model, according to [29], is used for classification and regression. This model is made up of a series of decision trees, where each is trained with a random subset of data and cast its vote for the outcome, as described in [30], as depicted in Fig. 2. This reduces overfitting and increases the accuracy of the model. It also allows the identification of the most important features for prediction.

Fig. 2. RF model classification process.

2) *K-Nearest neighbor*: The K-NN model is an SL algorithm used for classification and regression [31]. In the context of regression, the k nearest neighbor's method consists of estimating the value of a data point from the values of the k nearest neighbors to that point. K-NN is simple, efficient, and easy to understand, but it can be sensitive to outliers and does not work well with high dimensionality data [32]. The formulation for calculating the vector distance is represented in equation (1).

$$d(q, p) = \sqrt{\sum_{i=1}^n (q_i - p_i)^2} \quad (1)$$

where q_n represents the results of one observation and p_n also represents the results of another observation.

3) *Support vector machine*: The SVM model is an SL algorithm used for classification and regression [33]. This hyperplane is found by maximizing the distance between the

closest points of each class, called support vectors [34]. SVM is effective in high dimensionality spaces and can handle nonlinear data using kernel functions [35]. However, it can be sensitive to hyperparameter selection and requires a large amount of data processing resources.

4) *Logistic regression*: The LR model is an SL algorithm used for binary classification. It models the probability that a data point belongs to the positive or negative class using the logistic function [36]. The model is trained using the likelihood function and fit using optimization methods such as gradient descent [37]. The LR is simple and easy to understand but can have problems with nonlinear data and can be sensitive to outliers [38]. The model is represented in equation (2) and (3).

$$PY = 1|X = \frac{1}{1 + \exp w_{o+} + \sum_{i=1}^n w_i x_i} \quad (2)$$

and

$$PY = 0|X = \frac{\exp w_{o+} + \sum_{i=1}^n w_i x_i}{1 + \exp w_{o+} + \sum_{i=1}^n w_i x_i} \quad (3)$$

Where, $PY|X$ represents the parametric distribution, Y is the described value, and $X = x_1, \dots, x_n$ is a vector with continuous values.

5) *eXtreme Gradient Boosting*: XGB is a decision tree-based ML algorithm used for regression and classification [39]. XGB improves the model at each iteration by adding sequential trees that focus on the most difficult to predict data points [40]. It uses a combination of gradient boosting and regularization to avoid overfitting and improve model accuracy [41]. XGB is scalable and can be used on large and complex datasets.

B. Case Study

1) *Understanding and collecting the data set*: In this section, the main task is to analyze and understand the dataset on online student adaptability to extract relevant information that can help improve the online learning experience. The first step is to understand the context of online education and how students' adaptability affects their experience. The dataset used in this work was obtained from Kaggle, this dataset is composed of a population of 1205 students between high school and college. The dataset is composed of 14 attributes such as: gender, age, educational level, type of educational institution, technology student (yes/no), location, internet quality, economic condition, type of internet, type of device to connect to the internet, duration of classes, knowledge of LMS, class schedule and level of adaptability, as shown in Fig. 3.

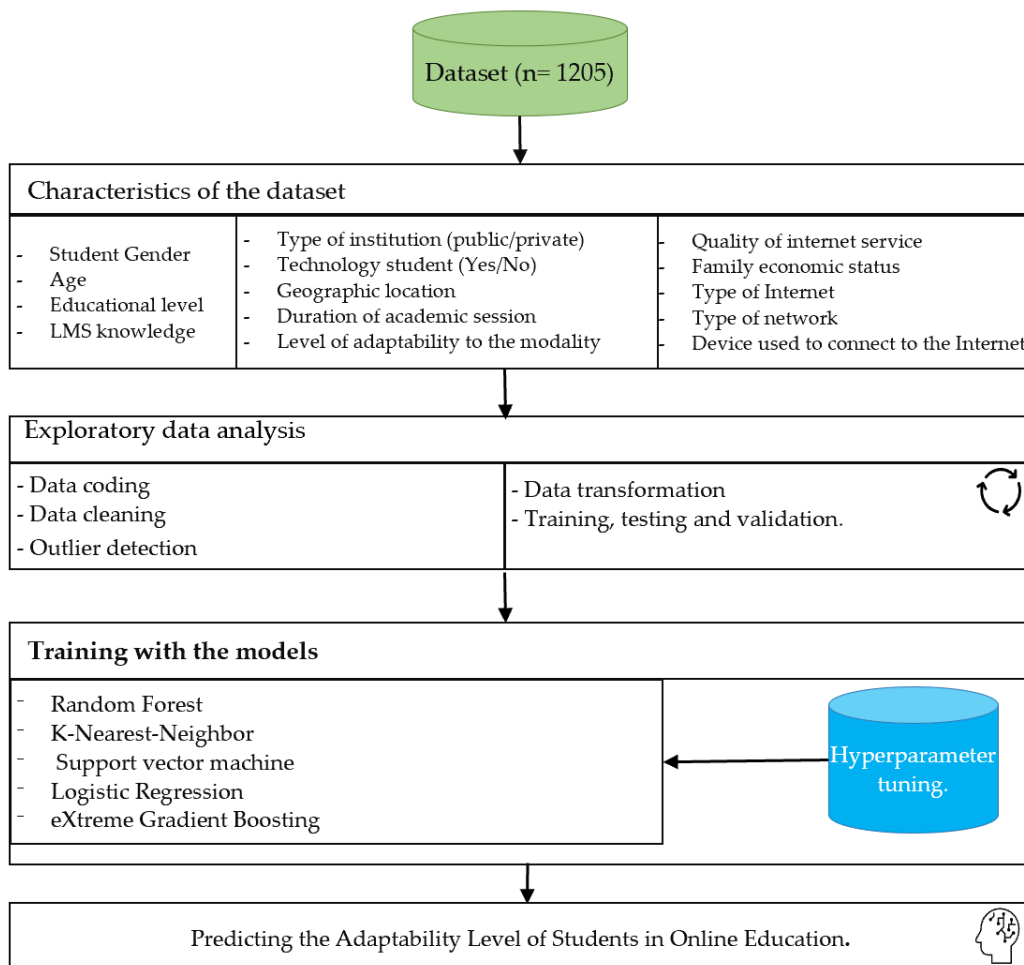

Fig. 3. The process shows the extraction, selection of attributes, analysis, training with ML models and training results.

Generally, when the data set is small, as is the case, and to solve this limitation, Synthetic Minority Over-sampling Technique (SMOTE) is used in this paper to deal with class imbalance in the data. SMOTE solves the problem by creating synthetic instances by interpolating the minority class in the dataset in order to increase the size of the minority class in the dataset. In this context, predicting the adaptability of online learners directly contributes to educators and educational program managers by anticipating students' needs and difficulties and providing immediate answers and supports to improve their online learning experience. In addition, ML methods directly help designers of online educational programs to improve the quality of their educational offerings and make them more accessible and effective for students.

2) *Data set processing*: The processing of the dataset involves performing a set of tasks, such as: data cleaning, transforming, and analyzing the collected data. As a first step we have to: import the libraries for loading the dataset, then we generally explore the data. In it, we can find the data types for each attribute, the content and description of the attributes, as shown in Table I. As a second step we proceed to eliminate any duplicate, missing or erroneous information. Also, outliers

and inconsistencies in the data are checked to ensure that they are accurate and reliable.

Next, the statistical values of the data set are checked for example, the number of students, unique values, frequency, and highest values as presented in Table II.

Performing a simplified analysis of the data set by constructing a general distribution of the characteristics, the following interpretation is reached. The gender variable is balanced, since the same number of males and females is applied to obtain a relevant result. Most of the students correspond to the age of 11-25 years; this is the age at which one speaks with confidence of sustainable adaptation to online learning. The values provided by the level of education indicate that most of the students have only a school education. This data correlates with a given timetable, in which many students are between the ages of 7 and 20. Existing educational services are provided by private institutions. This is due to the development of the educational market. It should also be noted that most of the educational programs are sold by telephone through the 4G network, which shows that people receive education at any place convenient for them.

Next, we analyze the number of students according to their level of adaptation in online education.

TABLE I. GENERAL ANALYSIS OF THE DATA SET

	Student Gender	Age	Educational level	Institution Type	Financial Condition	Internet Type	Device
0	Male	21	University	Non-public	Middle class	Wi-Fi	Tab
1	woman	20	University	Non-public	Middle class	Mobile Data	Mobile
2	woman	16	College	Non-public	Middle class	Wi-Fi	Mobile
3	woman	12	School	Non-public	Middle class	Mobile Data	Mobile
4	woman	15	School	Non-public	Lower class	Wi-Fi	Mobile
...
1201	woman	16	College	Non-public	Middle class	Wi-Fi	Mobile
1202	woman	16	College	Non-public	Middle class	Wi-Fi	Mobile
1203	Male	12	School	Non-public	Middle class	Mobile Data	Mobile
1204	woman	17	College	Non-public	Middle class	Wi-Fi	Mobile
1205	woman	11	College	Non-public	Lower class	Mobile Data	Mobile

TABLE II. DATA SET STATISTICS

	Count	unique	top	freq
Student's gender	1205	2	Male	663
Age range	1205	6	21-25	374
Student's educational level	1205	3	School	530
Type of educational institution	1205	2	private	823
Student's IT knowledge	1205	2	No	901
Student's geographic location	1205	2	Yes	935
Power system interruption	1205	2	Low	1004
Student's economic status	1205	3	Mid	878
Type of mobile / fixed Internet	1205	2	Mobile Data	695
Type of connectivity	1205	3	4G	775
Session duration	1205	3	1-3	840
LMS knowledge	1205	2	No	995
Device used	1205	3	Mobile	1013
Degree of student adaptability	1205	3	Moderate	625

According to the graphical representation presented in Fig. 4, it is observed that men tend to adjust more easily to new knowledge, while the rate of maladaptation is similar for both genders. In addition, it is evident that the optimal age for successful adaptation is between 21 and 25 years, while the worst adaptation occurs in people older than 26 years and in the age range of 16 to 20 years. This information suggests that age may play an important role in the ability to adapt to online education. The lower capacity to adapt to new knowledge can be attributed to various factors, both social and physiological. Importantly, those who belong to the middle class tend to take better advantage of online educational materials. In addition, a greater adaptive capacity has been observed among those students who reside in organized communities or environments, which may be related to economic and social factors. It is also important to consider that the level of adaptation to new knowledge is also influenced by the quality of the available Internet service.

Once the exploratory analysis of the data set has been completed, the next step is to perform the processing of the data set. As a starting point, it consists of dividing the data set in two, 80% will be used for training and 20% for testing. With

`Sklearn.Model_selection.train_test_split()`, it is possible to perform the splitting process by simply specifying the size of the test part for training. As in the exploratory analysis of the data set, nulls or missing values have been discovered. Therefore, it is necessary to remove them from the dataset in order to handle them, estimate those values and then add a mean value to the dataset, for which we use libraries such as: `Simple-Imputer ()` and `impute.fit_transform(x_train, x_test)`. We then proceed to normalize the data. There is no doubt that data normalization is a very important factor, since it consists of reorganizing and scaling each of the features according to the unit variance, so that all features can be compared equally. The following libraries are used for feature normalization: `StandardScaler()`, `tandardScaler.fit_transform(x_train_Impute, x_test_Impute)` and `data_train_normalized()`. Since the data set contains a relatively small number of observations, the SMOTE technique will be used to avoid over-fitting the data set. The objective of this technique is to compare the accuracy of the original data set with the accuracy of the sampled data set. This comparison involves comparing their accuracy. By using the SMOTE technique, class imbalance can be balanced, since class imbalance can lead to asymmetry and overfitting in training.

Fig. 4. Analysis of the level of adaptability.

3) *Training and data validation:* Dataset training is a process, in which ML models are fit to a dataset. During this process, the models are fitted to minimize the margin of error between the model predictions and the actual values of the data used in training the model. The purpose of this process is to achieve a model that can generalize well to unseen data, i.e., that can make accurate predictions on new data. For each

model is fitted with SMOTE technique, it means that, one uses the original data set, and the other uses the SMOTE balanced data set. For the parameter selection process, the cross-validation technique was used, which consists of training in two parts, first selecting one part of the data (training) and evaluating it with another part (test set), this process is repeated several times for different combinations. The result is

obtained by promising the results of each experiment, which gives us a more accurate assessment of the predictive ability of the model. Cross-validation is a very useful technique because it allows using all available data to train and evaluate the model, which can increase accuracy and reduce the risk of over-fitting. In addition, cross-validation allows us to compare different ML models and select the best model for our data set. To evaluate the performance of ML models, several measures are employed, which are defined as: a) True Positives (TP), in this work are classified as positive samples which are those students who have moderate level of adaptability to online education; b) True Negatives, in this work are classified as negative samples those students who do not have a level of adaptability to online education; c) False Positives, are the samples that have been misclassified as positive and d) False Negatives, are the samples that have been misclassified as negative, as seen in Fig. 5.

Fig. 5. Variable confusion matrix.

Fig. 5 shows the confusion matrix in general. For example, it can be seen that 211 samples are classified as positive (students with high level of adaptability), 186 samples are classified as positive (have high internet connectivity) and 167 samples are also classified as positive (students with moderate level of adaptability). After training the models, it is important to evaluate their performance to make sure it is accurate. This process follows the following steps: testing the models, in this work 20% of the dataset is used; evaluation metrics are used to assess the performance of the models, accuracy, recall, F1-Score and support, as shown in the following section in Table III.

IV. RESULTS

Training of various ML models, including RF, K-NN, SVM, LR and XGB, was carried out using a specific Kaggle dataset. Subsequently, a learning algorithm was developed to train the models. Subsequently, the performance of each model was evaluated using unobserved data. To carry out this evaluation, various metrics such as accuracy, precision, recall, ROC curve and F1 score were used. The results of these evaluations are presented in Table III.

TABLE III. RESULTS OF TRAINED MODELS

Random Forest

In this study, a standardized procedure has been carried out to calculate the true positive (TP) and false positive (FP) rate of all trained models. To illustrate this process, in the case of the RF model, the TP rate is obtained by dividing the number of true positives by the total number of positive cases. The FP rate, on the other hand, is obtained by dividing the number of false positives by the total number of negative cases. The same formula is applied for the other models (K-NN, SVM, LR, XGB). These rates are important metrics to evaluate the performance of a classification model and is applied to adjust the classification threshold of a model. For example, if you want to increase the rate of true positives, you can decrease the classification threshold of the model so that it predicts more samples as positive. However, this could also increase the FP rate. Therefore, it is important to find an appropriate balance between TP and FP. In this case, the RF, K-NN, SVM, LR and XGB models were trained, and the following performances were obtained: 91%, 85%, 76%, 67% and 92%, respectively.

Analyzing Table III, the RF and XGBClassifier models achieved the best rates in the f1-score, recall and accuracy metrics, in this order are analyzed. RF, 92%, 92%, 92%; XGBClassifier, 92%, 92% and 92%, although it is true that in this case, we analyze it at the average level. Therefore, it can be affirmed that the two models present optimal performances to predict the level of adaptability in online education; the second model to obtain better metrics is KNN with the following rates: 85% in F1-score, 85% in recall and 85% in precision; it is followed by the SVM model with 76% of F1-Score, 76% in recall and 77% of precision. Finally, the LR model achieved 68% in F1-Score, 67% in recall and 69% in precision. To reach a better interpretation of the results, it was decided to analyze the importance of each characteristic of the data set. For this purpose, the feature_importances technique was used to determine which features are the most important for the model. The calculation is based on how much each feature contributes to the model in terms of impurity reduction at the node of the tree where it is located. Therefore, the feature that obtains the highest score is considered the most important for the model. This is shown in Table IV.

TABLE IV. IMPORTANT CHARACTERISTICS OF THE DATA SET

#	Features	Feature importances
7	Financial Condition	16.35 %
1	Age	13.72 %
10	Class Duration	12.69 %
0	Gender	8.56 %
9	Network Type	7.54 %
3	Institution Type	6.08 %
2	Education Level	6.08 %
5	Location	5.59 %
8	Internet Type	5.54 %
12	Device	4.96 %
11	Self Lms	4.82 %
4	IT Student	4.37 %
6	Load-shedding	3.64 %

V. DISCUSSION

In the last three years, online education has experienced tremendous growth and has become a popular form of learning due to the COVID-19 pandemic. However, not all students have the same ability to adapt to this type of education. Some students may have more difficulty adapting to online education due to the lack of face-to-face interaction with the professor and their classmates, the need to be more autonomous and organized in their own study time. Predicting the level of adaptability of students in online education is an important factor for online educators, as it allows them to identify and support students who may have difficulties adapting to this type of education. ML methods are a useful tool for predicting the level of student adaptability in online education. Table IV shows that the variable economic condition, which represents the most important factor for student adaptability in online education, is followed in importance by the following variables: age, duration of sessions, type of network used, type of institution, level of education, geographic location, type of Internet, among other variables. ML models such as RF, KNN, LR, SVM, and XGB were used to analyze the data and rank

which of the models is optimal for predicting the level of student adaptability in online education. These ML models provided valuable information about which variables are the most important for students' adaptability in online education and how they are related to each other, as shown in Table IV. For example, Economic condition is the most important variable for adaptability, which represents 16.35% in importance, which is related to the results obtained in the study [20], where they concluded that student's financial condition plays a very important role in student's adaptability in online education. Similarly, the results of this work are related to [21], where they explored the gaps that exist in online and face-to-face education, and concluded that the variable of economic condition, age and Internet connection are determining factors for adaptability to online education. The results of the training with the predictive models showed that the RF (92%) and XGB (92%) model achieved the best rates for predicting the level of student adaptability in online education, which is related to the results obtained in the work [24], where they used ML classifiers and deep neural networks, and concluded that the SVM classifiers and the Decision tree, achieved the best results in accuracy and performance. AI has contributed significantly in the academic field, so much so that, unlike this work, in [23] and [25] examined perspectives, advantages and problems of AI in online education, for which they used different ML algorithms, and concluded that RF is the something-rhythm that achieved the best metrics, with an accuracy of 93%, therefore, it is the best suited for this type of tasks, this result is superior to that achieved in this work. The results will depend on the nature of the research and the volume of the data set. In the same line, in [26] they used IA to determine the influence on the adaptability of students in online education, using variables such as: teacher-student, parents and society, age, connectivity, among others. The results showed that AI has a positive influence on the adaptability of students in online education. Unlike the ML models used in this work to predict the level of adaptability of students in online education, in [28], they used the deep learning LSTM technique to analyze the performance of students in online education, where they obtained that deep learning techniques are a very good option to predict the level of adaptability, reaching an accuracy of 84. Predicting the adaptability level of students in online education using ML methods is a valuable tool for online educators. It can provide important information about which variables are most important for student adaptability in online education and how they relate to each other. In addition, it can be used to develop personalized support strategies for students who may have difficulty adapting to this type of education.

VI. CONCLUSIONS

After performing training and comparison of ML (RF, KNN, VSM, LR and XGB) predictive models for predicting the Adaptability Level of students in online education, using the Kaggle dataset consisting of 14 attributes, it reaches the following conclusions.

It was determined that the RF and XGBClassifier models obtained the best results in accuracy and performance. Therefore, for predicting the level of adaptability of students in online education, they are the best predictors, which suggests that these models can be useful for improving the effectiveness

of online education. Without detracting from the other models, they also obtained excellent performance results. The models used in this study demonstrated high prediction accuracy.

It was also found that the variables used in the set of variables are important for the accuracy of the predictions. Table IV shows the relevance of each of the variables for predicting the level of adaptability of students in online education, the most important being economic condition, age, duration of sessions, gender, type of network, type of institution, directly influencing the level of adaptability of students.

Finally, predictive ML models can be a valuable tool for predicting the level of student adaptability in online education. The use of ML models, such as RF, KNN, VSM, LR, and XGB, and the careful selection of variables can significantly improve the accuracy of predictions. These findings contribute in a significant way for online education and can help educators improve the effectiveness of their online educational programs. In the future, a possible development that would complement the use of the models would be the development of work to assess the academic performance of students in online education.

Abstract—The increasing use of powerful evasive ransomware malware in cyber warfare and targeted attacks is a persistent and growing challenge for nations, corporations, and small and medium-sized enterprises. This threat is evidenced by the emergence of the WhisperGate malware in cyber warfare, which targets organizations in Ukraine to render targeted devices inoperable, and the BlackCat malware, which targets large organizations by encrypting files. This paper outlines a practical approach to malware analysis using WhisperGate and BlackCat malware as samples. It subjects them to heuristic-based analysis techniques, including a combination of static, dynamic, hybrid, and memory analysis. Specifically, 12 tools and techniques were selected and deployed to reveal the malware’s innovative stealth and evasion capabilities. This methodology shows what techniques can be applied to analyze critical malware and differentiate samples that are variations of known threats. The paper presents currently available tools and their underlying approaches to performing automated dynamic analysis on potentially malicious software. The study thus demonstrates a practical approach to carrying out malware analysis to understand cybercriminals’ behavior, techniques, and tactics.

Keywords—Malware analysis; WhisperGate; BlackCat; malware sample; ransomware

I. INTRODUCTION

The geopolitical events in Ukraine at the start of 2022 were preceded by the devastating cyber warfare operation highlighted by WhisperGate malware (A malware that corrupts a system’s master boot record, displays a fake ransomware note, and encrypts files based on certain file extensions). WhisperGate is considered dangerous because it can launch cyber-attacks and compromise sensitive information against hardened targets. Since it was deployed in cyber warfare against Ukraine, it could exploit unknown vulnerabilities in a target’s security systems and cause significant harm. The destructive capabilities of WhisperGate make it a threat to individual, organizational, and national security. At the end of 2021, a sophisticated malware called BlackCat also known as “AlphaV,” emerged, targeting U.S. organizations and their affiliates in Europe, the Philippines, and other locations. While WhisperGate masquerades as ransomware targeting nation-states (in this case, Ukraine), BlackCat has emerged as deadly ransomware targeting U.S. and European retail, construction,

and transportation organizations. BlackCat appeared as an innovative ransomware-as-a-service (RaaS) group leveraging the Rust programming language and offering affiliates 80% to 90% of ransom payments [1]. Affiliates included Germany’s tank storage and terminal firm Oiltanking and energy firm Mabatnaft, Belgian energy firm Sea-Invest, and Dutch oil and gas firm Evos. These attacks underlined the growing vulnerability of critical infrastructure companies to malicious hackers [2]. Both pieces of malware were challenging to defend against due to their elusive and evasive nature, which intrigued cybersecurity analysts worldwide. Since the top three cyberattacks that organizations are most concerned about are ransomware, social engineering, and malicious insider activities [3], WhisperGate and BlackCat were ideal candidates for our practical malware analysis approach due to their stealth and evasive capabilities and the destructive consequences they can cause.

Multiple malware classes, such as worms, viruses, spyware, Trojan horses, rootkits, ransomware, keyloggers, and adware, are designed with specific functionalities namely data exfiltration, data encryption, and data destruction. Despite the widespread use of antimalware software, the number of malware infections continues to grow. Malware, especially zero-day malware, can evade antimalware solutions and even infect them with its built-in defensive mechanisms. Along with WhisperGate, malware deployed against Ukraine included HermeticWiper, IsaacWiper, HermeticWizard, and CaddyWiper. Once inside the initial network, it leverages that access to compromise user and administrator accounts in the active directory of Windows’ server and configures malicious group policy objects through Windows’ task scheduler [4].

This paper provides a practical approach to performing malware analysis using integrated tools and techniques to assess WhisperGate and BlackCat. The Microsoft Threat Intelligence Centre disclosed that WhisperGate, categorized as a wiper, targeted several organizations in Ukraine and was tracked as DEV-0586 with a design similar to ransomware but lacking a recovery mechanism [5]. BlackCat, which belongs to a sophisticated ransomware as a service (RaaS) family, extorts money from targeted institutions instead.

The structure of the remainder of this paper is as follows: Section II discusses extant literature on ransomware in general, the identified ransomware, and an evaluation of malware analysis techniques. Section III outlines the methodology, and Section IV focuses on the experimental analysis. Section V discusses the results, and Section VI concludes the research with suggestions on future research.

II. LITERATURE REVIEW

The section provides an overview of ransomware, discusses two specific types of malware (WhisperGate and BlackCat), and then evaluates malware analysis methodologies to focus on the appropriate technique(s).

A. Ransomware

Ransomware is considered one of the most threatening types of malware. Its attacks increased by 151% in 2012, averaging 270 cyberattacks per organization, with each successful breach resulting in a cost of \$3.6 million for the affected company [3]. Cyber-attacks predominantly occur through ransomware, social engineering, and malicious insider activity [3]. In particular, ransomware leverages social engineering methods to gain unauthorized access to the victim's network. Once an infection is spread, the user is extorted and asked for a monetary payment against the locked access [6], but there is no guarantee that they will regain access to their locked files after paying the ransom. Threat actors often receive the payment but still retain the data. These cybercriminals often request payment in cryptocurrency, as it is untraceable and allows them to evade responsibility [7]. Malwares leverage the Trojan by disguising themselves as legitimate software and download the malicious components, which negatively impact the system and tend to infect files and target other systems [8]. While commercial solutions are available, these are not 100% secure, because hackers use more sophisticated techniques to follow the evolution and bypass the protection techniques [9]. WhisperGate is classified as a wiper, i.e., it disguises itself as ransomware but instead aims to cause mass destruction by wiping out hard drives at targeted organizations [10].

Removing the ransomware or restoring the infected devices is ineffective, as the ransomware uses asymmetric cryptography [11], which makes it robust. The encryption makes it so that the victim is unable to access the data without first decrypting it using a key [12]. Threat actors usually ask for a ransom in exchange for the decryption key and target organizations that handle large amounts of sensitive data. The victim is faced with inaccessibility and damage to their data and often pays the ransom demand. Since most of the victims are threatened with their data and sensitive information being exposed [13].

Among the five types of ransomware—locker, crypto leakware, scareware, and pseudo-ransomware [14], WhisperGate comes under the pseudo-ransomware category, while BlackCat comes under leakware category. Also known as doxware, leakware presents a high-risk level because it is well-targeted to institutions such as banks or those that work with confidential and critical data. This ransomware does not destroy the data but threatens to release them into the public

domain. Furthermore, since the context can damage the institution's image, an even greater emphasis can be placed on the quick payment of a ransom. Accordingly, BlackCat operates as a RaaS option that permits earning a percentage of the ransom payment to all the persons who have low technical knowledge about how to create ransomware but are members of this network. It is only necessary that those members spread the ransomware as far as possible while the RaaS vendor can focus on how to make this malicious software cause even more damage.

B. WhisperGate

Unlike traditional ransomware campaigns where the motive is clear, the BlackCat campaign is believed to be pseudo, with its intention being to cause the destruction of infected systems, as evidenced by the Stage 4 wiper that overwrites data on the victim's system, making decryption impossible [15]. The malware that was explicitly launched against various Ukrainian organizations in geopolitically motivated attacks was first analyzed by the Microsoft Threat Intelligence Center and detected on January 13, 2022 [16]. The BlackCat ransomware campaign targeted Ukraine in 2021 prior to its physical invasion, but it was detected and neutralized before causing any severe damage [17]. Russian cyber operations have targeted Ukraine with destabilization efforts for years through attacks on critical infrastructure, influence operations, website defacement, and attacks against banks and military networks [16]. WhisperGate, while masquerading as ransomware, corrupts a system's master boot record, displays a fake ransomware note, and then encrypts files based on specific file extensions. While a ransomware message is displayed during the attack, the targeted data is destroyed and is not recoverable even if a ransom is paid [18]. The multi-stage infection chain downloads a payload that wipes the master boot record (MBR). Then, it downloads a malicious Dynamic-link library (DLL) file hosted on a discord server (a platform where people can interact with each other in real time), which drops and executes another wiper payload that destroys files on the infected machines [19]. The malware, which is designed to look like ransomware, is intended to render the targeted devices inoperable rather than to obtain a ransom, as it does not have an inbuilt recovery code. Using social engineering methods in an Advanced Persistent Threat (APT) campaign, the attackers might have used stolen credentials and likely had access to the victim's network for months before the attack [19]. The malware can also extend to extranet networks. The recommendations from the US Cybersecurity and Infrastructure Security Agency that organizations with ties to Ukraine should carefully consider how to isolate and monitor those connections to protect themselves from potential collateral damage are echoed.

Following the detection of WhisperGate, HermeticWiper, another similar malware masquerading as ransomware used against organizations in Ukraine, was discovered on February 23, 2022. The malware targets Windows devices, manipulating the master boot record and resulting in subsequent boot failure [18]. Since both these pieces of malware (WhisperGate and HermeticWiper) are similar, the WhisperGate malware was selected as an example to study. The diamond model of intrusion analysis (DMIA) illustrates (Fig. 1) the four

dimensions of the malware attack: the adversary profile, the affected infrastructure, the deployed capabilities, and the target. Specifically, the adversary deploys a capability over a specific infrastructure against a victim [20].

Fig. 1. DMIA model of WhisperGate malware attack.

C. BlackCat

BlackCat is a sophisticated and innovative ransomware family that surfaced in mid-November 2021. It operates as a RaaS business model, and it gained notoriety for soliciting affiliates in known cybercrime forums and offering them to leverage the ransomware and keep 80%–90% of the ransom payment [21]. BlackCat made headlines as one of the first ransomware families written in the Rust programming language, which is used to evade detection by conventional security solutions that may struggle to analyze and parse binaries written in Rust [5].

The rise of cybercrimes has been fueled by the anonymity and non-reversibility of cryptocurrencies, particularly Bitcoin, which makes ransomware payments simple for victims and risk-free for ransomware operators. The trend towards using cryptocurrencies such as Monero, which offers improved security, privacy, and anonymity, is growing, as Monero transactions cannot be traced back to a specific user or address, and the transaction history is kept private. Nonetheless, Bitcoin remains the most popular payment method for ransomware [14]. Among the 31 Ransomware listed by Unit 42, BlackCat has only the seventh largest number of victims listed on their leak site. However, while Lockbit 2.0 ransomware has a list of 50 victims over a period of six months, BlackCat has had an impressive record of 12 victims in just one month since its emergence tanner [21], which makes it a suitable candidate for analysis. In some cases, BlackCat operators use triple extortion by threatening to perform a Distributed Denial of Service (DDoS) attack on the victims' infrastructure: if the ransom is not paid, leak the information along with the data encryption [21]. The DMIA model illustrates the attack process (Fig. 2).

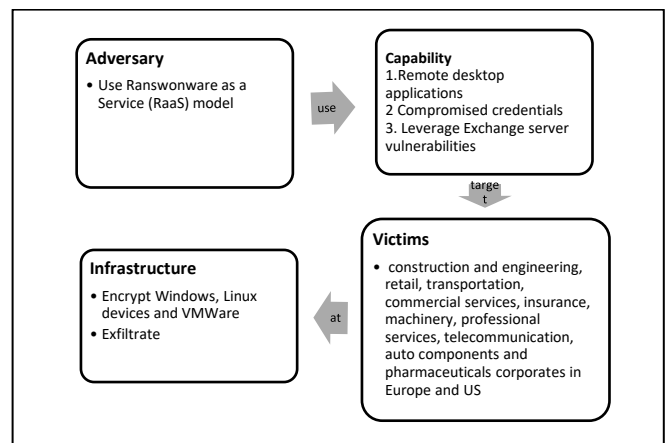

Fig. 2. DMIA model of a BlackCat malware attack.

D. Malware Analysis

Malware analysis applies program analysis and network analysis techniques to understand the behavior and evolution of malicious samples over time [22] and estimate the level of threat and harm a file can cause. Additionally, this kind of analysis helps identify a malicious file's purpose, origin, process execution, file monitoring, and hidden indicators [23].

Malware analysis from a heuristic-based detection (also known as anomaly or behavior based) consists of four types, namely, static, dynamic, hybrid and memory analysis [24]. Being heuristic-based, the proposed research focus on the static, dynamic, hybrid and memory analysis. First, static analysis was used to examine malware samples without the file's execution to extract necessary information from a suspicious file, which assisted us in classifying and identifying its execution. This information is usually gathered using static analysis tools, which examine the sample code more effectively [25]. Static analysis assists in the discovery of the binary code, which contains very useful information about the malicious behavior of a program in the form of op-code sequences, functions, and parameters. However, this method alone may not suffice for a zero-day malware (WhisperGate and BlackCat) before its discovery because new pieces of malware are created daily. The signature-based detection approach followed by the static analysis method requires frequent updates of the virus signature database, which is the method's main disadvantage [26].

Dynamic analysis is deployed, since hackers use various techniques, such as code obfuscation, dynamic code loading, encryption, and packing, to evade static analysis (including signature-based antivirus tools). Furthermore, dynamic analysis can help understand the analyzed file, thus improving detection capabilities [27]. In dynamic malware analysis, the suspicious files are executed and monitored in a controlled environment

[24]. Dynamic analysis includes function call monitoring, network simulation, and registry and file changes. Interactive behavioral properties are observed and analyzed after the simulation of malware. When malware is executed in a dynamic environment, it changes its behaviors. Therefore, static features can be extracted easily and correctly. Hence, the extraction of static features in a dynamic environment detects malware efficiently. The accuracy of dynamic malware analysis alone may instead not be efficient due to the malware's intelligent behaviors [28].

While both static and dynamic analysis techniques are effective on their own, in specific situations, an integrated technique combining the relative merits of each is more efficient. Hybrid analysis that combines both static and dynamic malware analysis is thus generally preferred [29]. Memory analysis, which is used in both malware analysis and malware forensics, involves both the acquisition and analysis phase, thus providing a more comprehensive view of the malware than static and dynamic analyses and an excellent way to analyze memory by preserving a system's contents [29]. Since malware can hide its code in the computer system effectively, it must execute its code in the memory to perform its tasks [24]. Therefore, based on the evaluation of static, dynamic, hybrid, and memory analysis, and having reviewed the efficiency and effectiveness of each of these approaches, the proposed research thus focusses on all four heuristic methods.

E. Methodologies Deployed in Malware Analysis

A survey of extant research presented relevant methods used for malware analysis, namely Eureka, disassembled code analyzer for malware (DCAM), malware analysis reverse engineering (MARE), and systematic approach to malware analysis (SAMA). Eureka, a framework allowing a static analysis of malware binaries, highlights the need to produce unpacked code. It provides Windows application programming interface (API) resolution to identify the system calls in the unpacked code [30]. Or-Meir et al. conducted an overview of existing dynamic analysis methods and provided a malware classification based on each category's behavior, mapping layouts, techniques, and flow comprising memory forensics using volatile tools [27]. Almashhadani et al. used the Lock family of crypto-ransomware as their case study for their comprehensive behavioral analysis (BA) of crypto-ransomware [31]. Their work assisted us in the malware analysis of BlackCat, as the latter showed similarities with crypto-ransomware. Ren et al. provided a three-level ransomware detection and prevention mechanism using virtual machines on Petya and NotPetya ransomware [32]. Similar to WhisperGate in terms of its behavior, NotPetya falls under the category of a wiper disguised as ransomware. Hence, its analysis assisted us in the analysis on WhisperGate.

DCAM is a static malware detection technique using code disassembly to recognize malware variants based on a common core signature with promising results on a set of malware [33]. MARE introduced a four-stage approach covering a structured analysis process that focuses on producing an objective outcome to detect malware followed by isolation and extraction phases, as shown by [34], who introduced the malware behavioral technique, malware reverse engineering,

and code analysis. The author in [35] proposed an automated analysis framework to analyze executable behaviors through a synergic combination of malware detection techniques, including using a virtual machine over a sandbox to enhance invisibility. SAMA provides detailed information on the working of malware, and its applicability over any type of malware makes it robust. It follows a four-stage approach, namely, an modified version of MARE, as shown by [36]. The authors pointed to the execution order provided by MARE and noted that code analysis must be executed along with behavioral analysis.

SAMA is a complete methodology for performing malware analysis, and malware analysts have used it to analyze the following malware threats: Stuxnet, Dark Comet, Poison Ivy, Locky, Careto, and Sofacy Carberp, including Flame and Red October, as shown by [36]. However, the authors did not explain how they used their tools for each step. Furthermore, through the use of SAMA, the authors have only partially discussed memory analysis. Additionally, the stage of packaging obfuscation is executed after the initial five steps of classification in SAMA. However, it would be more impactful to include obfuscation checking before any other step because the analysis could lead to incorrect results. Finally, a hybrid technique should be included as part of the methodology to perform an in-depth analysis, which is missing in SAMA. Accordingly, hybrid analysis was performed to obtain relevant information and fast results to assess WhisperGate and BlackCat malware. The proposed approach is illustrated against those presented in the literature in Table I. Specifically, the lab setup process and static, dynamic, code, and memory analysis is compared.

TABLE I. COMPARATIVE ANALYSIS OF ANALYSIS METHODOLOGIES

Research Methods	Lab Set-up	Static	Dynamic	Hybrid	Memory
DCAM	No	Yes	No	No	No
MARE	No	No	Partial	No	No
Vidarthi et al.	Partial	Yes	Yes	No	No
SAMA	Yes	Yes	Yes	No	Partial
Proposed approach	Yes	Yes	Yes	Yes	Yes

III. METHODOLOGY

Since the main objective of the paper is to illustrate a practical approach to carrying out malware analysis, the two sample pieces of malware were analyzed using the following integrated tools and the four analyses. The implemented methodology is shown in Fig. 3 and can be used as a guideline for future comprehensive malware analyses.

A. Lab Setup

Flare VM is an open-source collection of software installation scripts for Windows systems to easily setup and maintains a reverse engineering environment on a virtual machine. It was installed on Virtual Box hypervisor to analyze the encrypted malicious file downloaded from Malware Bazaar—a project from abuse.ch). Then, it was downloaded and installed on Windows 10 VM. A system snapshot was taken before each analysis to preserve the integrity of the

results and for future-reference analysis. The following sub sections discuss the rationale for choosing the four malware analysis techniques.

B. Applying Static Analysis

Static analysis examines the malicious sample by gathering maximum information without executing it by following a three-step phases approach: de-obfuscation, basic properties analysis (BPA), and advanced static analysis (ASA) (Fig. 4).

The cyber attacker uses obfuscation to intentionally disguise some attributes of the malware specimen by packing it. Hence, before proceeding with the analysis, the initial step should be to perform an obfuscation check and bring the sample to its unpacked state (BPA) In this respect, the file type and signature identification are crucial steps of static analysis to obtain useful information, such as the target operating system (OS) and the architecture of the suspicious file. Among Windows' basic executable files, the presence of portable executables in the form of .exe or .dll provides a glimpse of hexadecimal values and notes that are present in a file.

Malware hashing involves the generation of cryptographic hashes for a malicious file. Hashing algorithms are commonly used to generate hash values of the malicious files are MD5, SHA-256, and SHA-1. This step provides unique values that act as fingerprints for the malware samples. VirusTotal website allows for the flexibility to either upload a file or a URL or simply search the hash value of the sample, and it offers API-based support for detection and recognition by supplying the details of the previous records created by other researchers. String analysis extracts legible letters and words from the malware and focuses on critical information that can be fetched from strings, such as file names, IP addresses, registry keys, and URLs. However, an attacker may include fake strings to divert an analyst from disrupting their task, as strings provide an overview of what malware can do.

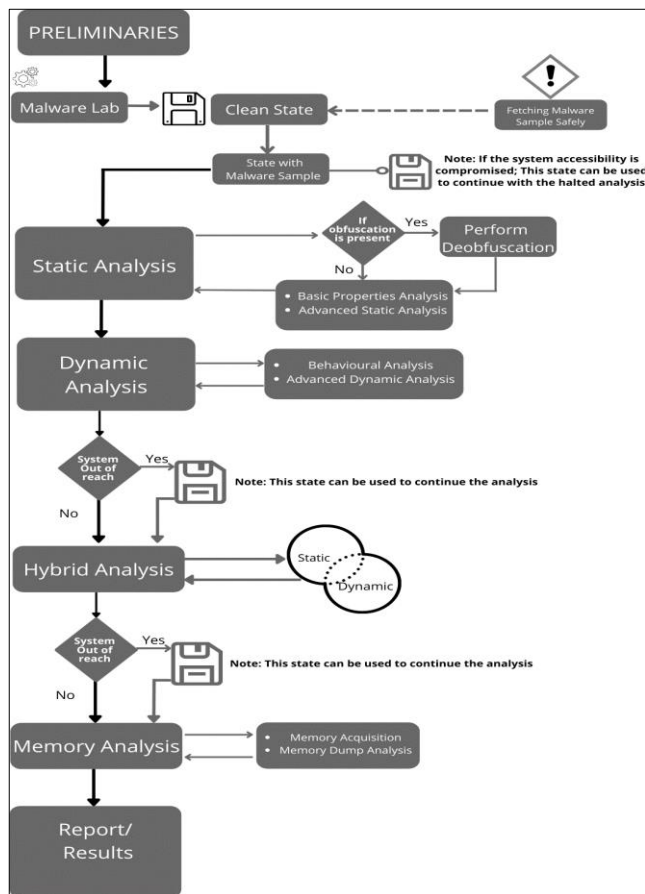

Fig. 3. Malware analysis methodology.

Fig. 4. The three-step phase of the static analysis.

The goal of advanced static analysis of the static code is to understand the malware code's design. This kind of analysis includes the analysis of the machine code by disassembling a file. Performing the static code analysis after BA is appropriate because it requires analyzing the processes and behavior of malware by comparing the two states, namely pre- and post-execution. Conversely, if static code analysis is performed before behavioral analysis, it might reduce the accuracy.

C. Applying Dynamic Analysis

Dynamic analysis implies the execution of the malware sample in a contained and safe environment (sandboxed) to understand the malware's functionality, which includes changes in registry and the files created by it. The objective is to cover two important phases of dynamic analysis, namely behavioral analysis (BA) and advanced dynamic analysis (ADA) (Fig. 5).

Fig. 5. The two step phase of dynamic malware analysis.

The objective of BA is to understand the suspicious behavior of malware through the interaction with the sample to gather maximum information. BA helps understand the changes in registry, network, and files. The methods in this step include domain name system (DNS) handling, snapshot comparison, process analysis, and registry analysis. DNS handling involves setting up a fake server to generate responses for the requests created by the suspicious file. When the malware is executed, it creates a DNS request so that it can perform the required malicious behavior. These requests are resolved by creating a fake server that fools the malware and generates the response. The snapshot comparison of Window's registry keys focuses on obtaining information about the changes in the number of registry keys and their values before and after the execution of the suspicious file. A registry key is an organizational unit that serves the purpose of an internal database and is used by the computer to store information related to configuration. In the process analysis stage, the malicious application is executed to elicit information regarding its behavior, namely the activities of the application and the details of threads, memory, handles, and the child processes created by it. Analysis of real-time registry, file system, and thread activity of the malicious file involves advanced monitoring of the applications using thread stacks, sessions created, and their activities. It also helps obtain information on the path the processes have traversed in the system, including the changes made. The objective of the ADA stage is to perform advanced analysis on the code by debugging the dynamic code by executing a file.

D. Applying Hybrid Analysis

Since hybrid malware analysis assist to obtain the benefits of both static and dynamic malware analysis [24], this increases their ability to detect malicious software correctly.

Furthermore, this analysis technique has all the strengths of static and hybrid analyses while overcoming the shortcoming they have when they are performed independently.

E. Applying Memory Analysis

The main objective of performing this stage is to gain information by monitoring memory changes. An analyst examines the memory dump to gain additional information on process execution and performs a restoration step to make a clean state for further analysis. Memory analysis is integrated with hybrid analysis when an analyst applies basic static analysis to the information gathered during interactive BA, namely the execution of malicious code to generate memory changes followed by dynamic analysis. This phase will be reverted to perform basic static analysis on that memory dump. The table below lists the tools used in malware analysis.

TABLE II. TOOLS AND TECHNIQUES USED IN MALWARE ANALYSIS

No.	Tools	Static	Dynamic	Hybrid	Memory
1	ExinfoPE	Y	X	X	X
2	Hex Editor	Y	X	X	X
3	PeStudio	Y	X	X	X
4	Virustotal	Y	X	X	X
5	Ghidra	Y	X	Y	X
6	ApateDNS	X	Y	X	X
7	Regshot	X	Y	X	X
8	Process Monitor	X	Y	X	X
9	IDA	X	X	Y	X
10	Procmon	X	X	Y	X
11	AccessData FDK	X	X	X	Y
12	Volatility	X	X	X	Y

IV. RESULTS AND ANALYSIS

This section presents a practical approach to analyzing malware using open-source and powerful tools (Table II). The WhisperGate malware is analyzed first, followed by the analysis of BlackCat malware. The preliminary lab setup was meticulously followed to ensure the status of the malware before and after each process (i.e., static, dynamic, hybrid and memory analysis). The following subsections highlight the experimental results obtained through the judicious use of appropriate tools.

A. Experimental Findings - WhisperGate

1) *Static analysis*: The static analysis followed a three-step approach, namely deobfuscation, BPA, and ASA. Exeinfo PE is a software that can be used to view executable file properties. When using the tool Exeinfo PE to deobfuscate and identify whether the malware was obfuscated (Fig. 6), it was found that the file was unpacked.

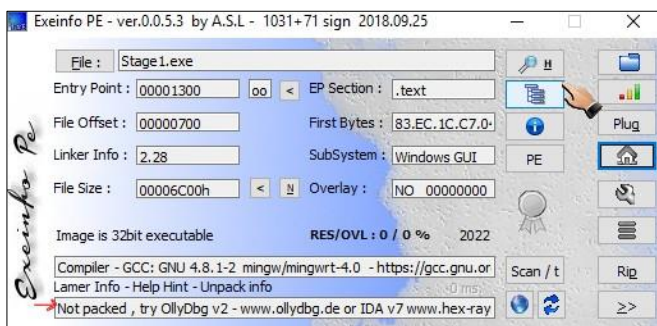

Fig. 6. Deobfuscation of WhisperGate using Exinfo PE.

In the File and Signature Identification step of BPA, the tools Hex Editor (Hxd) were used to obtain detailed information on the signature (Fig. 7 and 8), and PeStudio was used to identify the file type of the malware (Fig. 9). HxD is a tool that can inspect, compare, and verify files, disks, disk images, memory, and log files; patch errors, and repair disk structures. Used for malware detection, PeStudio analyzes the executable files and provides information about the file's properties, characteristics, and potential risks.

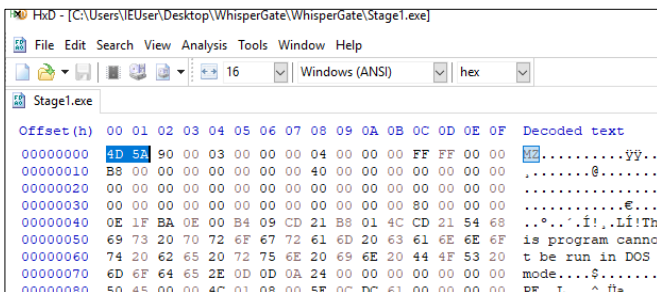

Fig. 7. File and signature identification of WhisperGate using Hxd.

The figure shows that the first two bytes contain 4D 5A, and the decoded text is MZ (which stands for Mark Zbikowski, a leading developer of DOS). Both these values are a crucial factor, which tells us that it is a portable executable. Another file signature that can be observed from the tool is the note that tells that "This program cannot be run in DOS mode." The decoded text states that "Your hard drive has been corrupted... In case you want to recover all hard drives of your organization, You, should pay us \$10k Dollars via bitcoin wallet ** and send message via tox ID ** with your organization name. We will contact you to give further instructions" (Fig. 8).

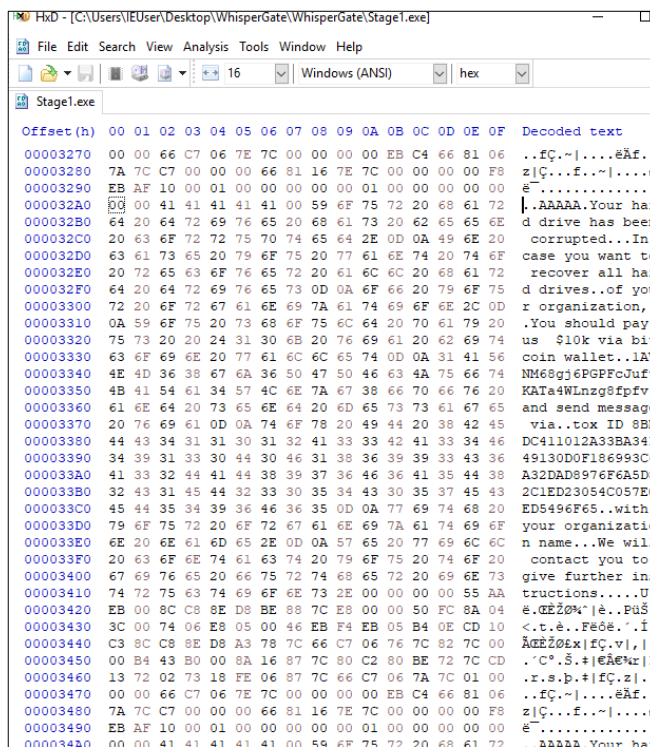

Fig. 8. Decoded text message of WhisperGate using Hxd.

After the signature identification, PeStudio was used to identify the correct type of file (Fig. 9). Based on the results, the file is built on a 32-bit CPU architecture with a file size of 27648 bytes.

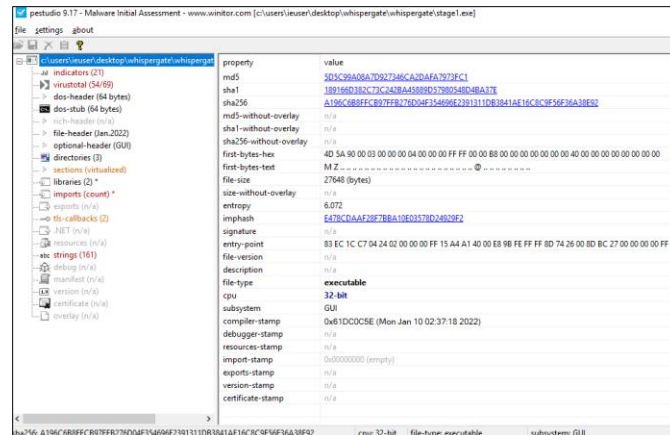

Fig. 9. File type identification of WhisperGate using PeStudio.

Upon hashing, PeStudio generated the hash values:

MD5 : 5D5C99A08A7D927346CA2DAFA7973FC1

SHA-1:

189166D382C73C242BA45889D57980548D4BA37E

SHA-256:

A196C6B8FFCB97FFB276D04F354696E2391311DB3841AE16C8C9F56F36A38E92

The API-based identification stage involves using the web-based tool VirusTotal. VirusTotal is an online portal where users can upload suspicious files. It uses antivirus engines and website scanners to detect various types of malware and malicious content. The identification and classification of the malware show a community score of 54 on a scale of 69, signifying malware detection by 54 security vendors out of 69. Details such as the history of the application, the compilation stamp, and the information of the target identified through the API are shown below in Fig. 10.

Fig. 10. API identification of WhisperGate from VirusTotal.

In the last step of BPA, namely string analysis, PeStudio was used to analyze the strings and retrieve useful information, as shown in Fig. 11.

encoding (2)	size (byte)	file offset	blacklist (4)	hex (23)	group (7)	index (16)
ascii	4	00333029	-	...	-	...

ascii	4	00333110	-	...	-	...

Fig. 11. String identification of WhisperGate using PeStudio.

A total of 161 strings were identified, four of which were blacklisted, and 16 carried the note “Your hard drive is corrupted,” indicating that malicious activity could be carried out using the sample. Advanced static analysis involves the single task of manually reversing the static code. The tool Ghidra (a free and open source reverse engineering tool) was used to disassemble the code and further examine the functions, which provided relevant information regarding the nature of the file, as shown in Fig. 12.

```

*(undefined4 *) (aparam_1 + iVar1) = 0;
*(undefined4 *) (stack0x00000000 + iVar1) = 0;

return 0;
    
```

Fig. 12. Code reverse of WhisperGate using ghidra.

The images taken from Microsoft documentation (Fig. 13 and 14) shows that the functions, CreateFileA (which opens a physical disk drive or a volume) and WriteFile (which writes data to the specified file or input/output (I/O) device) fall under the category of Data Access and Storage. Hence, it is possible to relate the general syntax with the disassembled code provided by Ghidra (Fig. 12), which contains the same two functions as the one from Microsoft documentation.

Fig. 13. The CreateFileA function that relates to the result in Fig. 12.

Fig. 14. The WriteFile function that relates to the result in Fig. 12.

From the disassembled code, useful information was extracted from the two functions. Their synchronization hints that a file is being opened and overwritten to execute a task. CreateFile accepts the parameter "Physical Drive," which is the name of the file being opened. The access mask used is "0xfffff0." WriteFile provides important details through the handle buffer. The handle returned by CreateFile is used by this function, while the buffer pvVar3 presents the variable Local 2020.

2) *Dynamic analysis:* The dynamic analysis followed two phases, namely BA and ADA. In BA, the malware was executed to interact with the sample to determine its behavior and intended purpose (see Fig. 5 for the four steps). In the DNS processing step, the ApatDNS tool (that aid analysts in DNS identification) was used to spoof DNS responses to DNA requests generated by the malware, as shown in Fig. 15.

Fig. 15. DNS spoofing of WhisperGate using the tool ApatDNS

During the execution of the sample, the tool successfully captured a list of DNS requests along with the timestamp, indicating that the malware was attempting to connect to different IP addresses for malicious purposes. In the snapshot comparison step, the Regshot tool was used to take sequential snapshots for the pre- and post-execution states to monitor the changes to the registry and files. RegShot that is a tool for controlling changes in the Windows registry can compare the state of registry entries "before" and "after" system changes. The pre- and post-execution snapshots are shown in Fig. 16. The images indicate information regarding the keys, values, and related attributes in the snapshot.

Fig. 16. The pre- and post-execution snapshots using regshot.

The Process Monitor tool was used in the Process Analysis step. Upon invoking the process name filter, the tool generated a list of sub-processes (Fig. 17). The Process Monitor is a troubleshooting and malware hunting monitoring tool for Windows that shows real-time file system, Registry and process/thread activity.

Fig. 17. Process monitoring of WhisperGate using process monitor.

The tool successfully displayed 258,678 events triggered by the malware sample. The main processes highlighted are, again, CreateFile and WriteFile (Fig. 17), and they provide useful information regarding the execution of malware. In particular, CreateFile offers the desired access for the malware to open a file, and WriteFile allows it to overwrite.

In the Registry and File Analysis step, the output generated by Regshot was used to compare the changes made in the registry values and the modifications in the system files, as shown in Fig. 18.

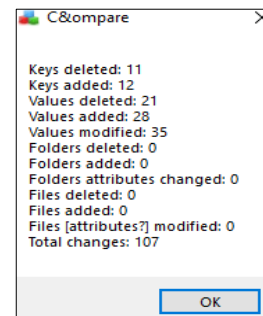

Fig. 18. Registry and file analysis of WhisperGate using regshot.

A total of 107 changes were observed, and the output file displays useful information, such as the addition and deletion of files and registry changes.

In the final ADA step, the IDA tool was used to obtain a debug view of the sample. The IDA tool creates maps of software's execution to display the binary instructions that are actually executed by the processor. The real-time import was used to obtain useful information, as shown in Fig. 19.

```

Fig. 19. The debug view of WhisperGate using the IDA tool.

Three vital imported files, CreateFile, CommandLine, and WriteFile, were observed. Out of the 53 imports, four imported an msvcrt library, and the remaining imported a KER-NEL32 library. After creating a breakout for the WriteFile, the file resumed at the GetCommandLine parser. The “stepinto” feature of the tool provides a view of the kernel-based library (Fig. 19).

3) *Hybrid analysis*: Hybrid malware analysis overcomes the shortcomings of individual malware analysis types, as relying on a single malware analysis method does not provide a comprehensive malware analysis report. In this stage, the information generated using the tools Ghidra and Procmon were integrated. Procmon is a utility for Microsoft Windows OS that captures and displays system and network activity. The static analysis provided an overview of the static code along with the basic properties, while dynamic analysis was applied simultaneously to strengthen the information gathered during the static analysis phase. As soon as the file was run, its behavior could be monitored and compare with the relevant information extracted from the static code analysis. This process highlights the importance of synchronization of both static and dynamic analyses (Fig. 20).

```

*(undefined4 *) (iParam_1 + iVar1) = 0;
*(undefined4 *) (stack0x00000000 + iVar1) = 0;
*(undefined4 *) ((int)sp_Stack4 + iVar1) = 3;
*(undefined4 *) (stack0xffffffff0 + iVar1) = 0;
*(undefined4 *) (stack0xffffffff4 + iVar1) = 3;
*(undefined4 *) (stack0xffffffff8 + iVar1) = PERM_ALL;
*(wchar_t **) (stack0xffffffffc + iVar1) = L"\\.\PhysicalDrive0";
*(undefined4 *) ((int)uStackY24 + iVar1) = 0x403bcf;
pVar3 = CreateFileW((LPCWSTR) (stack0xffffffffc + iVar1), (DWORD) (stack0xffffffff0 + iVar1),
    (DWORD) (stack0xffffffff4 + iVar1),

    (HANDLE) (iParam_1 + iVar1));
*(HANDLE *) (stack0xffffffffc + iVar1) = pVar3;
*(undefined4 *) ((int)sp_Stack4 + iVar1) = 0;
*(undefined4 *) (stack0xffffffff8 + iVar1) = 0;
*(undefined4 *) (stack0xffffffff4 + iVar1) = 0x200;
    
```

Fig. 20. Result of ghidra illustrating the buffer size.

The buffer size in Hexadecimal code 0x200 (last line in Fig. 20), is revealed as 512 in decimal. The first 512 bytes are equal to the exact size of the MBR buffer. The buffer contains the string “Your hard drive has been corrupted.” It is possible that the sample made an effort to corrupt the MBR, but this hypothesis could not be confirmed without performing a hybrid analysis.

To add value to the information, the thread activity overwriting the device's hard disk with a length of 512 bytes was analyzed. The images shown below (Fig. 21 and 22) provide details such as operation, path, offset value, and the result status of the operation.

Process	Thread	Operation	Path	Result	Offset	Length	I/O Flags
C:\Users\IEUser\Desktop\WhisperGate\WhisperGate\Stage1.exe	6524	OpenControlSet.Serv...	HKLM\System\CurrentControlSet.Serv...	SUCCESS			
Stage1.exe	6524	RegEnumKey	HKLM\System\CurrentControlSet.Serv...	NO MORE ENTRI...	Index: 1	Length: 80	
Stage1.exe	6524	RegCloseKey	HKLM\System\CurrentControlSet.Serv...	SUCCESS			
Stage1.exe	6524	CreateFile	\Device\Harddisk0\DR0	SUCCESS	Desired Access: All Access, Disposition: Open, Options: Synchron...		
Stage1.exe	6524	WriteFile	\Device\Harddisk0\DR0	SUCCESS	Offset: 0	Length: 512	I/O Flags: Non-cached, Priority: Normal
Stage1.exe	6524	CloseFile	\Device\Harddisk0\DR0	SUCCESS			

Fig. 21. The thread activity showing the overwriting of the hard disk.

Event	Process	Stack
Date:	4/4/2022 2:23:03.916660 AM	
Thread:	6528	
Class:	File System	
Operation:	WriteFile	
Result:	SUCCESS	
Path:	\Device\Harddisk0\DR0	
Duration:	0.0386311	
Offset:	0	
Length:	512	
I/O Flags:	Non-cached	
Priority:	Normal	

Fig. 22. Event view of the result of the thread activity (see Fig. 21).

The thread confirms the successful execution of the operation WriteFile in overwriting 512 bytes of memory in the hard disk. By synchronizing the use of static code obtained under advanced static analysis and the behavioral characteristic observed under the dynamic analysis, critical information about the malware were successfully gathered. Specifically, the nature of the malware is to write the 512 bytes of the hard disk and corrupt the MBR.

4) *Memory analysis*: This phase involves a two-step approach: memory acquisition and memory dump analysis. First, a memory dump of the infected state was obtained, and then the analysis was completed by analyzing this memory dump. In the memory acquisition step, the tool AccessData FTK Imager was used to capture the memory dump of the infected state, as shown in Fig. 23. AccessData FTK Imager is a computer forensics software that can create copies, or forensic images of computer data without making changes to the original evidence.

Fig. 23. Acquisition of the memory using the tool AccessData FTK imager.

Subsequently, the tool Volatility was used in the memory dump analysis step to analyze the memory dump of the infected state, which provided valuable information on the running processes (Fig. 24) and the mapping of physical offsets to virtual addresses (Fig. 25). Volatility is a command line memory analysis and forensics tool for extracting and

analyzing the volatile data that is temporarily stored in random access memory from memory dumps.

Fig. 24. View of the running processes using the tool volatility.

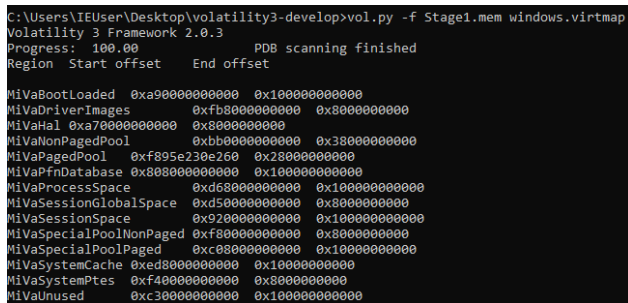

Fig. 25. View of the mapping of physical offsets to virtual addresses using the tool volatility.

While the images show a list of processes running, the Stage1.exe file is not visible. This indicates that the file has been executed with immediate effect to remove its traces. The virtual mapping provides an overview of the start and close offsets of different regions, such as BootLoaded DriverImages.

B. Experimental Findings - BlackCat

BlackCat malware can be analyzed in a similar manner. However, the analysis is not restricted to the tools which were used to analyze WhisperGate; rather, an analyst can use alternate tools as per the situation, but it should be ensured that the necessary parameters are evaluated according to the target. This section focuses on the findings resulting from the analysis of the BlackCat malware sample.

1) *Static analysis:* The static analysis followed a three-step approach: deobfuscation, BPA, and ASA. Deobfuscation using the tool ExeinfoPE revealed that the file was not packed (Fig. 26).

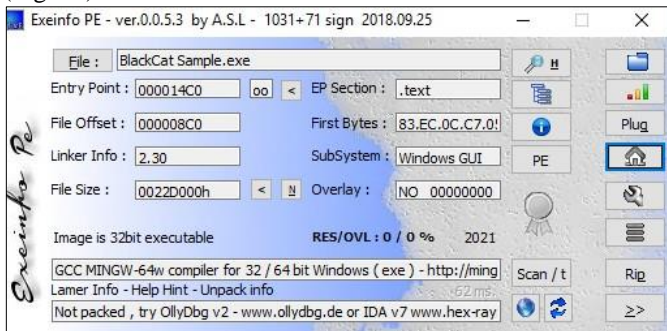

Fig. 26. Deobfuscation of BlackCat using exeinfo PE.

The tools HxD and Pestudnio were used in the BPA for file and signature analysis. The Hex view of the sample is provided in Fig. 27.

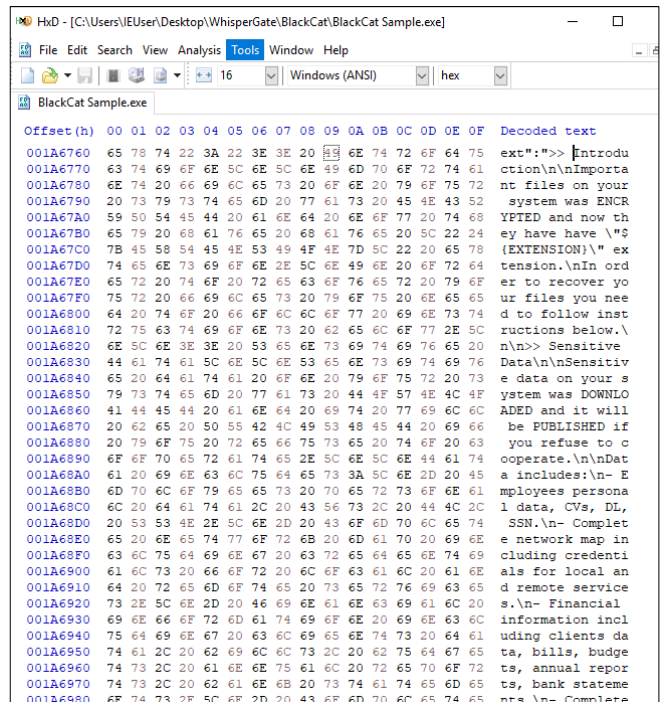

Fig. 27. Decoded text message of BlackCat using Hxd.

The findings revealed the malware to be a PE file with the following decoded text, as shown in Fig. 27: “Important files on your system were ENCRYPTED, and now they have, have. In order to recover your files, you need to follow the instructions below. Sensitive data on your system were downloaded, and they will be published if you refuse to cooperate. Data include: employees’ personal data, CVs, DL, SSN...Caution: do not modify files yourself. Do not use third party software to restore your data. You may damage your files; it will result in permanent data loss. Your data are strongly encrypted; you cannot decrypt it without a cipher key.”

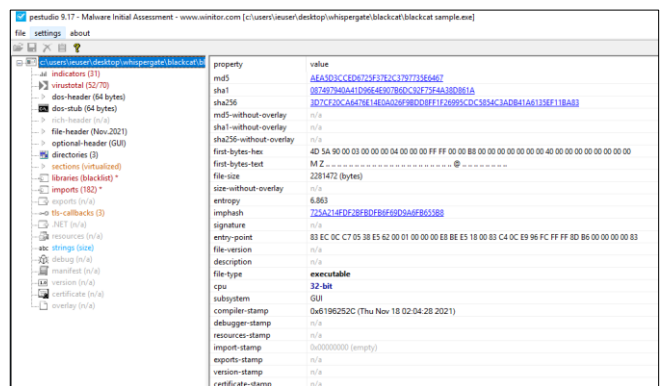

Fig. 28. PeStudio tool identifying the type of file.

After the signature identification, the tool PeStudio identified the type of file (Fig. 28). Based on the results, the file is built on a 32-bit CPU architecture with a file size of

2281472 bytes. In terms of hashing, the following values were obtained:

MD5 : AEA5D3CCED6725F37E2C3797735E6467

SHA-256: 087497940A41D96E4E907B6DC92F75F4 A38D 861°

SHA-1 : 3D7CF20CA6476E14E0A026F9BDD8FF1F26995C DC5854C3A

DB41A6135EF11BA83

The file was identified as a ransomware using Virustotal in the APU-based identification step, with a community score of 52/70.

String analysis through the tool PeStudio (Fig. 29) identified 13454 strings with 73 blacklisted. It was observed that the File-offset 0x0022C514 has a string value WriteFile. This is a critical finding that can assist in the advanced static analysis process.

encoding (2)	size (bytes)	file-offset	blacklist (73)	hint (208)	group (14)	value (13454)

ascii	18				execution	GetCurrentProcess

Fig. 29. String analysis of BlackCat using PeStudio.

In the advanced static analysis step, the tool IDA revealed the presence of GetCommanLineW, indicating the intended behavior of the sample when it utilized the command line for a specific task (Fig. 30).

00000000...	FreeConsole	KERNEL32
00000000...	FreeEnvironmentStringsW	KERNEL32
00000000...	FreeLibrary	KERNEL32
00000000...	GetCommandLineW	KERNEL32
00000000...	GetComputerNameW	KERNEL32

Fig. 30. Advanced static analysis step results using the tool IDA.

2) *Dynamic analysis:* To analyze the malware behavior, the tool ApatеDNS was used to monitor the DNS requests generated by the malware. However, no legitimate responses were identified (Fig. 31).

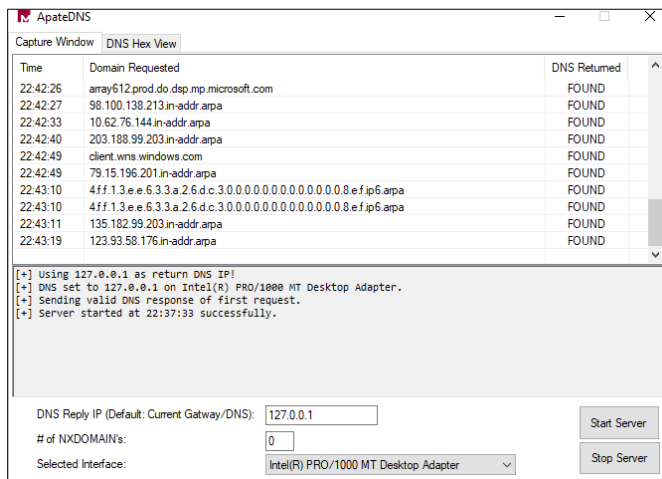

Fig. 31. DNS spoofing of BlackCat using the tool ApatеDNS.

The snapshot comparison tool Regshot was used to compare the snapshot of the registry before and after executing the executable (Fig. 32). The snapshots indicate the changes in the keys and values.

Fig. 32. The pre- and post-execution snapshots using regshot.

The tool Process Monitor was used for the process analysis, which revealed that 389633 processes were triggered on malware execution (Fig. 33). The CreateFile process was highlighted, but no such evidence of WriteFile was produced.

Fig. 33. The result from the tool process monitor with CreateFile highlighted.

In the subsequent step, the tool Regshot was used for registry and file analysis, which highlighted 138 changes (Fig. 34)

Fig. 34. Registry and file analysis using the tool regshot.

Using the ADA tool IDA, the snapshot revealed that the GetCommandLineW process imported a kernel-based library (Fig. 35).

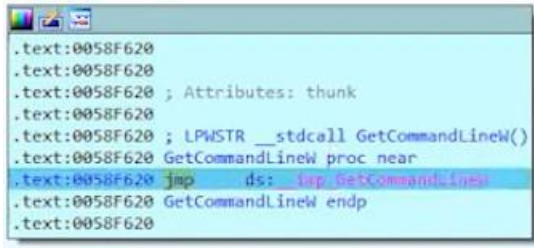

Fig. 35. Results of the snapshot using the tool IDA.

3) *Hybrid analysis:* In static analysis, information was gathered about the GetCommandLineW call. Through dynamic code analysis, the complete code was debugged to extract some useful keys: “h,” “p,” “e,” “-,” and “l.” By using the command prompt feature running ProcMon, it was surmised that the keys could be the instructions used in the command prompt, which could be executed to further examine the intended purpose (Fig. 36). Here, the command prompt executes the sample and passes a log file to a particular directory.

Fig. 36. Results from the command prompt running ProcMon.exe.

Fig. 37. Results from the tool process monitor.

When using the Process Monitor tool (Fig. 37), it was observed that the malware triggered almost 1.5 times (568,995) the number of processes executed by the same malware when compared to dynamic analysis (389,633). This time, the WriteFile operation was evident and confirmed based on the process executed through the command prompt. The directory set during the execution was successfully injected with the log file, thus corrupting the services.

Fig. 38. The wallpaper image dropped through the execution of the malware using cmd.

Once the file was executed through the cmd, it took 53 seconds to corrupt the services, along with dropping a note and wallpaper image (Fig. 38). This demonstrated the speed and potency of the malware in infecting the system.

4) *Memory analysis:* The tool AccessData FTK was used to capture the memory dump of the infected state (Fig. 39) at the initial memory acquisition step.

Fig. 39. Capturing the memory dump using the tool AccessData FTK.

Next, in the memory dump analysis step, the Processlist successfully showed the execution of the BlackCat sample in the infected memory dump (Fig. 40).

Fig. 40. Image showing the ProcessList upon execution.

Fig. 41. Image showing the ProcessList details for the malware sample.

The Processtree provides details such as the execution time and the offset value for the malware sample (Fig. 41). The command line operation shows the request to memory accessibility at a particular offset value (Process ID 3788 in Fig. 42).

Fig. 42. Image showing the result of the memory accessibility (PID 3788)

V. DISCUSSION

The proposed methodology is applicable for analyzing different malicious files. The case study provides a demonstration of malware analysis on WhisperGate and BlackCat. It is advisable for an analyst to prepare a summary report based on the experimental results of the sample. This section presents a report of the results relative to the two candidate pieces of malware used in the case study.

C. WhisperGate

The analysis of WhisperGate shows a deobfuscated .exe file with 32-bit CPU architecture carrying threatening information in a static approach. While performing dynamic analysis through the registry modification, the impact of malware was also noticeable. Its nature was identified through hybrid analysis that used both static and dynamic processes in which the malware overwrote the MBR. Changes in the disk led by the malware sample were observed through the offset mapping to the bootloader and driver images (Table III).

TABLE III. SUMMARY REPORT OF WHISPERGATE MALWARE

Static	Dynamic	Hybrid	Memory
An unpacked .exe file with a CPU architecture of 32 bits and threatening strings (message) was identified. The API-generated score of 54/69 indicates the presence of characteristics typical of ransomware and wipers. This finding allowed for classifying the malware as a suspicious file with a monetary purpose.	Post-execution impact was visible in the registry modification. Along with a trigger of 2,58,678 events, the WriteFile event brought attention to the modification/overwriting of the file.	Static analysis indicated a buffer 0x200 equal to 512 in decimal, which is indeed the size of MBR. Dynamic analysis generated a thread to overwrite 512 bytes of memory in the hard disk. This finding confirmed the nature of malware corrupting the MBR through overwriting	Virtual mapping of the offsets related to the BootLoaded and DriverImages brought attention to the possible changes in the disk.

Fig. 43 indicates the impact of running the malware sample WhisperGate showing the output “Your hard drive has been corrupted”. The sample overwrites the MBR and displays a ransom note demanding \$10k via cryptocurrency (“You should pay us \$10k via bitcoin wallet”), thus validating the experimental analysis.

Fig. 43. Image showing the impact of executing WhisperGate.

D. BlackCat

Like WhisperGate, the static analysis of BlackCat showed a deobfuscated .exe file with a 32-bit CPU architecture carrying a threatening note. The API score indicates that the sample is ransomware with a monetary purpose. Through registry modification performed in a dynamic approach, the use of the command prompt by the sample was observed. During the hybrid approach, both key identifications used for executing the command prompt were performed by the malware along with a threatening message, indicating the malicious nature of the sample as ransomware. In memory analysis, the same result was revealed through the command line request for memory access (Table IV).

TABLE IV. SUMMARY REPORT OF BLACKCAT MALWARE

Static	Dynamic	Hybrid	Memory
An unpacked .exe file with a CPU architecture of 32 bits and threatening Strings (message) was identified. The API-generated score of 52/70 indicated the presence of characteristics typical of ransomware, and a Trojan classified the latter as a suspicious file with a monetary purpose.	Post-execution impact was visible in the registry modification. Along with a trigger of 3,89,633 events, a kernel-based library for the GetCommandLine function indicated the usage of the command prompt by the sample.	Static analysis helped identify keys that were then used for executing via the command prompt in the dynamic analysis. An injected log file encrypting files and a background image showing a threatening message confirmed the malicious nature of the ransomware.	Command line operation requesting memory accessibility indicated the suspicious nature of the sample.

Fig. 44 indicates the impact of running the malware sample BlackCat. The sample corrupted the directory and displayed a background image with a threatening note of the ransom, thus validating the results of the experimental analysis performed using static, dynamic, hybrid, and memory analysis.

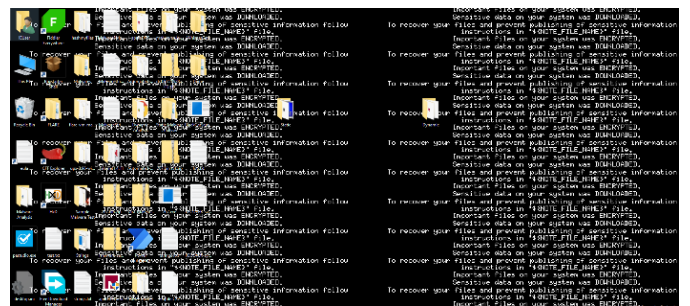

Fig. 44. Image showing the impact of executing BlackCat.

VI. CONCLUSION AND FUTURE WORK

The paper offers a comprehensive and practical approach to performing in-depth analyses of pseudo ransomware by illustrating two pieces of malware, namely WhisperGate (used in cyber warfare) and BlackCat (used to target critical organizations of target states). Twelve tools/techniques were selected, and a detailed description of the steps involved in the application, information extraction, analysis of results, and digital forensics is provided. The malware analysis was successfully executed through the use of static, dynamic, hybrid, and memory analysis and then validated. The detailed malware analysis using twelve tools revealed the embedded information and values in the malicious code for greater visibility and subsequent actions for information technology security personnel and forensic analysts. As malware attacks have rapidly risen with the appearance of innovative malware, the research demonstrated a successful methodology for analyzing potent malware through a comprehensive step-by-step approach. The work overcomes the limitations of relying on a single malware analysis technique thus providing a comprehensive approach to malware analysis.

WhisperGate came into the limelight at the beginning of 2022, when it was used to target multiple government and private organizations in Ukraine. The ransomware malware BlackCat was selected as a sample because it was reported to target European affiliations and U.S. organizations in late 2021. Out of the four malware analysis mentioned in the paper, hybrid analysis provided maximum information critical for the malware analyst to understand the extent of damage.

Three limitations have been observed in this study that can lead to further research. First, since only two pieces of malware (i.e., ransomware and pseudo ransomware) were observed, the experimented malware analysis methodology can be extended to diverse malware samples to validate the methodology. Secondly, since the study was limited to traditional malware analysis, appropriate machine learning methodologies can be deployed in future research to compare the findings with those obtained from traditional malware analysis. Thirdly, in this research, open-source tools were deployed for malware analysis that is already known to malicious hackers for circumventing the analysis process. Hence, future research can compare the results of open source tools with subscription based commercial tools.

A Cloud Native Framework for Real-time Pricing in e-Commerce

Archana Kumari¹, Mohan Kumar. S²

School of Engineering and Technology, CMR University, Bengaluru, India¹
Directorate of Research and Innovation, CMR University, Bengaluru, India²

Abstract—Real-time pricing is a form of 'dynamic pricing,' and it enables online sellers to adjust prices in real-time in response to variations in demand and competition to achieve higher revenue or improve customer satisfaction. As modern e-commerce implementations become more cloud-based, this paper proposes a cloud-native framework for a real-time pricing system. We take a requirement driven approach to come up with a modular architecture and a set of reusable components for real-time pricing. Following DSRM methodology, during the design phase, we identify and develop the theoretical foundations for key parts of the system, such as pricing models, competition and demand watchers, and other analytics components that fulfill the functional requirements of the system. At the stage of implementation, we describe how each of these components and the entire cloud application will be configured using an AWS cloud native implementation. As a framework, this work can support a variety of pricing models, demonstrating that multiple pricing models have been discussed. Other low-latency, reusable components described in this work provide the ability to react quickly to changes in demand and competition. We also provide a price-cache that decouples pricing model calculation from end-user price requests and keeps price query latency to a minimum. For a real-time system, where latency stands to be the most desired NFR, we validate the system for price-request latency (found to be a single digit of milliseconds) and market reaction latency (less than a second). Overall, our proposed framework provides a comprehensive solution for real-time pricing, which can be adapted to different business needs and can help online sellers optimize their pricing strategies.

Keywords—Real-time pricing; cloud-native design; system-design; pricing-framework; Amazon web services

I. INTRODUCTION

e-Commerce has become increasingly competitive; therefore, enterprises that intend to win must be able to offer their products and services at prices that are competitive with those of their rivals. Pricing is a crucial aspect of e-commerce, and proper pricing can help to attract and retain customers, increase sales and revenue, and optimize profits [1]. The term "dynamic pricing" refers to the practice of adjusting prices in response to fluctuations in supply, demand, and other factors in the market. Profits can be maximized, sales increased, customer happiness improved, and market share preserved by employing dynamic pricing [2]. Firms are looking to provide prices that are more personalized to each client by using a customer's location and purchase history, among other factors. Dynamic pricing is popular in industries other than e-commerce, including energy, transportation, and financial markets [3].

Real-time pricing is a form of dynamic pricing that involves adjusting prices in response to market factors as they take place in real time. Real-time pricing allows businesses to respond to market conditions in a near-instantaneous fashion, which can help them optimize their profits and minimize risk. By using real-time data, businesses can make more informed pricing decisions and ensure that they are not charging too much or too little for their goods or services [4].

Factors of Dynamic Pricing: Demand is the most important factor in dynamic pricing; when there is high demand, a company may be able to charge a higher price, and in the event of low demand, the company may need to lower the price in order to attract buyers. The amount of competition and what firms know about their prices can help them decide on pricing strategies like undercutting, matching, leading, or skimming. A company may use dynamic pricing to differentiate its prices based on customer segmentation. For example, a company may charge higher prices to customers who are more willing to pay, typically referred to as "myopic customers". Similarly, customer loyalty enables differentiated pricing, i.e., if a company has a loyal customer base, it may be able to charge a higher price for its products or services. Another crucial factor is the level of inventory, i.e., if a company has a limited supply of a product, it may be able to charge a higher price due to the scarcity of the product. Other pricing factors may include seasonality, time of day or week, weather, choice of payment methods, etc. [1] [2].

Cloud technology has undergone significant advancement in recent years, and there are several key developments like containers, serverless computing, AI/ML & IoT etc. The adoption of cloud computing has been growing rapidly in recent years. According to a report by IDC, global spending on cloud services is expected to reach \$1.3 trillion in 2025, up from \$706 billion in 2021 [5]. Cloud computing is increasingly important for businesses as they look to take advantage of cost savings, increased agility and flexibility, and improved scalability and reliability. A wide range of online businesses leverage cloud infrastructure to host stores, manage transactions, and offer integrations and extensions to customize and optimize their online presence [6]. Cloud native refers to a method of developing and deploying applications that fully utilize the cloud computing paradigm. Two popular cloud-native application development paradigms are: 1) Microservices architecture splits an e-commerce platform into discrete services that may be independently developed, deployed, and scaled [7]. 2) Serverless architecture leverages cloud services such as AWS Lambda to manage infrastructure

and run programs without servers. This decreases expenses and improves company agility [8].

A wide range of e-commerce businesses use cloud computing. Amazon's online business runs almost entirely on AWS [9], a platform that hosts and oversees its online store and other operations. Alibaba utilizes the cloud to power its operations on Alibaba Cloud, which handles and maintains all the company's business operations, including its e-commerce platform [10]. Apart from e-commerce businesses, there are cloud-based e-commerce platforms that host and administer online stores. Shopify [11] and Magento [12] are such popular e-commerce platform for establishing and managing online stores [11]. It leverages cloud infrastructure to host stores and manage transactions, and offers integrations and extensions to customize and optimize its online presence.

Real-time pricing has the potential to improve revenue and give businesses real-time control over prices. However, its implementation poses challenges such as real-time decision-making, managing large volumes of data, achieving scalability, and accommodating diverse product types. Cloud-native technology has become the preferred platform for contemporary e-commerce development, and designing a cloud-native application can help address many of these challenges. To increase adoption of real-time pricing by sellers, it is important to solve the challenge of real-time decision-making and develop a reusable framework that can be used for different e-commerce product types. The objective of this paper is to develop a framework for a real-time pricing system that helps online stores optimize revenues or other business specific pricing requirements. We will begin by identifying the requirements and specifications, using them to guide the design and build the necessary functional foundation. To implement the framework, we will use cloud-native technology, which offers cost-effectiveness, scalability, and quick time-to-market. In addition, we will follow the philosophy of "meeting customers where they are", by implementing the system on a popular cloud platform. Specifically, we have chosen AWS, which is currently the most widely used cloud solution.

The remaining sections of this paper are organized as follows: Section II surveys the existing literature, explores all the different types of work that has been carried out in the field of dynamic pricing. There we will also identify the lack of system design and implementation work in the existing literature, among other things as a research gap. The methodology and system requirements are discussed in Section III and Section IV, respectively. Section V presents the high-level design of the real-time pricing system, while Section VI focuses on the cloud-native implementation of the same. The results of this study are discussed in Section VII, and Section VIII provides the conclusion and potential future work.

II. LITERATURE REVIEW AND RESEARCH GAP

A. Background of Dynamic Pricing in e-Commerce

Dynamic pricing is a multi-disciplinary research area as it involves the integration of knowledge and techniques from multiple fields, including economics, mathematics, statistics, computer science, and behavioral psychology [13]. The primary goal of dynamic pricing is to adjust prices based on

various factors such as supply and demand, competition, and customer behavior, to remain competitive in the market [14]. Dynamic Pricing implementation may involve statistic, algorithms, and machine learning techniques to predict demand and adjust prices accordingly [15]. Dynamic pricing has several benefits, including increased sales, improved profit margins, and better customer satisfaction [16].

B. Algorithms for Dynamic Pricing

1) *Rule-based pricing*: This is dynamic pricing based on predefined rules and conditions that adjusts prices for goods and services accordingly. In this strategy prices are dynamically determined on factors such as demand, supply, competition, time of day, and other market conditions. [17].

2) *Competition pricing*: This refers to the practice of basing prices on those offered by competitors. It can be an effective strategy for a low-cost supplier entering a new market. However, blindly following competitive pricing can hinder a company's ability to capitalize on shifting customer perceptions of value and brand differentiation. [18].

3) *Linear programming approaches*: In order to maximize revenue, profit, or market share, among other business goals, linear programming can be used to optimize pricing decisions over time. Linear programming for dynamic pricing seeks to maximize a predetermined objective function by first developing a pricing model that factors in several factors, including but not limited to customer demand, product availability, and competitive pressure [19][20].

4) *Statistical and machine learning approaches*: (non) Linear regression can be used in dynamic pricing to model the relationship between the price of the product or service and the demand for it. One can collect data on past sales and prices and use it to train a linear regression model and possibly optimize sales revenues (or profit) based on a parametric model using (non) linear regression [21]. Machine learning algorithms like reinforcement learning (RL, which is typically used to maximize rewards in games) have the potential to solve dynamic pricing problems in various scenarios like varying demand and competitive settings. [22].

C. Cloud Native based Application Development

Cloud-native technology is becoming more popular as businesses seek ways to build and deploy software applications that can handle high traffic, frequent updates, and rapid scaling. Gannon et al. define cloud-native as the practice of developing and deploying highly scalable, resilient, and secure cloud-based software [23]. Cloud has popularized microservices that divides a larger application into smaller, more manageable services that can be built, deployed, and scaled independently. Kubernetes is an open-source container orchestration platform that automates the deployment, scaling, and management of containerized applications [24]. The current academic literature lists some interesting case studies conducted with cloud native technology. Using technologies such as microservice architecture, event-driven architecture, domain-driven design, and containerization, Pan et al. schedule CPU and GPU resources for their cloud-native online judge system [25]. A cloud-native smart operation management platform

architecture is proposed by Lang et al., which would centralize the technical architecture and data interaction of various operation subsystems [26].

D. Research Gaps

Although several studies have been conducted on pricing strategies for e-commerce, there is a lack of research that specifically addresses real-time pricing systems that can adapt to changing market conditions and customer types in real-time. There is also a lack of studies that examine the technical aspects of implementing real-time pricing systems, such as the selection of appropriate technology platforms, pricing algorithms and building reusable components.

III. METHOD

For this work, we use DSRM (Design Science Research Methodology), a research paradigm that emphasizes the generation and validation of prescriptive knowledge. Design science is a serious research approach for creating solutions to real-world engineering issues. As contrasted with how things are in the natural sciences, DSRM is concerned with how things ought to be, that is, with creating artifacts to accomplish things. The steps of the DSRM [27] process include problem identification and motivation, specification of the solution's objectives (requirements), design and implementation, demonstration, evaluation, and communication. Algorithms, user interfaces for computers and people, design approaches (including process models), and languages are among the kinds of artifacts for which design science research is often used. For this work, problem identification and motivation for a real-time pricing system have already been established (in the first section), for the next few sections, we are going to cover requirement, design, implementation, result analysis and will provide conclusion.

IV. REQUIREMENTS

A. Functional Requirement

FR1: A real-time pricing system should provide a suitable price, as per the business need, that optimizes revenue, customer experience or stakeholder's expectations.

FR2: Price should be able to be derived from one or more factors: market factors (demand, competition prices), inventory level, and possibly different customer segments.

B. Non-functional Requirement

NFR1: Configurability/Reusability - Depending on the product type and its current state in the product lifecycle, more than one pricing logic may be configured to run; i.e., the framework should have the ability to switch to different pricing logic.

NFR2: Response latency - Pricing response should be quick, and there should be very minimal deterioration in the price lookup.

NFR3: Reactive Latency - System should react to changes in factors listed in FR2 in an automated fashion within an acceptable time-frame.

NFR-4: Asses the aspects of availability, scalability, and infrastructure cost.

V. DESIGN

This section explains the theoretical design for a real-time pricing system that meets the functional requirement established in the previous section, as well as how it paves a way out for NFRs.

A. Typical Setup of Pricing-module in an e-commerce Application

In a typical e-commerce setup, the user interacts with the catalogue service, which sends them a list of products along with information like the price and the product's description. A product may have a static (fixed) price or be dynamically priced. When there is static pricing, a special database created just for this purpose provides the price data to the catalogue service. When there is dynamic pricing, the prices might need to be calculated on the fly. The catalogue service should contact the pricing service to learn the item's price. Fig. 1 provides an illustration of this variation. Even though dynamic pricing can automate the price generation process, a trivial implementation may result in longer "price-response" latencies and higher computational costs.

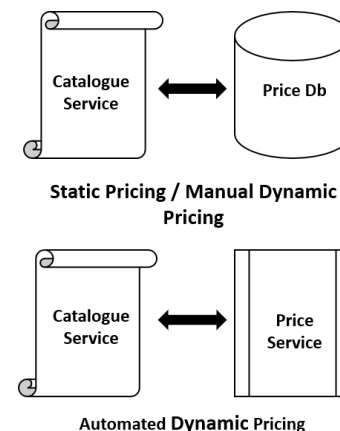

Fig. 1. Static vs dynamic pricing implementation.

B. Pricing Service - High Level Design

The functional requirements (FR1 and FR2) served as our inspiration for the high-level design of the pricing service that is presented below (Fig. 2). The pricing model is in charge of determining the prices. The model may be dependent on inventory, demand, and price competition. By depicting the components in Fig. 2 as distinct parts, we suggest that they can all function concurrently and prefetch/prebuild all the input required by the pricing model. The use of a pricing cache eliminates the need to invoke the pricing model, as it serves cached the pricing results produced by the model to the catalogue service.

Fig. 2. HLD for real-time pricing system.

C. Component Design

1) *Competition watcher*: The competition watcher component has the responsibility of routinely monitoring and reporting changes in competition prices. The interval at which the “competition watcher” can detect a change in competition prices will determine how quickly the real-time pricing system responds to market prices. A trivial design for this component would be to poll the market for prices at regular intervals. Better reactive latency (FR3) would result from shorter polling intervals, but at the cost of higher computational costs. An ideal polling frequency would be determined by considering how frequently the competition changes their prices. Let us say a competitor increases the price of her product at a rate of λ , Poisson's theorem can be used to calculate the probability that the price (PCP_t) will change during the period t. (shown in Eq.(1)).

$$PCP_t = 1 - e^{-\lambda t} \quad (1)$$

PCP_t becomes an input configuration parameter for the system for a given competitor; let us call it the desired probability (to detect the competition price change, denoted by DP). This helps figure out the polling interval for which the probability of competition price change is configured.

$$Polling\ Interval, T = \frac{\ln(\frac{1}{1-DP})}{\lambda} \quad (2)$$

Initially rate λ is unknown and can be trivially calculated by polling at a small period during the initial setup phase. Once λ is known, Polling interval T can be found using Eq. 2, and should be used to poll the prices. Should competition later increase the frequency of price change, it would be seen by the competition watcher that, number of price changes in the interval T, is more than 1/DP, and that would trigger a re-calculation of λ . When there are fewer samples than 1/DP in the competition prices, this means the competition has decreased their price change rate, and a new polling interval can be calculated using Eq. (2) again.

2) *Demand watcher*: Unlike in competition, where price changes can occur all at once and must be monitored at short intervals, the demand can be calculated once, for a specific time period, such as the previous hour or day. There could be two potential indicators of demand: 1) the price request rate and 2) the item sale rate. However, our understanding is that, sale is also a function of price, and price is variable; thus, in this work, we only consider the first one, i.e., the rate of incoming requests, as an indicator of demand. The architecture influences demand estimation procedure; however, the two most common approaches are:

- *Transaction database query*: Transaction databases are mostly relational databases with transaction time as an index. Using an SQL query, it is trivial for such a database to get the number of transactions in a certain time frame.
- *Transaction stream accumulators*: Another approach is to stream the transaction as it occurs and store the summary in a database table. This method is useful when there is no database from which to obtain information.

3) *Other analytics*: The pricing models (many of it) need analytics data, for example sale-probability, customer segments, existing inventory (or projection of upcoming replenishment). Most of the analytics do not change very frequently and hence computing them once (say daily) would suffice.

D. Pricing Models

1) *Rule base pricing*: This style of pricing involves the dynamic adjustment of a product's price in accordance with a predetermined set of rules. Such a rule may be formed by a combination of supply and demand, time of day, day of the week, and supply and demand alone. One straightforward illustration of this is to raise the price of the product during periods of high demand and lower it during periods of low demand. The model can react instantly to changes in market factors by automatically changing prices in accordance with a predetermined set of rules. The pricing logic in this method is typically quite simple; the main challenge is retrieving underlying factors like supply and demand.

2) *Competition pricing*: The term "competition-based pricing" refers to a pricing approach in which a company's prices change over time in response to the prices offered by its rivals. This strategy can be used to stay competitive in a market by matching or beating the prices of other companies. The implementation for this model has just one dependency, i.e., access to competition prices.

3) *Linear regression*: This pricing strategy uses linear regression analysis to ascertain the connection between prices and demand for a product. This can assist in identifying a product's ideal price point in order to maximize sales or profits. The first step is to use historical sales and pricing data to train a linear regression model that can forecast demand based on various prices. Different linear regression methods,

such as simple linear regression, multiple linear regression, and sophisticated techniques, can be used to train the model. The product's demand is then predicted at various price points using the model, which is then used to determine the price that will generate the most revenue (or profits).

$$\text{Price} = b_0 + b_1 \cdot \text{Demand} + b_2 \cdot \text{CompPrice} + b_3 \cdot \text{Time} \quad (3)$$

Eq. (3) shows the outcome of linear regression analysis, is an expression that can be programmed into pricing model to calculate prices over the period of the time. In the equation, b_0 represents the baseline price of the product, b_1 represents the elasticity of demand, b_2 represents the effect of competition on price, and b_3 represents the effect of time of day on price.

4) *Linear programming*: Linear programming (LP) is an optimization method in which the objective function and all constraints are linear. Linear programming dynamic pricing is a pricing strategy that employs linear programming to calculate the best price for a product. The dynamic pricing problem can be expressed as a linear program, with the goal of maximizing revenue or profits while keeping prices, demand, and costs in check. The objective function and constraints are expressed as linear equations, with the solution being the set of prices that maximizes the objective function [19] (Eq. (4)) while satisfying all constraints (Eq. (5) to Eq. (9)).

$$Y_{(\text{revenue})} = \sum_{t=1}^{t=T} \sum_{k=1}^2 P_t Q_{tk} S_{tk} \quad (4)$$

Constraints:

$$\forall k \in K, RC_k \geq \sum Q_{tk} \quad (5)$$

$$T_{(\text{target sale})} \geq \sum_{t=1}^{t=T} \sum_{k=1}^2 Q_{tk} S_{tk} \quad (6)$$

$$1 = \sum_{k=1}^2 C_k \quad (7)$$

$$P_t := \{P_t \in \mathbb{R}^n \mid P_{\min} \leq P_t \leq P_{\max}\} \quad (8)$$

$$Q_{tk} := \{Q_{tk} \in \mathbb{Z}^{m \times n} \mid 0 \leq Q_{tk}\} \quad (9)$$

Where:

R is the total expected number of price requests across k customer segments.

K is the customer segments ($K = 2$ for myopic and strategic customers setup),

C_k is the ratio of expected request count in the customer category (k) and total requests.

Q_{tk} is number of price response by the DP engine with price P_t in customer segment k . (This is LP Variable).

P_t is the price point to offer, its range is P_{\min} and P_{\max} .

S_{tk} is the sale probability at price P_t , customer segment k .

E. Pricing Cache

Client price requests for a product many times more frequent than change in market factors hence the price calculated by model can be cached to avoid the model invocation time, which is not just time but also computationally expensive. Pricing cache decouples the

expensive pricing process from servicing the pricing. If cache is not used, price request latency is given by 10, i.e., sum of latencies of model evaluation and sum of all the analytic fetch.

$$Lat_{pr} = Lat_{\text{price-model}} + \sum Lat_{\text{analytics}} \quad (10)$$

By using the cache, the price-request-latency simply becomes the latency of cache lookup (11).

$$Lat_{pr} = Lat_{\text{cache}} \quad (11)$$

Please note that, the pricing cache is considered large enough to hold the calculated pricing results for all the items, and hence cache miss penalties are not considered.

F. Product Module

A product module is a component or module that manages and provides access to product information. This includes information such as the pricing model, minimum and maximum price settings, available inventory, price exploration factor, and any other relevant settings required for the product's pricing model to function. This data is typically stationary and varies infrequently (say, monthly or quarterly). Also note that the product module does not need to be exclusive to pricing system; it can be shared across other e-commerce services (such as catalogue, order etc).

VI. AWS CLOUD IMPLEMENTATION

We will go over the specifics of this work's cloud implementation in this section. Real-time pricing system implementation requires compute, a database, and the ability to react to events. Most cloud service providers can easily meet these requirements, but we have chosen to implement AWS for the proof-of-concept and because it is the most widely used cloud service. Python was used exclusively throughout the work to program everything.

A. A Quick Review of AWS Services

Amazon Elastic Compute Cloud (EC2) is an AWS web service that allows users to rent virtual computers to run their own computer programs. Elastic Container Service (ECS) is a fully managed container orchestration service that allows you to run and scale containerized applications on a cluster of EC2 instances using Docker and Kubernetes. Amazon Elastic Container Registry (ECR) is a fully managed Docker container registry hosted by Amazon Web Services (AWS). Docker images can be safely and saleably stored, managed, and deployed using ECR. EventBridge is a serverless event bus service that connects applications by automating event scheduling and routing from sources such as DynamoDB to destinations such as Lambda functions, Lambda is a serverless computing service that allows you to run code without the need for server provisioning or management. Lambda-powered applications can respond to events and run functions automatically in response to triggers such as changes to data in DynamoDB or an EventBridge-triggered event. Lambda does have some limitations, such as a maximum amount of memory and limited concurrency, which should be considered for scalability. DynamoDB is a fully managed NoSQL key-value and document database that scales to provide millisecond performance. It is an excellent choice for applications that require consistent, fast performance as well as the ability to

manage large amounts of data. Applications can use DynamoDB Streams to react to changes in DynamoDB tables and invoke AWS Lambda to handle the change [28].

B. Component Implementation

1) *Competition watcher*: The goal of the Competition Watcher software is to obtain competitor product pricing information by scraping competitor websites. Web-scraping tools are commonly used for this purpose. Several libraries and frameworks, such as “Beautiful Soup,” [29] “Scrapy,” and “Selenium,” are available for web scraping in the Python programming language. Under Amazon Web Services, there are two possibilities for designing and building this:

a) *Event-bridge-based periodic Lambda invocation*: EventBridge allows you to schedule a Lambda for a specific time (Say every 30 minutes). Lambda executes the web scraping business logic and updates the competition prices in DynamoDB. DynamoDB Stream can then be used to retrigger the pricing process by triggering a lambda function.

b) *Docker workflow with ECS, ECR (running on EC2)*: In this approach, web-scraping logic is executed in a Docker container powered by EC2, ECS, and ECR Services to retrieve competition prices, detect changes, and store in DynamoDB. A DynamoDB stream, like the previous option, can be used to trigger a lambda function for pricing. This process can monitor hundreds of products, making it more cost-effective for large e-commerce setups.

2) *Demand watcher*: The demand watcher watches the ongoing demand periodically, and if there is a change in the demand, it is supposed to trigger the repricing by invoking the lambda function. Demand Watcher implementation is dependent on E-Commerce architecture implementation. Assume that E-commerce architecture has a database table called REQUEST and a REQUEST_TIME index on it. Demand SQL expression is shown in Fig. 3.

```
SELECT count(*) from REQUEST
where REQUEST_TIME > Now()-POLL_WINDOW
```

Fig. 3. Demand calculation in a period using existing RDBMS DB.

In many use cases, the above approach would work, except when users want more real-time demand tracking. The alternative is to use streaming analytics, for this purpose, first, the incoming price requests can be posted to a Kinesis analytics stream. This stream has a consumer, a lambda function that is configured with batch triggers on Kinesis updates. The lambda analyses and records the demand information in real-time into a DynamoDB. Dynamodb stream then triggers the pricing function to recalculate the price for the new demand (Fig. 4).

3) *Customer segmentation and sale probability*: For the analytics that do not change in real-time, like sale-probability and customer-segments, in order to be cost-effective, the framework would compute these periodically (say, once a day). We use the price request stream and order stream, and register lambda triggers (with the largest possible batch

size/window, i.e., 5K records and 5 minutes). Both the lambdas add/update the entries in the Analytics table (Fig. 5). Their logic updates and aggregates the incoming stream in the format shown in Table I. This serves as the common source for segmentation and sale probability calculators. Customer segmentation is done by aggregating the analytics table by customer-id and the ratio of purchases to requests. Those with a higher purchase to request ratio are classified as myopic, while the rest are classified as strategic. Table II shows DynamoDB schema for customer segmentation table. Sale-probability is calculated as sale to request ratio for each segment and at each price points. Table III displays the schema for DynamoDB table for the same. Please Note, since DynamoDB is a KV store, probability data is stored in json format, and pricing-model is expected to deserialize that before using.

TABLE I. ANALYTICS TABLE SCHEMA

Date	String	String	Float	Bool
Date	Cust-id	Product	Price	Purchased

Fig. 8. Competition pricing tracking.

Fig. 9. Competition response latency.

Fig. 10. Rule-based dynamic pricing.

Fig. 11 and 12 are the simulation outcomes for the linear programming-based pricing model. The solution for objective function (Eq. (4)) and constraint (Eq. (5) to Eq. (9)) can change the prices for changing demand or target sale-quantities and

maximize the revenue under the different circumstances. Fig. 11 shows optimal prices for different values of target sale-quantity, and Fig. 12 shows the same different demand values.

Fig. 13 and Fig. 14 explain the content and performance of the price cache. Fig. 13 is a snippet taken from AWS console depicting the content of price cache. Key shown in the Fig. 13 is the product-id, and the json value provides the price values for myopic and strategic customer.

It also has a default value, which is useful in situation when pricing-model is yet to provide any pricing value. Fig. 14 shows our typical distribution of price-request latency when using DynamoDB as a pricing cache. The latency is single-digit millisecond latency and comparable to static-pricing scenarios.

VIII. CONCLUSION

A. Summary and Discussion

Real-time pricing can help e-commerce owners; however, implementation requires careful handling of multiple requirements in order to perform dynamic pricing in real-time. Through this work, we defined functional and non-functional requirements and used them to guide our system design process. We created a pricing framework that can potentially provide the most suitable price for various products at different stages of their product lifecycle while taking a variety of market factors such as demand and competition into consideration (satisfying functional requirements FR1 and FR2).

The components (e.g., demand watcher, competition price fetcher, cache) are reusable, concurrent (designed with separation of concerns in mind), and allow plug-and-play of different pricing logic through the defined database schema (satisfies NFR1). By the virtue of design decision, price response latency (NFR2) equals to a cache-lookup which is similar to systems without dynamic pricing. The cache latency can further be improved (if required) by using DynamoDB-DAX [30]. It has been demonstrated in the result that, system response to any price change is within a single second, an acceptable latency in the context of e-commerce (NFR3). The cloud native building blocks (DynamoDB, lambda, etc.) inherently provide availability and scalability to our design and with the pay-as-you-go model for cost, cloud-native design satisfies the last one, NFR-4.

B. Research Contributions

Real-time e-commerce pricing is a relatively unexplored academic field. In the research gap analysis, we did not find any implementation-specific work, which emphasizes the timeliness of the pricing. As our first research contribution, we have been able to apply existing knowledge of 'dynamic pricing' to methodologically specify, design, and implement a real-time pricing system.

Other contribution of this research is the demonstration of cloud-native design principles for the implementation of real-time pricing. The framework provides, unlike anything else in the published literature, a low-cost (pay as you go) and scalable solution for real-time pricing by making use of cloud

implementation methodologies. By providing the ability to plug-and-play a pricing model for different e-commerce use-cases, the framework does not enforce 'one-size-fits-all', but rather promises flexibility while maintaining the reusability of building blocks.

C. Future Work

The primary goal of this work is to create a framework for a real-time pricing system, which has been demonstrated in the implementation and results section. However, because real-time pricing for e-commerce is going to evolve further, there are a few opportunities for future work:

- There is an opportunity to improve the analytics described by performing some finer optimizations. To give an example, advanced statistical techniques can be used to provide more accurate results for sale-probability estimation. Similarly, sophisticated forecasting techniques can be utilized to predict demand, which will help price the product more efficiently over the long run.
- Another potential area of research can be conducted on pricing models and their selection in the context of real-time pricing and cloud native. Models can be fast or time-consuming and may have different memory and compute requirements, leading to deployment choices such as serverless or containers.

A Deep Learning Approach for Sentiment Classification of COVID-19 Vaccination Tweets

Haidi Said¹, BenBella S. Tawfik², Mohamed A. Makhoulouf³

Department of Information Systems-Faculty of Computers and Informatics, Suez Canal University, Ismailia, Egypt^{1,2,3}

Abstract—Now-a-days, social media platforms enable people to continuously express their opinions and thoughts about different topics. Monitoring and analyzing the sentiments of people is essential for governments and business organizations to better understand people's feelings and thoughts. The Coronavirus disease 2019 (COVID-19) has been one of the most trending topics on social media over the last two years. Consequently, one of the preventative measures to control and prevent the spread of the virus was vaccination. A dataset was formed by collecting tweets from Twitter for over a month from November 13th to December 31st, 2021. After data cleaning, the tweets were assigned a positive, negative, or neutral label using a natural language processing (NLP) sentiment analysis tool. This study aims to analyze people's public opinion towards the vaccination process against COVID-19. To fulfil this goal, an ensemble model based on deep learning (LSTM-2BiGRU) is proposed that combines long short-term memory (LSTM) and bidirectional gated recurrent unit (BiGRU). The performance of the proposed model is compared to five traditional machine learning models, two deep learning models in addition to state-of-the-art models. By comparing the results of the models used in this study, the results reveal that the proposed model outperforms all the machine and deep learning models employed in this work with a 92.46% accuracy score. This study also shows that the number of tweets that involve neutral, positive, and negative sentiments is 517496 (37%) tweets, 484258 (34%) tweets, and 409570 (29%) tweets, respectively. The findings indicate that the number of people carrying neutral sentiments towards COVID-19 immunization through vaccines is the highest among others.

Keywords—COVID-19 vaccination; sentiment analysis; Twitter; machine learning; deep learning; natural language processing (NLP)

I. INTRODUCTION

Recently, the massive amount of data generated by users on social media platforms and advances in computational power provide a strong impetus for sentiment analysis to develop and become the top research field under natural language processing (NLP) [1]. Sentiment analysis (SA), also known as sentiment or opinion mining, is the computational analysis of people's opinions and emotions about different topics [2]. This automatic analysis plays a significant role in extracting useful insights for decision-makers in various application domains. SA is a research field that aspires to understand and extract the sentiment of unstructured content. This content can be text, audio, image, or video. Following the technical definition of sentiment analysis introduced by [3], in this sentence, "Mark likes the camera of Samsung S10", here Mark acts as the opinion holder expressing his positive sentiment towards the

aspect camera of entity Samsung S10. SA uses NLP, and machine learning (ML) techniques to extract the subjective information of a document and classify it according to its opinion orientation or polarity which can be positive, negative, or neutral. Subjective information carries only sentiments about a particular topic or entity, while objective text contains facts with no sentiments [4]. For instance, "Star Wars is an awesome movie". This sentence has a sentiment (awesome); thus, it is a subjective text, not an objective.

The explosive growth of social media applications (e.g., Facebook, Instagram, Twitter) witnessed today opens the door for a continuous stream of opinions and thoughts [5]. This Internet-generated content enables people to communicate with each other by sharing their sentiments and how they feel in the form of opinions or reviews about any topic. This consequently leads to the generation of an enormous amount of unstructured data. Business organizations need to process and analyze this data to support them in their decision making by gaining deeper insights into user sentiments, which will accordingly improve customer satisfaction. Furthermore, the study of public opinion about a specific topic or issue is very important to governments for the study of human activity and behavior as well as crisis management. Sentiment analysis provides governments with the valuable information necessary to take true actions in time.

Monitoring and analyzing the opinions and sentiments for extracting valuable information from them manually is a challenging task, in terms of time and exerted effort, due to the boom of various internet-based applications and sites. So, automated sentiment analysis or opinion mining systems are required to overcome this problem. Several machine learning and natural language processing-based approaches have been proposed to analyze these sentiments. However, recently deep learning-based approaches have shown significant results and higher performance in the field of sentiment analysis [6].

COVID-19 has dramatically affected every aspect of our lives and was declared a worldwide pandemic by the World Health Organization (WHO) [7]. Vaccination against COVID-19 was introduced as an urgent solution to prevent the spread of the disease among people and reduce death rates [8]. Therefore, analyzing the sentiments of people towards COVID-19 vaccination is essential for governments and health ministries to understand the public mood of people regarding the vaccination process against that virus. Consequently, vaccine campaigns can be developed targeting the hesitant and anti-vaccine groups of people to raise their awareness about the pivotal role of vaccines and boosters in containing the pandemic.

A long short-term memory (LSTM) is an extension of recurrent neural network (RNN). LSTMs can handle long-term dependencies between time steps of sequential data [9]. A Bidirectional gated recurrent unit (BiGRU) is used to learn features in both directions to produce a more meaningful output. This study combines the strengths of LSTM and BiGRU models to enhance the accuracy of sentiment classification. To the best of our knowledge, several studies navigated the public views regarding the COVID-19 vaccines before November 2021 [10-13]. However, many important events related to COVID-19 vaccines have occurred after this date, like the emergence of the Omicron variant [14] as well as boosters. Therefore, to fill this gap, we analyzed the tweets related to COVID-19 vaccination during this period of time to fully understand the public mood and perspectives towards COVID-19 vaccination acceptance or hesitancy. The main contributions of this study are as follows:

- Creating and preparing a large dataset of 4,093,986 tweets related to COVID-19 vaccination and vaccines for the sentiment classification task.
- Visualizing and analyzing the sentiments of people about the topic of COVID-19 vaccination.
- Proposing a hybrid approach to determine people's thoughts and opinions towards COVID-19 vaccination. The collected dataset was labeled using Valence Aware Dictionary and sEntiment Reasoner (VADER) lexicon-based approach. Moreover, Conventional machine learning classifiers were trained on the annotated dataset and tested on unseen data to evaluate their performance.
- Improving the classification accuracy by introducing an ensemble model (LSTM-2BiGRU), combining long short-term memory and bidirectional gated recurrent unit.
- A performance comparison of the proposed model with traditional machine learning classifiers, two individual deep learning models (LSTM, BiGRU), and state-of-the-art models to identify the top performer model on our collected dataset.

The rest of the paper is organized as follows: Section II provides an overview of the related work to our study. The subsequent section describes the dataset and methods used in the study. The fourth section presents and discusses the results of the conducted experiments. Finally, the last section concludes and summarizes the paper.

II. RELATED WORK

COVID-19 has seriously affected the daily lives of people in different sectors of life [15]. As a result, several studies were conducted to analyze people's sentiments towards COVID-19 and its related aspects. For example, the study in [16] focused on analyzing and understanding the sentiments of the Canadian people towards social distancing related to COVID-19 using a hybrid approach. They used SentiStrength, a lexicon-based approach, with Support Vector Machine (SVM), a machine learning approach, for sentiment analysis. To perform this study, they collected Twitter data for one month from an open-

source publicly available IEEE website. They applied the SVM algorithm by splitting the dataset into 80% for training and 20% for testing the data. Their experiment resulted in 71% accuracy for sentiment classification. By excluding the neutral sentiments from data, the accuracy of the model rose to 81%. Additionally, the accuracy reached 87% by reducing the test data to 10%. The results showed that 40% of the Canadian people have neutral sentiments, followed by 35% expressed negative sentiments and only 25% have positive sentiments towards social distancing. One of the limitations they faced during the study was the insufficient number of training examples.

The authors in [17] compared the effectiveness of two machine learning models, Naïve Bayes (NB), and logistic regression (LR), on Twitter data of varying lengths collected from February to March of 2020. The collected data was cleaned and prepared for analysis using the R programming language and its related packages. NB achieved 91% accuracy with short tweets (less than 77 characters), while the accuracy obtained using the logistic regression model was 74% with short tweets. However, the performance of both models (Naïve Bayes and logistic regression) significantly decreased to 57% and 52%, respectively, in the case of longer tweets. For future work, the authors of this work recommended extending this study with more data and additional methods. This will consequently help policy makers and businesses in understanding the public sentiment and perspectives for making the right decisions in time.

The study in [18] performed a sentiment classification task on 3090 tweets collected from 23 March to 15 July 2020. The collected text was labeled as fear, sad, anger, and joy. Each sentiment was mapped from 0 to 3 (fear:0, sad:1, anger:2, joy:3). They applied a new deep learning model called Bidirectional Encoder Representations from Transformers (BERT). They compared it to three other classification algorithms: LR, SVM, and LSTM. For all the classifiers, they split the dataset into 85% for training and the remaining 15% was used for testing purposes. Their experiment showed that the BERT model outperformed the other models by having 89% accuracy, whereas the other three models scored 75%, 74.775%, and 65%, respectively.

In [19], logistic regression and LSTM learning models were used along with two different word embedding techniques: CountVectorizer and TfidfVectorizer to analyze and study people's attitude towards COVID-19. The dataset used in this study consists of tweets collected from 03/16/2020 to 04/14/2020. The author used only original tweet and label columns from the given columns in the dataset to investigate people's reactions towards COVID-19 during this period of time. The data was initially labeled as five classes (positive, extremely positive, negative, extremely negative, and neutral) but the author manually grouped them into three classes (positive, negative, and neutral) for more precise classification. Then in the featurization stage, the original tweets were pre-processed and vectorized using the previously mentioned two vectorization methods. After that, logistic regression and LSTM models were used to classify the sentiments of the given COVID-19 related tweets. The LSTM/TF-IDF model achieved the best result with an F1 score of 0.85.

The authors in [20] used the keyword “COVID-19” to search tweets on Weibo, one of the largest Chinese social media platforms, and collected 45,987 tweets. They used a lexicon-based approach for sentiment analysis by matching their dataset with words in the sentiment dictionary. BosonNLP sentiment dictionary was selected in this study as it supports the Chinese language and is constructed from millions of labeled data, including Weibo, news, forum data, and others. For future work, they suggest combining their approach with deep learning (DL) or random forest (RF) classifier to achieve more accurate sentiment prediction results. Kuar et al. devised an algorithm called Hybrid Heterogeneous Support Vector Machine (H-SVM) that performs sentiment classification on COVID-19 tweets in study [21]. They compared the performance of their proposed algorithm with RNN and SVM. The H-SVM model outperformed the other two models in terms of precision (86%), recall (69%), and F1 score (77%).

In [22], the authors proposed a feature extraction technique by concatenating bag-of-words (BoW) and term frequency – inverse document frequency (TF-IDF). They used five machine learning models, such as RF, SVM, decision tree (DT), XGBoost classifier, extra tree classifier (ETC), and LSTM to analyze sentiments of COVID-19 tweets. The results showed that ETC outperformed all other models using their proposed feature extraction technique with an accuracy score of 0.93. The authors stated that the poor performance of the LSTM deep learning model is due to the small dataset. The authors of paper [23] conducted sentiment analysis on 11,960 tweets in the UK related to COVID-19 using three different ensemble models. The dataset was labeled manually by three independent annotators. The stacking classifier (SC) achieved the highest F1 score with 83.5% in comparison with the voting classifier (VC) and bagging classifier (BC) with 83.3% and 83.2% scores, respectively.

Researchers in this study [24] applied sentiment analysis to tweets about COVID-19 different vaccines. They found that 48.49% were neutral, 33.96% were positive, and 17.55% had negative feelings about the coronavirus vaccines. The study used LSTM and bidirectional LSTM (BiLSTM) deep learning models to predict the sentiments of the tweets. According to the study, the resulting accuracy is 90.59% for LSTM and 90.83% for Bi-LSTM. The authors of paper [25] combined convolutional neural network (CNN) with BiLSTM to classify the polarity of COVID-19 tweets as positive, negative, or neutral. They used the hybrid CNN-BiLSTM model with two word embedding pre-trained models: FastText and Global Vectors for Word Representation (GloVe) to obtain higher accuracy levels. The authors conducted experiments on a dataset of 40000 tweets collected from Twitter. The CNN-BiLSTM model with FastText yielded 99.33% accuracy, which is higher than the accuracy score of CNN-BiLSTM with GloVe (97.55%).

The authors in [26] proposed a hybrid feature extraction approach for COVID-19 tweets sentiment classification. They combined TF-IDF with FastText and GloVe to increase the performance of classification. This study applied seven machine learning classifiers in addition to one deep learning model (CNN). It was observed that the best performance was achieved by SVM using the TF-IDF with FastText word

embedding proposed technique. This study [27] presented a BiLSTM model for public opinion analysis of COVID-19-related discussions on social media. They performed sentiment classification using four different scenarios on three datasets collected from Twitter and Reddit platforms. One of the limitations they encountered is that the BiLSTM method is time-consuming. Also, they recommended applying multilingual sentiment analysis to get a global understanding of COVID-19 sentiments.

A new hybrid deep learning method is proposed in [28] to find the general sentiment of people in eight countries around the world. Their method is based on the fusion of four deep learning and one machine learning model. Their proposed model shows superior performance over the other models used in the study with 85.8% accuracy. In [29], the authors performed sentiment analysis on Nepali COVID-19 tweets using an ensemble CNN model. They proposed three different CNN models with three feature extraction techniques such as FastText (ft), domain-specific (ds), and domain-agnostic (da). In addition, they combined the three CNN models to form an ensemble CNN model. Their model achieved an accuracy of 68.7% for sentiment classification of tweets in the Nepali language.

This research [30] used three machine learning classifiers to predict people’s awareness of COVID-19 preventative measures in Saudi Arabia. For this purpose, they prepared a dataset of Arabic tweets related to COVID-19 preventative procedures. They applied four feature extraction techniques (unigram, unigram TF-IDF, bigram, and bigram TF-IDF) with each classifier. Their results show that the SVM classifier with bigram TF-IDF achieved the highest accuracy of 85%. Furthermore, the people in the south region of Saudi Arabia had the highest level of awareness, where they reacted positively towards COVID-19-related precautionary measures. The sentiments of COVID-19 tweets were analyzed using the BERT model in research [31]. They created two datasets by collecting tweets from India and the whole world from January 20, 2020, to April 25, 2020. The accuracy of their proposed model is approximately 94%.

III. MATERIALS AND METHODS

This study introduced an ensemble model based on a hybrid approach to analyze the sentiments of people towards COVID-19 vaccination. We collected a large dataset containing tweets related specifically to the COVID-19 vaccines and vaccination process. Tweets were cleaned and pre-processed before feeding them to the machine and deep learning models. VADER, a lexicon-based approach was used to assign positive, negative, or neutral polarity to the collected tweets. Afterwards, the annotated dataset was split for training and testing purposes. The lexicon-based approach is integrated with machine learning and deep learning-based approaches for sentiment classification. Accuracy, precision, recall, and F1 score were used to analyze the performance of the models. Fig. 1 depicts the architecture of the proposed methodology.

Fig. 1. Architecture of the proposed methodology.

A. Data Collection

To extract the COVID-19 vaccination-related tweets from Twitter, we applied for a Twitter developer account for the purpose of doing academic research. Accordingly, the Twitter developer team approved our request and enabled us to access Twitter’s application programming interface (API), which acts as an intermediary between the developer and the Twitter backend. Ultimately, the Twitter developer team provided us with the required credentials to authenticate access to the Twitter API. We used the Tweepy library in Python to interact with the Twitter API for collecting the required tweets. The data collection process was carried out on a daily basis from 13 November 2021 to 31 December 2021. Different hashtags were used to extract the tweets related to COVID-19 vaccines such as "#vaccinated", "#CovidVaccine", "#CovidVaccination", "#VaccinesWork", "#VaccineSideEffects", "#booster", "#AstraZeneca", "#Pfizer", and "#Moderna". In total, 4,093,986 tweets were extracted about vaccination against the coronavirus disease. The collected dataset shape is 4093986 by 5 columns, including tweet_id, text, favorite_count, created_at, and tweet_location. Table I shows a sample of some tweets from the collected dataset.

TABLE I. A SAMPLE OF TWEETS RELATED TO COVID-19 VACCINATION

Text
IM VACCINATED 🙏
I just got vaccinated on Tuesday and it hurts :(
@Dannyoconnor430 Get vaccinated to protect yourself.
So no need to panic ! Get vaccinated !! Protect yourself and others 😊 #omicron #covid #Valimai https://t.co/PAbdvkAGuA
@VishnuNDTV really a ridiculous rule for domestic passenger who r fully vaccinated.
Majority of mumps cases are among the vaccinated, CDC finds https://t.co/WuWbWy3AY via @nbcnews
@ScottATaylor waiting for the non vaccinated to get wise, so I can go out and have fun again
Saw a kid go up and thank the medical professional who vaccinated him today and my heart remembered the world has good in it
@FlutoShinzawa Good thing they are all double vaccinated.
@ABC Do what you want with your own body...But get vaccinated or lose your job

B. Data Cleaning and Preprocessing

After data collection and exploration, tweet texts were cleaned by removing noise or words that are irrelevant to our experiment. While extracting data from Twitter, all retweets were ignored by applying -filter: retweets to our search query.

In this study, we are interested only in analyzing the sentiments of tweets, so all the columns other than text were discarded. This led to having 4,093,986 rows and 1 column. In addition, duplicated tweets and rows with null values were removed. After these operations, the ultimate shape of the dataset became 1,411,324 rows by 1 column. Subsequently, irrelevant data elements to the sentiment analysis process were removed including hashtags (#), hyperlinks, mentions (@username), special characters, numbers, and punctuation marks. Table II shows some tweets before and after pre-processing operations. After labeling the tweets, we removed stop words and applied tokenization, case-folding, and stemming to avoid misleading the models.

TABLE II. A SAMPLE OF TWEETS BEFORE AND AFTER THE CLEANING PROCESS

Original raw tweets	Cleaned tweets
Please get vaccinated. https://t.co/YfZnFLRTSd	Please get vaccinated
Egypt bans unvaccinated people from public institutions#Egypt#vaccination#COVID19#coronavirus... https://t.co/0rvWPbaL8P	Egypt bans unvaccinated people from public institutions

C. Data Labeling using a Lexicon-based Approach

VADER is a lexicon-based approach used for text sentiment analysis. It depends on a dictionary comprising nearly 7517 features (words) with corresponding valence scores [32]. VADER sentiment analyzer returns a tuple of (neg, neu, pos, compound) for each sentence. A compound score is computed for each text, ranging from -1 (most negative feeling) to 1 (most positive feeling). It is a normalized score calculated by adding the scores of each word present in the sentence. If the compound score is greater than or equal to 0.05 then the tweet sentiment is considered positive and if it is smaller than or equal to -0.05 then the sentiment of the tweet is negative, otherwise the tweet is regarded as neutral. Some tweets with their polarity orientation are shown in Table III.

TABLE III. A SAMPLE OF TWEETS WITH THEIR CORRESPONDING SENTIMENTS

Tweets	Polarity
I just got vaccinated on Tuesday and it hurts	Negative
The city is starting to enforce the vaccine requirement to enter most indoor public spaces You MUST be vaccinated	Neutral
Good thing they are all double vaccinated	Positive

D. Sentiment Classification using ML and DL Models

This study used traditional machine learning in addition to deep learning models to classify the sentiments of tweets. LR, NB, DT, RF, and K-Nearest Neighbors (KNN) classifiers are implemented using scikit-learn library in Python. For our sentiment analysis task, two individual deep learning models, LSTM and BiGRU, were used in addition to our proposed ensemble model (LSTM-2BiGRU) to achieve higher levels of accuracy. The proposed model combines LSTM and BiGRU to obtain better results. In LSTM-2BiGRU, the output of the LSTM is fed to a stack of two sequential BiGRU layers for tweets sentiment classification.

E. Performance Evaluation

We used precision, recall, accuracy, and F1-Score to assess the performance of the sentiment classification models. These performance metrics are calculated using the following formulas:

$$\text{Precision} = \frac{TP}{TP+FP} \quad (1)$$

$$\text{Recall} = \frac{TP}{TP+FN} \quad (2)$$

$$\text{Accuracy} = \frac{TP+TN}{TP+TN+FP+FN} \quad (3)$$

$$\text{F1-score} = 2 * \frac{\text{Precision} * \text{Recall}}{\text{Precision} + \text{Recall}} \quad (4)$$

Where TP, TN, FP, and FN represent true positive, true negative, false positive, and false negative instances respectively.

F. Architecture of the Proposed Model

The structure of the proposed model is composed of seven layers, as given in Fig. 2 below. The first layer of the proposed model is an embedding layer, where the number of unique words in the vocabulary is 5000. Each word is represented by a vector of 100 dimensions. A dropout layer with a 0.5 dropout rate follows the embedding layer. After the dropout layer, an LSTM layer is applied with 128 units. The output of the previous layer is fed to a stack of two BiGRU layers with 100 and 64 units for each layer, respectively. The output of the first BiGRU layer is processed by the subsequent BiGRU layer to improve the accuracy of the model. BiGRU traverses the input data two times through a forward and a backward pass. Lastly a dense layer is used with three neurons based on the number of target classes (positive, negative, or neutral) and a softmax activation function. Before the previous dense layer, a dropout layer is placed with a rate of 0.5. The dropout layers are employed to reduce the complexity of the model as well as its propensity for overfitting. The LSTM-2BiGRU model was trained using 21 epochs and a batch size of 128. Early stopping was used to prevent overfitting of the model. The hyperparameters used to train our proposed model are listed in Table IV below.

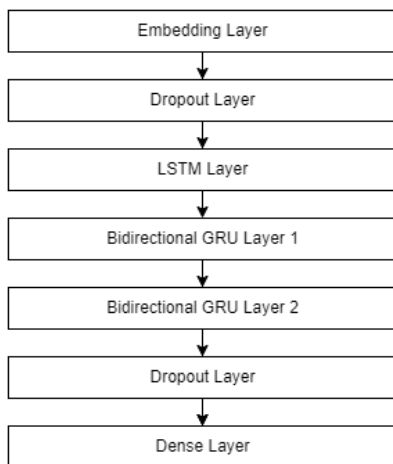

Fig. 2. Architecture of the proposed model.

TABLE IV. HYPERPARAMETERS USED FOR THE PROPOSED MODEL

Hyperparameter	Value
Optimizer	Adam
Loss	Categorical cross-entropy
Batch Size	128
Epoch	21
Dropout	0.5
Activation	Softmax

The pseudo-code below represents the steps taken to develop and evaluate the proposed model.

Algorithm 1: The pseudocode of the proposed model

- 1: **Import** Keras library for creating a deep learning model (M)
- 2: **Read** the collected dataset (D_i)
- 3: **Clean** the tweets from unwanted symbols like #, @, etc.
- 4: **Label** tweets using VADER tool
- 5: **If** the compound score >= 0.05
- 6: **Return** “Positive”
- 7: **Else If** compound score <= -0.05
- 8: **Return** “Negative”
- 9: **Else**
- 10: **Return** “Neutral”
- 11: **End If**
- 12: **Pre-process** cleaned tweets by removing stop words, applying case-folding, stemming, and tokenization
- 13: **Initialize** hyperparameters by setting input_dim=5000, output_dim=100, batch_size=128, epochs= 21
- 14: **For** no_epochs and batch_size **do**
- 15: **Train** the model (M)
- 16: **End For**
- 17: **Predict** the sentiment of unlabeled tweets using M
- 18: **Evaluate** the model and calculate the metrics accuracy, precision, recall, and F1-score
- 19: **Plot** the ROC curve of the model

IV. RESULTS AND DISCUSSIONS

This section demonstrates the results of sentiment analysis on COVID-19 vaccination tweets using machine learning and deep learning models. The collected dataset in this study is split into 85% for training the models and 15% for testing purpose on unseen and unlabeled data. The number of tweets in the training set is 1,199,625 while the testing set consists of about 211699 tweets. Fig. 3 shows a word cloud of the most frequent terms used in all the tweets. Fig. 4 to Fig. 6 present the key terms used in the positive, negative, and neutral tweets respectively.

TABLE V. SENTIMENT ANALYSIS RESULTS USING MACHINE LEARNING CLASSIFIERS

Model	Accuracy (%)	Precision (%)	Recall (%)	F1-Score (%)
Random Forest	87	87	87	87
Logistic Regression	87	87	87	87
Decision Tree	83	83	83	83
Naïve Bayes	80	81	80	80
KNN	57	68	56	55
Voting Classifier	88	88	88	88

TABLE VI. HYPERPARAMETERS SELECTED FOR MACHINE LEARNING MODELS

Algorithm	Hyperparameter
Logistic Regression	solver = 'saga'
Multinomial Naïve Bayes	default setting
Decision Tree	criterion = 'gini'
Random Forest	n_estimators = 100
KNN	n_neighbors = 3, weights = 'uniform'

C. Sentiment Analysis using Deep Learning Models

To attain higher levels of accuracy for our sentiment analysis task, two individual deep learning models are used including LSTM and BiGRU as well as our proposed ensemble model. The results of the deep learning models are provided in Table VII. The proposed LSTM-2BiGRU model shows a superior performance over the traditional machine learning and deep learning models used in the study. It achieved the highest accuracy score of 92.46%, followed by LSTM and BiGRU with accuracy scores of about 91%. It is important to mention that using an ensemble of LSTM and BiGRU improved the classification accuracy than using each model individually. Fig. 9 shows the receiver operating characteristic (ROC) curve for the proposed model. The micro-average value of the area under the curve (AUC) for the LSTM-2BiGRU model is 0.98.

TABLE VII. SENTIMENT ANALYSIS RESULTS USING DEEP LEARNING MODELS

Model	Accuracy (%)	Precision (%)	Recall (%)	F1-Score (%)
LSTM	91.98	92.70	91.28	91.97
BiGRU	91.97	92.59	91.43	92.00
LSTM-2BiGRU	92.46	92.97	91.94	92.44

Fig. 9. ROC curve for the proposed model.

D. Comparison with State-of-the-Art Studies

To assess the performance of the proposed LSTM-2BiGRU model with respect to recent studies, a performance comparison was conducted on four cutting-edge studies related to sentiment analysis. These experiments were performed using the collected dataset in this study. In addition, all the steps involved in the proposed approach were applied to the models in the selected studies to guarantee a fair and accurate comparison. The study [33] introduced a stacked BiLSTM model to determine the polarity of deep fake tweets. The authors of paper [34] performed sentiment analysis of tweets related to COVID-19 vaccination using LSTM model. Likely, Reshi et al. presented an ensemble model called LSTM-GRNN for carrying out the same task in research [35]. In addition, paper [36] combined LSTM and GRU to analyze sentiments and detect emotions of tweets related to cryptocurrency. Table VIII compares the result of our proposed model to the findings of cutting-edge studies relevant to our task. The output results show that the proposed model outperforms other models in recent studies with 0.92 accuracy.

TABLE VIII. PERFORMANCE COMPARISON WITH STATE-OF-THE-ART STUDIES

Reference	Model	Accuracy (%)
[33]	Stacked Bi-LSTM	91.94
[34]	LSTM	91.67
[35]	LSTM-GRNN	90.99
[36]	LSTM-GRU	90.75
This study	LSTM-2BiGRU	92.46

V. CONCLUSION

This study performs sentiment analysis on tweets related to the COVID-19 vaccination. To analyze the sentiments of the tweets, this study uses a hybrid approach based on two techniques: natural language processing and machine learning. For conducting experiments, tweets were extracted from Twitter, and the dataset was annotated using VADER. Accordingly, the proportion of people having neither positive nor negative feelings towards the COVID-19 vaccines is the highest among others. Considering the machine learning side of the hybrid approach, the dataset was split into 85% for training and 15% for testing. The sentiments of the tweets were analyzed using five machine learning classifiers: LR, NB, DT, RF, and KNN. To obtain higher accuracy for sentiment classification, two individual deep learning models (LSTM, BiGRU) were used in addition to our proposed ensemble model LSTM-2BiGRU. The experimental results show that the LSTM-2BiGRU model performs significantly better than all the traditional machine learning and deep learning models used in this study. With a 92.46% accuracy score, the proposed model proves its superiority in predicting the sentiments of tweets that are related to the vaccination aspect of COVID-19. However, it is important to point out that BiGRU is slow and requires more time for training due to its complex nature. In future, we aim to perform multimodal sentiment analysis as social media users express their feelings and opinions in multimedia forms, such as videos or images, rather than text solely.

Abstract—Motion sickness is a common scenario for users when they are exposed to a virtual reality (VR) environment. It is due to the conflict that occurs in the brain that tells the user that they are moving in the environment, but the fact is that the user's body is sitting still causing them to get symptoms of motion sickness like nausea and dizziness. Therefore, motion sickness has become one of the main reasons why users still do not prefer to use VR to enhance their productivity. Motion sickness can be overcome by increasing the user's comfort level of walkthrough in the VR environment. Meanwhile, a popular VR simulation which is widely used in many industries is a walkthrough in a VR environment at a certain speed. This paper is focused on presenting the result of walkthroughs in a VR environment using movement speed and based on frame rates performance and adopting the unified theory of acceptance and use of technology (UTAUT) model construct variables namely performance expectancy (PE) and effort expectancy (EE) to measure the user's comfort level. A mobile VR, 'VR Terrain' application software was developed based on the proposed framework. The application software was tested by 30 users by moving around in a VR environment with 4 different movement speeds that were implemented into four colored gates using a head-mounted display (HMD). A descriptive and coefficient analysis was used to analyze all the data. The blue gate revealed the most comfortable, outperforming all other three gates. Overall, the most suitable speed to use for VR walkthrough is 4.0 km/h. The experiment result may be used to create a parameter for the VR developers to reduce the VR motion sickness effect in the future.

Keywords—Virtual reality; motion sickness; head-mounted display; head lean movement; mobile VR; walkthrough technique; UTAUT; frame rate

I. INTRODUCTION

A. Background Study

Virtual Reality (VR) is the technology that provides almost real and believable experiences in a synthetic or virtual way [1]. Recent research says VR objects typically act similarly to their real-world counterparts. The user can interact with these things in line with the actual physics principles [2]. Users that use hardware devices like goggles, headphones, and special gloves encounter virtual worlds created and served by software [3]. Experiencing VR technology requires a system with designed computer software that can implement the technology and a head-mounted display (HMD) that allows users to see the VR environment [4]. The first HMD was invented and

developed by Sutherland in 1965, which was introduced as the ultimate display [5] and became available to the public commercially as the revival of VR with HMD at a low price [6].

However, there are common issues that occur involving the use of VR technology. Users are reported to often experience motion sickness when experiencing VR [7][8]. Motion sickness is generally detected after the symptoms appear. This indicates that the sickness has begun, and this effect is already uncomfortable for the user [9]. When it comes to motion sickness or VR related, many report that women are more susceptible than men. One of the classic examples is seasickness with a ratio of approximately 5:3 by Lawther and Griffin, (1988) [10]. Several factors of motion sickness in VR are associated with the HMD such as motion, field of view (FOV), latency, duration of use, and the VR environment [11][12][13][14][15]. These uncomfortable effects will inhibit future experiences of VR.

In this paper, researchers attempted to minimize VR motion sickness by measuring the comfortable level of experience in mobile VR through movement speed of walkthrough. The users must perform a walkthrough by moving around in the VR environment using the four levels of speeds that were implemented in the developed Android application software, 'VR Terrain'. The test evaluation was carried out by adopting some parts of Unified Theory of Acceptance and Use of Technology (UTAUT) [16]. For evaluation, the theory's construct variables namely performance expectancy (PE) and effort Expectancy (EE) were involved, as well as observing the frame rate value of the used device.

B. Paper Contribution

The contributions of the paper are the following:

- The description and the implementation of the VR walkthrough movement speed parameter.
- An Android application software to measure the users' comfortable level experience of VR walkthrough.
- Results of UTAUT and frame rate values for users' comfortable level experience of VR walkthrough.

II. RELATED WORK

A. Motion Sickness of Virtual Reality

One major theoretical issue that has dominated the field for many years concerns the motion sickness effect in VR. It is also known as cybersickness in terms of symptoms as they are similar. The only difference between the terms is that motion sickness is caused in the real world while cybersickness is caused by the virtual one [17]. With developers striving for higher constancy in VR, the content's specifics are becoming more complicated. Thus, this paper also highlights several factors and effects of VR motion sickness.

1) *Factor of VR motion sickness:* VR motion sickness is caused when the brain receives sensory input that does not match the movements of the body. Even though VR technology is becoming more advanced, users still experience motion sickness. This paper focuses on the factors that cause motion sickness among VR users, specifically involving the use of head-mounted display (HMD). There are five main factors that contribute to VR motion sickness: motion and speed, field of view, latency, duration of use, and environment. Rapid and intense movements [18][10][19], a narrow field of view [12][20][21], high latency [22][23][24], prolonged use [25][26][27], and overly stimulating environments [28][29][30] can trigger motion sickness in VR users. By understanding these factors and taking steps to mitigate them, it is possible to reduce the risk of VR motion sickness and improve the VR experience for users.

2) *Effect of motion sickness:* On the other hand, VR motion sickness occurs when a person experiences discomfort or disorientation while using VR technology, due to a mismatch between what they see and feel in the VR environment and what their body is physically experiencing [31]. The effects of VR motion sickness can include nausea [32][33][31], dizziness [34][35][29], headache [8][36][37], fatigue [38][39][40], and eye strain [41][12][37]. These effects can vary from person to person and negatively impact a person's overall enjoyment and use of VR technology. Understanding the effects of VR motion sickness is important for developers and designers of VR technology, as it can help them create more comfortable and effective VR environments for users. The goal of this research is to minimize the effects of VR motion sickness.

B. Head Lean Movement Technique for VR Walkthrough

The head lean movement technique allows for hands-free navigation in VR by relying solely on head movement and six degrees of freedom (6-DoF) tracking [42]. The user simply leans their head to move forward, making it easy to use. The smartphone's gyroscope measures the head movement. Studies have shown that this technique can be effective, but there may be a pause gap between inputs due to the user's tendency to look forward and downward while navigating [43]. Studies have also measured the effects of this technique on factors such as sickness, presence, usability, and comfort when experiencing VR. Previous research has employed this method with a variety of VR headsets, including the Oculus Rift,

Samsung Gear VR, and even the HTC Vive, on both mobile and desktop platforms. Table I below shows the head lean technique for VR.

TABLE I. HEAD LEAN TECHNIQUE FOR VR

Head Lean Technique			
No	VR Device	VR Platform	Author
1	Oculus Rift DK2	Desktop	[44]
2	Samsung Gear VR	Mobile	[42]
3	Samsung Gear VR	Mobile	[45]
4	HTC Vive	Desktop	[43]

C. Unified Theory of Acceptance and Use of Technology

A concept called the Unified Theory of Acceptance and Use of Technology (UTAUT) integrates eight separate hypotheses to explain why people adopt and use technology [16]. It can account for 50% of the variations in technology usage and 70% of the variations in willingness to use technology [46]. UTAUT was initially developed for usage in business environments, but it can be used in other contexts as well. The Technology Acceptance Model (TAM), the Theory of Planned Behavior (TPB), and Social Cognitive Theory (SCT) are among the models on perception, acceptance, and preparedness to employ technology that are combined in this study. Performance Expectancy (PE), Effort Expectancy (EE), Social Influence (SI), and Facilitating Conditions (FC) are the four variables used by UTAUT to validate users' capacity and willingness to adopt new technology.

1) *Performance expectancy:* Performance expectancy (PE) is the degree to which a person expects that using technology will help them execute their jobs more effectively [16]. Age and gender also determine the impact of PE [47]. The first fundamental factor used to determine UTAUT for consumers is the degree to which consumers benefit from using technology [48].

2) *Effort Expectancy:* Technology's early acceptance behavior is influenced by how easily it may be used [49]. Effort Expectancy (EE) stands for "the degree of system usability" [16]. For older people, online technologies could be challenging. Age, gender, and experience are also determining the impact of EE [47]. Regardless of the consumers' technological competency, the EE can be used to determine whether they anticipate experiencing difficulties when utilizing the system.

3) *Social Influence:* Social Influence (SE) refers to how much a person values other people's opinions about whether they should use new technology [16]. Subjective norms in technology adoption indicate social influence [50]. Age, gender, experience, and voluntariness of use are determining the impact of SI [47]. The intention to use technology is impacted by having active social contacts [51].

4) *Facilitating Conditions:* Facilitating conditions (FC) refer to the extent to which consumers believe they have the resources and technologies to support their use of modern technology [16]. Besides, awareness and motivation are what

encourage people to overcome technological obstacles. According to UTAUT, FC is the internal attribute of a target customer [16][47]. Only age and experience determine the impact of FC [47]. The enabling condition influences effort expectancy or ease of use and can predict the use of technology.

D. Frame Rates for Mobile VR

For mobile VR, keeping a high frame rate is very crucial. Smartphones, which are less powerful than desktop PCs or gaming consoles, power mobile VR systems. Because mobile devices have limited capabilities, it might be challenging to attain a high frame rate with mobile VR systems [52][53]. Mobile VR systems must also work under the constraints of the and motion tracking sensors, which can further cut down on the resources available for producing and showing VR content [54]. Notwithstanding these difficulties, high frame rate mobile VR has made tremendous advancements.

The Oculus Quest 2 and Samsung Gear VR are two examples of the most recent mobile VR systems that have made considerable advancements in offering a high-quality VR experience with a high frame rate [55][51]. For instance, the Oculus Quest 2 can display VR material at 72 FPS, which is quite near to the optimal frame rate of 90 FPS.

III. DEVELOPMENT AND IMPLEMENTATION

A. Application Software Development

For this paper, suitable hardware and software have been chosen to avoid any difficulties during the development of this virtual rehabilitation application. Hence, it was important to have the level of expertise in selecting the hardware and the software to ensure any problems that arise during this development process can be solved.

The VR Terrain application software was designed in the Unity editor version 2018. This editor enables developers to create apps, games, or 2D and 3D experiments on a variety of platforms, including PC, Mac, Linux, iOS, Android, Windows, and web. Prior to importing the models, a configuration setting must be done to enable the VR environment settings and the Android build support. Thus, three software packages needed to be imported and installed to produce a working Android mobile application with Unity 3D software. Therefore, an Android Software Development Kit (SDK), Java Development Kit (JDK) and Google VR SDK were added to the Unity editor. The first two software packages convert the application built into an '.apk' file. This file can only be compatible with Android Operational System (OS) smartphone devices. On the other hand, the Google VR SDK software package enables the development of applications for VR HMD or glasses.

Next, the 3D models had been selected and downloaded from the Unity store which can be accessed through the Unity 3D website, were then imported into the editor. Then, the models were modified, scaled, and moved to form a terrain that later was turned into a VR environment. A function called 'Character Controller' by Unity was created. This function applies as the camera that will give user an ability to see the VR environment in first-person view and rotate their head to change the viewing angle, allowing presence of immersion for

VR user. After .apk file was created when the development had been completed, it will be installed in the smartphone. Users can view the VR environment through the lenses in the HMD.

The head lean movement technique was applied to enable the user to humanly move from one place to another in the VE. The user needed to lean their head to the front and downward to simulate the walking movement. The head rotation plays an important part as it was set to a certain degree using a script. The script had also been added and applied a condition, which changed the movement speed of the character controller. The speed changed when there was a collision between the character controller and the gates.

There are four gates designed with four color variations which are green, blue, purple, and red. In order for user to change the movement speed when performing the walkthrough in the VR environment, the gates were set as collision objects, which means when the user makes contact with one of the gates, the movement speed will take effect and make the user virtually move at a specific level of speed. There are four levels of speeds set in VR Terrain application software which are 3, 4, 5 and 6 kilometer per hour (km/h) and individually connected the gates. When the user penetrates the green gate, they will move at a speed of 3 km/h. When the user penetrated the blue gate, they will move at speed of 4 km/h. When the user penetrates the purple gate, they will move at the speed of 5 km/h. When the user penetrates the red gate, they will move at the speed of 6 km/h.

Finally, the speed in kilometers per hour (km/h) and the frame rate information display were added into the application. This information was displayed on the top corner of the screen in the application to keep tracking their current uses of the walkthrough speed movement in the VR environment. This information was used in evaluation phase to strengthen the results and provide a valid outcome. Fig. 1 shows the screenshot of the application view in the smartphone.

Fig. 1. Application screenshot from mobile.

B. Implementation

Prior to the test, the users will be instructed to fill in the required consent form to prove that the users agreed to be subjects in the test session and the data obtained from the test was used and studied. Each subject was later given a consent form signing that they voluntarily agreed to allow their individual data to be collected and analyzed after the session ended. Note that this testing procedure was using the same smartphone to ensure quality of the research is guaranteed and to avoid data confusion.

The users were asked to wear HMD with the smartphone attached to the front. The VR Terrain application software was previously installed and launched before the device was attached to the headset. After the HMD had been properly attached, the users were instructed to move through one of the four colored gates and moved around the terrain before moving through another colored gate one at a time before ending the session. The users were also instructed to lean their head down to a minimal degree as it is the way they can move in the VR environment. The users were also able to change direction by turning their head left or right. The session ended after the users had moved through all the gates and moved around the terrain. After taking a rest for five minutes, the users were asked to complete an online self-survey regarding their session before returning home. Fig. 2 shows the flowchart of the testing procedure.

Fig. 2. VR terrain testing procedure flowchart.

C. Evaluation

In this paper UTUAT was used to validate the users' comfortable level walkthrough of VR Terrain application. Only two key constructs have been considered which are PE and EE. These two constructs were selected to validate the comfort level of the user when performing walkthrough in the VR environment using VR Terrain application. In addition, the frame rates of the VR Terrain were observed during the test was running.

1) *UTAUT evaluation:* Performance Expectancy (PE) and Effort Expectancy (EE) are two of the four components from the Unified Theory of Acceptance and Use of Technology included in this paper where each of the items brought out three items that were used to determine the users' comfort level of VR walkthrough for the reducing motion sickness in VR environment application software, VR Terrain application. For the evaluation of users' comfort level walkthrough of VR Terrain application, there are six variables used which are three variables each for PE and EE. The variables are different from one to another. These variables are as shown in Table II.

In the questionnaire, four colored gates (green, blue, purple, and red) are represented with six variables of PE and EE (PE1, PE2, PE3, EE1, EE2, and EE3), making the questionnaire to have a total of twenty-four items of UTAUT model variables assessment that the users are required to complete.

The data was collected and carried out to perform quantitative analysis using SPSS software. The analysis focused on finding PE and EE significant value (p-value) of the four colored gates. The least significant value was taken into account and declared as the most significant findings. Thus, the most comfortable movement speed to use in VR walkthrough was revealed. Table II below has also been adapted in the online questionnaire.

TABLE II. UTAUT RESEARCH VARIABLE

Variable	Item
Performance Expectancy (PE)	PE1: I find this movement speed of VR walkthrough useful for my study/future job.
	PE2: I find using this movement speed of VR walkthrough enables me to accomplish my task pleasantly.
	PE3: I find using this movement speed of VR walkthrough increases my chances of achieving things that are important to me.
Effort Expectancy (EE)	EE1: I find my interaction with this movement speed of VR walkthrough is clear and understandable.
	EE2: I find learning how to use VR walkthrough with this movement speed is easy for me.
	EE3: I find it is easy for me to become skillful at using with this movement speed of VR walkthrough.

2) *Frame rates evaluation:* The frame rates are measured in frames per second (FPS) as a measurement unit and dependent on the processing power of the device. Therefore, the same device has been used to test the VR Terrain application software as the display. This FPS was also validated to see whether it remained constant or underwent any change during the testing session.

IV. RESULT

A. Respondent Profiles

In this paper, the users' demographic profile (n = 30) was classified using frequency distribution. The profile of respondents consists of three descriptions of users that cover the respondents' age, gender, and experience with VR. Table III shows the profile of the respondents using the frequencies and percentages analysis.

TABLE III. RESPONDENT PROFILES

No	Respondent Profiles	Frequency (N)	Percentage (%)
1	Age		
	21	4.0	13.3
	22	19.0	63.3
	23	3.0	10.0
	24	4.0	13.3
2	Gender		
	Male	14.0	46.7
	Female	16.0	53.3
3	Experience with VR		
	Yes	24.0	80.0
	No	6.0	20.0

The demographic analysis provides a general view of the users, which is beneficial in understanding the respondents' background. Based on the result, the majority of the age of the respondents recorded was 22 years old (63.0%), followed by 21 years old (13.3%), and 24 years old (13.3%) participated for the prototype testing. Likewise, most of the respondents were females (53.3%) while males recorded with 46.7%.

Apart from this, the result shows that most of the respondents (80.0%), had experienced VR while only 20.0% of the respondents had not experienced VR before testing the VR Terrain application.

B. Performance and Effort Expectancy Descriptive Analysis

TABLE IV. PERFORMANCE EXPECTANCY DESCRIPTIVE ANALYSIS

No	Item	Frequency (N)	Min	Mean	Max	Std. Dev.
Green Gate						
1	PE1	30.0	1.00	3.07	5.00	1.60
2	PE2	30.0	1.00	3.00	5.00	1.58
3	PE3	30.0	1.00	3.23	5.00	1.59
Blue Gate						
4	PE1	30.0	1.00	3.27	5.00	1.51
5	PE2	30.0	1.00	3.37	5.00	1.56
6	PE3	30.0	1.00	3.33	5.00	1.53
Purple Gate						
7	PE1	30.0	1.00	3.73	5.00	1.28
8	PE2	30.0	1.00	3.50	5.00	1.41
9	P3	30.0	1.00	3.50	5.00	1.36
Red Gate						
10	PE1	30.0	1.00	2.93	5.00	1.51
11	PE2	30.0	1.00	2.90	5.00	1.47
12	PE3	30.0	1.00	3.03	5.00	1.47

TABLE V. EFFORT EXPECTANCY DESCRIPTIVE ANALYSIS

No	Item	Frequency (N)	Min	Mean	Max	Std. Dev.
Green Gate						
1	PE1	30.0	1.00	3.30	5.00	1.58
2	PE2	30.0	1.00	3.20	5.00	1.58
3	PE3	30.0	1.00	3.10	5.00	1.60
Blue Gate						
4	PE1	30.0	1.00	3.33	5.00	1.56
5	PE2	30.0	1.00	3.27	5.00	1.52
6	PE3	30.0	1.00	3.23	5.00	1.48
Purple Gate						
7	PE1	30.0	1.00	3.57	5.00	1.38
8	PE2	30.0	1.00	3.37	5.00	1.47
9	P3	30.0	1.00	3.40	5.00	1.38
Red Gate						
10	PE1	30.0	1.00	3.07	5.00	1.57
11	PE2	30.0	1.00	3.07	5.00	1.53
12	PE3	30.0	1.00	2.97	5.00	1.54

In Table IV, the mean score of performance expectancy ranges between 2.90 to 3.73, and the standard deviation ranges between 1.28 and 1.63. Meanwhile, Table V shows the mean score of effort expectancy which ranges between 2.97 to 3.57, and the standard deviation ranges between 1.38 and 1.60.

Both standard deviation scores are relatively small (less than 3). Thus the degree of performance expectancy and effort expectancy variations is within the normal distribution as proposed by Burn and Bush, (2010) [56].

C. Performance and Effort Expectancy Analysis Coefficient Result

TABLE VI. COEFFICIENT RESULTS OF PERFORMANCE EXPECTANCY

Model	Performance Expectancy (PE)	Unstandardized Coefficients		Standardized Coefficients	t	Sig.(p)
		B	Std. Error	Beta (β)		
1	(constant)	0.707	0.372		1.903	0.069
	PE_G	0.041	0.118	0.063	0.350	0.729
	PE_B	0.316	0.112	0.482	2.819	0.009
	PE_P	0.222	0.118	0.285	1.876	0.072
	PE_R	0.195	0.099	0.281	1.972	0.060

Dependent Variable: CL

Fig. 3. Performance expectancy (PE) beta (β) result summary.

Table VI shows the result coefficients table for performance expectancy (PE) on comfort level (CL). From the result, it shows that the highest beta value of performance expectancy (PE) is blue gate (0.482), followed by purple gate (0.285), red gate (0.281) and green gate (0.063).

The result concludes that the strongest comfort level for walkthrough in VR environment using VR Terrain application in terms of performance expectancy is Blue Gate ($\beta = 0.482, p = 0.009$). From the finding, walkthrough from Blue Gate (B) has helped the users to accomplish their task pleasantly. Moreover, the movement speed of Blue Gate has increased the user learning in VR environment.

In contrast, Green Gate (G) is not significantly achieving the comfort level for walkthrough ($\beta = 0.063$), as it did not reach the significant level ($p = 0.729 > 0.05$). Similarly Purple Gate and Red Gate received the same beta value ($\beta = 0.285, 0.281$), which are also not significant ($p = 0.072, 0.060$) to achieve comfort level in walkthrough. Fig. 3 above shows the summary of Performance Expectancy Beta results.

TABLE VII. COEFFICIENT RESULTS OF EFFORT EXPECTANCY

Model	Effort Expectancy (EE)	Unstandardized Coefficients		Standardized Coefficients	t	Sig.(p)
		B	Std. Error	Beta (β)		
1	(constant)	0.742	0.341		2.173	0.039
	EE_G	0.009	0.131	0.013	0.066	0.948
	EE_B	0.341	0.121	0.507	2.827	0.009
	EE_P	0.237	0.107	0.326	2.204	0.037
	EE_R	0.170	0.091	0.253	1.863	0.074

Dependent Variable: CL

Fig. 4. Effort expectancy (EE) beta (β) result summary.

Table VII shows the result coefficients table for effort expectancy (EE) on comfort level (CL). From the result, it shows that the highest beta value of effort expectancy (EE) is blue gate (0.507), followed by purple gate (0.326), red gate (0.253) and green gate (0.013).

The result concludes that the strongest comfort level for walkthrough in VR environment using VR Terrain application in terms of performance expectancy is Blue Gate ($\beta = 0.507, p = 0.009$). From the finding, walkthrough from Blue Gate (B) has helped the users to accomplish their task pleasantly. Moreover, the movement speed of Blue Gate has increased the user learning in VR environment.

In contrast, Green Gate (G) is not significantly achieving the comfort level for walkthrough ($\beta = 0.013$), as it did not reach the significant level ($p = 0.948 > 0.05$). Similarly Purple Gate and Red Gate received the same beta value ($\beta = 0.326, 0.253$), which are also not significant ($p = 0.037, 0.074$) to achieve comfort level in walkthrough. Fig. 4 above shows the summary of Effort Expectancy Beta results.

D. Result of Frame Rate Observations

The frame rate of a VR experience is a critical factor in determining the overall quality of the experience. A low frame rate can cause motion sickness and detract from the immersion of the experience, while a high frame rate can provide a smoother and more realistic experience. For this reason, the frame rate is one of the most important metrics to be measured and validated during VR Terrain application software testing. From the observation during the test, the collected frame rate data was analyzed to assess the performance of the VR Terrain software application.

TABLE VIII. RESULT OF FRAME RATE OBSERVATIONS

VR Walkthrough Movement Speed (km/h)	Frames Per Second (FPS)		
	59	60	61
	Frequency (N)		
3	0	0	30
4	0	0	30
5	2	25	3
6	2	27	0

According to Table VIII, there are four different movement speeds: 3, 4, 5, and 6 km/h. All 30 users performed the VR walkthrough at all four movement speeds, and the frame rate was recorded through the observation for each user at each speed. The data shows that for 3 and 4 km/h, all users experienced 61 FPS, with no one experiencing 59 FPS or 60 FPS. This indicates that the frame rate was consistently high for these speeds and that the VR experience was smooth and immersive.

For 5 km/h movement speed, however, the data tells a different story. Two users experienced 59 FPS, which is below the generally accepted standard for smooth VR experiences. 25 users experienced 60 FPS, which is generally considered to be the minimum frame rate for a smooth VR experience. Three users experienced 61 FPS, which is higher than the generally accepted standard, indicating that the VR experience was exceptionally smooth and immersive for these users.

Finally, for 6km/h movement speed, the data again shows some variability in the frame rate. Two users experienced 59 FPS, which is below the generally accepted standard for smooth VR experiences. 28 users experienced 60 FPS, which is generally considered to be the minimum frame rate for a smooth VR experience. No users experienced 61 FPS, indicating that the VR experience was not exceptionally smooth or immersive for any users at this speed.

Likewise, for 3km/h and 4km/h, the average frame rate was 61fps, as all users experienced this frame rate. For 5km/h, the average frame rate was 60fps, as 25 users experienced this frame rate, and it is generally considered to be the minimum standard for a smooth VR experience. For 6km/h, the average frame rate was 60fps, as 28 users experienced this frame rate.

In conclusion, the frame rate of a VR experience is a critical factor in determining the overall quality of the experience. In the context of a VR walkthrough, the frame rate has become even more important, as users are moving through a VR environment and a low frame rate can cause motion sickness and detract from the immersion of the experience. Based on the data collected, the average frame rate was consistently high for 3km/h and 4km/h, indicating a smooth and immersive VR experience in mobile device. However, for 5km/h and 6km/h, the frame rate was more variable, with some users experiencing frame rates below the generally accepted standard for a smooth VR experience (Kopczynski, 2021; Menakhin, 2016; Fuchs, 2017). Overall, this data highlights the importance of maintaining a high frame rate in VR walkthroughs to ensure a smooth and immersive experience for all users.

E. Result Summary

Overall, the blue gate (B) received the most positive result compared to the purple gate (P), red gate (R), and green gate (G). Likewise, the most comfortable walkthrough in VR recorded in terms of performance expectancy and effort expectancy was with the blue gate (B). Therefore, the result of PE and EE to support CL proposed that, 4 km/h is the most suitable movement speed to use for walkthrough in VR environment. Additionally, the VR walkthrough using VR Terrain application is smooth with the average frame rate of 61 FPS which is acceptable for VR experience for mobile device.

V. FUTURE WORK AND CONCLUSION

A. Future Work

The VR walkthrough application software can and should be further enhanced, so that the system is better, more efficient, and more effective. The suggestions for providing a better result are as stated below:

1) *Enhanced interfaces:* Future researchers can provide more information for users to see in the display such as the time engagement and the distance travelled for users to understand more about their current situation. Besides, the researchers can also use higher quality 3D object and create more realistic VR environment such as city environment, houses, and walking tracks to enhance the VR experience for the user.

2) *Cross-sectional study:* Currently, the research and development of VR environment using the walkthrough technique for minimizing motion sickness is only limited to technological science study. This research and development can be further studied across many regions especially in medical and human science since it involves motion sickness, which is the biological condition for humans. This indirectly contributes to more insight and increases the diversity of knowledge of VR.

3) *Expanding platform:* There are still some limitations to this technology that can be addressed in future versions of mobile-based VR Terrain. Therefore, future work is suggested to expand the testing of VR Terrain software application in desktop-based VR device such as using HTC Vive Pro or in a standalone VR device such as Oculus Quest 2. Desktop-based VR devices offer more advanced hardware and capabilities compared to mobile-based VR experiences. With more powerful hardware, these VR experiences can offer higher quality graphics, more complex interactions, and greater immersion. In addition, stand-alone VR devices offer the convenience of mobile-based VR without the need for an external device like a smartphone.

B. Conclusion

The developed VR Terrain application software was used for VR walkthrough to measure the users' comfort level VR walkthrough experience and was validated by adopting UTAUT model construct variables which are performance expectancy (PE) and the effort expectancy (EE) as well as the frame rate observations. The result of comfort level shows all

users found that VR Terrain application was useful and convenient to use. Overall, VR Terrain application was considered satisfying for the user to use for measuring comfort level of walkthrough in VE. The UTAUT analysis and FPS rate shows 4 km/h is the most comfortable to use for walkthrough in VE, in which the result indicates that 4.0 km/h movement speed can be used in walkthrough in VR environment to minimize the effect of VR motion sickness. Therefore, it can be said that the users' comfort level walkthrough measurement of VR Terrain application is useful for VR developer to use as a reference in minimizing the VR motion sickness effect.

ACKNOWLEDGMENT

Fusion Privacy Protection of Graph Neural Network Points of Interest Recommendation

Yong Gan¹, ZhenYu Hu²

School of Computer and Communication Engineering, Zhengzhou University of Light Industry, Zhengzhou, China

Abstract—For the rapidly developing location-based web recommendation services, traditional point-of-interest(POI) recommendation methods not only fail to utilize user information efficiently, but also face the problem of privacy leakage. Therefore, this paper proposes a privacy-preserving interest point recommendation system that fuses location and user interaction information. The geolocation-based recommendation system uses convolutional neural networks (CNN) to extract the correlation between user and POI interactions and fuse text features, and then combine the location check-in probability to recommend POIs to users. To address the geolocation leakage problem, this paper proposes an algorithm that integrates k -anonymization techniques with homogenized coordinates (KMG) to generalize the real location of users. Finally, this paper integrates location-preserving algorithms and recommendation algorithms to build a privacy-preserving recommendation system. The system is analyzed by information entropy theory and has a high privacy-preserving effect. The experimental results show that the proposed recommendation system has better recommendation performance on the basis of privacy protection compared with other recommendation algorithms.

Keywords—Recommendation algorithms; location protection; graph convolutional neural networks; k -anonymity

I. INTRODUCTION

With the rapid development of mobile Internet, a series of location-based social network (LBSN) services such as e-commerce and social software have attracted millions of users, who establish online links with other users on LBSN, share experiences and comments of visited points of interest[1], and the service platform analyzes user information and mines user preferences to recommend POIs to users. However, as the volume of data and the complexity of information, the traditional text-based collaborative filtering method is no longer applicable to the development of recommendation systems. In addition, the naturally existing geographic distance factor also has an impact on user activities, as human activity areas have the phenomenon of geographic aggregation[2]. Therefore, the geographic impact between users and POIs and between POIs is as important as the impact between users. Therefore, it makes sense to incorporate the geographic distance factor into a collaborative user or content-based filtering approach.

Compared with traditional methods, neural network-based recommendation algorithms can tap deeper features with local relevance and location invariance to extract potentially valid information from Euclidean spatial data[3]. Therefore, it is the mainstream practice in recommendation systems to use CNNs to extract hidden features from data such as users' social

relationships, comment texts and visit frequencies and fuse them, and then combine the check-in probabilities of geographic distance factors[4]. At this stage, the emergence of graph neural networks (GNNs) further improves the performance of recommendation systems[5]. As a natural bipartite graph structure (user-interest point nodalization), traditional collaborative filtering methods based on neural networks, although having powerful feature representation, are weak in handling higher-order interaction information of graph-structured data in non-Euclidean space[6]. Therefore, introducing GCN into the recommendation system to extract the connection features of user-interest point interactions through information transfer between graph nodes brings better entity representation and stronger interpretation capability to the recommendation system, thus improving the prediction accuracy of the model[7][8].

Since the recommendation system in LBSN lacks location protection measures for users when recommending POIs to them, they may face the threat of location leakage. Existing location protection methods for LBSN are mainly divided into three types: generalization[9][10], k -anonymity and encryption[11][12]. k -anonymity is a method that constructs an anonymous region containing $k-1$ users after removing the identification information from their real locations and query contents, so that the probability of identifying a user does not exceed $1/k$. k -anonymity is widely studied and applied because of its high privacy protection effect compared with other methods. However, existing approaches to location privacy protection exhibit significant limitations. First, recommendation systems utilize trusted third-party anonymous servers to protect user location information. This operation inherently leads to information leakage problems. Second, the generalization-based location protection mechanism generalizes the user's real location so that the user's virtual location exists at any point in the constructed larger virtual area, and the recommendation system calculates the recommendation result based on the user's virtual location, which leads to inaccurate recommendation results. k -anonymity technique, although it is effective for location protection, is less capable of protecting the user's location during continuous requests, because an attacker will analyze the user's action trajectory based on the user's location requests at multiple moments, and then infer the location visited by the user, exposing the user to security threats. Moreover, k -anonymity is achieved by sacrificing the quality of service in exchange for privacy protection [13].

Since the existing location-based point-of-interest recommendation system mainly calculates recommendation

results by analyzing users' social relationships and geographical factors, the deep interaction information between users and POI and users' comment information have more user characteristic information compared with the case of sparse social relationships of users, which can effectively improve the accuracy of the recommendation system. Therefore, how to improve both location privacy protection capability and recommendation system performance is the focus of this paper.

The main contribution of this paper is the design and analysis of a recommendation system that takes location protection into account. Because previous recommender systems did not focus on the protection of user location information, after continuous exploration it is found that privacy protection does not need to sacrifice the greater accuracy of the recommender system. User location information as the most important factor of the recommendation system calculation results, there exists the attack method against location information. The KMG method proposed in this paper is a controllable generalized geolocation algorithm, which calculates virtual location based on all user locations in the anonymous region and divides subanonymous regions based on the distance between real location and virtual location to achieve effective protection of user location without significantly reducing recommendation accuracy. The contribution of this paper in the recommendation system is mainly to fuse the deep interaction information and comment information between users and POI to obtain a more efficient and deeper recommendation algorithm, and integrate it with the location protection algorithm into one system.

II. RELATED WORK

First LBSN-based recommendation systems usually considers three factors: user similarity, social influence, and geographic influence[14]. The traditional method of recommendation by extracting user ratings and review features suffers from cold start and data sparsity. Park et al.[15] proposed ConvMF recommendation model, which integrates CNN into probability matrix decomposition can effectively capture contextual information and improve recommendation accuracy. Zhao et al.[16] proposed hierarchical dichotomous graph neural network, by stacking multiple graph neural networks(GNN) and alternating with clustering algorithm to obtain the potential preference information of users, which substantially improves the recommendation performance compared to the recommendation system with fused CNNs. Lin et al.[17] fused multilayer graph convolutional models with recurrent neural networks to capture user interaction graph information, which can accurately capture the rich potential implicit information between users-items. Shafqat et al.[18] transformed the similarity into the interaction probability between the neighbors of user nodes with different probability distributions using KL scatter to find the distance between them and perform clustering operations on neighboring nodes, and this method improves the efficiency of neighborhood aggregation for GCN models. The graph neural collaborative filtering model (NGCF) proposed by Wang et al.[19] is one of the classical recommender systems incorporating the GCN model, which embeds and models the user interaction information to obtain the higher-order connectivity between nodes and recommends items of interest to users. He et al.[20]

proposed the LightGCN model, which eliminates the feature transformation and nonlinear activation in GCN and improves the efficiency of neighborhood aggregation. However, existing location-based point-of-interest recommendation algorithms generally use fused social relationships without deep mining of user and POI node interaction information, and although GCN can extract the association relationship between users and POI well, most location-based recommendation algorithms do not take into account the advantages of deep learning for processing textual information. Therefore, this paper will use both GCN and deep learning methods to extract interaction information and text information respectively.

There is a correlation between user check-in to points of interest and geographic distance. Ye et al.[21] analyzed the effect of distance on user check-in on the Foursquare and Whrrl datasets and constructed probability distributions based on the POI distance of the same user check-in. Most of the points of interest checked-in by the same user are in a range of small mutual distance, i.e., the check-in locations have a geographic cluster area effect. They fit the check-in probabilities to a power-law distribution, and found that they could cover most (90%) of the POI pairs after eliminating those that did not fit the power-law distribution. Therefore, the power-law distribution can be used to model the distance between POI visited by the same user and calculate the check-in probability.

k -anonymity is one of the main methods for privacy preservation. Song et al.[22] proposed k -anonymity method, whose basic idea is to remove user identification information from data so that each user in the same equivalence class is identified with probability A , so it has high privacy preserving ability. Gruteser et al.[23] introduced the idea of k -anonymity into LBSN privacy preserving by generalizing the real location of the user into an anonymous region and fuzzy the spatial location information of the user. Liu et al.[24] proposed the B-privacy method, which delineates the area of the region according to the user's location no less than s and generates k virtual locations. Since the B-privacy method statically sets the parameters k and s , it leads to weak protection in areas with small population density. Since the above methods use virtual locations to obtain query results, which leads to low precision of results. Ji et al.[25] proposed to split the anonymized region into several dispersed subanonymized regions, which not only reduces the scope of the anonymized region, but also improves the precision of user queries. Although all these location protection methods effectively protect the user's location, they construct as large a virtual region as possible in order to enhance the security strength, resulting in uncertainty in the distance between the user's virtual location and the real location, which will have an uncertain impact on the recommendation effect when combined with the recommendation algorithm. Therefore, in this paper, by limiting the distance between the real location and the virtual location and fusing the construction of subanonymous regions, the virtual location can meet the security and ensure that it does not have a great impact on the accuracy of the recommendation system.

We construct an anonymous region containing k users based on their locations, and replace the center location with

the user location, and the recommendation algorithm recommends users based on the center location. If the distance between the center location and the user location is large, the anonymous region is divided into sub-anonymous regions, and the interest points are recommended again based on the center location of the sub-anonymous region. The recommendation algorithm extracts and fuses high-order interaction features, text features and rating features by LightGCN, CNN and latent factor model (LGCL) respectively, and then recommends POIs jointly with geographic distance factor check-in probability.

III. RECOMMENDATION ALGORITHM

The recommendation algorithm in this paper consists of two parts: the LGCL module and the geographic distance probability. The LGCL module is a nodalization of user-POI through the LightGCN model, which uses GCN to propagate aggregated user-item interactions on the graph and obtain an embedded representation of all user-item association relationships on the graph; the text feature extraction module is to process the text data into a collection of embedding vectors by BERT pre-training model, and then extract the text features by CNN; the rating data processing module obtains the implicit features of the rating matrix by the implicit semantic model (LFM). The geographical distance probability p^g is calculated using the naive Bayesian method based on the user's historical check-in distance. Finally, the features processed by the similarity module are fused and normalized to obtain \hat{f}'_{u_i} , and the POI is recommended to the user jointly with p^g . The structure of the recommended algorithm is shown in Fig. 1.

Fig. 1. Recommended algorithm structures.

A. LGCL Model

The ID features of the user and POI are first fed into the embedding layer, and the set of embedding vectors is represented as:

$$e_u^{(0)} = [e_{u_1}^{(0)}, e_{u_2}^{(0)}, \dots, e_{u_N}^{(0)}], e_p^{(0)} = [e_{p_1}^{(0)}, e_{p_2}^{(0)}, \dots, e_{p_M}^{(0)}] \quad (1)$$

where N users, M POI, $e_{u_i}^{(0)}$ and $e_{p_j}^{(0)}$ denote the c dimensional embedding vectors of user i , POI j , respectively.

Then the IDs of all POI nodes in all neighboring nodes of user u_i are embedded in the vector for aggregation operation. The propagation rule for the embedding representation of user u_i in the LightGCN model for layers L to $L+1$ by:

$$e_{u_i}^{(L+1)} = \sum_{p_j \in N_u} \frac{1}{\sqrt{|N_u|} \sqrt{|N_p|}} e_{p_j}^{(L)} \quad (2)$$

$$e_{p_j}^{(L+1)} = \sum_{u_i \in N_p} \frac{1}{\sqrt{|N_p|} \sqrt{|N_u|}} e_{u_i}^{(L)} \quad (3)$$

where N_u and N_p denote the set of neighboring nodes containing all u_i and p_j , respectively; $e_{u_i}^{(L+1)}$ and $e_{p_j}^{(L+1)}$ denote the expression of the embedding of u_i and p_j in LightGCN obtained after the propagation of L layers in $L+1$ layers.

In order to obtain better embedding aggregation, this paper introduces an attention mechanism to get the importance weight of each layer of propagation:

$$Attention_{u_i}^l = softmax(\mu_1 \otimes sigmoid(\mu_2 \otimes e_{u_i})) \quad (4)$$

where μ_1, μ_2 are adjustable hyperparameters, $Attention_{u_i}^l$ is the layer L weight; weighted summation of the embedding vectors for each layer yields the embedding expression for the association between u_i and p_j :

$$E_{u_i} = \sum_{l=0}^L Attention_{u_i}^{(l)} e_{u_i}^{(l)}, E_{p_j} = \sum_{l=0}^L Attention_{p_j}^{(l)} e_{p_j}^{(l)} \quad (5)$$

B. Text Feature Extraction Module

All comments of the same user or POI constitute the comment collection, respectively. Because the extraction of user and POI comment features is composed of two similar parallel network structures, only the extraction of user comment features is described in this paper. To simplify the calculation, let the number of comment texts of each user and POI be n and the length of each comment text be q . The comment set r_{u_i} of user u_i is input to the BERT pre-training model to obtain the comment embedding vector $e_{u_i} \in R^{n \times q \times d}$, where d is the output dimension of the BERT pre-training model.

The user comment embedding vector e_{u_i} is input to CNN for extracting semantic information features. Let the m convolutional kernels with step size s extract contextual features:

$$g_j = Relu(M_i * R + b) \quad (6)$$

where $Relu()$ is the activation function, $*$ denotes the convolution operation, and b_i denotes the bias.

After the convolution operation, the features g_j are fed into the max-pooling layer to generate features with higher values, which take the maximum vector w_i for the region $max(g_1, g_2, \dots, g_{d-s+1})$ corresponding to the convolution kernel, preserving the characteristics of the original feature vector and reducing the dimensionality.

Due to the fact that each comment in the comment collection expresses user preference features to a different degree, this paper introduces an attention mechanism that applies different weights to the comments and normalizes them using the softmax function:

$$h_i = softmax(Relu(\mu_3 \otimes g_i + b)) \quad (7)$$

Finally, the text information feature representation of the user u_i is obtained after processing in the fully connected layer:

$$C_{u_i} = \sum_{i=1}^n a_i h_i \omega_i + b_i \quad (8)$$

where a_i and b_i denote the amount of deviation from the weights of the fully connected layer, respectively.

C. Rating Data Processing Module

The rating can be regarded as a direct feedback, and the level of rating can express the user's liking of the POI. In this paper, we use the Latent Factor Model (LFM) to process the user rating matrix, the essence of which is to decompose the rating matrix to get the user feature matrix and the POI feature matrix, so that the implicit features can be expressed.

The LFM model is to decompose the scoring matrix R into a user feature matrix S_{N_t} and a POI feature matrix T_{tM} such that the matrix multiplication of S_{N_t} and T_{tM} is approximately equal to R , where t is the hidden feature vector dimension:

$$\hat{R}_{NM} = \sum_{t=1}^t S_{N_t} T_{tM} \quad (9)$$

To obtain accurate potential feature matrices of users and POIs, this paper obtains the feature matrices S_{N_t} and T_{tM} by iteratively minimizing the loss function, and the expressions are shown below:

$$Loss(S, T) = \sum_i^N \sum_j^M (R_{ij} - S_i T_j)^2 + \omega (\sum_i^N \|S_i\|^2 + \sum_j^M \|T_j\|^2) \quad (10)$$

To avoid overfitting add the regularization term, ω is the regularization parameter. To minimize the loss function, this paper iteratively optimizes the parameters by iteratively moving the variables along the direction of the negative

gradient of the loss function through the gradient descent method until convergence to the true scoring matrix.

D. Feature Integration

The final feature representations of users and POIs are obtained by fusing the associative relationship feature vectors E_u, E_p and text feature vectors C_u, C_p and scoring feature vectors S_u, T_p obtained from the LightGCN processing module, the text feature extraction module and the scoring data processing module:

$$U_{u_i} = E_{u_i} \oplus C_{u_i} \oplus S_{u_i}, P_{p_j} = E_{p_j} \oplus C_{p_j} \oplus T_{p_j} \quad (11)$$

The prediction of user u_i rating of interest point p_j is:

$$\hat{f}_{u_i} = U_{u_i} \otimes P_{p_j}^T \quad (12)$$

which is normalized to obtain \hat{f}'_{u_i} .

To minimize the difference between the predicted score \hat{f}_{u_i} and the true score f_{u_i} in the dataset, this paper uses a loss function to adjust the model parameters, which is calculated as follows:

$$loss = \sum_{i,j \in O} (\hat{f}_{i,j} - f_{i,j}) + \lambda \|\Theta\|^2 \quad (13)$$

where O denotes the number of samples in the training set; $\lambda \|\Theta\|^2$ is the canonical term and Θ is all trainable model parameters in the model, where λ is the adjustable coefficient of the canonical term, which is used to control the model parameters to prevent overfitting. This paper uses Adam to optimize the model parameters and minimize the loss function.

E. Geographical Distance Probability

The probability of a user signing up to a POI follows a power-law distribution of geographic distance probabilities, so this paper calculates the probability of a user signing up to a POI by modeling the distance between POIs with a power-law distribution, which is calculated as follows:

$$p[d(l_m, l_n)] = a \cdot d(l_m, l_n)^b \quad (14)$$

where a, b are the parameters of the power-law distribution and $d(l_m, l_n)$ is the distance between the point of interest l_m and l_n .

For the POI set $l_k (k=1, 2, \dots)$ around l_i , it has an effect on the probability of a user checking in to l_i . Therefore, under the influence of the set l_k , the probability of a user visiting l_i is calculated using the plain Bayesian method:

$$p^s = p[l_i | l_k] = \frac{p[l_k] \cdot \prod_{k=1, 2, \dots} p[d(l_i, l_k)]}{p[l_k]} \quad (15)$$

where the total number of check-ins is greater than l_i and the closest interest point is judged to have some influence on the set l_k of user check-ins to l_i . Finally, this paper normalizes the check-in probabilities as follows:

$$S_{i,j}^g = \frac{p_{i,j}^g}{z_i^g}, \text{ where } z_i^g = \max_{j \in L_k} p_{i,j}^g \quad (16)$$

F. Joint Recommendation Result

This paper integrates user similarity factors and geographic distance probabilities into a linear function, and then calculate the combined probability P of user u_i signing up to p_j :

$$P = (1-\alpha)\hat{f}_{i,j}' + \alpha S_{i,j}^g \quad (17)$$

where α and $1-\alpha(0 \leq \alpha \leq 1)$ represent the weights of the two factors, respectively, and when α is 0 means that the recommendation result is independent of the geographical distance factor.

IV. GEOLOCATION PROTECTION ALGORITHM

The KMG algorithm in this paper inherits the ideas of k-anonymity and location generalization, and changes the user's real location dynamically according to the locations of other users around. The individual location k-anonymity method has better protection for users who make location request services non-continuously, and poor protection for requesting continuous services, such as attackers who connect check-in records at different times to form trajectories, and can infer the user's true location by combining the direction and distance of the trajectories. Therefore, this paper combines k-anonymity techniques with location generalization techniques to provide better privacy-preserving capabilities for both individual service requests and consecutive requests.

A. Description of KMG Algorithm

The KMG protection algorithm is shown in Algorithm 1. The anonymous parameters k and L are set to 15 and 10, respectively. The specific scheme is as follows:

1) After receiving the location $l(x, y)$ of user u , the KMG protection algorithm finds the nearest remaining $k-1$ users according to his location and obtains their location information to generate the anonymous region, as in Fig. 2(a), and if the number of users in the anonymous region is less than k , a virtual user is generated. The center coordinates of k users in the anonymous region are calculated, and when the distance l between user u and the center coordinates is less than L , the center coordinates are replaced with the real locations of all users in the anonymous region and sent to the recommendation algorithm. Where x and y denote longitude and dimension respectively.

2) If there exists a user whose distance from the center coordinate is greater than L , the anonymous region is divided into n subanonymous regions, as shown in Fig. 2(b). Suppose the anonymous region is divided into 3 subanonymous regions.

The number of users k' in each subanonymity region is 5, and the first subanonymity region is formed by finding the nearest 4 users with user u as the center, and repeating the process of forming a subanonymity region by selecting a user as the center among the remaining users at random. The center coordinates are calculated based on the position of the user in each subanonymous region and sent to the recommendation algorithm instead of the position of the user in the subanonymous region.

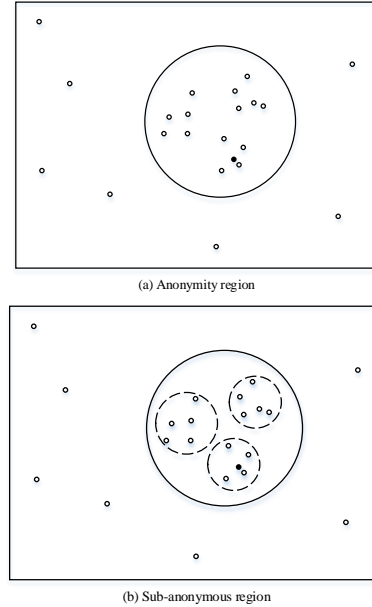

Fig. 2. Constructing anonymous regions and sub-anonymous regions.

3) *Virtual user generation*: Generating virtual users satisfies the principles of user distribution similarity and distance similarity. Firstly, the distance between existing users in the anonymous region is calculated and sorted, and the minimum distance between users is s . Virtual users are added in the space of any two users so that the distance between virtual users and users is not less than $s/2$ and does not overlap with the real user position.

Algorithm 1. KMG Algorithm

Input: k user locations $(L_1(x_1, y_1), L_2(x_2, y_2), \dots, L_k(x_k, y_k))$
Output: Returns the generalized location of all users in the anonymous region or sub-anonymous region (x', y')

```

1: if  $sum(L_i) < k$ :
2:      $sort \leftarrow dis(L_i, L_j), add(L_{k-i+1}, \dots, L_k)$ 
3:  $AR_0 \leftarrow Gen(L_i(x_i, y_i))$ 
4: if  $L \geq dis(L_i(x_i, y_i), AR_0(x_o^{(0)}, y_o^{(0)}))$ 
5:     return  $(x_o^{(0)}, y_o^{(0)})$ 
6: else:
7:      $k \% n == 0$  and  $n \geq 2$ 
8:      $(AR_1, AR_2, \dots, AR_n) \leftarrow Gen(L_a(x_a, y_a), L_b(x_b, y_b), \dots, L_n(x_n, y_n))$ 
9:     return  $(x_1^{(1)}, y_1^{(1)}), (x_2^{(2)}, y_2^{(2)}), \dots, (x_n^{(n)}, y_n^{(n)})$ 
10: end

```

B. Privacy Analysis based on Information Entropy

The uncertainty of information is proportional to the information entropy. Therefore, this paper uses Shannon entropy as a measure of the privacy-preserving ability of the model, and a larger Shannon entropy value indicates that it is more difficult for an attacker to distinguish the user's true location from the k locations. Shannon entropy is defined as follows:

Definition 1. Assuming that the random variable x takes values on a finite set X , the entropy of the random variable x is defined as

$$H(x) = -\sum_{x \in X} p(x) \log_2 p(x) \quad (18)$$

where $p(x)$ denotes the probability when the variable takes the value x .

The attacker successfully attacks and obtains the user location information in the anonymous region as an event set X . The successful attack on a single user's location information is an event x within the event set, and $p(x)$ denotes the probability of obtaining the user location information, which has a high uncertainty. The location protection method against this paper, this process needs to be divided into two cases. In the first case, if there is no sub-anonymous region, the attacker successfully obtains the anonymity region corresponding to the user and successfully identifies the user; in the second case, if there is a sub-anonymous region, the attacker successfully identifies the user on top of successfully obtaining the anonymity region and the sub-anonymous region. Since anonymous regions cannot be distinguished directly, the probability that the attacker successfully obtains the anonymous region where the user is located is $1/N$ (assuming there are N anonymous regions). If there is a sub-anonymous region, the probability that the attacker succeeds in obtaining the sub-anonymous region is $1/n$. The probability that the attacker succeeds in identifying the user from the anonymized region or sub-anonymous region in the second step is $1/k'$.

Therefore the probability of an attacker successfully obtaining user information is

$$p_u = \begin{cases} \frac{1}{kN} \\ \frac{a}{nk'N} \end{cases} \quad (19)$$

where a denotes the weight value for dividing sub-anonymous regions, and in this model if there exists $l > L$, then sub-anonymous regions are divided.

The entropy of the user can be obtained from (18) as:

$$H(u) = -p_{u_r} \log_2 p_{u_r} \quad (20)$$

The entropy of all users in the anonymous region is:

$$H(u) = \begin{cases} \sum_i H(u_r) \\ \sum_i \sum_j H(u_r) \end{cases} \quad (21)$$

Therefore, when a higher value of anonymization k is chosen, the higher the entropy value of the whole anonymization region, the higher the degree of privacy.

V. ANALYSIS OF EXPERIMENTAL RESULTS

A. Dataset Description

In this paper, we use the Yelp dataset, which is widely used for location-based social network research, as the experimental data. In this paper, the data set is divided by the filter condition that the total number of check-ins is greater than 10 and the number of comments is greater than 3. The data sparsity is 2.63×10^{-3} , and the check-in dataset contains user ID, POI ID, longitude, latitude, comments, ratings and time information. This paper randomly selects 80% of the check-in data from the dataset as training data, and the other 20% as test data.

B. Evaluation Metrics

To assess the recommendation quality of the recommendation $Top-K$, this paper uses $Precision@K$ and $Recall@K$ as evaluation criteria, where K denotes the number of recommended POIs ($K=5,10,15,20$).

$$Precision@K = \frac{A \cap B}{B} \quad (22)$$

$$Recall@K = \frac{A \cap B}{A} \quad (23)$$

Where A denotes the POI of user check-in in the test set and B denotes the POI in $Top-K$.

C. Comparison Approach

To verify the performance of the algorithm proposed in this paper, this paper compares the algorithm with the following three algorithms, all of which involve location privacy protection and point-of-interest recommendation. In this paper, the experimental dataset operation of the compared methods is the same as the method proposed in this paper, while generalizing the user location according to the location protection algorithm and using virtual location to make recommendations to users.

1) *USG[21]*: This method blends user preferences for POIs, social relationship influence and geographic influence, and calculates the probability of recommended POIs by the Naive Bayes method. Note that the USG model does not have location privacy protection.

2) *USD[26]*: This method is based on k-coordinate generalized user location and then POI recommendation, where the recommendation system is similar to the USG method. However, in terms of geolocation influencing factors, USD calculates the recommendation POI probability based on the check-in frequency.

3) *GLP[14]*: The GLP approach generalizes user locations based on population density (i.e., check-in density) and uses virtual locations to recommend POIs to users.

D. Experimental Parameters Adjustment

In order to achieve the best recommended performance, the experiment-related parameters are set in this paper as follows:

embedding vector dimension 64; BERT model output dimension d is 128; number of graph convolution iterations is 3; attention mechanism dimensions are 64 and 128, respectively; regularization coefficient λ is 1×10^{-4} . In addition, the experimental comparison model uses the parameter settings with the best results in the corresponding literature.

E. Regularization Coefficient

The regularization coefficient λ takes a range of $[1 \times 10^{-1}, 1 \times 10^{-2}, 1 \times 10^{-3}, 1 \times 10^{-4}, 1 \times 10^{-5}]$, which is essentially to adjust the hyperparameters in the LGCL model to make feature extraction more accurate and prevent overfitting. The parameters K , L and α are set to 5, 10 and 0.2, respectively. As shown in Table I, the values of $Precision@K$ and $Recall@K$ of the recommendation algorithm show a trend of increasing and then decreasing with the decrease of the regularization coefficient. When λ is 1×10^{-4} , both $Precision@K$ and $Recall@K$ reach the maximum; when λ is 1×10^{-5} , $Precision@K$ and $Recall@K$ decrease, and considering the overfitting problem, the regularization coefficient is 1×10^{-4} .

TABLE I. REGULARIZATION COEFFICIENT COMPARISON EXPERIMENT

Recommended performance	Regularization coefficient				
	1×10^{-1}	1×10^{-2}	1×10^{-3}	1×10^{-4}	1×10^{-5}
Precision@K	0.1473	0.1754	0.2041	0.2452	0.2270
Recall@K	0.0158	0.0182	0.0214	0.0232	0.0226

F. Geographical Distance Factor Weighting Analysis

The weight of the geographic distance factor has a significant effect on the performance of the recommendation algorithm. As shown in Fig. 3, the recommendation parameters K and L are set to 5 and 10, respectively. As the geographic weight α increases, $Precision@K$ and $Recall@K$ gradually decrease, and the recommendation algorithm achieves the best performance when α is 0.2.

G. L-value Analysis

The L value indicates the critical value of the distance between the real location and the center location of the anonymous region, which has a certain influence on the performance of the recommendation algorithm. The parameter α is set to 0.2. The range of the value of L is set to $[10, 60, 100, 150, 300]$. As shown in Fig. 4, with the fixed $Top-K$, the $Precision@K$ and $Recall@K$ of the recommendation algorithm gradually decrease as the parameter L increases. When the value range of L is $[10, 60, 100, 150]$, the recommendation performance is weakened, but there is no significant impact on the accuracy of the recommendation results. When K is 5, the Recall values when L is 60, 100 and 150 are 2.5%, 6.89%, 15.9% and 38.8% lower than the Recall values when L is 10, and the Precision is 0.9%, 1.2%, 2.3% and 5.8% lower, respectively. Therefore, $[10, 150]$ is a reasonable interval for the parameter L .

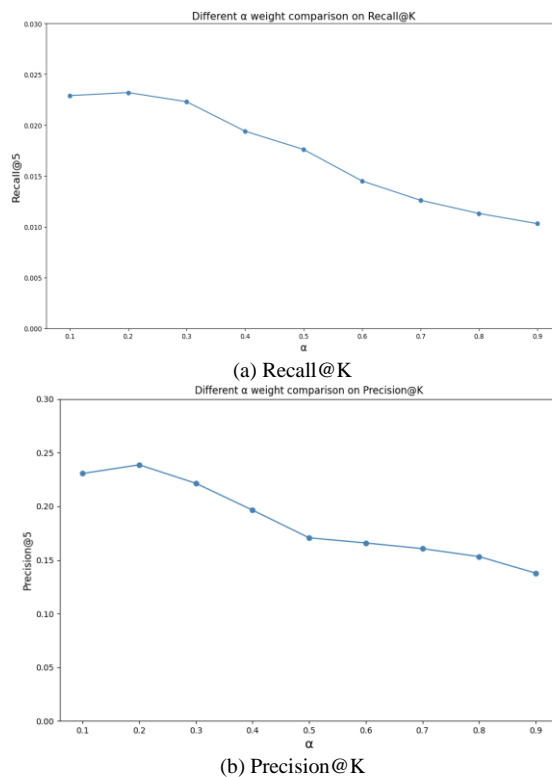

Fig. 3. Recall@K and precision@K of recommendation algorithm.

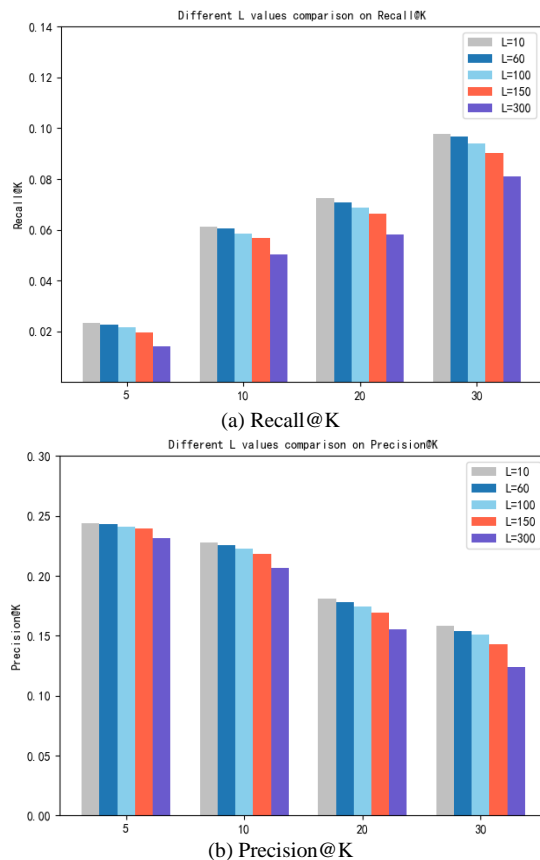

Fig. 4. Recall@K and precision@K of different l values.

H. Performance Comparison

Fig. 5 shows the recommended performance of Top-K (5,10,20,30) for all methods with α set to 0.2, respectively. Fig. 5(a) shows the *Recall@K* performance and Fig. 5(b) shows the effect of *Precision@K*. The performance of our method degrades as K increases. From the figure, it can be seen that the method proposed in this paper outperforms USG, USD and GLP in terms of accuracy and recall. By analyzing Fig. 5, it can be seen that the performance of the recommendation algorithms proposed in this paper are both higher than other comparison algorithms. Although the performance improvement of the method proposed in this paper is small compared with the USG method when K is taken as 5 (Recall and Precision are improved by 5.4% and 6.3%, respectively), the method proposed in this paper generalizes the processing for user location, and from the perspective of information entropy, the method in this paper has a better privacy protection ability. Thus a good balance between recommendation performance and privacy protection can be achieved by sacrificing a small recommendation performance.

Fig. 5. Performance comparison of different methods.

VI. CONCLUSION

In this paper, we propose a recommendation algorithm that integrates GNN and geographic distance based on geographic location privacy protection. The algorithm learns implicit features from interaction information, comment information, and geographic distance for user recommendations, and integrates k-anonymity and generalization techniques for user location privacy protection. Finally, the information entropy theory analysis and experiments on real datasets show that our proposed recommendation system with integrated location protection can better adapt to interest in LBSN while effectively protecting user location privacy compared to other algorithms point recommendation. Therefore, it is meaningful and feasible to integrate privacy protection in point-of-interest recommendation systems. Since recommendation systems in location services involve geographic location and information records, the next step of research will focus on improving information record protection on the basis of ensuring recommendation performance.

Abstract—With the rapid development of the Internet of Things technology, the security of the Internet of Things is becoming increasingly important. Internet of Things (IoT) identity authentication is an important means to ensure network security. However, common identity authentication protocols have problems such as insufficient security factor and low efficiency. A smart home IoT identity authentication protocol based on Chebyshev chaotic map is proposed to improve the security of identity authentication. To solve the problem of low security of session key, the LAoCCM identity authentication protocol based on Chebyshev chaotic map is proposed to update session key. To solve the problem that the number of chaotic maps is too high, AEAD algorithm is introduced to reduce the number of chaotic maps. The results show that the average authentication error of LAoCCM authentication protocol is 0.00085, which is significantly smaller than that of EDHOC and ZKOP authentication protocols. Therefore, the proposed LAoCCM identity authentication protocol based on Chebyshev chaotic map has higher security performance and authentication efficiency, which can effectively meet people's needs for information security of smart furniture.

Keywords—Chebyshev; chaotic map; internet of things; identity authentication; LAoCCM protocol; key agreement; EDHOC protocol

I. INTRODUCTION

The fast advancement of connectivity, automation, and sensing technologies has made the IoT increasingly popular. In recent years, many different areas have made extensive use of the Internet of Things, such as smart home, industry, healthcare, and public safety, enhancing daily convenience for people [1]. Among them, the smart home is based on the family house as the carrier, integrating various communication technologies, network information technology and automatic control technology, etc., to realize the intelligence, comfort and high efficiency of home life. While realizing the smart home, a large amount of personal information is required to be registered and used, and the network system is subject to various malicious attacks and illegal intrusions. The resulting network security problems have become increasingly prominent. How to protect the privacy of individuals in the Internet of Things environment has become a need right challenge [2]. The most straightforward approach entails enhancing the IoT network system's security performance. Chaos, as a special form of movement, has significant randomness in the movement process. It is one of the commonly used methods to improve the cryptographic security

factor by using chaotic transformation in information encryption systems [3]. As a kind of chaotic sequence, the chaotic map based on Chebyshev has unique advantages in the construction of cryptosystem [4]. Based on the above background, the main issues that need to be addressed are as follows. Firstly, the key performance of IoT devices used in smart homes is weak, and in complex and ever-changing network environments, their passwords are easily cracked, posing a threat to system security. In addition, most IoT identity authentication protocols have limited computing and communication capabilities, resulting in significant resource consumption during the computing process, which limits the actual usage environment. Therefore, the research purpose of this article is to improve the weak security performance and low efficiency of the smart home IoT identity authentication process by designing an improved Chebyshev identity authentication protocol. At the same time, it reduces the computation and energy consumption in the identity authentication process. With the gradual opening up of the Internet, the problem of privacy leakage has become increasingly serious. Combining Chebyshev chaotic mapping with privacy protection meets user needs while enhancing protocol security. Through this identity authentication protocol, the security performance of IoT devices in smart homes is improved, ensuring the privacy and property security of internet users, and meeting people's higher network security needs. It has significant theoretical and practical significance for ensuring the stable development of network information security.

This study describes a smart home IoT identity authentication protocol for identity recognition. This identity authentication protocol is applicable to identity authentication and recognition of various types of smart homes, achieving the maintenance of network security and ensuring the safe development of network information. The main contributions of this study are as follows. Firstly, based on the Chebyshev chaotic map, a key agreement protocol is constructed using its characteristics to encrypt and decrypt information. Secondly, in response to the problem of high frequency of Chebyshev chaotic mapping, the study introduces the AEAD algorithm to reduce the frequency of chaotic mapping. By optimizing and updating the session key through Chebyshev chaotic mapping, the security and effectiveness of smart home identity authentication are ensured.

II. RELATED WORK

Chebyshev polynomials are extensions of cosine and sine functions derived from multiple angles, and are widely used in mathematics, physics, and science and technology. Abbasinezhad-Mood D et al. [5] proposed to construct a public key cryptosystem based on Chebyshev chaotic map for the security problems of shared keys in existing V2G networks, and anonymize the key agreement scheme. The results show that the efficiency of the proposed key agreement is significantly higher than other commonly used key agreements. Using Chebyshev polynomial theory, Yxh A et al. [6] studied the motion change of a dynamic model in an intelligent structure. Studies have found that under certain conditions, the model will lose its stability and produce periodic and chaotic motion. Qi RX et al. [7] presented a Chebyshev-based identity authentication scheme for real-time access to solve security and privacy issues. The results show that the method studied has less computational overhead and higher security performance. When Joachimiak M et al. solved the Laplace equation's inverse Cauchy-type puzzle, they used Chebyshev polynomials to deal with the problem, and thought about regularizing the issue, so that the problem was effectively solved [8]. Safdari H et al. used the Chebyshev configuration method to discretize the spatial fractions when solving the spatiotemporal fractional advection-diffusion equation (STFADE), which proved to be more accurate than other solutions [9]. Bozkaya C et al. [10] used the Chebyshev collocation method to solve the magnetohydrodynamics problem of an incompressible electric fluid in a square pipe, and discretized the governing equation by implementing the pre-assigned collocation points in the physical space. Body mechanics analysis can achieve relatively accurate results.

An information network system based on Internet technology and communication technology is known as the Internet of Things, which can break through the limitations of time and space to achieve barrier-free information interaction. As the result of information development, the Internet of Things technology brings with it problems such as network security and information leakage that need to be solved urgently. To stop harmful assaults that the Internet of Things could experience, Wan Z et al. [11] designed an IoT node roaming authentication model to improve the Internet of Things' security authentication performance. The findings indicate that this method can successfully fight off many network threats and has lower energy consumption. Liang W et al. [12] designed a radio frequency identification system based on multiple selection arbitrators, aiming to realize two-way identity authentication between the server and the user, and improve the security performance of the Internet of Things. The test results show that the identity authentication protocol has a better ability to resist external attacks, while improving system stability. Prasad SK and others used the cryptographic primitives based on unclonable functions to develop the ID card identification protocol of the IoT platform, and used the characteristics of unclonable function keys that are difficult to copy and unpredictable to enhance the security performance of ciphers. Experiments have proved that the identity authentication method is feasible, and it provides effective support in the device authentication and data security of the medical Internet of Things network [13]. Al-Naji F and others

classified different attacks on the IoT and proposed corresponding solutions, and used continuous identity authentication instead of static identity identification to improve the Internet of Things system's security performance [14]. Zhang Q et al. [15] create a secure channel using the key agreement for the intelligent terminal of the Internet of Things, to guarantee the intelligent terminal's security throughout information transfer. The findings demonstrate that the major agreement has increased security and lower time cost and energy consumption. Aiming at the problem of limited wireless sensor network nodes, Sharif AO et al. redesigned a key agreement scheme to build a secure channel between users and sensor nodes. The lightweight identity Internet of Things-based authentication protocol wireless sensor proposed by the research has been widely used [16].

To sum up, there are many related researches on using Chebyshev chaotic map to solve the problem. At the same time, corresponding improvement methods have also been proposed for the network security problems existing in the Internet of Things. However, for the Chebyshev polynomial in the password design system, the study of the identity authentication protocol for the Internet of Things is relatively insufficient, and the research on the use of this advantage to create the identity authentication protocol for the Internet of Things is relatively insufficient. Therefore, the research aims to develop a system for Internet of Things identity authentication based on Chebyshev polynomial chaotic mapping for this problem to improve security and effectiveness in IoT authentication process.

III. IDENTITY AUTHENTICATION PROTOCOL FOR SMART HOME IOT BASED ON CHEBYSHEV CHAOTIC MAPPING

A. IoT Authentication Protocol based on Chebyshev Chaotic Map

The perception layer, network layer, and application layer make up an IoT system. Commonly used IoT authentication protocols include identity authentication based on hash operation, IoT lightweight authentication protocol based on elliptic curve (Ephemeral Diffie-Hellman Over COSE, EDHOC) and IoT authentication protocol based on Chebyshev chaotic mapping. However, the identity authentication protocol based on hash operation does not use public key system, and only uses hash function for information saving calculation, so its security performance is low. Although the EDHOC identity authentication protocol has achieved some improvement in security, its computational cost is much higher than the hash authentication protocol, and the operation process is more complex. Among them, chaotic cryptography is widely used due to its low computational difficulty and high security. Chebyshev chaotic maps, as a class of chaotic sequences, have unique advantages in constructing cryptographic systems. Chebyshev polynomials have good pseudo-random characteristics, sensitivity to initial conditions and system parameters, and can effectively meet the principles of confusion and divergence in cryptographic design systems. Compared to traditional public key cryptography, this method has more advantages in computational storage [17]. Chebyshev polynomial chaotic maps are divided into three types, and the one used in the study belongs to the first type of Chebyshev

polynomial. A Chebyshev polynomial is a sequence of orthogonal polynomials arranged recursively. The Chebyshev polynomial's expression $T_n(x) : [-1, 1] \rightarrow [-1, 1]$ is shown in formula (1).

$$T_n(x) = \cos(n \cdot \arccos(x)) \quad (1)$$

In formula (1), n defined as an integer, $x \in [-1, 1]$, is a variable. The Chebyshev chaotic map's iterative connection is shown in formula (2).

$$T_n(x) = 2xT_{n-1}(x) - T_{n-2}(x), n \geq 2 \quad (2)$$

In formula (2), $T_0(x) = 1$, $T_1(x) = x$. The initial Chebyshev polynomial is expressed as $T_2(x) = 2^2 - 1$, $T_3(x) = 4x^3 - 3x$, $T_4(x) = 8x^4 - 8x^2 + 1$. From the initial expression, it can be known that the first kind of Chebyshev chaotic map contains two characteristics, namely, the chaotic property and the semigroup property. When integer $n \geq 1$, the polynomial map $T_n(x) : [-1, 1] \rightarrow [-1, 1]$ is n a density-invariant chaotic map based on Lyapunov exponents. The semigroup property means that $r, s \in N$ the relation in formula (3) exists for any time.

$$T_r(T_s(x)) = T_s(T_r(x)) = T_{rs}(x) \quad (3)$$

In formula (3), $x \in [-1, 1]$. When x in the interval $(-\infty, +\infty)$, the extended Chebyshev polynomial can be obtained, as shown in formula (4).

$$T_n(x) = (2xT_{n-1}(x) - T_{n-2}(x)) \pmod{p} \quad (4)$$

In formula (4), $n \geq 2$, P represents a large prime number, mod representing the P modulo operation. When using the Chebyshev polynomial chaotic map for identity verification, it is necessary to design the corresponding public-key encryption, and the Diffie-Hellman key agreement method of the specific public key cryptosystem needs to convert the encryption method used into the corresponding cryptographic algorithm [18]. During identity authentication, the information needs to be identified, but to guarantee the security and effectiveness of the information, the information should be encrypted. Party A and Party B randomly select two digital sums, a and b after calculation, Party A obtains the relationship between the polynomial and a as shown in the formula (5) shown.

$$R_a = T_a(x) \pmod{p} \quad (5)$$

After calculation, Party B obtains the relationship between Chebyshev polynomial and b formula (6)

$$R_b = T_b(x) \pmod{p} \quad (6)$$

The calculation results are passed to both parties alternately. A encrypts the calculation result of B and the calculation result of his own random number that he has received a , and obtains a new encryption method as shown in formula (7).

$$SR_a = T_a(b) = T_a(T_b(x)) \quad (7)$$

In the same way, B encrypts the calculation result of A and the calculation result of its own random number, and obtains a new encryption method as shown in formula (8).

$$SR_b = T_b(a) = T_b(T_a(x)) \quad (8)$$

Formula (7) and formula (8) represent $T_n(x)$ Chebyshev polynomials with integer n order and parameters. x After the information passed is encrypted, the computation between the nonce and the session key SR is indistinguishable. On this basis, a Chebyshev chaotic mapping-based smart home IoT identity authentication technique is created. The authentication process is combined with the zero-knowledge proof proposed by Schnorr, which is defined as the ZKOP protocol in the study, so that the user's identity may be verified between them and the server. The specific process is shown in Fig. 1.

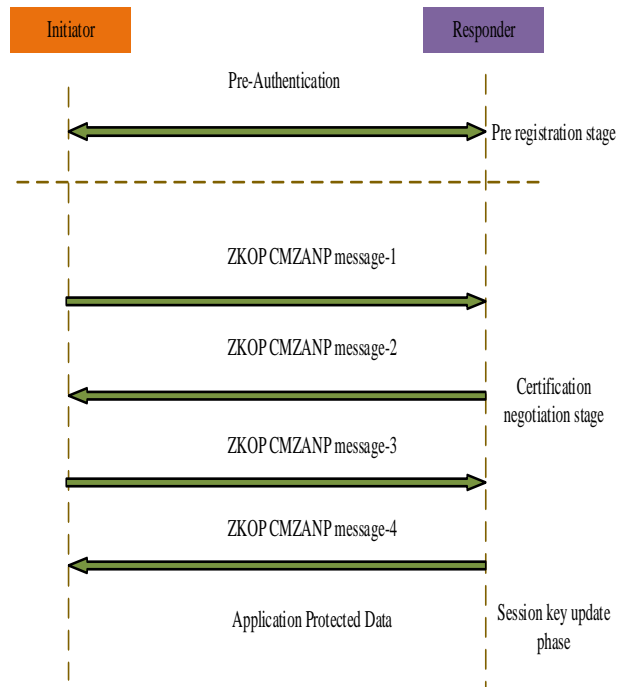

Fig. 1. Identity authentication protocol based on zero knowledge proof.

The identity authentication protocol process in Fig. 1 needs to experience multiple information interactions, which will affect the efficiency of identity authentication; at the same time, combined with zero-knowledge proof, it is concluded that the number of chaotic maps of Chebyshev chaotic maps is too high, which will aggravate the identity of IoT devices. Authentication pressure; in addition, in the Chebyshev chaotic map authentication process combined with zero-knowledge

proof, the session key only relies on automatic update, which cannot guarantee the security of information authentication.

B. LAoCCM IoT Identity Authentication Protocol based on Improved Chebyshev Chaos Mapping

Chebyshev chaotic map has good pseudo-random characteristics, which can meet the principle of confusion and diffusion in cryptographic design system. The application of chaotic cryptography based on Chebyshev polynomials has received more attention. However, the identity authentication protocol of Chebyshev chaotic map also has some shortcomings in the application process. First of all, too much information round-trip interaction directly affects the operation efficiency of the protocol. Secondly, the mapping times of chaotic mapping are too high, which will increase the pressure of IoT devices. Aiming at the above problems, the Lightweight Authentication over Chebyshev Chaotic Map (LAoCCM) is proposed to enhance the security capabilities of keys. The LAoCCM identity authentication protocol reduces the computation time of Chebyshev chaotic map by redesigning the authentication information generation and verification process, and completes the key update [19]. The LAoCCM protocol consists mostly of three steps, namely the pre-registration phase, the authentication negotiation phase and the session key update phase after the authentication negotiation. Table I displays several parameters related to the LAoCCM protocol procedure.

TABLE I. PARAMETER SYMBOLS AND MEANINGS IN LAOCCM PROTOCOL

Symbol	Meaning
DEV, GWN	IoT device and gateway GWN
P_A, P_B	Temporary public key of Chebyshev on both sides of the device and gateway
P_D, P_G	Authentication public key of both device and gateway
$T_n(x)$	Chebyshev polynomials of order n with parameter x
AEAD (K; Plaintext)	Encrypt additional data using the key K generated from the shared key
tD	Current time point of equipment
Extract	Production function of random key
Expand	Production function of symmetric key

During the LAoCCM protocol authentication process, both the IoT and the gateway hold the authentication public key $\langle D, P_D \rangle$ and authentication private key used by $\langle G, P_G \rangle$ them, where D and G represent the authentication private key of both, P_D and P_G represent the authentication public key of both. At the same time, the identifier ID_CRED_D sum of the corresponding authentication key is also required ID_CRED_G to retrieve the authentication key. In the authentication and key negotiation stage of LAoCCM, the first step is to judge the timeliness of the authentication information. At this time, it is necessary to use the Internet of Things to generate the current

timestamp t_{D1} for judgment, define the random number A , and calculate the Chebyshev polynomial such as formula (9) shown.

$$P_A = T_A(x) \pmod p \quad (9)$$

Before key negotiation, both parties need to determine the cipher suite SUITE-1 to use. Each SUITE-1 determines a set of cipher algorithms, including AEAD algorithm, hash algorithm, ECDH algorithm, etc. to encrypt information. However, in order to reduce the number of protocol round trips and the number of messages, the message round trip process can be simplified and the application auxiliary data can be transmitted with the message. Therefore, the application can use the AEAD algorithm in the selected cipher suite to protect the data to ensure the information security during the message round-trip process [20]. The IoT device will determine the used cipher suite suite-D, and pass the generated parameters to the gateway GWN, which is defined as Message 1; the second step is that the gateway checks the timeliness of the received information, and checks whether it conforms to the message in Message1. The cipher suite suite-D is used to judge the information. If the verification fails, the entire protocol is terminated; the gateway determines random number B and computes the Chebyshev polynomial if the verification is successful, as shown in formula (10).

$$P_B = T_B(x) \pmod p \quad (10)$$

In this stage, use Extract function and Expand function to decrypt the key, and use Extract to generate intermediate key (PRK). The gateway calculates the public information P_AB according to formulas (9) and (10), and thus two PRKs can be obtained, which are defined as PRK-1 and PRK-2 respectively. After the intermediate key is generated on the gateway side, the symmetric key K to be used needs to be generated, and the symmetric keys generated by the GWN are respectively defined as K-1 and K-2. After completing the above operations, use the gateway to construct a message authentication code, and use the AEAD algorithm in suite-D to encrypt K-1 and K-2, generate Mesange2 after encryption, and transmit the encrypted and authenticated information to the device for verification, and Verify Message2. The verification process is shown in Fig. 2.

Fig. 2. Message 2 validation process.

From the process in Fig. 2 that if the verification fails, the authentication protocol is terminated; if the identities of both parties pass the verification, formula (11) is obtained.

$$P_{AB} = T_A(P_B) = T_B(P_A) \quad (11)$$

After the server completes the PRK generation, the client must decrypt and authenticate the PRK, that is, the device ought to use the hash function to generate the symmetric key K-1, as shown in formula (12).

$$K_{1'} = \text{Expand}(PRK_{1}, H(\text{Message}_{1} \| t_{G1} \| P_{-}B)) \quad (12)$$

In formula (12), the $H(\cdot)$ hash function is represented, and the same can be obtained through the hash function to regenerate the symmetric key K-2, which PRK_{2} represents the intermediate key, as shown in formula (13).

$$K_{2'} = \text{Expand}(PRK_{2}, H(\text{Message}_{2} \| t_{G1} \| P_{-}B)) \quad (13)$$

The encrypted information is then decrypted and verified. If the decryption is successful, the gateway's identity is legitimate, and following identity authentication, the next stage of information transmission can be entered; if the decryption fails, it is considered that the identity of the gateway cannot pass the authentication, and the identity authentication protocol is terminated. After the device completes the processing of the gateway data, the encrypted information is decrypted and verified by the key K. If the verification is passed, the gateway also considers that the identity information is legal and can proceed to the next session key construction; if the verification fails, If the device authentication fails, the gateway will immediately terminate the authentication process. After the two parties complete the authentication and key negotiation process, the LAoCCM session key update phase is entered, that is, the two communicating parties perform subsequent data encryption and authentication through the session key. When updating the session key, after any party requests a key change, select a random number n , calculate its temporary public key and private key results, and pass the calculation results to GWN; and the receiver first needs to verify the information Timeliness and random challenges are calculated as shown in Equation (14).

$$P_{A} = T_A(x) \pmod{p} \quad (14)$$

Finally, verify the validity of the calculation's outcome. If the result is not valid, the information receiver terminates the key update operation; if the result is valid, it is considered that the applicant of the application has passed the identity verification and can start to generate the updated session key, as shown in formula (15) shown.

$$P_{GU} = T_G(T_u(x)) \quad (15)$$

After the session key is updated, the two parties realize the identity verification, and the update of the session key is completed, and the updated channel can be entered to continue the identity information authentication. In Fig. 3, the particular procedure is displayed.

Fig. 3. LAoCCM authentication protocol process.

After completing bidirectional authentication and key negotiation based on the above process, both parties encrypt and communicate subsequent data through shared session keys. If the session key needs to be updated at this time, either party will initiate a request to change the key. Since the above process has already implemented the complete process of identity authentication, it is necessary to ensure the security of the current session key, the legality of the identity of the session key applicant, and a brief update process when updating the session key. The LAoCCM IoT identity authentication protocol based on Chebyshev chaotic mapping realizes identity authentication by constructing key pairs multiple times to transmit information and encrypting the information.

IV. PERFORMANCE ANALYSIS OF LAOCCM IoT AUTHENTICATION PROTOCOL BASED ON CHEBYSHEV CHAOTIC MAP

Before you begin to format your paper, first write and save the content as a separate text file. Keep your text and graphic files separate until after the text has been formatted and styled. Do not use hard tabs, and limit use of hard returns to only one return at the end of a paragraph. Do not add any kind of pagination anywhere in the paper. Do not number text heads-the template will do that for you. Finally, complete content and organizational editing before formatting. Please take note of the following items when proofreading spelling and grammar: Aiming at actual performance of the LAoCCM IoT Chebyshev chaotic mapping-based authentication protocol, the data in the

Libsodium cryptographic library is used to evaluate the effectiveness of the LAoCCM IoT authentication protocol based on Chebyshev chaotic mapping. In view of the scalability of the protocol proposed in the study, the client obtains data by accessing nodes. However, when the node data increases, the workload of the client will also increase. In the LAoCCM protocol, the server completes most of the work of the protocol. Therefore, when the number of nodes increases, it only increases the burden of the server and has a small impact on the client. Because the server performance is generally high, the protocol proposed in the study has good scalability. The errors in the authentication negotiation process of the commonly used identity authentication protocol EDHOC, the Chebyshev chaotic map identity authentication protocol combined with zero-knowledge proof, and the LAoCCM scheme are compared, shown in Fig. 4.

Fig. 4. Error comparison of three identity authentication protocols.

From Fig. 4 that the error range of the EDHOC IoT identity authentication protocol is between 0.0013 and 0.0015, and the average error is 0.0014; the ZKOP identity authentication protocol error range is between 0.0011 and 0.0013, and the average error is 0.0012. The LAoCCM IoT proposed by the study. The error range of the authentication protocol is between 0.0008 and 0.0009, and the average error is 0.00085. The average error is 0.00055 less than the average error of the EDHOC authentication protocol and 0.00035 less than the average error of the ZKOP authentication protocol. The proposed LAoCCM authentication protocol is more accurate. Comparing the execution times of the above three identity authentication protocols, the results obtained are shown in Fig. 5.

Fig. 5. Comparison results of execution time message authentication.

Fig. 5 shows that as the amount of information increases, the execution costs of the three identity authentication protocols will increase, but the time required by each is drastically different. The EDHOC identity authentication protocol takes the most time, and as the amount of information increases, the time pressure for its operation increases. Taking 1000 pieces of information as an example, the identity authentication protocol takes 3 seconds; the ZKOP identity authentication protocol is significantly lower than the EDHOC protocol, the time required for 1000 pieces of information authentication is 1.5 seconds; the LAoCCM identity authentication protocol proposed by the study takes the least time, and it only takes 0.75 seconds for 1000 pieces of information to run; it is 2.25 seconds lower than the EDHOC protocol and 0.75 seconds lower than the ZKOP protocol second. It can be concluded that the authentication efficiency of the LAoCCM identity authentication protocol is optimal, which can significantly increase the effectiveness of authenticating. Comparing the calculation overhead results of the three methods during the key agreement stage, the results are shown in Fig. 6.

Fig. 6. Comparison results of computational overhead in key agreement phase.

From Fig. 6 that the time overhead of the three identity authentication protocols in the key negotiation stage increases with the increase of the amount of information. Among them, the EDHOC identity authentication protocol has the most time overhead, and the time overhead is 1.5 seconds when there are 1000 messages; the second is the ZKOP identity authentication protocol, which has more time overhead in the key negotiation stage, and the time overhead of 1000 messages is 1.15 seconds. The LAoCCM identity authentication protocol proposed by the research has the least time overhead in the key negotiation stage, and the time overhead is greater than that of the ZKOP identity authentication protocol only when there are about 400 pieces of information. The time overhead of the protocol at this stage is 0.75 seconds and 0.4 seconds lower, respectively. From the time cost of the key negotiation stage, the research proposes that the identity authentication protocol has faster key negotiation efficiency. In the realization process of the identity authentication protocol, the information's encryption, decryption, and interactive calculating programs are where the majority of the overhead is located. Table II displays the results of calculating the time overheads of the three authentication techniques.

TABLE II. COST COMPARISON OF DIFFERENT PROTOCOLS

Scheme	Time cost(ms)			Total	Communication cost(bits)
	User	GWN	SN		
EDHOC	/	10T CCM	10T CCM	10T CCM	/
ZKOP	2T CCM +1T E +9T H	1T CCM +5T H	/	3T CCM +2T E +14T H	994
LAoCCM	/	3T CCM +2T S +3T H	3T CCM +2T S +3T H	6T CCM +4T S +6T H	/

In Table II, TCCM represents the cost of Chebyshev chaotic mapping, TCCM=0.0025ms. TS represents symmetric encryption process, TS=0.0021ms. TH represents hash operation, TH=0.0947ms. TE represents the fuzzy extraction process, TE=0.1ms. In the above table, the overhead of the EDHOC protocol in the user phase Negligible, there are 10 times Chebyshev chaotic mapping operations in both the GWN process and the SN process, and the total overhead is 10 Chebyshev chaotic mapping operations; ZKOP protocol has 2 Chebyshev chaotic mapping operations in the User phase, 1 hash operation, 9 fuzzy extraction processes, 1 Chebyshev chaotic mapping operation and 5 hashing operations in the GWN stage; LAoCCM protocol has 3 Chebyshev chaotic mapping operations in the GWN stage and the SN stage respectively, 2 hash operations and 3 fuzzy extractions, in general, the proposed LAoCCM protocol has less time overhead and higher efficiency. To further evaluate the actual operational efficiency of the proposed solution, the study statistically analyzed the computational costs of the three protocols on the server and user sides, as shown in Fig. 7.

Fig. 7. Time cost of different protocols.

From Fig. 7, the time cost on both the server and user sides shows the same trend, with EDHOC having the highest time cost, followed by ZKOP. The proposed protocol scheme has the lowest time cost. When the number of visits reaches 50, the time cost of LAoCCM protocol on the server and user sides is 68ms and 75ms, respectively, significantly lower than the other two methods. Compared with the other two identity authentication protocols, in addition to saving the authentication time as much as possible, the identity authentication protocol's primary goal is to secure the privacy and security of information exchange, including forward security, post-item security, confidentiality, anti-camouflage attacks and Anti-replay attacks, etc. The security performance of the three authentication protocols is compared, and Table III presents the outcomes.

TABLE III. SECURITY ATTRIBUTES OF THREE AUTHENTICATION PROTOCOLS

Safety function	EDHOC	ZKOP	PAP	CHAP	EAP	LAoCCM
Forward secret	No	No	Yes	Yes	Yes	Yes
Backward security	Yes	Yes	Yes	Yes	Yes	Yes
Confidentiality	Yes	Yes	Yes	Yes	No	Yes
Replay attacks	Yes	Yes	No	Yes	Yes	Yes
Impersonation attack	Yes	Yes	Yes	Yes	Yes	Yes
Eavesdropping attacks	Yes	No	Yes	Yes	Yes	Yes
Denial of service attack	Yes	Yes	No	No	Yes	Yes

In Table III, Yes indicates that the protocol has the security performance, and No indicates that the protocol does not have the security performance. It can be seen from Table III that EDHOC protocol does not have forward security performance. ZKOP protocol does not have forward security and security against eavesdropping attacks. PAP protocol does not have replay security performance and denial of service attack performance. CHAP protocol does not have denial of service attack performance. The performance of EAP protocol in confidentiality is poor. Attackers can break the security performance of protocol transmission and obtain identity information through eavesdropping, modification, counterfeiting and other attacks. The LAoCCM protocol proposed in the study has passed the test in the aspects of forward security, backward security, confidentiality, replay attack, camouflage attack, eavesdropping attack and denial of service attack, and its security performance is significantly higher than that of EDHOC and ZKOP identity authentication protocols. The security of identity authentication protocols directly determines their availability in actual network environments. To verify the performance of the identity authentication protocol proposed in the research, 500 pairs of verification and response requests were constructed, and three identity authentication protocols were used to verify these data separately. The validation accuracy of the three methods in the application environment was statistically analyzed, and the results are shown in Fig. 8.

Fig. 8. Security analysis of identity authentication protocol.

As shown in Fig. 8, the overall security fluctuation of the EDHOC identity authentication protocol is the highest, followed by ZKOP. The LAoCCM identity authentication protocol proposed in the study has the highest security, with

the smallest difference in security in multiple experiments, with an average security performance of 99.12%. The average security performance of EDHOC and ZKOP in multiple experiments is 95.37% and 95.46%, which is significantly lower than the LAoCCM identity authentication protocol proposed in the study. Therefore, the security of this method can effectively meet the requirements of practical application environments. The cost of authentication will be impacted by how much energy is used by the identity authentication mechanism. The energy costs consumed by the three identity authentication protocols during communication and computing are tallied. Fig. 9 displays the outcomes.

Fig. 9. Comparison of energy consumption of different authentication protocols.

Fig. 9 displayed that the quantity of energy used in the three different IoT identity authentication protocols is quite different during the operation process. From Fig. 9 (a), when the information is transmitted in the three methods, the number of users who are switched on causes a progressive rise in energy usage. When the number of users is less than 300, the energy consumption of the EDHOC protocol is greater than the ZKOP protocol. As the number of users increases, the energy consumption of EDHOC tends to grow slowly. After more than 300 users, the energy consumption is less than that of the ZKOP protocol; the study suggested that the LAo CCM identity authentication technique used in the communication process used energy is significantly smaller than the other two methods, and as the number of users has grown, the energy consumption cost gradually decreases. When the number of users reaches 350, the energy consumption of EDHOC is 290J, the energy consumption of ZKOP protocol is 300J, and the energy consumption of LAoCCM protocol is 210J, which are 80J and 90J lower than the other two methods respectively. From Fig. 9 (b), the energy consumption gap between the three authentication protocols is relatively small when calculating, and the ZKOP protocol has the highest energy consumption; the EDHOC protocol has a large fluctuation when the number of users approaches 300, and the energy consumption significantly decreased, and then gradually increased; the energy consumption of the LAOCCM identity authentication

protocol proposed in the study is still smaller than the other two methods. Fig. 9 (c) shows the total energy consumption of the three identity authentication protocols during the communication and computing stages. When the number of users is below 200, the energy consumption of the EDHOC and ZKOP protocols is basically the same. When the number of users is above 200, the energy consumption of the ZKOP protocol is higher than that of the EDHOC protocol. Overall, the proposed LAoCCM identity authentication protocol has the least energy consumption and the best performance. The study above shows that the energy cost of the communication's LAoCCM authentication methodology and calculation process is smaller than the other two methods, and has better application performance.

Identity authentication security is an important influencing factor for the development of IoT devices. As an important aspect of IoT security, the storage, computing, and communication capabilities of most IoT devices are limited. To compensate for the shortcomings of existing identity authentication protocols, the IoT identity authentication protocol based on improved Chebyshev chaotic mapping is proposed. By updating the session key and using the AEAD algorithm to solve the problem of high number of chaotic mappings, the security, computing, and storage capacity of the identity authentication protocol are optimized. The study compares the EDHOC and ZKOP protocols. Comparison shows that the average error of EDHOC is 0.0014, the average error of ZKOP is 0.0012, and the average error of LAoCCM is 0.00085, which is significantly better than EDHOC and ZKOP. When the number of visits reaches 50, the time cost of the LAoCCM identity authentication protocol proposed in the study on the server and user sides is 68ms and 75ms, respectively, which is significantly lower than the other two methods. The total energy consumption of the three identity authentication protocols in the communication and computing stages of the LAoCCM protocol. When the number of users is below 200, the energy consumption of the EDHOC and ZKOP protocols is basically the same. When the number of users is above 200, the energy consumption of the ZKOP protocol is higher than that of the EDHOC protocol. Through the above comparison, it was found that the proposed identity authentication protocol based on improved Chebyshev chaotic mapping has better performance and can effectively meet practical application requirements.

V. CONCLUSION

Network security is the main problem brought about by the development of information technology. At this stage, the key scheme used in IoT devices has limited security performance and is prone to leakage risks. Cryptography is an important means to ensure network security. By encrypting information and constructing a two-party identity information authentication protocol to ensure basic information security. Chebyshev chaotic map plays a good role in this aspect, but the traditional Chebyshev chaotic map has problems such as too many mapping times and low efficiency. Meet the needs of identity authentication in smart homes. According to the experimental findings, the average authentication mistake of LAoCCM authentication protocol is 0.00085, which is 0.00055 less than that of EDHOC and 0.00035 less than that of ZKOP,

which is significantly smaller than that of EDHOC and ZKOP. It only takes 0.75 seconds, which is 2.25 seconds lower than the EDHOC protocol and 0.75 seconds lower than the ZKOP protocol; the energy consumption of LAoCCM in communication is 210J, which is 80J and 90J lower than the other two methods respectively. Therefore, the Chebyshev chaotic map-based suggested LAoCCM identity authentication mechanism provides superior security performance, higher authentication efficiency and more ideal practical application performance. However, there are still deficiencies in the study. First of all, the research and design of the Internet of Things identity authentication protocol needs to go through many information round-trip steps, and the operation is too complex. Secondly, the public key system of Chebyshev polynomial chaotic map is still developing, so there is still a lack of comprehensive and effective security proof. In the follow-up research, this problem needs to be studied and optimized.

Abstract—One of the dreadful diseases that shortens people's lives is lung disease. There are numerous potentially fatal consequences that can arise from interstitial lung disease, such as: Lung hypertension. This illness doesn't influence your overall blood pressure; instead, it only affects the arteries in your lungs. To prevent mortality, it is essential to accurately diagnose pulmonary illness in patients. Various classifiers, including SVM, RF, MLP, and others, are processed to identify lung disorders. Large datasets cannot be processed by these algorithms, which causes false lung disease identification. A combined new Spider Monkey and Lion algorithm is suggested as a solution to get around these limitations. Images of interstitial lung disease (ILD) were taken for the study from the publicly accessible MedGIFT database. The median filter is employed during the pre-processing step of ILD images to reduce noise and remove undesirable objects. The features are extracted using a hybrid spider Monkey and Lion algorithm. The lungs' damaged and unaffected regions are divided into categories using recurrent neural networks. Several metrics such as accuracy, precision, recall, and f1-score are used to evaluate the performance of the proposed system. The results demonstrate that this technique offers more precision, accuracy, and a higher rate of lung illness detection by processing a large number of computerized tomography representations quickly. When compared to other strategies already in use, the proposed model's accuracy is greater at 99.8%. This method could be beneficial for staging the severity of interstitial lung illness, prognosticating, and forecasting treatment outcomes and survival, determining risk control, and allocation of resources.

Keywords—*Interstitial lung disease; spider monkey lion optimization; recurrent neural network; medical image processing; diagnosis and identification; classification*

I. INTRODUCTION

In the U.S, lung disease is the most common cause of mortality. Lung disease affects the lives of over 400,000

Americans each year, and risk of death from this disease is rising even while they fall for other serious diseases like cancer. ILDs are a diverse group of more than 200 lung conditions that mostly affect the lung parenchyma but can also appear as respiratory or vascular symptoms. Numerous lung conditions, including interstitial lung disease, chronic obstructive pulmonary disease, and acute respiratory distress syndrome, are linked to the mechanical performance of the lung. ILD is a group of devastating disorders where fibrosis damages and stiffens lung tissue [1].

A class of extensive parenchymal lung ailments known as "interstitial lung diseases" are highly diseased and lethal. The establishment of a new categorization of idiopathic interstitial respiratory infections, which divides the condition into three categories—major, uncommon, and unclassified [2]. The updated version is unusual because it allows for the treatment of threatening matters in accordance with the disease classification. Foremost fatal interstitial lung disease, idiopathic pulmonary fibrosis exhibits a great degree of symptomatic variability. The therapist managing the impacted patient faces a substantial problem when dealing with ILD in an apparently healthy host that seems to be ordinary. A comprehensive group of specialists should examine a mix of diagnostic, radiology, and abnormal criteria that are used to diagnose an ILD [3]. The pathophysiology of these disorders has been linked to a number of variables, including genetic component, diseases, medications, thermal energy, and workplace and environmental durations.

Idiopathic pulmonary fibrosis, sarcoidosis, hypersensitivity pneumonitis, ILD as a symptom of connective tissue disease, drug induced ILD, and pneumoconiosis are the most common types of ILD. The most prevalent and serious type of ILD, IPF, has drawn the considerable attention in respiratory research. Interstitial fibrosis, also known as the common

technique of UIP, is visible on HRCT of the lung in IPF patients. Compared to other respiratory problems, ILD have a stronger link to health hazards. The pneumoconiosis is caused by asbestosis, silicosis, and coal worker's pneumoconiosis is typical instances of industrial disorders [4].

Infection and fibrosis of the lung tissue characterise the category of lung disorders known as ILD and pulmonary fibrosis. IPF is a specific type of ILD, and because of its unidentified origin, poor overall outcome, and moderate reaction to clinical treatment, IPF is frequently regarded as one of the most prevalent and significant ILDs. Although the treatment for ILD and pulmonary fibrosis can occasionally be complicated, it is based on the ILD's most likely origin. Additionally, the outcomes of the medical evaluation, auto-immune serologic analysis, chest CT imaging, and, if necessary, a lung sample must be added to the health information in order to make a precise ILD classification [5]. PFTs are crucial for care and typically reveal a sequence of a restrictive ventilator disorder with an aberrant continues to prove, but they mostly serve as a gauge for the extent of the condition and its prognosis by identifying a particular type of ILD [6].

A record-breaking volume of data has been generated as a result of the enormous progress in image capture technology, capacity growth, and the installation of bio-medical information collection equipment [7]. These data come from numerous (sometimes inconsistent) database systems, have a high dimension (Computed tomography, Magnetic resonance imaging, etc.), and are rich in variables. It provides healthcare information that is difficult, particularly on images [8]. DL assists in creating new ones. In addition, DL not only aids in disease detection but also evaluates the predicted goal and gives proactive forecast models to help doctors create efficient treatment protocols. Every scientific subject, especially medical image into regions, is involved in DL. The usage of a DNN model is implied by the phrase DL [9]. Various samples are inputted into the NN, and combines with parameters to produce digital output through non-linear processes. The classification of ILD is given in Fig. 2.

One of the crucial components of digital image processing used for medical planning in healthcare systems is medical imaging. Additionally, a significant amount of medical data is employed in medical field for scientific and educational purposes, such as clinical data visualisation. For quicker distribution, the clinical images are reduced and kept hidden. Due to their smaller system memory, compressed images have an extremely short transmission rate[10]. Typically, there are two types of compression: both lossy and lossless methods. With file format, input images are offered without any losses, and the output image is identical to the original image. However, compression ratio offers a lower compression ratio [11]. FFNN, which has loops in the hidden units, is often enhanced by recurrent neural network (RNN). It is capable of learning combinations. All stages and neurotransmitters share the same weights. The framework provides the model to take sample segments as input and determines the temporal link between the data. The representation of dynamical modification at a time series is handled using this Classifier [12].

The following criteria contribute identify interstitial lung disease:

- The research suggests the most appropriate deep-learning approach for identifying and classifying interstitial lung disease (ILD) from medical images.
- The dataset was gathered from patient medical images who had ILDs. The first scenario is pre-processing of medical images, the second is feature extraction and selection, and the third is categorization.
- The findings show that the proposed hybrid Spider Monkey and Lion algorithm has effectively selected the features and the deep learning-based recurrent neural network (RNN) is capable of recognizing the ILD classification.

The remaining part of this article has been organized as follows: Section II provides a detailed description of the most recent techniques for classifying interstitial lung disease. The dataset obtained from individuals with interstitial lung disease is described in Section III. Section IV covers the system structure and assessment method, which includes image pre-processing and the steps taken to develop the extraction of features for categorization. The findings and discussion sections are described in Section V accordingly. Lastly, Section VI presents the relevant outcomes of the study.

II. RELATED WORKS

In this paper [13], a convolutional neural network for classifying ILD sequences is evaluated. The network is composed of three dense layers, an averaged pooling with a size equivalent to the length of the final classification mappings, and five CNN layers with 22 kernels and LeakyReLU activations. Seven outcomes in the final deep network correspond to the classes taken into account: good health, grounded glassy opacity, micro nodules, standardisation, water supply systems, deformation, and a mixture of Aspects. This work used a sample of 14696 input images, obtained over 120 Computed tomography clinics, to train and test the CNN. This is the first deep Network created specifically for the issue. The efficiency of the utilised CNN in comparison to earlier techniques on a difficult collection was demonstrated by a similar evaluation. The classification results of Convolutional in evaluating respiratory signals (around 85.5 percentages) showed its potential. However, the work cannot involve CNN by expanding 3-dimensional data from Computed tomography volume scans and incorporating the utilised approach into a Computer aided system which helps radiologists by providing a differential diagnosis for Lung lesions. This study uses a limited dataset to evaluate the model, making it unsuitable for use in real-world conditions.

In order to extract relevant images, content-based image retrieval systems thoroughly analyse underlying image LL properties. This eliminates the need for speech recognition tags, textual descriptions, or phrases to be connected with the images. For resemblance identification and classification for a particular query image, a CBIR system preserves great image visualisations in the form of extracted features. The initial identification and categorization of lung disorders depending

on lung X-ray images are made possible by the CBIR system for the recovery of medical images suggested in the paper [14]. Balancing across several measurement approaches, extensive experiments on the benchmark dataset showed that the strategy improved precision by 49.7 %. Additionally, the area under the precision-recall curve values for all subclasses showed a 26.6 % enhancement. Due to its numerous levels and lengthy training period, this strategy is ineffective.

An intriguing development is the use of AI in the identification of chronic obstructive pulmonary disorders. Discovering commonalities in forensic test data allows AI systems to anticipate health outcomes or identify obstructionist traits. However, prospects for AI in the identification of acute respiratory disorders and to summarise recent trends has to be evaluated. The paper [11] provide an explanation for the use of AI in telehealth, breath research, lung sound assessment, and other management of cancer. By offering precise differentiated diagnosis, ML has yielded promising result in computerized pulmonary function interpretation. Modern DL models for obstructive classification tasks in Computed tomography include Convolutional neural network. Due of the extensive time and resource requirements, this approach is ineffective.

The paper [15] used a novel hybrid DL framework called VDSNet for the detection of lung illnesses in X-ray images. A database of National institutes of health chest X-ray images obtained from the Kaggle source is used for the assessment. The overall recognition accuracy for the full dataset is 73percentage points for VDSNet, whereas the maximum accuracy for natural grey, vanilla Color images, hybrid Neural VGG, basic CapsNet, and customized CapsNet are 68%, 69%, 69.4%, 61%, and 64%, respectively. VDSNet has a validation accuracy value of 73%, which is higher than the reference dataset's accuracy score of 71%. However, instead of 19 seconds for the measurement, VDSNet takes a time for training of 431 seconds for the whole data source. However, computerized chest X-ray diagnostic techniques is not enhanced in this work, so this paper focuses on the application of image data enhancement techniques such as colour space implants, kernel filtering, deep feature improvements, etc. The VDSNet approach can be used to analyse X-ray images of potential patients and healthy controls for the individuals who have pneumonia associated with COVID-19. When focusing on the large-scale dataset, this study research meets certain difficulties. Smaller datasets can therefore produce good accuracy, but they are ineffective for use in real-world scenarios.

An automatically generated method for the recognition and classification of ILD patterns is provided in the paper [16]. It is done by removing designs for the modest inter-class information variability and large intra-class value fluctuation by the use of translational and luminance effects, respectively. The Template-Matching Combined Sparse Coding approach is

a brand-new and effective dimensionality reduction technique that differs substantially from defined areas of interest inside lung parenchyma that are resistant to translational and illuminating changes. Using a framework comparison procedure, the converted image patches is matched to all potential models of the image. By minimising the objective function of the classification model between the translation enhanced image and the reference, the equivalent sparse matrices for the set of translation texture features and their corresponding framework are produced. For handling high-intra class characteristic variability challenges, a SVM is created, which improves classification performance. In this work, zone of interests of 5 lung tissue patterns - healthy, emphysematous, surface - are found and used. These designs were chosen from an internally multimedia record that includes high-resolution positron emission tomography image series. The method works more effectively than the majority of cutting-edge multi-class classification methods. Whenever the data set includes greater amounts of noise, it fails to function as well.

In the paper [17], authors classified lung HRCT extracted features into five classes: good material, emphysema, field glass, fibrosis, and micronodules using an enhanced DenseNet algorithm with small kernel DenseNet. The SK-design DenseNet's consists of two compact blocks and two different levels. Each thick block has six groups in it. The SK-DenseNet model is more efficient for extracting high level and minor pathologic information for ILD categorization utilising a convolution kernel in accordance with the properties of Computed tomography features of respiratory disease. According to experimental findings, the SK-DenseNet performed best than other Convolutional networks like DenseNet, AlexNet, VGGNet, and ResNet. However, iterations of the research will concentrate on images with ILD patter annotations. This method is not effective since the Indirect effects of hMIKO-1 on T and B cells and other cells of inflammation are also possible. Table I depicts the comparison of existing approaches' merit and demerits.

In an animal model of bleomycin-induced ILD, the paper sought to determine how the hybrid proteins known as human MIKO-1 affected murine macrophages activity and whether it had any protective effects. In order to do this, the phenotype of hMIKO-1-co-cultured thioglycolate-induced murine intraperitoneal lymphocyte was investigated. Since day 0 to day 14, mice were divided into regular and given different doses. Since day 28, the mice were put to death, and the organs are examined for collagen fibres, and for levels of gene transcription. In vitro, hMIKO-1 prevented murine macrophage from polarising toward an M2 preponderance [18]. In comparison to the BLM-alone category, the histologic grade of the lung pathology and the lung extracellular matrix components level were drastically decreased in the BLM + hMIKO-1 collective. This strategy is inappropriate for delivering a greater accuracy level.

TABLE I. COMPARISON OF EXISTING APPROACH MERIT AND DEMERITS

References	Method	Implementation	Advantage	Disadvantage
[13]	CNN	Python language	With no data loss, it lowers the considerable dimensionality of images.	This study uses a limited dataset to evaluate the model, making it unsuitable for use in real-world conditions
[14]	CNN	Python and MATLAB	It requires less work from humans to create its functions.	Due to its numerous levels and lengthy training period, this strategy is ineffective.
[11]	AI	PFT interpretation software	It can considerably boost accuracy while reducing errors.	Due to the extensive time and resource requirements, this approach is ineffective.
[15]	VDSNet	Tensorflow, Jupyter Notebook, and Keras	Much less time is needed for training.	When focusing on the large-scale dataset, this study research meets certain difficulties. Smaller datasets can therefore produce good accuracy, but they are ineffective for use in real-world scenarios.
[16]	B-MCSVM	-	It uses relatively little storage and performs well in high-dimensional areas.	Whenever the data set includes greater amounts of noise, it fails to function as well.
[17]	SK-DenseNet	GraphPad Prism version 7.0 software	It has more effectively utilized features	This method is not effective since the Indirect effects of hMIKO-1 on T and B cells and other cells of inflammation are also possible.
[18]	PSO and Fuzzy C-mean Clustering method	Python coding	In terms of processing efficiency, it is better in terms of speed and memory needs.	This strategy is inappropriate for delivering a greater accuracy level.

III. DATASET

Among the main obstacles to the development of DL in medical image analysis is the absence of enough training data, which are necessary to establish the accuracy of DL classifiers. The production of huge medical imaging datasets is difficult due to the annotation calls for a lot of input from medical professionals. In particular, several expert perspectives are needed to address the issue of human error. The collection includes medical information from patients with pathologically confirmed classifications of ILDs as well as high-resolution computerized tomography image series with 3-dimensional identified areas of diseased lung tissue. The goal of this effort is to make up for the dearth of publicly accessible datasets of ILD cases that may be used as a foundation for the creation and assessment of image-based computerised diagnostic tools. The present research makes use of the freely accessible MedGIFT database [19]. The database contains 108 HRCT images with annotations. It has 17 distinct ILD designs, each measuring 512×512 . A complete set of 1946 ROIs was offered from 108 HRCT imaging series. Five of the most common healthy and ILD patterns are taken into consideration in the present study. Since the database is multipattern, there is a chance that many patterns will coexist in a single slice.

IV. METHODOLOGY

The feature extraction phase of image recognition is crucial. A hybrid spider monkey and lion method is used for feature extraction, and RNN is used for classification. It is used to categorise the diseased portion of the lung for future prevention and find the fastest way for the infected region recognition utilising the distinctive hunting behaviour of lion and monkey. Fig. 1 represents the process of ILD prediction.

The basic process flow diagram for the steps of ILD prediction is shown in Fig. 1. The lung input image is first pre-

processed, and then features are retrieved using a combination of lion and spider monkey optimization. RNN was finally utilized to categorise the results.

A. Pre-processing

Pre-processing comes after the images has been chosen as the starting point for ILD diagnosis. The median filter has been used to improve the Lung images by reducing noise and removing unwanted items. A non-linear, well-organized simple image processing method called the median filter is frequently employed to lower noise in images. The result of the Median filter is given by Eq. (1).

$$\hat{g}(x, y) = \text{median}_{(a,b) \in T_{xy}} \{f(a, b)\} \quad (1)$$

Fig. 1. Process of ILD prediction.

For the goal of detecting arrhythmias, segmentation is the most crucial topic in informatics and the health industry. The main aim of this study is to create and build a reliable classification method using a RNN classifier that is SM and lion-based. Data pre-processing, image segmentation, extraction of features, and classification are the 4 stages of the heartbeat detection algorithm. The standard will be eliminated from the ECG signal when it first enters the information processing phase. The pre-processed sensor will go through the classification step, which will execute the segmentation using the Frequency response. The segmented data move on to the feature extraction phase, where features including wave features and temporal features will be recovered. Pre-processing the information is important since it helps to remove the signal's undesirable components, ensuring that the characteristics that are recovered are correct and suitable for blood pressure and heart rate identification. The retrieved characteristics will be sent to the classification stage, where the Spider Monkey and lion -based Recurrent neural network will be used to classify the disease (RNN classifier).

The hybrid Spider Monkey lion algorithm, which combines the Spider Monkey Optimization (SMO) and the lion algorithms, will be used in conjunction with the RNN in the suggested method. The Lion algorithm is a generalisation of interaction and the activities of lion whereas the SMO leverages the foraging behaviour of spider monkeys in a fission-fusion like framework to address the optimization model. Additionally, combining SMO with lion effectively captures the hunting and intellectual behaviour of the lion. The goal of the optimization ensures that the RNN is effectively tuned for precise predicting and classifying. The suggested method will be put into practise using the MATLAB tool, and its performance will be assessed using metrics like accuracy and excellent put. As a result, when compared to the current strategies, such as DL approach, hierarchical categorization, and research driven technique, the suggested strategy successfully performs the ILD classification and will achieve superior accurateness and excellent output.

B. SMO

A recently introduced stochastic improved algorithm called Spider Monkey Optimization takes its cues from nature. A kind of monkey that is included in the group of creatures that have a fusion and fission social structure is referred to as "spider money." These spider monkeys are frequently observed in groups and have skilled hunting habits. They facilitate food gathering in a variety of ways by sharing pertinent information with the other group members [20]. The advanced food-seeking strategy used by spider monkeys served as motivation for the invention of this SMO method. Fitness function is given in Eq. (2).

$$fitness\ function\ (F_i) = \begin{cases} \frac{1}{1+F_i} & \text{if } F_i \geq 0 \\ 1 + xyt(F_i), & \text{if } F_i < 0 \end{cases} \quad (2)$$

Six distinct aspects of the numerical method of SMO foraging behaviour for optimization techniques are covered in the subsequent subsections. SMO first creates a population of N spider monkeys at random. Each S_{ij} in SMO has the following initialization which is shown in Eq. (3).

$$S_{ij} = S_{minj} + X(0,1) \times (S_{maxj} - S_{minj}) \quad (3)$$

Where S_{minj} and S_{maxj} are lower and upper bounds in jth direction for S_i and $X(0,1)$ denotes a random number in the range [0, 1]. The next section describes all six phases of SMO in detail.

1) *Local Leader Phase (LLP)*: In this step, a current hire for a service user is obtained utilising the information provided by the group members via Eq. (4) and the local leader. The fitness value of the solution determines its excellence. The following iteration will focus on the option with the highest fitness (the new location is preferable to the existing position).

$$S_{newij} = S_{ij} + X(0,1) \times (S_{lpj} - S_{ij}) + X(-1,1) \times (S_{qj} - S_{ij}) \quad (4)$$

Where, S_{pj} and S_{qj} denote the positions local group leader and randomly chosen qth spider monkey respectively.

2) *Global Leader Phase (GLP)*: During GLP, each member updates their standpoint depending on knowledge from the firm's global leader and all members, as stated in Eq. (5).

$$S_{newij} = S_{ij} + X(0,1) \times (S_{Gj} - S_{ij}) + X(-1,1) \times (S_{qj} - S_{ij}) \quad (5)$$

Where, S_{Gj} shows the jth direction of the global leader. Furthermore, the fitness values is expressed in Eq. (6).

$$P = \frac{fitness_i}{\sum_{i=1}^K fitness_i} \quad (6)$$

Similar to LLP, further processing uses the better solution from the newly created position and the old position of the SM.

3) *Global Leader Learning (GLL) phase*: In this stage, the global leader takes the role with the consistent top fitness, and a global limitation monitor is used to track changes in the role of the global leader.

4) *Local Leader Learning (LLL) phase*: Local leader is given the necessarily lead with the best fitness. Similar to the GLL phase, the local limitation counter is incremented by one if the new position of the local leader is like the information and establishing.

5) *Local Leader Decision (LLD) phase*: When a local leader's local limit counter hits a certain count, all group members are reset using Eq. (7).

$$S_{newij} = S_{ij} + X(0,1) \times (S_{Lj} - S_{ij}) + X(-1,1) \times (S_{qj} - S_{ij}) \quad (7)$$

6) *Global Leader Decision (GLD) phase*: If the global leader location is not changed after a certain amount of iterations, it forms tiny size of subcategories. Each group's local leaders in GLD are chosen through the LLL procedure. If the global leader's position is not changed by a

predetermined threshold, all subgroups are combined into one group. SMO imitates the FFS organization in this manner.

C. Lion Optimization Algorithm

Analysing the behaviour of the lion, the computational solution for the Lion optimization method was developed. Hunting, running away to safety, straying, mating, migrating, defending, population stability, and convergence are examples of animal behaviours [21]. Such characteristics are expressed mathematically, and an efficient method is developed. The initial communities are produced using lions, an entirely arbitrary solution. The additional lions are randomly separated into P pride subdivisions, with S percentage of the prides being declared a female lion. Norm's lions are picked as the original population N. The optimum place for each lion is described as the best explanation from previous iterations and it is constantly altered throughout the optimization process. Each lion's ideal place can be found in the proud territory.

Young boys who reach sexual maturity are separated from their parents' dignity and go on to remain nomads, where they have less power than regular males. A nomad lion roams the searching area aimlessly in search of a better location (solution). A powerful nomad male forces the resident male out of the prides when they engage in combat. The regional male lion will take the spot of the nomads' male. Female desert lions occasionally join prides, while other nomadic female lions occasionally leave them. The lesser lion will be mercilessly killed for a number of reasons, including malnutrition and intensity of competition.

The inhabitants in the global optimum were first created spontaneously by the LOA. It observed each distinct solution as a "lion." A lion is described as follows for an Nv multidimensional optimization method which is shown in Eq. (8).

$$Lion = x_1 + x_2 + x_3 + \dots x_{Nv} \quad (8)$$

And the assessment of the minimization problem, as shown below, determines the cost (each lion's fitness value) which is shown in Eq. (9).

$$fitness\ value\ of\ lion = f(lion) = f(x_1 + x_2 + x_3 + \dots x_{Nv}) \quad (9)$$

The N pop alternatives were developed primarily at random in the problem space. A random selection of % N options was chosen as NL. P prides were created from the remnant population. Throughout the optimization process, a certain sexual identity was constant for each response in the LOA. In each pride, roughly 75–90 percent of total of the estimated workforce created in the preceding stage were referred to as female lions, with the remaining lions being male, to mimic this nature. Each lion identified its most frequented place while searching. Each pride built its region based on the regions that had been indicated. As a consequence, each pride's region was created by its supporters marking certain sites.

1) *Hunting*: A specific number of females search for food source in a team in each and every P to provide food for the

other P individuals. To surround and capture their food source, these hunting lions employ certain tactics. Typically, as lions hunt, they stick to a same routine. Every lioness changes her hunting position based on where she is and where the other lionesses are. As a result, some hunter lions rotate their prey and assault it from the other direction, and LOA employs opposition-based learning. In Eq. (10) hunter equation is expanded. Three "wings" of hunters are established. The centre wing has the best overall fitness, whereas the left and right wings are determined at random. The prey flees to a new area during a search as the predator gets fitter.

$$hunter = \begin{cases} rand((2 \times PY - hunter, PY), \\ (2 \times PY - hunter)) \\ rand((2 \times PY - Hunter, PY), \\ (2 \times PY - Hunter) < PY \end{cases} \quad (10)$$

D. Hybrid Spider Monkey and Lion Optimization

For particular jobs, it has been demonstrated that the SMO system integrates more quickly than alternative techniques. As a result, it can decelerate down as it approached the global ideal point. The probability of becoming trapped in the region of local optima rises as the algorithm continuously incorporates with the world wide optimal position. The SMO algorithm's dependency on search parameters seems to be another flaw. Based on the choices made, the accumulation rates may change. The SMO approach has undergone several modifications to increase its efficacy, with the main goal of balancing the incremental and radical features. Among the suggestions are tweaks to the developmental technique, adjustments to the parameters, adjustments to the upgraded criteria, and the introduction of better developing methods. It has been demonstrated that the lion is more efficient and has a better rate of success in multipurpose scenarios than the SMO, despite the fact that the lion's algorithms does not take acceleration into account. The flow diagram for the proposed method is given in Fig. 2.

$$fitness\ function\ (Fi) = \begin{cases} \frac{1}{1+f(x_1+x_2+x_3+\dots x_{Nv})} & \text{if } Fi \geq 0 \\ 1 + xyt(f(x_1 + x_2 + x_3 + \dots x_{Nv})), & \text{if } Fi < 0 \end{cases} \quad (11)$$

The process flow diagram for the hybrid spider monkey and lion optimization is shown in Fig. 2. When features are successfully extracted from ILD images, the fitness value is calculated.

E. Recurrent Neural Networks

The foundation of NN topologies is the idea that all signals are consecutively redundant. However, this presumption is erroneous and might be harmful for many applications, like time report and natural language processing where the relationships among successive training instances are crucial. A type of artificial neural network known as an RNN adds loops to the feed - forward neural network to increase its functionality. A recurrent hidden state, whose activation at each step depends on that of the preceding step, allows an RNN, unlike a feed - forward neural network, to process the complex combination. The system can display variable

temporal behaviour in this way. Fig. 3 depicts the basic structure of RNN.

Fig. 2. Flow diagram for the proposed method.

Fig. 3. Working process of RNN.

Fig. 3 depicts the fundamental layout of an RNN. Input, hidden, and output layers are all three layers. The ILD image results are successfully classified by using this approach.

V. RESULT AND DISCUSSION

Utilizing the images of the gathered plant leaves, the suggested strategy has been evaluated. To distinguish the diseased lung from the healthy lung, the suggested method employed hybrid spider monkey and lion optimization with recurrent neural network. The study assesses the 4 commonly

used evaluation metrics, including classification accuracy, precision, recall, and F1-score, which are described below.

With regard to the lung images that are obtainable, accuracy produces suitable results. In Eq. (12), accuracy is represented.

$$Accuracy = \frac{TN+TP}{FN+FP+TP+TN} \quad (12)$$

Precision thoroughly assesses a classifier's performance. Precision will be high if the lung image has low positives and low positives if the lung image has high positives. In Eq. (13) precision is represented.

$$precision = \frac{TP}{FP+TP} \quad (13)$$

Recall gauges how complete the classification is. More positive samples are found greater the recall. The Eq. (14) contains a representation of the recall formula.

$$Recall = \frac{TP}{FN+TP} \quad (14)$$

The F1-score measurement combines precision and recall. The F1-score measure is determined by calculating from the recognition rate. Eq. (15) represents the F1 measure.

$$F1 - score = \frac{2 \times Precision \times Recall}{Precision + Recall} \quad (15)$$

From Table II, the accuracy of the proposed system is 99.8% which is high compared to other existing approaches such as ACO is 98.6%, CNN is 98.97% and SMB is 97%.

The existing and proposed analyses for accuracy measurements were compared in Table II and Fig. 4 represents the graph of accuracy measure, the suggested hybrid spider monkey and lion obtained more effective results.

The existing and proposed analyses for precision measurements were compared in Table II and Fig. 5 represents the graph of precision measure, the suggested hybrid spider monkey and lion obtained more effective results.

The existing and proposed analyses for recall measurements were compared in Table II and Fig. 6 represents the graph of recall measure, the suggested hybrid spider monkey and lion obtained more effective results.

The existing and proposed analyses for F1-score measurements were compared in Table II and Fig. 7 represents the graph of accuracy measure, the suggested hybrid spider monkey and lion obtained more effective results.

TABLE II. PERFORMANCE COMPARISON MATRIX

Method	Accuracy	Precision	Recall	F1-score
ACO	98.6 %	96%	96%	97.6%
CNN	98.97%	98.3%	98.7%	98.7%
SMB	97%	96%	97%	96%
Hybrid spider monkey and lion	99.8%	99.9%	99.7%	99.89%

Fig. 4. Graph of accuracy measure.

Fig. 5. Graph of precision measure.

Fig. 6. Graph of recall measure.

Fig. 7. Graph of F1-score measure.

In this instance, the hybrid spider monkey and lion with RNN model outperformed the ACO, CNN, and SMB models. The accuracy percentages for ACO, CNN, and SMB are 98.6%, 98.97%, and 97%, respectively. Precision, recall, and F1-score have better rates in the hybrid spider monkey and lion method compared to other models, and the F1-score has attained the greatest rate compared to other models due to the accuracy rate of 99.8% in the hybrid spider monkey and lion model.

VI. CONCLUSION

Deep learning (DL), which has significantly outperformed more conventional ML algorithms in recent decades, has taken centre stage in the mechanization of our daily lives. DL -based apps will replace humans in some roles, and autonomous robots will handle the majority of everyday chores. In contrast to other real-world issues, DL is just slowly making its way into the healthcare industry, particularly in the field of medical imaging. It has been suggested to use full HRCT images in a two-stage hybrid deep learning network screening method for interstitial lung disease (ILD). The accuracy, precision, recall, and F1 measure are determined by the suggested approach. The developed method yields a high prediction accuracy of 99.8%, and the proposed model is subsequently used for medical diagnostics. In this study, the IL disease prediction system is based on an improved spider monkey and lion optimization with RNN. The feature extraction was done with hybrid spider monkey and lion optimization, while the classification was done with RNN classifier. The proposed approach is utilized to distinguish between diseased and healthy Lung. With maximum accuracy of 98.8%, precision of 99.9%, recall of 99.7%, and F1-score of 99.89%, the suggested spider monkey and lion optimization with RNN is better than the existing approaches. Future research will build on this work by attempting to forecast the incidence of other serious illnesses including cancer and other heart-related diseases with high computational speed.

Abstract—The utilization of computer vision technology is of the utmost significance in the examination of plant diseases. Research utilizing image processing to investigate plant diseases necessitates the analysis of discernible patterns on plants. Recently, numerous image processing and pattern classification techniques have been employed in the construction of a digital vision system capable of recognizing and categorizing the visual manifestations of plant diseases. Given the abundance of algorithms formulated for the purpose of plant leaf image classification for the detection of plant diseases, it is imperative to assess the accuracy of each algorithm, as well as its potential to identify diverse disease types. The main objective of this study is to explore accurate deep learning architectures that are more effective in deploying and detecting tomato diseases, thus eliminating human error when identifying tomato diseases through visual observation. and get more widespread use. An initial model was constructed from the ground up using a convolutional neural network (CNN), which was trained with 22930 tomato leaf images, and then compared to VGG16, Mobile Net, and Inceptionv3 architectures through a fine-tuning process. The basic CNN model achieved a training accuracy of 90%, whereas the training accuracies of VGG16, Mobile Net, and Inceptionv3 were respectively observed to be 89%, 91%, and 87%. The VGG16 model has a greater computational complexity than other approaches due to its considerable quantity of predefined parameters. Despite to be simpler, MobileNet proved to be the most efficient in terms of accuracy and thus is the most suitable for this research, due to its lightweight structure, fast functioning and adaptability for mobile devices. In contrast to other architectures, the suggested CNN architecture exhibits shallower characteristics, facilitating faster training on the same dataset. This research will provide a solid foundation for future scholars to easily improve the categorization of plant diseases, which is to develop algorithms that are lighter, faster, easier to run, and have higher accuracy.

Keywords—Deep learning; convolutional neural network; image recognition; plant diseases

I. INTRODUCTION

Agriculture continues to play a significant role in the economy, contributing considerably to foreign exchange earnings and gross domestic product. Tomatoes are a highly sought-after vegetable commodity worldwide due to their rich nutrient content, including organic acids, vitamins, essential amino acids, and natural fiber. It is cultivated both outdoors

and indoors. Globally, the annual output of fresh tomatoes is about 160 million tons, which is three times that of potatoes and six times that of rice. In recent years, China's tomato production has steadily increased in terms of cultivated area. According to statistics, China's tomato cultivation area will increase by 1.6% to 1.104 million hectares in 2020. China's tomato cultivation area will increase by 0.7% to 1.113 million hectares in 2021. China is the world's largest producer of tomatoes, with perennial production accounting for as much as one-third of the global total. According to statistics, in 2020 China produced approximately 65.15 million tons of tomatoes, an increase of 3.63 percent. China produces approximately 66.09 million tons of tomatoes in 2021, an increase of 1.44 percent. Nonetheless, numerous maladies on tomato plants cause substantial harm to the quality and yield of tomatoes.[1] Pathogens including bacteria, fungi, and viruses are responsible for producing disease in plants and can be transmitted through soil, water, and air.[2] The use of pesticides and climate change, which can alter the stage and rate of pathogen development, complicate the management of diseases.[3] Common tomato plant maladies include leaf blight, early blight, late blight, target spot, Septoria leaf spot, and yellow leaf curl virus.[4-5] These diseases can affect the leaves, stems, fruits, and roots of the entire tomato plant. If diseases are not controlled in proper time, they will cause significant losses and injury to the tomato plant. Every year, producers incur significant losses. Protecting tomato plants from these maladies is therefore essential for increasing yields. Traditionally, plant diseases are identified through visual observation with the assistance of trained personnel [6-7].

Numerous advancements have been made in computer vision technology in recent years, and there are more examples of applications in identifying and classifying the diseases of fruits and vegetable. Traditional computer vision techniques still require professional knowledge of these agricultural hazards. The development of artificial intelligence technology eliminates the requirement for professionals to conduct constant field observation. [8-9]. It also serves to minimize the possibility of human observational errors. Recent case studies demonstrate that soft computing models like neural networks [10], decision trees [11], support vector machines [12], and Nave Bayes [13] have been applied to the automatic classification of plant diseases. In recent years, deep learning has dominated computer vision. The proliferation of

smartphones, the integration of high-performance processors into cameras and mobile devices, and the developments of computer vision technology, particularly with the application of deep learning strategies, have facilitated the automation of diseases diagnosis utilising image recognition. [14]. Deep neural networks are a combination of deep learning and neural networks that replicate the brain's general operating principles. A deep neural network typically comprises an input layer, an output layer, and multiple hidden layers in between. A neural network with a single hidden layer is considered shallow in comparison.

In this paper, the input layer is trained to discover the optimal filter weight values [15]. The initial layer of a CNN model that takes in pictures as input is referred to as the inputted layer. Image height, width, and depth are fed into the input layer of the neural network. The depth indicates how many color channels the image belongs to. If the picture is an RGB picture, for example, it comprises three color components: red, green, and blue, thus the size of the picture is 3. However, if it is grayscale, its size is 1.

In between the input and output layers are the hidden layers. They will be used to identify particular characteristics. The undisclosed layer is used in this research to detect color and texture features that can be used for the categorization of tomato plant maladies. The output layer comprises category labels and has full connection. If we wish to classify an image into ten categories, we must designate ten labels in the fully connected layer. Convolutional neural networks have been revolutionary in several pattern recognition-related disciplines over the past decade [16]. Various deep learning architectures, such as VGG16, Inceptionv3, Mobile Net, Alex Net, Dense Net, and Google Net, have been proposed and all feature slight differences in their respective hidden layers. [17]. Despite all of these learning architectures, the classification of plant maladies remains imperfect.

Currently, CNN has been proven to be a very good choice for achieving plant disease detection in terms of accuracy [18]. Each structure has its limitations. An illustration of this is that certain architectures can be more intricate because a greater number of parameters require more time for processing, yet aid in generating a high degree of precision. The primary objective of this research is to ascertain the most effective classification technique of plant diseases with a view to enhancing this domain further. This is not only in terms of accuracy, but also in terms of speed and difficulty of deploying and adjusting.

However, many plant disease detection methods proposed are not to replace the current detection methods, but to supplement these methods [19]. Despite the promising findings of multiple research studies, the practical implementation of

these technologies has yet to be adequately explored. There has been a proliferation of computer-based applications that have demonstrated great efficacy, yet the efficacy of these architectures has not been properly appraised. The primary objective of this research is to analyse the efficacy of modern deep learning systems in regard to plant disease classification with the intent of attaining the highest level of accuracy. This research seeks to provide a definitive answer, rather than a hypothesis, that can be used to assist novice researchers in selecting a current deep learning algorithm that is most advantageous for their initiatives in the field of automated classification of plant diseases.

II. MATERIALS AND METHODS

A. Methodology Overview

The methodology implemented in the research is shown in Fig. 1. The process of constructing a model can be divided into five distinct stages: data collection, in which images are acquired and divided into the three primary folders of training, verification and testing; pre-processing, to guarantee that relevant traits are present; the selection of an appropriate architecture; the training and verification stage, in which the model is trained and verified to generate the final model; and the prediction stage. This stage furnishes the classifier with characteristic test images to assess its practical efficacy. The ensuing text contains an elucidation of each phase.

B. Data Collection

Ten different categories of 256x256 resolution images of tomato leaves affected by various diseases were procured from the Plant Village Library located on the Kaggle platform. The dataset is segregated into three distinct subsections, namely training, validation, and testing, which contain 17184, 4585, and 1161 images respectively. The utility of testing and verifying using two distinct datasets is to confirm the model's capacity to process new data. The test data is utilised to assess the efficacy of the ultimate model, whereas the verification data is employed to assess the performance of the model during the training phase. Table I illustrates the total amount of tomato leaf images that have been subjected to training, testing, and validation, and classified accordingly. As hardware, the ACER Aspire3 computer uses Intel core TM i5-8265U 1.66Hz, 8GB DDR4 memory, and NVIDIA GeForce MX230 for this research.

In this paper, the method of classifying diseased tomato leaf images focuses on automatically identifying the marks appearing as spots on the leaves, as shown in Fig. 2. Each picture represents a tomato leaf image that belongs to a certain category.

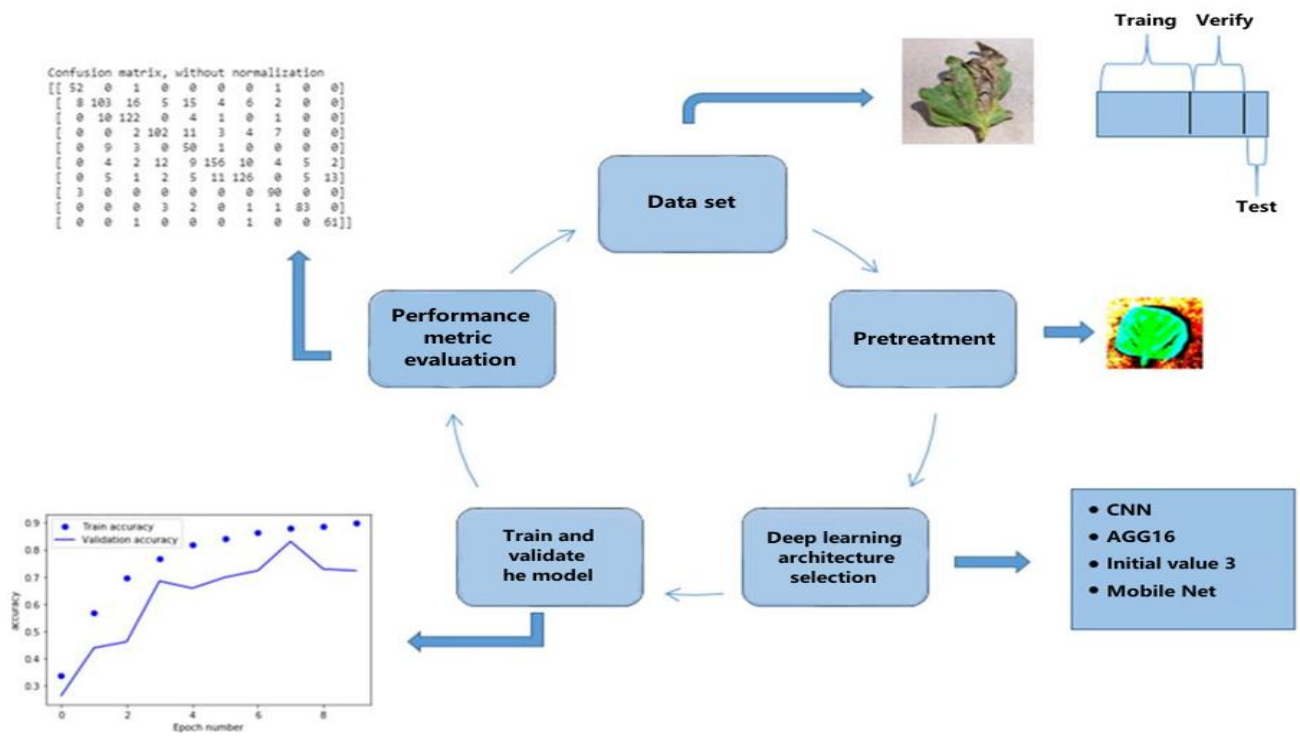

Fig. 1. Steps followed in the research method.

TABLE I. TOMATO LEAF IMAGES OBTAINED DURING THE STUDY

Disease type	Training data set	Validation data set	Test data set
Fine plaque	1684	425	54
Early blight	1761	480	159
Late blight	1713	463	138
Leaf mold	1753	470	129
Septicemic plaque	1682	436	63
Tetranychus	1537	435	204
Target spot	1659	457	168
Mosaic virus	1700	448	90
Yellow leaf curl virus	1868	490	93
Healthy leaves	1863	481	63
Total	17184	4585	1161

C. Image Preprocessing

Image preprocessing is a technique employed to improve the input image for subsequent manipulation, allowing for the pertinent characteristics to be accentuated for further

processing [20]. The utilisation of it aids in the alleviation of numerous issues, such as irradiance effects, illumination, and complications resultant from inadequate contrast. Fig. 3(a) and 3(b) demonstrate the difference in a diseased tomato image before and after pretreatment using the Keas input function, respectively. In the preprocessing stage, data standardization and data enhancement technologies are applied.

Data normalization is an essential step in guaranteeing that each pixel in a picture has a comparable dissemination of information. It facilitates rapid convergence of the network during the training process. To normalize the data for this study, the mean was subtracted from each pixel, and the output was divided by the standard deviation.

Following this step, each pixel was assigned a value between 0 and 1. Image enhancement is essential to the development of an efficient image classifier. To construct an accurate classifier, a large number of unique images is required. It is practically impossible to locate so much information. By employing data augmentation techniques, it is feasible to produce fresh data by transforming the current data. In this study, rotation, cropping, scaling, and horizontal and vertical rotating are used as enhancement options.

Fig. 2. Image of tomato leaves infected with the following virus, (Note: (a) fine plaque, (b) early blight, (c) late blight, (d) leaf mold, (e) septicemic leaf spot, (f) spider mite, (g) target spot, (h) Mosaic virus, (i) yellow leaf curl virus).

Fig. 3. Images of pretreated tomato leaves (a) before and (b) after.

D. Model Selection

Big data's availability and computational capacity are responsible for the success of deep neural networks. Therefore, it is essential to determine which designs are most effective and under what conditions they can be implemented.

1) *Convolutional neural networks (CNN)*: Convolutional neural network (CNN) is a deep learning model specifically designed to identify and analyse features from multidimensional data sets [21-22]. The selected CNN model consists of four convolutional layers, with subsequent implementation of batch normalization, maximal pooling, and discard layers. Moreover, there are two additional layers, which are dense and flat. Table II presents an overview of the network architecture, comprising of layer configurations and the corresponding number of parameters for training. Convolutional layers have the capability to detect distinct patterns of features, including edges and hues, among other characteristics. If one layer recognizes border patterns, the second layer will recognize line patterns. Each possesses an

abstraction level. Batch normalization resembles the preparatory normalization utilized in this study. The only distinction is that this paper employs a different type of layering. This paper makes the image more appropriate for the input layer by normalizing it during the preprocessing phase. In addition, batch normalization is used to make the image more suited for the hidden layer. Normalization of the activation layer's output is performed by subtracting the mean value and dividing by the standard deviation of the batch, resulting in improved stability and speed of the model. To prevent overfitting, the disintegrating and pooling layers are added [14]. In this model, the maximum pooling layer is utilized to reduce the overall size and thereby dynamically boost the computational performance. Each output is the corresponding data after applying maximum pooling to the inputs. Importantly, the maximum pooling contains only hyperparameters, so gradient descent does not necessitate learning. The dropout layer, as indicated by its name, drops out some neurons during training, but keeps them active during validation. As the model's complexity grows, it tends to overfit by memorizing all the weights, but the dropout layer solves this problem by randomly dropping out a portion of each layer during training.

The use of the Flatten Layer between the Merging Layer and the Dense Layer is generally recommended, as it facilitates the transformation of the Merging Feature Map into a single vector, subsequently allowing its passage to the Dense Layer. For each block, the Rectified Linear Unit (ReLU) activation function is employed, however, finally, after the final dense layer, the SoftMax activation function is implemented. The activation function checks which nodes meet the defined conditions in order to pass through the layer. A fixed learning

rate of 0.001 is used in the whole training process. The total quantity of epochs is designated to be ten, and the batch magnitude is established to be twenty-seven. The most advantageous amalgamation of parameter values is ascertained by modifying the super parameter. Once the model has been constructed, it must be compiled. The Adam optimization algorithm and the cross-entropy loss function are employed respectively in the compilation of the model as the optimizer and loss function. The model has been finally trained and stored in a .h5 file format.

TABLE II. OUTLINES THE PROPOSED CNN ARCHITECTURE MODEL

Layer	Output shape	Parameter
Conv2d	(None,254,254,32)	896
Max_pooling2d	(None,127,127,32)	0
Conv2d_1	(None,125,125,64)	18496
Max_pooling2d_1	(None,62,62,64)	0
Conv2d_2	(None,60,60,64)	36928
Max_pooling2d_2	(None,30,30,64)	0
dropout	(None,30,30,64)	0
Conv2d_3	(None,28,28,128)	73856
Max_pooling2d_3	(None,14,14,128)	0
Flatten	(None,25088)	0
Dense	(None,128)	3211392
Activation	(None,128)	0
Dropout_1	(None,128)	0
Dense_1	(None,10)	1290
Activation_1	(None,10)	0

2) *VGG16*: VGG16 is a famous CNN model, which was put forward by VGG of Oxford University. Compared with Alex Net [23], an improvement of VGG16 is to replace the larger convolution kernel (11x11, 5x5) in Alex Net with several successive 3x3 convolution kernels [24]. In this work, the VGG16 model which had been pre-trained was adjusted for the purpose of plant disease identification. In this study, Transfer Learning and Fine-Tuning are employed to classify diseased leaves, leveraging the fact that the VGG16 model has already learnt the characteristics of plant leaves. Utilizing the preprocessing input feature of Keras VGG16, preprocessing is applied before the image is supplied to the input layer. The VGG16 model contains a total of 138,357,544 parameters, which can be obtained from an online source. Given that the model has assimilated these characteristics, it is not indispensable to alter the weights throughout the entire learning procedure. Consequently, the weights are kept constant to impede modification. The number of parameters in the model has been reduced to 134,301,514 due to the freezing of weights. The ultimate model is in accordance with the Adam optimization algorithm and the cross-entropy loss function for classification. For this model, the learning rate is set to 0.001, the batch size is set to 27 and the number of epochs is set to 10. The model has been successfully trained and the weights have been stored in the .h5 format.

3) *MobileNet*: Mobile Net is an example of a lightweight and high-speed family of deep neural networks that can be deployed for categorization and pattern identification tasks, analogous to other convolutional neural networks. In spite of its diminutive size when compared to other models, it demonstrates remarkable performance. [25] The model's magnitude is primarily determined by the cumulative number of parameters. This research employed a model that was sourced from the web with the use of the Keras Library and pre-processed with Mobile Net's capabilities, which are commonly found to require fewer data augmentation procedures as compared to other models. After the process of refinement, the final model was composed of 3,239,114 parameters. The sample size was ascertained as 27, the number of epochs was established at 10, and the learning rate was maintained at 0.001. The model which had been trained was subsequently stored in .h5 format in order to be used at a later date.

4) *Inceptionv3*: Szegedy et al. discovered the initial concepts belonging to the family of deep neural networks [26] Several initial models were introduced, and each was designated initial VN, where N represents the version number.[27] In this investigation, Inceptionv3, the third version in the family, was utilized. A model with 21,802,784 parameters was obtained by utilising the Keras library. In addition to the initial architecture, a layer with global average pooling, a discarding layer, two layers with dense connections, and a densely connected output layer with ten nodes were included. The utilisation of a global average pooling layer facilitates the identification of features, while simultaneously reducing superfluous parameters. The number of epochs, learning rate, and batch size were set to ten (10), 0.001, and twenty-seven (27) respectively. The weights of the bottom 172 layers were kept constant while the higher layers were re-trained. Following the fine-tuning process, the total number of parameters in the final model was determined to be 23,387,434, which is slightly higher than the number of parameters present in the original model. The model is ultimately trained and stored in a .h5 format for potential later use.

E. Model Training and Validation

The fit function is used by inputting the train image, validating the image, setting the era size, and the steps of the era. Finally, the performance index is evaluated, and these steps are repeatedly performed by changing the parameter values using undiscovered data until the best combination of parameters is found to obtain a generalized accurate model.

III. RESULTS AND DISCUSSION

The objective of this research is to assess the effectiveness of different deep learning architectures commonly employed today, including CNN, VGG16, Mobile Net, and Inceptionv3. These models were constructed, optimized, and trained successfully. Table III presents the validation and training accuracy of each model, as well as the time taken for each model to complete training during each epoch.

TABLE III. MODEL ACCURACY

Model	Training situation	Verification situation	Mean value
	Accuracy	Accuracy	The time of each period
CNN	0.9018	0.8968	3652s
VGG16	0.8923	0.7894	6341s
Mobile Net	0.9112	0.9078	2949s
Inceptionv3	0.8734	0.8628	6068s

A confusion matrix was created for each of the deep learning models, as shown in Fig. 6, 7(a), and 7(b). The matrices represent the summary of predictions made by each model. The X-axis displays the predicted labels while the Y-axis displays the true labels. The dark labels in the matrix indicate the number of correct classifications made by the model. The test data was used to create the matrix, and it shows the prediction accuracy of each category. As is exemplified in Fig. 4, the bottom row of the confusion matrix indicates that all specimens with yellow leaf curl disease had been correctly categorized, consequently yielding a 100% predictive accuracy. The performance of the predictions for each disease category can be evaluated using these matrices. Despite being limited by space, the confusion matrices for Inceptionv3 and other CNN models can be viewed in Fig. 5(a) and 5(b).

Fig. 4. Confusion matrix of MobileNet.

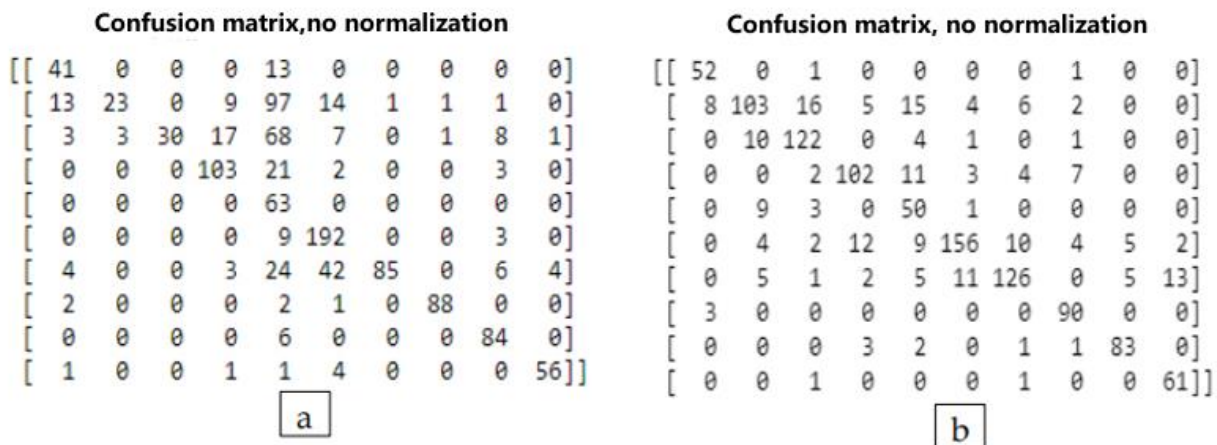

Fig. 5. Confusion matrix of (a) Inceptionv3 and (b) CNN.

The Matplotlib drawing library in Python was utilized for the creation of Fig. 6 and 7. Fig. 6 and 7 illustrate the

progression of training and validation accuracy/loss of each model over time.

Fig. 6. Training and verifying the accuracy of the model: (a) CNN, (b) MobileNet, (c) Vgg16 and (d) Inceptionv3.

Fig. 7. Loss of training and validation models: (a) CNN, (b) MobileNet, (c) VGG16 and (d) Inceptionv3.

Referring to the diagrams, we can observe the fluctuations in verification accuracy and loss for each training epoch. To evaluate the performance of the final trained model, an unseen image is fed to the model, and the predicted category and confidence are obtained. This is achieved through the use of OpenCV, a Python library. The purpose of this is to verify if the final model can accurately predict the unseen image. In Fig. 8(a), an image of a leaf affected by early blight is shown as an example.

Source:Category:Tomato Early Blight, Document: Toamto Early Blight Forecast; Classification: Tomato early blight, confidence:0.999915

Source: Classification:Tomato-tomato mosaic virus, file:Tomato-tomato mosaic virus 8b 8 90deg.JPG; Classification:Tomato mosaic disease virus,confidence:1.000000

Fig. 8. Prediction of the MobileNet model for (a) Mosaic virus and (b) early blight.

It was correctly classified into the correct category with a confidence level of one hundred percent. Fig. 8(b) depicts a leaf infected by mosaic virus. In addition, it was confidently classified into the correct category.

A summary of correctly and incorrectly classified images is presented in Table IV. The initial column of the table denotes the various disease categories, while the second column illustrates the sum of images presented to the Mobile Net model from each category. The third column signifies the sum of images accurately classified, while the fourth column indicates the aggregate of images misclassified.

Table IV presents a synthesis of the correct and erroneous classification of images for each disease type, coupled with the overall number of images supplied to the ultimate Mobile Net model from each category. The last column of the table gives the average accuracy of each category. Research has demonstrated that the yellow leaf curl virus has been accurately categorized with a mean accuracy of 100%. Table IV can be utilized to likewise evaluate other diseases. The deep learning

model has demonstrated remarkable enhancement in the categorization of plant diseases. This study seeks to contrast the efficacy of a Convolutional Neural Network (CNN) model developed from the ground up with that of a fine-tuning pre-training model using the Plant Village dataset from Kaggle. Training the VGG16 model was time-intensive due to the large parameter count. It can be concluded that an increase in the number of parameters also increases the time required for training the model.

TABLE IV. SUMMARY OF CNN MODEL PREDICTION

Species	Total	Correct value	Error value	Accuracy (%)
	Image	Classification value	Classification value	
Fine plaque	54	52	2	96
Early blight	159	131	28	82
Healthy	138	129	9	93
Late blight	129	121	8	94
Leaf mold	64	60	4	94
Septicemic plaque	207	165	42	80
Spider mite	168	118	50	70
Target point	94	88	6	94
Mosaic virus	90	88	2	98
Yellow leaf curl virus	84	84	0	100

When examining the training and validation accuracy of VGG16, it is evident that the former significantly exceeds the latter, indicating the model's strong performance on training data but weak performance on test data. This phenomenon is known as overfitting, which frequently results from an overly complex model. With its relatively smaller number of parameters, Mobile Net is less complex than Inceptionv3 and VGG16, making it better suited for effective detection. The prediction accuracy of Mobile Net and CNN models is 0.90 and 0.89, respectively, indicating their superior suitability for test data compared to VGG16. Fig. 6, 7(a), and 7(b) show that the classification accuracy of Fig. 6 is 100% compared to other models for the last category of matrices (yellow leaf curl). Determining the layers to freeze and train for the fine-tuning of VGG16 and Inceptionv3 necessitates more time. These models are difficult to train due to their high complexity and sensitivity pattern identification. In contrast, the proposed CNN architecture is slightly shallow, making it quicker to train on the same dataset. Accuracy is dependent on parameter identification, which requires prior experience. Mobile Net outperforms Inceptionv3 in terms of size, delay, and accuracy, and could easily be implemented in mobile devices and embedded vision applications. Although the CNN model in this study is less deep than other models, it is still easily applicable due to its reduced computational complexity.

IV. CONCLUSIONS

This study suggests that a basic convolutional model with a minimum of four layers can be enough for extracting the relevant features for categorising tomato plant diseases in comparison to other tuned models. VGG16 and Inceptionv3 have relatively more parameters, but do not reflect better recognition accuracy. This requires more time to refine, train and run on the one hand, and limits its deployment and fast recognition on smaller systems on the other. The suitability of Mobile Net and CNN for this study is due to its compactness, speed, and ability to run smoothly on mobile devices. With guaranteed high accuracy recognition, MobileNet and simple CNN structures are not only easier to deploy, adjust and work with in the areas covered by this study, their lighter weight structure allows them to have further development potential.

The aim of this investigation is to deliver a conclusive answer instead of a supposition, which will support upcoming scholars in opting for the most innovative and efficient deep learning algorithms and networks for their further research in the realm of automatic plant disease classification. Currently only tomato leaf images obtained from the internet were examined in this paper, and they will be further tested on real-time images detection program in the future, employing the CNN model developed throughout the research process.

V. FUNDING STATEMENT

Project support: This project is funded by the national Guilin University of Electronic Science and Technology Student Innovation and Entrepreneurship Training Program (No.202110595052).

Research on Recommendation Model of College English MOOC based on Hybrid Recommendation Algorithm

Yifang Ding*, Jingbo Hao

North China Institute of Aerospace Engineering
School of Foreign Languages
Langfang, 065000, China

Abstract—Establishing a reasonable and efficient compulsory education balance index system is very important to boost the all-around of compulsory education development, and then realize the course recommendation for students with different attributes. Based on this, the research aimed at the problems in college English education and evaluation, aimed to establish a college English MOOC education and evaluation system based on the improved neural network recommendation algorithm. The research first constructed the college English MOOC education and evaluation data elements, and then established a genetic algorithm improved neural network algorithm (BP Neural Network Optimization Algorithm Based on Genetic Algorithm, GA-BP), and finally analyzed the effect of the assembled model. These results show that the fitness of the GA-BP model reaches the set expectation when the evolutionary algebra reaches 10 times, and its fitness is 0.6. The corresponding threshold and weight are obtained, and the threshold and weight are substituted into the model. After repeated iterative training, the model finally reached an error of 10⁻³ when it was trained 12 times, and the expected accuracy was achieved. The R value of each set hovered around 0.97, and the fitting degree was high, which showed that the GA-BP model proposed in the study had a better fitting degree. The difference between the expected value and the output value is mainly distributed in the [-0.08083, 0.06481] interval. To sum up, the GA-BP model proposed in the study has an excellent effect on college English education and evaluation. This evaluation model has a faster learning rate and a higher prediction accuracy and more stable performance.

I. INTRODUCTION

With the advent of the Internet age, due to the continuous increase of users, the amount of digital information has increased rapidly, and it is difficult for traditional technical means to process it in a short period of time, resulting in information overload [1]. At present, information overload is an urgent problem to be solved. Traditional information retrieval methods cannot quickly and accurately find the most valuable learning resources from massive data [2]. The existing teaching methods cannot fully stimulate the subjects' interest in learning. The above characteristics of the recommendation system can quickly improve the user's retrieval speed for information, and at the same time ensure the validity of the information obtained by the user in the recommendation

system. It eliminates the distraction of users during use and improves the credibility of users [3]. In terms of learning and teaching, introducing the recommendation system into the learner's learning situation can make it easier for the subjects to obtain appropriate learning resources, so that the subjects can learn more focused and in-depth [4-5]. MOOC stands for Massive Open Online Course, also known as Massive Open Online Course. MOOC is a curriculum system with a large number of participants, no admission conditions, and an online carrier. Due to the high technical requirements of platforms that support large-scale registration for the operation of MOOC, it is difficult for a university to independently complete it. Therefore, in the MOOC process of implementing blended English teaching in universities, internationally mature MOOC platforms such as China University MOOC and Xuetang Online can be utilized, and teaching materials can be reasonably selected and rigorously designed based on actual teaching needs. Based on this, the study proposes a college English MOOC education and evaluation system based on the improved neural network recommendation algorithm, which can then realize the evaluation of MOOC courses and recommend corresponding courses to students with different attributes. The paper constructs a data mining algorithm and establishes a corresponding system. Based on this, it proposes an improved neural network model. The first part of the paper is an introduction, which introduces the background and motivation of the research; The second part is a literature review, summarizing the research of relevant scholars in different fields; The third part is the research method, which constructs the data mining algorithm in college English education and evaluation system, including the establishment of college English education and evaluation data elements, and the improved neural network algorithm based on genetic algorithm; The fourth part is the analysis of the application effect of improved neural network algorithms in college English MOOC education and evaluation; The fifth part is the conclusion, and the last part is the references.

II. RELATED WORK

Chinese and foreign scholars have conducted extensive discussions and researches on this. Features based on artificial intelligence algorithms. On this basis, in-depth research has been carried out, and it has been widely used in artificial intelligence. Through the simulation experiment of this model, it is proved that this method is correct [6]. Lunde et al in aim of

improving students' subject-related skills, it combines methods such as theoretical education on research topics, proximal validity and validity, and group discussions with social education students on Mental Development of SA-SH-Ext [7]. Sotomayor-Moriano et al. proposed a virtual laboratory environment for online practice using the standard process FDI system. Thanks to VLE, trainees can set the errors of sensors, according to the model of FDI, and perform performance tests on FDI systems. This paper uses a four-pot process (4 TP) FDI system as an example to demonstrate its application under various failure scenarios. At the end of the article, the practical experience of using these two patterns in FDI design is given [8]. Putra et al. collected by questionnaire survey. In the group test there are 9 respondents and in the larger group test there are 12 respondents. It was found that the textbook experts scored 4.06, the media professional scored 4.78, and the language professional scored 4.19, all of which are relatively feasible. The scores for the group test and the large group test are 3.36, 4.21, which shows that this set of materials is very interesting. This set of textbooks can be used as a reference for learning trigonometric functions [9]. Nursalam et al. The purpose of this paper is to conduct a study on the quantum education model established by SDN Salupompong, Level 4, Mamuju Regency, West Sulawesi. This thesis is based on narrative method and sequence method, and carried out 4 investigations and 2 experiments. The study found that in English language learning, students' learning performance was 3.7, while motivation was 3.53, and response to students was 3.44. Among the three effective scales, the effective scale is 3.55, which is a very effective teaching method [10].

Chaves GL et al. through four simulation experiments, the course allows students to explore the effects of glycolysis, TCA cycle, genetic modification on carbon redistribution, and other metabolic pathways. metabolism. there. Students responded positively to using OptFlux as an adaptive questionnaire [11]. Under the concept of "teaching factory", Mourtzis et al. proposed a hybrid model, which has been proven in practice. In the case study of the hybrid power laboratory, engineering students remotely guided the laboratory staff to make and assemble a custom remote-control vehicle. The advantages and limitations of existing methods are discussed, and their development trends are prospected[12]. A manual simulation experiment was conducted to test whether using durable, inexpensive yarn can help pre-med students understand fetal lateral folding. Changes in knowledge are evaluated before and after use. The survey showed that students found the activity to be rewarding and fun, and the model work was easy to carry out. The above research results show that 3D dynamic 3D modeling is an effective teaching method [13]. Sultana et al examines the role of quantitative-based teaching materials in primary school students. Experiments have proved that quantitative teaching methods are more effective than conventional teaching methods in teaching students to think critically. From the critical thinking ability gain test of the experimental class, it can be found that the N-gain value is 0.59. Then, add a new criterion to a test category. The results of the experiment showed that the score of critical thinking in the experimental group increased by 0.20 percentage points compared with the

control group. Then, include a gain of n in a lower standard [14]. C Gonzalez-Velasco et al. adopts the flipped classroom teaching method, conducts a comparative analysis of students at different education stages [15].

In order to improve the efficiency of cross-cultural teaching of college English, scholars such as Yin H have constructed an improved MOOC teaching platform based on cloud computing and artificial intelligence technology, and established relevant functional modules. The research results indicate that the model has better performance and can improve the efficiency of English cross-cultural teaching [16]. Yin H proposes a new MOOC remote learning resource recommendation method for college English, which addresses the issue of low efficiency in traditional college English remote education recommendation resources. The interest feedback model is applied to the recommendation system. The research results indicate that this method can improve the accuracy of recommendation results [17].

Therefore, in teaching evaluation, the method of using neural network technology for teaching evaluation is rare, and the application research in college English MOOC teaching and evaluation is even rarer. To this end, in the paper, the neural network model improved by genetic algorithm has been applied in English teaching and evaluation, thus improving the teaching system.

III. RESEARCH ON DATA MINING ALGORITHMS IN COLLEGE ENGLISH EDUCATION AND EVALUATION SYSTEM

A. Establishment of College English Education and Evaluation Data Elements

How to evaluate college English teaching should start from the following aspects and analyze the factors affecting English teaching [18].

As can be seen from Fig. 1, the research focuses on the factors affecting the teachers themselves and the factors affecting teaching evaluations from students. It is the influence of the teaching quality evaluation of universities established and selected by the research institute. Factors, and then label them. The order of labeling is from top to bottom. The ten influencing factors are used as the input variable data required by the model below. The specific labeling is shown in formula (1).

$$x = (X_1, X_2, \dots, X_n)^T \quad (n=10) \quad (1)$$

As shown in formula (1), x is the vector of influencing factors of English education and evaluation in colleges and universities X_i , and the value of its influencing factors. According to the relevant factors of English education and evaluation in colleges and universities shown in Fig. 1, experts can obtain the teaching quality level of each college, through the analysis of various influencing factors, the structure of the model of the result is obtained, and the initial value. On this basis, using the number of ANN nodes to find the number of hidden layer nodes. On this basis, combined with the relevant factors of college English teaching and evaluation, the network is trained until the expected training deviation is achieved.

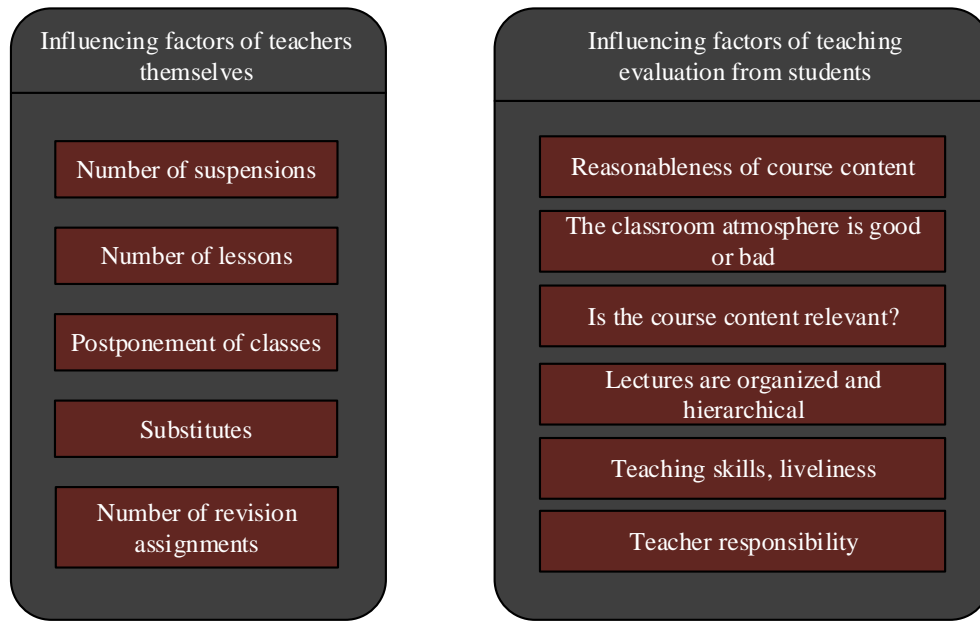

Fig. 1. The influencing factors of teaching quality evaluation in colleges and universities.

B. Improved Neural Network Algorithm based on Genetic Algorithm

The BP neural network has similar characteristics to human neurons, and can store a large amount of massive data Input and output training can be performed in the network without knowing the mapping relationship between variables. The basic idea of BP neural network is to reversely modify the forecast of the output layer, so that the deviation between the forecast result and the real data is closer to reality [19]. Its three-level network structure is shown in Fig. 2.

Fig. 2. Three-layer neural network topology.

As shown in Fig. 2, the BP neural network is divided into two stages: pre-activation and activation. Substituting it into the activation function [20], its mechanism and function are shown in formula (2) and formula (3).

$$g(x) = w_{ij}x_i + b_j \quad (2)$$

$$h(x) = f(g(x)) \quad (3)$$

In formula (2) and formula (3), x_i represents i the output value of the first neuron of the previous layer, w_{ij} represents the weight of the first neuron of the upper layer and the first j neuron of the previous layer, and represents the weight i of the first b_j neuron of this layer. j The critical threshold of the element, the relationship between its output x'_j and n input x_1, x_2, \dots, x_N can be expressed as formula (4).

$$X_j = \sum_{i=1}^N w_i \cdot x_i + S_j \quad (4)$$

In formula (4), S_j is the feedback signal. The BP neural network performs an iteration from the forward and backward directions, that is, starting from the input layer, performing continuous operations on the existing parameters, and then transmitting to the output layer along the forward direction of the network, and predicting it, and calculated its actual loss. The reverse transmission refers to the deviation between the previous forecast and the actual loss. The BP neural network performs an iteration from the forward and backward directions, that is, starting from the input layer, performing continuous operations on the existing parameters, and then transmitting to the output layer along the forward direction of the network, and predicting it, and calculated its actual loss. Backpropagation refers to the loss error between the predicted value and the real value obtained last time. Starting from the output layer, Using the gradient descending method, the parameters of each layer are reversely corrected until the deviation between the target [21]. The specific operation steps are shown in Fig. 3.

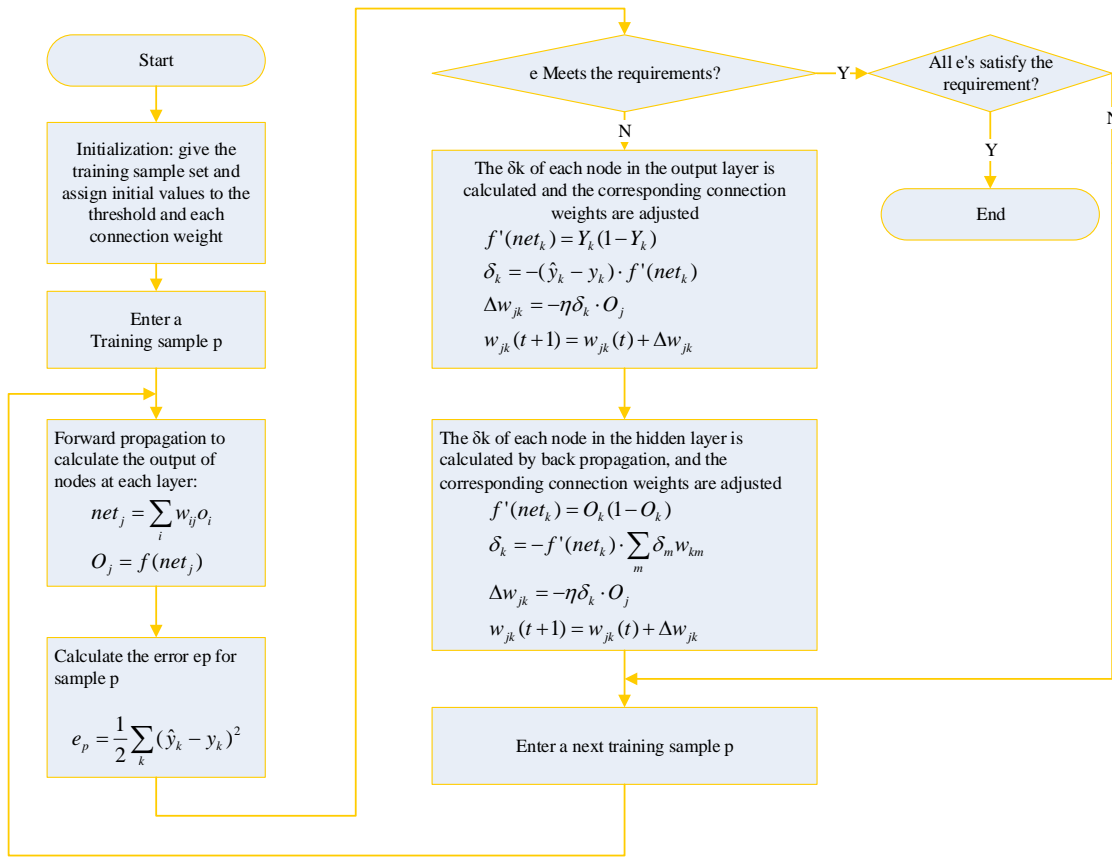

Fig. 3. BP neural network training flow chart.

Hidden layer output variable is shown in formula (5).

$$h_j = (h_1, h_2, \dots, h_p) = f\left(\sum_{i=1}^n w_{ij} x_i + a_j\right), j = 1, 2, \dots, p \quad (5)$$

In formula (5), a_j is the bias, and the actual output variable of the output layer is shown in formula (6).

$$y_k = (y_1, y_2, \dots, y_q) = \sum_{j=1}^p h_j w_{jk} + b_k, k = 1, 2, \dots, q \quad (6)$$

In Equation (7), the expected output variable of the output layer is shown in Equation (8).

$$d_k = (d_1, d_2, \dots, d_q), k = 1, 2, \dots, q \quad (7)$$

The error function is shown in formula (8).

$$E = \frac{1}{2} \sum_{k=1}^q (d_k - y_k)^2 \quad (8)$$

Assuming m training samples, the error function is shown in formula (9):

$$E = \frac{1}{2m} \sum_{l=1}^m \sum_{k=1}^q (d_k(l) - y_k(l))^2 \quad (9)$$

weight update formula is shown in formula (10).

$$\begin{cases} w_{ij} = w_{ij} + \eta h_j (1 - h_j) x_i \sum_{k=1}^q w_{jk} (d_k - y_k) \\ w_{jk} = w_{jk} + \eta h_j (d_k - y_k) \end{cases} \quad (10)$$

In formula (10), η is the learning rate, and the update formula of the bias is shown in formula (11).

$$\begin{cases} a_j = a_j + \eta h_j (1 - h_j) \sum_{k=1}^q w_{jk} (d_k - y_k) \\ b_k = b_k + \eta (d_k - y_k) \end{cases} \quad (11)$$

In the 1970s, genetic algorithms were introduced into computers and achieved great success in many practical problems in the 1980s, thus arousing great interest from people. Genetic algorithm refers to and imitates the genetic mechanisms and natural selection of organisms, adopting a "survival of the fittest" approach to continuously evolve the solution to a problem in competition, ultimately obtaining a satisfactory solution. It screens out random information exchange and fragments with strong adaptability in the sequence of the previous generation and reconstructs them into a new population, which is called "survival of the fittest". Sometimes new bits and fragments are added to the sequence, which is called "variation". By performing genetic operations such as selection, crossover, and mutation on the population, the optimization degree of the population during the evolution

process is continuously improved, ultimately approaching global optimization. Genetic algorithm has the advantages of global optimization, while BP neural network has better local search performance. However, since the BP network is randomly given the initial weight value, it will cause a situation. After the BP training, the total weight of each training and the total weight are different. In order to improve the quality of English teaching, this paper uses BP neural network and genetic algorithm to establish a new teaching evaluation system. In the weight optimization of the neural network, first initialize the group P and determine the size of the initial group; the second step is to sort the fitness function of each person, and then determine the individual in the network according to the probability value [22]. The selection method is shown in formula (12):

$$P_i = f(i) / \sum_{i=1}^n f(i) \quad (12)$$

In formula (12), is $f(i)$ the fitness of individual i ; The third step is to cultivate a new generation of individuals through genetic modification, and eliminate unqualified parents; the fourth step is to eliminate the new generation of individuals, insert them into the original population P, and perform fitness function calculations on them, and then use the error of the neural network to determine whether it meets the expectation, if it is satisfied, go to the sixth step; otherwise, go to step 3 and perform genetic manipulation; the sixth step, according to the error accuracy required by the neural network, on this basis, the best individual is selected as the weight of the neural network and operated on[23-24]. The probability of selecting individual i is shown in formula (13).

$$P_i = f_i / \sum_{k=1}^M f_k \quad (13)$$

Formula (13), the initial population is M and the fitness of individual i is f_i . After obtaining the probability of each individual, it will determine which individuals to mate with by random numbers between [0,1] Activities [21]. Since the interleaving mode has a great relationship with the actual coding situation, this article only discusses the coding method of floating-point numbers, and the form of arithmetic interleaving is as formula (14)[25].

$$\begin{cases} X_A^{t+1} = \partial X_B^t + (1-\partial)X_A^t \\ X_B^{t+1} = \partial X_A^t + (1-\partial)X_B^t \end{cases} \quad (14)$$

Formula (14), X is an individual and ∂ a parameter. If it is constant, it is an equation operation. If it is determined by evolutionary algebra, it is inconsistent. The last one is mutation, which uses the method of uniform mutation. Homogeneous mutation is to replace the gene values of all genes on a single chromosome with random numbers that conform to the average distribution with a certain probability[26]. The gene on each chromosome is regarded as a change point, and then according to different mutation points,

the initialization and termination of the genetic algorithm will be iterated repeatedly, and fitness calculation, replication and crossover will be performed in each iteration, genetic operation, such as a mutation, will not stop repeating until the end condition is reached[27]. Depending on the actual situation, different applications will have different end conditions. The end condition of this article is that it will stop when the number of repetitions is reached. The flowchart of the GA-BP neural network algorithm is shown in Fig. 4.

The initial value is compared with the adaptive function of BP neural network; obtain new populations through operations such as crossover and mutation until the goal is optimized, and then repeat the genetic operation until the genetic iteration is completed. By optimizing the BP neural network[28]. On this basis, the optimal initial value and minimum threshold can be obtained. This method mainly includes the initial and threshold of BP neural network, the learning and experiment of BP neural network[29-30]. Finally, the average cross-entropy of the verification set is calculated, and the model with the smallest average cross-entropy error of the verification set is determined as the final evaluation model, see formula (15).

$$Acc = \frac{1}{k} \sum_{i=1}^k acc_i \quad (i=1,2,\dots,k) \quad (15)$$

In formula (15), acc_i is the cross-entropy error of the first i verification set. Finally, the accuracy rate of college English teaching evaluation quality evaluation is recorded as formula (16).

$$P = \frac{N_{right}}{N_{all}} * 100\% \quad (16)$$

In Equation (16), N_{right} is several factors affecting the quality of English teaching, and N_{all} is the total number of items in the test set. Common accuracy evaluation indicators include recall rate (Recall) and F1 value[31-32]. The calculation method is shown in the formula (17) and formula (18).

$$Recall = \frac{TP}{TP + FN} \quad (17)$$

$$F1 = \frac{2 * Precision * Recall}{(Precision + Recall)} \quad (18)$$

Formulas (17) and (18), it TP represents the number of the samples that were actually positive and those that were predicted to be positive, referred to as true positive numbers, and so on TN , FP , FN are true negative numbers, false positive numbers, and false negative numbers[33-34]. Considering that in English teaching, it is of great significance to identify correct pronunciation and wrong pronunciation, so the accuracy rate is selected as the performance evaluation index of each model.

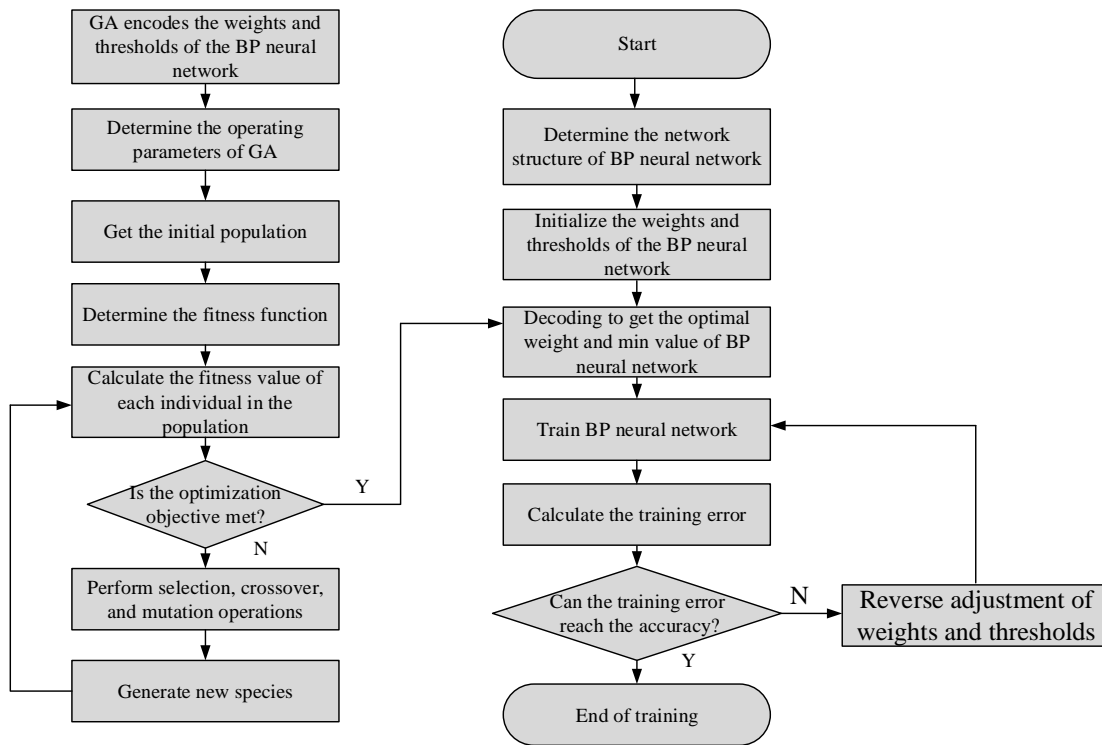

Fig. 4. GA-BP neural network algorithm flow chart.

IV. APPLICATION EFFECT ANALYSIS OF IMPROVED NEURAL NETWORK ALGORITHM IN COLLEGE ENGLISH MOOC EDUCATION AND EVALUATION

The study uses ten evaluation indicators of five universities as the input data of this study, and vectorizes the time to obtain the relevant teaching measurement score input matrix. Due to the difference in the dimension of each indicator, the deceleration rate of each indicator is different; adopting the same learning rate makes it difficult for the network training to achieve the optimal solution. At the same time, it avoids the gradient explosion caused by the index data with too large value, and the index with too small value is swallowed. Among them, in the experiment, the memory of each algorithm was 512Mb, the encoding tool was C++, and the operating system was Windows XP. The learning of BP network is an important content of BP neural network. In order to ensure the consistency of the distribution of numbers and models, this paper proposes a unified standard to combine the training set with the test set and standardize the data. Table I shows the details after normalization.

In the process of establishing the model, the Sigmoid function and the tanh function carry out the input data in the interval [0,1]. Most of them are in a suppressed state, and the differential interval is below 1. The gradient value shows an exponential decline with the increase of network depth, and there may be a gradual phenomenon. The Relu function is activated when the input value exceeds 0. It has a wide activation range and can well avoid the gradient disappearance phenomenon in network training. Neither the Reluc function nor the Reluc differential has performed any complicated mathematical operations, and will it be directly set to 0, thereby avoiding the participation of restricted neurons, thus making the learning of the neural network faster. However, Relu sets the initial state of the neuron to 0, so that it cannot perform subsequent operations, thus causing damage to the neuron during the learning process. Leaky_Relu is a modification of the Relu function, setting the inhibition state of Relu to a very small parameter α , which can well alleviate the weakness of the neural network. It needs to be adjusted continuously through network training, and α the setting is not easy to master. On this basis, different training errors and training times are obtained, as shown in Table II.

TABLE I. NORMALIZED DATA

-	x1 _	x2 _	x3 _	x4 _	x5 _	X 6	X 7	X 8	X 9	X 10
School 1	0.11	0.21	0.54	0.54	0.43	0.19	0.55	0.61	0.54	0.63
School 2	0.13	0.35	0.32	0.38	0.13	0.36	0.19	0.35	0.64	0.38
School 3	0.68	0.18	0.48	0.21	0.23	0.81	0.81	0.31	0.94	0.72
School 4	0.61	0.16	0.39	0.64	0.78	0.44	0.52	0.25	0.15	0.14
School 5	0.54	0.09	0.21	0.64	0.46	0.64	0.64	0.12	0.11	0.52

TABLE II. COMPARISON OF EXPERIMENTAL RESULTS BETWEEN RELU FUNCTION AND LEAKY_RELU FUNCTION

	Relu function		Leaky_ReLU function	
	Training error	Training time	Training error	Training time
The first time	0.0218	105	0.0238	118
The second time	0.0235	102	0.0240	123
The third time	0.0216	101	0.0209	109
The fourth time	0.0211	102	0.0210	115
fifth time	0.0219	103	0.0256	117

The BP neural network uses the Relu function as the initial function. BP neural network has a high recognition rate in the (0,1) interval. The output of the BP neural network is the graded gradient of the quality of school education, and its grade gradient is 0~8, which belongs to multi-category problems. Generally, it is a softmax function. This function is the probability of mapping the output of multiple neurons to the (0,1) interval, and the total probability sum of each neuron is 1. After determining the GA-BP model, import the normalized data into the model for further analysis, and first obtain its fitness curve and the training error curve of the neural network, as shown in Fig. 5.

As shown in Fig. 5, the improved BP neural network model of the genetic algorithm has the desired accuracy; as shown in

Fig. 5(a), when the fitness value is 10 times, the evolution algebra of the GA-BP model is 10 times. The set expectation has a fitness of 0.6, and the corresponding threshold and weight are obtained. As shown in Figure 5(b), the threshold and weight are substituted into the model, and repeated iterative training is carried out. Finally, when the training reaches 12 times, the model error of 10^{-3} was achieved, achieving the expected accuracy. The error histograms of each set are shown in Fig. 6.

As can be seen from the graph, the error of the training set is mainly concentrated at the zero point, and the difference between the expected and output is mainly at [-0.08083,0.06481]. The predictor results show that the model based on the GA-BP neural network has a higher predictive ability and better stability.

(a) Fitness curve of GA-BP neural network

(b) Graph of the training result of GA-BP neural network

Fig. 5. GA-BP neural network training performance renderings.

Fig. 6. The training error histogram of GA-BP neural network.

Fig. 7. Fitted curve after training.

Can be seen from Fig. 7 that the predicted value of the training set is relatively high, and deviations will occur in a few cases. The R values of each set hover around 0.97, and the fitting degree is high. The R value of the training set is

0.97024. The results show that the fitting effect of the GA-BP model established in this paper is better. By comparing the BP network and the GA-BP network, a conclusion similar to that in Fig. 8 is drawn.

Fig. 8. The average relative error of the two models.

From the relative error histogram in Fig. 8, it can be clearly seen that the absolute value of the relative error of the GA-BPNN model proposed in this study does not exceed the 5% limit of each evaluation index. Only the relative errors of individual evaluation indicators have big problems, their values are 4.52% and -3.84%, and the relative errors of other indicators are kept at a low level, and their errors are much smaller than those of the BPNN model. The GA-BP model proposed in the study has an excellent effect on college English education and evaluation. This evaluation model has a faster learning rate, higher prediction accuracy and more stable performance.

V. CONCLUSION

Under the current education model, traditional English learning methods are mostly teaching-based. Fostering student autonomy is a hot topic in education at the moment. How to let students focus more and learn in a broader range has also become a topic for scholars—the focus of attention. In the traditional classroom environment, with classrooms and libraries as the main body, the emergence of multimedia classrooms has increased the diversity of classroom teaching to some extent due to the wide application of computers. To ensure the fairness of compulsory education, it is highly relevant in terms of assessment of the teaching quality of the College English MOOC. This thesis aims to introduce genetic algorithm into college English teaching and evaluation and improve it. Deviations between the expected and the real values are essentially $[-0.08083, 0.06481]$. It can be known that the prediction performance of the model is robust. The R values of each set hover around 0.97, and the fitting degree is high. Finally, a comparative analysis of the relative prediction errors of the two models shows that the absolute value of the relative error of the proposed GA-BP model does not exceed that of each evaluation. The limit value of 5% of the index is better than a single algorithm. In short, the research can reflect the actual situation of delivering and assessing English in colleges and universities, and has substantial practical application value.

Employee Information Security Awareness in the Power Generation Sector of PT ABC

Ridwan Fadlika¹, Yova Ruldeviyani², Zenfrison Tuah Butarbutar³,
Relaci Aprilia Istiqomah⁴, Achmad Arzal Fariz⁵

Faculty of Computer Science, Universitas Indonesia, Depok, Indonesia^{1,2,3,4,5}

Abstract—Presidential Regulation No. 82 of 2022 demonstrates the Indonesian government's dedication to protecting Vital Information Infrastructure, which has become increasingly susceptible to cyber attacks. Intrusion detections at PT ABC reached 79,575 in 2021, and malware, botnets, targeted attacks, malicious websites/domains, and ransomware attacks may cause considerable financial losses. The implication of these incidents is that employees' awareness of information security is critical, in addition to security technologies like firewalls and monitoring tools. To enhance employees' knowledge of information security, this study aims to evaluate the information security awareness among PT ABC personnel using the HAIS-Q survey instrument alongside ISO/IEC 27001:2013 criteria. The study will provide valuable recommendations to improve the organization's security protocols. This research intends to investigate the correlation between employees' knowledge, attitude, and behavior towards information security. Data was collected through a questionnaire and analyzed using the Pearson Correlation, Cronbach's Alpha, descriptive statistics, linear regression, and Kruskal-Wallis test method. The study findings suggest that the overall information security awareness level among employees is "Good". However, certain areas like internet usage, information handling, asset management, incident reporting, and the use of mobile devices need improvement. To address these areas, the study recommends promoting information security awareness according to employee categories.

Keywords—Security awareness; data; information; ISO/IEC 27001:2013

I. INTRODUCTION

The Indonesian government through Presidential Regulation No. 82 of 2022 [1] pays attention to and is committed to protecting Vital Information Infrastructure due to the abuse of information and electronic transactions. Threats to the security of vital objects such as power plants have been experienced by the Gundremmingen nuclear power plant in Germany in 2016 where the "W32.Ramnit" and "Conficker" viruses were attacked through an employee's USB device¹.

The 2021 BSSN Report on Cybersecurity Monitoring reports that one of the background causes of data leaks is phishing [2]. The phishing method is where the hacker infiltrates malicious codes through an e-mail or website page

during internet browsing [3][4]. Monitoring data from PT ABC states that the number of intrusion detections during 2021 was 79,575. Cyber attacks such as malware, botnets, targeted attacks, malicious websites/domains, and ransomware attacking the company can result in significant financial losses [3][4]. The lesson learned from these incidents is the need for information security awareness among employees at PT ABC, as security technologies such as firewalls or monitoring tools play an important role in security, but the human factor must also be considered [4].

The measurement of awareness of information security has been the subject of numerous prior studies. Vina Effendy et al. (2022) conducted a study utilizing the HAIS-Q modeling to evaluate the level of information security awareness at XYZ polytechnic. The findings of the study revealed that the level of awareness was at a medium level at the research site, indicating the need for further monitoring to enhance the level of awareness. However, the authors did not provide recommendations based on employee criteria [5]. Another study by Aulia Zulfia et al. (2019) employed the HAIS-Q method to measure information security awareness at PT PQS. Nevertheless, the authors did not provide recommendations based on employee criteria [6]. In a similar vein, Rahardi Prakoso et al. (2020) measured awareness of information security among online transportation users using the HAIS-Q method. The authors identified the areas that require improvement, but did not provide recommendations based on sub-area categories among respondent demographics [7].

The Human Aspects of Information Security-Questionnaire (HAIS-Q) is a widely recognized tool for evaluating global information security awareness. Numerous studies, including [5][6][7][8][21], have utilized the HAIS-Q in various contexts, spanning commercial enterprises, academic institutions, and government agencies. Despite its extensive adoption, previous research has yet to integrate the HAIS-Q with the ISO/IEC 27001:2013 standard, and no research has specifically investigated the extent of awareness of information security among employees of PT ABC.

The motivation described above has instigated a research initiative aimed at assessing the awareness of information security of the PT ABC personnel. The HAIS-Q survey instrument, in conjunction with the ISO/IEC 27001:2013 criteria will be utilized to achieve this goal. The outcomes of this investigation will furnish recommendations for enhancing the organization's security protocols. It is expected that these

¹S. Christoph and A. Eric, 'German nuclear plant infected with computer viruses, operator says', *Reuters*, 2016, <https://www.reuters.com/article/us-nuclearpower-cyber-germany-idUSKCN0XN2OS>, (accessed 10 October 2022)

insights will have a favorable influence on the information security awareness level at PT ABC.

The ensuing section constitutes the second component of this paper and aims to expound upon the literature review. Subsequently, the third section delineates the theoretical framework, followed by the fourth section which explicates the research methodology. The fifth section comprises a thorough analysis and discourse of the outcomes. Finally, a conclusion will be presented to summarize the findings.

II. LITERATURE REVIEW

A. Information Security Awareness

The field of information security is concerned with safeguarding both information and the systems utilized to transmit, store, or manipulate it [9]. Management of information security entails not only considerations of technology, but also concerns pertaining to human users of the system, as evidenced by the importance of information security awareness [6]. Information security awareness encompasses two distinct dimensions, namely the degree to which users comprehend information security practices and the extent to which they are willing to adhere to organizational policies, rules, and guidelines [5]. The 2021 Annual Cybersecurity Monitoring Report [2] identifies weak human awareness as the primary factor contributing to anomalous network traffic. Cybersecurity training and awareness programs can be broken down into three components [10].

1) *Education*, which aims to impart wisdom on the importance of information security for the organization.

2) *Training*, which teaches users how to use security functions in the information system and in their work processes; and

3) *Awareness*, which builds on the foundation provided by education and training to promote individuals' knowledge of and adherence to best security, safety, and privacy practices [11].

B. HAIS-Q and KAB (Knowledge-Attitude-Behavior) Model

The Human Aspects of Information Security Questionnaire (HAIS-Q) is a validated assessment tool that enables the evaluation of individuals' level of awareness related to information security [12]. The HAIS-Q encompasses seven distinct domains, namely, password management, email usage, internet usage, social media utilization, mobile devices usage, information controlling, and incident reporting [4]. Furthermore, these seven areas are classified into three dimensions that are commonly known as KAB (Knowledge, Attitude, and Behavior) [13]. Each dimension can be elucidated as follows: a) Knowledge pertains to an individual's comprehension of information, b) Attitude denotes an individual's opinion, and c) Behavior pertains to an individual's disposition to undertake actions.

Users with high scores according to HAIS-Q perform better in phishing experiments, showing that HAIS-Q is a good framework for measuring users' information security awareness level [14].

C. ISO/IEC 27001:2013

The ISO/IEC 27001:2013 standards are universally employed for managing information security. These requirements dictate the establishment, implementation, maintenance, and continuous improvement of an organization's strategic decisions [15]. Moreover, they govern the application of management systems based on the PDCA approach, along with supplementary information security controls.

ISO/IEC 27001:2013 consists of 7 clauses and 14 information security control areas comprising 114 control points. Like other ISO standards based on high level PDCA this information security management system standard has a difference in clause 8, which is operation. The main point of attention is how to control information security risks outlined in Annex A.

This research focuses on some information security controls found in Annex A, within the scope of individuals' awareness of information security. Out of the 114 existing controls, some relevant to individual awareness will be selected, such as mobile devices (A.6.2.1), password management (A.9.4.3), email usage (A.13.2.3), internet usage (A.13.2.1), social media usage (A.18.1.4), information handling (A.8.3), incident reporting (A.16.1.3), and asset management (A.12.3 and A.12.5).

D. Validation and Reliability Test Method

1) *Validation test*: The method used to identify the validity of the questionnaire data is the Pearson Method [16]. Bivariate Pearson Correlation is used to determine the correlation between two variables x and y based on Eq. (1).

$$r = \frac{(\sum xy - \frac{\sum x \sum y}{N})}{\sqrt{(\sum x^2 - \frac{(\sum x)^2}{N})(\sum y^2 - \frac{(\sum y)^2}{N})}},$$
$$-1 \leq r \leq +1 \quad [16] \quad (1)$$

The variables in the formula are defined as follows: r is the Bivariate Pearson Correlation coefficient, N represents the number of data points, while x and y represent the first and second variables, respectively.

2) *Reliability test*: In identifying the reliability value of the questionnaire data, this research uses the Cronbach's Alpha method [16]. The Cronbach's Alpha value is used to measure internal consistency based on Eq. (2).

$$\alpha = \frac{k}{k-1} \left(1 - \frac{\sum s_i^2}{s_t^2} \right) \quad [16] \quad (2)$$

where k is the number of questions, s_i is the variance of each question item, s_t is the variance of the group, and α is the reliability value.

3) *Linear regression*: In the realm of hypothesis testing for the K-A-B relationship, the Linear Regression approach (as detailed in research [16]) is utilized to ascertain the degree to which the independent variable x can affect variations in the dependent variable y . Eq. (3) is employed to perform regression analysis and determine the R-squared value, which indicates the extent to which the independent variable can

account for variability in the dependent variable. The formula for R-squared, denoted as r^2 , is presented in study [16] as follows.

$$r^2 = \frac{(\sum xy - \frac{\sum x \sum y}{N})^2}{(\sum x^2 - \frac{(\sum x)^2}{N})(\sum y^2 - \frac{(\sum y)^2}{N})} \quad [16] (3)$$

In Eq. (3), N refers to the number of data points, x denotes the first variable, and y represents the second variable.

4) *Descriptive statistics*: The Mean value is used to determine the average value of a variable based on Eq. (4).

$$\bar{x} = \frac{\sum x}{N} \quad [16] (4)$$

where \bar{x} is the mean, N is the number of data, and x is the value of the variable.

The computation of the degree of variability in a variable is ascertained by the employment of the Standard Deviation (SD) value in accordance with Eq. (5), which is represented as:

$$\sigma = \sqrt{\frac{\sum x^2 - \frac{(\sum x)^2}{N}}{N}} \quad [16] (5)$$

In this formula, σ refers to the standard deviation value, x represents the value of the variable, N signifies the total number of data [16].

E. Significant Difference Test

The Kruskal-Wallis Test [16] is employed in statistical analysis to assess the degree of variation between two or more

groups, pertaining to a particular area of interest, by examining values that signify significant differences. As a non-parametric, rank-based test, this method utilizes the mean rank to determine the extent of variation between groups.

The mean rank value is calculated based on Eq. (6):

$$\bar{R}_A = \frac{\sum_{i=1}^{n_A} R_{Ai}}{n_A} \quad [16] (6)$$

where n_A is the number of samples in a particular group for a focus area, R_{Ai} is the rank of a focus area for a sample in a specific respondent group, \bar{R}_A is the mean rank of a focus area for a single respondent group, N is the number of data.

The Kruskal-Wallis Test for a single respondent group is calculated using Eq. (7):

$$H = \frac{n_A[\sum_{i=1}^{n_A} (R_{Ai} - (N+1)/2)^2]}{N(N+1)/12} \quad [16] (7)$$

III. THEORETICAL FRAMEWORK

The theoretical frameworks used in this research are the KAB Dimensions, HAIS-Q, and ISO/IEC 27001:2013. To measure the level of awareness of information security, it is required to measure the levels of Knowledge, Attitude, and Behavior from the employees' perspective, this is based on the theory proposed by Schrader & Lawless (2004) [13]. The researcher then focuses the measurement area on some measurement items based on HAIS-Q and ISO/IEC 270001:2013. The theoretical framework is shown in Fig. 1.

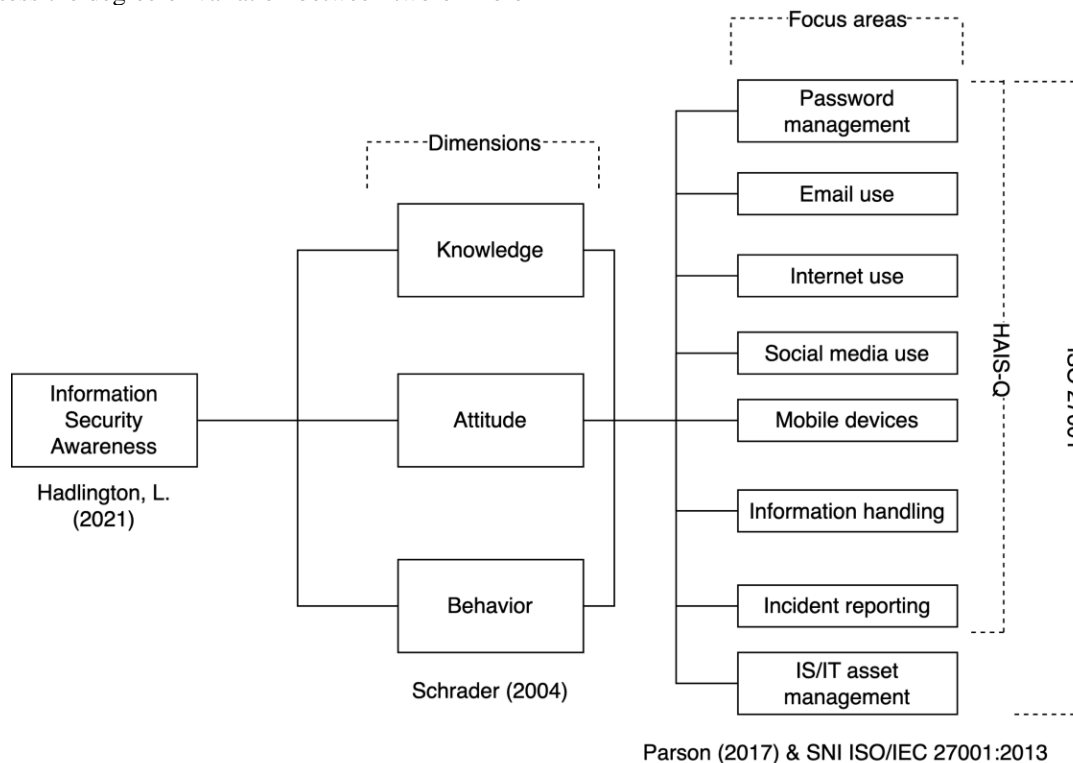

Fig. 1. Theoretical framework.

The research hypothesis consists of:

- H1: The knowledge dimension has a significant effect on the attitude dimension,
- H2: The knowledge dimension has a significant effect on the behavior dimension,
- H3: The attitude dimension has a noteworthy impact on the behavior dimension.

The visual representation of the proposed research hypothesis is depicted in Fig. 2.

Fig. 2. The research hypothesis.

IV. RESEARCH METHODOLOGY

This section explains four important things for collecting evidence that justifies the conclusion made, which are A) research instrument, B) stages of research, C) data collection method, and D) data processing and analysis method.

A. Research Instrument

This study utilizes a questionnaire as a research tool, incorporating insights from prior research works, including [5][6][7][8]. The questionnaire is comprised of question components from seven key areas of the HAIS-Q [12] and eight areas of the ISO/IEC 27001:2013 standard [15]. Notably, seven of these areas exhibit significant overlap, encompassing password management, email usage, internet usage, social media usage, mobile device usage, information controlling, and incident reporting. However, one area - pertaining to IT/IS asset management - does not share this overlap. Consequently, the focus areas for this study encompass password management, email usage, internet usage, social media usage, mobile device usage, information controlling, incident reporting, and IT/IS asset management. Additionally, each of these focus areas is further segmented into three distinct dimensions, namely Knowledge, Attitude, and Behavior (K, A, B), as outlined in Table I.

The research tool employed in this study comprises a comprehensive questionnaire consisting of 48 items that are designed to assess the levels of information security awareness among the respondents. The questionnaire is conducted to evaluate the knowledge, attitude, and behavior of the participants, pertaining to eight key areas of focus. Answers are given using the Likert scale 1-5 (1: Strongly Disagree, 2: Disagree, 3: Neutral, 4: Agree, 5: Strongly Agree).

B. Stages of Research

The stages of research of this study can be outlined as follows:

1) *Research problem identification*: Identify the research problem, which is the need to measure employee information security awareness in PT ABC.

2) *Literature review*: Conduct a comprehensive review of relevant literature on information security awareness, employee behavior, and security culture in the power generation sector.

3) *Research design*: Determine the research design, including the research approach, data collection methods, sample size, and data analysis techniques.

4) *Data collection*: Collect data from the employees using survey questionnaires.

5) *Data processing and analysis*: Analyze the data using the Pearson Correlation, Cronbach's Alpha, descriptive statistics, linear regression, and Kruskal-Wallis test method.

6) *Results interpretation*: Interpret the results and draw conclusions based on the findings, highlighting the level of employee information security awareness in PT ABC.

7) *Discussion*: Discuss the implications of the findings for PT ABC's information security management system and suggest recommendations for improving employee information security awareness.

8) *Conclusion*: Summarize the main findings and conclusions of the study, and highlight its contributions to the field of information security awareness in the power generation sector.

TABLE I. FOCUS AREA OF INFORMATION SECURITY AWARENESS

Focus Area	Sub-Area	Focus Area Code	Indicator Code (K, A, B)
Password management	Sharing password	MP	KMP, AMP, BPM
	Safe password usage		
Email use	Clicking on a link in an email from an unknown sender	EM	KEM, AEM, BEM
	Opening an email attachment from an unknown sender		
Internet use	Downloading a file	IN	KIN, AIN, BIN
	Entering information into the internet		
Social media use	Social media privacy settings	MS	KMS, AMS, BMS
	Posting about work		
Mobile devices	Sending sensitive information over Wi-Fi	PM	KPM, APM, BPM
	Hacking technique: shoulder surfing (observation)		
Information handling	Disposal of sensitive document printouts	PF	KPF, APF, BPF
	Use of USB/other removable media		
Incident reporting	Reporting suspicious behavior	PD	KPD, APD, BPD
	Reporting all incidents		
IS/IT asset management	Regulations regarding the installation of software on agency-owned IT assets	MA	KMA, AMA, BMA
	Data backup		

C. Data Collection

The current research utilized a questionnaire comprising 48 items, distributed via Google Form and administered to 150 employees of PT ABC using a sampling strategy. The questionnaire consisted of eight focus areas, each of which contained two questions pertaining to the dimensions of Knowledge, Attitude, and Behavior. The final sample size consisted of 130 participants, from whom the research team successfully obtained data.

D. Data Processing and Analysis Method

The method for testing validity is using Bivariate Pearson Analysis (Pearson Product Moment Correlation). The Pearson value for all variables is greater than the critical value of 0.172 based on the Pearson Critical Value Table with a sample size of 130 and a significance value of 0.05 2-tailed.

The reliability test was done using Cronbach Alpha, to test the reliability of the measurement indicators used in the research. According to J. Hair (2017), a Cronbach's Alpha value above 0.7 is considered reliable [17].

Linear regression is used to test the hypothesis with the help of SPSS software. The output from SPSS is then processed using Microsoft Excel for descriptive statistical analysis that produces mean and standard deviation data for each sub-area in the knowledge, attitude, and behavior dimensions. The index value is obtained by dividing the total score by the maximum Likert scale value (Y) multiplied by 100% as in Equation (8).

$$Indeks = \frac{Total\ Skor}{Y} \times 100\% \quad [18] \quad (8)$$

The subsequent course of action involves the computation of mean values for each dimension, based on the gathered index values. This leads to the assessment of level of information security awareness. Kruger and Kearney (2006) [18] have classified information security awareness levels into three tiers: Good (80 – 100%), Moderate (60 – 79.99%), and Poor (≤ 59.99%), as illustrated in Table II.

TABLE II. INFORMATION SECURITY AWARENESS CLASSIFICATION [18]

Awareness	Value (%)
Good	80 – 100
Average	60 – 79.99
Poor	≤ 59.99

The Kruskal-Wallis test is a statistical tool commonly utilized to ascertain the significance of categorical variables. Specifically, it is employed to evaluate and compare two or more groups within a particular domain, through the calculation of a significant difference value. This test is a non-parametric procedure, relying on the ranking of the observations (i.e., mean rank) [13].

V. RESULT AND DISCUSSION

A. Demographic of Respondents

The questionnaire was collected from 130 respondents. The demographics of the respondents in this research included job field, job title, education, and length of work at PT ABC. The composition of the respondents can be seen in Table III.

TABLE III. RESPONDENT DEMOGRAPHY

Categories	Total	Percentage
Field	Operation	49 38%
	Maintenance	25 19%
	Engineering	26 20%
	Administration	21 16%
	Other	9 7%
Job title	Structural	33 25%
	Functional	97 75%
Education	S2 (Master)	3 2%
	D4/S1 (Bachelor)	80 62%
	D3 (Three-year diploma)	18 14%
	SMA (High school)	29 22%
Job tenure	≤ 5 years	57 44%
	6 – 10 years	20 15%
	11 – 15 years	24 18%
	≤ 16 years	29 22%

In terms of job field, 38% are in the operations field followed by engineering, maintenance, and lastly, 16% are in administration, while 7% are in other fields. For job title, 75% are functional while the rest are structural. The most common education level among the respondents is D4/S1 with 62%. For length of work, the majority of the respondents have experienced for less than 5 years, accounting for 44%.

B. Validity and Reliability Test

The present study has conducted validity and reliability tests on the variables of interest. The outcome of these tests has been included in the appendix. Specifically, the Pearson correlation coefficient for the APD2 indicator code was found to be 0.108, which falls below the critical value of Pearson. Therefore, the APD2 variable has been excluded from further analysis. On the other hand, Table XV in the appendix presents evidence of the validity of all indicators related to the research variables. Subsequently, a reliability test was conducted, and the results have been presented in Table IV.

This study obtained a Cronbach's Alpha value of 0.919, indicating a high level of internal consistency reliability among the variables assessed. Based on the results of the validity and reliability tests, it can be inferred that the measurement variables utilized in this study exhibit strong validity and reliability.

C. Hypothesis Testing Results

The hypothesis testing was conducted using linear regression method which tests the significance between dimensions in the KAB modeling, which are the Knowledge dimension towards Attitude, the Knowledge dimension towards Behavior and the Attitude dimension towards Behavior.

1) Knowledge – Attitude: The regression coefficient value for the dimension of Knowledge towards Attitude shown in Table VI confirms the significance between the two dimensions (Sig: 0.000).

The findings presented in Table V and Table VI indicate a notable influence of the Knowledge dimension on the Attitude

dimension. The analysis reveals a strong positive correlation ($\beta = 0.803$) and a significant level of statistical significance ($sig < 0.001$) between the two dimensions, with a coefficient of determination (*R-squared*) of 0.644. The empirical relationship between the Knowledge and Attitude dimensions can be expressed by the equation $y = 8.492 + 0.849x$, where y represents Attitude and x denotes Knowledge.

TABLE IV. RELIABILITY TEST RESULT

Cronbach's Alpha	N of Items
0.919	48

TABLE V. COEFFICIENT OF DETERMINATION K-A

Model Summary				
Model	R	R-squared	Adjusted R-squared	Std. Error of the Estimate
1	0.803	0.644	0.642	4.596
Predictors: (Constant), K				

TABLE VI. REGRESSION COEFFICIENTS K-A

	Unstandardized Coefficients		Standardized Coefficients	t	Sig.
	B	Std. Error	Beta		
(Constant)	8.492	3.747		2.266	0.025
K	0.849	0.056	0.803	15.230	0.000

Based on these results, it can be concluded that Hypothesis 1 is supported, as the Knowledge dimension has a significant impact on the Attitude dimension.

2) *Knowledge – Behavior*: Table VIII shows the regression coefficient values for the dimension of Knowledge towards the dimension of Behavior.

Table VII and Table VIII present the findings of the analysis that demonstrate the Knowledge dimension's impact on the Behavior dimension (correlation $\beta = 0.685$, significance $sig < 0.001$, coefficient of determination *R-squared* = 0.470). The Knowledge-Behavior (K-B) dimensions' relationship can be described by the equation $y = 15.008 + 0.767x$, where y represents the Behavior dimension, and x represents the Knowledge dimension. Thus, the results indicate that an improvement in the Knowledge dimension can lead to a corresponding increase in the Behavior dimension.

Therefore, it can be concluded that Hypothesis 2 can be accepted. The dimension of Knowledge has a significant impact on the dimension of Behavior.

3) *Attitude – Behavior*: Table X shows the regression coefficient values for the relationship between the Attitude dimension and the Behavior dimension.

The analysis conducted on the data presented in Tables IX and X indicate that Attitude significantly influences Behavior, as evidenced by a strong positive correlation ($\beta = 0.807$) and a high level of statistical significance ($sig < 0.001$), with a coefficient of determination (*R-squared*) value of 0.652. These findings suggest that enhancing employees' attitude towards information security may effectively lead to a positive change

in their behavior, which can ultimately lead to better security practices in the organization. The Attitude-Behavior (A-B) relationship can be stated with the equation $y = 10.540 + 0.855x$ where y represents Behavior and x represents Attitude.

Therefore, it can be concluded that Hypothesis 3 can be accepted. The Attitude dimension has a significant impact on the Behavior dimension. The results of the hypothesis test as shown in Fig. 3.

TABLE VII. COEFFICIENT OF DETERMINATION K-B

Model Summary				
Model	R	R-squared	Adjusted R-squared	Std. Error of the Estimate
1	0.685	0.470	0.466	5.943
Predictors: (Constant), K				

TABLE VIII. REGRESSION COEFFICIENTS K-B

	Unstandardized Coefficients		Standardized Coefficients	t	Sig.
	B	Std. Error	Beta		
(Constant)	15.008	4.845		3.098	0.002
K	0.767	0.072	0.685	10.650	0.000

TABLE IX. COEFFICIENT OF DETERMINATION A-B

Model Summary

Fig. 3. The results of the hypothesis test.

D. Results of the Information Security Awareness Level Measurement

Table XI presents the findings of the information security awareness level measurement conducted at PT ABC.

The password management, email use, and social media use areas have all met the Good category with regards to the knowledge, attitude, and behavior dimensions. This suggests that employees have a high level of understanding, positive attitude, and appropriate conduct when it comes to password management, email use, and social media use. The results for

the internet use area have been classified under the moderate category, which requires significant attention. As highlighted in the introduction, the internet represents a vulnerable entry point for cyber attacks, including phishing, viruses, and data leakage [8]. Consequently, ensuring that employees exhibit wise and safe internet practices is essential to safeguard the company's information security. Given the moderate category classification, it is imperative for PT ABC to implement measures to improve information security awareness and enhance employee knowledge and behavior in this area.

The mobile device usage area has attained the good category concerning the knowledge and attitude aspects. However, with regards to the behavioral aspect, it is still classified in the moderate category.

In relation to information handling area and incident reporting, both knowledge and behavioral dimensions have achieved the good category; however, in terms of the attitude dimension, it is categorized as moderate.

The assessment of asset management area reveals that it has achieved the Good category with regards to the attitude and behavioral dimensions. However, in terms of knowledge, it has only reached the Moderate category, indicating a need for further improvement.

TABLE XI. RESULTS OF THE INFORMATION SECURITY AWARENESS LEVEL MEASUREMENT

Area/Dimension	Knowledge	Attitude	Behavior
Password management	89.54	83.15	88.92
Email use	83.54	85.69	81.46
Internet use	70.54	75.62	76.00
Social media use	87.23	85.00	81.08
Mobile devices	83.23	82.23	79.92
Information handling	89.62	79.62	87.69
Incident Reporting	85.15	75.31	83.54
IS/IT asset management	79.77	85.69	84.46

Indicators with moderate measurement results can be a priority improvement area that can be enhanced by the company.

1) Behavior dimension based on job tenure category: Table XII shows a significant difference in behavior levels based on the job tenure category in the focus area of email usage, where employees with working experiences of less than five years (mean rank 73.07) have a high value of behavior compared to employees with job tenure 6 to 10 years (mean rank 49.43). Within the information handling focus area, the highest value is in employees with more than 15 years of job tenure (mean rank 77.04) and the lowest is in employees with length of employment 5 to 10 years (mean rank 53.48). Within the incident reporting focus area, the highest value is in employees with more than 15 years of job tenure (mean rank 86.88; mean rank 82.43) and the lowest is in employees with job tenure of less than 10 years (mean rank 58.06; mean rank 58.70).

2) Behavior Dimension based on education level: Table XIII shows a significant difference in the habit of using social media; the lowest is in employees with a Master's degree background and the highest is in employees with a High School education background. The highest incident reporting habit is in employees with a SMA (High School) education background and the lowest is in employees with a Master's degree background.

TABLE XII. BEHAVIOR BASED ON JOB TENURE

3) Behavior dimension based on job position category:

Table XIV shows the behavior level based on job categories. The focus area with a significant difference value less than 0.05 is the incident reporting focus area. In the incident reporting focus area, the highest habit value is in functional employees (mean rank 76.26) and the lowest is in structural employees (mean rank 61.84).

E. Implications

Based on the research results, the following are the practical and theoretical implications:

1) *Practical implication:* The measurement of information security awareness at PT ABC is presented in Table XI. The results indicate that certain focus areas do not meet the Good category, which suggests that PT ABC should take necessary measures, such as training or actions, to enhance information security awareness. This can serve as a guide for the company to identify the specific areas that require improvement and facilitate the implementation of targeted interventions. Utilizing training programs can be an effective method for improving knowledge and awareness of potential security threats and risks [19]. The focus areas and dimensions that need to be improved are:

- Internet use

It is recommended that PT ABC offer training, socialization, and seminars to employees as a means of enhancing their knowledge and awareness of information security. Additionally, it is advised that the company establish regulations, actions, and punishments against employees who engage in behavior or activities that threaten the security of the company's information system within the internet use focus area. What is included in the internet use focus area such as downloading files carelessly to office devices, accessing

suspicious online sites, and entering information into online sites to assist work.

- Mobile devices

PT ABC is authorized to issue warnings, prescribe regulations, and take appropriate actions against employees whose practices may put the company's information system security at risk within the software device use focus area. What is included in the mobile device use focus area such as physical security of devices such as leaving laptops/mobile phones carelessly, sending sensitive information via online networks, and opening sensitive documents near strangers.

- Information handling

PT ABC has the authority to provide notifications, implement regulations, and execute appropriate measures towards employees whose conduct may jeopardize the security of the organization's information system within the information handling focus area. What is included in the information handling focus area such as putting/throwing sensitive documents carelessly, and inserting USB/removable media into office PC/laptops carelessly.

- Incident reporting

PT ABC has the authority to issue warnings, set rules, and take appropriate actions against employees who exhibit behaviors that pose a threat to the security of the company's information system within the incident reporting focus area. What is included in the incident reporting focus area such as reporting suspicious behavior in the office, reporting if there is a dangerous action from a colleague related to the information system security, reporting all incidents/events related to the information system security.

- IS/IT Assets Management

PT ABC can provide training/socialization/seminars to employees to improve their knowledge of asset management such as carelessly installing software, especially pirated software and related data backups.

Table XII - XIV shows the results of the measurement of the dimension of the habits based on the categories of work experience, education, and job type. This categorization can provide insight to the company to identify the strengths and weaknesses of awareness of information security and also facilitate the development of a customized information security training program for employees [20].

Based on the table, PT ABC can provide rules/actions in the more focused areas of information security system based on categories.

If based on work experience category, it is as follows:

- Within the focus area of email use, employees who have worked for over 5 years demonstrate inadequate knowledge of information security systems. Therefore, there is a pressing need to prioritize information security awareness-raising efforts in the email use sector for this category of employees.

- Within the focus area of information handling, employees who have served for 6-10 years exhibit reduced knowledge of information security systems. Consequently, there is a necessity to prioritize awareness-raising efforts on information security within the information handling sector for this group of employees.
- In the incident reporting focus area, employees who have worked for less than 11 years have a lower awareness of information security systems. Consequently, there is a need to focus more on enhancing information security awareness within the incident reporting sector.

Based on education, the focus of increasing awareness of information security can be more focused on the use of social media and incident reporting areas. The details are as follows:

- In the focus area of social media use, employees with S2 education have a lower awareness of information security systems; hence, it is imperative to give more consideration to the awareness of information security within the social media usage domain.
- In the incident reporting focus area, employees with D4/S1 and S2 education have a lower awareness of information security systems, therefore the incident reporting sector requires greater emphasis on information security awareness.

Then, based on job type, PT ABC can focus more on incident reporting on structural employees.

2) Theoretical implications

- In this research, it can be concluded that knowledge has a significant impact on attitudes and habits. Furthermore, the attitude dimension also has a significant effect on behavior.
- Measurement based on respondent category can be done to categorize participants in training/seminar/awareness-raising activities on information security.

VI. CONCLUSION

Based on research results, the overall average level of information security awareness among employees at PT ABC is considered good. The findings also highlight specific areas that require improvement to increase awareness about information security, such as internet usage, information handling, asset management, incident reporting, and the use of mobile devices.

The research also showed that the dimension of knowledge influences attitude and behavior, so the information security awareness improvement program can focus on increasing the dimension of knowledge, such as socialization, seminars, and training, as well as punishment systems or monitoring if it focuses on the attitude dimension.

ECAH: A New Energy-Aware Coverage Method for Wireless Sensor Networks using Artificial Bee Colony and Harmony Search

ZHOU Bing^{1*}, ZHANG Zhigang²

College of Artificial Intelligence
Jiaozuo University, Jiaozuo, Henan, 454000, China

Abstract—Wireless Sensor Networks (WSNs) offer diverse applications in the research and commercial fields, such as military applications, medical science, waste management, home automation, habitat monitoring, and environmental observation. WSNs are generally composed of a large number of low-cost, low-power, and multifunctional sensor nodes that sense, process, and communicate data. These nodes are connected by a wireless medium, allowing them to collect and share data with each other. To achieve network coverage in a WSN, a few to thousands of tiny and low-power sensor nodes should be placed in an interconnected manner. Over the last decade, deploying sensor nodes in a WSN to cover a large area has received much attention. Coverage, regarded as an NP-hard problem, is an essential parameter for WSNs that determines how the deployed sensor nodes handle each point of interest. Various algorithms have been proposed to tackle this problem. However, they often come with a trade-off between energy efficiency and coverage rate. Moreover, the scalability of the algorithms needs to be considered for large-scale networks. This paper proposes a novel energy-aware method combining Artificial Bee Colony (ABC) and Harmony Search (HS) algorithms to address the coverage problem in WSN, called ECAH. The proposed ECAH algorithm has been tested with various network scenarios and compared with other existing algorithms. The results show that ECAH outperforms the existing methods in terms of network lifetime, coverage rate, and energy consumption. Additionally, the proposed algorithm is also more robust and efficient as it can adjust to dynamic network environment changes, making it suitable for various network scenarios.

Keywords—Artificial bee colony; coverage; deployment; harmony search; wireless sensor network

I. INTRODUCTION

Recent years have seen a significant advancement in wireless and emerging technologies, particularly the Internet of Things (IoT) [1], Wireless Sensor Networks (WSNs) [2], artificial intelligence [3, 4], machine learning [5-7], smart grids [8], Blockchain [9, 10], 5G connectivity [11], and cloud computing have successfully brought many benefits to society.

WSNs are composed of economical, energy-efficient, and tiny sensor nodes which are widely employed in many applications [12-14]. For instance, in a military application, the WSN can be utilized for battlefield surveillance and asset monitoring [15]. Environmental monitoring, building monitoring, forest fire detection, and natural disaster prevention are examples of civil applications of WSNs [16].

The sensors have three prominent roles; sensing, computing, and wireless communication [14]. The sensors can shift separately after a random placement indicating the sensors' self-deploys. Some sensors have the self-repair ability where nodes can reposition themselves when another node fails [17]. Some environmental information, such as temperature, humidity, or other environmental data, is measured by each node periodically. This information should be sent to a central node named sink [18].

Coverage problems pose a major challenge to the development of effective sensor networks. In a sensor network, the coverage problem serves as an indicator of QoS [19]. The coverage is classified into three groups such as area, point, and barrier coverage. The WSNs aim to cover and manage an environment completely. There must be at least one sensor placed at each point in the area. In the area coverage, the best coverage occurs when the target area is fully covered by the lowest number of sensors [20]. The point coverage aims to cover the specific points of the environment. Sensors do not cover the whole area in this model; just some areas are covered. So, some particular points specify goals that need to be controlled. In barrier coverage, the sensors do not cover the entire area. At least one sensor controls the goals in barrier coverage, and all existing plans are controlled by that area. Maintaining connectivity and coverage requires finding the optimal number of active nodes [21].

Coverage in WSNs is an NP-hard problem, and many heuristic methods are proposed to increase the coverage rate in these networks. One of the developed metaheuristic algorithms is Harmony Search (HS). The HS algorithm has fewer mathematical requirements compared to other metaheuristic algorithms. With the HS algorithm, efficient regions are found within a reasonable timeframe. However, it suffers from non-convergence to an optimal solution, low convergence accuracy, and more time to reach optimal response. It is possible to improve accuracy and convergence rates by combining HS with the Artificial Bee Colony (ABC) algorithm. The ABC algorithm performs better than other evolutionary algorithms and optimizes harmony memory with its variants. This paper presents an algorithm combining HS and ABC algorithms to resolve the coverage optimization problem in WSNs. Briefly, the paper makes the following contributions:

- Maximizing the coverage rate in WSN;

- Minimizing the energy consumption in the WSN;
- Increasing the lifetime of the WSN.

The paper is organized in the following manner. The related work is discussed in Section II. The proposed hybrid algorithm is presented in Section III. Section IV reports the experimental results. The conclusion is discussed in the last part.

II. RELATED WORK

Many meta-heuristic algorithms have been adopted by researchers in recent years in order to improve the performance of WSNs, with various effects on the coverage area, network lifetime, the routing strategy, and node distribution. Each algorithm has its own advantages and drawbacks, and selecting the most suitable algorithm for a given application is an important step for successful deployment of WSNs. Therefore, it is important to understand the characteristics of each algorithm in order to make an informed decision. Additionally, many algorithms can be combined to further improve network performance. Finally, it is important to continuously evaluate and monitor the performance of a WSN to ensure optimal performance.

Ab Aziz, et al. [22] have utilized the PSO algorithm and Voronoi diagrams to optimize the coverage problem in the WSNs. In this work, the target area is a two-dimensional square environment, considered a convenient and practical model that can be used for different applications. The sensors are placed in the region of interest using the Voronoi diagram instead of the grid and PSO algorithm. In this work, the Voronoi diagram is produced initially on an unbounded area considering the position of sensors in a specific region of interest. This way, each boundary is covered with a set of randomly selected points. The proposed method performs well regardless of the number of sensors used or the size of the region of interest. On the other hand, there are some disadvantages to using the Voronoi diagram. One disadvantage is that it can be more difficult to generate the diagram for more complex shapes. Another disadvantage is that the diagram can be sensitive to changes in the position of the sensors, which can lead to inaccurate results.

Also, Panov and Koceski [23] have solved the area coverage problem in WSNs using the HS algorithm. The HS algorithm determines the location and number of the optimal sensor nodes in this study. Therefore, the network coverage and cost can be improved. To start the HS algorithm, harmony memory stores an initial population of solution vectors. Each vector represents a sensor node location denoted by its real number. Based on the obtained results, the HS algorithm requires more iterations than the PSO algorithm. Thus, HS achieves faster convergence and rapid evaluation than other heuristic methods. However, the HS algorithm also has some drawbacks. One such drawback is that the HS algorithm can be easily trapped in a local optimum. This is due to the fact that the HS algorithm relies on the harmony memory to generate new solutions. Thus, the HS algorithm is not as effective as other heuristic methods in terms of escaping local optima.

In addition, Fidanova and Marinov [24] developed an algorithm based on the ACO algorithms for addressing the coverage issue in WSNs, focusing on reducing nodes and increasing coverage. Pheromone trails are bound by a fixed upper and lower bound in the proposed method. Thus, part of the possible movements and repetition of the similar and identical solution will prevent the accumulation of high pheromones. Their method implementation utilizes two main features of the ACO algorithm, an in-depth exploration of space in search of the best solution and extensive research into the best solution. Compared to simulated annealing and cataclysmic mutation algorithms, the ACO optimization algorithm needs fewer evaluations to achieve good results. In addition, the ACO algorithm reaches similar or higher fitness values with 2000 times less effort than simulated annealing or cataclysmic mutation.

Maleki, et al. [25] have suggested a new hybrid method based on the differential evolution (DE) and PSO algorithms for the distribution of the sensors for area coverage in WSNs. The hybrid method considers two factors, suitable distribution of the sensors and their energy consumption. In the hybrid method, the most optimized points for n sensors are searched according to the PSO algorithm for covering p -aimed points. Searching takes place based on the particles near the goal and can cover the ground suitably, and then the mutation and crossover operations on n sensors take place using the DE algorithm. The hybrid method increases the network's lifetime, reduces energy use and covers all points optimally. The authors have compared the proposed hybrid method with the PSO algorithm to demonstrate its efficiency. Results prove that the hybrid algorithm has a better coverage ratio and network lifetime than the PSO algorithm.

To obtain a specific coverage ratio, Qin and Chen [26] developed an area coverage algorithm based on differential evolution. WSNs are monitored to maximize their lifetime using the proposed algorithm. To realize the optimization process by WSNs, coverage of continuous areas is translated into coverage of discrete points. The main objective is to maintain coverage performance while consuming minimal energy. Binary differential evolution is redeveloped in the area coverage algorithm to find an improved node subset and satisfy coverage requirements. It has been demonstrated that the differential evolution area coverage algorithm provides 90% network coverage and is energy efficient and computation efficient.

He, et al. [27] have developed a model for optimizing WSN coverage using an improved marine predator algorithm. The algorithm improves its solution accuracy by introducing a dynamic inertia weight adjustment approach to the exploration and exploitation stages of the global exploration and local exploitation phases. A multiple random leading method is also employed in the improved algorithm to improve information exchange between population members and to jump out of local optimums. Wu, et al. [28] studied a sensor-based angle coverage judgment method. To monitor the planting region from k angles, using topological analysis, a multi-objective optimization function is developed based on the relationship between targets and sensors. In experiments, judgement was found to be more efficient than the other methods.

According to the above discussion, the majority of existing research focuses on reducing energy consumption or improving network coverage. In the proposed method, both enhancements to the lifetime of the networks and coverage issues are addressed in order to maintain a balance between the amount of energy consumed and the total area covered by the sensors in the sensing region. The proposed method optimizes the deployment of sensors in order to maximize the coverage while minimizing energy consumption. It also addresses the problem of network heterogeneity and scalability, making it an attractive choice for large-scale WSNs. In the first step, the optimal position of the sensors is calculated. The radius of the sensing region required for maximum coverage is then determined. In the next step, the hybrid algorithm is used to place the nodes in their optimal positions. The network lifetime is then improved by optimizing the transmission range of the nodes. Finally, the coverage and lifetime of the network are evaluated and the performance is compared with other algorithms.

III. PROPOSED METHOD

The sensor position has the main factor in the coverage problems. Sensors should be placed to ensure the total usage of the sensing ability, increasing the covered area. On the other hand, optimal coverage increases network lifetime and also reduces network power consumption.

A. Network Model and Assumptions

The problem is premised on the following assumptions:

- All sensors have a similar sensing radius;
- The nodes are mobile and homogeneous;
- The deployment strategy is a random type;
- The sensing model is a probabilistic model;
- All sensors cover an area of two dimensions.

According to the problem assumptions, the sensing area contains N randomly distributed nodes. The density of all nodes is homogeneous and uniform. All nodes are capable of performing sensing, receiving, and transmitting. For each sensor, three radius types of the same size are considered, sensing radius represented as R_s , communication radius defined as R_c , and uncertainty sensor detection radius illustrated as R_e . The network model of the suggested method is shown in Fig. 1.

B. Coverage Problem Definition

The optimum position of the network sensors in the area is considered the main challenge in WSN coverage [29]. After the sensors are positioned for the first time in the static version, they cannot move in the network, which is a limitation for this version of sensor deployment [30]. However, the sensors in dynamic networks can move along coordinates within the mission space. Sensors gather data around an area that falls under their detection ranges (like their location) and then share that information with their neighbors. The communication of sensors with each other and sharing of their information causes effective detection in a network [31]. Therefore, in the coverage problem, the positional flexibility

of the mobile sensors is used to enhance the ratio of the covered area. Generally, the coverage ratio of the WSN is computed via Eq. 1 [31], in which t denotes the overall size of the area of interest, s signifies the set of the nodes, and c_i refers to the coverage of a sensor i .

$$CR = \frac{\sum c_i}{t} \quad i \in s \quad (1)$$

a) Sensing Models

Searching the adequate coverage and monitoring ability depends on the sensing model. Two kinds of sensing models, such as binary and probability sensing models, are mainly applied in the study of WSN [32].

Binary sensing model: An area with radius R_s is the coverage area of sensor nodes in a two-dimensional plane. This circular area is called the sensing disk. R_s is called the sensing radius, which is determined by the physical properties of the sensing unit. Consider the coordinates of the node S_i are $S(X_{si}, Y_{si})$ in the binary sensing model, for any point P at (x, y) on the plane, the probability of that node S_i can detect the events that occur on P calculated by Eq. 2. Where $d(S_i, P)$ stands for the average Euclidean distance from the sensor node to the demand point in the plane, calculated by Eq. 3.

$$C_{xy}(S_i) = \begin{cases} 1 & x < 0 \\ 0 & otherwise \end{cases} \quad (2)$$

$$d(S_i, P) = \sqrt{(x_{si} - x)^2 + (y_{si} - y)^2} \quad (3)$$

Probability sensing model: The binary sensing model enables the detection of events. Nevertheless, the sensor node detection capability is unstable in virtual application environments due to interference from ambient noise and a decrease in signal strength. Implementing the probability sensing model in real-world environments is more practical since, instead of considering the sensor's radius and distance from the target, multiple dependent factors must be considered. Fig. 2 illustrates the probability sensing model. Probability is determined by Eq. 4 [32].

$$C_{xy}(S_i) = \begin{cases} 1 & d(S_i, p) \leq R_s - R_e \\ e^{-(\alpha_1 \lambda_1 \beta_1) / (\lambda_2 \beta_2 + \alpha_2)} & R_s - R_e < d(S_i, p) < R_s + R_e \\ 0 & d(S_i, p) \geq R_s + R_e \end{cases} \quad (4)$$

In Eq. 4, R_e ($0 < R_e < R_s$) refers to the uncertainty in the sensor detection radius. Sensor node characteristics are represented by $\alpha_1, \alpha_2, \beta_1, \beta_2, \lambda_1$, and λ_2 , where λ_1 and λ_2 are expressed as Eq. 5 and Eq. 6.

$$\lambda_1 = R_e - R_s + d(s_i, i) \quad (5)$$

$$\lambda_2 = R_e + R_s + d(s_i, i) \quad (6)$$

Due to overlapping sensors of sensing areas, this type of sensing model compensates for low detection probability potential. Eq. 7 determines this joint sensing probability when a demand point i lies in the overlap area of a set of sensors (s_{ov}).

$$C_{xy}(k_{sov}) = 1 - \prod_{s_i \in s_{ov}} (1 - C_{xy}(s_i)) \quad (7)$$

In Eq. 7, if $C_{xy}(k_{sov}) > C_{th}$, demand point p is considered to be effectively covered, where C_{th} refers to the coverage threshold, and its value is application dependent. The proposed method uses a probabilistic sensor detection model that includes points of different probabilities in the area. In this model, the area coverage is determined using probabilistic terms, so the results are realistic.

b) Coverage Model

Eq. 8 calculates the area coverage rate of the node set, where, $R_{area}(k_{sov})$ stands for the total ratio of the coverage area and $m \times n$ is the size of the sensing area.

$$R_{area}(k_{sov}) = \frac{\sum_{x=1}^m \sum_{y=1}^n C_{xy}(k_{sov})}{m \times n} \quad (8)$$

c) Energy Consumption Model

Energy efficiency is a very important issue in WSNs due to the limitation of battery resources. We need mechanisms that keep the energy resources because these mechanisms affect the network lifetime. In general, there are two mechanisms for conserving energies in a WSN, reducing the sensing range and planning of the sensor node activity. In cases where setting the sensing range is permissible, active sensors should dynamically adjust their sensing ranges so as to meet the entire sensing objective [33]. Energy savings can be achieved by reducing the communication range when an option to adjust the range of sensor communication radius would exist. In the proposed method, the introduced energy model in [33] is used to calculate the energy. According to the model, the consumption energy of the sensors is calculated via Eq. 9-11, where l denotes the length of the data transmitted, d_0 signifies threshold transmission distance, d represents the distance between sensor nodes, $E_{T,x}$ refers to the consumed energy for transmission, $E_{R,x}$ stands for the consumed energy for reception, E_{elec} specifies the amount of dissipated energy per bit to run the transmitter or the receiver circuit, and E_{Fs} and E_{Tr} depend on the transmitter amplifier model. The value of E_{elec} , E_{Fs} , and E_{Tr} are $E_{elec} = 50nJ/bit$, $E_{Fs} = 10pJ \times bit^{-1} \times m^{-2}$, $E_{Tr} = 0.0013pJ \times bit^{-1} \times m^{-4}$, and d = transmission radius or communication range.

$$E_{T,x}(l, d) = l \times E_{elec} + l \times E_{Fs} \times d^2 \text{ .if } d < d_0 \quad (9)$$

$$E_{T,x}(l, d) = l \times E_{elec} + l \times E_{Tr} \times d^4 \text{ .if } d > d_0 \quad (10)$$

$$E_{R,x}(l, d) = l \times E_{elec} \quad (11)$$

d) Lifetime Model

The length of time between the initial deployment of the network and running out of the energy of the first relay node defines the network lifetime. In this work, lifetime is expressed according to the seconds, and for a single node, it can be estimated with Eq. 12 [33], where $e_{initial}$ is the initial energy of sensor nodes and e_{total} refers to the amount of consumed energy for data transmission and reception calculated by Eq. 13.

$$\text{Lifetime} = \frac{e_{initial}}{e_{total}} \quad (12)$$

$$e_{total} = E_{T,x}(l, d) + E_{R,x}(l, d) \quad (13)$$

e) Objective Function

Objective functions are one of the most vital factors in optimization algorithms. According to the energy and lifetime models, both of these models depend on the distance between the sensors. Also, according to the network coverage definition, the network becomes an optimal coverage when the distance between the sensors is less than their sensing radius. On the other hand, as the coverage rate increases, more sensors will be active, and reducing the number of active sensors will result in a lower coverage rate. The problem is mathematically described as follows: given a set of N potential sensors, $k = \{s_1, s_2, s_3, s_4 \dots s_N\}$. In this regard, the optimization goal is calculated as follows.

$$z = \max(f_1, f_2) + \min(f_3) \quad (14)$$

In Eq. 14, f_1 , f_2 , and f_3 stand for the coverage rate, network lifetime, energy consumption, respectively. The fitness function is calculated using Eq. 15, where w_1, w_2 and w_3 are weight coefficients used to normalize coverage, energy, and network lifetime values.

$$\text{Fitness} = w_1 \left(\frac{\sum_{x=1}^m \sum_{y=1}^n C_{xy}(k_{sov})}{m \times n} \right) + w_2 \left(\frac{1}{(l \times E_{elec} + l \times E_{Fs} \times d^2) + (l \times E_{elec})} \right) + w_3 \left(\frac{e_{initial}}{(l \times E_{elec} + l \times E_{Fs} \times d^2) + (l \times E_{elec})} \right) \quad (15)$$

C. Proposed Coverage Algorithm

Due to the NP-Hard nature of the area coverage problem in WSN, the optimal approximate solution could be suitable. The traditional greedy algorithm is inefficient in solving the coverage problem, and finding the best solution is impossible. In the previous methods, the optimal results are not included in the coverage rate, energy consumption, and network lifetime. In this work, a new hybrid method is suggested based on the ABC and HS algorithms for resolving the coverage problem of the WSNs. The HS algorithm is one of the latest and the easiest methods to optimize the issues inspired by music. This algorithm has premature and slow convergence problems, particularly over the multimodal fitness landscape. Also, convergence to the optimal solution occurs slower [34].

In the present work, the ABC algorithm is used to improve the accuracy and convergence of the HS algorithm and to optimize harmony memory. Honey bees' intelligent foraging behavior is crucial in generating an ABC algorithm as a new swarm intelligence method. Harmony memory can be improved using the ABC and its variants. A significant advantage of the ABC algorithm is its ability to seek global and local results throughout each iteration. This advantage is compared to GA, PSO, and other intelligent computing methods. Therefore, finding optimal solutions increases and is avoided in the stuck of local optimization. The hybrid method uses the HS algorithm as the primary global search technique. In contrast, the ABC algorithm is the subprocedure of the local search and optimizes the harmony memory.

The coverage problem of the WSNs is proportional to the behavior of honey bees to find the optimal position of food sources and how the musician plays music. The position of the food sources represents the coordinates of the sensors in the sensing area, the value of each food source indicates the

network coverage rate, and the maximum value for the fitness function represents the highest coverage rate for each sensor. In terms of the parameters of the HS algorithm, each harmony vector represents an optimal position for the sensors. The harmony vector components also represent the decision variables, i.e., coverage rate, energy consumption, and sensor lifetime.

a) Preparing the Hybrid Method

This step consists of two sub-steps, the production of the initial population and the initialization of the harmony memory. In general, the HS algorithm has five main steps. Steps 1 and 2 are used in the first step of the proposed method, and steps 3, 4, and 5 are used to improve the newly generated solutions and update the harmony memory in the third step of the proposed method.

Generation of an initial population: This step generates the initial population (initial solutions) randomly. The initial population for the coverage problem is the coordinates of the sensors based on (x,y) in the sensing area. At this step, each sensor's coordinates (x,y) are generated, and the sensors are distributed under these coordinates in the sensing area. The size of the population should be equal to the size of the harmony memory.

Initialization of harmony memory: After generating the initial population of the sensors in steps 1-1 and distributing these sensors in the sensing area based on their x and y coordinates, a harmony vector is generated for each sensor. After generating the harmony vector for each sensor, the fitness function for each vector is calculated. Then the harmony memory is initialized with these vectors and their fitness values. Each harmony vector consists of three decision variables, coverage rate, energy consumption, and network lifetime. The harmony vector structure and harmony memory are described as follows.

- Harmony vector: Each solution in the HS algorithm is referred to as a harmony vector, representing the number of parameters of the optimization problem in a D-dimensional vector. Since the optimization parameters in the coverage problem are the coverage rate, energy consumption, and the sensors' lifetime, the harmony vector is considered a three-dimensional vector.
- Harmony memory: The HS algorithm uses a harmony memory to store possible solutions (harmony vectors) and their objective function values [35]. The number of initial populations determines harmony memory size. Eq. 16 represents harmony memory as a matrix.

$$\text{Harmony memory} = \begin{matrix} & \text{Decision variables} & & \text{Fitness function} & \\ \left[\begin{array}{cccc|c} x_1^1 & x_2^1 & x_3^1 & \dots & x_D^1 & f(x^1) \\ x_1^2 & x_2^2 & x_3^2 & \dots & x_D^2 & f(x^2) \\ x_1^{HMS} & x_2^{HMS} & x_3^{HMS} & \dots & x_D^{HMS} & f(x^{HMS}) \end{array} \right] & & & & (16) \end{matrix}$$

- Improving the harmony memory using the ABC algorithm

In this step, harmony memory is improvised by the ABC algorithm. The solution to the optimization problem is represented by the position of food sources in the ABC algorithm. A food source's nectar amount corresponds to the associated solution's fitness (quality). The employed artificial bees are located in the artificial bee colony's first half, and the onlookers are placed in the second half. Also, each food source has only one employed bee. Conforming to the above description, in the coverage problem, the location of the sensor nodes in the sensing area identifies the food sources, and each food source's value is defined as the sensor nodes' coverage value. In this step, a bee is assigned to each position of sensors in the sensing area. These sensors perform a series of movements and change their current position in the worker and onlooker bee phases. Changing the sensor's position makes the sensors find their optimal position, increasing the network's coverage. Generally, the ABC algorithm has four main phases: initialization, employed bees, onlooker bees, and scout bees' phase. The initial population of ABC algorithms is the harmony vectors generated and evaluated in step 1.

Employed bee phase: The particular group of bees is called employed bees that use the available food sources. Each of the employed bees keeps the profitability of the associated food

source and then returns to the hive and performs the waggle dance. Worker bees dance in different parts of the hive area to communicate with other bees. Generally, there are three types of dances: round, waggle, and tremble. In this phase, the new solution's fitness value (nectar amount) is essential in modifying the current solution by employing bees. When the fitness value of the new food source is higher than the old food source, the bee updates her position with the new one and rejects the old one. A position update equation for the j^{th} dimension of each i^{th} candidate in this phase is shown in Eq. 17 [34].

$$V_{ij} = X_{ij} + \varphi_{ij}(X_{ij} - X_{kj}) \quad (17)$$

In Eq. 17, $\varphi_{ij}(X_{ij} - X_{kj})$ is called step size. Although k is determined randomly ($k \neq i$), φ_{ij} is a random number between $[-1, 1]$. In the coverage problem, these working bees display the sensors. In this phase, these sensors change their current coordinates by Eq. 17. In the new position, the fitness function (objective function) is calculated, and a greedy selection is applied to the existing coordinates and old coordinates of the sensors.

Onlooker bee phase: Following the employed bee stage, the onlooker bee stage begins. In this stage, the employed bees share their fitness and position information with the onlookers in the hive [43]. Analyzing the available information, the

onlooker bees choose (roulette wheel selection method can be used) a solution with a probability P_i , related to its fitness. The probability P_i is calculated using Eq. 18 [34], where fit_i refers to the fitness value of the i^{th} solution.

$$P_i = \frac{fit_i}{\sum_{i=1}^{HMS} fit_i} \quad (18)$$

Like the employed bees, the onlooker bees change the position of their memory and check the fitness of the candidate source. Like an employed bee, the bee also memorizes the new position and forgets the old one when the new one has a higher fitness value. In the coverage problem, after the sensors have changed their current positions in the worker's bee phase and calculated the fitness value for each of their new positions, in this phase, for each of these sensors, a probability value based on Eq. 18 and the fitness value of each of the sensors is calculated. Then, using a roulette wheel selection method, a random position is selected, the sensors are positioned in the chosen position, and then the same as in the employed bee phase, by Eq. 17, the current position of sensors is changed. Then the new position is compared with the current position, and choose a better position by selecting a greedy selection.

Scout bee phase: The scout bees are generally responsible for finding new food sources around the hive. Food sources are expected to be abandoned after a specified amount of time (called "limit") if their position has not been updated [36]. These bees choose new food sources based on Eq. 19, where lb and ub are lower and higher bounds of the decision variables, respectively.

$$X_{ij} = lb_j + rand(0.1)(ub_j - lb_j) \quad (19)$$

According to the above principle, an indicator is defined as a trial index for each network sensor in the coverage problem.

$$x_i^{new} = \begin{cases} x_i(k) \in \{x_i(1), x_i(2), \dots, x_i(k)\} & r_1 > HMCR \\ x_i(k) \in \{x_i^1, x_i^2, \dots, x_i^{HMS}\} & r_1 \leq HMCR \\ x_i(k) + r_2 \times BW & r_1 \leq PAR \end{cases} \quad (20)$$

Evaluation and updating of harmony memory: Comparing the new candidate harmony and the worst harmony vector in the harmony memory leads to updating the harmony memory. New candidate vectors replace the worst harmony vectors if they are improved.

HS algorithm termination check: The termination condition in the HS algorithm depends on the number of

In the worker and onlooker bees phase, if the new position of sensors has a higher value for coverage rate, these sensors memorize the new position and forget its current position; otherwise, these sensors keep their current position, and one unit adds to the trial index of these sensors. In this phase, these trial indexes will be examined for all sensors; if the trial index value for each sensor is higher than the specified limit, it means this position does not have a good value for the coverage, and then this position should be abandoned. The sensors should create a new position based on Eq. 19.

b) Improving New Harmony Vectors and Updating Harmony Memory

At this step, a new solution (new harmony vector) generated by the three phases of the ABC algorithm was developed and stored in harmony memory. Three sub-steps are included in this step.

Improvisation of new harmony vectors: Three rules, including a Harmony Memory Consideration Rate (HMCR), a Pitch Adjustment Rate (PAR), and random numbers (r_1 and r_2), are used to improve a new harmony vector X^{new} according to the HS algorithm, in which random numbers r_1 and r_2 ranging from 0-1 are generated. Memory consideration generates the decision variable $X^{new}(k)$ if r_1 is less than HMCR; otherwise, random selection achieves $X^{new}(k)$. If r_1 is greater than HMCR, the decision variable $X^{new}(k)$ is generated randomly using Eq. 19. A slight adjustment can be made by perturbing once $x_i(k)$ and selecting one of the stored good values, with a probability of PAR. Lastly, fret width (FW or BW) determines the maximum pitch variation allowed. The new harmony vector is described in Eq. 20 [34].

decision variables, namely, sensor coverage, sensor energy consumption and sensor lifetime. In other words, the repetition loop for optimizing the new harmony vector with PAR probability is repeated three times. The first repetition is for the first component, the second repetition is for the second component, and finally, the third repetition is for the third component of the new harmony vector.

TABLE I. VARIABLES IN SIMULATION

Parameters	Definition	Value
A (m×n)	Terrain of experiment	20×20(m) - 500×500(m)
N	Number of sensor nodes	20 -210
D	Transmission radius (nodes distance)	Changeable for variant scenarios
E_{total}	Total energy for data transmission	Changeable for variant scenarios
MaxIT	Maximum iteration	Changeable for variant scenarios
HMS	Harmony memory size	Changeable for variant scenarios
R_s	Sensing radius	Changeable for variant scenarios
L	Data generated by each node	100 bit
HMCR	Harmony memory consideration rate	0.96
PAR	Pitch adjustment rate	0.68
Limit	Abandonment criteria	100
R_e	Uncertainty radius for sensor detection	$R_s/2$
$E_{initial}$	Initial energy	2 J
E_{elec}	Energy consumed by radio electronics	50nJ/bit
E_{Fs}	Energy consumed by the power amplifier	$10pj \times bit^{-1} \times m^{-2}$
E_{Tr}	Energy consumed by the power amplifier	$0.0013pj \times bit^{-1} \times m^{-4}$
V_{ij}	New position for sensors	-
X_{ij}	Current position for sensors	-
P_l	Roulette wheel selection probability	-
fit_i	New position fitness	-
r1 and r2	Random numbers between 0 and 1	-

TABLE II. FIRST SCENARIO PARAMETERS

Sensing radius					Number of sensors		Network size		
1.5	2	2.5	3	4	5	20	20×20		
Harmony search parameters									
HMCR=0.9		PAR=0.4		FW=0.2		$\alpha_1=1$	$\alpha_2=0$	$\beta_1=1$	$\beta_2=0.5$

B. Dataset

The performance of the proposed method is compared with the performance of the HS [23], PSO [22], ACO [24], multi-objective GA [37], ABC [31], and hybrid PSO with DE [25] algorithms. Therefore, we considered the datasets and parameters used in these studies.

C. Obtained Results

This section compares our method with previous methods in six scenarios and shows its performance. In each scenario, the results are compared with those of previous methods. Lastly, the final scenario presents the effect of the number of sensors and the sensing radius on the network's coverage rate, energy, and lifetime.

In the first scenario, we used the parameters that are listed in Table II. Table III shows the results of applying our method and HS algorithm in area coverage for the different radii. The near-optimal solution for our approach is provided in fewer iteration than for the HS algorithm, as shown in Table III. The network environment for ECAH and HS algorithms with radius=2 m are shown in Fig. 3 and 4, respectively. The results demonstrate that our proposed approach can provide an optimal or near-optimal solution with faster convergence in

terms of time and number of iterations. Furthermore, our proposed method can achieve a better coverage rate in a shorter time compared to the HS algorithm.

TABLE III. RESULTS FROM APPLYING THE PROPOSED METHOD AND HS FOR AREA COVERAGE WITH DIFFERENT RADIUSSES

Radius (m)	Iteration (HS)	Iteration (ECAH)	Coverage rate (HS)	Coverage rate (ECAH)
1.5	7000	100	24.66%	53.71%
2	7000	100	45.97%	55.39%
2.5	7000	850	85.25%	77.66%
3	7000	1000	93.16%	93.34%
4	7000	100	99.50%	100%
5	7000	150	100%	100%

TABLE IV. SECOND SCENARIO PARAMETERS

Simulation parameters		
Sensing radius	Number of sensors	Network size
5	45	50×50

Fig. 3. The network environment in ECAH.

Fig. 4. The network environment in HS.

Table IV shows the parameters used in the second scenario. Our method and PSO algorithm were applied to the coverage of an area with a radius of 5 meters, as shown in Table V. The network environment for the proposed algorithm and the PSO algorithm with radius=5 m is shown in Fig. 5 and 6, respectively. PSO algorithm found the best coverage after the 100th iteration, whereas our method found it after 46 iterations. This shows that our method is significantly more efficient and accurate in finding the best coverage in a given area. It is able to find the best coverage in fewer iterations, indicating that it is more precise in its calculations and requires less time and resources to achieve the desired results.

TABLE V. RESULTS FROM APPLYING THE PROPOSED METHOD AND PSO FOR AREA COVERAGE WITH RADIUS=5

Fig. 6. The network environment in PSO.

In the third scenario, the parameters of [24] are used, shown in Table VI. Table VII gives the results of applying ECAH and ACO algorithms to area coverage for radius=22 m. The network environment for ECAH and ACO algorithms with radius=22 m is shown in Fig. 7 and 8, respectively. The ECAH has found the best coverage in the 85th iteration, while the best coverage of the ACO algorithm is achieved in the 100th iteration. The results show that the ECAH algorithm was able to achieve the best coverage in fewer iterations than the ACO algorithm, indicating that it is more effective and efficient in finding the best coverage in this network environment.

Table VIII shows the parameters adopted from reference [37] for the fourth scenario. Several sensors and iterations are used to conduct the experiment, which shows the detailed results in Table IX. The ECAH has found the best coverage in the 85th iteration, while the best coverage of the GA algorithm is achieved in the 100th iteration. According to the obtained results, the GA with 39 sensors and 100 iterations has reached the optimal coverage, but the proposed method has been optimized with 30 sensors and 100 repeats. The network environment for ECAH and GA algorithms with radius=13 m and N=40 are shown in Fig. 9 and 10, respectively.

TABLE VII. RESULTS FROM APPLYING ECAH AND ACO FOR AREA COVERAGE WITH RADIUS=22

TABLE IX. RESULTS FROM APPLYING ECAH AND GA FOR AREA COVERAGE WITH DIFFERENT RADIUS

Number of nodes	Best iteration for optimal coverage in GA		Best iteration for optimal coverage in ECAH	
	Iteration	Coverage rate	Iteration	Coverage rate
N=39	60	93.92%	60	99.92%
	120	95.6%	120	99.95%
N=40	80	94.40%	49	100%
N=37	120	95.6%	102	99.92%

TABLE X. FIFTH SCENARIO PARAMETERS

Simulation parameters				
Sensing radius		Number of sensors		Network size
7		100		100×100
Artificial bee colony parameters				
$\lambda 1 = 1$	$\lambda 2 = 0$	$\beta 1 = 1$	$\beta 2 = 0.5$	“limit”=100

Fig. 9. The network environment in ECAH.

Fig. 10. The network environment in GA.

In the fifth scenario, we used the parameters of [31], which are shown in Table X. Table XI gives the results from applying ECAH and ABC algorithms for area coverage with radius=7 (m). According to the obtained results, ABC has found the best coverage in the 703rd iteration, while the optimal coverage of the ECAH algorithm is achieved in the 652nd iteration. The network environment for ECAH and ABC algorithms with radius=13 m and N=40 are shown in Fig. 11 and 12, respectively.

In the sixth scenario, we used the parameters of [25]. These parameters are shown in Table XII. Table XIII gives the results of applying ECAH and hybrid DEPSO algorithms for area coverage with radius=40 m. The network environments

for ECAH and hybrid DE and PSO algorithms with radius=40 m and N=40 is shown in Fig. 13 and 14, respectively. Fig. 15 shows an overview of the coverage rate of the existing methods. As shown in Table XIV, the proposed method requires fewer iterations for convergence to optimal coverage than existing methods, which the proposed method has inferior runtime and higher run speed compared to existing methods.

TABLE XI. RESULTS FROM APPLYING ECAH AND ABC FOR AREA COVERAGE WITH RADIUS=7

Radius (m)	Iteration (ABC)	Iteration (ECAH)	Coverage rate (ABC)	Coverage rate (ECAH)
7	1000	1000	97.52%	98.59%

V. CONCLUSION

Coverage problem is one of the most critical research fields for WSNs. The network's lifetime is increased by creating optimized coverage in WSNs. In addition, the optimal coverage causes the optimal consumption of the network energy. This paper combined the HS and ABC algorithms to increase the area coverage and the lifetime of the WSNs. The efficiency of the hybrid method is demonstrated by comparing it with HS, ABC, ACO, GA, hybrid DE, and PSO algorithms. Our method outperforms previous methods according to the simulation results. We hope that we will be able to find better and more optimized methods using other meta-heuristic algorithms for WSNs coverage problems. This algorithm will be improved in the future and applied to WSN coverage optimization in more complex environments. Additionally, the algorithm will be extended to a wide range of IoT optimization problems.

Abstract—The Internet of Things (IoT) has emerged as a transformative technology that has revolutionized the field of healthcare. One of the most promising applications of Internet of Things (IoT) in healthcare is patient health monitoring, which allows healthcare providers to remotely monitor patients' health and provide prompt medical attention when needed. This research work focuses on developing an Internet of Things (IoT)-based patient health monitoring system aimed at providing a solution for patients, particularly the elderly, who face the risk of unexpected death due to the lack of medical attention. The proposed system utilizes a heartbeat sensor and an Infrared IR temperature sensor connected to Arduino UNO and Nodemcu, respectively, to monitor the patient's vital signs. The sensors collect the data, which is then sent to an Internet of Things (IoT) web platform via a Wi-Fi connection. The Internet of Things (IoT) platform displays the real-time data of the patient's health status, including the temperature and heartbeat rate, which can be monitored by doctors and nurses. The system is designed to send alerts to healthcare providers in the event of any medical emergency, ensuring that prompt medical attention can be provided to the patient. The significance of this research work lies in its potential to revolutionize the healthcare industry by providing a more efficient and effective means of patient health monitoring. The system can be used to monitor a large number of patients simultaneously, which is particularly beneficial in hospitals with a large patient load. Moreover, it can reduce the workload of healthcare providers, allowing them to focus on other critical tasks. This innovative system has the potential to improve the overall quality of healthcare services and lead to better health outcomes for the society.

Keywords—Patient health monitoring; Internet of Things (IoT); Arduino UNO; Nodemcu ESP8266; thingspeak; wearable device; temperature value; heartbeat value; remotely

I. INTRODUCTION

In today's digital age, the integration of the internet has transformed various industries, including healthcare. The emergence of Internet of Things (IoT) technology in health monitoring systems has revolutionized the way we approach healthcare [1]. With the widespread usage of the internet, coupled with the increasing efficiency of devices and gadgets, we can now monitor patients around the clock using Internet of Things (IoT)-based health monitoring systems. These devices constantly examine factual data and produce vital signs that

can be accessed remotely via web connectivity. This not only enables real-time patient monitoring but also facilitates prompt crisis response services. As such, Internet of Things (IoT)-based gadgets provide both recognition and emergency response services, which are critical components in ensuring optimal patient care.

The traditional approach to patient monitoring in hospitals and healthcare facilities can be tedious and often results in unequal treatment of patients. Medical staff is required to manually check multiple vital signs of patients, which can be time-consuming and prone to errors. Furthermore, patients' families or relatives need to visit them for updates on their condition, which can be inconvenient and burdensome [2]. Additionally, many hospitals still rely on outdated paper-based recording systems, which are prone to errors and can result in missing or illegible data [3]. These issues can lead to a waste of time and resources, as well as compromise patient care. However, the implementation of an Internet of Things (IoT)-based patient health monitoring system can revolutionize healthcare by providing real-time remote monitoring of patients, digital storage of patient information, and immediate check-ups for individuals to maintain optimal health [4]. The proposed work presented in this study marks a new pathway towards solving numerous problems that have been plaguing the healthcare industry and society at large. The current system of healthcare services has been marred with inefficiencies and management issues, which necessitates the need for a more effective and sophisticated approach to healthcare services. The IoT system is the perfect match for this modern era, with its real-time monitoring, sophisticated data collection and storage, and alert systems that have proven to be highly effective. This proposed work represents a step ahead of the current healthcare system, with its ability to solve numerous issues and monitor patients accurately and in real-time. Despite the impressive results of previous studies and proposed projects, the medical industry has been slow to adopt Internet of Things (IoT)-based systems. This study seeks to create an updated, reliable, and innovative healthcare system that will meet the growing expectations of society in terms of saving lives and advancing medical technology development [5][6].

To achieve the lofty goal of this endeavor, it is imperative to concoct a novel and innovative approach to the management

of hospital and clinic system operations, with a thorough and effective methodology in place. The objectives of this work are to assist health staff in monitoring and recording patient data frequently at specific times, which is especially important for hospitals with a large number of patients where unexpected fluctuations can occur. Additionally, with the numerous data collections that occur for each monitored patient, all recorded data will be saved in one place - a cloud-based system - which is more efficient than the current method used. Lastly, an alert system functions as an emergency detection tool that can send notifications via email to the administrator or health staff, allowing immediate action to be taken based on the condition of the patient during panic situations.

This study has made several contributions to the field of healthcare by developing an Internet of Things (IoT)-based patient health monitoring system that can remotely monitor patients' vital signs and provide prompt medical attention in case of any medical emergency. The system uses heartbeat and temperature sensors connected to Arduino UNO and Nodemcu, respectively, and sends data to an Internet of Things (IoT) web platform that displays real-time data of the patient's health status. This innovative system has the potential to revolutionize the healthcare industry by providing a more efficient and effective means of patient health monitoring, which will ultimately lead to a better quality of life and improved health outcomes for the society.

The remainder of this paper has been organized as follows: Section II discusses the related works. The background of the study is described in Section III. Section IV describes the system implementation methods. Section V describes the results, Section VI describes the discussion and finally, the conclusion is described in Section VII.

II. RELATED WORK

To achieve the intended target, it is crucial to delve into the fundamentals and knowledge garnered from prior studies. Previous works have delved into health monitoring systems that utilize wireless technology. As the health monitoring system is an integral part of the Internet of Things (IoT) system, it is imperative to scrutinize past works that employ comparable strategies and aspire to similar objectives as this research endeavor.

A. Classic Health Monitoring

The classic method of patient health monitoring has been a stalwart in healthcare institutions such as hospitals and clinics since its inception in the early 2000s. Despite its extensive use over the years, this approach falls short in terms of its ability to accurately monitor a large number of patients within a set time frame. Health staff, comprising doctors and nurses, is tasked with physically examining and recording patient data. Patients are required to queue or wait their turn for checkups, while those confined to their beds require round-the-clock monitoring. Patient data is painstakingly recorded by hand in a patient booklet and stored in physical form on shelves [7].

B. Wearable Smart Health Monitoring

Pradhan, S., Zainuddin, A. A., and Sahak's research project [8] offers an intriguing insight into the myriad methods

employed to monitor health status. The authors devised a plethora of sensors to keep a watchful eye on the real-time health of animals. Their study utilized an array of sensors, including those that measured temperature, respiration rate, heart rate, and humidity rate [9][10]. To control this project, they employed the Raspberry Pi, complete with its built-in Wi-Fi module. Additionally, they created a cloud-based platform to store and transmit sensor data, while an Android mobile application system was used to gather real-time data on the animal's health state. This project effectively underscores the feasibility of wearable devices, which may be a fitting solution for our research endeavor.

C. Real Time Health Monitoring Devices

A trustworthy patient monitoring system that allows medical professionals to keep track of patients in the hospital or during their daily activities has been developed by A. Abdullah, A. Ismael, A. Rashid, A. Abou-Elnour, and M. Tarique [11][12]. The system employs mobile devices for wireless patient monitoring and enables real-time transmission of data on the patient's physical condition. The project aims to collect and analyze vital physiological data from patients to accurately determine their health and fitness levels. Additionally, the system can send text messages or email reports with important health information to patients. Healthcare professionals can provide valuable medical advice by utilizing the information in these messages. The authors utilized multiple sensors, an Arduino microcontroller, and LabVIEW software to develop the system [13][14].

D. Focused Health Monitoring

Masud, Muhammad and Alhumyani proposed a health monitoring system that focuses on three vital signs of patients: temperature, blood pressure, and heartbeat [15]. The system uses a microcontroller and several sensors to collect and visualize the data on a Liquid Crystal Display (LCD) and store it in cloud-based storage. This system is designed to assist healthcare professionals in monitoring multiple patients simultaneously. The authors employed microcontrollers such as Arduino and Nodemcu, as well as Ubidots software, to implement the project [16][17]. The system has been tested and has demonstrated good accuracy in monitoring patients' vital signs introducing a novel tree-based deep model for automatic face recognition in a cloud-based environment that strikes a balance between computational efficiency and high accuracy. The model divides the input volume into multiple volumes and creates a tree structure for each volume, where each branch of the tree is represented by a residual function comprising of a convolutional layer, batch normalization, and a non-linear function. Rigorously evaluated on publicly available databases, the proposed model achieves remarkable accuracies, surpassing the current state-of-the-art deep models for face recognition.

E. Smart Patient Monitoring using Databases and Physically Sensors

Chee Yuan, L. and Kong have proposed a health monitoring system that uses physical sensors [18]. The system involves attaching sensors to the patient's body to monitor their health data, which is then stored in a database built using Personal Home Page (PHP). While this method is effective for storing patient data remotely, it requires the use of contact

sensors that must physically touch the patient's body. Despite this limitation, the system is functional and can be implemented in health departments [19].

F. Internet of Things IoT Health Monitoring

V. Akhila, Y. Vasavi, K. Nissie, and P. V. Rao have utilized IoT and sensor technologies to develop a system that can monitor a patient's health condition in real-time [20]. The authors tested the system by monitoring the health condition of a real individual. The project involved the use of Internet of Things (IoT) and microcontroller like Arduino to gather data from analogue sensors. In the healthcare industry, the combination of IoT with Arduino microcontroller has proven to be effective in monitoring and collecting current patient health condition data [21]. This work describes the use of Arduino UNO as a sensor node and gateway in a remote health monitoring system. The system utilizes GSM for communication between doctors and patients, and Wi-Fi for transmitting sensor data to a web-based IoT platform. The ATMEGA 328p microprocessor, installed within the sensor nodes, measures temperature, pulse rate, and blood pressure readings using the temperature sensor and HP/BP sensor. The data is displayed on an LCD attached to the Arduino and transmitted to the cloud server via the Wi-Fi module. This technology allows for continuous monitoring of the health of severely ill patients and seniors suffering from heart and blood pressure disorders.

G. Contactless Internet of Things IoT Patient Health Monitoring

The framework suggested by Dipti S. Gandhamwar and Sunil Kuntawaris [22] is used to remotely monitor patients' wellbeing. Sensors such as the heartbeat sensor, temperature sensor, and SpO₂ sensor are used to estimate important parameters. The suggested model enables medical professionals to check on patient wellbeing from any location and helps people consult experts anywhere in the world. The system combines the Internet of Things (IoT) and remote sensor technology for effective health monitoring, and sensor data must be available consistently. The data is archived and viewable on the web server [23]. The system is set up to send a message to the specialist if the sensor data exceeds the threshold values. The main benefit is a reduction in the amount of time specialists and patients need to intervene in times of crisis. By recommending a minimally expensive framework for saving lives, with the hope that individuals will be amenable, the goal is achieved. The limitation of the specialist's accessibility is considered, and the proposed model does not include the pulse-checking framework [24].

III. BACKGROUND OF THE STUDY

Smart technology is a combination of sensor-based, data-driven, and programmable technologies that also incorporate artificial intelligence. The integration of traditional medical scaling with advanced technology has resulted in patient health monitoring, which offers numerous benefits, such as monitoring vital signs like heartbeat rate, temperature rate, and respiration rate, which can help facilitate faster medical intervention. Currently, the Internet of Things (IoT) is considered the leading solution for developing innovative health monitoring systems [27]. Patient health monitoring

systems provide a more accessible and cost-effective alternative to the traditional clinical conduct, allowing for improved access to healthcare facilities.

The goal of this proposed research is to develop a patient health monitoring system based on the Internet of Things (IoT). By minimizing doctor visits, hospital stays, and daily diagnostic tests, this system aims to reduce healthcare costs [28]. The sensors are connected to an Arduino Uno microprocessor that tracks and transmits the data collected to ThingSpeak, which can generate alerts. Health staff can monitor patients' health using IoT technology and identify any unusual readings in terms of temperature and heartbeat. ThingSpeak can display patient data in real-time. This system can save a lot of time in measuring and monitoring a patient's health at a specific time, making IoT technology reliable and efficient. The use of IoT-based patient monitoring systems has enormous potential for healthcare professionals to observe tiny aspects of a patient's well-being [29]. Therefore, the system must check and analyze the data in detail, with ThingSpeak serving as an IoT platform.

Medical facilities in remote areas are often inaccessible to local communities [20]. As a result, many people ignore minor health issues that could indicate larger problems, such as changes in body temperature or heart rate. When these issues progress to the point of being life-threatening, medical attention is sought, resulting in unnecessary expenses. This is especially important to consider in the event of an epidemic spreading to an area without easy access to doctors. Providing patients with smart sensors that can be remotely monitored could save many lives and help prevent the spread of illness [30].

The main goal of this proposed work is to develop a practical and effective system for Internet of Things (IoT)-based patient health monitoring, and to study its wellness, operation methods, theoretical framework, and impacts [31]. The recommended system is depicted in Fig. 1, and it uses two sensors to detect the patient's body temperature and heartbeat. The sensors are connected to a microcontroller unit that processes the input data from both sensors. The collected data is then sent to or stored in an IoT database. This database allows doctors or health staff to retrieve the data and monitor the patient's current health condition from anywhere via the base station.

Fig. 1. Smart health monitoring system process flow.

The flowchart of the object recognition process is shown in Fig. 2.

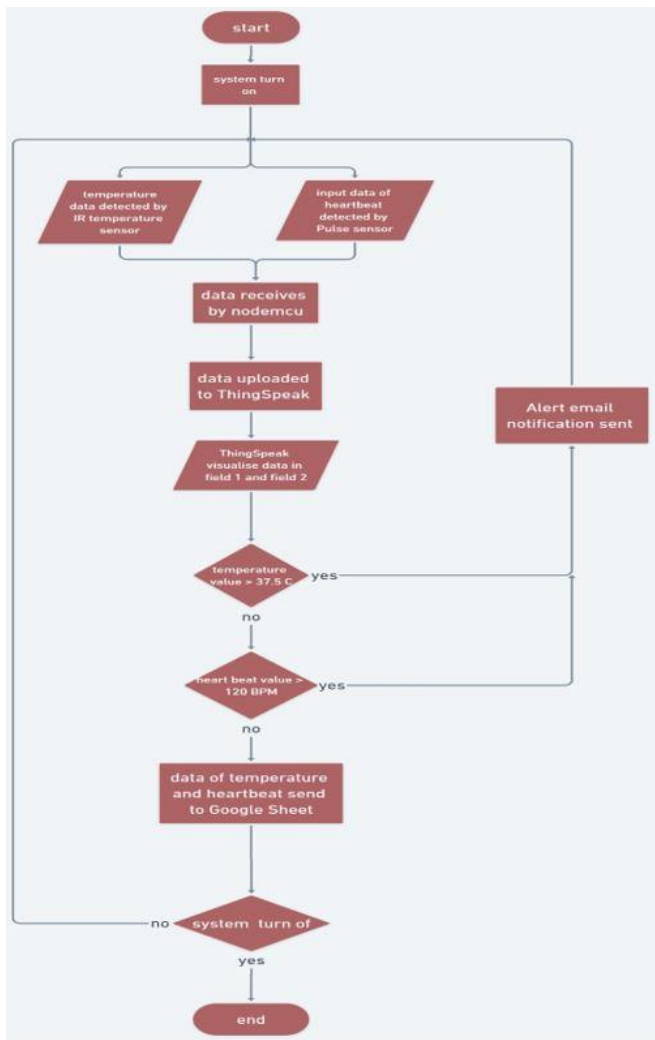

Fig. 2. Flowchart of the system.

IV. SYSTEM IMPLEMENTATION METHODS

Fig. 2 illustrates the steps involved in developing this system. Firstly, the hardware components necessary for the project were carefully selected. The Arduino Integrated Development Environment (IDE) was chosen as the software platform for coding due to its user-friendly interface and ability to process input signals and generate corresponding output signals. The project involves placing sensors on the patient's body to record vital signs. The MLX90614 sensor will be used to measure the patient's body temperature, while the Heartbeat module or pulse sensor will monitor the patient's pulse rate. The microcontroller will process the data obtained from both sensors, checking the condition of the patient against pre-set parameters. All data collected will be converted to a list and notification of any abnormal readings will be sent to the administrator. This feature is particularly useful in cases where the patient's health is at risk, and prompt action is required.

A. Hardware Development

This section provides an explanation of the hardware components used in the system. The Arduino UNO is used as the microcontroller and receives and sends data from the pulse sensor to Nodemcu through UART serial communication. The pulse sensor is not compatible with Nodemcu and needs to be connected to Arduino UNO instead. The Arduino UNO is powered by a 9V battery which is also used to power up the pulse sensor. The connections between the pulse sensor and Arduino UNO are established by connecting the VCC pin to 3.3V of Arduino, GND pin to GND of Arduino, and analog pin to A0 of Arduino. The paragraph also mentions that the hardware components are functioning properly as they indicate light when turned on.

Nodemcu is a microcontroller with a built-in Wi-Fi module that is well-suited for this Internet of Things (IoT) system as it can transmit data via the internet to the desired IoT platform. ThingSpeak platform is used in this system. Nodemcu is powered by a 9V battery. Serial communication with Arduino is established via the Receive RX and Transmit TX pins on each microcontroller, allowing pulse sensor data from Arduino to be read. Infrared (IR) temperature sensor is connected to Nodemcu to read temperature data. The IR temperature sensor requires a voltage of 3.3V, which is provided by connecting VCC to 3.3V of Nodemcu and GND to Ground GND of Nodemcu. The Serial Clock (SCL) and Serial Data (SDA) pins are connected to D1 and D2 of Nodemcu, respectively.

B. Software Development

This section describes the coding and data transmission process for the IoT-based patient health monitoring system. The coding is necessary for the pulse sensor to read the heart beat data, which is then transmitted to the Nodemcu microcontroller via serial communication. The pulse sensor library is included in the coding, and the data is read using the library's provided read data value. The data is then sent from Arduino UNO to Nodemcu, where it is received and combined with the temperature data from the Infrared IR temperature sensor. The combined data is then transmitted to the ThingSpeak platform for monitoring. The system settings provide the ThingSpeak host and Application Programming Interface API key necessary for obtaining the data. Fig. 3 shows how to access this information. ThingSpeak is a useful technology for IoT applications as it allows for remote monitoring and management of data processing. It collects, analyzes, and visualizes sensor data, and can also initiate responses.

ThingSpeak in this work is platform to visualize data receives from Nodemcu which are temperature value and heartbeat value for monitoring purpose in real time using internet. IFTTT is also used in this work by connecting it to ThingSpeak as it acts for alert message via email when there is misreading over the value or threshold that have been set when reading data from Nodemcu such as for temperature value when exceeding 37.5 and for heart beat when exceeding 120 BPM.

Fig. 3. Coding for setup IoT data transmission.

V. RESULTS

Upon completing the hardware and software development for this work, it is imperative to conduct testing to determine if the desired goals have been achieved. To this end, an Infrared IR temperature sensor is connected through ESP8266, while the pulse sensor is connected through Arduino UNO, as depicted in Fig. 4. Both microcontrollers are powered by a 9V battery to initiate the circuit and system. Serial communication, specifically universal asynchronous receiver/transmitter (UART) communication, facilitates interaction between the two microcontrollers. In this transmission of serial data, various serial protocols are employed and adhered to.

Fig. 4. Complete hardware circuit communication.

To collect data from the patient, the sensors are positioned in a way that aligns with the patient's position on the bed. The pulse sensor is placed on the fingertip while the Infrared IR temperature sensor is placed on the patient's forehead. The sensors are placed in these locations due to their compatibility with the patient's environment and the specifications required for data collection. In Fig. 5, the collected data is uploaded from the Nodemcu to ThingSpeak, with the temperature value on field 1 and the patient's heartbeat value on field 2. The uploaded data is then sent to a pre-set email on IFTTT and uploaded to a Google spreadsheet.

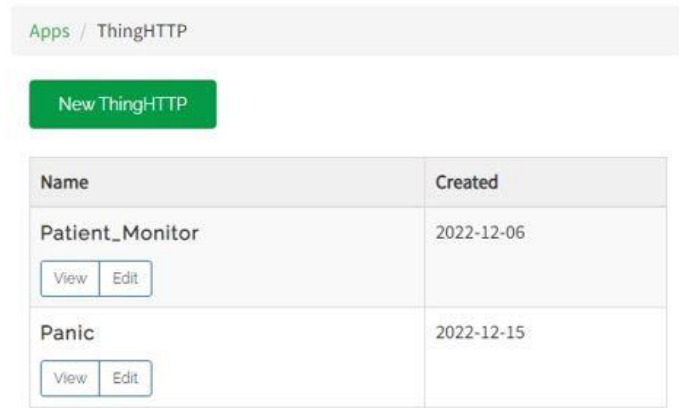

Fig. 5. ThingSpeak channel created.

To set up the IFTTT account, login is required followed by creating a new applet with two actions for triggering. The first action, "Patient_info," involves sending patient data, such as heartbeat and temperature, to a spreadsheet row via email. The second action, "Panic," alerts via email if needed (see Fig. 7). The actions should then be reviewed to ensure proper functioning. To connect the data from ThingSpeak to email, ThingHTTP and React must be configured, and the actions created in IFTTT must be triggered. Finally, save all the data and test the system.

	A	B	C	D
5	January 14, 202	Patient_info	35.6 (C)	88 (BPM)
6	January 14, 202	Patient_info	34.6 (C)	92 (BPM)
7	January 14, 202	Patient_info	35.7 (C)	86 (BPM)
8	January 14, 202	Patient_info	35.1 (C)	76 (BPM)
9	January 14, 202	Patient_info	36.4 (C)	79 (BPM)
10	January 14, 202	Patient_info	35.4 (C)	72 (BPM)
11	January 14, 202	Patient_info	34.9 (C)	72 (BPM)
12	January 14, 202	Patient_info	35.8 (C)	75 (BPM)
13	January 14, 202	Patient_info	36.4 (C)	83 (BPM)
14	January 14, 202	Patient_info	36.9 (C)	98 (BPM)
15	January 14, 202	Patient_info	37.4 (C)	100 (BPM)
16	January 14, 202	Patient_info	35.6 (C)	88 (BPM)
17				

Fig. 6. Google spreadsheet showing data collected.

When the data uploaded to ThingSpeak meeting the condition set in ThingHTTP the alert message will be send through email saying it is panic condition for the patient as well as sending the data values of temperatures and also heartbeat as can see in Fig. 6. The condition set for temperature is when value of data is exceeding 37.5 Celsius while for heartbeat is when value of data is exceeding 120 Beat Per Minute BPM.

Fig. 7. Alert notification send via email.

Based on the detailed results and implementation of this work, it can be concluded that it holds promising potential for future development in the medical sector. Comparing it to other related works listed in Table I, this system shows good accuracy in collecting data through sensors and efficiency when implemented in the medical sector. However, there are a few areas for improvement to ensure the sustainability of this work. For instance, incorporating additional sensors can enable tracking of more health conditions, while high-quality sensors can stabilize the readings of data for longer periods. Additionally, using MySQL and Personal Home Page PHP as the database can cover a lot of patient data.

TABLE I. COMPARISON BETWEEN CURRENT AND RESEARCHED SYSTEM

YEAR	METHOD	NUMBER OF PATIENT TEST FOR MONITORING PER HOUR	NUMBER OF PATIENT CAN COVERED/ MONITORED PER HOUR	PERCENTAGE OF COVERED PATIENT	DATA RECORDED ACCURACY COMPARED TO ACTUAL DATA	REFERENCE
2009	CURRENT SYSTEM THAT USED WRITING METHOD FOR COLLECTING PATIENT DATA WHEN CHECK UP	50	14	28%	85%	[7]
2015	HEALTH MONITORING USING MOBILE DEVICE	50	36	72%	90%	[11]
2020	MONITORED THREE BASIC HEALTH CONDITION WITH DIFFERENT MODES	50	33	66%	89%	[15]

VI. DISCUSSION

The Patient Health Monitoring System, developed with the objective of utilizing ESP8266 and Arduino with an Internet of Things (IoT) platform, has been successfully implemented and tested through various iterations. As indicated in the results section, the hardware circuit connection in Fig. 4 provided the best and most functional means of collecting patient data, including temperature and heartbeat. The collected data is shown in real-time on ThingSpeak, making it easier for medical staff to monitor patients, while also being stored in Google Sheets for future reference. Despite its success, the system still has some limitations, particularly in terms of the reliability of the sensor data due to varying price and quality. This system has significant potential for further development and implementation in the medical sector, including clinics, hospitals, and pharmacies. It is imperative to continue improving the system by adding more features, reliable hardware, and ensuring that it is user-friendly and affordable for commercial use.

VII. CONCLUSIONS

In conclusion, the implementation of the Internet of Things (IoT)- Patient Health System brings a positive impact to the healthcare industry by providing an efficient and effective means of patient health monitoring. The Internet of Things (IoT)- Patient Health System and the proposed system presented in the research both aim to remotely monitor the vital signs of patients and provide prompt medical attention when needed. The system has successfully met all the objectives and has been able to monitor patients and alert healthcare professionals in real-time. The system integrates microcontrollers, sensors, and the ThingSpeak Internet of Things (IoT)- platform with email notifications to create a systematic and efficient healthcare system. This system provides a solution to the problem of handling a large number of patients during sudden outbreaks of diseases such as Covid-19, potentially improving patient outcomes and saving lives. Similarly, the proposed Internet of Things (IoT)-based patient health monitoring system presented in the research has the potential to improve the overall quality of healthcare services and lead to better health outcomes for society. The system's ability to remotely monitor the vital signs of patients, display real-time data on an Internet of Things (IoT)- platform, and send alerts in the event of a medical emergency can reduce the workload of healthcare providers, allowing them to focus on other critical tasks. The current system can be further improved by incorporating additional sensors like oximeters and blood pressure devices to provide a comprehensive analysis of the patient's health condition. Upgrading the sensors with newer models that offer advanced features can enhance the accuracy of the collected data. In the future, implementing this system in hospitals and clinics can help address patient data management and monitoring issues. The integration of Internet of Things (IoT)- technology in healthcare paves the way for healthcare professionals to concentrate on urgent issues and emergencies, expanding their roles in the healthcare industry. The utilization of Internet of Things (IoT)- capabilities can make healthcare more efficient and effective in providing high-quality patient care.

ACKNOWLEDGMENT

The authors would like to thank Centre for Research and Innovation Management (CRIM) for the support given to this research by Universiti Teknikal Malaysia Melaka (UTeM).

Integrated Methodology for Information Security Risk Management using ISO 27005:2018 and NIST SP 800-30 for Insurance Sector

Arief Prabawa Putra¹, Benfano Soewito²

Computer Science Department-BINUS Graduate Program-Master of Computer Science, Bina Nusantara University, Jakarta, Indonesia 11480^{1,2}

Abstract—The development of Information and Communication Technology (ICT) in the Industrial Revolution 4.0 era shows very fast and disruptive developments that encourage increased use of Information Technology (IT) services within organizations. However, there is a risk of creating vulnerabilities and threats to owned information systems. Plans and strategies are required to implement information security risk management to address vulnerabilities in threat events. This research is a case study of the Enterprise Resource Planning System in the Insurance Sector. The proposed methodologies for integrating information security risk management using ISO/IEC 27005:2018 as a risk management framework and NIST SP 800-30 Rev. 1 as guidance for risk assessments. The risk evaluation stage is the process of comparing the results of the risk analysis with the risk criteria to then determine whether the risk rating is acceptable or tolerable. For risk treatment and control using the ISO/IEC 27002:2022 framework.

Keywords—Risk management; information security; ISO/IEC 27005; NIST SP 800-30; ISO/IEC 27002

I. INTRODUCTION

The adoption of information and communication technology (ICT) during the fourth industrial revolution 4.0 shows very rapid and disruptive advances that support the growth of information technology services [1]. The use of ICT affects the development of a country through the development of the dissemination of knowledge, especially from developed and developing countries, and through innovations [2]. Almost all enterprises use ICT to obtain information or process data more quickly, precisely, and accurately [3].

However, along with the use of the internet, there are many sources of threats that come from inside and outside the organization. In different parts of the world, the number of cyberattacks is growing at an alarming rate and causing financial losses [4]. This can threaten the continuity of business activities in the organization, including the insurance sector.

ZZZ Insurance is part of the government of the Indonesian insurance sector, which uses an Enterprise Resource Planning (ERP) system to run its business. ERP is an integrated system used by organizations to manage day-to-day business activities, such as financial and accounting, cash management, procurement, and asset management. Their system integrates not only internal parties but also external parties, such as health social security agencies, hospitals, population and civil

registration agencies, and aggregators. One aspect of ICT that needs to concern every organization is information security. Information security can be formed by implementing controls, which include policies, processes, procedures, organizational structures, and functions of software and hardware [5]. These controls need to be implemented, monitored, reviewed, and required to ensure security and achieve the goals of the business organization.

Therefore, steps are needed in detecting vulnerabilities to threats inside and outside the organization. Therefore, procedures must be made to discover vulnerabilities to both internal and external threats. In addition, the importance of implementing organizational risk management in the software lifecycle is to produce proper supervision and responsibility and increase effectiveness and efficiency [6]. Planning and strategy are needed to overcome these vulnerabilities if a risk or threat occurs.

The need for planning and strategies to overcome these vulnerabilities in the event of a risk or threat if it disrupts Business Continuity (BC) [7]. Implementing Business Continuity Planning (BCP) is critical in an organization to anticipate if a disaster occurs and ensure that the business can continue to operate, or at the very least, that the organization can continue to provide its services after the disaster [8].

Therefore, it is necessary to implement information security risk management in enterprise systems organizations. Many standards are used in the implementation of risk management, including ISO 27005, which is widely applied in profit and non-profit organizations in other countries. Based on recommendations from another study, ISO 27005 is one of the international standards that is easy to implement in providing guidelines for information security risk management [9], [10]. Other studies also use the NIST 800-30 standard, where integrating qualitative and quantitative methodologies to give accurate and reliable risk data for decision making is the optimal method for risk assessment [11].

The purpose of this research was to conduct an information security risk assessment using ISO/IEC 27005:2018 as a risk management framework and NIST SP 800-30 revision 1 as a reference matrix of qualitative and quantitative risk levels. In accordance with the ISO/IEC 27002:2022 framework, the recommended controls include risk treatment and risk acceptance. This guideline is used to determine and implement information security risk

management controls inside an information security management system (ISMS) based on ISO/IEC 27001 [12].

II. LITERATURE REVIEW

A. Risk Management

Risk management is the process of identifying risks, assessing their relative magnitudes, and taking steps to reduce them to an acceptable level [13]. Information security risk management is a practical step in managing the risk of an organization's information security and aims to provide protection for organizational information and assets [14]. Risk management has three main processes: risk identification, risk assessment, and risk control.

The implementation of risk management in non-profit organizations provides several benefits, including planning basic information technology resources, providing decision-making support systems for leaders, and improving operational performance in terms of the maturity level of the risk management process. The combination of risk management processes based on ISO 31000:2018 and ISO 9001:2015 aims to provide guidelines for risk management principles and their application processes at the organizational, strategic, and operational levels [15]. Implementation of Enterprise Resources Planning (ERP) in the organization will increase the added value of the organization and support decision-making management [16].

Several other studies regarding the application of risk management standards in government agencies include the design of information security management for data communication applications at the XYZ Institute using ISO 27005 and NIST SP-800-30 [17]. Information security risk assessment with a combination of ISO 27005 information security standards and National Institute of Standards and Technology (NIST) SP 800-30 revision 1 adapted to organizational conditions [18]. The importance of conducting a cybersecurity risk assessment of the heart of electronic devices to determine the severity of the threat, prioritize the most significant risks and ensure effective risk management using a combination of ISO/IEC 27005 and NIST SP 800-30 [19]. The implementation of information security risk management (ISRM) in government agencies at the Bali Regional Police regarding System-Based Electronic Governance (EBGS) is an attempt to protect the risk of valuable assets [20]. In the industrial era 4.0, cloud computing has become widely used in the government sector, so security is now part of risk management [21]. The proposed cloud computing security model includes data security, risk assessment, regulation, compliance, and requirements.

An organization knows the importance of implementing risk management and making it the main step in minimizing the risks that will occur. The successful implementation of risk management in government agencies is influenced by several factors, namely risk management, policy development, and policy compliance [22].

B. ISO/IEC 27005

ISO/IEC 27005 is part of the ISO 27000 series. ISO 27005:2018 is a standard used to provide guidance for information security risk management [14]. ISO 27005 supports the general concepts described in ISO 27001 and is designed to assist in the proper implementation of information security based on a risk management approach. ISO 27005 has stages, namely context establishment, risk assessment (risk identification, risk analysis, risk evaluation), risk treatment, risk acceptance, risk communication and consultation, and monitoring and review.

C. NIST SP 800-30

NIST (National Institute of Standards and Technology) Special Publication (SP) 800-30 is a guide that aims to provide risk assessment of organizational and government information systems and is a complement to NIST SP 800-39 guidelines. The latest version of NIST SP 800-30 is revision 1. The risk assessment approach for NIST SP 800-39 revision 1 is supported by security standards and other guidelines to manage information security risks. The risk assessment approach to NIST SP 800-39 revision 1 is supported by security standards and other guidelines to manage information security risks [23]. NIST SP 800-30 can be used to complement the ISO 27005 standard in conducting risk assessments.

NIST 800-30 provides a basis for the development of an effective risk management program, as well as a definition and practical guidance for assessing and mitigating a risk that exists in an IT system. This framework has nine steps of risk management activities, starting with system characterization, threat identification, vulnerability identification, control analysis, likelihood determination, impact analysis, risk determination, control recommendations, and the results document of the risk assessment report.

III. RESEARCH DESIGN

This research uses a case study of ZZZ Insurance ERP system. As seen in Fig. 1, the proposed method uses the ISO/IEC 27005:2018 framework as the main risk management framework is integrated with the NIST SP 800-30 revision 1 risk assessment guideline. Recommendations for control using are the ISO/IEC 27002 framework.

Fig. 1. Integrated methodology.

Beginning with research preparation includes identifying problems, collecting data, and context organization. In identifying problems, it is necessary to explain the problems faced by the organization, which are presented in the form of background and problem formulation, as well as solutions to the problems faced, which are presented in the form of goals and benefits.

The next stage is the collection of data obtained from document reviews, interviews, Forum Group Discussions (FGD), and observations. Document review is conducted to understand the organization in detail. During the interviews and FGD stages, it was conducted to find out the conditions and needs for information security in the organization.

Next, define the context of the organization to consider the impact that both internal and external factors have on the company's operational activities and its ability to achieve targets. The risk management process must be aligned with the corporate culture, processes, structure, and strategy. To prepare a risk assessment, it is necessary to first set the organizational context.

Risk assessment is a structured approach to identifying and analyzing uncertainties that exist in the achievement of organizational goals. Based on interviews with risk owners and IT risk officers in the organization, risk assessment aims to:

- Recognize the risks that may occur in the organization.
- Understand the risk so that the significance of the risk can be assessed, and the level of risk can be evaluated based on the organization's risk criteria.

- Identify possible risks that can be accepted or modified.
- Considering the relative impact of various risk-reduction treatment options.

At the risk treatment stage, risk scenarios that trigger risk appetite are mitigated and prioritized to receive risk treatment in the form of information security control recommendations and information security target setting based on ISO/IEC 27002:2022. The results of a series of risk management design stages are communicated to top management to confirm their suitability.

IV. RESEARCH AND DISCUSSION

A. Context Establishment

Risk criteria are used to rank risk levels as unacceptable or acceptable. Risk criteria can include several limits with a target risk scale that are adjusted to the needs of the organization. Based on the results of the interview with management, this research refers to the NIST SP 800-30 revision 1 framework standard based on the level of risk shown in Table I.

TABLE I. RISK SCALE

Scala	Description	Semi Quantitative Value	
Very High	Have a negative impact	$4,0 < x \leq 5,0$	5
High	Almost certainly have a negative impact	$3,0 < x \leq 4,0$	4
Moderate	A medium probability results in a negative impact.	$2,0 < x \leq 3,0$	3
Low	A Small probability gives a negative impact	$1,0 < x \leq 2,0$	2
Very Low	A low probability has a negative impact.	$x \leq 1,0$	1

In determining the context, impact criteria using the level option are based on the level description in NIST SP 800-30, shown in Table II. Likelihood criteria using impact considerations that allow the threat to occur, as well as the possibility of starting or occurring, are listed in Table III.

TABLE II. IMPACT OF THREAT EVENT

Scala	Description	Value
Very High	Several severe or catastrophic negative effects on organizational operations, assets, individuals, or the nation	5
High	Severe or catastrophic adverse effect on organization operation, assets, individuals, or the nation.	4
Moderate	Serious adverse effect on an organization's operations, assets, individuals, or the nation.	3
Low	Limited effect on organization operation, assets, individuals, or the nation.	2
Very Low	Negligible adverse effect on organization operations, assets, individuals, or the nation.	1

TABLE III. LIKELIHOOD OF THREAT EVENT RESULTING IN ADVERSE IMPACTS

Scala	Description	Value
Very High	If the threat event is initiated or occurs, it is almost certain to have adverse impacts.	5
High	If the threat event is initiated or occurs, it is highly likely to have adverse impacts.	4
Moderate	If the threat event is initiated or occurs, it is somewhat likely to have adverse impacts.	3
Low	If the threat event is initiated or occurs, it is unlikely to have adverse impacts.	2
Very Low	If the threat event is initiated or occurs, it is highly unlikely to have adverse impacts.	1

B. Risk Assessment

At this stage, an assessment of the identified risks has been carried out, and an evaluation has been carried out for each risk scenario [24].

1) *Risk identification*: Risk identification is the process of finding, recognizing, or describing risk attributes. Risk identification includes identification of risk sources, events, and causes in the organization.

a) *Asset identification*: The process of asset identification begins with a weighted factor analysis of all ERP assets. Each information asset is scored for each critical factor and assigned a weight for each criterion. The weighting value is obtained from risk owner and IT risk officer in the organization.

To calculate weighted factor analysis, where each asset is scored for a critical factor and given a weight for each criterion. Criteria of weighted factor analysis consist of criterion 1 (impact to revenue – 30%), criterion 2 (impact to profitability – 40%), and criterion 3 (impact to public image – 30%). For scoring a critical factor, scores range from 0.1 to 1.0, and criteria are weighted from 1 to 100; each is weighted to indicate the importance of the criteria set for the organization [13]. The range of values obtained with reference to NIST SP 800-30 revision 1. Table IV shows that example of a weighted factor analysis worksheet.

TABLE IV. WEIGHTED FACTOR ANALYSIS WORKSHEET

Information Asset	Criterion 1 (30)	Criterion 2 (40)	Criterion 3 (30)	Weighted Score
IT Procedures and Policies	0,8	0,9	0,6	69
Network Topology	0,4	0,4	0,4	40
Server	0,8	0,9	0,7	81
ERP System	0,8	0,9	0,7	81
...				
IT Operation	0,8	0,8	0,7	77

In this discussion, we first identify two types of assets based on organization conditions, namely main assets consisting of business processes and activities, and information, and supporting assets consisting of all assets:

hardware, software, network, site, personnel, and organizational structure [14].

Based on asset identification, the total number of identified primary assets is 9 assets, consisting of 3 business process and activities assets and 6 information assets. For identified supporting assets, 53 assets consist of 14 hardware assets, 18 software assets, 2 network assets, 11 site assets, and 8 personnel assets. Table IV is an example of asset identification with the following asset codes: A1-IT Procedures and Policies, A2-Network Topology, Source Code A3, Server-A4, A5-ERP System, until A62-IT Operation, as shown in Table V.

TABLE V. ASSET IDENTIFICATION

Asset Code	Asset Type	Asset Category	Risk Owner	Location
A1	Primary Asset	Business Processes and Activities	Head of ICT Division	Head Office
A2	Primary Asset	Information	Infrastructure Department	Head Office
A3	Primary Asset	Information	System Department	Head Office
A4	Supporting Asset	Hardware	Infrastructure Department	Head Office
A5	Supporting Asset	Software	System Department	Data Center
...				
A62	Supporting Asset	Personnel	Head of ICT Division	Head Office

b) *Threat Identification*: This research divides threat sources into two categories: adversarial and non-adversarial threat sources. Threat sources identified in this research were obtained from 12 adversarial sources and 18 non-adversarial sources.

In this discussion, the adversarial threat sources are as follows: S1: distributed denial of service, S2: injection, S3: intrusion, S4: malware, S5: social engineering, S6: sniffing, spoofing, or phishing, S7: website attack, S8: employee, S9: external stakeholder, S10: lack of employees, S11: unauthorized access, and S12: failure to maintain physical facilities.

Non-adversarial threat sources are as follows: S13: error requirement and design system, S14: human error (least privilege), S15: human error (personnel IT), S16-limited budget allocation for training, S17: obsolete technology, S18: lack of monitoring and control, S19: lack of expertise, skills, and employee behavior, S20: lack of employee information security awareness, S21: insecure password, S22: the application crashes, S23: error connection database, S24: operation system crashes, S25: web server crashes, S26: failure to backup data, S27: broken communication data, S28: failure data, S29: limited storage media, S30: devices end of support, S31: short-circuit, S32: power supply failure, S33: unstable power supply, S34: interruption of service from the provider, S35: rodent, S36: overhead, S37: maintenance fiber optics; S38: fire, S39: earthquake, and S40: thunderbolt.

Then, identify all threats that interfere with information security aspects such as Confidentiality (C), Integrity (I) and

Availability (A) on assets that have been identified. The following are questions to ask when identifying threats:

- What are the threats to the asset that you know or suspect?
- What are the most dangerous threats to the organization?
- What are the most expensive threats to recover from in the event of an attack?
- What are the threats that require the greatest expenditure to prevent them?

After getting the source of the threat in the ERP System, then identify this threat. For each asset, 35 threats have been identified, with different sources of threat. Table V explained that in the ERP system, T1: errors in making policies, procedures, or other relevant documents; T2: dissemination of information by unauthorized parties; T3: cybercrime; T4: broken access control; T5: failure of hardware, a network device, or physical facility assets; and until T35: unauthorized access.

Threat events are obtained from threat sources that have been defined through event logs and interviews with IT risk officers. Relevance was obtained according to NIST SP 800-30 revision 1, shown in Table VI.

TABLE VI. THREAT IDENTIFICATION

Asset Code	Threat Event	Threat Source	CIA
A1	T1	S8, S9, S18, S19	C+I
A2	T2	S8, S9, S15	C
A3	T2	S8, S9, S15	C
A4	T3	S1, S2, S3, S4, S5, S6	C+I+A
	T5	S11, S15, S27, S29, S31, S32	A
A5	T3	S2, S3, S4, S6, S7	C+I+A
	T4	S8, S9, S14, S21, S30	C+I+A
	T5	S13, S22, S23, S24, S25	I + A
...			
A62	T35	S8, S15, S18, S20	C+I+A

c) *Identification of existing controls:* The next step is to identify the security controls that the company has implemented to protect the organization's assets from threats. In this discussion through the observation method obtained 52 security controls on assets. For example, of the existing control in this case, namely: C1: periodically review internal IT policies, procedures, and circulars, C2: classified information (controlled restricted, unclassified information, controlled, and public), C3: non-disclosure agreement, C4-restriction of access control, C5: information security awareness, education, and training program, C6: rollback procedure, C7: periodic review of access rights, C8: using a strong password according to best practice recommendations, C9: implemented least privileges, C10: log access control

failures, C11: periodic maintenance of physical assets, C12: apply periodic updates or firmware to the most recent hardware, network devices, and software versions, and until C52: monitoring and controlling.

d) *Identification of vulnerabilities:* Identification of vulnerabilities means the extent to which the company has implemented controls to protect assets from threats. Vulnerabilities that have no corresponding threat may not require the implementation of control, but they do need to be identified and monitored. However, implementing ineffective controls or controls that don't work properly can be a vulnerability. In obtaining our vulnerability results, we used vulnerability sources references from the OWASP top ten [25].

The results of the study found 46 vulnerabilities, and Table IV shows the vulnerabilities for each asset based on the controls that have been implemented. The following is an example of controls in this discussion: V1: ineffective implementation of information security policies, V2: unencrypted documents and files, V3: vulnerable and end of support components, V4: insecure design system, V5: cryptographic failures, V6: no backup components, V7: software or hardware misconfigurations; and until V46: lack of information security practices.

TABLE VII. IDENTIFICATION OF VULBERABILITIES

Asset code	Existing controls	Vulnerability	Severity
A1	C1	V1	Low
A2	C2, C3	V2	Low
A3	C2, C3	V2	Low
A4	C5, C7, C8, C9, C12	V4	Moderate
	C6	V3, V5	Moderate
A5	C5, C7, C8, C9, C12	V4	High
	C4, C10	V5	Moderate
	C11, C52	V3, V5, V7	Moderate
...			
A62	C4, C7, C52	V46	Moderate

2) *Risk Analysis:* Risk analysis is the activity of mapping assets, asset values, threats, security controls, vulnerabilities, and impacts on CIA aspects. Risk analysis is intended to obtain the results of an impact assessment and identify possible information security risks.

In this research, we calculate the risk with a formula [13]: Risk is the probability of a successful attack on the organization (loss frequency = likelihood * attack success probability) multiplied by the expected loss from a successful attack (loss magnitude = asset value * probable loss) plus the uncertainty of estimates of all stated values.

Loss frequency is a measurement of the likelihood of an attack combined with the probability that it will succeed if it targets an organization. Loss magnitude is a combination of the asset value and the likelihood of its loss in an attack.

As shown in Table VIII, the risk analysis obtained 142 moderate level, 97 at low level, and 13 at very low level. levels of risk in the ERP system, with 2 at high level, 30 at

TABLE VIII. RISK ANALYSIS

Asset Code	Threat event	Threat Source	CIA	Existing Control	Vulnerability	Risk	Level of Risk
A1	T1	S8, S9, S18, S19	C+I	C1	V1	0,20	Very Low
A2	T2	S8, S9, S15	C	C2, C3	V2	1,44	Low
A3	T2	S8, S9, S15	C	C2, C3	V2	1,64	Low
A4	T3	S1, S2, S3, S4, S5, S6	C+I+A	C4, C5, C7, C8, C9, C12	V4	2,88	Moderate
	T5	S11, S15, S27, S29, S31, S32	A	C6	V3, V5	2,23	Moderate
A5	T3	S2, S3, S4, S6, S7	C+I+A	C4, C5, C7, C8, C9, C12	V4	3,12	High
	T4	S8, S9, S14, S21, S30	C+I+A	C4, C9, C10	V5	2,11	Moderate
	T5	S13, S22, S23, S24, S25	I+A	C11, S2	V3, V5, V7	2,47	Moderate
...							
A62	T35	S8, S15, S18, S20	C+I+A	C4, C7, C52	V46	2,73	Moderate

3) Risk Evaluation: Risk evaluation in this discussion aims to compare the results of risk analysis with risk criteria and then determine whether the risk rating is acceptable or tolerable. The stages of risk evaluation include compiling risk priorities based on the amount of risk, provided that:

- The highest level of risk gets the highest priority.
- If there is more than one risk with the same risk magnitude, the risk priority is determined based on the sequence of impact areas from the highest to the lowest according to the loss magnitude.
- If there is still more than one risk that has the same magnitude and area of impact, then the risk priority

is determined based on the order of the highest to the lowest risk category according to the loss frequency.

- If there is still more than one risk that has the same magnitude, loss magnitude, and loss frequency, then the risk priority is determined based on the judgment of the risk owner.

Table IX shows as risk appetite based on semi-quantitative based risk rating guidelines with NIST SP 800-30 revision 1 and two risk treatment criteria (likelihood and overall level of impact).

TABLE IX. RISK APPETITE

Overall likelihood (Threat event occurs and result in adverse impact)	Level of impact				
	Very Low (1)	Low (2)	Moderate (3)	High (4)	Very High (5)
Very High (5)	Accept	Mitigation	Mitigation	Mitigation	Mitigation
High (4)	Accept	Mitigation	Mitigation	Mitigation	Mitigation
Moderate (3)	Accept	Accept	Mitigation	Mitigation	Mitigation
Low (2)	Accept	Accept	Accept	Mitigation	Mitigation
Very Low (1)	Accept	Accept	Accept	Accept	Accept

Risk determination is the first step before risk prioritization. Priority risk matrix is classified based on NIST

SP 800-30 revision 1 and is a matrix of the relationship between assets and threats, show as in Fig. 2.

Fig. 2. Risk matrix.

C. Risk Treatment and Risk Acceptance Strategy

1) Risk treatment strategy: Risk treatment aims to control dangerous risks by developing relevant treatments to control the causes of risk, measuring the effectiveness of the treatment, and if the estimated risk value remains at an intolerable level, preparing alternative treatments.

According to ISO/IEC 27005:2018, there are four options available for risk treatment, namely risk modification, risk avoidance, risk sharing, and risk retention. In this discussion, we found 142 risks with unacceptable decisions for 32 modification risks. Total risk acceptance is 110, of which there are 90 risk retention, 2 risk avoidance, and 18 risk sharing.

In selecting the risk treatment that has been sorted based on risk priority from the highest to the lowest risk level. The following is an example of a risk priority in Table X.

TABLE X. RISK TREATMENT

Priority	Risk Scenario	Level of Risk	Decision	Risk Appetite
1	A5, T3	High	Mitigation	Risk Modification
2	A4, T3	Moderate	Mitigation	Risk Modification
3	A62, T35	Moderate	Mitigation	Risk Modification
...				
142	A1, T1	Very Low	Accept	Risk Retention

2) Risk Acceptance Strategy: This activity is carried out to describe more clearly some of the security controls that have been selected for risk treatment. In this discussion, we propose that an information security team be created to define the roles and responsibilities, or Person in Charge (PIC), of information security activities in every organization.

In establishing information security controls, PIC is required to be responsible for risk acceptance, as shown in Table XI.

TABLE XI. RISK ACCEPTANCE

Priority	Risk Scenario	Control with ISO/IEC 27002:2022	PIC
1	A5, T3	<p>Organizational controls: 5.1 Policies for information security 5.37 Documented operating procedures.</p> <p>People controls: 6.3 Information security awareness, education, and training</p> <p>Technology controls: 8.7 Protection against malware 8.20 Networks security 8.23 Web filtering</p>	Head of Department Information Technology System
2	A4, T3	<p>Organizational controls: 5.1 Policies for information security 5.37 Documented operating procedures.</p> <p>People controls: 6.3 Information security awareness, education, and training</p> <p>Technology controls: 8.7 Protection against malware 8.20 Networks security 8.32 Change management</p>	Head of Department Information Technology Infrastructure and Service
3	A62, T35	<p>Organizational controls: 5.1 Policies for information security 5.17 Authentication information</p> <p>People controls: 6.2 Terms and conditions of employment 6.3 Information security awareness, education, and training</p> <p>Physical controls: 7.7 Clear desk and clear screen</p> <p>Technology controls: 8.2 Privileged access rights</p>	Head of Department Information Technology Infrastructure and Service
...			

32	A5, T4	<p>Organizational controls: 5.1 Policies for information security 5.15 Access control</p> <p>People controls: 6.3 Information security awareness, education, and training</p> <p>Physical controls: 7.7 Clear desk and clear screen</p> <p>Technology controls: 8.2 Privileged access rights 8.3.2 Secure coding</p>	Head of Department Information Technology Infrastructure and Service
----	--------	--	--

According to research findings, there are 10 controls on 14 types of threats for organizational control (clause 5), 5 controls on 7 types of threats for people control (clause 6), 3 controls on 4 types of threats for physical control (clause 7) and 14 controls on 11 types of threats for technology control (clause 8), as shown in Fig. 3.

Fig. 3. Determination controls on risk categories.

For documentation and monitoring risks, we are using a risk register. The risk register provides holistic information about risks and enables stakeholders to make decisions regarding those risks and their management. The risk owner or PIC uses the risk register to document and manage risks to asset organizations.

V. CONCLUSION

Risk management principles are something to consider when preparing the framework and forming the foundation for risk management practices. The risk management process must also be aligned with the corporate culture, processes, structure, and strategy. We use an integrated ISO/IEC 27005:2018 and NIST SP 800-30 revision 1 framework, to make it easier to implement in organizations.

Context establishment is the process of determining the basic parameters in risk management by providing an understanding of the internal and external environments in management implementation. The risk assessment has three stages, namely risk identification, risk analysis, and risk evaluation. Risk identification includes risk sources, events, and causes, and impacts on each asset. Risk identification is sourced from historical data, theoretical analysis, expert opinion, and stakeholder needs.

Risk analysis is a systematic process to determine how often an event occurs, the risk of the impact that might occur, and the size of the consequences that arise from the event. The

results of risk analysis obtained: 142 levels of risk with a high level (high) of 2 risks, a moderate level (moderate) of 30 risks, a low level (low) of 97 risks, and 13 levels of very low (very low).

Risk evaluation is the process of comparing the results of risk analysis with risk criteria to then determine whether the risk rating is acceptable or tolerable. There are 142 identified risk priorities, of which 110 are acceptable and 32 are unacceptable. We have developed this research up to the risk treatment stage by providing control recommendations using ISO 27002:2022 guidelines. The risk management strategy in this case aims to eliminate the threat of risk so that it does not become an obstacle in efforts to achieve organizational goals.

Risk treatment option depends on the risk appetite and risk tolerance. In this case, we use several options to deal with these risks, such as risk modification to reduce risk through selecting controls so that the risk is acceptable, avoiding risks by avoiding activities or conditions that may pose risks, sharing risks by working with third parties who are able to deal with risks, and accepting risks without taking further action.

Excellent Centre of Innovations and New Science, Universitas Medan Area, Medan, Indonesia^{1, 2, 3}

Abstract—Ulos is one of the Batak culture's traditional heritage fabrics. Ulos cloth is divided into several types, each with a distinct function. Ulos Ragi Hotang, Ulos Pinunsaan, Ulos Tumtuman, Ulos Ragi Hidup, and Ulos Sadum are the five Batak ulos motifs. The Batak ulos motif has evolved over time and is now well-known in other countries. However, many ordinary people have difficulty distinguishing between ulos cloth and other fabrics. This study categorizes the different types of ulos cloth so that it can be used by ordinary people who are unfamiliar with the different types and functions. The Convolutional Neural Network is the method used (CNN). CNN is used to recognize and classify images. CNN's main feature is that it detects feature patches from locations in the input matrix and assembles them into high-level references. The Modular Neural Network (MNN) is then used to break down large and complex computational processes into smaller components, reducing complexity while still producing the desired output. 80% of the data for the training process, 20% for testing. The accuracy value achieved is 97.83%, the loss value is 0.0793, the val loss is 2.1885, and the val accuracy is 0.7429.

Keywords—Ulos; classification; convolutional neural network; modular neural network; deep learning

I. INTRODUCTION

Indonesia has a rich cultural diversity. Language, ethnicity, religion, and community beliefs are all part of the community. The Toba Batak are a tribe found throughout North Sumatra [1]. In everyday life, the Batak tribe maintains culture, as evidenced by the performance of traditional events with a distinct feature, namely, ulos [2].

Ulos are used in Toba Batak traditional ceremonies, with different types and functions depending on their roles. At first glance, Batak Ulos appear to have the same motif or size, but this is not the case [3]. If you want to learn more about the different types of Batak Ulos, you can talk to weavers or those who work with ulos. The motif of the Batak ulos has, of course, evolved over time, and it is now well known not only in Indonesia, but also in other countries [4].

Toba Batak has five different types of ulos. Ulos Ragi Hotang is used in wedding traditions. Ulos Pinunsaan is worn by kings and used in large customary events. The first child of sedition wore Ulos Tumtuman. Ulos Yeast Life as a metaphor for finding happiness in life. Ulos Sadum is commonly given as a gift to officials.

One of the long-standing problems in computer vision that has yet to be solved is the classification of objects in images in general [5]. How to replicate the human ability to understand image information so that computers, like humans, can recognize objects in images. The feature engineering process is generally very limited in that it can only apply to specific datasets and cannot generalize to any type of image. This is due to various differences between images, such as differences in viewing angles, scale, light conditions, object deformation, and so on [6,7].

There are several algorithms that can be used in image processing. They include Nave Bayes, Support Vector Machines, and Neural Networks. A Neural Network is a commonly used algorithm [8]. The workings of neural networks in the human brain inspired the development of neural networks. Digital image processing algorithms have also been developed in tandem with technological advancements. The Convolutional Neural Network is a deep learning development [9,10].

Deep learning is an artificial intelligence (AI) method that teaches computers to process data in ways similar to how the human brain does. Deep learning models are capable of recognizing complex patterns in images, text, sound, and other data in order to generate insights and accurate predictions [11]. Deep learning methods can be used to automate tasks that would otherwise require human intelligence, such as describing an image or transcribing a sound file into text. In digital image recognition, the Convolutional Neural Network method produces the most significant results. This is due to the fact that CNN is based on an image recognition system in the human visual cortex [12].

A modular neural network is a collection of different neural networks that work independently to produce output without interacting with one another. Each neural network performs different sub-tasks by obtaining distinct inputs from other networks [13]. The benefit of this artificial neural network is that it divides large and complex computational processes into smaller components, reducing complexity while still producing the desired output. Interfaces between modules in such a modular architecture can be viewed as "information relays" that encode, delimit, and disseminate critical information [14].

II. RESEARCH METHODOLOGY

A. State of the Art

The following is a classification model formation scheme for CNN and MNN.

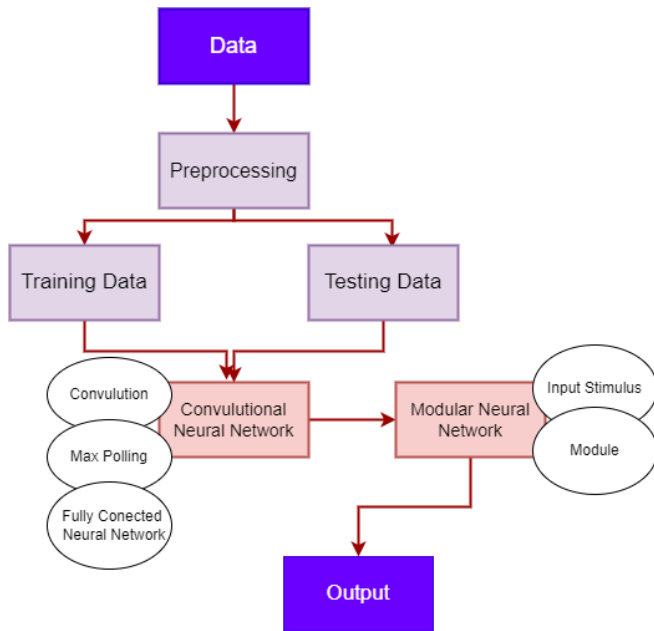

Fig. 1. State of the art.

The stages of the research can be seen in Fig. 1 [15,16].

- Data
- Data pre-processing to sort.
- Training to identify the features of each image, followed by labelled neurons to activate the image, and finally classification. Batch size and epoch are initialization parameters in the training process.
- The image is multiplied by a 32x32 kernel on three filters in the first convolution. The image is multiplied by the 64x64 kernel in the second convolution. The third convolution is an image multiplied by a 64x64 kernel with three filters. The resulting feature will make use of the same padding as well as the ReLu activation function. Using three dense layers, the first and second dense 128 layers, and the third 64 layers, the ReLu activation function was used.
- Testing to determine how well the system detects and calculates the number of images in the image. The fitting models obtained from the previous training stages were compared during validation.
- Using a circular control area around each output, the Modular Neural Network selects the number and location of inputs that affect each output. The control area uses each input's response range to identify the critical input and discard the rest.

B. Data Collection

Images obtained from observations at UD. Ulos and

Songket Tamariska Tarutung, North Tapanuli, North Sumatra Province. Images in the JPEG format were captured with a smartphone camera. There are 200 images in total, including Ulos Ragi Hotang, Ulos Pinunnaan, Ulos Tuntuman, Ulos Ragi Hidup, and Ulos Sadum [17]. See Fig. 2 for types of ulos.

Fig. 2. Types of Ulos. (a) Ulos ragi hotang, (b) Ulos Pinunnaan, (c) Ulos tuntuman, (d) Ulos ragi hidup, (e) Ulos sadum [17].

C. Convolutional Neural Network (CNN)

CNN consists of several layers. The CNN architecture has the following components [18,19,20]:

1) *Input layer*: This layer is the first to load and enter data, which is then carried over to the next layer.

2) *Convolution layer*: The convolution layer performs the convolution operation on the output from the previous layer. This layer serves as the foundation for CNN operations.

3) *Activation layer*: To convert a node's input signal into an output signal. The output results will be carried over to the next layer [21].

$$A(x) = \max(0, x) \quad (1)$$

$$C_i = \frac{a^{xi+\text{LOG}(b)}}{\sum_{k=1}^S a^{xi+\text{LOG}(b)}} \quad (2)$$

xi is the strength value of the neuron. $\text{Log}(b)$ constant value that can be determined [22].

$$\frac{\partial ai}{\partial aj} = C_i(\delta ij - Cj) \text{ with } \delta ij$$

$$= \begin{cases} 1, & \text{if } i = j \\ 0, & \text{if } i \neq j \end{cases} \quad (3)$$

- 4) *Max polling*: minimizing the number of parameters and calculations needed.
- 5) *Dropout*: To prevent overfitting problem.
- 6) *Fully connected layer*: All neuron activation layers in the previous layer are fully connected.

Fig. 3. CNN architecture.

Fig. 3 depicts the relationship between weighted units used to determine the effect of one object on another. CNN has one or more convolution layers that perform the convolution operation on the input before passing the results in the form of output to the next layer [23].

Several learning parameters, including batch size and epoch, must be set. Table I shows an explanation of the parameters [24].

TABLE I. INITIATION PARAMETERS

Parameter	Information
Batch Size	The number of data samples sent to the neural network in a single epoch.
Epoch	The number of rounds completed from the start of the first dataset to the end.

D. Modular Neural Network

Modular is a self-contained system that interacts with the overall architectural function to perform complex tasks. To achieve local computation, an explicit Action must be performed, so that the system being modeled becomes a meaningful function. In eq. (4), (5) and (6), static functions are represented in two dimensions [25, 26].

$$A(c(x), h(x)) = [3x] + [-x^2 + x] \quad (4)$$

$$c(x) = 3x \quad (5)$$

$$h(x) = -x^2 + x \quad (6)$$

Fig. 4. Modular neural network structure.

A modular neural network structure in Fig. 4 [27].

- Tasks should be broken down into subtasks.
- Modular architecture organization
- Communication between modules

A vector can be used as the target response. On the network, each input vector is represented. Eq. (7) represents the MNN output [28].

$$h = \sum_{i=1}^k c_i y_i \quad (7)$$

c_i shows the weight on the number of network outputs resulting from the response, as explained by the deterministic transformation. Eq. (8) can be used to express the response [29].

$$a = R_i(x) + \epsilon_i \quad i = 1,2,3, \dots, n \quad (8)$$

III. RESULT AND DISCUSSION

Training data can account for up to 80% of the total. In the training process, the iteration parameter is set to 100 epochs, and the batch size is set to 32. The training procedure is carried out and is repeated 100 times in order to obtain the desired feature extraction. Table II shows the amount of training and testing data.

TABLE II. TRAINING DATA AND TESTING DATA

Distribution of Testing & Training Data	Amount of data
Training 80%	100
Testing 20%	35

The test employs 35 test data, with 7 images in each Ulos category. The model is used directly in the process of calculating accuracy. fit() method by calling the validation folder's directory and then executing it with the CNN method.

TABLE III. RESULTS BASED ON PARAMETERS

Epoch	Loss	Accuracy	Val Loss	Val Accuracy	Time
50	0.3315	0.8768	1.4779	0.6571	4 minute 13 second
75	0.2361	0.9203	0.9707	0.6571	20 minute 45 second
100	0.0793	0.9783	2.1885	0.7429	18 minute 40 second

Fig. 5. MNN modeling paradigm [26].

MNN modeling paradigm is shown in Fig. 5. Table III shows the goal of determining model parameters: to compare the best models based on parameter values. It is re-optimized based on these parameters by dividing the smallest modules into the greatest number. The best accuracy results are found in the 100th epoch, which is 97.83%.

Fig. 6. Accuracy and loss at epoch 100.

Fig. 6 shows that the training and validation graphs on accuracy have the same pattern as the training and validation graphs on loss.

Fig. 7. Visualization of trends in trains and tests in epoch 100.

The accuracy and loss graphs have diverse patterns, as seen in Fig. 7. Due to insufficient data, this occurs and the pattern keeps repeating.

Fig. 8. Accuracy and loss at epoch 75.

An accuracy validation chart that follows the pattern of training results is shown in Fig. 8. Similar results can be obtained with the loss validation graph that mimics the training outcomes.

Fig. 9. Visualization of trends in trains and tests in epoch 75.

Fig. 9 shows the accuracy and loss graphs have different patterns. This is due to too little data so the pattern repeats.

Fig. 10. Accuracy and loss at epoch 50.

Fig. 10 displays a validation graph for accuracy and a validation graph for losses that follow the pattern of training results.

Fig. 11. Visualization of trends in trains and tests in epoch 50.

Fig. 11 shows the accuracy and loss graphs have different patterns due to too little data.

IV. CONCLUSION

The testing procedure is by using 35 test data with 7 images in each Ulos category. Because CNN already has a feature learning phase or process, it can classify objects without the need for additional feature extraction. When the process achieves accuracy, the use of MNN facilitates classification, where the process makes it easier to understand behavior or features in images to make them easier to recognize, and it increases in terms of time. Accuracy was 97.83%, loss was 0.0793, val loss was 2.1885, and val accuracy was 0.7429.

Enhancing Customer Relationship Management Using Fuzzy Association Rules and the Evolutionary Genetic Algorithm

Ahmed Abu-Al Dahab¹, Riham M Haggag², Samir Abu-Al Fotouh³
Business Information Systems, Helwan University, Helwan, Egypt^{1,2}
Accounting Information Systems, Mansoura University, Mansoura, Egypt³

Abstract—The importance of Customer Relationship Management (CRM) has never been higher. Thus, companies are forced to adopt new strategies to focus on customers, given the competitive climate in which they operate. Also, companies have been able to maintain customer data within large databases that contain all information related to customers, thanks to the tremendous technological development seen recently. Multilevel quantitative association mining is a significant field for achieving motivational associations between data components with multiple abstraction levels. This paper develops a methodology to support CRM to improve the relationship between retail companies and their customers in the retail sector to retain existing customers and attract more new customers, by applying data mining techniques using the genetic algorithm through which an integrated search is performed. The proposed model can be implemented because the proposed model does not need the minimum levels of support and trust required by the user, and it has been confirmed that the algorithm proposed in this research can powerfully create non-redundant fuzzy multi-level association rules, according to the results of these experiments.

Keywords—Customer relationship management (CRM); fuzzy association rule mining; multilevel association rule; quantitative data mining

I. INTRODUCTION

Customer Relationship Management (CRM) is a critical component of an organization's information system architecture on which organizations fully rely to improve business relationships with customers. Depending on information technology, including the Internet, data warehouses, data mining, etc. After-sales service achieves a lot of the results that are obtained, which enable companies to talk, link, and exchange goods and services with their customers through various of media, including the Internet, call centers, phone calls, faxes, sales personnel, and surveys to attract new customers and retain customers and increase the happiness of customers, and gain the trust and loyalty of customers, which mainly contribute to achieving the greatest return on profitability.

One of the most important factors in the survival of companies is the relationship that binds the company to their customers. It is important to understand that when companies collect a large volume of unmanaged data, such as consumer transactions or sales, decision-makers will not benefit much from this type of data. Companies must use modern

technologies that help analyze a huge amount of data, process it, and convert it into useful information that can be understood and analyzed, which will give them good management skills and ideal basic competitiveness in the market [1].

In the information age, data mining is one of the newest and fastest-growing sub-solutions in machine learning. Knowledge discovery from data (information) is a variety of techniques for extracting common patterns from large or high-dimensional data.

Sets are technologies that provide us with accurate information that we may apply in a variety of fields, including business, engineering, and medical sciences. To find new knowledge, different strategies can be used to produce interesting rules known as association rule mining [2].

The Genetic Algorithm (GA) is a representative model that draws inspiration from the theory of natural evolution. Genetic algorithms are used because they are the most advanced and least complex algorithms when compared to other algorithms, for the variety of applications that they can be used for, and because they employ the scientific research method to identify the set of repetitive elements. This approach is better and easier to use than other genetic algorithms this heuristic method is used routinely to maintain high-quality responses in order to simplify the research of problems, dealing with them, the ability to address them, and the selection of the best solutions and results. These algorithms are widely used in mining important data to determine association rules. They are also used to find association rules in practical issues such as business databases and fraud detection [3].

Data mining efforts aim to identify association rules at the individual concept level, finding more comprehensive and meaningful knowledge by processing data and extracting the required information at the same time by exploring the different levels of ideas. Classifications of related elements can be thought of as hierarchical trees, pre-mapped for real-world uses. Inner nodes define classes or concepts that are created from lower-level nodes; [4] the leaf nodes of the hierarchical tree represent the real elements that the transactions are searching for. Fig. 1 provides a straightforward illustration of this. There are many reasons to mine multilevel association rules, including (a) the fact that these rules are more logical and user interpretable. (b) We can find answers to unwanted and

undesirable rules using the rules of the multilevel association. Applications that use spatial data analysis are encouraged [5].

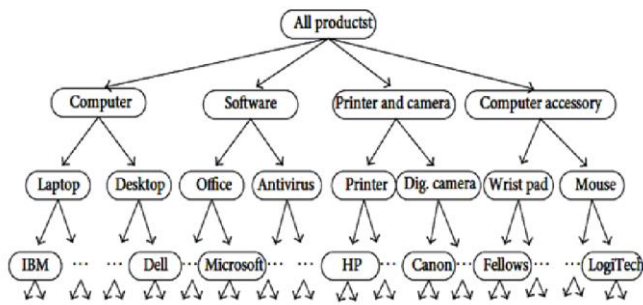

Fig. 1. The established taxonomy.

A. Motivation and Rationale

Customer contact and after-sales services have become major components of corporate strategies due to the increasing competition for retail activities. In the past, companies used to focus more on selling products and services than on looking into the details of the people who made those purchases and neglecting their wants and needs. And because of the abundance of competition, companies needed to intensify efforts to retain their existing customers, because it was difficult to obtain new ones. In addition, when economic and social conditions were adjusted for, customers were less likely to respond positively to any marketing communications from companies due to their lifestyles [6]. Companies have evolved from product/service-focused strategies to customer-focused strategies as a result of this environment. Thus, developing lasting relationships with clients has become a major strategic objective. In fact, to maintain a positive business relationship with customers, companies that want to stay ahead of the curve must constantly improve service standards. Some companies have invested in building large databases, which enable them to keep a large amount of data related to customers. Numerous data are collected for each customer, allowing analysis of the consumer's complete purchase history. But the knowledge gathered is rarely used to build enterprise processes such as Customer Relationship Management (CRM). In fact, most companies do not incorporate knowledge into their decision-support processes. Information overload and knowledge starvation are recurring problems caused by massive amounts of data. The rate at which analysts can process data has lagged behind in terms of whether the data is usable and relevant to the application [6].

Several trials have been directed at effectiveness (number of bases) and performance (speed). Quality has been neglected in the context of mining the rules of quantitative correlation. The mining algorithms in modern multilevel quantitative correlation rules completely rely on intensive looks at the database to obtain regular models that transcend all the different levels of abstraction [7]. Only users can plan the minimum support related to personal databases and this is based on the assumption of mining algorithms [8] Mining quantitative association rules is not a manageable expansion of mining categorical association rules. Since the search space is unlimited, we aim to detect a measurable set of exciting

solutions (quantitative rules), near the optimal answers. This illustrates why we have decided to solve this search problem with meta-heuristic routines, mainly genetic algorithms [9].

Each of the rules can be regularly defined or inferred and this can confuse the user when managing quantitative correlation rules mining. But more importantly, and some of these rules do not produce new knowledge and these rules may be redundant; some attempts to sell redundant controls in flat datasets. However, datasets can have multiple concept levels or a hierarchy/taxonomy, so the redundancy in these datasets requires modification. This topic is one of the stages of this research. Currently, the approach here is to identify all redundant rules and eliminate them immediately, as a result of which the number of rules that the user has to deal with will be reduced and the information content will not be reduced [10]. To locate familiar elements at different levels of abstraction, this paper presents a modified version of the Apriori algorithm with the aim of mining fuzzy multilevel association rules in large databases [11].

B. Research Problems

Understanding and meeting consumer needs are essential responsibilities for a business to compete in this day of intense competition. As a result, customer relationship management (CRM) now ranks highly among company concerns. How businesses attract new clients and retain existing ones is crucial in today's cutthroat culture. CRM is thought to use appropriate analytical devices with limited materials to attract the most valuable consumers and heighten their desire to increase purchases. The manager can search and examine a vast amount of data using data mining methods to find significant patterns and rules. This approach may also be seen as a means of acquiring knowledge to locate ambiguous association rules to carry out CRM since interactions between the expert system and users can be facilitated by fuzzy knowledge representation. The purpose of this study is to introduce the field of data mining, explicitly mining multi-level quantitative fuzzy correlation rules, to support CRM managers. To achieve precisely defined excellence, it is imperative that by answering these questions, it is probable to be provided in a basic manner. For our research, there are several dominant difficulties that we determined to gather around and seek to crack these challenges and they are:

- Boolean features can be studied as an exceptional example of categorical features and is an important student for generalizing Boolean data mining algorithms for quantitative features, however, we have to either obtain different algorithms or somehow transform the problem of quantitative correlation rules into a Boolean problem. Accordingly, we will use a novel approach to discover quantitative correlation rules emerging from a dataset with multiple concept levels.
- Due to the number of bases, this expands greatly with the number of elements. But this complication will be done by using some advanced algorithms that can cut the search space very efficiently [18]. Choosing this issue mainly helps the user when examining the ruleset. However, the process of developing more valuable quality measures for the rules through the use of the

genetic algorithm with the fitness function (relative confidence of the association rule) and the aim to confirm the most intriguing association rules is indicative of the advanced goals to solve this problem [22].

- Without prior knowledge, the purpose of these valid (estimated) intervals is to extract quantitative data which can be a very complex task. Moreover, these time intervals may not be sufficiently agreeable for experts to quickly gain non-intuitive knowledge from these generated rules. This fuzzy organic function can help with these problems.
- We can completely and effectively specify that there are no redundant association rules in hierarchical datasets.

C. Problem Statement

Market information in the actual world typically contains measurable quantities; therefore developing a sophisticated data-mining algorithm capable of working with quantitative data presents a difficulty to researchers in that field [7] The multilevel association rules mining problem can be defined as follows:

The following elements represent $I = \{i_1, i_2, \dots, i_n\}$ and Γ is a classification tree through which the multilevel taxonomic relationships between these elements can be clarified as an example of that field awareness. Element i_1 is the parent of i_2 and element i_2 is the descendant of i_1 if and there are some advantages of element i_1 over i_2 . Through which only leaf nodes are displayed within the database. The symbols DD represent a database of transactions where each transaction in the database DD is a set of elements as $T \subseteq I$. Each of the transactions is associated with an identifier $TTIIDD$. The symbol P represents the set of positive integers, and the symbol IV denotes the set $I \times p$. Couple $\langle x, v \rangle \in IV$, which means the quantitative attribute x , with the respective values and that $v \in IV$, $\{\forall \langle x, l, u \rangle \in I \times p \times p / l \leq u\}$, l represents the lower bound and u stands for the upper bound of p . The next trio $\langle x, l, u \rangle \in IV$ and denotes the quantitative x with a value within the interval $[l, u]$. Note that the coefficient TT contains the item $x \in I$ if x in TT or x is the parent of some of these elements in TT . In addition, the transaction X includes $\subseteq I$ with the condition that TT holds each element of X .

The multilevel association rule is a product of the $X \Rightarrow Y$ model, where $X \subseteq I$, $Y \subseteq I$, and $X \cap Y = \emptyset$. No element in YY is the source of any element in X ; This is $Y \cap C$ estors $(x) = \phi$ because the pattern rule " $x \Rightarrow$ ancestors $(x) = \phi$ " is fairly true with 100% confidence, and is redundant. X and Y may each contain Γ elements of any level of Γ [12][13][14].

Quantitative association rule mining still has some restrictions, such as [11]: (1) the design's adoption of a separation of the quantitative attribute prevents it from being usable by all users and attributes. (2) Users, and even specialists, frequently find it challenging to supply certain thresholds, such as the minimal amount of support, curiosity, and confidence. (3) If we use quantitative features, the search space may be very big. Fourth, the algorithm's specified rules may be too numerous to handle.

II. LITERATURE REVIEW

In this section, we compare quantum correlation rule mining algorithms taking into account the shape of these rules, and discuss the drawbacks and advantages of each technique, and the type of database that can be used. [15] [16]:

1) *Discretization*: The primary objective of this is to convert quantities of data into Booleans by examining the separation of numerical features into groups of intervals. Then this algorithm can be processed to detect the logical association rules to prepare the rules of quantities. Two main representations of the sections are included. Fixed partition, in which the groups of spacers are separated, and another type, where the ends of the spacers are overlapped with each other.

Beyond being the first effort on this topic, the main advantage of this approach is that it can manipulate numerical and categorical data in the same way. Disjoint sets incur harm from the Min_Sup and Min_Conf thresholds, whereas overlapping sets experience the cutting boundary problem. Situations (disjointed or overlapped), however, produce complications. Information will always be lost if intervals are used instead of the actual continuous data. The guidelines we provide will simply be an assessment of the ideal outcomes. Another issue is the expansion of the characteristics dimension; here, the issue is the requirement for additional memory and processing time for these data.

2) *Adjusted difference analysis*: This approach is based on using discretization and adjusted difference analysis to identify relationships between two properties. Any combination of numbers and categories might be used for the two qualities. This method may distinguish between positive and negative association rules without the requirement for user support or confidence criteria. The fact that it does not require any user criteria and can acquire a new substantial objective measure of the association rules are two of its benefits. Similar to the first strategy, this one has discretization issues that are a drawback. Additionally, this method is unmistakably thought of as producing a special case rule because the rules are always between just two characteristics.

3) *A fuzzy approach based on integrating the concepts of fuzzy logic and fuzzy sets with the Apriori algorithm*: It reforms numerical data into fuzzy member between $[0,1]$ with a membership function; then operates with the fuzzy member with an adjusted Apriori technique that can comfortably extract the rules, which are stated in linguistic terms. These approaches are based on the fuzzy additions to the classical association rules mining by establishing support and confidence in the fuzzy rule. While the mining results are straightforward to interpret by human operators, two shortcomings still insist on implementing such fuzzy approaches to the original problems. One is the computational time for mining from the database, and the other is the precision of deduced rules. A more formal description, as well as a survey of the existing methods of quantitative association rule mining, can be found in [17].

Numerous scholars have absorbed fuzzy multilevel association rules mining in the literature [13–17]. Without specifying the actual minimum support, certain of these solutions suggested multilayer membership functions via systems of ant colonies and genetic algorithms. Setting the functions for each item and then determining the minimal supports are used to increase computing performance. Other projects benefited from the efficiency and versatility that were done using OLAP and data mining techniques [12].

Up-to-date, there exist only a few algorithms for quantitative multilevel fuzzy association rule mining (QMLFRL). For example, in [25] the authors advised a QMLFRL based on the idea that the minimum support for an item at a higher taxonomic concept is valued as the minimum of the minimum supports of the items pertaining to it, and an item minimum support for an itemset is established as the maximum of the minimum supports of the items enclosed in the itemset. Under this limitation, the characteristic of downward closure is conserved, such that the original Apriori algorithm can be simply prolonged to find fuzzy large item sets..

The authors of [26] provide a brand-new, very innovative genetic-based strategy for choosing criterion values for common item sets. That is the method, an advanced coding technique is chosen, and both the fitness functions have some assurance. The user-specified minimum support is not necessary for our model. Using the genetic algorithm, a thorough search can be carried out. The experiment's findings show that the suggested approach is able to generate fuzzy multilevel association rules that are non-redundant.

The authors of [5] proposed a new technique for extracting quantitative association rules that may concurrently learn rules and quantize an attribute by using a clustering algorithm. They carried out clustering utilizing all qualities simultaneously ahead of time, and they extracted the clusters in the rules from the "association" feature. The authors' technique is superior to the traditional Cartesian product-type quantization technique in terms of total Rule extraction and quantization accuracy, which was supported by the numerical experiments.

The concept threshold - common item groups that are generated by the evolutionary algorithm - is used in the additional pertinent work provided in [3] to develop the quantitative dataset-based rules. In this example, crossover and mutation are used to unify the rule in various ways and can detect the co-occurrence of item sets. Here, comprehensibility, interestingness, and confidence are the three objectives being investigated. As a result, the created laws have developed the principle of multi-objective association. By achieving these goals, the search space for fitness functions is reduced. Finally, distribution-based optimal criteria are developed regarding the numerically valued attribute (A rule's right side displays the distribution of the values for numerical qualities like the mean or variance.)

The advantage of the previous systems is that they contain language terms that make established rules seem much more natural to human specialists; nonetheless, they may produce a

significant amount of fascinating association rules. However, since the sparseness of data in three dimensions, makes it not always easy to establish efficient association rules (meeting the lowest level of confidence and assistance) between data points at low (basic) variations in abstraction. Other related issues include (1) inadequate support for hierarchies that are needed to change over time (2) Real-world application requirements cannot be satisfied by algorithm efficiency; (3) the potential to eliminate the connection between several notion levels; (4) Their approach allowed users to specify various things with differing minimal supports[20][27].

To the book [18] that it is necessary to have a customer relationship management system from the requirement of a comprehensive analysis of the market and the study of consumer needs, product developments, and product life cycles. Information mining is the collection of data on the conduct of product sales over time to analyze different market trends. With this information, a product life cycle can be established and new products with some new improvements can be developed according to market trends and customer desires. Although it is usually a good idea to keep arbitrators global, fuzzy arbitrators operate on a group parameter that can be either general or class-specific. They base their choices on a comprehensive review of the product's sales figures in addition to analyzing other data.

Customer relationship management (CRM) seeks to create a "Learning Relation" with customers to help businesses concentrate on their needs, which are the cornerstone of all corporate operations. Businesses put their consumers at the center of management and operations by monitoring client reactions to specific goods and services. Businesses gain the knowledge necessary to raise the caliber of their goods and services by doing this. In other words, businesses find innovative strategies to keep their current clients, attract new customers, and encourage customers' contributions and loyalty to businesses through regular contact and complete knowledge [19].

A. Research Contribution

By examining several analytical characteristics of customer relationship management in the retail industry, the thesis idea presented in this study contributes to the marketing literature. In addition, it provides recommendations for companies on how they can benefit from using CRM analytics to help customers achieve understanding, which enhances customer connection. This paper incorporates the idea that was developed and inspired in part by work on QMLFRL, but that a genetic algorithm is used to calculate a minimum level of confidence and a minimum level of support for each level in this classification regardless of the nature of this data; this makes the system automated. Previous studies, it has fully investigated single-level association rule mining with GA, such as multi-target mining rules and single-level association mining rules. However, when setting up big data analysis, multilevel forms of correlation rules are regularly powerful. Multilevel association rules require big data mining to be a more efficient and effective method. GA-based multilevel association rule mining in this paper is only one attempt to discover multilevel association rules in big data with high efficiency.

III. THE PROPOSED MODEL

This project's main goal was to create practical Heuristic techniques used to mine multilevel association rules in huge datasets, with the primary goal of determining the minimal support and minimum confidence levels for each taxonomic level automatically. By utilizing the genetic algorithm's capacity to swiftly identify without completing exhaustive searches, numerous solutions can be found simultaneously in a huge multidimensional problem. our proposed technique can improve mining efficiency while maintaining the desired precision but avoiding the exhaustive list of potential association rules The definitions listed below are those connected to multilevel association rules [12][13][14]:

The first definition: the element set defines that X is the set of data objects known as the set of data elements $\{X_i, X_j\}$, where $X_i, X_j \in I$. which supports this set X in set S , $\sigma(X/S)$ is the number of transactions (in S) containing X versus the total number of transactions in S . The confidence of $X \Rightarrow Y$ in S , $\phi(X \Rightarrow Y/S)$, is the fraction of $\sigma(X \cup Y/S)$ is in competition with $\sigma(X/S)$, i.e., the probability that element set Y occurs in S when element mining occurs that X occurs in S .

The second definition: is that the group of elements X is very large in the groups at level L if the size of the support X is not less than the corresponding minimum of the support σ_L' Confidence in the $X \Rightarrow Y/S$ rule is very high at L if its confidence ratio is not lower than the equivalent minimum confidence threshold for ϕ_L'

Third identification: The rule $X \Rightarrow Y/S$ is very strong if $X \Rightarrow Y/S$ is large at the current level and the confidence of $X \Rightarrow Y/S$ is high at the current level.

The fourth definition: This mysterious transaction, denoted by the symbol T , is presented by that

$$\bar{T} = \{(x, \mu(x)) \mid \forall x \in I, 0 \leq \mu(x) \leq 1, \mu: I \rightarrow [0,1], \bar{T} \subseteq T$$

Where T is a general set of those coefficients, and $\mu(x)$ is a degree of membership in x .

Fifth definition: A The set of soft quantitative coefficients is denoted by symbols T_q' . Let (F, E) is the soft set over the universe U and $X \subseteq E$, F stands for the fuzzy energy set of U , and E is the set of parameters. It is defined as the set of X attributes that support a transaction if:

$$T_q' = \{(\langle x, l, u \rangle, e) \mid \forall \langle x, l, u \rangle \in I \times p \times p \mid l \leq u, e \in E\}$$

In general, the focus is always on digging into association rules on a single conceptual level. And some applications cannot locate the link in the multiple abstract levels in the large databases of transactions, where each of those transactions consists of a set of elements and its classification (hierarchy) on these elements, it is expected that the links between these elements will be discovered in any level of this classification. To investigate the process of searching for multi-level association rules, everyone wants to bear the cost of this data in a multi-level association and that on the multiple levels of this abstraction and these effective methods of mining in multi-level rules. We can achieve the first specifications by

producing classifications of concepts, from the primitive level of concepts to the higher level of those concepts, or we can find more efficient and effective methods for the process of exploration and research in the rules of the multi-level association.[13].

Only one modification of the Apriori algorithm, which deals with datasets within databases, particularly transaction records, or records including a certain number of fields, or which uses a multi-level "bottom-up approach" has been made to ML_T2L1 [21] [30]. Which runs the ML_T2L1 algorithm from the transaction table and these tables contain the hierarchical information in which it is encoded. Each of these levels deals with the data set completely separately. The next first: level 1 search (which is the highest level in the levels of the hierarchy) is done for very large groups of 1 item using the Apriori algorithm. Secondly, we then use the list of large group1 items from level 1 to correct, revise and cut the data set of this transaction for any element that does not have any predecessor or recurrence in the large group1 list of level 1 , which eliminates any transaction that may It has no items in common (so it only has rare items when grading using the Level 1 Big List of 1 Item). This is through the large 1 -item level 1 list, after which the large 2 -item level 1 list is completed (this using the dataset cleaned from before). Then large item sets are inferred from level 1 and this process is repeated until there are no duplicate item groups to find in level 1 . This is because ML_T2L1 only selects items that are offshoots of these duplicate items in level 1 (essentially they must be descended). From this level this set can be for large 1 element) and is always recursive by itself, and the collections of elements are completed at level 2 of the iterative transaction table. For level 2 the large 1 -item groups are built, from which the 2 large groups are determined and then the 3 large item groups, and so on. From the same well-filtered datasets) and so on. The fixes for ML_T2L1 so that all these levels are explored using the Apriori algorithm or the large 1itemsets are not displayed at the level of the proposed system core steps are as follows: [13][14][23][20] [27] [30-32] :

Fig. 2. Shows how the elements in perform as members.

Input: A collection of N transactional quantitative data D , a predetermined Γ with the sum of the parent element groups $\{i_1, i_2, \dots, i_n\}$, the set of membership functions for each of the elements in the different levels. In our example, all the organic functions have the same form as we can see in Fig. 2; but the primary x-axis for each element is determined based on the

highest quantitative value of each element with which it is associated. Finally, the parameter f is determined by the minimum support α_k and the minimum confidence λ_k that is gained by the genetic algorithm.

The Output: a set of fuzzy multi-level association rules without the constraints of minimum support and optimal trust.

Step 1: All previously defined labels are compiled using their order symbol "*" and numbers based on the formula, $C = \rho * 10 + i$, where i is the position number of the node at the current level l , C denotes the symbol of the node i^{th} at this current level and ρ is the parent symbol of node i^{th} at that current level.

Step 2: All clause terms are interpreted in each transaction statement and the encryption scheme is approved. Then we define $k = l$ and $r = l$ where $k, l \leq x$ is the number of the last level, x is the number of the level in a specific classification and r indicates the number of elements that have been saved in the set of recurring elements.

Step 3: We group all elements with the same first k number in each D_i transaction, and enter all quantities of elements in these similar groups into D_i . This stands for the j -th group I_j^k of D_i as v_{ij}^k .

Step 4: We have explored a lot of membership functions for each of the different data items where each data item has its features and each has its membership function, and then we convert the v_{ij}^k value of each transaction D_i of all encrypted group I_j^k to fuzzy set f_{ij}^k (Eq. 1) by plotting a v_{ij}^k over all the given membership functions, where I_j^k is the j -th element in level k , v_{ij}^k is the quantum value of I_j^k in D_i and h_j^k is the number of fuzzy regions of I_j^k , R_{jl}^k ($1 \leq l \leq h_j^k$) is the l -th fuzzy region of I_j^k , f_{ij}^k is the fuzzy organic value of R_{jl}^k

$$\left(\frac{f_{ij1}^k}{R_{j1}^k} + \frac{f_{ij2}^k}{R_{j2}^k} + \dots + \frac{f_{ijh}^k}{R_{jh}^k} \right) \quad (1)$$

Step 5: We construct the candidate set C_1^k by summing all the fuzzy regions (through linguistic terms) with organic values greater than zero. Where the numerical principal values k_{jl} for each fuzzy region are R_{jl}^k in the

$$\text{Transactional data as } s_{jl}^k = \sum_{i=1}^n f_{ijl}^k$$

Step 6: Check to see if the value $S_{k_{jl}}$ for each R_{jl}^k region in C_1^k is greater than or equal to the lower bound of α_k which represents the lower bound of the best support for level k that can be obtained by applying this genetic algorithm to the set of coefficients Included at all this level according to Γ (see. Genetic algorithm. 1). Whether R_{jl}^k is boundary matched, then we put it into the large l -items L_1^k collection of level k . that:

$$L_1^k = \{R_{jl}^k \mid S_{k_{jl}} \geq \alpha_k, R_{jl}^k \in C_1^k\} \quad (2)$$

Step 7: If L_1^k is empty, we can go to step 3, where $k = k + 1$; If it doesn't, then we create a C_2^k requester array of $L_1^1, L_1^2, \dots, L_1^k$ to catch the "level crossing" group of elements. Therefore, the pool of C_2^k applicants created must fulfill the following conditions: (1) each pool must consist of two items

in the C_2^k and contain at least one item only. L_1^k . (2) the two regions in a group consisting of two elements may not have the same name as this element. (3) that in a hierarchical relationship in this classification, the names of the elements in the set may not be made up of only two elements. (4) the two bulk element sets each containing a candidate element set of 2 must have support values greater than or equal to the minimum From the support, $\alpha_{k=2}$, in each case.

Step 8: If L_1^k is null, then increase k by one, $r = l$, and go to step 3 else set $r = r + l$.

(A) create the candidate set C_2^k in the case of $r = 2$, where C_2^k is the set of elements that have been nominated with the two elements at the k level of the set.

$L_1^1, L_1^2, L_1^3, \dots, L_1^k$ to learn the "level intersection" of the set of repeating elements. Therefore, each of these groups must contain or contain at least two elements in C_2^k ; but at the same time L_1^k contains only at least one element; Note that the first element must not be the same as the next in the classification. The two possible combinations are made in C_2^k .

(B) create the candidate group C_r^k if $r > 2$, where C_r^k is the group of elements that were nominated with r -items at the k level of L_{r-1}^k and this is done in the same way and the same steps mentioned in the previous steps.

Step 9: For each of the obtained r -itemset s with element set (S_1, S_2, \dots, S_r) in C_r^k :

The value of fuzzy S is computed in all data for each D_i transaction by using the minimum operator

$$\text{as } f_{is} = \min (f_{is1}, f_{is2}, \dots, f_{isr})$$

B) Estimate the scalar cardinality of S in all of the Transactional data as $\text{count}_s = \sum_{i=1}^n \int i_s$

If those numbers are greater than or equal to the set of elements you predetermined including $S = (S_1, S_2, \dots, S_r)$, $r > 2$ as follows: minimum support α_k place S into L_r^k .

Step 10: In the case of L_r^k is equal to nothing, then we increase the K by only one and move on to the next step for that; if you did not increase r by one, we move to step 8 immediately.

step11: If $k > x$ the next STEP, else set $r = 1$ go to step 3

step12: produced fuzzy association rules for every common r - Itemset, including $S = (S_1, S_2, \dots, S_r)$, $r > 2$ as follows:

- Catch all the rules $A \rightarrow B$ where $A \subset S$, $B \subset S$ and $A \cap B = \emptyset$, $A \cup B = S$.
- Calculate the confidence level for each association rule using by $\frac{\sum_{i=1}^n \min (f_{is})}{\sum_{i=1}^n \min (f_{iA})}$.

Step 13: Bases that have high confidence values λ_k and are not less than a pre-determined confidence threshold are selected, where λ_k represents the pre-determined least

confidence value of the k -level that was found from the application of the genetic algorithm.

Step 14: We delete all redundant rules in multilevel data sets, and this rule R_1 is considered redundant in rule R_2 if (1) the set of elements X_1 consists of at least two elements and at least one of them consists of a descendant of On the contrary, (2) the group of elements in X_2 consists of at least two elements, provided that at least one of them is a descendant of these elements in X_1 , and (3) all other non-original elements in X_2 are all It is in the X_1 element group. In the additional case (4) the confidence interval for R_1 (C_1) is less than or equal to the confidence interval for R_2 (C_2).

A. The Extraction of Parameters using the Genetic Algorithm

We define a genetic algorithm as a type of deep search algorithm that is used to mine the minimum support and minimum support for each taxonomic level. It searches a variety of options to deal with a given problem [26]. The algorithm generates a "big set". One of the scientific solutions to each problem that allows this algorithm to "evolve" over many generations, to find the right optimal solution for each problem. This algorithm begins by selecting a set of solutions (known as chromosomes) on which to start the algorithm. To create a new population, solutions from a single population are selected and maintained. The structure of the basic genetic algorithm is as follows: (see Fig. 3).

Procedure genetic algorithm

```
begin (1)
  t = 0;
  initialize P(t);
  evaluate P(t);
  While (Not termination-condition) do
    begin (2)
      t = t + 1;
      select P(t) from P(t - 1);
      recombine P(t);
      evaluate P(t);
    end (2)
  end (1)
```

Fig. 3. Structure of the genetic algorithm [30].

1) [Start] Make arbitrary n-chromosome samples (relevant solutions to the issue).

2) [Fitness] Examine the population's fitness (qualifying) function $f(x)$ for each chromosome x .

3) [The new population] evolves frequently and generates a new population once the new population is complete, by repeating these following steps.

Selection: Through the population, two of the parents' chromosomes are selected based on their fitness (the higher the level of fitness to the better, the higher the possibility of selection).

Crossover: The crossing over of parents to produce a new generation (children) if there is a possibility of a crossover, and the offspring is the exact reflection of the parents in the case of no crossover possibility.

Mutation: The GA creates a fresh generation of mutations at each spot with a mutation probability (site on the chromosome).

Accepting: In the new society, the privileged new generation is stored.

1) [Replace] control freshly produced population to improve the algorithm's path.

2) [TEST] If the final condition is met, the program terminates and gives the best solution in this current set to them.

3) [Loop] Go the step 2.

The GA maintains a population of results $p(t)$ during repetition t . r'_i, r'_n , where r'_i refers to the rule set that is produced at random for each level. The function is used to evaluate each answer. $E(\bullet)$ and $E(r'_i)$ is an indicators of how suitable a solution is. A person's fitness value determines whether they have the necessary ability to live and procreate in the next generation. The next iteration is $(t+1)$. A new resident is formed based on the procedures (2) and (3) [30].

B. Data Encoding

A population often consists of several sets of rules. The coding method used by the system is called the Michigan approach, in which each chromosome is treated as a set of all applicable rules. For each level, with this approach, randomly generated association rules are introduced into each level. Michigan technology uses binary coding for its encryption, which is (0, 1), where the number "1" indicates that the knowledge base is included in the knowledge base, while the number "0" indicates that it is excluded, that is, it does not use it. The main advantage of this technique is that all the rules of the rule are codified, or in other words encrypted, and accordingly, there is no necessity to conduct a quantitative analysis of these rules that cannot be dispensed with, to know and determine that the method in which it is dealt with works as planned or not because it is quite unlike the Bates method, which compiles all possible rules at runtime Genetic algorithm. The size of the chromosome is inversely related to the size of the base of the base, meaning that if the size of the base of the bases increases, the size of the number of groups of elements also increases. Noting that the large size of the chromosome is a major defect [8][29] [31].

C. Generic Operators

It is common to use genetic factors for reproduction, crossover, and mutation. To achieve genetic operators, it is not necessary to select a single member of the population to work on. The aggregation plan depends primarily on the level of physical fitness of the entire population. The system controls the elections in the style of the roulette wheel model. Multiple parents and mutants are selected depending on their fitness, that is, the higher the value of the fitness function a candidate has, the higher the probability of being selected. To implement the sampling of the roulette wheel, first, all applicant values are normalized so that they have the same chance range, then a random number between 0 and 1 is estimated using the chance number function, and a candidate is tested based on a match between this value and an adjustment value The value is based on suitability and, accordingly, the candidate is elected [31].

After an individual has been selected, cloning operators do not move the individual as it is selected; instead, they just replicated it using the existing population through the new population without transfer. Starting with two selected and selected individuals, the intersection operator moves to the transition point (a number among l and $L-l$ being an integer, anywhere L is the length of the strings) chosen at random. The mutation is the third genetic factor. Random shifts in population composition and arrangement can intermittently or irregularly produce beneficial results by deviating from the local optimum. In GA, the sole purpose of this mutation is to oppose each leg of this chain, *i.e.* change 0 to 1 and vice versa change 1 to 0 with the chance of p_m [31].

The algorithm stops working when it reaches a state of deterioration or decay - if the chromosome produced changes between the best and the worst in the population, and this is by less than 0.1%. The implementation is completed when the final number of these generations that the user previously specified reaches. In addition, the algorithm avoids randomly generating the initial set because it can appear in rules that exclude training data in cases where the fitness is too low. Accordingly, a population of the same rules that are locked and contain at least one training instance may result in overfitting in the relevance of this data. The evidence showed that initializing non-random methods can improve the accuracy of the solution and can significantly reduce the running time. [24]. As a result, we developed a new approach to adapting practice case selection to serve as a “seed and foundation” for generating these rules based on a change in the groups of elements within each level. [32].

In general, the genetic factor helps to manage population heterogeneity and prevent early alignment with the local optimum [27]. The primary goal is the exploration of fascinating association rules. As a result, the fitness function is very necessary to check the significance of the chromosome, and it also greatly influences the convergence of the genetic algorithm. In this case, the proposed system checks two different fitness functions. The initial function of fitness is the congruent confidence of the corresponding correlation rule as in Eq. 3, while the connection between the confirmation (conf) and support (sup) properties of the second fitness function, which is necessary to determine the correlation rule (see Equation 4) [8] [12] [27]. The parameters α and β are the important factors for the confidence balance, support in the fitness function, $\beta+\alpha=1$. Using the GA approach to mine confirmed association rules from the huge database, the threshold for the fitness function had to be determined in advance; In this case. $\alpha=\beta=0.5$.

$$f_1: \text{rconf}(X \rightarrow Y) = \frac{\text{sup}(X \cup Y) - \text{sup}(X) \times \text{sup}(Y)}{\text{sup}(X)(1 - \text{sup}(Y))} \quad (3)$$

$$f_2(x \rightarrow y) = \alpha \times \text{sup}(x \rightarrow y) + \beta \times \text{conf}(x \rightarrow y) \quad (4)$$

By implementing the suggested approach, only the most interesting rules are announced by the fitness function-defined interestingness measure, as opposed to standard mining models that produce an infinite number of interesting rules. Because GA performs a find and deals globally with attribute cooperation better than greedy rule selection algorithms, they

are the preferred method for learning high-level prediction rules [27].

Very briefly, the evolutionary method that has been proposed here for mining quantum correlation rules is driven particularly by the following: (1) the passed rules may be too many to handle; (2) the search space may be too large when we encounter quantitative attributes; (3) users, even experts, usually get bored when specifying the minimum support; and (iv) quantitative attribute splitting is not available for every attribute and user [22]. However, mining association rules fall short in terms of benefits; they also have several flaws, most notably a sophisticated algorithm. With the number of things, the number of rules grows exponentially. However, certain sophisticated algorithms are used to tackle this complexity and effectively reduce the search space. The second challenge is choosing intriguing rules from a set of rules, or attaining rules from rules.

The proposed work tackles the second issue, which essentially helps the user scan the rule set, and useful quality controls on the rules are implemented based on genetic algorithms. Usually, managing association rule mining results in a large number of rules being discovered or inferred, confusing the user. More importantly, some of these criteria might not be necessary and produce no new information. Some efforts have been made to address duplicate rules in flat datasets, but redundancy in these datasets needs to be focused on because they can contain a hierarchy/taxonomy or compound idea levels. One of the characteristics of this study is this problem.

IV. EXPERIMENTS AND RESULTS

We perform various experiments in this section to evaluate the performance of the proposed strategy and validate the improvements. Experiments are performed on a computer Intel® Core™ i5-2450M CPU @ 2.50 GHz, running on a Windows 7, 64-bit operating system, x64-based processor, and 6 GB of memory. All codes are implemented under MATLAB version 7.8.0.

A. Dataset

We have relied on the information contained in [28] because it is considered an important standard to be used for comparison. And this incoming information consists of the data of the goods, their quantities, and their elements declared in each purchase container that was marketed, which is known as the market basket data. Each set of data contains more than 1,000 sales receipts for sales in a food warehouse, and each asset contains 7 contracts (10,000 transactions). The pre-determined classification in the first level contains 7 nodes that describe the items that were made in this test, and the second level consists of 14 nodes related to flavor, taste, taste or different types of other stocks and comes in the third level, which consists of 48 nodes that express information about factories and production companies. These transactions contain a database that contains some data such as the name of the product, its shape, and the quantity of the goods that were purchased. However, it is not permissible in any way to use the same element more than once in one transaction.

B. Methodology

The methodology proposed by investigating various analytical CRM characteristics in the retail industry, this thesis contributes to the marketing literature. Additionally, it offers recommendations for businesses on how analytical CRM is used to facilitate consumers' acquisition of information, which in turn improves the relationship with customers. This thesis also emphasizes the potential of large-scale database data mining techniques for CRM.

It was compared to the method typically used in [28] which proposes a method for mining multi-level fuzzy quantitative association rules that applies the GA optimization approach. The goal was to (1) enhance multi-level optimum support and confidence employed to obtain interesting rules to unearth fresh in-depth data. (2) Removing unnecessary rules that were present in the conventional method. Both approaches consolidate fuzzy boundaries rather than explicit border intervals by inferring large item collections top-down and with increasing depth.

In contrast to the conventional method, which relies on specialists to decide these values manually the suggested approach enables the mining of association rules based on the most advantageous recalculated mining parameters (min sup, min conf). By using GA to determine these characteristics, the suggested system becomes more universal and independent from context. The min-sup and min-conf criteria were chosen at 0.29 and 1.8 for each taxonomic level in the investigations.

In the first experiment, by using the data set we test whether we can provide association rules within a given time frame with a fixed number of first generations. From the results presented in Table I, we see that the initial population size ranges from 30 to 100. We can infer the most robust association rules in the dataset but if the population is too large, and quite the opposite if the population is too small The GA-based algorithm is similar to the stochastic algorithm. Because the computational complexity is rising rapidly, we cannot obtain complete association rules immediately. However, as we can see, there is a high chance that most association rules have already been discovered, even with a small population and a short time frame. As a result, we decided to choose 50 cohorts as the default cohort for the data set because it is compatible with the approach.

TABLE I. THE CONNECTION BETWEEN THE AMOUNT OF MULTILEVEL ASSOCIATION RULES AND THE NUMBER OF INITIAL GA POPULATION (GENERATION NO. 10 APPLYING MICHIGAN ENCODING USING F1)

No. of Initial population	30	50	70	100
N0. Of association rule (Redundant)	3709	608	608	608
N0. Of association rule (non-redundant)	1734	348	348	348

As the Michigan primary coding approach is the proposed system, the primary set used is the chromosome. This is the most important reason for the stability of the number of bases extracted with the initial set, which consists of 50 chromosomes, and each chromosome contains a comprehensive depiction of the rules and laws based on the

Michigan method, and therefore each set will include the least number of these initial sets in the selected bases.

Through the following set of experiments, and using the method based on the GA algorithm, we have verified the applicability of the extracted association rules, instead of the traditional algorithm without GA. And that is to measure its value through the 10,000 transactions, using the f_1 function formula through the initial group = 50, the generation number = 10, and the mutation rate = 0.1. The data set results are shown in Table II.

TABLE II. CONTRAST STUDY

Methods	No. Of Non-Redundant Rules	Calculated min-sup	Calculated min-conf	Time (Sec)
Proposed Method with GA	348	L1=0.95 L2=0.67 L3=0.27	L1=1.12 L2=1.45 L3=1.92	450 s
Traditional method without GA [8]	2282	0.28 (L=1 to 3)	1.7 (L=1 to 3)	400 s

TABLE III. COMPARISON STUDY OF THE 2 FITNESS

Fitness Function	levels	Computed Fitness	No. of association rules (non-redundant)
f_1 (Eq. 3)	level 1	1.90	348
	level 2	1.97	
	level 3	2.06	
f_2 (E.q.4) $\alpha = \beta = 0.5$	level 1	1.07	2248
	level 2	1.26	
	level 3	1.47	

TABLE IV. EVALUATION OF USING DIFFERENT GA PARAMETERS, THE PROPOSED SYSTEM F1

Parameters ratio	No. of association rules (.redundant)	No. of association rules (non-redundant.)
Mutation= 0. 9 Crossover = 0.1	750	418
Mutation=0.8 crossover=0.2	750	418
Mutation= 0.7 crossover= 0.3	608	348

As a result of the above, we find that the approach proposed by us, which is based on the GA algorithm, takes a little more time, by an estimated rate of about 13%, so that it can identify the rules of association with high relevance compared to the traditional method. But concerning quality, the system proposed by us can extract rules of higher quality and more interesting by about 17% of the total rules that were extracted from the comparative system based on the traditional method. In general, the decision maker will be hindered if there are a large number of rules extracted from the market basket analysis. The proposed system based on the GA algorithm

presents us with the most interesting rules according to the fitness function, which is responsible for the evaluation that simulates how perfect the answer is: the higher the number provided by the proposed system, the better the solution, and vice versa.

Through the implementation of the third group of experiments, to compare the suitability of the mined association rule using either the fitness function that takes both support and confidence characteristics into account (Eq. 4). or even a fitness function that takes the relative confidence of the associated association rule into account (Eq. 3). Note that the experiment was performed based on the previous configuration of the GA. Accordingly, and through the results presented in Table III, we find that the use of f_1 improves the mining of association rules and generates an additional improvement in the rate of mined association rules while reducing the amount of extracted rules by 83%. Through this experiment, we conclude that the fitness function is a very crucial issue in the success of GA. This was shown clearly as GA did not get any benefit or advantages from using the f_2 state, and thus we got the same amount of bases extracted as we did use the traditional method (about 2248).

The use of f_1 mainly helps in improving the performance of GA, and this is through the optimal extraction of interesting rules, because of the support of each of the elements separately, as well as the calculation of the union support of the elements in each of these rules, and this is quite the opposite of the function that performs based on use support and confidence for each rule, according to the standard case used in current mining algorithms (such as the Apriori algorithm).

By studying the effect of the GA factor settings on the proposed system, which includes both the mutation rate and the crossover rate, and after it has been compared with several multilevel quantitative mining algorithms. Then we'll just change the setting to just one parameter at a time leaving the setting for another parameter at its default value to keep the number of blend settings small. Table IV shows us the number of (non-redundant) association bases that the system was able to identify in the used dataset with the mutation rate changed from 0.7 to 0.9. The above table shows that decreasing the mutation rate will reduce the number of bases extracted by 17%. This regression is very clear. Managing mutations to maintain genetic heterogeneity from one generation to the next was the main reason for this decline. In GA, intersection operators are used very extensively to supervise the population to focus on one of the best solutions yet. Mutation factors are frequently used to provide exploration (exploitation). As a result, while an intersection tries to focus on a specific area of the scene, a mutant does its best to avoid convergence and explore additional areas.

V. CONCLUSION

The proposed system provides rules based on interesting metrics, and we can easily extend the capabilities of the system if needed by changing the fitness function, and the final results show us the possibility of using quantitative correlation rules to support CRM managers. As the proposed system based on association rule mining maintains a very high accuracy when

comparing the proposed algorithm with traditional methods. In addition, the extracted rules are very close to reality. This is because different organic functions are adopted for each unique element. The minimum level of support and confidence is improved. Finally, the non-redundant algorithm was used to improve the quality and application of rules to facilitate interactions between the expert system and the users. This method can be viewed as a knowledge acquisition tool for market basket discovery and analysis (MBA), which helps CRM managers to improve their decision-making process. Future work involving the use of CRM is supported by an association rule based on genetic taboos that use GA to modify the fuzzy membership function of each element.

Abstract—The automotive industry has experienced swift development with the rapid growth of the economy. The increasing number of vehicles has led to deteriorating road traffic conditions, increased consumption of nonrenewable energy, and excessive vehicle emissions. To tackle the problems of fuel efficiency and safety control for vehicle platoons, this study suggests a novel leader-follower optimal control method for vehicle platoons to improve fuel efficiency. Depending on where vehicles are in a platoon, they are classified into two categories: the leader vehicle and follower vehicles. The differing driving circumstances of these two types of vehicles are considered in this paper by using various control methods. On the one hand, the leader vehicle uses an approximate fuel consumption model to improve computational efficiency. At the same time, speed and acceleration are constrained to obtain the speed optimization curve. The follower vehicle uses a distributed receding horizon control method, which calculates the vehicle's speed optimization profile online. On the other hand, a linear following model is used to prevent collisions between vehicles and ensure the safety of the vehicle platoon. The simulation experiment has demonstrated that this speed optimization control method can reduce the fuel consumption of the vehicle platoon and ensure the safety of the vehicles.

Keywords—Vehicle platoon speed optimization control; leader vehicles; follower vehicles; distributed re-eding horizon control method; vehicle platoon fuel consumption control

I. INTRODUCTION

In recent years, all industries have experienced swift development with the rapid growth of the economy. The automotive industry is no exception. According to the Ministry of Public Security, by the end of March 2022, the number of motor vehicles in the country was expected to reach 402 million, including 307 million cars. Moreover, this growth projected 487 million motor vehicle drivers, including 450 million car drivers [1]. The increasing number of vehicles has led to deteriorating road traffic conditions, increased consumption of nonrenewable energy, and excessive vehicle emissions [2]. A typical approach to addressing these problems is to accelerate the development of intelligent transport systems, and vehicle platoon control technology has received widespread attention as an important component of these systems [3].

One useful means to address to improve fuel efficiency problem is to control vehicles in a common lane to run in platoons with small inter-vehicle spacing. Arranging vehicles into a queue with a smaller distance between vehicles can effectively improve traffic flow efficiency and reduce traffic

congestion. At the same time, this strategy can also decrease the air resistance of vehicles in the vehicle platoon to reduce vehicle platoon fuel consumption and exhaust emissions. The coupling between vehicles during vehicle platoon operation is readily apparent, and vehicle platoon fuel consumption is greatly influenced by air resistance. Thus, appropriately controlling vehicle platoon speed can significantly reduce vehicle fuel consumption [4].

Platoon speed optimization control methods involve the use of advanced control algorithms and techniques for real-time monitoring and control of platoon speed. Common implementations of optimal platoon motion control include traditional proportional-integral-derivative control (PID), model predictive control (MPC), fuzzy control (FC), adaptive cruise control (ACC), rolling horizon control (RHC), and other methods. In addition, artificial intelligence techniques such as machine learning can be used to analyze and process the movement data of vehicles in a platoon, thereby improving the accuracy and efficiency of control. The platoon motion optimization control method has a wide range of promising applications in the fields of vehicle manufacturing and autonomous driving technology.

The remaining part of this paper is organized as follows: Section II briefly covers the related work. Section III is an introduction to the relevant models, including the fuel consumption model and the linear-following model. In Section IV, a leader-follower vehicle speed optimization control method for the vehicle platoon is given to reduce the overall fuel consumption of the platoon. This method includes two parts: the pilot vehicle speed optimization control method and the follower vehicle speed optimization control method. Section V presents the simulation validation and analysis. The practicality and effectiveness of the method are verified under simulation experiments and comparisons with other methods. Section VI presents the contributions and conclusions of this study.

II. RELATED WORKS

Initial research on fuel consumption-oriented speed optimization control methods focused on speed optimization control methods for a single vehicle. Many scholars have focused their attention on the influence of the road environment on vehicle fuel consumption. Regarding the study of fuel consumption of vehicles at signalized intersections, Xiaolin Tang et al. [5] proposed a multiobjective hierarchical optimal (MOHO) strategy by building a road model based on the real phase and position information of traffic signals. This

strategy can improve passenger ride comfort and fuel economy. According to Ding Feng et al. [6], the established vehicle dynamic model and an instantaneous fuel consumption model can yield the ideal constant speeds corresponding to circular curves of various radii. Jiaqi Ma [7] et al. proposed a fuel consumption optimization method for connected and automated vehicles (CAVs) on rolling terrains. This method is based on established vehicle dynamics and fuel consumption models. The newly developed algorithm was validated on a CVA platform, and the eco-drive's fuel-saving benefits were quantified.

As vehicle fuel consumption is closely related to aerodynamic drag [8], controlling vehicles to run in platoons with small intervehicle spacing in a common lane is reasonable. In fact, this approach can effectively reduce the fuel consumption of a platoon. Multiple studies [9-12] have shown that platooning can reduce fuel consumption.

In recent years, many scholars have focused their attention on the issue of vehicle platoon control. There are currently many control methods concerning vehicle platoons. The choice of vehicle In recent years, many scholars have focused on the issue of vehicle platoon control, and man control methods are currently available for vehicle platoons. The choice of vehicle control method usually depends on the specific control objectives, constraints, and environmental factors. Common control models include proportional-integral-derivative control [13, 14], adaptive cruise control [15, 16], and model predictive control [17-20]. These control methods have been extensively researched to reduce platoon fuel consumption. Communication delays will reduce the robustness of the vehicle platoon. Xu Zhu et al. [21] designed a distributed proportional-integral-derivative con-troller to improve the robustness of the vehicle platoon by obtaining strong stability conditions and upper bounds on communication delays. Cooperative adaptive cruise control (CACC) vehicles can improve the stability of the vehicle platoon and reduce emissions and fuel consumption. Yanyan Qin et al. [22] investigated the correlation between these two factors. Stability conditions for the vehicle platoon are calculated using car-following models to explore the relationship between stability and emissions. RHC and MPC are two methods based on predictive control, with the main difference being the design of the controller and how it is calculated. MPC achieves high-precision control of the system state by building a dynamic model of the system and using optimization techniques to solve for the state and control signals over several future time steps. RHC achieves high accuracy in the control of the system state by decomposing the control problem into a series of subproblems and solving each subproblem using a predictive model. Valerio Turri et al. [23] proposed a method that can dynamically calculate the optimal speed profile based on the fuel consumption of the vehicle platoon and enable real-time control of the vehicle platoon based on the DMPC method. In Chunjie Zhai et al.'s study [24], an ecological cooperative look-ahead control problem (Eco-CLC) based on distributed model predictive control (DMPC) was presented. The study addressed an autonomous vehicle platoon travelling on highways with varying slopes. Moreover, a particle swarm optimization approach with numerous dynamic populations increases

computational efficiency. To improve the fuel economy of a parallel hybrid electric vehicle (HEV), Bo Zhang et al. [25] formulated a receding horizon control problem based on a cost function of energy consumption and optimized it with a sequential quadratic programming algorithm. The results of the simulation platform validate that the pro-posed strategy can improve fuel economy.

Existing efforts to optimize vehicle platoon speed for fuel consumption often focus on setting the speed of the leader vehicle as a reference speed for the follower vehicle and optimizing the speed of the vehicles in the vehicle platoon on this basis. However, adopting a fixed reference speed for the leader vehicle is not reasonable for realistic road conditions. In addition, most of the speed optimization control strategies for vehicle platoons have complex cost functions and additional constraints, resulting in reduced computational efficiency. Therefore, the construction of the optimization problem and improvement of computational efficiency warrant exploration.

To address the aforementioned issues and lower the vehicle platoon's fuel consumption, this study proposes a fuel consumption-oriented vehicle platoon speed optimization control method based on a fuel consumption model. To improve the efficiency of the calculation, a simpler approximate fuel consumption model is used for the pilot vehicle. Because the motion states of the following vehicle are constrained by the vehicle ahead, the follower vehicles use a distributed receding horizon control method. This technology, which is both forward looking and real time, enables the vehicle platoon's ideal speed profile to be forecasted in advance based on the current driving traffic scenario and road environment for fuel consumption.

III. INTRODUCTION TO RELATED MODELS

A. Fuel Consumption Model

The fuel consumption model describes the relationship between vehicle driving and vehicle fuel consumption. Fuel consumption is influenced by the vehicle's performance (such as tractive effort, engine torque, mass, etc.), road features (such as the slope of a road), and traffic circumstances (traffic volume). Fuel consumption models can be broadly classified into three categories according to their form: instantaneous fuel consumption models, mode fuel consumption models, and average speed fuel consumption models. The instantaneous fuel consumption model is based on the relationship between fuel consumption and the instantaneous state of the vehicle. The fuel consumption model used in this study is such a model. The leader vehicle and the follower vehicle operate with different constraints and use different fuel consumption models. The leader vehicle is not constrained by the vehicle in front of it and uses a simpler fuel consumption model, which improves the efficiency of the calculation. Follower vehicles are also subject to more stringent constraints and use a more stringent fuel consumption model to enable the vehicle to travel safely and smoothly.

The fuel consumption model used in this study for the leader vehicle is an approximate fuel consumption model obtained by a quadratic approximation [26] to the Australian Rod Research Board (ARRB) model proposed by Akcelik. A

special case of an approximate fuel consumption model is where just the square of the acceleration can be used as a proxy for minimizing fuel consumption. This particular approximate fuel consumption model reduces computational effort and increases computational efficiency. At the same time, the fuel consumption calculated with this fuel consumption model does not significantly differ from the actual fuel consumption. The expression for this parameter is shown below.

$$\tilde{f}(v(t), a(t)) = \frac{1}{2} a(t)^2 \quad (1)$$

$\tilde{f}(v(t), a(t))$ denotes the secondary approximate instantaneous fuel consumption. $v(t)$ and $a(t)$ denote the velocity and acceleration of the vehicle at moment t .

However, when the vehicle is on the road, the fuel consumption of the vehicle depends not only on the acceleration of the vehicle but also on various other factors, such as engine speed, gear ratio, torque, and efficiency. The following approximate fuel consumption model is chosen for the fuel consumption model of the follower vehicle, as the movement ecology of the follower vehicle is more complex than that of the leader vehicle [27]. The fuel consumption model is expressed as follows:

$$f_{i,v}(t) = \begin{cases} b_0 + b_1 v_i(t) + b_2 v_i^2(t) + b_3 v_i^3(t) + \hat{a}_i(t)(q_0 + q_1 v_i(t) + q_2 v_i^2(t)) & a_i(t) \geq 0 \\ 0 & a_i(t) \leq 0 \end{cases} \quad (2)$$

where $b_0, b_1, b_2, b_3, q_0, q_1,$ and q_2 are parameters of fuel consumption model. When the acceleration $a_i(t)$ is greater than zero, the first part of the expression, $b_0 + b_1 v_i(t) + b_2 v_i^2(t) + b_3 v_i^3(t)$, represents the fuel consumption generated per unit time of the vehicle at velocity $v_i(t)$, and the second part, $\hat{a}_i(t)(q_0 + q_1 v_i(t) + q_2 v_i^2(t))$, represents the additional fuel consumption generated by the corresponding equivalent acceleration $\hat{a}_i(t)$ at velocity $v_i(t)$. Moreover, $\hat{a}_i(t) = a_i(t) + a_G(t)$, $\hat{a}_i(t)$ denotes the equivalent acceleration related to the acceleration $a_i(t)$ and the acceleration $a_G(t)$ caused by the ramp. In this study, the ramp of the road is not considered; therefore $\hat{a}_i(t) = a_i(t)$.

B. Linear Car-Following Model

A car-following model uses kinetic theory to investigate the change in motion of followers if the vehicle in front of them changes its motion state when the platoon is driving in a single non-overtaking lane. A mathematical model [28] is also used to create a model that is more consistent with the actual vehicle motion. In a platoon, the leader drives in traffic situations with low traffic density and large workshop distances without being influenced by surrounding vehicles and in a free-motion state. The follower vehicles are affected by traffic rules, the performance of the vehicle, and the surrounding vehicles. To

ensure safe driving, the speed of the follower vehicle is adjusted to avoid collisions with the vehicle in front of it; it cannot be driven at will by the driver's intentions and is not in a free-motion state. A diagram of the vehicle platoon's linear car-following model is shown in Fig. 1.

Fig. 1. Schematic diagram of the vehicle platoon's linear car-following model.

The vehicle platoon in Fig. 1 consists of $n-1$ vehicles, and $x_i(t)$ denotes the motion state of the follower vehicle i , $x_i(t) = [p_i(t), v_i(t), a_i(t)]^T$. The motion state $x_i(t)$ contains the position $p_i(t)$, the velocity $v_i(t)$, and the acceleration $a_i(t)$ of vehicle i . D denotes the distance between vehicles.

In the linear car-following model, when the motion of the previous vehicle changes, the motion of the follower vehicles also changes. If the reaction time is h , then the velocity of vehicle $i+1$ at moment $t+h$ can be expressed as:

$$\ddot{p}_{i+1}(t+h) = \lambda \left[\dot{p}_i(t) - \dot{p}_{i+1}(t) \right] \quad (3)$$

Where $\lambda = \frac{1}{h}$, λ and h denote the response sensitivity and delay time.

$\ddot{p}_{i+1}(t+h)$, $\dot{p}_i(t)$ and $\dot{p}_{i+1}(t)$ denote acceleration of the vehicle $i+1$ at time $t+h$, the velocity of the vehicle i and the velocity of the vehicle $i+1$ at time t respectively.

IV. OPTIMAL CONTROL METHOD OF VEHICLE PLATOON LEADING-FOLLOWING SPEED

The speed optimization problem for a platoon can generally be described as follows: given a starting point and an endpoint for each vehicle in the vehicle platoon, the overall vehicle platoon fuel consumption is minimized subject to certain constraints. In this study, a platoon of n vehicles is driven in a single lane for a distance on a road section without overtaking or changing behaviour. The communication topology chosen for this study is the predecessor-leader following type (PLF). This communication topology allows each follower vehicle to obtain information about the motion state of the leader vehicle and the previous vehicle. All vehicles in the platoon are divided into a leader vehicle and a follower vehicle. Different optimal control methods are employed for the leader vehicle and the follower vehicle to reduce the overall fuel consumption of the vehicle platoon along a specific segment of a one-way road. p_i , v_i , and a_i denote the position, velocity, and acceleration of vehicle i ($i=0,1,\dots,N-1$), respectively. l_i , d_i , and del_i denote the length of vehicle i , the desired workshop distance, and the error between the actual workshop distance and the desired workshop distance, with vehicle $i=0$ and others being followers. The leader vehicle must reach its final

state within a time range of T , where x_e and v_e are the final positions and the vehicle's driving speed, respectively. The time range T is within a reasonable range and can be obtained using constraints.

A. Optimal Speed Control Method for Leader Vehicle

To minimize the fuel consumption of the leader vehicle, the following fuel consumption optimization problem is used to control the leader in this study.

$$\min J_0 = \int_0^T f(v_0(t), a_0(t)) dt \quad (4)$$

where J_0 denotes the amount of fuel consumed by the leader vehicle while driving for T hours. $a_0(t)$ and $v_0(t)$ denote the leader vehicle's acceleration and speed at time t . T denotes the total driving time. $f(v_0(t), a_0(t))$ denotes the instantaneous fuel consumption of the leader vehicle. The instantaneous fuel consumption model used in this study is a special case, $f(v_0(t), a_0(t)) = \tilde{f}(v_0(t), a_0(t)) = \frac{1}{2} a_0(t)^2$.

Here, the Hamilton function is used to transform the optimization problem into an extreme value problem and to solve the leader vehicle equation of motion state, which contains the acceleration $a_0(t)$, the velocity $v_0(t)$, and the displacement equation $p_0(t)$, all of which are multiple functions of time t . The expressions are as follows:

$$a(t) = c_1 t + c_2 \quad (5)$$

$$v(t) = \frac{1}{2} c_1 t^2 + c_2 t + c_3 \quad (6)$$

$$p(t) = \frac{1}{6} c_1 t^3 + \frac{1}{2} c_2 t^2 + c_3 t + c_4 \quad (7)$$

Where c_1 , c_2 , c_3 , and c_4 are constants in the equation. These four constants can be solved by known conditions (velocity v_{00} , position P_{00} at the initial moment of the leader vehicle and velocity v_{0e} , position P_{0e} at the end moment) and constraints.

The leader vehicle has certain constraints on speed and acceleration during the actual driving process.

For the safety of the vehicle, the velocity $v_0(t)$ needs to be limited and the speed constraint of the leader vehicle can be expressed as:

$$0 \leq v(t) \leq v_{\max} \quad (8)$$

To ensure the comfort of the passengers riding in the process of the vehicle, it is necessary to constrain the acceleration of the leader vehicle, and the constraint can be expressed as:

$$a_{\min} \leq a(t) \leq a_{\max}, (a_{\min} \leq 0, a_{\max} \geq 0) \quad (9)$$

Where v_{\max} , a_{\min} , and a_{\max} are the maximum speed of the vehicle, the minimum acceleration, and the maximum acceleration possible, respectively.

To meet the above condition restrictions, the total duration T of the journey must be within a reasonable range rather than an arbitrary time. If the velocity of the leader vehicle at the initial moment $v_{00} = 0$, the initial position $p_{00} = 0$, the velocity at the end moment $v_{0e} = 0$ and the final position $p_{0e} = X$, where X is a constant and T denotes the total distance traveled by the leader vehicle. If the starting velocity v_{00} and the starting acceleration a_{00} of the leader vehicle are other values, it is still possible to solve for a range of values for the total time T . The equations of states (6) and (7) for the leader vehicle allow the solution of the unknown parameter

$$c_1 = -\frac{12X}{T^3}, c_2 = \frac{6X}{T^2}, c_3 = 0, c_4 = 0.$$

The acceleration for the leader vehicle is a monotonically decreasing function. When $t = 0$, equation (5) takes a maximum value. When $t = T$, the equation takes the minimum value. The range of T values can also be obtained using the acceleration constraint in (9).

$$\begin{cases} T \geq \sqrt{\frac{6X}{a_{\max}}} \\ T \geq \sqrt{\frac{6X}{a_{\min}}} \end{cases} \quad (10)$$

Similarly, the maximum and minimum values of the vehicle speed can be found in (6). When $t = 0$ or $t = T$, the speed equation takes the minimum value. The maximum point of the function is the maximum value when $t = -\frac{c_2}{c_1}$.

Combining this with the velocity constraint, (8) gives a range of values for T .

$$T \geq \frac{3X}{2v_{\max}} \quad (11)$$

Combining (10) and (11) can be obtained from the leader vehicle driving the total time T range of values.

B. Optimization of the Speed of the Follower Vehicles

The fuel consumption minimization problem of the follower vehicles is solved using the distributed receding horizon control method. The time slice of size T_0 is in the time domain of the total platoon driving time T , which is considered the look-ahead domain of the vehicle. At the same time, the look-ahead domain T_0 is divided into M time slices h (h is the reaction time of the follower vehicles). When the optimal control sequences for the follower vehicles in the look-ahead domain are solved, the first step of the optimal control sequences is applied. The dynamic planning diagram is shown in Fig. 2 below.

Fig. 2. Follower vehicle dynamic planning diagram based on the distributed receding horizon control method.

The total fuel consumption of the vehicles moving in the forward-looking domain at time T_0 is minimized if the total fuel consumption of each subsequent vehicle is minimized at time T_0 . The overall fuel consumption of the vehicles throughout all of the time T is minimized if the total fuel consumption of all the vehicles throughout the forward-looking domain T_0 is minimized. Thus, the speed optimization problem based on the combined fuel consumption of the vehicles in front of it can be changed into a speed optimization problem based on the fuel consumption of each vehicle. Eq. (12) shows the total fuel consumption J_1 for all follower vehicles driving T_0 . The optimal control problem for single-follower driving T_0 is shown in (13).

$$J_1 = \sum_{i=1}^{n-1} \int_t^{t+T_0} f_{i,v}(x_i(s), u_i(s)) ds \quad (12)$$

$$\min F = \min \sum_{i=1}^{n-1} \int_t^{t+T_0} F_i(x_i(s), u_i(s)) ds \quad (13)$$

where F_i denotes the cost function of the follower vehicle i , expressed as follows:

$$F_i = \psi_i f_{i,v}(x_i(t)) + \frac{1}{2} \beta_i (u_i(t))^2 + (r_i(t) - y_i(t))^T (r_i(t) - y_i(t)) \quad (14)$$

where the first term relates to the fuel consumption of the vehicle. β_i and ψ_i denote the corresponding weights and are constants. $f_{i,v}(x_i(t))$ denotes the immediate fuel consumption of the follower vehicle i . It is obtained through (2).

$u_i(t)$ is the vehicle's control input in the second period. The nonlinear model [29] was transformed into a linear model by using a linear feedback technique [30]. The computation is simplified. The structural formula is defined as follows:

$$u_i(t) = k_1 v_0(t) - k_2 v_i(t) + k_3 a_0(t) - k_4 a_i(t) \quad (15)$$

Where k_1 , k_2 , k_3 , and k_4 denote various parameters. $v_0(t)$ and $a_0(t)$ denote the leader's velocity and acceleration in a platoon, respectively.

The third term is related to minimizing the difference between the reference output and projected value. The prediction error is assumed to be the difference between the

predicted output $y_i(t)$ and the reference output $r_i(t)$. This quantity of feedback is added to achieve feedback correction. $x_i(t) = [p_i(t), v_i(t), a_i(t)]^T$ denotes the motion state of vehicle i in the platoon at time t . $p_i(t)$, $v_i(t)$ and $a_i(t)$ denotes the position, speed, and acceleration of vehicle i at time t . $y_i(t) = [v_i(t), a_i(t)]^T$ denotes the predicted output, including the speed and acceleration of the follower vehicle i at time t . $r_i(t) = [v_{oi}(t), a_{oi}(t)]^T$ denotes the output of the follower vehicles, i.e., the desired speed and acceleration of the follower. It is obtained using the linear following model.

With the PLF communication topology, the leader vehicle can broadcast messages to all follower vehicles. When the motion state of the leader vehicle changes the motion state of all followers also changes. Their reaction times are the same, both being h . The reference speed and acceleration output of the follower vehicle in a platoon at time t can be obtained from the leader vehicle and the current vehicle speed and position at the previous moment, as follows:

$$a_{oi}(t) = \lambda(v_0(t-h) - v_i(t-h)) \quad (16)$$

$$v_{oi}(t) = \lambda(p_0(t-h) - p_i(t-h)) \quad (17)$$

where $\lambda = \frac{1}{h}$, $a_{oi}(t)$, $v_0(t-h)$, and $v_i(t-h)$ signify the sensitivity, the follower vehicle's acceleration at time t , the leader vehicle's velocity, and the follower vehicle's velocity at time $t-h$, respectively. The symbols $v_{oi}(t)$, $p_0(t-h)$, and $p_i(t-h)$ denote the velocity of vehicle i at time t , the position of the leader vehicle, and the position of the follower vehicle i at time $t-h$.

The forward-looking domain T_0 is split into M time slices to numerically solve the optimal control issue. Euler's approach is then used to discretize the vehicle's motion state. A Hamiltonian function is constructed from the equation of the state and cost function of the vehicle. The prediction output equation can be solved according to the control equation, the costate equation, and the state equation. The constructed Hamiltonian function is solved iteratively to provide the predictive motion state equation, as shown in (18).

$$y_{i,k+1}(t) = (A_i h + I_3)^{k+1} x_{i,0}(t) + \sum_{j=0}^k (A_i h + I_3)^{k-j} B_i h u_{i,j}(t), \quad (18)$$

$$k = 0, 1, \dots, M-1$$

where $x_{i,0}(t) = [v_{0,i}(t), a_{0,i}(t)]^T$ denotes the current state, and I_3 is a third-order unit matrix.

According to (18), the predicted motion state equation can be represented by the current state information $x_{i,0}(t)$ and the future control sequence $u_{i,j}(t)$ together. The necessary condition for solving the optimal solution of the equation is

that the control equation $\frac{\partial H}{\partial u_i} = 0$. The optimal control series is obtained by an iterative algorithm. The first step in obtaining the optimal series is then applied as the control input for the next moment of the platoon.

V. SIMULINK SIMULATION VERIFICATION AND ANALYSIS

A. Experiments and Simulink Simulation

Three main methods are available for studying the fuel economy of vehicles: wind tunnel experiments, road experiments, and simulation methods. Among these three methods, wind tunnel experiments provide more accurate control of the influences that affect vehicle platoon fuel consumption. Road experiments are more realistic and reliable. Simulation experiments are more cost-effective, safer, and simpler than the other two methods. Therefore, this study chose to verify the feasibility of the method through simulation experiments.

The vehicle platoon in the simulation experiment consists of ten vehicles. The vehicle platoon traveled 2000m. The powertrain model parameters of the vehicles are shown in Table I.

TABLE I. VEHICLE POWERTRAIN MODEL PARAMETERS

Vehicle Parameters	Identifier	Data	Unit
Mass	m_i	1464	kg
Air Resistance	ρ	1.29	kg / m ³
Cross-sectional Area	A_i	2.2	m ²
Drag Coefficient	c_{di}	0.35	—
Mechanical Drag	d_{mi}	5	N
Time Constant of an Engine	ζ_i	0.25	—

Set the controller parameters to meet the requirements: $k_1 = 0.2516$, $k_2 = 0.51175$, $k_3 = 0.2601$, $k_4 = 0.1021$, $M = 150$. To ensure the safe movement of the vehicle platoon, according to the speed regulations, vehicles in a platoon should not exceed 50km/h on a one-way urban road. Therefore, the speed constraint for the leader vehicle is $0 \leq v_i \leq 13.9m/s$. At the same time, a typical vehicle can currently accelerate from zero to 100m/s in 10s. The average acceleration is $2.2778m/s^2$. The maximum acceleration can be up to $6m/s^2$. As a result, the acceleration of a typical vehicle when braking is $-6m/s^2$. Therefore, the acceleration constraint is $-6m/s^2 \leq v_i \leq 6m/s^2$. According to the literature [23], the acceleration restriction is typically set to $-2m/s^2 \leq v_i \leq 2m/s^2$ to make passengers feel comfortable. The leader vehicle's maximum velocity and acceleration are as stated above. The range of values for the total duration can be determined by combining (10) and (11). This study's total running time is $T = 250s$.

Under the direction of the integrated controller, Simulink simulations can be used to determine the acceleration-time

curve and velocity acceleration-time curve for each vehicle in the vehicle platoon, as shown in Fig. 3 and Fig. 4. From Fig. 3, it is noticed that that each vehicle in the vehicle platoon will swiftly finish the speed-up. All vehicles' acceleration values fall within the range $-0.8m/s^2 \leq v_i \leq 0.8m/s^2$. The vehicles' consistent acceleration improves the comfort of the passengers. From Fig. 4, the speed of all vehicles satisfies the speed constraint for vehicles traveling on a one-way urban road, which should not exceed 50km/h. The vehicles in the vehicle platoon converge at the same speed for all vehicles and stabilize within the vehicle platoon at around ten seconds.

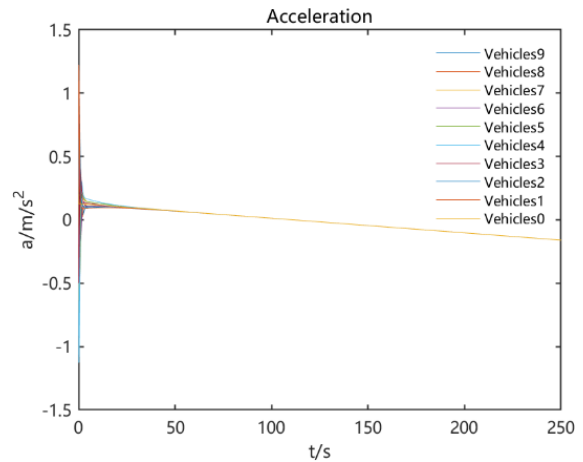

Fig. 3. Acceleration-time curve.

Fig. 4. Velocity-time curve.

For the follower vehicles in the platoon, use the parameters in the fuel consumption model: $b_0 = 0.1569$, $b_1 = 2.450 \times 10^{-2}$, $b_2 = -7.4152 \times 10^{-4}$, $b_3 = 5.975 \times 10^{-5}$, $q_0 = 7.224 \times 10^{-2}$, $q_1 = 9.681 \times 10^{-2}$, $q_2 = 1.078 \times 10^{-3}$. The vehicle length is $D = 3m$. According to the Road Traffic Safety Law of the People's Republic of China, when the speed is below 50km/h, the safe distance between vehicles is not less than 50m. Therefore, this study sets the desired vehicle distance $od_i = 60m$. The fuel consumption-time curve for the vehicle platoon is shown in Fig. 5. Compared to other controllers, the

vehicle platoon using the controller provided in this study consumes less fuel and saves significantly on fuel consumption. The curve of the workshop distance error over time is shown in Fig. 6, with the maximum workshop distance error not exceeding 8 meters. The workshop distance is still within the safe workshop distance range, ensuring the vehicle platoon's safety.

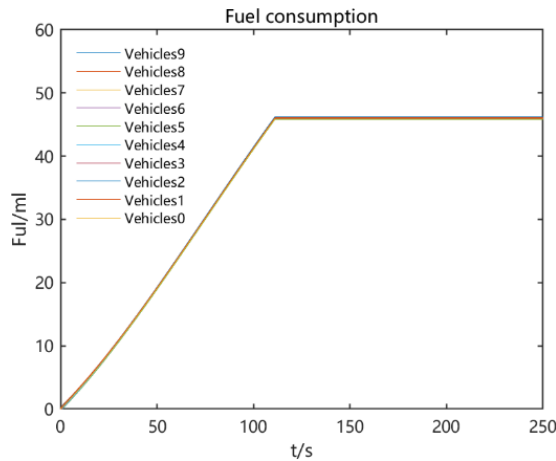

Fig. 5. Fuel consumption-time curve per vehicle.

Fig. 6. Workshop distance error-time curve.

B. Analysis and Comparison

The following comparison will focus on five characteristics of the four controllers, including (1) the utilization of vehicle platoon technology. Using vehicle platoon technology, a collection of vehicles is arranged into a platoon beside a workshop. It is essential and of considerable practical value to use the platoon as a focal point for vehicle speed optimization problems because it has major benefits in the four key areas of enhancing traffic capacity, decreasing emissions and traffic accidents, and reducing fuel consumption. (2) The optimization of the speed of the leader vehicle is also considered. The current literature on optimal vehicle platoon speed control often focuses on setting the speed of the leader vehicle as a reference speed for the follower vehicles. Adopting a fixed reference speed for the leader vehicle is not reasonable in light of actual traffic conditions. In this study, speed optimization is applied to the lead vehicle of a vehicle platoon on this basis.

(3) The possibility of boosting the computational effectiveness is also considered. Increasing the computational efficiency is crucial since solving fuel consumption-focused speed optimization problems can be computationally taxing due to complex traffic conditions and a large number of moving vehicles. (4) Predictive control is then applied. The vehicle's movement is analysed and processed by predictive control. The speed of the vehicle can be quickly changed when unforeseen circumstances arise. (5) Lastly, the decision to increase fuel effectiveness is made. Since oil is a nonrenewable energy source, energy usage needs to be decreased. Fuel consumption and vehicle emissions should be lowered. It is essential to increase vehicle fuel efficiency and environmental protection.

In the same simulation environment, the integrated controller in this work is contrasted with the three controllers in the following literature based on five factors. Table II presents the outcomes.

TABLE II. COMPARISON WITH OTHER CONTROLLERS IN TERMS OF FUNCTIONALITY

Characteristics	this paper	Literature [27]	Literature [24]	Literature [23]
Using platoon technology	✓		✓	✓
Speed optimization of the leader vehicle	✓			
Improving computational efficiency	✓	✓	✓	
Enabling predictive control	✓		✓	✓
Improving fuel efficiency	✓	✓	✓	✓

The literature [27] focuses on enhancing the calculating efficiency. While the computations are simplified, significant fuel savings are achieved, but this process applies to a more demanding environment. The literature offers a state-constrained multi-objective switching control approach [24]. In addition to increasing fuel efficiency, it can also increase vehicle stability and safety. The leader vehicle's state of motion is known and used as a reference state for the follower vehicles in this procedure. State limitations are prevalent in the control strategies suggested in the literature [23]. State limitations decrease efficiency and raise computing complexity. By classifying the vehicle platoon's vehicles and streamlining calculations while enhancing computing efficiency, the controller in this study increases the vehicle platoon's fuel efficiency. Due to the lack of vehicles in front of the leader vehicle, it has a relatively simple traffic environment. The leader vehicle fuel consumption model is simplified to improve the efficiency of the calculation. Speed and acceleration constraints are also added to improve the safety of the vehicle. For the follower vehicles, the distributed receding horizon control method is used, which is forward looking and real time.

Vehicle fuel consumption is one of the most important indicators of vehicle fuel economy, reflecting the fuel consumption of the vehicle during the driving process. Vehicle fuel consumption as an evaluation indicator of the method plays an important role in evaluating vehicle performance and energy efficiency. Under the same simulation environment, the

fuel consumption of each vehicle in the platoon under the classification controller in this paper is calculated and compared with that under the controllers set up in other literature according to the fuel consumption model, as shown in Fig. 7. The data relating to the total fuel consumption of the platoon under the controllers set up in other literature is analyzed, and the results in Table III show that the reduction in fuel consumption of the platoon under the action of the classification controller is significant.

Fig. 7. The fuel consumption of the vehicles in the platoon based on the classification controller in this paper was compared with fuel consumption under controllers set up in other literature.

TABLE III. COMPARISON OF VALUES WITH OTHER CONTROLLERS IN TERMS OF FUEL CONSUMPTION

Fuel consumption	this paper	Literature [31]	Literature [22]
Total value	468.81	523.13	513.29
Average value	46.88	52.31	51.32
Minimum value	46.60	48.81	50.40
Maximum value	47.62	56.91	52.12
Median value	46.76	51.99	51.71
Standard deviation	0.33	3.03	0.70

VI. DISCUSSION

This section includes the main conclusions obtained during the experimentation. Furthermore, future work is included on how to continue the line of research, based on the premises of this article.

A. Conclusion

This paper is mainly oriented toward a vehicle platoon fuel consumption problem and the platoon fuel consumption problem. A novel leader-follower optimal control method for vehicle platoons to improve fuel efficiency is proposed. The vehicles are divided into leader vehicle and follower vehicles according to their position in the platoon and are controlled differently and optimally.

Firstly, the leader vehicle uses a relatively simple fuel consumption model to simplify the fuel consumption model of the vehicle and the optimization problem oriented to fuel consumption, improve the efficiency of the method calculation, and shorten the time for the vehicle to obtain the queue information. The vehicle transmits information about its movement status to other vehicles around it promptly so that the vehicle itself and surrounding vehicles can react accordingly to unexpected situations and reach safe driving purposes.

Secondly, the follower vehicles, being constrained by the vehicle in front, can choose a more complex and accurate fuel consumption model and a more sophisticated speed optimization control algorithm for real-time control based on the motion of the vehicle in front. The follower vehicles use a distributed rolling horizon control method. This method decomposes the global control problem into several local control problems through collaboration between vehicles in the platoon and achieves the global control objective through local control of each vehicle. It solves the optimal speed profile of the platoon online and is more real-time.

Finally, to ensure the safety of the platoon, the speed, and acceleration of the leader vehicle are constrained. The dynamic model of the vehicle queue is combined with a car-following model to ensure the safety of the platoon and a distributed rolling horizon control method to minimize the overall fuel consumption of the platoon.

The method reduces vehicle crashes and enhances vehicle platoon safety. This method has been developed based on experimental and simulation results to increase computational efficiency and decrease vehicle platoon fuel consumption. Additionally, the vehicle platoon's general safety is guaranteed.

B. Future Work

Due to the non-renewable nature of energy and the increase in air pollution, fuel consumption-oriented research, whether for vehicles or platoons, has practical significance and a wide range of application scenarios. However, as the actual road conditions are more complex and variable, there is still a gap in the actual application, and the research is not comprehensive enough. Combining the research results of this paper, the following outlook is given for the future research of fuel consumption-oriented vehicle and platoon movement optimization control methods:

1) *Further optimisation of the control algorithm:* For different vehicle types and driving conditions, more precise and efficient control algorithms should be developed to make the vehicle more energy efficient during the driving process. At the same time, it should be considered that the control method can be applied to roads with gradients, signals, etc. that are closer to reality.

2) *Exploring new optimisation strategies:* The current approach to optimized motion control is mainly based on model-based predictive control. In the future, more flexible and efficient optimization strategies, such as deep learning-based control methods and neural network-based control

methods, can be explored to further improve the efficiency of vehicle and platoon motion and fuel consumption reduction.

3) *Enhanced stability control of the platoon*: The platoon is more stable and does not transmit this disturbance, which is amplified by the disturbance that occurs in the leader vehicle.

ACKNOWLEDGMENT

We would like to thank all the reviewers for their valuable comments. This work was financially supported by Henan Provincial Science and Technology Research Project (232102210142).

A Review of the Recent Progress on Crowd Anomaly Detection

Sarah Altowairqi, Suhuai Luo, Peter Greer

School of Information and Physical Sciences, The University of Newcastle, Newcastle, Australia

Abstract—Surveillance videos are crucial in imparting public security, reducing or avoiding the accidents that occur from anomalies. Crowd anomaly detection is a rapidly growing research field that aims to identify abnormal or suspicious behavior in crowds. This paper provides a comprehensive review of the state-of-the-art in crowd anomaly detection and, different taxonomies, publicly available datasets, challenges, and future research directions. The paper first provides an overview of the field and the importance of crowd anomaly detection in various applications such as public safety, transportation, and surveillance. Secondly, it presents the components of crowd anomaly detection and its different taxonomies based on the availability of labels, and the type of anomalies. Thirdly, it presents the review of the recent progress of crowd anomaly detection. The review also covers publicly available datasets commonly used for evaluating crowd anomaly detection methods. The challenges faced by the field, such as handling variability in crowd behavior, dealing with large and complex data sets, and addressing the imbalance of data, are discussed. Finally, the paper concludes with a discussion of future research directions in crowd anomaly detection, including integrating multiple modalities, addressing privacy concerns, and addressing crowd monitoring systems' ethical and legal implications.

Keywords—Crowd anomaly detection; advanced computer science; intelligent systems; video surveillance application; machine learning

I. INTRODUCTION

The field of crowd anomaly detection is rapidly growing, with increasing interest in identifying abnormal or suspicious behavior in crowds. Crowds can be found in various settings, such as public gatherings, transportation hubs, and shopping centers. The ability to detect anomalies in crowds has many important applications, including public safety, transportation management, and surveillance. The variety and frequency of indoor and outdoor activities that draw big crowds have been fast expanding, which has raised the likelihood of illegal gatherings, disturbance situations, mass stampedes, and other anomalous events greater than before [1]. The size and density of the crowds at huge gatherings have resulted in several public safety crises in recent years, such as the famous stampede on New Year's Eve of 2014 at Shanghai Bund group [2], Mina stampede during Hajj 2015 [3], etc. Surveillance applications are becoming more crucial for efficient crowd-control analysis. Such video surveillance systems must watch for unexpected crowd behavior, like crowd instability or chaos.

Video surveillance should be able to identify violent altercations or traffic accidents quickly and accurately. The

effectiveness of traditional methods is significantly constrained by the amount of human effort needed to make judgments manually. However, there is a rising need to express desired irregularities in an automatic and understandable manner as activities become more complicated and there are more possibilities to reason about. It is critical to comprehend the distinction between a crowd and a group. A group is any gathering of people for social interaction that can range in size from a few to many. On the other hand, a crowd is a group of people who have congregated in an uncontrolled or organized way for similar or dissimilar reasons. A crowd might thus be modelled in terms of many aspects, such as size, cohesiveness, structure, period, motive, and closeness. According to [4], the crowd is either structured or unstructured, the structured crowd moves in the same direction, speed, and pattern as in a marathon, a line of people waiting, or people using an escalator, etc. But the unstructured crowd exhibits complete uncertainty in their behaviors. Such crowds can be seen in marketplaces, shopping malls, etc., where the behavior is entirely uncertain.

In summary, this paper provides a comprehensive overview of crowd anomaly detection (CAD), beginning with a brief explanation of CAD systems and their importance in the research field. In Section III, we delve into the typical components of a CAD system, and the different taxonomies of CAD systems. The typical components include object density estimation, object tracking and object behavior analysis. Major taxonomies of crowd anomaly detection systems are presented based on the label availability and anomaly types used to categorize anomalies. Section IV provides an overview of recent advancements in crowd anomaly detection, while Section V presents a detailed analysis of the performance of various existing CAD systems and techniques. In Section VI, we outline publicly available datasets that can be used for crowd anomaly detection research. The challenges faced by existing systems are discussed in Section VII, including accuracy, computational complexity, and handling real-world scenarios. Finally, in Section VIII, we conclude with a summary of the key findings and potential future directions for research in this field. By the end of this paper, readers will have a comprehensive understanding of the current state of the art in crowd anomaly detection and will be equipped with the necessary knowledge to overcome existing challenges and push the boundaries of this research field even further.

II. CROWD ANOMALY DETECTION (CAD)

Crowd anomaly detection (CAD) is the process of understanding the overall characteristics of a crowd in a video,

such as density, flow, and demographic information. The crowd's density is the number of people per unit area and is used to measure the congestion level in a crowd. The flow of a crowd is the direction and speed of movement of people and is used to measure the level of mobility in a crowd. Several techniques have been developed to detect crowd anomaly in recent years. These techniques include image processing, computer vision, and machine learning. Image processing techniques, such as background subtraction and blob detection, are used to extract information about the density and flow of a crowd from video footage. Computer vision techniques, such as object detection and tracking, are used to extract information about the demographic characteristics of a crowd. Machine learning techniques, such as neural networks and, recently, deep learning models, are used to analyze the extracted information and make predictions about the crowd.

Anomaly detection in crowds can further be defined as identifying specific individuals or groups of people behaving abnormally, such as loitering, running, or moving against the flow of the crowd. This method involves tracking the movement of individuals in a crowd using computer vision techniques such as object detection and object tracking. Once an individual is tracked, their behavior can be analyzed to determine if it is normal or abnormal. Recently, anomaly detection and its analysis in social crowds have become a significant area of research. Due to the variety of anomalous events, crowd anomaly detection is a practical and challenging topic for computer vision. Automatic security analysis of crowd behavior is now possible when there are odd crowds or anomalous congestion. Because of activities like terrorist activities, fights, strange and suspicious movements, etc. automated detection of abnormal behavior in the crowd is of utmost relevance. In traditional systems, becomes the operators' responsibility to supervise the security surveillance to ensure safety closely. This is a significant challenge, resulting in costly and inaccurate decision-making. Therefore, creating a system that is free from errors and without any fatigue, providing real-time functionality, will have sufficient effects on managing crowd behavior.

The emergence of several sophisticated algorithms and the availability of high computational powers heightened the quantity and quality of the research in crowd anomaly detection. Computer vision algorithms that utilise image processing, machine learning and pattern recognition depict the challenges in crowd behavior analysis [5-7]. Some of its most crucial applications are crowd control, video surveillance, and the design of intelligent public spaces [8-14]. The intelligent environment, which is essential for public safety, can help to redirect the crowd and help the planner to design the public area with the most available space [4].

The increased number of research publications in the top publications related to crowd anomaly detection indicates the growing interest and demand in this field [5]. Fig. 1 presents the number of recent papers published on crowd anomaly detection. Crowd anomaly detection (CAD) is identifying unusual or abnormal behavior in a crowd using data analysis techniques, typically with the help of video cameras, sensors, or other monitoring devices. The goal of crowd anomaly detection is to identify situations that may pose a risk to public

safety or security, such as the presence of suspicious individuals or activities, overcrowding, or potential hazards. In order to achieve this goal, crowd anomaly detection systems employ machine learning algorithms and computer vision techniques to analyze data sources in real-time. By recognizing typical patterns of behavior, such as standing, sitting, or walking in specific areas, these algorithms can be trained to detect any deviations from the norm. In such cases, the system sends an alert to relevant authorities or security personnel, who can take the necessary steps to investigate the matter.

Fig. 1. Number of papers published on crowd anomaly detection.

III. COMPONENT AND TAXONOMY OF CROWD ANOMALY DETECTION

The general structure and flow of a crowd anomaly detection system is shown in Fig. 2. The anomaly detection system starts with the raw video data collected by the CCTV cameras. The sensor data are then pre-processed using various methods to lower signal noise and go through a feature extraction process. These features might include things like color, texture, motion, or shape. The goal is to identify patterns in the video that can help distinguish normal behavior from anomalous behavior.

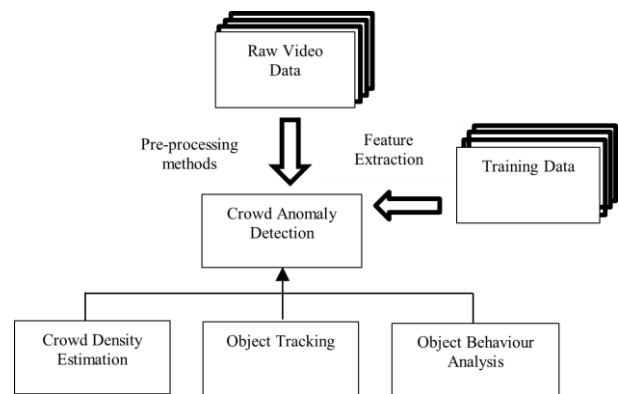

Fig. 2. Flow and structure of crowd anomaly detection.

Crowd anomaly detection system typically consists of three main components: crowd density estimation, object tracking, and object behavior analysis. Here is an overview of how these components work together. Crowd density estimation: The first step in crowd anomaly detection is to estimate the density of people in the scene. This can be done using various computer vision techniques such as background subtraction, foreground detection, or optical flow. The goal is to identify the regions of the scene where people are present and estimate the number of people in each region. Object tracking: Once the crowd density has been estimated, the next

step is to track individual objects (i.e., people) in the scene over time. This is typically done using a tracking algorithm that assigns a unique ID to each object and updates its position as it moves through the scene. Many different tracking algorithms are available, but some common techniques include Kalman filtering, particle filtering, and graph-based tracking. Object behavior analysis: Once individual objects have been tracked, the next step is to analyze their behavior to detect anomalies. This typically involves comparing the behavior of each object to some predefined normal behavior model. For example, the system might look for objects that are moving in an unusual direction, moving faster or slower than expected, or loitering in one area for an extended period. There are many different techniques for object behavior analysis, including rule-based methods, machine learning, and anomaly detection algorithms. The overall flow of the system is typically iterative, with the crowd density estimation and object tracking components running continuously in real time. The object behavior analysis component typically runs periodically (e.g. every few seconds) to detect any anomalies in the behavior of the tracked objects. When an anomaly is detected, the system can generate an alert or trigger some other action (e.g. turning on lights, sounding an alarm, or notifying security personnel).

Crowd density estimation is an important area of research with practical applications in managing and monitoring crowds in density populated locations such as subway stations, sports stadiums, and convention centers. With increasing population and urbanization, it is common for a large crowd to gather quickly. Precisely predicting the emergence of crowds and gauging their density is crucial for effective event planning and crowd management. The recent COVID-19 pandemic further highlights the importance of crowd density estimation, as social distancing policies were implemented to prevent the spread of the virus [15]. There are two primary methods for crowd density estimation: counting objects and estimating the density map [16]. CNN-based algorithms are preferred due to their better image and video sequence performance. A generic deep learning model for the automatic feature extraction from crowd scenes for crowd anomaly detection has been shown in Fig. 3. Techniques based on CNN, such as Scale Pyramid Module Network [17] and Attention Networks [18], are being used for crowd density estimation and counting. Attention Networks are capable of counting individuals in photos while considering scales by selecting appropriate global and local scales using the attention mechanism. Tracking the crowd is crucial in CAD systems, as it involves analyzing image sequences to determine the motion and trajectory of objects, specifically pedestrians. The process begins with detecting objects in a video and filtering them for tracking. The monitoring of pedestrian movement is an essential aspect of understanding crowd behavior. Object tracking can be challenging, as it requires following one or more objects over time. Automated tracking systems are needed to keep up with the movement of pedestrians in a crowd. Identifying and defining regions of interest (ROIs) is the first and most important step in this

process. This can be difficult due to various factors, such as the camera's view, orientation, and resolution. Once the ROI features have been extracted, the tracker can then follow the object of interest.

These models receive either supervised or unsupervised training. In order to take the necessary action, such as dispersing the crowd, when the crowd density exceeds a predetermined threshold, the degree of congestion can be calculated. The objects are tracked, and the anomaly is analyzed by utilizing the objects under tracking and their behavior. A final decision can be made in real-time whether the crowd state is normal or abnormal.

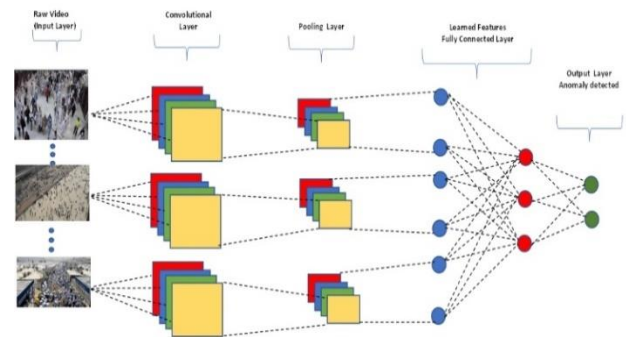

Fig. 3. A deep learning model for the automatic feature extraction from crowd scenes for crowd anomaly detection.

The research on crowd anomaly detection can be categorized into two types based on the availability of labels and the type of anomalies. The different types of crowd anomaly detection methods and related works on them are given in the following subsections.

A. CAD based on the Availability of Labels

Based on the availability of labels, the models used for crowd anomaly detection are divided into supervised/semi-supervised, unsupervised, hybrid, and one-class neural networks, as shown in Fig. 4. Supervised learning: This type of anomaly detection relies on labelled data, where the anomalies and normal behavior are defined beforehand. The model is trained on this labelled data, which can then be used to detect anomalies in new, unseen data [15], [16]. Semi-supervised learning: This type of anomaly detection also relies on labelled data, but it also uses unlabeled data to enhance the model's performance. The model is trained on labelled and unlabeled data, which can then be used to detect anomalies in new, unseen data. Unsupervised learning: This type of anomaly detection does not rely on labelled data. Instead, it uses techniques like clustering and dimensionality reduction to identify patterns in the data. Any deviation from these patterns can then be considered an anomaly. Given that they use labelled data, supervised anomaly detection approaches outperform unsupervised ones in terms of performance. From a series of annotated data instances (training), supervised anomaly detection learns the separation border. Using the learned model, it then divides a test instance into normal and anomalous classes (testing).

Fig. 4. Crowd anomaly detection based on the availability of labels.

Overviews of deep learning-based semi-supervised algorithms for anomaly identification were done in [15] and [6]. Unsupervised crowd anomaly detection is a significant study area, both for fundamental machine learning research and practical applications. One of the deep core architectures for unsupervised anomaly detection is autoencoders, as described in [17]. Discriminative boundary surrounding the majority class is learned by different anomaly detection techniques, as stated by Perera and Patel in their works [18], [19]. Any test instance that falls outside of this boundary is considered anomalous. To discover robust features, deep learning models are frequently utilized as feature extractors [20]. The hybrid models use two-step learning and are demonstrated to provide cutting-edge outcomes [21]. Robust characteristics are retrieved from the deep neural network's hidden layers to help separate them from the irrelevant features that can hide the existence of abnormalities. In deep hybrid models, one class Radial Basis Function (RBF) and Support Vector Machine (SVM) classifiers are used as inputs instead of more conventional techniques. A robust anomaly detection model needs both an anomaly detector and a feature extractor to be built on complicated, high-dimensional domains. One-class neural networks (OC-NN) combine deep network capabilities to extract more rich representations of data with a one-class objective, such as a hyperplane [22] or hypersphere [23], to distinguish all the typical data points from the outliers. Data representation in the hidden layer is learned by optimizing the objective function designed for anomaly detection. The experimental findings in [22] show that OC-NN may achieve equivalent or higher performance than current state-of-the-art approaches for complex datasets while having reasonable training and testing times in comparison to the existing methods.

B. CAD based on the Type of Anomaly

Crowd anomaly detection techniques can also be categorized based on the type of anomaly they handle. Mainly three types of anomalies are handled: point, contextual or conditional, and collective or group, as shown in Fig. 5. Most of the literature is devoted to pointing out anomalies. Point anomalies frequently signify an irregularity or deviation that occurs at random and may not have a specific meaning. A data instance that might be regarded as anomalous in a certain context is known as a contextual anomaly, also known as a conditional anomaly. By considering contextual and behavioral variables, a contextual abnormality is found. Time and space are two contextual elements that are frequently used. In contrast, the behavioral characteristics could be a pattern of financial spending, the occurrence of system log events, or any characteristic that characterizes typical behavior. Collective or group anomalies are abnormal groups of individual data points where each individual point, when

viewed separately, appears to be a typical instance of data but, when observed collectively, exhibit an unexpected characteristic.

Fig. 5. Crowd anomaly detection based on the type of anomaly.

IV. RECENT PROGRESS ON CROWD ANOMALY DETECTION

In recent years, there has been a growing body of literature on crowd anomaly detection. Studies focus on various techniques and applications, including computer vision-based approaches, machine learning algorithms, and real-time anomaly detection. In this section, we review the most recent works on crowd anomaly detection and highlight their key findings and contributions to the field. The field of crowd anomaly detection and analysis has seen significant growth in recent years as the importance of understanding and managing crowd behavior has become increasingly apparent. With the proliferation of surveillance cameras and social media, there is a vast amount of data available for analyzing crowd behavior. As a result, numerous studies have been conducted on various aspects of crowd anomaly detection. However, with so much literature available, it can be difficult to gain a comprehensive understanding of the current state of research in this field. This literature review aims to address this issue by providing a comprehensive overview of the current state of research in crowd anomaly detection and analysis. By combining all available works on this topic, this literature review will provide a holistic view of the field, highlighting the most important contributions and identifying gaps in existing literature. A comprehensive examination of the various techniques used in the visual analysis of crowd behavior for surveillance purposes was conducted in [6]. In this study, recent research on crowd anomaly detection was classified based on the level of analysis and the types of anomalies observed. Several machine learning and deep learning approaches have been proposed to analyze crowd anomaly detection. A review of the different classical methods, such as the Spatial-Temporal Technique (STT), optical flow, Gaussian mixture model (GMM) and Hidden Markov model (HMM), has been done for the identification of the crowd abnormal behavior in [13]. Many recent studies in crowd anomaly analysis utilise deep learning methods. The different attributes of Convolution Neural Network (CNN) and the various optimization methods used in the context of crowd behavior analysis have been presented in [24]. Another literature review on intelligent video surveillance using various deep learning techniques for crowd detection was conducted in [17]. This work examined the use of Long-Short Term Memory (LSTM) networks, VGG16, and YOLO specifically. Additionally, [18] also conducted a detailed study of the various deep learning methods used for crowd counting and analysis, which are key components of crowd anomaly detection. Different methodologies utilized for counting the crowd have been reviewed and compared, presenting the various trends in CNN and traditional machine learning methods [25, 26].

Aggregation of Ensembles (AOE), a combination of four classifiers over sub-ensembles of three tuned Convolutional Neural Networks (CNNs) on crowd datasets, is proposed by [27] as a method to detect abnormalities in movies of crowded scenes via majority voting. A different classifier is used to process each sub-ensemble independently. A sub-ensemble of CNNs is composed of the CIFAR-10 AlexNet [28], GoogleNet [29], and VGGNet [30] networks. In this situation, CNNs acted as feature extractors, feeding Linear SVM, Quadratic SVM, Cubic SVM, and a SoftMax classifier and other classifiers. Several video frames are selected and analyzed to extract the features. A video is deemed abnormal if more than 10% of the batch's frames fall into this category. The publicly available datasets such as the Avenue dataset, UCSD Ped 1 and UCSD Ped 2, and AOE training and evaluation, were employed for this analysis.

A dual branch network was proposed in [35] as a framework for social multiple-instance learning. This approach uses a two-stream neural network consisting of an interactive dynamic stream and a spatiotemporal stream. The spatiotemporal stream processes RGB video clips. A 3D ConvNets (C3D) model that has already been trained on Kinetics and UCF-101 is used to extract features from the video after it has been divided into smaller pieces using a video segmentation method. The output is fed into a fully linked network after the features have been fed into a one-dimensional dependency attention capture module. The second channel receives force maps of social interactions as input. Maps of social interactions in a scene are created using the social force model [14]. They evaluate the effectiveness of their strategy on the UCF Crime dataset using the receiver operating characteristic (ROC) curve and area under the curve (AUC) metrics [31]. Comparisons with four more techniques were made throughout the evaluation. The dynamic network allows for a compact representation of moving video frames, which reduces false-positive anomaly alarms due to spatial limitations. This is the second advantage of their use. They employ the perturbation visual interpretation technique for identifying anomalies in order to give the results more credibility. The results presented were competitive with many of the similar works.

A general adversarial network-based abnormal behavior analysis in the massive crowd was proposed in [53], where a case study of the Hajj pilgrimage is considered. In this work, the dynamic features were extracted using optical flow. It uses a transfer learning strategy and U-Net and Flownet to distinguish large crowd scenes' normal and abnormal behaviors. This system has shown a very high accuracy in smaller video scenes such as UMN and UCSD, with 99.4% and 97.1%, respectively, whereas a considerably low accuracy on large datasets such as the Hajj dataset. The authors describe the need for improvement in anomaly behavior accuracy by collecting more annotated Hajj datasets and extracting complex features that utilise deeper models.

Behavior understanding becomes a difficult task with the fact that anomalies are not well defined and would occur very less frequently. Researchers have been trying to address these issues to make the learning algorithms robust in detecting the anomaly in the video. In [32], a new approach based on

Generative Cooperative Learning (GCL) has been employed for addressing the low frequency of anomalies and contributing towards the avoidance of manual annotations. The generator and discriminator networks in the model get trained in a cooperative style, thus enabling unsupervised learning. This approach has been found to be showing consistent improvement in UCF crime and ShanghaiTech, which are considered to be the well-cited large-scale video datasets.

A deep convolutional neural network (DCNN) architecture was proposed in [21] for detecting crowd anomalies. The architecture utilized the VGG16 model, which included ten convolutional layers and three max pooling layers. For crowd counting, they employed six convolutional layers with a dilation rate of 2 and a kernel size of 3x3. Another approach was proposed by Sagar [22], who presented a network architecture for crowd counting using a feature extractor based on ResNet. It extracts the details of an object at different scales by down-sampling the block with dilated convolutions and further up-samples the block using transposed convolution. In the analysis of crowd dynamics, Recurrent Neural Networks (RNNs) based models have been utilized [23]. In this work, the Bhattacharya distance was applied to detect a given frame's emotional state order to select the optimal keyframe for the video. To describe the scene, the Space-Time Interest Points (STIP) descriptor was used, with features being extracted from the keyframes. The RNN model was trained using an improved version of the Butterfly optimization algorithm, which enables it to distinguish between normal crowd behavior and behaviors associated with fighting, fleeing, walking, anger, happiness, and violence. The problem of vanishing and exploding gradients is addressed by Long-Short Term Memory (LSTM) networks [24], which are an extension of Recurrent Neural Networks (RNNs). LSTM has a longer memory capacity and can retain information for an extended period.

Most crowd anomaly detection robustness is analyzed based on the temporal consistency among the frames. The temporal features were considered for anomaly prediction based on the motion information using optical flow analysis [33, 34]. But there should be some system to distinguish between fake and real sequences for temporal consistency that lead to an anomaly or normal behavior. The anomaly behavior can be well detected by the optical flow methods, which are good for analyzing the short-term temporal relationship between adjacent frames. But eventually, these methods fail, especially in videos where events based on a long-term temporal relationship occur. To overcome such issues, a novel method based on a bi-directional architecture that introduces the inconsistencies on three different levels such as temporal-sequence, cross-modal, and pixel, has been proposed [35]. The bidirectional predictive network introduced in this work regularizes the predictive consistency. The long-term temporal relationship in the video sequences is identified by the discriminator developed in work. This method outperformed all other state-of-the-art learning methods on several datasets such as UCSD Pred2, ShanghaiTech and CUHK Avenue. Recent literature reviews have been conducted on the topic of crowd anomaly detection, providing in-depth coverage of the

various frameworks, taxonomies, methods, and techniques used. These reviews also included information on various datasets, such as the Hajj dataset used for video surveillance during the Hajj pilgrimage in Saudi Arabia. The Hajj pilgrimage is known to be the largest human gathering in the world, with an estimated of 2.5 to 3 million participants from various regions globally [9].

A summary of the different types of crowd anomaly detection is given in Table I.

TABLE I. SUMMARY OF THE CROWD ANOMALY DETECTION METHODS

Approach	Anomaly	Dataset	Performance
SSD-VGG16 [15]	Bullet train, pedestrian	PASCAL VOC, Railway	Overall accuracy=98.01% Detection accuracy=99.55%
SSD-VGG16 [16]	Small object	ILSVRC CLS-LOC, Railway	Accuracy =96.6%
3D-CNN LSTM [36]	Panics, fighting, protest	UMN, CAVIA, Web	Accuracy=0.995% Accuracy= 0.974% Accuracy= 0.926%
CNN RNN [37]	Use mobile in class, fighting, fainting	KTH, CAVIAR	Accuracy=87.15%
CNN Residual LSTM [38]	Fighting, explosion, accidents, shooting, robbery, shoplifting,	UCF-Crime, UMN, CUHK Avenue	Accuracy=78.43 % Accuracy=98.20 % Accuracy=98.80%
GAN [39]	Biking, fighting, vehicle, running	CUHK Avenue UCSD, ShanghaiTech Campus.	AUC=86.6% AUC=96.9% AUC=82.5% AUC=73.8%
Optical Flow GAN [40]	Standing, sitting, sleeping, running, moving in opposite, non-pedestrian	UMNScene1 UMNScene2 UMNScene3 UCSD, HAJJ datasets	Accuracy=99.4% Accuracy=97.1%, Accuracy=97.6%, Accuracy=89.26% Accuracy= 79.63%
Convolutional Neural Networks (CNNs) and Random Forests (RFs) [41]	standing, running, moving in opposite or different crowd directions, and non-pedestrian entities	UMN, UCSD, HAJJv2 dataset	Accuracy= 99.77% Accuracy= 93.71%. Accuracy=76.08%.
Convolutional Neural Network (CNN) [42]	Wheelchairs, skateboarders, motor vehicles, bicycles and crossing pedestrian tracks.	Violent Flows, UCSD, CUHK Avenue	Accuracy =90% Accuracy= 99.98% Accuracy=95%
Convolutional Long-Short-Term Memory (ConvLSTM) network and a Convolutional AutoEncoder. [43]	cyclists, skaters, cars	UCSD ped2, Shanghai Tech Campus.	AUC=95.6% AUC=73.1%

3DConv, Convolution Long Short-Term Memory (ConvLSTM) [44]	Vehicle and bicycle movement, throwing objects, running, Arrest, Abuse, Accident, Burglary, Explosion.	UCSD Ped1, UCSD Ped2, Avenue UCF-crime dataset	AUC=80.7% AUC=85.3% AUC=81.0% AUC=75.82%
CNN, RNN KNN, Optical Flow [45]	Bicycles, skateboards, wheelchairs	CUHK Avenue UCSD, UR fall Shanghai Tech Campus,	AUC=80.68% AUC=96.01% AUC=91.28% when k=10 AUC= 0.703 Optical flow module
Conv-LSTM [46]	Violence	Standard crowd anomaly	Accuracy =95.16%
Vgg-16 and LSTM [47]	Non-pedestrian	UCSD Ped2 CUHK Avenue	frame level: 95.0%, pixel level: 72.5% frame level:87.3%, pixel level: 93.8%
Cascaded attention model, Two Convolutional layers, Adam [48]	Fighting, Running, Robbery, lying down, crossing and car accident.	UCSD Ped2 CUHK Avenue, Shanghai Tech Campus	AUC =0.974, AUC=0.867, AUC= 0.736
3DCN, Transformer Adam [49]	Fighting, Running, Burglary, Fire and Assault.	Shanghai Tech Campus, UCF-Crime	AUC = 0.976 AUC = 0.832
GCN technique [50]	Fighting, Running, Burglary, Fire, Abnormal walking, lying down, group gathering and Assault.	UCSD, UCF-Crime, Shanghai Tech campus.	AUC =0.93, AUC=0.82 AUC=0.84.
motion attention, location attention. [51]	Fighting, Running, Burglary, Fire, Abnormal walking, lying down, group gathering, Assault, theft and Explosion.	UCSD Ped1, UCSD Ped2, CUHK Avenue, Shanghai Tech campus, UMN, Street Scene.	AUC=0.942, AUC=0.929, AUC=0.805, AUC=0.803, AUC=0.988 AUC=0.730.

V. PERFORMANCE COMPARISON

There are advantages and disadvantages to the crowd anomaly detection models that have been put forth so far. Most models just provide the output and estimate the findings in terms of accuracy, sensitivity, and specificity, failing to address the issue of output uncertainty. One of the issues that various anomaly detection techniques in a video frameset have in common is that they don't look at various situations including computational cost, pixel occlusion, noise and efficiency. To evaluate the models' performance and contrast it with other approaches, the following factors were considered:

1) The first is an analysis based on the amount of time required to run the algorithm for model estimation and a cost

analysis based on an estimate of the overall expenses associated with evaluation and error analysis.

2) Analysis of the uncertainty based on the dispersion of mean squares of error in different iterations and the average weight estimate of precision and recall on evaluating the performance.

3) Investigating the sensitivity to noise based on the classification of crowd behaviour, particularly in the presence of artifacts such as noise, a changing temperature, pixel occlusion, and low received frame quality.

4) Generalizations of the approaches for identifying and classifying person and group behavior in unseen frames.

Performance comparison of the most common datasets used in the CAD with different methods was shown in this section. The datasets used for the comparison are UMN [14], UCSD (University of California, San Diego) and UCSD Ped [53]. Performance comparison of UCSD on six different methods has been shown in the Fig. 6. CNN has the highest accuracy, with a score of 99.98%. GAN and CNN+KNN+Optical flow methods also have high accuracy, with scores of 96.90% and 96.01%, respectively. CNN+RF has a moderate accuracy score of 93.71%, while Optical Flow GAN has the lowest accuracy score of 89.25%.

In Table II, a performance comparison of UMN and UCSD Ped2 datasets are given. It can be observed that on the UMN dataset, the combination of CNN and random forest method achieved the highest performance, while on the UCSD Ped2 dataset; the Cascaded Attention CNN achieved the highest performance. It is also interesting to note that the UMN-Method achieved a higher performance than any of the methods applied to the UCSD Ped2 dataset.

Fig. 6. Performance comparison of different methods on UCSD.

TABLE II. PERFORMANCE COMPARISON ON UCSD AND UMN DATASETS

UMN-Method	3D-CNN-LSTSM	CNN-Residual LSTM	Optical Flow GAN	CNN+RF
Performance	99.50%	98.20%	98.03%	99.77%
UCSD- Ped2 Method	Conv LSTM	Conv LSTM+ Conv Encoder	Vgg-16 LSTM	Cascaded Attention CNN
Performance	83.00%	95.20%	95%	97.40%

IV. PUBLICLY AVAILABLE DATASETS

Over the past few years, there has been a surge in the number of datasets devoted to crowd anomaly detection. These data sets can be used to analyze, compare and improve the performance of crowd anomaly detection systems.

Applications related to crowds, including counting, density estimates, categorization, activity recognition, and anomaly detection, use real crowd datasets. The majority of visual real crowd datasets have focused on counting tasks, including UCSD, PETS2009, UCF-CC-50, Mall, Shanghai Tech, etc. In a recent study, SIMulated Crowd Datasets (SIMCD) were presented for use in creating models for predicting and detecting crowd anomalies [52]. The details of these datasets along with many other datasets available for crowd anomaly detection have been given in Table III. The name of the dataset, the size of the dataset, a small description and a short scenario are mentioned in the table.

TABLE III. DETAILS OF THE PUBLICLY AVAILABLE DATASETS FOR CROWD ANOMALY DETECTION

Name	Scale	Description	Scenario
UMN [14]	Small	The collection consists of films from 11 different escape event scenarios shot in 3 various indoor and outdoor settings.	Crowd behavior anomaly detection
UCSD Peds 1 UCSD Peds 2 [53]	Small	Videos by a stationary camera gazing down on pedestrian walkways. peds1: perspective distortion and groups of people walking. Peds2: Camera-parallel pedestrian movement.	Abnormal crowd behavior detection
CVCS [54]	Medium	Cross-view, cross-scene, multi-view counting using a synthetic dataset. Each scenario in the dataset has roughly 100 camera views and consists of 31 scenes. For each scene, 100 crowd multi-view photos were taken.	Multi-view crowd counting
Grand Central [55]	Medium	It is collected from the New York Grand Central Station.	Crowd train station dataset
HAIJv1 [40]	Large	It is collected from pilgrims passing through hall passages in Haram masjid, Mecca, Saudi Arabia	Human abnormal behavior in Hajj
Shanghai Tech Part A Part B [56]	Large	It has 13 scenes with complex light conditions and different camera angles. It contains 130 abnormal events and over 270,000 training frames.	Crowd counting and density estimation
Violent flows [57]	Large	Video footage of crowd fighting together with industry-recognized benchmark standards for testing the accuracy of both the classification of violent and non-violent crowd behavior and the identification of violent outbreaks. 246 videos are included in the data collection. All of the videos	Classify and detect violent and non-violent behavior

		were downloaded from YouTube.	
WWW Crowd [58]	Large	A rich dataset for crowd understanding is provided by 10,000 videos with more than 8 million frames from 8,257 different scenes.	Crowd understanding
UCF-CC-50 [59]	Large	Extremely dense crowd dataset for crowd counting	for crowd counting
Multi-Task Crowd [60]	Large	A recent 100 image dataset that is completely annotated for crowd recognition, violent behavior detection, and categorization of density level.	Crowd counting, violence detection, and density level classification
UCF-Crime [31]	Large	It is made up of 1900 uncut, lengthy real-world surveillance movies that include 13 actual oddities like fighting, car accidents, robberies, and other crimes in addition to everyday occurrences.	Crowd behavior anomaly recognition, crowd behavior
Mall [61]	Medium	Webcams with public access are used to gather data. The video has 2000 frames, and each frame's annotations note the head position of each pedestrian.	Crowd counting
Street Scene [62]	Large	It is made up of video clips shot from a stationary USB camera looking down on a two-lane street with bike lanes and sidewalks, with another 35 clips used for testing.	Video anomaly detection.
CUHK-Avenue [63]	Small	It is a collection of short clips recorded by a single outdoor surveillance camera aimed at the side of a building facing a sidewalk. It has 15 sequences. Each one lasts approximately 2 minutes. There are 14 unusual events, including running, throwing objects, and loitering.	Abnormal event detection.

VI. CHALLENGES AND LIMITATIONS

In crowd scenarios with a variety of conditions, a reliable crowd anomaly detection algorithm tries to evaluate both local and global density and reliably anticipate crowd behaviour. The model's performance is significantly impacted by the changing circumstances. Therefore, it's crucial to first comprehend these difficulties and how they could affect the performance of the model. The development of more reliable models is aided by a thorough grasp of these difficulties.

a) Difficult to monitor crowd behaviour in various settings. For instance, it is significantly simpler to count and track the individuals in images captured by a single CCTV camera (such as those in the Mall dataset [61]) than to count people in images captured by numerous security cameras (such as those in the WorldExpo'10 dataset [64]). Drone surveillance often involves changing the scene, which makes it more difficult when combined with other variations such as scale variations.

b) When items belonging to the same class (in this case, humans) appear at various sizes in both a single photograph and across various images, it's referred to as scale variation. The distance (between the camera and the objects) and the perspective impact in the same image are the two factors that affect scale. Scale changes are additionally seen in photos with various resolutions. In crowd anomaly detection research, scale variation is one of the most prevalent issues that significantly affect model performance.

c) In different images, there are different numbers of people or other subjects of interest. Typically, low density visuals are simpler to understand than high density images. Similarly, another difficulty is when the same image shows various densities of people in multiple areas.

d) The distribution of objects in crowd photos may vary in different scenarios. For example, seats in a sports arena are evenly distributed among people, with constant spacing between objects, whereas in crowded streets, things might be distributed at random. In the absence of other features that would alter the accuracy, uniformly dispersed crowds can be estimated more precisely than non-uniform crowds.

e) Occlusion has been a major challenge in video analysis, and it is even difficult for crowd anomaly detection. The term occlusion describes how objects overlap. Intra-class occlusion refers to the overlapping of similar items (like humans), but inter-class occlusion refers to the overlapping of distinct objects (like automobiles, walls, and other people). Dealing with occlusion is frequently difficult. In the presence of occlusion, it is problematic for both the object detectors and the annotators to accurately annotate the objects as well as forecast them. Occlusion makes it challenging to distinguish between object borders in frames by interweaving semantic elements. It can also be challenging to learn when the object's pixel values are comparable to those of the background. Occlusion can limit the effectiveness of crowd anomaly detection systems as it makes it difficult to identify individuals in a crowd, leading to false positives or false negatives. Techniques like using multiple cameras or machine learning algorithms can help mitigate the effects of occlusion, but it can still be a significant challenge in dense and complex crowds.

f) Due to the different lighting conditions, the illumination in an image can change during the day and in various areas of the same image. This makes learning difficult because the same object (like people) in the same image will have varying pixel values. Other conditions which make CAD difficult include changes in the weather, noise and pixelation in images, rotation of objects, etc.

Some of the limitations of current crowd anomaly detection methods are given below:

- High computational cost: Some methods, such as deep learning-based methods, require a large number of computational resources to train and test, which can be a limitation in real-world applications where computational resources are limited.
- Need for annotated data: Many methods, such as deep learning-based methods, require a large amount of annotated data to train the models, which can be a limitation in real-world applications where data is limited or difficult to annotate.
- Ethical and privacy concerns: some methods, such as facial recognition-based methods, may raise privacy concerns, and it is important to ensure that the method is used in compliance with relevant laws and regulations.
- Limited ability to detect novel anomalies: Many methods are designed to detect known anomalies and may not be able to detect novel or unknown anomalies. Many methods focus on detecting anomalies but don't provide any insight into the root cause of the anomaly.
- Limited scalability: Many methods are not designed to handle large crowds and may not be able to scale to handle large amounts of data. Limited ability to handle multiple anomalies: Many methods focus on detecting a single type of anomaly and may not be able to handle multiple types of anomalies simultaneously.

VI. SUMMARY

This review paper provides an in-depth analysis of crowd anomaly detection and its importance in real-world surveillance and security. The latest research on crowd analysis is reviewed and summarized, with a focus on the major components of crowd anomaly detection, such as crowd density estimation, object tracking, and object behavior analysis. The paper also provides a summary of research based on different taxonomies, including the type of anomaly, and the type of dataset labels of the anomaly. Publicly available datasets used for crowd analysis were also reviewed, including the types of anomalies they address. Considerations for evaluating model performance and current challenges in the field were also discussed. In light of the review, the paper provides directions for future research, including the need for model generalization for different anomalies in different scenarios, designing application-specific crowd anomaly detection s, and effectively selecting the most appropriate models for analysis to reduce unnecessary resource usage and carbon emissions. The paper also provides directions for future research, including the incorporation of generative models, graph-based methods, reinforcement learning, transfer learning, online learning, ensemble methods, multi-task learning, domain adaptation, active anomaly detection, and meta-learning which have the potential to significantly improve the performance of crowd anomaly detection systems and address current limitations in the field. Overall, this review paper offers valuable insights and a comprehensive

understanding of the field of crowd anomaly detection, which will aid researchers in developing robust solutions to address the current limitations of the system.

VII. FUTURE DIRECTIONS

Some of the research directions based on the challenges identified by the various researches are mentioned next. The same benchmark datasets are used to train and evaluate the majority of crowd counting methods. So, model generalization hasn't been studied much, or studies are limited to the models that were fine-tuned on one dataset after being pretrained on another. However, the results that are normally published come from the refined model. This causes a significant disparity in the generalization of crowd counting models across different scenes, which warrants more research. It would be fascinating to observe model generalization in a variety of unusual situations, such as interior and outdoor videos, CCTV photos, drone photographs, etc.

An effective model must be able to run on a variety of hardware platforms with diverse computational capabilities, including servers, drones, cameras, mobile phones, etc., in order to support the potential applications of crowd anomaly detection. Applications (such as real-time or non-real-time), types of surveillance (such as CCTV-based surveillance or drone-based surveillance), and scenarios (shopping malls, metro stations, stadiums, etc.) all have different performance requirements. Therefore, it is ineffective to create a single optimal model with the highest accuracy for all applications, surveillance techniques, and circumstances. In actuality, such a model will be big, need a lot of computing power for fine-tuning, and have lengthier inference delays given the current trends in crowd anomaly detection model design. Applications requiring real-time inference, limited on-chip memory, and battery-powered devices will not be compatible with such a strategy. As a result, we anticipate and have also seen some recent attempts to have application-specific model designing, such as lightweight models for real-time applications on resource-constrained devices, and dense models for maximum accuracy over dense crowds in server-based systems.

The selection of deep or shallow neural networks is to be studied in detail. For sparse datasets with low crowd-density images, such as those from UCSD [53], Mall [61], and ShanghaiTech Part B [56], shallow models provide reasonably sufficient accuracy, and deeper models may not be necessary for the circumstances depicted in these datasets. Deeper models are typically used to achieve higher accuracy over large datasets, but these efforts often result in deeper and more complicated architectures. Unsurprisingly, single-scene crowd analysis and sparse multi-scene crowd detection are the two tasks with the fewest requirements. Even relatively tiny accuracy gains are the focus of most research efforts, and the ensuing model complexity is frequently disregarded. This leads to an increase in model complexity for a minor and frequently insignificant gain in accuracy. We think it's important to look into benchmarking for model training and inference times for crowd models. It's high time that researchers think about green computing and help to conduct low carbon emission systems for their research.

Incorporating domain knowledge, temporal information and multiple modalities into anomaly detection methods can improve their performance and make them more robust to different scenarios. Incorporating generative models, such as generative adversarial networks (GANs) and variational autoencoders (VAEs) can improve the ability to detect novel or unknown anomalies and can also be used to generate synthetic data for training models. Incorporating graph-based methods, such as graph convolutional networks (GCNs) and graph recurrent networks (GRNs), can improve the ability to model the relationships and interactions between individuals in the crowd. Ensemble methods, such as an ensemble of classifiers and an ensemble of experts, can improve the robustness and generalizability of the models by combining the predictions of multiple models. The concept of meta-learning can be used, which allows the model to learn how to learn, can improve the ability to adapt to new data and tasks, and can also improve the interpretability of the models. Developing interpretable models, such as decision trees and rule-based models, that can provide insight into why a certain behavior is considered abnormal can make the methods more understandable and trustworthy. Incorporating explainable AI(XAI) can reveal the reason for a certain decision and can improve the interpretability of the models and make the methods more trustworthy.

There are further many possible future directions in terms of techniques and methods used for crowd anomaly detection, such as incorporating generative models, graph-based methods, online learning, ensemble methods, multi-task learning, domain adaptation, active anomaly detection, and meta-learning. These techniques and methods can help to improve the performance and robustness of crowd anomaly detection models and make them more suitable for real-world applications.

Improving Brain Tumor Segmentation in MRI Images through Enhanced Convolutional Neural Networks

Kabirat Sulaiman Ayomide¹, Teh Noranis Mohd Aris², Maslina Zolkepli^{3*}

Faculty of Computer Science and Information Technology, Universiti Putra Malaysia, Serdang, Malaysia

Abstract—Achieving precise tumor segmentation is essential for accurate diagnosis. Since brain tumors segmentation require a significant training process, reducing the training time is critical for timely treatment. The research focuses on enhancing brain tumor segmentation in MRI images by using Convolutional Neural Networks and reducing training time by using MATLAB's GoogLeNet, anisotropic diffusion filtering, morphological operation, and sector vector machine for MRI images. The proposed method will allow for efficient analysis and management of enormous amounts of MRI image data, the earliest practicable early diagnosis, and assistance in the classification of normal, benign, or malignant patient cases. The SVM Classifier is used to find a cluster of tumors development in an MR slice, identify tumor cells, and assess the size of the tumor that appears to be present in order to diagnose brain tumors. The proposed method is evaluated using a dataset from Figshare that includes coronal, sagittal, and axial views of images taken with a T1-CE MRI modality. The accuracy of 2D tumor detection and segmentation are increased, enabling more 3D detection, and achieving a mean classification accuracy of 98% across system records. Finally, a hybrid approach of GoogLeNet deep learning algorithm and Convolution Neural Network- Support Vector Machines (CNN-SVM) deep learning is performed to increase the accuracy of tumor classification. The evaluations show that the proposed technique is significantly more effective than those currently in use. In the future, enhancement of the segmentation using artificial neural networks will help in the earlier and more precise detection of brain tumors. Early detection of brain tumors can benefit patients, healthcare providers, and the healthcare system as a whole. It can reduce healthcare costs associated with treating advanced stage tumors, and enables researchers to better understand the disease and develop more effective treatments.

Keywords—MRI brain tumor; anisotropic; segmentation; SVM classifier; convolutional neural network

I. INTRODUCTION

All essential biological systems are controlled by the central nervous system (CNS), which is composed of the brain and spinal column which are the most important organs in our bodies' systems. The functions include speaking, moving, and thinking. They are made up of supporting cells called glial cells and nerve cells called neurons, which communicate with one another and with the rest of our body by both sending and receiving impulses via nerves. Magnetic resonance imaging (MRI), a category of imaging technology, provides accurate images of the anatomical anatomy of the human body, especially the brain, and provides useful data for biomedical research and clinical diagnosis. A brain tumor is the growth of malignant, abnormal cells in the brain [1]. There are numerous

varieties of brain tumors and these tumors may be malignant (cancerous) or benign (noncancerous). Cancer may begin in any other parts of the body before spreading to the brain or it may begin there (primary brain tumors) (secondary, or metastatic, brain tumors). The rate of growth of a brain tumor might vary greatly. A brain tumor will have an effect on how well your nervous system functions based on how quickly it develops and where it is. Your treatment options are influenced by the type of brain tumor you have as well as its size and location. A learning model for the classification of lung and pancreatic tumors was introduced [2] where a knowledge transfer served as the foundation for the learning model's 3D CNN architecture. The stated accuracy metrics of the transfer learning-based algorithms were superior to those attained by manually developed techniques. Applications specifically connected to neuro-oncology have increased interest in transfer learning. Deep data from brain MRI images have been extracted in research using trained networks. Transfer learning may be used to work with smaller datasets, as illustrated by studies that applied AlexNet and GoogLeNet to grade gliomas from MRI scans [1]. In terms of efficiency metrics, GoogLeNet performed better than AlexNet, where GoogLeNet's work on classifying brain anomalies used deep transfer learning and obtained impressive classification performance [2]. Wavelet transform (WT) [3] is an important strategy for feature extraction from MR brain images, but it necessitates a substantial amount of storage and is computationally expensive. Wavelet transform (WT) allows analysis of images at various levels of resolution due to its multiple-resolution analytic property [4]. Principal component analysis is appealing because it observe the impact the dimensionality of data and lowers the computational cost of processing new data [5]. The supervised classifier shows better performance than the unsupervised classifier in terms of classification success rates, regardless of the fact that all of these strategies led to successful outcomes. The classification accuracy of the preponderance of previous methods was less than 95%, therefore the purpose of the proposed research is to find a method that is significantly accurate. A CNN-based deep learning model was successfully used to solve the classification task for brain tumors. CNN-based classifier systems give a completely automated classifier that doesn't required manually segmented tumor regions, which is a benefit. For the purpose of identifying traits from brain MRI, a CNN architecture was introduced [6] where the effectiveness of the algorithm was enhanced by using CNN features and a classifier model from the category of extreme learning machines (ELM). Recall measures for the class meningioma were somewhat low for this trial; however they were quite high for the class pituitary

tumor. It illustrates that there are boundaries on the classifier's ability to discriminate. SVMs, which are state-of-the-art supervised classification methods based on machine learning theory, are currently used in many applications. Due to their extreme precision, exquisite mathematical tractability, and simple geometric interpretation, SVMs outperform existing methodologies like artificial neural networks, decision trees, and Bayesian networks by a massive margin [7]. Manual segmentation of brain tumors that is usually very challenging and time-consuming is frequently done by experts.

The remaining part of the paper is organized as follows: Section II the related works to the proposed approach. Section III describes the dataset use magnetic resonance brain image and the classifier settings which include the anisotropic filtering, support vector machine filtering, deep classification neural network feature and deep convolutional neural network. Section IV gives details of the experiment performed presents evaluation results and provides discussion on the results. Section V provides the conclusion of the study.

II. RELATED WORKS

The feature extraction approach uses a Stationary Wavelet Packet Transform (SWPT)[6]. The best feature is then selected by implementing a hybrid of adaptive black widow and moth flame optimisation (HABWMFO). The feature values undergo clustering in order to perform segmentation. For segmentation, the Adaptive Kernel Fuzzy C Means clustering technique (AKFCM) was developed. Finally, and certainly not least, the Dolphin-SCA deep learning method, which is based on deep CNN, implemented the Hybrid Convolution Neural Network-Long Short-Term Memory (CNN-LSTM) component to improve the accuracy of tumor classification.[7]. It helps with accuracy and enables efficient classification selections. Dolphin-SCA (Dolphin Echolocation based Sine Cosine Algorithm), along with the fuzzy deformable fusion model, were used to segment the data. The features were extracted using Power LDP and statistical traits (skewness, mean, and variance). The information was used to classify brain tumors using the Deep Convolution Neural Network, which trains using Dolphin-SCA. Brain tumors are segmented using a hybrid k-means algorithm and the fuzzy c-means technique [8]. For automatically identifying brain tumor cells in MRI MRI images, a deep CNN model has been created. On synthetic and real-time datasets, it has been tested [9]. Using the GoogLeNet and AlexNet architecture, the CNN network is trained on the training dataset, and the performance of the data model is assessed on the test dataset. The model's performance is evaluated using the metrics accuracy, sensitivity, specificity, and AUC integrating an implemented extreme learning machine with a hybrid feature extraction technique [10]. Using the RELM (regularised extreme learning machine), the tumor kind was classified. A Deep Wavelet Auto-encoder (DWA), which combines the auto-encoder, a fundamental feature reduction property, and the wavelet transform, an image decomposition method, is used for picture reduction [11]. A brain imaging dataset was produced using a DWA-DNN image classifier. A CNN-based U-net [12] for segmenting the tumor has been introduced where the transfer learning is based on a Vgg16 pre-trained convolutional foundation. To grade the tumor, a fully connected classifier was utilized.

III. MATERIALS AND METHOD

In the proposed approach, a novel upgraded classification model is proposed in an attempt to enhance tumor segmentation performance. Enhanced Convolutional Neural Networks are used to segment brain tumors. Automatic segmentation is carried out using the BAT algorithm, which strips the skull from the MRI image before applying the loss function to preprocess it. Deeper architectures are built utilising smaller kernels. Despite decreasing the probability of computational complexity given a network includes fewer weights [13].

The proposed methodology incorporated anisotropic diffusion, morphological operation, and SVM segmentation. On the figshare open dataset, the suggested approach had the best classification performance. Combining transfer learned deep CNN features and SVM classifier models improve performance. The combination excels even with less training samples utilised in the original input space on the dataset conducted in MATLAB, achieving the highest classification accuracy. The dataset comprises of 3064 brain MRI images taken from 233 patients who have been diagnosed with one of the three forms of brain tumors, which are meningioma, glioma, or pituitary tumors. The T1-CE MRI modality includes the axial, sagittal, and coronal images. It includes 1426 brain MRI images with glioma (corresponding to 89 patients), 708 meningioma photos (related to 82 patients), and the remaining 930 pituitary tumor images (belonging to 62 patients). Each image is 512x512 pixels in size and is accessible mat files. The input layer for Google Net's original RGB colour image design was 224x224x3. In the proposed approach, which aims to segment tumor using MRI images, automatic classification has been performed under Anisotropic Diffusion as tumor found and no tumor found. CNN, a successful deep learning method, was used as a classifier within the scope of the study. CNN architectures were used GoogLeNet. The classification results were obtained using the original MRI brain images, and the images obtained by using SVM. Then, new classification results were calculated using a framework from the obtained results.

A. Anisotropic Diffusion Filter

In order to perform morphological operations on the MRI image and determine if the patient's brain contains a tumor or not, the picture was first filtered using an anisotropic diffusion filter to lessen contrast between adjacent pixels. The image was then manually turned to black and white using a threshold value after being scaled. It is the first step in identifying potential tumor locations [14]. Morphological techniques have been used on the semi-processed image to acquire data on the areas and solidity of the likely places. The statistical average of many MRI pictures with tumor has been used to calculate the minimal value of both of these characters. The final detection result was then delivered using it [15]. Although the majority of the time the simulation technique can produce accurate results, it cannot function when the tumor is hollow or too small. getting an MRI scan, using an anisotropic diffusion filter to filter the image, processing the image with morphological operations in detail, the tumor is divided up by a specific border, if there is no tumor, image processing is finished; otherwise, the tumor's location is estimated. Tumor

identification is based on density and size [16]. Each parameterized image that results from shape-adapted smoothing is a combination of the original image and a filter that depends on the local content of the original image. As a result, anisotropic diffusion transforms the original image in a non-linear and space-variant way. The photos are blurred with the anisotropic filter without losing any edges.

$$\frac{\partial I}{\partial t} = \text{div} (c(x, y, t), \nabla I) = \nabla c \cdot \nabla I \quad (1)$$

where the diffusion coefficient is denoted by $c(x, y, t)$. It is chosen to maintain image edges and regulates the rate of diffusion. The ground-breaking Perona-Malik paper's projected diffusion co-efficient is as follows:

$$c(|\nabla I|) = \exp\left(-\frac{|\nabla I|}{K}\right)^2 \text{ or } c(|\nabla I|) = \frac{1}{1+\left(\frac{|\nabla I|}{K}\right)^2} \quad (2)$$

B. Data Pre-Processing

Morphology is a technique for removing visual cues like boundaries and skeletons that aid in the legation and recital of region shapes. It works by enlarging things, filling gaps, and then connecting all the broken things. The size of the thing is also diminished. The erosion process in a binary image eliminates the foreground background pixels. The image is subjected to morphological opening after being converted into a binary image [17]. To segment out the tumor spot from the image, a Binary tumor masked window must be created. Noise removal occurs during the pre-processing step and can be accomplished using a variety of spatial filters, including linear and nonlinear filters (Median filter). After segmentation, morphological processing is used to remove undesirable parts, and other artefacts, such as text, are removed.

C. Morphological Operation

It entails image opening, image closing, dilation, erosion operations, and a conclusion has been made regarding whether or not there is a tumor present in the MRI picture and whether it is normal or pathological. It is also where the RGB to grey conversion and reshaping happens. It has a median filter to reduce noise. The likelihood of noise appearing during a modern MRI scan is extremely low. It might come as a result of heat influence. The images frequently employs the following elements: threshold, edge, pixels, cluster, and neural network [18]. The study of morphology focuses on form-based image processing. An output image of the same size is produced by adding a structural element to the previously processed input image. Every surrounding pixel is compared to every input pixel, and the comparison's findings are used to determine the values of the corresponding output pixels. Erosion and dilation are the two primary morphological processes. Pixels are either added to the boundaries of the objects during dilation or subtracted from them during erosion, depending on the size and shape of the structuring elements. When comparing, the dilation action gives the output the greatest value of the adjacent surrounding pixels, while the erosion operation gives the output the lowest value of the nearby surrounding pixels. There are various clustering techniques, including the mountain, K-means, fuzzy C-means, and subtractive approach.

The most popular clustering method is called k-means clustering [19]. Compared to hierarchical clustering, it is more straightforward, speedier, and capable of handling a high number of variables.

The technique of segmenting an image into different parts or sections is known as picture segmentation. The main objective is to make the visual representation simpler or transform it into something else that is more straightforward and analytically insightful. It is employed to identify borders and objects in pictures. Every pixel in an image has a label assigned to it, and pixels with the same label have similar properties. Image classification is a well-known issue in image processing. The main objective of image classification is to foretell the categories of the input images using the features. Various classifiers exist, including ANNs (Artificial Neural Networks) and SVMs (Support Vector Machine). The segmentation stage is crucial for a thorough analysis of a picture because it determines how accurate the succeeding phases will be [20]. However, due to the wide variety of lesion shapes, sizes, and colours as well as various skin types and textures, effective segmentation is challenging. Additionally, some lesions have uneven borders, and occasionally, the border between the tumor and the skin is smooth. Many algorithms have been put up to solve the issue. Thresholding, edge-based or region-based, supervised and unsupervised classification approaches are some general categories that can be used to describe them. The normalisation intensity values for the MRI images in the dataset were likewise pre-processed [21].

```

    return;
end
```

Fig. 1. Morphological operation.

The intensity values between 0 and 1 were scaled using a min-max normalisation approach and resized to 224x224. The three channels were then produced by replicating the greyscale values three times because MRI pictures are greyscale images. A five-fold cross-validation at the patient level was followed by the evaluation of the created system using the Figshare dataset as shown in Fig. 1.

D. Convolutional Neural Network (CNN) for Tumor Classification in MRI Images

A deep neural network and deep learning architecture called a convolutional neural network (CNN) is applied by using transfer learning, where a deep neural network is utilized to both create new CNNs from scratch and to employ ones that already exist. The deep learning architecture is produced by combining sub-layers such as the convolution layer, activation function, pooling layer, flattening layer, and completely connected layer. The convolution layer is where the convolution procedure is carried out by segmenting the image[22]. On the other hand, activation functions are architectural elements that, depending on their function types, produce new outputs from their inputs. The layer on which pooling operations are carried out in order to reduce the larger image size caused by the convolution process is known as the pooling layer. Prior to entering the classification layer, the picture whose convolution procedures have been finished must be transformed from matrix to vector form. Feature matrices are converted into feature vectors by the process of flattening. [23][24]The classification procedure employing feature vectors and machine learning is the fully connected layer. One of the options, including support vector machines and artificial neural networks, might be chosen as machine learning.[3] Within the parameters of the study, brain tumors were segmented using transfer learning and a convolutional neural network. Feed-forward training of CNNs begins with the first input layer and continues to the final classification layer; following that, error back-propagation begins with the final classification layer and moves forward to the first convolutional layer. In a forward pass computed as follows, neuron j of layer l-1 provides input to neuron I in layer l.

$$\bar{I} n_i^l = \varepsilon_d^\Pi = 1^{w_{ij}^l \cdot x_j + b_i} \quad (3)$$

The output is computed by a nonlinearity ReLu function:

$$\text{Out}_i^l = \max(0, \text{In}_i^l) \quad (4)$$

Equations (3) and (4) are used by all neurons in the convolutional and fully connected layers to calculate the input and provide an output in the form of nonlinear activation. The K-by-K square window sliding on the N-by-N feature map is used by the pooling layer, which uses the maximum or average value of the features inside the window. It produces a single value from the K K region, reducing the spatial dimension of the feature map from N N to N/K N/K. The Softmax function is used in the last layer to calculate the classification probability for each tumor type.

$$\text{out}_i^l = \frac{e_i n_i^l}{\varepsilon_{i \in \text{Out}_k^l}} \quad (5)$$

By minimising the following cost function with regard to the unknown weights, back-propagation algorithms train

ACNNs. X I is the ith sample in the training set with the label yi, and The training set's overall training sample count is indicated by m.

$$C = -\frac{1}{m} \sum_i^m (p(y^i | X^i)) \quad (6)$$

E. Figshare Dataset of T1-CE MRI Modality MRI Images

The figshare dataset is freely accessible and frequently used to test classification and retrieval techniques. It consists of 3064 brain MRI pictures from 233 patients who have been identified as having one of the three types of brain tumors (meningioma, glioma, and pituitary tumors). The coronal, sagittal, and axial views are all part of the T1-CE MRI modality. It includes 1426 brain MRI images with glioma (corresponding to 89 patients), 708 meningioma photos (related to 82 patients), and the remaining 930 pituitary tumor images (belonging to 62 patients). Each image is 512x512 pixels in size and is accessible as.mat files. The input layer for GoogLeNet's original RGB colour image design had a size of 224x224x3.

F. Classifier Settings

1) *Anisotropic filtering*: The primary goal of image filtering is to eliminate noise from digital photographs. The noises severely impair the image's quality. The noise in the image can be removed in a variety of methods. In a noisy environment, the majority of image processing algorithms struggle to function. Fig. 2. Indicate the pre-processing tool is the image filter. Anisotropic Filter, one type of filter, is utilized in the propsoed approach for denoising. In order to explain the image diffusion process, the generic anisotropic diffusion equation is introduced as follows:

$$\frac{dx}{dy} = \text{div}(c(m, n, t) \nabla c \cdot \nabla x + c(m, n, t) \nabla x) \quad (7)$$

where, c (m, n, t) is the diffusion coefficient and ∇ is the image gradient.

The signal pixels exhibit weak diffusion action, noise pixels exhibit high diffusion action. As a result, noise can be reduced while maintaining the signal. The fixed step size for each iteration or the entire iterative process of the image can be adopted by a variety of diffusion models. Here, a more effective iteration step is suggested in the equation, where 1/4 is employed to guarantee the equation's convergence.

$$dt = \frac{1}{4} c \quad (8)$$

Iterative processes are used to produce the final output phase image. Iteration error (IE), whose formula is used to manage the iterative number during the iteration process.

$$1E = \frac{\|I^n - 1^{n-1}\|}{\|1^{n-1}\|} \leq T_i e \quad (9)$$

The iterative procedure is terminated by $IE \leq \text{Tolerance}$ (Tie).

Fig. 2. Input and output of anisotropic filter.

2) *Support vector machine filtration:* In order to avoid over-fitting and local minima and improve generalisation capabilities, SVM relies on a different induction principle known as structural risk minimization. Algorithms for SVM use a set of mathematical functions referred to as the kernel. SVM has proven to have greater generalisation abilities in sparse samples and high dimensional space. The goal is to locate the best separating hyperplane that can accurately categorise all samples. Image segmentation is the process of dividing an image into different sections. Data is inputted into the kernel, which then transforms it into the desired form [25]. SVM employ a variety of kernel functions, including sigmoid, radial basis function (RBF), polynomial, linear, and nonlinear. For sequence data, graphs, text, pictures, and vectors, kernel functions may be introduced. However, RBF is the most popular type of kernel function because it has a localised and finite response along the entire x-axis, doesn't increase computational complexity, effectively overcomes the problem of dimensionality, and returns the inner product between two points in an appropriate feature space. The maximum-margin hyperplane can be fitted using KSVMs in a changed feature space. In Fig. 3, the classifier may be a hyperplane in the higher-dimensional feature space, but nonlinear in the original input space if the transformation is nonlinear and the transformed space is higher dimensional.

Formula for defining a hyperplane is

$$P(x) = \alpha_0 + \alpha^T z \quad (10)$$

where, α is the Weight vector, α_0 is the Bias and z is the training instances that are closest to the hyperplane. Best Possible Plane Legation is

$$|\alpha_0 + \alpha^T z| = 1 \quad (11)$$

The distinction between a point z and a hyperplane is revealed in the result.

$$(\alpha, \alpha_0): D = \frac{|\alpha_0 + \alpha^T z|}{\|\alpha\|} \quad (12)$$

The canonical hyperplane's numerator is one, and the difference between it and the support vectors is,

$$D = \frac{|\alpha_0 + \alpha^T z|}{\|\alpha\|} = \frac{1}{a} \quad (13)$$

For the canonical hyperplane, the numerator is equal to 1, and the difference from the support vectors is,

$$M = \frac{2}{a} \quad (14)$$

In the end, the maximising problem for M and the minimising problem for a function are the same. $R(\infty)$ is constrained in numerous ways.

Fig. 3. Find a separating straight line for a set of 2D points that may be linearly divided into two classes.

3) *Deep convolutional neural network features:* On a variety of difficult visual analysis tasks, deep convolutional neural networks have been consistently outperforming other methods. Recently, deep convolutional neural networks have been used to classify images from enormous image datasets. In order to enable the description of latent concepts for pattern recognition, a deep CNN is able to automatically learn fundamental filters and combine them in a hierarchical manner. However, overfitting and lengthy processing times are issues with many deep CNNs. In order to learn the characteristics of brain MRI pictures with tumors, the suggested algorithm makes use of updated and improved GoogLeNet. In the remainder of the paper, the features retrieved using a modified version of GoogLeNet will be referred to as deep CNN features. GoogLeNet is referred to as a deep network, having a total of 22 learnable layers [26]. It has a fully connected layer, nine inception modules, two pooling layers, two convolutional layers, and two pooling layers. Once more, an inception module has a pooling layer in addition to six convolution layers. The architecture of the module includes filters in the sizes 1x1, 3x3, and 5x5. It is anticipated that filters with various kernel sizes will detect various data patterns. At the conclusion of each module, the feature maps corresponding to various filters are concatenated. Additionally, smaller kernel convolutions are carried out before bigger kernel convolutions. They are designed to reduce computations' dimension. The training set was used to train the modified GoogLeNet (after pre-processing). Heuristic adjustments were made to the network's hyperparameters to speed up the convergence of the loss function during training.

Deep convolutional neural network with features with support vector machine classifier: The modified GoogLeNet's pooling layer, which was implemented after the previous inception module, was used to extract features. After that, the traits were categorised using SVM. We used a multi-class SVM model with error-correcting output code (ECOC). A one-

vs-all strategy was used for multi-class categorization. There were three binary SVM learners with linear kernels.

Principles of Linear SVMs:

Given an N-size, p-dimensional training dataset of the following kind

$$\{(x_n, y_n) | X_n \in \mathbb{R}^p, y_n \in \{-1, +1\}\}, n = 1, \dots, N \quad (15)$$

where, either y_n is -1 or 1, which corresponds to class 1 or class 2. A p-dimensional vector represents each x_n . We want the support vector machine that separates class 1 from class 2 along the maximum-margin hyperplane.

$$wx^- = b0 \quad (16)$$

where, W is the hyperplane's normal vector and represents the dot product. The W and b should be chosen to maximise the margin between the two parallel hyperplanes while maintaining data separation. Thus, we use the following equations to define the two parallel hyperplanes:

$$wx^- = b1 \quad (17)$$

Binary SVMs pick up on the decision function $f(\cdot; w, b): \mathbb{R}^p \rightarrow \{-1, +1\}$ defined by $f(x; w, b) = \text{sign}(w \cdot x - b)$. Let Y now be a collection of $t > 2$ classes, which stands for the classes of tumor types. Now, we're going to take a look at t output functions, one for each class, that express the degree of certainty for each prediction. Equation defines the output function for a stylish $\in Y$.

$$F(x, \omega, b) = \langle w, \varphi(x) \rangle + b \quad (18)$$

To boost the forecast's level of confidence, the predicted class y_b for a given point x is determined, with the formula $y_b = \text{argmax}_y Y f_y(x; w, b)$. Finding w and b parameters that, at the very least, substantially result in accurate predictions and satisfy equation is what training is all about. $w, b; f_y(x) > f_u(x; w, b)$.

IV. RESULTS AND DISCUSSION

The performance of the proposed approach is validated using performance matrices like Accuracy, Precision, F-measure and Loss. The MATLAB application from MathWorks is used to carry out the experimental process. Brain tumors are recognised by a GoogLeNet deep learning algorithm. The Convolutional Neural Network and Sector Vector Machine are coupled to choose and classify the features (CNN-SVM). Anisotropic filter is utilized as a pre-processing tool, while morphological analysis is used as an optimisation tool. The values of the underlying variables should be generated using the continuity equation in order to evaluate the efficacy of the suggested approach.

A. Metrics for Performance

The measurements for the suggested model are provided in the section, some of which have been examined and verified. The following mathematical diagram illustrates the study of performance measures [6]:

1) Accuracy: Many correct patterns to the total number of patterns is how accuracy to precision ratio is calculated.

$$\text{Accuracy} = \frac{TP+TN}{TP+FN+FP+TN} \quad (19)$$

2) Precision: Precision is the ratio of positively anticipated values to all positively predicted values.

$$\text{Precision} = \frac{TP}{TP+FP} \quad (20)$$

3) Recall: The true positives and false negatives numbers are obtained using the recall measure. The equation below shows that the recall and sensitivity are both known quantities.

$$\text{Recall} = \frac{TP}{TP+FN} \quad (21)$$

4) F-score: The precision and recall values that are combined to get the F-score are used to calculate the score. The observation can be used to calculate the recall and precision weighted average.

$$\text{F-score} = 2 \frac{\text{precision} \times \text{recall}}{\text{precision} + \text{recall}} \quad (22)$$

5) Loss: One maximum performance metric to evaluate the effectiveness of the SVM classifier. Moreover, it is evaluated using the error function.

B. Performance Analytics

The suggested model outperforms previous models, as shown by the statistical statistics provided above. The proposed approach is illustrated and flowchart in Fig. 4 in the approach recommended in the suggested technique.

Fig. 4. The proposed methodology's flowchart process.

TABLE I. COMPARISON OF THE PROPOSED AND EXISTING METHODS' PERFORMANCE

Predictive Methods	Performance of Classifier				
	Accuracy	Precision	Recall	F-Measure	Loss
DNN	0.8641	0.8365	0.8254	0.86	1.6522
SVM	0.7225	0.7212	0.7356	0.73	1.2566
ANN	0.8316	0.7963	0.7792	0.83	0.9325
Hybrid CNN-LSTM	0.9785	0.9538	0.9781	0.96	0.7840
Proposed Method	0.9864	0.9317	0.9860	0.97	0.8630

In Table I, accuracy is represented by 0.9864, precision by 0.9317, recall by 0.9860, F-measure by 0.97, and loss using the proposed technique is represented by 0.8630. The accuracy rating for the Hybrid CNN-LSTM is 0.9785, the precision rating is 0.9538, the recall rate is 0.9781, the F-Measure is 0.96, and the loss rate is 0.7840. The accuracy rating for the

ANN method is 0.8316, the precision rating is 0.7963, the recall rate is 0.7792, the F-measure is 0.83, and the loss rate is 0.9325. Precision, recall, accuracy, and loss value for the SVM technique are 0.7225, 0.7212, 0.7356, and 1.2566, respectively, for the overall F-measure. Additionally, using the DNN technique, the accuracy is 0.8641, precision is 0.8365, recall is 0.8254, F-Measure is 0.86, and loss is 1.6522.

In Fig. 5, the accuracy of the CNN-SVM brain tumor detection is displayed. It takes about 32 seconds to complete the training process and displays the accuracy result with 58 epochs per iteration. Also, the accuracy is indicated by the blue graphical line. As a result, for a successful evaluation procedure, the performance of the proposal can be trained and validated. As a result, the performance is quite effective for the suggestion.

Fig. 5. The results that are accurate based on the graphical representation.

As seen in the graph below, the suggested attribute selection utilising the CNN-SVM model results in a loss with the least degree of detection error. When iteration is increased, the detection error of the suggested solution decreases. The suggested methodology is shown to improve accuracy and error function as a result. Fig. 6 Illustrates the loss function of the transfer learned model during training.

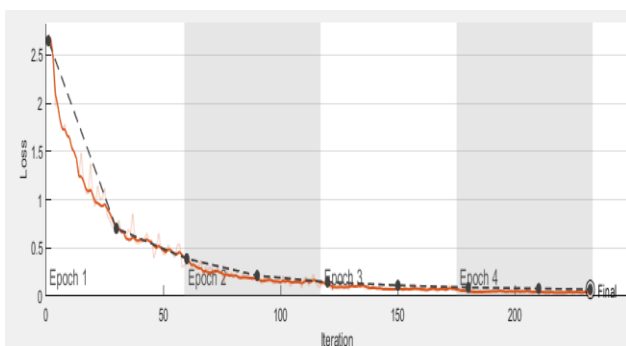

Fig. 6. The loss function of the transfer learned model during training.

The model's accuracy is demonstrated in Table II. By analysing the results and processing time. It may also be concluded that processing speed and results depend on the gradient of the pixels, the size of the image, and the quality of the image.

TABLE II. THE RESULTS OF THE TIME RESEARCH ON VARIOUS IMAGES OF BRAIN TUMORS SHOWING HOW TIME DEPENDS ON THE PREDICATED CRITERIA

No	MRI Brain Image.jpg	Preprocessing Time in seconds	Type of Image	Remarks	ACC %
i		16.268	-	Tumor not found	97
ii		19.989	Benign	Tumor found	99
iii		14.719	Benign	Tumor found	98
iv		29.401	Benign	Tumor found	99
v		11.451	Benign	Tumor found	96
vi		12.866	Malignant	Tumor found	95
vii		11.121	Malignant	Tumor found	97
viii		13.275	Malignant	Tumor found	99
ix		14.224	Malignant	Tumor found	96
x		16.263	-	Tumor not found	99

V. CONCLUSION

The proposed research combines Deep CNN characteristics and an SVM classifier powered by GoogLeNet's convolutional neural network (CNN) to segment brain tumors. The modified GoogLeNet's pooling layer, which was implemented after the previous inception module, was used to extract features. After that, the traits were categorised using SVM. Image processing has been successfully used to locate tumors in MRI brain scans, efficiently identifying the tumor's position by illuminating the area if it were there.

A database of 2D tumor image data is generated from the MRI scans acquired from different angles of a specific patient and the images are analyzed to pinpoint the precise 3D location of the tumor. The proposed method of classifying brain images using CNN and SVM has the potential to be a useful tool for computer assisted clinical diagnosis. The attributes increased performance when employed with tested classifier models. The most significant new finding of the study is a strategy for integrating them to distinguish between benign and malignant MRI brain as it produces a successful early tumor detection technique using computer-aided diagnosis. Early detection of brain tumors can benefit patients, healthcare providers, and the healthcare system as a whole. Patients can benefit from early detection by receiving timely treatment, which can improve their chances of survival and reduce the risk of complications. Healthcare providers can benefit by being able to provide more effective treatment and improve patient outcomes. Early detection can also reduce healthcare costs associated with treating advanced stage tumors. Additionally, early detection can enable researchers to better understand the disease and develop more effective treatments.

The future work can be advanced by regularly improving the model's accuracy by training it on larger and more comprehensive datasets. Several improvements are still feasible despite the successes presented in this research; there was a significant misclassification of samples from the dominant, and the phenomena of overfitting with smaller training data was noted. These problems should be addressed in the domain's future study, perhaps with data augmentation and additional fine-tuning of the transfer learnt model.

Abstract—The visual quality of photographs and videos can be negatively impacted by various weather conditions, such as snow, haze, or rain, affecting the quality of the images and videos. Such impacts may greatly affect outdoor vision systems that rely on image/video data. It has recently drawn a lot of interest to remove rain streaks from a single image. Several deep learning-based methods have been introduced to address the issue of removing rain streaks from a single image. Still, the efficiency of rain streak removal with enhanced quality is challenging. Hence, a novel deep-learning method is introduced for rain streak removal. The proposed Extended Generative Adversarial based De-raining (Ex_GADerain) is the enhanced version of a traditional Generative adversarial network (GAN). The proposed Ex_GADerain introduced a Self-Attention based Convolutional Capsule Bidirectional Network (SA-CCapBiNet) based generator for enhancing the rain streaks removal process. Also, the loss function estimation using the adversarial loss and the mean absolute error loss minimizes the information loss during training. The minimal information loss enhances the generalization capability of Ex_GADerain, and hence the enhanced performance is acquired. The quality assessment of a derained image based on various assessment measures like SSIM, PSNR, RMSE, and DSSIM improved performance compared to the conventional rain streak removal methods. The maximal SSIM and PSNR acquired by the Ex_GADerain are 0.9923 and 26.7052, respectively. The minimal RMSE and DSSIM acquired by the Ex_GADerain are 0.9367 and 0.0051, respectively.

Keywords—Deep learning; rain streaks removal; image generation; quality measure; capsule network; adversarial learning

I. INTRODUCTION

In recent scenarios, outdoor vision systems are mainly impacted by awful weather conditions, including rain [1]. Due to the large light scattering and motion velocities, the raindrops generally produce bright streaks in the captured images or videos through cameras [2]. Such conditions can highly influence the image's visual quality and also degrades outdoor vision systems' efficiency [3]. Also, it affects the efficacy of several computational vision mechanisms like event detection, scene analysis, and object detection and action recognition. Thus, such effects due to rain can be resolved by performing an automated rain streak removal process [4]. During rainy conditions, the streaks of rain generate haziness and blurring impact in images because of

light scattering [5]. Thus, effective approaches are highly needed for many practical applications to remove rain streaks from the captured images or videos [6].

The primary goal of raindrop removal is to reduce the rain effects, which has been analyzed extensively [7]. Computer vision techniques mainly consider a pure image as input for understanding a scene. However, the available rain streaks can blur the scene and degrade the performance of such techniques [8]. The major problem in deraining approaches is exploiting the necessary attributes of rain streaks and the pure image [9-12]. The model-based methods define the removal of rain streaks as an optimization issue [13]. It contains hand-crafted regularizers that mention the preceding knowledge of a solution, like repeatability, high-frequency probability of the rain streaks and the image's piecewise smoothness [14]. Nevertheless, such model-based mechanisms are unsuitable for rainy conditions since the degradation process can become more complicated [15]. To solve this issue, learning-based schemes are utilized to learn the essential attributes from the data like convolutional filters, stochastic distributions and Gaussian mixture models (GMMs) [16-18]. In recent years, deep learning techniques are becoming more popular for detection analysis. Such techniques can acquire the data characteristics by a trained deep neural network and with an effective representation capability, attaining appropriate outcomes and promoting the data to a large extent.

The conventional deep learning techniques face two difficulties while removing rain streaks. At first, the trained network's efficiency is mainly based on the training data. For instance, the deep detail network (DDN) is mainly focused on understanding the nonlinear mapping in detail layer to the rain streaks with straightforward network structures. Secondly, because of the complicated network design, several deep learning techniques can suffer [19]. The rain streaks removal methods are generally categorized based on the input type. Single-image methods are employed when the input is in image form. On the other hand, the single image techniques demand the need of image priors to regain the fundamental background scene, such as nonlocal self-similarity prior, dictionary-based sparse prior, GMM-based layer prior and low rank prior [20]. However, the existing methods face several challenges while eliminating rain streaks in the images.

A. Research Questions

Some of the research questions concerning the proposed rain streak removal process are:

- 1) What is the need for including the noise removal technique through the filtering process?
- 2) How the efficient of the de-raining process enhanced with minimal computational complexity?
- 3) How the hybrid deep learning process generates the de-rained image by the generator module of the framework?
- 4) How the proposed method solves the problems faced by the existing methods?

The proposed study attempted to design a deep-learning model for removing rain streaks from input images. The major contributions of the research are:

- To develop a novel Extended Generative Adversarial based Deraining framework for eliminating awful rain streaks in input images.
- To attain needed information about rain streaks, a detailed layer is extracted in the proposed work with a hybrid filtering method.
- To obtain a de-rained image, a Self-Attention-based Convolutional Capsule Bidirectional Network is introduced in the generator block of the proposed framework.
- To evaluate different performance matrices for analyzing the efficacy of proposed framework with other existing methods.

II. RELATED WORKS

Some recent studies on rain streaks removal through different techniques are described as follows: Wang et al. [21] developed a kernel-guided convolutional neural network (KGCNN) for eliminating rain streaks from a single image. This existing study involved three important steps for performing rain streak removal. The motion blur kernel was initially learned through a plain neural network named parameter network from the raining patch's detail layer. Next, the learned motion blur kernel was stretched into a degradation map with a similar spatial size as the rainy patch. Finally, the developed deraining network, along with the ResNet design, was trained with the help of stretched degradation map with the detail patches. The simulation analysis shows that the developed model obtained optimal performance; however, the overall processing time is enhanced.

Lin et al. [22] introduced a sequential dual attention network for removing rain streaks in a single image. For this purpose, the proposed study designed a framework named Sequential dual attention based Single image DeRaining deep Network (SSDRNet) model. An inherent correlation between rain streaks in a given input image should be more powerful than that among the rain streaks and background of an image. Thus, a two-stage learning mechanism was applied to acquire the spread of rain streaks in an image effectively. The developed two-stage deep neural network contains three

varied blocks such as multi-scale feature aggregation modules (MAMs), sequential dual attention blocks (SDABs) and residual dense blocks (RDBs). The details about rain streaks of the given image were learned through the developed two-stage mechanism and perfectly eliminates the noise. The simulation results show that the developed model achieved more appropriate SSIM and PSNR values than other methods.

Hettiarachchi et al. [23] introduced conditional generative adversarial networks (CGANet) to ignore rain streaks in the provided single images. This existing work utilized the adversarial loss in generative adversarial networks (GANs), which affords a new component to the loss function. It helps to maintain the outcome and assists in obtaining higher performance. Here, a generator network was employed to map the rainy images to de-rained images and a discriminator network was utilized to categorize actual and created de-rained images. Varied performance measures were employed to compute the efficacy of a developed model through synthesized and realistic images. The result analysis shows that the developed CGANet model has more potential than other competing methods.

Darney et al. [24] presented the rain streak removal process through a dictionary-based sparsity process with MCA estimation. This existing study introduced a sparse coding process to eliminate rain streaks by applying morphological component analysis (MCA). Using MCA, estimation, of course, becomes effortless to manage the rainy streaks in the provided images. Through sparse decomposition, removing and estimating each sample redundancy is highly feasible. To obtain optimal MSE and PSNR outcomes from the recovered images, the developed MCA scheme is integrated with the process of sparsity coding. Furthermore, the developed model attained reduced MSE value; however, the computational complexity is enhanced.

Chang et al. [25] presented the curriculum learning model for eliminating the rain streaks from input images. This study uses a direction and residual awareness network to ignore unwanted rain streaks to obtain a clear image. To prove the efficacy of a developed model, a statistical analysis was performed on the extended-scale actual rainy images and plotted that rain streaks in normal patches exhibit principal directionality. By applying a direction-aware network, the directionality property was endowed and helps to differentiate rain streaks from an image edge. Finally, residual aware block (RAB) was introduced to analyze the relationship between the image and residual. This model assisted in learning the balance parameters to emphasize the necessary image features and provided positive outcomes.

Yang et al. [26] devised a rain streak removal process using the fractal band learning based strategy based on self-supervised approach. Here, the discriminative features were extracted from the input rained image using the fractal band learning strategy. Besides, the regularization of the network was devised for enhancing the generalization capability of the network through the cross scale learning approach. The robustness of the model was depicted through the quantitative analysis. Still, the failure in considering the texture features degrades the performance of the model.

Wang et al. [27] designed a deep learning based image de-raining model, wherein the shared source residual module was incorporated in the conventional deep convolutional neural network for making the skip connection to solve the vanishing gradient issues. The computational overhead evaluated by the designed model was minimal with enhanced outcome. Still, the method degrades its performance compared to state of art methods due to the negative perception.

Ran et al. [28] introduced an image de-raining through the patch analysis. In this, patch analysis was devised based on the task driven strategy, wherein K-shot learning was utilized for removing the rain streaks from the image. Besides, the computational overhead of the designed model was minimized through the skip connections and accomplished superior outcome in removing the rain streaks. Still, the computational complexity of the model was higher.

Wang et al. [29] suggested a rain streak removal method using the joint depth estimation approach. Here, the dilated residual network was incorporated in the generator module of the conventional GAN network for generating the depth map to remove the rain streaks. The robustness of the model was proved based on both the quantitative and qualitative analysis. Still, the processing time of the model was higher.

B. Problem Statement

The rainy weather environment highly influences the visibility of scene objects in acquired real-time images. Similarly, the visualization of a high-definition image captured by cameras degrades mainly under outdoor weather scenarios, including fog, snow and rain. These worst visual quality of real-time images can impact the nature of image surveillance, computer vision and multimedia applications. Hence, eliminating the rain streaks from the captured images is an essential demand in real-time multimedia applications. The rainy image generally defines the linear sum of the rain layer and a background image. In this case, restoring a blurred image due to rainy streaks is challenging because of several interconnection feasibilities among a specific image's rainy and background layers. Different techniques were developed to separate rainy streaks and clear images effectively. However, they failed to afford an appropriate performance because varied orientations and shapes of rain streaks degraded the images. Thus, to overcome limitations observed in previous studies, the proposed study introduced an effective rain streak removal mechanism by inspiring the higher efficiency of deep learning techniques. The proposed Ex_GADerain approach removes the rain streaks from the image more efficiently by incorporating the novel SA-CCapBiNet in the generator module of the conventional GAN technique. Besides, the computation overhead is reduced through the detail layer extraction through the CGBiF.

III. PROPOSED EX_GADERAIN-BASED RAIN STREAKS REMOVAL

Varying weather conditions like rain, snow, fog, and haze influence the visual quality of outdoor captured images. Rain patterns generate more effects on the image's visual quality than others. In addition, the rain patterns also degrade the forward and background information of an image. Thus,

removing rain streaks from the captured images improves the necessity. Most recently, deep learning models have gained more attention for removing rain streaks in images. Therefore, the proposed study planned to design a deep learning mechanism called Extended Generative Adversarial based De-raining (Ex_GADerain) framework to eliminate the rain streaks from the provided input images.

The proposed framework involves four stages: image acquisition, detail layer extraction, de-raining operation and classification. Initially, the input images are acquired from the publicly available dataset. The detail layer is extracted through Cross Guided Bilateral Filtering (CGBiF) method to attain essential information about rain streaks, removing unwanted noises. Then, the detail layer is provided as an input of the proposed Ex_GADerain framework. This framework contains two important blocks: generator and discriminator. The generator block produces the de-rained image through a new Self-Attention based Convolutional Capsule Bidirectional Network (SA-CCapBiNet) model. The discriminator block of the GAN model classifies whether the generated de-rained image is real or fake. Thus, the proposed deep learning framework effectively removes the rain streaks from the input dataset images. The block diagram for Ex_GADerain-based Rain Streaks Removal is depicted in Fig. 1.

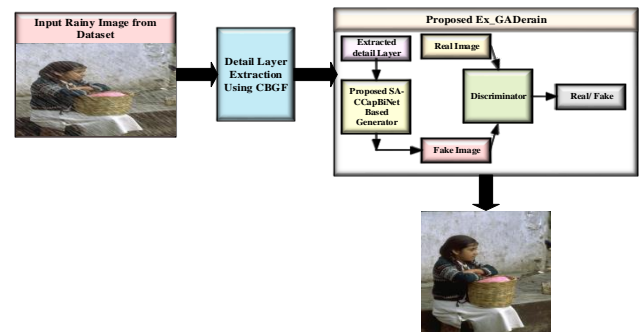

Fig. 1. Block diagram for Ex_GADerain-based rain streaks removal.

C. Image Acquisition

The rain streaks removal from the rained image using the proposed Ex_GADerain acquires the input rain-streaked image from the rainy image dataset [26]. Let A be the dataset with a total of t images, from which f^{th} image is taken for processing the proposed Ex_GADerain. It is expressed as,

$$A = \{A_1, A_2, \dots, A_f, \dots, A_t\} \quad (1)$$

Where, the f^{th} image in the dataset is indicated as A_f .

D. Detail Layer Extraction

The detail layer extraction is devised using cross guided bilateral filter (CGBF). In this, a guided image with weight and robust properties is utilized along with the bilateral filter. The CGBF comprises two different filters for performing filtering and kernel identification. In the traditional cross-bilateral filter (CBF), nearby pixels' geometric closeness and gray-level similarities are considered in the image to perform the filtering operation. In contrast, the guided bilateral filter

(GBF) uses a guided image indication based on similar pixels in the neighbourhood concerning an image. The hybridization of characteristic behaviour of both the GBF and CBF constitutes the CGBF [31]. The CGBF-based detail layer extraction is depicted in Fig. 2.

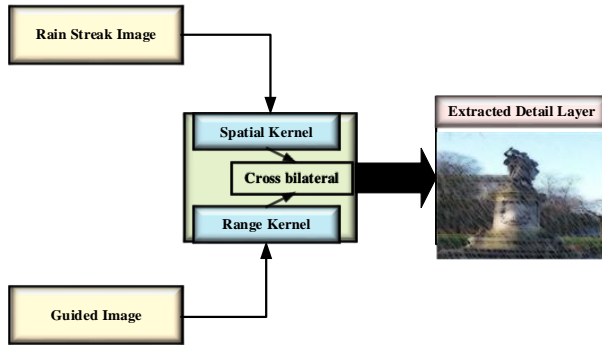

Fig. 2. CGBF-based detail layer extraction.

The outcome of a CGBF-based detail layer extraction is formulated as,

$$d_{DLE}(M,N) = P_{DLE} = \frac{1}{W_{M,N} \sum_{M,N \in W_{M,N}} S \cdot Y_{\sigma k}(|M-N|) Y_{\sigma g}(|P(M)-P(N)|) P(N)} I_{M,N} V_{M,N} + J_{M,N} \quad (2)$$

The outcome of a CGBF filtering is the detail layer extraction, which is represented as $d_{DLE}(M,N)$. M and N Refers to the adjacent pixels in the location $P(M)$ and $P(N)$, and the guided image is indicated as S . The range and spatial kernel functions concerning the CGBF are formulated as:

$$Y_{\sigma k}(|M-N|) = e^{-\frac{|M-N|^2}{2\sigma k^2}} \quad (3)$$

$$Y_{\sigma g}(|P(M)-P(N)|) = e^{-\frac{|P(M)-P(N)|^2}{2\sigma g^2}} \quad (4)$$

Where, the spatial kernel function is notated as $Y_{\sigma k}$, and the range function is notated as $Y_{\sigma g}$. The constraints are notated as σg and σk respectively. The smoothing of an image is employed for the reduction of error based on coefficients of the guided filter $I_{M,N}$ and $J_{M,N}$ and is formulated as,

$$I_{M,N} = \frac{\sum_{i \in W_{M,N}} V^i U^i - V^{M,N} U^i}{\sigma_{M,N}^2 + \gamma} \quad (5)$$

$$J_{M,N} = U^i - I_{M,N} V^{M,N} \quad (6)$$

Where, guided and original image's mean indicated as V^i and U^i respectively. The window function is indicated as W , and the regularization constant is indicated as γ . The variance

is notated as $\sigma_{M,N}^2$. The extracted detail layer is fed into the Ex_GADerain module for de-raining the image and classification.

E. Ex_GADerain-based Rain Streaks Removal

The rain streaks image filtered by the cross-guided bilateral filter is fed into the proposed Extended Generative Adversarial based Deraining (Ex_GADerain) for obtaining the de-rained image. The proposed Ex_GADerain is the improved version of traditional GAN. The GAN comprises networks, adversarial and generative components, each with specific functions.

a) *Networks*: The networks are utilized for training; hence, deep neural network (DNN) is utilized in GAN for learning.

b) *Adversarial*: The learning of a network is devised by the adversarial settings of a GAN.

c) *Generative*: The generation of data is performed by the generative model through the probabilistic approach.

GAN's work utilizes various network learning approaches termed discriminator and generator to make better decisions. Initially, GAN's generator produces a fake outcome based on the given input to confuse the discriminator. Hence, the role of a discriminator is to identify the original sample from the combined original and fake samples. Generating a fake outcome and identifying an original sample by the discriminator continues repetitively until optimal learning [32]. The proposed Ex_GADerain is depicted in Fig. 3.

Fig. 3. Proposed Ex_GADerain.

The reason behind the consideration of GAN for acquiring the de-rained image is its high-quality image outcome for performing the image processing tasks. Here, the generator is utilized for generating the de-rained image. Hence, the rain streaks removal process is further enhanced by incorporating Self-Attention based Convolutional Capsule Bidirectional Network (SA-CCapBiNet) model on the generator side. The proposed SA-CCapBiNet is designed by hybridizing the Convolutional Capsule Network, Bidirectional Long Short Term Memory (BiLSTM), and the self-attention module. The illustration of a proposed SA-CCapBiNet for a generator is portrayed in Fig. 4.

Fig. 4. Architecture of proposed SA-CCapBiNet for generator.

1) *Proposed SA-CCapBiNet-based generator module*: The traditional GAN utilizes DNN in the generator module to generate real and fake images. In the proposed Ex_GADerain technique of de-raining the rained image, SA-CCapBiNet is utilized in the generator for generation images. The newly devised SA-CCapBiNet is the hybridized structure of Convolutional Capsule Network (CCap), Bidirectional Long short term memory (BiLSTM), and self-attention mechanism. A detailed description is given below.

2) *Convolutional capsule network (CCap)*: The convolutional neural network (CNN) is a deep learning architecture commonly utilized for image processing tasks due to its promising solution. The two unique features utilized by CNN have shared weights and local connections. In addition, the parameter reduction is employed by CNN through the replicated weighting criteria. The outcome of the CNN is expressed as,

$$y_q^h = a \left(\sum_{p=1}^{F_{map}} y_p^{h-1} * r_{pq}^h + e_q^h \right) \quad (7)$$

$$a(y) = \max(0, y) \quad (8)$$

Where, the outcome of a past iteration $h-1$ concerning the p^{th} feature is indicated as y_p^{h-1} , the total features are notated as F_{map} , the q^{th} feature concerning the current iteration h is expressed as y_q^h , and the activation is notated as $a(\cdot)$. The convolution operation is indicated as $*$.

a) *Activation*: Rectified Linear Unit (ReLu) is utilized to transform the features nonlinearly to learn the complex features more accurately.

CNN's pooling operation is utilized for feature reduction, which causes information to be lost. Also, the CNN limits performance by changing scale, translational and rotational variance, but superior performance is acquired with the CapsuleNet. Thus, the combined Convolutional Capsule Network (CCap) is utilized in the proposed SA-CCapBiNet method.

b) *CapsuleNet*: The input to CapsuleNet is CNN's feature vector output. The CapsuleNet output is estimated using the Squashing function and is formulated as follows,

$$w_q = \frac{\|u_q\|^2}{\alpha + \|u_q\|^2} \frac{u_q}{\|u_q\|} \quad (9)$$

where, u_q refers to the input, the activation function is indicated as squashing function and is represented as w_q , in which the long vector is shrunken into the required length based on α and the short vector is shrunken to the length zero. The CapsuleNet acquires the input as,

$$u_q = \sum_p s_{pq} Wei_{pq} v_p \quad (10)$$

Where, the weight factor is notated as Wei_{pq} , and the outcome of a capsule is indicated as v_p .

Then, an expression for the coupling coefficient s_{pq} is formulated as,

$$s_{pq} = \frac{\exp(x_{pq})}{\sum_n x_{pn}} \quad (11)$$

Where, the probabilities of two coupled capsules are notated as x_{pq} and x_{pn} respectively.

The coupling coefficient is updated iteratively based on dynamic routing. The outcome of a subsequent layer is shared with the parent layer for each capsule's output, which is called dynamic routing. Here, the weight updation based on dynamic routing considers the adjacent capsule for enhancing the similarity between two coefficients. Thus, the combined CCap network replaces the single neuron with the neuron vector to enhance rain streaks removal efficiency. The features mapped using the CCap are fed into the BiLSTM to generate fake images to confuse the discriminator. The architecture of a CCap Network is depicted in Fig. 5.

Fig. 5. Architecture of convolutional CapsuleNet (CCap).

3) *BiLSTM*: The outcome of CCap is taken as input to the BiLSTM module for capturing the long-term dependency information. The BiLSTM comprises several LSTM cells, wherein a gating mechanism is utilized to capture the essential

attribute mapping. The architecture of BiLSTM is depicted in Fig. 6(a), wherein the LSTM cell is portrayed in Fig. 6(b).

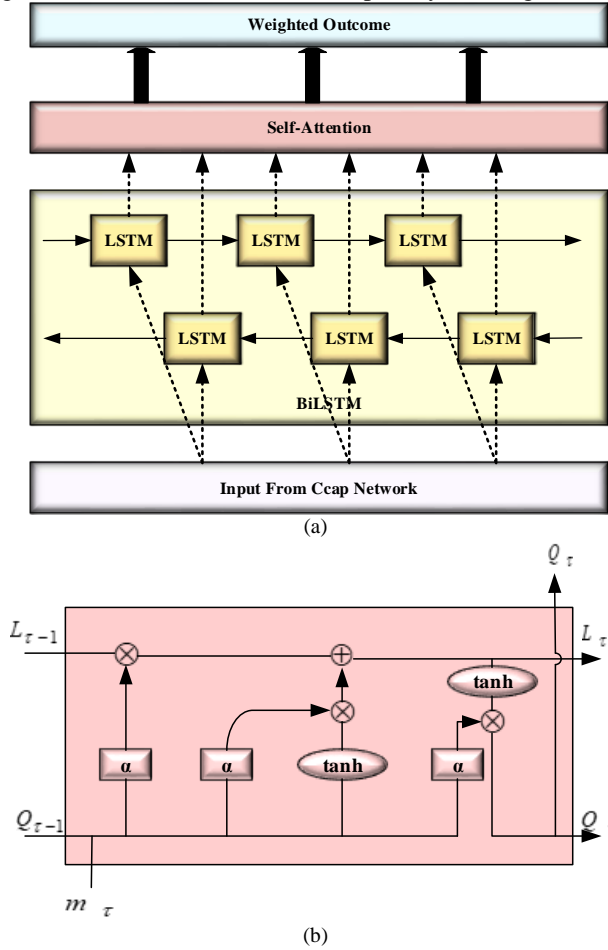

Fig. 6. Architecture of (a) BiLSTM and (b) LSTM cell.

a) *LSTM*: A recurrent neural network (RNN) with the memory unit constitutes the LSTM and is designed to overcome the issues concerning the vanishing gradient that limits the generalization capability. The gates and cell functioning are the major concept utilized in LSTM for making decisions. Cell state is utilized to maintain the information for further processing, which helps to minimize the vanishing gradient issue.

b) *Cell State*: The memory cell of LSTM constitutes the cell state, wherein the decision concerning the information removal or insertion is devised using the gating mechanism. The functioning is performed through sigmoid and point-wise multiplication for information maintenance. The cell state result is either '1' or '0', in which the information removal is devised for zero outcomes and the information maintenance is devised for the outcome '1'. Here, \tilde{L}_τ refers to the cell state and its new state is notated as L_τ . The formulation for the cell state based on the hidden state and input is expressed as,

$$\tilde{L}_\tau = \tanh(Z_L[Q_{\tau-1}, m_\tau] + X_L) \quad (12)$$

$$L_\tau = G_\tau * Q_{\tau-1} + R_\tau * \tilde{L}_\tau \quad (13)$$

Where, X_L refers to the bias and Z_L refers to the weight, hidden state is notated as $Q_{\tau-1}$, the input message is indicated as m_τ , forget gate's outcome is indicated as G_τ , and the outcome of the input gate is indicated as R_τ .

c) *Forget Gate*: The less informative features are removed by the forget gate, which is evaluated as,

$$G_\tau = \alpha(Z_G[Q_{\tau-1}, m_\tau] + X_G) \quad (14)$$

Where, the sigmoid activation is indicated as α the bias and weight concerning the forget gate are notated as X_G and Z_G respectively. Here, the outcome of a sigmoid function decides whether the information is remembered or forgotten.

d) *Input Gate*: The role of an input gate is to regulate the information that needs to be included in the cell state by using the sigmoid function. Feature filtering is employed for information maintenance by considering the input and hidden state. The sigmoid gate devises the filtering of information, and the expression for the input gate outcome is,

$$R_\tau = \alpha(Z_R[m_\tau, Q_{\tau-1}] + X_R) \quad (15)$$

Where, the outcome of an input gate is indicated as, and the bias and weight concerning the input gate are notated as X_R and Z_R , respectively.

e) *Output Gate*: The feature vector generation using the tanh function and filtering using the sigmoid function are devised in the output gate for better decision-making. The outcome of an output gate is,

$$G_\tau = \alpha(Z_G[Q_{\tau-1}, m_\tau] + X_G) \quad (16)$$

$$Q_\tau = D_\tau * \tanh(L_\tau) \quad (17)$$

Where, the outcome of a gate is indicated as G_τ , and the bias and weight concerning the input gate are notated as X_G and Z_G respectively.

f) *BiLSTM*: The information processing is devised in only one direction by the existing LSTM; hence, considering the past information is impossible. Thus, considering previous information, backward processing is essential, accomplished through backward information processing. Let \vec{P}_τ be the

forward direction-based processing and \overleftarrow{P}_τ be the backward direction processing of the BiLSTM. The architecture with both directional behaviours is depicted in Fig. 5. The outcome of BiLSTM is formulated as,

$$P_\tau = \vec{P}_\tau \oplus \overleftarrow{P}_\tau \quad (18)$$

Where, the outcome of BiLSTM is notated as P_τ , and the summation operation is notated as \oplus . The outcome of BiLSTM is more efficient due to considering both the subsequent and preceding information.

g) *Self-attention*: The assignment of weights among the extracted features is devised in the self-attention module. Here, the weights are employed for the features extracted by the BiLSTM, wherein the highest weight is assigned for the most significant attributes. The correlation between the currently hidden and high-dimensional vectors is utilized for weighting the attributes. The hidden vector formulation is expressed as,

$$\mu_{\tau} = \tanh(Z_z * Q_{\tau} + X_z) \quad (19)$$

Where, the hidden vector is notated as μ_{τ} , the hidden state is indicated as Q_{τ} , the bias is indicated as X_z and the weight is notated as Z_z . Then, the outcome of an attention module is expressed as,

$$Attn = \sum_{\tau} \eta_{\tau} * Q_{\tau} \quad (20)$$

Where, the variable η_{τ} is calculated as,

$$\eta_{\tau} = \frac{\exp(\mu_{\tau} * \mu_z)}{\sum_{\tau} \exp(\mu_{\tau} * \mu_z)} \quad (21)$$

Here, the high dimensional feature is indicated as μ_z . An outcome of the self-attention module is the de-rained image.

4) *Generator-discriminator operation*: Here, the proposed SA-CCapBiNet generator acquires the input data $p(m)$ and the noisy variable $p(c)$, in which the input is the rain streaks image. While performing the rain streaks removal process, the attributes like texture information and higher order colour are maintained during the image translation.

a) *Loss Function*: The loss of a proposed Ex_GADerain is minimized through the min-max optimization issue and is expressed as,

$$MIN^G MAX^D = K_{m \sim p(m)} |\log D(m)| + K_{c \sim p(c)} |\log(1 - G(c))| \quad (22)$$

Where, the discriminator is indicated as D , the generator is indicated as G , the expectation operator is indicated as K , the input rain streak image is indicated as $p(m)$ and the noisy image is indicated as $p(c)$. The role of a discriminator is to correctly identify the fake image generated by the generator and try to maximize $\log D(m)$. In contrast to the generator, SA-CCapBiNet tries to minimize the $\log(1 - G(c))$. Thus, the min-max optimization is devised in GAN for enhancing the image de-raining process.

In addition to the adversarial loss function, the mean absolute error is included for generating the blurred image. Thus, the loss function of the proposed Ex_GADerain is expressed as,

$$L_{MAE} = K_{m,b,c} \left[\|m - G(c,b)\| \right] \quad (23)$$

Where, the mean absolute error is notated as L_{MAE} , the generated image is indicated as $G(c,b)$ in the region (m,b,c) . Then, the total loss of a proposed Ex_GADerain is formulated as,

$$L_{Total} = L_{Ex_GADerain}(G.D) + \beta L_{MAE}(G) \quad (24)$$

Where, the parameter utilized for controlling the weights is indicated as β .

Thus, learning based on the loss function enhances the accuracy of a de-raining process and provides an efficient outcome.

F. Classification of Input Image

The outcome of the self-attention module is utilized for decision-making regarding whether the concerning input image is rained image or not. For this, this softmax activation is utilized and is formulated as,

$$C = \text{soft max}(Z_c s + X_c) \quad (25)$$

Where, the classification outcome is indicated as C , the input vector is indicated as s , the bias is indicated as X_c and the weight is notated as Z_c .

Hence, the outcome of a proposed Ex_GADerain is the classification of an input image as rained or not.

IV. RESULTS AND DISCUSSION

The proposed Ex_GADerain technique is analyzed by implementing the proposed methodology in PYTHON programming language using an 8GB RAM PC with Windows 10OS. The experimental outcome and various assessments are devised to portray the excellence of the Ex_GADerain method.

a) *Dataset Used*: The rainy image dataset [30] analyses the proposed method's performance. The dataset has 1000 normal images with 14 rainy images with different magnitudes and orientations of rain streaks. The rainy image was generated using photoshop.

A. Experimental Outcome

The experimental outcome of a proposed Ex_GADerain is illustrated in Fig. 7, wherein the rain-streaked image is portrayed in Fig. 7(a), the detail layer extracted image is portrayed in Fig. 7(b) and the de-rained image is portrayed in Fig. 7(c).

Fig. 7. Experimental outcome of Ex_GADerain: (a) Input rainy Image, (b) Detail layer extraction and (c) De-rained image

Fig. 7 shows that removing the rain streaks using the proposed Ex_GADerain technique obtained a visually better outcome. Still, the quality of a de-rained image is analyzed through image quality assessment measures.

B. Image Quality Assessment

The outcome of a proposed Ex_GADerain-based de-rained image is assessed based on various image quality assessment measures like structural similarity index measure (SSIM), Dissimilarity index measure (DSSIM), peak signal to noise ratio (PSNR), and root mean square error (RMSE).

1) *Structural similarity*: The similarity between the de-rained images acquired by the proposed Ex_GADerain and the original image is measured through the SSIM measure. By setting various windows, the quality of an image is measured. Let's consider a window size $B \times B$ for both the de-rained and original images. Then, the expression for the SSIM is formulated as,

$$SSIM_{t,o} = \frac{(2M_t M_o + s_1)(2\sigma_{to} + s_2)}{(M_t^2 + M_o^2 + s_1)(\sigma_t^2 + \sigma_o^2 + s_2)} \quad (26)$$

Where, the mean concerning the de-rained image is indicated as M_t , the mean concerning the original image is indicated as M_o , and the covariance is notated as σ_{to} . The variance for the de-rained and original image is notated as σ_t and σ_o respectively. The stabilization factors are notated as s_1 and s_2 , respectively. The analysis based on the similarity index of a proposed Ex_GADerain method is depicted in Fig. 8. The similarity between the derained outcomes of the proposed Ex_GADerain with an original image with 50% learning and 40 epoch is 0.7015, which is 0.9697 with 90% of learning data. The similarity value with 90% learning data is

closer to the maximal value 1, which depicts the excellence of a proposed method in removing the rain streaks in a rainy image. The detailed analysis of Ex_GADerain based on SSIM is depicted in Table I.

Fig. 8. Analysis of Ex_GADerain based on SSIM.

TABLE I. ANALYSIS OF EX_GADERAIN BASED ON SSIM

Epoch	Training Data				
	50	60	70	80	90
20	0.6955	0.7673	0.7756	0.9212	0.9545
40	0.7015	0.7765	0.7849	0.9378	0.9697
60	0.7197	0.7837	0.7926	0.9415	0.9726
80	0.7209	0.798	0.8005	0.9569	0.9888
100	0.7353	0.8009	0.8175	0.9695	0.9935

2) *Dissimilarity measure*: The dissimilarity between the de-rained image and an original image is measured through DSSIM. The formulation for finding the DSSIM is expressed as,

$$DSSIM_{t,o} = \frac{1 - SSIM_{t,o}}{2} \quad (27)$$

Fig. 9. Analysis of Ex_GADerain based on DSSIM.

TABLE II. ANALYSIS OF EX_GADERAIN BASED ON DSSIM

Epoch	Training Data				
	50	60	70	80	90
20	0.1955	0.173	0.156	0.0412	0.0245
40	0.1915	0.165	0.149	0.0378	0.0197
60	0.1997	0.137	0.126	0.0315	0.0126
80	0.1109	0.1009	0.0997	0.055	0.0215
100	0.1053	0.0994	0.0975	0.0195	0.0035

Where, the dissimilarity is notated as $DSSIM_{t,o}$. The analysis of Ex_GADerain based on DSSIM is portrayed in Fig. 9. With 60% of data learning and 20 epochs, the DSSIM evaluated by the Ex_GADerain is 0.173, which is 0.0994 for 100 epochs with the same training data. Thus, the epoch value enhancement improves the de-raining process by reducing the dissimilarity between the images. Likewise, for 70% of learning data and 80 epochs evaluated, the DSSIM of 0.0997 is 0.0215 with 90% of learning data. Thus, the increased amount of learning data minimizes the image's dissimilarity, indicating the more accurate removal of rain streaks. Thus, the minimal value of dissimilarity is acquired with higher learning data and epoch values. Also, the minimal DSSIM between the de-rained and original image depicts the better outcome of the proposed Ex_GADerain method. The detailed analysis of Ex_GADerain based on DSSIM is portrayed in Table II.

3) *Peak signal-to-noise ratio*: The reconstructed image quality from the rainy image based on the noise level is measured through the PSNR. The ratio between the original image and the noise evaluated based on the error defines the PSNR. Here, the error measure of the de-rained image is evaluated through the mean square error (MSE). Then, the formulation of PSNR is expressed as,

$$PSNR = 10 \log_{10} \frac{Value_{peak}}{MSE} \quad (28)$$

Where, the peak value of a de-rained image is notated as $Value_{peak}$. The MSE is formulated as,

$$MSE = \frac{\sum_{R,C} (I_t(R,C) - I_o(R,C))}{R * C} \quad (29)$$

Where, the number of rows is indicated as R , the number of columns is indicated as C , and the intensity of an original and derained image is notated as $I_o(R,C)$ and $I_t(R,C)$, respectively. The analysis based on PSNR is depicted in Fig. 10. The maximal PSNR acquired by the Ex_GADerain is 26.4052 with epoch 80 and 80% of learning data, which is 26.5457 with 90% of learning data with epoch 80. Here, the PSNR value also elevates with the epoch and learning data percentage enhancement. The larger value of PSNR measured in decibels depicts a better outcome, and the detailed analysis is portrayed in Table III.

Fig. 10. Analysis of Ex_GADerain based on PSNR.

TABLE III. ANALYSIS OF EX_GADERAIN BASED ON PSNR

Epoch	Training Data				
	50	60	70	80	90
20	23.5955	23.6673	23.7756	23.8212	23.9545
40	24.5015	24.6765	24.7849	24.8378	24.9697
60	25.5197	25.6837	25.7926	25.8415	25.9726
80	26.0962	26.2372	26.3155	26.4052	26.5457
100	26.4353	26.7009	26.8175	26.7695	26.9135

4) *Root mean square error*: RMSE is an error measure that evaluates the error in the de-rained outcome based on the MSE. The formulation for the RMSE is defined as,

$$RMSE = \sqrt{MSE} \quad (30)$$

The analysis based on RMSE is depicted in Fig. 11. The RMSE evaluated by the Ex_GADerain method is 2.3955 with 20 epochs and 50% learning data, 2.1573 with learning data of 60%, 1.7312 with learning data of 80%, and 0.9445 with learning data of 90%. The analysis shows that the error gets minimized with more information learning. The higher amount of data the classifier learns enhances the generalization capability and minimizes the error in removing the rain streaks. The difference between the original and derained image based on the error magnitude accomplished minimal error that indicates the enhanced quality of the rain streaks removal process. The detailed analysis is depicted in Table IV.

Fig. 11. Analysis of Ex_GADerain based on RMSE.

TABLE IV. ANALYSIS OF EX_GADERAIN BASED ON RMSE

Epoch	Training Data				
	50	60	70	80	90
20	2.3955	2.1573	1.856	1.7312	0.9445
40	2.2915	2.145	1.849	1.7478	0.9597
60	2.1997	2.137	1.8326	1.7515	0.9626
80	2.1109	2.0031	1.8223	1.7421	0.9545
100	2.1053	2.0009	1.8175	1.7395	0.9435

C. Comparative Analysis

The existing image de-raining techniques like CGAN [21], KGCNN [22] and SSDRNet [23] are compared with the proposed Ex_GADerain method to depict the performance enhancement. Fig. 12 depicts the comparative analysis. The SSIM estimated by the Ex_GADerain method is 0.9562 with 60% of data learning, which is higher than the conventional methods. Conventional KGCNN acquired the SSIM of 0.9336, CGAN of 0.7796 and SSDRNet of 0.7736, respectively. The dissimilarity measures of the EX_GADerain method is 0.0126 with 70% of training data; the traditional methods like KGCNN, CGAN, and SSDRNet accomplished the higher DSSIM value of 0.0315, 0.126, and 0.147, respectively. The error estimation based on RMSE estimated by the Ex_GADerain method is 0.9545 with 80% of training data, which is minimal compared to the traditional methods like KGCNN, CGAN and SSDRNet that acquired the RMSE value of 1.7421, 1.8223, and 2.0031 respectively. The maximal PSNR acquired by the Ex_GADerain method is 25.8552, with 50% of data learning. The traditional KGCNN, CGAN and SSDRNet methods acquired the minimal PSNR of 25.6549, 24.2887, and 23.9778, respectively. Thus, the Ex_GADerain method accomplished superior performance for all quality measures.

Fig. 12. Comparison in terms of (a) SSIM, (b) DSSIM, (c) PSNR and (d) RMSE.

D. Analysis based on the Classification

The detection of the rainy or non-rainy input image is devised by the proposed Ex_GADerain technique prior to the rain streaks removal.

Fig. 13. Analysis based on the classification.

TABLE V. OVERALL PERFORMANCE ANALYSIS

Metrics/ Epoch	20	40	60	80
Accuracy	92.3576	93.479	94.286	95.1852
Recall	91.5763	92.482	93.655	94.1032
Precision	78.3517	79.252	80.127	81.0779
F-measure	84.4512	85.296	86.542	87.1063

The image detected as rainy is utilized for removing the rainy streaks to acquire the de-rained image. The outcome of the classification task based on the performance measures like accuracy, precision, recall and F-Measure is portrayed in Fig. 13. The outcome based on the classification task based on overall performance analyzed in Table V.

1) Accuracy and loss: The accuracy and loss analysis of a proposed Ex_GADerain method based on the testing and training data by varying the epoch is depicted in Fig. 14. The accuracy of training is higher compared to the testing process. Likewise, the loss concerning the testing process is higher than the training process.

Fig. 14. Accuracy and loss analysis: (a) Accuracy and (b) Loss.

E. Complexity Analysis

The complexity analysis of a proposed Ex_GADerain with the conventional methods is depicted in Fig. 15. While training the data, the time complexity of the Ex_GADerain method is 65.34ms, which is 6.76%, 3.13%, and 1.21% improved performance compared to the traditional KGCNN, CGAN, and SSDRNet. Likewise, the time complexity of rain streaks removal methods while testing is 12.56ms, 13.91ms, 14.89ms, and 15.78ms for Ex_GADerain, KGCNN, CGAN, and SSDRNet methods. Here, the proposed Ex_GADerain acquired minimal time complexity compared to the traditional testing and training methods.

Fig. 15. Complexity analysis.

F. Comparative Discussion

The best outcome of Ex_GADerain based on various assessment measures along with the traditional KGCNN, CGAN and SSDRNet is depicted in Table VI. The maximal similarity of the de-rained image with the original image evaluated by the Ex_GADerain is 0.9923, which is 3.13%, 18.35%, and 18.84% enhanced performance compared to conventional KGCNN, CGAN and SSDRNet methods. The maximal PSNR evaluated by the Ex_GADerain is 26.752, 1.72%, 1.93%, and 2.31% enhanced performance compared to conventional KGCNN, CGAN and SSDRNet methods. The minimal RMSE acquired by Ex_GADerain is 0.9367, which is 45.30%, 48.03%, and 52.87% enhanced performance compared to conventional KGCNN, CGAN and SSDRNet methods. The minimal DSSIM acquired by Ex_GADerain is 0.0051, which is 74.63%, 94.59%, and 94.83% enhanced performance compared to conventional KGCNN, CGAN and SSDRNet methods. Here, Ex_GADerain accomplished excellent performance compared to the conventional rain streaks removal methods.

TABLE VI. COMPARATIVE DISCUSSION

Metrics/ Methods	KGCNN	CGAN	SSDRNet	Ex_GADerain
SSIM	0.9612	0.8102	0.8054	0.9923
PSNR	26.2464	26.1891	26.087	26.7052
RMSE	1.7125	1.8023	1.9875	0.9367
DSSIM	0.0201	0.0942	0.0987	0.0051

The analysis depicts the enhanced performance of the Ex_GADerain method based on various assessment measures. Rain streak removal using the Ex_GADerain utilizes the detail layer extraction for smoothing the rainy image. It also reduces the error through the guided filtering technique. The SA-CCapBiNet-based generator in generating fake images by removing the rain streaks. Here, the proposed SA-CCapBiNet reconstructs the de-rained image through the enhanced capability of feature representation. Also, the consideration of long term dependencies among the information enhances the rain streak removal capability of the model by solving the vanishing gradient issues. Besides, the texture and colour

information maintenance during the rain streaks removal process enhances the quality of a derained image. Considering mean absolute error with the adversarial error for evaluating the loss function minimizes the information learning and makes the generalization more efficient. Thus, the quality assessment of the derained image and the classification tasks acquired better performance.

V. CONCLUSION

Rain streaks removal using the proposed Ex_GADerain from the rainy image accurately reconstructed the derained image. The proposed SA-CCapBiNet-based generator enhances the deraining process by considering the long-term dependencies and the generated features' past information. Also, the weight updation based on the dynamic routing of a convolutional capsule network enhances the efficiency of rain streak removal through the neuron vector instead of a single neuron. The self-attention criteria weight the more appropriate features with higher weights, making the rain streak removal more efficient. The quality assessment of the derained image based on various assessment measures like SSIM, PSNR, RMSE, and DSSIM improved performance compared to the conventional rain streak removal methods. The maximal SSIM and PSNR acquired by the Ex_GADerain are 0.9923 and 26.7052, respectively. The minimal RMSE and DSSIM acquired by the Ex_GADerain are 0.9367 and 0.0051, respectively. However, the error evaluated by the proposed method is higher. Hence, in the future, a novel rain streak removal method with optimized deep learning will be designed for handling bad rainy conditions

Abstract—Human activity recognition is widely used in smart cities, public safety and other fields, especially in smart home systems where it has a pivotal role. The study addresses the shortcomings of Markov logic networks for human activity recognition and proposes a human activity recognition method in smart home scenarios - an activity recognition framework based on Probabilistic Soft Logic (PSL). The framework is able to deal with logical uncertainty problems and provides expression and inference mechanisms for data uncertainty problems on this basis. The framework utilizes Deng entropy evidence theory to provide an evaluation method for sensor event uncertainty, and combines event calculus for activity modeling. Comparing the PSL method with three other common recognition methods, Ontology, Hidden Markov Model (HMM), and Markov logic network, on a public dataset, it was found that the PSL method has a much better ability to handle data uncertainty than the other three algorithms. The average recognition rates on the ADL and ADL-E sub datasets were 82.87% and 80.33%, respectively. In experiments to verify the ability of PSL to handle temporal complexity, PSL showed the least significant decrease in the average recognition rate and maintained an average recognition rate of 81.02% in the presence of concurrent and alternating activities. The human activity recognition method based on PSL has a better performance in handling both data uncertainty and temporal complexity.

Keywords—Human activity recognition; probabilistic soft logic; MAP inference; temporal complexity; data uncertainty

I. INTRODUCTION

With the rise of smart cities and smart homes and the rapid development of related technologies, human activity recognition has become a hot topic of research for many researchers [1]. In the smart home environment, human activity recognition can help the smart home system to form a human “understanding” based on the activities being performed by the residents, and then provide better and smarter living services to the residents [2-3]. With the new iteration of wireless sensing devices, the research focus of smart home systems is gradually shifting from data collection to high-level information integration and activity recognition [4]. Human activity recognition includes sequential activity recognition and composite activity recognition, while the latter is more in line with the alternating and concurrent characteristics of daily activities [5-6]. Problems related to activity recognition have been classified into 12 main research types based on three different metrics: number of recognized users, activity

complexity and perceptual patterns [7]. In order to further optimize the structure and function of smart home systems and provide a more convenient, comfortable, and safe living environment for people with inconvenience, especially the elderly, the study focuses on the identification of complex activities based on dense sensing in a single user environment of smart home systems. Firstly, a human activity recognition framework based on Probabilistic Soft Logic (PSL) is proposed, and an event preprocessing mechanism is proposed based on the characteristics of dense sensing. The reduction of irrelevant and redundant data is achieved through fragment partitioning and event merging. In addition, an event uncertainty calculation method based on DS evidence theory is proposed for data uncertainty in activity recognition, and activity modeling is carried out by combining Event Calculus (EC) and PSL. It is expected that the ability to relax first-order logical constraints through PSL and the ability to describe event persistence through EC will allow for conflicts in the knowledge base, enhance the freedom of the activity model, and further enhance its ability to handle logical uncertainty and temporal complexity problems.

Section II of the article describes the relevant work, focusing on the current research status at home and abroad, and provides a detailed explanation of the improvements and technical roadmap of the research. The first section of Section III proposes a human activity recognition framework based on PSL, which provides a detailed introduction to segment partitioning, event merging, and calculation methods for event uncertainty. Subsection B of Section III provides an activity modeling method based on PSL-EC and proves the equivalence between PSL-EC and complex activity descriptions. Section IV verifies the effectiveness of the PSL method through experiments and compares it with current mainstream activity recognition methods. Section V summarizes the research methods and results, and concludes by summarizing and organizing them.

II. RELATIVE WORK

Human activity recognition is an important research field in the Internet of Things, especially in smart homes, which focuses on understanding human behavior and further predicting human action intentions and motivations. A deep neural network model using convolutional neural networks and gated recurrent units was proposed by Dua et al. for activity time series data collected by wearable sensors, and the model

was used to automatically extract and classify human activities. More than 95% accuracy was obtained on all three datasets, demonstrating the excellent recognition and classification performance of the model [8]. Zhang et al. proposed an approach combining convolutional neural networks and activity recognition attention mechanisms for sensors and mobile devices in smart healthcare applications and systems. The approach incorporates attention into a multi-headed neural network to improve the accuracy and feature extraction of activity recognition [9]. Bianchi et al. designed an activity recognition system combining a wearable device with deep learning, where the wearable system embeds an inertial measurement unit and WiFi to send the collected data to a cloud service. The system minimizes inference resources, saves cost, and achieves 97% accuracy in the recognition of 9 activities [10]. Agarwal and Alam propose a lightweight deep learning model for human activity recognition based on the feature that edge computing can reduce communication latency and network traffic, which overcomes the disadvantages of deep learning computationally intensive. Experimental results obtained on six daily activity data from testers show that the proposed model extends the ability to handle data uncertainty in activity recognition due to most existing machine learning and deep learning techniques [11]. Artikis et al. by defining the probability of maximum intervals and the confidence rate of such intervals. A linear time algorithm is then proposed to compute the full probabilistic time intervals for a given dataset and the performance of the method is evaluated on a benchmark activity recognition dataset [12].

Due to the uncertainty and temporal complexity of human daily activities, two main activity recognition methods, data-driven and knowledge-driven, have been derived. Data-driven methods mainly include Hidden Markov Model (HMM), support vector machine, dynamic Bayesian model, etc. Tran et al. investigated multiple recognition methods in multi-user scenarios and conducted evaluation experiments on the same dataset, while exploring the effectiveness and recognition efficiency of temporal learning algorithms using sequential data and non-temporal learning using temporal manipulation features the effectiveness and recognition efficiency of algorithms [13]. Li et al. proposed a method to analyze the significance of sensor data contribution based on sensor state frequency and inverse type frequency for daily behavior recognition of a single user in a multi-tenant smart home scenario Xi'an. The method is used to measure the contribution of specific types of sensors to a certain type of behavior recognition, and then construct a spatial distance matrix based on the layout of environmental sensors to achieve context awareness and reduce data noise. Based on this, an activity recognition algorithm based on wide time domain convolutional neural network and multi-environmental sensor data for daily activity recognition is also proposed [14]. Scholars such as Ashari P have conducted in-depth analysis of data fusion and multi classifier system technologies for human activity recognition, particularly systems based on mobile and wearable devices, focusing on sensor pattern based activity monitoring and classification methods used for behavior analysis, environmental monitoring, and other activities in smart home environments. They have identified the advantages, applications, and shortcomings of deep learning

fusion methods for human activity recognition [15]. Asghari et al. proposed an online application of hierarchical HMM to detect the current activity in a real-time stream of sensor events, and also to detect activities that occur during an activity, i.e., interrupted activities. The proposed approach is validated on two different smart home datasets and the experimental results demonstrate its effectiveness and superiority [16]. The knowledge-driven recognition approach reduces the dependence on data for activity recognition and usually uses Ontology or rules for activity modeling and reasoning. Zhang et al. proposed a knowledge-based multi-intelligence collaboration approach. This layered architecture for smart homes that combines Ontology and multi-intelligence technologies aims to automatically acquire semantic knowledge and support heterogeneous and interoperable services. A generic inference algorithm based on the properties of disordered actions and activity events is proposed in this architecture for real-time inference of continuous composite activities and personalized services. Then a new idea is introduced to allow intelligences to learn knowledge of human activities autonomously and to transform them. The feasibility, effectiveness and stability of the proposal are verified through an extensive experimental evaluation at [17].

Comprehensive domestic and international related research can find that most of the commonly used recognition models are hybrid-driven approaches that mix two modeling methods, such as Markov Logic Networks (MLN). However, although MLN is used as an effective framework to address uncertainty and complexity, it adopts hard constraints on closed atoms and cannot effectively describe continuous variables of sensor data classes, resulting in low efficiency and inability to meet real-time requirements. Therefore, in view of the shortcomings of MLN method for human activity recognition, a PSL based activity recognition framework is proposed. PSL adopts Lukasiewicz logic instead of Boolean logic to transform integer linear programming problem into convex optimization problem for solution. Then, DS evidence theory was used to compensate for the lack of measurement of event uncertainty in PSL, and the activity modeling method PSL-EC was proposed in conjunction with EC, aiming to achieve efficient and accurate human activity recognition.

III. PSL-BASED HUMAN ACTIVITY RECOGNITION IN SMART HOMES

A. PSL-Based Human Activity Recognition Framework

In smart home systems, especially in most voice-activated systems, a key part of implementing an intelligent control system is the recognition of human activities [18]. Many researchers have proposed many excellent recognition frameworks for different environments, but most of these frameworks focus on the monitoring of the user's own characteristics and are weak in monitoring situational information. To address the uncertainty and complexity issues in daily activities, a PSL based activity recognition framework is proposed. From an application perspective, the framework divides the smart home control system into data collection layer, event management layer, and application layer. This section mainly studies the event management layer, which is

divided into three sub tasks: event preprocessing, activity modeling, and activity inference. Event preprocessing is further divided into three parts: fragment partitioning, event merging, and event uncertainty calculation. Firstly, this section adopts a dynamic fragment partitioning method based on information quantity to address the characteristic of the unfixed sampling rate of raw sensor data. Then merge the redundant information within the fragments and consider the triggering frequency of the event; Finally, evaluate the uncertainty of these events based on DS evidence theory. The structure of the human activity recognition framework based on PSL is shown in Fig. 1.

Fig. 1. Human activity recognition framework based on PSL.

In Fig. 1, the framework divides the smart home control system into a data collection layer, an event management layer, and an application layer. The data collection layer is responsible for collecting scenario information in the smart home environment and transmitting it to the event management layer through the wireless sensor network, which includes both sensors and network components deployed in the environment. The event management layer is responsible for transforming the received raw data into high-level scenario information, which can be divided into three parts by function: event pre-processing, activity modeling, and activity inference. The application layer is responsible for integrating the identified user activities and requests and is divided into two subtasks: decision making and service management. Event pre-processing is responsible for converting raw data into probabilistic events, which mainly includes three parts: fragmentation, event merging and event uncertainty calculation. Due to the sensor inexpensiveness and activity complexity in the smart home environment, usually a single behavior can be sensed by multiple sensors. Therefore, the study divides the relationship between sensors and activities into two categories: one sensor sensing multiple activities and multiple sensors sensing one activity. For the PSL model, the size of the problem increases exponentially with the number of formulas and the sensor information is susceptible to multiple factors. Therefore, the study first excludes irrelevant scenario information by segmenting the original sensor data, and then merges the sensor events within the segments to approximate the redundant information. Finally, the credibility of the observed evidence is measured by calculating the uncertainty of the events. Common segmentation methods include the interactive window method and the segmentation method based on unique attributes. The sensor trigger moments when a particular user performs a specific activity in the experimental dataset are shown in Fig. 2.

Fig. 2. Sensor trigger time chart when a user performs a specific activity.

By observing the sensor triggers when users perform different activities in the experimental dataset, it can be seen that the number of sensors triggered by different activities is stable at around 55. Therefore, the study adopts a fragmentation method based on the number of sensors based on the feature that the number of sensors triggered by different targets in the activity is more average. The method constitutes a range of values for the window length based on the average number of sensors triggered by the activities counted in the training data, and the window length is dynamically selected based on the current sensors, and the computational expression is shown in Equation (1).

$$L_s^* = \arg \max_{w_{s_l}} \{P(w_{s_l} / A_m)\} \quad (1)$$

In Equation (1), L_s^* is the optimal window length corresponding to the active A_m . The range of values is $[w_{s_l}, w_{s_l}]$, where $w_{s_l} = \min\{\bar{w}_s(A_1), \bar{w}_s(A_2), \dots, \bar{w}_s(A_m)\}$, $w_{s_l} = \text{median}\{\bar{w}_s(A_1), \bar{w}_s(A_2), \dots, \bar{w}_s(A_m)\}$, and $\bar{w}_s(A_m)$ represent the average of the number of sensors triggered by the activity A_m . The expression of the relationship between sensors and activities is shown in Equation (2).

$$A^* = \arg \max_{A_m} \{P(A_m / S_i)\} \quad (2)$$

A^* in Equation (2) represents the optimal activity of the sensor S_i . Combining Equation (1) and Equation (2) yields the probability estimation formula for the sensor and window length as shown in Equation (3).

$$w_s^* = \arg \max_{w_{s_l}} \{P(w_{s_l} / S_i)\} = \arg \max_{w_{s_l}} \{P(w_{s_l} / A_m) \times P(A_m / S_i)\} \quad (3)$$

There is still a large amount of redundancy in the segmented data, so event merging is required before modeling to avoid overly bloated recognition models. Most traditional merging methods address the case where multiple sensors are triggered at the same time and can therefore be merged into one event, generalizing the sensor data associated with one

event and ignoring the temporal impact range of sensor events. To address this problem, the study proposes an STF-EC algorithm that considers sensor trigger time and frequency in event merging. The algorithm first sets a time decay function to limit the impact range of the event, and then marks the recurring sensor events and records the number of times the sensor triggers. The impact range is calculated as shown in Equation (4).

$$R(e_i^a, e_j^a) = \begin{cases} 1, & e_i^a.SID \in Uact_i \ \& \ e_j^a.SID \in Uact_i \\ 0, & otherwise \end{cases} \quad (4)$$

In Eq. (4), $R(e_i^a, e_j^a)$ represents the sensor dependence between two atomic events e_i^a and e_j^a . $R(e_i^a, e_j^a) = 1$. Then it indicates that two sensors correspond to one event and can be combined if they are within the time constraint. The time dependence of the two atomic times is calculated as shown in Equation (5).

$$T(e_i^a, e_j^a) = \exp(-\delta |e_i^a.T - e_j^a.T|) \quad (5)$$

The final uncertainty event corresponding to that atomic time is generated and the number of occurrences of that event is recorded. The study calculates the event uncertainty based on the evidence fusion mechanism in DS evidence theory. First, we assign weights to sensor information based on Dun entropy theory, and then combine the weights and observations to calculate the uncertainty of the event. Dun entropy is a generalized version of information entropy, which is defined as shown in Equation (6).

$$DS = -\sum_{i=1}^N m(H_i) \log_2 \frac{m(H_i)}{2^{H_i} - 1} \quad (6)$$

In Equation (6), DS denotes the Dun entropy. H_i denotes the i th proposition in the identification framework, and H_i^* denotes the number of elements in the proposition. The relationship between sensor weights and Dun entropy is defined as shown in Equation (7).

$$r_i^{pst} = f(DS^*) = (1 - DS^*) \exp(DS^*) \quad (7)$$

In equation (7), DS^* is the normalized Dun entropy. In the problem of activity identification, the sensors used as evidence have different levels of reliability, so the uncertainty of the events is calculated using a weighted fusion as shown in Equation (8).

$$\hat{u} = \sum_{i=1}^n \alpha_i x_i \quad (8)$$

In Equation (8), \hat{u} is the uncertainty of the event, x_i indicates the sensor measured data, and α_i is the weight of the data in the fusion. n indicates the number of sensors corresponding to the sensor event x_i .

B. Combining PSL and EC for Human Activity Modeling and Inference Methods

Unlike general machine learning methods, PSL is essentially a first-order logical knowledge base with weights, so the process of activity modeling is similar to the construction of a knowledge base. In the application environment of smart home, the daily life has the characteristics of alternation and concurrency, and the activity model can directly determine the accuracy of activity recognition[19-20]. The way of rule definition also largely determines the scale of the problem in PSL reasoning, which in turn affects the recognition efficiency of the recognition framework. Therefore, the study proposes the activity modeling method PSL-EC, which combines PSL and EC, to solve the problem of logical uncertainty and temporal complexity in daily activities by using the logical expression uncertainty of PSL and the characteristics of EC for activity persistence modeling. The activity modeling part includes two sub-tasks: rule definition and weight learning, and the rules in PSL can be classified into soft rules and hard rules by rule type, which are used to describe the uncertainty relationship between “event” and “activity” and the domain knowledge of activity recognition, respectively. The activity modeling approach of PSL-EC uses the classical discrete event algorithm as a template to define rules based on specific problems in the activity recognition domain and to model the continuity of activities. Then existing parametric learning methods for first-order logic formulas are used to deal with logical uncertainty. In daily life, users perform activities characterized not only by temporal complexity, but also by diversity in daily life based on different execution habits. The sensor events and durations triggered by different users performing the same activity are shown in Fig. 3.

Fig. 3. Sensor events and duration triggered by different users performing the same activity.

Daily activities may seem to be irregular, but different users often have certain patterns embedded in their starting and ending actions when performing a particular activity. Assuming that daily activities are only related to start and end actions, the predicates in the event algorithm can be approximately reduced, thus streamlining the predicate structure. The study defines the start and end conditions of an activity as soft rules, and assigns weights to the formulas through parameter learning. The core of the event algorithm lies in the use of the law of inertia to describe the continuity of events, i.e., the state of an activity is determined only by its start and end conditions. The study defines hard rules based on the axioms of event algorithms and the law of the number of event triggers. The defined soft rules and hard rules are shown in Table I.

TABLE I. SOFT AND HARD RULES OF FRAMEWORK

Rule type	Number	Describe
Soft rule	1	$\forall Timestept : Happens(pa_1, t) \wedge Happens(pa_2, t+1) \rightarrow Initiates(a, t+1)$
	2	$\forall Timestept : Happens(pa_1, t) \wedge Happens(pa_2, t+1) \rightarrow Terminates(a, t+1)$
	3	$\forall Timestept : Happens(pa_1, t) \wedge [pa_1, frequency > K] \rightarrow Terminates(a, t+1)$
Hard rule	1	$\forall Timestept_1, t_2 : HoldsAt('close the front door', t_1) \wedge (t_1 + 1 \leq t_2) \rightarrow HoldsAt('open the front door', t_1)$
	2	$\forall Timestept_1, t_2 : HoldsAt('set the table', t_1) \wedge (t_1 + 1 \leq t_2) \rightarrow HoldsAt('eat breakfast', t_1)$
	3	$\forall Timestept_1, t_2 : HoldsAt('eat breakfast', t_1) \wedge HoldsAt('clear the table', t_1 + 1) \rightarrow HoldsAt('eat breakfast', t_1 + 1)$

The original version of the PSL model can be generated by rule definition, and these formulas are often given the same weights, so more appropriate weighting is needed through parameter learning. Commonly used weight learning methods are maximum likelihood estimation and maximum pseudo-likelihood estimation, and weight maximum pseudo-likelihood estimation uses pseudo-likelihood probabilities instead of likelihood probabilities. PSL-based inference needs to be performed in a closed PSL, so its inference problem is similar to that of probability maps. Activity inference is another important part of the study, and the activity inference mechanism in PSL includes maximum posterior probability inference and marginal probability inference. The PSL model constructed by activity modeling is defined as $P = (F_i, W_i)$, where F_i is the formula template in the model and W_i is the corresponding weights. The first step in performing Maximum A Posteriori Probabilistic Inference (MAP) is to convert the arithmetic and logical rules in PSL into a linear constraint form. This form of rule can be easily converted into the form of Horn clause as shown in Equation (9).

$$\left(\bigvee_{i \in I_j^+} l_i \right) \vee \left(\bigvee_{i \in I_j^-} \neg l_i \right) \quad (9)$$

In Eq. (9), L denotes the set of all words l_i included in a clause, and I_j^+ and I_j^- denote the set of non-negative and negative words, respectively. The PSL model includes soft and hard rules, both of which can be transformed into potential functions ϕ and inequality constraints φ as shown in Eq. (10).

$$\begin{cases} \phi(y, x) = \max \left\{ 1 - \sum_{i \in I_j^+} l_i - \sum_{i \in I_j^-} (1 - l_i), 0 \right\} \\ \varphi(y, x) = 1 - \sum_{i \in I_j^+} l_i - \sum_{i \in I_j^-} (1 - l_i) \leq 0 \end{cases} \quad (10)$$

In PSL, the MAP inference problem can be described as finding the maximum probability distribution of possible worlds with the set of variables Y given the sequence of observations $X = \{x_1, x_2, \dots, x_m\}$, where the normalization factor Z is fixed, as shown in Equation (11).

$$\arg \max_{s \in S} P(S = s) = \arg \max_{y \in Y} P(y|x) \quad (11)$$

According to Equation (11), it can be learned that the maximum probability distribution of possible worlds is equal to the distance between that world and the closure rule is minimized, so the MAP inference problem in PSL can be defined as shown in Equation (12).

$$\begin{cases} \arg \max_{s \in S} P(S = s) = \arg \min_y f_w(y, x) \\ s.t. \varphi_k(y, x) = 0, \forall k \in \varepsilon \\ \varphi_k(y, x) \leq 0, \forall k \in I \end{cases} \quad (12)$$

In Equation (12), S represents the set of possible worlds consisting of x and y , and ε and I represent the set of equational constraints and inequality constraints in PSL, respectively. The MAP inference problem in PSL is a convex optimization problem rather than an integer linear programming, thus giving birth to a consistent optimization algorithm for efficiently solving large-scale optimization problems. The core of this algorithm is the Alternating Direction Multiplier Method (ADMM). Assuming that the hidden predicates constituting the soft and hard rules in the model are different, let y_j be the state variable appearing in the potential function $\phi_j(y, x)$, $j = 1, 2, \dots, m$ and y_{k+m} be the state variable appearing in the hard constraint φ_k , $k = 1, 2, \dots, r$. For each hard constraint define an indicator function I_k as shown in Equation (13).

$$I_k [\varphi_k (y_{k+m}, x)] = \begin{cases} 0, & \text{the constraint is satisfied} \\ \infty, & \text{otherwise} \end{cases} \quad (13)$$

Finally, the variable Y_i is set to be a copy of the variable y_i $i = 1, 2, \dots, m+r$, so the MAP problem in PSL can be defined in the form shown in Equation (14).

$$\begin{cases} \arg \min_{y_i \in [0,1]} \sum_{j=1}^m w s_j \phi_j (y_i, x) + \sum_{k=1}^r I_k [\varphi_k (y(L, k+m), x)] \\ s.t. y_i = Y_i \end{cases} \quad (14)$$

Combining Eq. (12) and Eq. (14), it can be seen that it is feasible to solve the MAP problem in PSL according to the ADMM approach. The data flow of the human activity recognition framework based on PSL is shown in Fig. 4.

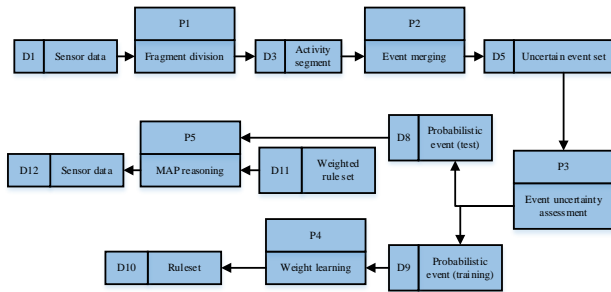

Fig. 4. Data flow of human activity recognition framework based on PSL.

As shown in Fig. 4, there are five core processing modules of the recognition framework, of which the weight learning and MAP inference modules use the platform’s original approach. The sensor data is segmented by calculating the window length corresponding to the sensor through the fragment partitioning module. Then, the sensor and time dependencies of the event are calculated in the event merging module, and uncertain events are generated by merging based on the event dependency. In the event uncertainty evaluation module, the corresponding relationship between the event and the sensor is first calculated and stored, and then the uncertainty is evaluated based on the calculated comprehensive weights. Finally, human activity recognition can be achieved through weight learning and MAP inference modules.

IV. RESULTS OF PSL-BASED HUMAN ACTIVITY RECOGNITION IN A SMART HOME ENVIRONMENT

In the superiority test of the PSL-based activity recognition method, the practicality test of the PSL method for solving the data uncertainty problem and the temporal complexity problem was focused on, and a comparative experiment was conducted with three existing recognition methods (Ontology, HMM, MLN) under two datasets. The datasets for the validity experiments are collected in the TWSTBED apartment of the WSU CASAS project, where 78 sensors including motion sensors, kettle sensors, faucet sensors, pillbox sensors, temperature sensors, etc. are deployed. The validation experiments of the PSL method’s ability to deal with data uncertainty use the ADL activity dataset containing the error data set, including both ADL and ADL-E. The ADL dataset

contains 6415 data obtained by 24 testers performing 5 different activities, while ADL-E is obtained by performing artificial activity omissions and errors based on ADL. The experiments to verify the ability of the PSL method to handle temporal complexity take the Interweaved ADL activity dataset with alternate execution activities, which consists of two parts of data obtained by 21 testers executing sequentially and by executing 8 activities in any order. Both sets of experiments were conducted using the ten-fold cross-check method, i.e. the data were equally divided into 10 parts, of which 9 parts were used as training data and 1 part was used as test data. The activities in the ADL dataset and the Interwoven ADL dataset are shown in Table II.

TABLE II. LIST OF ACTIVITIES IN THE ADL DATASET AND INTERWOVEN ADL DATASET

ADL dataset		Interweaved ADL Dataset	
Number	Activity	Number	Activity
SA1	Make a phone call	AC1	Fill medication dispenser
SA2	Wash hands	AC2	Watch DVD
SA3	Cook	AC3	Water plants
SA4	Eat	AC4	Answer the phone
SA5	Clean	AC5	Prepare birthday card
/	/	AC6	Prepare soup
/	/	AC7	Clean
/	/	AC8	Choose outfit

The performance evaluation indicators of other methods use the common F1 score, which is calculated as shown in formula (15).

$$F1 = \frac{2 \times \text{Precision} \times \text{Recall}}{\text{Precision} + \text{Recall}} \quad (15)$$

In Equation (15), $\text{Recall} = TP / (TP + FN)$, $\text{Precision} = TP / (TP + FP)$, TP is the number of correctly identified activities, FN is the number of unidentified activities, and FP is the number of incorrectly identified activities. The experiments started with event pre-processing of the data, and the average duration of the activities and the number of triggered sensors in the CASAS dataset is shown in Fig. 5.

Fig. 5. Average duration of activity and number of triggered sensors in the CASAS dataset.

According to Fig. 5, the sensor corresponds to a window length in the range of [43, 54]. Then, event merging and uncertainty calculation are performed to transform the sensor data into probabilistic events. After defining the activity rules of the model, the PSL activity model is generated by learning the weights of the soft rules based on the training data. Finally, test data and PSL activity model are input, MAP inference is performed and the identification results are compared with the correct results. Experiment 1 verifies the ability of PSL method to handle data uncertainty, and the experimental results under ADL dataset and ADL-E dataset are shown in Fig. 6.

Fig. 6. Results to verify the ability of PSL method to deal with data uncertainty.

According to the experimental results of each method in Fig. 6(a) and Fig. 6(b) on the ADL dataset, it can be seen that the PSL method has good recognition performance for various activities, especially for activities SA1, SA2, and SA4. The average recognition rate for the three activities on the ADL dataset reached 87.44%, and even on ADL-E, it can maintain an average recognition rate of 83.42%. The execution methods of activities SA3 and SA5 have diversity, while the rules of PSL and MLN are manually defined, so the recognition performance of these two methods for SA3 and SA5 is slightly worse. The method of HMM is to establish recognition models based on training data, so the recognition rates for activities SA2 and SA5 are both above 70%. According to the experimental results on the ADL-E dataset in Fig. 6(b), it can be seen that the recognition rates of all methods have decreased, especially the Ontology method which decreased by 8.38%, followed by the MLN method which decreased by 5.76%, while the PSL method has the least significant decrease, with an average recognition rate of only 2.54%. The experimental results show that PSL has the best comprehensive recognition performance and can maintain good recognition performance even in the presence of erroneous activities, with a certain degree of recognition stability. The average recognition rate of each activity in two datasets using different recognition methods is shown in Fig. 7.

Fig. 7. Average recognition rate of activities in two data sets by different methods.

In Fig. 7, the PSL method achieved the highest average recognition rate, with an average recognition rate of 82.87% and 80.33% on the ADL and ADL-E datasets, respectively, while the Ontology method had the lowest recognition rate, with 74.73% (ADL) and 68.20% (ADL-E), respectively.

The average recognition rates of the four recognition methods on two datasets were 71.47% (Ontology), 79.39% (HMN), 74.47% (MLN), and 81.60% (PSL), respectively. The experimental results further demonstrate that the PSL method can maintain excellent recognition performance even in the presence of erroneous data, and verify the effectiveness of PSL in dealing with data uncertainty. The validation results of the ability of different algorithms to deal with temporal complexity are shown in Fig. 8.

Fig. 8. Results of verifying the ability of different algorithms to deal with temporal complexity.

As shown in the experimental results of each method on the Sequential dataset in Fig. 8(a), PSL has the highest recognition rate among the four methods for 7 activities other than activity AC8, and the recognition rate for all other activities except for activity AC3 is above 80%. In the experimental results of each method on the interleaved dataset in Fig. 8(b), although the recognition rate of PSL for activities decreased under alternating and concurrent execution, the average recognition rate for activities is still the highest among the four methods, with an average recognition rate of 81.16%. The average recognition rate of each activity in two datasets using different recognition methods is shown in Fig. 9.

Fig. 9. Average recognition rate of each activity in two data sets by different recognition methods.

From Fig. 9, When there are alternating and concurrent recognition actions, the average recognition rate of the four activity recognition methods has decreased, with the HMM method showing the greatest decrease in recognition rate, with the average recognition rate decreasing from 80.32% to 74.65%. Although the average recognition rate of PSL on the Interleaved dataset has also decreased, it only decreased by

2.17%, and the decrease is not significant. It is still the highest average recognition rate among the four methods, maintaining an average recognition rate of 81.02%. The experimental results show that PSL can maintain the stability of activity recognition even when there are alternating and concurrent actions in recognition, verifying the effectiveness and superiority of PSL in processing temporal complexity data.

V. CONCLUSION

With the emergence and rapid development of smart cities and smart homes, ambient intelligence is widely used in various fields as an important part of artificial intelligence research. The study proposes a PSL-based activity recognition framework for human activity recognition in smart home scenarios, gives an evaluation method for sensor event uncertainty using DS evidence theory, and proposes an activity modeling method PSL-EC in conjunction with EC. the PSL method is compared with three other common recognition methods Ontology, HMN, and MLN on a publicly available dataset for experiments. to verify the ability of PSL to handle data uncertainty and temporal complexity. the ability of PSL to handle data uncertainty is far superior to the other three algorithms, with average recognition rates of 82.87% (ADL) and 80.33% (ADL-E) on the two sub-datasets. the average recognition rate of PSL decreases in the presence of concurrent and alternating activities is the least significant among the four methods, with declined by 2.17% and maintained the average recognition rate of 81.02%. The comprehensive experimental results show that the PSL-based human activity recognition method has excellent performance for both data uncertainty and temporal complexity. The different perception modes in the current smart home environment have their own advantages, so there is a trend towards a mixed use of multiple perception modes. However, these different patterns of scenario information exhibit heterogeneity, and current methods lack effective measures for processing these heterogeneous information. As an effective tool for eliminating information heterogeneity, ontology methods have been widely applied in other fields. However, the ability of ontology reasoning to handle uncertain information is poor, so future research can focus on the combination of ontology with methods such as MLN and PSL.

ACKNOWLEDGMENT

The research is supported by “The 14th Five-Year Plan” Project of Shaanxi Provincial Education Science Planning in 2022, “Research on the innovative application of project driven teaching mode based on OBE concept in application-oriented undergraduate colleges - taking “Android Program Design” as an example” (No. SGH22Y1838).

Design of Virtual Experiment Teaching of Inorganic Chemistry in Colleges and Universities Based on Unity3D

Xia Hu

Hunan University of Arts and Science, Chemistry and Materials Engineering College, Changde, 415000, China

Abstract—Focusing on the high-cost issues and many risk and uncontrollable factors in chemical experiment teaching in modern colleges and universities, a virtual reality inorganic chemistry (IC) simulation experiment strategy based on Unity3D technology is studied. Starting from the needs of IC experiment teaching, a collision detection algorithm (CDA) between the experimental environment and the virtual scene with Unity3D as the main technical framework is designed. The results show that the collision detection (CD) time of the CDA designed in the research is 99ms, the detection average value is 95.29%, and the accuracy variance is 0.021. The above values are better than the same type of algorithm. This shows that the CD accuracy and efficiency are higher, and the performance is stronger. In addition, the virtual chemistry experiment designed in the research can significantly improve the students' using attitude from the three main aspects of perceived ease of use (PEU), immersion and interactivity, and then enhance the students' learning effect. Therefore, the method of virtual experiment teaching of IC in colleges and universities based on Unity3D is effective and provides a new idea for modern teaching reform.

Keywords—Unity3D; inorganic chemistry; virtual reality; collision detection algorithm

I. INTRODUCTION

With the growth of contemporary computer technology, virtual reality (VR), a simulation technology based on computer technology, has gradually developed and matured. Driven by external experiential equipment and internal diverse functions, VR has gradually become a limited second reality environment. In this simulated environment realized with the external environment and equipment, users can get more intuitive experience and feedback than traditional computers. Therefore, VR technology is often used in interactive simulations such as online stores. Teaching experiment simulation is the main application direction [1-3]. It is very important to model the physical elements in the simulation environment. This is because the physical elements often need to interact with each other according to the operation of the experimenter during the experiment to completely restore the experimental process. Once there is a problem with the physical modeling, the experimental simulation will be unreal, and the feedback given to the operator will not be intuitive [4-6]. As the recently emerging 3D game production engine, Unity3D has its own particle system, physics engine, sky box and other engine elements that focus on interactivity. It includes functions such as scene view, game view, layer panel, engineering panel and monitoring panel, etc. which can

directly edit 3D virtual objects and mobilize 3D resources. Through these functions, it is easy to realize such functions as architectural visualization, 3D animation, 3D interactive environment editing, etc [7-9]. In teaching virtual experiment design, the application of Unity3D can not only give students a better virtual experiment experience, but also help schools save resources, realize self-development, and have stronger realizability.

Therefore, the research relies on Unity3D and other tools to use the interactive development environment to apply virtual reality technology to design the virtual experiment teaching of IC in colleges and universities. From the theoretical perspective of embodied cognition, the research integrates with virtual simulation technology, mobilizes learners' body movements and sensory perception systems in a highly realistic virtual learning environment, and helps learners to construct an instruction system. It not only enriches the practical research of embodied cognition in teaching applications in China, but also provides new ideas for the design of virtual simulation experiments. The virtual experiment teaching of IC in colleges and universities based on Unity3D has provided valuable theoretical and practical basis for the application of 3D technology in experimental teaching, and has played a certain role in promoting modern teaching reform.

II. RELATED WORK

The range of applications for Unity3D has grown significantly over the past few years, and the related research has also been increasing. Szłęg's team custom-developed a software that could simulate the operating environment of underwater autonomous robots using Unity3D. The software solved expensive hardware and high damage rate during the testing of underwater autonomous robots. Through this software, factors such as caustics and buoyancy of the underwater environment could be simulated to realize virtualized operation tests. The research results show that the software is robust in practical applications [10]. Zhu combined Unity3D with AI algorithms and applied them to game research and development. The researchers combined the behavior tree algorithm with the learning algorithm to establish a game NPC intelligent action model. By applying Unity3D technology to games, an intelligent game model was formed. The research results showed that the model could efficiently implement the intelligent behavior of NPC, and the system run more efficiently [11]. The Artal-Villa team applied Unity3D technology to traffic simulation, and proposed a framework

that could simulate the needs of pedestrians in traffic and restore the interactive relationship between vehicles and pedestrians. The research combined Unity3D with urban simulation open-source traffic simulator through transmission control protocol, and performed 3D simulation according to 2D scene. The findings showed that the traffic visualization ability of the system was strong [12]. Toriz applied Unity3D technology to the teaching system of the flipped classroom, and designed a laboratory classroom for landscape learning. The study analyzed the academic performance of the student group applying Unity3D technology through quantitative and qualitative dual analysis methods. The findings displayed that the average grades of these students significantly improved [13]. Wang's team used Unity3D technology to realize the research and development of the autonomous driving simulation system of unmanned ships, and designed the autonomous control simulation frameworks in the ocean and river driving scenarios in the system. Research used machine learning algorithms to enhance adaptive capabilities for autonomous navigation and control of unmanned ships. The research results showed that after algorithm optimization, the unmanned ship could successfully avoid obstacles in the simulation [14].

The research on virtual simulation experiments is also gradually enriched under the environment of rapid development of technologies such as Unity3D. For example, the Bogusevski team used 3D virtual technology to realize the simulation of campus experiments, thereby solving the problem that campus experiments were difficult to carry out under the condition of limited budget available on campus. The results showed that the study had a strong practicality [15]. Makransky et al. applied VR technology to the design of immersive simulation laboratory. The research used a pre-and post-test method to analyze whether the VR laboratory simulation program could improve students' self-learning effectiveness and scientific career vision. The results showed that students who used VR laboratory simulation programs had higher self-learning efficacy and scientific career vision [16]. Zhang combined VR technology with relay vibration protection algorithms, established a current protection simulation model in a VR simulation environment, and studied

the protection scheme under fault conditions. The results showed that the simulation scheme designed in the research could effectively simulate and demonstrate the micro electric protection model and current protection scheme [17]. The Schnack team applied VR technology to a simulation of a virtual store and compared it to a traditional computer desktop store. The research used hardware devices such as head-mounted displays, hand-held and body-sensing tracking devices to realize immersive store shopping simulations. The participants could interact on-site by moving their bodies. The research results showed that virtual store simulation technology was beneficial to promote customers' desire to buy [18]. O'Connor M's team proposed a simulation teaching strategy that combined 3D simulation technology and clinical radiology teaching experiments. The study used headsets and hand controllers in a VR kit to provide students with real-time experimental feedback, and simulated anatomy and radiology experiments through virtual ray simulation technology. The results showed that the teaching strategy of the research design gave students constructive feedback while reducing the risk of the experiment [19]. From the research related to Unity3D and virtual experimental teaching, the application area of VR and Unity3D in teaching experiments has greatly improved the teaching effect. However, most of the relevant researches are concentrated in the teaching subjects such as physics and medicine, which emphasize experimental operation. Therefore, the study applies Unity3D technology to chemistry teaching to establish a theoretical foundation for incorporating new technology into the teaching of chemistry experiments.

III. IC VIRTUAL EXPERIMENT TEACHING DESIGN BASED ON UNITY3D

A. Application Analysis of Virtual Experiment Teaching and Construction of Virtual Environment

When designing the virtual experiment teaching of IC, the research starts with students' interactive learning perception and experience cognitive habits in the VR learning environment. The learning of students is divided into three stages: VR, perceptual interaction and embodied cognition stage. The whole process is shown in Fig. 1.

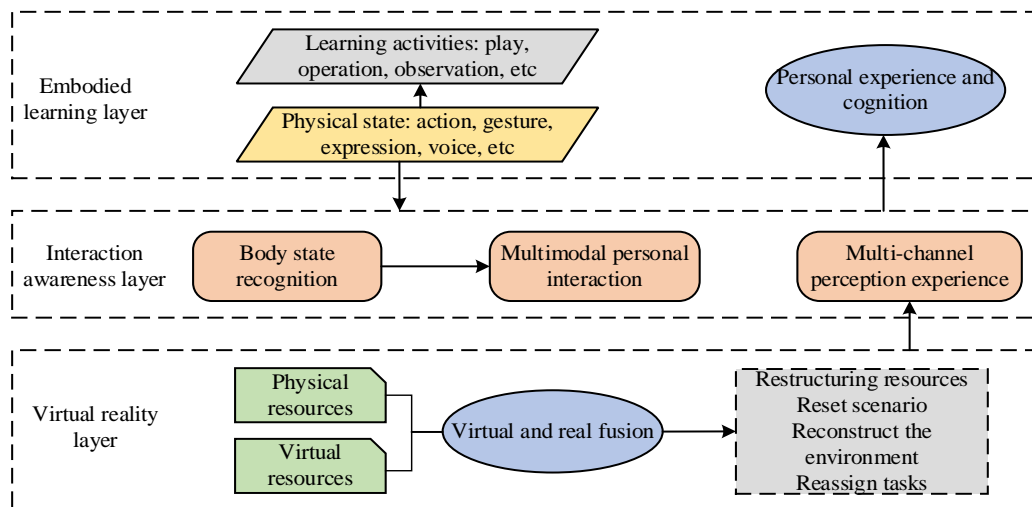

Fig. 1. Learning process.

The Unity3D platform is mainly used as the main technical carrier in the teaching design of IC virtual experiments. Unity3D is a game engine that includes functions such as virtual scenes, virtual 3D objects and physical calculations. This technology can realize the development of highly interactive applications such as architectural visualization, 3D games and animations, and support publishing on mobile platforms. This research focuses on using the physics engine to simulate Newtonian mechanics, and realizes the control, movement, and change of virtual objects in the virtual scene through scripts. This function can provide students with more intuitive and real experimental feedback. To realize the functional effect of the virtual experiment of IC, the study makes full use of VR technology to help students experience and establishes a computer simulation operating system in the virtual world. Through this system, the simulated natural environment required by users is constructed, so that students can feel the visual, auditory and tactile senses in the real scene in the virtual experiment. The research and design system is divided into 3D interactive characteristics, which are conception, immersion and interactivity. They are shown in Fig. 2.

Fig. 2. 3D interactive features.

VR is widely employed in education, mainly including virtual laboratory, teaching, and skill training. The application of VR technology in these aspects can improve teaching quality, students' learning efficiency, expand students' thinking, and enhance students' practical ability. According to the different needs of users for the VR environment and the different implementation methods, there are four subsets of the VR system: immersive, augmented, distributed and desktop VR systems. The specific composition is displayed in Fig. 3.

Fig. 3. Types of virtual reality systems.

The immersive VR system isolates the user's senses from the real world through devices like data gloves and helmets, and makes them fully immersed in the virtual environment. This type of system has a significant sense of immersion, but due to its high requirements for equipment and large investment, its development is also subject to certain restrictions. The augmented VR system refers to calculating the virtual information stored in the computer through the penetrating head-mounted display while the user observes the real environment. The virtual image obtained from the virtual information is superimposed on the real object to deepen the user's feeling of the real object. The distributed VR system relies on the immersive VR system, and enables people in different physical locations to share resources on the basis of the network to achieve a high collaborative work. Desktop VR systems use the computer screen as a channel for VR and user interaction. Users observe the VR environment through the screen, and interact with objects in the VR through simple devices. Through the device, the user can perform operations such as rotation and scaling on the controlled virtual object. Based on the cost of campus application, as well as the convenience of teaching when using the system for students, the research mainly uses desktop VR for virtual experiment design.

Virtual experiment is a VR learning resource that uses virtual equipment to conduct experimental exploration in a virtual environment constructed by a computer. The experimental environment of the virtual test is not limited by the site, which reduces the possible hazards in the real test and saves manpower and capital costs. The simulation experiment designed in the study is shown in Fig. 4.

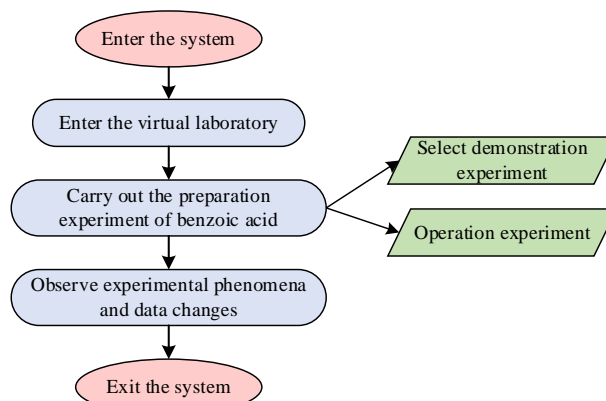

Fig. 4. Simulation experiment.

B. Virtual Anti-Collision Strategy Design

Aiming at the virtual experiment teaching of IC in colleges and universities, the research begins with the geometric modeling of chemical experiment instruments in VR. The objects in the virtual experiment are basically composed of geometric objects. Geometric modeling needs to process the topological and geometric information. Topological information is the relationship between each component that constitutes a geometric object. Geometry-related information is the position and size of objects in geometric space. The 3D graphics generate new graphics after operations such as

position movement and size adjustment. Such geometric transformation of 3D graphics is based on the coordinate origin and axes, and is realized through homogeneous coordinate transformation. When the 3D graphics are transformed, the point $P(x, y, z)$ is transformed $P'(x', y', z')$ in the geometric space. The coordinate transformation method is shown in formula (1).

$$\begin{cases} x' = x + C_x \\ y' = y + C_y \\ z' = z + C_z \end{cases} \quad (1)$$

In formula (1), C_x is translation amount of P on the X axis. C_y indicates the translation amount of P on the Y axis. C_z is translation amount of P on the Z axis. The matrix of translation of P is shown in formula (2).

$$C_1 = \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ C_x & C_y & C_z & 1 \end{bmatrix} \quad (2)$$

According to formula (2), the translation coordinate of P is displayed in formula (3).

$$[x' \ y' \ z' \ 1] = [x \ y \ z \ 1] \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ C_x & C_y & C_z & 1 \end{bmatrix} = [x \ y \ z \ 1] C_1 \quad (3)$$

When performing scale transformation on 3D graphics, if the center of the object is $P(x, y, z)$, then the point is transformed based on the coordinate axis. The scales of the transformation in the three mutually perpendicular directions of the coordinate system are u , v , and w . When the three transformation ratios are equal, the 3D graphics are transformed in equal proportions. When the $P(x, y, z)$ is changed $P'(x', y', z')$, the transformation matrix is shown in formula (4).

$$C_2 = \begin{bmatrix} u & 0 & 0 & 0 \\ 0 & v & 0 & 0 \\ 0 & 0 & w & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} \quad (4)$$

The scale transformation coordinate formula of the point P is as formula (5).

$$[x' \ y' \ z' \ 1] = [x \ y \ z \ 1] \begin{bmatrix} u & 0 & 0 & 0 \\ 0 & v & 0 & 0 \\ 0 & 0 & w & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} = [x \ y \ z \ 1] C_2 \quad (5)$$

When a 3D object is rotated in the geometric space, the matrix of the point P' is different for coordinate axes. When the point P rotates around the X axis, the transformation of its coordinates on the X axis is shown in formula (6).

$$x' = x \quad (6)$$

The coordinate transformation of P on the Y axis is shown in formula (7).

$$y' = y \cos \alpha - z \sin \alpha \quad (7)$$

The coordinate change of P on the Z axis is shown in formula (8).

$$z' = y \sin \alpha + z \cos \alpha \quad (8)$$

In formula (7) and formula (8), α is rotation angle of P around the X axis. The transformation matrix can be obtained as formula (9).

$$C_3 = \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & \cos \alpha & \sin \alpha & 0 \\ 0 & -\sin \alpha & \cos \alpha & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} \quad (9)$$

Then the coordinate transformation formula of P around the X axis is shown in formula (10).

$$[x' \ y' \ z' \ 1] = [x \ y \ z \ 1] \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & \cos \alpha & \sin \alpha & 0 \\ 0 & -\sin \alpha & \cos \alpha & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} = [x \ y \ z \ 1] C_3 \quad (10)$$

The transformation matrix of P rotating around the Y axis is as formula (11).

$$C_4 = \begin{bmatrix} \cos \beta & 0 & -\sin \beta & 0 \\ 0 & 1 & 0 & 0 \\ \sin \beta & 0 & \cos \beta & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} \quad (11)$$

In formula (11), β is rotation angle of P around the Y axis. Then the coordinate transformation formula of P rotating around the Y axis is shown in formula (12).

$$[x' \ y' \ z' \ 1] = [x \ y \ z \ 1] \begin{bmatrix} \cos \beta & 0 & -\sin \beta & 0 \\ 0 & 1 & 0 & 0 \\ \sin \beta & 0 & \cos \beta & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} = [x \ y \ z \ 1] C_4 \quad (12)$$

The transformation matrix of P rotating around the Z axis is as formula (13).

$$C_5 = \begin{bmatrix} \cos \gamma & \sin \gamma & 0 & 0 \\ -\sin \gamma & \cos \gamma & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} \quad (13)$$

In formula (13), γ is rotation angle of P around the Z axis. Then the coordinate transformation formula of the P point rotating around the Z axis is shown in formula (14).

$$[x' \ y' \ z' \ 1] = [x \ y \ z \ 1] \begin{bmatrix} \cos \gamma & \sin \gamma & 0 & 0 \\ -\sin \gamma & \cos \gamma & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} = [x \ y \ z \ 1] C_5 \quad (14)$$

Based on the basic transformation principle of 3D graphics in geometric space, the experimental scene of chemical experiments, the required equipment and their transformed positions in the geometric space of virtual experiments are geometrically modeled on Unity3D platform. After the geometric modeling of the experimental scene and objects is completed, CD technology is used to detect and process whether objects in the scene collide or not. The movement of objects in a virtual scene must also obey the objective law of the movement in reality, that is, two objects cannot occupy the same physical space. The CD technology will detect and obtain the information of the objects contact and cross-section. According to different virtual scenes, CDA are mainly divided into time-based and space-based. According to the different requirements of time changes, there are three types of time-based CDA, as shown in Fig. 5.

The static collision algorithm is suitable for use when objects in the virtual scene are stationary and do not collide. The discrete CDA detects whether objects in the virtual scene

collide at different discrete moments t_0, t_1, \dots, t_n . The continuous CDA is to continuously detect whether there is a collision between objects in the virtual scene within a time interval $[t_0, t_1]$. CDA based on space is broken up into two types according to image and object space. The algorithm solves the problem according to the 2D projection image information of the 3D object in the scene and the depth information of the image. The algorithm based on the object space solves the problem interactively according to the intersection of the 3D object with other 3D objects in the virtual space. The hierarchical bounding box algorithm (HBBA) is the most commonly used. It is suitable for object CD in more complex virtual 3D scenes. HBBA uses a bounding box slightly larger and simpler in shape than the object to wrap it around, making it a substitute for the geometric characteristics of the object. Common bounding boxes are spherical, AABB and OBB bounding boxes, as shown in Fig. 6.

In the virtual scene interaction, to enhance the speed of CD, the research proposes an improved CDA based on quantum technology ant colony (AC). The algorithm combines the AC algorithm with quantum computing technology, and improves the convergence speed of the AC algorithm through quantum computing technology. The representation of quantum AC algorithm is displayed in formula (15).

$$q_i = \left[\begin{array}{c} \cos(t_{i1}) \cos(t_{i2}) \dots \cos(t_{in}) \\ \sin(t_{i1}) \cos(t_{i2}) \dots \cos(t_{in}) \end{array} \right] \quad (15)$$

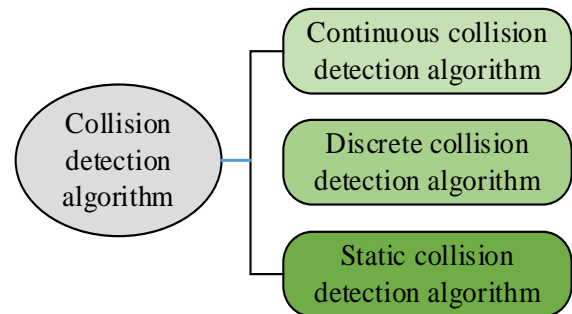

Fig. 5. Time-based collision detection algorithm.

Fig. 6. Enclosure types.

In formula (15), $t_{ij} = 2\pi rand(i, j = 1, 2, \dots, m)$, the value range is a random value in $[0,1]$. m indicates the population size of the AC algorithm. In the AC algorithm, the ants calculate the path transition probability through the information appeal and heuristic information on the moving path, and then use the moving probability to calculate the movement of the ant to the next position. The path transition probability is shown in formula (16).

$$p(x_s) = \frac{[\tau(x_s)]^\alpha [\eta(x_s)]^\beta}{\sum_{x_s \in X} [\tau(x_s)]^\alpha [\eta(x_s)]^\beta} \quad (16)$$

In formula (16), X represents the position set of feature points of the ant colony in the search space. x_s represents the target position formed by the ant under the dual guidance of pheromone intensity and visibility. $\tau(x_s)$ means the pheromone intensity of the target position of the ant. $\eta(x_s)$ represents intensity of information generated by heuristics at the target location. α represents the weight of the information strength. β represents the weight of the heuristic information strength. The research mainly uses the quantum revolving door to update the position of the ants. The formula (17) demonstrates how the quantum revolving door works.

$$\begin{bmatrix} \cos t_{si} \\ \sin t_{si} \end{bmatrix} = \begin{bmatrix} \cos \theta_i & -\sin \theta_i \\ \sin \theta_i & -\cos \theta_i \end{bmatrix} \begin{bmatrix} \cos t_{ri} \\ \sin t_{ri} \end{bmatrix} \quad (17)$$

In formula (17), i is the serial number representing the probability amplitude of the qubit. θ_i represents the rotation angle of the probability amplitude. The study introduces mutation operators to enhance the diversity of races. The mutation operations are mainly realized by quantum NOT gates, as shown in formula (18).

$$\begin{bmatrix} 0 & 1 \\ 1 & 0 \end{bmatrix} \begin{bmatrix} \cos \varphi_{ki} \\ \sin \varphi_{ki} \end{bmatrix} = \begin{bmatrix} \cos\left(\varphi_{ki} + \frac{\pi}{2} - 2\varphi_{ki}\right) \\ \sin\left(\varphi_{ki} + \frac{\pi}{2} - 2\varphi_{ki}\right) \end{bmatrix} \quad (18)$$

In formula (18), φ represents the state. The next position of the ant in the algorithm is determined by the strength and heuristic of the pheromone. The update rule of pheromone is shown in formula (19).

$$\begin{cases} \tau(x_s) = \tau(x_r) + \text{sgn}(\Delta f) * |\Delta f|^\alpha \\ \eta(x_s) = \eta(x_r) + \text{sgn}(\Delta \partial f) * |\Delta \partial f|^\beta \end{cases} \quad (19)$$

In formula (19), x_r represents the position that the ant is right now. x_s represents the new position formed after the ant changes its position. Once all the ants have completed the

position update, the pheromone intensity can be updated according to the formula (20).

$$\tau(x) = \begin{cases} (1-\rho)\tau(x) + \rho f(x), x = \tilde{x} \\ (1-\rho)\tau(x), x \neq \tilde{x} \end{cases} \quad (20)$$

The algorithm outputs the best individual with the collision threshold of the group by continuously updating until it reaches the iteration termination condition. When objects interact in a Unity3D scene, the situation is more complicated. For complex scenes, a simple CDA may result in penetrating objects or CD errors. If a grid collider is used, the computation of detection will be increased. Therefore, the improvement idea of the research is to combine the two algorithms. First, a spherical bounding box is established around the object to exclude objects that cannot be interacted with in the scene for a short time. Then a mesh collider is established for the object, so that the two CD calculations are performed on objects whose bounding boxes of two spheres have overlapped. The specific algorithm steps are as follows: establish a spherical bounding box for each object in the scene, and calculate the spherical bounding box according to the triangle information in the model. According to the i triangle the vertex vector of a , b , c and the patches n in a triangle, the calculation method of sphere enter o as shown in formula (21).

$$o = \frac{1}{3n} \sum_{i=1}^n (a+b+c) \quad (21)$$

The maximum distance d from the sphere center to all vertices is used as the radius of the spherical bounding box. Then a mesh collider is built for the 3D objects in the virtual scene, and the intersection calculation is performed for the spherical bounding box. If the intersection occurs, the next step of monitoring is not required. Finally, the object intersected by the spherical bounding box is monitored and calculated by the mesh collider. In interaction, the improved CDA is used to add colliders to the relevant instruments in the chemical experiment, and label the objects in the script to distinguish different objects.

IV. ANALYSIS OF TEACHING EFFECT OF VIRTUAL EXPERIMENT IN IC

A. Performance Analysis of Collision Algorithm

When analyzing the teaching effects of IC virtual experiments, the research first analyzes the collision algorithm designed for the research, and selects the SOLID CDA and the RAPID CDA as a comparative analysis. First, in the case of model collision and intersection, the detection intersection numbers of different algorithms are compared. Table I depicts the outcomes.

From Table I, the algorithm designed in the study always maintains the state with the largest number of detections in the range from 100 to 1000 intersecting facets. The detection ability of the algorithm designed in the research can be improved when detecting the number of intersecting triangles faces in the model. The algorithm designed in the study has the

strongest detection capabilities. The model performance comparison is shown in Fig. 7.

TABLE I. COMPARISON OF MODEL INTERSECTION DETECTION

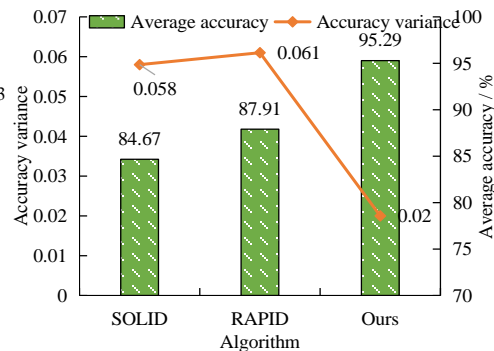

Number of Triangle Faces Intersected by the Model	Number of Intersections Detected by Different Algorithms		
	SOLID algorithm	RAPID algorithm	The algorithm designed in this research
100	88	98	100
200	186	190	194
300	278	282	294
400	342	370	386
500	462	444	474
600	512	512	562
700	576	582	656
800	694	658	762
900	718	730	858
1000	802	802	924

From Fig. 7, in CD time, the algorithm designed by the research only takes 99ms to complete the CD. The SOLID algorithm takes 105ms. The RAPID algorithm takes 132ms. The algorithm designed by the research has a significant advantage in CD efficiency. At the same time, the comparison of detection accuracy that the accuracy fold line of the algorithm designed in the study is at the highest position, in the range of 90% to 100%. The detection average is 95.29%, which is higher than the 84.67% of the SOLID algorithm and the 87.91% of the RAPID algorithm. The accuracy variance is 0.020, which is better than 0.058 of the SOLID and 0.061 of the RAPID. In the random collision performance test, the model designed by the research has advantages in both detection efficiency and accuracy.

From Fig. 8, as the sampling features increases, the detection time also increases under the premise of achieving the same detection rate. Therefore, the feature samples should be adjusted in practical applications according to the requirements, and then simultaneously satisfy the effect of detection real-time and accuracy.

(a) Collision detection accuracy of three algorithms

(e) Random collision detection rate comparison

Fig. 7. Model performance comparison.

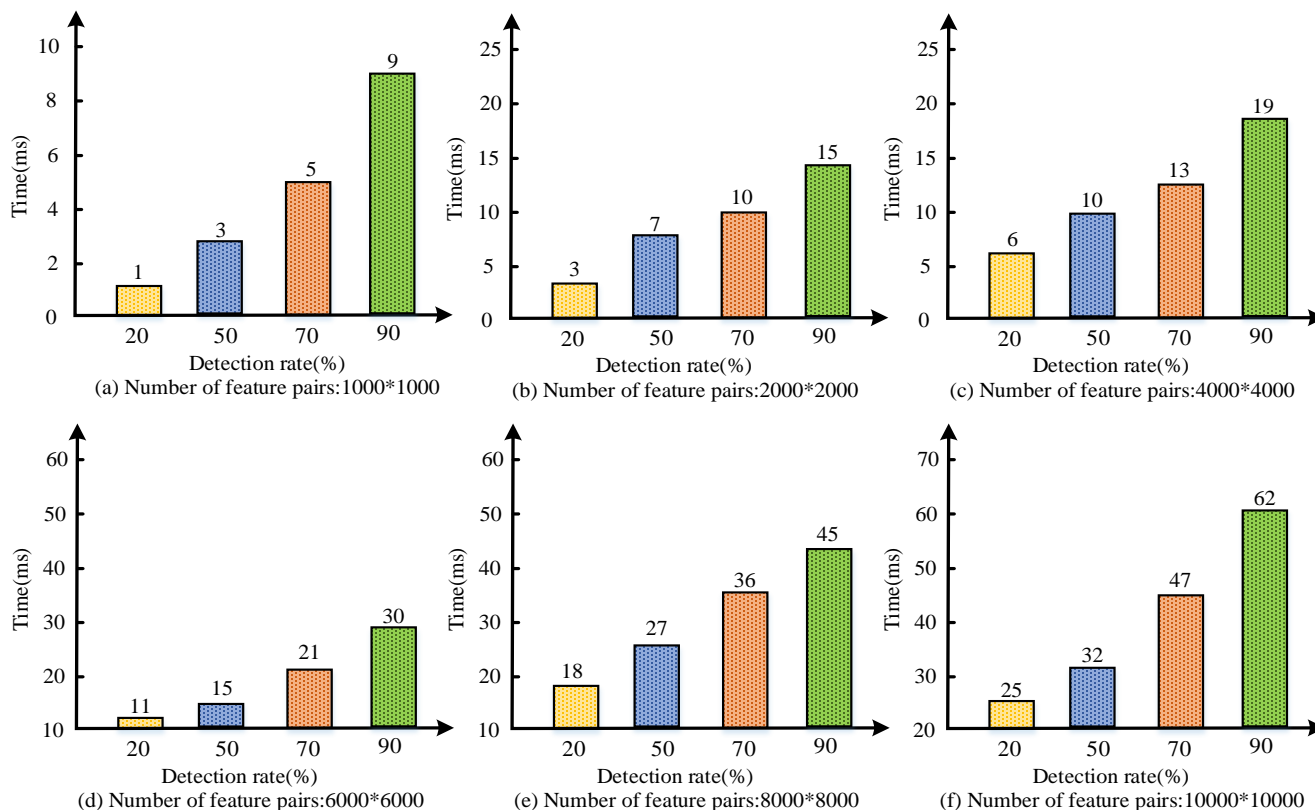

Fig. 8. Model performance comparison.

B. Analysis of Teaching Effect

In the effect analysis, the study adopts the method of teaching class experiment, and the experiment is conducted by grouping students. Questionnaires are distributed to investigate the teaching effect. Table II depicts the experimental settings.

TABLE II. TEST SETTINGS

Test subject	Type	Students at this chemistry course stage
	Quantity	52
	Group	2
	Number of people in each group	26
Test content		IC manipulative experiment
Virtual experiment hardware equipment		HTC VIVE
Virtual experiment software equipment		3ds Max
Data collection method		Questionnaire
data processing software		IBM SPSS Statistics 24

The research conducted a reliability and validity test on the distributed questionnaire. Table III depicts the results.

Cronbach’s Alpha coefficient of the research data is 0.782, which is above 0.75, indicating that the reliability is good. The KMO sampling suitability quantity is 0.652, and the significance is 0.000, which is above 0.6, and the validity is good. The study uses regression analysis to discuss the effects of virtual experiments on students’ learning motivation and use

attitude. The independent variables use four elements in the process of virtual experiments. They are PEU, perceived usefulness (PU), immersion and interactivity. Table IV displays the multiple regression analysis’s findings.

TABLE III. RELIABILITY AND VALIDITY TEST

Reliability test	Cronbach’s Alpha coefficient	0.782	
	Number of items	19	
Validity test	KMO Sampling Suitability Quantity	0.652	
	Bartlett’s test of sphericity	Approximate chi-square	443.843
		Significance	0.000
		Degrees of freedom	171

TABLE IV. MULTIPLE REGRESSION ANALYSIS RESULTS

Independent variable	Dependent variable	Standard coefficient	Adjusted fit	Significance
PEU	Learning motivation	0.691	0.467	0.000
PU		0.465	0.198	0.001
Immersion		0.578	0.318	0.000
Interactivity		0.412	0.156	0.003
PEU	Attitude	0.643	0.401	0.000
PU		0.107	0.172	0.002
Immersion		0.622	0.374	0
Interactivity		0.516	0.251	0.000

In learning motivation, the PEU and immersion of virtual experiments have the most significant impact on learning motivation, and the significance coefficients of the two variables are both 0.000. Followed by PEU, the significance coefficient is 0.001. The last is interaction, and the significance coefficient is 0.003. In use attitude, the PEU, immersion and interactivity of the virtual experiment have the most significant impact on it, and the significance coefficients of the three variables are all 0.000. Followed by PU, the significance coefficient is 0.002. Therefore, the Unity3D-based IC virtual experiment strategy in colleges and universities can significantly improve students' attitudes and use attitudes in chemical experiment teaching from the three main aspects of PEU, immersion and interactivity, thereby improving students' learning effects.

V. CONCLUSION

To solve the practical problems such as high consumption cost and many risk factors in chemical experiments in colleges and universities, starting with the characteristics of IC experiment teaching, a collision detection algorithm between virtual experiment environment and virtual scene based on Unity3D technology was designed. When designing the virtual experiment teaching of IC, it start with the students' interactive learning perception and experience cognition habits under the virtual reality learning environment, and divide the students' learning into three main levels: virtual reality, perception interaction and embodied cognition. At the same time, research was conducted on geometric modeling of chemical experimental instruments in virtual reality, and a virtual anti-collision strategy was designed, ultimately forming a virtual experimental teaching mode. The study analyzed experimental teaching through multiple regression analysis. The results show that in collision detection model performance, the algorithm designed in the study completed collision detection in just 99 ms, with the accuracy line at the highest position, within the range of 90% to 100%, with an average detection value of 95.29%; The accuracy variance is 0.020, and the numerical values are better than algorithms of the same type; And as the number of sampled features increases, the detection time of the algorithm increases while achieving the same detection rate. The collision detection algorithm designed in the research has superior performance. In teaching effectiveness, the survey data of the study has a Cronbach Alpha coefficient of 0.782, greater than 0.75, indicating good reliability. At the same time, the KMO sampling suitability scale is 0.652, greater than 0.6, with a significance of 0.000, indicating good reliability. The virtual experimental teaching designed for research can have a significant impact on learning motivation from PEU and immersion, with a significance coefficient of 0.000 for both variables. At the same time, it can have a significant impact on usage attitude from PEU, immersion, and interactivity, with a significance coefficient of 0.000 for all three variables. From this, the research designed model can effectively improve students' learning effectiveness in chemical experimental teaching. However, in practical applications, the number of feature samples should be adjusted in real-time according to the needs to simultaneously meet the real-time and accurate detection requirements. At present, 3D display mainly relies on the development of stereoscopic

display and sensing technology. The current system's three-dimensional sense cannot meet the needs of the system, and further research is needed in 3D display.

VI. DISCUSSION

The collision detection model designed in the study only completed collision detection in 99ms, with an average detection rate of 95.29%. Compared with previous studies, it significantly improved the collision detection speed and average detection rate in 3D displays. The study used regression analysis to analyze the impact of virtual chemistry experimental teaching on students' learning motivation and usage attitude. In learning motivation, the PEU and immersion of virtual experiments have the most significant impact on learning motivation, with significance coefficients of 0.000. In terms of usage attitude, the PEU, immersion, and interactivity of virtual experiments have the most significant impact on usage attitude, with significance coefficients of 0.000. From this, in virtual chemistry experimental teaching, the three aspects of PEU, immersion, and interactivity can significantly improve students' attitudes towards use, thereby enhancing their learning outcomes. From the theoretical perspective of embodied cognition, the research integrates with virtual simulation technology, mobilizes learners' body movements and sensory perception systems in a highly realistic virtual learning environment, and helps learners to construct an instruction system. It not only enriches the practical research of embodied cognition in teaching applications in China, but also provides new ideas for the design of virtual simulation experiments.

Abstract—The 3D reconstruction of medical images plays an important role in modern clinical diagnosis. Although the analytic-based, the iterative-based and the deep learning-based methods have been popularly used, there are still many problems to deal with. The analysis-based methods are not accurate enough, the iteration-based methods are computationally intensive, and the deep learning based methods are heavily dependent on the training of the data. To solve the default that only the single scan sequence is included in the traditional methods, a reconstruction method driven by the non-subsampled shearlet transform (NSST) and the algebraic reconstruction technique (ART) is proposed. Firstly, the multiple magnetic resonance imaging (MRI) sequences are decomposed into high-frequency and low-frequency components by NSST. Secondly, the low-frequency parts are fused with the weighted average fusion scheme and the high-frequency parts are fused with the weighted coefficient scheme that guided by the regional average gradient and energy. Finally, the 3D reconstruction is performed by using the ART algorithm. Compared with the traditional reconstruction methods, the proposed method is able to capture more information from the multiple MRI sequences, which makes the reconstruction results much clearer and more accurate. By comparing with the single-sequence reconstruction model without fusion, the experiments fully prove the accuracy and effectiveness.

Keywords—Multiple magnetic resonance imaging; 3D reconstruction; non-subsampled shearlet transform; the algebraic reconstruction

I. INTRODUCTION

Nowadays, the modern imaging technologies, such as the nuclear magnetic resonance imaging (MRI), the computer tomography (CT), sonography, have been popularly used by the clinicians to obtain the two-dimensional tomographic images of patients. These diagnostic techniques have great advantages over the traditional diagnostic methods in observing the structure of human tissue, extracting relevant information, and determining a reasonable course of treatment [1]. For example, CT can help to determine the size, shape, and extent of lesions in the examination of lung cancer and show the clear structure of the bone [2-3]. Ultrasound detection can be used to screen the fetus for malformations during the pregnancy check-up [4-5], and MRI can accurately show the tissue and tumors in the brain without interference from the skull during cranial examinations [6-7].

However, 2D images are isolated, static and abstract, making it difficult for physicians to infer the shape, size and

location of the lesions. Thus, it is necessary to convert 2D images into relational, dynamic, and concrete 3D reconstruction models [8-10]. On the other hand, the 3D reconstruction has been successfully applied in recent years, all of which can be classified into three schemes: the analytic scheme, the iterative scheme and deep learning scheme. For the first one, Feldkamp et al. proposed the filtered back-projection (FBP) [11-12], it solves the shape artifacts by convolving the projection before back-projection under each acquisition projection. FBP is very fast and supports the targeted reconstruction. But the filters are easily to produce obvious vibration and blur in the results. For the second scheme, Gordan et al. proposed the algebraic reconstruction technique (ART), which the reconstruction procedure is treated to be the problem of solving the mathematic equations [13-14]. It calculates the value of each voxel by solving the linear equations. In addition, the loop iterations will continuously optimize the objective function until the error is small enough to determine the simulated projection data is fully matched with the detection data. For the third scheme, Wang S et al. proposed the famous DeepVO model [15], where the recurrent convolutional neural network is employed to infer the pose directly from the source videos without any traditional visual odometry, improving the visual odometry loop in 3D reconstruction [16]. It can meet the real-time performance very well, but the accuracy is not satisfactory. Panigrahy C et al. proposed an improved PCNN model which uses the adaptive dual channel with a weighted parameter to fuse MRI sequences and SPECT images, and Seal A et al. proposed a wavelet transform method with random forest and à-trous strategy to fuse PET and CT images [17-18]. They fused different types of images, combining information from different images into one image, and have achieved very good results of reconstruction.

Considering the advantages and limitations of all these methods, with the aim of solving the problem that only one sequence can be included in the reconstruction, a pre-fused 3D reconstruction method is proposed. Firstly, multiple MRI sequences were decomposed into high-frequency and low-frequency parts, and then different strategies are used to fuse the low-frequency and high-frequency parts. Finally, ART reconstruction is performed on the images after fusion. This method concentrates the useful information of multiple sequences into one reconstruction model, which is helpful to observe the overall morphology of the lesions and their relationship with the surrounding structures in multiple directions and angles [19-20].

The contributions in this paper are summarized as follows: (1) The NSST transform based fusion algorithm is used to fuse the multiple MRI sequences and collect the useful information of each sequence; (2) The ART algorithm is used for 3D reconstruction, which makes the reconstruction be more accurate; (3) The Multiple sequences are pooled into a reconstruction model, which is more informative than the reconstruction model of a single sequence.

The rest of the paper is organized as follows. Section II briefly describes the related work and Section III, the proposed model. In Section IV, extensive experiments are used to evaluate the model. Finally, Section V gives a few concluding remarks.

II. RELATED WORK

A. The Nuclear Magnetic Resonance Imaging Sequences

In order to evaluate the various parameters of the detected tissue, weighted scans that highlight certain tissue characteristics can be obtained by adjusting the time parameters. Short echo time and repetition time can generate T1 sequence, long echo time and repetition time can generate T2 sequence and T1CE sequence can be generated by injecting contrast agent into the blood before MRI [21-22].

In Fig. 1, the differences between the three sequences are shown. In the T1-weighted image, the white is white matter, the gray is gray substance, and the black is cerebrospinal fluid, so the T1-weighted scans can be used for tomographic anatomy [23]. In the T2-weighted image, the highlighted area is usually the lesion, so the location and size of the lesion can be clearly shown from the T2-weighted scans [24]. As in T2-weighted image, the highlighted area in T1CE-weighted image is generally the lesion [25]. Furthermore, because of the contrast

agent, it can be used to reveal the intra-tumor conditions and discriminate the tumor and non-tumor lesions.

B. The Detail of the Non-Subsampled Shearlet Transform

The NSST is an advanced multi-scaled geometric analysis tool with translation invariance, simple computational cost and multi-dimension, which has been popularly used in many fields of computer vision [26-27].

As shown in Fig. 2, the process mainly includes two parts: non-subsampled pyramid (NSP) decomposition and direction localization [28]. The NSP uses a two-channel non-down-sampling filter bank to make the multi-scale [29]. The input image is decomposed by one level of NSP to produce a low-frequency part and a high-frequency part, and each subsequent level of NSP is iterated over the low-pass component to obtain the singularities in the image. So that, the two-dimensional image is decomposed by levels of NSP to obtain the subband images with the same size of the input image, which includes one low-frequency image and images of the same size but different scales. The direction localization is implemented by a shearlet filter (SF). From the pseudo-polarized coordinates to Cartesian coordinates, the Meyer wavelet is applied to construct a window function to obtain the shearlet filter, and the decomposed sub-band image is convolved with the Meyer window function in two dimensions to obtain the directional subband image.

Another good property is that there is no down-sampling operation in the process of the NSST, which makes it have translation invariance [30]. In addition, the NSST has very good localization properties and high directional sensitivity, and satisfies the parabolic scaling properties. All the above properties guarantee the great ability of capturing the important medical features from the MRI.

Fig. 1. Three examples of the MRI.

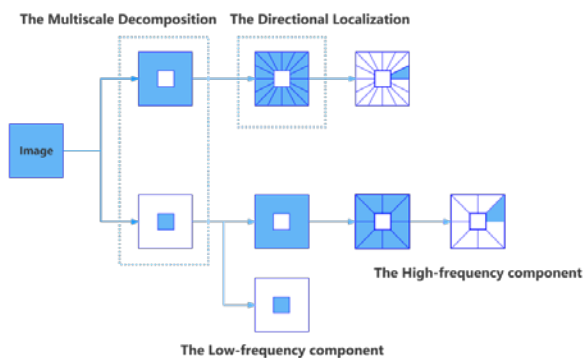

Fig. 2. The discrete process of the NSST.

C. The Algebraic Reconstruction

The basic idea of the Algebraic Reconstruction Technique (ART) is to transform the image reconstruction problem into a problem of solving a linear system of equations [31-32]. As the 2D section of a 3D object shown in the Fig. 3, it is divided into several discrete pixel regions, and set the image values inside each pixel region to be uniformly distributed, and denote the image values in the i -th pixel region by X_i .

Fig. 3. The detection process to the 2D section.

Similarly, the detector plane is divided into the discrete projection cells and denote the projection value in the j projection cell by p_j . Then the detection process can be represented by a linear system as Equation (1).

$$\begin{pmatrix} x_{11} & x_{21} & \dots & x_{m1} \\ x_{12} & x_{22} & \dots & x_{m2} \\ \dots & \dots & \dots & \dots \\ x_{1n} & x_{2n} & \dots & x_{mn} \end{pmatrix} \begin{pmatrix} f_1 \\ f_2 \\ \dots \\ f_n \end{pmatrix} = \begin{pmatrix} P_1 \\ P_2 \\ \dots \\ P_n \end{pmatrix} \quad (1)$$

In theory, tomographic images can be obtained by solving the algebraic equations. But in practice this approach cannot be ideally achieved. Firstly, the system of equations has a unique solution only when the projection data is equal to the unknown image pixels, which is not actually satisfied. Secondly, there is seriously statistical noise in the projection data P obtained by nuclear medicine imaging, so when the ill-conditioned nature of the system transmission matrix C is serious, the direct solution method will be seriously disturbed by noise, and the obtained solution may be the same as the real situation. Therefore, an iterative method is usually used [33].

D. The Limitations of the Previous Research

In general, the 3D reconstruction methods can be classified into three types: the analytic-based methods, the iterative-based methods and the deep learning-based methods. The analytic-based methods are often only applicable to a certain scenario. They have achieved great performance, but there still have some problems. The iterative-based methods optimize the reconstruction process by using the idea of algebraic iteration, they require extensive calculations. The deep learning-based methods usually employee the complex neural networks, which require large amounts of data to train.

III. PROPOSED METHOD

A. The Whole Process

The whole process of the algorithm is shown in the Fig.4: (1) Perform the NSST decomposition on the three groups of MRI sequences to obtain their respective high and low frequency components; (2) For the low frequency part, the

weighted fusion method driven by guided filtering is used [34]; for the high frequency part, the fusion rule combining the average gradient, the regional energy index weighting coefficient and the larger absolute value is used [35]; (3) Perform ART on the fused information to obtain a 3D reconstruction model.

Fig. 4. The whole process of the proposed reconstruction method.

B. The Extraction and Fusion of the Information

The low-frequency part contains the energy of the image, and the coarse features in the image is correlated. Each pixel is not independent, and the pixels at any position of the pixel can show strong correlation. The low-frequency part is simply taken the maximum value or weighted average. Therefore, the weighted fusion method driven by the guided filtering is applied in this part. Taking the selected slices in the sequence as the guiding image and the other slices as the input image, use the low-frequency components of the original slices to subtract the respective output images of the guided filter to obtain the sharpened image. The improved regional sum of Laplacian energy (SML) of the sharpened image is used to determine the fusion weights, and then the low-frequency subband coefficients of the fused image are calculated by Equation (2). The A and B in Equation (2) can be expressed by Equation (3) and Equation (4).

$$A(m, n) = \frac{A}{B} \quad (2)$$

$$A = \sum_{i=1}^3 \omega_i(m, n) a_i(m, n) \quad (3)$$

$$B = \sum_{i=1}^3 \omega_i(m, n) \quad (4)$$

The high-frequency parts are mainly the feature information, such as the edge, textures of the input image. The human visual system is not sensitive to pixels, but sensitive to the edge, orientation and texture information of the image. The regional energy retains the input image details and also reflects the correlation of the input image. The larger the area energy,

the richer is the detailed information of the image. The average gradient of the image reflects the sharpness of the image, as well as the expressive ability of the image to the contrast of small details and the texture transformation characteristics of the image. Therefore, this paper proposes a fusion rule of regional average gradient and regional energy to jointly guide the weighting coefficient for high-frequency components. The following rules are adopted for high frequency components as Equation (5).

$$T^{l,k}(i,j) = \frac{1}{m \times n} \sum_{i=0}^{m-1} \sum_{j=0}^{n-1} \sqrt{A} \quad (5)$$

In Equation (5), A can be expressed as Equation (6).

$$A = \left(\frac{\partial f(i,j)}{\partial x} \right)^2 + \left(\frac{\partial f(i,j)}{\partial y} \right)^2 \quad (6)$$

In Equation (3), m and n are the rows and columns of the sequence slice. Respectively, $f(i,j)$ is the coefficient of the high-frequency component at pixel point (i,j) , and $T^{l,k}(i,j)$ is the average gradient at pixel (i,j) .

C. The Reconstruction Algorithm

It is well known that the reconstruction can be transformed into a system of linear equations as Equation (7).

$$\begin{cases} c_1 f = p_1 \\ c_2 f = p_2 \\ \dots \\ c_n f = p_n \end{cases} \quad (7)$$

$c_j = (c_{1j}, c_{2j}, c_{3j}, \dots, c_{nj})$ is the vector dot product operation. If we take the N components of the image to form an N dimensional space, then each set of estimates of the image is a point in this N dimensional space, and each of the linear equations in the set of equation is an $N-1$ dimensional hyperplane in this N dimensional space, which is orthogonal to the vector c_j . If the system of linear equations has a unique

solution, then these N hyperplanes have a unique intersection which is the solution we require.

From the initial image estimate f^0 , project this point onto the hyperplane represented by the first equation, use the projection point as the first image estimate f^1 , project the projection point onto the second hyperplane again to obtain a new projection point f^2 , continue to implement this procedure until the projection of all equations is carried out. Then the process of f^n can be expressed by the Equation (8).

$$f^n = f^{n-1} - \frac{(f^{n-1} \cdot c_n - p_n)}{c_n} \quad (8)$$

Finally, it can be further deduced into the Equation (9).

$$f^n = f_i^{n-1} - c_{in} \frac{\sum_i (f_i^{n-1} \cdot c_{in})}{\sum_i c_{in}^2} \quad (9)$$

IV. EXPERIMENTS AND DISCUSSION

The platform used for the experiments is the CentOS Linux x64, with CPU of Intel(R) Xeon(R) Silver 4114 and GPU of NVIDIA Tesla GPU in the memory of 16GB.

To verify the effectiveness of the fusion method and the effect of the 3D reconstruction result, two experiments with two datasets are implemented. Firstly, to verify the fusion method, the T1, T2, TICE sequences are compared with the fused sequences. The image definition (FD), standard deviation (STD), edge strength (EIN), information entropy (EN), and spatial frequency (SF) are the objective evaluation criterion for the effect of the fusion method. EN, STD and SF are the typical metrics of image fusion. EIN and FD can measure the segmentation and sharpness of the image edges, the clearer the edges; the more complete the shape of the individual organs will be after 3D reconstruction [36].

As shown in Table I, all the five metrics of the fused sequence are higher than the original sequence, proving the effectiveness of the proposed fusion method.

TABLE I. The comparison of T1, T2, TICE and the fusion results

Methods	EN	STD	SF	EIN	FD
T1	2.64	38.35	6.68	162.21	105.47
T2	2.55	35.42	6.74	164.14	107.31
TICE	2.56	40.94	7.17	165.45	108.95
Fusion	2.72	40.97	7.22	165.56	110.63

The ART is used to model the original sequences and the fused sequence separately, and observe the details of the model from the top, bottom, left and right directions to compare the texture, structure and clarity of the model.

As shown in Fig. 5 to Fig. 6, the images in (a)-(d) are 3D reconstructions of T1 sequence, (e)-(h) are 3D reconstructions

of T2 sequence, (i)-(l) are 3D reconstructions of TICE sequence and (m)-(p) are 3D reconstructions of fused sequence. The pictures of the top left, right and bottom directions are cropped. The bottom right corner is an enlarged image of the same region, so the details of the reconstructed model can be clearly compared. In the first three sets of reconstruction models, some areas are blurred and not smooth enough, but in

the proposed reconstruction model, the same areas are more smooth and clear without blurring. By comparing the enlarged area, the proposed reconstruction model is also clearly visible after zooming it, unlike the unfused reconstruction model that has blurring. The fused reconstruction model has clear texture, rich detailed information and good visual effect. In the comparison of the reconstruction model and the reconstruction

model before fusion, especially in the enlarged areas, it can be found that the results from the reconstruction method after fusion is much smooth, more feature details are remained, and the visual quantity is much better than the other results. All the facts fully prove the effectiveness and progressiveness of the proposed model.

Fig. 5. The comparison of the 3D reconstruction results for the first group.

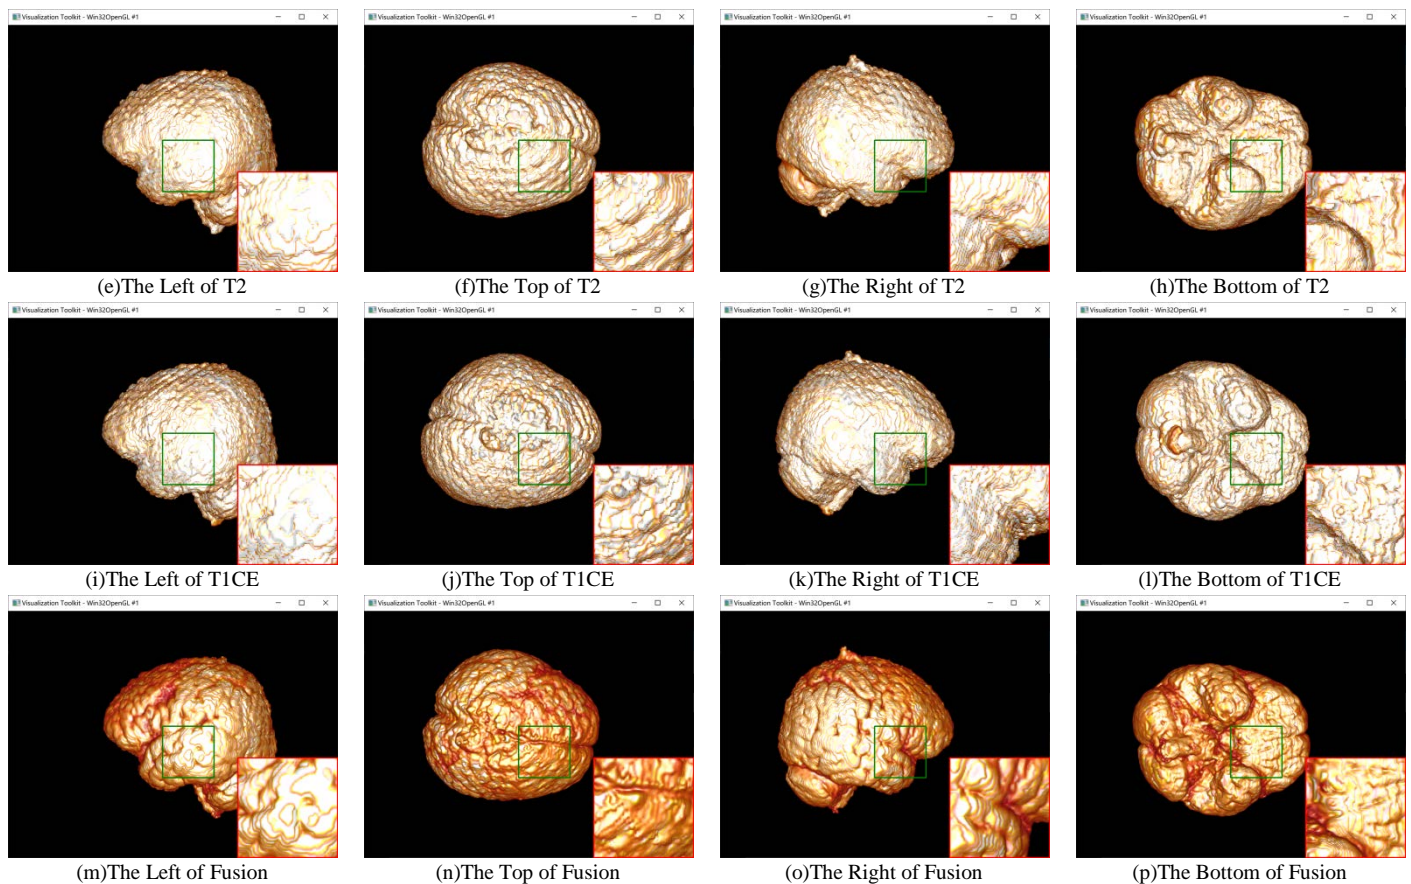

Fig. 6. The comparison of 3D reconstruction results for the second group.

V. CONCLUSION

An effective 3D reconstruction method, driven by NSST fusion scheme and ART, is proposed in this paper. Compared with other reconstruction methods, the reconstructed model can maintain more feature information by fusing multiple MRI sequences before reconstruction, which successfully meets the need that the reconstructed model contains more MRI sequence information. The post-fusion reconstructed model is compared with the pre-fusion reconstructed model by careful experiments. The proposed reconstructed model after fusion produces the good results with much clearer texture, smoother surface, and more detailed feature information.

In the future work, the proposed model will be optimized and extended to the other tasks of reconstruction, such as the Positron Emission Tomography (PET) and the Single-Photon Emission Computed Tomography (SPECT).

Integrating Dropout Regularization Technique at Different Layers to Improve the Performance of Neural Networks

B. H. Pansambal¹, A.B. Nandgaokar²

Department of Electronics & Telecommunications Engineering,
Dr. Babasaheb Ambedkar Technological University, Lonere, 402103, India

Abstract—In many facial expression recognition models it is necessary to prevent overfitting to check no units (neurons) depend on each other. Therefore, dropout regularization can be applied to ignore few nodes randomly while processing the remaining neurons. Hence, dropout helps dealing with overfitting and predicts the desired results with more accuracy at different layers of the neural network like ‘visible’, ‘hidden’ and ‘convolutional’ layers. In neural networks there are layers like dense, fully connected, convolutional and recurrent (LSTM- long short term memory). It is possible to embed the dropout layer with any of these layers. Model drops the units randomly from the neural network, meaning model removes its connection from other units. Many researchers found dropout regularization a most powerful technique in machine learning and deep learning. Dropping few units (neurons) randomly and processing the remaining units can be considered in two phases like forward and backward pass (stages). Once the model drops few units randomly and select ‘n’ from the remaining units it is obvious that weight of the units could change during processing. It must be noted that updated weight doesn’t reflect on the dropped units. Dropping and stepping-in few units seem to be very good process as those units which step-in will represent the network. It is assumed to have maximum chance for the stepped-in units to have less dependency and model gives better results with higher accuracy.

Keywords—Convolutional layer; visible layer; hidden layer; dropout regularization; long short term memory (LSTM); deep learning; facial expression recognition

I. INTRODUCTION

Idea behind introducing the dropout layer (technique) helps classifying accuracies with minimized error rate than without having the same. Many applications process the large data and it is expected to have better accuracy with minimized loss and error rate. Applications will process data from different source e.g., speech, images, videos etc.

This adaptive nature helps developing a robust model. It is also possible to introduce the dropout layer with fully connected layers, recurrent layer such as long short-term memory layer (LSTM) and convolutional layer. There are visible layers, hidden layers and dropout layer can be added later to get better classification of the objects. Actually, dropout is a regularization technique which trains ‘n’ neural networks in parallel. Neural networks are complex due to various hidden layers. It is necessary to find the relationship between those neurons. If model fails to regularize the network

properly then relationship results into noise. There are many techniques that exist to avoid noise, and overfitting and are ‘early stopping’, ‘dropout regularization’, ‘weight penalties’, and ‘short weight sharing’. It’s a type of generalization and in some cases if the network is larger and complex may consume more memory and time. Dropping and selecting the neurons may consist of ‘n’ iterations and after each iteration network may get changed. Few researchers termed ‘dropout mechanism’ as an ‘ensemble mechanism’ because after each iteration network changes and can be termed as sub-network (new). Actually these are the structures and bunch of these sub-networks can be used for training purpose. Objective is to prevent the overfitting in the model and train the given dataset. To achieve an error rate with minimized losses dropout layer can be added in the proposed model. In some cases, adding dropout have effect of making training process noisy and one can say the model becomes ‘adaptive’ which learns from every phase. In dropout regularization method few neurons are randomly dropped and select other neurons.

Section II gives introduction to existing methods with advantages and gaps to implement the proposed system. Section III focused on proposed model with algorithmic details and methodologies. Section IV elaborates the results obtained in proposed approach with different dropout rates, epochs, and batch sizes. In the end conclusion remarks the implemented approach with future research directions.

II. LITERATURE REVIEW

Authors [1, 24] have developed a model which extracts features from given images and trained the model to process the upcoming features automatically. Authors have focused on important aspect of the emotion recognition i.e. working on static and dynamic images i.e. real-time images or images extracted (frames) from the video. Model processes the video as sequences of different frames and each frame consists of images. Model processes the features extracted from given images automatically by introducing 03 steps as follows –

- Image acquisition
- Feature extraction
- Expression recognition

Authors [2] also suggested, one can use support vector machine (SVM), naïve bayes, lexicon methods to recognize emotions from different conversations. Hence model generates

different vectors according to the different statements/conversations. Model helps identifying sentiments of people and knowing the depth of conversation. Model could help analyzing different styles of conversations, time required for certain conversation etc.

Authors [3, 22] have introduced robots and embed a proposed model to process real-life images. In this model robot extracts images from camera, video etc. and analyzes these frames. FERW model – facial expression recognition in the wild processes the features and gives corresponding feedback.

Authors [4, 11, 18] have used CNN and auto-encoders to extract different features from images for classification purpose. Authors have proposed 06 architectures out of which 02 are trained on Japanese female facial expressions and 04 with Berlin database. 02 architectures dealt with image-based emotions and 04 with speech recognition. CNN architecture consists of 03 convolution layers, 03 pooling layers, 03 dense layers with output layer. These convolution and pooling layers helps in extracting different features from emotions. Auto-encoder helps in reducing the dimensions. Authors [5, 6, 25] suggested that, ML machine learning and methods especially from the deep learning techniques can handle complex feature extraction from images and also helps in classifying them accordingly. “Gabor Filter” is applied to analyze the textures, edge detection, and extracting different features from the images. Authors pointed good response in edge detection can be obtained after application of the Gabor filter. Authors [7] have focused on 06 elementary emotions like happy, sad, fear, anger, surprise and disgust. Using MATLAB deep learning methods are implemented to extract and process the features from images. Model processes the JAFFE dataset which consists of 06 elementary emotions. System processes large volume of data. However, data could be labeled or unlabeled. Authors [8] have proposed a model to process unlabeled data. A hybrid label-less learning is proposed to automatically process the unlabeled data. Main advantage of this approach is human intervention is almost reduced and model automatically labels the data. Authors have proposed “LLEC” label less learning for emotion cognition. Authors suggested when labeling the unlabeled data prediction probability plays an important role. Entropy is used as a measure to assess the prediction uncertainty. Authors [9] have proposed a model using IoT devices which captures the images of the human and passes to the system. Model uses motion sensor to detect the motion of human. Camera attached with the module gets activated once the motion sensor detects the motion of human and captures the image using HAAR - feature based cascade classifier. Authors [10, 13, 26] have proposed a comparative approach for different deep learning architectures available in “Keras” for emotion recognition. Pre-trained models like VGC-16, ResNet152V2, Inception V3 and Xception etc. Authors have used 02 datasets Cohn-Kanade dataset and JAFFE Japanese female facial emotion. All the pre-trained models are evaluated on these datasets and their accuracies are measured.

A three-class annotation approach [12, 19, 23] is proposed to get the stimuli behind emotions. Authors have developed emotion classification framework using LSTM. Framework also consists of threshold scheme and categorizes emotions in

different segments like anxiety, anger, disgust, sadness and joy etc. and ratings are assigned in the range from 1 to 9. Authors have also used EEG signals and facial videos to extract the features from images. Authors have also concluded EEG feature-based classifier can give better accuracy when used with thresholding scheme. Authors [14, 27] have considered 05 emotions and developed a model based on deep convolutional neural network. Model is based on few layers like convolutional layer, dropout, fully connected layer and features are extracted from images. Using convolution filter represents the features of interests. Back-propagation algorithm can be embedded in the framework to reduce the errors. Activation function is introduced – ReLu (rectified linear unit) to make negative values zero. If any overfitting of the data is observed then dropout layer can be used to reduce the same.

An interesting topic “micro expression” in the emotion recognition is presented by the authors [15] using deep learning architecture. Authors have used FEREC-2013 database to extract the different features to identify the micro expressions. Model is based on cross-entropy loss function and uses “Adam optimizer”. This optimizer helps training and providing best results and also reduces the losses. To handle the overfitting of data, dropout layer can be introduced which reduces the overfitting of the model. With the confusion matrix authors have shown different emotions and their scores obtained. Authors [16] have proposed an LDL- label-distribution learning model with conditional probability function to reduce the entropy. A framework EDL-LBCNN is implemented using CNN on the s-JAFFE dataset. Basic emotions like happiness, sadness, fear, anger, surprise and disgust are accurately evaluated. Framework consists of 04 convolutional layers and single LBC (local binary convolutional layer. Initially framework extracts the features from grayscale images. Once the features are extracted next phase is to concatenate them and pass to the next phase. LBC (local binary convolutional layer) consists of few trainable parameters and fixed size of filters. Output of this layer is generation of feature map and in the next layer i.e. FC layer (fully connected layer) concatenates the feature maps generated by CNN and LBC layer. Authors [17, 18, 21] have used LSTM and CNN to learn speech emotion features. Interesting approach proposed by the authors is *combining facial and speech expression*. Advantage of this **fusion approach** is, it gives information of audiovisual features. High levels of features are extracted using deep neural networks. Audio features are extracted using *pyAudioAnalysis* an open-source library. Local features of data and global training features can be extracted using *CNN – convolutional neural network*. A multi-modal fusion is carried out on different features, also known as early-fusion or feature-level fusion. Model also consists of decision level fusion known as late-fusion. There is score level fusion implemented in the model to calculate the classification scores. Authors have combined happy and excite category into excite and works on remaining basic emotion like excite, sad and neutral. Authors [20] have implemented a pose-guide estimation model where features are extracted using few methods like pyramid histogram orientation gradient method (PHOG), edge histogram descriptor (EHD) and local binary pattern (LBP). Canny detector is introduced to extract the edge of the image. LBP helps in converting image into integer array. Authors have

evaluated their proposed model on the 04 datasets – CK+, JAFFE, CASIA and AR dataset. Model works on 03 steps - target pose estimation, template generation, and target matched.

III. PPROPOSED METHODOLOGY

‘Regularization’ is a technique that can be used in neural network to reduce the complexity of the proposed model. Once regularization is successfully implemented it helps generalizing the *new* data in efficient manner. The reason behind this approach is model randomly ignores the ‘n’ neurons and focus on the remaining neurons only. It is obvious that, there would be a significant difference in considering all the neurons and considering few one. With the selected neurons, model can run effectively and produce the results with better accuracy. Therefore, one can say with the help of regularization technique such as ‘dropout’ it is possible to obtain the useful and effective networks.

Fig. 1. Dropout regularization.

Drops hidden and visible units from the network, selects few from the remaining neurons as shown in the Fig. 1 and Fig. 2. Model temporarily removes the units as shown in the Fig. 2. One important point in this scenario is even if the weights of the neurons get changed it will not affect the skipped neurons. As its name indicates **‘dropout’** randomly drops few units from the given datasets. E.g. if the defined dropout rate is 0.2 then it randomly drops 20% units from the given collection. As discussed earlier, dropout layer can be added with the visible layer, hidden layer and other network layers. During processing the units/objects it creates combinations from all the defined layers. Model trains the dataset in iterations and randomly drops new units based on probability hyper parameter ‘P’. Many authors have termed this concept as formation of thinned network. Model further integrates these thinned networks to identify the *key properties*. However, this phase requires intensive processing the large datasets as there are many thinned networks. Objective behind adding the dropout layer in training the given data is to minimize the overfitting and achieve greater accuracy. Application of dropout method helps reducing the error rate significantly.

Fig. 2. Successful execution of dropout regularization.

A. Algorithmic Details

Idea behind application of dropout regularization is as follows-

- Consider there are ‘i’ inputs in the given network.
- If each of these ‘i’ units produces the output ‘o’ e.g. $O_1, O_2, O_3, \dots, O_n$
- Sum of these outputs $S_1 \dots S_n$
- Model should consider probabilities for these sums using individual scores like $P_1, P_2 \dots P_n$
- When model drops few neurons randomly and selects others from the remaining neurons, forms different sub-networks.
- Using the outputs and different sums calculated model can find possible probabilities of future sub-networks.

To implement the dropout function with a single layer, one must draw as many samples from a Bernoulli (binary) random variable as our layer has dimensions, where the random variable takes value 1 (keep) with probability $1-p$ and 0 (drop) with probability p . One easy way to implement this is to first draw samples from the uniform distribution $U [0, 1]$. Then, model can keep those nodes whose corresponding sample is greater than ‘p’ and drop the rest.

Table I explains the results obtained by applying the dropout layer with different dropout rates to the visible layer. Table I elaborates the different dropout rates i.e. 20%, 30%, 40% etc. applied to the visible layer and results obtained using the same. Model also rechecks the results obtained with a specific dropout rate i.e. 20% in the example as shown in the Table I. Similarly dropout rate can be applied to the hidden layer in the network. Table II elaborates the same with different dropout rates to measure the accuracy of the model. If the proposed model consists of ‘n’ iterations then each time new neurons (elements) will be dropped randomly with the dropout regularization technique. This technique is applied during training phase only.

IV. RESULTS AND DISCUSSION

In a network one can add ‘dropout layer’ to the hidden and visible layer etc. As shown in the Table I and II dropout regularization applied with different dropout rates, epochs at visible and hidden layer. Accuracy of the proposed model can be checked by using small as well as high dropout rates. It is obvious that, larger network will consist of ‘n’ neurons and with the dropout regularization technique one can get better performance. Table I and II shows the effective results obtained at different layers. It is also true that if the network is larger with ‘n’ neurons then training the neurons could be bit expensive.

Table I elaborates application of different dropout rates and epochs at the visible layer of the neural network. Overall the proposed model gives baseline efficiency with approx.85.55% (6.54%). One can observe as shown in Table I that batch size is very important along with epochs and dropout rates. Dropout rate 0.20 indicates 20% data can be randomly removed and remaining will be considered.

The first parameter dropout rate is the probability ‘p’ that a given unit (s) will drop out. In Table I, the different probabilities are used 0.2, 0.3, 0.4 and 0.5 which means roughly 20%, 30%, 40% and 50% units will drop out. The value 0.5 has been experimentally determined to be close to the optimal probability for a wide range of models, but feel free to experiment with other probabilities. To check the effectiveness, it is suggested to use variety of dropout rate in different cycles.

TABLE I. REGULARIZATION WITH DIFFERENT EPOCHS AND DROPOUT RATIOS

Dropout	Epochs	Batch size	Results mean and standard
0.20	300	16	Visible: 85.57% (6.18%)
0.30	400	18	Visible: 87.93% (7.57%)
0.40	500	20	Visible: 83.21% (8.26%)
0.20	300	16	Visible: 86% (7.98%)
0.20	300	16	Visible: 85.45% (7.81%)

It is a good approach to average the observations obtained by evaluating the sample data with different dropout rates, epochs and batch size. To improve the performance of neural networks especially in overfitting and regularizing the sample data one can integrate the dropout technique at different layers like hidden and visible layer. Fig. 5 and Fig. 7 give Bayes analysis for the sample data by weighting the settings for prior and posterior probabilities.

It is presumed that every neuron in the neural network has p% of dropout. Many researchers treat dropout technique as an ensemble method. Application of dropout technique at hidden and visible layers helps approximate the sample data and proved that it is computationally very cheap than other approaches.

Fig. 3. Flexplot for the visible layer.

Fig. 3 Flexplot gives visual representation for the results obtained with different dropout rates.

A. Bayesian Correlation Pairwise Plots

Dropout rate - epochs

Scatterplot

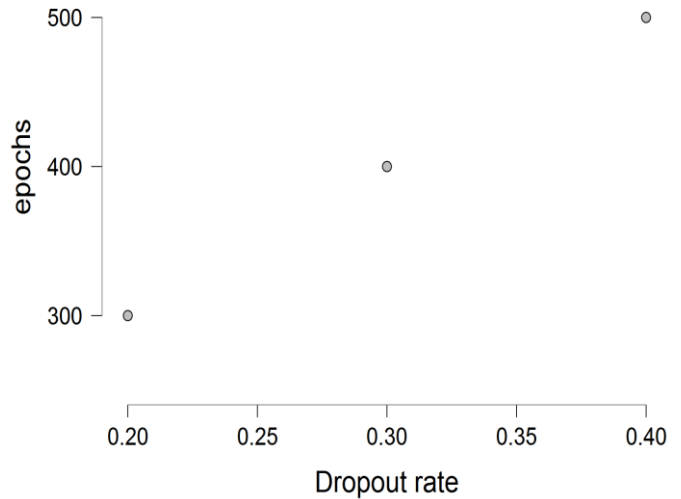

Fig. 4. Dropout rate v/s epochs.

Above Fig. 4 gives visual analysis for different dropout rates with ‘n’ epochs. Both the factors are very important if there are large distributions.

TABLE II. BAYESIAN PEARSON CORRELATIONS

	n	Pearson's r	BF ₁₀
Dropout rate-epochs	3	1.000	1.505
Dropout rate- batch size	3	1.000	1.505
Epochs- batch size	3	1.000	1.505

BF_{10} indicates bayes factor in favor of H_1 over H_0 . Bayesian Pearson correlation helps measuring strength of linear relationship between different variables. Table II gives sample observation for different approaches i.e. dropout rate vs epochs, dropout rate vs batch size, and epochs vs batch size as shown in Table III. The important factor in this observation is BF_{10} which may give different values for 'n' samples. Based on this factor one can categorize observed samples into *anecdotal evidence*, *moderate* and *strong evidences*.

TABLE III. REGULARIZATION WITH DIFFERENT EPOCHS AND DROPOUT RATIO (HIDDEN LAYER)

Dropout	Epochs	Batch size	Results mean and standard
0.20	300	16	83.62% (10.73%) performance degraded on hidden layers
0.30	400	18	Hidden: 83.71% (7.98%)
0.40	500	20	Hidden: 85.17% (5.81%)
0.20	300	16	Hidden: 84.12% (6.79%)
0.20	300	16	Hidden: 84.12% (6.79%)

Fig. 5. Bayes factor robustness check.

Bayes factor robustness check is used for the wide range of prior distribution. It helps researchers to distinguish the obtained results in different segments like weak, moderate and strong evidence. Each iteration with different batch size, epochs and dropout rate one can get a new thinned neural network. For the large sample data proposed model with the dropout mechanism can have low classification errors. Even if the network is larger with the help of dropout technique one can reduce overfitting as shown in Fig. 6 to 8.

Dropout rate - batch size

Scatterplot

Fig. 6. Dropout rate v/s batch size.

Fig. 7. Bayes factor robustness check for batch sizes.

Linear Modeling

Fig. 8. Plot of the statistical model.

V. CONCLUSION

Although dropout is a potent tool, it has certain downsides. A dropout network may take 2-3 times longer to train than a normal network. Finding a regularizer virtually comparable to a dropout layer is one method to reap the benefits of dropout without slowing down training. This regularizer is a modified variant of L2 regularization for linear regression. An analogous regularizer for more complex models has yet to be discovered until that time when dropout drops out. One can propose a model with enhanced dropout mechanism i.e., having an effective method for randomly dropping neurons. Future work may include integrating the complex data from image, video etc. and improving the generalization of new data. Results can be improved with the hybrid approach like combining L2 regularization and dropout regularization techniques. If the network is larger and consists of maximum neuron then future research work can be directed to reduce the time complexity required for dropping and selecting the neurons. With the application of dropout technique every unit can act independently and this approach helps breaking co-adaptation in the neural networks.

Abstract—Malignant brain glioma is considered as one of the deadliest cancer diseases that has a higher fatality rate than the survival rate. In terms of brain glioma imaging and diagnosis, the processes of detection and segmentation are manually done by the experts. However, with the advancement of artificial intelligence, the implementation of these tasks using deep learning provides an efficient solution to the management of brain glioma diagnosis and patient treatment. Deep learning networks are responsible for detecting, segmenting, and interpreting the tumors with high accuracy and repeatability so that the appropriate treatment planning can be offered to the patient. This paper presents a comparison review between two state of the art deep learning networks namely convolutional neural network and capsule network in performing brain glioma classification and segmentation tasks. The performance of each published method is discussed along with their advantages and disadvantages. Next, the related constraints in both networks are outlined and highlighted for future research.

Keywords—Deep learning; convolution neural network (CNN); capsule network; segmentation; classification; brain glioma

I. INTRODUCTION

Brain gliomas are the tumors that grow from the glial cells that support the brain and the spinal cord. There are three types of glial cells involved in the evolution of brain cancers: astrocytes in astrocytoma or glioblastoma tumors, oligodendrocytes in oligodendrogliomas, and ependymal cells in ependymomas tumors. Astrocytomas are mostly found in the cerebrum and cerebellum and can be in the form of slowly growing or fast-growing tumor. Slowly growing tumor is termed as low-grade glioma while fast growing tumor is called high grade glioma. The second type is oligodendroglioma. It is a rare type of brain tumor that attaches to the cerebrum. Lastly, is the ependymomas type that can occur in any section of the brain or spinal cord, most commonly near the cerebellum and lower spinal cord.

Brain gliomas are classified into two types: benign tumor and malignant tumor with cancerous cells [1,2,3]. These brain gliomas are also graded based on the staging endorsed by The World Health Organization. Low-grade gliomas (LGGs) are classified as WHO Grade II infiltrative brain tumor that typically appear solid and non-enhancing on magnetic resonance imaging (MRI) scans [3,4,5,6], in which the patient

may be treated with a watch-and-wait approach. High-grade gliomas (HGG), which can resemble LGG on an MRI scan, are typically classified as WHO Grade III or Grade V tumor. The mistakenly interpreted HGG as LGG causes the patient to suffer due to the watch-and-wait strategy although HGGs are extremely aggressive and advance very quickly.

Doctors may use a variety of methods to determine the type and the staging of the primary brain tumor and metastatic brain tumor. It is common that Magnetic Resonance Imaging (MRI) is used in the early stage of brain diagnosis to capture the presence of brain tumor and the necessary biopsy or surgery to obtain tissue sample in identifying the type of the tumor. Magnetic Resonance Imaging (MRI) employs magnetic fields to create a detailed image of the body with the assistance of a special dye known as a contrast medium (gadolinium) administered via intravenous, pill, or liquid to swallow. The dye enhances the MRI image by giving a more accurate depiction of the tumor. With the aid of the diffusion weighted imaging and perfusion imaging methods used in MRIs, soft tissue, joint, and organ abnormalities can be visualized in many different areas of the body, including the brain and joints.

Treatment of a brain tumor requires a multidisciplinary approach that includes surgery, radiotherapy, and chemotherapy. A neurosurgeon will remove the tumor tissue and have it examined to determine the type. To reduce intracranial pressure and relieve symptoms, any excess cerebrospinal fluid will be drained. If the tumor cannot be removed because of its location or if there is a high risk of complications after surgery, radiotherapy and chemotherapy will be used. Radiotherapy and chemotherapy are both commonly used to kill cancer cells by using high-energy x-rays or anti-cancer drugs [7]. Every person can have a different prognosis. The likelihood of survival is influenced by the type of tumor, the severity of the disease, the size and location of the tumor, the presence or absence of metastases, the tumor's response to treatment, the patient's age and general health, and the patient's tolerance for drugs, procedures, or therapies.

Deep Learning (DL), a subfield of Artificial Intelligence (AI), is one of the techniques used for analyzing raw data and extracting relationships in data sets, specifically in the

diagnosis and treatment planning of brain tumors. Deep Learning (DL) automatically learns representations and features from raw MRI image to perform the classification and segmentation of brain glioma. This approach overcomes the issue of manually computing and selecting relevant attributes from the images [8]. Since years ago, the deep learning method has showed its effectiveness to solve many issues and its application in biomedical imaging is outstandingly significant including in MRI brain glioma detection and analysis. As per current, the diagnostic, prognostic, and treatment evaluation of the brain glioma are manually handled. However, manual interpretation has its own limitations, facing the risk of ineffective patient management. Thus, deep learning approach will aid the clinical experts in making wise decisions regarding urgent clinical needs and the necessary treatments [9].

This paper discusses the previously proposed deep learning architectures utilized in classifying and segmenting the brain glioma in MRI images. We focus on CNN architecture and capsule network architecture [10], discussing their performance in terms of the advantages, and disadvantages as well as the prospective works.

II. LITERATURE REVIEW

A. Brain Glioma Classification

Various deep learning methods have been used in previous studies to classify brain glioma. The classification tasks can be implemented into two stages. The first stage is to classify the tumor into normal (benign) and abnormal (malignant) cases. The second stage is to further classify the malignant cases into the specific cancer type. The classification task is a difficult and challenging problem due to the inhomogeneous intensity, atypical shape of the tumors and tissue structures, and different types of noise in the MRI images. The designation of the cancer type is also equivalently difficult as the glioma tumors have similar patterns amongst each other.

Early detection and classification of brain tumors are critical in determining the most appropriate treatment for the patient. Computer aided diagnosis (CAD) based on deep learning is important in assisting the experts and clinicians with more detailed and consistent interpretation, as well as estimating the survival period of brain glioma patients [11] where the image features are extracted from the MRI image through a self-learning approach. Image processing for tumor identification begins with pre-planning, image division, extraction, and gathering. The image will then be automatically analyzed, which improves the identification of the brain structures [12].

The first deep learning algorithm used in image classification and segmentation is CNN. To improve the algorithms' accuracy, CNN has undergone several upgrades, including an adaptation of LeNet with changes to the arrangement and number of layers. Additionally, medial residual block (MidResBlock) classifier, which is based on a network of LeNet, is created by adding information about middle convolution layers to the output of each layer [13].

Another type of CNN is called Residual Neural Network (RNN) enables extremely deep training by using a shortcut

connection to skip one or more layers and by utilizing data augmentation to increase the dataset size and improve the accuracy [14]. The VGG16 high performance network is used in studies that use the fuzzy c-mean algorithm for segmentation before moving on to classify the segmented images. Each image is processed through the input layer, convolution layer, max pooling layer, drop out layer, fully connected layer, soft max function, and classification layer.

To capture more specific characteristics without incurring additional computational costs when using large filters in the convolution layer, dilation is implemented in CNN [15]. Another hyper parameter that is used along with this architecture is the dilation rate, which is higher on the outer layers for learning coarse features and lower on the inner layers for focusing on finer features to achieve the best results.

Deep CNN can extract multiple levels of features from image-based data and reveals distinguishing features between classes for classification problems [16,17]. While most studies focus on MRI or Computed Tomography (CT) images, histopathological images have a high potential in the background. To get the best results from this methodology, two factors must be considered: preprocessing and CNN architecture. Patch extraction, abnormal patch detection, intensity, contrast enhancement, and background removal are all part of the preprocessing process, while CNN models are trained to extract features from images, match features with clinical data, and predict relevant brain tumor types using linear or nonlinear methods [17]. Although CNN has been widely utilized to aid human inspection in tumor classification, it has its own limitations that must be addressed.

Capsule Network is proposed to alleviate the limitations of CNN, with the focus on maintaining image resolution and improving classification accuracy. It begins with segmented tumor regions as input and consists of a single CapsNet convolutional layer [18]. The Capsule Network demonstrates that it tends to account for everything in the input image, including the background, resulting in less detail in the image when compared to other methods [19]. The highest accuracy is achieved by reducing the number of feature maps from 256 to 64. Capsule Network sensitivity also supports the ability to access tumor surrounding tissues without distracting it from the main target [20].

Bayesian CapsNet [21] has been developed to handle uncertainty that tends to be incorrect and should be handed to a human expert for review and confirmation. Using Bayesian may result in lower accuracy and the need to filter out predictions with uncertainty over 0.15 and 0.1 to achieve more than 50% accuracy, in addition to higher computational costs. To better understand how the brain uses spiking signals and local learning rules, spiking networks on neuromorphic devices are also being conducted on CapsNet. Image-processing technology performs better because of increased use of neuromorphic computing and fresh learning algorithms [22].

DensNet201 and Inception V-3, two multiple-level feature extraction and concatenation methods, were employed for the diagnosis of brain tumors before features were sent to Softmax

for classification as in [23]. For DensNet 201 and Inception, features were taken out of DensNet blocks and the pre-trained Inception V3 model, respectively. This approach combined scratch-base models, more layers, and data augmentation techniques. A different screening and classification strategy that has been demonstrated to be effective and efficient in classifying gliomas, meningiomas, and metastatic brain tumors that is the combination of DenseNet-LSTM (CNN) and

holistic 3D MRI [24]. The YOLOV2-Inception V3 is an improved version of the pre-trained Inception V3 model, which segments data based on Kaput entropy after features are extracted from the mixed layer of the Inception V3 model [25]. Table I presents recent deep learning-based classification techniques for brain tumors based on CNN and Capsule network including several other published methods [26, 27, 28, 29, 30, 31, 32, 33, 34].

TABLE I. RECENT METHODOLOGIES FOR BRAIN GLIOMA CLASSIFICATION USING CNN AND CAPSULE NETWORK

Ref.	Methods	Accuracy
19	Capsule Network	86.56%
20	Capsule Network	90.89%
21	Bayesian CapNet	73.6% (0.15) 73.9% (0.1)
23	Inception V-3 DensNet 201	99.34% 99.15%

B. Brain Glioma Segmentation

Machine learning algorithms play a critical role in enabling efficient and accurate image segmentation in the field of medical imaging. Classical learning models are less accurate, require more samples for efficient classification, and have a simpler structure when compared to deep learning techniques. There is significant evidence that accurate segmentation of various tumor subregions can lay the groundwork for quantitative image analysis to predict patient overall survival. Brain tumor segmentation is important not only in the diagnosis of brain glioma, radiation therapy, and clinical surgical planning, but it also increases the chances of a brain glioma patient's survival. Several methodologies have

been used to facilitate the segmentation of brain glioma, which include:

1) *Cascaded neural network*: Cascaded Dual-Scale LinkNet is used to improve segmentation precision. The architecture consists of two networks, the first of which learns features of specific areas of the brain tumor, while the second focuses on border areas and learns more detail about features [35]. The Deep Cascaded Neural Network system consists of two steps: (1) TLN subnet is used to localize the brain tumor and (2) ITCN subnet is used to classify the identified tumor regions into four tumor sub regions. This method can prevent pixel label imbalance where TLN merged different tumor

subregions into whole tumor and ITCN used the same number of image patches of each class to train [36].

2) *Convolutional neural network (CNN)*: CNN is the most widely used technique for image analysis and computer interventions, and its success rate is quite high when compared to other techniques. It is an improved version of the Artificial Neural Network (ANN) in terms of moving from manual decision and extraction to automated feature extraction from input data [37]. As a per-pixel classifier, multiple information from a small patch around each point is labelled, only standard intensity pre-processing is applied to the input data as scanner differences, and no post-processing is applied to the CNN output [38]. To overcome the lack of image specific adaptation and lack of generalizability to previously unseen object class, image-specific fine tuning is adapted in CNN model for unsupervised or supervised to significantly improve segmentation accuracy [39].

Features on the image will be extracted by building multiple layers of convolution layers in CNN. Smaller perceptive domain is used in front shallower convolution layer to allow learning some local features of image while larger perceptive domain in use in deeper convolution layer to learn more abstract features like size, location, and direction information. The CNN-based algorithm has three layers, namely convolution layer, pooling layer, and full connection layer. The preliminary product is obtained by multiplying the input image with the weights via the convolution layer. Filter matrix is chosen, for example by letting the step length to 1 and padding on the original image to obtain an input vector x . A pooling layer is being introduced to reduce abstract dimensionality and prevent over-fitting. The output is the classification probability gained from the regression in fully connected layers [39,40].

CNN has encoder and decoder parts, which allow discriminative comparison to be done easily and provide system extensibility [41]. The encoder part is responsible for extracting spatial information, after which the semantic map is inserted into the decoder part to produce the full-resolution probability map. UNet's modified architecture [42] includes three residual blocks in both the encoding and decoding phases, and each encoding employs batch normalization and the Parametric Rectified Linear Unit (PReLU). U-five Net's residual blocks are modified in both encoding and decoding while group normalization is used to add stability. DAU-Net with normalization is used to boost domain adaptation, which are then combined to produce U-Net (DAU-Net) [43].

3) *3D dense-UNets*: A triple segmentation network is created separately to predict the entire tumor, the tumor core, and the tumor enhancement. Three additional steps are included to maintain a high number of convolution layers while fitting into GPU memory. If a layer generated more feature maps than the initial number of convolution feature maps, the layer's total number of feature maps is reduced by one-fourth. A compression factor of 0.75 is applied to the total number of feature maps generated at the end of each dense

block. A bottle neck block is then utilized to connect the encoder and decoder parts of the network [44].

4) *Deep CNN*: Deep CNN consists of an architecture component for designing a network model and a learning algorithm to optimize the calculated parameters during the training phase. DCNN's architecture is made up of convolutional, pooling, Rectified Linear Unit (ReLU), and one fully connected layer. Each layer performs a simple computational operation, and each grid is only connected to a subset of the layers. Due to limited memory space and the number of parallel GPUs, higher volume data is difficult to handle [45].

Other architectures can be adapted to segment glioma, meningioma, and pituitary tumor tissues. DCNN ResNet50 employs skip connections to avoid gradient degradation when training a deeper network [14]. A combination of HCNN and CRF-RRNN models was proposed previously, in which the HCNN generates image slices at mixed scales to better leverage location while the CRF-RRNN takes the output and produces a segmentation based on the slides input into HCNN [45,46]. The FCNN is being improved by adding a Dense Micro-Block Difference feature to help with spatial consistency and utilizing Fisher vector encoding to texture rotation and scale [47], while 3D CNN focuses on intensity inhomogeneity by using N3T-spline to reduce noise and intensity in 3D scans and a T-spline for smoothing the output [48]. The Hourglass Network is an encoder-decoder with several residual blocks that is modified with five down sampling layers to perform better and be less computationally intensive [49]. Previous research has also proposed an ensemble network based on Model Cascade (MC) Net and One-Pass Multi-Task (OM) Net. Two MC-Nets are modified, one to improve encoder-decoder feature map coverage and the other to increase the effectively extract semantic feature at different resolutions. To create a more detailed model, an additional residual block is added to the original ON-Net [50].

5) *Region based CNN*: The region proposal network (RPN) is created by adding an extra convolutional layer that outputs the objectness score at image locations and the bounds of the region of interest (ROI). Using RCNN, it is possible to train a classifier on a smaller dataset and create bounding boxes with variable lengths. RPN will check the object's location, adjust to fit the dimension, use Region of Interest (ROI) pooling, and extract the features. The information is then used by RCNN to classify the content [51].

Before utilizing 3D volumetric CNN to fully leverage the 3D spatial contextual information of volumetric data, the RCNN model is applied to the largest area of tumor for tumor grading [52]. The 2D Mask R-CNN-based method yielded 0.935 (sensitivity), 0.972 (specificity), and 0.963 (accuracy), while the 3DConvNet method yielded 0.947 (sensitivity), 0.968 (specificity), and 0.971 (accuracy).

6) *Deep convolution neural network fusion support vector machine (DCNN-F-SVM)*: The traditional segmentation method involves training a suitable classifier on a training set before setting it up for verification. In contrast, this model comprises of three stages: (1) preprocessing, feature

extraction, and CNN and SVM training (2) running the final segmentation result through testing (3) utilizing the CNN-SVM cascade classifier [53]. These three stages are divided by DCNN-F-SVM. To obtain the mapping from the image space to the tumor label domain, DCNN is trained in the first stage. The second stage involves feeding the integrated SVM classifier with the test images along with the labelled output of the DCNN. In the third stage, a deep classifier that has more layers is trained by iteratively connecting the DCNN and the integrated SVM classifier.

7) *Capsule network (CapsNet)*: The concept of a capsule network was first proposed by Sabour et al. [54] to address a significant CNN shortcoming. The Capsule Network (CapsNet) extends the functionality of the conventional CNN by adding a new layer referred to as capsule layers, where each component is a capsule represented by a vector. It should represent a feature as well as the feature's characteristics, such as its location, texture, and deformation. The attitude matrix, W and the original input vector, U are processed in the capsule network to produce the final input vector, U . The final input vector, U is then multiplied by the appropriate weight, c and added to obtain the vector, s . Finally, a nonlinear function converts s into the final vector, v to enable the transition between the underlying and high-level feature. If the position of the high-level feature being pushed out by different underlying features points roughly in the same direction, the object has a high probability of existence [33].

One disadvantage of dynamic routing is that it can only be implemented in a fully connected manner. DeepCaps has been introduced to go deep into the architecture by skipping connections within a capsule cell that allow for good gradient flow in back propagation. Meanwhile, 3D convolution is used to generate votes from the capsule tensor to help route a localized group of capsules to a higher level. This combination allows architecture to go deeper while requiring less computational complexity [55]. According to the study, CapsNet performs better with a limited amount of training data and is suitable for detection or segmentation due to its high performance under class-imbalance for typical biomedical image database constraints [56].

8) *Segmentation capsule network (SegCaps)*: SegCaps is a modification to the original dynamic routing algorithm that makes it act locally when routing children capsules to parent capsules. It also allows the capsules within the same capsule type to share transformation matrices. This reduces the

memory and parameter burden and enables it to operate on large image sizes ranging from 32 x 32 pixels to 512 x 512 pixels. To compensate for information loss, the concept of deep convolutional-deconvolutional has been introduced for pixel level predictions of object labels. Finally, the masked reconstruction of the target class is extended as a regularization strategy for the segmentation problem [57,58,60]. The capsule segmentation task consists of [59]:

a) *Primary capsule*: Graphics inverse processes include convolution, reshape function or squash function and input image is fed into a couple of convolution layers.

b) *Higher layer capsule*: Due to the ability to trace the activation's path, the hierarchy of the parts can be easily sorted out. Additionally, it confirms the earlier prediction.

c) *Loss calculation*: Once the decision has been made, the classification takes place to determine whether the decision is correct or close to perfect.

Automatic glioma segmentation in brain MRI images had been conducted using CapsNet [61] by training the network into two steps (80% is used for training and 20% used as the validation data). Since capsule network has the capability to generalize novel viewpoint, it learns the spatial relationship between features using dynamic routing of capsules. The two-step training method resulted in about 3% improvement in dice score on validation and uses fewer data for training and contains 95.4% less parameter. From there it can be concluded that SegCaps can overcome the problem of data limitation. Results have also shown that SegCaps has been successful in segmenting the enhancing tumor core area. SegCaps only stores feature map indices and uses them in the decoder to achieve good performance. In comparison to other architectures, it is more efficient in terms of memory and computation [62]. According to previous research, SegCaps can capture the contours of the tumor core better than the contours of the entire tumor [63]. SegCaps can segment a small tumor region of the tumor core, but it tends to ignore the inner areas of the tumor core. When it comes to whole brain tumors, SegCaps is unable to capture fine-grained details, particularly when the region is exceptionally small, and the boundaries are coarse. Despite its capabilities, the algorithm is much slower, with higher computational complexity and a longer execution time. Table II shows some of the most recent research results on brain tumor segmentation based on CNN and capsule network specifically for the complete tumor (whole tumor), the tumor core that consists of enhancing, non-enhancing and necrotic parts and on the enhanced tumor only.

TABLE II. RECENT METHODOLOGIES FOR BRAIN GLIOMA SEGMENTATION USING CNN AND CAPSULE NETWORK

C. Dataset for Brain Tumor Analysis

Deep learning tasks necessitate a large dataset for training and validation. For brain tumor analysis, various datasets are publicly offered like BraTS. The images are mostly available in NifTI, DICOM, JPG, and PNG formats, and they are described in native (T1) and post-contrast T1-weighted (T1Gd), T2-weighted (T2), and T2 Fluid Attenuated Inversion Recovery (T2-FLAIR). Since the dataset is derived from MRI patient cases, each one contains 154 - 155 sliced human brain images, implying that for each case of subset, there are 155 images in that subset. This preview most likely using Brain Tumor Segmentation Challenge (BraTS 2013-2018). The Brain Tumor Dataset (Public and Private) and The Cancer Genome Atlas are two other common sources of datasets used for brain tumor analysis (TCGA).

III. DISCUSSION

Since the early stages of deep learning development, Convolution Neural Networks (CNN) have been utilized to meet current requirements and improve classification and segmentation of brain glioma. CNN is made up of several layers; the convolution layer extracts image features, the pooling layer checks whether the features are present or not regardless of their position, and the max-pooling problem. Then, the full connection layer will predict the output of the learning features from the previous two layers.

However, CNN has limitations that lead to results that are not accurate enough, such as complex calculation if a standard multi-layer perceptron (all layers are fully connected) is used because the image dimensions are too large. Other disadvantages include loss of information in the pooling layer, such as spatial resolution, and the need to over-train all possible angles to overcome it, which consumes more time

and resources. It also demonstrates the inability to identify complex field-of-view images such as overlaps, mutual masking, and different backgrounds. Many modifications to the CNN algorithm have been made, such as DCNN, U-Net, RCNN, FCNN, and others while improving the performance of CNN.

Capsule Network (CapsNet) is a new deep learning methodology for brain tumor classification and segmentation. CapsNet is made up of four layers: a convolution layer for extracting features, a primary layer for storing feature vectors using eight convolution operations, a digital layer for storing higher level features in the form of vectors, and an auxiliary layer for replacing capsules with their lengths. CapsNet reduces the number of connections by using capsule group neurons and fewer parameters. Even though fewer parameters are used, CapsNet's viewpoint invariance allows it to recognize images and objects efficiently regardless of the viewpoint from which they are observed. Due to the typical dataset constraints of medical images, this also leads to object detection and image segmentation being more helpful.

CapsNet can solve the effect of max pooling in CNN, as this unit only examines whether attributes and features are present or not regardless of their position. CapsNet can resolve this issue by capturing part-whole relationships that consider both the existence of the features and their orientation. Furthermore, max pooling causes translational invariance, which results in incorrectly sized, positioned, or ordered components of the correct image. CapsNet uses equivariance by considering the position, proportional and translational invariances to tackle invariance problem.

However, there are several things that need to be improved in CapsNet for future research, such as the uncertainty in testing on larger images and the inner loop in dynamic routing by agreement algorithm, which causes the training to slow down. CapsNet may have the weakness to accurately identify interested region in images with a more varied background and very close identical objects due to noise and crowding. Since CapsNet is still in its early stages, more changes and improvements can be made to the algorithm, particularly to the dynamic routing and convolution strides.

Furthermore, there is substantial evidence that accurate segmentation of various tumor sub-regions can provide the foundation for quantitative image analysis to predict patient overall survival. In the future, it may help to lay a more precise and accurate foundation to understand unique tumoral characteristics, as well as better insights into the quantitative and qualitative aspects of a patient's disease care. Imaging analysis may improve glioma treatment and management by determining tumor heterogeneity, more comprehensive identification of tumor genotype, cases of progression and pseudo progression, tumor grading, and survival prediction.

In general, computer-assisted diagnosis makes a significant contribution in terms of speed. Deep learning approaches benefit from adapted automatic feature acquisitions to reduce time spent on manual practice. With the introduction of GPUs, computation processes become much faster, and more data can be trained. The amount of training

data increases computational performance and accuracy as well.

IV. CONCLUSION

This paper reviews the performance between two neural network architectures to classify and segment the brain glioma, namely CNN and CapsNet. It is concluded that CapsNet can overcome data loss and has a higher level of image classification and segmentation accuracy than CNN, but it involves more parameter training and requires more training time. The CNN model outperforms CapsNet in terms of less memory and training time. This review may serve as a guide in establishing future deep learning-based methods to further improve the brain glioma classification and segmentation performance.

ACKNOWLEDGMENT

The authors would like to thank the Ministry of Higher Education Malaysia and Universiti Kebangsaan Malaysia for the University Research Grant: GUP-2019-023 to support this work.

Fuzzy Reasoning based Reliability Fault Prediction of CNC Machine Tools

Jie Yu, Tiebin Wang*, Weidong Wang, Gege Zhao, Yue Yao

School of Mechanical and Resource Engineering, Wuzhou University, Guangxi, China

Abstract—CNC machine tools are the infrastructure of the manufacturing industry, and many fields cannot do without them. This paper studies the fault data of a series of CNC machine tools, and predicts the fault level based on the activity parameters of Gutenberg Richter curve and fuzzy information theory. Apply the Gutenberg Richter curve model to the reliability analysis of CNC machine tools, and use this model to fit the curves separately. Fit the activity parameters of each stage with curves, and the results show that the b value can reflect the fault activity frequency of CNC machine tools. Due to the correlation and fuzziness between system faults, it is more appropriate to use a fuzzy neural network with strong adaptability and good learning ability, which can easily adjust parameters, and can express a more complex, high-dimensional nonlinear system through fewer conditions. The use of fuzzy reasoning can link the nonlinear relationship between fault level, b-value, and N-value. Analyze the error between the predicted fault level and the original level, and the small error indicates that the model has good predictive ability. Applying this predictive ability to the reliability research of CNC machine tools will yield good results.

Keywords—CNC machine tools; reliability; fuzzy inference; fault prediction

I. PREFACE

The failure of the CNC machine tool is recorded in real time, and the surrounding environment, the quality of its own components, and the operation of the controller all have a certain impact. Once a CNC machine tool has a high-impact failure it can bring great losses, not only affects the processing process, but also consumes personnel to detect and repair and time. In the reliability study of CNC machine tools, the quality of each component is tested and predicted to reduce the possibility of failure and reduce the loss caused by failure. If you can better predict the failure of CNC machine tools, it will reduce a lot of unnecessary trouble and loss. There will be some connection between some subsystem failures of CNC machine tools, and the failure of one system may cause the failure of another system as well, a phenomenon called system fault correlation [1]. The fault generation may be spontaneous or may be caused by other system correlations, and because of this uncertain relationship, fuzzy reasoning is used to study the method. Currently, there are many ways of fault prediction, statistical prediction techniques, mathematical prediction techniques, intelligent prediction techniques, and information fusion techniques, and it is very important to study fault prediction techniques to improve the maintenance and security of equipment [2].

Gutenberg and Richter proposed the famous earthquake magnitude relationship $\lg N = a - bM$ by studying the activity characteristics of the California earthquake. This relationship is one of the important properties of seismic activity research and has been widely used in the study of earthquake related issues. In this relation, M is the magnitude, and N represents the number of earthquakes in the area with a magnitude greater than or equal to M in a certain period of time. The values of a and b are constants, a-values reflect the average level of seismic activity in the area, and b-values reflect the proportional relationship between large and small earthquakes. Jie Yu proposed to use Gutenberg–Richter (G-R) curve analysis method to analyze the relationship between the failure level and the occurrence frequency of a series of CNC lathes. This is a useful attempt in the reliability analysis method research of CNC lathes, and some conclusions have been drawn.

Zheng et al. [3] and Wang et al. [4] proposed to use fuzzy information theory to analyze the relationship between the precursor anomalous elements and seismic elements of earthquakes, and to take the b value of 0.65 as the anomaly indicator based on the fuzzy matrix of b values calculated by different parameters with corresponding magnitude and the fuzzy information inference results. Wang et al. [4] proposed to use the beta value of the frequency of the magnitude of the gamma distribution also as an earthquake prediction indicator. Fuzzy theory is also used for CNC machine tool fault diagnosis, and the fuzzy diagnosis model is easy and simple to use and widely applied through its strong structural knowledge expression and ability to handle incomplete information. Fuzzy neural networks have been widely used in various fields and fuzzy systems have good superiority in dealing with complex nonlinear systems.

The whole paper is divided into four sections. The first section talks about the research background of the article, the second section talks about the research method fuzzy inference method used in this paper, the third section talks about the reliability fault prediction of CNC machine tools based on fuzzy inference, and the last section summarizes the paper, the shortcomings of the current research and the outlook for future research.

II. FUZZY INFERENCE

At the University of California, USA, Professor Zadeh introduced the concept of fuzzy sets in 1965 after years of research. Suppose the range U under study is the set, denoted

as {u}, and U is called the theoretical domain, and the elements u inside the domain are denoted. $\mu_F : U \rightarrow [0, 1]$

$$u \rightarrow \mu_F(u) \tag{1}$$

$$0 < \mu_F(u) < 1 \tag{2}$$

The mapping μ_F denotes the affiliation function of a fuzzy set U. $\mu_F(u)$ is called the affiliation of u to the fuzzy set U. The value interval of the subordination is [0,1], when the subordination function is $\mu_F(u)=1$, then the element u belongs to the domain U completely. When the subordination function is $\mu_F(u)=0$, then the element u does not belong to the domain U at all. When the subordination function is $0 < \mu_F(u) < 1$, then for the element u, it partially belongs to the theoretical domain U; the larger the value $\mu_F(u)$ of then, the greater the degree to which u belongs to the theoretical domain U; the smaller the value $\mu_F(u)$ of then, the smaller the degree to which u belongs to the theoretical domain U [5].

In classical set theory, the boundaries of the objects studied are clear; an element is affiliated with 1 if it belongs to a set, and 0 if it does not belong to a set.

$$f_A(x) = \begin{cases} 1, & x \in A \\ 0, & x \notin A \end{cases} \tag{3}$$

Reasoning is the process and way of thinking in which a new judgment is derived from a known judgment or judgments according to certain laws, and it is a thinking activity in which an unknown result is derived from known conditions [6]. Fuzzy reasoning is based on fuzzy set theory and fuzzy logic, and represents the probability that an event may occur by a likelihood value, which takes any number between 0 and 1 [7]. It is a process of converting input into output by fuzzy rules in an uncertainty inference method, and the result obtained is a fuzzy set or affiliation function. Fuzzy rules are the rules on which fuzzy inference is performed and can usually be expressed in natural language.

III. FUZZY INFERENCE-BASED RELIABILITY FAULT PREDICTION OF CNC MACHINE TOOLS

A. Fault Data Sample Collation

The data comes from collaborative teams. The cooperation team has established a long-term cooperative relationship with machine tool manufacturers.

The collected fault data were stage-wise analyzed and integrated into a total of 100 sets of sample data. 70 sets of data were used for training and 30 sets of data were used for detection through ANFIS. The inputs were two nodes: the N value and the b value, and the output was the predicted rank M. The data samples were listed in Table I.

TABLE I. TABLE OF OUTPUT PREDICTION LEVELS M

^a: N: fault numbers; M: fault levels.

^b: The b-value is the slope of a straight line, indicating the degree of activity of the fault occurrence.

B. Predictive Model Modeling

We applied the seismic G-R curve model to the CNC machine tool and analyzed the fault activity parameters of the CNC machine tool. Since the fault signs and faults of CNC machine tools are also fuzzy in nature, and fuzzy neural networks have good fuzzy reasoning and adaptive learning capabilities [8-11]. Nonlinear relationships can be well modeled.

The model has only two rules, as follows.

Rule 1:

$$\text{if } x \text{ is } A_1 \text{ and } y \text{ is } B_1 \text{ then } f^1 = p^1x + q^1y + r_1;$$

Rule 2:

$$\text{if } x \text{ is } A_2 \text{ and } y \text{ is } B_2 \text{ then } f^2 = p^2x + q^2y + r_2;$$

$$\text{Final output: } f = f_1 + f_2$$

For any input variable $[x, y]$, the output of this inference system, f is the weighted average of the two rule outputs, and then we get:

$$f = \frac{\omega_1 f_1 + \omega_2 f_2}{\omega_1 + \omega_2} = \bar{\omega}_1 f_1 + \bar{\omega}_2 f_2 \quad (4)$$

$$\bar{\omega}_1 = \frac{\omega_1}{\omega_1 + \omega_2} \quad (5)$$

$$\bar{\omega}_2 = \frac{\omega_2}{\omega_1 + \omega_2} \quad (6)$$

ω_1, ω_2 are the product of the values of the affiliation functions in general.

The network structure is shown in the figure below (see Fig. 1).

Fig. 1. Takagi-Sugeno fuzzy neural network model structure diagram.

Takagi-Sugeno fuzzy neural network model is divided into five layers: input layer, fuzzification layer, rule layer, defuzzification layer, and output layer. The fuzzy rule front piece is the first three layers, and the rule back piece is the last two layers. The square shape indicates the untrainable nodes and the circle indicates the trainable nodes.

Layer 1: Input layer. The n nodes in this layer are connected to the input vector $X = \{X_1, X_2, \dots, X_n\}$ and transmit the input value X to the next layer, A and B are the fuzzy linguistic variables of the input X .

Second layer: fuzzification layer. This layer has $n \times m$ nodes, m is the number of fuzzy sets of each variable, each node represents a linguistic variable value, the input of the i group of m nodes is X_i , the output is the affiliation function of

each input variable belongs to the fuzzy set of each linguistic variable value $\mu_i^j(X_i)$, $\mu_i^j(X_i)$ is the j fuzzy set of X_i .

Layer 3: Rule layer. Each node represents a fuzzy rule, and the specific role is to match each input variable to the corresponding fuzzy rule, and to calculate the fitness of the input value to each rule. The mathematical equation is calculated as follows.

$$\omega_j = \mu_1^i \mu_2^i \dots \mu_i^i \quad (7)$$

Layer 4: Normalization layer. This normalizes the incoming model data from the previous layer for calculation.

$$\bar{\omega}_j = \frac{\omega_j}{\sum_{i=1}^m \omega_j} \quad (8)$$

Layer 5: Output layer, output layer y is the weighted sum of the network results after the rule.

$$y = \sum_{j=1}^m \bar{\omega}_j y_j \quad (9)$$

y_j is the weighted sum of the posterior pieces of each rule.

The more the antecedents are satisfied, the stronger the rule is and the more it guides the output. The learning algorithm mainly adjusts the parameters to make the final output have better results.

The following figure shows the structure of the Sugeno fuzzy system model (see Fig. 2).

Fig. 2. Sugeno fuzzy system model.

The advantages of this model, which is a nonlinear model, is very adaptable, can easily adjust parameters, can express more complex, high-dimensional nonlinear systems with fewer conditions, and is insensitive to parameter changes [12-17]. Its output variables are constants or linear functions and the output is an exact quantity.

C. Model Matlab Simulation

The adaptive neuro-fuzzy inference system can be implemented in Matlab using a toolbox or an editor [17-21]. The goal is to make predictions about fault levels, based on the number of faults and the value of the active parameter b as input. 100 sets of data are input, 70 sets of data are used for training and 30 sets of data are used for detection. The inputs are two nodes: N values and b values, and the outputs are the predicted levels M . The initial FIS is formed with two variables as inputs, four fuzzy subsets for each input quantity, and four

regular outputs for each subset, for a total of 16, and finally these subsets are clarified to produce 1 output quantity. The network structure is illustrated below (Fig. 3).

Fig. 3. Model system structure diagram.

Training on 70 sample data, the training error of the model can reach 0.142 after 9 training sessions, which can obtain good prediction results. The following figure shows the training error curve (from Fig. 4 to Fig. 8).

2.5	2.5	0.0	4.5	4.1	0.4
3	3.0	0.0	4	4.1	-0.1
3	3.2	-0.2	4.5	4.2	0.3
3	3.1	-0.1	4	4.0	0.0
2.5	2.5	0.0	4	4.1	-0.1
2.5	2.5	0.0	4	4.1	-0.1
3.5	3.7	-0.2	4	4.0	0.0
3.5	3.6	-0.1	4	4.1	-0.1
3	2.5	0.5	4.5	4.3	0.2
3	2.9	0.1	4.5	4.3	0.2
3	2.8	0.2	4.5	4.2	0.3
3.5	3.8	-0.3	4	3.9	0.1
3.5	3.7	-0.2	4	3.9	0.1
3.5	3.8	-0.3	4	3.9	0.1
3	2.7	0.3	4	4.0	0.0
3	2.7	0.3	4	4.0	0.0

The fault level prediction curve has the same trend as the original curve (shown in Fig. 9), and the maximum error from the predicted fault level does not exceed 0.5 (shown in Fig. 10), indicating that this fuzzy model is suitable for predicting the fault level in this way.

Fig. 9. Fault level prediction data and original data trend line graph.

Fig. 10. Fault error cluster bar chart.

IV. CONCLUSION

The fault data of CNC machine tools have been collected and analyzed, and then the Gutenberg–Richter (G-R) curve relationship in the earthquake has been applied to CNC machine tools. The physical meaning of the parameters is studied to describe the failure grade of the CNC machine tools. By comparing the b-value and the ratio of large failure to small failure with time, it is proved that b-value can reflect the ratio of large failure to small fault over a period of time.

CNC machine tool faults are random and fuzzy in nature, but there may actually be close relationships linked internally, as fuzzy neural networks have good adaptability and can solve nonlinear fuzzy system capabilities. The non-linear relationship between fault level and b-value and N-value can be linked by using fuzzy inference. With 100 data samples, 70 samples were used for model training, and the training error did not exceed 0.15. 30 samples were then used for model testing, and the predicted fault levels were analyzed for error with the original levels, and the error was not significant indicating that the model has good prediction capability.

The results of this paper are more reasonable and will provide a basis for the future studies.

When using fuzzy reasoning method for fault prediction, the influence of various other factors on the prediction is not considered, and only the relationship between activity parameters and earthquake magnitude is predicted. Explore other influencing factors during later research.

Using Machine Learning Algorithm as a Method for Improving Stroke Prediction

Nojood Alageel, Rahaf Alharbi, Rehab Alharbi, Maryam Alsayil, Lubna A. Alharbi

Faculty of Computers and Information Technology
University of Tabuk
Tabuk, Saudi Arabia

Abstract—Having sudden strokes has had a very negative impact on all aspects in society to the point that it attracted efforts for better improvement and management of stroke diagnosis. Technological advancement also had an impact on the medical field such that nowadays caregivers have better options for taking care of their patients by mining and archiving their medical records for ease of retrieval. Furthermore, it is quite essential to understand the risk factors that make a patient more susceptible to strokes, thus there are some factors that make stroke prediction much easier. This research offers an analysis of the factors that enhance the stroke prediction process based on electronic health records. The most important factors for stroke prediction will be identified using statistical methods and Principal Component Analysis (PCA). It has been found that the most critical factors affecting stroke prediction are the age, average glucose level, heart disease, and hypertension. A balanced dataset is used for the model evaluation which was created by sub-sampling since the dataset for stroke occurrence is already highly imbalanced. In this study, seven different machine learning algorithms are implemented: Naïve Bayes, SVM, Random Forest, KNN, Decision Tree, Stacking, and majority voting to train on the Kaggle dataset to predict occurrence of stroke in patients. After preprocessing and splitting the dataset into training and testing sub-datasets, these proposed algorithms were evaluated according to accuracy, f1 score, recall value, and precision value. The NB classifier achieved the lowest accuracy level (86%), whereas the rest of the algorithms achieved similar accuracies 96%, f1 scores 0.98, precision 0.97, and recall 1.

Keywords—Stroke prediction; machine learning; PCA; decision tree; KNN; majority voting; Naïve Bayes

I. INTRODUCTION

Strokes or cerebrovascular accidents are considered among the top three causes of morbidity and mortality in many countries all over the world [1], such that it accounts for around 10% of the world-wide deaths which makes it the second leading cause of death. As an estimation, approximately 700,000 individuals suffer from strokes each year, and by the year 2030, it is expected that this number will be greatly increased and will cause a medical cost of 240 billion dollars in the US alone [2].

The world health organization WHO defines stroke as a brain-related illness such that it leads to the dysfunction of the brain, and it could be focal, acute, or diffuse. This dysfunction is mainly a result of vessel problems and it lasts for longer than 24 hours. Ultimately, there are many types of strokes

depending on the exact origin of the dysfunction, which defines four main types of strokes: ischemic stroke, subarachnoid hemorrhage, cerebral venous sinus thrombosis, and intra-cerebral hemorrhage [3].

In general, brain strokes can be classified as either ischemic or hemorrhagic. Ischemic strokes are the predominant type and they account for approximately 70% of the total stroke incidents [4]. Ischemic strokes occur as a result of clots in vessels, or hypotensive vasoconstriction, arterial tears, and sickle cell anemia [5]. On the other hand, hemorrhagic strokes account for approximately 15% of the total incidents, yet their effects are usually more detrimental as they often lead to serious morbidity and death [6]. Hemorrhagic strokes occur due to many causes among which are the vascular malfunction and uncontrolled hypertension [7].

When considering the risk factors or the reasons behind the occurrence of strokes, these can be divided into two types of factors depending on their origin, meaning that there are factors that can be changed or modified, and factors that cannot be modified [8]. Some of the modifiable (changeable) factors is hypercholesterolemia, diabetes, and hypertension. On the other hand, the non-modifiable factors include age, gender, and the genetic factors in play [9].

The traditional stroke identification methods are usually the magnetic resonance imaging MRI and Computed Tomography CT scans which are expensive and invasive [10]. However, since the stroke occurrence is a very time-sensitive issue, dealing with it in a timely efficient manner is very important because in most cases, death or permanent damage from stroke can be prevented if the diagnosis happens early on [11], [12]. Therefore, it is essential to develop medical tools and devices that allow physicians to diagnose a stroke without being invasive or uncomfortable, through relying on biomarkers for example or studying the risk factors. Machine learning poses as the perfect tool for predicting whether a stroke can occur or not based on different factors. Machine Learning is capable of diagnosing, treating, and predicting disease through analyzing clinical data.

In this research, the aim is to develop and implement a machine learning-based system for the accurate prediction of future occurrence of stroke in patients based on several features including age, gender, BMI, and medical history. The primary objective is to get this system to predict the occurrence of stroke by 100% accuracy so that lives can be saved. The

contributions that are provided in this report can be listed as follows:

- Predictive analytics approach to predict stroke recurrence is suggested.
- Machine learning and neural network algorithms are implemented.
- A publicly available dataset of electronic health records is used.
- The subsampling techniques for balancing the dataset is followed.
- Dimensionality reduction techniques are implemented in analyzing the attributes.
- The most impactful features for predicting strokes are picked out and shown.

Thus, after mentioning the contributions, it can be said that the added value of this paper lies in the fact that it uses simple algorithms to achieve high accuracies with explainable results, instead of using complex algorithms. More precisely, the majority of the chosen algorithms were able to score similarly high results.

The rest of the paper is distributed as follows: Section II is the literature review where some studies are mentioned with their relative results. Section III is for describing the details of the methodology followed in this study. Section IV shows the results that were obtained by the proposed model. Finally, the paper is concluded with Section V as a conclusion.

II. LITERATURE REVIEW

Since technologies like machine learning and deep learning can greatly benefit the medical sector by increasing the accuracy of stroke prediction, many studies were conducted to explore how exactly machine learning models can be used in predicting strokes. In this section, a group of similar studies that relied on freely available datasets such as Kaggle and datasets from local hospitals or labs were selected.

Dritsas and Trigka [13] gathered data from Kaggle such that the participants were 3254. The dataset consists of 10 independent features such as age, BMI value, glucose level, smoking status, hypertension, and whether the individual had contracted a stroke before. Data preprocessing was performed on the dataset, and class balancing was implemented through a resampling method known as SMOTE. Machine learning models namely Stacking, Decision Tree, Random Forest, Majority Voting, Naïve Bayes, Multilayer Perceptron, KNN, Stochastic Gradient Descent, and logistic regression were used for predicting stroke or no-stroke. It appears from the results that the stacking classifier performed best and achieves 0.989 AUC value, with 0.974 precision and 0.974 recall. The other high performing models were Random Forest, KNN, and Majority Voting.

Rakshit [14] also relied on the Kaggle dataset and some of the algorithms as [13] namely Decision Tree, Naïve bayes, Support Vector Machine, Random Forest, K-Nearest Neighbor and Logistic Regression. According to their results, the best

performance was recorded by Decision Tree followed by KNN (96.3%).

Using Kaggle dataset, Sailasya and [15] discussed the prediction of stroke based on machine learning algorithm namely Logistic Regression, K-Nearest Neighbour, Random Forest, Support Vector Machine, Naïve Bayes, and Decision Tree algorithms. Undersampling method was used to handle the imbalanced data. The results showed that among these algorithms, Naïve Bayes had the best performance with 82% overall accuracy compared to 80 % for both K-NN and support vector machine, and 78% for logistic regression.

Emon et al. [16] collected information for 5110 patients were taken from Bangladesh's medical clinic. Then, ten different machine learning classifiers, which are ANN, MLP, K Neighbours algorithm, SGD, QDA, AdaBoost, Gaussian, QDA, GBC, and XGB were used. The weighted voting classifier offered the highest accuracy of about 97%, GBC and XGB classifiers achieving 96% accuracy, right before AdaBoost classifier that scored 94% accuracy. On the other hand, the lowest accuracy was recorded by the SGD classifier with a value of 65%.

Shoily et al. [17] used KNN, Naïve Bayes, J48, and Random Forest classifiers. They gathered data from multiple sources to create their dataset of 1058 individuals overall and took a total of 28 features. The authors performed integer encoding to make the machine learning algorithms suitable for WEKA processing. After that, feature selection took place, and the models were trained and tested then evaluated according to f1 score, accuracy, precision, and recall. In terms of accuracy, Random Forest as well as KNN and J48 achieved the same results: 0.998 accuracy, 0.998 f1 score, 0.998 precision and 0.98 recall, whereas Naïve Bayes achieved 0.856 accuracy and 0.861 f1 score.

Abedi et al. [18] created a dataset termed "GNSIS", which is a collection of electronic health records from 2003 to 2019. Data preprocessing was performed, and the individuals within the dataset were classified into six groups totaling 2091 individuals, 1 group consists of those who didn't contract stroke in the last 5 years, and the other 5 groups are of stroke patients. After that, the dataset was split into training and testing by 80 to 20 ratio, where data imputation was also done. From the dataset, 53 features existed including BMI, diastolic blood pressure, creatinine, and smoking status. Then, four feature selection sets were created with exclusion of some features at times, and six machine algorithm models were used each in all of the 5 recurrence prediction window, which makes 24 models in total. For 1year prediction window, Random Forest achieved the better results with 90% accuracy, whereas the average accuracy of all models was 88%. The average accuracy achieved in the 5 years prediction window was 78%, thus the wider prediction window results in less accurate performances.

Relying on electronic health records, Nwosu et al. [19] used a dataset published by McKinsey & Company, containing 11 different attributes including body mass index, heart disease, marital status, age, average blood glucose, and smoking status. In the dataset, 548 patients suffered from stroke whereas 28524 patients didn't suffer from any previous strokes, thus the

dataset needed downsizing. In fact, 1000 downsizing experiments were done to avoid sampling bias. After that, 70% of the dataset was selected for training and 30% for testing. Over the 1000 experiments, the Neural Network model achieved the best accuracy of 75.02%, followed by Random Forest at 74.53% accuracy and Decision Tree at 74.31%.

In [13], the dataset was large and their study was able to score very similar results to ours, even though at times our metrics were better. However, they did not mention the scored accuracy. Similarly, our proposed model achieved better performances than [14].

It's noteworthy that the proposed method in this study achieved 96.7% accuracy, which is significantly higher than the accuracy of [15] (80%).

In [16] the authors chose complex algorithms such as ADABOOST and XGB and were only able to achieve similar results to ours, whereas we achieved the high performances using much simpler algorithms, which is more desirable.

In [17] the study relied on 28 inputs to predict stroke occurrence, which is usually difficult to obtain from patients for a quick prediction. Conversely, the proposed algorithms in the proposed system in this paper relied on 9 factors only as an input. In addition, [17] used a much smaller dataset.

Similarly, [18] used a very high number of input, which is not desirable for ML algorithms.

III. METHODOLOGY

Machine learning permits the advancement of a system by making it capable of learning and improving from past experiences without the need of constant continuous programming. These systems learn through machine learning how to analyze data to identify patterns that help them make decisions in the future without the help of humans.

The real influence of machine learning becomes crystal clear in the fields that deal with a huge amount of data such as retail, health, government, finance, and transportation. This is mainly due to the decision-making capabilities of machine learning since it can understand the data and fit them into the different models such that human can rely on them for decisions. Machine learning models are efficiently used for identifying diseases and computing risk satisfaction in the healthcare sector. The previous are only a few examples of the capabilities of machine learning.

Nonetheless, real-life data cannot be simply directly processed by the selected machine learning algorithms which is why data preprocessing is an essential step before applying the ML models. After that, the available dataset must be divided into training and testing datasets. The training step is performed in order to teach the algorithm about the data. In addition, unknown data can be predicted through ML algorithms, yet the prediction results are checked against each other.

This study is dedicated to implementing machine learning algorithms for stroke prediction, since it is a dangerous and common disease. Machine learning is often suitable for datasets due to its simplicity, structure, and compatibility with

a wide range of machine learning platforms and tools. For this reason, machine learning algorithms were chosen in this study. However, the limitation of this method is that it requires many inputs for the model to be able to make predictions. It is possible that when predicting a person's status, not all inputs are available, and then the model will not be able to predict. This issue was removed since the chosen dataset was large.

In general, a wide set of attributes are used to predict strokes such as gender, age, and blood pressure data among many others. Additionally, the performance of a number of machine learning algorithms was examined to see which one is best suited for predicting stroke incidence based on the dataset. Ultimately, the chosen ML algorithm must give the predictions with the highest accuracy.

A. Implementation

In this section, the machine learning algorithms that will be implemented and put to the test are presented and described.

1) *Naive bayes*: In the cases when the features are highly independent, the Naïve Bayes NB algorithm can lead to probability maximization [20]. There is a feature vector f_i for every subject i at that class c such that $P(c|f_1, \dots, f_n)$ is maximized. The formula that defines the conditional probability is as in (1):

$$P(c|f_1, \dots, f_n) = P(f_1, \dots, f_n|c) / P(c) P(f_1, \dots, f_n) \quad (1)$$

In (1), $P(f_1, \dots, f_n|c) = \prod_{j=1}^n P(f_{ij}|c)$ resembles the features probability given class, whereas the previous feature probability is resembled by $P(f_1, \dots, f_n)$, and previous class probability is resembled by $P(c)$. Through maximizing the numerator of 1, its number is also maximized, and the optimization becomes as in (2):

$$\hat{c} = \arg \max_c P(c) \prod_{j=1}^n P(f_{ij}|c) \quad (2)$$

2) *Random forest*: There are multiple decision trees in a Random Forest (RF) classifier [21]. When these independent trees are combined in an ensemble through resampling, the results become subsets of instances that are used for classification and regression. In a random forest, the final output is a result of majority voting, since each independent tree generates its own classification outcome.

3) *K-Nearest neighbors*: K-nearest neighbors (KNNs) classifier depends on Manhattan or Euclidean distances to evaluate similarities or differences between instances in the dataset [22]. More often than not, the Euclidean distance is the metric of choice in KNN classifiers. In stroke prediction, the features vector of the new samples would be f_{new} . The closest K vectors (neighbors) to f_{new} is determined through KNN. After that, the class where most neighbors belong is given the f_{new} value.

4) *Decision tree*: In the proposed Decision Tree model [23], J48 resembling the single classifier, and RepTree [24] resembling the base classifier were chosen. The classes are denoted by the leaf nodes, whereas the features are denoted by the internal nodes. The Gini index technique is employed by the J48 classifier in order to split a single feature

at each node. Gini index is a fast and simple decision learner that is capable of building a DT through the gained information as an impurity measure and pruning via reduced-error pruning.

5) *Majority voting*: Soft or hard voting is implemented through simple majority voting, assuming an ensemble of K basis models. This method allows the prediction of the class label associated to an instance [25]. The hard voting collects the votes related to each class label and chooses the one with most votes as an output, that is the candidate class. On the other hand, the predicted probabilities for every class label are collected by soft voting, and the class label with the largest probability is predicted. In the proposed model, the hard voting is adopted. Its general function of hard voting is represented by (3):

$$\max \sum_{k=1}^K 1 P_{k,c} \quad (3)$$

Such that $P_{k,c}$ is the prediction or probability of k-th model in class c, and $c = \{\text{Stroke, Non - Stroke}\}$.

6) *Stacking*: One of the ensemble learning techniques is the Stacking, where the predictions of multiple heterogeneous classifiers are integrated within a meta-classifier. Usually, the training set is used for training the base models whereas the outputs of the base models are used to train the meta-classifier. Here, J48, RF, NB, and RepTree were chosen to be included in the stacking ensemble classifier. The predictions of these collective classifiers are used for training a logistic regression meta-classifier.

The influence of machine learning parameters on the performance of a model can vary depending on the specific algorithm used, the dataset being analyzed, and the problem being solved. However, in general, adjusting the values of these parameters can have a significant impact on the accuracy and speed of a machine learning model. In this study, several parameters for the different algorithms were modified to make sure better results are achieved. The modifications to the parameters of each algorithm are shown in Table I.

TABLE I. THE CHANGED PARAMETERS FOR EACH ALGORITHM

Algorithm	Specific Parameters
<i>KNN</i>	- Number of neighbors (k): value is 6 - Distance metric: (Euclidean distance)
<i>SVM</i>	- Kernel type: default kernel is radial basis function (RBF) - Regularization parameter (C): default value is 1.0
<i>DT</i>	- Tree depth: 3
<i>NB</i>	No modifications
<i>RF</i>	- Number of trees in the forest: default value is 100 - Maximum depth of each tree: 9

B. Pre-Processing

1) *Dataset description*: For this study, the dataset of choice was adopted from Kaggle. The dataset comprises a large number of participants of which only those above 18 years old are chosen, making the total of the participants 3254.

The 9 input attributes (most of which are nominal) as well as the target class are briefly described in Table II.

TABLE II. DESCRIPTION OF THE ATTRIBUTES/FEATURES IN THE DATASET

Risk factor	Description	Details
<i>Age (year)</i>	The actual age of participants	All of the participants are older than 18
<i>Gender</i>	Whether the participants is male or female	In the dataset, 1260 participants are males, and 1994 participants are female
<i>Hypertension</i>	The participant suffering from hypertension or not	12.54% of the participants in the dataset are hypertensive
<i>Heart disease</i>	The participants suffering from heart diseases in general or not	6.33% of the participants in the dataset suffer from heart diseases
<i>Marital status</i>	The participant is married or not	In the dataset, 79.84% of the participants are married
<i>Work type</i>	The work status of the participants	65.02% of them work in the private sector, 19.21% are self-employed, 15.67% have a job, while 0.1% have never worked
<i>Residence type</i>	Whether the participant lives in an urban or rural place	51.14% of the participants in the dataset live in urban place whereas the rest live in rural places
<i>Avg glucose level (mg/dL)</i>	The average level of a participant's blood glucose	Numerical values for each patient
<i>BMI (Kg/m2)</i>	Participant's body mass index of the participants	Numerical values for each patient
<i>Smoking status</i>	Whether a participant currently smokes or not	22.37% of the participants smoke, 24.99% of them have smoked in the past, and 52.64% of them have never smoked
<i>Stroke history</i>	Whether the participant has had a stroke previously or not	5.53% of the participants have previously had a stroke

2) *Data pre-processing*: If the data were kept in their raw form, it might negatively affect the quality of the predictions, which is why data preprocessing is essential. In the raw data, there might be some missing values and redundancy as well as noisy data, so tasks like data discretization and reduction of redundant values are performed. Furthermore, one of the data pre-processing tasks is to balance the classes through selecting one of the available resampling techniques. In the proposed workflow, the SMOTE technique will be used so that the participants can be distributed over the stroke and non-stroke classes in a balanced way. In more details, the minor class which belongs to the stroke participants, oversampling was done to increase the number of participants in this class. In addition, there were not missing or null values, so neither dropping nor data imputation was applied.

C. Proposed Workflow

The details of the proposed approach and methodology can be summed up in a workflow chart presented in Fig. 1.

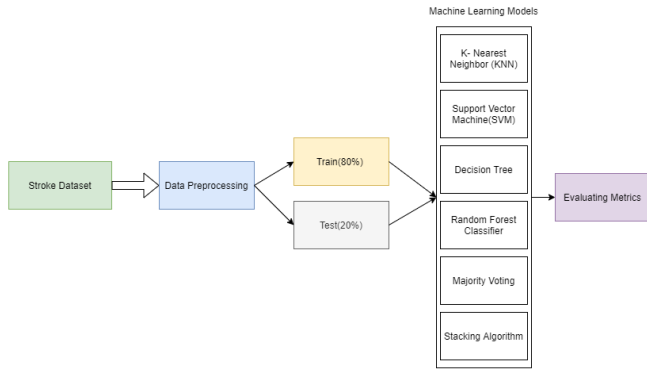

Fig. 1. Workflow of the proposed model.

Initially, the Kaggle dataset with 3254 participants is acquired. Then, the data is visualized to determine the specifics such as visualization of column and the relevant attributes. In this stage, the distribution of the participants can be visualized over the different features such as the age and gender distribution. After that, data preprocessing takes place where the data is being prepared through reduction of redundant information or resampling. In this approach, the SMOTE technique is selected. Later, the data is split into 80% for training and 20% for testing. Six different algorithms were selected to perform the predictions: Naive Bayes, Random Forest, K-Nearest Neighbors, Decision Tree, Majority Voting, and Stacking. These algorithms are then evaluated according to the evaluation metrics.

D. Evaluation

A group of performance metrics were chosen to evaluate the performance of the chosen machine learning methods. The most commonly used metrics in general will also be used in this study [see (4), (5), (6) and (7)]. Sensitivity, which is also termed Recall, represents the true positive results where participants who have had a stroke were successfully classified into the stroke class from the collective totality of the participants. Precision on the other hand specifies how many of those who had a stroke actually belong to this class. Whereas, Recall shows how many of those who had a stroke are correctly predicted. F-measure is the harmonic mean of the precision and recall and sums up the predictive performance of a model.

$$Precision = TP / (TP + FN) \quad (4)$$

$$Precision = TP / (TP + FP) \quad (5)$$

$$F\text{-Measure} = 2 \cdot Precision \cdot Recall / (Precision + Recall) \quad (6)$$

$$Accuracy = (TN + TP) / (TN + TP + FN + FP) \quad (7)$$

Where, true positive is designated by TP and false negative is designated by FN, false positive is designated by FP and true negative is designated by TN.

On the other hand, Area under curve (AUC) is also a beneficial metric, where the values must be between 0 and 1,

such that the higher the AUC value, the better the performance. If the model can discriminate between the instances of two classes perfectly, then AUC would be 1. Conversely, if the model fails to distinguish between any instances, the AUC would be 0.

IV. RESULTS

A. Data Visualization

The dataset can be visualized where each of the features or attributes are analyzed separately and against each other. Fig. 2, for instance, illustrates how the participants from the dataset are distributed according to age and gender. It can be seen that the patients have an average of 41 years old, and that there are slightly more females than males, specifically, 56% of the participants are female.

Fig. 2. Distribution of data by age and gender.

On the other hand, Fig. 3 shows how the patients who had suffered from a previous stroke are distributed according to age, where it becomes clear that approximately all of them were older than 40 years old, and the largest number of stroke patients was 80 years old. While the patients who didn't suffer from stroke were distributed among the different age groups.

Fig. 3. Distribution of patients who suffered from a stroke and those who didn't according to age.

In addition, Fig. 4 shows that the majority of the participants didn't suffer from any heart diseases, nor did they suffer from Hypertension.

Fig. 4. Distribution of data over heart disease and hypertension cases.

Moreover, 25% of the patients were obese, and 18% of the participants were overweight according to Fig. 5.

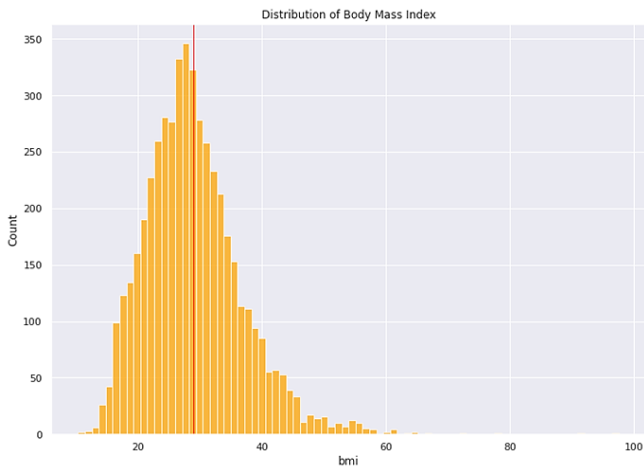

Fig. 5. Distribution of data according to BMI.

In Fig. 6 depicts that the majority of the patients were smokers, followed by a large group of participants with unknown smoking status (1544 participants).

Fig. 6. Distribution of data according to smoking status and relation to stroke.

Additionally, the majority of the participants are employed in the private sector. Meanwhile, the data was almost equally distributed between living in rural and urban areas, as depicted in Fig. 7.

Fig. 7. Distribution of data according to work type and residency.

Furthermore, the participants in the dataset scored mostly healthy levels of blood glucose (below 100) as shown in Fig. 8.

Fig. 8. Distribution of data according to average glucose level.

B. Model Evaluation

After acquiring the data, preprocessing it, and visualizing it, it was used to train and test several classifiers whose role was to predict whether a stroke occurs to a patient or not. The evaluation results for each classifier are presented in Table III.

TABLE III. EVALUATION OF THE DIFFERENT CLASSIFIERS IN TERMS OF ACCURACY, F1 SCORE, RECALL, AND PRECISION

Algorithm	Accuracy	F-1 Score	Recall	Precision
<i>KNN</i>	0.9633	0.98	1.00	0.97
<i>SVM</i>	0.9674	0.98	1.00	0.97
<i>Decision Tree</i>	0.9674	0.98	1.00	0.97
<i>Gaussian NB</i>	0.8655	0.93	0.89	0.97
<i>Random Forest</i>	0.96741	0.98	1.00	0.97
<i>Voting Classifier</i>	0.9674	0.98	1.00	0.97
<i>Stacking Classifier</i>	0.96741	0.98	1.00	0.97

In addition, these evaluation metrics can be seen in Fig. 9 which clearly illustrates that in fact, all of the proposed algorithms in this study have similar results in predicting the stroke occurrence in patients, except for Naïve Bayes which clearly has the worst performance among these classifiers.

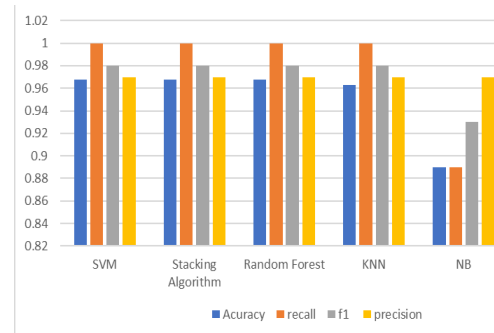

Fig. 9. Evaluation of different algorithms according to several evaluation metrics.

However, taking into consideration that the stacking classifier is an ensemble model, it can be said that choosing stacking algorithm might enhance the prediction results in case of stroke.

V. CONCLUSION

Stroke is among the top medical accidents that lead to death but even in the case of survival, stroke leaves serious implications on the lives of its patients. A patient who has previously suffered from brain stroke, shall he remain alive, might suffer the consequences in what seems like paralysis, among many other life-long complications. Since there are several risk factors that enhance the chances of strokes, its prediction beforehand is possible. Machine learning algorithms have been employed for this purpose promising fast and efficient prediction results.

In this study, the aim was to develop the optimal system that can predict stroke occurrence with high accuracy based on several risk factors collected about the patients. Here, multiple machine learning algorithms are implemented such as Naïve Bayes, SVM, Random Forest, KNN, Decision Tree, Stacking, and majority voting to check the results provided by each algorithm. After that, the choice of the optimal algorithm will be made depending on the evaluation results.

After appropriate preparation of the data, it was divided into training and testing parts such that all of the proposed algorithms are tested for their ability of predicting stroke occurrence. The evaluation metrics of choice were accuracy, f1 score, recall value, and precision value. Ultimately, the results showed that the selected algorithms perform quite well in predicting the strokes, such that SVM, DT, RF, KNN, Voting, and stacking classifier almost scored the same values. The algorithms scored 96% accuracy, 0.98 f1 score, 1 recall value, and 0.97 precision value. However, the achieved results suggest that the Naïve Bayes algorithm might not be the best choice for creating a stroke prediction model since it scored less accuracy levels (86%), less f1 score (0.93), less Recall (0.89), but the same precision value (0.97).

Deep Learning Localization Algorithm Integrating Attention Mechanism in Database Information Query

Yang Li, Xianghui Hui, Xiaolei Wang, Fei Yin*

College of Information and Management Science, Henan Agricultural University, Zhengzhou 450046, China

Abstract—This study aims to solve the problems of traditional indoor car search positioning technology in terms of positioning accuracy and functionality. Based on database technology and deep learning technology, an LSTM model with attention mechanism was established. This model can simultaneously extract temporal and spatial features, and use attention mechanism for feature importance recognition. The entire positioning model has been designed as a triple functional entrance that includes positioning, car storage, and reverse car search, enhancing the user's coherent experience. The data results show that the root mean square error of the LSTM (Attention) model designed in the study is 0.216, and the variance is 0.092. Among similar positioning models, the index value is the smallest, while the CDF line rises the fastest and the maximum value is the highest. The research conclusion indicates that the LSTM (Attention) indoor positioning model designed in this study has better computational performance and can help users achieve more accurate positioning and vehicle navigation.

Keywords—LSTM; attention mechanism; positioning; database

I. INTRODUCTION

Indoor vehicle positioning has always been a problem that many people need to solve in real life, and existing positioning technologies often have shortcomings such as significant positioning error and single positioning function. With the continuous maturity of the Internet of Things and intelligent computing technology, its application in the field of smart cities is also deepening. This comprehensive application based on life network interaction can be found in various aspects. Among them, deep learning technology, as an intelligent computing technology, has been widely applied and widely used [1-3]. Deep learning technology relies on database technology and modern network technology, utilizing network technology to achieve interaction between people and things, and utilizing database technology to store, manage, and update information [4-6]. As an intelligent computing technology based on human vision, attention mechanism can extract highly important target regions in global scenes, filter out impurities for the current task, and retain more important regions [7-9]. The main goal of this study is to use deep learning technology to solve the problem of vehicle positioning in the city, improve the accuracy and stability of positioning. This technology can not only be applied to indoor vehicle search, but also to many other indoor positioning problems, making it a positioning research of certain importance. In the future, this indoor vehicle positioning method based on database and deep learning technology can help people find parking spaces more conveniently, improving the efficiency and convenience of urban transportation. To achieve the research objectives, a

LSTM model with attention mechanism was established based on database technology and deep learning technology. This model can simultaneously extract temporal and spatial features. On this basis, the entire positioning model has been designed as a triple functional entrance that includes positioning, car storage, and reverse car search, enhancing the user's coherent experience.

II. RELATED WORKS

With the maturity of intelligent computing technique, the utility of deep learning algorithms in various fields has gradually deepened. Bédard et al. [10] applied deep learning algorithms to the medical field, and constructed a mouse pattern of sodium dextran sulfate colitis through convolutional neural networks. The study mainly used medical slide pictures as the main samples to establish training dataset, and based on this network pattern is trained. The pattern can improve overall efficiency of medical compound screening. Yu et al. [11] applied the deep learning algorithm to the prediction of the operating load of the power system, and selected the short-term load prediction suitable for the machine learning scheme as the main research direction, and designed a deep learning pattern for the nonlinear problem. The pattern can significantly improve the prediction efficiency. Shen et al. [12] applied the convolutional neural network algorithm to the short-term prediction problem of subway traffic passenger flow, and combined the auto-encoder to perform convolutional coding summation to solve the passenger flow matrix problem. At the same time, the back-propagation strategy was used to solve the optimization problem of matrix weight parameters. It shows that the technique can predict more accurately than the traditional pattern, and the pattern has a significant influence on the forecast prediction of passenger flow between stations. Tang et al. [13] proposed a low-cost image acquisition strategy that combines UAVs with intelligent algorithms, through which researchers can conduct more efficient and low-cost ground image acquisition. The strategy mainly uses a convolutional neural network with 12 layers to layer and recognize images. The research results show that this strategy is less time-consuming and more accurate than other strategies, and is more suitable for ground sampling. Wang et al. [14] proposed a fault localization pattern based on multi-class features, which constructs a ranking pattern from the perspectives of depth pattern and breadth pattern, and explores the relationship between different features. It means pattern designed in the study has a greater performance advantage in early troubleshooting than the traditional pattern. This research also adopts the deep learning method to design the localization

pattern. The research also integrates attention mechanism in the pattern design.

Attention mechanisms are used in different types of pattern designs. Zheng et al. [15] combined attention mechanism with 3D-network. By embedding the attention mechanism into the first level of the convolutional neural network, the band attention vector in the band selection process was learned, and then the plant Prediction of chlorophyll content. The research results show the pattern has higher classification accuracy than other types of patterns such as genetic patterns. Lai et al. [16] designed an attention application mechanism based on convolutional neural network that is, designing an excitation module after the convolutional layer of the convolutional neural network, and then forming an attention convolutional network pattern to emphasize important features. Research results show that the pattern can minimize the number of redundant candidates, thereby improving the efficiency of the pattern. Xiao et al. [17] combined an attention mechanism learning pattern with a bilinear efficiency network for the identification and classification of radar jamming signals. It shows that the bilinear network pattern based on the attention mechanism can extract signal features more efficiently and achieve the effect of automatic signal interference type classification. Wang et al. [18] proposed a temporal convolutional neural network pattern that combines soft threshold technology and attention mechanism, and applied it to the prediction of machine remaining life. The pattern does not need to perform overall feature preprocessing, but directly Multi-channel sensors for data input and retain valid features during feature extraction. It shows that the prediction performance of this pattern is more outstanding better than similar patterns. Shobana and Murali [19] designed an automatic review pattern based on attention mechanism for the difficult problem of manual review of online customer reviews. The pattern can perform abstract review through encoding-decoding and solve the problem of manual repetitive labor. The review efficiency of this pattern is more outstanding than that of similar patterns. This research designs a database-based indoor positioning pattern design. The pattern integrates the characteristics of the attention mechanism, making the indoor positioning more accurate and more practical.

III. ATTENTION-LSTM LOCALIZATION PATTERN DESIGN

A. Attention-LSTM Car-Finding and Positioning Pattern Framework Design

The indoor positioning pattern researched and designed is mainly based on the database-based position fingerprint indoor vehicle positioning pattern. The pattern mainly searches the data stored in the database and the position fingerprint in the positioning area through the fingerprint positioning strategy, and finally achieves indoor positioning. In order to adapt to the search strategy of fingerprint positioning, the pattern must have a certain intelligent learning ability, so as to ensure the accuracy and efficiency of the query in the query process. The research mainly combines the LSTM (Long Short-Term Memory) temporal network with attention mechanism to design the pattern for deep learning, and the pattern framework is mainly designed in combination with the main functional requirements of indoor car-finding and positioning. The

Attention-LSTM car-finding and positioning pattern designed by the research can be mainly divided into three functional parts, namely, the car-finding navigation module, the vehicle temporary storage module and the reverse car-finding module formed according to the user's car-finding and positioning requirements. The specific functional flow of the car-finding navigation module and the vehicle temporary storage module is shown in Fig. 1.

Fig. 1. Car search navigation module and vehicle temporary storage module.

Fig. 2. Reverse car search module.

The sub-figure (a) in Fig. 1 describes the car-finding navigation module. The car-finding navigation module mainly serves to receive the user's query target signal, and to determine whether the query target position actually exists. Once the module determines that there is a target position, the A* (A-Star) algorithm can be used for shortest path navigation. The A* algorithm is a search algorithm for the shortest path. The algorithm converts the path planning into a graph search problem, and converts the overall search area into a set of two-dimensional map arrays to complete the transformation and search of elements in the area, and then converts the entire search area into a set of two-dimensional map arrays. After the search is completed, the shortest distance from the target starting point to the target destination will be displayed according to the distribution of obstacles in the map. The sub-picture (b) in Fig. 1 is the vehicle temporary storage module, which is mainly responsible for meeting the needs of users in the vehicle storage process. The corresponding location fingerprint can be formed, which is convenient for the user to perform subsequent reverse car search. The operation mode of the reverse car search module is shown in Fig. 2.

The reverse car-finding module is a module for car-finding and navigation based on the location fingerprint. In the pattern, the location fingerprint of the vehicle is mainly composed of two parts of information, namely vehicle information and positioning information. The search path associated with the location. Therefore, in the reverse car storage module, the pattern will first confirm the vehicle information to confirm whether the vehicle actually exists. After confirming the real existence of the vehicle, the pattern will further determine the vehicle location according to the search path. Once the vehicle position is determined successfully, the navigation part can be entered, and the shortest path navigation can be carried out through the A* algorithm. Since the indoor positioning of the pattern mainly adopts the indoor Bluetooth technology, it is necessary to arrange the Bluetooth beacons according to the indoor environment and the characteristics of the positioning algorithm. However, in this process, the strength evaluation of the received signal needs to be solved. The research mainly uses the logarithmic normal path pattern for evaluation. The evaluation of signal propagation distance and received signal strength variation, the specific calculation process is shown in Equation (1):

$$RSSI(d) = RSSI(d_0) - 10 * n * \lg \frac{d}{d_0} + N_{\sigma} \quad (1)$$

In Equation (1), the *RSSI* received signal strength is *d* expressed, and the distance between the signal transmitter and the receiver is expressed. This distance is often expressed by the closest distance of signal propagation, which is the *d₀* reference distance, the *n* attenuation factor, and *N_σ* the random noise.

B. Attention-LSTM Positioning Mechanism Design

Indoor positioning strategies based on deep learning patterns often use neural networks as a feature extraction tool, through which effective features of received signals are extracted, and location estimation is performed based on the features. However, when most neural network patterns perform feature extraction and position calculation, the calculation of position information lacks time, that is, the temporal continuity of signals in the positioning process cannot be fully calculated [20-21]. Therefore, when designing the indoor vehicle positioning mechanism, the research mainly selects the LSTM pattern as the basic positioning pattern. Unlike other neural networks, the LSTM pattern itself has a strong processing ability for time series. In the case of introducing the attention mechanism, its consideration Feature selection with screening is performed simultaneously with the dual features of spatial and temporal features, as shown in Fig. 3.

Fig. 3. Basic framework of the pattern.

Fig. 3 describes how the attention mechanism and the LSTM algorithm are combined in the overall pattern. The pattern will input information A, information B, and information C into the LSTM pattern respectively after receiving information A, information B, and information C. These three signals contain their own spatial characteristics, and they also have time domain continuous characteristics between each other. After the LSTM pattern extracts its features, it will be introduced into the attention mechanism module. The attention mechanism module will target the importance of the signal, and finally form an effective feature unit with temporal and spatial features. The feature unit is the main basis for calculating the position coordinates. The LSTM pattern itself is evolved based on the network pattern. The network pattern has specialized processing capabilities for sequence data. The calculation equation for single data is shown in Equation (2):

$$y = f(Wx + b) \quad (2)$$

In Equation (2), the cyclic network *x* performs a linear transformation on a single input value, and the linear transformation *Wx + b* is expressed *y* as *f(·)* When facing a series of data, the calculation method of the network pattern state at the current moment is as shown in Equation (3).

$$s_t = f(U \cdot x_t + W \cdot s_{t-1}) \quad (3)$$

In Equation (3), *U* and *W* are all pattern parameters that need to be learned, *x_t* representing the input value at a certain moment, *s_{t-1}* representing the network state at a certain moment in the past, which *t* is a time expression. The calculation method of the pattern output value at the current moment is shown in Equation (4).

$$o_t = g(V \cdot s_t) \quad (4)$$

Equation (4) is *V* the pattern parameter that needs to be learned. The LSTM pattern adds a transfer state to the RNN pattern, as shown in Fig. 4.

Fig. 4. LSTM pattern construction.

In Fig. 4, the input variable is composed of two different element states. The element states are combined to form a

splicing vector, and the splicing vector forms four different types of outputs after four different operations, which are Z_f , Z_i , Z , Z_o , where Z_f , Z_i , Z_o are all three gated states, and Z represent the updated state value after the unit is updated. Z The calculation method is shown in Equation (5).

$$Z = \tan h(w[x_t, h_{t-1}]) \quad (5)$$

Weight parameter h_{t-1} is represented in Equation (5), and w , x_t respectively represent two different information states of the input variable. The calculation method of the forget gate Z_f is shown in Equation (6).

$$Z_f = \sigma(w_f[x_t, h_{t-1}]) \quad (6)$$

In Equation (6), the σ activation function is expressed. The input gate Z_i is calculated as shown in Equation (7).

$$Z_i = \sigma(w_i[x_t, h_{t-1}]) \quad (7)$$

Output gate Z_o is calculated as shown in Equation (8).

$$Z_o = \sigma(w_o[x_t, h_{t-1}]) \quad (8)$$

Under the attention mechanism, the pattern can extract information that is more critical to the current target from the global information. In a time-series-related environment, the influence of input elements at different times on output elements. At the same time, the attention mechanism change applies more attention to the input features with high influence. The flow of the LSTM (attention) localization pattern formed under the attention mechanism is shown in Fig. 5.

Fig. 5. Attention LSTM positioning pattern process.

Assuming that the input element values in Fig. 5 come from a given input sequence, and the vectors in the sequence are all one-dimensional vectors, the sequence is expressed as shown in Equation (9).

$$\begin{cases} X = [x_{t-2}, x_{t-1}, x_t] \\ x_i = [r_1, r_2, r_3, \dots, r_k] \end{cases} \quad (9)$$

In Equation (9), x_{t-2} , x_{t-1} and x_t respectively represent the input signal at three consecutive time points, and t represent a certain moment, i represent the general name of different moments, and represent x_i a one-dimensional vector in the signal. After the NN structure operation of LSTM, the pattern will obtain the output vector Y , which is expressed as Equation (10).

$$\begin{cases} Y = [y_{t-2}, y_{t-1}, y_t] \\ y_i = [v_1, v_2, v_3, \dots, v_n] \end{cases} \quad (10)$$

A one-dimensional vector is represented in Equation (10). y_i Under the action of the attention mechanism, the pattern will obtain the importance vector in this part $\hat{\delta}$, and the specific equation is shown in Equation (11).

$$\begin{cases} \hat{\delta} = [\alpha_{t-2}, \alpha_{t-1}, \alpha_t] \\ \alpha_i = [u_1, u_2, \dots, u_n] \end{cases} \quad (11)$$

A one-dimensional vector is represented in Equation (11). α_i The final calculation equation of spatiotemporal features is shown in Equation (12).

$$o_t = \sum_{i=0}^2 \alpha_{t-i} \square y_{t-1} \quad (12)$$

The output network of the pattern is mainly composed of Droup level and SoftMax level. The Droup level is mainly used to solve the overfitting problem of the pattern, and the Droup leve randomly disconnects part of the network connection to prevent the occurrence of overfitting. The SoftMax layer is mainly used for multi-classification of the positioning problem, and the final position probability can be written in the form of Equation (13).

$$\sum_{i=0}^n P_i = 1 \quad (13)$$

In Equation (13), i represents the position, and P_i represents the probability of being located at the position. The final position of the pattern output can be expressed in two ways. The first way is the maximum probability way, as shown in Equation (14).

$$\begin{cases} p_t = \max(p) \\ position_x = x_t \\ position_y = y_t \end{cases} \quad (14)$$

The position in Equation (14) is $position = (position_x, position_y)$ expressed in terms of positioning coordinates. The second representation method is the weighted average representation method, as shown in Equation (15).

$$\begin{cases} position_x = \sum_{i=0}^n p_i \cdot x_i \\ position_y = \sum_{i=0}^n p_i \cdot y_i \end{cases} \quad (15)$$

IV. LSTM-CNN POSITIONING PATTERN POSITIONING EFFECT ANALYSIS

A. Pattern Performance Analysis

When analyzing the localization effect of the LSTM-CNN localization pattern, the research will analyze from the two perspectives of the LSTM-CNN pattern's operational performance and the pattern's localization effect. In the data analysis, the research mainly uses the underground garage on the first floor below ground as the main data collection site. In the study, the beacons were evenly arranged in the indoor environment, and the coordinate positions of the signals were recorded. After the data is obtained, 80% of the experimental data is training set, and the other 20% is test set. Since the LSTM pattern requires information sequence input, the research assumes that the order size is 3 when selecting the data set, so the available data sets are combined as shown in Table I.

Based on the data set setting, the research will explore whether adding attention mechanism to the pattern will affect the performance of the pattern. In the comparison process, the research uses four patterns: LSTM pattern, LSTM (Mean pooling) pattern, LSTM (Max pooling) pattern, and LSTM-attention pattern, the variance of four indicators to analyze, the specific data results are shown in Fig. 6.

TABLE I. DATA SET COMBINATION

Order size 1		Order size 2		Order size 3	
Signal order	Position representation n	Signal order	Position representation n	Signal order	Position representation n
x_0	y_0	$[x_0, x_1]$	y_1	$[x_0, x_1, x_2]$	y_2
x_1	y_1	$[x_1, x_2]$	y_2	$[x_1, x_2, x_3]$	y_3
x_2	y_2	$[x_2, x_3]$	y_3	$[x_2, x_3, x_4]$	y_4
...

x_{n-1}	y_{n-1}	$[x_{n-2}, x_{n-1}]$	y_{n-1}	$[x_{n-3}, x_{n-2}, x_{n-1}]$	the_{n-1}
x_n	the_n	$[x_{n-1}, x_n]$	the_n	$[x_{n-2}, x_{n-1}, x_n]$	the_n

Fig. 6. Performance index comparison.

In Fig. 6, according to maximum error, the maximum error value of the data obtained by the LSTM pattern is 0.71, the max-error of data obtained by the LSTM (Mean pooling) pattern is 0.41, and the max-error of data obtained by the LSTM (Max pooling) pattern is 0.41. The maximum error value of the data obtained is 0.38, while the maximum error value of the data obtained by the LSTM-attention pattern designed by the research is 0.17. The max-error of the data obtained by the LSTM-attention pattern is the smallest, much less than The other three patterns; in terms of minimum error, the maximum error value of the data obtained by the LSTM pattern is 0.11, the maximum error value of the data obtained by the LSTM (Mean pooling) pattern is 0.06, and the data obtained by the LSTM (Max pooling) pattern. The maximum error value of the LSTM-attention pattern is 0.07, and the maximum error value of the data obtained by the LSTM-attention pattern designed by the research is 0.02. The min-error of the data obtained by the LSTM-attention pattern is also the smallest, much smaller than the other three. According to mean square error, the mean square error of the data obtained by the LSTM pattern is 0.23, the mean square error of the data obtained by the LSTM (Mean pooling) pattern is 0.18, and the mean square error of the data obtained by the LSTM (Max pooling) pattern. The mean square error is 0.17, and the mean square error of the data obtained by the LSTM-attention pattern designed by the research is 0.11. The mean square error of the data obtained by the LSTM-attention pattern is the minimum value, which is much smaller than the other three. In terms of variance, the variance difference of the data obtained by the LSTM pattern is 0.19, the variance of the data obtained by the LSTM (Mean pooling) pattern is 0.15, and the variance of the data obtained by the LSTM (Max pooling) pattern is 0.13, while The variance of the data obtained by the LSTM-attention pattern designed in the research is 0.07. It can be seen that the variance of the data obtained by the LSTM-attention pattern is the minimum value, which is much smaller than the other three

patterns. In summary, the LSTM-attention pattern designed by the research has the smallest values in the four indicators of maximum error, minimum error, mean square error, and variance. LSTM pattern shows stronger capability in both accurate and stable performance. In addition, the research starts from the perspective of different order sizes of data input, analyzes the accuracy changes of the patterns under different order sizes, and uses the CDF (Cumulative Distribution Function) to compare the accuracy. The specific data differences are shown in Fig. 7.

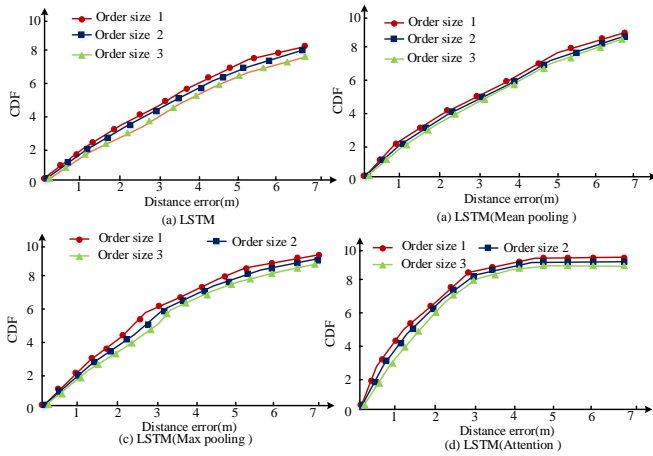

Fig. 7. Cumulative probability distribution function.

In Fig. 7, the CDF values of the order size 1, order size 2, and order size 3 of the LSTM pattern all show a uniform upward trend. When the distance error reaches 7, order size 1, order size 2. The CDF value of order size 3 reaches around 80%. It can be seen that the rising trend of CDF value is slow, and the highest CDF value does not reach 90%; order size 1, order size 2, order size of LSTM (Mean pooling) pattern 3 The CDF values of the three data order sizes also show an upward trend. Although the upward trend is also uniform, when the distance error reaches 7, the CDF values of order size 1, order size 2, and order size 3 reach more than 90%. It can be seen that The accuracy of the LSTM (Max pooling) pattern is better than that of the LSTM pattern; in addition, the CDF values of the order size 1, order size 2, and order size 3 of the LSTM (Max pooling) pattern also show an upward trend. The upward trend is faster than that of the LSTM (Mean pooling) pattern in the first half of the rise, and the speed of reaching the high CDF value area is faster. When the distance error reaches 7, the CDF values of order size 1, order size 2, and order size 3 are the same. When it reaches more than 90%, it can be seen that the accuracy of the LSTM (Max pooling) pattern is more outstanding than that of the LSTM (Mean pooling) pattern; the LSTM-attention pattern designed by the study has three order sizes: 1, order size 2, and order size 3. The CDF values of the data order size all show an upward trend. It can be seen that the first half of the data line of the LSTM-attention pattern has the fastest upward trend, while the second half of the line has a relatively stable trend. When the distance error reaches 3, the order size is 1, the sequence The CDF values of length 2 and order size 3 both reach more than 90%, and are close to 100% when the distance error reaches 5. The overall precision of

LSTM-attention pattern designed by the research is higher and the performance is better, indicating that the attention mechanism can indeed significantly improve the computing function of the LSTM pattern.

B. Quantitative Analysis of Positioning Effect

In the analysis of the positioning effect of the overall pattern, the research mainly adopts the method of comparing the positioning effects of different positioning patterns. First, the positioning accuracy and stability of different patterns are compared, and then the positioning and navigation routes are compared. The comparison of positioning accuracy and stability data is shown in Fig. 8.

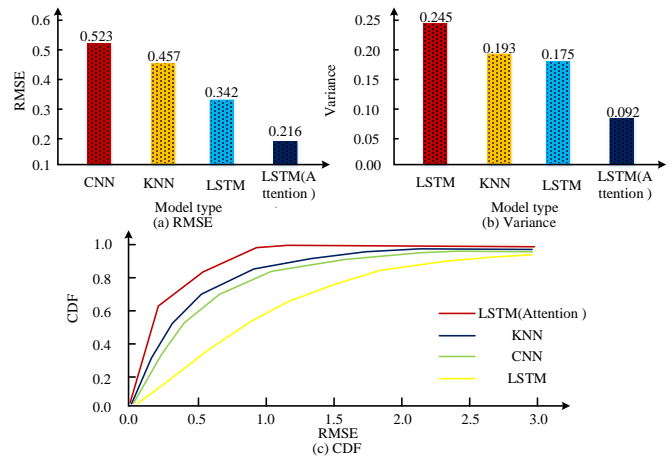

Fig. 8. Pattern comparison.

As can be seen from Fig. 8, according to root mean square error, the root mean square error of the CNN pattern is 0.523, the root mean square error of the KNN pattern is 0.457, the root mean square error of the LSTM pattern is 0.342, and the LSTM-attention pattern The root mean square error is 0.216. From the comparison, the root mean square error of the LSTM-attention pattern is the smallest; in terms of variance value, the variance value of the CNN pattern is 0.245, the variance value of the KNN pattern is 0.193, and the variance of the LSTM pattern is 0.175. The figure is 0.175, and the variance figure of LSTM-attention pattern is 0.092. From the comparison point of view, the variance figure of LSTM-attention pattern is the smallest; in terms of CDF value changes, it can be seen that among the four patterns, the fastest rising speed is LSTM. (Attention) pattern, and in the final accuracy effect presentation, the LSTM-attention pattern that shows the highest CDF value is also the LSTM-attention pattern, followed by the KNN pattern, the CNN pattern again, and the LSTM pattern. Although the KNN pattern and the CNN pattern show a higher rising speed and a better rising trend, they still show certain disadvantages compared with the LSTM-attention pattern designed by the research. Compared with else patterns, the LSTM-attention indoor positioning pattern designed by the research has higher positioning accuracy and positioning stability, and can reflect better results in practical applications. The research also compares the positioning and navigation routes of the four patterns, and the comparison results is Fig. 9.

Fig. 9. Positioning and navigation effect.

In Fig. 9, the navigation route of LSTM pattern shows the shape of multiple right-angle corners, the overall navigation route is relatively complex, and the final navigation target point deviates and fails to reach the target point accurately. Both the positioning ability and the navigation ability are insufficient; the navigation route of the CNN pattern shows the form of right-angle corners and oblique interspersed routes. The overall navigation route is also more complicated, but the pattern locates the target point more accurately, and the final navigation route is completed. more precise guidance. However, it can be seen from the route planning that the route planning is redundant and not simple and direct; the navigation route of the CNN pattern also shows the form of right-angle corners and obliquely interspersed routes, and the overall route planning is simpler and more direct. It shows relatively accurate target point positioning ability; the navigation route of the LSTM-attention indoor positioning pattern designed by the research shows an accurate oblique interspersed route form. Among the four patterns, the navigation route form is the most concise, and finally reaches the target point accurately. It can be seen that compared with the other three positioning patterns, the LSTM-attention indoor positioning pattern designed in the study has the best positioning effect and navigation effect, and can obtain the best effect in actual indoor positioning and navigation.

V. CONCLUSION

To solve the issue of insufficient accuracy of indoor spatial positioning in traditional methods, an indoor positioning pattern with temporal and spatial characteristics is established based on LSTM pattern, and on this basis, the attention mechanism is integrated into the pattern, so that the pattern can Features are effectively screened, and features with higher importance are retained for more precise positioning and navigation. The research shows the LSTM-attention pattern designed in the study has higher index values of 0.17, 0.02, 0.11, and 0.07, in line with maximum error, minimum error, mean square error, and variance, respectively, than other LSTM patterns that do not incorporate the attention

mechanism. The global operation effect of the LSTM-attention pattern is more outstanding. At the same time, the CDF data trend that the LSTM-attention pattern rises faster and the highest value is the highest. In addition, in terms of positioning and navigation effect, the root mean square error and variance of the LSTM-attention pattern designed by the study are 0.216 and 0.092 respectively, the index value is the smallest, the CDF curve rises the fastest, and the maximum value is the highest. The navigation route of the LSTM-attention pattern is the most direct and accurate. The LSTM-attention pattern is more stable and accurate than similar patterns, with better positioning and navigation effects.

Develop an Olive-based Grading Algorithm using Image Processing

Dongliang Jin

School of International Business, Zhejiang Guangsha Vocational and Technical University of Construction,
Dongyang 322100, China

Abstract—Olives come in a number of external and internal varieties. The Shengeh kind, which is available in three colours—green, brown, and black—was chosen at random by the researchers to ensure that the sample was diverse. To avoid discoloration throughout the experiment, 150 healthy olives were harvested and stored correctly. These olives had not been subjected to any external harm, such as crushing or milling. The particular kind of olives were kept chilled at 2°C and preserved in water. This study investigates the possibility of grading Shengeh cultivars from olives that have different uses, based on color using image processing. After preparing images of olives using MATLAB software and image processing techniques, olives are graded based on their color in three categories: immature with green, semi-ripe with brown, and ripe with black. The results showed that image processing technology can be used to grade olives of the Shengeh type in terms of their ripeness as a single-color grain with acceptable accuracy. The HSV color space is one of the best color spaces to separate the colors of the olive cultivar. The accuracy of the software for detecting olives with the mentioned degrees is 98%, 96%, and 100%, respectively.

Keywords—Image processing; grading; color; olive; MATLAB; HSV

I. INTRODUCTION

Olives are native to the Mediterranean and sub-Mediterranean climates, and altitude has a definite effect on their composition. Olives grow well at altitudes of 400 to 2000 meters depending on the climate [1,2]. *Olea europaea* is almost a small tree species of the Oleaceae family and is widely distributed from the Mediterranean, North Africa, South Asia, North to South China, Scotland, and Eastern Australia. The olive tree is evergreen and has small, solid leaves that are stacked on top of each other [3]. The fruit of the olive plant is of the shaft type. The most famous species of this plant is called *Olea europaea*, which used since ancient times to prepare olive oil and to eat its fruit. Olive trees grow very slowly [4], even when they grow freely without pruning, but when they are able to grow normally over several years, sometimes their trunk diameters increase dramatically.

One of the salient features of olives is their ability to adapt to different geographical areas. In modern olive cultivation, in order to select suitable cultivars, a set of traits such as fertility, resistance to pests and unfavorable natural conditions, high oil content, good oil quality, suitable size and shape, and high ratio of meat to the kernel are important. For example, in Iran, a number of cultivars have survived under local conditions, but on the other hand, due to being confined to a specific area, there has not been much genetic diversity [5]. Most of the olive

groves in Iran are composed of local yellow and oily cultivars and Fish mi, Shengeh, and Mari cultivars are also observed at limited levels.

Today, the quality of appearance of fruits and agricultural products cannot be evaluated using color methods using traditional methods. Olive is a valuable product that has nutritional and medicinal value and has different cultivars in different regions with different climates that are offered to the consumer market both as canned products and as its products (Eaton oil). Grading of olive products, in order to be used in the production of various products, is always considered by food industry factories. Most existing traditional olive grading systems have the disadvantages of reduced efficiency, low grading speed, and high cost [6,7]. Therefore, it is important to increase the speed and reduce the cost in the grading and recognition system of size, color, shape, and defects of olives; one of the procedures used for this purpose is the use of machine vision and image processing.

Image processing, computer image analysis, or more precisely, the ability of a machine to perceive what it sees around it simultaneously without the need of human observation. This technology is actually one of the branches of electronic engineering that aims to achieve a kind of robotic eye. This technology is used in various fields such as agriculture, medicine, automated industrial production, remote sensing of machine guides, robots, and of course the food industry. One of the important features of the car's visual system, in addition to its high speed and accuracy, and economic efficiency, is the possibility of examining materials in all types of visible and invisible light (infrared, ultraviolet, etc.). Exploration and development of machine vision methods for grading and fruit separation operations accelerate new techniques for estimating the quality characteristics of agricultural products [8,9], due to the importance of olives as valuable products with high nutritional, medicinal, and cost values. Traditional systems use machine vision and image processing in isolation, grading, and other applications that are cost-effective and have higher speeds.

The machine vision system is a non-destructive and scientific method for measuring the spectrum of colors at non-uniform levels. Usually, the color factor is examined to evaluate the quality of agricultural products by image processing. Among the physical characteristics of agricultural products, color is expressed as the most important appearance properties of products [10]. Color is the most important property of an image; in fact, everything in an image is a component of the color stored in the pixels of the image [11-

13]; based on the fact that each color can be reconstructed based on a combination of three main colors. Placing the image in different color spaces and calculating the mean and standard deviation of color intensity in image pixels, in different color spaces, the color information of the image can be extracted.

Traditional olive grading methods have many uses for a variety of purposes, but they are time-consuming and costly. In addition, the performance of these methods is not guaranteed. These factors make it possible to develop practical methods of grading olives. Olive color image processing is one of these methods, which is non-destructive, efficient, and cost-effective through the methods of computer vision systems, and also provides more stable results. In general, computer vision systems are based on olive imagery; even while crossing the production line and then processing the image and analyzing the image's work. Computer vision systems not only recognize the size, shape, color, and texture of olives but also determine the numerical properties of the olive with the shooting scene. The use of machine vision systems in olive processing factories in addition to the separation and grading of high quality and low-quality olives in terms of color, size leads to the development and design of new olive grading systems in olive product production lines for various uses that can be mentioned as one of the applications of researches [19-25].

This study investigates the possibility of grading Shengeh cultivars from olives that have different uses, based on color using image processing, and the question that image processing is the ability to provide an algorithm for grading cultivars, canned and oily olives for increasing the speed of grading and reducing waste in each of the production lines is responsible. The main objectives of this paper are to investigate the possibility of presenting the Schengen diet olive grading algorithm based on color using image processing. In addition, the possibility of developing an olive grading system using artificial intelligence (artificial neural networks or emphysema) is being investigated.

In summary, this paper has the following contributions:

- 1) Proposing an image processing algorithm to olives' grading of the Shengeh type in terms of their ripeness using intensity-level based on HSV color feature analysis.
- 2) Developing an automated olive grading system in order to tackle the interior and exterior feature analysis of the different types of olives.
- 3) Conducting extensive experiments and performance analysis to evaluate and validate the efficacy of the proposed algorithm.

The remainder of this paper is consists of Section II which presents the related works, Section III that describes materials and methods, Section IV presents results and discussion. Finally, conclusion is presented in Section V.

II. RELATED WORKS

Pronce et al. [22] used a computer vision-based system to automatically count and calculate the quantity and size of individual olive fruits. The suggested method separates the olives from the background using image processing techniques, and then utilises machine learning algorithms to calculate an

estimate of the olives' mass and size based on attributes taken from the segmented pictures. The findings demonstrate the efficacy and precision of the suggested approach, with a counting accuracy of 97.5% and a size and mass estimation error of less than 5%. The efficiency and precision of the procedures involved in olive harvesting, grading, and quality control might all be enhanced by using this technique. However, this work is conducted under controlled laboratory conditions.

This research [23] suggested a 3D imaging-based vision-based system for automatically evaluating mangoes according to their volume. The system takes several 2D pictures of the mangoes from various perspectives, and then it uses stereo vision and form from shading algorithms to create a 3D model. The 3D model is then used to determine the mangoes' volume, and a grading system is created using the volume measurements. The outcomes show how well the suggested strategy performs when it comes to precisely grading mangoes according to their volume. A drawback of the study is that it only analyses the system on a small sample size; bigger datasets and testing in more scenarios are required to determine the system's generalizability and scalability.

The authors in [24] proposed a method for categorising various types of olive fruits based on their visual traits using image processing and convolutional neural networks. The method employs a convolutional neural network to categorise the types based on the derived characteristics after extracting features from the photos of olive fruit using image processing techniques. The outcomes show that the suggested approach can categorise different types of olive fruit with an accuracy of up to 97.5%. The system's generalizability and scalability must be tested further on bigger datasets, which is one of the study's limitations because it only analyses the system on a very small dataset.

III. MATERIALS AND METHODS

The method of conducting the research is after photographing the object or the desired fruit (olive of Shengeh cultivar) which is inside a box with lighting. Image storage eliminates factors such as image noise, image background, as well as reduced light reflection in images for detailed examination, and then image processing by MATLAB software to identify and grade olives based on perceptible changes in the color spectrum. The tree of this cultivar is olive with medium growth power, with a tall crown, and thin and medium distance between nodes. Medium leaf size, oval bayonet leaf shape, medium leaf size with leaf length 6.8cm, leaf width 1.1cm. The surface of the leaf is glossy, smooth with dark green top color and the back color of the leaf is gray-green, as shown in Fig. 1.

The flowering of this cultivar of olives is such that it flowers very early but the browned petals fall later than other cultivars. Medium inflorescence length (26 mm); the number of flowers in the average inflorescence is 12 flowers. The inflorescence has many branches and lateral flowers [14,15]. The average fruit weight (average 5.2 mg), average fruit size, and ovoid shape (fruit length is 2.6 mm, and fruit diameter is 1.9 mm). Lentil or low, the ratio of flesh to the medium core (8.6), the shape of the fruit in position A is almost asymmetric,

in the position of the largest diameter in the center of the fruit, the tip of the fruit is round, early ripening, the color of the fruit when ripe is black. The percentage of oil in the dry matter is medium (50%) as shown in Fig. 2.

As you can see in Fig. 3, the closed weight of this cultivar of olives is on average 0.6 g, with a core length of 46.5 mm. In unfavorable dry climatic conditions, Shengeh olives that are sensitive to the cold, shrink and fall off the tree. In the tropics, the skin of the trunk and main branches suffers from sunburn [16-18].

After preparing the desired photos of olives, MATLAB software will be used to process the images. Content software has different toolboxes that students and engineers in each field can use the toolbox to suit their problems. One of these tools is image processing, which will be used in the present study. After saving the images, the olives are transferred to MATLAB software for detailed examination. First, actions such as noise cancellation, light reflection, image background, etc. are performed on the images. Then, by placing images in color spaces, determining different color parameters of HSV and RGB, drawing histogram diagrams of color parameters, and determining the noticeable color spectral changes of three random samples in color spaces, grading olives samples based on color characteristics (transparency and opacity). Canned and oily types and the separation of waste samples of olives are discussed.

IV. RESULTS AND DISCUSSION

Olive is one of the fruits that is consumed orally and its oil is used for medicinal, food, and industrial purposes. Today, with the increase in production of this product, the need to produce mechanized equipment with high accuracy in measurement and separation, to increase the efficiency of harvesting and processing of the product is essential, and in recent years the use of non-destructive and fast sight machine with computers and cameras Digital has become widespread and popular. Among the applications of machine vision in the agricultural sector is the classification of products. Traditional sensory evaluation methods have applications in determining food quality, but these methods are time-consuming and costly. In addition, the performance of this method is either not guaranteed and uniform and stable quality control of food products with this method are either not possible. These factors motivated the development of alternative methods such as image processing. In traditional methods, computer vision systems are efficient and cost-effective, and also provide more stable results.

In this study, an olive-based grading algorithm has been developed using image processing. Due to the fact that olives have a variety of domestic and foreign cultivars, Shengeh cultivar olives with three colors of black, brown, and green are randomly selected, of which 150 cultivars are processed as a research sample. Shengeh cultivar olives are prepared after a random collection of 150 healthy and without external damages such as crushing for olives (black, brown, green) in two different stages of harvest (late summer and mid-autumn). The olives are stored in water and refrigerated at 5°C for proper storage and to prevent discoloration in the experimental process. After preparing the images of the olives, they are manually classified by the author into three categories according to color: immature (green), semi-ripe (brownish), and ripe (black). Then, for color grading of olives, HSV color space is used in MATLAB software and the accuracy of the software for grading olives is evaluated.

The $L^*A^*B^*$ color space is used less frequently than the HSV color space in other works. However, due to the advantages of this color space, it has been considered in this study. For example, to filter green in an image, this range includes a spectrum that is dark green on one side and light green on the other. To separate it in RGB color space, it is not possible to select linearly, i.e. each channel with a desired color range condition. Because of such problems, the image is transferred to the HSV color space, which is composed of Hue,

Saturation, and Value components. Olive is also suitable for HSV color space due to its green color spectrum.

In the first step, a graphic interface is designed in Fig. 4. By pressing the loading button, you can select the type of olive that is displayed in the first image box. By pressing the HSV Show button, first, the image goes from RGB color space to HSV color space and then three layers of this color space are displayed in order. In the end, by pressing the Grade button, the type of olive is determined in terms of immature, semi-ripe, and ripe.

Fig. 5 shows the graphical interface execution view. In designing the graphical interface, various elements such as buttons or other elements are used so that the user can use the program in a simpler and more understandable way.

In Fig. 5, by clicking the loading button, the desired image is selected from a database of 150 olive varieties, of which 50 are immature olives, 50 are semi-ripe olives, and the last 50 are related to ripe olives. In the image below, an example of a ripe olive is selected, which is black. Fig. 6 shows the selected olive image by the program and displays it.

At this stage, according to Fig. 7, the olive type selected in the previous step, which is in RGB color space, is converted to HSV color space, which can be seen as HSV image in the image below, and then three layers of this color space include hue, saturation, and value that the appearance of olives in these three layers can also be seen in the image. Fig. 8 shows the determined degree of the olive by pressing the Grade button.

In the final step, by pressing the Grade button of the olive grade, according to its color in the HSV color space, it is determined that it is immature, semi-ripe, or ripe.

In the following, the results obtained from the software and its accuracy in diagnosis are examined, which can be seen in Table I and Fig. 9.

The table and diagram above show information about Shengeh cultivar olives and indicate that in total the number of samples is 150, of which 50 olives are in the category of immature with green color, 50 are semi-ripe with a brownish color. And the last 50 numbers belong to the mature category, the color of which is black. According to the male output, the number of correct diagnoses of the olive grade of Shengeh cultivar for the immature category is 49%, which is 98%, for the semi-mature category, 48, which is equivalent to 96%, and for the mature category, this number is equal to 50, which is equal to 100%, which is the highest. The diagnosis belongs to the degree of ripe olives and the lowest diagnosis belongs to the semi-ripe olives.

In order to classify using a neural network, among the extractive properties, different sets are selected as input and transferred to the neural network as input. Among 150 samples, the percentage of samples (105 samples) is used randomly for neural network training and validation and the remaining 30% (45 samples) are used for neural network testing. The structure of the multilayer perceptron neural network is shown in the Fig. 9.

Fig. 10 shows the structure of the multilayer perceptron neural network, which includes input, layers 1 and 2 as input and output layers, and finally network output. Table II contains the values of the artificial neural network parameters of the multilayer perceptron, including the number of layers and neurons in these layers, the transmission function used, the reverse propagation network training function, and the reverse propagation weight/bias learning function. The transfer function is selected by default.

In artificial intelligence topics, this table is used to determine the value of evaluation indicators such as accuracy. Accuracy is how many of the selected samples are correct. True depends on how many of the available correct samples are selected. Table II shows the results of test data classification using a multilayer perceptron artificial neural network classifier.

According to the values in the table above (perturbation matrix), the accuracy of the algorithm is expressed in the grading of olives of Shengeh cultivar, the accuracy of the algorithm is 98% for immature with 49 correct diagnoses, 96% for semi-ripe with 48, and 50 for mature olives. It is exactly equal to 100%. It is clear that the numbers on the main diameter of the matrix represent the number of correct classifications. Therefore, if all the numbers that are not on the original diameter are zero, the algorithm has maximum accuracy. To obtain the function of a classifier, it is sufficient to divide the sum of the elements of the original diameter by the sum of the total elements of the matrix. The efficiency for classifying the above algorithm is 98. This is divided by the division of the elements of the original diameter, which is equal to 147, which is equal to the total number of samples, which is 150.

Table III shows the performance criteria of the perturbation matrix for the classification of the artificial neural network, which indicates that the sensitivity and strength of the olive grading algorithm of the immature Schengen cultivar is 96, semi-ripe is 94, and ripe is 98. On average, the accuracy of the algorithm for grading olives of Shengeh cultivar is 98%.

TABLE II. COMPARISON OF CLASSIFICATION RESULTS OF IMMATURE, SEMI-MATURE, RIPE CLASSES

Classes	Immature	Semi-Mature	Ripe	Total Data	Wrong Classification	Total Correct Classification
Immature	49	1	0	50	2%	98%
Semi-Ripe	1	48	1	50	4%	96%
Ripe	0	0	50	50	0%	100%

TABLE III. THE SENSITIVITY, ACCURACY, AND PERFORMANCE VALUES FOR IMMATURE, SEMI-MATURE, AND MATURE CLASSIFICATIONS

Artificial neural network			
Classes	Sensitivity	Accuracy	Performance
Immature	98	96%	98
Semi-Ripe	96	94%	
Ripe	100	98%	

V. CONCLUSION

This paper presents an image processing-based method to grade the type of olive in terms of its ripeness as a single grain of color. In this method, the color-based feature using HSV color space as one of the best color spaces is used to separate the colors of the cultivar. Using this feature, the olive regions can be extracted. Then using analysis of extracted region, the grading task is performed. As experimental results showed, the accuracy of the method for detecting olives is 98% in the immature group, 96% in the semi-ripe group, and 100% in the ripe group. The average accuracy of the software is generally equal to 98%. However, the limitation of this method is sensitivity to light condition especially in olive region extraction. For direction of future study, deep learning-based methods can be explored to improve the proposed method.

Abstract—In recent years, the population of sick and elderly people who are alone and need care has increased. This issue increases the need to have a smart home to be aware of the patient's condition. Identifying the patient's activity using sensors embedded in the environment is the first step to reach a smart home where the people around the patient can leave the patient alone at home with less worry. In literature, a variety of methods for detecting the performance of users in the smart home are discussed. In this study, a method for abnormal behavior detection and identifying the level of risk is proposed, in which fuzzy logic is used in cases such as when the activity start. Experimental results demonstrate that the proposed method achieved satisfied performance with 90% accuracy rate that presented better results compared to other existing methods.

Keywords—Smart home; abnormal detection; behavior analysis; activity recognition; elderly people; fuzzy logic

I. INTRODUCTION

Over the past few years, the global elderly population has been steadily increasing, according to statistics from the World Health Organization (WHO). By 2363, the number of people aged 56 and above is projected to reach two billion, accounting for 22% of the elderly population [9]. The first cause of dependence and need in the elderly is considered and there are not enough people to take care of this population. With paying attention to the increase in the number of elderlies compared to people, the incidence of this disease has increased and the issue of taking care of them is also more important now [2,3].

Designing a smart home can help these people in a very effective way. Smart home uses user behavior among the sensors embedded in the environment. It has been investigated that he plays the role of a caretaker and only if he feels the need Musk, he informs it to one of the dependents of the patient - for further investigation; informs one of the problems that can be for an elderly person. The phenomenon of falling is usually accompanied by complications and physical disabilities and even death. So according to a report, death in people over 65 years of age 2007 to 2016 has increased by 31% [4,5].

In the phase of examining abnormal behavior, it should be noted whether the detection of abnormal behavior is for the purpose of detecting cyber-attacks on the smart home system or if it is meant for abnormal activities that occur by the patient

himself. In relation to the first case, various articles [23-25] have been proposed to identify attacks by examining the sequence of various events performed by the user. But in this article, abnormal behavior refers to the second state and the abnormality of the patient's own activity is investigated.

In fact, there are two methods for detecting the abnormality of behavior, in the first method, normal behavior is modeled, and any new input that does not match this model is considered as abnormality. But in the second method, a pattern is found for the anomalies by using the background data, and with the entry of new data, if they match this pattern, they are identified as anomalies. The first strategy seems to be more efficient and realistic, because abnormal data is rarely seen in real life. As shown in Table I [10, 26], Forkan and colleagues have pointed out two defects of the anomaly detection system. The first one is the inability to predict the leading anomalies, and the second one is that the use of a context for decision-making has caused more false alarms [20].

All these issues increase the importance of designing a system to determine the unusual activity of users. In this research, firstly, user activity identification is presented in different ways. Secondly, determining the degree of abnormality of activity in different articles is discussed and in the third part, the model is presented for determination of the unusual level of user activity in smart homes and it is reviewed. Fourthly, the experimental results of the proposed method are presented and the method is compared to other methods. Finally, the paper concludes in the last section.

The research gap in this study is the lack of a method for detecting abnormal behavior and identifying the level of risk in smart homes for sick and elderly people who are alone and in need of care. While various methods have been proposed to detect users' performance in a smart home setting, there is still a need for a more comprehensive approach that can monitor and detect abnormal behavior in real-time and provide a level of risk assessment. This study aims to fill this gap by proposing a method that uses fuzzy logic to detect abnormal behavior and assess the level of risk, particularly when an activity starts. This will enable caregivers to monitor the patient's condition remotely and take appropriate actions when necessary, thereby providing better care and support for vulnerable individuals in smart homes.

TABLE I. ANALYSIS OF CURRENT ANOMALY DETECTION METHODS

Method	Advantages	Disadvantages
Classification (supervised)	Measure the accuracy of the model using the confusion matrix	1. It is needed huge data for the training phase 2. Manual labeling by humans
Clustering and statistics-based (unsupervised)	Not required to sample data	1. Efficiency depending on the type of data distribution 2. Not optimized for anomaly detection

II. RELATED WORKS

Numerous studies have been conducted on the security, energy management, and detection of user behavior—just a few of the features of the smart home [10-8]. In the behavior identification section, some researches identify unusual user behavior by using fall detection and some by using different data mining and analysis algorithms. The user's prior actions have generated funds for a variety of categories of individuals, including those with partial paralysis, Alzheimer's illness, Parkinson's disease, heart disease, children, and others [11].

In the user activity detection research area, different algorithms are used. In [92, 93] is used Flocking Algorithm and stated to detect user behavior. Comparing this algorithm to other approaches has the benefit that there is no need to determine the initial cluster number, but this system has not done any work in the field of assessing the risk for the elderly.

In [14], a hybrid algorithm called CBC-AR has been used. This approach uses the PCA technique to choose a set of features initially; then, the K-means algorithm is used to cluster the data. The NN-K algorithm is then used to classify each cluster individually in order to increase accuracy. However, this technique has a very low sensitivity to specific actions, such as leaving home and doing the dishes. It also needs better sensitivity to determine the risk factor.

According to the author in [9], modeling user behavior is inappropriate since people conduct a hierarchy of actions for a task, grouping into Alone. Clustering is employed in this article as part of a brand-new hybrid approach dubbed pattern-K. The FP Growth algorithm is used in this approach to find recurring patterns in the primary raw data after some pre-processing. The actions are clustered using the patterns that the algorithm has discovered in the following phase, and the last step employs the neural network algorithm to forecast the user's future behavior. As their results showed, the advantage of this method is to detect simultaneous and separate activities and also it has also been able to analyze the activities in different periods of time with different interpretations, however, no report of the results and final accuracy of the tests has been presented.

In the article [15], the SVM algorithm, which is effective for data classification, has been used in such a way that a series of features are first selected using the PCA algorithm, and after normalizing the data, the aforementioned algorithm is applied to the data.

In the article [6, 7] a hierarchical method for diagnosis of their activities and their abnormality have been used. The hierarchical framework is designed in such a way that the factors with higher priority are in lower layers, and each layer is executed if the lower layer reports abnormality of activity. In each layer, one of the artificial intelligence algorithms called MLN has been used to get its output. The algorithm's benefit is

that in each layer, depending on the structure defined for it, both soft rules (rules obtained by the system from the routine in the data) and hard rules (rules known by people) can be used. However, this method is not enabled to identify the complex activities.

In the article [18], ESN is used to predict the activity values of a person. The benefit of this strategy over the others is that input data may be fed into the system at any moment, whereas with the earlier ways, the data had to be entered into the system all at once.

In the article [19], it has been investigated that it is possible for more than one person to live in a house, and to solve these problems. They used video cameras in three dimensions, and by processing these videos, the speed, type of behavior and other characteristics of each user can be determined. Different Bayesian networks characterized by these features are obtained and the best model is extracted using algorithms such as the hill climbing algorithm.

The accuracy of forecasting the following event (activity) using probabilistic approaches and LSTM networks was compared in the article [20], utilizing binary sensors, and this method reached 83% accuracy.

In the article [21], machine learning algorithms and ultrasonic sensors were used to predict the activity of one or two users present at home. The suggested system is able to identify the activities and residents in the house, which, of course, is less accurate in some activities when both people were at home.

In the article [22], in order to predict the next activity of the user, the activities are placed in separate nodes and by using the definition of fuzzy rules and FSM structure, it jumps from each node to another node, but in this article, a solution is also proposed to determine the level of risk. It has not been done and the accuracy is between 86 to 99% for different activities.

According to investigation of previous studies, although various methods have been proposed to deal with detecting abnormal behavior and identifying the level of risk in smart homes for sick and elderly people, still it is required to improve the accuracy rate in abnormal behaviors detection. This study aims to fill this gap by proposing a method that uses fuzzy logic to detect abnormal behavior and assess the level of risk, particularly when an activity starts. This will enable caregivers to monitor the patient's condition remotely and take appropriate actions, when necessary, thereby providing better care and support for vulnerable individuals in smart homes.

In the following, a new method for identifying and determining the amount of risk that arises in the occurrence of each activity is discussed. In this method, one of the important things in Alzheimer's patients, i.e., "starting time of each

activity" is also investigated, from which one can understand the abnormality of the patient's behavior.

III. METHODOLOGY

One of the most important steps in detecting the abnormal state of users in smart homes is to determine the risk level of each activity, which causes each activity to be categorized as absolute, normal or abnormal. To take advantage of this feature, fuzzy logic has been used at this stage. The three characteristics of the activity start time, the duration of the sensor being on and the duration of the sensor being off are factors that are effective in determining the level of risk caused by the activity of a user living at home, which will be explained in detail below.

A. Activity Start Time

One of the important and influential factors in detecting the level of abnormality of an activity is the start time of that activity, which has been investigated using fuzzy logic. As shown in Fig. 1, this system gives the activity start time and the type of detected activity to the fuzzy logic to check the level of abnormality of the detected activity and the level of abnormality of the activity with three levels of warning: safe, moderate and high. If this warning is high, the result is sent to the output and does not go to the next layers, but if the warning is moderate, the warning level is sent to the next layer for further checks.

In the phase of examining the activity start time, it should be noted that Alzheimer's patients usually suffer from depression at sunset, and this state sometimes continues until the end of the night, and this state is called sunset syndrome [37, 36]. Therefore, this period of time should also be considered in dividing the day and night, and the patient's behavior during these times should be examined more carefully. After considering these things, a day with 24 hours is divided into five parts, which can be seen in Fig. 2:

- Midnight, which is from 12 o'clock to about 6 am
- Day, which is evening, from morning to noon
- Sunset, this is the time of sunset when the patient collapses due to various reasons such as depression,
- 4) Night, at this time until the end of the night, there is a possibility of depression, but this level of depression and anxiety is minor than at sunset and has fewer effect, but it is still important
- 5) Before sleep, this time is around 22:00 to 20:00.

The next input is the type of activity that is being performed, since according to the research done on this group of patients, indiscriminate reminders to Alzheimer's patients cause their disease to worsen, in order to prevent this issue, only a series of activities are considered that they are performed outside of normal hours. These activities are dinner, sleeping, resting (things like watching TV), preparing food, washing dishes, cleaning the house, and leaving the house.

Rules are defined once the fuzzy inputs are defined based on these inputs and taking into account the daily habits of the Alzheimer's patient, for example, if the patient washes dishes

or prepares food at 2 in the morning, this is abnormal and by giving a lot of warning to the patient's caregiver informs him that the patient is probably not in a suitable mental condition and examines his condition. A diagram of the defined rules can be seen in Fig. 3. To define the rules, we consider the usual behavior of most people in the society (which was also obtained by examining the behavior of several elderly people) and assume that this person only sleeps and goes to the bathroom at night, and as a result, does things like cleaning the house and watching TV. It is unusual for this person if he does start preparing food from his sleep

B. Sensor ON Duration

Another key element in evaluating the degree of the unusualness of action is the length of time that each sensor is active. The patient may attempt to alert others to his health worsening and rescue himself if a sensor is on excessively. For this reason, a sensor is left on more than usual. It is also crucial to consider the nature of the activity. For instance, a patient may be cleaning a room in the house, which would be okay if the sensor did not switch off for roughly 30 minutes. With these considerations in mind, the third layer, which receives three entries, then assesses the unusualness of the activity. As shown in Fig. 4, these three inputs are,

- the duration of the sensor being on
- the type of sensor
- the type of activity that are given to the fuzzy logic and using defined rules. Outputs the degree of abnormality

A series of activities such as cleaning the house are activities that because the person is moving, the location sensor does not turn off even for half an hour, and this is normal. Therefore, the three activities of washing dishes, preparing food and cleaning the house are considered. Different sensors interpret the length of time as indicating something different. For instance, if a person is awake and sitting on the sofa, likely watching TV, it makes sense that the sensor in that location will not switch off. Or the sensors that have the ability to cover a space, the patient may go to any part of that space (where this sensor is in that space), stay on and stay on for a longer time or the door sensors that detect the opening and closing of the door can be on for up to 20 minutes. In this research, we divide the sensors into 6 groups. This division is comprehensive, as a result of being off during that period of time the next layer is also included, for example, if a person goes to the toilet or bathroom and according to the structure of the existing smart home, if there is no sensor in the toilet or bathroom, it is normal that no movement is reported for 20 minutes.

Based on this, the sensors are divided into the following six types:

- Sleep sensors, where the patient sleeps and as a result, it is natural for them to be off for a long time.
- Sensors that are included in the rest. They may have a high rate of coverage and remain active for a considerable amount of time (but not to the extent of sleep sensors).

- Blind spot sensors, which are situated in a location that is not, for a long distance, covered by any other sensor.
- Door sensors that record when a door opens and closes.
- In front of the toilet and bathroom doors are toilet sensors.
- Other sensors, which include sensors that do not fit into any of the aforementioned categories.

C. Sensor OFF Duration

As it was stated before, falling in the elderly is very dangerous and brings problems for them. The elderly will find it challenging, and a person with Alzheimer's may forget to wear the sensor after taking a bath or changing into new clothes if wearable sensors are employed to monitor the recurrence of this issue. This layer determines whether it is normal or abnormal if there is no indication of the user's presence in other areas and the user is in one location for an extended time. It also measures the time between a sensor turning off and the first sensor turning on after that. If it is marked and in a static state, it is dangerous and there is a possibility of the patient falling or getting worse. This time is different based on the sensor's type. For instance, if the bed sensor goes off for a few hours, it is normal because the person may have fallen asleep, but if the sensor in front of the toilet goes off for 30 minutes, there is a possibility of danger because

the patient may be ill and as a result, he stayed in the bathroom for an unusual amount of time.

As shown in Fig. 5, the fuzzy logic of this layer has two inputs: the time the sensor is off and the type of sensor, which is divided into 6 groups as described in the previous section. And the duration of being off is divided into the same four categories in which the intervals are longer in this case.

The rules of the fourth layer are such that if the type of sensor is "toilet" and the patient enters the bathroom for more than 40 minutes, no sensor is turned on and there is no information about the patient, the patient is probably sick or something bad happened in the bathroom. For example, rule number 2 states that if the sensor is off for a moderate duration (about 6 to 40 minutes) and the type of sensor should be sleep sensor. The fact that the individual may have slept off on his bed makes this behavior reasonable, or in the case of the predefined rule, it is stated that if the duration is too long and more than two hours. In the case of any type of sensor except the sleep sensor, this is abnormal, and the longer this time is more than two hours, the greater the risk, because according to the behavior of the person under investigation and the research that has been conducted on several elderly people, sitting for more than two hours in the bathroom or toilet, as well as for resting and watching TV and for crossing blind spots, is considered unnatural.

IV. RESULTS AND DISCUSSION

To check whether our fuzzy logic is working properly, we could not find a dataset that includes checking the degree of abnormality of the activity. For this reason, we randomly selected a number of transactions of the Aruba dataset from the collection of CASAS datasets [38], the number of which was 48 transactions, and after obtaining the results of the system, according to the form prepared by a doctor and a person familiar with the behavior Elderly people and Alzheimer's were filled, a comparison was made between the results, which is given below as an example of the steps of the work method.

In order to check that "if the patient washes the dishes at 10 o'clock in the morning," in the first step, after the type of activity was detected using one of the algorithms of the activity type determination section, washing the dishes, this activity along with its start time was classified into the next step. The second one is sent and there, according to the rules defined for each person, the level of abnormality of that activity is determined in three stages. These scenarios were given to two experts in the same way and their average opinions about each scenario were calculated and compared with the specific results from the system.

In order to validate the system, we collected data for 20 individuals which 4 individuals exhibit abnormal behavior (i.e., positive) and 16 individuals exhibit normal behavior (i.e., negative). As experimental results shown, our algorithm correctly identifies 3 individuals with abnormal behavior and misclassifies 2 individuals with normal behavior as abnormal. In this case, we can calculate the performance metrics as shown in Table II,

TABLE II. OBTAINED VALUSE FOR PERFORMANCE METRICS

Performance Metric	Value
True Positive (TP)	16
False Positive (FP)	1
True Negative (TN)	2
False Negative (FN)	1

Based on TP, FP, TN and FN, True Positive Rate (TPR) and False Positive Rate (FPR) are calculated as shown in Table III.

TABLE III. OVERALL PERFORMANCE

Performance Metric	Formula	Value
True Positive Rate (TPR)	$TP / (TP + FN)$	94%
False Positive Rate (FPR)	$FP / (FP + TN)$	33%
Accuracy	$(TP + TN) / (TP + FP + TN + FN)$	90%

In order to compare the proposed method with other existing methods, we experimented the Farhad et al. [14] and Casagrande et al. [20] on these 20 individuals. This experiment is conducted to prepare a fair comparison based on the same dataset. It is not tailored for a specific individual and is developed based on the demands and routines of old and Alzheimer's patients in general. Despite this, it offers decent accuracy. It is anticipated that if the patient's unique habits learned from his caregiver were taken into account, the accuracy would be better than it is now. Table IV presents the performance comparison between the proposed method and other existing methods.

TABLE IV. PERFORMANCE COMPARISON BETWEEN PROPOSED METHOD AND OTHERS

Method	Accuracy rate
Casagrande et al [20]	84%
Fahad et al [14]	88.6 %
The proposed method	90 %

As experimental results and overall performance comparison which obtained by TPR, FPR and accuracy rate, the proposed method achieved better accuracy rate in abnormal behavior detection compared to other existing methods.

V. CONCLUSION

In this research, firstly, a review of the works done in detecting the user's performance in the smart home, which includes two subcategories of fall detection and activity detection, was done. In the following, fuzzy logic was used to determine the level of risk of the patient's activity so that the habits of each patient can be obtained in the form of rules in accordance with his special conditions, and these rules can be used to determine the level of abnormality of the activities. In order to reach the defined goal, three options were used and according to them, the level of abnormality was reported. In

order to reach the defined goal, three options were used and according to them, the level of abnormality was reported. These options include (1) the start time of the activity, (2) the duration of the sensor being on, and (3) the duration of the sensor being off and the patient actually being motionless. Another noteworthy point is that in the proposed method, due to the implementation of the method for people with special conditions, the wearable sensors were not used. Because in the case of using such sensors to check the occurrence of problems, it is difficult for the elderly, and especially for an Alzheimer's person, it may be associated with forgetting to wear the sensors after certain conditions such as going to the bathroom or changing clothes. Anyway, according to these mentioned conditions, the implementation of this layer also produces good results with 90% accuracy.

For future works, it is suggested to use a method to individualize this system and detect the presence of several users at home and implement the system for heart patients, children, etc. Furthermore, the hardware implementation of this model can also be of great help to make it more accurate.

BREPubSub: A Secure Publish-Subscribe Model using Blockchain and Re-encryption for IoT Data Sharing Management

Hoang-Anh Pham

Ho Chi Minh City University of Technology (HCMUT), 268 Ly Thuong Kiet St., District 10, Ho Chi Minh City, Vietnam
Vietnam National University Ho Chi Minh City (VNU-HCM), Linh Trung Ward, Ho Chi Minh City, Vietnam

Abstract—As a result of the incredible growth and diversity of IoT systems and applications over the past several years, an enormous amount of sensing data has been generated, which is critical for developing IoT-based intelligent systems. So far, it has taken a significant amount of time and money to collect sufficient sensing data for these smart systems leading to demands of sharing or exchanging available and valuable data to reduce the time and money spent on the data collection process. However, ensuring the data sharing process's integrity, security, and fairness is fraught with challenges. This paper proposes a Blockchain-based model that supports a secure publish-subscribe protocol for data sharing management by addressing three criteria such as confidentiality, integrity, and availability. In addition, the proposed model adopts a re-encryption technique to optimize shared data storage with multiple users and enhance the security of the data exchange process in a transparent and public environment like Blockchain. We have developed a DApp to demonstrate the feasibility of our design and evaluate its performance.

Keywords—Publish-subscribe; blockchain; re-encryption; IoT data sharing

I. INTRODUCTION

The Internet of Things (IoT) is a term that refers to the fusion of sensor technologies, big data, artificial intelligence, and network infrastructure. Sensors operate as senses in IoT devices, collecting data about their surrounding environment. These data can be analyzed locally on IoT end-devices or transferred to remote servers for advanced analysis. IoT devices can take actions based on the analytical results via actuators. Currently, IoT is one of the core technologies in the industry 4.0 era and plays a crucial role in many aspects of our lives, from inside to outside of society. IoT is ubiquitous, yet it is not always visible. IoT is renovating physical objects into an ecosystem of information that can be shared between implanted, portable, and even wearable devices. This will enrich our lives with both data and technology. However, building a sufficient database system to manage and store those IoT data spends a lot of time, money and is inefficient. Poor management might result in the loss of sensitive data such as health status, lifestyle patterns, and device control.

Traditional IoT access management programs are mainly built on popular access management models such as discretionary access control (DAC) [1], attribute-based access control (ABAC) [2], role-based access control (RBAC) [3], or capability-based access control (CapBAC) [4]. It's worth mentioning that in the aforementioned management methods, a centralized entity confirms object access permissions. As a

result, it can lead to a single point of failure. To address this issue, distributed CapBAC models have been developed [5][6], in which IoT devices themselves, rather than a centralized entity, authenticate access. However, IoT devices are small, low-power, and have limited computing capacity, thus they can't serve as an access authorization entity.

In the meanwhile, the decentralized architecture enables Blockchain to work efficiently without a central authority. It allows participants to conduct transactions securely, even though the fact that they may not trust one another in a trustless network. Various studies presented systematic investigations and reviews of the potential use cases of Blockchain beyond cryptocurrencies, focusing on how Blockchain may mitigate certain problems in IoT, such as access control [7][8], security and privacy [9][10]. Combining Blockchain and IoT is more applicable since smart contracts can automatically execute agreement terms and conditions after being digitalized, built, and stored on Blockchain. In addition, the execution of smart contracts on Blockchain is precise and transparent to all parties in the ecosystem. Therefore, Blockchain is a viable option for IoT access control management.

Many works have been studied to demonstrate the potential of incorporating Blockchain into IoT under various application scenarios such as shared economy [11], data trading management [12], authorization [13], smart-home [14], healthcare [15], access control [16][17], and IoT cloud [18]. These works inspired us to contribute a study on applying Blockchain to an IoT application scenario, such as access control management. Regarding IoT access management, it can take several forms, such as device ownership management, data disclosure management, and data sharing management. Within the scope of this study, we focus on a data management system that can manage and distribute data between people who own the equipment that generates the data and those who need to access and utilize those IoT data under a publish-subscribe protocol. As above-mentioned, Blockchain combined with IoT will be an efficient solution to solve the problems encountered in centralized architecture when managing IoT data. Additionally, we adopt re-encryption methods to minimize the storage but still secure shared data. All data sharing transactions between system participants are kept transparent and immutable. Consequently, tracking transactions and settling inter-party disputes are simple, and non-repudiation is assured. Some factors like smart contract security and transaction costs are taken into account while evaluating the system. The main contributions of our work are summarized as follows.

- Propose a Blockchain-based model for IoT data sharing management under publish-subscribe fashion.
- Utilize proxy re-encryption to enhance the security of the data exchange process and optimize the storage space for sharing data with multiple users.
- Develop a DApp to demonstrate the feasibility of the proposed model and evaluate the performance in terms of transaction's cost.
- Conduct additional tests to validate security issues related to smart contracts in Blockchain, such as re-entrancy attack.

The rest of this paper is organized as follows. Section 2 summarizes related works to clarify the scope of our study. Then, Section 3 describes the architecture of our proposed system with explanation in detail. The implementation and evaluation will be discussed in Section 4, and Section 5 provides the final concluding remarks and future works.

II. RELATED WORKS

The industrial revolution 4.0 brings tremendous global changes, particularly in the Internet of Things, machine learning, and big data. The amount of data created by sensors is enormous and sensitive, posing challenges for access management in the IoT that may be handled in various methods. However, as above-mentioned, our study only focuses on the issue of IoT data storage and sharing management. The proposed system, unlike traditional models, eliminates the role of the third-party service during data exchange between a *Data Owner* DO, who has data to share or sell, and a *Data User* DU, who wishes to purchase the data. Our proposed model employs Blockchain, a decentralized architecture to strengthen the security of the data exchange process, in which all actions are executed via smart contracts, like other existing works.

Both DO and DU are identified using the Blockchain's key system. Everyone on the Blockchain network will own a key pair, including a private key (secret key) and a public key generated from the private key. Each user in the system will be identified by the address associated with the public key. Key pairs are used for encryption during data storage and exchange and for creating IDs for network users. The system will use the Blockchain network environment (e.g., Ethereum) to allow the DO and DU to exchange data. Instead of relying on a third-party intermediary for data sharing, the system performs data exchange using sets of rules and management rules built on Smart contracts.

Unlike conventional methods without Blockchain, data sharing is transparent and public via smart contracts. Every share transaction is recorded on the decentralized network, making changing the transaction history incredibly impossible. At the same time, utilizing the Blockchain network platform's public and private keys combination helps secure data integrity and security, avoiding intermediaries stealing, decrypting, and exploiting data (i.e., a man-in-the-middle attack).

Our proposed solution is comparable to the work given in [19], which largely solves the problem of sharing data that the Aggregator wants to share their collected data and does not have to expose the secret key of subscribers to decrypt the data

packet. Each data slot, as well as each subscriber, will have a unique re-encryption key, which will prohibit subscribers from reading all of the data in the system. Furthermore, because both the Aggregator and the Publisher interact with Blockchain, there is no single point of failure, and all actions are recorded in Blockchain as verifiable and trustable transactions. When Aggregator publishes data, they must sign it with their private key, which helps to prove who owns that data packet. Furthermore, data is fragmented into chunks and kept across several storage nodes when utilizing distributed hash-tables, making it challenging to assemble data. However, the work in [19] has yet to present detailed implementation and performance evaluation.

Another similar work [20] primarily comprises a gateway that receives and processes data from IoT devices before re-encrypting and sending it to DU. The authors have successfully developed a PoC system to demonstrate the proposed idea. However, its current model still has some security and performance issues.

- First, since the gateway listens to all events from smart contracts, bottleneck concerns may arise when the number of queries is significant enough. For example, if multiple DUs try to request data simultaneously, the gateway will get overloaded, resulting in a single-point failure. Although, the authors also attempted to tackle the problem by limiting access to a certain number of times. However, it is not practicable and creates an overhead for managing access in the smart contract.
- Second, when receiving a data request event, the gateway will retrieve data from cloud storage, encrypt it with DO's private and DU's public keys, and then transfer data packets to DU accordingly. To do the re-encryption, the gateway must store DO's private key, which can be readily compromised on the gateway. As a result, if hostile parties attack the gateway, they can obtain the DO's private key and data packets, allowing information to leak.
- Third, the work in [20] did not utilize a proxy re-encryption; instead, as demonstrated in Fig. 1, whenever a DU requests data, DO will decrypt the encrypted data with DO's secret key sk_{Pub} (private key), and then encrypt data again with DU's public key pk_{Sub} before uploading data back to the Storage for sharing to DU who will download shared data and decrypt it with DU's secret key sk_{Sub} . This procedure will be repeated for different DUs, which will consume time (due to multiple encryption and decryption) and storage space (due to duplicates of the same data with different encryption). Leveraging proxy re-encryption can overcome the above issues. As demonstrated in Fig. 2, DO does not need decrypt the data, instead, DO will generate and share the re-encryption key rk_{Sub} for each DU. Then, DU can use this re-encryption key to decrypt the shared data.

III. THE PROPOSED APPROACH

A. System Design

Fig. 3 illustrates the architecture of our proposed model, in which data can be gathered from IoT end-devices and

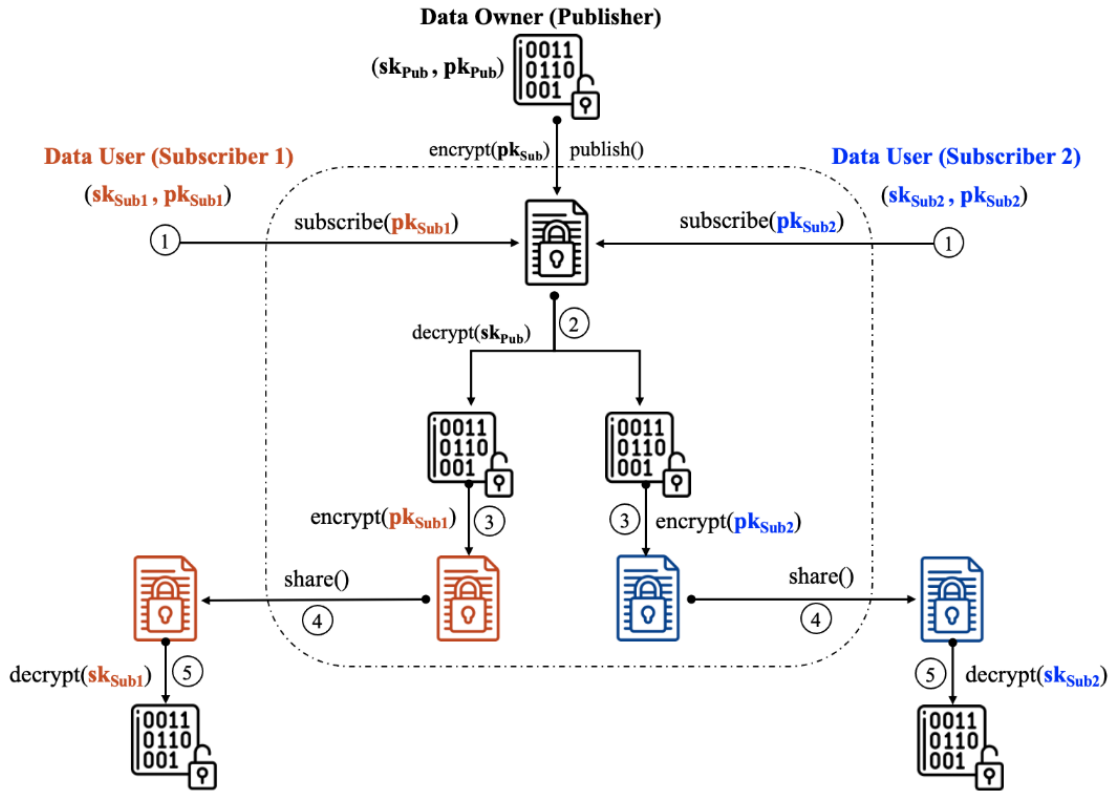

Fig. 1. Repeated encryptions/decryptions and multiple copies of shared data in the sharing process without using re-encryption.

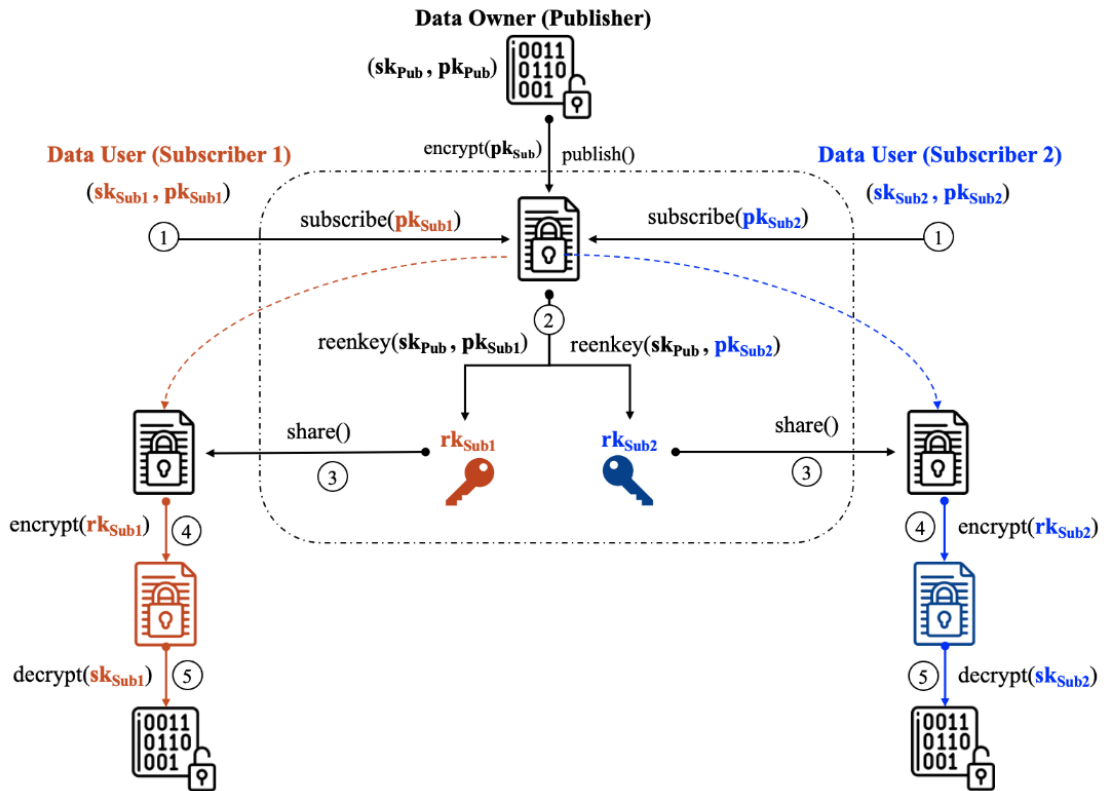

Fig. 2. Optimize shared data storage by using re-encryption.

subsequently transferred to the *Off-chain Storage* via the *Data Management System* (DMS). The proposed model adopts IPFS - a distributed system, as the Off-chain Storage for storing and gaining access to data and files via content identifiers (CID). The detail of the publish-subscribe process between DO and DU can be summarized in eight steps as follows.

- 1) The DO register IoT devices information to smart contract, including device's name, description, and price per day that will be used as a parameter to calculate the amount of money the subscriber has to pay.
- 2) When the DU subscribes to a device, he must send the subscription fee to the smart contract that corresponds to the device and the time period for which he wishes to get shared data. The fee will be retained in the smart contract until it is confirmed by the DU after successfully receiving data.
- 3) The DO will receive an event once a DU subscribes to data from the smart contract.
- 4) As shown in Fig. 3, DO collects the data from IoT devices and sends these data to the DMS, which will encrypt data by DO's public key before uploading it to IPFS to get the CID. Then, DMS will create the re-encryption key from the corresponding DU's public and DO's secret keys. Finally, DO publishes the CID of encrypted data and the list of re-encryption keys to the smart contract for sharing data with DUs.
- 5) The DU listens and receives the published data or updates key-event in order to get the CID of encrypted data and list of re-encryption key or new list of re-encryption key from the smart contract.
- 6) The DU goes to the IPFS to get both the encrypted-data and corresponding re-encryption keys.
- 7) The DU extracts the corresponding re-encryption key. In order to get the raw data, the DU will perform two steps of decryption sequentially. First, the DU will re-encrypt the encrypted-data with re-encryption key, then continue to decrypt re-encrypted data with DU's private key.
- 8) If the data is valid, the DU will certify on the smart contract that the data was received accurately. Once the DU confirms successful data reception, the subscription fee pre-paid by the DU will be transferred to the DO via the smart contract.

B. Implementation

We use many technologies, including Blockchain platform, programming languages, development framework, and libraries as summarized in Table I, to develop a prototype to demonstrate and evaluate the proposed model. Meanwhile, Fig. 4 depicts whole sequence diagram of the data sharing management process between DO and DU that correctly executes eight steps described in the proposed model as shown in Fig. 3. In addition, Fig. 5 shows a snapshot of the WebApp that displays all DO's registered devices that are ready to share and be subscribed by users.

Since IoT data collection is not the main objective in our current study, we use virtual devices to generate data for evaluating the sharing management in the proposed model on Blockchain.

Fig. 3. System architecture of the proposed model.

TABLE I. IMPLEMENTATION DESCRIPTION

Modules	Implementation descriptions
Blockchain platform	Ethereum
Smart Contract	Solididy
Data Management System (DMS)	Nodejs, Express
Communication between DMS and IPFS	ipfs-http-client
Proxy Re-encryption	recryptjs
DApp testing	Truffle, Ganache

Fig. 4. Sequence diagram of the publish-subscribe procedure in the proposed model.

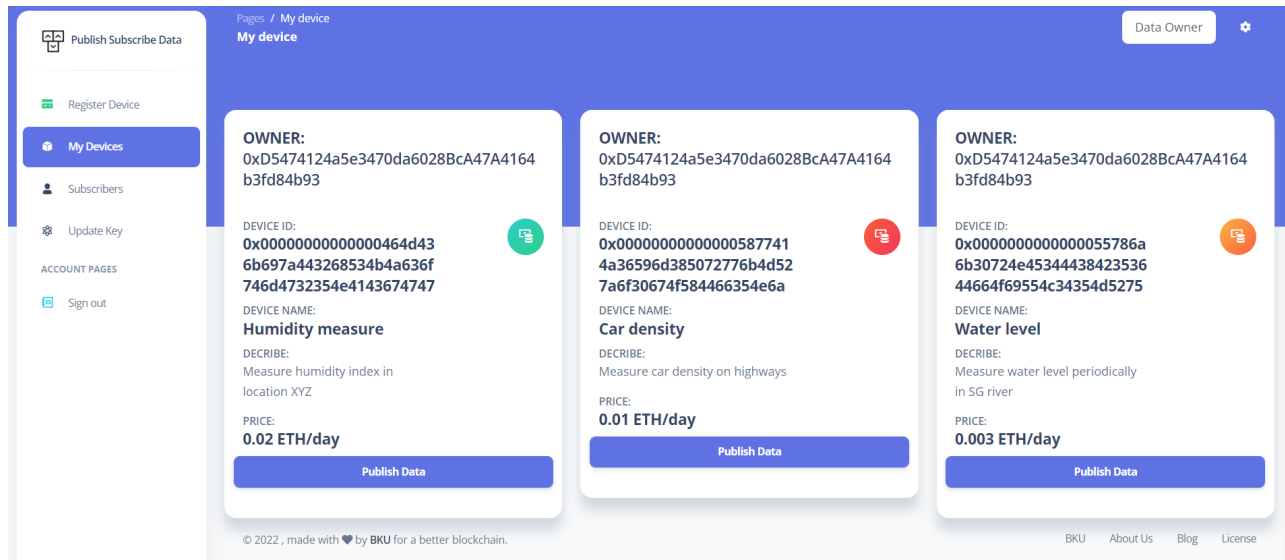

Fig. 5. A snapshot of our WebApp displaying all registered devices that are ready to publish data for sharing.

IV. EXPERIMENTS AND EVALUATION

A. Smart Contract Testing

Since all functions related to publish-subscribe process are executed via smart contracts, it is critical to validate the correction of smart contract's execution. We use Truffle, which is a framework for developing dApps on Ethereum to perform testing on smart contracts written in Javascript. In addition, we utilize Ganache, toolkit in Truffle framework, to build a virtual Ethereum environment on a personal workstation for testing smart contracts before real deployment. We develop numerous testing scripts written in JavaScript that might occur in our proposed model and ensure that all scenarios are passed. Table II summarizes descriptions of 10 testing scenarios conducted in our study.

In addition, smart contracts can hold a lot of values, so they can become the subjects for hackers, such as Re-entrancy attack, that happens when a function in a smart contract calling to a function in an external malicious smart contract. Then, the malicious smart contract can call back to the original one. By that way, attackers can drain the fund of the smart contract. As illustrated in Fig. 6, when we call transfer function, smart contract will check balance of the caller. If the condition is satisfied, it begins to transfer the cryptocurrency to receiver before updating the balance. However, the victim smart contract will call the malicious smart control in order to transfer cryptocurrency. Then, the malicious smart contract will call transfer again since the balance is still not updated. Therefore, attackers can drain all the money inside the victim's smart contract. In our implementation, we adopt checks-effects-interactions pattern in smart contracts to prevent this attack.

B. Security Analysis

Data security of the proposed model is discussed according to four main criteria as follows:

- **Confidentiality:** Combining asymmetric encryption and re-encryption based on public and private key

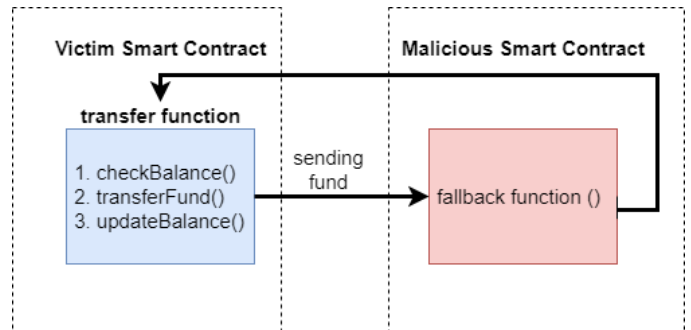

Fig. 6. An illustration of re-entrancy attack.

pairs allows only the DO and authorized DU to access and read the shared data. All the stored secret keys in the database are encrypted with a secret key phrase. Therefore, all the key is confidential.

- **Integrity:** Since IPFS is a distributed content-addressing database, which means that the CID of a file is like the hash of a file. Each content will generate a unique CID; therefore, with a given CID, the integrity of the data is guaranteed. Furthermore, Blockchain assures that transactions are not tampered with and that the entire transaction process is transparent and traceable.
- **Availability:** The decentralized architecture of Blockchain networks and file storage eliminates single points of failure and protects smart contract services from DDoS attacks, hence enhancing service availability.
- **Immutability:** DU can trust that once DU received the data and re-key CID. No one can revoke the privilege including DO thanks to the combination of SC on blockchain and decentralized database (IPFS). Data once publish will be record permanently and DU

TABLE II. SCENARIOS FOR TESTING SMART CONTRACTS

No.	Scenario Name	Description	Expected Result
1	SC-Deploy	Check the deployment of a smart contract.	Successful deployment
2	Dev-Register	DO registers a new device with non-existing ID.	Be able to retrieve device information via device ID.
3	Dev-Register-E	Check if a device is registered with existing ID.	Raise an error message "duplicate device ID".
4	Subscribe	Check if a DU is able to subscribe a registered device.	Subscribe device successfully.
5	Subscribe-E1	DU can not subscribe a registered device due to payment fee.	Raise an error message "not enough money to subscribe".
6	Subscribe-E2	DU can not subscribe a unregistered device	Raise an error message "non-existing device".
7	Publish	Check if a DO is able to publish data belonging to his registered device.	Data can be published.
8	Publish-E1	DO can not publish data because of data duplication.	Raise an error message "data duplication".
9	Publish-E2	DO can not publish data belonging to not-owned devices.	Raise an error message "non-self-owned device".
10	Confirmation	Check if money is transferred to DO after DU confirmed successful data reception.	Payment is successful.

always can retrieve the data.

C. Gas Fee Estimation

Besides security threats, gas fee optimization is another parameter that should be considered. The gas fee will affect a lot on the topic's practicality. One of the ways that we can reduce the cost fee on each function call without changing the structure of the code is to put the appropriate data location of the variable and function argument. There are three locations to store our variables, including *storage*, *memory*, and *calldata*. The fees for those three locations are different, and we can decide where to store them depending on specific purposes.

- The *storage* is the most expensive one since the lifetime of the variable is limited to the contract's lifetime.
- The less expensive one is *memory*, which is mostly used for function arguments since it only lasts in the function call, you can read and modify the variable in memory.
- The least one is *calldata*, which behaves mostly like memory but is not able to modify the variable. In our smart contracts, we mostly chose *calldata* for our complex variable location which will reduce the gas fee for each function call.

Regardless of the content, the length of each data CID is fixed at 46 characters (base58), which means that the CID size is the same for all data. Therefore, the gas price of a smart contract in our model will not depend on the data packet length because we only store the link of data (IPFS CID) on the Blockchain. After performing multiple tests, gas fees of main actions in the proposed model via smart contracts are approximated in Table III.

The cost for each transaction corresponding to each above action via smart contracts will be computed by a product of gas fee and gas price. While the gas fee will not change for the same workload, the gas price will depend on the specific Blockchain network used. Each user can offer their own gas price; the higher the gas price, the more likely their transaction will get picked. The transaction will never be picked if the gas price is too low. Based on the gas fee estimated in Table III, we estimate the transaction's costs in two popular Blockchain

TABLE III. GAS FEE ESTIMATION FOR EACH ACTION VIA SMART CONTRACTS IN OUR PROPOSED MODEL

Action	Gas
Deploy smart contract	2606585
Register devices (data collectors)	174668
Publish data	216969
Subscribe devices (data)	70763
Confirm (two data packets)	58359

networks such as Ethereum and Binance Smart Chain (BSC), as presented in Tables IV and V, respectively.

TABLE IV. ESTIMATED COSTS IN ETHEREUM

Action	Gas	Cost (ETH)	Cost (USD)
Deploy smart contract	2606585	0.0417	69.89
Register devices (data collectors)	174668	0.0028	4.69
Publish data	216969	0.0034	5.70
Subscribe devices (data)	70763	0.0011	1.84
Confirm (two data packets)	58359	0.0009	1.51

*The gas price is 16Gwei and ETH price is 1,676\$ collected on 14-March-2023 from <https://etherscan.io/gastracker>

TABLE V. ESTIMATED COSTS IN BINANCE SMART CHAIN (BSC)

Action	Gas	Cost (BSC)	Cost (USD)
Deploy smart contract	2606585	0.0013	3.98
Register devices (data collectors)	174668	0.0009	0.27
Publish data	216969	0.0011	0.33
Subscribe devices (data)	70763	0.0004	0.11
Confirm (two data packets)	58359	0.0003	0.09

*The gas price is 5Gwei and BSC price is 305\$ collected on 14-March-2023 from <https://bscscan.com/gastracker>

V. CONCLUSION

We presented a Blockchain-based method to resolve a critical issue in today's IoT, data sharing management. The

proposed model allows Data Owners to securely share their data with Data Users in a publish-subscribe fashion via smart contracts on Blockchain. Like other existing works, adopting smart contracts on a decentralized architecture enables a trustless data sharing mechanism without a third party, increasing service availability. Moreover, the proposed method also inherits the characteristics of Blockchain in enhancing data security in terms of confidentiality, integrity, and availability. However, Blockchain and smart contracts still have security threats themselves. In our implementation, we utilized the checks-effects-interactions pattern to prevent the re-entrancy attack on smart contracts. Besides, we also conducted testing scenarios to guarantee the correct execution of smart contracts before actual deployment.

Compared to previous works, the proposed model employs a proxy re-encryption to minimize shared data storage and enhance data security and privacy in a transparent environment like Blockchain. In addition, we successfully developed a DApp to demonstrate and evaluate how the proposed model works.

ACKNOWLEDGMENT

The authors acknowledge Ho Chi Minh City University of Technology (HCMUT), VNU-HCM for supporting this study. The authors also sincerely thank Mr. Long P. Duong and Mr. Phuc M. Nguyen for their assistance in implementing and conducting experiments.

A Review of Trending Crowdsourcing Topics in Software Engineering Highlighting Mobile Crowdsourcing and AI Utilization

Mohammed Alghasham, Mousa Alzakan, Mohammed Al-Hagery

Department of Computer Science, College of Computer, Qassim University, Buraydah 51452, Saudi Arabia

Abstract—Today's modern technologies and requirements make the utilization of crowdsourcing more viable and applicable. It is one of the problem-solving models that can be used in various domains to reduce costs and time. It is also an excellent way to find new and different ideas and solutions. This paper studies the use of crowdsourcing in software engineering and reveals adequate details to highlight its significance. A few recent literature reviews have been published to address specific topics or study general attributes of papers in crowdsourced software engineering. This paper, however, explores all recent publications related to software and crowdsourcing to find the trends and highlight mobile and AI usage in software crowdsourcing. The findings of this paper show that most research papers are in the areas of software management and software verification and validation. The results also reveal that machine learning and data mining techniques are predominant in software management crowdsourcing and software verification and validation. Furthermore, this study shows that the methods and techniques used in general crowdsourcing apply to mobile crowdsourcing except in mobile testing, where there is a need for clustering and prioritization of test reports.

Keywords—Software engineering; crowdsourcing; mobile crowdsourcing; software management; software verification and validation

I. INTRODUCTION

The word engineering in the field of software was inspired by the field of architecture engineering, where the design and building go through defined steps, even though the software has different characteristics. For example, a step in designing a building, for example, should take many considerations, such as budget, before sketching the design of the building. Similarly, when building software, the first step should not be coding the software, especially in large software and systems. The globalization of the current world forced both fields to adopt and use outsourcing, dispatch part of the software or building steps/processes to another company, to compete and evolve, especially when they lack time, workers, expertise, or other reasons. Consequently, the availability of the Internet to a tremendous number of users with various backgrounds and expertise adds more opportunities and challenges to the current working process, which leads to the use of heterogeneous users of the Internet in the working process for both fields. This new methodology was later called crowdsourced and defined by [1] in 2006, and also, different terminologies could refer to the same methodology as provided by [2].

In the crowdsourcing era, in its early days, it has been preliminarily defined as a problem-solving model [3], and

recently, it has been reviewed in a wide range of domains [4]; software engineering, in between, has gained a considerable share in this emerging field [5], [6]. The notion of a problem-solving model for crowdsourcing is suggested by [3] for various applications while providing model examples and denoting contentious points such as crowds diversity, crowds exploitations, and intellectual labor, as well as other topics. A recent comprehensive literature review of all various fields where crowdsourcing has been utilized is authored by [4], which is the first literature to investigate all possible domains related to crowdsourcing. As crowdsourcing has been adopted in various domains, it has become an important topic. One of these domains is software engineering, which started with two publications in 2008 and a total of 509 publications at the end of 2020 [6]. For example, one publication [5] shows the possibility of engaging in empirical studies with crowdsourcing and presents the lesson learned to others for a successful one. Nevertheless, crowdsourcing is a promising technique employed in uncountable areas of SE regardless of other fields, and it is still ongoing research.

A number of recent literature reviews have been published that address crowdsourcing in software engineering. The study of the relationships for both co-authors and citations through social network analysis without considering the contextual content of papers is presented by [6]. Despite that, the research provides cohesive and extensive relationships and connectivity regarding basic publication attributes, such as authors' locations. The paper researches and reviews all of the publications until 2020. Another review [7] provides a baseline understanding of microtasks and explores previous research within crowdsourcing while listing and verifying microtask activities and their categories, which could be helpful for researchers and platforms. For integrating agile development methodology with crowdsourcing, a literature review is carried out to specify challenges and summarize them into five categories [8]. An overview of key processes and platforms, as well as other matters, to facilitate the adaptation of CSSD by organizations and highlight obstacles that make organizations reluctant to recognize CSSD is conducted by [9].

This paper is structured as follows: in this section, an introduction and motivation to crowdsourced software engineering is provided. Section II discusses the research methodology, research questions, and how the research is conducted. Then, Section III describes the literature outcomes, which are divided into areas related to software engineering. In Section IV, the research questions are answered by listing and discussing the findings. The conclusion of this literature review is in Section

V. Finally, suggestions for future work are in Section VI.

II. RESEARCH METHODOLOGY

The research methodology is an essential and well-defined step in literature review papers. Hence, this section presents the research questions and discusses the process for searching and selecting research papers and extracting and approaching the data.

A. Research Questions

This section provides answers to the following three listed questions:

- **RQ1: What are the directions and trends in crowd-sourced software engineering?** The aim is to investigate and analyze the recent topics in crowdsourced software engineering.
- **RQ2: Did the papers focus on mobile crowdsourcing? Can general crowdsourced software engineering methods be used in mobile crowdsourcing?** The aim is to examine mobile crowdsourcing and conventional methods within mobile software engineering crowdsourcing.
- **RQ3: Did the papers in the review use AI? What type of AI did the papers use? In what areas did the papers use AI?** The aim is to explore the algorithms that the literature uses and in which areas of software engineering they are employed.

B. Conducting the Research

The first step in each research topic is to choose relevant keywords to find all relevant papers. Unrelated keywords could lead to small numbers of papers without any further hope of obtaining additional suitable research papers. Subsequently, gradually, more keywords are added, and the list of all keywords that are used within advanced search queries is as follows:

- (“Crowdsourcing” OR “crowdsourced” OR “crowd” OR “crowdsource”) as (CrowdKeywords)

The first query, (CrowdKeywords), is used in conjunction with the following ones:

- (CrowdKeywords) AND (“Software Engineering”)
- (CrowdKeywords) AND (“Software Development”)
- (CrowdKeywords) AND (“Software Design”)
- (CrowdKeywords) AND (“Requirements” or “crowdRE”)
- (CrowdKeywords) AND (“Software” or “testing” or “test” or “defect”)

As shown in Fig. 1, the search is first established through scholarly search engines online, without engaging in manual search activities, such as printed journals, and excluding books and thesis. There are a large number of databases. The papers are collected from IEEE, ACM, Science Direct, SpringerLink,

Wiley Online Library, MDPI, AIMS Sciences, and Airiti. Additionally, this review focuses solely on recent papers and contributions, so any research paper published before 2022 is filtered out. After the preliminary collection of more than 100 publications, stored in a reference manager software, by reading just titles and keywords, all the collection papers are validated against the following criteria:

- 1) Papers must be very recent, and there are no duplications.
- 2) For quality control, remove preprinted or publications that are not peer-reviewed.
- 3) To ensure the relevance of collected publications, at least two authors review each paper’s abstract to check whether the paper is related to the scope of the research or not.

Fig. 1. Research methodology.

Next, the remaining 41 papers are exported from the reference manager to a spreadsheet. The spreadsheet contains the main attributes of each research paper and other details related to this research, such as the paper title, type, library, authors, date, the software engineering area, subarea, keywords, aim, objectives, main points, and summary. When the paper is selected to be included in the spreadsheet file, all details need to be obtained and filled out in the spreadsheet. With the help of the reference manager software, the keywords are also exported instead of manually filling them out. Still, several papers’ keywords are manually extracted, which indicates inconsistent standardization between databases. These keywords are processed differently, and a program is developed that is executed inside the spreadsheet to handle the data. The program simply fetched all keywords with their corresponding paper and then clustered them based on each keyword.

III. LITERATURE OUTCOMES

In this section, the papers selected for review are discussed. This literature review is divided into five subsections based on the problems the research papers solve. The subsections are software management, software specification, software development, software verification and validation, and software evolution. Fig. 2 depicts these subsections. Furthermore, two subsections: software management and software verification and validation, are further divided into subsubsections.

A. Software Management

Since software management is an extensive topic, its topics are further divided into subsections according to what is discussed in the selected papers. These subsections are productivity and motivation, task and crowd worker recommendation, trust issues, task pricing, and project documentation. Fig. 3 shows the subsections of software management.

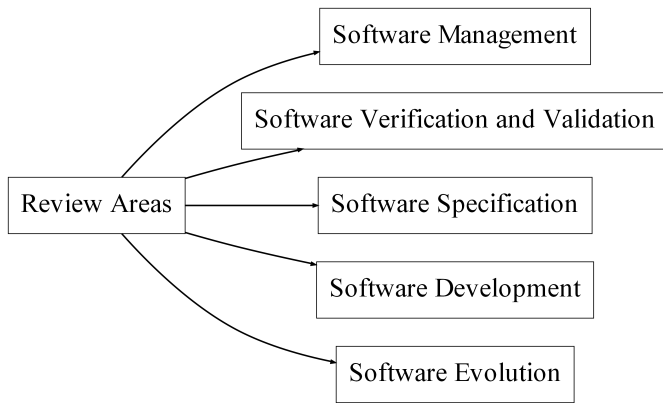

Fig. 2. Literature outcome main areas.

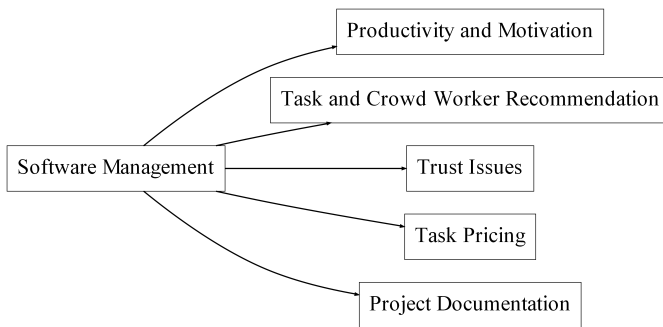

Fig. 3. Software management subareas.

1) *Productivity and motivation*: The authors of [10] investigate the collaboration of crowd workers in transient teams versus solo developers using a data-driven empirical study. The results show that the experience of teamwork affects the teams' performance in both the long and short term. In particular, the results show that individuals in each team can learn in the short term by getting support and sharing ideas with other members. Furthermore, in the long term, the members learn from working with other experienced team members. The paper contributes strategies for collaborative contest designers, platform operators, and crowd workers. These strategies include increasing the complexity of the contests, emphasizing virtual teams in contests, or reducing the number of total medals.

While [10] examines the effects of working solo as a developer or in teams on performance and learning, the authors of [11] study the effects of game elements that exist in several crowdsourcing platforms on individual contributors. Multiple crowdsourcing platforms use game elements such as contests, leaderboards, and rankings with the intent to motivate crowd workers. The results show that there is a different effect on the performance and effort of workers depending on their abilities. Data from TopCoder shows that feedback has a positive effect on high-scoring workers and a negative effect on low-scoring individuals.

Unlike [10], [11], the writers of [12] define, explain, and justify the area and use of the microtasks programming approach, regarding functions programming, on the factors

such as team size, the time needed for new developers, and the velocity of the whole project. Moreover, they have conducted an experiment to study the positive and negative sides without focusing on areas related to the design and maintenance of microtasks. The experiment has shown several advantages of adopting microtasks, especially for the short project schedule. Overall, this study establishes a path for software corporations and encourages them to use microtasks, which could lead to the involvement of external developers, crowdsourcing in particular.

2) *Task and crowd worker recommendation*: The authors of [13] state that crowd workers often choose their testing tasks from whatever is immediately available. This abrupt choice could lead to wasted time and effort for both the tester and the requester. Furthermore, it could lead the tester to the inability to discover and find the bugs in the assigned task. Thus, the authors of this paper propose a context-aware personalized crowdsourced software testing method for task recommendation named PTRec. This method uses contextual, historical data and the preferences of the tester to recommend the appropriate task. PTRec consists of two models that are able to extract 60 features automatically to help the tester choose a suitable task. The goal is to reduce wasted efforts and the number of unpaid tasks. PTRec also uses the random forest learner technique to find the proper testing task which matches the workers' interests and expertise. Tests on 2404 crowd workers and 636 tasks reveal that this approach has 82% precision and saves the efforts of exploring tasks by 81%.

In addition to [13], another research [14] has proposed a new recommendation model which considers users' preferences. This method is a capability-corrected long- and short-term attention network (CLEAN). It outperforms the existing traditional models. The model considers the gradual interest changes of workers and the constraints and skills needed to perform the tasks while incorporating the contextual data of tasks besides common attributes.

According to the authors of [15], existing studies use one-time recommendations based on the knowledge of the worker at the start of a new task. Furthermore, they assert that this recommendation has a popularity bias. In other words, the methods in these studies recommend almost all of the tasks to users with the highest experience. To remedy these issues: this study proposes iRec2.0, which is a context- and fairness-aware in-process crowd worker recommendation method. iRec2.0 achieves its stated goals by modeling the dynamic testing context, using a learning-based technique, and applying a multi-objective optimization component. The outcomes of the evaluations show that this method has the potential to divide the tasks fairly among the users, decrease the testing process time, and save costs.

In [16], the authors assert that the quantity and quality of the completed tasks are directly affected by task recommendation. The authors also state that previous task recommendation modules focus on one user only per task. Unlike [13], [15], the authors of [16] present a method to recommend tasks and coworkers for these tasks. This method operates on the user's performance history on previous tasks in combination with a social network component for the coworker recommendation. This method checks and informs users if it is best to complete this task independently or if they should seek help from a

friend in their social network. This method factorizes a user-task rating matrix to get the latent matrix. Then it applies a greedy method to select tasks for each user. The method calculates the intimacy data and the extroversion data of users with their friends in the social network to recommend coworkers. The results by the authors show that it outperforms the current existing algorithms.

Crowdsource contribution is open to every qualified person. This openness could pose a problem of malicious workers and malicious task submissions. To tackle these problems, the authors of [17] propose a method named Outlier Detection for Streaming Task Assignment. Its goal is to detect malicious crowd workers. This technique uses an evolving time series to model the arrival of workers and their task submissions. This framework has a novel method based on Generative Adversarial Network (GAN), which is socially aware and can work with time series. The authors also propose a novel method to train the loss functions of GANs with social awareness. It also has the capability to assign tasks to users similar to [13]–[16]. This method uses a greedy algorithm to improve the efficiency of the process of task assignment.

Whereas [13]–[17] focus on task assignment, [18] focuses on the reliability of recruits. In [18], the authors investigate four different crowdsourcing platforms and a computer science (CS) mailing list to determine the reliability of their recruits for empirical software development studies. The crowdsourcing platforms are Prolific, Appen, Clickworker, and Mechanical Turk. The authors' criteria of reliability are programming skills, privacy, and security attitudes. For the university CS students, the authors also consider self-efficacy. The results show that while university CS students rated themselves lower than other crowdsourcing participants in secure development and self-efficacy, 89% of them answered all programming skills correctly. Furthermore, the study shows that university CS students are the most cost-effective recruits.

Out of all the studies on task management in this paper, only one study highlights the need for coordination in the platform for doing tasks related to software design between designers and clients. Therefore, it identifies all potential coordination limitations encountered in the process and promotes coordination propositions with the help of a questionnaire. The feedback from participations through the questionnaire verifies the limitations and welcomes the purpose solution to alleviate the lack of coordination in platforms [19]. Moreover, another study proposes four steps to task flow from the beginning of constructing the task until the aggregation of the results, and this solution is evaluated in two ways. Also, the crowdsourcing platforms have the advantage of incorporating and implementing proposed approaches [20].

3) *Task pricing*: Is giving crowd workers the ability to choose their preferred incentive will result in better performance and solution quality? Is one type of incentive for all participants an optimal motivator? In [21], the authors of this paper empirically investigate the effects of giving the choice of reward to participants on the quality of the solution submitted. The results of this work show that when participants can choose their preferred incentive, they will spend more time on their assigned tasks and produce better-quality solutions in contrast to participants who offered one type of incentive. The results show the importance of having a flexible reward

structure and allowing participants to select what matches their motives.

Both [21], [22] state that personalized pricing can yield better resulting tasks than common pricing, which is pricing with no personalization. The authors of [22], though, remark that personalized pricing is arduous to incorporate into some systems due to its complexity. Therefore, [22] investigate two schemes: personalized pricing per worker and common pricing with bonus payments after task completion to explore their impacts. The results show that with the proper bonuses, common pricing is close to an approximation of optimal personalized pricing.

The authors of [23] argue that instead of having a fixed price for tasks, there should be a dynamic system for pricing tasks to incentivize crowd workers. Accordingly, The authors of this paper propose a system called CrowdPricer, which gives, in addition to the base payment for the accomplished tasks, bonuses for completing tasks which is the recommended method by [22]. In addition, CrowdPricer increases the utility expectation of the requester to guarantee profits. To achieve its stated goals, CrowdPricer learns the effect of bonuses on the quality of the delivered tasks using deep time sequence modeling. The authors' experimentations using a crowdsourcing platform and simulations show that using CrowdPricer results in higher-quality task solutions and maximizes the utility of the requester.

4) *Trust issues*: Several critical and ordinary trust issues are raised in the crowdsourcing implementation. The authors [24] present these issues by conducting a survey with practitioners, listing nine critical issues as “deficient assistance to best practices”, “malicious code”, “lack of licensed software utilization”, “loss of data”, “network security risks”, “quality of workers”, “social attacks”, “crowd legal action”, and “loss of intellectual property”. Additionally, the study results are validated via a focus group of four experts in academia. One of the issues of intellectual property is investigated in the context of testing reports by one paper [25]. It proposes a system for intellectual rights confirmation with the integration of blockchain and the implementation of other methods. This system would overcome problems, such as code plagiarism, and prevent unwanted modifications of data with the help of the blockchain decentralized methodology [25]. Another paper [26] indicates the need for implementing blockchain to diminish unwelcome behavior raised by centralized systems. However, it showed that the quality of previous works regarding keeping traceability or increasing privacy is less than required. Therefore, it proposes STPChain based on blockchain, which better preserves traceability and improves privacy, including preventing wrong actions.

5) *Project documentation*: The paper [27] studies the effect of using various types of media as a documentation type and focuses solely on instructional screencast documentation. As the popularity of this type has recently increased, especially for crowd-based content and new developers, the paper suggests a platform for this content. In addition, the platform could have essential functionalities such as making the content searchable and linking its content to other artifacts.

B. Software Specification

As there is a vague overlap between crowd-based requirements engineering (CrowdRE) and market research (MR) primarily caused by the incremental use of automation, one study explains and identifies them. Furthermore, after providing various scenarios and equivalent implementation of both CrowdRE and MR, the study implies the overall benefits of CrowdRE, which could be sufficient [28].

Specialized public web forums and general user stories format are a great way to elicit crowd opinions and experiences on many topics. The authors of [29] use Reddit forums to collect requirement engineering data by analyzing the discussion in the forums. In particular, the authors propose crowdsourcing requirement engineering by valuation argumentation (CrowdRE-VArg) to identify and prioritize issues, design changes, and new features and decide on the appropriate requirements. CrowdRE-Varg uses machine learning and natural language processing to analyze end-users supporting and attacking arguments in discussions from users' posts on Reddit. Their results show the validity of the approach for using Reddit as a platform for rational mining and the eliciting of opinions. Another paper [30] analyzes user stories and proposes CREUS, Crowd-based Requirements Elicitation with User Stories, as an iterative process practical design for conducting pull feedback after engaging in three case studies. It provides qualitative analysis of user stories or feedback as the main contribution besides quantitative results as usual case studies.

Software requirement engineering (RE) is a challenging process, and it requires the constant availability of the stakeholders, which is not guaranteed. To handle the problems of RE, the author of [31] proposes a conceptual framework that combines the crowdsource software development (CSSD) approach with the SCRUM software development approach. The framework collects the data from the crowd at large, which increases efficiency and reduces costs. This framework consists of four main layers designed to use the features of both approaches. The layers deal with document preparation, prioritization of tasks, planning, design, and retrospective meeting. On the other hand, [32] present specific challenges regarding requirements for a specific area. The authors show and discuss the needs of older well-being adults for intelligent assistance systems through crowd-based requirements engineering (crowd-RE). Also, it demonstrates the crowd-RE process and some challenges in this area.

One research [33] studies prototype validation. It develops a platform that uses the crowd to obtain feedback and validate the prototype iteratively before actual development. First, it conducts a design science study to address the vague of applying crowd-workers and prototype validation in platforms. Then, through the formed knowledge and implementation, it develops a platform that tackles the difficulties. Moreover, the study is valuable for building new or enhancing current mechanisms with the crowd-validation process.

C. Software Development

In [34], the authors aim to identify the percentages of vulnerabilities in code submitted by participants in code in competitive programming (CP) platforms. This paper focuses on data, 6.1 million submissions to be exact, from the CodeChef

CP platform. The results show that 34.2% of submissions have software vulnerabilities. The authors did not find conclusive evidence to correlate the number of vulnerabilities with the leaderboard position of the participant. Furthermore, the study shows that participants do not follow secure coding practices, and even when a participant with perfect scores reattempts the task, the study shows there are no security improvements in the new submission. One way to mitigate these issues is to use crowdsourcing. The authors of [20] suggest that instead of using automated or manual anti-pattern detection methods, which consume time and lack certainty, the use of crowdsourcing and propose four steps for task flow.

D. Software Verification and Validation

On the subject of software verification and validation, the selected papers solve problems in software testing and usability, test report clustering and prioritization, and quality of defects reports. Fig. 4 shows the subareas of software verification and validation.

Fig. 4. Software verification and validation subareas.

1) *Software testing and usability*: After analyzing the problems that developers face in crowdsourced software development (CSD), the authors of [35] concluded that crowdsourcing is more fitting for software testing than software development. The authors state that the main advantages of crowdsourced software testing (CST) are reducing the time and cost of software testing. Furthermore, the authors express that better tools make developers work efficiently. Hence, the paper proposes a new testing program that incorporates crowdsourcing and open-source sharing techniques. An example of using crowdsourcing in testing is [36]. The authors of [36] did a comprehensive study to compare the cost and time of using novice crowd and expert heuristics in usability inspection. A single expert's heuristic usability inspection leads the novice crowd. The results show that, on average, both methods detect the same usability issues. However, the novice crowd method takes less time to identify the problems and costs less than the expert heuristic usability inspection.

To overcome the challenges of testing human-AI interactions and collaborations, the authors of [37] propose a Human-AI Intergation Testing framework (HINT). HINT is a crowd-based framework that uses a humans-in-the-loop workflow to test AI-based experiences. This framework aims to solve the drawbacks of existing methods by simulating AI experiences that evolve over time, allowing rapid testing, providing early feedback during the development phase, and evaluating crowd workers and AI in offline testing. In addition, to overcome problems that exist in current testing implementation for IoTs, another research [38] develops a new crowdsourcing test system oriented toward the Internet of things with the integration of blockchain technologies as a potential solution. The system

consists of two modes, online and offline testing. The device or devices in the online mode, which are the main focus of interest, are real devices. In this case, testers engage and test the devices online with multi-thread technology implemented to allow concurrent testers, which is helpful, especially for limited hardware resources. The offline mode is to test the devices physically. Besides all security that the system provides, it contributes to a dependable online testing system for IoTs, especially with the lack of online testing for IoTs.

Regarding fault localization and exploiting the power of crowdsourcing, only one research [39] has investigated this area. It has a distinguished and unfamiliar approach for automated fault localization (AFL) in crowdsourcing software engineering by exploiting the solutions of all works and making them one set of referenced solutions. The main point is that when encountering fault statements, each statement in buggy programs is referenced and evaluated with an equivalent statement from other solutions.

2) *Test report clustering and prioritization:* The authors of [40] assert that an issue of the previous research papers dealing with the clustering of test reports is that the papers do not take into account the semantic connection between the screenshots and text in the analyzed test reports, which results in suboptimal results, especially in the deduplication of test reports. Therefore, This paper proposes a method using semi-supervised clustering using deep image understanding to analyze crowdsourced mobile application test reports. This method is SemCluster. SemCluster creates semantic binding rules from the semantic connection between screenshots and text descriptions in test reports. The results of this paper show that SemCluster outperforms the state-of-the-art method in six metrics of clustering results. Another approach [41] uses a fused features approach after obtaining text and screenshots features and then using common classification algorithms.

Liu et al. in [42] state that in addition to the large number of test reports produced by crowdsourcing that needs inspecting, one specific issue of mobile application test reports is that they have more screenshots than text descriptions of the tests. In addition to this paper, [40], [41], [43], [44] deal with these issues as well. To solve the issues of the number of reports and screenshots, the authors of [42] propose a novel method to understand text and images to cluster test reports. This method uses natural language processing to calculate the distance between reports. It also uses Spatial Pyramid Matching (SPM) to compute the similarity of the screenshots in the reports. The authors tested the method on 1400 screenshots and more than 1600 test reports from six industrial crowdsourced projects. Tests show that this method results in up to 37% improvement over the baseline in the average percentage of faults detected (APFD). Moreover, only the following paper [41] points out that existing automatic test report classification techniques are incompatible with crowdsourced mobile test reports as they contain incomplete texts, as well as the previously mentioned screenshots.

In [43], the authors propose and evaluate a method adapted from the prioritization of test reports in regression testing. This method sorts test reports in two phases. First, to process the text of the reports, this method uses natural language processing and word segmentation. Second, to prioritize the test reports, the paper uses a combination of a genetic algo-

rithm, two greedy algorithms, and an adaptive random test case prioritization algorithm. It aims to make it easy and efficient for developers to check reports according to their priority. The results show that this method has promising performance in prioritizing the test reports, with an average percentage of faults detected (APFD) of more than 0.8.

The authors of [44] devise a new method called DivClass to prioritize test reports. DivClass combines diversity and classification strategies to order the reports for inspection. A feature of this method is that it handles duplicate test reports similar to the method proposed in [40], [42]–[44] in which they use natural language processing to analyze the test reports in one of their method steps. The next step in [44] is to build a similarity matrix using an asymmetric computation strategy. The final step consists of the previous two steps to prioritize the reports. The authors state that it reduces the number of tests to inspect, reducing the inspection cost. It also improves DivRisk, the state-of-the-art method, by 14.12% on average and has 0.8887 APFD.

3) *Quality of defect reports:* Three studies [45]–[47] provide ways to enhance the quality of the defect reports generated by usually non-expert crowds. The first research [45] studies the reports, which contain a good and bad description of bugs, submitted by crowdsourcing, usually non-professional testers. After it shows possible quality indicators, the paper proposes CTRQS as a framework to qualify test reports using analytical indicators based on dependency parsing. Therefore, in the end, just the reports that describe the defect better should be processed for localization and fixing. The second paper [46] attempts to generate more promising defect reports results by adding more than one tester participating together to find and report defects instead of one tester working alone. The result shows an enhancement regarding the quality of the final report by decreasing the invalid reported defects and increasing the report of difficulty defects. On the other hand, the third research [47] states the need for improving the crowd-workers instead of only establishing techniques for the quality of crowdsourced testing reports. Also, it indicates that enhancing the knowledge and abilities of testers from the beginning will provide better-quality reports. Therefore, this study proposes an assistant approach to suggest, guide, and educate crowds by exploiting Android's automated testing results.

In a different area of software quality, one research [48] suggests using crowdsourced workers, who meet minimum quality requirements, as a third party to evaluate and certify software meant for public users based on the available software documents and templates. Then, a quantitative quality score is assigned to the software-specific version, and the evaluation process is repeated after each considerable change in the current software version. Another area of research [49] claims that almost all previous techniques study the duplicated defects without false defects. Hence, this paper contributes by using duplicated defects to build a model which can provide a high estimation accuracy for valid defects. Furthermore, the model accuracy increases when the approach is applied to crowdsourced testing.

E. Software Evolution

In [50], Reis et al. use supervised machine learning methods with crowdsourced data collected over three years to identify code smells. The authors focus on Java code and three types of code smell, which are long methods, god classes, and feature envy. The data is collected from about a hundred teams, each team with an average of three members. The results of the papers prove the feasibility of crowdsemling using supervised machine learning techniques applied to data collected from software developers (wisdom of the crowd). However, the authors state that further studies are needed to cover other types of code smells. The authors are currently developing an Eclipse IDE plugin which should simplify the crowdsourcing process. This plugin collects data about the code, identifies code smells, and gets the developer’s opinion regarding the data detected by the plugin.

IV. RESULTS AND DISCUSSION

RQ1: What are the directions and trends in crowd-sourced software engineering? After collecting and analyzing the 41 papers published in 2022, This research reveals that the collected papers discuss the following five areas: software management, software specification, software development, software verification and validation, and software evolution. The most discussed area in crowdsourced software engineering is the area of software management. Out of the 41 papers, 17 papers deal with various software management problems. This review also determines that the least papers, one paper, are in the area of software evolution, even though it is an essential and costly activity in software engineering. Table I shows the areas, the count of the papers, and the paper selected in these areas.

TABLE I. AREAS OF THE SELECTED PAPERS

Area	Selected	Papers
Software Management	17	[10], [11], [13]–[27]
Software Specification	6	[28]–[33]
Software Design & Implementation	2	[20], [34]
Software Verification & Validation	15	[35]–[49]
Software Evolution	1	[50]

Continuing the discussion on the directions and trends of the research in crowdsourced software engineering, in this review, both software management and software verification and validation are divided into subareas based on the collected papers. Table II shows the subareas of software management, the collected and selected papers, and the number of papers in each of the subareas. Software management has five subareas shown in Table II. A look at the areas of software management shows that most research papers in this literature review, which are 7 out of 17, are on task and crowd worker recommendations. There are three papers in each of the following fields productivity and motivation, task pricing, and trust issues in software. The least number of papers which is one study is on project documentation.

In the subarea of software verification and validation, there are 15 papers spanning three subareas. There exist five studies

TABLE II. SUBAREAS OF SOFTWARE MANAGEMENT

Subareas	Selected	Papers
Productivity & Motivation	3	[10]–[12]
Task & Worker Recommendation	7	[13]–[19]
Task Pricing	3	[21]–[23]
Trust Issues	3	[24]–[26]
Project Documentation	1	[27]

in each one of the three subareas. Table III shows the details of the subareas and papers of software verification and validation.

TABLE III. SUBAREAS OF SOFTWARE VERIFICATION AND VALIDATION

Subareas	Selected	Papers
Testing & Usability	5	[35]–[39]
Test Report Clustering & Prioritization	5	[40]–[44]
Quality of Defect Reports	5	[45]–[49]

The results of the Tables I, II, and III lead us to conclude that the most trending topics in crowdsourced software engineering are two. First, the topics that deal with software management especially managing tasks, workers, and motivation. Second, all the subareas of software verification and validation. These subareas are software testing and usability, test report clustering and prioritization, and quality of defect reports.

Furthermore, an analysis of all keywords in the papers was conducted to investigate the trending topics from different viewpoints. The keywords are also used to see how diverse the papers are in the context of subtopics. As a result, the number of different keywords is more than 180 words from 41 papers. Table IV shows the keywords that appear in three papers or more, only the top eight keywords are listed, and the common keywords to the primary research topic are excluded, such as crowdsourcing, software engineering, and software. The results agree with the previous conclusion that software management and testing are the most dominant topics. Moreover, the selected papers in this review are more diverse, covering various subtopics, as there are 162 keywords that are unique and used only in one paper.

TABLE IV. MOST COMMON KEYWORDS THAT APPEAR IN PAPERS

Keywords	Selected	Papers
Crowdsourced testing	9	[13], [15], [25], [41], [42], [44], [45], [47], [49]
Task Analysis	7	[13], [19], [42]–[44], [47], [49]
Testing	5	[13], [37], [42], [45], [47]
Computer Bugs	5	[13], [42], [44], [45], [47]
Software Testing	4	[43], [44], [46], [49]
Requirements Engineering	3	[28], [31], [32]
Mobile Applications	3	[42], [45], [47]
Software Quality	3	[20], [26], [50]

RQ2: Did the papers focus on mobile crowdsourcing? Can general crowdsourced software engineering methods be used in mobile crowdsourcing? Mobile development comes with its own set of problems, especially in software testing [40]–[44] describe these issues. In this review, there are ten papers that focus exclusively on mobile crowdsourcing, specifically mobile testing. The remaining papers, 31 papers,

focus on general software engineering crowdsourcing, which is applicable to mobile crowdsourcing as well. Table V lists the papers with their focus area. These results lead us to deduce that the crowdsourcing methods in general software engineering crowdsourcing are suitable for mobile crowdsourcing, except for mobile testing methods highlighted by [40]–[44].

TABLE V. PAPERS FOCUS

Focus	Selected	Papers
Mobile Crowdsourcing	10	[13], [15], [16], [40]–[45], [47]
General Crowdsourcing	31	[10]–[12], [14], [17]–[39], [46], [48]–[50]

RQ3: Did the papers in the review use AI? What type of AI did the papers use? In what areas did the papers use AI?

TABLE VI. AI IN PAPERS

AI Methods	Selected	Papers
ML & DM	14	[13]–[17], [23], [29], [30], [40]–[44], [50]
None	27	[10]–[12], [18]–[22], [24]–[28], [31]–[39], [45]–[49]

Yes, 14 papers use AI techniques, while 27 do not. Specifically, the papers use either Machine Learning (ML) or Data Mining (DM) methods. Table VI list the papers that use the AI methods. However, not all AI is applied to all the areas of crowdsourced software engineering. Table VII shows the areas and papers in which AI methods are employed. In Table VII, the results show that test report clustering and prioritization and task and worker recommendation use AI the most, with five papers each. Two papers in software specification use AI. Both task pricing and software evolution have one paper each that uses AI techniques.

TABLE VII. AI AREAS IN THE SELECTED PAPERS

Area	Selected	Papers
Test Report Clustering & Prioritization	5	[40]–[44]
Task & Worker Recommendation	5	[13]–[17]
Software Specification	2	[29], [30]
Task Pricing	1	[23]
Software Evolution	1	[50]

V. CONCLUSION

This literature review examines and studies the latest papers in crowdsourced software engineering to find the current trends and directions of the research literature. This paper focuses exclusively on all the publications of 2022 to get a clear and accurate picture of the crowdsourcing landscape. This review also answers a number of relevant and current questions. It answers whether the papers focus solely on mobile crowdsourcing and whether general crowdsourced software engineering methods apply to mobile crowdsourcing. Furthermore, it discusses the question of AI usage in the papers. In particular, this research checks whether the selected papers incorporate machine learning or data mining techniques into their proposed crowdsourcing solutions. The results of this literature review show that the largest number of contemporary research focuses on

software management and software verification and validation. In mobile crowdsourcing, the results show that while general crowdsourcing methods work for most mobile crowdsourcing activities, mobile testing requires specific techniques to deal with the large number and the nature of tests. The results also show the papers that use machine learning and data mining methods to tackle specific crowdsourced software engineering areas.

VI. FUTURE WORK

One of the least discussed topics in software engineering crowdsourcing is secure software development. Crowd workers come from diverse places and have different programming and security backgrounds. Therefore, they will have various goals to achieve and different experiences. In this research, paper [34] shows the percentage of vulnerabilities in competitive programming platform submissions. The study did not find a connection between the leaderboard position of the participants and the number of vulnerabilities in their submitted code. Furthermore, even the resubmissions of full-scoring tasks did not have security improvements. These results beg the following research questions: Is it possible to have a crowdsourcing platform for secure software development? How to incentivize crowd workers to submit secure code? Can the incentivization techniques in [21]–[23] be used to encourage secure coding practices? Will it affect software verification and validation? These are all questions that need further research.

There are many possible areas of improvement in the quality of crowdsourcing that can be investigated. One of them is the minimum number of crowd workers engaging in one task. Each type of task requires a different number of workers, and in this way, the power and quality of crowd wisdom can be exploited in a cost-effective manner. Moreover, the crowds must be certified for the required type of tasks before joining crowdsourcing platforms. Certification will ensure higher quality workers. Alternatively, to encourage worker certification, certified workers can be paid more than non-certified ones. There could be several types of certifications depending on the type of platform or task. In addition, to our knowledge, there are no established crowdsourcing standards of best practices that ensure continuity and portability for both tasks and processes.

ACKNOWLEDGMENT

The researchers would like to thank the Deanship of Scientific Research, Qassim University, for funding the publication of this project.

Evaluation of Wood Species Identification Using CNN-Based Networks at Different Magnification Levels

Khanh Nguyen-Trong*

Posts and Telecommunications Institute of Technology, Hanoi, Vietnam*

Abstract—Wood species identification (WoodID) is a crucial task in many industries, including forestry, construction, and furniture manufacturing. However, this process currently requires highly trained individuals and is time-consuming. With the recent advances in machine learning and computer vision techniques, automatic WoodID using macro-images of cross-section wood has gained attention. Nevertheless, existing works have been evaluated on ad-hoc datasets with pre-fixed magnification levels. To address this issue, this paper proposes an evaluation of deep learning-based methods for WoodID on multiple datasets with varying magnification levels. Several popular Convolutional Neural Networks, including DenseNet, ResNet50, and MobileNet, were examined to identify the best network and magnification levels. The experiments were conducted on five datasets with different magnifications, including a self-collected dataset and four existing ones. The results demonstrate that the DenseNet121 network achieved superior accuracy and F1-Score on the 20X dataset. The findings of this study provide useful insights into the development of automatic WoodID systems for practical applications.

Keywords—Wood species identification; convolutional neural network; ResNet50; DensNet

I. INTRODUCTION

Wood species identification (WoodID) is a critical aspect in various industries, including forestry, construction, and furniture manufacturing [1], [2]. The identification process involves determining the type of wood based on its unique physical and anatomical characteristics such as growth rings, knots, ray patterns, and texture [3]. In many countries, this process is currently performed manually by forestry experts. The manual process not only poses a challenge in terms of cost and time, but also limits the ability to scale up the identification process to meet the demands of the growing timber industry. This highlights the need for a more automated and accessible approach to WoodID, which could have a significant impact on the efficiency and effectiveness of the forestry industry.

Recently, with the development of machine learning and computer vision techniques, automatic WoodID has received increasing attention. Numerous deep-learning-based methods have been proposed in the literature, which rely on the unique visual characteristics of wood cross-sections [4]. Owing to the widespread availability of low-cost portable digital cameras and stereo microscopes, most of these works used macroscopic images of transverse sections of wood. For example, these studies have been applied to automatic identification of North American hardwood species [5], European tree species [6], Chinese wood species [7], Japanese wood species [8], or

Indonesian commercial wood [9]. They have demonstrated their high accuracy, robustness, and efficiency compared to traditional methods that involve manual feature extraction.

Among the deep learning methods applied for WoodID, Convolutional Neural Network (CNN) based approaches have gained widespread use. Examples of these networks include VGG16 [10], ResNet50 [11], DenseNet [12], and MobileNet [13]. The advantage of using CNNs is that they can automatically identify relevant features in the input images, eliminating the need for manual feature extraction. The availability of large annotated datasets and advancements in hardware and software have further driven the application of CNNs in this field.

These networks have proven their ability to effectively handle the complex macroscopic characteristics of wood and accurately recognize species, as demonstrated, for example, in studies focusing on Pacific and Colombian Amazon wood species [14] and Brazilian flora species [15]. This makes them suitable for practical application in countries where illegal logging is a prevalent issue, such as Vietnam.

Although of the high performance in WoodID, there is no concrete recommendation as to which magnification level is most suitable. These studies applied various magnification levels with different wood species datasets. Besides, the application of these advanced techniques is still limited in many underdevelopment countries, such as Vietnam, where access to resources and data might be scarce. Therefore, there is a need for suitable solutions that consider the best network architecture and magnification level of macroscopic images of wood cross-sections. This would not only aid in better forestry management, but also support efforts to curb illegal logging.

In this study, we evaluated the performance of different convolutional neural networks (CNNs) for WoodID using macro-images of wood cross-sections at various magnification levels. Our objective was to propose a practical and effective CNN-based method for this task. To the best of our knowledge, this is the first attempt to evaluate WoodID on different magnification levels, which has led to the development of a more accurate and practical method not only in Vietnam but also in other countries.

We examined the proposed method's performance on five datasets with different magnifications, including a self-collected dataset of popular imported wood species in Vietnam and four existing ones. The study's results provided insights into the effectiveness of different networks and magnification levels for WoodID.

The remainder of this paper is structured as follows. Section II discusses relevant previous studies. Section III provides the details regarding the evaluated networks. The experimental evaluation is presented in Section IV, and finally, some concluding remarks and a brief discussion are provided in Section V.

II. RELATED WORKS

Convolutional Neural Networks (CNNs) have been widely used in previous studies for WoodID using images of transverse cross-sections of wood. Popular CNN architectures, such as VGG16, ResNet, DenseNet, and MobileNet, have been proposed and trained on various datasets with different magnification levels. In this study, we focus on the methods that employ two main image levels, namely microscopic and macroscopic transverse cross-sections of wood, to investigate the effectiveness of CNNs for WoodID.

For the first level, previous studies have typically utilized dedicated microscopic devices to capture wood cross-section images [16]. For example, Silva *et al.* [17] presented a method to automatically classify wood species using microscopic images of 77 commercial Central-African timber captured at 25x magnification with an Olympus BX60 microscope and an Olympus UC30 digital camera. Geus *et al.* [18] introduced a wood image dataset consisting of 281 species, with three sets of 20 samples each, corresponding to transverse, radial, and tangential sections, taken on an Olympus SZX7 stereo microscope at 20x magnification. V. Stagno *et al.* [19] conducted a study using NMR to capture samples, including one softwood and four hardwood species. The samples were boiled in distilled water until saturation, and microscopy images were captured using a Zeiss EVO LS10 Environmental Scanning Electron Microscope (ESEM) with EDS. Low vacuum mode was chosen to obtain cross-sectional images of the wood, with a working distance ranging from 4.5 to 5.0 mm and an electron high tension of 20.00 kV. Magnifications of 300x and 1000x were used. The data were acquired using a Bruker Avance-400 spectrometer operating at 9.4 T with a 10 mm micro-imaging probe and XWINNMR and ParaVision 3.2 software.

For macroscopic level studies, digital magnifying glasses connected to smartphones or computers are often used to capture images of wood cross-sections [20]–[22]. These images are taken at different levels of magnification, typically ranging from 10-50X. For example, Saenz *et al.* [23] captured images of 11 forest species using a smartphone with a CMOS sensor and a magnification of 3.9 microns per pixel (about 20x of magnification). The area of interest was 2.5mm x 1.9mm, and lighting was provided by the device.

Lee *et al.* [24] proposed a dataset of 25 species from Yunnan Province, China. The woodblocks were first collected and cut by an electric moto saw into 1 cm³ pieces and flattened with sandpaper (400 grit, 800 grit, 1000 grit). The images were taken using a mobile phone (OnePlus 3, China) and a 20X magnifying glass, with the original image size being 2048 × 1024 pixels. The central 300 × 300 pixels were selected as the experimental material, as they were clearer and less fuzzy than the other areas. A total of 3000 images were obtained, with which each species including 120 images.

In another study, Filho *et al.* [25] used a Sony DSC T20 camera to capture images of 46 species with a resolution of 150 dpi using artificial lighting. Meanwhile, Sun *et al.* [7] used a mobile phone and a 20X magnifying glass to capture images of 25 wood species with a resolution of 2048x1024 pixels. The images were polished and the middle 300x300 pixels were cropped for clearer results. The dataset was divided into two parts for training and testing, with 2498 images for training and 502 images for testing.

In a study conducted by Souza *et al.* [15] in 2020, 46 Brazilian wood species were collected from the Wood Anatomy and Quality Laboratory (LANAQM) at Federal University of Paraná (UFPR) in Curitiba, Paraná. The transversal surfaces of the samples were sanded with a 120 sandpaper, and macroscopic images were taken using a Zeiss Discovery V 12 stereo microscopes with a resolution of 2080 × 1540 pixels and a 10× magnification. This resulted in a total of 1,901 images.

Additionally, in 2021, de Geus *et al.* [14] introduced a new dataset of 11 Brazilian wood species with high commercial value, with all images being taken from the transverse section using a low-cost portable microscope connected to a smartphone with a resolution of 640 × 480 pixels. The dataset consists of 440 images, with 40 images for each of the 11 species.

Various methods have been proposed in the literature, including traditional machine learning (i.e., k-NN, SVM, ANN) and deep learning (i.e., VGG16, ResNet50, SqueezeNet, DenseNet). Traditional methods require fewer data but rely on handcrafted features, while deep learning models demand more data, but perform automatic feature extraction, resulting in higher accuracy. Among these methods, CNN-based networks have been the most successful for WoodID, with several studies achieving high accuracy rates using different networks such as VGG16, ResNet50, SqueezeNet, and DenseNet. For example, de Geus *et al.* [14] obtained an accuracy of 98.13% with DenseNet, while Lee *et al.* [24] achieved an accuracy of 99.6% with ResNet50. However, each proposed method has specific parameters, such as network architecture and magnification levels, and no concrete recommendation has been made regarding the optimal magnification level for CNN-based WoodID. Therefore, this study aims to evaluate the performance of common CNN-based networks for WoodID using macroscopic images of wood cross-sections at different magnification levels, with a focus on evaluating their practicality for use in Vietnam.

III. MATERIALS AND METHODS

This section provides a comprehensive overview of the data collection process and the Convolutional Neural Network (CNN) based methods applied in the recognition of wood species. To provide a comparative and objective measure of different wood species, we collected five datasets from different regions, including Vietnam, Pacific and Colombian Amazon, and China. Three popular CNN architectures were examined and evaluated on these datasets, including ResNet50, MobileNetV2, and DenseNet121.

A. Data Preparation and Collection

The study utilized five datasets, including (i) VN_26, a self-collected dataset, (ii) WRD_21, a Southeast Asia wood

dataset published by Sun [26], (iii) BFS_46, the Brazilian flora species dataset collected in 2020 [15], (iv) BD_11, the Brazil dataset collected in 2021 [14], and (v) PCA_11, a dataset containing wood from Pacific and Colombian Amazon region [23]. The datasets include macro-images of wood cross-sections captured by different devices at various magnifications and resolutions. Wood samples were sometimes sanded and polished to improve image quality.

The VN_26 dataset contains 26 wood species imported to Vietnam, as presented in Table I, with samples collected from different locations on the wood cross-section. We captured the images at three magnification levels (10x, 20x, and 50x) with three different types of microscopes. Each image set has a different resolution and image size. The surfaces of the samples were treated by sanding and polishing before being captured.

The WRD_21 dataset includes 1,126 macro-images of 21 Southeast Asia wood species [26], as presented in Table II. To create the dataset, the authors polished the cross-section of each wood block using 200 grits and 400 grits sandpaper in sequence and then cleared any remaining dust with a toothbrush. Next, they marked a circular area on the wood block to serve as the fingerprint area, which ensured that the same location for subsequent captures could be chosen. They then used a 20X magnifying glass to acquire an image of the marked area. Finally, the macro-images were captured by a Huawei Honor 8 cellphone.

The BFS_46 dataset, as presented in Table III, was col-

lected in 2020 and contains 1,901 images of 46 Brazilian flora species with two different sizes (640x480 pixels and 2080x1540 pixels). The wood samples were obtained from the Wood Anatomy and Quality Laboratory (LANAQM) at the Federal University of Paraná (UFPR) in Curitiba, Paraná. They were then sanded with 120 grit sandpaper. The authors used a Zeiss Discovery V 12 stereo-microscope at 10x magnification to capture the macro-images with a resolution of 150 dpi.

The BD_11 is another Brazilian dataset collected in 2021, consisting of 11 high-commercial-value wood species, as shown in Table IV. The timber samples were not polished; instead, the authors used a pocket knife to cut them to expose the anatomical characteristics. The samples were captured using a low-cost portable microscope connected to a smartphone with a resolution of 640x480 pixels. To account for variance in anatomical characteristics, each species comprises 40 images, with four image samples extracted from 10 different specimens.

The PCA_11 dataset contains 10,792 images of 11 wood species captured using a digital microscope device at 20x magnification, as presented in Table V. First, timber samples from the Pacific and Colombian Amazon region were aggregated and moistened to increase contrast. Next, they were captured with a digital microscope device at a resolution of 640x480 pixels.

In general, these datasets were collected by capturing images of wood samples using either microscopes or digital

cameras. In some cases, the samples were treated by sanding and polishing to improve the image quality. The resolution and size of the images varied among the datasets.

B. Convolutional Neural Network Architecture

In this study, we focus on deep learning techniques to recognize wood species based on macro-images of wood cross-sections. To achieve this, we utilized several well-known Convolutional Neural Network (CNN) architectures, namely

ResNet [11], DenseNet [12], and Mobilenet [13], which have been widely applied in the field. Each of these models has its strengths and weaknesses. We compared their performance to determine the most effective architecture for WoodID on the studied datasets. In this section, we provide an overview of each network and its specific characteristics.

TABLE VI. RESNET50 ARCHITECTURE

1) *ResNet50*: ResNet50 is a deep convolutional neural network architecture that was introduced by Microsoft researchers in 2015 [11]. It is part of a family of ResNet models that were designed to address the problem of vanishing gradients in deep neural networks. The authors introduce shortcut connections that allow the gradient signal to bypass some layers during training.

ResNet50 has been widely used in various computer vision tasks, including object detection, image segmentation, and image classification. It has achieved state-of-the-art performance on several benchmark datasets, including ImageNet, which contains over one million images from a thousand different classes. ResNet50 has shown remarkable accuracy and efficiency in recognizing different types of objects, including

wood species, making it a popular choice for many practical applications.

The network consists of a series of convolutional and pooling layers, followed by multiple residual blocks, and finally a global average pooling layer and a fully connected layer, as shown in Table VI.

2) *Densenet*: DenseNet121 is a deep convolutional neural network that was introduced in 2017. It is part of the DenseNet family of models, which is based on the idea of densely connecting each layer to every other layer in a feed-forward fashion [12]. This architecture allows for a deeper and more efficient network that can achieve higher accuracy with fewer parameters compared to traditional architectures like VGG or ResNet.

DenseNet121 consists of 121 layers, with a total of 8.06 million parameters. It has a similar structure to other DenseNet models, where each layer is densely connected to every other layer in a feed-forward fashion. The difference with DenseNet121 is that it uses smaller filters and less dense connections between layers, which allows for better memory usage and faster training. The model also includes skip connections, which help to mitigate the vanishing gradient problem and improve the flow of information throughout the network. Overall, DenseNet121 is a powerful deep learning model that has shown excellent performance in a variety of computer vision tasks, including WoodID.

3) *MobileNet*: MobileNet is a deep learning architecture designed for mobile and embedded devices with limited computational resources. It was introduced by Google in 2017 and has gained significant popularity due to its efficient and lightweight design [13]. The network uses depthwise separable convolutions that separate the spatial and channel-wise convolutions in a standard convolutional layer, as presented in Table VII. This design reduces the number of computations required while maintaining a high level of accuracy.

MobileNet has several variants, including MobileNet v1, v2, and v3. MobileNetV1 was the first version of the architecture and was introduced in 2017. It uses depthwise separable convolutions with a width multiplier, which reduces the number of channels in the network, making it more lightweight. MobileNetV2, introduced in 2018, builds upon the original architecture and introduces several improvements, including linear bottleneck layers and inverted residuals. These changes improve the accuracy and reduce the number of computations required. MobileNetV3, introduced in 2019, focuses on improving the speed and accuracy of the architecture further. It uses a combination of channel and spatial attention modules to improve the network's performance while maintaining its lightweight design. In this study, we evaluated the performance of MobileNetV2.

IV. EXPERIMENTS

A. Dataset

In this study, we utilized a total of five datasets, of which the VN_26 dataset was self-collected while the remaining four were obtained from existing sources. For the VN_26 dataset, wood samples measuring 1 inch (2.54 cm) in size were collected from different locations on the cross-section

TABLE VII. MOBILENET ARCHITECTURE

Layer	Output Shape	Kernel size	Stride
Input	224 × 224 × 3	-	-
Convolution	112 × 112 × 32	3 × 3	2
Depthwise Convolution	112 × 112 × 32	3 × 3	1
Pointwise Convolution	112 × 112 × 64	1 × 1	1
Depthwise Convolution	56 × 56 × 64	3 × 3	2
Pointwise Convolution	56 × 56 × 128	1 × 1	1

Pointwise Convolution	14 × 14 × 512	1 × 1	1
Depthwise Convolution	7 × 7 × 512	3 × 3	2
Pointwise Convolution	7 × 7 × 1024	1 × 1	1
Global Average Pooling	1 × 1 × 1024	-	-
Fully Connected	1000	-	-

of the wood. The collected samples were then processed by surface sanding using sandpaper and polished with 600-grit sandpaper to ensure that the surface texture of each sample was uniform. A small blade was used then to cut this surface. Fig. 1 presents the steps to prepare and collect this dataset. This standardized process of sample preparation allowed us to maintain consistency across the dataset and ensured that the resulting images were of high quality, making them ideal for use.

The dataset was captured using three different types of microscopes at three magnification levels (10x, 20x, and 50x) to obtain a comprehensive set of images. For the 10x dataset, a PCE microscope equipped with a 0.3-megapixel CMOS sensor was used to capture images with a magnification of 10x and a resolution of 640x480 pixels. The 20x dataset was captured using a handheld Dino-Lite electronic microscope, which had a resolution of 1.3 megapixels, a magnification of 20x, and resulted in images of size 1280x1024 pixels. To achieve focus, a distance of 5 cm was maintained between the lens and the sample. Lastly, the 50x dataset was captured using a Wi-Fi Microscope with a magnification ratio of 50x-1000x and resulting in images of size 640x480 pixels.

By using different types of microscopes, we were able to capture images with varying levels of detail, which helped in creating a diverse dataset. The VN_26 dataset thus obtained serves as a valuable resource for studying wood characteristics. The comprehensive set of images obtained at different magnifications provides ample opportunities to evaluate WoodID at different levels of microscopy.

Table VIII presents an overview of five used datasets. The datasets differ in the number of classes, the total number of images, and the magnification levels, as well as in image resolutions available. For example, the VN_26 dataset has the highest number of classes and images, with images available at 640x480 and 1280x1024 pixel resolutions. In contrast, the WRD_21 dataset has fewer classes and images, with images available at a lower resolution of 300x300 pixels. The BFS_46 dataset has a high number of classes but a relatively low number of images, with images available at two different resolutions of 640 x 480 and 2080 x 1540 pixels. Finally, the BD_11 and PCA_11 datasets have similar characteristics, with a lower number of classes but a high number of images available at a resolution of 640 x 480 pixels. To ensure the robustness and generalizability of the models, each dataset was

Fig. 1. The VN_26 dataset preparation and collection.

split into three subsets with a ratio of 70:15:15 for training, validation, and testing.

TABLE VIII. FIVE DATASETS USED IN THIS STUDY

Dataset	Number of classes	Total images	10X	20X	50X	Resolution (pixel)
BFS_46	46	1,901	X			640x480 & 2080x1540
WRD_21	21	1,126		X		300x300
PCA_11	11	10,792		X		640x480
BD_11	11	440			X	640x480
VN_26	26	7,800	X	X	X	640x480 & 1280x1024

B. Preprocessing

Before training and evaluating the models, we performed several pre-processing steps on the collected dataset. Firstly, the wood identification experts filtered out the poor-quality images, such as blurry and skewed images. The dataset was then re-collected to ensure an adequate number of images for each species (VN_26). Next, all images were normalized to ensure that the pixel values were within the range of [0, 255]. We then applied techniques to resize them to avoid losing important information.

To enrich the training dataset, we applied various data augmentation techniques such as randomly rotating images within a range of 10 degrees, flipping images randomly horizontally and vertically. These techniques increased the diversity of the training dataset and helped to prevent overfitting of the models.

Finally, we saved the images and their corresponding labels in HDF5 format. HDF5, short for Hierarchical Data Format version 5, is a data model, library, and file format for storing and managing large and complex data. HDF5 provides a flexible and efficient way to store and retrieve large numerical arrays, metadata, and other types of data that are common in scientific computing and data analysis.

Overall, these pre-processing steps played a crucial role in improving the performance of the models and ensuring accurate WoodID. The resulting dataset was of high quality and was well-suited for training deep learning models.

TABLE IX. EXPERIMENTAL SCENARIOS

	Purpose	Network	Dataset
1	Data augmentation evaluation	DenseNet121	PCA_11
2	CNN evaluation on existing datasets	DenseNet121, ResNet50, MobileNetV2	WRD_21, BD_11, BFS_46, PCA_11
3	CNN evaluation on dataset mixed magnifications	DenseNet121, ResNet50, MobileNetV2	VN_26
4	CNN evaluation on dataset with different magnifications	DenseNet121, ResNet50, MobileNetV2	10X, 20X, 50X subsets

C. Experiment Scenarios

To evaluate the performance of studied deep learning models on various datasets and configurations, we conducted four experiment scenarios, as presented in Table IX. In the first scenario, we evaluated the effect of data augmentation on the PCA_11 dataset. We trained the DenseNet121 model with an input image size of 224x224 pixels, and a batch size of 32 for 500 epochs using the Adam optimizer with a learning rate of 0.001 and the category cross-entropy loss function. We stopped training if there was no improvement in the validation loss after 200 epochs. Regarding the second scenario, we trained DenseNet121, ResNet50, and MobileNetV2 on four datasets: WRD_21, BFS_46, BD_11, and PCA_11. The input image size was 224x224 pixels, and we performed training with a batch size of 64 using the Adam optimizer with a learning rate of 0.001. The category cross-entropy loss function was used, and training was stopped if there was no improvement in the model after 200 epochs.

For the third scenario, we trained the same three models on the self-collected dataset, VN_26, which includes three levels of image magnification. The input image size and other parameters were identical to those used in the first scenario. In the fourth scenario, these four models were separately trained on three subsets of VN_26, corresponding to the three magnification levels. The same parameters as the previous scenarios were applied, but we stopped training if there was no improvement after 300 epochs.

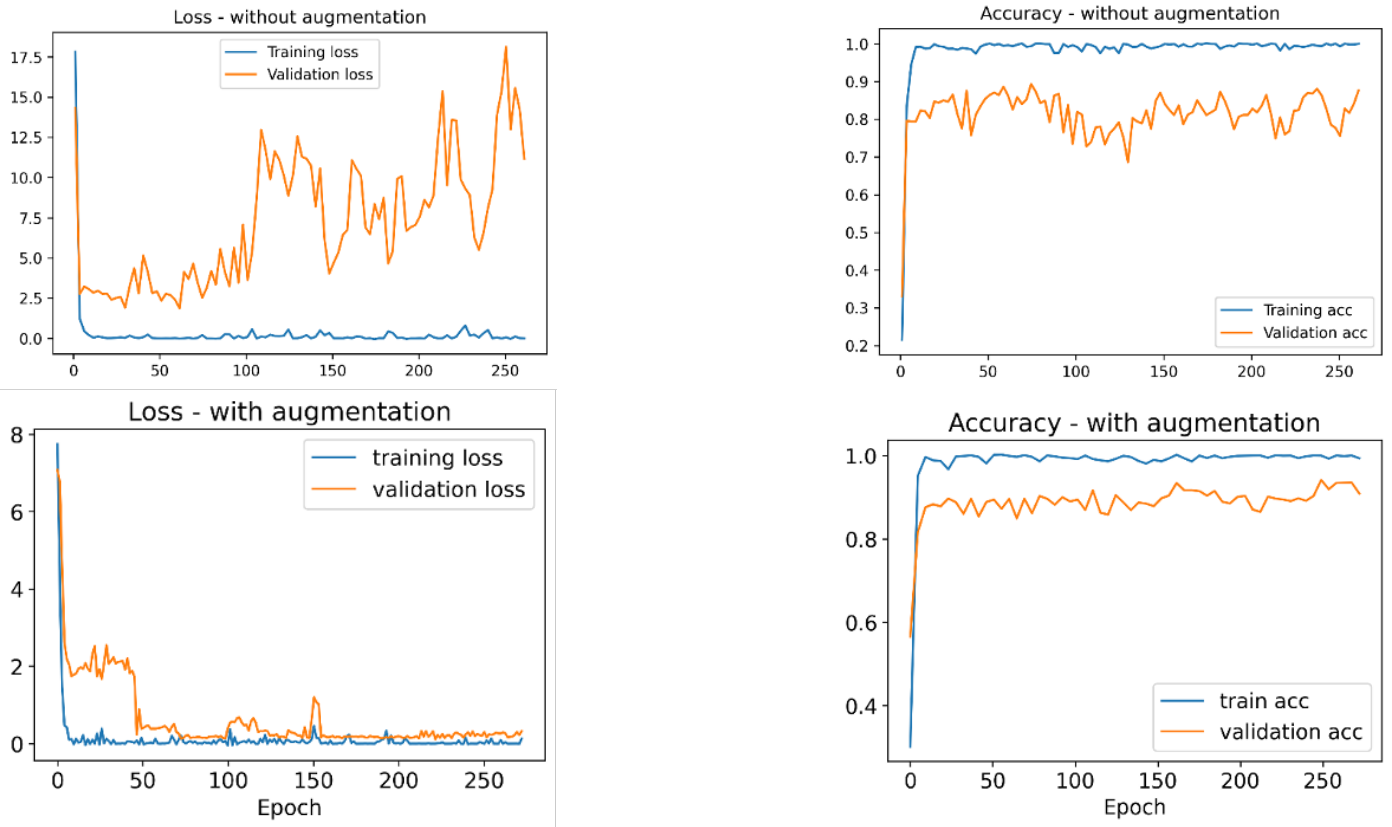

Fig. 2. Experiment 1 – Training loss and accuracy progresses with and without data augmentation.

D. Results and Discussion

The obtained results from the first experiment are depicted in Fig. 2, showing the progress of loss and accuracy during the training process on both the non-augmented (the upper plots) and augmented (the lower plots) datasets. It was observed that without data augmentation, the gap between the training and validation accuracy remained large and constant, while the gap between the two loss progresses tended to increase, indicating an overfitting trend. However, with data augmentation, the overfitting was mitigated, as the gap between the two loss progresses was small, and the accuracy gap was reduced. Consequently, the model achieved a higher accuracy of over 95.9% on the validation dataset.

TABLE X. EXPERIMENT 2 - PERFORMANCE OF DEEP LEARNING MODELS ON THE FOUR EXISTING DATASETS

Dataset	Model	Acc	F1-Score	Precision	Recall
BFS_46	Resnet50	87.77%	87.89%	88.35%	87.46%
	MobilenetV2	97.05%	97.08%	97.09%	97.08%
	Densenet121	98.21%	98.22%	98.23%	98.21%
WRD_21	Resnet50	76.12%	76.43%	80.27%	73.28%
	MobilenetV2	94.34%	94.67%	94.52%	94.85%
	Densenet121	97.11%	97.56%	97.39%	97.55%
BD_11	Resnet50	87.24%	63.67%	80.23%	53.91%
	MobilenetV2	96.82%	96.43%	96.16%	96.45%
	Densenet121	97.26%	97.54%	97.37%	97.29%
PCA_11	Resnet50	87.36%	76.15%	80.86%	73.23%
	MobilenetV2	96.25%	96.34%	96.23%	96.25%
	Densenet121	97.78%	97.86%	97.35%	97.66%

Table X presents the outcomes of the second experiment,

demonstrating that all models achieved high accuracy levels in most cases. The best accuracy of 98.21% was achieved by DenseNet121 models on the BR_46 dataset, whereas the Resnet50 model achieved lower accuracy levels ranging from 76% to 87% across different datasets. The F1-Score had a similar trend to accuracy. Regarding precision and recall, all models showed high values, indicating a good ability to identify true positives and true negatives correctly. Notably, MobileNetV2 and DenseNet121 models consistently achieved higher precision and recall values than the Resnet50. Overall, the results suggest that the choice of the CNN model can significantly affect the accuracy and performance of WoodID, with DenseNet121 being the most effective models in this study. Additionally, the dataset choice could impact the model's performance, with some datasets being more challenging to classify than others.

For the third experiment, the results presented in Table XI show that all three models achieved high accuracy levels, ranging from 86.13% to 99.53%. Notably, the DenseNet121 model outperformed the other two models, achieving the highest accuracy, F1-Score, precision, and recall, with a score of 99.52% and 99.53% in all metrics. In contrast, the MobileNetV2 and ResNet50 models obtained lower accuracy levels, with MobileNetV2 performing better than ResNet50. To gain further insights, we also examined the loss and accuracy progress of the MobileNetV2 and DenseNet121 models, as shown in Fig. 3. The accuracy of both models increased steadily, with validation accuracy closely following the training accuracy. The loss progresses of MobileNetV2 showed a

Fig. 3. Exp3: Training loss and accuracy progresses of DenseNet121 (the upper images) and MobileNetV2 (the lower images) on the VN_26 dataset.

slight overfitting trend, while those of DenseNet121 tended to decrease and approached the training loss progress. It means that MobileNetV2 may not generalize well to new data, while DenseNet121 has a better generalization ability in the model. Overall, the results suggest that DenseNet121 is the most effective model for WoodID on the VN_26 dataset, achieving high accuracy and generalization ability. These findings are consistent with previous studies that have shown the effectiveness of DenseNet121 on other datasets.

TABLE XI. EXPERIMENT 3 - PERFORMANCE OF DEEP LEARNING MODELS ON THE ALL VN_26 DATASET

Model	Acc	F1-Score	Precision	Recall
Resnet50	86.13%	86.30%	85.08%	87.34%
MobilenetV2	98.13%	98.15%	98.11%	98.10%
Densenet121	99.52%	99.53%	99.53%	99.53%

The fourth experiment aimed to evaluate the performance of the three CNN models on the three magnification subsets of the VN_26 dataset, including X10, X20, and X50. As shown in Table XII, all three models achieved high accuracy levels across all magnification levels. Specifically, DenseNet121 outperformed the other models in all metrics, reaching an accuracy of from 99.12% to 99.89% in all levels.

At the X10 magnification level, Densenet121 achieved

TABLE XII. EXPERIMENT 4 – PERFORMANCE OF DEEP LEARNING MODELS ON THE DIFFERENT MAGNIFICATION LEVELS

X levels	Model	Acc	F1-Score	Precision	Recall
X10	Resnet50	86.11%	86.14%	86.61%	85.72%
	MobilenetV2	98.91%	98.82%	98.80%	98.15%
	Densenet121	99.56%	99.61%	99.50%	99.52%
X20	Resnet50	84.64%	83.75%	84.17%	83.34%
	MobilenetV2	99.67%	99.68%	99.68%	99.68%
	Densenet121	99.89%	99.89%	99.89%	99.89%
X50	Resnet50	85.70%	85.90%	86.60%	85.30%
	MobilenetV2	98.32%	98.13%	98.35%	98.31%
	Densenet121	99.12%	99.15%	99.20%	99.14%

the highest accuracy, F1-Score, precision, and recall, with values of 99.56%, 99.61%, 99.50%, and 99.52%, respectively. Meanwhile, at the X20 magnification level, Densenet121 significantly outperformed the other two models, achieving the highest accuracy of 99.89% across all metrics. At the X50 magnification level, all three models achieved high accuracy levels, with Densenet121 and MobilenetV2 achieving the highest accuracy of 99.12% and 98.32%, respectively.

Furthermore, the loss and accuracy progress of all three models were analyzed, and no overfitting trends were observed, as shown in Fig. 4. This indicates that the models were able to generalize well to the test data and were not simply

Fig. 4. Exp4: Training loss and accuracy progresses of DenseNet121 on the X20 subset.

memorizing the training data. Among the three magnification levels tested, X20 was found to be the best magnification level for WoodID, with all three models achieving the highest accuracy levels at this magnification. This may be due to the balance between image resolution and information content, which is important for accurately identifying wood species.

TABLE XIII. PERFORMANCE COMPARISON BETWEEN MOBILENETV2 AND DENSENET121

Model	Total parameters	Predicted time (s)	Acc	F1_score
DenseNet121	7,589,451	4.15	100%	100%
MobileNetV2	2,947,915	1.97	99.6%	99.6%

Table XIII provides a comparison between DenseNet121 and MobileNetV2 models. DenseNet121 has a larger number of parameters, which results in a longer predicted time. However, it achieves a higher accuracy and F1 score. On the other hand, MobileNetV2 has fewer parameters, leading to a faster predicted time, but slightly lower accuracy and F1 score. Based on the differences in the number of parameters and predicted time, MobileNetV2 is a suitable choice for low-configuration devices where computational resources are limited. Meanwhile, DenseNet121 can be used for powerful servers where accuracy is critical, and the model's complexity is not a concern.

Overall, we observed that higher magnifications lead to higher accuracy up to a certain level, after which the accuracy can decrease. Specifically, the results indicated that the 20x magnification level outperformed the 10x level in terms of accuracy, F1-Score, precision, and recall for all three models: ResNet50, MobileNetV2, and DenseNet121. This suggests that a higher magnification level provides more information, which allows for better differentiation of wood species.

However, the performance of the models on the 50x magnification level was worse than the 20x and 10x levels. This can be explained by the fact that the 50x level is too close, which can miss important information about the wood structure. At this magnification level, it is possible that the image captures only a small portion of the wood, which may not be representative of the entire sample.

Therefore, our study suggests that the optimal magnification level for wood species recognition is 20x, as it provides enough information without sacrificing accuracy due to the over-saturation of details.

V. CONCLUSION

In conclusion, this study evaluated the performance of three popular CNN models, MobileNetV2, ResNet50, and DenseNet121, for wood species identification using datasets at different magnification levels. The results demonstrated that data augmentation and the choice of CNN model significantly affected the accuracy and generalization ability of wood species identification. Moreover, the datasets used in the study also impacted the model's performance, with some datasets being more challenging to classify than others.

Overall, the DenseNet121 model consistently outperformed the other models in terms of accuracy, F1-Score, precision, and recall, making it the most effective model for wood species identification across all experiments. Furthermore, the study found that X20 magnification level was the best magnification level for wood species identification, as all three models achieved the highest accuracy levels at this magnification level.

Future work in this area may involve further exploring the impact of different data augmentation techniques on wood species identification. Additionally, the study may be extended to include a larger and more diverse dataset to further test the robustness of the CNN models. Moreover, future research could investigate the transfer of learning techniques for wood species identification to reduce the computational cost and increase the efficiency of the training process. Lastly, it is worth considering the combination of different image processing techniques, such as texture analysis and segmentation, with CNN-based networks to further improve the accuracy of wood species identification.

A Review of Milgram and Kishino's Reality-Virtuality Continuum and a Mathematical Formalization for Combining Multiple Reality-Virtuality Continua

Cristian Pamparău

MintViz Lab-MANSiD Center, Ștefan cel Mare University of Suceava, 13 Universitatii, Suceava, 720229, Romania

Abstract—We explore in this paper theoretical contributions that are related to Milgram and Kishino's Reality Virtuality Continuum by conducting a systematic literature review. From this study, we draw inspiration for our proposed mathematical formalization of combining multiple Reality-Virtuality Continua in a single, mixed reality experience. Also, we provide a definition for XR transition protocol. To complete our contribution, we discuss two potential examples that will exemplify our formalization and identify future work to be addressed.

Keywords—Systematic literature review; reality-virtuality continuum; mixed reality; transitional interfaces; mathematical formalization; XR transition protocol

I. INTRODUCTION

In 1994, Milgram and Kishino [1] introduced the Virtuality Continuum, an imaginary axis having real and virtual as its opposite ends. In the next year, the axis was renamed as Reality-Virtuality Continuum [2] (RVC), the name in use today. While introduced this Continuum, they also defined the “Mixed Reality” term as being anywhere between the extrema of this continuum. At the same time, the “Augmented Reality” term was introduced as the augmentation of real with virtual objects, and also “Augmented Virtuality” referring to the augmentation of virtual with real objects.

Since its introduction in 1994, Milgram and Kishino's RVC has been widely cited and used by researchers (according to Google Scholar, at the time of writing this paper, the paper published in 1994 was cited 7540 times, and the follow-up paper from 1995 was cited 4133 times¹). However, many papers built upon on this continuum to introduce or to develop XR systems; see next section for details. There were also some papers that used this continuum to expand their work by introducing new formalizations, conceptualizations or even for redefining Mixed Reality; a specific type of contribution is represented by the concept of traversable or transitional interfaces [3], in which a user can navigate, manipulate, and transit to other mixed reality experiences with a different level of augmentation, *i.e.*, different points of the Reality-Virtuality Continuum or other conceptual spaces.

Traversing or exploring this continuum was already addressed in scientific literature. For example, in 1999, Milgram and Colquhoun [4] formalized the transitions in RVC; also,

Grasset *et al.* [5], [3] addressed this topic in both practical and theoretical ways. A few years later, Roo *et al.* [6] introduced a taxonomy for transitioning RVC, while Jetter *et al.* [7] proposed his own definition for *transitional interfaces*. Recently, Pamparău and Vatavu introduced the concept of a journey in ARTV Continuum [8] as a transition between two points of this continuum, that is a 2D space where the vertically axis represents Milgram's RVC and the horizontally axis is also Milgram's RVC, but used in the context of Television. Hence, they invited participants of their experiment to view and explore the same video in four different augmentation levels; see [9] for details, and section III for details regarding previous work on transitional interfaces.

While the scientific literature explores the concept of traversable or transitional interfaces, these contributions involve experiencing different levels of augmentation and immersion of the same application, *i.e.*, on the same RVC. We propose in this paper to explore and formalize the possibility of combining multiple Reality-Virtuality Continua; to this end, such transitional interfaces allows transition not *on the same mixed reality experience*, but *between different mixed reality experiences*. To this end, we address the following research questions:

- RQ₁**. What theoretical contributions were introduced in scientific literature based on and related to Milgram and Kishino's Reality Virtuality Continuum [1]?
- RQ₂**. How can the identified theoretical contributions be classified?
- RQ₃**. Based on these findings, how can we formalize the combination of multiple Reality-Virtuality Continua?

In line with these research questions, we make several contributions, as follows:

- 1) We conduct a Systematic Literature Review (SLR) in order to identify theoretical contributions that are related to Milgram and Kishino's Reality Virtuality Continuum and classify these contributions in three categories, such as (1) *extensions*, (2) *integrations* and (3) *analogies*.
- 2) Based on these findings, we introduce a mathematical formalization of combining multiple Reality-Virtuality Continua, and propose a definition for *XR transition protocol*, for which we discuss several potential applications.

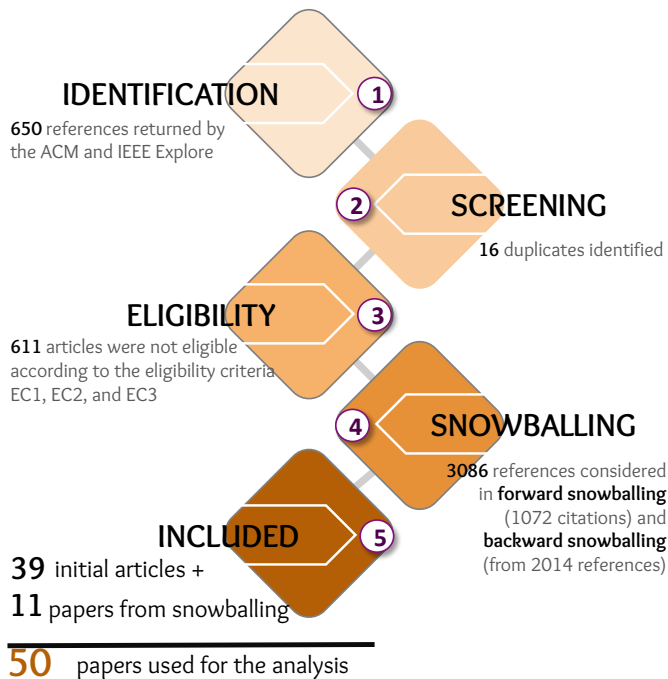

Fig. 1. The results of the *identification*, *screening*, *eligibility*, *snowballing*, and *inclusion* stages of our SLR.

II. STUDY DESIGN

We conducted a Systematic Literature Review, for which we employed the Best Practice Guide [10], and implemented *identification*, *screening*, *eligibility*, *snowballing*, and *inclusion* stages. Fig. 1 presents the results obtained after each stage, illustrated using the PRISMA (Preferred Reporting Items for Systematic reviews and Meta-Analyses) diagram [11].

In order to identify keywords for our initial query, we examined Milgram's papers that introduces, discuss and explore Reality-Virtuality Continuum (RVC) [1], [2], [4]. To this end, in the *identification* stage, we searched for scientific paper relevant to our scope by using the following query [All: "reality-virtuality continuum"] OR [All: "virtuality continuum"] OR [All: "rv continuum"] AND [E-Publication Date: "(01/01/1995 TO 12/31/2022)"] for ACM Guide to Computing Literature² and the adapted version for IEEE Explore Database: "(("Full Text & Metadata": "reality-virtuality continuum") OR ("Full Text & Metadata": "virtuality continuum") OR ("Full Text & Metadata": "rv continuum"))", filtering only Conferences and Journals from 1995-2022 interval, as the most comprehensive bibliographic databases focused on the field of computing. The query returned 251 bibliographic results on ACM and 399 on IEEE Explore, resulting a total number of 650. During the *screening* stage, we read the abstract to determine their relevance to our scope of investigation. In this stage, we identified 16 duplicates and a retracted paper, remaining 633 results for the next stage. In the *eligibility* step, we read each paper and used the following criteria to filter out results not relevant to our scope of investigation, *i.e.*, theoretical

²<https://libraries.acm.org/digital-library/acm-guide-to-computing-literature>

contributions related to Milgram and Kishino's RVC:

- EC₁: *The paper is academic* and underwent peer review. Magazine articles, workshop descriptions, proceedings descriptions, books, white papers, and tutorials were excluded. In this stage, 56 papers were excluded.
- EC₂: *The paper is about mixed reality*. We exclude all the results that referenced the RVC, but addressed other topics. In this stage, 25 papers were excluded.
- EC₃: *The paper presents a contribution that is directly related to the RVC instead of simply referencing it*. We excluded 512 papers in this stage, mostly presenting XR systems.

We used these eligibility criteria to identify peer-reviewed theoretical contributions that are directly related to Milgram and Kishino's RVC. After the eligibility stage, we arrived at a number of 39 relevant papers, for which we applied two snowballing procedures [12]: (1) *backward snowballing*, where we analyzed the references of all the eligible papers, total of 2014 papers, and (2) *forward snowballing*, where we analyzed their Google Scholar citations, total of 1072. From the *backward* stage, we identified 7 additional papers, and from the *forward* stage, we identified 4 additional papers that met our three eligibility criteria. Our final set of papers contains 50 academic papers published between 1998 and 2022. These papers were analyzed and the following information were extracted to address our research questions:

- 1) Contributions from papers that referenced RVC for introducing an *extension* of this continuum. An illustrative example for this category is represented by the recent revision of Milgram and Kishino's RVC introduced by Skarbez *et al.* [13]. We used this information to address RQ₁ and RQ₂.
- 2) Contributions from papers that used RVC in order to introduce an *integration* of RVC in other concepts, such as Vatavu *et al.* [8]'s ARTV or Jeon and Choi [14]'s visuo-haptic MR taxonomy. We used this information to address RQ₁ and RQ₂.
- 3) Contributions from papers that referenced RVC for introducing a theoretical contribution based on an *analogy* with this continuum. These papers didn't modify or alter this continuum, but employed correspondences or analogies with this axis, as Popoveniuc and Vatavu [15] did when introduced transhumanism: a philosophical and cultural framework for Extended Reality applied to Human Augmentation. We used this information to address RQ₁ and RQ₂.
- 4) Information about the *validation of the scientific contributions*, with five categories: (i) examples from *prior work*, *e.g.*, papers from scientific literature or prototypes from industry, (ii) *demonstration*, *e.g.*, working prototype or application without a user study, (iii) *user study*, *i.e.*, studies for valuable feedback on proposed systems involving representative end users, (iv) *implications*, *e.g.*, future implications or guidelines for future work, and (v) *no validation* at all; see Fig. 3. We used this information to complement our findings in relation to RQ₁ to RQ₂.

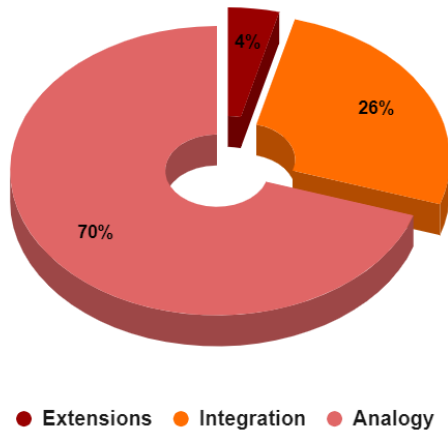

Fig. 2. Overview of contribution types of our extracted papers.

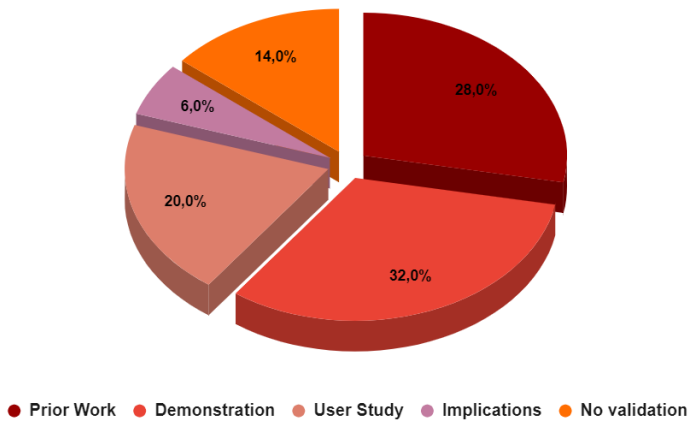

Fig. 3. Overview of validation types of our extracted papers.

III. RESULTS

We present a meta-analysis of 50 scientific papers that proposed theoretical contributions directly related to Milgram and Kishino's RVC.

A. Extensions of RVC

In our investigation, we identify two papers that propose an extension of RVC. Firstly, Ridel *et al.* [16] introduced *revealing flashlight*, "a new interaction and visualization technique in spatial augmented reality that helps to reveal the detail of cultural heritage artifacts" [16, p. 1]. To this end, they proposed an extension of RVC to account for see-through and spatial augmented reality. In their extension, Augmented Reality from RVC is divided into Spatial Augmented Reality and See-Through Augmented Reality. In order to validate their extension and explore spatial augmented reality concept, the authors introduced "revealing flashlight" prototype which is configured to augment a real artifact at a fixed location, by using one single video-projector. Also, they identified three characteristics involved in using a classical flashlight for illuminating an object, such as (1) spot, corresponding to the illuminated spot of the flashlight's lighting cone, (2) distance, corresponding to the distance between the flashlight and the illuminated point on the surface, and (3) the angle between the

light direction and the normal of the illuminated point on the surface.

Another important extension was introduced by Skarbez *et al.* [13], who revisited Milgram and Kishino's Continuum, proposing an alternative definition of mixed reality. Their work started by extending the discussion from only visual displays, to "the multiple senses" [13, p. 2], including interoceptive (that monitor the body's internal state) and exteroceptive senses (that responds to stimuli that come from outside the body). To this end, the authors argues that "there is a discontinuity on our revised continuum, because true virtual reality exists only when all senses - exteroceptive and interoceptive - are fully overridden by the computer-generated content" [13, p. 4]. As an example of pure virtual reality, the authors mentioned the Matrix films, where both interoceptive and exteroceptive senses are stimulated by the technology. In this new light, the Milgram and Kishino's Virtual environment became External Virtual Environment, and the pure virtual environment was named as "Matrix-like" Virtual Environment. One of the limitations of the Milgram and Kishino's RVC that Skarbez *et al.* [13] identified is the absence "of an observer or a user with senses other than visual and prior life experiences", arguing that "the notion of an environment without an experiencing being - the aforementioned observer - is incomplete"; therefore, "the mediating technology, content conveyed, and resulting user experience must be considered together to adequately describe MR experiences" [13, p. 2]. To this end, they proposed a revised definition of a Mixed Reality environment, "in which real world and virtual world objects and stimuli are presented together within a single percept" [13, p. 4].

B. Integrations of RVC

We identified some papers that integrate the RVC axis into new concepts; such theoretical contributions can be classified into two categories: (1) concepts, definitions and taxonomies, and (2) design spaces or conceptual frameworks.

1) *Concepts, Definitions and Taxonomies.*: A few papers from our SLR introduced concepts, definitions or taxonomies, and some of them were proposed for different types of mixed realities. For example, Steve Mann [17] defined the term mediated reality and for a better understanding, he proposed the taxonomy of Reality Virtuality Mediality Continuum, that is a two orthogonal continua, where the horizontal axis is represented by RVC and the vertical one represents Reality Mediality continuum. Kubota *et al.* [18] proposed the concept of Transformed Reality as a new approach that alters users' perception of the world using computation, into a form that the user prefers. They introduced the level of transformation axis when integrating Transformed Reality in RVC. They also proposed an algorithm for edge and shadow extraction, and used it in a new system, "Anime Glasses", that converts natural scenes into anime style in real time. Finally, Pamparău and Vatavu [9] proposed a definition for a journey in ARTV continuum [8] as a transition between two points of this continuum, that is a 2D space where the vertically axis represents Milgram's RVC and the horizontally axis is also Milgram's RVC, but used in the context of Television.

2) *Design Spaces or Conceptual Frameworks.*: In our investigation, we found papers that proposed conceptual frameworks or design spaces by integrating the RVC axis. For

instance, Kraus *et al.* [19] addressed human-human communication during the use of immersive teleoperation interfaces. Their work was based on real-life examples by introducing classification that consists of a 2D space, one for *copresence* (single user teleoperation by an immersed user communicating with a non-immersed user, collaborative teleoperation by two connected, immersed users, and joint teleoperation by two colocated, immersed users), and one for *virtuality*, *i.e.*, Milgram's RVC axis. When introducing Haptic Augmented Reality, Jeon and Choi [14] proposed a visuo-haptic Mixed Reality taxonomy, which consists of two orthogonal reality-virtuality continua, one from visuals and one for haptics. Another two dimensional framework is represented by virtual environments for advanced modeling (VEAM) [20], which is the intersection of Milgram's RVC and Advanced Modeling Techniques, such as (1) mental models, (2) models and representations, (3) and metaphors and theories.

Some papers proposed conceptual frameworks or continua that consists of more than two dimensions. For instance, Stapleton *et al.* [21] broke down the Milgram's RVC in two dimensions, *i.e.*, Physical Reality (the venue), and Virtual Reality (the content), that combined with Imaginary Reality (the story), results in Compelling Mixed Reality (the play). This new resulting spaced was named as Mixed Fantasy Continuum. In a follow-up work, Stapleton *et al.* [22] proposed a new dimension for RVC, Imaginality, that is able to produce its own internal perception to influence the external perception of Physical and Virtual Reality. Williams *et al.* [23] proposed the Reality-Virtuality Interaction Cube, a three dimensional continuum which combines the Plane of Interaction, a framework for characterizing interactive technologies in a 2D spaced informed by the Model-View-Controller design pattern, and the Milgram's RVC, while Lee *et al.* [24] introduced the Ubiquitous VR Space, a 3D space that consists of: (1) Milgram's RVC, (2) Static-Dynamic Context Continuum, and (3) Personal-Social Activity Continuum. Recently, Guan *et al.* [25] introduced the domain of an Extended Metaverse Agent based on a combination of Milgram's RVC and the MiRA cube, for which two prototypes were proposed, and Vatavu [26] addressed Sensorimotor Realities by proposing a six-dimensional conceptual space: (1) Sensory Mediation, (2) Motor mediation, (3) Virtuality, (4) Imaginarity, (5) Body augmentation, and (6) Environment augmentation.

C. Analogies with RVC

Most of the theoretical contributions that we identified in our SLR were introduced as a correspondence, or an analogy with RVC. In this category, we identified 70% of our papers; see Fig. 2 for a visual representation. Same as in Section III-B, we classified these contributions in a few categories, such as (1) *spanning or transitions* between different states of conceptual spaces, (2) *definitions or concepts*, (3) *taxonomies, conceptual frameworks or design spaces*, and (4) *other* forms of theoretical contributions; see next.

1) *Spanning or Transitions between different states of Conceptual Spaces.*: There are some works that proposed the possibility of exploring transitions in different design spaces, an idea that was addressed for the first time more than 20 years ago, when Koleva *et al.* [27] introduced the concept of mixed reality boundaries, and also traversable interfaces

(boundaries) as a particular example. These interfaces are able to "provide a mechanism for people to dynamically relocate themselves along this [Milgram's RV] continuum" [27, p. 156]. In the same year, Koleva *et al.* [28] formalized the concept of traversable interfaces, which creates the illusion that physical and virtual worlds are blended together so that users can physically cross between them, repositioning themselves along the reality-virtuality continuum. According to the authors, at one moment they could be primarily located in either augmented reality or augmented virtuality, "according to their interest and whether they want the physical or virtual to be their primary focus" [28, p. 233]. Roo and Martin [6] proposed a conceptual framework to allow incremental transition from pure physical to pure virtual experiences in a unique reality. This framework consists of six levels, such as (1) physical world, (2) augmented surfaces, (3) mid-air digital content, (4) object decoupling, (5) body decoupling, and (6) pure virtual world.

This topic was also addressed in the last couple of years. For instance, George *et al.* [29] defined the user possibility to explore transitions between Milgram's RVC states without taking the headset off as *seamless transition* concept (SeaT), proposing a design space for further investigating of seamless, bi-directional transitions, that consists of four dimensions, such as (1) motivation for transition (social interaction and collaboration, physical integrity & orientation, awareness, and interaction with physical & virtual objects), (2) availability (user-triggered, system-triggered and continuous), (3) modality (visual, audio or haptic), and (4) the act of transitioning itself. By exploring to the same concept, Jetter *et al.* [7] introduced Transitional Interfaces (TI) term, that enable users to move between different locations within the RVC; TIs allows users to choose the technology that best supports the task at hand and fulfills their information need. Finally, last year Wang *et al.* [30] proposed a design space for single-user cross reality applications that consists of four dimensions: (1) transition and concurrent usage (a user transits from one point on the RVC to another, a user moves a visualization from one point on the RVC to another, a user interacts with multiple systems that belong to different points on the RVC concurrently), (2) output device, (3) input device (interacting with multiple systems along the RVC, interacting with one system along the RVC), and (4) interaction (transiting to another reality, moving a visualization across realities, selecting object across realities, and manipulating object across realities).

There are also works that introduced transitional interfaces by means of demonstrative applications. For example, Billinghurst *et al.* [31] focused on the implementation of MagicBook, the first example for transitional interfaces concept. Also, Casas *et al.* [32] introduced the concept of Multi-Reality Games that encompasses interactions with real and virtual objects to span the entire spectrum of RVC.

2) *Definitions or Concepts.*: Milgram's Reality-Virtuality Continuum was a source of inspiration for more than 25 years. For instance, in 1998, Raskaret *et al.* [33] introduced a new concept, Spatially Augmented Reality (SAR) that describes realities where virtual objects are rendered directly within or on the user's physical space. A few years later, Huynh *et al.* [34] defined Blended Reality (BR) as "the realm where the real and virtual worlds blend together as one space, letting

users and real objects interact with virtual objects in a direct and physically natural manner” [34, p. 894]. The concept of blended reality was also discussed by Robert *et al.* [35], defining it as “extending mixed reality, enabling the fluid movement of blended reality characters between the fully virtual and the fully physical” [35, p. 361].

From the papers that present analogies with RVC, we found contributions on multimodal AR or XR. For instance, Rosa *et al.* [36] introduced three concepts for an understanding of multimodal AR: (1) redefinition of ‘real’ and ‘virtual’ in terms of stimuli, (2) a new analysis of AR based on current definitions - combination of a basis and an augmentation, instead of combining real and virtual, (3) a classification system for different forms of multimodal MR for the basis-augmentation model. When trying to define XR, Rauschnabelet *et al.* [37] employed prior work on XR and qualitative insights from XR professionals. They proposed a few propositions and a new conceptual framework. First, they “posit that X - in XR - represents a placeholder (similar to an X variable in algebra) for any form of new reality” [37, p. 5]. Then, when refining AR and VR, they started from the question: “Is the physical environment, at least visually, part of the experience?” [37, p. 6] If the answer is Yes, then AR is defined as a continuum (Assisted-Mixed-Reality Continuum) where local presence is located between Assisted Reality (left) and Mixed Reality (right) extremes; this categorization depends on the level of local presence perceived by the user. If the answer is no, then VR is revised as a continuum where telepresence is located between Atomistic Virtual Reality (left) and Holistic Virtual Reality (right) extremes; this categorization depends on the degree of telepresence perceived by the user. Finally, they proposed new definitions for Augmented Reality, as “a hybrid experience consisting of context-specific virtual content that is merged into a user’s real-time perception of the physical environment through computing devices” [37, p. 13] and Virtual Reality, as “an artificial, virtual, and viewer-centered experience in which the user is enclosed in an all-encompassing 3D space that is - at least visually - sealed off from the physical environment” [37, p. 13].

3) *Taxonomies, Conceptual Frameworks or Design Spaces.*: Inspired by Milgram and Kishino’s RVC, Benford *et al.* [38] proposed a taxonomy for classifying approaches to shared spaces according to the three dimensions of transportation, artificiality, and spatiality. Lindeman and Noma introduced a continuum ranging from the physical environment to the human brain, which could be called as “where the mixing of real and computer-generated stimuli takes place” [39, p.], while Grasset *et al.* [5] conceptualized the Physicality Continuum that applies to Books. The main points of this continuum are: (1) Virtual Book, (2) Virtual Augmented Book (traditional AR Book), (3) Mixed Reality Book, and (4) Real Book. Speicher *et al.* [40] employed a series of interviews with domain experts and made a literature review, proposing a conceptual framework for Mixed Reality composed of seven dimensions: (1) Number of Environments (one, many), (2) Number of Users (one, many), (3) Level of Immersion (not, partly, fully), (4) Level of Virtuality (not, partly, fully), (5) Degree of Interaction (implicit, explicit), (6) Input (any), and (7) Output (any).

Theoretical contributions were also proposed in the field

of Augmented or Mixed Reality. Based on the existing taxonomies that they identified in scientific literature, Normand *et al.* [41] introduced a new taxonomy composed of four axes: (1) number of degrees of freedom of the tracking required by the application and the tracking accuracy that is required, (2) augmentation type (augmenting the world, or augmentation is linked to the user), (3) application-based, covering the temporal base of the displayed content, and (4) rendering modalities that go beyond visual AR. Hirzle *et al.* [42] conceptualized a 2D design space for gaze-interaction: the first dimension D1 (y-axis) is used to classify HMD technology; this is composed of device type (VR or AR), display type (monoscopic or stereoscopic), and word knowledge (full/none). The second dimension, D2 (x-axis) is composed of two parameters: oculomotor depth cue (vergence/accommodation) and ocularity (monocular/binocular). Also, Phajit *et al.* [43] formalized a 3D taxonomy for AR-for-HRI: perception augmentation (augmented human perception and augmented robot perception), functional role of AR (artificial timescale, augmented comprehension of the present reality and augmented control) and augmentation artifact type (augmented embodiment, augmented interactive objects, augmented user interface and augmented scene). When exploring the field of ARTV, Saeghe *et al.* [44] conducted a SLR from which identified six themes and a set of cross-cutting design decisions. Also, they used these themes for proposing a design space with six dimensions: (1) abstraction, (2) interaction, (3) time, (4) display, (5) context, and (6) editorial control. Finally, Holz *et al.* [45] introduced the notion of Mixed Reality Agents (MiRA), which are defined as agents embodied in a Mixed Reality Environment. Also, they introduced a taxonomy that classifies MiRAs along three axes: (1) agency (based on weak and strong notions outlined by Wooldridge and Jennings in 1995 [46]), (2) corporeal presence (the degree of virtual or physical representation of a MiRA), and (3) interactive capacity (the ability to sense and act on the virtual and physical environment).

In our investigation, we identified more diverse contributions. For instance, Chuah *et al.* [47] formalized the idea of Embodied Conversational Agents (ECAs) for which proposed a taxonomy that consists of two dimensions and 7 subdimensions, such as (1) Occupancy of the Physical Space (that consists of (1.1) Size Fidelity, (1.2) Position Fidelity, (1.3) Form Fidelity, (1.4) Concordance with the Physical Space, and (1.5) Range of Valid viewpoints subdimensions), and (2) Interaction with the Environment (that consists of (2.1) ECA’s Awareness of Changes to Environment, and (2.2) ECA’s Ability to Change Environment subdimensions). Genay *et al.* [48] proposed a taxonomy of virtual embodiment experiences by defining “body avatarization” continuum, from Real Body, to Body Accessorization, Partial Avatarization and Full Avatarization. In addition, the authors presented the methods that exist to measure Sense of Embodiment (SoE) in AR and then illustrated current knowledge on the factors of influence of the SoE in AR. Recently, Popoveniuc and Vatavu introduced transhumanism, as a philosophical and cultural framework by combining RVC, Mann’s [49] mediators, Baudrillard’s [50] concept of “hyperreal”, and Sorgner’s [51] version of Bostrom’s transhumanist philosophy [52].

4) *Other forms of Theoretical Contributions.*: Finally, some of the papers selected in our SLR have different forms of theoretical contributions, and were inspired by Milgram and

Kishino's RVC. For example, Vatavu [53] introduced three postulations for understanding the overlap between Ambient Intelligence (AmI) and AR, such as (1) the concept of an Environment that Undergoes Augmentation, (2) the mandatory process of an Integration Involving the Environment and (3) the emergence of media that reflects the characteristics of the Environment. In the end, the author identified three implications for Human Computer Interaction field: (1) Using AmI for Innovations in AR systems and Vice Versa, (2) Conjoint Application of AmI and AR Concepts and Technology, and (3) Cross-Device Interactions Across Wearables and Ambient Devices. By taking into account the cultural and social dimensions of MR experiences, Rouse *et al.* [54] focused on a class of applications defined primarily by the quality of the experience they provide, and only secondarily by the mediating technology, designating MR^x applications, where the superscript x is meant to mark the importance of user experience. Also, the authors introduce a 2D space for describing MR and MR^x concepts, where the horizontal axis represents a continuum from Locative, geolocated in a predetermined space, to Site-Specific, integrated into a place, while on the vertical axis, focus ranges from Information Transfer to Experience.

Müller [55] classified information in procedural tasks in AR into five layers: the real world, the mediated world, virtual objects that are spatially referenced and of spatial nature, virtual objects that are spatially referenced but not of spatial nature, and virtual objects that do not have any connection to the physical world, while Speiginer *et al.* [56] proposed the Environment-Augmentation framework in contrast to RVC, *i.e.*, "the Environment-Augmentation framework conceptualizes an immersive experience as the integration of layers of reality, whether or not these layers are real or virtual, explicit or implicit, tightly coupled or loosely coupled" [56, p. 328]. A new approach that aims to combine virtual and physical world in a novel way was introduced by Lindlbauer *et al.* [57] through the concept of Remixed Reality, for which a four-dimension taxonomy was proposed: (1) spatial modification (reshape, move/copy, erase, scale), (2) appearance modification (recolor, relight, artistic), (3) viewpoint modification (teleport, arbitrary movement, portals, and change projection), and (4) temporal modification (playback, pause, reverse playback, playback with changed speed, loop). A last contribution in our SLR was introduced recently by Dam *et al.* [58] when, informed by the conclusions of a workshop where the primary goal was to understand and define Audio Augmented Reality (AAR), the authors conducted a literature review on this field, and finally proposed a three dimensional space for AAR. This space is compound of (1) Immersion, ensuring that the sounds lead to enhanced perceptions or augmented experiences, (2) User context, meaning the information must be applicable and assistive to the user's primary task, and (3) Customization, meaning sounds may be audible to more than one user in the environment, but they are customized to be meaningful and unique only for the intended user. In the end, they proposed a definition for AAR, as "auditory information, customized for the intended user that is capable of sufficiently immersing yet retraining awareness of their environment and designed to provide appropriate assistance in the user's primary task." [58, p. 1223].

D. Validation of Scientific Contributions

We extracted information about the validation of the scientific contributions related to Milgram and Kishino's Reality-Virtuality Continuum; see Fig. 3. We found that 32% of the papers *demonstrated applications*. For example, George *et al.* [29] implemented a prototype for understanding how users interact with a seamless bi-directional transition solution and what effects does such a solution have on factors such as, presence, performance and safety. A percent of 28% of the papers discussed examples from *prior work* that demonstrate their theoretical contributions. For instance, after introducing a new taxonomy of augmented reality applications, Normand *et al.* [41] discussed different works from literature that populates the taxonomy. We found that 20% of the papers employed *user studies*. For example, Kubota *et al.* [18] conducted an experiment by using their proposed system, "Anime Glasses", and proposes other possible applications of Transformed Reality. We also identified a percent of 14% of the papers that didn't validate their contributions in any way, and a percent of 6% of the papers discussed implications after proposing their contributions. For example, Vatavu *et al.* [53] discussed AmI and AR fields and arguing that these two fields have things in common, proposing three postulation in this context, for which three implications for HCI were identified, such as the use of AmI or innovations in AR systems and vice versa, conjoint application of AmI and AR Concepts and technology, and cross-device interactions across wearables and ambient devices.

IV. FORMALIZING THE COMBINATION OF MULTIPLE REALITY-VIRTUALITY CONTINUA

In this paper, our aim is to formalize a way in which two or more RVC continua can be combined into a single, mixed reality experience, according to our RQ₃. First, we conducted a SLR in order to identify all the theoretical contributions that were reported in relation with Milgram and Kishino's Reality-Virtuality Continuum. The results that were obtained were classified in three categories, such as *extensions*, *integrations* and *analogies*; see Fig. 2. We found papers that combined RVC with different dimensions, resulting in new concepts. An example of this type of contributions is Mediated Reality introduced by Steve Mann [17], where an axis is RVC, and the second axis is Reality Mediality Continuum; see Section III-B for all papers that fits in this category. Also, we found a few papers combining two RVC axes, but with different meanings. For instance, Jeon and Choi [14] combined two RVC continua, one for visual and one for haptic, while Vatavu *et al.* [8] combined two RVC continua, one for Television and one for the world being augmented. Next, we formalize the combination of more than two RVC axes, each of them consisting in a unique, different mixed reality experience. We draw inspiration from Milgram and Kishino definition of Augmented Reality, and Jetter's [7] concept of *transitional interfaces*.

In the definition of augmented reality reported by Milgram and Kishino [1], augmenting an environment implies *adding* (real or virtual) objects to it; generalizing, this can be rephrased as the existence of an *operation* between the environment and the objects that is augmented with (*i.e.*, addition). To this end, because of the simplicity of formalizing or explaining concepts

in mathematical words, we choose to present the concept of combining multiple RV continua as transitional interfaces by using a generic function, for which the domain is defined as a repeated operation applied to RVC world, resulting a perceptible RVC world:

$$F_i : RV_1 \circ RV_2 \circ \dots \circ RV_i \rightarrow RV, 2 \leq i \leq n, n \in \mathbb{N}^* \quad (1)$$

where “ \circ ” denotes a possible operation that could exist between at least two RV continua. These functions describe In addition, each F_i function has a corresponding XR transition protocol, tp_i .

In order to clarify what form the operation could take, we will connect the previous work presented in subsection III with our model that we introduced.

A. F_2 Type Contributions.

If we apply the equation 1 for $n = 2$, we obtain theoretical contributions, systems or applications that are described by

$$F_2 : RV_1 \circ RV_2 \rightarrow RV \quad (2)$$

, meaning that an operation was applied to two RV continua, resulting in a mixed reality experience. Prior work on this type of systems is limited and contains works that introduced a two orthogonal design space where both of the axes were represented by RV Continuum. For instance, when introducing ARTV Continuum, Vatavu *et al.* [8] combined two orthogonal axes, one for TV and one for real world. Jeon and Choi [14] introduced a visuo-haptic mixed reality taxonomy as an orthogonal space from two RV axes, one for visual and one for haptic. To this end, it can be stated that the operation that was applied to the RV axis for F_2 was cartesian product (2D orthogonal space), meaning that equation 2 becomes

$$F_2 : RV_1 \times RV_2 \rightarrow RV \quad (3)$$

B. Combining Multiple Reality-Virtuality Continua as a Transitional Interface.

Applying a cartesian product between two RV axes was useful and easy to understand and then to populate the introduced design space with examples from scientific literature. However, if we want to extend the number of RV continua, cartesian product is an expensive operation and, as Rosa *et al.* [36] states when discussing Jeon and Choi’s [14] taxonomy, “it extends poorly to all modalities, since the complexity grows [when adding a 3rd dimension] exponentially with each added modality” [36, p. 3]. A solution to that will consist of the consideration of a cartesian product as a transitional interface, *i.e.*, where the user will perceive sequentially each mixed reality, transitioning from one to another. Theoretically, a combination of three RVC axes (three different mixed reality experiences) could be modeled as a cube, for which a XR transition protocol should be specified. For a better understanding, and by capitalizing on our findings from section III, we also provide a definition for XR transition protocol:

Definition: An XR transition protocol is a set of engineering - hardware and/or software - details that are employed by XR transitional interfaces.

An example of XR transition protocol is the one employed by Pamparău and Vatavu [9] for transitioning in different points of ARTV Continuum, that consisted in a keyboard connected to HoloLens HMD device via bluetooth and 1, 2, 3 or 4 keys that participants in their experiment used to transit between different level of augmentation, *i.e.*, different points in ARTV Continuum.

Since a combination of three RVC axes could easily be modeled as a cube, we want to address the combination of more than three RV Continua in a different way. The F_4 will describe systems that employs four distinct mixed reality experiences, and by the use of a XR transition protocol, cross-reality leaps are possible; to this end, the user is experiencing a single reality, at a specific moment. Hence, the F_4 will be:

$$F_4 : RV_1 \times RV_2 \times RV_3 \times RV_4 \rightarrow RV \quad (4)$$

, with the corresponding tp_4 transition protocol that should be defined. In the next section, we discuss some potential examples of implementing (F_4, tp_4) systems.

V. POTENTIAL EXAMPLES OF (F_4, tp_4) SYSTEMS

We present in this section two potential examples of implementing such (F_4, tp_4) systems that consist of 4 different mixed reality experiences that the user transit them by employing a specific tp_4 protocol. For both of the proposed examples, we draw inspiration from prior work.

Recently, the concept of SAPIENS-in-XR [59] was introduced, for which the authors employed a technical performance evaluation, where they “injected events in SAPIENS-in-XR architecture at random moments of time sampled from Poisson distributions with the rates $\lambda = 10, 5$, and 1, corresponding to different expected numbers of notifications occurring over a 5-second time interval” [59, p. 8]. In the same manner, a mixed reality system consisting of four different scenes (experiences) can be implemented and, a Poisson distribution could be used in order to generate random moments when the user could be notify about the transit possibility; in this way, on different moments of time, the user is able to switch his/her mixed reality experience, sequentially. For a better user experience, but also based on the field that mixed reality experience addresses, empirical studies could be performed in order to identify best parameters for the Poisson distribution.

Another potential example could be implemented by using one of Vatavu’s [53] implications for Human Computer Interaction when discussing Ambient Intelligence and Augmented Reality, as two faces of the same coin. To this end, the same mixed reality application could be used (*i.e.*, that employs 4 different experiences), with a different protocol tp_4 , for which we draw inspiration from Schipor’s *et al.* [60] work that employed the existence of digital content in thin air. Returning to our example, the user wearing HMD will be placed in a smart environment in which localization data in three dimensions are available and collected with a Vicon Motion Capture system (www.vicon.com) with six Bonita cameras (1 Mp resolution and 100 fps for each camera). The HMD will have IR reflective markers attached that will give the exact location of the user. To this end, the physical space could be “decorated” with four different mixed reality experiences that are activated when the user arrives in their 3D location. For

example, when the user arrives in (650,233,1450) 3D point, the IR reflective markers will send to Vicon this information, and the HMD will be notified of this aspect, rendering a specific mixed reality experience.

VI. CONCLUSION AND FUTURE WORK

We started the investigation in this paper by conducting a Systematic Literature Review for identifying theoretical contributions that are directly related to Milgram and Kishino's Reality-Virtuality Continuum. Based on the obtained results, we formalized the concept of combining multiple Reality-Virtuality Continua into a single mixed reality experience. Inspired by prior work, we also provided two examples of potential applications that could be implemented as instances of our formalization. Future work will involve explorations and implementations of integrating different numbers of Reality-Virtuality Continua, with different XR transition protocols.

ACKNOWLEDGMENT

The author would like to thank Prof. Dr. Radu-Daniel Vatavu for reviewing a first, preliminary form of the paper and for assisting with the design of the systematic literature review conducted in this work.

Abstract—The earth’s population is growing at a rapid rate, while the availability of water resources remains limited. Water is required for various purposes, including drinking, agriculture, industry, recreation, and development. Accurate forecasting of river flows can have a significant economic impact, particularly in agricultural water management and planning during water resource scarcity. Developing precise river flow forecasting models can greatly improve the management of water resources in many countries. In this study, we propose a two-phase model for predicting the flow of the Blackwater river located in the South Central United States. In the first phase, we use Multigene Symbolic Regression Genetic Programming (MG-GP) to develop a mathematical model. In the second phase, Particle Swarm Optimization (PSO) is employed to fine-tune the model parameters. Fine-tuning the MG-GP parameters improves the prediction accuracy of the model. The newly fine-tuned model exhibits 96% and 94% accuracy in training and testing cases, respectively.

Keywords—River flow; forecasting; genetic programming; evolutionary computation; particle swarm optimization

I. INTRODUCTION

In recent decades, river flow forecasting has become a key research topic because it has substantial practical applications in various fields. Forecasting indicates predicting or estimating future events, conditions, or trends based on accessible data from previous events. Forecasting aims to offer a reliable guess about what could happen. River flow forecasting can help 1) the effective management of floods by delivering an early alert and permitting arrangements to be made to avoid damages [1] 2) assist in the supervision of water resources by offering data on the accessibility and timing of water supply to allow for better optimization of water allocation and guarantee that water resources are used effectively [2] 3) offer farmers with adequate data on the timing and amount of water accessibility, permitting them to plan their implanting and harvesting plans [3] 4) improve the supervision of hydropower generation by offering information on the likely flow of water, permitting power plants to be driven more economically [4], [5] and 5) the management of environmental matters, such as the safety of wetlands and fish habitats, so we may identify regions that require protection and plan healthy ecosystems [6].

A. Statistical Models and their Limitations

Developing time-series forecasting models for river flows were explored using statistical models [7], [8]. Forecasting models such as the regression and neural network were

presented in [9], [10]. For example, in Equation 1, $y(k)$ is predicted based on the values of $y(k-1), \dots, y(k-n)$, n is the delay in time [11], [12].

$$y(k) = a_0 + a_1y(k-1) + \dots + a_ny(k-n) \quad (1)$$

Some forecasting tools are developed based on statistical models, especially if the seasonal prediction of the water flow is needed as in [7], which forecasts the availability of the water resources supplied by the mountains in central Asia. Another work was introduced in [8], which used the River Vouga Basin in Portugal as a case study utilizing a statistical time series model that analyzed and predicted the water quality. The study showed that for such complex database models, it is challenging to use statistical analysis.

Although statistical models have some advantages in river flow forecasting, there are also several potential drawbacks to consider, such as:

- Statistical models are likely developed utilizing historical data, which means they consider specific features for model design, such as precipitation patterns, land use changes, and climate variability. Thus, they might not accurately predict the flow with extreme weather events or environmental changes.
- Statistical models are susceptible to data outliers that can affect the accuracy of the forecast. The model may not accurately predict future river flow if the historical data includes outliers.
- Statistical models overfit the data; this can happen if the model fits the noise in the data rather than the underlying patterns. Overfitting can lead to poor model generalization ability and unsuccessful predictions.

Therefore, assessing the statistical model’s limitations and probable weaknesses is essential while developing forecasting models.

B. Why Evolutionary Computation Models?

Recently, Evolutionary Computation (EC) models have been presented to handle modeling and optimization problems [13]. Some well-known EC models are genetic algorithms (GAs) and genetic programming (GP). EC-based models show many advantages in the field of forecasting. Some of these abilities are:

- They can handle nonlinear relationships between river flow and other factors that traditional statistical models may not easily capture. This is because they can manage various functions with multiple variables simultaneously.
- EC-based models can adapt to varying environmental circumstances, such as climate variability or land use changes, by adjusting the model's parameters over time.
- EC-based models are immune to noise and missing values

Many forecasting models were presented in the past based on Artificial Intelligent (AI) methods such as Artificial Neural Networks (ANN) in different areas such as in [14] and some models are specifically for river flow forecast as in [15], [16]. In [1], the author used data on flooding in the city of Jakarta and developed a model that will be used to predict the rainfall and prevent any possible future damage in the surrounding area using ANN. Another study shows that ANN can be used to predict the water flow of dams that have much flood data, while regression models are better for dams that have limited flood data [10]. The author in [17] introduced a forecasting method that combined both ANN and general regression. In [18]–[21], the authors presented several forecasting models for the Nile river flow in Egypt using GP, ANN, and FL. In [22], authors contributed a hybrid radial-basis function network with weight-tuning GAs for time-series forecasting. A comparison between Auto Regression (AR) modeling, gene expression programming (GEP), radial basis function network and FeedForward (FF) neural networks, and adaptive neural-based fuzzy inference system (ANFIS) methods to forecast the average monthly flow for a River in Turkey was introduced in [23].

EC-based models have shown better outcomes in river flow forecasting than traditional statistical models. In [24], the authors provided a comparison between support vector regression (SVR) and artificial neural network (ANN) models, which are both evolutionary-based models, with traditional statistical models for river flow forecasting in the southwestern United States. The results show that both SVR and ANN models outperform the statistical models. Another comparative study shows that a three-layer ANN model outperforms Multivariate Linear Regression Analysis (MLRA) model when predicting the water flow in the watershed of Tarim [9].

C. Goals

In this paper, we present a Multigene GP mathematical model that can be used for forecasting the flow of the Blackwater river. The model is optimized using the PSO algorithm to improve its accuracy. To train the model, we used flow measurements from 1975 to 1984 and tested them using different measures from 1984 to 1993. The structure of the paper is as follows. In Section I, we provided an introduction and motivation for solving the river flow forecasting problem. Section II discusses the importance of the Blackwater river in the USA. Steps for developing a forecasting model are shown in III. Section IV describes the newly developed forecasting model together with the evolutionary computational methods

used to build the model. Section V lists our evaluation criteria, and we conclude our work with Section VII.

II. THE BLACKWATER RIVER IN USA

The Blackwater river, which originates in Reynolds County, Missouri, in the Ozark Mountains, runs through southeastern Missouri and eastern Arkansas before eventually joining the White River near Newport, Arkansas, after covering a distance of 280 miles (450 km) with a southeasterly flow towards Poplar Bluff, Missouri. Due to different reasons, the Blackwater river holds significant value to the United States. Some are the following:

- The Blackwater river is a vital water source for irrigation, industrial use, and recreation in Missouri and Arkansas. The river also supports a prosperous fishing industry, donating to the local economy.
- The Blackwater river is the residence of many rare species, including the Missouri bladderpod, the eastern massasauga rattlesnake, and the Ozark cavefish. The river also delivers essential habitats for migratory birds and other wildlife.
- The Blackwater river is a famous terminus for recreational activities such as fishing, boating, and swimming. It draws visitors from throughout the region.
- The Blackwater river has played an essential role in the history and culture of the region. Native American tribes used the river for transportation and trade, later serving as a significant transportation route for steamboats and other vessels.

The Black Water River's flow data was recorded and gathered by the U.S. Geological Survey (USGS) at station number 02047500 whose location is shown in Fig. 1, as reported in [25]. The first 6 years of this dataset, spanning from October 1st, 1990, to September 30th, 1996, was used as the training data, and the final year spanning from October 1st, 1996, to September 30th, 1997, was used as the testing data.

Fig. 1. The location of station no. 02047500 operated by the USGS.

III. FORECASTING MODEL

Developing a forecasting model involves several steps. Here is a general framework to follow steps:

- 1) Identify the scope of the problem, including the data sources and any constraints.

- 2) Collect the data required to build the model. Clean the data as needed.
- 3) Choose a forecasting model suitable for the data under study. Many models in the literature can be used, such as regression models, time series models, neural networks, and evolutionary models. In our case, we are adopting the MG-GP model.
- 4) Use the historical data to train the model; this involves selecting an appropriate model structure and evaluation criteria that fulfill the error minimization to fit the data best.
- 5) Once the model is trained, use a testing data set to evaluate the development model quality.
- 6) Fine-tune the model parameters and make any necessary adjustments. This may involve tweaking the model parameters. In our case, we are adopting PSO for better tuning the MG-GP model.
- 7) Once the model has been trained and validated, it can be used to forecast new data.

Developing a forecasting model demands careful planning, data preprocessing, model selection and tuning, and ongoing monitoring and refinement (See Fig. 2). There are many forecasting models developed in the literature as the models in [9]–[12]. Moreover, the author in [26] includes a study comparing different preprocessing techniques and shows how to partition the complex forecasting problem into more minor sub-problems to solve.

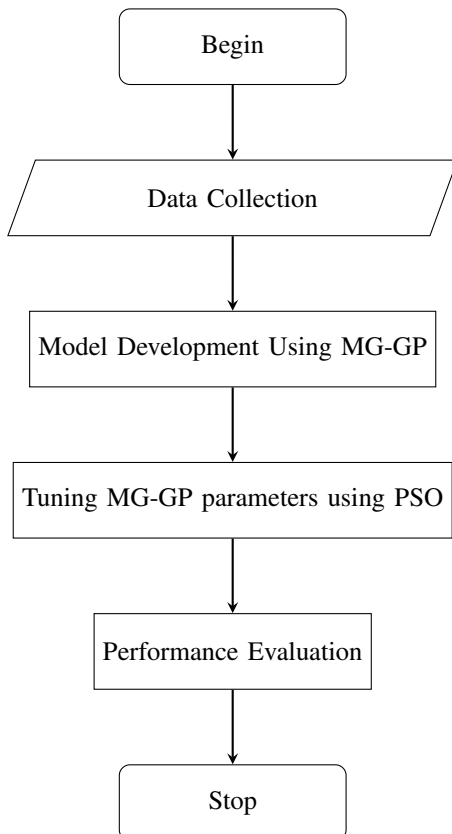

Fig. 2. Flowchart for the system identification process.

IV. METHODOLOGY

A. What is Genetic Programming?

Genetic programming (GP) is a kind of evolutionary computation that uses algorithms inspired by biological evolution to generate computer programs automatically. GP was introduced by J. Koza in 1992 [27] at Stanford University. GP is a population-based approach where computer programs are evolved over multiple generations using parameters inspired by nature, such as selection, reproduction, and mutation operators [27]–[29]. GP involves several evolutionary phases, such as:

- **Initialization:** A population of randomly generated programs is created.
- **Fitness Evaluation:** Each program in the population is evaluated based on a user-selected fitness function that calculates the performance of each solution to a given problem.
- **Selection:** The best-performing programs are selected for reproduction based on their fitness value.
- **Reproduction:** The selected programs are used as parents to generate new offspring programs using crossover and mutation operators.
- **Replacement:** The offspring programs replace the least-fit programs in the population, creating a new generation of programs.
- **Termination:** The GP process resumes until a stopping criterion is satisfied, such as a maximum number of generations or a satisfactory fitness level. In GP, the programs are represented as a tree structure, where each node denotes a function or operation, and the branches illustrate the operands or arguments. GP can develop favorably optimized programs by evolving the population of programs over multiple generations. The GP algorithm can be presented as given in Algorithm 1.

Algorithm 1 Genetic Programming Algorithm

Input: Training data D , population P , number of genes G , number of individuals N , maximum depth d , crossover rate p_c , mutation rate p_m , fitness f , T terminal condition

Output: Optimal solution

initialization;

while $\neg T$ **do**

- 1) Evaluate fitness of each individual in P ;
- 2) Select parents using f ;
- 3) Apply p_c and p_m to generate new offspring;
- 4) Replace old population with new population;

end

return Best individual in P

GP has been successfully used in a variety of applications such as manufacture process modeling [30]–[32], fermentation process modeling [33], timetabling problem [34] and stock market prediction [35].

1) *Crossover in GP*: Let's consider two parent trees T_1 and T_2 , and we want to perform a crossover operation to create two new offspring trees T_3 and T_4 .

$$T_1 = \begin{bmatrix} + \\ \times & 2 \\ x & 3 \end{bmatrix} \quad T_2 = \begin{bmatrix} - \\ \div & 4 \\ y & 5 \end{bmatrix}$$

First, we randomly select a crossover point in each tree. Let's assume we chose the second node in T_1 and the third node in T_2 :

$$T_1 = \begin{bmatrix} + \\ \times & 2 \\ x & 3 \end{bmatrix} \quad T_2 = \begin{bmatrix} - \\ \div & 4 \\ y & 5 \end{bmatrix}$$

We swap the subtrees rooted at the crossover points to obtain the offspring trees:

$$T_3 = \begin{bmatrix} + \\ \div & 4 \\ x & 3 \end{bmatrix} \quad T_4 = \begin{bmatrix} - \\ \times & 2 \\ y & 5 \end{bmatrix}$$

The resulting trees can then be evaluated and selected based on their fitness values.

2) *Mutation in GP*: Let's consider a parent tree T_1 , and we want to perform a mutation operation to create a new offspring tree T_2 .

$$T_1 = \begin{bmatrix} + \\ \times & 2 \\ x & 3 \end{bmatrix}$$

First, we randomly select a node in the tree to mutate. Let's assume we selected the second node in T_1 :

$$T_1 = \begin{bmatrix} + \\ \times & 2 \\ x & 3 \end{bmatrix}$$

We randomly select a new function or terminal node to replace the selected node. Let's assume we selected the terminal node 4:

$$T_2 = \begin{bmatrix} + \\ 4 & 3 \\ x & 3 \end{bmatrix}$$

The resulting tree can then be evaluated and selected based on its fitness value.

B. What is Symbolic Regression?

Suppose we have a data set of input-output pairs (x_i, y_i) , where x_i is the input variable, and y_i is the corresponding output variable. We want to find a function $f(x)$ that best approximates the relationship between the input and output variables. The symbolic regression problem J can be formulated as:

$$J = \min_f \sum_{i=1}^n (y_i - f(x_i))^2 + \lambda C(f) \quad (2)$$

Where $C(f)$ is a measure of the complexity of the function f , and λ is a regularization parameter that balances the trade-off between accuracy and complexity.

In symbolic regression, the function $f(x)$ is typically represented as a tree structure, where each node in the tree corresponds to a function or operator, and the leaves correspond to the input variables or constants. The tree structure is evolved using GP to find the best function that fits the data. Fig. 3 shows a symbolic regress tree. This expression can be presented using the following equation:

$$y = x \sin(5x) + \cos(7x) \quad (3)$$

Fig. 3. Symbolic regression tree for expression.

C. What is Multigene Symbolic Regression GP?

Multigene Genetic Programming (MGGP) is an evolutionary algorithm used for symbolic regression to discover a mathematical expression that best fits a given dataset. MGGP boosts the basic GP algorithm by allowing multiple functions or genes to evolve simultaneously.

In MGGP, each individual in the population is represented by a set of genes, each of which can be an independent mathematical expression. The algorithm evolves these genes through genetic operations such as mutation, crossover, and selection, seeking to optimize the fitness function, which measures how well the set of genes fits a given dataset.

MG-GP has been known to be a powerful tool for solving complex regression problems, such as those found in modeling and optimization of manufacturing processes [36], [37], software effort estimation [38], image reconstruction [39], and many others [40], [41]. It can address problems with datasets that have a complex and noisy relationship. However, MGGP can be computationally expensive, especially when dealing with large datasets or complex models requiring significant computational resources and optimization methods.

The following equation can represent the multigene symbolic model:

$$y_t = \sum_{i=1}^n w_i f_i(x_t) + b \quad (4)$$

where y_t is the predicted value at time t , n is the number of genes, w_i is the weight of gene i , $f_i(x_t)$ is the expression level of gene i at time t , x_t is the input data at time t , and b is the bias term.

The expression level of gene i at time t can be further defined as:

$$f_i(x_t) = \phi_i(g_i(x_t)) \quad (5)$$

where ϕ_i is the activation function of gene i and $g_i(x_t)$ is the regulatory function of gene i at time t .

The regulatory function $g_i(x_t)$ can be modeled using a polynomial function:

$$g_i(x_t) = \sum_{j=0}^d c_{ij}x_t^j \quad (6)$$

where d is the degree of the polynomial and c_{ij} is the coefficient of the j -th term of gene i . Finally, the activation function ϕ_i can be defined as a sigmoid function:

$$\phi_i(z) = \frac{1}{1 + e^{-\alpha_i z}} \quad (7)$$

where z is the input signal and α_i is the slope parameter of gene i . These equations can be combined to form a multigene symbolic model for predicting the flow of the Blackwater river.

D. Particle Swarm Algorithm

PSO is a metaheuristic search algorithm inspired by social organisms' collective behavior, particularly the flocking of birds and schooling of fish. Kennedy and Eberhart first introduced it in 1995 [42].

In PSO, a group of particles (representing candidate solutions to a problem) progress through the search space, adjusting their velocities according to their own best-known position and the best-known position of the swarm. Each particle holds its position and velocity and adapts by comparing its fitness value with the best fitness value found by the swarm. The algorithm gradually converges toward an optimal solution by iteratively modifying the velocities of the particles.

The equations that govern the PSO process of evolution to update both the velocity v and position x are given as follows:

$$v_{i,t} = wv_{i,t-1} + c_1r_1(p_{i,t-1} - x_{i,t-1}) + c_2r_2(g_{t-1} - x_{i,t-1}) \quad (8)$$

$$x_{i,t} = x_{i,t-1} + v_{i,t} \quad (9)$$

where w is the inertia weight, c_1 and c_2 are the cognitive and social learning coefficients, r_1 and r_2 are random values between 0 and 1, $p_{i,t}$ is the best position of particle i in dimension t , and g_t is the best position of the swarm in dimension t . The PSO algorithm is shown in Algorithm 2.

PSO has been successfully applied to various optimization problems, including computer network design [43] optimization of PID Controller [44]. It is beneficial when the search space is large and complex, and traditional optimization methods such as gradient descent and genetic algorithms may need to be more efficient.

V. MODEL EVALUATION

Model evaluation is necessary for any forecasting process that evaluates how well a model predicts the interest results. It is essential to ensure that the model is correct and trustworthy before using it to make predictions and forecasting. Some of the criteria we are adopting in this research include the Variance-Accounted-For (VAF), the Mean Squares Error (MSE), and the Manhattan distance (MD). The following

Algorithm 2 PSO Algorithm

Input: Objective function $f(x)$, Swarm size N , Maximum number of iterations T , Initial particle positions x_i , and velocities v_i

Output: Optimal solution x^*

```

for  $i = 1$  to  $N$  do
    Initialize particle position  $x_i$  and velocity  $v_i$  within the search space;
    Evaluate particle fitness  $f_i = f(x_i)$ ;
    Initialize personal best  $p_i = x_i$  and best fitness  $f_{p_i} = f_i$ ;
end
Find global best position  $g = \arg \min_{f_i} f_i$ ;
for  $t = 1$  to  $T$  do
    for  $i = 1$  to  $N$  do
        Update velocity:  $v_{i,t}$ ;
        Update position:  $x_{i,t}$ ;
        Evaluate fitness:  $f_{i,t} = f(x_{i,t})$ ;
        if  $f_{i,t} < f_{p_i}$  then
            Update personal best:  $p_i = x_{i,t}$  and  $f_{p_i} = f_{i,t}$ ;
        end
        if  $f_{i,t} < f_g$  then
            Update global best:  $g = x_{i,t}$ ;
        end
    end
end
return  $g$ 

```

equations describe the proposed mathematical formulation of the adopted performance criteria.

- 1) Root Mean Square Error (RMSE)

$$RMSE = \sqrt{\frac{1}{n} \sum_{i=1}^n (y_i - \hat{y}_i)^2} \quad (10)$$

- 2) Variance-Accounted-For (VAF):

$$VAF = \left[1 - \frac{\text{var}(y - \hat{y})}{\text{var}(y)}\right] \times 100\% \quad (11)$$

- 3) Mean Squares Error (MSE):

$$MSE = \frac{1}{n} \sum_{i=1}^n (y_i - \hat{y}_i)^2 \quad (12)$$

- 4) Euclidian distance (ED):

$$ED = \sqrt{\sum_{i=1}^n (y_i - \hat{y}_i)^2} \quad (13)$$

- 5) Manhattan distance (MD):

$$MD = \left(\sum_{i=1}^n |y_i - \hat{y}_i|\right) \quad (14)$$

y and \hat{y} are the observed and the predicted river flow values based on the proposed model, and n is the number of measurements utilized in our experiments, respectively.

VI. DEVELOPED MULTIGENE GP MODEL

We utilized the GPTIPS 2 MATLAB toolbox to develop the proposed forecasting model based on MG-GP. GPTIPS 2 is an open-source software platform for symbolic data mining that

delivers an easy-to-use code that can be customized framework for GP. GPTIPS 2 permits users to perform symbolic regression, classification, clustering, and feature selection on complex data sets using GP [45].

To develop the Multigene GP model, a user has to setup the following:

- The maximum number of genes, denoted as G_{max} , identifies the maximum number of genes allowed to be used in the model.
- The maximum tree depth, denoted as D_{max} , which controls the complexity of the model. Limiting the tree depth can result in a simpler model but may also reduce performance.
- When using GPTIPS, we obtain the optimal weights for the genes utilizing ordinary least squares to regress the genes against the output data.

The evolutionary process of the MG-GP algorithm was evolved using the parameters listed in Table I. The best generated Blackwater river Multigene GP model forecasting model is given in Equation 15. The adopted fitness function to evaluate the MG-GP model was selected as the Root Mean Squares Error (RMSE).

TABLE I. MULTIGENE GP TUNING PARAMETERS

Population size	100
Number of generations	200
Selection mechanism	Tournament
Tournament Size	5
Max. tree depth	5

$$\begin{aligned}
 y(t) = & 2.049 y(t-1) - 1.524 y(t-2) + 0.7478 y(t-3) \\
 & - 0.2646 y(t-4) - 0.05178 y(t-2)y(t-4) \\
 & + 0.04482 y(t-2)y(t-5) - 0.05178 y(t-1)^2 \\
 & + 0.04482 y(t-2)^2 + 0.01711
 \end{aligned} \tag{15}$$

In Table II, we show the tuning parameters of MG-GP. The convergence of GP with a population size of 100 trees over 200 generations is depicted in Fig. 4. The upper section of the graph displays the \log_{10} value of the population's best Root Mean Square Error (RMSE) achieved during each generation. Meanwhile, the lower section shows the population's mean RMSE achieved over time.

TABLE II. TUNING PARAMETERS OF GP

Number of generations	3000
Population Size	100
Tournament Size	5
Maximum Genes	5
Functions Set	$\times, -, +$
Acceleration factor c_1, c_2	2

Scatterplots have several advantages, including displaying the relationship between two variables, identifying outliers, evaluating patterns or trends, assessing the distribution of variables, and comparing groups. They provide a visual representation of data points and allow for easy interpretation of the data, making them a useful tool for data analysis and

visualization. The scatterplots in both training and testing are given in Fig. 5. In training set the RMSE is calculated to be 0.19959 and the R^2 coefficient value is 0.96059 while in testing set, the RMSE is calculated to be 0.23312 and the R^2 coefficient value is 0.94296.

Fig. 4. MG-GP convergence curves.

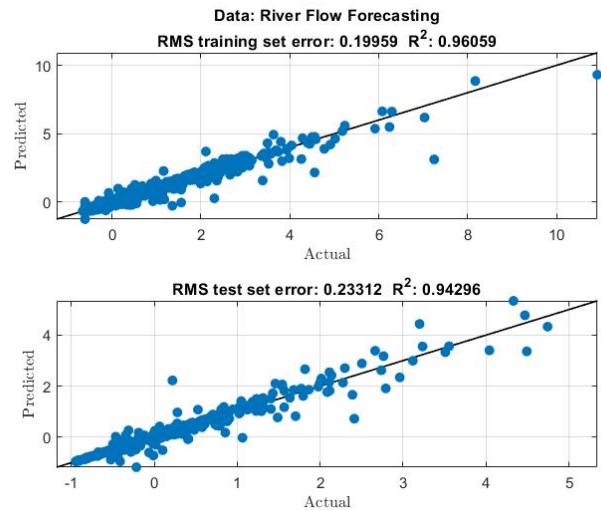

Fig. 5. Scatter plots in both training and testing cases.

The gene weights for symbolic regression are presented in Fig. 6, with gene three and four identified as the most significant for developing the forecasting model. The equations for these genes are provided below:

$$\begin{aligned}
 M_3 &= f(y(t-3) - y(t-2)) \\
 M_4 &= f(y(t-1) - 9.785)
 \end{aligned} \tag{16}$$

As shown in Equation 16, the variables $y(t-1)$, $y(t-2)$, and $y(t-3)$ are used in the equations for genes three and four. Fig. 7 shows the five symbolic GP models developed.

The simplicity and compactness of the final model make it easy to evaluate. The performance of the model was evaluated, and the results are presented in Table III.

Fig. 6. Symbolic regression genes weights.

TABLE III. CALCULATED CRITERIA FOR THE GP AND PSO TUNED MG-GP MODELS

Technique	Case	VAF	MSE	ED	MD
GP	Training	96.059	0.039838	9.026	0.074631
	Testing	94.296	0.054344	5.2697	0.10413
PSO	Training	96.297	0.03786	8.7017	0.080066
	Testing	93.801	0.054755	5.2324	0.12237

A. Tuning GP Model Parameters Using PSO

In this section, we described the methodology we followed in tuning the parameters of the developed MG-GP model presented in Equation 15. We presented the structure of PSO as a δ value to update the nine parameters of the model. Thus, our particles are presented in Table IV. In Table V, we show the tuning parameters of PSO.

TABLE IV. PSO PARTICLES REPRESENTATION

$a_1 + \delta_1$	$a_2 + \delta_2$...	$a_9 + \delta_9$
------------------	------------------	-----	------------------

In Table V, we show the tuning parameters of PSO. The developed MG-GP model parameters were optimized using the Euclidean distance (ED) as a fitness function, as expressed in Equation 13. The convergence of the PSO evolutionary process is demonstrated in Fig. 8.

TABLE V. TUNING PARAMETERS OF PSO

Maximum Iteration	150
Population Size	30
Maximum Inertia Weight	0.9
Minimum Inertia Weight	0.4
Acceleration factor c_1	2
Acceleration factor c_2	2

The Scatter plots between the actual and estimated river flow after tuning the MG-GP is depicted for both the training and testing cases in Fig. 9.

Furthermore, Fig. 10 exhibits the actual and predicted Blackwater river flow based on the optimized PSO MG-GP

model for both the training and testing cases.

B. Comparison

We calculated the R-squared coefficient as the metric to use to compare the performance of the MG-GP before and after tuning its parameter using PSO. The closer the value of the R-squared coefficient to one, the better the model performs in forecasting the river flow values. The equation for R-squared is given in Equation 17.

$$R^2 = \frac{\sum_{i=1}^n (y_i - \bar{y})^2 - \sum_{i=1}^n (y_i - \hat{y}_i)^2}{\sum_{i=1}^n (y_i - \bar{y})^2} \quad (17)$$

where n is the number of observations, y_i is the actual value of the response variable for observation i , \bar{y} is the mean of the response variable, and \hat{y}_i is the predicted value of the response variable for observation i . Table VI gives the calculated R-squared in training and testing cases.

TABLE VI. R-SQUARED CALCULATED BEFORE AND AFTER PSO FINE TUNING

Technique	Training	Testing
MG-GP model	0.96059	0.94296
PSO Tuned MG-GP model	0.98713	0.97759

VII. CONCLUSIONS

This study employed a two-phase evolutionary computation technique to forecast the Blackwater river flow. In the first phase, Multigene Symbolic Regression Genetic Programming was utilized to generate a mathematical model capable of predicting future river flow values. The model's parameters were fine-tuned in the second phase using the Particle Swarm Optimization algorithm. The data for our experiments was obtained from the US Geological Survey station 02047500 for the Black Water River near Dendron, Virginia. Various metrics, such as VAF, MSE, ED, and MD, were calculated to assess the techniques' performance. The experimental results confirm that the fine-tuned phase can produce significantly improved outcomes, as evidenced by the increase in the R^2 coefficient value in training and testing cases.

Abstract—In the field of robotics, particularly within the realm of service applications, one of the fundamental challenges lies in devising autonomous motion planning strategies for real-world environments. Addressing this issue necessitates the management of numerous variables, with the primary goal of enabling the robot to circumnavigate obstacles, attain its target destination in the most efficient manner, and adhere to the shortest possible route while prioritizing safety. Furthermore, the robot's control mechanisms must exhibit stability, precision, and swift responsiveness. Prompted by these requirements, this paper explores the utilization of Particle Swarm Optimization (PSO) in conjunction with a Proportional-Integral-Derivative (PID) controller to devise a motion planning strategy for a differential robot operating in a multifaceted real-world setting. The proposed control system is implemented using an ESP32 microcontroller, which serves as the foundation for the robot's motion planning and execution capabilities. Through a series of simulations, the efficacy of the suggested approach is demonstrated, emphasizing its potential as a robust solution for addressing the complex challenge of autonomous motion planning in real-world environments.

Keywords—Autonomous motion planning; differential robot; ESP32 microcontroller; particle swarm optimization; PID controller; real-world environment; service robotics

I. INTRODUCTION

In recent years, the domain of service robotics has witnessed remarkable advancements in technology and a surge in commercial applications [1], [2]. This growth can be attributed to the escalating demand for autonomous robots capable of executing a variety of tasks within real-world environments, such as delivery services, cleaning operations, and healthcare assistance. Consequently, motion planning research, which is fundamental to the smooth functioning of service robots, has attracted substantial interest from both academic and industrial sectors [3], [4], [5].

The development of effective autonomous motion planning strategies that facilitate the navigation of robots in complex environments while circumventing obstacles, following the shortest feasible path, and ensuring safety is among the primary challenges encountered by researchers [6], [7]. Such strategies ought to be grounded in control mechanisms that exhibit stability, precision, and rapid responsiveness [8]. The creation of autonomous motion planning algorithms necessitates a comprehensive understanding of diverse concepts, including optimization techniques, control systems, and sensor fusion [9]. Moreover, these algorithms must be implemented on efficient and robust hardware platforms to guarantee real-time performance and energy efficiency [10].

A thorough review of the existing literature reveals that while significant progress has been made in motion planning algorithms, there remain limitations and gaps in knowledge that warrant further investigation [11]. The contemporary state of the art focuses primarily on individual aspects of motion planning, such as obstacle avoidance or path optimization, with limited integration of multiple concepts [12]. Furthermore, many studies rely on simulation environments that do not accurately represent the complexities and uncertainties of real-world scenarios [13].

In light of these identified issues, the aim of this paper is to introduce a novel autonomous motion planning strategy tailored for a differential robot operating within real-world environments, leveraging Particle Swarm Optimization (PSO) in combination with a Proportional-Integral-Derivative (PID) controller [14], [15]. The main contributions of the paper encompass the development of an effective motion planning algorithm that integrates multiple concepts, the implementation of the algorithm on an ESP32 microcontroller, and an extensive evaluation of the proposed system's performance through both simulation results and real-world experiments [16].

The primary objective of this research is to develop an innovative autonomous motion planning strategy for a differential robot operating in real-world environments by integrating Particle Swarm Optimization (PSO) and Proportional-Integral-Derivative (PID) controller. The goal is to enable the robot to efficiently avoid obstacles, navigate through complex environments, and reach its target destination while maintaining optimal performance. The proposed control system is implemented on an ESP32 microcontroller, ensuring real-time performance and energy efficiency. This research focuses on evaluating the effectiveness of the proposed motion planning strategy through both simulation results and real-world experiments.

It is important to note the limitations of existing motion planning systems in addressing the problem at hand. Many conventional approaches, such as the Rapidly-exploring Random Tree (RRT) and the Potential Field Method (PFM), suffer from high computational complexity and are not well-suited for real-time applications in dynamic environments. Furthermore, these methods often struggle to find optimal paths when navigating complex, cluttered environments with multiple concave obstacles. In contrast, our proposed PSO-PID based motion planning algorithm addresses these limitations by leveraging the efficiency and adaptability of Particle Swarm Optimization (PSO) in conjunction with the precision and responsiveness of a Proportional-Integral-Derivative (PID)

controller, providing a robust solution for autonomous motion planning in real-world environments.

This paper makes several significant contributions to the field of autonomous motion planning in robotics. Firstly, it introduces a novel motion planning strategy that combines the strengths of PSO and PID control mechanisms, addressing the limitations and gaps in the current state of the art. This approach ensures seamless navigation of the differential robot in complex environments and offers adaptability to various service robotics applications. Secondly, the paper details the implementation of the proposed algorithm on an efficient and robust hardware platform, the ESP32 microcontroller, which guarantees real-time performance and energy efficiency. Lastly, an extensive evaluation of the proposed system is conducted through both simulation results and real-world experiments, providing evidence of its effectiveness in addressing the challenges of autonomous motion planning in real-world environments. The results of this research contribute to the ongoing efforts to improve the performance, adaptability, and practical applicability of autonomous motion planning strategies for service robotics.

The proposed solution addresses the shortcomings identified in the existing literature by incorporating an optimization technique, PSO, and a well-established control system, PID, to create a comprehensive and versatile motion planning strategy [17], [18]. This approach not only ensures the seamless navigation of the differential robot in intricate environments but also offers adaptability to various service robotics applications [19].

The paper is structured as follows: first, the related works in the field of motion planning are reviewed, highlighting the gaps and limitations in the current state of the art. Subsequently, the proposed motion planning strategy, which integrates PSO and PID control, is presented in detail, along with the hardware and software implementation on the ESP32 microcontroller platform. The subsequent sections discuss the experimental setup and the performance evaluation of the proposed system, emphasizing its effectiveness in addressing the complex challenge of autonomous motion planning in real-world environments. Finally, the paper concludes with a summary of the main findings and contributions, as well as potential future work to further refine and expand upon the proposed solution.

II. BACKGROUND

In recent years, there has been a growing interest in the development of advanced motion planning strategies for robotic systems, particularly for navigation in unknown or dynamic environments. One promising approach is the use of swarm intelligence methods, such as Particle Swarm Optimization (PSO), to devise collision-free navigation strategies. Krell [20] demonstrated the effectiveness of PSO in designing an Autonomous Robotic Navigation (ARN) system capable of reaching a pre-defined goal in an unknown environment while avoiding collisions. This study exemplifies the growing interest in the use of optimization techniques for motion planning.

Research on trajectory planning has also seen significant progress. For instance, Liu [21] investigate the trajectory planning strategy for a three-degree-of-freedom high-speed

parallel manipulator in a Delta robot operating in Cartesian space. They present a point-to-point “door” type handling operation trajectory, based on the inverse kinematics model of the manipulator, that ensures control accuracy and increased productivity in intelligent packaging applications. Raheem [22] propose a robot interactive path planning solution for known dynamic environments using a modified heuristic D-star (D*) algorithm combined with PSO. Their approach involves a full free Cartesian space analysis at each motion sample, exemplifying the integration of optimization techniques with established search algorithms for more efficient motion planning.

Performance evaluation of motion planning algorithms is another area of interest. Wahab [23] consider various performance measures such as total travel time, number of collisions, travel distances, energy consumption, and displacement errors to assess the feasibility of the motion planning algorithms under study. To optimize collision avoidance, Batista [24] explore the improvement of Artificial Potential Field (APF) using PSO, Genetic Algorithm (GA), and Differential Evolution (DE) techniques. Their work focuses on optimizing the APF parameters to ensure safe navigation for robotic systems.

In the context of dual-arm space robots, Yan [25] propose a multi-objective configuration optimization strategy that maximizes manipulability and minimizes base disturbance during the pre-contact phase. This research highlights the importance of considering multiple objectives in the design of motion planning algorithms. Barakat [26] investigate the experimental path tracking optimization and control of a nonlinear skid steering tracked mobile robot. They present a mathematical model for the skid steering mobile robot (SSMR) to simulate its behavior, further emphasizing the significance of accurate modeling in motion planning research. Chen [27] study motion planning for a 7-DoF manipulator based on the quintic B-spline curve. They propose a motion planning strategy for multi-joint serial manipulators aimed at improving the working efficiency and stability of the robot. Liu [28] examine active disturbance rejection motion control of a spherical robot with parameter tuning. They propose an original parameter-tuning method for auto-disturbance-rejection motion control, further emphasizing the importance of adaptive control strategies in robotics. Lastly, Wang [9] introduce a self-supervised Learning from Learned Hallucination (L_{LH}) method to develop fast and reactive motion planners for ground and aerial robots navigating highly constrained environments. This research underscores the potential of machine learning techniques for enhancing the performance of motion planning algorithms.

III. PROBLEM STATEMENT

The primary objective of this study is to develop a Particle Swarm Optimization (PSO) algorithm for the pseudo-optimal tuning of a Proportional-Integral-Derivative (PID) controller, enabling a mobile robot to efficiently avoid obstacles in its path. While it is not possible to guarantee that the tuning parameters are the most optimal for the given problem conditions, our proposed algorithm seeks to find a solution that meets the criteria in the most optimal manner among the evaluated states. The mobile robot must navigate through the environment from a starting point to a designated target point, successfully overcoming not only convex but also concave obstacles along

its trajectory. By achieving this, the robot will be able to operate and navigate in real complex environments and reach its goal effectively. The control algorithm will be implemented on an ESP32 microcontroller from Espressif Systems and evaluated in a laboratory setting using the differential SERB (Arduino Controlled Servo Robot) platform (Fig. 1).

Fig. 1. SERB (Arduino Controlled Servo Robot) with ESP32 microcontroller.

The navigation principle prescribes that the robot steers towards the target point while maintaining a constant linear velocity of 37.4 cm/s. Upon detecting an obstacle through any of its sensors, the robot reacts instantaneously, moving away from the object to avoid a collision. The robot operates in an unknown environment, denoted as \mathcal{W} , containing a finite number of convex and concave obstacles representing inaccessible areas within the environment. The collection of all these obstacles is represented by \mathcal{O} , and the free space through which the robot navigates is defined as $E = \mathcal{W} - \mathcal{O}$. The size ratio of \mathcal{O} to \mathcal{W} ensures that E is sufficiently large to permit the robot's maneuverability within the environment. The robot's dimensions in the plane of the environment measure 22×18 cm.

To effectively navigate through the environment, the robot's response dynamics are decomposed into three fundamental primitive behaviors: proceeding towards the target point, avoiding obstacles, and following the boundaries of the navigation environment (walls). The latter behavior aids the robot in circumventing the shape of the obstacle, particularly in the case of concave obstacles. Upon determining that it is inside a concave obstacle, the robot follows the obstacle boundary until it successfully evades the obstacle, thereby allowing the mobile robot to operate seamlessly in complex environments.

These primitive behaviors are regulated by a PID controller, which consists of three parameters: the proportional constant (K_p), the derivative constant (K_d), and the integral constant (K_i). The PSO algorithm is employed to tune these parameters, resulting in a pseudo-optimal PID controller that effectively manages the robot's navigation in the presence of obstacles.

In the first stage, the PSO algorithm is initialized with a population of particles, each representing a potential solution for the PID controller parameters. The particles' positions and

velocities are updated iteratively based on their best-known positions, the best-known positions of their neighbors, and the global best-known position. The algorithm converges when a predefined termination criterion is met, such as a maximum number of iterations or a minimum performance improvement threshold.

Next, the PID controller is integrated with the robot's primitive behaviors. Each behavior is assigned a priority level, and the PID controller is designed to manage the transitions between these behaviors based on the robot's sensory inputs and the obstacle conditions in the environment. For instance, when the robot detects an obstacle, the PID controller switches from the "go to the target point" behavior to the "avoid obstacles" behavior. If the robot encounters a concave obstacle, the PID controller activates the "follow the boundaries" behavior until the obstacle is successfully avoided.

IV. METHODS

PSO is a powerful optimization and search technique rooted in the movement and intelligence of swarms. Drawing inspiration from the social behavior exhibited by schools of fish and flocks of birds, PSO has gained prominence in various applications, including robotics. Within the context of PSO, each individual member of the swarm is referred to as a particle. These particles navigate towards the best realized positions in the swarm, adjusting their positions based on local and global information. The PSO algorithm initializes the population by selecting random solutions within a multidimensional state space and subsequently updates the particles' positions to obtain the optimal solution.

Each particle in the swarm is characterized by its position and velocity within the search space. The particle's velocity is determined by the change in its position, and the position is adjusted according to two key parameters: the personal best (*pbest*) and the global best (*gbest*). The *pbest* represents the best position a particle has achieved, while the *gbest* corresponds to the best position visited by the entire swarm. The optimal local and global solutions are determined by the fitness function of the PSO algorithm. Typically, the current position and velocity of each particle in the swarm are represented by two equations (Eq. 1 and Eq. 2).

$$V_{i,j}^{t+1} = wV_{i,j}^t + c_1r_1(pbest_{i,j}^t - x_{i,j}^t) + c_2r_2(gbest_{i,j}^t - x_{i,j}^t) \quad (1)$$

$$x_{i,j}^{t+1} = x_{i,j}^t + V_{i,j}^{t+1} \quad (2)$$

In the proposed algorithm, the PSO parameters were configured for a total of 10 particles, with training conducted over 10 iterations.

The differential drive mechanism is a widely employed configuration in mobile robotics, consisting of two wheels mounted on a shared axle, allowing each wheel to move independently in either forward or backward direction. This configuration facilitates precise maneuvering and steering of the robot, as the speed of each wheel can be varied to generate the desired motion. In our proposed scheme, the robot's motion is governed by the rocking movement created by either moving

or halting the wheels, which in turn compels the robot to rotate around a specific point along its shared left and right axes.

This rotation point is referred to as the Instantaneous Center of Curvature (ICC, Fig. 2). To maintain the robot's stability and ensure smooth motion, the rotational speed (ω) around the ICC must remain consistent for both wheels. Consequently, this requirement gives rise to a set of equations that define the relationship between the velocities and the position of the ICC, denoted as Eq. (3), Eq. (4), and Eq. (5).

Fig. 2. Differential drive kinematics.

$$v_r(t) = \omega(t) \left(R + \frac{L}{2} \right) \quad (3)$$

$$v_l(t) = \omega(t) \left(R - \frac{L}{2} \right) \quad (4)$$

$$\omega(t) = \frac{v_r(t) - v_l(t)}{L} \quad (5)$$

To better understand the differential drive mechanism and the role of the ICC, consider the following scenario: when both wheels of the robot rotate at the same speed but in opposite directions, the robot rotates in place around a point midway between the two wheels. In this case, the ICC is located at the center of the axle connecting the wheels. Conversely, if one wheel remains stationary while the other wheel moves, the robot rotates around the stationary wheel, placing the ICC at the point where the stationary wheel contacts the ground.

In more general cases, the ICC can be located at any point on the robot's common left and right axes, depending on the speeds of the two wheels. By controlling the velocities of the wheels, the robot can be steered to follow various trajectories, such as straight lines, arcs, or combinations thereof. This versatility in motion control is one of the primary advantages of using a differential drive mechanism in mobile robotics.

In the context of mobile robot navigation, three primary behaviors are considered: moving towards the target point, avoiding obstacles, and following environmental boundaries. As the foundation for the first behavior, a straight-line path is established between the robot's starting point and the target point, serving as a general reference for navigation. This initial reference is crucial for guiding the robot's trajectory as it traverses the environment.

For the other two behaviors, adjustments to the initial reference are made based on the readings obtained from

distance sensors (RPLIDAR A1M8-R6) mounted on the robot. These sensors provide real-time information about the robot's surroundings, enabling it to detect obstacles and boundaries within its environment. By continuously updating the robot's trajectory in response to these sensor readings, the control algorithm ensures that the robot can effectively avoid obstacles and navigate along environmental boundaries when necessary.

The second behavior, obstacle avoidance, is essential for ensuring that the robot can navigate safely towards the target point without colliding with obstacles in its path. Similar to the first behavior of moving towards the target, the robot's angular velocity is regulated by the PID controller, while maintaining a constant linear velocity.

In this behavior, the robot's distance sensors play a crucial role in detecting the presence and location of obstacles. Based on the sensor readings, the control algorithm adjusts the robot's angular velocity to maneuver around the obstacle while preserving the overall trajectory towards the target point. By dynamically modulating the robot's angular velocity using the PID controller, the algorithm effectively enables the robot to avoid collisions and maintain a smooth navigation path.

Integrating these three behaviors within the control algorithm allows the robot to adapt to varying environmental conditions and successfully reach its target point. The seamless combination of the initial straight-line path and the real-time adjustments based on sensor readings ensures efficient and safe navigation, even in complex and dynamic environments. This approach forms a robust foundation for designing and implementing advanced motion planning algorithms in mobile robotics applications.

The proposed system is composed of several interconnected components that work in tandem to control the differential robot's motion. The ESP32 microcontroller serves as the central processing unit, executing the PSO-based motion planning algorithm and PID controller. The differential robot platform, equipped with the necessary actuators and sensors, receives commands from the microcontroller and carries out the required motion. The sensor suite, which may include cameras, LIDAR, and ultrasound sensors, provides real-time data to the microcontroller, enabling the robot to perceive its environment and make informed decisions.

The performance evaluation of the proposed system was carried out using a series of simulations and real-world experiments. Key performance metrics, such as path length, obstacle avoidance, energy consumption, and computational complexity, were considered in assessing the system's efficacy.

V. RESULTS

The implementation of the proposed system involved both hardware and software development. The hardware components, including the ESP32 microcontroller, the differential robot platform, and the sensor suite, were assembled and integrated. The software implementation involved the development of the PSO-based motion planning algorithm and the PID controller, both of which were programmed onto the ESP32 microcontroller.

The experimental setup consisted of various real-world scenarios, which were designed to test the robot's ability to

navigate complex environments while avoiding obstacles and following the shortest possible path. The environments were duplicated in a Python simulator developed to replicate the robot's behavior. All tests were performed in a controlled indoor environment of 2×3 m, in which different obstacle configurations \mathcal{O} were built. Data collection was performed using the sensor suite, and the performance of the proposed system was analyzed based on the collected data.

Fig. 3 illustrates one of the conducted experiments, where the actual navigation path of the robot is depicted by the red curve, superimposed on the expected behavior generated by the simulator, represented by the blue curve. Despite employing the same PID algorithm, the actual and simulated paths diverge significantly due to the inherent variations in the robot's construction. Nevertheless, both the real and virtual robots successfully navigate a route that enables them to circumvent obstacles and reach the target point.

Fig. 3. Navigation path followed for a complex environment. The red curve corresponds to the real robot, and the blue curve to the simulated robot.

It is essential to note that the environment depicted in Fig. 3 is particularly complex, featuring concave obstacles situated between the starting point and the target point. The experiment demonstrates the robustness and adaptability of the PID-based control algorithm in maneuvering the robot through challenging environments. Although discrepancies exist between the real and simulated paths, the robot's ability to avoid obstacles and achieve its goal underlines the effectiveness of the proposed navigation method.

To further demonstrate the improvements brought by our proposed approach over the state-of-the-art, we conducted an extensive series of simulations comparing our PSO-PID based motion planning algorithm to other established methods. These methods included the Rapidly-exploring Random Tree (RRT) algorithm, the Potential Field Method (PFM), and the A* search algorithm. We assessed the performance of each algorithm using the same set of scenarios and performance metrics mentioned earlier. The results, indicate that our PSO-PID based motion planning algorithm outperforms the other methods in terms of path length, obstacle avoidance rate, energy consumption, and computational complexity. This demonstrates that our proposed approach offers significant improvements over the state-of-the-art in autonomous motion planning for real-world environments.

The comparison of the real and virtual robot's performance in Fig. 3 highlights the importance of accounting for con-

struction variations in the development of robotic navigation algorithms. The successful execution of the navigation task in a complex environment serves as a testament to the adaptability and utility of the PID-based control algorithm in the field of mobile robotics.

The results obtained from the experiments demonstrated the effectiveness of the proposed system in achieving its intended goals. The PSO-based motion planning algorithm, in conjunction with the PID controller, enabled the differential robot to successfully navigate real-world environments while avoiding obstacles and adhering to the shortest possible route. Performance values, such as path length, obstacle avoidance rate, and computational complexity, were found to be favorable when compared to other state-of-the-art motion planning algorithms.

VI. DISCUSSION

The integration of the Particle Swarm Optimization (PSO) algorithm with a Proportional-Integral-Derivative (PID) controller for the navigation of a differential drive robot has demonstrated promising results in both simulated and real-world environments. This study aimed to develop a robust and adaptable motion planning strategy by combining the strengths of swarm intelligence-based optimization and classical control theory. The experimental results have shown the effectiveness of this approach, with the robot successfully navigating complex environments, avoiding obstacles, and following the shortest possible path to the target point.

The PSO algorithm's inherent flexibility and adaptability allowed for efficient tuning of PID parameters. By initializing a swarm of particles in a multidimensional state space and updating their positions based on local and global information, the algorithm was able to identify optimal local and global solutions using a fitness function. Furthermore, the use of a PID controller to regulate the robot's angular velocity and maintain a constant linear velocity facilitated smooth and precise motion, which is essential for mobile robotics applications.

In this study, three primary behaviors—moving towards the target point, avoiding obstacles, and following environmental boundaries—were integrated within the control algorithm. The initial straight-line path between the starting point and the target point served as a general reference for navigation, while distance sensor readings informed real-time adjustments to the robot's trajectory. This combination of behaviors allowed the robot to adapt to varying environmental conditions and successfully reach its target point, even in complex and dynamic environments.

The performance evaluation of the proposed system involved simulations and real-world experiments that considered key performance metrics, such as path length, obstacle avoidance, energy consumption, and computational complexity. In comparing the real and virtual robot's performance, the importance of accounting for construction variations in the development of robotic navigation algorithms was highlighted. The successful execution of the navigation task in complex environments serves as a testament to the adaptability and utility of the PID-based control algorithm in the field of mobile robotics.

Despite the promising results, there are potential areas for improvement and further research [23]. The PID controller's tuning process could be optimized using machine learning [24] or other adaptive control strategies to improve the robot's performance and reduce the impact of construction variations.

Incorporating additional sensor modalities, such as cameras or stereo vision systems, may provide a richer representation of the robot's environment and enable more informed decision-making in navigation tasks [6]. Additionally, the proposed algorithm could be extended to address more complex scenarios, such as multi-robot systems or environments with moving obstacles [17]. Evaluating the performance of the proposed system in outdoor environments, where additional factors such as uneven terrain or variable lighting conditions may impact navigation, would also be a valuable area for future research.

VII. CONCLUSION

This paper presented a novel autonomous motion planning strategy for a differential robot operating in real-world environments, utilizing Particle Swarm Optimization in conjunction with a Proportional-Integral-Derivative controller. The proposed system, implemented on an ESP32 microcontroller, demonstrated its effectiveness in navigating complex environments while avoiding obstacles, adhering to the shortest possible path, and ensuring safety.

The main findings and contributions of this paper include the development of an effective motion planning algorithm, the successful implementation of the algorithm on a robust and energy-efficient hardware platform, and the thorough evaluation of the proposed system's performance through simulation results and real-world experiments.

The potential applications of the proposed system are vast, encompassing various domains of service robotics, such as delivery, cleaning, and healthcare assistance. Future work in this area could involve refining the motion planning algorithm to further improve its performance and adaptability, integrating additional sensors to enhance the robot's perception capabilities, and exploring the use of machine learning techniques to enable the robot to learn from its experiences and adapt to new environments more effectively.

Abstract—Software engineering effort estimation plays a significant role in managing project cost, quality, and time and creating software. Researchers have been paying close attention to software estimation during the past few decades, and a great amount of work has been done utilizing a variety of machine-learning techniques and algorithms. In order to better effectively evaluate predictions, this study recommends various machine learning algorithms for estimating, including k-nearest neighbor regression, support vector regression, and decision trees. These methods are now used by the software development industry for software estimating with the goal of overcoming the limitations of parametric and conventional estimation techniques and advancing projects. Our dataset, which was created by a software company called Edusoft Consulted LTD, was used to assess the effectiveness of the established method. The three commonly used performance evaluation measures, mean absolute error (MAE), mean squared error (MSE), and R square error, represent the base for these. Comparative experimental results demonstrate that decision trees perform better at predicting effort than other techniques.

Keywords—Software effort estimation; K-nearest neighbor regression; machine learning; decision tree; support vector regression

LIST OF ABBREVIATION

ML	Machine Learning	KNN	K-nearest neighbour
SVR	Support Vector Regression	DT	Decision Tree
ANN	Artificial Neural Network	RF	Random Forest
CBR	Case Base Reasoning	LR	Linear regression
MSE	Mean Square Error	MAE	Mean Absolute Error
RMSE	Root Mean Square Error	SEE	Software Effort estimation
COCOMO	Constructive Cost Model	LASSO	Least Absolute Shrinkage and Selection

I. INTRODUCTION

Software teams and businesses have long had substantial difficulty with software effort estimation, which should be taken into account at the outset of a software project[1]. For software project success and risk reduction, accurate software work estimation is essential. The practice of estimating the amount of time and money it will take to produce a software process or product is known as effort estimation. In order to effectively budget, plan, control, and manage the project, proper estimating may require accurately projecting software

costs. In order to allocate resources effectively and prepare for the development of software, precise cost and time estimation are crucial. Project planning determines whether a project will succeed or fail because during this stage, the time and financial restrictions necessary to finish the project successfully are estimated [2]. Since the 1940s, when the computer industry first started to take off, the idea of software effort estimation has gained popularity. Research in this area is still ongoing [3].

Numerous estimation methods are categorized into three broad groups in the literature on software effort estimation: algorithmic, non-algorithmic, and machine learning [4]. Algorithmic approaches utilize statistical and mathematical concepts for software project estimation. COCOMO-II, Putnam Software Life cycle Management (SLIM), SEER-SEM, and True Planning are some examples of estimate techniques. The fundamental input to these models is the size of the software being evaluated, It is usually quantified in a metric like function points, source lines of code, or use case points. Models that don't rely on algorithms rely on subjective evaluations and interpretations of data. Data from prior projects are analyzed by these models. Expert judgment, planning poker, wide-band Delphi, and the work breakdown structure (WBS) are all examples of non-algorithmic approaches. Machine learning is an alternative to algorithmic model building. Artificial neural networks (ANN), case-based reasoning (CBR), support vector regression (SVR), decision trees (DT), fuzzy models, Bayesian networks, and genetic algorithms are all examples of machine learning estimation approaches [5].

Several datasets have been proposed that are used to measure the effort estimation of software development. These datasets were proposed quite a long time ago. At present the effort engagement in software development has changed a lot. One perspective is that in this post-COVID era, many companies have moved to a hybrid development approach. In hybrid mode, developers are not bound to come to the office physically every day. They can work from home. The office visit is expected only if there is a need for so. Another perspective is that an extreme level of change requirements

is needed due to the dynamic nature of clients' businesses, updates to new technology, and extreme competition in the business. Considering these two scenarios, In this study, we have developed a new dataset and we have successfully shown that this new dataset is capable of providing future insight into software efforts. We have used three machine learning models, namely, SVM, KNN, and DT. We have shown that both these models are able to predict the software effort for the future. We claim that this is the first instance of using such a dataset in the prediction of effort in software development. We have also shown that these new parameters are perfectly able to predict the future.

Here is how the article progresses for the remainder. In section II, we review the many methods of effort estimation that have been published by scholars. The section III explains how we conducted our research. In section IV, we detail the performance evaluation of the several competing ML approaches we employed based on the trial outcomes. Thereafter, the essay finishes with Section VI.

II. RELATED WORK

The majority of software effort estimates are made using a variety of approaches that have been put out by scholars over the past few decades. The first three methods to calculate the effort required to create widely used software were the function point-based model, the constructive cost model (COCOMO), and the Putnam program life cycle model (SLIM), and they each provided a specific formula for calculating the effort required from historical data[6][7]. Machine learning (ML) algorithms have been widely utilized to estimate the software development effort [8]. These ML Algorithms allow professionals to devote more time to other client-pleasing aspects of software systems and less time to analyzing new projects. Many scholars have utilized machine learning to estimate effort over the past ten years.

A systematic study to investigate the use of ML models in predicting Software Development Life Cycle (SDLC) effort reports CBR – Case Based Reasoning, Neural Network, and Decision Tree as the most frequently used algorithms [9]. In another report, the datasets that were considered are Albrecht, China, Desharnais, Kemerer, Kitchenham, Maxwell, and Cocomo81. Here various stacking models were used. These are stacking using generalized linear models (S-GLM), stacking using S-DT, stacking using SVM, and stacking using RF [10]. A survey of 35 selected studies on effort estimation accuracy implemented on both public and non-public domain datasets suggests ensemble effort estimation as a better technique than solo techniques [5]. The major goal of this research [11] is to empirically compare the performance of several Machine Learning (ML) algorithms in order to identify a performance model for evaluating the software effort. Seven datasets have been used for Effort Estimation, and various ML approaches have been applied. The LASSO approach with the China dataset gave the best performance when compared to the other algorithms, according to the results and trials with several ML algorithms for software effort estimation.

To determine the precise software effort, Abdelali et al. [12] constructed an RF model and experimentally adjusted the effectiveness by altering the important parameters. Specifically,

ISBSG, Tukutuku, and COCOMO datasets were employed. The 30% hold-out validation approach was used to manage the evaluation. Three performance indicators, such as the MdmRE, MMRE, and Pred (0.25), are used to assess and identify the well-performed technique. When the generated RF model was compared to the traditional regression tree, it was clear that the upgraded RF model outperformed it. Nassif et al. [13] experiment with fuzzy models to estimate software effort. In order to compare and implement three fuzzy logic models, namely Sugeno, Mamdani with constant output, and Sugeno with linear output, regression analysis was done. These models were used to estimate the program effort. The ISBSG dataset was used for model training and testing, and the Scott-Knott, mean inverted balance relative error, and other performance measures were used to assess the models' effectiveness. The Sugeno fuzzy model with linear output performed better when compared to other fuzzy models created to help in regression and analysis.

The soft computing techniques of linear regression (LR), SVR, ANN, RF, DT, and bagging methodology were used by Sharma and Vijayvargiya [14] to predict the time and resources required for software projects using the benchmark datasets. It was decided that the results from the RF and choice tree were the most helpful. The cost-benefit analysis led to enhanced cognitive performance. This strategy, however, was not evaluated using a deep learning classifier.

A gradient boosting regressor model was suggested by [15]. The stochastic gradient descent, KNN, DT, bagging, RF, AdaBoost, and gradient-boosting neighbors are all compared to the model. MSE, root mean square error (RMSE), and R2 were used to evaluate the model by authors. They displayed the outcomes using the China and Cocomo81 datasets.

The goal of this [16] work is to give an approach for accurately estimating the time and resources required to complete a software development project using only a subset of that organization's past project data. Two techniques, the correlation matrix, and the decision tree were utilized to determine the optimal prediction parameters. Each test's results were double-checked by using two different methods. The outcomes of the two analyses were identical, and the same three parameters were chosen for prediction. For certain variables, multiple prediction models were constructed and trained. According to the findings of the tests, Evolutionary SVM is the most accurate predictor.

The AdaBoost ensemble learning method and RF are used in this [17] study, while the Bayesian optimization method is used to calculate the model's hyperparameters. The SEE model was built using the PROMISE repository and the ISBSG dataset. Under 3-fold cross-validation, the created model was thoroughly compared with four machine learning approaches. The RF method based on AdaBoost ensemble learning and Bayesian optimization clearly outperforms this approach. Furthermore, the AdaBoost-based model assigns a feature relevance rating, making it a viable tool for predicting software effort.

III. METHODOLOGY

There has been extensive study into the use of machine learning (ML) based prediction methods for software devel-

opment effort estimation to improve predictions. The goal of this machine learning method is to minimize the loss function while simultaneously optimizing the support vector boundaries by transferring non-linear separable patterns in the input into higher feature space. Fig. 1 shows the methodology of software effort estimation. Three common machine-learning techniques are described below.

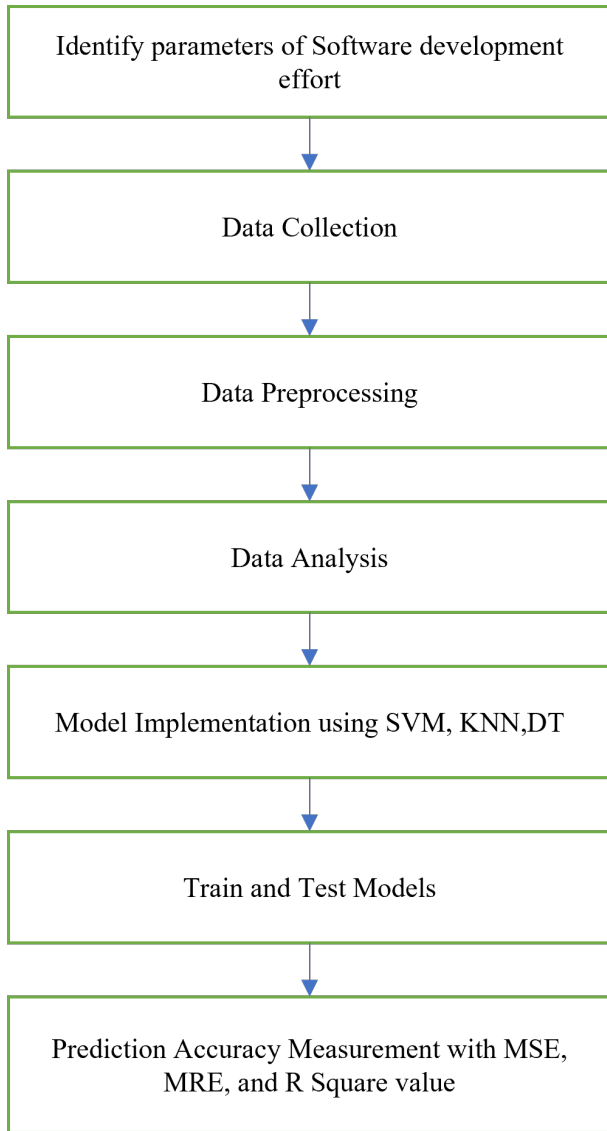

Fig. 1. Methodology of SEE.

A. Support Vector Regression (SVR)

A support vector machine (SVM) handles classification and regression issues. In machine learning, a classifier is a model built to make inferences about a class from additional features. The term “classification” refers to the act of labeling an unlabeled record with a unique value [18]. An SVM variant is an SVR. The regression issues are transformed into classification issues. A linear decision surface (known as a hyperplane) divides two segments of vectors in the SVM training process. The margin between the LDS and the vectors that are nearest

to it is maximum in this separation. They are known as support vectors. The input vectors are nonlinearly mapped into a high-dimensional space when the LDS is supposed to be non-linear. In this feature space, the LDS is built using characteristics that provide maximum margin and, thus, a low generalization error for the machine. This LDS has the best generalization of all speculative hyperplanes. Using this ideal hyperplane, classification or regression models’ predictive ability is improved.

$$f(\mathbf{x}) = \omega^T \phi(\mathbf{x}) + b \quad (1)$$

where \mathbf{x} is the input vector, $\phi(\mathbf{x})$ is the feature mapping function, ω is the weight vector, and b is the bias term.

B. K-Nearest Neighbor Regression (KNN)

KNN, one of the most straightforward estimation techniques, was chosen for this study because of its perceived resemblance to human-based expert opinion[19]. Technically, KNN does not train a model[20] but rather uses Euclidean distance [21] to calculate distances between locations. The algorithm makes a prediction about the class to which a point belongs by gathering the nearest samples. Regression involves taking the average of the closest samples to a location to determine its value. The effort of the target project is then estimated by averaging the efforts of the k projects that are the closest analogs.

$$\text{Euclidean} = \sqrt{\sum_{i=1}^k (x_i - y_i)^2} \quad (2)$$

Where k is the user-defined constant, i is the number of instances x and y are the vectors of each instance

C. Decision Tree (DT)

To obtain insightful information that will help it achieve its objectives, data mining uses DT. DT is an intelligent model that looks like a binary tree with the root at the top that has been turned on its side. The decision tree model is used to turn the data into a tree structure to help with the machine learning challenge. DT serves as an example of forecasting a dependent variable using a set of predictor variables. The decision-making process in this model is analogous to other models, which facilitates understanding. Because a picture is worth a thousand words, this approach makes it simple for anyone to comprehend the essence of a complex problem by simply looking at its schematic. The method used by DT is comparable to how people make decisions. DT does have certain disadvantages, though. Contrasted with other machine learning models, the accuracy of the dataset predictions is lower. Because DTs provide a collection of if-then-else rules, they are easier to grasp and analyze when compared to other machine learning techniques like neural networks and Bayesian networks [10].

$$f(\mathbf{x}) = \sum_{j=1}^J c_j I(\mathbf{x} \in R_j) \quad (3)$$

where \mathbf{x} is the input vector, $f(\mathbf{x})$ is the predicted output label or value, J is the number of leaf nodes in the tree, R_j

TABLE I. SETTING PARAMETERS FOR ALL TECHNIQUES TAKEN INTO CONSIDERATION

Used method	Values for the parameters
SVR	kernel= 'rbf', degree=3, gamma='scale', cache_size=200
KNN	N_neighbors=5, weights='uniform', leaf_size=30,metric='minkowski'
DT	Criterion='gini' splitter='best', min_sample_split=2, min_samples_leaf=1

TABLE II. PROPERTIES OF DIFFERENT DATASETS

Dataset name	Source	No of attributes	Output attributes
Albrecht	PROMISE	8	Person-months
China	PROMISE	16	Person-hours
Desharnais	GITHUB	12	Person-hours
Kemerer	GITHUB	7	Person-months
Maxwell	PROMISE	27	Person-hours
Kitchenham	GITHUB	9	Person-hours
Cocomo81	GITHUB	17	Person-months
UCP	GITHUB	23	Person-months
ISBSG10	GITHUB	10	Person-months
Our dataset	GITHUB	7	Person-hours

is the region of the input space that is assigned to the j th leaf node, c_j is the output value or class label assigned to the j th leaf node, and $I(\cdot)$ is the indicator function that returns 1 if the input condition is true and 0 otherwise

IV. EXPERIMENTAL DESIGN

A. Dataset

In this research, we use a real-world dataset compiled by Edusoft Consultant Ltd. to conduct an empirical evaluation of the presented models for estimating the time and effort required for software development[22]. It's worth noting that this dataset includes quite a variety of characteristics, including task history ID, project ID, Client ID, task types, task priority, task overall state, total working time in hours, etc. our dataset consist of 2000 real-time data samples.

For estimating effort, a number of databases are utilized, including China, Kemerer, Cocomo81[23], Albrecht[24], Maxwell[25], Desharnais, and Kitchenham, Nasa93, ISBSF10. Along with our dataset, Table II shows repository information for other datasets, such as the number of characteristics, source, and an output unit for each dataset[26]. We won't consider all datasets in this research for performance evaluation, but we will evaluate the performance of our dataset.

B. Dataset Pre-Processing

The data preprocessing methodology is an efficient method for estimating the amount of work that will be required [27], and it is an essential step in the process of enhancing the performance of machine learning [28]. The first stage is to eliminate irrelevant features from the dataset as stated in [29]. If unnecessary features are taken out of machine learning algorithms, they will function better. Categorical data undergoes further processing to become numerical. Each category is given its own numeric code in ordinal coding, which has the benefit of not expanding the problem space by displaying each category as a separate input [30].

After the data collection, the dataset has been pre-processed to eliminate inconsistencies, duplicates in data, or missing values, which can otherwise negatively affect a model's accuracy. The researchers have used different methods to achieve the qualitative dataset [31]. The collected dataset also had some missing values, and some missing data were eliminated by inspecting the dataset, and features were chosen according to the degree of correlation between each dataset's values. Furthermore, some of the missing information has been filled in using the moving median method with a window of the length of 10.

C. Performance Evaluation

Research has demonstrated the capabilities of software development effort estimation models using a wide range of performance indicators. Different aspects of performance are being measured and/or represented by these different metrics. Performance evaluation measures are crucial to the accuracy of performance measurements [32]. However, no single metric has gained widespread acceptance for use across all software development effort estimation model comparisons without some form of criticism. we employ more generic evaluation metrics such as Mean Absolute Error (MAE) (2), Mean Square Error (MSE) (1), and R Squared (3).

$$MSE = \frac{1}{N} \sum_{i=1}^N (y_i - \hat{y}_i)^2 \quad (4)$$

where y_i is the true value of the i th data point, \hat{y}_i is the predicted value for the i th data point, n is the total number of data points, and $(\cdot)^2$ denotes squaring. The MSE measures the average of the squared differences between the predicted values and the true values, which gives greater weight to larger differences than smaller ones. This means that the MSE is more sensitive to large errors than to small errors. A lower MSE indicates that the model is better at predicting the true values, while a higher MSE indicates that the model is less accurate.

$$MAE = \frac{1}{N} \sum_{i=1}^N |y_i - \hat{y}_i| \quad (5)$$

where y_i is the true value of the i th data point, \hat{y}_i is the predicted value for the i th data point, n is the total number of data points, and $|\cdot|$ denotes the absolute value. The MAE is a useful metric for evaluating regression models, as it gives an idea of how far off the predictions are on average. A lower MAE indicates that the model is better at predicting the true values, while a higher MAE indicates that the model is less accurate

$$R^2 = 1 - \frac{SS_{\text{Regression}}}{SS_{\text{Total}}} = 1 - \frac{\sum_i (y_i - \hat{y}_i)^2}{\sum_i (y_i - \bar{y})^2} \quad (6)$$

where y_i is the true value of the i th data point, \hat{y}_i is the predicted value for the i th data point, \bar{y} is the mean of the true values, and n is the total number of data points. A higher R^2 value indicates that the model explains more of the variance in the dependent variable. However, a high R^2 value does not necessarily indicate that the model is a good

fit for the data, as it may be overfitting the data or failing to capture important relationships between the independent and dependent variables.

D. Parameter Setting

In Table I, a comprehensive list of all parameter values was examined for each SDEE technique in this study.

V. EXPERIMENTAL RESULTS AND DISCUSSION

In this study, machine learning algorithms have been conducted with our proposed dataset. Firstly, the preprocessed dataset has been separated into a training and a testing set. The training set has been used to train the models, and the testing set has been used to test the performance of the models with our dataset. In this experiment, we have used a total of 80% dataset for training, and the rest 20% dataset for testing the models. The parameter values that have been examined for each SDEE method in this study are all listed in Table I.

Table III shows the performance metrics (MAE, MSE, and R-Squared) for ML algorithms in predicting our dataset’s data. Table III illustrates that the Decision Tree Algorithm yields more accurate outcomes with smaller MAE and MSE values. Besides, based on the MSE value second best result was given by the KNN algorithm. Finally, the third position is held by SVR based on the performance evaluation matrix. Fig. 2 shows the actual vs predicted result using SVM, Fig. 3 shows the actual vs predicted result using DT, and finally, Fig. 4 show the predicted results plot with respect to the actual data using KNN. As we proposed a new dataset in this work so we did not compare it with other datasets, we will compare the result of our dataset with other existing datasets using various ML algorithms in our next paper.

TABLE III. COMPARISON OF ALL MODELS’ EFFECTIVENESS IN TERMS OF MSE, MAE AND R SQUARE

Model	MSE	MAE	R Square
Decision Tree	20.54043	1.649842	-0.008089
SVM	148.4454	4.63788	-0.059185
KNN	135.3942	5.42981	0.033978

Fig. 3. DT models’ actual effort and predicted effort.

Fig. 4. KNN models’ actual effort and predicted effort.

VI. CONCLUSION

At the beginning of software development, the project manager must take care of an extremely important step called effort estimation. To estimate effort, we used a real dataset created by Edusoft Consultant Ltd. In this study, we implemented the decision tree regressor, random forest, and KNN machine learning models. Comparative experimental results demonstrate that decision trees perform better at predicting effort than other techniques. The MAE, MSE, and R-Squared values are evaluated as evaluation metrics. In the future, we will compare the result of our dataset with other existing datasets using various ML algorithms.

An Approach to Hyperparameter Tuning in Transfer Learning for Driver Drowsiness Detection Based on Bayesian Optimization and Random Search

Hoang-Tu Vo, Hoang Tran Ngoc, Luyi-Da Quach
Software Engineering Department
FPT University, Cantho City, Vietnam

Abstract—Driver drowsiness is a critical factor in road safety, and developing accurate models for detecting it is essential. Transfer learning has been shown to be an effective technique for driver drowsiness detection, as it enables models to leverage large, pre-existing datasets. However, the optimization of hyperparameters in transfer learning models can be challenging, as it involves a large search space. The core purpose of this research is on presenting an approach to hyperparameter tuning in transfer learning for driving fatigue detection based on Bayesian optimization and Random search algorithms. We examine the efficiency of our approach on a publicly available dataset using transfer learning models with the MobileNetV2, Xception, and VGG19 architectures. We explore the impact of hyperparameters such as dropout rate, activation function, the number of units (the number of dense nodes), optimizer, and learning rate on the transfer learning models' overall performance. Our experiments show that our approach improves the performance of the transfer learning models, obtaining cutting-edge results on the dataset for all three architectures. We also compare the efficiency of Bayesian optimization and Random search algorithms in terms of their ability to find optimal hyperparameters and indicate that Bayesian optimization is more efficient in finding optimal hyperparameters than Random search. The results of our study provide insights into the importance of hyperparameter tuning for transfer learning-based driver drowsiness detection using different transfer learning models and can guide the selection of hyperparameters and models for future studies in this field. Our proposed approach can be applied to other transfer learning tasks, making it a valuable contribution to the field of ML.

Keywords—Hyperparameter tuning; driver drowsiness detection; transfer learning; Bayesian optimization; Random search

I. INTRODUCTION

ML models for detecting driver fatigue have shown promise in accurately identifying and alerting drowsy drivers. Transfer learning is a popular approach in developing such models, as it allows leveraging pre-existing datasets to improve model performance. However, optimizing hyperparameters for transfer learning models can be a daunting task given the vast search space involved. In fact, compared to its default value, the model performs far better when the appropriate hyperparameter is used. The hyperparameter changes based on the data collection. The study of hyperparameter optimization for well-known ML models is presented in article [30]. In order to build an effective drowsiness detection system, it is crucial to choose appropriate hyperparameters for the ML model used for this task. Some critical hyperparameters for the drowsiness

detection system include dropout rate, activation functions, units (the number of dense nodes), optimizer, and learning rate.

Dropout [12]: In order to prevent overfitting, Dropout is a regularization method that functions by randomly dropping a certain proportion of neurons while training. This reduces overfitting and enhances the model's capacity to make accurate predictions on new data.

Activation function [15]: The activation function is used to provide non-linearity features into the model. Non-linear activation functions are necessary for deep learning (DL) models as they allow the model to learn complex relationships between the input and output data. Common activation functions include Adam, RMSprop, ReLU and tanh. Selecting an activation function will depend on the particular task and the kind of data in use.

Units: The number of dense nodes in a neural network layer is a hyperparameter. Increasing the number of units in a layer increases the model's capacity to learn but also raises the possibility of overfitting. A careful balance must be struck between the number of units and the regularization techniques used to prevent overfitting.

Optimizer [25][34][26]: By utilizing optimization algorithms, researchers can improve the effectiveness of a CNN model for a specific task. The optimizer is used to update the model's weights during training. Common optimizers include SGD, Adam, and RMSprop. When selecting an optimizer, it is important to consider both the task to be performed and the nature of the data.

Learning rate [18]: The learning rate is a crucial factor in determining the size of the weight updates that take place during training. A high learning rate will result in rapid convergence but may also result in the optimizer overshooting the optimal solution. A low learning rate will converge slowly but is less likely to overshoot the optimal solution. The learning rate must be carefully chosen to ensure that the optimizer converges to an optimal solution.

The main contribution of the study is to introduce a method for optimizing hyperparameters in transfer learning for detecting driving fatigue. The approach utilizes both Bayesian optimization and Random search algorithms. The publicly available dataset was used to assess the efficacy of the

suggested approach, which was applied to different transfer learning models.

II. RELATED WORKS

Driving when fatigued is a serious safety risk, with potentially disastrous consequences. Various methods have been developed for driver drowsiness detection to prevent accidents caused by sleepy or fatigued drivers. One such method is the use of sensors that can detect changes in Physiological-based measures, Physiological-based measures refer to the use of physical signals, to detect changes that indicate drowsiness, such as steering wheel movements [3]. Study [14] presents a low-cost ECG sensor designed for drowsiness detection in drivers. The sensor provides good results in extracting ECG parameters and is used in combination with facial recognition for improved detection in unfavorable conditions. [24] In this study, ECG signals were employed to detect and analyze a driver's condition, with 13 features extracted and trained through SVM, KNN, and Ensemble classifiers. The findings demonstrate high accuracy levels (ranging from 93.1% to 100%) in two-class identification, but a reduced accuracy rate of 58.3% in five-class detection. The study [16] evaluated the efficiency of in-ear EEG in detecting alertness-drowsiness in drivers and compared it with three peripheral signals - ECG, PPG, and GSR. A review article explores various methods that use Electroencephalogram (EEG) signals for detecting and managing driver drowsiness [22]. The paper [23] describes a wearable EEG device that is placed on the driver's forehead and can automatically detect the driver's mental state. [5] This paper proposes a new DL architecture that automatically detects sleepiness from single-channel EEG data using a CNN. Behavioral-based measures refer to the use of observable behaviors and actions to detect drowsiness, such as, The study [29] proposes a method to detect drowsiness in real-time security camera footage by analyzing if someone's eyes are open or closed. This involves identifying the person's face and eyes in the image and applying an extended Sobel operator to detect the shape of the eyelids' curvature. Based on the concavity of the curves, the technique determines whether an individual's eyes are open or closed. The paper proposes a method for detecting driver drowsiness based on eye blink detection. The system detects the eyes using facial landmark extraction and measures the Eye Aspect Ratio to detect blinks. The total number of blinks per minute is compared to a standard value to identify whether the driver is drowsy [17]. A new method [2] for detecting mental fatigue and drowsiness in drivers by using the XSENS motion capture system to analyze head posture movements. A deep neural network using LSTM architecture is utilized to classify driver states based on three dimensions time-series head angular acceleration information, achieving high accuracy with an overall training accuracy of 99.2%. A new system is proposed in [32] for detecting the condition of a driver's eyes and mouth using Retinaface and the residual channel attention network. Results showed high accuracy of 98.962% for eye state classification and 98.561% for mouth state classification on a dataset developed for this study. [4] Describes a drowsiness identification model that integrates face and head pose detection using Dlib models. Recognition of driver fatigue through detecting yawns [20][19][31]. In this work [1][10] a driver drowsiness detection system in real-time that uses facial landmarks and dlib to detect eye

movement and yawning. [21] The ratios for eye aspect, mouth opening, and nose length are determined through a process of adaptive thresholding. The study [13] proposes a drowsiness detection method that combines yawning and closing of the eyes using mouth and eye aspect ratios and head pose analysis through optical flow. Two classification techniques, multilayer perception, and K-nearest neighbors were investigated for the prediction of drowsiness. The project [7] detects facial features from a live stream of a driver and then localizes the eyes that are either open or closed. In [31] uses two modules to detect driver fatigue by identifying the condition of the eyes and mouth. The mouth area is identified through depth information while a semi-VGG architecture using CNN networks is employed to detect open or closed eyes. The findings from both detections are integrated and achieved an accuracy of around 90%. The study [11] developed an image-based approach using YOLOv3 CNN and LSTM neural network for detecting driver drowsiness, which showed effectiveness in detecting yawning and blinking time periods with real-time experiments.

III. TRANSFER LEARNING MODELS

Transfer learning is a machine learning (ML) technique to enhance the learning process by utilizing a pre-trained model for a new task. Transfer learning models are neural networks that have been trained on a large dataset, typically for image recognition or natural language processing tasks, and then adapted for a new task with a smaller dataset. The basic idea behind transfer learning is that a model that has learned to recognize certain features in one domain can be re-purposed to recognize similar features in another domain. There are several approaches to implementing transfer learning models, but they generally involve modifying the pretrained model to suit the new task. This might involve adding new layers to the model, changing the total of neurons in the existing layers, or fine-tuning the weights of the existing layers. One of the most evident advantages of transfer learning is that it can considerably minimize the volume of data needed to train a fresh model since many of the relevant characteristics have already been learned by the pre-existing model. This can be particularly useful for tasks where there is limited labeled data available. Transfer learning can be advantageous in that it helps to enhance the performance of a model since the pretrained model has already learned to recognize a variety of crucial features in the input data. Examples of transfer learning in various fields include Computer Vision: Pretrained models can be fine-tuned on a smaller dataset of medical images to detect specific types of tumors in X-ray images. Natural Language Processing: Pretrained models can be further adjusted on a smaller dataset of news articles to detect fake news. Speech Recognition: Pretrained models for speech recognition can be fine-tuned on a smaller dataset of spoken commands to control a smart home device.

The study aims to use is to use Bayesian Optimization and Random Search to find hyperparameters for the Transfer Learning model, including VGG19 [28], MobileNetV2 [27] and Xception [8]. The experiments carried out for this research are listed in Table I and the search space for hyperparameters is given in Table II.

TABLE I. THE TECHNIQUE INVOLVES LEVERAGING A PRE-TRAINED NETWORK FOR FEATURE EXTRACTION AND THEN TUNING THE MODEL THROUGH FINE-TUNING

Models	VGG19	Xception	MobileNetV2
Usage of pre-trained	The technique involves leveraging a pre-trained network for feature extraction and then tuning the model through fine-tuning to improve its effectiveness		
Description	Remove the classification layer at the top of the pre-trained model. A new model head is constructed on top of the base model. This includes an AveragePooling2D layer. A Flatten layer to transform the output into a vector. A layer that is Dense and specifies the number of units and activation function. A Dropout layer to prevent overfitting. A Dense layer which is typically used in the final output layer of a neural network with a softmax activation function is added to output the probability distribution over four classes. During the training process, the weights of the base model layers are frozen to prevent updating, while only the weights of the new head model are updated		
Hyperparameter	Dropout rate, Activation function, Number of units, Optimizer, and Learning rate		

TABLE II. THE SEARCH SPACE FOR HYPERPARAMETERS

Hyper parameter	Search space
Dropout rate	values=[0.0, 0.1, 0.2, 0.3, 0.4, 0.5]
Activation function	values=['softplus', 'softmax', 'softsign', 'relu', 'hard_sigmoid', 'tanh', 'sigmoid']
Number of units	values=[32, 64, 128, 256, 512, 1024, 2048]
Optimizer	values=['Adadelta', 'Adagrad', 'Adam', 'RMSprop', 'SGD', 'Adamax', 'Nadam']
Learning rate	values=[1e-1, 1e-2, 1e-3, 1e-4, 1e-5]

IV. HYPERPARAMETER OPTIMIZATION

The main goal of hyperparameter optimization is to automate the process of hyperparameter tuning and make it more efficient. The overall objective of a hyper-parameter optimization problem is to achieve [30].

$$x^* = \arg \min_{x \in X} f(x) \quad (1)$$

Where $f(x)$ is the objective function; x^* is the configuration of hyperparameters that generates the optimal value for $f(x)$; the hyperparameter x can assume any element in the search space X .

A. Grid Search

Grid search [30] is a popular method used for exploring the configuration space of hyperparameters. This method involves evaluating all possible combinations of hyperparameters. Grid search is a straightforward approach that can be easily implemented and parallelized. However, it becomes less efficient when the number of hyperparameters increases, as the number of evaluations required to search the entire configuration space grows exponentially.

B. Random Search

Random search [30] [6] [33] is a simple and straightforward hyperparameter optimization method that is commonly used in ML. The approach involves randomly sampling hyperparameters from a specified search space, and evaluating the resulting models on a validation set to determine the performance of each set of hyperparameters.

One of the main advantages of Random search is its simplicity and ease of implementation. It requires minimal tuning and can be easily parallelized, allowing for efficient use of computational resources. Additionally, Random search can often outperform more sophisticated optimization methods for low-dimensional hyperparameter spaces. A significant

drawback of both Grid search and Random search is that each evaluation made throughout the search process is independent of any prior evaluations. Therefore, while selecting the next set of hyperparameters to assess, these approaches do not consider the outcomes of earlier evaluations.

C. Bayesian Optimization

Bayesian optimization [30][9] is a probabilistic approach to global optimization that is commonly used in ML, optimization, and experimental design. The goal of Bayesian optimization is to find the optimal set of hyperparameters that maximizes a given objective function, such as the accuracy of DL and ML models or the efficiency of a manufacturing process.

Several models, such as the Gaussian Process (GP), Random Forest (RF), and Tree-structured Parzen Estimators (TPE) models, can be used as the surrogate function in Bayesian optimization to simulate the distribution of the objective function, to approximate the unknown objective function. Iteratively updating the surrogate model with new observations of the objective function as the optimization process progresses, allowing for more accurate predictions of the optimal set of hyperparameters.

One of the main advantages of Bayesian optimization is its ability to efficiently optimize complex, high-dimensional, and non-convex functions with noisy and expensive evaluations. This makes it particularly useful for optimizing the hyperparameters of DL and ML models, which often involve complex and high-dimensional spaces. Furthermore, Bayesian optimization is able to handle constraints and multi-objective optimization problems.

V. METHODOLOGY

A. Dataset and Data Preparation

The dataset used in this study consists of a total of 3064 images, which were collected for the purpose of driver drowsiness

detection. The dataset is composed of four categories: eyes closed, eyes open, yawning, and no yawning. There are 726 images of eyes closed, which were obtained by capturing the eye region of subjects when their eyes were closed. Similarly, there are 726 images of Eye Open, which were obtained when subjects had their eyes open. The third category, Yawn, consists of 820 images, which were captured when subjects were yawning, and the fourth category, No Yawn, consists of 812 images, which were captured when subjects were not yawning. The dataset was partitioned into three distinct sets: training set, testing set, and validation set - in a random manner. The distribution of the dataset can be found in Fig. 1 and Fig. 2.

Fig. 1. A dataset distribution.

Fig. 2. Samples of drowsiness disease images. (a) Eye open, (b) Eye closed, (c) Yawn (d) No yawn.

B. Model Evaluation Metrics

In this research, the effectiveness of the DL models was examined using a variety of metrics. These metrics include

Precision, Recall, F1-score, and Accuracy. Accuracy was used to measure the overall effectiveness of the models in predicting the target variable. Precision was used to measure the proportion of true positive results among all the positive predictions is being calculated, while recall was used to measure the ratio of correctly predicted positive instances out of all actual positive instances in the dataset is being evaluated. F1-score, which combines both precision and recall, was used to provide a balanced view of the model's performance, especially in cases where the classes are imbalanced. By utilizing multiple evaluation metrics, were able to achieve an in-depth comprehension of the model's performance.

$$Accuracy = \frac{TP + TN}{TP + TN + FP + FN} \quad (2)$$

$$Precision = \frac{TP}{TP + FP} \quad (3)$$

$$Recall = \frac{TP}{TP + FN} \quad (4)$$

$$F_1 - Score = \frac{Precision * Recall}{Precision + Recall} \quad (5)$$

In which, TP: True Positive, TN: True Negative, FP: False Positive, FN: False Negative.

C. Results

In order to train the DL model, the images were altered in size to either 224 x 224 for the VGG19, MobileNetV2, and Xception architectures. Removing the original fully connected Layer in MobileNetV2, VGG199, and Xception base network and changing them with new fully-connected Layers, then fine-tuning to a dataset for detecting drowsiness. The models of architecture utilized in this research are displayed in Fig. 3. During our experiments, we employed the Bayesian optimization and Random search techniques to adjust a set of five parameters that are fine-tuned within the neural networks. Specifically, we fine-tuned the dropout rate, activation function, units (number of dense nodes), optimizer, and learning rate.

Three models, VGG19, Xception, and MobileNetV2, were trained and tested on a given dataset. Bayesian optimization and Random search were employed to fine-tune the models. VGG19 achieved an accuracy of 0.97039 with Bayesian optimization, and 0.96875 with Random search. Xception obtained an accuracy of 0.98355 with both Bayesian optimization and Random search, while MobileNetV2 achieved the highest accuracy of 0.98684 with Bayesian optimization and 0.98190 with Random search. Overall, the results show that MobileNetV2 outperformed the other models with the highest accuracy in Bayesian optimization. The optimized hyperparameters found using Bayesian Optimization and Random Search for VGG19, Xception, and MobileNetV2 models are shown in Table III and is used to conduct various test scenarios described in Table I.

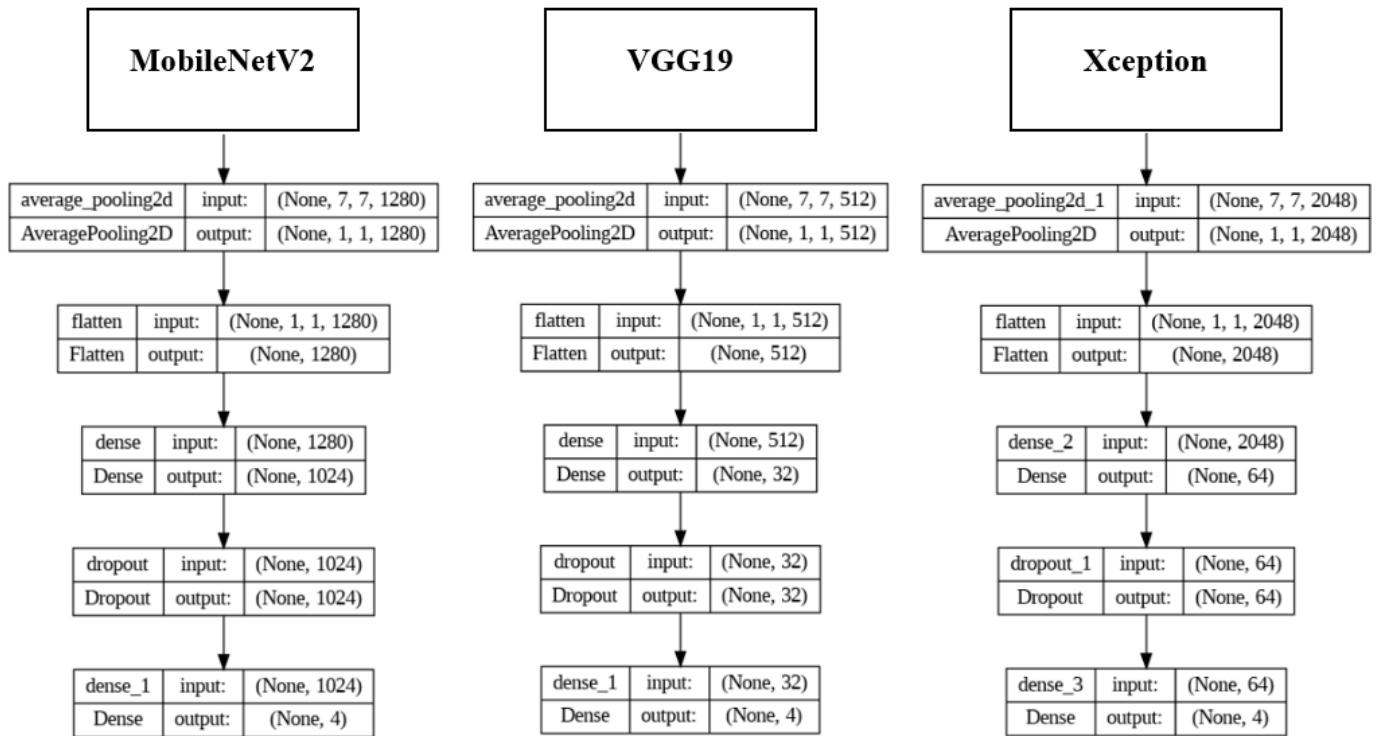

Fig. 3. Removing the original fully connected Layer in MobileNetV2, VGG199, and Xception base network and changing them with new fully connected Layers.

1) *VGG19*: Fig. 4 displays the optimized confusion matrices for the VGG19 model that have been optimized using Bayesian optimization and Random search techniques. The VGG19 model’s training and validation performance metrics including loss and accuracy are shown in Fig. 5. To get these results, Bayesian optimization and Random search strategies were also used. The precision, recall, F1-score, and accuracy were achieved during the evaluation of this model on each class using the best hyperparameters determined by Bayesian optimization and Random search presented in Table IV.

2) *Xception*: The optimized confusion matrices for the Xception model are shown in Fig. 6, which were produced using both Bayesian optimization and Random search methods. Additionally, using the above optimization techniques, Fig. 7 shows the Xception model’s performance during training and validation. The precision, recall, F1-score, and accuracy achieved during the evaluation of this model on each class using the best hyperparameters determined by Bayesian optimization and Random search are presented in Table V.

3) *MobileNetV2*: Both Bayesian optimization and Random search methods were utilized to create the optimized confusion matrices for the MobileNetV2 model, as presented in Fig. 8. Additionally, Fig. 9 showcases the performance during training and validation of the MobileNetV2 model, obtained through the application of the aforementioned optimization methods. The precision, recall, F1-score, and accuracy were achieved during the evaluation of this model on each class using the best hyperparameters determined by Bayesian optimization and Random search presented in Table VI.

The classification performance of the three optimized mod-

els is displayed in Fig. 10. In terms of precision, the MobileNetV2 model performs better than all the others. Compared to Random search, Bayesian optimization is more effective at obtaining optimal hyperparameters.

VI. CONCLUSION

In this study, we proposed an approach for hyperparameter tuning in transfer learning for driver drowsiness detection using Bayesian optimization and Random search algorithms. We evaluated our approach on a publicly available dataset using transfer learning models with the MobileNetV2, Xception, and VGG19 architectures. We explored the impact of various hyperparameters including dropout rate, activation function, number of units, optimizer, and learning rate on the performance of the transfer learning models.

Our experiments show that our approach improves the effectiveness of the transfer learning models, obtaining cutting-edge results on the dataset for all three architectures. We also compared the performances of Bayesian optimization and Random search algorithms in terms of their ability to find optimal hyperparameters and demonstrated that Bayesian optimization is more efficient in finding optimal hyperparameters than Random search.

Our findings highlight the importance of hyperparameter tuning in transfer learning-based driver drowsiness detection and provide insights into the impact of different hyperparameters on the effectiveness of the transfer learning models. Furthermore, our proposed approach can be applied to other transfer learning tasks, making it a valuable contribution to the field of ML.

Overall, our study emphasizes the significance of selecting appropriate hyperparameters to achieve optimal performance in transfer learning models for detecting driver sleepiness and provides a framework for doing so. The results of this study can guide the selection of hyperparameters and models for future research in this area.

FUTURE WORKS

Further investigations can be carried out to explore the impact of other hyperparameters, such as weight decay and batch size, on the effectiveness of transfer learning models for detecting driver sleepiness. Furthermore, the combination of multiple optimization techniques, such as Bayesian opti-

mization, Random search, and Hyperband can be researched to further improve the efficiency of hyperparameter tuning. Finally, the proposed approach can be extended to real-time sleepiness detection for drivers using mobile devices. The implementation of optimized transfer learning models on such devices can enable real-time monitoring of driver drowsiness, thus enhancing road safety.

Abstract—COVID-19 is a serious infection that cause severe injuries and deaths worldwide. The COVID-19 virus can infect people of all ages, especially the elderly. Furthermore, elderly who have co-morbid conditions (e.g., chronic conditions) are at an increased risk of death. At the present time, no approach exists that can facilitate the characterization of patterns of COVID-19 death efficiently and systematically is applied by adapting the Apriori algorithm. Validation and evaluation of the proposed approach are based on a robust and reliable dataset collected from Health Affairs in the Makkah region of Saudi Arabia. The study results show that there are strong associations between hypertension, diabetes, cardiovascular disease, and kidney disease and death among COVID-19 deceased patients.

Keywords—COVID-19; association rules; Apriori algorithm; patterns; death; chronic diseases

I. INTRODUCTION

COVID-19 first appeared in the Chinese city of Wuhan in December 2019, and it was the starting point of the disease spreading to the world. It was officially announced by the World Health Organization (WHO) on March 11, 2020 a pandemic [1]. Many attempts were involved to engage latest technologies for diagnosing and treating COVID-19 patients [2].

The Kingdom of Saudi Arabia (KSA) was not immune from that virus, as the virus spread rapidly. The first confirmed recorded case appeared in the KSA on March 2, 2020 [3]. There were several factors that contributed to the spread of the virus in the KSA, including its geographic location, trade exchanges with China, and its religious and recreational tourism industries [4], [5]. The KSA had previous experiences with epidemics. Viruses such as the Middle East Respiratory Syndrome (MERS-CoV), helped to control and deal well with the pandemic [6]. Since the start of the pandemic until 10 Nov 2022, there have been 284,273 cases and 9,426 deaths of COVID-19 in the KSA [7].

As a precautionary measure, the KSA had implemented strict curfews, shut down all non-essential services, required

everyone to wear masks, and closed its air, sea, and land borders. [8], [9]. The government had also transferred education to distance education in all public and private schools, universities, institutes and training centers [10]. Furthermore, Saudi Arabia intensified health care and established field hospitals to cope with the likely increase in COVID-19 patients, and relied on WHO and Ministry of Health protocols when treating COVID-19 patients [11], which significantly decreased the rate of death and hospitalization [12]. In the latest informed statistics during the writing of the last chapter of this research on December 29, 2022, the confirmed cases exceeded 816,470 cases, and 9,610 deaths of COVID-19 patients [13].

Most of the previous studies showed that the large number of people who died from COVID-19 had one or more chronic diseases in a remarkable way. Hence, the need to study those patterns of death from chronic diseases that are more frequent. Understanding these patterns helps to identify the factors that increase the risk of death in this group of people, and thus can help in developing better strategies to control the pandemic and provide a priority care. The issue of obtaining the database of the deceased patients from COVID-19 is difficult due to confidentiality, privacy, and sensitivity of medical data. In this proposed work, the medical data is officially obtained through health protocols from the Health Affairs in Makkah Al-Mukarramah region in the Kingdom of Saudi Arabia.

Our work is motivated by Apriori Association Rules (ARA) algorithm that was introduced in [14], which extracts the most frequent and appearing patterns from a specific database according to the degree of support and confidence [15]. Our work is similar to the work presented in [16]. However, we, in this study, discover COVID-19 death patterns from deceased patients rather than discovering COVID-19 infection patterns.

The remainder of the paper is organized as follows: In Section II, we present related works. In Section III, we describe and analyze the dataset and discuss our proposed approach for detecting death patterns among COVID-19 patients. In Section IV, we describe the experimental procedure based on the algorithm used. Section V discusses the Weka program while Section VI details implementation of Weka program in

our study. Section VII presents the results and discussion. In Section VIII, we conclude our study and present our future work.

II. RELATED WORK

Several research works thoroughly studied the COVID-19 patterns. In this section, we review the most recent related works.

Robert et al. [17] introduced the present COVID-19 situation among diabetics, newly diagnosed diabetics, diabetic ketoacidosis, and programmatic initiatives including immunizations. The study method involved performing a literature study through the use of PubMed, Google, and Scopus Up until July 15, 2021. The study results had shown that most research conducted in the KSA had shown diabetes as one of the most common comorbidities among COVID-19 patients. There had been few works conducted in the KSA on COVID-19-induced diabetic ketoacidosis and newly diagnosed diabetes. The Saudi ministry had implemented a number of steps, including thorough recommendations and prioritized immunizations, to reduce the impact of COVID-19 among individuals with diabetes. Telehealth services were heavily utilized in Saudi Arabian diabetes clinics during the COVID-19 pandemic.

Geng et al. [18] attempted to comprehend the risk variables for symptom deterioration and death in COVID-19 patients. By establishing the predictive value of chronic diseases for COVID-19 severity and mortality, this systematic review intended to fill the gap. The study results had revealed that hypertension was a fairly prevalent illness among COVID-19 patients, linked to mortality, admission to the intensive care unit (ICU), acute respiratory distress syndrome, and higher severity. Asthma was linked to a lower likelihood of COVID-19 death, while chronic obstructive pulmonary disease was the best predictor of COVID-19 severity, ICU admission, and fatality. Instead of mortality, the fat patients were more likely to develop severe COVID-19 symptoms. The patients were more likely to develop severe COVID-19 instances and die if they had cancer, chronic liver disease, chronic renal illness, or cerebrovascular disease.

Wang et al. [19] conducted searches in several databases for articles published until April 6, 2020, and after selecting a very large number of published articles. Only 34 articles were reached after sorting. Among the pre-existing chronic diseases were having high blood pressure, cardiovascular disease, kidney disease and diabetes associated with the risk of infection with the virus. The results confirmed that people with pre-existing chronic diseases had an increased risk of developing more serious complications in COVID-19 patients, and severe organ damage or dysfunction was linked to an increased death rate. The study showed that acute kidney disease and heart injury were closely associated with a 3-4-fold higher risk of death associated with COVID-19. The study suggested that healthcare providers need to put those who have a history of high blood pressure and cardiovascular diseases under observation and be subject to continuous follow-up.

Al Mutair et al. [20] collected information from several private hospitals in the KSA between April 2020 to June 2020. The study was based on descriptive and inferential

analysis of the results and on the data analysis of COVID-19 patients' information. The study was classified into two categories: survivors (recovered) and non-survivors (deceased). The inferential reading showed that 31.8% of the survivors were in the age group of 30-40 years, and 24% were in the age group of 21-30 years, and among the non-survivors, the study showed that 66% of the non-survivors over 50 years old, and that 86% of the non-survivors were males. The results showed that 63.8% had no history of chronic diseases Hypertension (HTN), that 19.8% had one of HTN or diabetes mellitus (DM), and that 16.4% had a history of chronic diseases HTN and DM together. The study indicated a strong relationship between differences in age, gender, chronic diseases and deaths associated with COVID-19 in general, and that advanced age and males and the presence of chronic diseases such as high blood pressure and diabetes among COVID-19 patients are prevalent among the deceased patients. The study indicated that there were poor predictive factors that led to the possibility of an increase in the death rate that may reach 9 times among males over the age of 50 years and who have a history of chronic diseases. There is an association between HTN and mortality, and there is an increasing number of deaths among males.

Similar to our work, Alafif et al. [16] explored the most common infection patterns for patients who had recovered from COVID-19, and they were able to collect 131 records of people who recovered from COVID-19 using the survey method through a questionnaire by communicating with them or with their relatives by direct contact. The ARA algorithm was used on the manually collected data to explore the most common infection patterns. The study concluded that there were strong association rules with high confidence scores among males, weight above 70 kg, height above 160 cm, and fever patterns. Also, Alafif et al. [21] predicted the status of COVID-19 patients using their patterns as COVID-19 treatments and diagnosis were reviewed in [22].

From the previous studies, we find most of these studies confirm that the age factor, males, non-Saudis, and those with chronic diseases are the most at risk of death among people infected with the COVID-19, with differences in ratios, study sample and place of study. It was also found that the most prevalent chronic diseases among those infected and deceased from the COVID-19 virus are hypertension, diabetes, cardiovascular disease and kidney disease.

We did not find any previous study that dealt with the same topic and finding of the most frequent chronic diseases found among the deceased due to the COVID-19 death pattern, as we are in this study to discover the death patterns of chronic diseases that were among the deceased and the most frequent.

We discuss the results of our study and a comparison with previous studies in the discussion section, clarifying the compatibility with previous studies and the contradiction of their results.

III. METHODOLOGY

Fig. 1 shows the course of the study stages, from defining the study sample, obtaining the database, the stages of cleaning, coordinating and arranging the database, and analyzing the data, then the stage of selecting the study tools, which

is the ARA algorithm, followed by the use of two methods to apply the algorithm through manual calculations and the Weka program to verify the conformity of the outputs and finally the stage of writing the results.

A. Association Rules Algorithms

In our modern era, the uses of artificial intelligence are abundant to utilize as much as possible. These can be employed in several fields, including data science, data mining, data analysis, and serial cases that in the past took effort a long and hard time. The most classic algorithm is the ARA algorithm, which is considered the originator of the recursive element mining algorithm [23].

The amount of information or data being maintained in databases has dramatically increased in recent years. Latent knowledge mining is crucial to enhance decision-making when the size of available databases grows exponentially. The critical phase of the knowledge discovery process is data mining. Predictive and descriptive tasks are the two broad categories into which data mining's primary tasks are typically categorized. While the descriptive tasks aim to extract previously undiscovered and significant information from massive databases, such as patterns, associations, changes, anomalies, and substantial structures, the predictive tasks aim to forecast the value of a given attribute based on the standards of other characteristics. These goals of data mining can be met in many ways [24].

There has been more than one algorithm whose works are based on association rules, such as the ARA algorithm, the ECLAT algorithm, and the FP Growth algorithm, but the ARA algorithm is the most famous. The ARA algorithm appeared by Agrawal et al. in 1993 as one of the tools for mining databases of association data. The ARA algorithm extracts recurring patterns are based on the strength of the degree of support and confidence and provide services through their analysis to planning and marketing managers to facilitate the administrative and marketing process and help make appropriate decisions [25].

The main task of the ARA algorithm is to extract the duplicate elements with iterative operations by scanning the database more than once according to the minimum support limit, excluding other data and filtering [26].

Association rules that explore recurring, relational, or causal patterns between groups of itemset emerged from the database. The rules of association were used through the exploration and analysis of shopping cart data at the beginning, and their use has evolved in several areas due to their efficiency and effectiveness in results. The science of data mining is of great importance to obtain information from large or small sources of various categories and to present it for optimal use. The rules of the association are one of the most important methods of data mining. There are several measures by which the strength of the degree of correlation of the algorithm outputs is measured, and we have relied on two measures support and confidence. The method of knowledge discovery in database, is called Data mining. It is based on extracting important patterns from large databases and then analyzing that data to give beneficial information, ideas, and solutions. Through what the discovery of knowledge in databases provides in terms of methods and methods for extracting interesting remarkable

patterns in the shortest possible and appropriate period and taking paths at the intersection point of data stores and machine learning, and statistics systems. Data mining is known as applying algorithms to desired patterns found in large databases [27].

The ARA algorithm is an intriguing way to determine what we need to buy or get suggestions for what we need. We are all aware that the e-commerce platform has a variety of approaches. Flipkart, Amazon, Snapdeal, and other online retailers, are what it exactly is. The application proposes items to buy when we attempt to purchase in the online store. It anticipates additional clients who usually make purchases together. This method also enables us to understand how various things are predicted [28].

B. Apriori Algorithm

The Apriori algorithm is an analogue algorithm for association base mining (association base mining) and ranks among the top ten data mining algorithms. Association rule mining is a significant research direction in data mining. It is also a long-standing topic whose main task is to find the inner connection between things [29]. The association rules approach can be implemented using various methods to draw out relevant links between variables or items in a large database by identifying more frequent item combinations. As long as those itemsets appear in the dataset sufficiently and frequently, it recognizes the frequently occurring items in the database and expands them to larger and larger itemsets. If an itemset is frequent, then all of its subgroups' items will also be frequent, according to the Apriori algorithm. In other words, any subset of a frequent itemset must also be frequent [30].

C. History of the ARA

The first algorithm to be suggested for frequent itemset mining was the ARA algorithm. Later, it was enhanced by R Agrawal and R Srikant [14]. The result was known as Apriori. The join and prune steps of this algorithm are used to condense the search space. Finding the most common itemset is done iteratively. The term ARA refers to the algorithm that determines the rules of association between items. It refers to the relationship between two or more objects [15]. To put it another way, we can say that the ARA algorithm is a leaning association rule that examines whether customers of product (A) also purchase product (B) [31].

D. The ARA Algorithm Template

To find the huge l-items, the algorithm initially counts the occurrences of each item. These stages make up the second step. The candidate itemsets C_k are first created using the large itemsets L_{k-1} . After that, the database is scanned to determine the support of candidates in C_k , which involves increasing the count of all candidates included in a certain transaction t . After that, $supp_min$ is used to compare the support of each candidate k -itemset. Only when the support is more than the minimal support given by the user, $supp_min$, is the k -itemset frequent. The algorithm then deletes all rules that do not satisfy the criterion of $supp_conf$. The next stage is to identify those rules with confidence greater than or equal to the user-specified $supp_conf$ [32].

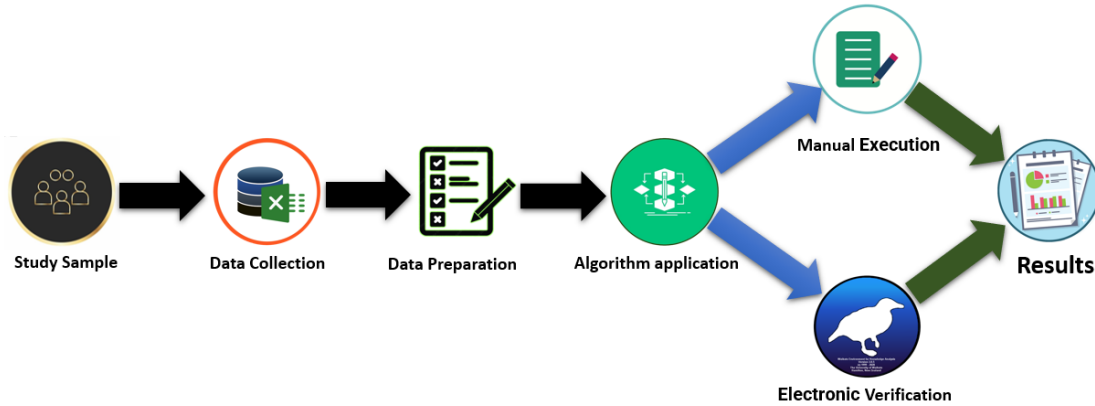

Fig. 1. The pipeline methodology of the proposed approach.

E. Components of the ARA Algorithm

The ARA algorithm consists of more than one component, there are several measures by which the strength of the degree of correlation of the algorithm outputs is measured [33], and we have relied on two criteria; support and confidence. The term support refers to the frequency of itemset in the dataset on all parameters and is defined as follows:

$$Support(X \Rightarrow Y) = \frac{x \cup y}{TotalTransactions} \quad (1)$$

The term (confidence) refers to the frequency of the dataset of utmost Y in transactions containing X , which are defined as:

$$Confidence(X \Rightarrow Y) = \frac{supp(x \cup y)}{supp(x)} \quad (2)$$

We employed the ARA algorithm to compute the probability of the appearance of the most frequent chronic diseases along with other chronic diseases in the database of the deceased patients from COVID-19 to provide the results to medical providers to take the necessary precautions or provide appropriate health care. In an iterative process, the data is filtered to extract the itemset that achieves the minimum support, and then it is re-read to extract a new itemset, considering $k+1$. As appears in Fig. 2.

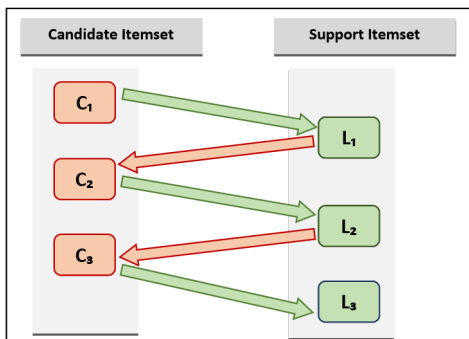

Fig. 2. Filtering iterations.

Fig. 3 shows a simple example of the work of the ARA algorithm in analysing the shopping cart, where the database is completely read, and then each item and its number of repetitions is separately determined. Then, the itemset is filtered according to the minimum support specified in advance by the user, which we call $C1$ to produce a grouping of the dataset that meets the minimum support as a single item 1 -Itemset with the exclusion or deletion of any item that does not meet the threshold of the minimum support and this is what we call $L1$.

With $L1$ we iterated the process but with two items together $K+1$ or 2 -Itemset which is the process of filtering the groups of itemset $C2$ comparing the number of iterations with the minimum support, and then trimmed the elements that did not meet the threshold of the minimum support. The process was repeated according to the repetition of the itemset with the increase of $K+1$ each time, meaning that in the third time, the itemset was three with each other 1 -Itemset and compared the number of iterations with the threshold of the minimum support until we reached that it was not possible to create a new group of itemset because the minimum support was not achieved. There was a logical consequence that a non-frequent set cannot be in a set of frequent itemsets. Next, we computed the specific confidence value for those potential itemsets that were most frequent, Accordingly, we saw the strength of that confidence and the correlation of the group of elements whether appearing next to each other or not.

F. Dataset

Our study is based on an Excel database of those who died due to COVID-19 and had a disease or chronic diseases that contributed to the death. After taking approval, the database was obtained from the information centre at Al-Noor Specialist Hospital in Makkah. We processed, audited, revised, and corrected the database, as it initially contained 18,785 records, most of which were duplicates, incomplete, or invalid. The reason for its large size is due to the placement of more than one record for the same patient, where each one contains its patient's daily and weekly condition development independently, but neither an update nor a placement of a cell for the new case, as well as the patient's data, such as medical

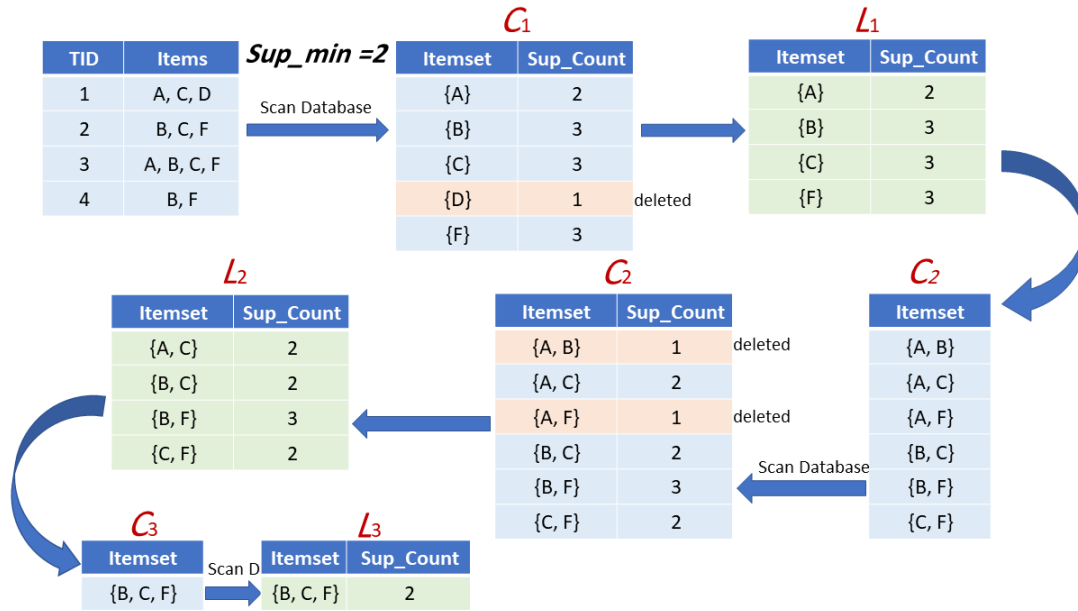

Fig. 3. A simple example of the workflow of the ARA algorithm.

number, age, gender, and nationality. Some patients had more than 43 records for each of them individually. This is a large number and major reason for the records to search 18,785. This is if we know that every patient data has a recurrence. At the end of the corrections and audits, the number of valid records for the study was only 349 for those who died due to COVID-19 and were accompanied by one or more chronic diseases such as diabetes, hypertension, cardiovascular, kidney diseases, immunodeficiency, blood diseases, cancer, immunodeficiency, cardiovascular, and obesity. The dataset is publicly available on¹.

G. Database Analysis

The database included 349 records of those who died of COVID-19 and had one or more chronic diseases, and the number of registered diseases amounted to 10 different ones, as shown in Fig. 4.

Fig. 4. Chronic diseases and how often they appear in the database in the study population.

The percentage of the non-Saudis was more than of the Saudis, according to the results of the database analysis of the deceased patients. The non-Saudi number was 217 and the Saudis was 132, as shown in Fig. 5.

The number of non-Saudi constitutes from 20 different countries. The countries are Jordan, Afghanistan, Indonesia, Pakistan, Burma, Bangladesh, Thailand, Chad, Tunisia, Syria, Sudan, Philippines, Palestine, Malaysia, Egypt, Morocco, Mauritania, Nigeria, India, and Yemen.

Fig. 5. The ratio of Saudi to non-Saudi COVID-19 patients in the study population.

Fig. 6 shows that the analysis results of the database also showed that the number of males exceeds the number of females in deaths. According to the previous studies we reviewed, they were fully compatible with the fact that the number of males exceeded the number of females since the onset of the disease until the date of writing the study.

¹<http://www.kaggle.com/datasets/abduhrahmanalomaly/discovering-covid-19-death-patterns>

Fig. 6. The ratio of males to females in the study population.

Fig. 8. Distribution of age groups in the study population.

Also, the database records of the deceased patients also show a diversity of blood groups. The blood group O+ is more prominent, followed by A+, then B+, and then the rest of the blood groups, as shown in Fig. 7. However, there are many records in the database of unknown blood types (not recorded) from the source and written in the field (unknown). Fortunately, we do not rely on blood type to explore the most frequent patterns of the cause of death, as the type of chronic diseases and their nomenclature are the study subjects for the implementation of treatment operations.

Fig. 7. Types of blood groups in the study population.

The strength of youth appears in all aspects, as the nature of youth is strength, vitality, activity, and endurance of hardships, as well as the case when diseases are infected, we find the strength of immunity or resistance, which is different from the elderly.

The study showed the disparity in the ages of the deceased patients with COVID-19. They had chronic diseases, as the ages of young people age range from 15 to 45 which represented only 13% of the total of deceased patients according to the study's database.

On the other hand, we find that the elderly, whose age ranges from 46 to over 80, are the highest percentage of deaths, reaching 87%. Fig. 8 shows the distribution of ages by age groups into groups.

Fig. 9. Total deaths by years in the study population.

COVID-19 appeared at the end of the year 2019 and spread in the year 2020, the disease spread largely and frighteningly, as well as the number of deaths, then the percentage decreased in the following year 2021 until the percentage decreased significantly in the year 2022. Fig. 9 shows the number of deaths during the three consecutive years 2020, 2021 and 2022, and the significant difference between them.

IV. IMPLEMENTATION OF ALGORITHM

In our study, we relied on the ARA algorithm to discover (patterns of death) according to strong association rules through the database of deceased COVID-19 patients. In this section, we manually applied the ARA algorithm at first, the database file (Excel) was manually emptied and written as in Table IV. The medical file number for each deceased patient has been replaced by serial numbers. The names of chronic diseases (patterns) were abbreviated with corresponding letters for ease of writing. We had 10 different types of chronic diseases (patterns) in the database, and their names have been abbreviated with Latin letters for ease of reading, writing, and dealing with them during the manual analysis, as explained in Table I.

TABLE I. LIST OF TYPES THE DISEASES AND THEIR ABBREVIATIONS

Disease Name	Abbreviation
Kidney Diseases →	K
Hypertension →	H
Cardiovascular →	C
Diabetes →	D
Respiratory →	R
Blood Diseases →	B
Obesity →	O
Liver Diseases →	L
Cancer →	N
Immunodeficiency →	I

The minimum support was determined according to our reading and estimation of the size of the records and the presence and frequency of patterns in the database. The minimum support is 7.

TABLE II. RESULTS OF THE INITIAL FILTERING PROCESS FOR THE DATASET (L1)

Patterns	Supp_Count
{B}	15
{C}	130
{D}	43
{K}	140
{L}	8
{O}	13
{R}	20
{H}	130

We first performed the process of reading all the patterns, an element of an element from the database (1- frequent), and the number of supporting each element. This is called a filtering process C1 as in Table III. Depending on the predetermined minimum support, the patterns were pruned (deleted) and excluded for the items that did not meet the minimum support. Table II embodies L1.

TABLE III. SCANNING THE DATABASE AND READING ALL PATTERNS AND THEIR FREQUENCY (C1)

Patterns	Supp_Count	
{B}	15	
{C}	130	
{D}	43	
{I}	2	deleted
{K}	140	
{L}	8	
{N}	6	deleted
{O}	13	
{R}	20	
{H}	130	

According to the results of the first filter C1 in Table III, it is clear that the pattern set I and N did not achieve the minimum support 7, and pruning (deletion) was implemented. Table V shows the second filtering process C2 which was performed by reading two 2-frequent items for all patterns from Table II (L1).

In the next step, the filter results L2 were extracted for every two items (2-Itemset) according to the minimum support from reading Table V (C2), and the patterns that did not meet the minimum support were excluded. Many patterns for which the number of supporting was below the threshold were excluded. 7 frequent patterns 2-itemset were obtained as it appears in Table VI.

TABLE VI. RESULTS OF THE SECOND FILTRATION PROCESS (L2) 2-ITEMSET

Patterns	Supp_Count
{B, H}	7
{C, D}	9
{C, K}	30
{C, H}	31
{D, K}	15
{D, H}	28
{K, H}	38

After knowing the number of support and obtaining a successful reading for each of the two elements (L2), and since there is a repetition that fulfilled the minimum condition for support, we moved to the next step through which all the three elements (patterns) read 3-Itemset, i.e., forming new triple patterns based on the results of Table VI (L2).

In Table VII, (C3), the data was filtered with a 3-Itemset for every three items. The number of repetitions was computed based on the results of Table V.

Through the results of the 3-Itemset reading of the three repetitive patterns, only two groups that met the threshold of support are shown C, K, H and D, K, H. The first group of elements was repeated 13 times, and the second 10 times, as shown in Table VIII.

We continued filtering the data to generate a new set of items (Patterns) for every four 4- Itemset, where there were two sets, and the number of supporting for each set was greater than the threshold minimum support.

In Table IX (L4), 4- Itemset data is filtered for every four items, and the number of repetitions is computed based on the results of Table VIII (L3), which achieved the threshold minimum support. The pattern set shows C, D, K, and H.

TABLE IV. LIST OF TYPES (CHRONIC DISEASES) DATABASE RECORDS OF COVID-19 DEATHS

ID	Patterns (Diseases)	ID	Patterns (Diseases)	ID	Patterns (Diseases)	ID	Patterns (Diseases)
1	H,D	89	H,R	177	K,H	265	C
2	K	90	C	178	H	266	B
3	K	91	K,I	179	H	267	L
4	C	92	H,D,R	180	C	268	K

V. USING WEKA PROGRAM

Weka is an acronym for Waikato Environment for Knowledge Analysis and is developed by the University of Waikato in New Zealand [34]. Weka is an open-source software that contains a set of algorithms and graphics for data analysis and predictive modeling, which is easy to access and use with a graphical interface. The third version of WEKA was fully developed through the Java language in 1997. It is used in applying several tools and is freely available according to the GNU General License. The program can run on any operating system because it is implemented on the Java platform to data pre-processing, classification, regression, clustering, correlation base mining, visualization, and modeling [35], [36].

TABLE IX. THE RESULTS OF THE FILTRATION PROCESS (L4)

Patterns	Supp_Count
{C, D, K, H}	13

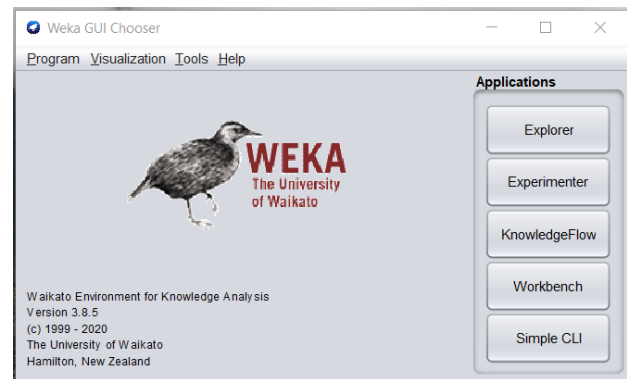

Fig. 10. Weka main interface [31].

VI. DATA PREPARATION AND IMPLEMENTATION USING WEKA

To use the Weka program, there is a command that must be modified on the database, a copy of the database (Excel) to convert it to a system (YES - NO) with the extension (.csv) with values separated by commas so that the program read it and deals with it, according to the program settings and apply the ARA algorithm. After opening the file in the program, it is converted and saved with the program extension (.arff) to apply the algorithm and extract the results.

Fig. 10 shows the program's main graphic interface, and in Fig. 12 shows the window for selecting working files and selecting the classification type and algorithm. In Fig. 11, we can see the settings for the algorithm, such as the amount of support and confidence.

Fig. 11. Apriori algorithm properties settings window for support and confidence.

Fig. 12. The window for selecting rules and categories (Associate).

VII. RESULTS AND DISCUSSION

A. Manual Results

Through our manual calculations of the ARA algorithm, we explore a set of 4-itemset recurring patterns, which are the most frequent patterns and have a strong correlation base for the probability of appearing next to each other, which are C, D, K, H.

Each pattern has a certain frequency with one or more other patterns explored C, D, K, H, where we find more than one association rule that we read with differences in confidence. According to the rule of Apriori algorithm that states, if an itemset is frequent, then all of its subgroups' items will also be frequent. In other words, any subset of a frequent itemset must also be frequent. Here is a reading of more than one association rule for the set of detected patterns that have high confidence:

- {K, D} \Rightarrow {H} - {D} \Rightarrow {K}
- {D} \Rightarrow {H} - {K, H} \Rightarrow {C}
- {H, C} \Rightarrow {K} - {H} \Rightarrow {K}
- {H, D} \Rightarrow {K} - {K} \Rightarrow {H}
- {K, C} \Rightarrow {H} - {C} \Rightarrow {K}

Table X shows the number of appeared of the most frequent patterns (support) in the 349 records of the database, where we counted each pattern individually. Then, every two patterns were counted together, counted the number of recurrences for every three patterns, and finally, every four patterns were computed together in the database.

TABLE X. SUPPORT COMPUTATIONS FREQUENCY FOR ALL MOST FREQUENT PATTERNS IN DATABASE

Patterns	Appearance (frequency)	Patterns	Appearance (frequency)
{C}	130	{D, K}	15
{D}	43	{D, H}	28
{K}	140	{K, H}	39
{H}	131	{C, K, H}	13
{C, D}	9	{D, K, H}	10
{C, K}	34	{C, D, K, H}	13
{C, H}	31	—	—

TABLE XI. COMPUTATION OF SUPPORT FOR THE MOST FREQUENT PATTERNS

Association Rule	Compute of Support
{Kidney, Diabetes} \Rightarrow {Hypertension}	146/349 = 0.418 = (41.8%)
{Diabetes} \Rightarrow {Hypertension}	174/349 = 0.498 = (49.8%)
{Hypertension, Cardiovascular} \Rightarrow {Kidney}	171/349 = 0.489 = (48.9%)
{Hypertension, Diabetes} \Rightarrow {Kidney}	168/349 = 0.532 = (53.2%)
{Kidney, Cardiovascular} \Rightarrow {Hypertension}	165/349 = 0.472 = (47.2%)
{Diabetes} \Rightarrow {kidney}	183/349 = 0.524 = (52.4%)
{Kidney, Hypertension} \Rightarrow {Cardiovascular}	169/349 = 0.484 = (48.4%)

Before we compute the degree of confidence for the results, we need to compute the support for all groups of itemsets frequent in the results according to the predefined confidence rule.

Table XI shows the computation of the support for all the patterns explored by applying the ARA algorithm, which appeared as the highest results with a strong association rule. In Table XII, we computed the confidence for these results and verified them according to the confidence rule of the ARA algorithm. The results showed a strong association rule between the patterns.

Table XII above reveals that we established seven clear rules and discovered that two of the four patterns were the most frequent among patients who died from the Covid-19 virus, as the confidence rate exceeded 60%:

- {kidney, Diabetes} \Rightarrow {Hypertension} (66.6%).
- {Diabetes} \Rightarrow {Hypertension} (65.1%).

TABLE XII. COMPUTATION OF CONFIDENCE FOR THE MOST FREQUENT PATTERNS

Association Rule	Compute of Confidence
{Kidney, Diabetes} \implies {Hypertension}	10/15 =0.651 = (66.6%)
{Diabetes} \implies {Hypertension}	28/43 =0.651 = (65.1%)
{Hypertension, Cardiovascular} \implies {Kidney}	13/31 =0.419 = (41.9%)
{Hypertension, Diabetes} \implies {Kidney}	10/29 =0.357 = (35.7%)
{Kidney, Cardiovascular} \implies {Hypertension}	13/34 =0.382 = (38.2%)
{Diabetes} \implies {kidney}	15/43 =0.348 = (34.8%)
{Kidney, Hypertension} \implies {Cardiovascular}	13/39 =0.333 = (33.3%)

Through the previous two patterns with a high degree of confidence, we noted that hypertension and diabetes were common and present in both patterns. In the first reading of these results among the most frequent patterns, we found that the deceased patients who had chronic diseases such as kidney disease and diabetes also had hypertension with a high confidence level of 66.6%. We also found that the deceased patients who had diabetes also had hypertension with a high confidence level of 65.1%.

This confirms that chronic diseases have significantly impacted the incidence of death among those infected with COVID-19, especially when we found that there were deceased patients who had more than one chronic disease or more. In this case, we found that there was a strong correlation between the diseases of the kidney and diabetes and the emergence of hypertension with a confidence degree of 66.6%.

In the second degree, diabetes led to the emergence of hypertension disease with a confidence level of 65.1%. In other words, the deceased patients who were suffering from kidney disease and diabetes together were also likely to have high blood pressure. In degrees less than 50% confidence, we found that the emergence of hypertension and cardiovascular diseases led to the emergence of kidney disease.

B. Weka Results

After the database has been converted and modified to suit the settings of the Weka program. The program was implemented through the (Associate) tab, and some modifications were made to the graphical algorithm options by opening the algorithm options window (Apriori) to implement and show the algorithm results in the program in Fig. 13, The following is a display of the top three results:

- kidney=**K** Diabetes=**D** \implies Hypertension=**H** (0.67).
- Diabetes=**D** \implies Hypertension=**H** (0.65).
- Hypertension=**H** Cardiovascular=**C** \implies kidney=**K** (0.42).
- kidney=**K** Cardiovascular=**C** \implies Hypertension=**H** (0.38).
- Hypertension=**H** Diabetes=**D** \implies kidney=**K** (0.36).
- Diabetes=**D** \implies kidney=**K** (0.35).

- kidney=**K** Hypertension=**H** \implies Cardiovascular=**C** ((0.33).

Fig. 13. Program outputs of Weka.

It is noted in the Weka results that it rounds the results to the nearest number, and thus there is a very slight difference in some numbers. They indicate that the pattern set C, D, H, K is the most frequent pattern in the database of COVID-19 deaths. They are cardiovascular - disease - diabetes - hypertension - kidney disease

The occurrences of each of the two patterns were binarily repeated according to the following numbers:

- Cardiovascular with diabetes 9 times.
- Cardiovascular with kidney disease 30 times.
- Cardiovascular with hypertension 31 times.
- Diabetes with kidney disease 15 times.
- Diabetes with hypertension 28 times.
- Kidney disease with hypertension 38 times.

We conclude that those who had chronic diseases (kidney disease and diabetes) often had a hypertension with a high confidence level of 67%. This is if we know that the number of occurrences of kidney diseases and diabetes together in the database of the study is 15 times and that of hypertension is 10 times next to (kidney diseases and diabetes).

Also, those who had diabetes often had hypertension with a high confidence degree of 65%. Where diseases appeared and repeated 43 times, hypertension appeared 131 times, and the two diseases together diabetes appeared next to hypertension in the database 29 times. There were who carried hypertension and cardiovascular diseases and often had kidney disease, but this confidence level was less than 50%.

VIII. CONCLUSION

Discovering death patterns contributes to enhancing the capabilities of healthcare decision-makers in order to know the most frequent and prevalent chronic diseases among the

deceased from COVID-19. In this research, we proposed to use the ARA algorithm to detect death patterns from the data of deceased COVID-19 patients. A non-clinical COVID-19 database, consisting of COVID-19 death patterns was presented and analyzed. The results of manual calculations and our experimental results showed strong association rules with high confidence scores between hypertension, diabetes, cardiovascular, and kidney disease. The results are confirmed by a study of Al Mutair et al. [20] that there is an increase in deaths due to high blood pressure and diabetes. The results are also confirmed by the study of Geng et al. [18], which indicated that cardiovascular diseases and kidney diseases were frequent among the deaths from COVID-19 patients at a high rate. The study of Wang et al. [19] matches with our results and stated that there is a link between high blood pressure and heart disease among patients who died of COVID-19.

Studying the death patterns of people with COVID-19 who have chronic diseases contributes to the medical knowledge in the medical domain, as it helps to understand the most factors that affect the severity of the disease to identify patients who need more special care. Understanding these patterns helps to develop better strategies to control the epidemic by giving more attention and care and priority care to COVID-19 patients. However, this study is only limited to a small number of deceased COVID-19 patients due to challenges of obtaining their medical data from one medical institution. However, in the future, more data will be collected from different medical institutions. Also, this study can be extended to include the analysis of environmental genetic factors that may affect the risk of death with COVID-19.

Highly Accurate Deep Learning Model for Olive Leaf Disease Classification: A Study in Tacna-Perú

Erbert F. Osco-Mamani¹, Israel N. Chaparro-Cruz²
Department of Computer Science and Systems Engineering^{1,2}
Universidad Nacional Jorge Basadre Grohmann, Tacna, Perú^{1,2}

Abstract—Deep learning applied to computer vision has different applications in agriculture, medicine, marketing, meteorology, etc. In agriculture, plant diseases can cause significant yield and quality losses. The treatment of these diseases depends on accurate and rapid classification. Olive leaf diseases are a problem that threatens the crop quality of olive growers. The objective of this work was to classify olive leaf diseases with Deep Learning in olive crops of the La Yarada-Los Palos area in the Tacna region, Peru. Disease classification is a critical task, nevertheless, for the most common diseases in the region: virosis, fumagina, and nutritional deficiencies, there is no dataset to train deep learning models. Due to the latter, a novel dataset of RGB olive leaf images is elaborated and published. Then, an extensive comparative experimental study was conducted using all possible configurations of Learning from Scratch, Transfer Learning, Fine-Tuning, and Data Augmentation state-of-the-art methods to train a modified VGG16 architecture for the classification of Olive Leaf Diseases. It was demonstrated experimentally: (i) The ineffectiveness of Data Augmentation when the model Learning from Scratch, (ii) A high improvement by using Transfer Learning vs Learning from Scratch, (iii) Similar performance using Transfer Learning vs Transfer Learning + Fine-Tuning vs Transfer Learning + Data Augmentation, and (iv) Very high improvement using Transfer Learning + Fine-Tuning + Data Augmentation. This led us to a Deep Learning Model with an accuracy of 100%, 99.93%, and 100% in the training, validation, and test sets and F1-Score on the validation set of 1, 0.9901, and 0.9899 in the Nutritional Deficiencies, Fumagina, and Virosis olive leaf diseases respectively. Replication of the results is ensured by publishing the novel dataset and the final model on GitHub.

Keywords—Olive; leaf diseases; disease classification; deep learning; data augmentation; transfer learning; fine-tuning; VGG16

I. INTRODUCTION

Tacna is the leading nationally producer of olives [1]. Peru is the second-largest exporter of olives and third-largest exporter of olive oil in South America [1]. With over 22,897 hectares under olive cultivation and an average yield of 7,995 kg/ha, olive production and processing is critical to the local and regional economy [2]. Tacna accounts for 81.4% of the olive area that exists in Peru [3]. Despite its importance, olive cultivation is still managed traditionally and the use of data is incipient. Pests and diseases such as *Orthezia Olivicola* and fruit borer can significantly reduce the number of fruits per harvest [4]. This and other problems will be exacerbated by impending climate change [5].

The problems derived from pests and diseases affect the production and the production cycle as they affect leaves, flowers, and fruits and can initiate neighboring cycles [6]. In addition, the scarcity of diagnostic tools in underdeveloped

countries has a devastating impact on their development and quality of life. Therefore, there is an urgent need to automatically classify plant diseases with affordable and easy-to-use solutions.

To reduce olive harvesting diseases, it is necessary to create and modernize technologies for efficient productivity. Adequate and fast classification of olive leaf diseases could prevent quality and crop losses. There is research related to the classification of olive leaf diseases [7] with datasets collected in countries such as Saudi Arabia [8], [9] or Turkey [10], [11], [12]. However, for the most common diseases in the region of Tacna-Perú: virosis, fumagina, and nutritional deficiencies, there is no dataset to train computer vision models for classification.

Deep Learning has become the artificial intelligence method by excellence for solving a variety of problems, including those related to computer vision [13]. The area of computer vision encompasses a large number of tasks such as segmentation, detection, and classification, among which are those related to diseases. In disease problems, Deep Learning has been shown to be state-of-the-art in both agricultural and medical applications using CNN architectures [14], [15], [16]. Deep Learning models learn directly from data and require large datasets to obtain good accuracies. To avoid the latter, some techniques have been well proven to obtain models with better results, such as Data Augmentation [17], [18], [19], Transfer Learning [20], [21], [22], and Fine-Tuning [23], [24]. But there is no study on the impact of each and combination of these techniques.

In this context, CNNs such as the well-known VGG16 architecture [25] could be trained to classify olive leaf diseases. VGG16 model was the winner of the ImageNet Large Scale Visual Recognition Challenge (ILSVRC) [26], which consists of classifying 1.2 million labeled images into a hundred classes using a 133GB dataset. The model already trained on this gigantic dataset is available, and through techniques such as Transfer Learning and Fine-Tuning, one can take advantage of feature extraction to train another classifier, if the new task and dataset have similarity to the initial task and dataset.

In this paper, our main contributions are: (i) A novel and public olive leaf disease classification dataset for the classification of virosis, fumagina, and nutritional deficiencies diseases that affect olive harvests in Tacna-Perú. (ii) Conduct an extensive comparative experimental study using all possible configurations of Data Augmentation, Transfer Learning, and Fine-Tuning techniques to train a modified VGG16 architecture for olive leaf disease classification. (iii) Obtain and publish a Highly Accurate Deep Learning model trained using

Data Augmentation, Transfer Learning, and Fine-Tuning that solves the olive leaf disease classification task.

The rest of this paper is organized as follows: Section II provides the necessary background to understand the work. Section III presents the novel olive leaf disease classification dataset. Section IV defines the materials and methods used to carry out the experiments. Section V sets the experimental setup and pipeline of experiments. Section VI presents the experimental results and performance analysis of them. Section VII presents the discussion. Finally, Section VIII provides the conclusion and further work.

II. BACKGROUND

A. Deep Learning

Deep Learning is a sub-field of machine learning that consists of using multiple layers of non-linear processing to learn data representations with multiple levels of abstraction [27].

B. CNNs

Convolutional Neural Networks (CNNs) are designed to process multiple types of data, especially two-dimensional images, and are directly inspired by the visual cortex of the brain. In the visual cortex, there is a hierarchy of basic cells: simple and complex [28]. A CNN can extract the image features without the need for this process to be performed by hand as before 2011, finally, adding a neural network at the end allows the classification task to be performed.

Fig. 1 shows a typical CNN architecture. Feature extraction consists of convolution layers (C1, C2, C3) and pooling layers (P1, P2). The classification consists of fully connected layers (FC) and an output layer [29].

Fig. 1. Typical CNN architecture, based on [29].

C. VGG16 Architecture

The VGG16 architecture [25] was proposed by Simonyan and Sisserman in 2014, they developed the convolutional neural network in the Oxford Visual Geometry Group (VGG16). This architecture is constituted of 13 convolutional layers, each group of convolution layers is followed by a max pooling layer composing the feature extraction or base model, which is followed by three fully connected layers as classification or top model, hence the name includes 16. Finally, a softmax layer is added to the classifier.

VGG16 is a classification model which is able to classify 14M images of 1000 different categories (Imagenet dataset - ILSVRC 2014) with 92.7% accuracy. Despite the existence of more recent models, the simplicity of this architecture makes

it perfect for applying techniques such as Transfer Learning and Fine-Tuning. The network (model and trained weights) is available in Keras. Fig. 2 shows the architecture of VGG16.

Fig. 2. VGG-16 architecture overview, based on [30].

D. Underfitting and Overfitting

Underfitting is a scenario where the model is not adjusted to the training dataset, causing a high error rate. In training across epochs, this happens when the model is not sufficiently capable of modeling the relationship between input and output.

When a model performs well with training data, it is necessary to consider a control group to ensure that the model performs well with data with which it has not been trained. That control group is better known as the validation set. It is possible for the model to perform very well on the training data but poorly on the validation data, which is known as overfitting (lack of generalization) [13].

E. Transfer Learning

Transfer Learning is a machine learning technique that seeks to leverage an already trained model for one task (pre-trained) into another [13], based on the assumption that the data with which the model has been initially trained are in the same feature space and have the same distribution as the new data. In cases where the latter is true, one could use the freeze feature extraction base of a pre-trained model and link it to a new classification network (with weights randomly initialized) to train only the latter and obtain good results.

This process results in a fast convergence of the model, either due to the constraints of feature extraction that have been frozen or due to the good compatibility of the dataset domains. When this is not sufficient, it is also necessary to train the feature extraction base, through a technique called Fine-Tuning.

F. Fine-Tuning

Fine-tuning is a technique that is applied over Transfer Learning to finish adjusting the model to the new dataset [13], for that purpose the feature extraction layers are unfrozen and the complete model is trained. It is important that this process is carried out after having trained the model classification layers and selected the best epoch for Fine-Tuning.

Fine-tuning allows the model to improve the feature extraction to obtain a better result in the classification task. The need to use Fine-Tuning, indicating that the feature space and distribution of the datasets (pre-trained and new) are not exactly the same, the distance between the feature space and distribution of datasets can be reflected in the model improvement.

G. Data Augmentation

Data augmentation is the generation of synthetic data by perturbing the original data [13], this artificially allows to have a larger amount of data and avoids biases related to the perturbations performed. The use of this technique reduces the need for large amounts of data to train Deep Learning models. In addition, when data are difficult to obtain, it is possible to use Data Augmentation as a regularization technique to generalize better.

Data augmentation also prevents model overfitting by adding diversity and some randomness to the dataset, which allows models to be trained over more epochs. The most used deformations or transformations are related to rotation, zoom, width and height shift, and horizontal and vertical flips. It is very important to use these transformations taking into consideration the problem domain in order not to obtain undesired results.

H. Learning from Scratch

Learning from Scratch is the process of training a model with randomly initialized parameters or weights. This is the usual process when pre-trained models are not used. When pre-trained models are used, the weights are not randomly initialized, but rather those that have been fitted to a pre-training dataset are loaded. This process may be necessary in cases where a pre-trained model compatible with the dataset being worked with is not encountered.

I. Confusion Matrix

A confusion Matrix is an NxN table that summarizes the number of correct and incorrect predictions that a classification model made, where N is the number of classes. The following values are calculated: *TP* are True Positive, *FP* False Positive, *FN* False Negative, and *TN* are True Negative. Taking these values into account, different classification metrics can be calculated.

J. Classification Metrics

1) *Accuracy*: Number of correct predictions over the total number of predictions.

2) *Loss*: It is a measure of how much error is being made in the prediction. Specifically, this value will be 0 when the prediction is equal to the desired output. For multiclass classification, the categorical cross-entropy loss is often used, the definition of which is as follows:

$$L_{CE} = - \sum_{i=1}^n t_i \log(p_i), \text{ for } n \text{ classes} \quad (1)$$

where t_i is the truth label and p_i is the Softmax probability for the i^{th} class.

3) *Precision*: Try to answer the following question: What proportion of positive identifications was correct? In the case of multi-class classification, one metric per class is obtained; is defined as follows:

$$\text{Precision} = \frac{TP}{TP + FP} \quad (2)$$

4) *Recall*: Try to answer the following question: What proportion of real positives was correctly identified? In the case of multi-class classification, one metric per class is obtained; is defined as follows:

$$\text{Recall} = \frac{TP}{TP + FN} \quad (3)$$

5) *F1-Score*: It is a single score defined as the harmonic mean of precision and recall. In the case of multi-class classification, one metric per class is obtained; is defined as follows:

$$F_1 = 2 \frac{\text{precision} \cdot \text{recall}}{\text{precision} + \text{recall}} = \frac{2TP}{2TP + FP + FN} \quad (4)$$

III. NOVEL OLIVE LEAF DISEASE CLASSIFICATION DATASET

A. Data Acquisition and Processing

Images of olive leaves found in crops at La Yarada-Los Palos in the Tacna region of Peru were collected in August of 2019 with the next most common diseases in the region.

1) *Virosis*: The name is descriptive of this disease of olive foliage due to the curved or sickle shape shown by the leaf affected with this disease. The disease is common in all commercial varieties of olives grown in South America [31].

2) *Fumagina*: It is a species of fungi, blackish in color, that covers plant tissues as a layer of soot, which hinders photosynthesis so that the affected olive trees see their productive capacity diminished. This layer comes off when passing the finger over the affected parts [32].

3) *Nutritional Deficiency*: Leaves with abnormal colorations at the terminal end of the leaves such as phosphorus and potassium [33].

The RGB images of 3984 x 2656 px were taken using a Canon EOS Rebel T6i 24.2MPX camera and fixed configurations (55 mm focal distance, 1/200s aperture, ISO-400). To highlight the characteristics of the leaves and keep the image focused and stable, a device was used to stabilize and focus the mobile device at a height of 30 cm. Each leaf was placed showing its frontal area on a blank sheet of paper.

One way to distinguish between diseased leaves is to focus on the level of green, brown, and yellow color. However, this is a criterion that does not apply to all cases, and an agronomic expert is usually required. Fig. 3 shows samples of the images taken.

The procedure for the construction of the olive leaf diseases dataset includes three phases. (i) First, images of olive trees

Fig. 3. Samples of images and classes of dataset.

are captured, selecting three diseases according to the study. (ii) Second, after the images are collected, they are given to an agronomist specialist expert in olive disease images. (iii) Finally, the specialist filtered the images and manually labeled them according to their characteristics.

The total images acquired resulted in 773 useful images, of which 258 are nutritional deficiency disease, 257 are fumagina, and 258 are virosis. In order to have class balance, a 77:19:3 split was performed to form the training, validation, and test sets. Table I specifies the final number of images per class and dataset.

TABLE I. NOVEL OLIVE LEAF DISEASE CLASSIFICATION DATASET SIZE

Category	Training Set	Validation Set	Test Set	Total
Deficiencies	200	50	8	258
Fumagina	200	50	7	257
Virosis	200	50	8	258
Total	600	150	23	773

Finally, the novel olive leaf disease dataset is made available in our GitHub for further use and evaluation.

IV. MATERIALS AND METHOD

A. Experimental Platform

For the design of the experiments and their execution, the following computer hardware was made available to us through a Google Colab Pro subscription: GPU 1x Nvidia Tesla T4 with 15GB of RAM and CPU 1x Xeon Processors @2.3Ghz with 12.7 GB of RAM.

Keras, one of the main Deep Learning APIs written in Python, was used in this study. It is compatible with multiple back-end neural network computation engines and runs on the TensorFlow machine learning platform. Versions were: Keras 2.11.0 and Tensorflow 2.11.0 as the backend in a Python version 3.8 environment. Each epoch of training takes 12 seconds and the total amount of time for 10 runs of all experiments was 33.3 hours.

B. Deep Learning Architecture

The selected Deep Learning architecture was VGG16 [25], chosen because it extracts features at a low level by using a smaller kernel size, demonstrating a good feature extraction capability for image classification. As a Deep Learning classification architecture, it is composed of 2 sub-models: feature extraction (base) and classification (top). Feature extraction was carried out by a convolutional neural network. Table II

TABLE II. VGG16 BASE MODEL ARCHITECTURE

Layer (type)	Output Shape	Number of Parameters
input_1 (InputLayer)	224 x 224 x 3	0

Total		14,714,688

presents the architecture of the feature extraction basis of VGG16 and the number of parameters.

Classification was carried out by a dense neural network. Original VGG16 architecture [25] uses three sequential dense layers as classifier (top-model), that allow mapping the model input to 1000 classes (because it was conceived for Imagenet). The architecture was modified by replacing the top-model with a max-pooling layer (to reduce the dimensionality of the extracted features) connected to a dense layer that maps the model input to 3 classes. Table III presents our modified VGG16 architecture and the number of parameters.

It was hypothesized that only one dense layer is sufficient to map features to classes, due to the complexity of our dataset compared with ImageNet, and perform the problem task. This hypothesis is proven through our experiments.

TABLE III. OUR MODIFIED VGG16 ARCHITECTURE

Layer (component)	Output Shape	Number of Parameters
input_1 (Input Layer)	224 x 224 x 3	0
vgg16_base_model	7 x 7 x 512	14,714,688
Base Model (Feature Extraction)		14,714,688
GlobalAveragePooling2D (new)	512	0
Dense (new)	3	1,539
Top Model (Classification)		1,539
Total		14,716,227

V. EXPERIMENTAL SETUP

Fig. 4 presents the complete pipeline of every experiment carried out which is detailed below.

The following comparative objectives were considered in order to achieve the objective of the study:

- 1) To determine the effect of Data Augmentation.

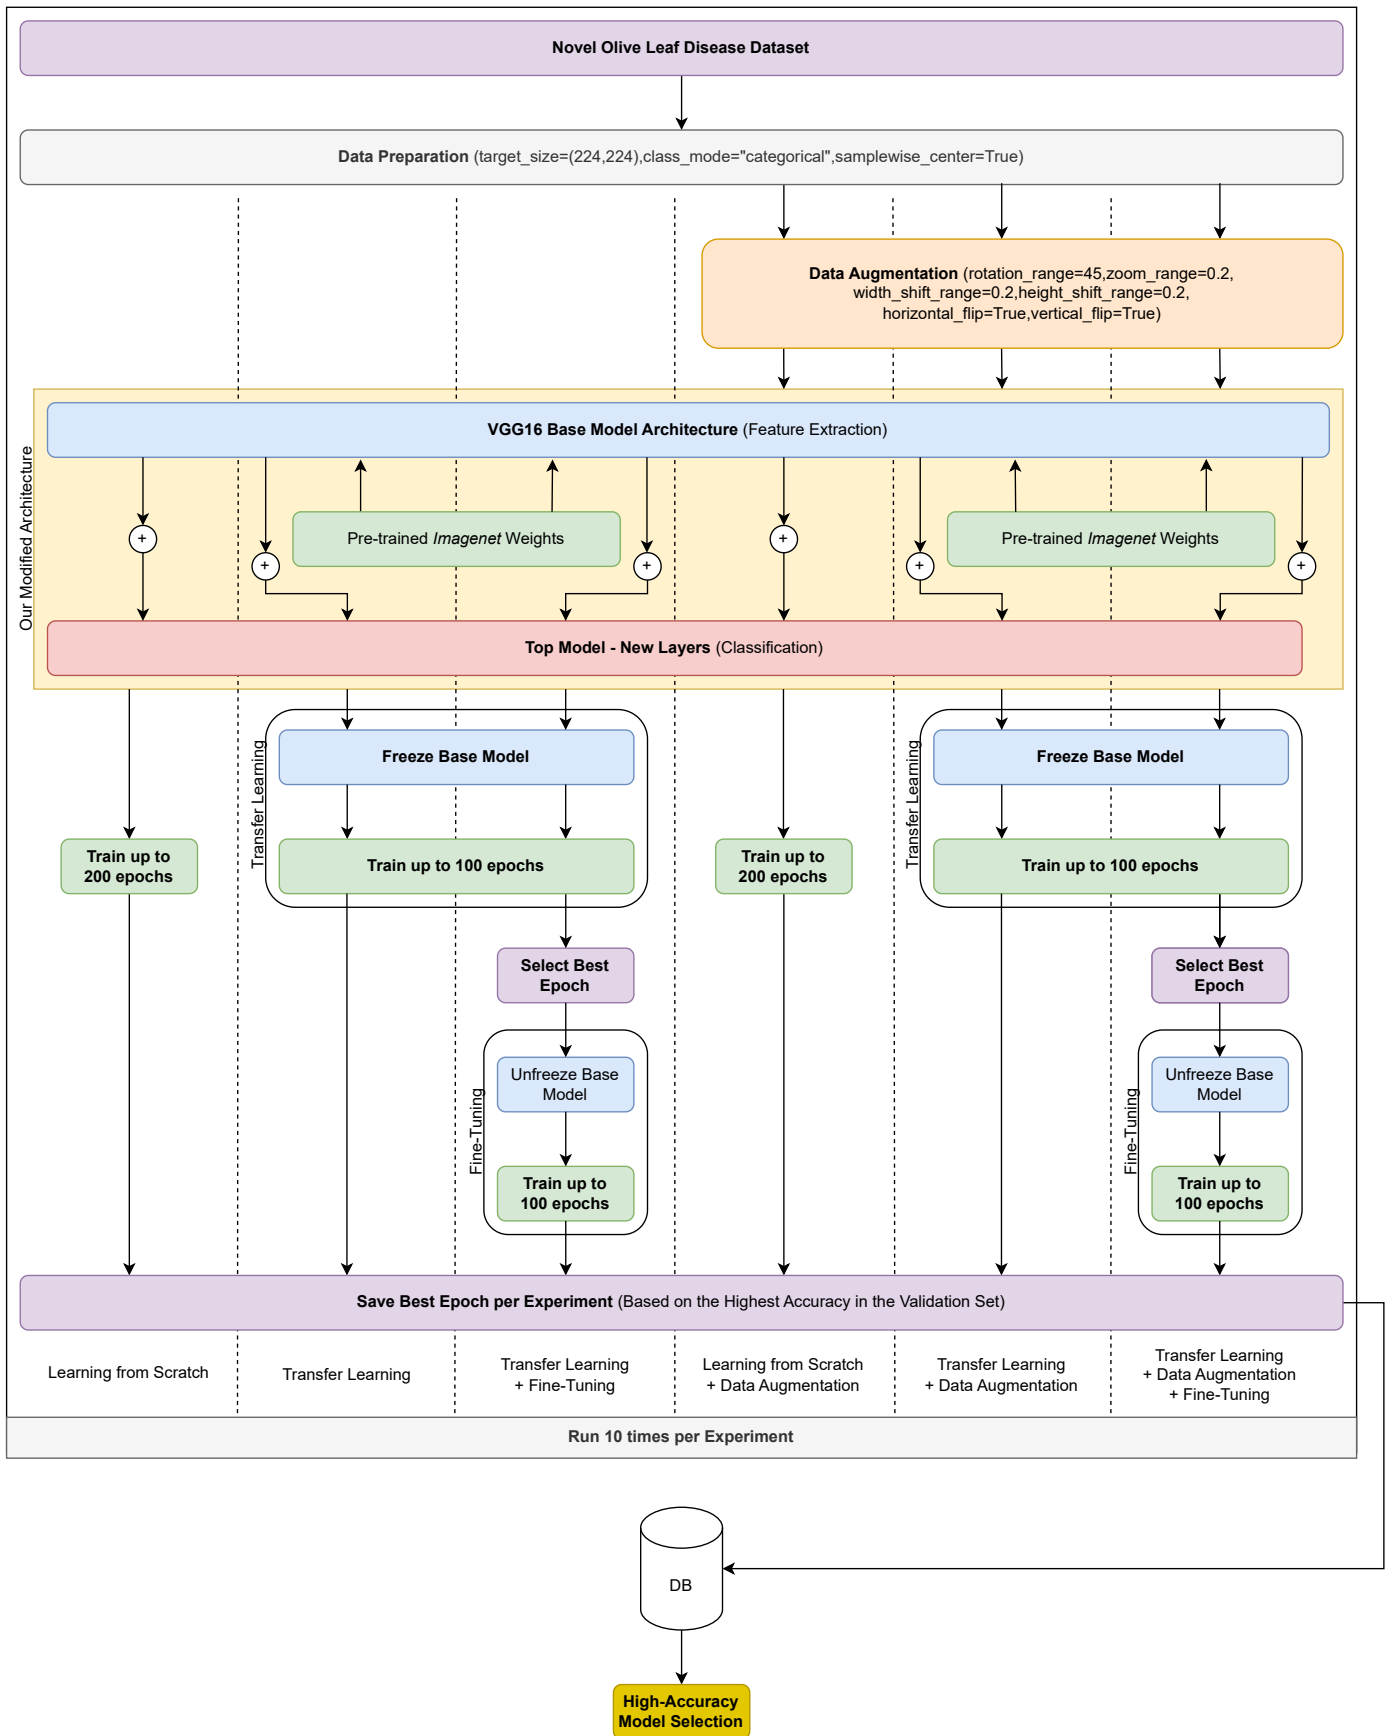

Fig. 4. Pipeline of experiments.

- 2) To determine the effect of Transfer Learning.
- 3) To determine the effect of Fine-Tuning.

For data preparation, the RGB images in the dataset were resized to the input size of the selected architecture (224,224) and each sample was scaled to mean 0. In addition, the labels of each of the images are categorized as a dummy variable to match the output size of the modified architecture. This was done in all experiments.

For Data Augmentation, which is used in some experiments, the images sent to the model for training are artificially enhanced through the following random transformations:

- 1) 0-45 degree random rotation.
- 2) 0.8-1.2 zoom.
- 3) 0-0.2 of total width shift.
- 4) 0-0.2 of total height shift.
- 5) Horizontal flip.
- 6) Vertical flip.

We describe this configuration as “Aggressive Data Augmentation” because it achieves a transformation that rotates the image from 0° to 359° with a variety of zooms, shifts, and flips.

Finally, for training models, the loss was Categorical Cross Entropy and the optimizer was ADAM [34].

In order to obtain more trustworthy results, each of the following experiments of all possible setups of Transfer Learning, Fine-Tuning, and Data Augmentation was run 10 times:

A. Learning from Scratch

For this experiment, the modified architecture was trained up to 200 epochs and the best-performing epoch is selected.

B. Learning from Scratch + Data Augmentation

For this experiment, the images sent to the model for training were artificially enhanced through Data Augmentation. Then, the modified architecture was trained up to 200 epochs and the best-performing epoch was selected.

C. Transfer Learning

For this experiment, pre-trained Imagenet weights were loaded into the base model of our modified architecture. Then, the base model was frozen and only the top model was trained up to 100 epochs.

D. Transfer Learning + Fine-Tuning

For this experiment, the best epoch of the Transfer Learning experiment is taken to unfreeze the base model and train the whole architecture up to 100 epochs.

E. Transfer Learning + Data Augmentation

For this experiment, the images sent to the model for training were artificially enhanced through Data Augmentation, and pre-trained Imagenet weights were loaded into the base model of our modified architecture. Then, the base model was frozen and only the top model was trained up to 100 epochs.

F. Transfer Learning + Data Augmentation + Finetuning

For this experiment, the best epoch of the Transfer Learning + Data Augmentation experiment is taken to unfreeze the base model and train the whole architecture up to 100 epochs.

For all experiments, the evaluation for best epoch selection was made taking into account the accuracy in the validation set. Because the experiment was run 10 times, each selection of the best model was stored in a database in order to finally select the highest accurate model.

All numbers of epochs frame the underfitting and overfitting processes of model training, so in none of the cases was the number of training epochs insufficient.

VI. EXPERIMENTAL RESULTS

A. Impact of Data Augmentation

From Fig. 5, the accuracy in the training set and validation set over 200 epochs is presented with an interquartile range on a model trained Learning from Scratch. The best validation accuracy was 0.86 with a validation loss of 0.558051.

From Fig. 6, the accuracy in the training set and validation set over 200 epochs is presented with an interquartile range on a model trained Learning from Scratch. The best validation accuracy was 0.8 with a validation loss of 0.641917.

Fig. 5. Accuracy of learning from scratch.

Fig. 6. Accuracy of learning from scratch + data augmentation.

Although the accuracy was higher without using data augmentation, the loss was lower when using data augmentation, which means that without data augmentation the model was

less sure of its prediction. On the other hand, without the use of data augmentation, the best validation accuracy was reached in 63 epochs, with the use of Data Augmentation it was reached in 130 epochs, which shows that Data Augmentation allows for avoiding overfitting in training. Moreover, both models achieve similar performances.

It is worth mentioning that, while the model without data augmentation remains stationary, the model trained without data augmentation decreases in validation value. This denotes that Learning from Scratch was not able to update the model in such a way that it adjusts to the variability of the data caused by our aggressive data augmentation.

Fig. 7. Accuracy of transfer learning vs transfer learning with data augmentation.

From Fig. 7, the accuracy in the training set and validation set over 200 epochs is presented with an interquartile range on a model trained Transfer Learning (left side), Transfer Learning + Data Augmentation (left side), Transfer Learning + Fine-Tuning (right side), and Transfer Learning + Fine-Tuning + Data Augmentation (right side).

For Transfer Learning the best validation accuracy was 0.93333 with a validation loss of 0.374403 and was reached at epoch 18, for Transfer Learning + Data Augmentation the best validation accuracy was 0.953333 with a validation loss of 0.178807 and was reached at epoch 76, for Transfer Learning + Fine-Tuning the best validation accuracy was 0.94 with a validation loss of 0.300271 and was reached at epoch 101, and for Transfer Learning + Fine-Tuning + Data Augmentation the best validation accuracy was 0.993333 with a validation loss of 0.018128 and was reached at epoch 176.

The accuracy was higher in the validation set using Data Augmentation in Transfer Learning and Transfer Learning + Fine Tuning. On the other hand, without the use of Data Augmentation, the best validation accuracy was reached before vs with the use of Data Augmentation. Moreover, both models achieve similar performances.

Data Augmentation when applied improves accuracy by 2% in Transfer Learning and 5% in Transfer Learning + Fine Tuning. This difference is consistent with the fact that Data Augmentation generates a greater variety of input data and Fine-Tuning is able to take advantage of this variety because it has unfrozen feature extraction layers.

From Fig. 8, the loss in the training set and validation set over 200 epochs is presented with an interquartile range on a

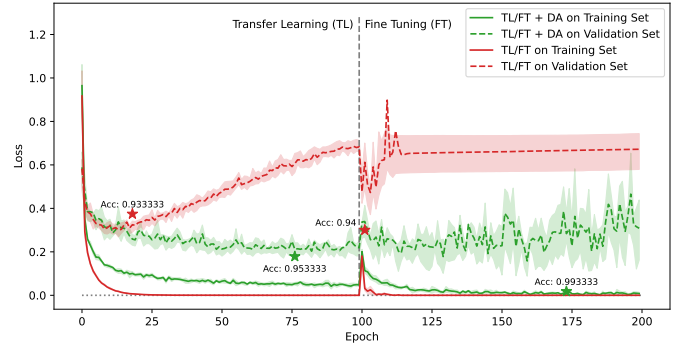

Fig. 8. Loss of transfer learning vs transfer learning with data augmentation.

model trained Transfer Learning (left side), Transfer Learning + Data Augmentation (left side), Transfer Learning + Fine-Tuning (right side), and Transfer Learning + Fine-Tuning + Data Augmentation (right side).

It can be observed that training using Data Augmentation avoids the rapid overfitting to which the model is prone due to the low variability of the data.

Furthermore, the use of Data Augmentation in Fine-Tuning did not show an improvement over 1% when Data Augmentation was not applied, where the model tends even more quickly to fall into overfitting than in Transfer Learning.

B. Impact of Transfer Learning

Fig. 9 shows the average accuracy over all experiments. The difference between using any configuration of Learning from Scratch vs any configuration using Transfer Learning was noticeable in the graph so that the lines do not overlap at any point. The use of transfer learning, regardless of also using data augmentation, improved the accuracy by at least 10% on average.

Fig. 9. Average accuracy of all experiments.

Fig. 11 shows the run with the best validation accuracy over all experiments. Again, the difference between using any configuration with Learning from Scratch vs any configuration using Transfer Learning is noticeable in the graph so that the lines do not overlap at any point. The use of transfer learning, regardless of also using data augmentation, improved the accuracy by at least 7.33333% on the best experiment run.

C. Impact of Fine-Tuning

From Fig. 7 (described above), for Transfer Learning (with or without Data Augmentation) the best validation accuracy was 0.953333 with a validation loss of 0.178807 and was reached at epoch 76, for Transfer Learning + Fine-Tuning the best validation accuracy was 0.993333 with a validation loss of 0.018128 and was reached at epoch 173.

Fine-Tuning when applied improves accuracy by less than 1% in Transfer Learning and 4% in Transfer Learning + Data Augmentation. This difference is consistent with the fact that some specific-domain problems need an adjustment in the feature extraction layers of the model to improve the performance.

Additionally, without Data Augmentation the difference between Transfer Learning and Transfer Learning + Fine-Tuning was similar.

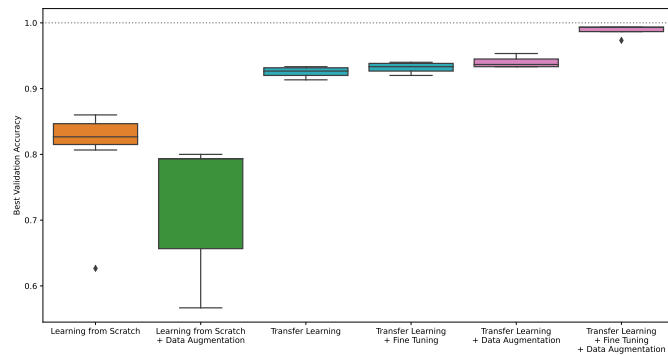

Fig. 10. Boxplot of validation accuracy.

From Fig. 10, all experiments are presented in a boxplot that resumes the best validation accuracies over 10 runs of each experiment. It can be observed that the use of Fine-Tuning over Transfer Learning without Data Augmentation gave similar results. Additionally, there was a clear improvement and separation between the values with respect to the combined use of Transfer Learning + Fine-Tuning + Data Augmentation. Furthermore, the range of values was lowest than in any other experiment.

D. Highly Accurate Deep Learning Model

From Fig. 11, the best run of all experiments is presented. The criterion used was to choose the model in whose: best epoch with the highest accuracy and lowest loss in the validation set has been obtained. Therefore, the model of run 0, epoch 173, loss 0.000008, accuracy 1.0, validation loss 0.018128, validation accuracy 0.993333 that made use of Transfer Learning + Fine-Tuning + Data Augmentation was selected as a Highly Accurate Deep Learning Model.

From Table IV, metrics of all experiments are presented, and the best values are highlighted in bold. In the validation set, the best result was obtained for all metrics in the combined use of Transfer Learning + Fine-Tuning + Data Augmentation, except for the interquartile range. However, taking into consideration the Q4-Q1 range this result was still the best. This demonstrates, due to the execution of 10 runs, that the result

Fig. 11. Best run accuracy of all experiments.

is the product of a consistent improvement provided by the experiment setup.

Once the model has been selected, is submitted to the test set to corroborate the performance. Table V shows the confusion matrix of the selected model over training, validation, and test sets. In overall sets, only in the validation set, there is one sample that belongs to the virosis class but is classified as fumagina by the model.

Table VI shows additional metrics for each disease to be classified. The average F1-Score over all diseases was 0.9933 on the validation set. The value coincides with the average accuracy of the model in the validation set due to the fact that the dataset is balanced with respect to its classes.

Finally, the highly accurate model is made available on our GitHub for further use and evaluation.

VII. DISCUSSIONS

Regarding other studies related to the detection of olive leaf diseases [7], [8], [9], [10], [11], [12], it is not possible to make a direct comparison because those studies and the present are case studies of different olive leaf diseases in different countries. However, we agree with them that it is possible to classify olive leaf diseases using Deep Learning.

The results obtained reaffirm the findings regarding the use of Data Augmentation [17], [18], [19], Transfer Learning [20], [21], [22], and Fine-Tuning [23], [24]. In addition, our extensive experimental comparative study introduces new findings on the combination of these techniques, which are presented in the conclusions.

VIII. CONCLUSIONS

A novel and public olive leaf dataset for the classification of Virosis, Fumagina, and nutritional deficiencies diseases that affect olive harvests at La Yarada-Los Palos in Tacna Region, Perú was presented.

In addition, extensive comparative experimental studies were conducted using all possible configurations of Data Augmentation, Transfer Learning, and Fine-Tuning with the next conclusions: (i) Ineffectiveness of Data Augmentation when the model Learning from Scratch, (ii) High improvement by using Transfer Learning vs Learning from Scratch, (iii) Similar performance using Transfer Learning vs Transfer Learning

+ Fine-Tuning vs Transfer Learning + Data Augmentation, and (iv) Very high improvement using Transfer Learning + Fine-Tuning + Data Augmentation.

Finally, a highly accurate Deep Learning model (100%, 99.33%, and 100% of accuracy in the training, validation, and test set respectively) based on modified VGG16 architecture using Data Augmentation, Transfer Learning, and Fine-Tuning to solve the olive leaf disease classification task was obtained and published. F1-Score was 1 for the diseases in training and test sets, and 1, 0.9901, and 0.9899 in the Nutritional Deficiencies, Fumagina, and Virosis diseases.

Making the dataset and selected model public allows for the reproducibility of the results. Future works could deploy this trained model to a mobile or edge device for validation and agricultural use, experiment with different Data Augmentation

configurations, and compare VGG16 with other models.

ACKNOWLEDGMENT

We would like to express our appreciation and thanks to the NVIDIA Deep Learning Institute (DLI) for providing the Free Faculty Development Workshop “Fundamentals of Deep Learning” on February 18, 2022.

This research was supported by Canon, Sobrecanon, and Mining Royalties of the Universidad Nacional Jorge Basadre Grohmann - Tacna - Perú.

Enhanced MQTT Architecture for Smart Supply Chain

Raouya AKNIN[✉], Youssef Bentaleb

Ibn Tofail University, Engineering Sciences Laboratory, Kenitra, Morocco

Abstract—In industry 4.0, the use of smart supply chains has become necessary in order to overcome the shortcomings of traditional supply chains, such as overstocking, delivery delays, and stock out. However, the use of smart supply chains has introduced new security challenges because of the internet of things (IOT) constraint nature. Thus, the problem raised is ensuring the supply chain security requirements while taking into consideration the properties of the constraint environment. For this purpose, this paper aims to strengthen the authentication and data transmitting processes of the Message Queuing Telemetry Transport (MQTT) protocol, as the most used protocol for communication in the IOT environment, using blockchain and smart contracts. The new MQTT architecture allows to avoid a single point of failure, to ensure data immutability and to automatize the authentication mechanism as well as the publishing and the subscribing processes. In addition, the use of a one-time password (OTP) instead of a permanent one is another security measure used to protect the architecture from identity spoofing. The new architecture comprises three phases: Registration, Connection, and Publishing. Each phase is automatically controlled by a smart contract. For attack simulation tests, the smart contracts are implemented in a remix environment. The results of the simulation tests show that the new architecture is robust and resistant to different attacks.

Keywords—Smart supply chain; internet of things; MQTT protocol; blockchain; smart contracts; Ethereum; solidity; one-time password

I. INTRODUCTION

Industry 4.0 has proven its effectiveness in managing and optimizing the value chain. It thus enables better production with minimal cost and increased accuracy. The use of various technologies such as internet of things (IOT), cloud computing, artificial intelligence, and big data in order to interconnect different production and control units, collect data and analyze it has offered better visibility, quick decision-making, and intervention in the best time frame. The successful transformation of industries towards 4.0 requires first a review of supply chain management as a crucial element in managing the relationships between the different stakeholders involved in the product life cycle from raw materials acquisition until the delivery of the final product to the customer. Indeed, traditional supply chains have created several challenges, such as overstocking, delivery delays, and stockouts. Although the integration of IOT in supply chain management has solved the above challenges, security issues have arisen and have become more and more worrisome. Indeed, smart supply chains are subjects of several attacks that threaten data confidentiality, integrity, and availability due to security policies that have been breached to meet the constrained environment's requirements. Research works addressing the supply chain security challenges have either used the IOT protocols' native security mechanisms or have

proposed a robust solution without considering the constrained environment nature. Hence, the challenge is to fit the supply chains security requirements while taking into consideration the constrained environment properties. This paper will propose a security enhancement of the Message Queuing Telemetry Transport (MQTT) protocol, one of the most used protocol in the IOT environment, thanks to its lightness in terms of resources and bandwidth, without affecting the protocol's overall operation and its performances. The new architecture is based on smart contracts and consortium blockchain in order to automatize access control, publishing, and subscribing processes of devices involved in different stages of the product life cycle as well as to ensure the security of shared data between the supply chain's stakeholders. It is composed of three phases: Registration, Connecting, and Publishing phases. Each phase is controlled by a smart contract. In the registration phase, stakeholders' trusted administrators register the devices in the blockchain, define the topics that they have the rights to publish and subscribe on and recover the necessary keys for connection and transmitting data. Before, publishing or subscribing, the devices must first be connected to the broker network using one-time password (OTP) for authentication. Once the authentication data are approved, they can publish or register in a topic according to the rights granted by their administrators. To further strengthen the architecture, this paper will propose some security measures to protect the supply chain from different attacks. Indeed, it uses a broker network instead of one to avoid a denial of service. It uses the OTP for connection to the broker network in order to protect the device from identity spoofing. It also automatically verifies the packet number before any transaction to protect the architecture from reply attacks. The simulation tests attack will show that the new architecture is resilient to these attacks. The remainder of this paper is structured as follows: Section II will discuss research works that address the smart supply chains security challenges. Section III will report the main smart supply chain management challenges. Section IV will review some preliminary concepts needed for the proposal. Section V will describe the proposed MQTT architecture for the supply chain. Section VI will implement the smart contracts used for the registration, the connection, and the publishing phases using remix IDE. Section VII will show the results of attack simulation tests. Section VIII will describe the contribution of this paper in addressing smart supply chains challenges. Section IX will summarize the main ideas discussed in this article.

II. RELATED WORKS

In this section, we will introduce research works addressing the security challenges in supply chain management.

Article[23] proposed an architecture and an implementation of automated supply chain management for position and shipment tracking using global positioning system (GPS) and Radio Frequency Identification (RFID) technologies respectively. The proposed architecture has used MQTT protocol for communication, however, it used native security mechanisms which are not suitable for transmitting a critical data. Article[22] proposed a conceptual framework for supply chain management using blockchain and smart contracts in order to reduce the involvement of third parties and improve data security. However, it focused only on product purchasing and the agreement between buyer and seller while the supply chain management requires the involvement of different stakeholders participating in the product life cycle. Article[20] proposed an implementation of a food tracing system based on permissioned blockchain for the food supply chain. The security supply chain requirements regarding data privacy, confidentiality and access control are fully respected. However, because the supply chain is composed of different stockholders, it will be preferable to use a consortium blockchain instead of a permissioned blockchain. Moreover, the solution used a blockchain in constrained environment which can cause problems of resources and bandwidth. Article [21] applies Cyber Threat Intelligence with Machine Learning techniques to analyze and predict threats against supply chains. However, it focused only on analyzing and predicting the threats without offering the necessary countermeasures. Hence, the proposed solution will be efficient for an already secured architecture. After analyzing the aforementioned research works, it turns out that the papers either use the IOT protocols native security mechanisms for supply chain management which does not fit the security requirements of supply chains, or propose robust security solutions without considering the constrained environment properties. The architecture proposed in this paper aims to improve the security of the MQTT protocol in order to fit the security supply chain's requirements without affecting the overall operations neither the lightness of the protocol. The solution is based on consortium blockchain to allow the interaction between different stakeholders and smart contracts to automatize the authentication, the publication, and the subscription processes as well as to ensure data confidentiality, integrity, and availability. The advantage of this architecture is that only the broker's network interacts with the blockchain and the smart contracts which eliminate the use of the blockchain in the constrained environment. To avoid using the Transport Layer Security (TLS) protocol in this environment, the parameters for calculating the OTP are exchanged on different channels, making it impossible for a hacker to retrieve it. Verification of the packet numbers by smart contracts is another security measure used to avoid replay attacks.

III. SMART SUPPLY CHAIN ISSUE

The goal behind supply chain management is to supervise the product life cycle from the purchase of the raw material until the product's deliverance to a customer. The supply chain is composed of many independent entities that must share the data with each other. The use of IOT devices in the supply chain management such as sensors, Radio Frequency Identification (RFID), and Global Positioning System (GPS) improves the performances as well as the transparency in the

whole process product life cycle. The gathered data in each step must be shared with other entities. Hence, the MQTT protocol is the fittest protocol thanks to its publish-subscribe model. Indeed, the IOT components can share the data in a specific topic and the subscribers in this topic can receive the data thanks to the intermediate server called a broker. However, the native security measures are insufficient to ensure the security supply chain requirements, and it can make it a subject of many attacks, namely Man in the middle attack, Denial of service, reply attacks, identity spoofing, Information Disclosure, Privilege Escalation, Tampering Data, and so on [15]. In fact, MQTT Messages are not natively encrypted and the data is exchanged in plaintext. Hence any network sniffer can acquire valuable information such as : IP broker, credentials, Name of a topic, Data payload, MQTT port number, and so on. By having this information, several attacks can be carried out. First, a hacker can steal the credentials during the connection establishment phase and then publishes the wrong data on behalf of the legitimate publisher. Moreover, since the credentials are permanent, the hacker can use them forever until the client changes them. Data integrity is also a challenge for the current MQTT architecture since the hacker can modify the MQTT messages content including the topic name that the legitimate publisher had published in. Another attack scenario targeting data integrity can happen when a hacker sends malicious firmware to subscribers in order to transform them into botnets [16] [17] [18]. The proposed solution for this challenge is the use of the Transport Layer Security (TLS) protocol. However, it doesn't seem to be a good alternative since it increases the computational overhead on resource-constrained devices. Another attack type that MQTT is facing is a Denial of service (DoS). Since the Broker presents a single point of failure in MQTT architecture, it can be a target of many DOS attacks. Hence, when a broker is broken down, communication between publisher and subscriber is no longer possible. The Slow DoS against Internet of Things Environments (SlowITe) attack is one among other DOS attacks that target the MQTT protocol. Indeed, it tries to saturate the broker with the maximum possible connections in order to deprive the legitimate clients to connect to the broker [19]. In order to overcome these challenges, the proposed architecture will use a blockchain and smart contract in order to automatize and strengthen the authentication process as well as to ensure data confidentiality and integrity. It will base on a consortium blockchain since the supply chain entities are independent . Indeed, each entity which composed the supply chain has a trusted node called device administrator who registers the IOT devices in the blockchain as well as the topics that has the right to publish or subscribe on a. For instance, the transportation company register the GPS device in the blockchain in order to publish in the Geolocalisation topic. The entities concerned by product tracking such as the customer, the Retailer and the manufactory, are registered in the blockchain as subscribers on this topic.

IV. PRELIMINARIES

This section is a reminder of the main concepts and the technologies used in this proposal.

A. Supply Chain

Supply Chain can be defined as a connected set of resources and processes that are involved in providing goods to customers. It establishes a multistakeholder collaboration environment between different entities that are involved in the product life cycle (manufacturers, suppliers, distributors, retailers and transportation, information and other logistics management service providers) from the raw materials sourcing until the deliverance of finished goods to the end consumer [1][2]. In industry 4.0, the term “smart supply chain” or “digital supply chain” is used to describe the adoption of innovative technologies across all supply chain stages in order to increase the performances and improve customer service [3][4].

B. MQTT Protocol

Message Queuing Telemetry Transport (MQTT) is a publish-subscribe protocol used as an alternative to Hypertext Transfer Protocol (HTTP) in the constraint environment. As depicted in Fig. 1, The MQTT architecture is composed of three components: the publisher that sends the data related to a specific topic, the subscriber that is registered in a specific topic in order to receive a notification when this topic is updated and the broker is an intermediary server that gets the data from different publishers and sends them to subscribers that are already registered in this topic. MQTT protocol used a Transmission Control Protocol (TCP) as an underlying transport protocol [5] [6]. It uses port 1883 for unencrypted messages and port 8883 for encrypted ones. Before publishing or subscribing to any topic, the clients must be connected to a broker. The native authentication method used by the MQTT protocol is the login and password transited in plaintext format [6]. MQTT protocol offers to publishers and subscribers a feature of choosing quality of service (QOS) levels depending on the network condition, the device characteristics and the application criticality: in QOS 0, the message is delivered at most once without any acknowledgment; in QOS1, the message is delivered at least one time. Hence, the sender keeps the message stored until the reception of an acknowledgment; in QOS 2, the message is delivered exactly one time without any duplication [7].

C. Blockchain

Blockchain is a distributed database composed of a list of ordered blocks and it runs on a Peer to peer network [9]. Each block is structured as follows: A header that contains information related to the block namely Block version, Timestamp, Merkle tree root hash, Parent Block hash and nonce, which is a random number for verifying the hash. This information varies based on the blockchain network provider. A body that contains transactions. Each block is linked to the previous one thanks to the Parent block hash field which makes the blockchain immutable from frauds. Special nodes in the network, called Miners, hold the responsibility of adding a block to a blockchain. For this purpose, a consensus algorithm is used in order to reach a common agreement between untrusted nodes and define the winner miner. Proof of work and Proof of stake are the most used consensus algorithms [9] [6].

Fig. 1. The MQTT architecture [8].

D. Smart Contract

Smart contract was first introduced by Szabo in the mid-1990s in order to minimize contracting cost between transacting parties and to avoid accidental exceptions or malicious actions during contract performance. He suggested translating a contract into code that will be self-executed when predetermined conditions are met. The advent of the blockchain technology has made the implementation of smart contract possible [10]. Nowadays, the term of smart contract is popularly used to refer [9] to code scripts that run synchronously on multiple nodes of a distributed ledger namely blockchain. Ethereum is the most popular platform to implement a smart contract.

E. Ethereum

Ethereum is an open-source blockchain platform that enables the development of smart contracts [12] using a Turing-complete programming language called “solidity” [11]. Then a solidity compiler transforms a source code into bytecode in order to be interpreted by Ethereum Virtual Machine (EVM). The interaction between Ethereum smart contracts and the users is through transactions. Indeed, the Ethereum platform supports two types of accounts: user accounts and smart contract accounts. This latter is assigned to the contract, once it is deployed. User account is assigned to the Ethereum users in order to deploy contracts and to interact with them. Ether is the cryptocurrency used in the Ethereum platform. The transaction cost is defined according to two parameters: Gas limit and Gas price. Gas limit is the maximum amount of gas that the user can pay and the Gas price is the amount of Ether that the user is willing to pay for one unit of gas [13].

V. THE ENHANCED MQTT ARCHITECTURE

The architecture presented in this section is a security enhancement of the current MQTT protocol architecture. The goal is to strengthen the protocol’s security to meet supply chain requirements without disrupting its normal operation. This architecture is based on blockchain and smart contracts to automatize authentication, publication, and subscription. It aims also to ensure data confidentiality and integrity. As depicted in Fig. 2, it is composed of clients (Publisher and subscriber) which represent the IOT devices used by each entity in supply chain and the broker network which execute automatically smart contracts. The choice of consortium blockchain allows each supply chain entity to have a trusted administrator who registers the devices in the blockchain as well as the topics which can publish or subscribe on. The communication between the components is divided into three phases: The

Fig. 2. The enhanced MQTT architecture.

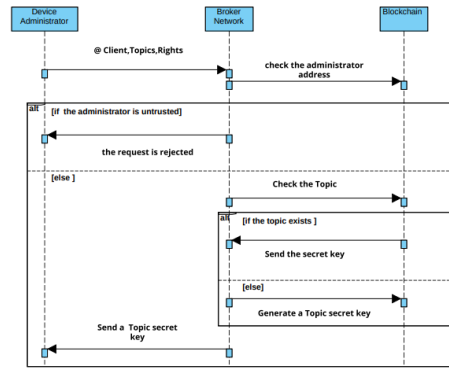

Fig. 3. Registration sequence diagram.

registration phase, the Connecting phase and the Publishing phase. Each phase is automatically controlled by a smart contract. To address the drawbacks of permanent password, the new architecture is based on OTP (One Time password) for authentication. This password that becomes invalid in few minutes protect the architecture from the identity spoofing.

A. Registration Phase

During this phase, the device administrator (Trusted node) calls the registration smart contract in order to register his devices in the blockchain and to recover the necessary keys for OTP calculating and for messages encryption. These keys are communicated to the devices in an out-of-band mode. Since the exchanged information is critical and the administrator has no computation and memory constraints, the TLS protocol can be used in this phase. After this transaction, for each device, a token containing the device address as well a list of topics that the device has the right to publish or subscribe on is generated and stored in the blockchain. Also, for each new topic a key is automatically generated and stored in the blockchain. The main steps of the registration phase are shown in Fig. 3.

B. Connecting Phase

As the current MQTT architecture, before publishing or subscribing in the topic the client must first connect to the broker. In this architecture, the device calls the connecting smart contract to connect to the broker network. Before allowing the communication, first the smart contract verifies the device registration and the Packet Number in order to avoid a Reply attack then it sends a challenge necessary for the one-time password (OTP) calculating. The device calculates the OTP and sends the a hash OTP. The smart contract verifies the hash OTP and then allows the connection to the broker network. The main steps of the connecting phase are shown in Fig. 4.

1) *OTP calculating*: The authentication process is based on one-time password (OTP) in order to avoid identity spoofing. The OTP calculation is based on or function. The inputs of this function are respectively :the list of publication's key Topics, the list of subscription's key Topics and the challenge. The detail of OTP Calculating is depicted in the equation (1):

$$OTP = F(LKP, LKS, challenge) \quad (1)$$

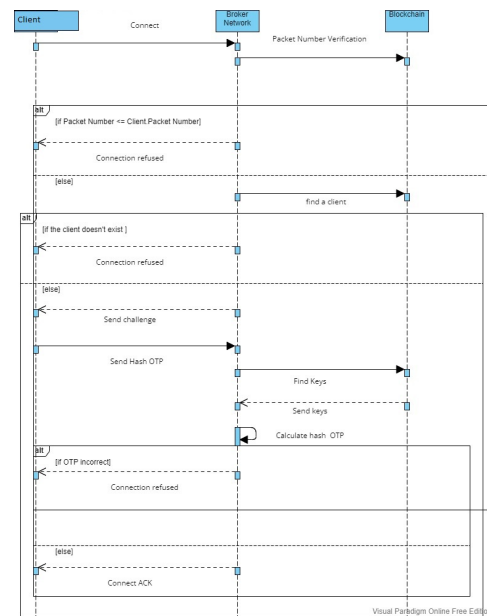

Fig. 4. Connection sequence diagram.

- F :is OR function.
- LKP: the list of publication's key Topics.
- LKS: the list of subscription 's key Topics.

N.B List of Keys and function are communicated to the device in outband mode.

C. Publishing Phase

As depicted in Fig. 5, the publishing process is the same as the current MQTT architecture in overall. However, we have added some security measures in order to strengthen the architecture. Indeed, in this phase, the device first calls the publishing smart contract. This latter checks its rights on publishing in this topic before allowing it to publish. Then, it notifies all the subscribers in that topic. In order to ensure data confidentiality, the published messages are encrypted with the topic key.

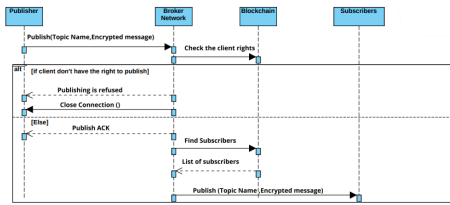

Fig. 5. Publishing sequence diagram.

VI. SMART CONTRACTS IMPLEMENTATION

The authentication mechanism as well as the publication and the subscription processes are implemented in smart contracts for automatization. They are implemented in consortium blockchain and executed by broker network. The smart contracts proposed in this paper are developed using solidity language in a remix environment.

A. Registration Smart Contract

In order to register his device, the Device administrator calls the `regisrationMain` function depicted in Fig. 6, This function allows the device administrator to interact with the registration smart contract. The administrator communicates to the function the following information: client address as well as the topics that the device has the right to publish or subscribe. Before allowing device registration, the smart contract first verifies the administrator privileges. Then it stores in the blockchain the required device information for authentication, publication and subscription. It also creates a topic if it doesn't exist. Finally, it sends to the administrator the necessary keys for OTP calculating as well as for messages encryption.

B. Connecting Smart Contract

The functions used to interact with the connecting smart contract are: `connectionMAin` in Fig. 7 and `OTPVerification` in Fig. 8. When a device sends a connecting message to the broker network, the `connectionMAin` function verifies the packet number in order to avoid a reply attack and then, it checks the existence of the device in the blockchain. After the previous verifications, the function sends a challenge to a device. In its turn, the device calculates the Hash OTP using the method detailed in the connecting phase section and calls the `OTPVerification` function. This latter verifies the hash OTP to allow or deny the connection.

C. Publishing Smart Contract

The interaction between the device and the publishing smart contract is through the `publish` function in Fig. 9. Indeed, the device calls this function for a publishing request. The function verifies the client's rights. Once the publishing is allowed, it sends a notification to all subscribers on this topic.

VII. SIMULATION TESTS

A. Case Study

In this section, we will perform simulation tests attack through a case study. Considering the simplified supply chain

```

function regisrationMain(address client_address,Topic memory client_right)
public returns (uint){
bool check_administrator=checkingAdministrator(msg.sender);
if (check_administrator==false){
emit ConnectionMessage("You don't have a privilege to add devices!The
connection is closed");
return (0);
}
else {
adddevice(client_address, client_right);
bool ccheck=CheckTopic(client_right.name);
if (ccheck==false){
uint key_Topic= addingTopic(client_right.name);
emit ConnectionMessage("The client is added to the blockchain and
the key is generated");
return(key_Topic);
}
else
for (uint h=0;h<i;i++){
bool
comparaison=stringComparison(Keys[h].name,client_right.name);
if (comparaison==true){
emit ConnectionMessage("The client is added to the blockchain and
the key is sent");
return(Keys[h].key);
}
}
}
}
    
```

Fig. 6. Resgistration main function.

```

function connectionMain(uint Packet_Number) public returns (uint) { @infinite gas
bool check_packet=Packet_verification(Packet_Number);
if (check_packet==false){
emit ConnectionMessage("Reply attack is detected and the connection is refused");
return(0);
}
else {
uint i=Clients[msg.sender].IntPacketNumber=Packet_Number;
if (Clients[msg.sender].taille_mapping==0){
emit ConnectionMessage("connection is unauthorized for unregistered device");
return(1);
}
else {
emit ConnectionMessage("The challenge is sent");
challenge =calc(challenge);
return (challenge);
}
}
}
    
```

Fig. 7. connection main function.

```

function OTP_Verification(uint hashOTP_Client) public returns (bool) { @infinite gas
uint i=Clients[msg.sender].taille_mapping;
for (uint j=0;j<i;j++){

Fig. 9. Publish function.

depicted in Fig. 10 and supposing that the products are sensitive to temperature and humidity. Hence, it is important to monitor these parameters in the whole product life cycle through respectively temperature and humidity sensors. The Manufactory adds product information such as Fabrication date, end date and product ingredients in RFID Tag. This information will be published through a RFID reader. In the distribution phase a manufacturer, a retailer as well as the customer need to know the product location that is why a GPS device is used in this phase. Each entity in the supply chain has an end

Fig. 10. Simplified supply chain [14].

device in order to monitor the product manufacture. Device Administrator of each entity ensures the configuration and the maintenance of devices belonging to it. In order to collect customers’ feedback, the trusted retailer administrator adds the end device customer in the blockchain to publish his feedback later . The topics are structured in hierarchical way. Tables I, II, III, IV, V, VI, VII, VIII, IX,X, XI, XII, XIII, XIV, XV bellow summarizes the topics and the devices using in this case as well as the Devices’ rights for each topic.

B. Attack Simulation Tests

This section describes, for each phase, the nominal scenario as well as scenarios of possible attacks.

1) Registration phase:

- 1) Scenario 1: The nominal scenario
 - A trusted Administrator (supplier Administrator for example) calls the registrationMain function to register his device (Supplier Temperature sensor for example). The device has the following address (0x4B20993Bc481177ec7E8f571ceCaE8A9e22C02db). Table I depicts the device’s rights (Fig. 11).
 - The smart contract verifies the administrator address, then it registers the device in the blockchain and sends the secret topic key to the administrator (Fig. 12).
- 2) Scenario 2: Device is added by an untrusted administrator:
 - An unknown administrator tries to add a new Device. As depicted in Fig. 13, an error message is displayed.

2) Connecting phase:

- 1) Scenario 3: The nominal scenario
 - A registered Device (Supplier Temperature sensor for example) calls connectionMain function to connect to the broker network.
 - The Smart contract verifies that the device is already registered, checks the packet number to avoid a reply attack and then sends a challenge Fig. 14.
 - After receiving the challenge, the device calculates the OTP and sends the hash OTP Fig. 15.
 - The OTPVerification function verifies that the sent OTP is correct, then it allows the connection to the broker network Fig.16.
- 2) Scenario 4: The Device sends a wrong Hash OTP
 - A registered device (Supplier Temperature sensor for example) calls connectionMain function to connect to the broker network.

and an error message is displayed Fig.19

3) Publishing phase:

1) Scenario 7:The nominal scenario:

- A registered Device (Supplier Temperature sensor for example)who has address (0x4B20993Bc481177ec7E8f571ceCaE8A9e22C02db) calls publish function in order to publish in “Temperature /raw Material”Fig. 20 .
- The smart contract verifies the Supplier Temperature sensor’s rights. Then it returns the addresses of all subscribers in the Topic Fig. 21.

2) Scenario 8: The topic doesn’t exist in the Devices’s list or it doesn’t have the right to publish on:

- A registered Device (End device Manufactory firm for example) publishes in “Temperature

Fig. 18. Log Message: Unregistered client (Scenario 5).

Fig. 19. Log Message: Reply attack (Scenario 6).

/raw Material” topic (doesn’t have the right to publish on) .

- As depicted in Fig. 22, the network broker refuses the publishing in the topic, the connection is closed and an error message is displayed.

C. Discussion and Studies

The solution proposed in this paper responds to the problem raised, which consists in designing an architecture that meets the supply chains security requirements while taking into consideration the constrained environments properties. The attack simulation test scenarios have been designed to test the resistance of the new architecture to the attacks and security issues already mentioned in section III. Denial of service (DOS) and distributed denial-of-service (DDOS) attacks that jeopardize data availability have been addressed through the decentralized architecture of the blockchain and the use of a broker network instead of one. The use of the consortium blockchain perfectly meets the need of the supply chain, which stipulates the communication and sharing of data between several independent entities. Each entity designates an administrator who registers the entity’s devices as well as the topics on which they are allowed to publish or subscribe on (Scenario 1). Unlike the standard MQTT architecture where any device can connect, publish or subscribe in the broker, the new architecture allows connection only for already registered devices (Scenario 5). The devices publication is also allowed only for topics designated by administrators in the registration phase (Scenario 8). To avoid MAN in the middle attacks and preserve data confidentiality in a constrained environment, the authentication data exchange is carried out in several stages. Firstly, when registering devices, the administrator collects the keys necessary for calculating the OTP, which will be communicated to the device in out-of-band mode (Scenario 1). Then, during the connection phase, the broker network sends a challenge, another parameter used in the OTP calculation, to a device (Scenario 3). After calculating the OTP, the device sends the OTP hash for verification. Thus, even if a hacker is positioned between the device and the broker network, he does not have all the information needed to spoof the device’s identity. Reply attacks are avoided thanks to packet number verification (Scenario 6).

VIII. THE CONTRIBUTION OF THE ARTICLE

The goal of this paper is to enhance the MQTT security protocol in order to fit the supply chain requirements and without affecting the overall operation of this protocol. It proposed a holistic solution based on blockchain and smart contracts to automatize the authentication, connecting and

Fig. 20. Device publication transaction (Scenario7).

Fig. 21. List of subscribers (Scenario7).

Fig. 22. Log message: Publishing is refused (Scenario 8).

publishing processes. It used a consortium blockchain since supply chain requires interaction between independent entities. Each entity appoints a trusted administrator who registers the devices in the blockchain as well as the topics that it has the right to publish or subscribe on. The TLS protocol can be used in this phase since the devices are not constrained. All the necessary keys used for OTP calculating are communicated in this phase. The paper proposed several security measures to protect the architecture from the most common attacks and to ensure data confidentiality, integrity and availability. Indeed, it used a broker network instead of one to avoid a denial of service. It used the OTP hash for connection to the broker network in order to protect the device from identity spoofing. It also automatically verified the packet number before any transaction to protect the architecture from reply attacks. The simulation tests attack showed that the new architecture is resilient to these attacks.

IX. CONCLUSION

In summary, this paper proposed a MQTT security improvement in order to fit supply chains requirements. It aims to address security challenges without affecting the overall operation or performances. The new architecture is based on blockchain and smart contracts in order to avoid a single point of failure, to ensure data immutability and to automatize the authentication mechanism as well as the publishing and the subscribing processes. The paper proposed several security measures to strengthen the MQTT architecture. Indeed, it requires the device registration before network integration. This task is performed by a trusted administrator of each supply chain entity. To lighten the protocol, the architecture has used a TLS only in this phase when the required keys for computing OTP and encrypting messages are communicated to device administrator. This later communicates this critical information to the device in out band mode. It is also based on OTP for authentication which protects the architecture from man-in-the-middle attacks. Packet number verification is another security measure used in this architecture in order to avoid a reply

attack. The attack simulation tests are shown the resistance of our architecture against malicious attacks. On the other hand, this paper is limited only to the implementation and the test of the smart contracts side, that is why in our future work, we will try to implement the end-to-end mechanism and perform the attack tests simulation on the whole architecture.

Abstract—Over the past few decades, the volume of data has increased significantly in both scientific institutions and universities, with a large number of students enrolled and a high volume of related data. Furthermore, network traffic has increased with post-pandemic and the use of online learning. Therefore, processing network traffic data is a complex and challenging task that increases the possibility of intrusions and anomalies. Traditional security systems cannot deal with such high-speed and big data traffic. Real-time anomaly detection should be able to process data as quickly as possible to detect abnormal and malicious data. This paper proposes a hybrid approach consisting of supervised and unsupervised learning for anomaly detection based on the big data engine Apache Spark. Initially, the k-means algorithm was implemented in Sparks MLib for clustering network traffic, then for each cluster, K-nearest neighbors algorithm (KNN) was implemented for classification and anomaly detection. The proposed model was trained and validated against a real dataset from *Ibn Zohr* University. The results indicate that the proposed model outperformed other well-known algorithms in detecting anomalies based on the aforementioned dataset. The experimental results show that the proposed hybrid approach can reach up to 99.94 % accuracy using the k-fold cross-validation method in the complete dataset with all 48 features.

Keywords—Anomaly detection; big data; Apache Spark; k-means; KNN

I. INTRODUCTION

The growth of digital technology and the internet has resulted in an explosion of data creation and consumption in various fields, including science and education. Universities and research institutions are generating and collecting a vast amount of data, including research findings, academic papers, student records, and administrative data.

In addition, the COVID-19 pandemic has significantly impacted the way education is delivered, with many institutions transitioning to online learning to maintain social distancing and reduce the spread of the virus. This shift has led to an increase in network traffic, as students and faculty members access online resources, participate in virtual classes, and communicate through online platforms. Processing such network traffic data is a complex and challenging task that increases the possibility of intrusions and anomalies. Therefore, universities and research institutions need to ensure that their digital infrastructure can handle the increased data volume and network traffic, while maintaining data security and privacy, but these pillars are not sufficient without anomaly detection.

Several security strategies have been implemented to secure

networks; firewalls are an example of strategies used as a basic packet filter. Studies demonstrate that firewalls are not sufficient in providing secure environment [1][2]. Therefore, combining anomaly detection with firewalls can provide a safer network.

In machine learning (ML)-based anomaly detection, the anomaly is represented through a set of features that comprises the expected behavior of a system. Therefore, the ML model is expected to classify other events correctly if they present the same behavior during the training phase. Although, in a real-world environment, such as scientific institutions and universities, where the network traffic changes daily, either due to new attack discoveries or responding to new students' requests. Traditional security systems cannot deal with such high-speed and big data traffic. Real-time anomaly detection should be able to process data as quickly as possible to detect abnormal and malicious data.

The contribution of this paper is proposing a hybrid approach consisting of supervised and unsupervised learning for anomaly detection. Furthermore, the big data engine Apache Spark is used to provide continuous monitoring through real-time network traffic processing. The proposed approach is divided to three main components. (1) Data preprocessing to prepare data for feature extraction in machine learning. The dataset used in this analysis includes both numerical and symbolic representations, with 46 numerical attributes and 2 symbolic attributes. (2) Features selection based on K-means clustering in order to partitionate the dataset into K non-overlapping clusters based on their feature values. (3) Anomaly detection through clustering-based methods which are commonly used by analyzing the relationship between data instances and clusters. The existence of a large distance between an instance and the clusters can be used to identify an anomaly. In the suggested approach, the K-Nearest Neighbors (KNN) algorithm was applied with cross-validation techniques to detect network traffic anomalies.

The proposed model was trained and validated against a real dataset from *Ibn Zohr* University, and aimed to minimize false negatives and optimize true positives. The results indicate that the proposed model outperformed other well-known algorithms; in detecting anomalies based on the aforementioned dataset; compared to other well-known algorithms such as Random Forest [3], Support Vector Machine (SVM) [4], Naive Bayes [4] and Gradient Boosting [5]. The experimental results show that the proposed hybrid approach can reach up to 99.94 % accuracy using the k-fold cross-validation method in the

complete dataset with all 48 features.

The rest of this paper is organized as follows: Section II, present related work. Section III presents the proposed approach. Section IV reports and analyze experimental results. Section V presents general observations and considerations. Finally, the conclusion and expected future work are given in Section VI.

II. RELATED WORK

The issue of designing an efficient intrusion detection system has been discussed in many articles [6]. In order to achieve this goal, researchers have been working for many years on different aspects. Mainly, improving the accuracy of intrusion detection by minimizing the false detection rate. Another aspect concerns real-time intrusion detection, especially in a big data environment [7]. In this direction, this section reviews the prior work on applying machine learning techniques to support real-time processing.

Vimalkumar and Radhika [8] have designed a big data framework for intrusion detection using classification methods and Apache Spark as a platform for implementing intrusion detection in smart grids using big data analytics. However, the accuracy obtained is less than 80% and the DNN prediction time is higher compared to other models.

The authors in [9] have evaluated multiple classification algorithms using Apache Spark on the full UNSW-NB15 dataset. The performance achieved 97.49 % accuracy for Random Forest. Nevertheless, with the absence of any computation platform details, it is hard to validate the extremely high accuracies reported. Zhang et al. [10] proposed a real-time intrusion detection system for high-speed network environments using a distributed Random Forest detection model based on Spark. Their experimental results showed that the framework has a shorter detection time, achieves higher accuracy, and can realize real-time intrusion detection in a high-speed network environment. Gupta and Kulariya [11] proposed the use of Apache Spark for fast and efficient network intrusion detection. The authors compared the performance of five classifiers on the datasets KDD99 and NSL-KDD. The Random Forest method achieved the best accuracy on both datasets. In the same direction of using machine learning techniques to improve IDSs and to reduce the FPR and FNR, the authors of [12] developed a prototype IDS using the k-means algorithm implemented in Sparks MLlib.

In recent years, deep learning technologies are widely conducted in the field of intrusion detection [13][14]. For example, Mighan and Kahani [15] proposed a scheme that combines the advantages of a deep network and ML algorithms on Apache Spark. They used stacked auto-encoding network for feature extraction followed by several classification algorithms on The ISCX 2012 dataset. In the same direction, Chen et al. [16] proposed a method which uses the fusion convolutional neural network (FCNN) for feature extraction and stacked ensemble (SE) for classification.

Table I compares the related works in terms of data streams feature, ML algorithms and datasets that they have used, and the metrics used for evaluation. Some features in Table I such evaluation metrics are assigned * since there is no information available for that feature in related paper.

III. THE PROPOSED MODEL

This section presents the proposed hybrid approach consisting of supervised and unsupervised learning for anomaly detection. Let us recall that the aim of the proposed model is to provide continuous monitoring through real-time network traffic processing based on the big data engine Apache Spark. The general architecture can be described in Fig. 1.

The system presented in this article is designed as follows: for each new instance data captured in NetFlow format, Apache Spark Streaming is used as network traffic processing tool. The captured traffic from the input data is collected and streamed with Apache Kafka to Spark for processing. The captured packets from the input data as well as data transmission are mainly implemented by Kafka. This later is used because of its power to stream a huge amount of data in real time. Kafka mainly includes a producer and a consumer as shown in Fig. 2. The input application report messages through the producer API, and the output application subscribes to the message through consumer API.

To enhance detection efficiency, this proposed architecture makes use of the Apache Spark framework, as an open source powerful, scalable and fast distributed data processing engine in big data. Apache Spark provides a large number of libraries, such as MLlib and Spark Streaming. These tools allow Spark to support not only Streaming data processing but also machine learning algorithms. The current popular streaming frameworks mainly include Samza, Strom and Spark. Moreover, the use of Apache Spark framework is proved with the performance comparison of the literature [17].

1) *The proposed algorithm* : A joint algorithm is proposed for all layers to identify intruder flows. First, for each captured packet, the algorithm checks whether the incoming packet belongs to an already registered flow (lines 1-8 of Algorithm 1). A flow is defined as a five-tuples: IP source, IP destination, source port, and destination port (scr_{IP} , dst_{IP} , scr_{Port} , dst_{Port} , respectively). If the packet does not belong to a registered flow, then it is registered as a new distinct flow based on its scr_{IP} , dst_{IP} , scr_{Port} , dst_{Port} and a new sequence file is created for this flow by putting packet information into the first line (line 3 of Algorithm 1). On the other hand, if the packet belongs to a registered flow, then the packet information is simply sent to the particular sequence file corresponding to the registered flow (lines 6 and 7 of Algorithm 1). When the duration threshold deviates, the sequence file is sent to one of the preprocessing nodes to compute the flow parameters. The preprocessing nodes are equipped with a parameter calculation code to measure the feature values (lines 11 and 14 of Algorithm 1). In order to consider the big data environment, the code can be run in parallel by taking the sequence file as input in the distributed processing. Finally, the calculated feature values are sent to the decision server, which is equipped with several machine learning classifiers to decide whether the flow is an intrusion or normal flow based on its extracted features (line 17 of Algorithm 1). The complete system's flow is depicted in Fig. 3.

A. Data Preprocessing

The preprocessing step is critical for preparing data for feature extraction in machine learning. The real dataset used in

this analysis includes both numerical and symbolic representations, with 46 numerical attributes and two symbolic attributes. To enable the use of symbolic attributes in the subsequent analysis, they are converted to numerical values, ensuring that all features are represented on the same scale. [21] emphasized that data normalization is an essential preprocessing step to

eliminate the dimensionality effect and improve the accuracy of the model. StandardScaler is a widely used normalization method that scales input features to have a mean of 0 and a standard deviation of 1, which helps to remove biases caused by different units or scales of measurement as given in Eq.1. For numerical attributes, each value is normalized over the

range [0,1] based on its deviation from the feature’s mean and standard deviation. By standardizing the data in this way, the effect of dimensionality can be reduced, leading to more accurate and reliable analysis of the data [22].

$$X' = \frac{X - \mu}{\sigma} \tag{1}$$

Where X is a feature vector containing the original values, μ is the mean of the feature vector X , σ is the standard deviation of the feature vector X and X' is the scaled feature vector, with mean 0 and variance 1.

B. Clustering

K-means clustering is a widely utilized unsupervised learning algorithm in data analysis and machine learning [22]. K-means partitions the dataset into K non-overlapping clusters based on their feature values, with objects that belong to the same cluster having similar feature values [21]. The K-means algorithm consists of four main steps: first, it initializes the number of clusters K and the initial centroids for each cluster.

Next, it iterates over all objects in the dataset and computes the distances between them and the centroids of each cluster. Based on this, it assigns the objects to the nearest cluster centroid. In the third step, it recalculates the centroids for each cluster based on the objects that are currently assigned to it. Finally, the algorithm repeats the second and third steps until the centroids of all clusters no longer change.

In order to determine the distance or similarity between two objects, it is necessary to use a distance function. The most commonly utilized distance metric is the Euclidean distance, which is defined as the square root of the sum of the squared differences between corresponding features in two input vectors, as illustrated in Equation 2. However, given that various features are often measured using different scales or metrics, it is crucial to normalize them before applying the distance function. An alternative to the Euclidean distance is the Mahalanobis distance function. This distance metric incorporates statistical correlations between different features by utilizing the inverse covariance matrix, as shown in Equation 3. However, the Mahalanobis distance can be computationally intensive, particularly for high-dimensional feature vectors. The Euclidean distance was utilized for the initial evaluation of the proposed anomaly detection method because the database was pre-normalized.

$$d(x, y) = \sqrt{\sum_{i=1}^m (x_i - y_i)^2} \tag{2}$$

$$d(x, y) = \sqrt{(x - y)^T S^{-1} (x - y)} \tag{3}$$

The K-means clustering algorithm is utilized for preprocessing training datasets that may consist of both normal and anomalous traffic. This is achieved without the need for prior labeling. The proposed approach is based on the assumption that normal and anomalous traffic can be distinguished by creating separate clusters in the feature space. The K-means clustering algorithm divides the training data into K clusters, without distinguishing between clusters that reflect time intervals of normal or anomalous traffic. For instance, an anomalous

cluster may be identified through a higher average number of packets. Clusters that are closely located to each other may arise due to either an unsuitable selection of K or the homogenous nature of the training data, where either there is no anomalous traffic or the anomalous traffic is similar to the normal traffic. A fundamental challenge of the K-means clustering method is to determine the appropriate number of K-clusters. Our study addresses this issue by concentrating on the evaluation criteria for optimizing clusters. Selecting the optimal value of k for K-means clustering is a crucial step in data analysis. This paper used the Silhouette approach to identify the optimal k value for *Ibn Zohr* dataset. The Silhouette method computes the silhouette coefficient for all instances across a range of k values. Equation 4 used to calculate the silhouette coefficient for each instance.

Silhouette coefficient:

$$\frac{b - a}{\max(a, b)} \quad (4)$$

C. Anomaly Detection and Attack Classification

Clustering-based methods are commonly used to detect anomalies by analyzing the relationship between data instances and clusters. The existence of a large distance between an instance and the clusters can be used to identify an anomaly. The proposed approach utilizes the K-Nearest Neighbors (KNN) algorithm with cross-validation techniques to detect network traffic anomalies.

KNN [23] algorithm is founded on the principle that objects or instances which are similar tend to be situated in close proximity. One commonly used distance metric in KNN is the Euclidean distance method. After computing the distance between the current data point and the query data point, the KNN algorithm sorts the distances and their corresponding indices and stores them in a collection. The classification of instances in the KNN algorithm involves taking the mode of the first K labels from the sorted collection. Although KNN is a non-parametric algorithm that is simple and easy to understand, it can become slow when processing large datasets and may struggle to make accurate predictions in high-dimensional datasets. Furthermore, the process of selecting an appropriate value for K in KNN can be a significant challenge. The KNN algorithm can be implemented in six steps

- Selecting the number of neighbors (K);
- Computing the Euclidean distance;
- Selecting the K nearest neighbors;
- Counting the number of data points in each category among the K nearest neighbors;
- Assigning the new data point to the category with the highest number of neighbors, and
- Creating the K -NN classification model for future predictions.

The selection of an appropriate value for the hyperparameter K is crucial in achieving high accuracy when using the KNN algorithm. In this study, cross-validation was used to assess the performance of different K values on the test dataset. Cross-validation methodology involves segmenting the

dataset into multiple subsets, and subsequently training the KNN model iteratively on one subset while testing it on the remaining subsets. This methodology permits the estimation of the KNN model's performance on new data, and facilitates the identification of the optimal K value that yields the best results. The use of cross-validation ensures that the KNN model neither overfits nor underfits the data, and guarantees optimal performance on previously unseen data. The dataset was partitioned into training and testing sets, with 70% of the data designated for training and 30% for testing. The training dataset was then passed through the KNN classifier for classification.

D. Decision Making

To evaluate the effectiveness and efficiency of the suggested method in detecting anomalies, a comparison was performed against well-known classification techniques such as Random Forest (RF), Support Vector Machines (SVM), Naive Bayes (NB), and Gradient Boosting (GB). The comparison enabled the determination of the relative performance of the proposed approach and the identification of its strengths and weaknesses. Additionally, experiments were conducted using various evaluation metrics to provide a comprehensive assessment of the model's performance. The aim was to demonstrate the superiority of the proposed method in accurately detecting anomalies in the *Ibn Zohr* university network. The results of the comparison are presented in the following section.

1) *Random forest* [3]: is an influential machine learning technique that combines decision trees with ensemble learning. The algorithm employs multiple decision trees that are trained on different subsets of the training data and features. Each tree independently provides a prediction, and the final output is the average prediction of all the trees. The algorithm works by partitioning the feature space into smaller subsets recursively, utilizing various metrics such as Gini impurity or entropy. The decision trees in Random Forest are created using a randomized feature selection process that reduces model variance and overfitting. The algorithm's benefits include its high accuracy, noise robustness, and capacity to handle high-dimensional data. However, the algorithm's computational cost can be significant, and its interpretability may be compromised due to its ensemble nature.

2) *Support vector machine* [4]: is a renowned machine learning algorithm that is widely used in both classification and regression tasks. The method works by creating a hyperplane that separates classes and maximizes the margin between them. This optimal hyperplane is identified by finding a subset of training data points called support vectors that lie nearest to the hyperplane. To handle non-linear decision boundaries, SVM transforms the input data into a higher-dimensional space using a kernel function, such as linear, polynomial, or Gaussian. The choice of kernel function depends on the nature of the problem.

3) *Naive bayes* [4] : is a well-known algorithm utilized in classification tasks. It is based on Bayes' theorem, which states that the probability of a hypothesis given the data is proportional to the product of the prior probability of the hypothesis and the likelihood of the data given the hypothesis. Naive Bayes is considered "naive" because it assumes that all features are independent of one another, simplifying the

computations but possibly leading to suboptimal performance in cases where the features are highly correlated.

4) *Gradient boosting* [5]: Gradient Boosting [5] is a machine learning algorithm commonly utilized in regression and classification tasks. The approach involves the combination of multiple weak learners, generally decision trees, to form a strong learner. Learners are added incrementally, with each new learner attempting to correct the errors of the preceding one. Gradient Boosting uses the gradient descent optimization algorithm to find optimal weak learner parameters. It achieves this by iteratively adjusting the parameters of the learners to minimize a loss function, such as mean squared error or log loss. The gradient of the loss function is calculated with respect to the output of the preceding learner, which is utilized to train the next learner. Gradient Boosting is highly customizable, with hyper parameters like the number of learners, learning rate, and maximum depth of trees, which can be tuned.

IV. EXPERIMENTAL RESULT

In this section, the dataset and the performance metrics used for the comparison are described in order to conduct the different experiments carried out. Then, the results that were obtained by using the proposed hybrid method in the big data ecosystem are presented and discussed. Apache Spark and Python language are used. All experiments are conducted using a machine with 1.5 GHz Intel Corei7 CPU@, 16 GB RAM, and with Ubuntu 20.04 trusty installed.

A. Dataset

In order to verify the effectiveness of the proposed approach a real dataset is used collected from digital data related to network traffic of *Ibn Zohr* university. The dataset was collected in the presidency of *Ibn Zohr* which consists of several faculties. The total size of the dataset is up to one million records. Data are sent mainly by network devices installed by *nfcapd* which is a *netflow* capture daemon of the *nfdump* tools. *nfcapd* reads *netflow* data from the network and stores it into files. The output file is automatically rotated and renamed every 5 minutes.

B. Performance Metrics

To evaluate the performance of an anomaly detection algorithm, four fundamental metrics can be used: true positive (*TP*), which represents the number of correctly identified attacks, true negative (*TN*), which represents the number of accurately identified normal connections, false positive (*FP*), which denotes the number of normal connections wrongly identified as attacks, and false negative (*FN*), which signifies the number of attack connections erroneously identified as normal [24]. Subsequently, the proposed approach is evaluated using the following metrics:

1) *Accuracy*: provides a measure of how well the classification model is able to accurately classify data instances, regardless of whether they are classified as positive or negative. It is calculated as the proportion of the total number of correctly classified records in a dataset over all the rows in that dataset.

$$Accuracy = \frac{TP + Tn}{TP + Tn + Fp + Fn} \quad (5)$$

2) *Precision*: measures how many of the positive predictions made by the model are actually correct. It is calculated as the ratio of true positive predictions to the total number of positive predictions made by the model.

$$Precision = \frac{TP}{TP + FP} \quad (6)$$

3) *Recall*: measures how many of the positive instances in the dataset were correctly identified by the model. It is calculated as the ratio of true positive predictions to the total number of actual positive instances in the dataset.

$$Recall = \frac{TP}{TP + FN} \quad (7)$$

C. Implementation and Experimental Results

1) *Selecting the optimal number of clusters*: Let us recall that data instances are grouped using K-means clustering technique. We have conducted a graph of Silhouette score vs *K* which represent an effective way to visualize and select the optimal number of clusters (*K*). Cluster cohesion and separation are measured using the Silhouette score. Cluster cohesion refers to how closely related the data points are within the same cluster, while cluster separation refers to how well-separated the clusters are from each other. A higher Silhouette score indicates a better clustering outcome (i.e. it implies that the data points are more closely related to their own cluster and less closely related to neighboring clusters). The ideal *K* number for finding abnormalities in *Ibn Zohr* data is thought to be the *K* value that corresponds to the highest Silhouette score. The cluster value *K* of 2 exhibits the highest Silhouette score, making it the best *K* value for anomaly identification, as shown in Fig. 4.

Fig. 4. Evolution of *K* value vs. silhouette score.

2) *Apply k-means clustering Using optimal cluster value of K*: To identify anomalies in each cluster, *KNN* with cross-validation is used. The ideal number of folds for *k*-fold cross-validation is determined by comparing the average performance metrics obtained for different values of *k*. The best *k* value is determined by the greatest average accuracy. The proposed approach first determines the optimal number of folds for cross-validation, then evaluates the performance of the *KNN* model on new, unseen data using cross-validation techniques such as *k*-fold cross-validation. The average distance

to the k nearest neighbors for each point is then calculated using Euclidean distance to determine the boundary between different classes and identify the most relevant. Finally, the plot method is applied to visualize the average distance to the k nearest neighbors for each point in the *Ibn Zohr* dataset.

Fig. 5 shows the results of the anomaly detection algorithm conducted on the *Ibn Zohr* dataset. It is shown that the algorithm was able to successfully separate the anomaly instances from the normal ones. Anomalies are presented by the points that are far from the group of points in the feature space.

Fig. 5. Anomaly detection using KNN.

The proportion of anomalies identified by the model for various cluster values, as well as the non-linear connection between the cluster value and the number of observed anomalies, are depicted in Fig. 6. Anomalies, especially, tend to form their own clusters as the cluster value increases and may be incorrectly identified as normal data instances. Additionally, normal cases may form clusters, leading to some of them being wrongly classified as anomalies based on cluster threshold values.

Fig. 6. The number of detected anomalies Vs. cluster number.

3) *Effectiveness analysis of the proposed anomaly detection model using optimal K:* In order to evaluate the effectiveness and efficiency of the suggested method in detecting anomalies, a comparison is performed against well-known classification techniques, such as Random Forest (RF), Support Vector Machines (SVM), Naive Bayes (NB), and Gradient Boosting (GB). The experimental data have been split into 70% as

training data and 30% as test data. The evaluation metrics include accuracy, precision, and recall.

The results of the comparison using *Ibn Zohr* data are presented in Table II. Our approach is found to outperform the other models with consistently higher accuracy score. In contrast, Naive Bayes is found to achieve a lower accuracy score compared to the other evaluated methods.

TABLE II. COMPARISON OF THE APPROACH WITH THE OTHERS

Method	Accuracy (%)	Precision (%)	Recall (%)
RF	99.88	99.66	99.46
SVM	99.81	99.33	99.30
NB	95.04	73.77	100
GB	99.89	99.73	99.5
Our approach	99.94	99.92	99.5

4) *Effectiveness analysis of the anomaly detection model for different cluster values:* The performance of clustering-based anomaly detection methods can be significantly influenced by the choice of the number of clusters, represented by K . Therefore, identifying the optimal cluster value is crucial for achieving optimal results. Additionally, the choice of cluster value has a significant impact on the classification of anomalies in *Ibn Zohr* dataset.

A comparison of various cluster values ranging from 2 to 11 was conducted, and the results are presented in Table III. Our model achieved the highest classification accuracy of 99.94% for $K = 2$, while GB had the highest accuracy value of 99.75% for both $K = 2$ and $K = 4$. RF had the best accuracy value of 99.61% for $K = 4$, while SVM achieved the best accuracy value of 99.49% $K = 3$. NB achieved the best accuracy value of 97.66% for both $K = 2$ and $K = 4$.

TABLE III. ACCURACY COMPARISON FOR DIFFERENT k VALUES

Cluster Value	RF	SVM	NB	GB	Our approach
2	99.49	99.38	97.66	99.75	99.94
3	99.57	99.49	93.69	99.66	99.80
4	99.61	99.36	97.66	99.72	99.75
5	99.44	99.35	96.48	99.48	99.71
6	99.35	99.17	90.54	99.30	99.70
7	99.26	99.23	94.29	99.38	99.67
8	99.12	97.94	83.38	99.21	99.53
9	99.15	98.98	87.04	99.30	99.75
10	99.36	99.33	82.68	99.51	99.78
11	99.25	98.90	78.24	99.35	99.70

Based on the above analysis, it can be concluded that the optimal cluster values are $K = 3$ and $K = 4$, as they yielded better performance across most classifiers. However, since the accuracy value never exceeded 99.75%, the effectiveness of the model in terms of the trade-off between accuracy and computation cost is demonstrated for the optimal cluster value of $K = 2$.

V. DISCUSSION

The proposed anomaly detection model is based on the K-means clustering algorithm [21]. To determine the most suitable number of clusters, the Silhouette method was employed, which yielded $K = 2$ as the optimal value. Following this direction, the K-nearest neighbors (KNN) algorithm is applied in each cluster to identify anomalies in the whole dataset.

To ensure the reliability of the proposed model, cross-validation was implemented, and the optimal number of folds was determined using the K-fold method [25][26]. By selecting the most suitable value of K through K-fold cross-validation, overfitting was reduced, and the accuracy of the model was improved. Furthermore, to obtain the best possible results, an investigation is conducted of the data behavior for the global cluster, varying the number of clusters from $K = 2$ to $K = 11$. The findings indicated that the combination of the K-means clustering algorithm, KNN anomaly detection technique, and cross-validation was a remarkably successful method for identifying anomalies in the *Ibn Zohr* dataset. However, increasing the cluster value could result in anomalies themselves forming their own clusters, which could lead to some anomalies being classified as normal data instances.

Although better accuracy was achieved for the proposed anomaly detection model for $K = 2, 3, 9,$ and 10 , with the best accuracy being 0.994 , a trade-off between accuracy and computation cost was observed. The evaluation of the K-means-based anomaly detection model showed that it was effective for the optimal cluster value of $K = 2$. However, the model's accuracy was found to be sensitive to the balance between the number of anomalies detected and the classification accuracy. Increasing the cluster value K could result in poor anomaly detection, as illustrated in Table III. Despite the use of the *Ibn Zohr* dataset to evaluate the effectiveness of the model, the methodology could be extended to other domains, such as IoT analytics and cybersecurity, and could prove useful for rule-based analysis based on specific datasets.

VI. CONCLUSION

The growth of digital technology and the Internet has led to a significant increase in data creation and consumption in universities and research institutions. Consequently, processing the resulting network traffic data has become a complex and challenging task, which increases the likelihood of intrusions and anomalies. Therefore, the primary objective of this paper is to address the issue of scalable network intrusion detection in a big data environment. The proposed hybrid model was validated using a real dataset from *Ibn Zohr* university. The evaluation results indicate that the suggested approach is efficient in detecting various anomalies. In addition, the effectiveness of the proposed model was verified by comparing its performance with other well-known models using different metrics.

The suggested framework's efficacy was evaluated using Apache Spark, a large data processing tool, and machine learning algorithms. The suggested model's performance was further examined using a hybrid machine learning method that blends k-means and KNN to identify anomalies.

Future work aims to integrate real-time anomaly identification to enable quick response and mitigation of any security breaches, thereby safeguarding all network traffic and protecting the privacy of all users on the *Ibn Zohr* university network.

ACKNOWLEDGMENT

The authors would like to express their gratitude to *Ibn Zohr* Presidency for providing their genuine dataset to assess the effectiveness of the proposed approach in this study.

Egypt Monuments Dataset version 1: A Scalable Benchmark for Image Classification and Monument Recognition

Mennat Allah Hassan^{1,2,*}, Alaa Hamdy¹, Mona Nasr²

Faculty of Computer Science, Misr International University, Cairo, Egypt¹

Faculty of Computers and Artificial Intelligence, Helwan University, Cairo, Egypt²

Abstract—The success of machine learning (ML) as well as deep learning (DL) depends largely on data availability and quality. The system’s performance is frequently more affected by the amount and quality of its training data than by its architecture and training specifics. Consequently, demand exists for challenging datasets that both precisely measure performance and present unique challenges with real-world applications. The Egypt Monuments Dataset v1 (EGYPT-v1) is introduced as a new scalable benchmark for fine-image classification (IC) and object recognition (OR) in the domain of ancient Egyptian monuments. EGYPT-v1 dataset is by far the world’s first large specified such dataset to date, with over seven thousand images and 40 distinct instance labels. The dataset composes different categories of monuments such as pyramids, temples, mummies, statues, head statues, bust statues, heritage sites, palaces and shrines. Several advanced deep network architectures were tested to appraise the classification difficulty in the EGYPT-v1 dataset, namely ResNet50, Inception V3, and LeNet5 models. The models achieved accuracy rates as follows: 99.13%, 90.90%, and 92.64%, respectively. The dataset was predominantly created by manually collecting images from the popular global online video-sharing and social media platform, Youtube, as well as WATCHiT, Egypt’s top streaming entertainment service. Additionally, Wikimedia Commons, the largest crowdsourced media repository in the world, was used as a secondary source of images. The images that comprise the dataset can be accessed on the GitHub repository <https://github.com/mennatallahhassan/egypt-monuments-dataset>.

Keywords—Deep learning; landmark datasets; landmark recognition; monument datasets; monument recognition

I. INTRODUCTION

Within the realm of computer vision, IC and OR are key research topics that have been extensively investigated for years. The objective of IC is to [1], [2], [3], [4]. The objective of OR [5], [6] is the computer vision task of recognising a particular instance of an object, as opposed to its category. For example, it is interested in instance-level labels such as “Karnak Temple in Luxor” or “Khufu Pyramid in Giza” rather than simply “Karnak” or “Khufu” when labeling images.

When ML and DL techniques for image classification and instance-level recognition (ILR) tasks have progressed, methods have improved in their robustness and scalability, and they have started solving standard datasets.

Furthermore, despite the fact that increasingly largescale classification datasets, for instance, CIFAR-10 [7], ImageNet [8], in addition to OpenImages [9], have become standard

benchmarks, there still needs to be monument datasets for fine-grained instance recognition and classification. A monument refers to a structure that has been erected and can take many forms, including busts, crosses, statues, fountains, mausoleums, obelisks, pyramids, reliquaries, sarcophagi, steles, graves, or triumphal arches. In addition, smaller-scale forms such as medals and commemorative plaques can also be considered monuments [10]. Generally, the world is full of monuments; remarkably, Egypt contains a third of the world’s monuments; parts of these monuments are displayed in the most famous museums all over the world [11]. This paper presents the Egypt Monuments Dataset v1 (EGYPT-v1), a novel scalable dataset for IC and ILR. More than seven thousand images of forty-one different monuments and historical landmarks are available in EGYPT-v1, as seen in Fig. 1. Fig. 2 illustrates its geographic distribution across Egypt. The instance recognition task uses a training dataset of 5,833 labelled images and 1,945 labelled images as a test set, that includes ground truth information regarding the instance classification (IC) and ILR tasks. Although our primary objective for Egypt Monuments Dataset v1 is to recognize historical landmarks and monuments, the solutions developed to overcome the obstacles, can be easily adapted to address other instance-level recognition challenges, including artwork recognition.

The primary objective of Egypt Monuments Dataset v1 is to replicate real-world circumstances and, consequently, introduces several complex hindrances. There are thousands of images representing tens of classes in EGYPT-v1. The degree of intra-class variation is significantly elevated, with images of a single class exhibiting both indoor and outdoor views and images that possess a tangential association with a particular class, like museum paintings. The Egypt Monuments Dataset v1 is intended to be used as a novel benchmark for IC and ILR.

The dataset, training instance labels, classification and recognition ground truth data, and metric computation code are accessible to the public.

In summary, this paper presents the Egypt Monuments Dataset v1, a novel and challenging benchmark for fine-image classification and object recognition in the domain of ancient Egyptian monuments. The RELATED WORK section compares the existing monument/landmark image classification and recognition datasets with our novel proposed dataset. The dataset consists of many images and distinct instance labels

Fig. 1. An overview of the EGYPT-v1 dataset composed of over 7k images for 41 classes.

representing various categories of monuments. All details have been explained in the DATASET OVERVIEW section. The performance of several advanced deep network architectures on the EGYPT-v1 dataset has been evaluated. The accuracy rates have been illustrated in the EXPERIMENT section.

This paper also discusses the dataset's creation, distribution, and potential applications in instance-level recognition challenges, including recognition. Overall, the EGYPT-v1 dataset aims to replicate real-world circumstances and provide a valuable tool for researchers and practitioners in computer vision.

II. RELATED WORK

Image recognition's challenges extend from simple image classification (e.g., "human face" or "building") through fine-grained tasks that distinguish between models, and styles (such as "Head Sculpture" and "Ancient Temple") to recognition on an instance level (as "Portrait Head of Queen Tiye at the Neues Museum, Berlin, German" and "The Great Temple

of Ramesses II, Aswan, southern Egypt"). Identifying ancient Egyptian monuments and historical landmarks is the primary focus of our novel dataset. Subsequently, datasets for image classification and recognition were scrutinized, with particular attention given to those most relevant to our research. Table I presents the existing datasets for monument/landmark image classification and recognition, along with our proposed novel dataset.

1) *City-scale datasets*: The datasets regarding Oxford [1], as well as Paris [12], consist of a huge number of landmark images found in both cities, collectively belonging to 11 categories. Additional datasets concentrate on photography from a specific city: Rome 16k [16]; Singapore Landmark-40 [19], including over 13,000 images from Singapore city. The dataset used in this study was created by collecting images from a range of different sources. Specifically, 40% of the images were obtained from Google Images, 40% were sourced from Flickr, and 5% came from Photobucket. The remaining 15% were acquired through manual means. This

portion comprised Geotagged Streetview Images [15], which consisted of approximately 17,000 photographs of Paris and San Francisco Landmarks [17], containing over 1.7 million images; Qutub Complex Monuments' Images containing 1,286 images for five famous monuments in Delhi, India; 24/7 Tokyo [20], including a thousand images under various lighting situations; and Paris500k [21], including 501,000 images.

2) *Country-scale dataset*: Indian heritage monuments dataset (IHMD) [24] contains 6,959 images of 413 classes. This dataset has been collected from image search engines using web scrappings such as Google Images, Bing Images, Wikimedia and Flickr.

3) *Continent-scale datasets*: The datasets that are more recent in origin contain images that have been sourced from a notably wider range of locales within the same continent than the older datasets. Within the European Cities (EC) 50k dataset, there are images of 20 landmarks that are distributed across 9 cities [14], including unannotated images from 5 additional cities that were used as distractors. Another version of this dataset has 1 million photos from 22 cities; however, all annotated photographs come from only one location [26].

4) *Worldwide-scale datasets*: The more expanded datasets have images of landmarks globally. The Landmarks-PointCloud dataset includes 205,000 images of 1,000 well-known landmarks [18]; The Landmark URLs dataset of approximately 192,000 images is classified into 586 landmarks. 168,882 images are utilized for fine-tuning in experiments, while the remaining 20,668 images are utilized to validate parameters [3]. The Revisited Oxford dataset, as well as Revisited Paris dataset are two other recent examples of global landmark datasets, each comprising eleven landmarks and roughly a million images [27]. The Google Landmarks Dataset, which is the dataset from which the data used in this study was drawn, originally consisted of 2.3 million photographs taken at 30,000 unique landmarks. However, this dataset is unstable due

to copyright limitations. It declines over time as photographs are destroyed by the users who upload them [22]. To our best knowledge, no such large unique, collected country-scale datasets with ground truth Egyptian ancient monuments and landmarks visibility information are publicly available yet.

III. DATASET OVERVIEW

A. Purposes

The purpose of the Egypt Monuments Dataset v1 is to simulate the following constraints of industrial monument/landmark recognition. It is *scalable* to encompass all ancient Egyptian monuments and landmarks worldwide, as they are not confined to Egypt alone. There are numerous discoveries and expeditions concerning ancient Egyptian monuments *Intra-class variability*. Images of monuments and historical landmarks are captured both indoors and outside, in a variety of lighting circumstances and from a variety of vantage points. In addition, there will be images that are connected to well-known ones. *Public availability*. The dataset aims to help the research community solve the scarcity of Egyptian ancient monument datasets that face researchers in this domain [28]. Our dataset was explicitly built to account for these difficulties.

B. Data Distribution

The Egypt Monuments Dataset v1 contains 41 diverse monuments and heritage sites from 6 out of the 28 governorates of Egypt; As indicated in Table II, this dataset of ancient Egyptian monuments and landmarks is truly unique and one-of-a-kind. By far, statues are the most frequent type, followed by temples, then pyramids. Approximately 37% of the monuments with over 2,000 images are located in Luxor, while about 27% are in Cairo.

C. Dataset Construction

The process of gathering data and constructing the ground truth is described in this section.

1) *Data sources*: WatchiT, a leading Egyptian streaming entertainment platform, and Youtube, a global online video-sharing platform, are the primary sources for the Egypt Monuments Dataset v1. Then there is Wikimedia Commons, the most extensive online collection of user-submitted images, videos, and other media. Millions of photos of famous landmarks, taken by an active community of photographers and partner organizations like libraries, archives, and museums, are available on Wikimedia Commons under Creative Commons and Public Domain licenses. The goal of Wiki Loves Monuments, a yearly competition, is to add more high-quality landmark images to the site, while classifying them based on a detailed taxonomy of cultural heritage sites around the world. Images were also sourced from Google Images in addition to the aforementioned Wikimedia Commons.

2) *Annotation*: Notably, ground-truth annotation is notoriously difficult. Given that it is difficult to predefine what monuments or heritage sites are and that they are only sometimes clearly apparent, identifying monuments is challenging. Furthermore, for certain heritage sites, such as The Giza Pyramids and The Bent Pyramid, images can be captured from a considerable distance.

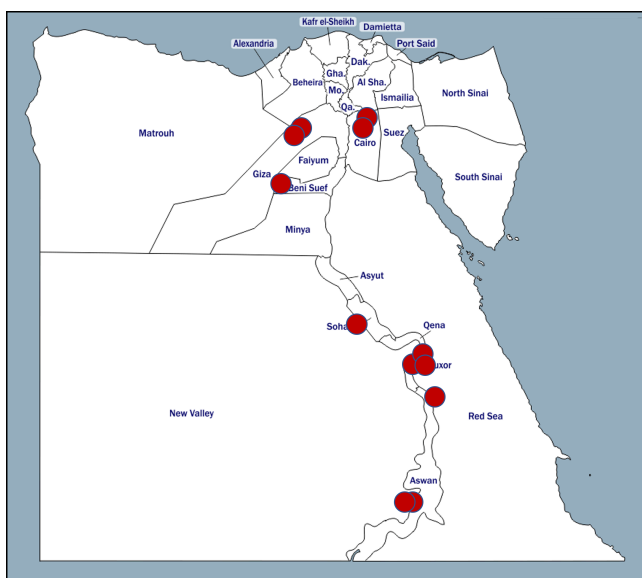

Fig. 2. Egypt map highlighting the distribution of ancient Egyptian monuments and heritage sites across Egypt regarding Egypt Monuments Dataset v1. (Starting from Cairo and reaching to Aswan).

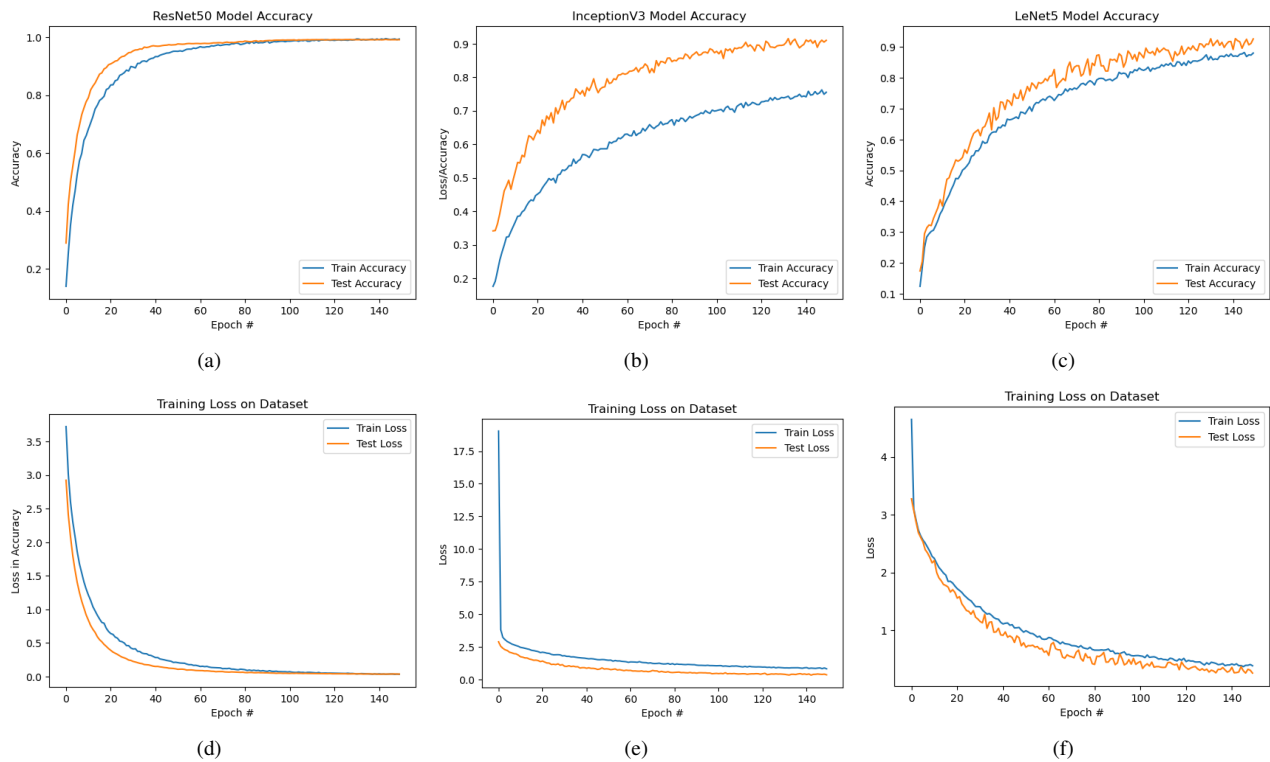

Fig. 3. (a) ResNet50 Model's Accuracy. (b) InceptionV3 Model's Accuracy. (c) LeNet5 Model's Accuracy. (d) Training Loss of ResNet50 Model. (e) Training Loss of InceptionV3 Model. (f) Training Loss of LeNet5 Model.

IV. EXPERIMENT

In this study, the utilization of the dataset is illustrated, and various baseline models that can be used as a reference for future research are introduced. Furthermore, an analysis of the outcomes obtained from the real-world challenge is provided. The findings discussed in this part are all relevant to the ground truth of version 1 of the dataset. Herein, the efficacy of recognizing the visual features of the EGYPT-v1 dataset using cutting-edge classification techniques is evaluated.

Experiments using various advanced deep network architectures have been conducted, such as ResNets [29], Inception V3 [30], and LeNet5 [31] models, to assess the level of classification difficulty in our EGYPT-v1 dataset. To train the models, data augmentation techniques have been employed.

Networks have been fine-tuned using pre-trained weights of ImageNet, optimized with Adam [32] and $1e-05$ for the learning rate. Training and testing have been conducted with images sized at 224×224 .

As shown in Table III, a performance comparison table was created to differentiate the three models. The models under examination are RESNET50, Inception V3, and LeNet 5, all of which are representative of deep learning techniques. The results of our analysis are presented in Table III in the document.

Upon close scrutiny of the graph presented in Fig. 3(a), it can be noted that the testing accuracy of ResNet50 surpasses the training accuracy after 90 epochs. In addition, a trend of improvement is observed in both the training and testing

accuracy curves as the number of epochs progresses. The ResNet50 model attains 99.69% for training accuracy and 99.13% for testing accuracy at the completion of the training process. The dissimilarity between these two accuracy values is negligible, which indicates that the model is not partial to training images, and can perform with comparable efficiency in recognizing unobserved images. In contrast, as depicted in Fig. 3(d), the loss function performance is nearly indistinguishable for both curves. It is worth noting that saturation is observed for both curves at around epoch 110. The ability of the loss function to produce consistent results suggests that the model is not prone to overfitting concerns and can distinguish unknown data as efficiently as it classifies recognized data.

In Fig. 3(b), upon completion of training, InceptionV3's accuracy on the training data was 93.31%, while its accuracy on testing data was 90.90%. The substantial gap in accuracy scores indicates overfitting, a situation in which a model excels on training data while it shows inferior performance on new, unseen data. Overfitting can be addressed by reducing the model's complexity, increasing the training data volume, or implementing regularisation techniques. In Fig. 3(e), if the loss graph is examined closely, it can be seen that initially, the testing loss was significantly lower than the training loss. The training and testing loss demonstrated a decreasing trend as the epochs' number increased. Based on Fig. 3(f), it appears that the model has not fully converged and may benefit from additional training epochs. To confirm this speculation, an additional experiment was conducted, as shown in Fig. 4. The InceptionV3 model was trained on the same dataset with 600 epochs and achieved an accuracy of 96% with a loss curve

TABLE II. INSIGHTS OF THE EGYPT-V1 DATASET, CONTAINING 41 DIVERSE CLASSES DISTRIBUTED IN 6 GOVERNORATES OF EGYPT

Monument/Heritage Site Name	Category	Located in	# Images
The Great Temple of Ramesses II	Temple	Aswan	1283

that plateaued at 60%. The model’s performance may benefit from more training epochs, as indicated by these results.

In Fig. 3(c), the graph demonstrates that the training and testing accuracy curves of the LeNet5 model display a consistent upward trend as the epochs’ number increases. Notably, the testing accuracy is continuously more unstable than the training accuracy curve. Upon completion of the training process, it attains 94.29% for training accuracy and 92.64% for testing accuracy. Besides Fig. 3(f), when analyzing the

TABLE III. EVALUATION METRICS

Model	Type	Measurement			
		Accuracy	Precision	Recall	F1-Score
ResNet50	Train	99.69%	99.73%	99.67%	99.70%
InceptionV3		93.31%	96.52%	90.53%	93.37%

loss graph, it is evident that, in the beginning, the loss during testing was lower than the loss during training. However, as the epochs’ number progressed, both the training and testing loss curves showed a decreasing trend.

In terms of generalization, an experiment has been conducted with the ResNet50 model, as it is the highest accuracy among the three models. It has predicted new, unseen data of the same domain with an accuracy of 97.43%. Notably, the unseen data size is over 35 thousand images suggesting that the dataset is scalable.

V. CONCLUSION

The Egypt Monuments Dataset v1 is introduced as a new benchmark for classification and instance recognition on a country-wide scale. Unlike many current computer vision datasets, this dataset has the following features: 1) it was gathered by individuals who are not computer vision professionals for a specific goal, making it unbiased; 2) unlike previous datasets, it is a better representation of real-world challenges; 3) it presents a classification challenge with a long-tail distribution; and 4) it has practical applications in the fields of conservation and Egyptology.

In terms of domain coverage, the EGYPT-V1 dataset demonstrates scalability by covering most of the famous pharaonic monuments allocated in Egypt. In addition, the proposed approach performs well across different subcategories. The approach’s ability to perform well on a diverse range of data within the same domain suggests that the dataset is scalable.

Future plans involve undertaking object detection tasks. It is also planned to increase the size of the dataset where Egypt, in particular, is home to one-third of the world's monuments. This approach would promote the development of new methods for measuring errors. Finally, it is anticipated that this dataset will have value in examining how to train humans in recognizing intricate visual classes, and experimentation with human learning models is intended.

ACKNOWLEDGMENT

The authors extend their gratitude to Cercle, a live-stream media platform specializing in the film and broadcast of DJ sets and live performances within cultural heritage sites and landmarks through electronic music and video mediums. We would like to acknowledge Cercle for their collaboration in providing cultural heritage videos for our use. The authors also express their appreciation to WatchiT, a video-on-demand service for Arabic content online, with a unique collection of diverse entertainment options, including movies and TV shows, for their support of our work.

Exploring the Joint Potential of Blockchain and AI for Securing Internet of Things

Md. Tauseef, Manjunath R Kounte, Abdul Haq Nalband, Mohammed Riyaz Ahmed
School of Electronics and Communication Engineering, REVA University, Bengaluru, India

Abstract—The emergence of the Internet of Things (IoT) has revolutionized the way we interact with the physical world. The rapid growth of IoT devices has led to a pressing need for robust security measures. Two promising approaches that can enhance IoT security are blockchain and artificial intelligence (AI). Blockchain can offer a decentralized and tamper-proof framework, ensuring the confidentiality and integrity of IoT data. AI can analyze large volumes of real-time data and detect anomalies in response to security threats in the IoT ecosystem. This paper explores the potential of these technologies and how they complement each other to provide a secured IoT system. Our main argument is that combining blockchain with AI can provide a robust solution for securing IoT networks and safeguarding the privacy of IoT users. This survey paper aims to provide a comprehensive understanding of the potential of these technologies for securing IoT networks and discuss the challenges and opportunities associated with their integration. It also provides a discussion on the current state of research on this topic and presents future research directions in this area.

Keywords—IoT; blockchain; AI; security; attacks; decentralization

I. INTRODUCTION

The emergence of Industry 4.0 in the 21st century marked a significant change in the industrial paradigm, leading to improvements in social, economic, and political conditions[1]. Industry 4.0 enables the use of cyber-physical systems such as the IoT, big data analytics, cloud manufacturing, and fog computing, supported by cutting-edge technologies such as blockchain, AI, and mobile networks [2]. The integration of IoT, blockchain, and AI enhances human-machine interaction and brings the physical and digital worlds closer than ever before [3]. These technologies are expected to offer numerous benefits and opportunities, including self-awareness, self-prediction, self-comparison, self-reconfiguration, and self-maintenance [4].

The IoT is the driving force behind Industry 4.0, enabling seamless inter-connectivity of various devices and objects to construct a network infrastructure that continuously regulates and manages sensing, processing, and communication processes without human intervention [5]. The daily introduction of new applications and services is one of the many advantages of the IoT system. According to Statista [6], in 2020, there were about 50 billion IoT devices worldwide. By the end of 2025, that number is expected to reach over 75 billion devices.. Fig. 1 describes the timely growth in the number of IoT devices. The IoT market is expanding at an almost exponential rate. It was valued at USD 743 billion in 2015, which increased to approximately USD 1710 billion by the end of 2019 [7]. The global IoT market is expected to be worth

Fig. 1. Growth of IoT devices over the time 2015 to present.

186 billion dollars by the end of 2023, while the market for intelligent homes will be around 130 billion.

IoT has predominantly adopted the centralized architecture model for storing and processing sensor data. The central server serves as the network's manager, handling all requests from various nodes and overseeing task scheduling and distribution [8]. It saves costs by not requiring the installation of multiple workstations of hardware and software, as most processing tasks are managed by the centralized server. However, this architecture model has several challenges, including scaling issues due to the increasing number of IoT devices and various security and privacy concerns [9]. Table I summarizes the challenges posed by centralized IoT architecture. It is challenging to address the fundamental security concerns for such a large information ecosystem. Additionally, the centralized IoT model is susceptible to security breaches, single points of failure, and malicious assaults like DDoS and Sybil attacks[10][11].

Blockchain technology can help to address key security requirements in IoT, thanks to its "security by design" feature. The majority of IoT's architectural flaws can be fixed using blockchain's characteristics, including immutability, transparency, auditability, data encryption, and operational resilience. Blockchain is a decentralized network where all users have full control over peer-to-peer (P2P) monitoring of all network transactions[12]. Another technology that can strongly influence IoT is AI. Integration of AI into IoT devices can make them smart and intelligent [13]. AI can be used to train machines to understand novel material based on the training process they have already undergone. The goal of AI in IoT is to use IoT devices to gather relevant data and draw useful conclusions from that data. AIoT, or the merging of AI and the IoT, can be used to improve data analysis, human-machine

TABLE I. SUMMARY OF CHALLENGES IN CENTRALIZED MODEL OF IOT

Reference	IoT Challenge	Description
[9]	Security	Security is one of the primary issues (particularly DoS attacks) with centralized IoT design, because all data storage and processing operations are carried out by a single central server.
[10]	Single Point of Failure	Single point of failure is a problem since the server controls connections and carries out all processing tasks. If the server fails, the entire network of devices will stop working.
[14]	Access and Diversity	System should be accessible for all users with their dynamic needs. Yet, the centralized system requires that users access the data uniformly by adhering to the same protocols. Also, most of the centralized systems only support a single operating system, which restricts network diversity. IoT system includes heterogeneous and diverse devices, this will result in a serious issue that needs to be handled.
[15]	Inflexibility	A significant workload is generated by the centralised server's control over activities of communication and processing between all IoT network nodes. The centralized server schedules the workload to manage this workload and avoid peak-load problems. However, due to the constrained schedule and associated delay, this restricts user flexibility while performing their own duties.
[16]	Privacy	Sensitive data is among the real-time data types that IoT devices collect, such as habits, password, financial and personal information, etc. The centralised third-party server, which has complete control over this acquired data, keeps them all in one place while also violating their privacy. However, keeping it in one place could make it more vulnerable to intrusions.
[17]	Cost	The network's central server handles all of the communication and processing tasks, which place a heavy demand on the hardware and software needed to handle the workload. It also requires sizable storing storages that can hold data from diverse IoT devices.
[18]	Scalability	Among the main issues linked with the centralised architecture is scalability. Controlling and attempting to control all the network's nodes via a centralized server can scale successfully only in small networks. Using centralized system to big corporate organizations will be illogical. The centralised solution cannot scale and operate well since the number of Internet of Things devices is constantly growing.

interactions, and IoT operations [19]. The integration of decentralized AI has grown recently, enabling the execution and storage of an investigation or dynamic on verified, carefully annotated, and shared data on the blockchain in an automated, decentralized manner without middlemen[20][21]. Blockchain-based AI techniques can provide decentralized reasoning on how to promote safe and trust in the exchange of information and decision results over numerous independent operators who can contribute, organize, and vote on additional decisions [22]. This paper presents the joint potential of blockchain and AI for securing the industrial IoT system. The contributions made by this paper are as follows:

- Details of numerous security concerns in IoT ecosystem are described.
- Presented a concise literature review on security issues and their solutions.
- An architectural framework that integrates blockchain and AI for a secured IoT has been proposed.

The remainder of the study is organised as follows; in Section II, we go over the background of the IIoT, Blockchain, AI, and security concerns with IoT. We provide a full assessment of the literature on security-related issues, challenges, and solutions in Section III. In addition, this part illustrates how blockchain and AI combine to create a safe IoT environment. We provide the proposed architectural framework for combining blockchain and AI to improve IoT security in Section IV. We present high-level blockchain-driven AI and AI-driven blockchain as examples of how AI and Blockchain can be applied in IoT use cases. Section V provides the conclusion to the research findings.

II. BACKGROUND

The Industrial Internet of Things (IIoT) emerged from the intersection of manufacturing technology, industrial automation, and data sharing. Fig. 2 illustrates the timeline of the significant events that have contributed to IIoT's development. The evolution of Industry 4.0 has been fuelled by numerous game-changing advancements, including the availability of low-cost sensors, big data analytics, AI and machine learning (ML), the IoT, robotics, edge computing, standard communication protocols, and enhanced security technologies such

as encryption, authentication, and intrusion detection. As IIoT continues to progress, it has the potential to revolutionize various industries, such as manufacturing, logistics, healthcare, and energy. The impact of IIoT on these sectors is expected to be substantial, with efficiency, safety, and productivity improvements. For example, IIoT devices can help identify bottlenecks and optimize production processes in manufacturing, while in healthcare, connected devices can monitor patient health and aid in timely interventions. Overall, the IIoT represents a significant opportunity for businesses to transform their operations and unlock new value.

A. Evolution of Industry 4.0

The development of Industry 4.0 can be traced through several key milestones. It began with the digitization of production processes, which involved integrating digital technology like sensors and smart machines into industrial equipment and systems. This increased automation and data collection, laying the foundation for the next phase. The second phase involved the development of interconnected factories and supply networks. This was made possible through the adoption of IoT technologies, which allowed machines and gadgets to communicate with each other and share data in real time. Connected factories and supply chains became a reality, and this marked a significant advancement in Industry 4.0's evolution. The third phase saw the emergence of advanced analytics and artificial intelligence technologies that could analyse and make sense of the massive amounts of data produced by connected factories and supply networks. These technologies are employed to raise productivity, anticipate and avoid equipment breakdowns, and improve the production cycle. As machines and robots become more sophisticated, a collaboration between humans and machines has become a primary focus of Industry 4.0. This involves developing systems that allow people and machines to coexist in harmony, with machines handling routine jobs and people focusing on those that require creativity and problem-solving abilities. With the increased use of digital technology, cybersecurity has emerged as a critical issue for Industry 4.0. Companies have invested in technology and procedures to secure their systems from cyber-attacks, and this has become a hallmark of Industry 4.0's development.

Fig. 2. Evolution of industrial revolution 4.0.

TABLE II. SECURITY ATTACKS IN IOT ECOSYSTEM

IoT Level	IoT Layer	IoT Protocol	IoT Security Attacks
Deployment	Application	CoAP, MQTT, AMQP, REST	DDoS Attack, Repudiation Attack, SQL Injection Attack, Cross-Site Scripting, Parameter Tampering, Slowloris Attack, HTTP Flood Attack
Data	Transport, Network	UDP, TCP, DCCP, RSVP, SCTP, CLNS, QUIC, DDP, IGMP, EIGRP, IPsec, ICMP, IPv6, IPv4, RIM, OSPF	Smurf Attack, SYN Flood, Mitnick Attack, Injection Attack, DoS Attack, Opt-ack Attack, IP Address Spoofing, Worm Hole Attack, Byzantine Attack, Resource Consumption Attack, Black Hole Attack
Device	Physical	ISDN, DSL, USB, IDA, CAN, Bluetooth, Ethernet	Access Control Attack, Disconnection of Physical Links, Physical damage

B. Security Concerns in IoT

The IoT devices gather and transmit vast amounts of data, including sensitive or private information such as medical records or video footage from home security systems. Ensuring the security of this data is critical to protect privacy and prevent identity theft. Unfortunately, IoT devices are frequently targeted by cybercriminals because they are often insecure and provide an easy entry point to a larger network. Successful cyber-attacks can result in data breaches, financial losses, and even physical harm. Additionally, many critical infrastructure systems, such as power grids and transportation systems, are controlled by a large number of IoT devices [23]. If these systems are compromised, the consequences can be severe, including widespread disruption, financial losses, and even loss of life. It is essential that IoT devices adhere to strict data privacy and security regulations in industries such as healthcare and banking to avoid legal repercussions and reputational harm. To ensure the security of IoT devices, it is necessary to implement security measures at three different levels: device, data, and deployment [24]. These levels correspond to the IoT's architectural layers, with specific protocols used in each tier of the IoT architecture to protect against related security attacks (Table II). Techniques such as encryption, authentication, and access control can be used to secure sensitive data from unauthorized access. IoT devices are often deployed in remote or harsh environments, making them vulnerable to physical attacks such as theft or manipulation. Physical security mea-

asures such as tamper-evident seals, firmware upgrades, and patches can help guard against these risks. Additionally, cyber attackers can compromise IoT devices and use malware such as DDoS, HTTP flood, SQL injection, and parameter tampering to control the devices and exploit their vulnerabilities. It is crucial to protect against these threats by regularly updating firmware and applying security patches.

C. Blockchain for IoT Security

Blockchain technology offers solutions to several security challenges facing IoT systems, such as data privacy, data integrity, and device authentication. By providing a secure, decentralized, and immutable system, it can defend against DDoS attacks, data manipulation, and unauthorized access. Its architecture combines hash algorithms with decentralized ledgers that use public and private keys, offering a potent alternative to the internet [25]. Blockchain ensures secure data storage and can prevent rogue IoT devices from entering the network. It can also reduce the costs of litigation caused by disagreements [26]. Transactions are protected by a consensus mechanism that ensures their integrity even in the presence of faults or hostile conditions, thus enabling a stable blockchain [27]. Moreover, blockchain can be combined with smart contracts to increase dependability and radio-frequency identification is safeguarded by attribute-based access control mechanisms [28]. In blockchain, each block contains its data, the previous block's hash, and the security hash code. It can offer secure

TABLE III. ENABLERS OF SECURED IOT SYSTEM

		Blockchain for IoT Security
Data privacy	PD	Data can be protected by using blockchain to store it in a decentralized, tamper-proof manner. Blockchain's public-key encryption ensures that only authorized parties can access the data.
Data integrity		Data integrity is guaranteed by the tamper-proof ledger in blockchain, which is immune to hacking and data modification. This guarantees the accuracy and dependability of the data that IoT devices collect.
Device authentication		Blockchain offers a safe and decentralized method for IoT device authentication. Each gadget can be given an own digital identity, making it simple to trace it down and confirm its legitimacy
DDoS		Blockchain establishes a distributed network of nodes capable of validating and verifying data sent by IoT devices. By limiting the amount of devices that may access the network, this can assist avoid DDoS attacks.
		AI for IoT Security
Anomaly detection		AI assists in identifying potential security concerns, such as malicious activity or unexpected network traffic, and alerting security teams to take appropriate action by detecting anomalies in the behaviour of IoT devices and networks.
Predictive maintenance		IoT device monitoring and forecasting of potential failures and maintenance needs. By doing this, security lapses brought on by unsecured or infected devices may be avoided.
Behavioral analytics		Investigate trends in the actions of IoT users and devices to look for potential security risks. An IoT device may have experienced a security breach if it suddenly starts transmitting significant amounts of data at odd hours.
Cyber threat intelligence		To address potential security concerns in IoT devices and networks, collect and evaluate data about known cyber threats and vulnerabilities. This can assist businesses in taking preventative measures to safeguard their networks and devices from threats.
Identity and access management		For IoT networks and devices, AI can be utilised to enhance identification and access control. In order to assist prevent unauthorised access to devices and networks, this may also include user authentication, authorisation, and access control.

data transfer over IoT device nodes, and its lightweight and sustainable algorithm employs decentralized techniques for authentication in distributed resource-constrained systems [29]. Certain companies might be capable to handle dependability issues with a double-chain design that uses data and transaction blockchain for storage, distribution, and data reliability, but there are risks related to privacy vulnerability [30]. Various studies have examined the use of blockchain in securing IoT, such as [31] and [32], which provided an overview of the security issues with IoT and how blockchain can be applied to address them. However, [33] critically analyzed the limits of using blockchain-based IoT platforms, offered a taxonomy of blockchain typologies, weighing their benefits and drawbacks in incorporating them into IoT. Several ideas have been proposed for using blockchain and AI technologies to address specific security issues of IoT, such as allowing smart contracts, IoT devices to update their firmware, or developing a system in which devices can acquire “money” by exchanging resources or data for goods or services [34]-[36]. Table III summarizes how blockchain and AI technologies individually help address security concerns of IoT.

D. AI for IoT Security

The integration of AI into the IoT devices can significantly enhance their performance and security. AI can simulate human learning processes such as decision-making, problem-solving, and object identification, making IoT devices intelligent and more efficient. By combining AI and IoT, businesses can generate useful data and obtain insights, making their operations more effective [37]. One of the main benefits of using AI in IoT is its ability to quickly identify potential security threats and holes. AI can examine network traffic and user activity trends, identify vulnerabilities, and prioritize them according to their severity [38]. With AI, businesses can automate the patching of IoT devices, ensuring that they are up-to-date with the latest security patches, reducing the chance of security breaches [39]. AI can also track user and IoT device behaviour, detecting any unusual activity that might point to a security breach, allowing organizations to respond quickly to threats. Secure access control, offloading, and virus detection can be provided by AI-based authentication employing machine learning to preserve data privacy [40]. By

TABLE IV. IOT SECURITY CONCERNS ADDRESSED BY BLOCKCHAIN AND AI

Security Issues Addressed by Blockchain	Security Issues Addressed by AI
Verification of Identity	Intrusion detection system
Self-healing and detection of firmware	Malware detection
Address space and privacy preservation	Anomaly detection
Secured communication and data integrity	Unauthorized IoT devices identification
Authorization and authentication	Distributed denial-of-service
Information sharing and access control	Jamming attack, Spoofing attack
Secure computation and storage	Authentication, Eavesdropping
Trust-management	False data injection, Impersonation

using the analytical capabilities of AI, businesses can uncover patterns and make better decisions about IoT data collection. AI can enhance the object identification technique utilized by smart cameras, enabling them to recognize dangerous objects like knives and guns instantly. However, AIoT frameworks are prone to data security and privacy issues. To address these issues, researchers are developing solutions such as blockchain, which offers greater protection than conventional security measures since it cannot be altered. Many AIoT applications can incorporate blockchain to boost security. The security concerns that blockchain and AI address when used independently with IoT are listed in Table IV. Overall, the combination of AI and IoT can significantly enhance businesses' operations and security. By using AI, businesses can identify potential threats quickly, automate patching, and make better decisions about data collection. Integrating blockchain into AIoT applications can enhance security, ensuring data privacy and reducing the risks of security breaches.

E. Convergence of Blockchain and AI for IoT Security

The combination of blockchain, IoT, and AI is becoming exceptionally important in the realm of digital transformation, particularly for IoT security. With this convergence, new business strategies are emerging that involve the creation of autonomous profit centers made up of autonomous agents, such as sensors, vehicles, machines, trucks, cameras, and other IoT devices. These autonomous agents will have digital twins through IoT, enabling them to independently send and receive money through blockchain technology and make decisions using AI and data analytics. As a result, we predict that

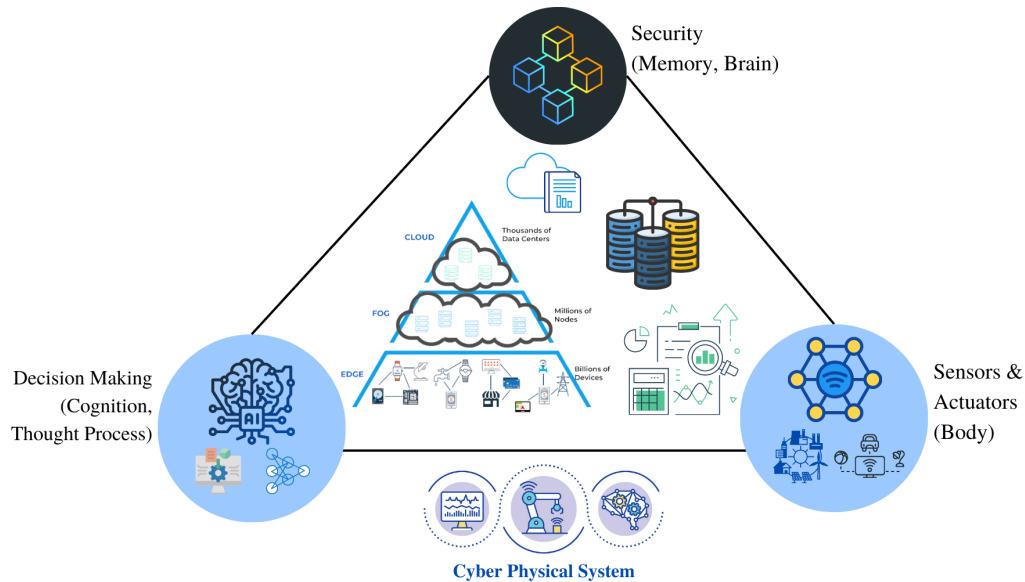

Fig. 3. Convergence of blockchain, AI towards secured IoT.

industrial firms will undergo a digital transition as these autonomous business models continue to evolve.

In recent years, IoT devices have collected an enormous amount of data centrally, causing security and space issues [41]. However, the integration of AI, blockchain and IoT offers a solution to this problem by creating a distributed database [42]. Decentralized AI, which is a growing concept, integrates these two technologies to allow for distributed, unmediated execution and storage of data on the blockchain without middlemen. Blockchain is expected to be a reliable platform for storing vast volumes of data that AI works with. With the blockchain's smart contract functionality [43], it is possible to keep track of member participation and transactions while accessing information. An autonomous system and machine can then choose exact and reliable option outcomes that are verified and acknowledged by all blockchain mining centers [44]. These decisions cannot be contested and can be supported by anyone with a stake in the outcome.

Blockchain, AI, and IoT have successfully combined, as seen in Fig. 3. The integration of these technologies can address several critical issues such as accuracy, latency, centralization, privacy and security issues in IoT. Decentralized reasoning provided by blockchain-based AI algorithms can benefit a large number of independent operators who may contribute, organize, and vote on new decisions [45]. Blockchain databases have hash values that are digitally signed to ensure secure and reliable processing of transactions. AI algorithms are used to solve issues related to accuracy, latency, security, and privacy, and to enhance big data analysis. The decentralization of blockchain networks eliminates the single point of failure in a cloud server, making it more efficient and reliable for data analysis. By integrating AI and blockchain technology, the IoT can be aided with better decision-making capabilities.

To further enhance the integration of blockchain, AI, and IoT, there are several areas that need to be addressed. For

instance, the integration of these technologies requires a strong and secure infrastructure, as well as effective governance and regulatory frameworks. There is also a need to address the ethical and social implications of using these technologies, such as issues related to data security, privacy and bias. Moreover, the adoption of blockchain, AI, and IoT will require a significant investment in research and development, as well as in the training of personnel to effectively manage and maintain these technologies. Nevertheless, the benefits of this convergence are substantial, including increased efficiency, improved security, and better decision-making processes. As these technologies continue to evolve, it is likely that we will see even more innovative ways to combine them. The convergence of blockchain, AI, and IoT has the potential to transform the way we live, work, and interact with one another. It is an exciting time to be at the forefront of this convergence and to witness the transformative power of technology.

The Big Data revolution has been a key driver of the AI revolution, as it enables businesses to divide vast databases into manageable, organized components. Additionally, the value of data has propelled the development of blockchain technology, as its distributed ledger offers a new, more efficient way to store data. This combination has the potential to significantly transform how information is handled, analyzed, and shared, ultimately making operations inside a company more efficient and effective. As AI continues to evolve, we may see the emergence of new AI systems, such as logic-based systems, bio-inspired systems, collaborative agents, cyber-physical intelligent systems, and ubiquitous AI or pervasive intelligence systems, which could fundamentally change our daily lives.

Machine Learning, a branch of AI, has gained significant popularity in recent years due to its ability to analyse huge data flows. It has found applications in various fields such as business, entertainment and research. Many countries and organizations, including Google, Amazon, Facebook, Microsoft,

Fig. 4. Research trends in blockchain, AI, IoT and cyber security.

IBM, Apple, Intel, Alibaba, Baidu, and Uber, have invested heavily in developing cutting-edge ML goods, programs and platforms that can be used as cloud services to run ML models effectively, known as MLaaS. Cloud computing is a popular and cost-effective platform for running ML models used in many IoT and smart city services and applications, such as text classification, automated language processing, facial recognition, speech recognition, computer vision and speech synthesis. Additionally, several nations have launched ambitious national AI initiatives in less than a year [46], indicating the potential impact of ML and AI on various sectors.

The integration of Blockchain, AI, and IoT has been the subject of many experiments and hypotheses, but further research is necessary to develop a functional and reliable digital component that properly combines the three. Cloud computing is crucial in today's world and facilitates online connectivity. However, the vast amount of data handled by this system highlights the need for automated systems with quality of service (QoS) standards. The convergence of Blockchain, AI, and IoT is identified as a critical technology to meet this requirement. Consequently, the extensive use of AI and blockchain integration will bring about exciting advancements in Industry 4.0. Instead of only discussing software, algorithms, automation, robotics, and hardware, businesses are now exploring more sophisticated concepts such as producing and manufacturing items on-demand, dematerialization, and disintermediation. Industry 4.0 emphasizes distinct pillars including information transparency, support, and connection, and it represents the first major revolution that moves from a tech-centric state to a more sophisticated one.

III. LITERATURE REVIEW

A. Security Requirements in IoT

IoT devices need strong security measures to prevent unwanted access and data breaches since, like any linked system, they are susceptible to cyber-attacks. In the IoT ecosystem, some of the primary security requirements are; only devices or users that have been authenticated can access the network. This can be done via techniques including digital certificates, biometric identity, two-factor authentication, and password protection. To prevent unlawful interception, data transferred between IoT devices should be encrypted[47]. Data in transit and at rest should be protected using robust encryption techniques like Advanced Encryption Standard (AES) and RSA algorithm. Access control - It is important to prevent unauthorized access to network data. This group can include additional access control techniques as well as attribute- and

role-based access control. IoT devices should be built to constantly download and install firmware upgrades to address security holes and enhance functionality. In order to prevent malicious firmware updates, devices should provide a method for confirming the integrity of firmware upgrades. Physical security - In order to avoid unwanted access or tampering, IoT devices should be physically secure[48]. These can include steps like secure boot procedures, tamper-resistant designs, and physical security controls like locks and access cards. Privacy - IoT devices should respect user privacy by only gathering information that is required and handling it securely. Users should be clearly informed by devices about the types of data being gathered and how they are being used. Network security - IoT devices should be built to function safely on both public and private networks, among other network environments. This may involve taking precautions like installing firewalls, installing intrusion detection and prevention systems, or using secure communication protocols like VPNs. In order to stay abreast of the most recent security threats and vulnerabilities, a solid security strategy for the IoT ecosystem should be multi-layered, proactive, and constantly developing.

B. Avenues of Cyber Attacks in IoT

The connection between IoT devices offer several opportunities for cyber criminals to find flaws and launch assaults. Here are a few typical IoT ecosystem cyber-attack vectors. Poor authentication methods - IoT devices are susceptible to assaults like brute force attacks, dictionary attacks, and password cracking attacks if they employ weak or default passwords or have no authentication mechanisms at all. Unsecured communication protocols: IoT devices that employ these protocols are susceptible to replay, eavesdropping, and man-in-the-middle attacks. IoT devices that run out-of-date or unpatched software may contain vulnerabilities that attackers can take advantage of[49]. Buffer overflows, SQL injections, and cross-site scripting attacks are some examples of these flaws. IoT devices are susceptible to malware and ransomware infections, which might jeopardize the ecosystem's overall security. DDoS assaults, botnet attacks, and other malicious activities can all be carried out via malware on a system. Physical tampering: IoT devices that lack physical security are susceptible to physical tampering, which gives hackers access to the system without authorization, gives them the chance to steal data, or modifies the device's behaviour [50]. Social engineering - Social engineering attacks, such as phishing assaults or pretexting, which deceive users into disclosing sensitive information or installing malware, can be used to target IoT devices. Fig. 4 depicts research trend in the domains of Blockchain, AI, IoT and Cyber security

TABLE V. RELATED SURVEYS ON IOT SECURITY

Reference	Year	Description
[53]	2014	Three layers of IoT security are examined, as well as the appropriate fix.
[54]	2016	The proposed design is built on IoT middleware, and each layer's specifics are detailed. The authors also discussed the IoT middleware system's adaptability and security challenges.
[55]	2016	Presented the reference model and the edge-side security threads. The countermeasure to the potential solutions was also discussed in the study.
[56]	2017	Outlined the merging of the IoT with Cyber-Physical Systems. Detailed examination of the privacy and security issues. The integration of edge/fog computing with IoT is considered.
[57]	2017	The study surveyed participants about their privacy and security concerns with IoT applications and devices. The authors looked at the authentication process for the IoT system. IoT applications built on a four-layer architecture provide difficult security challenges that are thoroughly explained.
[58]	2017	The authors of this study looked into modern security concerns in IoT applications. The risks and vulnerabilities of the system are thoroughly investigated in terms of communications, architecture, and applications. The paper's conclusion offers a strategy for resolving several security problems.
[59]	2018	The paper offers a thorough analysis of IoT security layer-by-layer. Suitable countermeasures and a model of probable dangers are thoroughly examined.
[60]	2018	Look at the danger and security model for IoT applications. The article discussed a few IoT system problems, including access control, trust management, and authentication.
[61]	2018	IoT systems' many standardized architectures have been reviewed, and the current solution strategy for security and interoperability is described.
[62]	2019	Examined the hazard and security in IoT applications. The use of Blockchain, edge computing, fog computing, and alternative solution approaches was suggested.
[63]	2020	There is a newly emerging technology that can address IoT security concerns. During a thorough investigation, the authors discovered that artificial intelligence, blockchain technology, and machine learning are the current approaches being used to address the IoT security problem.
[64]	2021	Security, trust, and faultless communication issues affecting the integration of IoT with blockchain are examined. Described in detail the study process used to examine the problems with the integration of blockchain, AI, and IoT.
[65]	2022	The IoT, blockchain and AI-based authentication in cybersecurity are all combined in this paper to give researchers a full, high-quality study on authentication and session keys.

TABLE VI. SOLUTIONS TO IOT SECURITY ATTACKS/CHALLENGES

Reference	Technique Used	Security Attack/Challenge	Measure Taken	Description
[66]	Edge computing using permission based blockchain for Smart Grid Network	The use of viability and the allocation of funds are under attack	transparent agreements updated on the blockchain	Solves the problems of intelligent systems, information security, and viability security by combining square chain and limit registration approaches.
[67]	Distributed security model using blockchain, edge cloud, and software-defined networking	Security attacks at edge layer of IoT network	SDN based gateway to hinder the doubtful flows.	By computing suspicious network traffic flows and preventing suspicious flows, the SDN-based gateway's dynamic network traffic flow management aids in the detection of security assaults and lowers their frequency.
[68]	Privacy protection of location data mining	Protection of location data records	Differential privacy mechanism	Using a multi-level query tree's structure and a different privacy method, you can query and publish location data on databases.
[69]	Privacy protection technique for location data	Privacy protection for location data	Location sensitivity for location recommendation	It uses check-in frequencies and location trajectories to determine a threshold for categorizing the sensitivity level of the places.
[70]	Privacy protection is integrated to machine learning	Classification process for local differential privacy protection	Logistic regression is applied for noise addition and feature selection	To achieve classification utilizing noise addition and feature selection, local differential privacy protection is created.

C. Related Work

Some study has already been done by researchers on the topic of how AI and IoT may work together to improve computation and decision-making in IoT systems. The work employs an master attack in the IoT to enable AI-based smart city applications [51]. In Zou et al. [52], similar explanations of fog and edge computing in IoT may be found. The Blockchain network employs a number of consensus techniques to reach consensus among the nodes. The design and potential uses of the Blockchain are thoroughly explained in the authors' essay [71]. In their study [72], the authors examined the concept, relevant research on IoT security and a possible approach to a solution using blockchain. The authors proposed a secure architecture for internet of things applications built on a distributed Blockchain system [73].

The authors' paper [74] briefly discusses how Blockchain technology is used in the Internet of Things. In paper [75], the authors assess the several Blockchain options for IoT security challenges as well as their implementation issues. To analyse and calculate the massive data collection using a machine learning technique, an effective framework [76] is needed. The authors of paper [77] examine the security concerns raised by using machine learning to a smart grid application. The authors

of article [78] discuss intrusion detection in Internet of Things applications. Table V summarizes the related survey works in the area of IoT security.

IoT issues were divided into four groups in Kshetri et al. research's [79]: (i) Cost and Capacity Limitations (ii) Deficient Architecture (iii) Downtime and Unavailability of Services on Cloud Servers (iv) Susceptibility to Manipulation. Their research covered the significance of blockchain in enhancing general security in supply chain networks as well as potential Blockchain solutions to each IoT concern. IoT datasets, which are used by the academic and expert communities, are one of the issues Banerjee et al. [80] examined when researching IoT security solutions. A standard for communicating IoT data values among research and expert communities, other pertinent partners, and vendors is necessary given the potentially conscious character of IoT datasets. In the future, blockchain technology should be made accessible to secure the security of IoT applications. Li et al. [81] offered a thorough analysis of the security risks to blockchain technology and talked about analogous actual attacks by extending well-liked Blockchain systems. They examined the blockchain technology security augmentation options. Table VI summarizes the techniques and countermeasures to address security attacks in IoT.

TABLE VII. INNOVATIONS THROUGH THE CONVERGENCE OF BLOCKCHAIN, AI AND IOT

Reference	Enablers	Innovation Domain	Use case	Description
[82]	Big data, 5G, Cloud Computing	Software Engineering	Blockchain-as-a- service (BaaS)	Cloud-based infrastructure and management provided by a third party for businesses developing and running blockchain applications. BaaS performs the back-end management for a platform or app built on blockchain in a manner similar to that of a web host.
[83]	Digital Twin	Data analytics	Intelligent money transaction - own profit centers (Autonomous agent)	IoT-based digital twins that can send and receive money via blockchain technology and act independently as economic agents can all do this.
[83]	Deep Reinforcement Learning	Block producers, consensus algorithm, block size, and block interval	Blockchain enabled IoT System	Framework for performance tuning to increase throughput.
[84]	Decentralization, AI algorithms	Digitally signed hash values, Data validation	Secure banking system	Reduces difficulties with accuracy, latency, privacy and security, and centralization.
[85]	Open source software	Bitcoin Protocol	Trust Management	It increases confidence in the system when a miner completes Proof of Work (PoW) without the aid of a bank or other centralised authority. Blockchain technology makes consumers think that no one can be trusted and that no one can make a claim to be one as a result.
[86]	Edge computing	Control and manage computation workload distribution	Data integrity and ensuring its availability and user accountability	Giving dispersed IoT hardware a reliable way to distribute computation-workload control and management across a large number of nodes.

D. Blockchain for AI in Addressing IoT Security

The AI can complete all tasks without outside influence with the aid of the Blockchain. Hence, all analysis and decision-making may be done on a private and secure platform. A decentralized AI platform also prevents data manipulation. Although AI and machine learning are two distinct methodologies, they are somewhat interconnected. The AI program employs a method called machine learning to respond to the tasks that are put in front of it. Unsupervised learning and supervised learning are the two types of learning that can be employed when creating and training an AI. Blockchain can be used in the context of AI to protect data produced by IoT devices, which is frequently utilized to train AI models. Blockchain can aid in preventing data tampering, manipulation, and unauthorized access by building a secure, decentralized record of this data. This can safeguard users' privacy while enhancing the accuracy and dependability of AI models. Securing device communication is another potential use for blockchain-based AI in IoT security. Without a centralized authority or middleman, devices can establish safe communication channels by using blockchain-based smart contracts to verify one other's identities. Attacks like man-in-the-middle attacks, which are frequent in IoT environments, could be avoided as a result of this.

E. AI for Blockchain for Addressing IoT Security

AI can help blockchain technology overcome some of its drawbacks, such as consensus procedures. Nodes can validate transactions rapidly and effectively in Proof of Work (PoW) or Proof of Stake (PoS) by using AI. Also, as the mining process uses a lot of energy, AI can help blockchains use less energy. This is possible by implementing AI technologies that have proven successful in reducing energy consumption. Using federated learning, for instance, which can offer a decentralized learning system, can help alleviate the scalability problems of blockchain. Also, while blockchain offers greater security than current technologies, AI can add an extra layer of security. IoT device data is analysed by AI algorithms to spot patterns and anomalies that can point to security lapses or other risks. AI can assist in preventing and reducing security concerns by continuously monitoring the data produced by

IoT devices and using machine learning algorithms to spot anomalous activity. Digital signatures are used by blockchain-based systems to verify transactions. These signatures can be examined by AI systems to find patterns that might point to fraud or other sorts of harmful behaviour. This could aid in limiting illegal access to IoT networks or devices. IoT devices produce a lot of data that can be used to forecast when a gadget is most likely to break down. This might lessen security threats that might be brought on by a corrupted or broken device. Strong authentication procedures are needed for blockchain-based systems to make sure that only authorized users can access devices and networks. To identify individuals and prevent illegal access, AI algorithms can be employed to examine biometric data such as facial recognition or voice recognition. In summary, the blockchain and AI work together to enhance the security of the IoT ecosystem. As outlined in Table VII, the blockchain and AI work together to pave the road for innovations in the IoT space.

IV. PROPOSED ARCHITECTURAL FRAMEWORK

Security, privacy, and scalability concerns can be addressed by designing a new framework for a Blockchain-based AI-enhanced IoT system. Fig. 5 depicts the proposed layered architectural framework for secured IoT. The layers of proposed architecture are as follows:

1) *Perception layer*:: IoT devices that gather and send data to the system are part of the perception layer. The system's core elements are IoT devices. They are in charge of gathering (sensing), storing, acting upon, and sending information to the system. They gather information from a variety of sensors, including temperature, humidity, and motion sensors.

2) *Network layer*:: This layer includes communication network that links the IoT devices to the system. To protect against any unauthorized access or data tampering, the network needs to be trustworthy and secure. VPNs and cryptographic protocols like SSL/TLS can be used to increase network security.

3) *Security layer*:: This layer contains the security defenses against cyber-attacks, including access control, encryption, and authentication. It guarantees the system's availability, integrity,

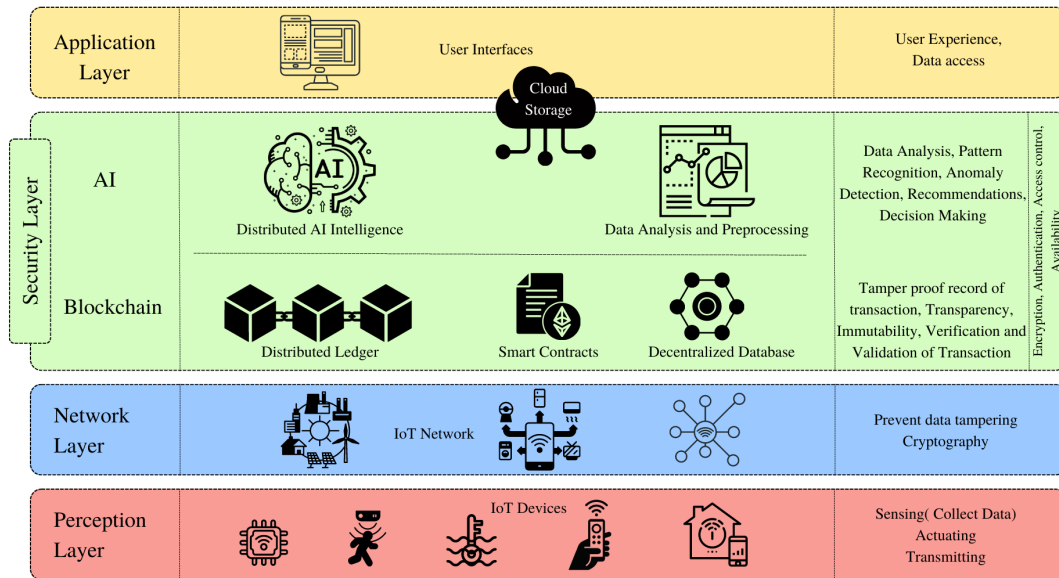

Fig. 5. Architectural Framework Integrating Blockchain and AI for Secured IoT.

and secrecy. The data gathered from the IoT devices is stored in the cloud and on the Blockchain. A distributed ledger in the Blockchain keeps a tamper-proof record of all transactions. It guarantees the system’s immutability, transparency, and security. Blockchain offers a secure, distributed database for storing all of the transactions. Large volumes of data are stored in the cloud storage, which also gives the system scalability. Smart contracts are self-executing agreements that uphold the system’s laws and regulations. They aid in the automation of the transactions’ validation and verification processes. The data gathered from IoT devices is stored and processed using cloud computing. It gives the system flexibility, scalability, and affordability. The distributed ledger of the blockchain offers a new way to store data in a more efficient manner. Blockchain and AI working together has implications for a variety of fields, including Security: AI and blockchain may combine to provide an additional line of defense against online dangers. Uncovering suspicious events is one of the most challenging issues facing upcoming businesses. Some, however, are already utilizing machine learning technologies that help in instantly spotting them. Speed – Combining the two technologies may speed up the delivery of information and data, improving the efficiency and speed of consumer interactions with enterprises. Service customization will increase over the coming years, and large companies’ or businesses’ recommendation systems will become widely used.

The artificial intelligence algorithms used to analyze the data gathered from IoT devices are included in this layer. AI assists in spotting trends, patterns, and abnormalities in the data. Additionally, it offers suggestions and forecasts based on the data analysis. AI offers insightful information that aids in decision-making. The data gathered from IoT devices is processed using data analytics. It assists with spotting trends, patterns, and abnormalities in the data.

4) *Application layer*:: User interface, data analytics, and other programs that enable the system’s functionality are all included in the application layer. The system’s data and analytics are accessed through the user interface, which is also used to interact with the system. IoT device data is processed using data analytics, which offers insightful information.

The proposed framework offers a safe, scalable, and effective solution to manage IoT devices, gather data, and use AI and data analytics to make wise decisions. While the use of AI and data analytics provide useful insights and aids in making decisions, the usage of Blockchain protects the security, transparency, and immutability of the system. An additional layer of defense against cyber-attacks is offered by the security layer.

V. CONCLUSION

Blockchain and AI coming together is a promising way to secure the IoT ecosystem. IoT devices are prone to cyber-attacks, and a decentralized architecture supported by blockchain and AI can offer a practical solution to improve the security of these devices. The purpose of this suggested framework is to investigate the potential benefits of this convergence for secure IoT. The framework can improve the data acquired by IoT devices in terms of security, transparency, and privacy. Additionally, it can lessen the need on centralized middlemen and offer a decentralized platform for data transfer and communication amongst IoT devices. The IoT ecosystem’s security and the development of the digital future may both benefit from the integration of blockchain and AI. Several theories and tests have been conducted in an effort to connect AI, IoT, and Blockchain; nevertheless, more research will be needed to build a digital strategy that might effectively combine the three for a reliable and useful digital component. Unlike any previous period in history, cloud computing is incredibly important today and enables online connections. The

massive amount of data handled by this computing system emphasizes the necessity for automated systems with (QoS) standards. Identification of essential technologies is necessary to meet this demand, and it currently looks that Blockchain, AI, and IoT are these convergent technologies.

Abstract—We conducted a Systematic Literature Review on scientific papers that examined the interaction between operators and drone swarms based on the use of a command and control center. We present the results of a meta-analysis of nine scientific papers published in the ACM DL and IEEE Xplore databases. Our findings show that research on human-drone swarm interaction shows a disproportionate interest in hand gestures compared to other input modalities for drone swarm control. Furthermore, all articles reviewed exclusively explored gestures and the size of the swarm used in the studies was limited, with a median of 3.0 and an average of 3.8 drones per study. We compiled an inventory of interaction modalities, recognition techniques, and application types from the scientific literature, which is presented in this paper. On the basis of our findings, we propose four areas for future research that can guide scientific investigations and practical developments in this field.

Keywords—Human swarm interactions; input modalities; swarm control

I. INTRODUCTION

Interacting with drone swarms is becoming fascinating for many people, but is still futuristic for many fields of scientific study [1]. However, the human-drone swarm interaction is made possible by the large amount of work done by researchers and practitioners in this field. The scientific community has investigated and proposed new technologies [2], artifacts [3], and interaction techniques [4] to make human-drone interaction possible and allow operators to accept drone interaction and rides in public spaces [5]. This work has revealed numerous benefits to society, such as finding survivors in emergency situations [6], [7], [8], [9] or escorting lone drones moving at night [10]. Other scientific papers have focused on the guidance of drones by people crossing roads [11] or providing personal assistance [12]. These proposals with drones used on a large scale have also come with many applications and fields of use. Despite the potential drone swarms they create, a quantitative analysis of how research has developed is lacking. We find drones in a multitude of fields, from professional environments [13], leisure [14], or semi- or fully autonomous modules [15]. However, we identify drones that are used singularly [16] or are part of a swarm [17]. This exemplification highlights the diversification of domains with drones, and we, therefore, propose a high-level perspective of current and future use cases for drone swarm interaction. See Fig. 1.

Fig. 1. Description of concept interaction between operators and drone swarms, based on the use of a command and control center.

First, this article describes the selection process, which represents a domain analysis of $N=59$ scientific articles on the interaction between operators and drone swarms based on the use of a command and control center. Second, our results have led to several future research directions. Finally, we conclude with fundamental observations and research opportunities for the field.

To the best of our knowledge, this is the first paper to analyze a scientific paper in this form; therefore, we propose the following.

- 1) We report results from the Systematic Literature Review conducted on the interaction between operators and drone swarms based on the use of a command and control center.
- 2) We draw implications for future research on the interaction between operators and drone swarms based on the use of a command and control center.
- 3) We propose four research directions for the scientific community to structure future scientific (A. *Input modalities and interaction technique*, B. *User studies and evaluations*, C. *Involvement of Multiple Drones in Simulations*, D. *Control and Command Devices and Prototypes*) investigations and practical developments in this area.

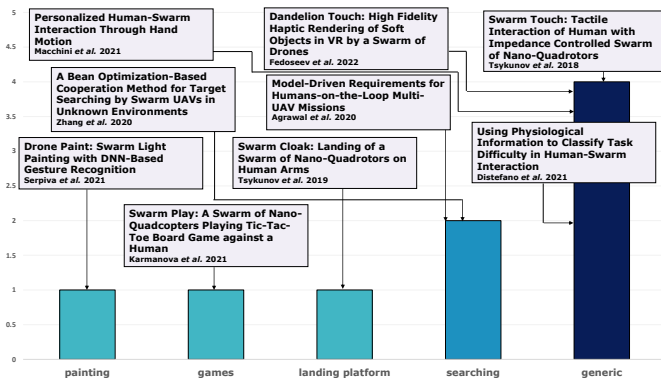

Fig. 2. Type of application interaction between operators and drone swarms, based on the use of a command and control center.

II. STUDY DESIGN AND SCOPING REVIEW

Previously published research in the field of human-drone swarm interaction has, for example, presented various activities in which drones are used for monitoring and assessing earthquake damage [18], investigating maritime spill [19], and delivering defibrillators [20]. All these applications involve human operators who will interact with drones through an interface, directly or indirectly, to capture images or plan drone routes. Previous research has described other forms of interaction [21], including voice and haptic interfaces [22], [23], but these have not been identified for interactions with drone swarms for emergency response.

Therefore, we present the method underlying the formation of our study during the systematic literature review of the literature to address the two research questions in the II-B section that are focused on our area of investigation for the interaction between operators and drone swarms, based on the use of a command and control center.

The substantial growth in drones in recent years¹ does not lead to a clear direction in which application domains these drone swarms are needed and what interactive modalities are required with them.

That is why we aim to map the systems and applications that have been described, studied, or envisioned in the scientific literature and that are based on the interaction between operators and drone swarms based on the use of a command and control center. There are a few scientific studies that have analyzed in detail, challenges, application domains, and detailed descriptions of previous works, all of which have focused on human-drone interaction [24], [25].

These surveys offer useful information to the community of researchers and practitioners. However, they do not provide a systematic exploration of previous work that looked at the interaction between operators and drone swarms based on the use of a command and control center in terms of the systems and applications that have been used. Here, we take a broader angle and propose a systematic literature review of the scientific literature that addresses the interaction between operators and drone swarms, based on the use of a command and control center, classifying the purposes of the applications,

the domains, how data were collected, and also the systems that were used to interact with drone swarms.

A. Chosen Methodology and Steps

We conducted a systematic literature review, using the methodology proposed by Siddaway *et al.* [26] and Liberati *et al.* [27], to perform a critical analysis of the current state-of-the-art in terms of the interaction between operators and drone swarms based on the use of a command and control center. Implementing this approach was based on the identification of references of interest for our study, and therefore we identified, using queries with a specific footnote query in the ACM Digital Library² and IEEE Xplore³ databases, where we identified and analyzed a body of N=59 scientific articles.

Our motivation for conducting this survey of systems and applications that address the interaction between operators and drone swarms is to provide an overview of the systems and applications, how they interact with them, and current and future use cases studied and envisioned in the scientific literature. In the following, we explain the survey method used, our research questions formulated, and how we selected and categorized the relevant articles for our study.

We have carried out data mapping that targets applications in the interaction between operators and drone swarms, based on the use of a command and control center according to the following steps:

B. First Stage: Identifying the Research Questions for Our Study

To explore the scope of applications targeting human-drone swarm interaction based on the use of a command and control center, we formed the following questions.

- RQ1:** “What are the categories of applications studied or considered in human-drone swarm interaction?”
- RQ2:** “What kind of interaction modalities has been described, studied, or designed for human-drone swarm interaction based on the use of a command and control center?”

C. Second Stage: Identifying Relevant Articles

We based our selection on academically evaluated research articles. We therefore selected the ACM Digital Library, which contains more than 3M records, and IEEE Xplore, these being the main digital libraries in Engineering and Computer Science. To identify works that could be integrated into our study we used to query:

```
"query": {  
  Abstract:  
  ((interaction* AND swarm*) AND  
  (drone* OR uav*) AND  
  (tool* OR platform* OR  
  application* OR system*))  
}  
"filter": {NOT VirtualContent: true}
```

¹<https://www.nytimes.com/2020/05/23/style/drones-coronavirus.html>

²<https://dl.acm.org/>

³<https://ieeexplore.ieee.org/Xplore/home.jsp>

Using asterisks (*) to avoid focusing the search on a single word. Note that we focused our search on drones, and UAVs are the most popular type of consumer drone, according to the analysis by Wojciechowska *et al.* [28]. The formed query was used for both databases.

D. Third Stage: Selecting Relevant Articles

Our analysis included reviewed articles and large-scale academic articles, such as extended abstracts (e.g., postings and demonstrations), but also articles from workshops. In our selection process, we did not include sites websites or other media, as we intend to focus on classifying the purposes of the applications, the domains, how data was collected but also the systems that were used to interact with drone swarms but also on image object recognition technologies encountered in the interaction between operators and drone swarms, based on the use of a command and control center. All the selections that we refer to will be called articles throughout this scientific article. For all articles identified using queries from ACM and IEEE Xplore, we used the following exclusion criteria.

- EC1:** *Mandatory article was written in English, abstract and the content article.* From our analysis, we have identified two articles that do not meet the criteria [29], [30]
- EC2:** *Considers interactions between humans and drone swarms.* Our analysis excluded 42.37% of the articles from the total aggregate gathered from the two queries. Among these, we identify articles such as [31], [32], [33].
- EC3:** *Does not show one or more types of interaction.* We have excluded all articles that show no interaction with drone swarms. Our analysis reduced cumulative work by 32.20%, excluding articles such as [34], [35], [36].

After the identification process, N=59, duplicate elimination, D=3, followed. As a result, the selection and analysis process of the articles remained, N=56, which were selected based on title and abstract. Subsequently, 56 articles were evaluated for eligibility criteria based on the full text. This process eliminated 47 articles that did not follow our research direction.

Therefore, this process resulted in nine articles, which were considered relevant to the formulation of the proposed aim, and based on these we completed the aims for interaction between operators and drone swarms, based on the use of a command and control center.

E. Fourth Stage: Charting the Data for Relevant Articles

Charting is a technique to synthesize and interpret quantitative data and involves sorting the material according to the issues and themes proposed by Hilary *et al.* [37]. The process started by establishing the scopes, methods of shape recognition, and other metrics to be presented in the scientific articles. Data extraction was carried out for each item that constitutes the body of scientific articles. Each time a new domain was identified, we recorded it in the table, so that later we could quantitatively report the results that we would present. Where applications did not specify a particular domain, we noted it

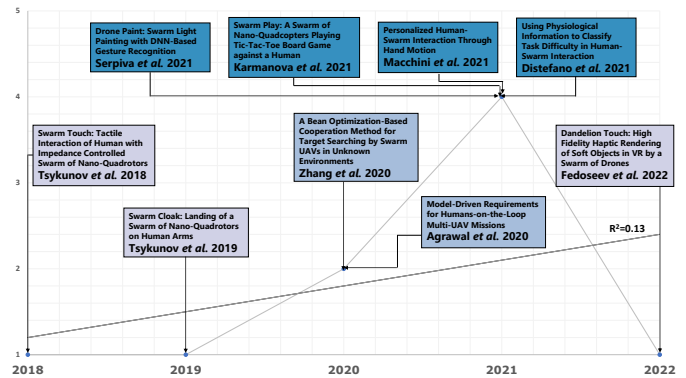

Fig. 3. Distribution by year of articles on the interaction between operators and drone swarms, based on the use of a command and control center.

as generic. In addition to application areas, algorithms, and other measurements, we also performed an analysis of the distribution of articles by year; see Fig. 3.

III. FINDINGS RESULTS

The analysis was conducted using nine scientific articles [4], [38], [39], [40], [41], [42], [43], [44], [45]. This section is dedicated to selected articles on the application areas of interaction between operators and drone swarms, based on the use of a command and control center.

In terms of ① *application types*, painting applications account for 11% of our body of work, in which we have the “Drone Paint” application by Serpiva *et al.* [4], in which he proposes a system capable of interacting with a swarm that controls the swarm’s trajectory through gestures. Another category of applications is dedicated to games, or entertainment, that occupies 11% of the total body of work, where “Swarm Play” has Karmanova *et al.* [38], which proposes the game Tic-Tac-Toe, using a swarm of drones, winning against a human user. Generic applications, which occupy the largest place in our body of work, are applications that aim to control robotic systems, such as drone swarms through navigation algorithms [40]. See Fig. 2.

The reviewed articles were published between 2018 and 2022, where the maximum ② *number of publications* was in 2021. A total of 33.33% articles were identified in the ACM Digital Library database and 66.66% articles were identified in IEEE Xplore. See Fig. 3.

The ③ *validation systems* were carried out by *user study* in the proportion of 22.22%, and we still have 66.67% of systems that were validated by *technical performance*, and 11.11% *demonstration*.

From the point of view of human-drone swarm interaction, we identify 4 scientific articles describing the system by which the swarm interacted with the drone. The drones used in the studies were simulated using the “ros framework” [4], [39], [43] and the “mocap framework” [38] and the drone type was “crazyflie 2.0.” This analysis aimed to present information that was selected using a research question *RQ1*.

A. Interaction Modalities and Recognition Technique

To address the second research question, *RQ2*, in II-B on technologies for object recognition in images we present the following information. In our case we will present the interaction modalities that have been identified to send different commands to drone swarms. From our body of work, which covers human-drone swarm interaction, we have identified only gestures, and several Machine Learning algorithms that we will present. This information was extracted from the four steps described.

Therefore, the largest set of gestures for human-drone swarm interaction was 8. The gestures are executed in front of a camera “Logitech HD Pro Webcam C920 of @30FPS”, which are recognized using the algorithm, Machine Learning, DNN (Deep Neuronal Network). The system aims to control a swarm of drones to paint different surfaces of buildings, and the commands it was “one,” “two,” “three,” “four,” “five,” “okay,” “rock,” and “thumbs up” were used to achieve this goal. The drones being simulated and their feedback were observed on the computer [4].

Dandelion Touch proposes a haptic display that is being used for a new type of haptic feedback for VR systems that does not require any wearable or portable interface. To achieve this approach, Fedoseev *et al.* [43], proposes a set of 4 gestures, “moving forward”, “moving backward”, “moving right”, “moving left” and uses an “Oculus Quest Vive Pro” headset.

Swarm Touch, proposes a system that targets human-drone swarm interaction, and receives vibrotactile feedback. The gestures used for swarm control are grouped into two categories, which are “extended state (increasing distance, constant distance, decreasing distance), contracted state (increasing distance, constant distance, decreasing distance)” [44].

In terms of algorithms used in the literature, we find SVM (System Vector Machine) and CNN (Convolutional Neural Network) [45], Robot Bean Optimization Algorithm [41], Body Machine Interface (BoMI) [40], Basic Algorithm [38], DNN (Deep Neural Network) [45]. The articles [39], [41], [43], [44], do not present the recognition algorithm.

B. Data Collection in Drone Swarm Applications

Before reporting on how the data was collected, we first focused on how the researchers validated the proposed systems. Thus, we submitted for analysis the  type of study of each scientific paper we analyzed.

Out of the amount of scientific articles we extracted, 88.9% of validated the system through an experimental study. For example, Macchini *et al.* [40], proposes an experimental study for the use of a Body Machine Interface (BoMI) to control a drone swarm. The main observation made in this study is given by the fact that users usually use their hands to control the drones, and therefore used a Leap Motion controller to track the movements of the hand movements. This implemented a Machine Learning algorithm to customize the BoMi interface, based on a rigorous calibration process. The study demonstrated that users received positive feedback on use compared to a remote control.

Another approach, by which the system is validated by experiment, we find in the work of Serpiva *et al.* [4], proposes a drone swarm control system by drawing the trajectory with hand gestures, and gesture recognition is based on the Deep Neural Network (DNN) algorithm. The experiment shows that the accuracy of gesture recognition is 99.7%, which allows the user to have a high accuracy in drawing the drone trajectory compared to the mouse drawing. The system gives the user the possibility to create their own art objects using drone swarms.

The only scientific work that uses a questionnaire is that of Agrawal *et al.* [42] in which they use a drone swarm for emergency scenarios such as search and rescue or fire surveillance. Using artificial intelligence, drone swarms operate autonomously, but nevertheless human intelligence and domain expertise are very important for mission deployment. The proposed system is a meta-model to describe the interactions between human operators and the autonomous swarm. The answers to the questions show that the modeling of interactions through artificial intelligence is supported in drone missions.

The proposed systems are also aimed at interacting with drone swarms, and at the same time being able to receive various information back from these drones. Therefore, our investigations in the literature show that data transmission is performed on PC systems [4], [38], through visual feedback [43], or even tactile feedback [39].

For data manipulation, which also aims at gestural interaction with drone swarms, we find algorithms such as Machine Learning, and Deep Neural Network [4] used to recognize hand gestures. Our analysis also identifies algorithms such as Basic [38], used for the Tic-Tac Toe game. Other algorithms identified in the literature are Body Machine Interface (BoMI) [40], which is used to interact with drone swarms using hand gestures captured by Leap Motion, Robot Bean Optimization algorithm [41], used to search for people using drone swarms in unknown environments, and last but not least, Support Vector Machine and Convolutional Neural Network [45], used to classify tasks that were analyzed using an EEG (electroencephalogram) headset.

IV. RESEARCH IMPLICATIONS

Our investigations show that research on the interaction between operators and drone swarms, based on the use of a command and control center has been limited, focusing on only a few types of applications, adopting entirely hand gestures, meanwhile, half of the works investigated in our SLR did not involve participants in the experimental studies presented.

Based on these findings, we formulate several research directions to encourage more work on the interaction between operators and drone swarms, based on the use of a command and control center about our research questions *RQ1* and *RQ2* from Section II-B.

We structure these research directions into the following:

- A. *Input Modalities and Interaction Techniques,*
- B. *User Studies and Evaluations,*
- C. *Involvement of Multiple Drones in Simulations,*
- D. *Control and Command Devices and Prototypes.*

For each category, we identify several opportunities for future work.

A. Input Modalities and Interaction Techniques

Our analysis revealed a limited number of interactions, all based on hand gestures, with a total of 15 gestures reported. For example, Serpiva *et al.* [4] proposes a dictionary of 8 gestures: “one,” “two,” “three,” “four,” “five,” “okay,” “rock,” and “thumbs up” for a painting app. Fedoseev *et al.* [43], proposes a set of 4 gestures: “moving forward,” “moving backward,” “moving right,” and moving left” for an application that achieves high-performance haptic rendering of objects in the virtual environment. Tsykunov *et al.* [44] proposes a set of 4 gestures: “extended state (increasing distance, constant distance, decreasing distance),” “contracted state (increasing distance, constant distance, decreasing distance),” for a human-kick interaction application in which vibrotactile feedback is received. Unfortunately, these interaction modes have not been evaluated by the user, and consequently, their implementation for drone control remains unknown. Thus, an immediate implication of our findings in relation to the formulated research questions is that more studies are needed to considerably increase the set of gestures for the interaction between operators and drone swarms but at the same time also new input modalities using e.g. wearable devices.

B. User Studies and Evaluations

The previous research direction referred to the importance of input modalities and interaction techniques for the interaction between operators and drone swarms. In the following, we highlight the need for user studies and evaluation of the results, since 55% of the articles presented user studies. For example, the largest number of users involved in a study on the interaction between operators and drone swarms was in the paper [38], in which an experiment was conducted on a game-like application. The second paper in which there were participants in the experiment is Macchini *et al.* [40] in which users’ hand movements are captured using Leap Motion. There were also participants in studies in articles [4], [43] in which seven participants were identified, and the smallest number of users in the studies was 6 [44]. It is therefore necessary to have more users in the studies to be proposed, while at the same time having more methods to evaluate the users. As we have mentioned, in all the studies in which there were participants, we only had experimental status. At the same time, we have to increase the average ages because for the mentioned articles we identify a mean of 8.6 (SD=2.8) and a median of 7.0 participants per study.

C. Involvement of Multiple Drones in Simulations

The use of multiple drones to compose the swarm can be beneficial for more complex missions. We, therefore, present the number of drones that composed the swarm, and then how many swarms were used in our selected articles that focus on the interaction between operators and drone swarms, based on the use of a command and control center. Thus, the largest number of drones was identified in Macchini’s paper *et al.* [40] in which the 20 drones were used for an application in which the drones were controlled by gestures captured by a Leap Motion controller. The articles that presented drone swarms consisting of only four flying devices were [38], [39], [44], and the article that identified the smallest drone formation was composed of three flying devices in Fedoseev *et al.* [43]

proposing “Dandelion-Touch” a new type of haptic feedback in VR systems where no portable or wearable interface is required. Therefore, we identify swarms of small drones that are all simulated. Thus, there is an urgent need to form much larger drone swarms, observe user behavior, and also understand how difficult it is to interact with large drone swarms. At the same time extending multiple drone groups, subjected the same user to interact with one or more drones, or even with different swarms he has under management. Using more drones that have a radar device integrated into the ambient intelligence environment [46].

D. Control and Command Devices and Prototypes

The use of devices to control and command drone swarms is necessary because our investigations have uncovered wearable devices such as webcams in the works [4], [38], but also devices such as leap motion [40]. Thus, we suggest that there is a great need for new devices to control and command drones. For example, in Tsykunov *et al.* [44] a smart glove is used to control the drone swarm. Our suggestion is that you can introduce another glove to control one drone in the swarm, and the other to control the whole swarm. Another presented work uses a headset for the interaction between human and drone swarm. An overview of the system functions and control commands for drone-based aerial photography and video, as well as a dictionary of gestures can be found in the scientific article [47]. Therefore, there is an urgent need for new devices to interact with drones but at the same time develop systems that combine known and tested devices.

V. CONCLUSION

This scientific paper presents a systematic literature review on the interaction between operators and drone swarms based on the use of a command and control center. We highlight that drone swarms are used in different types of applications, but we have not identified a defining one for the scientific community. In terms of drone interaction, only hand gestures are used and feedback is distributed to different wearable devices.

To understand the potential of drone swarms, the results show that there is still a need for contributions, and at the same time to test more interaction modalities, algorithms adapted for drone swarms, and more experimental results. Our investigations have shown that control systems are in their infancy and that few devices are used to form control systems, mainly focused on the visualization of drone information and to a very small extent on drone control.

The proposed implications serve the scientific community to encourage work in the field of drone interaction, which can be applied in different domains whereby we want to emphasize that more work is needed to understand the challenges of interacting with drone swarms, user interaction preferences, and performance in the use of these systems, for which we have proposed four research directions. We hope that our contributions will stimulate the development of new research directions for the interaction between operators and drone swarms based on the use of a command and control center.

ACKNOWLEDGMENT

This research was funded by the project “119722/Center for Knowledge Transfer to ICT-CENTRIC Enterprises, Subsidiary Contract 22081/05.10.2022, Autonomous Recognition and Support Platform - PARS”, contract no. 5/AXA 1/1.2.3/G/13.06.2018, SMIS code 2014+ 119722 (ID P-40-305)

Abstract—With the advancement of technology, people are now able to monitor their health more efficiently. Mobile phones and smartwatches are equipped with sensors that can measure real-time changes in blood pressure, SPO2, and other attributes and public them to service providers via web applications (called web apps) for health improvement suggestions. Moreover, users can share the collected health data with other people, such as doctors, relatives, or friends. However, using technology in healthcare has raised the issue of privacy. Some health web apps, by default, intrusively gather and share data. Additionally, smartwatches may monitor people's health status 24/7. Therefore, users want to control how their health is processed (e.g., collected and shared). This can be cumbersome as they would have to configure each device manually. To address this problem, we have developed a privacy-preference prediction mechanism in the web apps called IM2P-Medical: towards Individual Management Privacy Preferences for the Medical web apps. To capture individual privacy preferences in the web apps, our model learns users' privacy behavior based on their responses in different medical scenarios. In practice, we exploited several machine learning algorithms: SVM, Gradient Boosting Classifier, Ada Boost Classifier, and Gradient Boosting Regressor. To prove the effectiveness of the proposed model, we set up several scenarios to measure the accuracy as well as the satisfaction level in the two participant groups (i.e., expert and normal users). One key point in this research's selection of participants is its focus on those living in developing countries, where privacy violation issues are not a common topic. The main contribution of our model is that it allows users to preserve their privacy without configuring privacy settings themselves.

I. INTRODUCTION

Monitoring health with technological devices and web apps has gained great popularity in this day and age. In fact, the market value of health monitoring devices in 2019 was \$25,78.56 million and is predicted to soar to \$44,861.56 million in 2027¹. The devices can track multiple values like blood pressure, heart rate, and sleep quality and send them to a web app for visualization. Based on the collected data

(called Evidence-based disease management [1], [2]) from these sensors, several approaches could detect the corresponding diseases. Furthermore, these devices can monitor users' metrics everywhere due to their portability. Thanks to these gadgets, hospitals can better support their patients, and people can take care of their health more efficiently. However, due to the vast amount of data that can be collected, the use of health-monitoring devices and web apps faces doubt from those value data privacy [3]. Thus, there is a demand for a solution that manages how personal data is collected by health devices and web apps.

Conventionally, users can manually adjust their privacy preferences via web apps' or devices' settings. However, this can be cumbersome and may not be effective. On the other hand, an automated solution that can suggest security settings for a user based on his/her personality or privacy preference can bring better results [4]. In this paper, we introduce our privacy preference prediction solution. Our system learns a user's security perspective and makes suitable suggestions for changing privacy settings.

Due to some economic barriers in developing countries, their citizens lack healthcare services and institutions. Thus, the privacy issues of the medical data are ignored. Currently, there are no medical data protection standards like the developed countries (e.g., European countries - GDPR²) to protect the user privacy issues. To address this drawback, our model focuses on individual privacy preferences w.r.t medical data - especially, in developing countries. Our dataset explores the feedback from the developing countries' citizens, e.g., Asia, Africa, and Latin America.

Moreover, most current health systems are focused on protecting users' medical data [5], [6]. For example, Son et al. [7] emphasizes the importance of user privacy preferences that are placed alongside the system's privacy policy. This means that the requestor must satisfy both privacy policy and privacy preferences in order to be able to access the patient's medical data. Besides, Hoang et al. [8] provide a mechanism to handle

¹<https://www.alliedmarketresearch.com/patient-monitoring-devices-market>

²The GDPR document is available at https://edps.europa.eu/data-protection/data-protection/glossary/d_en#data_minimization

conflicts between the privacy policy and privacy preferences where it depends on prioritizing patient treatment or reducing the risk of personal information leakage. In addition to the above studies, the systems that build smart contract models for medical facilities using Blockchain technology also take care of users' privacy preferences, for example, Nghia et al. [9], [10], [11]. In these studies, the patient role was given full discretion in sharing their data with stakeholders. Moreover, the priority of treatment is also exploited in the approach of [12], [13], where patients allow access to their personal data in case of an emergency. Also, in the medical-related system, several studies deployed the individual privacy preference based on blockchain technology (e.g., blood donate [14], [15] or IoT medical sensors [16] via the transmission messages protocol [17]).

To make this suggestion function work, we introduce IM2P-Medical: Towards individual management privacy preferences w.r.t medical data based on a Machine Learning system, i.e., built based on Semi-Supervised Learning. The reason for choosing the Semi-Supervised Learning method is to be able to reduce the amount of data required while preserving the prediction accuracy. The data for this system was gathered via a questionnaire. This questionnaire aims to learn respondents' perspectives or attitudes toward privacy. We distribute the questions to two types of people. The former type was people who had a background in IT and privacy, such as IT students (i.e., expert participants), while the latter group included various types of people called average users (i.e., normal participants) - see Sect. IV-B. who responded to the questionnaire on the Internet.

The key contributions of this paper are three-fold, including i) designing the individual privacy preferences architecture w.r.t medical data (i.e., IM2P-Medical - Sect. II); ii) balancing the user burden and accuracy based on the semi-supervised learning approach (i.e., Implementation - Sect. III); and iii) proving the effectiveness of the IM2P-Medical based on the two participant dataset.

The remainder of this paper is organized as follows. Sections II and III introduce the IM2P-Medical architecture and implementation (i.e., training strategy, algorithm, and questionnaire). Section IV presents experimental results, whereas related work are discussed in Section V. Finally, Section VI concludes the paper.

II. IM2P-MEDICAL ARCHITECTURE

Fig. 1 shows the interaction process among the parties in the proposed model, including i) Users; ii) Personal data; iii) People; iv) Service Providers, and v) IM2P-Medical. The main roles and responsibilities of these parties in the system are presented as follows:

User (also known as the data owner): they have the right to make a decision whether to share their personal data by responding with consent (Yes) or disagree (No). The data in their possession includes normal data (i.e., easy to share) and personal data (i.e., medical data).

Personal data: the data that needs to be protected because they are highly identifiable. As a result, a malicious user can

obtain other types of user data based on the exploitation of this data pool. This study focused on grouping personal data in the medical environment which can be exploited by sensors or smartphones (e.g., heart rate, SPO2, calories burned).

People: Can act as a user (in some specific cases). **People** represent other users (in the same or not the same system) who have a relationship (e.g., relative, friend,) with the owner of the data. This party can have more than one relationship with the data owner.

Service providers: the party provides the necessary medical services to users (e.g., health monitoring, disease diagnosis, online doctor)³. This target group provides a specific type of health care service; in return, the user must provide the data requested by the service provider. In a traditional environment, users have to provide virtually any type of data to service providers, ignoring privacy risks [18]. Previous studies have shown that applications collect more data than what they need for the supported services [19]. In this paper, any data manipulation request must be accompanied by a corresponding purpose to eliminate this drawback.

IM2P-Medical: this party automatically identifies privacy preferences for each individual. Specifically, this model identifies users' privacy behaviors based on their responses to service providers' access requests. Besides, Fig. 1 also depicts five main components of IM2P-Medical including: data types; relationship(s); context; access request(s); and purpose(s). The relationship between IM2P-Medical and the remaining parties is presented as follows:

- **Data types:** the types of data (e.g., location, heart rate, etc). In fact, the identification of personal data also depends on the user's sense of privacy. Each individual will make a different decision depending on many factors. It is not possible to define all possible possibilities in this study. So we're targeting the kind of medical data that are being exploited by the user's sensors, wearable devices, and smartphones. To ensure that our survey achieves its stated objectives (i.e., risks of personal information disclosure), we also emphasized in our survey that these medical data can easily be exploited through their device without any notification to the user.
- **Relationship(s):** This group of attributes also greatly affects the issue of sharing personal data. A user can easily share their walking record (e.g., steps, distance traveled, start and end locations) for a day with his/her friends or personal training etc. Users will share or not share their data depending on each specific relationship.
- **Context:** depending on the specific context, users can (not) share their data regardless of the same data type and relationship. For example, in healthcare scenarios (hospitals, clinics), heart rate data can be shared with **People** as healthcare workers (e.g., doctors, nurses); however, same data types and relationships but different contexts (e.g., sports participation) - users can opt-out of sharing. To be able to capture each user's data

³The service provider can reserve several services, but we target the medical environment

sharing behavior, we exploit sub-attributes (i.e., data types; relationship(s); access request(s); purpose(s)) on the context-specific (see Sect. III-C for more details).

- **Access request(s):** This component is closely associated with the service provider. In contrast to **People**, where users voluntarily share their data with a specific purpose (i.e., decided by themselves), the data retrieval process for service providers is the opposite. Specifically, the structure must include the party of the request for access (e.g., medical or fitness apps) and the corresponding purpose (discussed in the next section). Users judge between the benefits and risks of privacy to make a decision.
- **Purpose(s):** One of the important pieces of information to decide whether users share their data or not is the purpose of access. In particular, a series of analyses have shown that requests for supporting the application's service will be accepted more than advertising purposes. To clarify this, we also emphasize the importance of access intent in our survey scenarios (see Sect. III-C for more details).

III. IMPLEMENTATION

A. Self-training

Self-training or "Self-learning" is the most basic of pseudo-labeling approaches [20]. They consist of a single supervised classifier that is iteratively trained on both labeled data and unlabeled data that has been pseudo-labeled in previous iterations of the algorithm. At the initial procedure, a supervised classifier is trained on only the labeled data. The outcome of the classifier is used to obtain predictions for the unlabeled data. Then, the most confident of these predictions is added to the labeled data set, and the supervised classifier is re-trained on both the original labeled data and the newly obtained pseudo-labeled data. This procedure is typically iterated until no more unlabeled data remain.

Several applications and variations of self-training have been put forward. For instance, Rosenberg et al. [21] applied self-training to object detection problems, and showed improved performance over a state-of-the-art (at that time) object detection model. Dopido et al. [22] developed a self-training approach for hyperspectral image classification. They used domain knowledge to select a set of candidate unlabeled samples, and pseudo-labeled the most informative of these samples with the predictions made by the trained classifier.

B. Algorithm

Algorithm 1 applies self-training model to label the *apps* in *UApp* dataset. Specifically, it applies the SVM algorithm (several supervised methods) to pseudo-label the apps in the unlabeled data set (*UApp*) (see line 4). For the other supervised learning algorithm, we do the same idea.

C. Questionnaire

To make accurate suggestions, effectively learning users' behaviours is of paramount importance. We have meticulously

Algorithm 1 selfTraining(*LApp*, *UApp*, *supAlg*)

```
1: input: training apps LApp, target apps UApp, list of supervised algorithms supAlg.
2: output: label for UApp.
3: for each  $app_i \in UApp$  do
4:    $label_{app_i} = SVM(app_i)$ ;
5:    $UApp - \{app_i\}$ ;
6:    $LApp \cup \{(app_i, label_{app_i})\}$ ;
7: end for
```

designed a questionnaire for the learning purpose. Our questionnaire focuses on observing how users will adjust their privacy preferences in multiple contexts. To be specific, from our questions, we expect to answer three queries:

- 1) Given a specific context, how will participants share different types (e.g., heart rate, SPO2, burned calories) of data with other people (e.g., friends, relatives, doctors)?
- 2) Given a specific context, how will participants share the data for a certain purpose (e.g., analysis, education, ads)?
- 3) Given a specific context, how will participants share data with service providers (e.g., medical apps, fitness apps)?

For each query, we develop an appropriate type of question. In each question, there are a number of parameters whose values can be activities, individuals, permissions, etc. Participants have three options, they may completely agree, completely disagree or partly agree with the statement.

In the following parts of this section, we will explain the given questions and introduce the list of parameters.

1) *Sharing data with others in a specific context:* In this type of question, we attempt to understand how people share personal data with others when they are doing certain activities. We classify possible activities into two groups: indoor and outdoor. An example of an outdoor activity question is: "You are playing sports. Do you want to share your location with your doctors?". In this example, we want to know if the user is willing to share their location with a doctor while playing sports.

The general structure of the questions is: "You are *an activity*. Do you want to share your *information* with a *person*". Three parameters are required: the activity, the information to share and the person to share with. We have prepared a set of possible parameters' values as given below (Table I to III).

TABLE I. THE SAMPLES OF ACTIVITIES

ID	Activity name
1	playing sport
2	relaxing
3	doing daily activities
4	at home
5	at work
6	having treatment at home
7	at the hospital
8	under an emergency

Questionnaire participants have three options to choose: Yes (without restriction), No or Yes (with restriction). If they

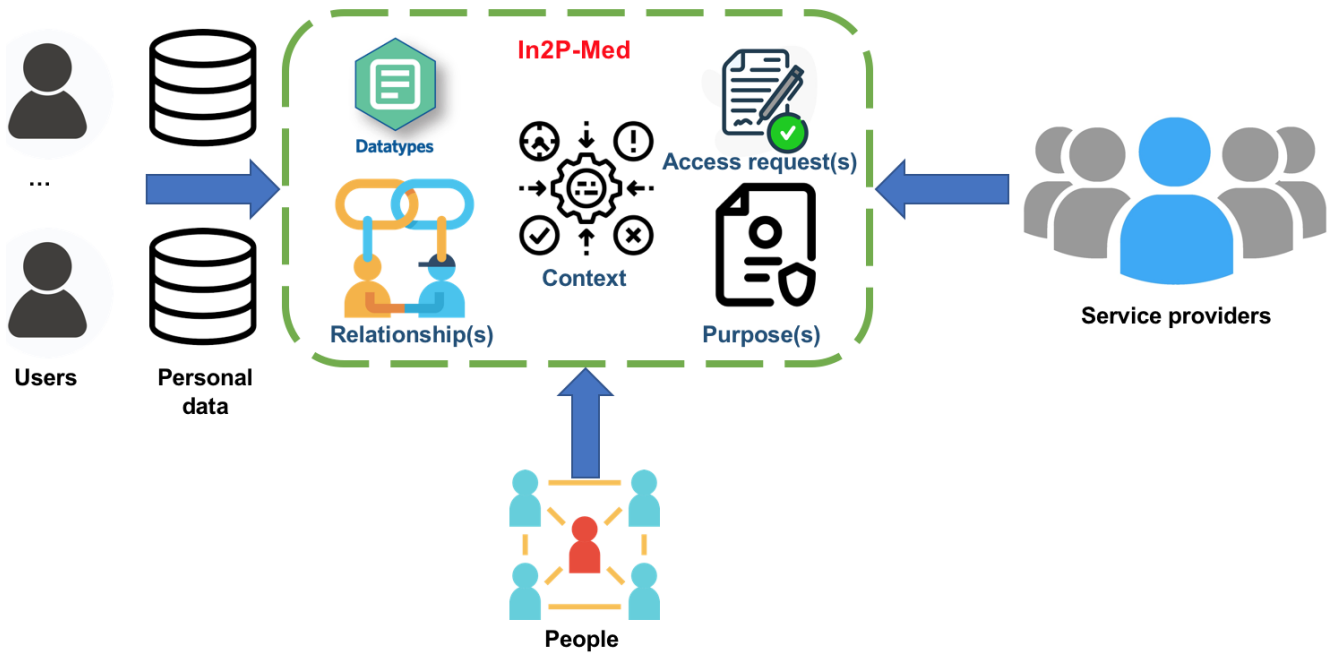

Fig. 1. IM2P-Medical architecture.

TABLE II. THE SAMPLE OF COLLECTIBLE INFORMATION

ID	Data item	ID	Data item	ID	Data item
1	name	7	steps	13	sugar level
2	phone number	8	heart rate	14	fat level
3	email	9	weight	15	travel distance
4	location	10	height	16	sleep
5	age	11	SPO2	17	health goal
6	gender	12	calories		

choose the first option, they are unconditionally willing to share data with an individual. However, if they choose to share with restrictions, they may want to implement some controls. For instance, they may share only once every 1 hour. Choosing “no” means that sharing under the given context is out of the question.

2) *Granting permissions in a specific context*: This type of question is intended to learn if users allows applications to access devices’ components such as Bluetooth or Wifi.

The general structure of the question is: “You are *an activity*. Do you allow your device to access your *a component*?”. There are two parameters required: the activity like in the first type of question and the device’s components being granted access. We have prepared a set of possible parameters’ values as given below (Table IV). Besides, we use the same set of answers in this type of question.

3) *Sharing data with applications in a specific context*: In this type of question, participants are surveyed if they allow applications in a specific category to collect data for a particular purpose. As an example, we may ask if they permit vendors making Health apps to collect usage information for marketing purposes.

The structure of the questions is: “Do you want your *data* to be collected by *an app category* for the *purpose*

purposes ? (service provider x information collected)”. Three parameters are required: the collected data, the app’s category and the collecting purpose. We have prepared a set of possible parameters’ values as given below (Table V).

We also use the same set of answers in this type of question (Table VI).

IV. EXPERIMENTAL RESULTS

A. Experiment Setting

In our tests, each participant had to take part in two phases i) they make their choice about whether to share medical data in each context different in the training period ii) they participate in the evaluation of the prediction results from our algorithms and give the satisfaction level of the corresponding algorithms. To achieve this goal, we have developed a web application to that requires interaction with participants through the two phases mentioned above. Specifically, participants label questions that share data during the learning phase (i.e. data set training data), then give their feedback on the labels generated by the models predict in the testing phase (i.e. test data set), and finally rate their satisfaction level on our predictive models.

More precisely, in the first phase, participants were asked to label each sentence (i.e. Yes (Y), No (N), or Maybe (M)) about sharing data in each term-specific scene as described in III-C. During the training phase, participants have to give answers to all 20 questions over a while. The minimum time is 10 minutes (an average of 30 seconds for an answer). After the labeling, the collected training dataset is built using algorithms learning is covered in Section III-B, specifically the -based approach to supervised learning and semi-supervised learning. To evaluate learning strategies, during the beta phase, the web app displays 20 new questions for those who participate.

TABLE III. THE ROLES OF REQUESTER

ID	Relationship	ID	Relationship	ID	Relationship	ID	Relationship
1	Friends	2	Family members	3	Doctors	4	Nurses

TABLE IV. PERMISSIONS

ID	Permission	ID	Permission	ID	Permission
1	Bluetooth	4	File Storage	7	Wifi
2	Camera	5	Microphone	8	Identity
3	Location	6	Sensors	9	Contacts

We randomly select prediction strategies instead of trying to define strategies according to the expected degree of accuracy. The main purpose is to remove all user prejudices about the algorithms in the back, which will be better than the previous algorithms. Specifically, four predictive models (five assessment questions/per model) are applied in this paper, including SVM, Gradient Boosting Classifier, Ada Boost Classifier, and Gradient Boosting Regressor.

For each new question in the experimental phase, the participants gave feedback on the labels, i.e. agree (Y) or disagree (N) - and in the case of disagreement, they must provide the correct label. For example, our forecast label is "Y", but their expected result is "M". They will give feedback on the label as no agree (N) and reselect the outcome they expected. In addition, in the 20 questions at a stage of the test phase, we reused four questions that appeared in the test phase corresponding to four predictive models. Specifically, each prediction model will have four sentences of new questions, and 1 question is randomly selected out of 20 questions during the experimental stage. The main purpose of this work is to divide into two groups of people based on their choices for that question for both periods, specifically, the selection group, the same selection, and the different selection group. The details of this comparison will be presented in section IV D 2. Finally, we collected the satisfaction level of the participants with the project guesses generated by each model. Participants can answer Yes (100%), No (0%), or Maybe (50%). The average time for answering each question at the test stage was 30 seconds. So each person participating in the survey must spend at least 20 minutes completing both learning and testing. To remove unsatisfactory answers, we have set the timer to track participants' time answering questions. If they spent less than the desired time (i.e. less than 30 seconds for a question), participants could not move on to the next question.

B. Participants

The primary purpose of this paper is to build an automatic medical data-sharing model that meets the privacy requirements of the users. We also want to explore the issue of sharing private data in developing countries where privacy is not widely aware of, especially in terms of sensitive data like medical. To achieve the above purposes, we conducted surveys. Our models are in countries in Asia, Africa, and Latin America. Besides that, there is a difference between the survey respondents on security and privacy, we categorized the differences between these two groups of users. Specifically, in the expert user group, we collected feedback from students as well as teachers who are studying and working at FPT University

(Vietnam) majoring in Information Security at two campuses in Ho Chi Minh City. Ho Chi Minh City and Can Tho. For the normal user group, we used the tool Microworkers⁴ to collect user feedback participants from developing countries.

1) *Expert users*: : For expert users (students and teachers of information security), we sent an email to the students who participated in the survey for four weeks (September 2021). There were a total of 20 qualified participants out of 32. The majority of participants were disqualified for not answering enough required questions. The average age of participants is 21.5, with the oldest and youngest being 29 and 18, respectively. Besides, about 15% of the participants were female (3/20).

2) *Normal users*: : The main purpose of this user group is to satisfy the requirement of diversity in terms of age, education, gender, and culture. We choose developing countries in two regional groups, including Latin America and Asia-Africa. We got 209 valid responses out of 296 participants. Each participant was paid \$3. The number of participants belonging to the above two regional groups is 85 and 124, respectively. The mean age is 31.06 (minimum is 18 and oldest is 70) and 28.29 (the smallest age is 18 and the largest is 59). Out of a total of 85 responses, 42 were female (49.41%). The number for Asia-Africa is 25.6% (32 out of 125 participants).

C. Confusion Matrix

We used conventional measures to evaluate the accuracy of the proposed learning methods. Specifically, we exploited the 3X3 confusion matrix corresponding to the three labels (Y, N and M) (Table VII), where the columns represent the predicted labels (generated from approaches) and possible rows of values actual (participant opinion) and cells represent Error (E) or True Positive (TP). From the confusion matrix, we determined the evaluable metrics given in Table VIII.

D. Evaluation

In the evaluation, we performed a series of measurements to find the most appropriate algorithm in detecting the sharing behavior of personal medical data, given a specific context. Specifically, in the first test, we compared the accuracy obtained by different learning approaches (specifically between supervised learning and semi-supervised learning). We first compared the semi-supervised soft clustering method and the hard clustering techniques. This comparison aims to evaluate whether a semi-supervised system has good accuracy even with a reduced training set.

In the second test, we compared the accuracy of the proposed prediction models, namely SVM, Gradient Boosting Classifier, Ada Boost Classifier, and Gradient Boosting Regressor. As the results displayed in Section IV D 3, the semi-supervised-based approach gave better results than the supervised approach. Therefore, we apply the semi-supervised model to all four proposed algorithms.

Actual value: N	$E_{N,Y}$	TP_N	$E_{N,M}$
Actual value: M	$E_{M,Y}$	$E_{M,N}$	TP_M

1) *Supervised learning and semi-supervised learning comparison:* In this section, in addition to demonstrating which approaches (in particular supervised learning and semi-supervised learning) provide better prediction results with small data sets, we also wanted to test the difference between

TABLE VIII. METRICS DEFINITION

Accuracy	$(TP_Y + TP_N + TP_M) / \#samples$
Pre_Y	$TP_Y / (TP_Y + E_{N,Y} + E_{M,Y})$
Pre_N	$TP_N / (TP_N + E_{Y,N} + E_{M,N})$
Pre_M	$TP_M / (TP_M + E_{Y,M} + E_{N,M})$
Re_Y	$TP_Y / (TP_Y + E_{Y,N} + E_{Y,M})$
Re_N	$TP_N / (TP_N + E_{N,Y} + E_{N,M})$
Re_M	$TP_M / (TP_M + E_{M,Y} + E_{M,N})$
$F1_X$	$2 * (Pre_X * Re_X) / (Pre_X + Re_X)$, where $X \in \{Y, N, M\}$

homogeneous and heterogeneous user groups in terms of data sharing decisions.

To achieve the above goals, we first compare the accuracy between supervised learning and semi-supervised learning approaches by building a training set that is a subset of the original training set (with 10, instead of 20 questions). Specifically, in the new dataset, the number of questions in the shuttered train is ten and in the test set is 30 (including ten questions transferred from the train set). The main purpose for this reallocation of questions is that we wanted to aim for an approach that can balance the effort spent by the user to build the training set and the accuracy of the applied algorithm. A good approach that can satisfy the above criteria is the one that only has a small number of questions in the training set and ensures an acceptable accuracy. To meet the above requirements, we used a semi-supervised learning approach for the SVM algorithm, decision tree, and supervised learning for both SVM and Decision tree. We compared the accuracy of the SVM algorithm for both approaches as well as two different algorithms (SVM and decision tree) to get the most general view when choosing strategies to build predictive models.

Fig. 2 shows the accuracy between SVM and Decision tree on both approaches: semi- and supervised learning. It shows that the semi-supervised-based approach is always better than supervised learning for both SVM and Decision tree algorithms as well as groups of participants (same and non-same). SVM algorithm has higher accuracy than the Decision tree for all cases. Besides, the same answer group has the highest accuracy in each algorithm. This proves that the approach

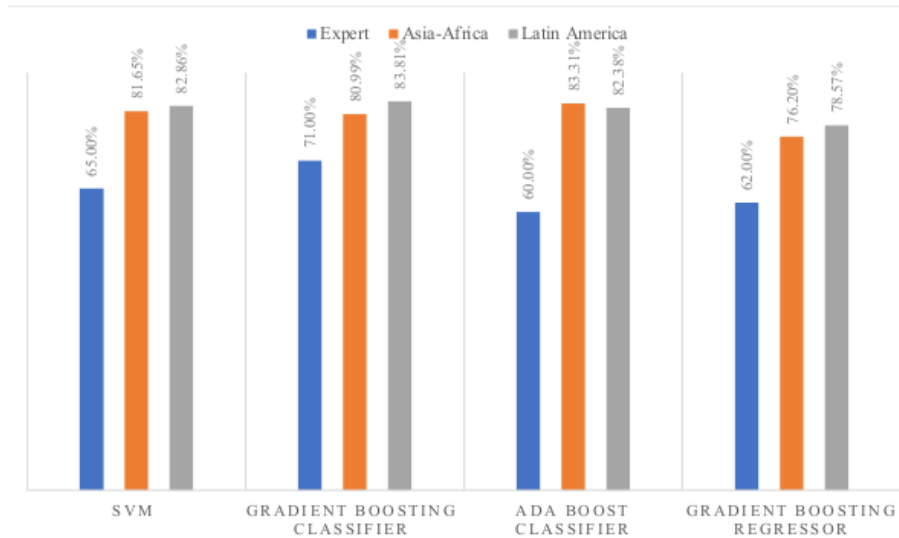

Fig. 3. Accuracy level of four classification models.

based on semi-supervised learning gives high accuracy even when trained on a small data set. In the following section, we apply a semi-supervised learning approach to delve into the analysis of accuracy, F1 score as well as the satisfaction of survey participants.

2) *Answer prediction model accuracy*: Fig. 3 depicts the accuracy of four predictive models for all three datasets (expert, Asia-Africa, and Latin America). The group with the lowest accuracy was experts from 60-71%, while the highest accuracy group was the group of participants from Asia-Africa and Latin America from 76.20% to 83.81%. This proves that the behavior of the user group is often easier to capture than the expert user group. Indeed, based on a manual analysis of users' comments on the reasons for their choice, we found that the difference between the two groups of users lies in the context of sharing personal data in the medical environment. In the case of ordinary users, they only care about the object to be shared or the type of data requested. Meanwhile, the experts evaluated all three groups of data, the shared audience, and especially their context. In particular, they are very careful when sharing high-risk data (motion data, location) with any individual (including relatives and friends). On the other hand, user groups are often more comfortable sharing personal data. They are willing to trade personal information to choose the services or utilities that the services or applications bring. Moreover, they trust the personal data protection mechanism of the service or application as well as the group of people who share it closely (relatives, friends).

3) *Satisfaction level*: This section evaluates the satisfaction level of four prediction algorithms for all three datasets (see Fig. 4). Specifically, all approaches have high satisfaction for all three datasets (from 90% to 98.81%). The algorithm with the highest satisfaction is the Gradient Boosting classifier (95% - 98.81%). Meanwhile, the algorithm with the lowest satisfaction level is SVM (95% - 98.81%). This experiment proves that the semi-supervised learning-based approach brings about a high level of satisfaction for all three groups of participants.

4) *F1 score*: Finally, we measured the score F_1 for each label (Y, N, M) in all three datasets (Expert, Asia-Africa, America Latin). The F_1 score considers both the precision and the recall aspect (see Table VII). There is a difference in approach four compared to the other approaches: this algorithm does not correctly predict any Yes or No answer options, but only predicts all possible answer options. This can be seen as a minus when applied to these models to identify user behavior in complex contexts.

Table IX shows the comparison of the four prediction models for the test dataset.

V. RELATED WORK

Privacy problems have always been captivating researchers. To discover potential privacy infringement from browsing the Internet with a mobile phone, Collin Mulliner [23] tracked all HTTP headers sent to web services providers. From this activity, he could estimate the amount of covertly leaked personal information. Threats that come from unsecured applications have also been meticulously summarized by Jain et al. in their paper [24].

There have been multiple papers introducing various approaches to adjust privacy preferences dynamically. These proposed approaches do not only apply to applications but also to a wide range of other cases.

By introducing a Context-aware Privacy Policy Language (CPPL), Behrooz et al. [25] aimed to minimize the number of privacy policies that need analysis. In their work, the language filters policies that are relevant to the current scenario using context. The expectation of this research is to enhance the user experience of mobile users in general.

To cope with the issue of ever-changing contexts, Alom et al. [26] proposed a context-based privacy management system that utilizes machine learning algorithms. In their system, privacy preferences for a new context are automatically determined based on existing ones. To be specific, the authors

build a classifier that can detect which users’ preferences may be changed as well as the extent of that change. Therefore, given a new scenario, the classifier can predict users’ choices. In their work, Lin et al. [27] also use machine learning to determine the most appropriate privacy preferences for the users. This is done after the system has created a collection of candidate configurations for a particular user.

Bahirat et al. [28] proposed a data-driven approach to designing privacy-setting profiles for IoT devices. Using scenario-based input, the system generates a collection of default privacy settings for the devices, and it is the responsibility of the users to pick one manually.

Knijnenburg et al. [29] introduced a system that supports privacy decisions by modeling privacy concerns. This approach is also known as user-tailor privacy, in which users are provided with private information and non-invasive controls. However, given the variance in people’s perspectives on privacy, creating a general privacy model can be complicated.

There are also methods of adjusting privacy preferences specifically for smartphones. For instance, by taking contextual information into account, Yuan et al. [30] developed a machine learning-based privacy model for sharing photos. In their work, Sanchez et al. [31] developed a privacy preference recommendation system for personalized fitness apps. In their approach, the first profile users’ traits and data permission preferences with machine learning clustering algorithms before designing

privacy setting recommendation strategies. In their attempts to preserve users’ privacy when using health applications, V. Koufi et al. [32] proposed an access control framework used in PHRManager. PHRManager is an Android app that gives authorized users access to Personal Health Records.

VI. CONCLUSION

This paper has introduced IM2P-Medical, a solution on how to learn users’ privacy preferences and suggest appropriate settings for medical data (i.e., health-monitoring devices and apps scenarios). Specifically, semi-supervised learning can help understand people’s perspectives while requiring fewer data to be explained in great detail. Moreover, a collection of questions for understanding users’ thinking on privacy was also shown. The questions were then distributed to two types of participants (normal and expert).

At the end of the project, the satisfaction of users was gathered. Additionally, four models on how to minimize users’ burdens were explained in the evaluation section. In this section, we also compare semi-supervised learning to prove the effectiveness of our model. The result indicates that semi-supervised learning can potentially conserve users’ privacy.

The paper is the first attempt toward a user-centric model for healthcare systems, so it is extremely urgent to identify future development directions. Specifically, we plan to analyze user behavior to build a set of privacy settings recommen-

dations for new users to apply to the medical system. A blockchain-based solution is a potential option to validate service providers' claims about how much data mining is required. On the other hand, an extensive and in-depth study (e.g., increasing the number of participants, compared with users in developing countries) will also be launched soon.

ACKNOWLEDGEMENT

This work would not have been possible without the Mr. Le Thanh Tuan support in implementation and evaluation process. We also express our sincere gratitude to the students and crowd-workers who joined our survey.

Anomaly Discover: A New Community-based Approach for Detecting Anomalies in Social Networks

Hedia Zardi, Hajar Alrajhi

Department of Computer Science-College of Computer, Qassim University, Buraydah 51452, Saudi Arabia

Abstract—In this paper, a new method called Anomaly Discover is provided for detecting anomalies in communities with mixed attributes (binary, numerical and categorical attributes). Our strategy tries to identify unusual users in Online Social Networks (OSN) communities and score them according to how far they deviate from typical users. Our ranking is based on both users' attributes and network structure. Moreover, for effective anomaly detection, the context-selection process is performed for choosing relevant attributes that demonstrate a strong contrast between normal and abnormal users. So the anomaly score is defined as the degree of divergence in the network structure as well as a context-specific subset of attributes. To assess the efficacy of our model, we used real and artificial networks. We then compared the outcomes to those of two state-of-art models. The outcomes show that our model performs well since it outperforms other models and can pick up anomalies that competing models miss.

Keywords—Anomaly detection; community anomaly; anomaly ranking; social networks; relevant attributes

I. INTRODUCTION

In data analysis, anomaly detection (also called outlier detection) is identifying items that raise suspicions by differing from the majority of the data. The rising popularity of social networks has attracted some malicious users who have been abusing them. Because of this, it becomes essential on social networks to identify anomalous users. It aims to find users whose activities deviate significantly from regular users, which affects widely different areas such as the detection of social email senders, and detection of fake accounts.

For analyzing relationships in networks, graph-based anomaly detection (GBAD) approaches were used to detect abnormal patterns. In fact, social networks often have data objects linked to each other, so they can be represented as graph networks. The nodes in graph $G(N, E)$ refer to individuals, whereas the edges refer to relationships. The nodes and connecting edges make up a simple graph. On the other hand, nodes and/or edges with related features such as work status, individual ages, type of interaction, and duration, make up the attributed graph(also known as the labeled graph). The attributed networks combine a topological structure with a rich set of features.

The anomaly detection methods in plain graphs analyze the interactions between nodes and employ the network structure to extract graph-centric features and quantify the nodes' closeness. However, the anomaly detection methods in attributed graphs employ the graph's structure and the coherence of

attributes as auxiliary information to find patterns and identify anomalies. Unfortunately, few research has considered attributed graphs. In addition, most of these methods focus only on numerical node attributes; but, real-world networks' node attributes are made up of many attribute types. Therefore, the approaches that consider the network structure and users' attributes, depend on the inclusion of all of a given network's attributes. This makes them inadequate for application to today's networks, which feature ever-growing numbers of attributes. Furthermore, the existence of irrelevant attributes in these networks is inevitable and obstructs anomaly detection. Thus, the context selection process of selecting relevant attributes that show a high level of contrast between normal and anomalous users is crucial for effective anomaly detection.

The community-based approaches are well-known graph-based strategies suggested to address the challenge of anomaly detection [1], [2], [3], [4], [5], [6], [7], [8], [9], [10], [11]. These approaches are based on detecting groups of nodes that are densely connected to each other in the graph and to different communities. Actually, anomalous nodes under this setting can be defined as identifying "bridge" nodes that do not have a direct relationship to a specific community [4].

The aim of this work is to present a new approach to the detection of anomalous users in social networks. Our approach is a community-based approach in attributed graphs which considers both the nodes' attributes and the network structure. A node behavior, which would be considered normal across the entire network, may appear as anomalies within the community context. For this reason, our approach is based on the selected context of relevant attributes. In our approach's first step, we start with the detection of the different communities in the network. In the second step, the nodes will be ranked based on the network structure and attributes similarity. The ranking scores given to the nodes represent the anomaly degree for each node, where a high score indicates an anomalous node, and a low score indicates a normal node.

This paper is organized as follows. In Section II, a summary of the state-of-the-art that reviews the existing works in the field of anomaly detection in a social network is provided. Section III is dedicated to the details of our proposed method for anomaly detection. In Sections IV and V, the performance of our approach is examined and the results obtained by our experiments are presented. A summary and our recommendations for future works are provided in Section VI.

II. RELATED WORKS

Due to the great interest in the discovery of anomalies in recent times, a variety of algorithms have resulted. We will discuss some of the suggested methods in this section. These methods can be divided into two groups according to the basic idea of the approach, structure-based approaches and community-based approaches for unlabeled (plain) and labeled (attributed) graphs.

A. Structure-based Approaches

The concept behind structure-based approaches [12], [13], [14] is that to inspect both normal and anomalous nodes' characteristics, the structural properties are checked. To find abnormal nodes, specific graph matrices are calculated. Akoglu et al. [12] proposed a feature-based model called OddBall. This method finds patterns that the majority of the graph's egonets follow in relation to the egonet-based features it extracts. The 1-step neighborhood surrounding a node, which includes the node, is referred to as a node's egonet. The main eigenvalue of the weighted adjacency matrix of the egonet, the weight of the egonet, the number of each node's neighbours, and the number of egonet's edges are all examples of egonet features. These features are then analyzed for each egonet, and based on how much they deviate from a particular pattern, an outliers score is given. In [13], the authors use the same previous approach, but with a different metric called a brokerage, which is defined as how many times a node bridges a connection between two other nodes when there is no direct link between them. In [14], the neural network model is used to construct graph-centric attributes to identify the nodes as abnormal or normal. Degree centrality and closeness centrality, in addition to betweenness centrality, were used singly and in combination to improve the model's accuracy. Anomalous nodes have a greater degree of proximity centrality, and betweenness centrality.

B. Community-based Approaches

Community approaches are based on the concept of finding groups or communities of densely connected nodes in a network and then detecting the abnormal nodes within these communities. Anomalous nodes are described as nodes that do not show the same characteristics compared to other nodes belonging to the same community or that cannot be assigned to any community [3]. So, in the first stage, Community-based approaches start with the community detection process that groups the nodes into groups that contain dense relationships inside those groups and a few connections between other groups (see Fig. 1).

The second stage consists of detecting community anomalies by finding the nodes that do not deserve to be in this community. An anomaly is a node that has different properties compared to the members of its community and that is not very connected to them. Some approaches identify the nodes as either anomalous users or normal users (see Fig. 2). Some other approaches give a score to each user that determines the degree of its abnormality.

Community-based approaches are more effective at spotting anomalies in attributed graphs. In these approaches, the context of the node is specified by the community because it should share qualities with other nodes within its community.

A node is considered abnormal when it deviates from these typical characteristics. Community-based approaches can be divided into approaches for plain graphs and approaches for attributed graphs:

- Community-based approaches in plain graphs [4], [5] only depend on the structural information of the network. They look at how nodes are related and use the network structure to extract useful information.
- Detecting community anomalies in attributed graphs requires considering both the nodes' attributes and the network structure [9], [10], [11], [1]. Some approaches use the entire attributes space, which is a disadvantage because they are subjected to the curse of dimensionality, which comes with a slew of issues, including longer runtime. Some other approaches select a set of relevant attributes (called context) to filter the full attributes space and select only relevant ones that show a high level of contrast between normal and anomalous users.

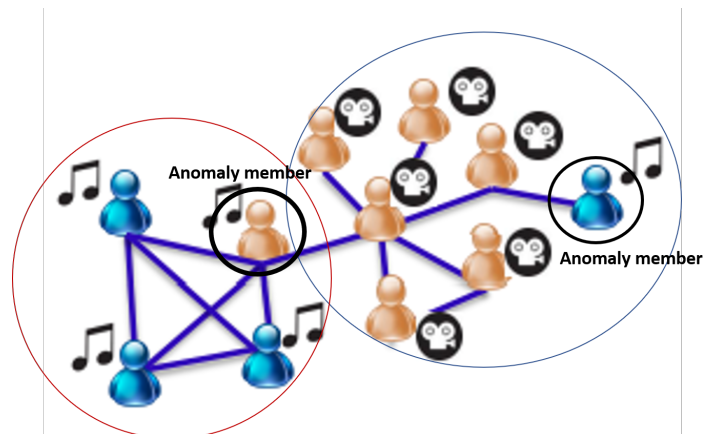

Fig. 2. Community-based anomaly detection in the graph.

III. "ANOMALY DISCOVER" APPROACH

A. Basic Idea

In this work, we present the "Anomaly Discover" approach which is a community-based method for detecting anomalous nodes in social networks. These community anomalies are the nodes that are entrenched within certain graph communities and have deviating attribute values, making them undetectable by global techniques that look for deviation throughout the whole graph node range. As a result, we concentrate on

anomalous nodes that differ from their peers in terms of the structure of the graph and the attributes of the node. While some nodes are strongly connected to their communities, the attribute values can vary significantly amongst nodes, for that, we examine these two factors. By introducing context selection, we concentrate on a subset of important attributes. Context selection reduces the issue of unrelated attributes spreading the full-attributes space and concealing anomalous nodes. Context selection is another technique used to reduce the algorithm's time complexity. There are two phases in our methodology. Firstly, the network is split into communities. A community is a collection of users (that is nodes) who are closely connected and who have similar attributes. So, nodes that lack these features should be regarded as abnormal. So this phase aids in the detection of aberrant nodes that render the community definition invalid. We adopt a modularity-based strategy to split the network since it is fast and can handle enormous networks. In the second phase, for each node, the anomaly score is calculated. By considering both attribute and structure information, this score is utilized to rank nodes depending on the degree of their abnormality. For that, the abnormal nodes are given higher rankings than the usual nodes, which are given lower rankings. Two components make up our score: (i) a structure-based score that considers the graph structure and (ii) an attribute-based score that considers attribute data.

B. Approach Description

In our model, the first phase involves obtaining the communities, and the second phase involves associating the nodes with the anomaly scores. We outline each phase of our method in this section.

1) *First phase: Community detection:* We divide the graph into communities in the first phase to identify the most linked nodes. In our model, we apply the Louvain Algorithm [15], which is a well-known modularity-based strategy for detecting communities in graphs. We employ the Louvain algorithm because of its speed and efficacy. This approach initially allocates each node to a distinct community in order to maximize modularity gain, and then iteratively moves each node to its neighbor. It comes to a halt when further modularity gains are no longer attainable. Gains in modularity are calculated as follows:

$$\delta Q = \left[\frac{\sum_{in} + 2k_{i,in}}{2m} - \left(\frac{\sum_{tot} + k_i^2}{2m} \right) \right] - \left[\frac{\sum_{in}}{2m} - \left(\frac{\sum_{tot}}{2m} \right)^2 - \left(\frac{k_i}{2m} \right)^2 \right] \quad (1)$$

where \sum_{in} represents the sum weights of the edges inside C , \sum_{tot} represents the sum of weights of the edges incident to nodes in C , k_i represents the sum of weights of the edges incident to node i , $k_{i,in}$ represents the sum of weights of the edges from i to other nodes in C and the sum of the weights of all the network's edges are represented by m . Then, when this value is determined for all communities i is linked to, the community that resulted in the greatest modularity increase is assigned to i . In the absence of an increase, i stays inside its original community. All nodes are subjected to this process regularly and sequentially until no more increases in modularity are possible. Once this local modularity maximum is attained, the first stage is finished.

In the second step of the algorithm, each node is combined into a single community, and a new network made up of nodes from the first phase's communities is created. Next, the first phase is applied once more to the new network.

2) *Second phase: Anomaly scoring:* In this step, we characterize the anomalous nodes within the communities using the attribute and structural data. As a result, the node's anomaly score must take into account its deviation within the necessary attributes as well as its community relationships. This score introduces new issues, as it requires combining data from both of the components described in this section: the variance in relevant attribute values of and community connections. The attribute-based score and the structure-based score, that are explained in the following subsections, make up our anomalous score.

Structure-based score: In structure-based scoring, we use a similarity measure to examine the node's relevance. We also look at how connected a node is to the members of its community. Within a community anomaly nodes are consequently less comparable, connected, and influential. In this work, the Jaccard similarity measure and node connectivity are used to calculate the structure-based score, as follows:

$$StrAnomaly(v) = 1 - Jacc(v) * con(v) \quad (2)$$

Where $Jacc(v)$ is the Jaccard index of node v and $con(v)$ is the connectivity of node v . A metric known as node connectivity is used to evaluate how strongly connected a node is to its surrounding neighbourhood. A node produces a high value when its connection to its community is higher than the average connection for the community. The following is a description of the node connectivity:

$$con(v) = \frac{nb(v)}{\frac{\sum_{j=1}^C nb(v_j)}{|C|}} \quad (3)$$

where nb represents neighbors of the node within the community, and $|C|$ represents the nodes' number within the community. The node with high community connectivity has a high score $con(v)$ and vice versa. Anomaly nodes have a low connectivity score compared to normal nodes, which are high in connectivity.

The Jaccard Similarity measure is used to measure the similarity of the node to its community in a graph and hence similar and dissimilar nodes can be detected. This similarity index is used to identify anomalies nodes in the community. The Jaccard index for each node in a community is the sum of the edges the node has with other nodes in the similar community and all other nodes in the graph. In other words, the intersection of the number of node neighbors in the graph over the union of the number of nodes in the similar community. The following is how the Jaccard index is calculated:

$$Jacc(v) = \frac{|ng(v) \cap cv(v)|}{|ng(v) \cup cv(v)|} \quad (4)$$

Where $ng(v)$ represents the neighbors of the node v in the graph, and $cn(v)$ represents all nodes in the same community with node v . The value of the Jaccard index should range in: $0Jacc(v)1$. A Jaccard index of 1 means the node is fully

connected to other nodes in the similar community and vice versa.

Attribute-based score: The objective of the attribute-based score is to quantify the difference in a node's attributes from those of other nodes within the similar community considering subset of related attributes that are chosen in accordance with the context. Considering that many real-world networks are heterogeneous, this attribute similarity function facilitates the combination of attributes of various types. We employ Yi Yang's original Unsupervised Discriminative Feature Selection (UDFS) algorithm to identify relevant attributes [16]. Its goal is to select the data representation features with the highest discriminating. The algorithm optimises the features and produces a ranking and weighting of the features. Additionally, to filter the entire space of attributes, they are ranked according to their UDFS scores as follows:

$$\min_{W^T W=1} Tr(W^T M W) + \gamma \|W\|_{2,1} \quad (5)$$

where ω^i is denoted by the i -th row of W , i.e., $W = [\omega^1, \dots, \omega^d]^T$, the objective function represented in eq. 5 can also be expressed as:

$$\min_{W^T W=1} Tr(W^T M W) + \gamma \sum_{i=1}^d \|\omega^i\|_2 \quad (6)$$

As a result, a new representation of χ_i employing only a select few features is provided for a datum $\chi_i, \chi_i = W^T x_i$. As an alternative, we can rank each feature $f_i |_{(i=1)}^d$ based on $\|\omega^i\|_2$ in descending order and choose the features with the highest rankings. As a consequence, we'll select a subset of the most crucial attributes with size N , where N is a parameter that our algorithm takes into account as input. Given the context (relevant attributes), we can estimate the attribute-based score, which can be defined as the average of all the scores for the relevant attributes. This attribute-based score is defined as:

$$AttrAnomaly(v) = \frac{\sum_{a_r \in A} S(v, a_r)}{n}, \forall a_r \in A \quad (7)$$

where $S(v, a_r)$ represents the attribute score of node v for the attribute $a_r, \forall a_r \in A$, and in the set A of relevant attributes the number of attributes is represented by n , which is define as:

$$S(v, a_r) = \frac{\sum_{j=1}^C d(v, v_j)}{|C|}, \forall v_j \in C \quad (8)$$

where v_j stands for the other nodes within the community, the nodes' number in the community is denoted by $|C|$, and the distance between the nodes v and v_j is represented by $d(v, v_j)$, which is assigned either to zero or one. When $d(v, v_j)$ is zero, this means that the distance between the these nodes is equal to or less than the mean distance (Md), otherwise, it is set at one.

$$d(v_j, v_j) = \begin{cases} 0 & \text{if } |a_r(v_i) - a_r(v_j)| \leq Md(C_{(v)}, a_r) \\ 1 & \text{Otherwise.} \end{cases}$$

where $a_r(v_i)$ represents the the attribute a_r 's value in the node v_i attribute vector, and the mean distance of attribute a_r of node v is denoted by $Md(C_{(v)}, a_r)$ within the community which is illustrated as follows:

$$Md(C_v, a_r) = \frac{\sum_{i,j=1}^C (a_r(v_i) - a_r(v_j))}{p} \quad (9)$$

where the distance between the node v_i and the node v_j for the attribute a_r is represented by $(a_r(v_i) - a_r(v_j))$, and in each community the number of node pairs is represented by p . This distance for binary attributes is determined by the *simple matching coefficient* between the nodes v_i and v_j for the a_r attribute:

$$(a_r(v_i) - a_r(v_j)) = \frac{\sum_{k=1}^d (a_{rk}(v_i) \wedge a_{rk}(v_j)) \vee (\neg a_{rk}(v_i) \wedge \neg a_{rk}(v_j))}{d}$$

The *Jaccard similarity index* between the "1-of-N" binary encodings of $(a_r(v_i)$ and $a_r(v_j))$ gives the distance for categorical attributes; in other words:

$$(a_r(v_i) - a_r(v_j)) = \frac{\sum_{k=1}^d a_{rk}(v_i) \wedge a_{rk}(v_j)}{\sum_{k=1}^d a_{rk}(v_i) \vee a_{rk}(v_j)}$$

The *Euclidean distance* between $(a_r(v_i)$ and $a_r(v_j))$ is what determines this distance for numeric characteristics; that is,

$$(a_r(v_i) - a_r(v_j)) = \frac{1}{1 + \sqrt{\sum_{k=1}^d (a_{rk}(v_i) \wedge a_{rk}(v_j))^2}}$$

where d is the attribute's a_r dimensions, $(a_{rk}(v_i))$ is the value of the attribute's a_r k -th coordinate for node v_i , and \neg , \wedge and \vee are the logical operators for NOT, AND, and OR, accordingly.

Anomaly score:: To rank nodes in every community and recognize anomalous nodes, we next use both the structure-based and attribute-based scores to get an aggregate anomaly score (those with a higher anomaly score). Calculate each node v anomaly score as below:

$$AnomalyScore(v) = StrAnomaly(v) + (1-\alpha)AttAnomaly(v) \quad (10)$$

where the weight used to regulate the relative importance of attribute-based anomaly and the structure-based anomaly is represented by α .

C. Algorithm

First, we use the Louvain algorithm to partition the graph into communities (line 1). Then, we determine each node's Jccard similarity (line 3). Before assigning the structure-based score, we iterate over each node to determine its connectedness(line 6). Afterward, we determine each attribute's UDFS score (line 8), and we choose the N attributes corresponds to lowest score of UDFS to be the relevant attributes (line 9). Then, for each community, we iterate, comparing the distance

between the node and its community nodes with the community mean distance using the relevant attributes (lines 10-16). Finally, the anomalous score of the nodes from G is returned (line 20) by combining the structure-based score and attributes-based score (lines 17-19). The name (AnomalyDiscover), an integration of the words community and anomaly, refers to our algorithm for community-based anomaly detection.

Algorithm 1 Anomaly Discover

Require: $G : (V, E)$, A : Attributes, N : number of select attributes

Ensure: Ranking of all $v \in V$

```
1:  $C \leftarrow$  Louvain Method( $G$ )
2: Initialize empty vectors  $StrAnomaly$ ,  $AttrAnomaly$ ,
    $AnomalyScore$  for all  $v \in V$ 
3:  $Jacc \leftarrow$  Jaccard similarity index for all  $v \in G$  (Eq. 4)
4: For each  $v \in G$  do
5:   Compute connectivity( $v$ ) (Eq. 3)
6:   Compute  $StrAnomaly(v)$  (Eq. 2)
7: End For
8: For all  $a_r \in A$  calculate UDFS score (Eq. 6)
9:  $A' \leftarrow$  subset of  $N$  attributes with the lowest UDFS score
10: For each community  $C_k$  in  $C$  do
11:    $Md \leftarrow$  mean values of attributes from  $A'$  in  $C_k$  (Eq.
   9)
12:   For each  $v_i$  in  $C_k$  do
13:      $s_{v_i} \leftarrow$  a dictionary containing for each attribute
        $a_r$  of  $v_i$  its anomaly score
14:     Compute  $AttrAnomaly(v)$  (Eq. 7)
15:   End For
16: End For
17: For each  $v \in G$  do
18:   Calculate the anomaly score using the Eq. 10
19: End For
20: Return  $AnomalyScore$ 
```

D. Complexity Analysis

First, the graph is partitioned into communities by applying the Louvain algorithm, which has a running-time cost $O(v \log v)$ for the number of graph nodes. After that, the Jaccard similarity measure is calculated, and that costs $O(v + e)$, where the number of edges in the graph is represented by e . Next, the $StrAnomaly$ score is calculated with the nodes' number linear cost. The context is then defined using the UDFS score, which has a cost of $O(mv^2)$, where m represents the total attributes' number. Consequently, the computational complexity of the Anomaly Discover model is $O(\max(mv^2, v + e))$. When all of the graph nodes are allocated to one community, which happens when a quadric analysis is carried out for each community, this is the worst-case scenario. As a result, the algorithm performs better on a real network with a large number of communities.

IV. EXPERIMENTAL EVALUATION OF PERFORMANCES

To study the performance of the "Anomaly Discover" method, we compared it with two well-known algorithms which are CODA and ConSub that we briefly introduce in this section:

- CODA [17] is one of the most popular models used for anomaly detection in social network communities. In this model, community detection and anomalous node identification are done in a single step. It utilizes the entire attribute set of nodes.
- ConSub's [7] concept is a statistically-based selection of a subset of all attributes of the nodes. This subset demonstrates dependencies inside the graph structure. To find abnormal nodes in the communities, a subset of attributes is chosen and used with the DistOut distance-based outlier model.

A. Evaluation Measures

In order to evaluate the performance of the community-anomaly detection model and establish its validity on synthetic and real datasets, we compare the acquired nodes' ranks of the model with the ground truth. The Area Under the Curve (AUC) is one of the most important performance metrics for anomaly ranking and classification models. AUC measures how well the model can differentiate between two classes; a greater value of AUC means a more effective model. In a machine learning classification task, comparing the actual classes to the predicted classes of the model. Hence, the results can be categorized into four groups: true positives, false positives, true negatives, and false negatives. True positives are actual anomalies that the model predicted correctly as anomalies, while true negatives are actual normals that the model predicted correctly as normal. On the other hand, false positives are actual normals that the model predicted as an anomaly, while, false negatives are actual anomalies that the model predicted as normal. Specificity is the proportion of correctly identified negatives, whereas sensitivity is the proportion of correctly detected positives. We provide several thresholds in the classification model and to create the ROC curve, sensitivity (also referred to as the true positive rate) is plotted against the false positive rate which is calculated as $(1 - \text{Specificity})$.

So, the optimum model is the one that reliably detects all positives and all negatives at a specified threshold value while still obtaining the highest levels of specificity and sensitivity. The top-left portion of the ROC plot contains the greatest value. The area under the curve (top-left corner) consequently represents the ROC curve's ability to reach the highest level of specificity and sensitivity.

The model's runtime is the second metric considered in this evaluation since it's crucial to see if the model can accurately identify the community abnormality in a timely manner. If a shorter runtime is possible, it is better if the outcomes are high-caliber.

B. Real Benchmark Dataset

The Book network and Disney network serve as our testbeds in this part, and the performance of our model is compared to that of the CODA and ConSub models. The only variable in our suggested model is how many attributes to include. The number of characteristics was set to half-number and 10 attributes maximum; adding more characteristics increased the run-time without notably enhancing the quality.

TABLE I. MODELS PARAMETER SETTING

CODA	Number of communities= 8	Anomaly percentage= 0.05	Link importance= 0.01
ConSub	Size of interval= 10	The number of Monte Carlo iterations= 150	The significance level=0.05

Table I provides information about the other models' parameter settings.

We compare our findings with those of ConSub and CODA in order to assess our methodology using the following real networks:

- **Disney Network:** the Amazon co-purchase network was divided up into a Disney network that exclusively considered Disney DVDs. In the graph, each product is characterized by 30 properties, including review ratings, product prices, and other information. The network has 124 nodes and 334 edges. The network, although being a tiny dataset, is used to test the majority of anomaly detection models because of its intricate graph and attribute structure. The ground truth of whether an object is an abnormality or normal is not available for this real-world dataset. As part of a user experiment to determine the dataset's ground truth, high school students personally classified each object as normal or an abnormality.[18] presents a thorough explanation of the dataset and the user experiment.
- **Book Network:** this network which was based on Amazon Co-Purchase Network, includes books that users have tagged as "amazon fails" [19]. On Amazon, customers could use tags to describe items, and different tags like the "amazon fail" tag was used to indicate dubious products. The network has 1468 nodes, 3695 edges, and 28 attributes that are used to describe each object. The basis for this dataset was established by classifying a book as an anomaly when at least 20 users had labeled it as an "amazon fail".
- **Enron Network:** we employ email transmission as edges between email addresses on the Enron communication network. Spam dataset outliers were defined as addresses that have sent spam. This network contains 13 533 nodes, 176 967 edges. There are 20 attributes present in each node that provide aggregate information about the average number of recipients, the average content length, or the time interval between two mails [19].

C. Synthesis Benchmark Dataset

Evaluating anomaly detection methods is not a straightforward process due to the lack of suitable datasets containing anomalies and the lack of ground truth that defines which data points are actual abnormalities. As a result, performance evaluation is typically the purpose of synthetic datasets. These datasets are utilized to compare a model's performance on synthetic versus real data. Based on [7], synthetic datasets of various attribute counts and sizes are created. To replicate the characteristics of real networks, the graph is created by following a power-law distribution. Relevant attributes obtained values from a Gaussian distribution, while irrelevant attributes

obtained values from a uniform distribution. To ensure there were no abnormal values in the relevant attributes, the tails of each Gaussian distribution were truncated using a hyper ellipsoid (see Fig. 3). Anomaly nodes' characteristic values were modified to be random numbers beyond the boundaries of their communities' hyper ellipsoids. The anomalous nodes number within the communities is determined by the anomaly ratio, which is 10%. Only when at least two pertinent attribute combinations are taken into account can the anomalies be found.

The graphml file and the true file are the two files that make up any synthetic dataset. The graph and each node's properties can be found in the graphml file. The true file includes the actual nodes, with a ground truth value of 0 for normal nodes and 1 for anomalous nodes. We use synthetic datasets that contain 1000 number of nodes and various characteristics 2, 10, 20, 40, 60, and 80 to assess the performance of the model's as the number of attributes increases. To evaluate how well the model performs when the network size is increased, we use synthetic datasets with varying numbers of nodes and ten attributes. We configured our model parameter to be the half-number of attributes to test the impact of increase in attributes a while utilising the same configuration in the real network trials for the other models.

V. RESULTS FOR REAL AND SYNTHESIS DATASETS

A. Results for Real Datasets

1) *Disney network:* Fig. 4 and 5 illustrate our model's results applied on the Disney network in contrast to CODA and ConSub. The findings show that the "Anomaly Discover" model produces good-quality outcomes with an AUC of .83 (see Fig. 4). In contrast, the other models produce results of poorer quality, with an AUC of.82 for ConSub and.50 for CODA, respectively. The ConSub model performs better than the CODA model, which produces the lowest-quality outputs. In Fig. 5, the runtime evaluation is displayed. The CODA model comes in second with a runtime of 6.05 seconds, just 0.04 seconds behind the "Anomaly Discover" model.

At 8.93 seconds, the ConSub model is the slowest model. The “Anomaly Discover” model yields the best outcomes for identifying community abnormalities, according to this experiment on the Disney Network, out of the three methods. Among the three, the “Anomaly Discover” model is the fastest. While the ConSub model delivers high-quality findings but operates slowly, the CODA model is recognised as the least effective model for identifying community-anomalies in a real-world network.

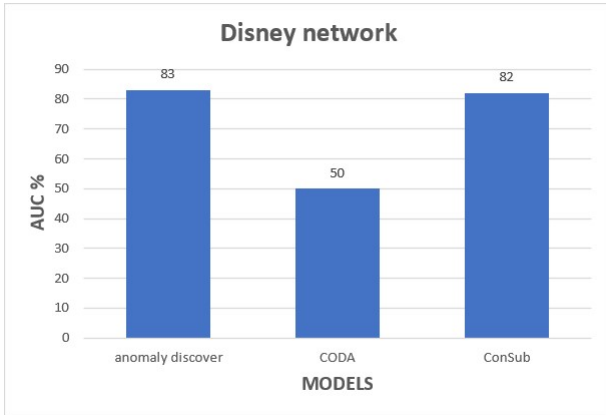

Fig. 4. AUC and ROC curve for the disney network.

Fig. 5. Evaluation of runtime for disney network.

2) *Book Network*: By computing the AUC, Fig. 6 shows how well the “Anomaly Discover”, CODA, and ConSub models perform. In comparison to the other models, the “Anomaly Discover” model produces least findings (see Fig. 6), whereas ConSub produces the highest-quality results (AUC = 0.60). The “Anomaly Discover” model outperforms the CODA models in the Book network’s runtime evaluation, which shows that it executes in 12.48 seconds and yields the best results. The CODA model is the slowest at 36 seconds (see Fig. 7).

3) *Enron network*: The outcomes of our model on the Enron network in comparison to CODA and ConSub are shown in Fig. 8 and 9. The figures demonstrate that our model produces good-quality outcomes with an AUC of .78 (see Fig. 8), but it was the slowest (see Fig. 9). In contrast, the CODA produces a result that has lower quality with an AUC .46 but it was the fastest. ConSub produces a result inferior to the “Anomaly Discover” model, but it was faster than our model.

Fig. 6. AUC and ROC curve for the book network.

Fig. 7. Evaluation of runtime for book network.

Fig. 8. AUC and ROC curve for the enron network.

Fig. 9. Evaluation of runtime for enron network.

B. Results for Synthesis Datasets

1) *First experiment:* We evaluate our model performance as we add more attributes using the AUC curve with datasets of 1000 numbers of nodes. The variance in AUC of the tested models as the number of features rises is depicted in Fig. 10. In comparison to ConSub and CODA, our model results in the best AUC, which ranges from 0.88 to 0.98. Fig. 11 illustrates the runtime evaluation by showing the runtimes with increasing numbers of attributes. In spite of the fact that CODA runtime often grows as the number of characteristics does as well, “Anomaly Discover” and ConSub both provide the best scalability in this regard. It’s important to keep in mind that matrix operations are costly, and with CODA, they are performed for each attribute, increasing the runtime.

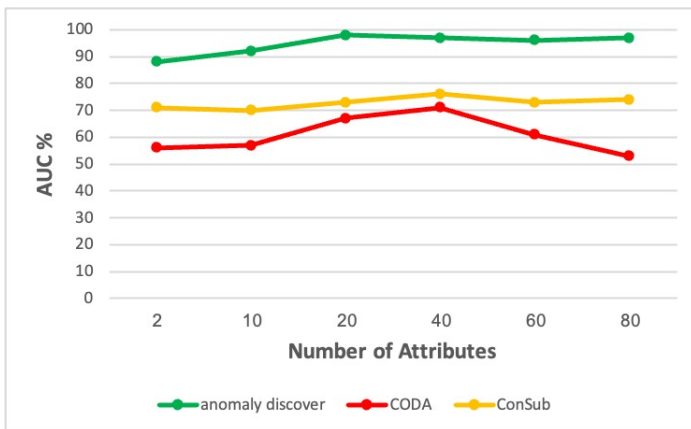

Fig. 10. Variations in AUC using different number of attributes for each tested models.

2) *Second experiment:* Networks with 500, 1000, 2000, 3500, 6000, and 10000 nodes are utilised to evaluate the model with a larger network. In the smallest network, the AUC of the “Anomaly Discover” model is 0.93, and in the largest network, it is 0.90. In fact, when compared to the other models, “Anomaly Discover” has the greatest AUC (see Fig. 12). Fig. 13 displays the evaluation of the runtime as the network size increases. ConSub has overall faster runtimes than the other

Fig. 11. Variations in runtime using different number of attributes for each tested models.

models, although the “Anomaly Discover” outperforms CODA in networks with 500, 1000, 2000, and 3500 nodes, while CODA outperforms “Anomaly Discover” in networks with 6000 and 10000 nodes.

Fig. 12. Variations in AUC using the different number of nodes for each tested models.

C. Discussion

The outcomes of these tests show how well “Anomaly Discover” works to identify community anomalies in both real and synthetic networks. In fact, we’ve achieved things that are extremely intriguing, which earlier approaches like ConSub [7] couldn’t. As the model defines the pertinent network properties rather than taking into account the entire attribute space, it increases the number of attributes while still producing high-quality results and scalability. As a result, the model is appropriate for applications used today, when the number of attributes is increasing. Since the ConSub model also describes the network context, whereas CODA [17] simply considers the network attributes, it performs better than CODA in terms of performance.

VI. CONCLUSION

In this study, we focused on finding anomalous users in online networks. In particular, we are seeking to identify

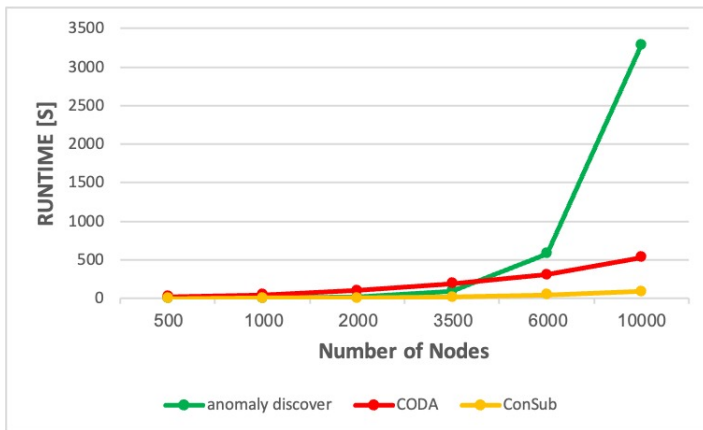

Fig. 13. Variations in runtime using different number of nodes for each tested models.

anomalies that diverge from their communities in comparison to normal users who frequently share numerous attributes with their members of the community. In fact, by using both structure information and attributes information, we were able to create an anomalous ranking score to efficiently find complicated anomalies that differed in either their characteristics values or their structure, or both. To highlight any deviation in these values, the context is selected, which is a subset of the relevant attributes. Given that many real-world networks are heterogeneous, this approach enables the combining of the attributes of mixed types.

We next go over different ways that an extension of our suggested approach could be implemented. Other features of online social networks, such as user communication through comments or message exchange, could be evaluated to find anomalies, though. While they might have common attribute values and structural characteristics with their community, these data might signify an unexpected communication pattern, making them a useful indicator of anomalous nodes.

A Particle Swarm Optimization with Imbalance Initialization and Task Rescheduling for Task Offloading in Device-Edge-Cloud Computing

Hui Fu, Guangyuan Li, Fang Han*, Bo Wang

Faculty of Engineering, Huanghe Science and Technology College, Zhengzhou, China 450006

Abstract—Smart devices, e.g., smart-phones, internet-of-thing device, has been prevalent in our life. How to take full advantage of the limited resources to satisfy as many as requirements of users is still a challenge. Thus, in this paper, we focus on the task offloading problem to address the challenge by device-edge-cloud computing, by PSO improved with the imbalance initialization and the task scheduling. The imbalance initialization is to increase the probability that a task is assigned to a computing node such that the node provides a longer slack time. The task scheduling is to reassign tasks with deadline violations into other nodes, to improve the number of accepted tasks for each offloading solution. Extensive experiment results show that our proposed algorithm has better performance than other ten classical and up-to-data algorithms in both the maximization of the accepted task number, the resource utilization, as well as the processing rate.

Keywords—Cloud computing; edge computing; task offloading; task scheduling; particle swarm optimization

I. INTRODUCTION

In our life, smart devices, e.g., smart-phones, Internet-of-Thing (IoT) devices, are becoming popular, and they are appearing everywhere. As the life quality improves, people request a wide variety of services by their devices. But smart devices generally have limited resource capacity due to their small spaces. Thus, smart devices cannot satisfy all requirements of their users. Edge computing and cloud computing are two of commonly used ways to address this issue. Edge computing places a few servers close to devices, aiming at providing low latency services [1]. Cloud computing extends the capacity of devices by its abundant computing resources, but it usually has poor network performance [2].

Device-edge-cloud computing (DECC) combines benefits of edge and cloud computing, which provides services by not only local device resources but also low latency edge servers and abundant cloud servers [3]. How to make these heterogeneous resources cooperate well is a kind of very challenging work for high service quality and resource efficiency in DECC. Therefore, several works focused on the task offloading or scheduling to address this challenge. The task offloading problem is to decide which and how many resources for each task's processing [3]. The offloading problem has been proofed as NP-hard, because tasks and resources generally are discrete, and the task processing models and the optimization objectives are usually non-convex.

To solve the task offloading problem, existing works mainly exploited two kinds of approaches, heuristics and meta-heuristics, based on their desires. Heuristics use local search strategies to provide local best solutions with a very few overheads. For example, Wang et al. [4] proposed two heuristic algorithms for the offloading problem. The first one is iteratively assigning the task to an edge server (ES), which provides the minimal response time. The second one, load balance, iteratively assigns the task to the ES such that the ES can satisfy the most tasks' requirements. Only when there is no available edge resources, these two algorithms assign tasks to the cloud for their processing. Sang et al. [5] and Chen et al. [6] presented multi-stage heuristic algorithms for task offloading in DECC, which both considers to use abundant cloud resources at first for task processing, to improve the overall accept ratio. Heuristics generally provide solutions with limited performance, because they only exploit local search strategies.

Meta-heuristics exploit global search strategies, inspired by some natural or social laws. Meta-heuristics can provide better solutions than heuristics many times, benefiting from their global search abilities, with a few costs. Such as, Wang et al. [7] and Song et al. [8] applied genetic algorithm (GA) to improve the deadline violation and the delay, respectively. Alqarni et al. [9] and Wang et al. [10] made use of Particle Swarm Optimization (PSO) for the delay minimization and the user satisfaction maximization.

No heuristic or meta-heuristic has the best performance as there is no such thing as a free lunch. Thus, a promising way to achieve better performance is combining two or more heuristics and meta-heuristics for hybrid heuristics. Mahenge et al. [11] proposed a hybrid swarm intelligence offloading algorithm, by using the position update strategies of both PSO and Grey Wolf Optimizer to optimize the energy consumption of devices. To combine benefits of both swarm intelligence and evolutionary algorithm, Wang et al. [13] used GA at first, and then applied PSO with the population provided by GA. Hafsi et al. [12] sequentially employed GA and PSO on each iteration of the population evolution. Nwogbaga et al. [14] performed a mutation operator on each individual at the end of each iteration for PSO, to avoid trapping to local best solution. These works only sequentially performed two meta-heuristics without considering their integration, which provides a low combination efficiency.

Therefore, in this paper, we aim at designing a hybrid heuristic algorithm for providing a good task offloading solution in DECC, by improved PSO. Specifically, we rep-

*Corresponding Authors.

resent task assignment solutions as integer coded positions of particles, and use PSO for the position updates. And by the earliest deadline first (EDF) heuristic algorithm for the task scheduling on each computing node, we can achieve a task offloading from each particle position. To improve the performance of PSO, we propose to use an imbalance idea for the population initialization, where the computing node for a task's processing has a possibility positively associated with its capacity. This can take full use of the easily trapping into local best position, by increasing the probability that the initialized particles are near the global best position. To improve the offloading solution, we reschedule tasks with deadline violations to other computing nodes for each assignment solution, i.e., each particle position. We conduct extensive experiments to evaluate the performance of our proposed algorithm, and the results confirm the superior performance in optimizing the number of tasks with requirement satisfactions and the resource efficiency, compared with ten of classical and up-to-data heuristics and meta-heuristics.

In the following, we state the task offloading problem of DECC in Section II. The improved PSO is illustrated in Section III. Experimental evaluations are presented in Section IV, and we conclude our work in Section V.

II. PROBLEM STATEMENT

In a considered DECC system, there are D devices, E ESs, and C CSs, which can be seen as $D + E + C$ computing nodes (respectively represented as $n_i, 1 \leq i \leq D + E + C$). For node n_i , there are g_i computing capacity. For data transferring, the network transmission speed between n_i and $n_{i'}$ is $b_{i,i'}$. If there is no network connection between n_i and $n_{i'}$, $b_{i,i'} = 0$. And within one node, there is no latency for data transfer, i.e., $b_{i,i} = 1$.

In the DECC system, there are T tasks ($t_j, 1 \leq k \leq T$) launched by these D devices for processing. We use binary constants $l_{i,j}$ to indicate the relationships between tasks and devices, where $l_{i,j} = 1$ means t_j is launched by n_i , and $l_{i,j} = 0$, otherwise. For every task, say t_i , the nodes that can accept its request for processing include the device launching it, ESs having network connections with this device, and CSs. Therefore, we can use $l_{i,j}, 1 \leq i \leq D + E + C, 1 \leq k \leq T$, to indicate whether n_i can be used for processing t_j , where $l_{i,j} = \sum_{i'=1}^D (l_{i',j} \cdot (b_{i',i} \neq 0))$, for $D + 1 \leq i \leq D + E + C, 1 \leq j \leq T$.

For task t_j , the amount of required computing resources, i.e., its computing size, is c_j . The input data amount of t_j is a_j , and the deadline is d_j which means t_j must be finished before d_j . Without loss of generality, we assume $d_1 \leq d_2 \leq \dots \leq d_T$. Then, if task t_j is offloaded into ES or CS n_i , the data transfer latency is

$$\tau_{i,j}^D = \frac{a_j}{\sum_{i'=1}^D (l_{i',j} \cdot b_{i',i})}. \quad (1)$$

where $\sum_{i'=1}^D (l_{i',j} \cdot b_{i',i})$ is the transmission speed between the device launching t_j and the ES or CS n_i . The computing latency of t_j in node n_i is

$$\tau_{i,j}^C = \frac{c_j}{g_i}. \quad (2)$$

In this paper, we ignore the transfer latency of the output data for each task, as the result generally has much less amount than the input [15], [16].

For multiple tasks assigned to one computing node, the data transfers and the computing are processed sequentially. It has been proofed that EDF yields an optimal schedule for minimizing the number of task deadline violations in a computing node [17], which is the major objective in the paper. Therefore, we can deduce the finish time of each task on every node with EDF processing order. Then, the earliest complete time (ft_j^D) of the data transfer for a task can be deduced by Eq. (3). Where $x_{i,j}$ is the binary variable to indicate where t_j is assigned to n_i for its processing (1 is yes, and 0 is no).

$$ft_j^D = \sum_{i=1}^{D+E+C} (x_{i,j} \cdot \sum_{j' \leq i} (x_{i,j'} \cdot \tau_{i,j'}^D)), 1 \leq j \leq T. \quad (3)$$

For a task's computing on a node, it can be started only when its data transfer finishes and the node is available, where the node is available only when the its previous task finishes its computing. Thus, the finish time of a task's computing, i.e., its finish time, can be calculated iteratively by Eq. (4).

$$ft_j = \max\{ft_j^D, \sum_{i=1}^{D+E+C} (x_{i,j} \cdot \max_{j' < j} \{x_{i,j'} \cdot ft_{j'}\})\} + \sum_{i=1}^{D+E+C} (x_{i,j} \cdot \tau_{i,j}^C), 1 \leq j \leq T. \quad (4)$$

Then, based on above formulations, the task offloading problem in the DECC system can be expressed as

$$\text{Maximizing } N = \sum_{i=1}^{D+E+C} \sum_{j=1}^T x_{i,j}, \quad (5)$$

subject to

$$ft_j \leq d_i, 1 \leq j \leq T, \quad (6)$$

$$x_{i,j} \in \{0, 1\}, 1 \leq i \leq D + E + C, 1 \leq j \leq T. \quad (7)$$

Where the objective (5) is maximizing the number of tasks whose deadlines are met, and the constraints mainly include the deadline requirements (Eq. 6) and the atomicity of every task (Eq. 7). In this work, we consider the hard deadline, where if the deadline of a task is satisfied, the task is accepted for its processing, and it is rejected, otherwise. Due to the discrete decision variables ($x_{i,j}$) and the non-convex constraints (see Eq. 4 and 6), the task offloading problem generally is hard to solve. Existing tools, e.g., lpsolve [18] and MathWorks [19], can provide exact solutions, but has exponential complexity at worst. Therefore, in the following section, we present a hybrid heuristic offloading algorithm to solve the problem with a polynomial time.

Fig. 1. The flow chart of PSOINRS.

III. THE PSO WITH IMBALANCE INITIALIZATION AND TASK RESCHEDULING

PSO has been applied to solve optimization problems in various fields, due to its easy implementation and good performance. But PSO has some drawbacks which prevent its more wide application. Therefore, in this section, we integrate two improvement strategies on PSO to achieve a better offloading solution for DECC, and proposed a hybrid heuristic offloading algorithm, PSOINRS (PSO with imbalance Initialization and task Rescheduling). The algorithm flow chart is shown in Fig. 1.

In PSOINRS, a position of particles represents a task assignment solution. The dimension number of particles is identical to the task number, and the value in a dimension indicates the node that the corresponding task is assigned to.

At first, for the population initialization of PSO, we propose an imbalance approach to improve the particle density in the possible best positions. Intuitively, a task has more possibility to be processed by the node providing longer slack time (the closeness to the deadline). Therefore, PSOINRS initializes the position of a particle by setting the possibility of a node positively associated with the deadline tightness that the node provides, where the probability that t_j is assigned to n_i is

$$p_{i,j} = \frac{s_{i,j}}{\sum_{j'=1}^T s_{i',j}}, \quad (8)$$

where $s_{i,j} = d_j - ft_j$ if t_j is assigned to n_i and $ft_j \leq d_j$, and $s_{i,j} = 0$, otherwise.

After the population initialization, PSOINRS evaluates the fitness of each particle according to its position. Given a position, we can easily achieve a task assignment solution. By EDF ordering scheme, we achieve a offloading solution from the task assignment solution. Then, we proposed to use the task rescheduling in PSOINRS to improve the solution quality for each position. The task rescheduling is scheduling tasks with deadline violations to other nodes by EDF to improve the optimization objective (5).

Except the imbalance initialization and the task rescheduling for mapping a position into a task offloading solution, PSOINRS updates the positions of particles identical to PSO, as shown in Fig. 1.

IV. PERFORMANCE EVALUATION

For evaluating the performance of our proposed algorithm presented in the previous section, we simulate a DECC environment based on related works and the reality. In a simulated DECC, there are 10 devices, 5 ESs, and 10 CS types. For each device, there are [1.8, 2.5]GHz computing capacity. Each device is randomly connected with an ES. Each ES or CS type has [1.8, 3.0]GHz computing capacity. The data transfer rate of a device to an ES or CS is set as [80, 120]Mbps, and [10, 20]Mbps, respectively. There are 1000 tasks randomly launched by these devices. Each task has [0.5, 1.2] GHz computing size, and [1.5, 6] MB input data. The deadline of a task is set as [1, 5]s.

We compare our proposed algorithm with First Fit (FF), First Fit Decreasing (FFD), EDF, Short Job First (SJF), random (RAND), GA, GAR [20], PSO, PSOM [14], and GAPSO [13]. RAND is randomly initializing a population, and provide the best individual. We use the following performance metrics for the evaluation of each algorithm, the number of tasks with deadline satisfactions, the overall computing resource utilization, the computing rate, and the data processing rate. The rate of computing and data processing is the computing size and the input data amount of tasks with deadline satisfactions.

Fig. 2 shows the number of tasks with deadline satisfactions when applying different offloading algorithms, which is one of the most commonly used metrics for evaluating the user satisfaction or the quality of service (QoS). From this figure, we can see that PSOINRS has 8.73%–36.8% better performance than others. This verifies the performance superiority of our proposed algorithm. The benefits of PSOINRS are mainly the imbalance initialization and the task rescheduling, which will be both evaluated and illustrated in the followings.

Fig. 3 gives the resource utilizations achieved by these offloading algorithms, which is one of the most frequently used metrics for the quantification of the resource efficiency. As shown in the figure, heuristics (FF, FFD, EDF, and SJF) has better utilizations than meta-heuristics (GA, GAR, PSO, PSOM, GAPSO, and PSOINRS). This is mainly because heuristics prioritise processing tasks locally or in low-latency edge resources, while meta-heuristics pursues the global optimization objective for maximizing the number of accepted tasks, because the task processing with a low data transfer latency has a high computing resource utilization, which is mainly decided by the ratio between the data transfer latency and the computing delay.

Fig. 2. The accepted task numbers achieved by various methods.

Fig. 3. The resource utilizations achieved by various methods.

Fig. 4. The computing rates achieved by various methods.

Fig. 5. The data processing rates achieved by various methods.

Fig. 4 and 5 presents the rates of the computing and the data processing when applying these offloading methods. From these figures, we can see that our proposed algorithm has the fast processing rate. Our algorithm has 12.0%–36.9% faster computing rate, and 10.7%–39.6% faster data processing rate than others.

Next, we evaluate the performance of our improvement strategies, the imbalance initialization and the task rescheduling, and the experimental results are shown in Fig. 6 and 7, where PSOIN and PSORS are respectively PSO with the imbalance initialization and the task rescheduling. From these figures, we can see that the imbalance initialization can improve GA by 1.73% and PSORS 12.1%, which verifies the validity of the imbalance initialization. In Fig 7, we can see that offloading algorithms with the task rescheduling can achieve 18.5%–189% better performance than that without it in processing rate. Thus, the task rescheduling strategy is deserved to be integrated into offloading algorithms.

From Fig. 6 and 7, we also can see that the imbalance initialization can decrease the performance of PSO, while the task rescheduling can make up the degradation and improve both the accepted task number, the utilization and the processing rate. This inspires us that the combination of multiple improvement strategies may produce good solutions, even though a signal improvement strategy degrades the overall performance.

V. CONCLUSION

In this paper, we focus on the task offloading problem in DECC systems. We first formulate the problem as a discrete non-convex optimization model, which is hard to be solved. Then, we propose a PSO-based algorithm to solve the task offloading problem, where we use the imbalance initialization and the task rescheduling to improve the performance of PSO on the solving offloading problem in DECC. Extensive experiments are conducted and results verify the superior performance of our proposed algorithm.

Abstract—Air pollution is a major environmental issue and machine learning techniques play an important role in analyzing and forecasting these data sets. Air quality is an outcome of the complex interaction of several factors involving the chemical reactions, meteorological parameters, and emissions from natural and anthropogenic sources. In this paper, we propose an efficient combined technique that takes the benefits of statistical techniques and machine learning techniques to predict/forecast the Air Quality and Pollution in particular regions. This work also indicates that prediction performance varies over different regions/cities in India. We used time series analysis, regression and Ada-boosting to anticipate PM 2.5 concentration levels in several locations throughout Hyderabad on an annual basis, depending on numerous atmospheric and surface parameters like wind speed, air temperature, pressure, and so on. Dataset for this investigation is taken from Kaggle and experimented with proposed method and comparison results of our experiments are then plotted.

Keywords—Air quality; forecasting; machine learning; statistical techniques

I. INTRODUCTION

Today, all cities have attracted significant attention in the context of urban development approaches [2,3]. The Internet and developments in broadband networking are seen as enablers of e-services and are becoming increasingly important for urban development and addressing the massive air pollution problem. Citizens and governments around the world have witnessed and expressed growing concern about the impact of air pollution [4] on human health, as well as advocated sustainable development to address air pollution challenges. The result of modern manufacturing is a mixture of liquid droplets, solid particles, and gas molecules that is dispersed throughout the atmosphere. The high concentration of particulate matter of size $PM_{2.5}$ has a major negative impact on human health.

Recent studies have focused on rigorous statistical learning algorithms for evaluating air quality and predicting pollution levels. Neural networks have been employed by Raimondo et al. [5], Garcia et al. [6], and Park et al. [7] to build models for forecasting the occurrence of individual pollutants, such as particles less than 10 microns (PM_{10}). To train their models, Raimondo et al. [5] employed a support vector machine (SVM) and an artificial neural network (ANN). Their best ANN model had a specificity of nearly 79 percent and a false-positive rate of only 0.82 percent, while their best SVM model had a specificity of 80 percent and a false-positive rate of only 0.13 percent. For AQI category prediction, Yu et al. [8] suggested

RAQ, a random forest technique. After that, Yi et al. [9] used deep neural networks to predict AQI categories. For forecasting AQI levels, Veljanovska and Dimoski [10] used several settings to surpass k-nearest neighbour (k-NN), decision tree, and SVM. Their ANN model outperformed all other algorithms examined, with an accuracy of 92.3 percent.

The deep learning architecture is suitable for solving air pollution prediction problems and nonlinear problems, and to learn long-term dependencies from time-series data[23]. In [24], authors presented deep learning solution to predict the hourly forecast of $PM_{2.5}$ concentration in Beijing, China, based on CNN-LSTM, and other hybrid deep learning techniques for air pollution analysis is presented in [25].

A. Air Quality Monitoring

The CPCB recommends a combination of physical, wet-chemical, and continuous online measuring procedures for each parameter. Analyzers for measuring PM_{10} , $PM_{2.5}$, SO_2 , CO , NO_2 , O_3 , NH_3 , and Benzene are provided in air quality monitoring systems [10,11,13]. Using filter-based air samplers, the metallic parameters Pb, Ni, and As are assessed offline.

The ambient air quality monitoring station (AQMS) having the following systems:

- PM_{10} & $PM_{2.5}$: It Measures particle mass concentrations ranging from 0 to 5 mg/m^3 with a lowest detection limit of 1 g/m^3 . It works on the principle of Beta Ray Attenuation. A PM_{10} intake and a $PM_{2.5}$ inlet are included in the equipment.
- NO_x and NH_3 : Based on the chemiluminescence technique, with a detection range of 0 to 2000 g/m^3 and a minimum detection limit of 0.5 g/m^3 .
- SO_2 Analyzer: Operates on the UV Fluorescence technique, with a detection range of 0 to 2000 g/m^3 and a minimum detection limit of 0.5 g/m^3 .
- CO Analyzer: Uses the Non-Dispersive Infrared Spectrometry (NDIR) method to measure CO levels ranging from 0 to 100 mg/m^3 with a detection limit of 0.03 g/m^3 .
- O_3 Analyzer: Works on the UV Photometry principle, with a range of 0 to 2500 g/m^3 and a minimum detection limit of 0.5 g/m^3 .

- BTEX (Benzene, Toluene, Ethylbenzene, Xylene): GC/PID for automatic monitoring of BTEX in air with a minimum detection threshold of 10 ppt in ambient air.
- Multigas Calibrator: used to manually, remotely, or automatically calibrate gas analyzers for quality assurance. Up to 20 points of multi-calibration Ultrasonic Wind Sensor, Barometric Pressure, Temperature, Relative Humidity, Rainfall, Solar Radiation, and other features of an automatic weather station (AWS).
- Except for the AWS, all of these instruments are kept in a room or walk-through shelter with an appropriate sampling system for gaseous and particulate matter measurements.

B. Our Contribution

In this research,

- 1) We propose an effective combination method to forecast and anticipate air quality and pollution in specific areas by combining the advantages of statistical and machine learning methods.
- 2) Additionally, this research suggests that prediction accuracy differs between Indian cities and regions.
- 3) We predicted annual PM 2.5 concentration levels in different places throughout Hyderabad using time series analysis, regression, and Ada boosting, depending on a variety of meteorological and surface characteristics like wind speed, air temperature, pressure, and so on.
- 4) The investigation's data set was obtained via Kaggle, and the suggested strategy was tested.

C. Organization of the Paper

The remaining paper is structured as follows- Literature review in this domain is presented in Section II. Section III provides preliminaries related to machine learning and other statistical techniques. Section IV presents our proposed hybrid method. The experiment results with comparative results are mentioned in Section V. Conclusions are discussed in Section VI.

II. RELATED WORK

Gopalakrishnan (2021) [26] used Google Street View data and machine learning to predict air quality in various locations throughout Oakland, California. The author created a web application that can predict pollution levels in any city and neighbourhood. Sanjeev (2021) [27] examined a set of data that would include pollutant concentrations as well as meteorological factors. Castelli et al. (2020) [28] used the Support Vector Regression (SVR) ML algorithm to forecast air quality in California in terms of pollutants and particulate levels. The researchers claimed to have created a novel method for modeling hourly atmospheric pollution. In [29] Doreswamy et al. (2020) investigated ML predictive models for PM concentration forecasting in the air. The authors examined six years of Taiwanese air quality monitoring data and applied existing models. They claimed that predicted and actual values were extremely close. Based on 11 years of data,

Liang et al. (2020) [30] investigated the performance of six ML classifiers in predicting Taiwan's AQL. Madan et al. (2020) [31] compared the performance of ML algorithms and twenty different literary works over pollutants studied. The authors discovered that many works used meteorological data such as humidity, wind speed, and temperature to more correctly estimate pollutant concentrations. They discovered that the Neural Network (NN) and boosting models outperformed the other leading machine learning (ML) algorithms. Monisri et al. (2020)[32] gathered air pollution data from a variety of sources in order to create a mixed model for predicting air quality. The proposed model, according to the authors, aims to assist people in small towns in analysing and forecasting air quality. Based on ML classifiers, Nahar et al. (2020) [33] created a model to predict AQI. Their proposed model accurately detected the most contaminated areas. Patil et al. (2020) presented some research papers on various machine learning techniques for AQI modeling and forecasting. Multi-agent systems[11,12] have been proposed as a helpful apparatus for huge scope frameworks like Important traffic and air quality control). The significant objective of such a framework is to help street administrators with traffic the board tasks while likewise further developing air quality on the course. Many examinations have proposed the use of MAS innovation in traffic signal and the executives frameworks, for example, (Namoun et al. 2013), which proposes an incorporated technique for demonstrating transportation framework and streamlining transportation in metropolitan regions to diminish fossil fuel byproducts.

In the hybrid classification PM2.5 fixation determining models, highlight determination is seldom applied in several techniques. Nonetheless, assuming that a PM2.5 fixation determining model's feedback incorporates an enormous number of elements (PM 2.5 etc.), it could be hard to prepare the model and increment the preparation time. This affects the PM2.5 fixation anticipating model's power [14]. At the same time, muddled info information might bring about overfitting of the model and a decrease in model precision [15]. The guideline parts investigation (PCA), stage space transformation (PSR), and angle helped relapse tree are at present famous component choice methodologies (GBRT).

Notwithstanding, on the grounds that these techniques assume a direct framework, they might be insufficient for air contamination focus arrangements, bringing about issues, for example, inability to accomplish worldwide ideal decrease. The fluffy hypothesis based unpleasant sets characteristic decrease (RSAR) strategy offers the benefits of unambiguous stop measures and no boundaries [16]. Through the reliance between particular ascribes, RSAR can decide the objective property's fundamental trait set. The RSAR calculation [17] is a well known review point. Information mining and examination as often as possible utilize grouping methods [33]. K-implies grouping (KC) [18], probabilistic c-means (PCM) [19], fix clustering [20], and other bunching approaches exist. The KC algorithm, when compared to others, gives an advantage based on easy procedure, quick computation speed, and great clustering results; as a result, it is currently the most extensively used clustering algorithm[21]. Combining the RSAR and KC algorithms allows the RSAR method to generate suitable, which is a promising exploration course.

III. MACHINE LEARNING TECHNIQUES

Atmospheric particulate matter (PM) is one of the pollutant that may have a significant impact on human health. Data collected from various regions of country can be analysed using various models : a multiple linear regression model, a neural network models and other machine learning models. In this section, we present some significant statistical preliminaries, soft computing based methods and mathematical notations [2,4,7].

A. Artificial Neural Network

It is a collection of classifiers whose standard project for future and utility are similar to the algorithmic model of human cerebrum structure [1]. The precise organisation of neuronal organisation varies for order enquiry. To begin, the topological structure and number of organisation hubs present in the core layer are resolved throughout the preparation. For example, n-dimensional planes and hyperplanes have no eccentricity, unlike SVM. In any event, preparing informational collection measures takes time and results in less precise and proficient results. Fig. 1 provides ANN framework and its input parameters.

- For singleton data sequence, $x_0, x_1, x_2, x_3 \dots x_{(n)}$ depicts several data items to the computational network. Each input is being multiplied with a corresponding weights. These weights are depicted as $w_0, w_1, w_2, w_3 \dots w_{(n)}$. These weight represents the major strength of any specific node.
- Here b is considered as a bias value. A certain bias value permits to move the enactment increasing or decreasing work.
- In most straightforward cases, these items are added, taken care of a transfer function (activation function) to produce an outcome, and this outcome is sent as yield.

$$x_1.w_1 + x_2.w_2 + x_3.w_3 \dots x_n.w_n = \sum x_i.w_i$$

- Presently, enactment (activation) function is applied, i.e. $\phi(\sum x_i.w_i)$

B. Support Vector Regression

Its well known that the categorization method comes in either supervised method or unsupervised method. Therefore, in the field of ML, support vector network architecture comes in the category of supervised machine learning standards. An SVM [2, 3] is the description of features / attribute states in the plane, alongside the non-direct hyperplanes for detachment task in order. A few boundaries like gaussian parts, standard deviation and fluctuation of information, bit capacities are some critical boundaries which influence the exhibition of SVM.

Fig. 2 provides the SVM framework and its representation.

1) Linearly-separable data aided Binary classification:

- **Goal:** we need to discover the hyperplane (for example choice limit) directly isolating to listed class. The limit of listed the condition: $w^T x + b = 0$.
- Any of the classes that falls this decision boundary must be label to 1. i.e., x_i such that $w^T x + b > 0$ will be having respective $y_i = 1$.
- Likewise, anything underneath the choice limit ought to have labeling - 1. i.e., x_i s.t. $w^T x + b < 0$ will possesses respective $y_i = -1$.

C. Learning

This section lists out various types of learning and tries to find out the answer of the question that, why deep learning outperforms over other traditional algorithms? The discussion is given below.

Types of learning:-

Various learning methods are mentioned below:-

1) *Active learning:* It picks a subset of an unstructured and basic event for reason for marking. The dynamic learner acquires bigger precision utilizing decreased measure of events.

2) *Kernel-based learning:* It is demonstrated to be a predominant approach to upgrade the computational potential proficiently. It is profitable with respect to that, both direct just as non-straight vector bit utilitarian strategies are available

to manage the non-linearity of information in N-dimensional element space.

3) *Transfer learning*: It is primarily advantageous as it can productively apply information, which has been adapted already so as to discover answer for new issues in quick, optimal and successful way.

4) *Distributed learning*: This sort of learning restrains the bunch arrangement, in which one processes thread is designated to each group in plan to perform multi-stringing in parallel and distributed fashion.

5) *Deep learning*: This learning considers more muddled, compartmented measurable examples of data sources and figures out how to be robust for new areas when contrasted with customary learning frameworks.

6) *Supervised learning*: It deals with learning a function from available training set data. A supervised learning algorithm uses the accessible training information and makes an induced capacity, which can be used further for the purpose of mapping the new ones.

7) *Unsupervised learning*: It manages unlabeled information without taking any predefined dataset for its preparation. This learning can be considered as an intense apparatus for look for patterns and trends and analysing available data. It is commonly employed for clustering similar input into logical groups.

8) *Classification*: is learning an specific function that maps (orders) an information thing into one of a few predefined categories [24]. Instances of grouping techniques utilized as a feature of information revelation applications remember the arranging of patterns for money related business sectors and the computerized recognizable proof of objects of revenue in enormous image oriented data sets [25]. The bank may exploit the characterization districts to consequently choose whether future credit candidates will be given an advance or not.

9) *Regression*: is learning a limit that maps a data thing to a real-valued esteemed forecast variable. Relapse applications are many, for instance, predicting the proportion of biomass present in a backwoods given distantly detected microwave estimations, assessing the likelihood that a patient will endure given the after effects of a bunch of analytic tests, anticipating shopper interest for another item as a component of promoting use, and foreseeing time arrangement where the information factors can be time-slacked adaptations of the prediction variable.

10) *Clustering*: is a typical graphic assignment where one looks to distinguish a limited arrangement of classifications or bunches to portray the information. The classes can be commonly exclusive and thorough or comprise of a more extravagant portrayal, for example, various leveled or covering classifications. Instances of bunching applications in an information disclosure setting incorporate finding homogeneous sub populaces for various customers in advertising data sets and distinguishing subcategories of spectra from infra-red sky estimations.

D. Information and Decision System

An instance of *information system* is represented as pair (U, A) where,

U : denotes - a kind of non-empty set.

A : denotes - a non-empty type finite set of features.

However, A *decision table* is a system possessing the form $S = (U, C \cup \{d\})$ where -

C : denotes set of conditional variables.

d : denotes the decision variable.

E. Uncertainty Approximation

The approximation extent of an uncertain variety of concept in a knowledge space is performed as follows - Let $S = (U, R)$ be a certain approximation space, X be a type of concept in that space, then, the *lower approximation*(inf) is-

$$\underline{R}X = \{x \in U \mid [x] \subseteq X\}$$

upper approximation(sup) is-

$$\overline{R}X = \{x \in U \mid [x] \cap X \neq \emptyset\}$$

where, $[x]$ can be considered as equivalence class, possessing an element e .

IV. PROPOSED METHOD

We propose an efficient method that uses statistical method and machine learning techniques for Air Quality Predication. In this section, we present our proposed method in phased manner as follows:

A. Data Preprocessing

Various preprocessing procedures, in overall, come before the learning phase. In India, O₃, PM_{2.5}, PM₁₀, CO, SO₂, and NO₂ pollutants are monitored with respect to its concentration. Our method used the air quality data [22] between Nov 2019 to April 2020, that are collected from several monitoring stations across major metropolitan cities such as Delhi, Mumbai, Chennai, Bangalore and Hyderabad of India and reported via the Govt website [22]. At any given time, an inaccurate parameter will not influence the global data group.

B. Feature Selection

To get an efficient representation of data, the auto encoder procedure must capture very important features using several measures which are part of the method.

Given sequence of data points $x(1), x(2), x(3), \dots, x(N)$, where $x^i \in R^D$, an auto encoder first encodes the info vector x to a more elevated level secret portrayal y in view of condition (1), and after ward it unravels the portrayal y back to a remaking z , determined as in condition (2):

$$y = f(W_1x + b) \quad (1)$$

$$z = g(W_2y + c) \quad (2)$$

where W_1 and W_2 are weights chosen for the procedure and b and c are the vectors of corresponding function. We utilized the strategic sigmoid capacities for $f(x)$ and $g(x)$ in this method.

$$\text{Sigmoid function} = 1/(1 + \exp(-x))$$

The boundaries of this neural organization are enhanced to limit the normal remaking error:

$$j(\theta) = \frac{1}{N} \sum_{i=1}^N M(x^{(i)}, z^{(i)}) \quad (3)$$

In this a loss function is M . We involved the customary squared blunder in our method.

C. Statistical Modeling

The underlying dividing step can be done at least numerous times to wipe out the non-stationarity of the mean capacity, and the accompanying quantifiable approach for showing is used as the info data exhibits proof of non-stationarity in the sensation of mean.

BEGIN PROCEDURE {

Consider, process PROC(α, β, γ) where; α, β, γ are +ve integers.

α : no. of lags.

β : difference degree

γ : order of the moving average model

for an input time series pollution data D_t , here index of integer is t and D_t are real numbers.

PROC(α', γ) is given by -

$$D_t - a_1 D_{t-1} - \dots - a_{\alpha'} D_{t-\alpha'} = \varepsilon_t + \theta_1 \varepsilon_{t-1} + \dots + \theta_\gamma \varepsilon_{t-\gamma} \quad (4)$$

above equation can be equivalently represented as -

$$\left(1 - \sum_{i=1}^{\alpha'} a_i M^i\right) D_t = \left(1 + \sum_{i=1}^{\gamma} \theta_i M^i\right) \varepsilon_t \quad (5)$$

here, M is lag operator

a_i - autoregressive parameters

θ_i - average part parameters

ε_t are represented as error terms

$\nabla \varepsilon_t$ are considered to be iid (independent, identically distributed) variables and these are normal distribution samples with zero mean.

Consider the polynomial $\left(1 - \sum_{i=1}^{\alpha'} a_i M^i\right)$ has a unit root of multiplicity β . The mentioned polynomial also can be rewritten as -

$$\left(1 - \sum_{i=1}^{\alpha'} a_i L^i\right) = \left(1 - \sum_{i=1}^{\alpha' - \beta} \varphi_i M^i\right) (1 - M)^\beta \quad (6)$$

with polynomial factorization property,

$\alpha = \alpha' - \beta$ and given as -

$$\left(1 - \sum_{i=1}^{\alpha} \varphi_i M^i\right) (1 - M)^\beta D_t = \left(1 + \sum_{i=1}^{\gamma} \theta_i M^i\right) \varepsilon_t \quad (7)$$

this can be further generalized as -

$$\left(1 - \sum_{i=1}^{\alpha} \varphi_i M^i\right) (1 - M)^\beta D_t = \delta + \left(1 + \sum_{i=1}^{\gamma} \theta_i M^i\right) \varepsilon_t \quad (8)$$

where, drift $\rightarrow \frac{\delta}{1 - \sum \varphi_i}$

} END PROCEDURE

D. Model Evaluation

To build a model to predict concentrations, we used two different machine learning algorithms including a simple linear regression model and non linear regression. The NO2 dataset was split into test/train data and a cross-validation approach was applied to the training dataset. We use Linear Regression and A da-boosting for improving efficiency of the results.

When the quantity of PM 2.5 and PM 10 pollutant particles in the atmosphere is indeed very high, it has a negative impact on our health and can cause life-risk issues in a less period of time. Particulate matter has been shown to have an effects on peoples health, often at the genetic level, according to studies. So we are emphasising our work to forecast the concentration of PM 2.5 levels in the atmosphere. "Hyderabad Weather with Air Quality index and Covid" dataset is used. The dataset [22] is downloaded into .csv format. Brief about the datasets are as follows: It consists of a total of 5 months of data between October 2019 to April 2020 as described below:

- Date: dd/mm/yyyy
- Humidity
- Wind Speed
- Dew Point
- Temperature
- Pressure
- Festival (Rating out of 5)
- Lockdown (0 for No, 1 for Yes)
- Covid-19 Cases in Hyderabad
- Air quality (PM2.5)

Fig. 3 shows the first 10 rows along with the column values of the dataset when reading the csv file into the colab file.

```
df = pd.read_csv('/content/Hyderabad-AirQ -2019-20.csv')
df.head(10)
```

	Date	Humidity	Wind Speed	Dew Point	Temperature	Pressure	Festival	Lockdown	Covid-Case	PM2.5
0	01-10-2019	83.0	4.5	76.0	81.9	28.1	0	0	0	84
1	02-10-2019	81.6	4.6	77.4	83.6	28.1	0	0	0	83
2	03-10-2019	82.0	3.7	75.3	81.7	28.1	0	0	0	81
3	04-10-2019	85.4	2.7	73.9	78.6	28.1	0	0	0	94
4	05-10-2019	87.4	3.5	75.3	79.4	28.1	0	0	0	112
5	06-10-2019	86.3	2.5	73.3	77.9	28.1	4	0	0	97
6	07-10-2019	82.9	2.4	76.0	81.6	28.1	0	0	0	126
7	08-10-2019	86.2	3.1	76.3	80.6	28.0	3	0	0	125
8	09-10-2019	88.7	1.7	74.5	78.1	28.0	0	0	0	132
9	10-10-2019	85.6	3.4	72.9	77.3	28.1	0	0	0	138

Fig. 3. First 10 rows along with column of the dataset.

We pre-processed it, check if there is any null value inside it and removed it. After the data has been cleaned and pre-processed, it is submitted to later experiment, which includes time series analysis and determining the total impact

of each characteristic on the PM 2.5 value. Date is also an impacting factor which shows the PM 2.5 values increasing or decreasing with time. So we grouped them and find the values of each attribute. Fig. 4 shows the grouped values of each attribute. With the help of these values we are plotting the variation of PM 2.5 w.r.t date. Fig. 5 shows graph plot of PM 2.5 vs Date.

```
[ ] df= df.groupby("Date").mean()
df.head(10)
```

Date	Humidity	Wind Speed	Dew Point	Temperature	Pressure	Festival	Lockdown	Covid-Case	PM2.5
01-03-2020	62.5	5.3	67.3	82.7	28.1	0	0	1	113
01-04-2020	62.0	3.9	72.0	92.6	28.1	0	1	96	120
01-10-2019	83.0	4.5	76.0	81.9	28.1	0	0	0	84
01-11-2019	82.7	4.8	75.3	81.3	28.1	1	0	0	57
01-12-2019	80.7	5.5	71.7	79.2	28.2	0	0	0	147
02-03-2020	58.9	4.6	67.3	84.0	28.1	0	0	1	114

02-10-2019	81.6	4.6	77.4	83.8	28.1	0	0	0	83
02-11-2019	79.8	4.3	75.3	82.4	28.1	2	0	0	61
02-12-2019	86.3	5.8	71.1	75.3	28.2	0	0	0	144

Fig. 4. Grouped values of the dataset.

The format of date is $xx - zz - yy$ where xx is date, zz is month and yy is year. The value of PM 2.5 is increasing yearly. In December its value is higher as compared to other months. December is a winter month, so we say that in the winter months PM 2.5 value is high.

Fig. 5. PM 2.5 vs Month.

The effect of wind on PM 2.5 is also investigated. The PM 2.5 value was found to be lower when the wind speed was high, and vice versa. Fig. 6 shows a scatter plot of wind speed vs PM 2.5 value, which confirms that we have higher wind speed concentrations. It's also worth noting that when the wind speed is between 6–10m/s, PM 2.5 levels are essentially non-existent.

Fig. 6. Effects of PM 2.5 due to wind speed.

The impacts of humidity on PM 2.5 is investigated. The value of PM 2.5 value was found to be lower when the humidity value ranges between 30 gm^3 to 60 gm^3 . Its value increases to $120 \mu\text{m}$ when humidity value ranges between 60 gm^3 to 80 gm^3 . Fig. 7 shows a scatter plot of humidity vs PM 2.5 value.

Fig. 7. Effect of humidity on PM 2.5 values.

The effect of dew drops on PM 2.5 was found to be lower when dew drops value ranges between $60^\circ\text{F} - 65^\circ\text{F}$ and PM 2.5 value increases when dew points value ranges between 65° to 75° . Fig. 8 shows a scatter plot between PM 2.5 vs Dew Points

Fig. 8. Effect of dew points on PM 2.5.

Similarly the impacts of temperature on PM 2.5 is investigated. Its value was found lower when the value of temperature

increases whereas the value of PM 2.5 increases when the temperature is lower. It shows that at winter season PM 2.5 value increase into the atmosphere. Fig. 9 shows a scatter plot between PM 2.5 vs Temperature.

Fig. 9. PM 2.5 vs temperature.

Also the effects of pressure is investigated on PM 2.5. Fig. 10 shows a scatter plot between PM 2.5 and Pressure.

Fig. 10. PM 2.5 vs pressure.

V. EXPERIMENT RESULTS AND COMPARATIVE ANALYSIS

We present experiment results of our proposed methods and efficiency analysis among several methods.

A. Metrics

Firstly, we brief the metrics used for measuring the results are discussed below:

1) *Mean Absolute Error (MAE)*:: It refers to the size of the difference between the predicted and true value of an observation. The average of absolute errors for the entire group is used to calculate the size of mistakes for a group of forecasts and observations.

$$MAE = \frac{1}{n} \sum_{i=1}^n |\tilde{Y}_i - Y_i|$$

In this N is the total number of data items, y_i is i -th measurement, and \tilde{Y}_i is its respective prediction.

2) *Root Mean Square Error (RMSE)*:: One of the most often used approaches for assessing the validity of estimates is root mean square error, also known as root mean square deviation. It uses Euclidean distance to demonstrate how far predictions differ from observed true values.

$$RMSE = \sqrt{\frac{\sum_{i=1}^n |Y_i - \tilde{Y}_i|^2}{n}}$$

In this N is the total number of data items, y_i is i -th measurement, and \tilde{Y}_i is its respective prediction.

3) *R2_score*:: The coefficient of determination, often known as the R2 score, is used to assess the performance of a linear regression model.

$$R2_{score} = 1 - \frac{\sum_{i=1}^n (Y_i - \tilde{Y}_i)^2}{\sum_{i=1}^n (Y_i - \mu)^2} \quad (9)$$

In this N is the total number of data items, y_i is i -th measurement, and \tilde{Y}_i is its respective prediction and μ is the mean of actual values.

B. Methods: Experiment Results

We present experiment results of our proposed methods by adopting linear regression, Ada-boosting and XG-boosting on standard data sets available on Kaggle [22].

1) *Linear regression*: We get the values of R2 is very less or nearly equal to 0.5. Absolute mean error is 27.33 when temperature vs PM 2.5 Linear Regression calculated. Root mean square error is 30.31 when temperature vs PM 2.5 Linear Regression is calculated. Table I shows the comparative result of mean absolute error, mean square error and r2 score. Fig. 11(a), (b) show the comparative analysis graph. As absolute mean error and root mean square error are the errors so when their value is small, then the model is good. And $r2_score$ calculates the accuracy of the model so when their value is high, model is good.

TABLE I. COMPARATIVE RESULT OF EVALUATION METRICS.

Factors/Error	MAE	RMSE	R2_score
Humidity	29.51	35.99	-0.07
Wind Speed	35.39	41.93	-0.54
Dew Point	31.58	34.58	-0.06
Temperature	27.33	30.31	0.2
Pressure	29.28	33.86	0.0

(a) Training (left) and testing (right) results for PM2.5 vs. Humidity

(b) Training (left) and testing (right) results for PM2.5 vs. Wind speed

(c) Training (left) and testing (right) results for PM2.5 vs. Dew-point

(d) Training (left) and testing (right) results for PM2.5 vs. Temperature

(e) Training (left) and testing (right) results for PM2.5 vs. Dew Pressure

Fig. 11. Training and testing results.

Fig. 11(a) represents training and testing results between PM2.5 and Humidity. Fig. 11(b) represents training and testing results between PM2.5 and Wind speed. Fig. 11(c) represents training and testing results between PM2.5 and Dew-point. Fig. 11(d) represents training and testing results between PM2.5 and Temperature. Fig. 12. Comparative analysis of mean square errors and root mean square error.

Fig. 12 shows the comparative analysis of mean square errors and root mean square error.

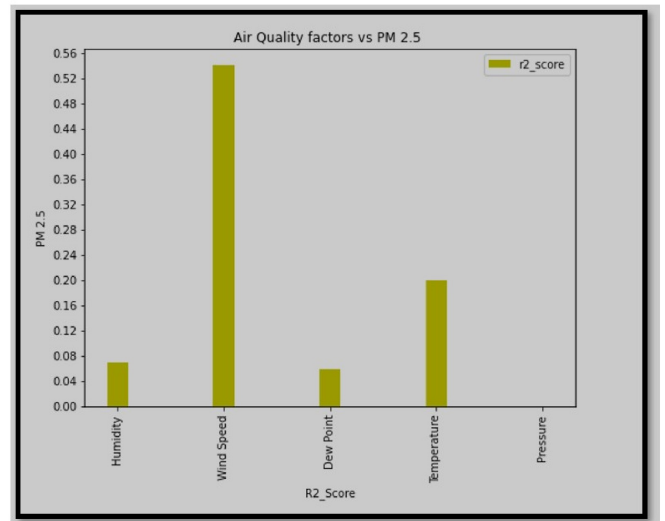

Fig. 13. Comparative analysis of r_2_score on atmospheric factors.

2) *Ada-Boosting*: We get the values of R2 is very less or nearly equal to 0.38. Absolute mean error is 22.39 when temperature vs PM 2.5 Ada-Boosting Regression calculated. Root mean square error is 26.42 when temperature vs PM 2.5 Ada-Boosting Regression is calculated.

Table II shows the comparative result of mean absolute error, mean square error and r_2 score. Fig. 13 and 14 shows the comparative analysis graph.

TABLE II. COMPARATIVE RESULT OF EVALUATION METRICS

Factors/Error	MAE	RMSE	$R2_score$
Ada- Humidity	27.68	35.55	-0.10
Ada-Wind Speed	29.33	36.41	-0.16
Ada-Dew Point	27.35	30.76	-0.17
Ada-Temperature	22.39	26.42	0.38
Ada-Pressure	28.99	33.44	-0.02

Fig. 14. Comparative analysis of mean square errors and root mean square error using Ada-Boosting.

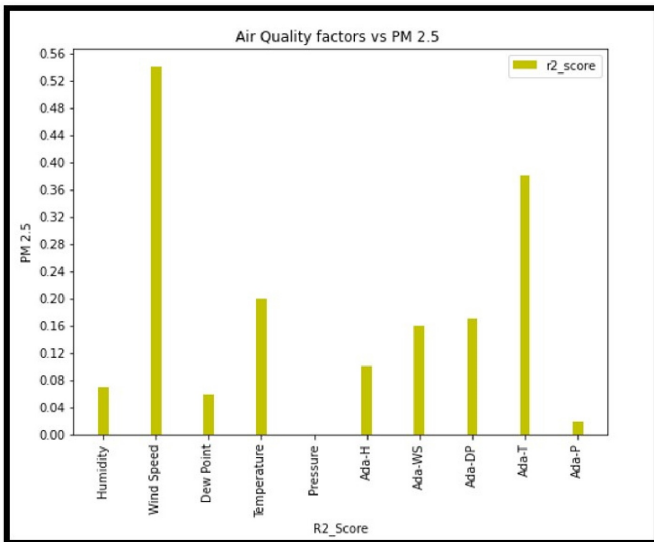

Fig. 15. Comparative analysis of $r2_score$ using Ada-Boosting.

3) *XG-Boosting regression*: We get the values of $r2_score$ is very less or nearly equal to 0.23 when PM 2.5 vs Humidity is calculated. Mean Absolute error is 28.09 when humidity

vs PM 2.5 XG-Boosting Regression calculated. Root mean square error is 35.07 when dew points vs PM 2.5 XG-Boosting Regression is calculated. Table III shows the comparative result of mean absolute error, mean square error and $r2$ score. Fig. 15 and 16 show the comparative analysis graph.

TABLE III. COMPARATIVE RESULT OF EVALUATION METRICS

Factors/Error	MAE	RMSE	$R2_score$
XGB- Humidity	28.09	37.62	-0.23
XGB-Wind Speed	32.31	42.10	-0.5
XGB-Dew Point	28.67	35.07	-0.07
XGB-Temperature	29.65	38.92	-0.32
XGB-Pressure	28.30	32.87	-0.05

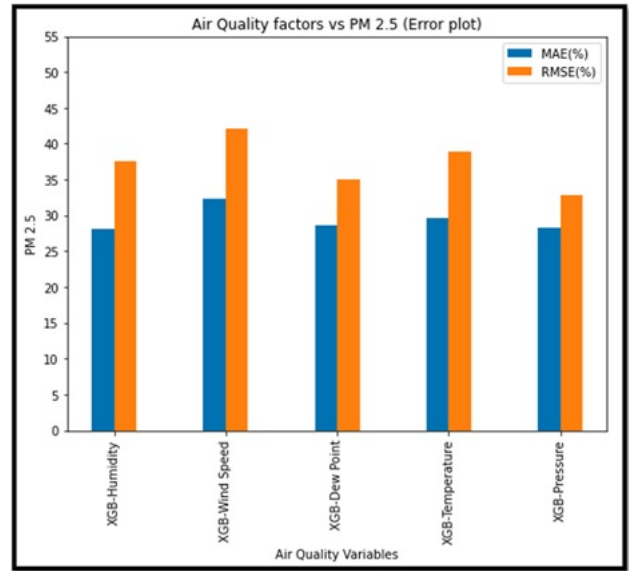

Fig. 16. Comparative analysis of mean square errors and root mean square error using XG-Boosting.

Fig. 17. Comparative analysis of $r2_score$ using XG-Boosting.

4) *Efficiency analysis of models:* Final comparative result of all the models are given in a Table IV and the comparative graph is shown in Fig. 17.

TABLE IV. COMPARATIVE RESULT OF EVALUATION METRICS

Factors/Error	MAE	RMSE	R2_score
LR-Humidity	29.51	35.99	-0.07
LR-Wind Speed	35.39	41.93	-0.54
Dew Point	31.58	34.58	-0.06
L-Temperature	27.33	30.31	0.2
Pressure	29.28	33.86	0.0
Ada- Humidity	27.68	35.55	-0.10
Ada-Wind Speed	29.33	36.41	-0.16
Ada-Dew Point	27.35	30.76	-0.17
Ada-Temperature	22.39	26.42	0.38
Ada-Pressure	28.99	33.44	-0.02
XGB- Humidity	28.09	37.62	-0.23
XGB-Wind Speed	32.31	42.10	-0.5
XGB-Dew Point	28.67	35.07	-0.07
XGB-Temperature	29.65	38.92	-0.32
XGB-Pressure	28.30	32.87	-0.05

VI. CONCLUSION

Worldwide, air pollution is responsible for around 1.3 million deaths annually according to the World Health Organization (WHO) [11]. The depletion of air quality is just one of harmful effects due to pollutants released into the air. In this paper, we propose an efficient combined technique that takes the benefits of multi-agent systems, statistical techniques and machine learning techniques for forecasting Air Quality utilizing supervised machine learning procedures. We used Linear Regression and Ada-boosting for improving efficiency of the results. As part of our future work, we will improve our results using various deep learning techniques. Further, we will explore whether adopting lag meteorological variables and tuning the hyper parameters to improve the accuracy of the model.

Fraud Mitigation in Attendance Monitoring Systems using Dynamic QR Code, Geofencing and IMEI Technologies

Augustine Nwabuwe, Baljinder Sanghera, Temitope Alade, Funminiyi Olajide
Department of Computer Science, Nottingham Trent University, Nottingham, NG11 8NS UK

Abstract—Attendance monitoring is a vital activity in several organizations. Due to its importance, many attendance monitoring systems have been developed to automate this process. Despite several advancements in automated attendance management solutions, attendance fraud remains an issue as some end users can manipulate known vulnerabilities, such as proxy attendance, buddy-punching, early departure, and so on. In this paper, a fraud-resistant attendance management solution is developed by harnessing technologies such as geofencing, dynamic QR code and IMEI Checking. The proposed solution is comprised of a single-page web application where QR code can be enabled for attendance registration, and a mobile application, where end-users can scan generated QR code to register their attendance. Attendance cheating via QR code sharing is prevented by encoding the polygonal coordinates of the event venue in the QR code to determine if the user is within the venue. The proposed system solves the problem of proxy attendance by registering and verifying the end user's device IMEI number. Results obtained from testing indicate that attempts at committing a variety of attendance frauds are effectively mitigated.

Keywords—Attendance management systems; fraud prevention; dynamic QR code; geofencing; IMEI verification; software algorithms; mobile application

I. INTRODUCTION

Mobile technologies have changed the way attendance is monitored. Whether it is in schools, colleges, universities or organisations, attendance monitoring systems play a vital role in effective student or staff management. Certain metrics and statistics from attendance data can reveal vital information that can help management identify underlying problems that otherwise may not have been discovered [1]. Attendance monitoring has become ever more important in higher education institutes due to evidence of a positive correlation between attendance, engagement, and academic achievement [2]. Moreover, the UK visas and immigration (UKVI) require UK universities to ensure that all international student visa holders are engaging satisfactorily with their courses. Poor attendance or failure to engage with programmes could lead to being withdrawn from the university and the student visa being curtailed [3]. Despite the importance of attendance, high levels of student non-attendance continues to be a problem in schools and universities [4]. It is also worth noting that with a large student population, effective monitoring of attendance is a problematic task as users constantly look for ways to manipulate attendance monitoring systems, leading to inaccurate and false records. Current electronic techniques for attendance monitoring include the use of quick response (QR) code scan [5], radio frequency identification (RFID) [6], near field communication

(NFC) [7], biometrics technology [8], and global positioning systems (GPS) [9]. Each method has its own pros and cons such as cost, power, ease of deployment and operation, communication, privacy and accuracy, and attendance cheating. For instance, QR code attendance management systems which involve users using their smartphone to scan a QR code are vulnerable to fraud as the generated code can be easily shared amongst colleagues to commit attendance fraud. RFID-based attendance systems where attendance is completed by placing an RFID card on an RFID reader is a common approach. However, a crucial challenge with RFIDs is that students are unable to mark their attendance on days when they have lost or forgotten their ID cards, as RFID tags are embedded in the user's ID card. RFIDs are relatively expensive, and susceptible to buddy-punching, as users can fraudulently help their colleagues mark their attendance [6]. Biometric-based solutions such as face recognition, fingerprint recognition, and voice recognition are convenient as there are no lost cards and replacement problems given that users are essentially their own authentication. Face recognition technology uses image processing techniques to extract features and match a human face from a digital image or video against a database of faces. However, they are prone to the issue of false rejects, mismatch errors, and may not work if a user has an injury or scar [8]. There are also ways to invalidate face recognition systems, such as using a prepared photo or recorded video [10]. Biometric-based solutions are relatively costly and may also expose students' privacy. Furthermore, none of the above techniques effectively capture the problem of early exits and lateness. Tracking and maintaining accurate attendance records remains a challenge. Consequently, it is vital to understand the benefits and challenges of various approaches in order to effectively develop and deploy an attendance monitoring system that is highly resistant to attendance fraud and manipulation. This paper proposes to combine multiple fraud-prevention techniques including geofencing, dynamic QR code and international machine equipment identity (IMEI) checking to increase the reliability of attendance data and significantly reduce the possibility of committing attendance fraud. The main contributions are as follows:

- 1) A mobile application is built to allow users to be authenticated and carry out QR code scanning.
- 2) A single-page web application is developed to generate QR code, manage end user devices and user access, monitor and track attendance activities.
- 3) Geofencing around an area of interest, such as lecture venue or company location is implemented to prevent

end users from registering their attendance outside a specified virtual geographic boundary.

- 4) IMEI checking feature is implemented to ensure that end-users can only register their attendance from their own personal mobile device.
- 5) A new algorithm is created as a final layer of fraud prevention to ensure that generated QR code changes dynamically at set intervals.

The rest of the paper is organised as follows: Relevant related work is presented and analysed in Section II. Details of the system architecture and the core functionality of the proposed attendance monitoring system are discussed in Section III. The system performance under different scenarios of attendance fraud is examined in Section IV, and conclusions are presented in Section V.

II. BACKGROUND AND RELATED WORK

A. Radio Frequency Identification (RFID) based Solutions

Various approaches have been widely explored in literature to automate attendance monitoring in educational settings and organisations. Among these, radio frequency identification (RFID) based attendance monitoring systems [11] – [13], which utilize RFID Tags, also known as a transponder, attached to the identity (ID) card of the individual to be tracked is a popular approach. Students complete their attendance monitoring by placing their RFID card on a RFID reader. In [11], a RFID-based attendance monitoring system is proposed where each student record, and lecture schedules is electronically linked to the RFID tag of the student ID card. The RFID readers are then connected to a server for the information to be stored and processed in a database. Authors in [12] proposed and developed a RFID-based attendance management system with additional functionalities such SMS and email that notify stakeholders including parents and managers when specific metrics are triggered. More recently, RFID-based attendance monitoring systems that combine Internet of things (IoT) technology have also been proposed [13], where IoT devices are used to log, track and fetch attendance data on the cloud and made available for the user anytime and anywhere. Although RFID-based solutions can greatly improve attendance monitoring, the drawbacks are also obvious including but not limited to queuing problems during peak periods, recognition distance, lost or forgotten student ID cards. The cost of deploying RFID readers is relatively high. More critically, RFID-based solutions are susceptible to fraud via buddy-punching, as users could help their colleagues clock in and out of events [14]. As attendance is recorded and checked once, it is not possible to respond to the problem of early departure from scheduled events.

B. Near-Field Communication (NFC) based Solutions

The near-field communication (NFC) empowered attendance system similar in concept to RFID-based solution is proposed in [15], where a strategically located reading device exists to capture access attempts of users with embedded NFC devices, like phones and ID cards. Face identification was incorporated into the NFC-based attendance solution proposed in [16] to create a much more robust system. To enhance the security of NFC-based attendance system, the one-time

passwords (OTP) technology was integrated in [17]. NFC-based solutions are a more cost-effective alternative to RFIDs and are better optimised for power consumption. However, they are also susceptible to the problem of fake attendance or buddy-punching by students and employees.

C. Biometric based Solutions

To overcome the prolonged process of attendance marking associated with ID-based attendance management systems, biometric-based attendance methods are preferred. Biometric-based attendance management systems use users' distinct biological or physiological characteristics such as face, fingerprint, and iris to verify their requests [18]. A typical biometric system will include a reader, software for converting the scanned biometric data into a digital format and a database to store biometric data for future comparison. In [19], images of the user's fingertips are captured, and characteristics such as whorls, arches and loops are recorded. A major challenge with fingerprint-based attendance system is that it cannot recognise a wet or dirty finger [20]. An Iris recognition-based attendance system that utilizes biometric entropy was proposed in [21], where specific eye highlights peculiar to each user were extracted and transformed into a 512-digit Iris Code number. This code was stored as a unique identifier in a database and used to identify users. Face recognition technology is one of the most widely used in biometric-based attendance management systems due to its advantages of greater security, improved accuracy, and capability to easily integrate with other systems [22]. The underlying technologies in face recognition system are based on artificial intelligence and machine learning [23]. A face recognition attendance management system that utilizes the local binary pattern (LBP) algorithm and techniques like bilateral filtration and histogram equalization was proposed in [24]. The technique helped to address some of the issues associated with face recognition accuracy, like varying lighting conditions, image background, and noise in face images. This improved the recognition efficiency to as much as 95%. Biometric-based solutions are convenient; however, they are prone to the issue of false rejects (mismatch errors) and may not work if a user gets injured or scarred [9]. There are also ways to invalidate face recognition system such as using a prepared photo or recorded video [10]. Biometric-based solutions are relatively costly and may expose students' privacy [25].

D. QR Code based and Geolocation based Solutions

In recent years, QR code technology has significantly improved the efficiency and cost of deploying attendance monitoring systems. With the increasing popularity of mobile devices, attendance checking-related applications are deployed on mobile devices, and users can complete attendance checking by scanning a QR code. In [26], a QR code-based attendance management system was proposed which allows users to log on to a web-based application with their mobile phones and complete their attendance by scanning a QR Code generated by the class tutor using the QR code scanner on the web application. Mobile support for QR code makes it cost-effective as no special reading devices or ID cards are required but the problem of an imposter signing in remains. A user can bring the mobile phones of others into the classroom

to complete the attendance checking for them. Furthermore, given that QR code is unencrypted [27], the generated code can be easily shared amongst colleagues to commit attendance fraud. Aiming at solving this problem, location aware QR code attendance management systems have been proposed in [28], where users are required to scan a static QR code generated by the event organizer with a mobile application. Event details and the user’s location are stored in a remote database. Users are not allowed to register their attendance outside a specified virtual geographic boundary, known as a geofence. In [29], a mobile presence control information system that utilize the real-time location capabilities of mobile devices was used to demonstrate the effectiveness and reliability of mobile-based geolocation service. A geolocation-based attendance management system which uses geofencing to create a virtual box representing the classroom was proposed in [30] where the user’s exact location is then retrieved using GPS coordinates from their mobile devices. Other location-based attendance monitoring systems that use static QR Code and geolocation were proposed by [31] and [32]. The shortcoming of location-based attendance checking systems is proxy attendance where users can easily log in with their colleagues’ credentials on their devices and register their attendance.

E. International Mobile Equipment Identity (IMEI) based Solutions

The problem of proxy attendance in geolocation-based attendance management system can be addressed via the IMEI number. IMEI is a unique identification number allocated to each mobile device that serves as a base identification for every mobile phone [33]. It is a fifteen-digit number comprised of a type allocation number (TAC), a serial number and a check digit. It enables each device to be uniquely distinguishable from other mobile devices, as no two mobile phones have the same IMEI numbers. In [33], a solution to monitor the attendance of traffic officers was proposed that utilizes geolocation and IMEI number of the user’s mobile phone to monitor their attendance and effectively reduce cases of attendance cheating. A web-based student presence system that utilizes a combination of QR code and IMEI numbers was proposed in [34]. The IMEI number uniquely identified each student’s mobile device, and every attendance registration attempt was validated against it. Attendance fraud was reduced by ensuring that one student could use only one mobile device.

Therefore, this paper presents the design of a robust fraud-resistant attendance monitoring solution that integrates dynamic QR code, geolocation, geofencing, and IMEI checks to reduce attendance fraud. It is worth noting that no previous studies have explored the combination of these technologies and their potential to effectively mitigate fraud in attendance monitoring systems as illustrated in Table I.

III. PROPOSED ATTENDANCE MONITORING SYSTEM WITH FRAUD MITIGATION

A. System Architecture and Techniques

In this investigation, a robust attendance monitoring system that can effectively guard against fraud is achieved by combining dynamic QR code, geofencing, and IMEI technologies. The system primarily consists of two main parts as shown

TABLE I. COMPARISON OF CURRENT ATTENDANCE MONITORING SOLUTIONS WITH PROPOSED SOLUTION

in Fig. 1(a): a cross platform mobile application (app) for registering and collecting user information; and a single-page application (SPA) for administration and data analysis. The mobile app is developed to register the unique IMEI

Fig. 1(a). System architecture of the proposed attendance monitoring system with fraud mitigation.

number that precisely identifies the user’s mobile device (UE), detect the entry and exit of a UE by collecting geographical location (geo-location) of the UE every minute, scan a dynamic QR code to record attendance, and upload these data for processing. The SPA is developed to undertake administrative functions such as dynamic QR code generation, user and role management, event management, attendance management and analysis. The system is developed using the MERN (MySQL, Express, React, Node) development architecture as shown in Fig. 1(b), consisting of MySql for storing data, ExpressJS for URL routing and HTTP (hypertext transfer protocol) requests and responses handling, ReactJS for building the system’s user interfaces, and NodeJS as the runtime environment [35].

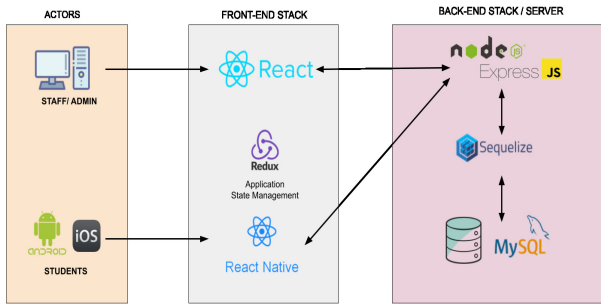

Fig. 1(b). Developmental framework of the proposed attendance monitoring system.

B. System Implementation

The techniques used for fraud mitigation including authentication and authorization, dynamic QR code generation, geofencing and IMEI checking are presented in the following sub-section.

1) *Authentication and authorization:* One of the main components of the proposed system is a robust authentication and authorization mechanism. To enable secure authentication, JavaScript object notation (JSON) web tokens (JWTs) are used, where for a successful login attempt by a user that provides correct credentials, a JWT access token and another JWT refresh tokens is generated and returned to the user agent [36]. To prevent security issues with JWT access tokens, they are stored in the application state managed by the Redux middleware, while the refresh tokens are stored in HTTP-ONLY cookies. This call happens automatically without affecting the user experience. The access tokens are given a short expiration time of 1 hour, while the refresh tokens are given a longer expiration time of 48 hours. The refresh tokens are automatically retrieved and used to generate a new access token whenever the access tokens expire. Fig. 2 presents the JWT authentication design process. The system uses a permission-based architecture [34] to maintain authorization which can be attached to defined roles and assigned to users. This design pattern enables flexible, dynamic, and robust authorization management. Permissions are checked at both the client and server sides to ensure that only authorized users can perform restricted tasks. Unauthorized user attempts at restricted resources are denied.

2) *Geofencing enforcement:* Geofencing is one of the main techniques for fraud mitigation in the proposed system where attendance registration is available only within a defined geofenced area. Users outside of the defined geo-fenced area will not be allowed to register their attendance for a scheduled event. Geofencing is implemented using Google Maps API [37] where each point on the geofence corresponds to a latitude and longitude coordinate as illustrated in Fig. 3. The entire geofence is thus an array of different latitudes and longitudes, forming a polygonal virtual boundary. For a given event, an authorized user must assign a venue in addition to other event information such as delivery method, date and time when creating a timetabled event. The system automatically records latitudes and longitudes to detect when the user enters and

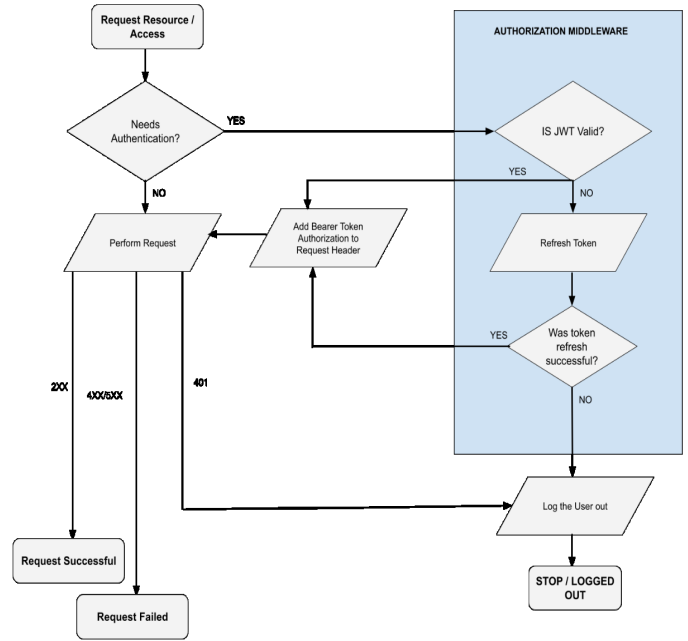

Fig. 2. JWT authentication workflow.

exists the defined geo-fenced area. The system enables the authorized administrative user to disable geofencing for events conducted online. As such, events marked as online will skip the geofence enforcement during attendance registration.

Fig. 3. Geofencing an event venue.

3) *Dynamic QR Code Generation and Scanning:* A critical fraud mitigation component of the proposed attendance monitoring system is dynamic QR code generation. For a given scheduled event, an authorized user such as a tutor can generate and display a two-dimensional QR code for attendance registration. The QR code generated encodes event information such as event title, date, start and end times, and more critically, the geofence polygonal coordinates of the event venue. Given that QR code are not encrypted, the contents of the generated QR code are encoded using base64 encoding format [38]. This makes the encoded content to appear encrypted and serves to prevent fraudulent users who may attempt to scan the QR code using a different QR code scanner. Fig. 4(a) illustrates the encoded data when scanned with a different scanner. A closer examination of the decoded

data shows information separated using slashes, as shown in Fig. 4(b). The individual components of this data are retrieved using JavaScript's split method [36]. The QR code is displayed on a screen where authenticated users can scan it using their UE. The entire process of scanning, decoding and retrieving the QR code encoded data occurs within milliseconds. One of the valuable pieces of information in the decoded data is the geofence polygonal coordinates of the event venue. With this data and the actual geocoordinate of the user, it is possible to determine if the user is within the venue's geofence. The ray casting algorithm [39] is modified and used to solve the problem of identifying whether a point is inside or outside of a polygon, a common geospatial problem in geofencing. Algorithm 1 shows the implementation of this algorithm.

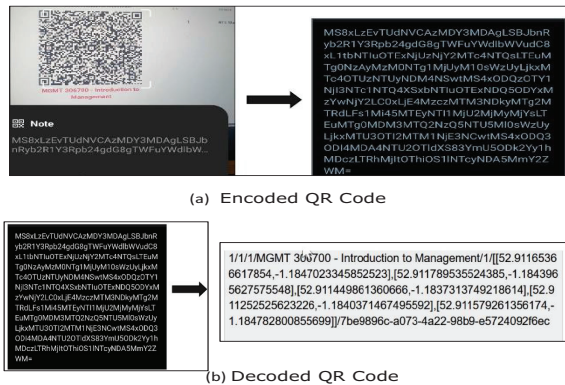

Fig. 4 QR code data.

The QR code generated automatically refreshes every 20s to solve the problem of proxy attendance via QR code sharing. In the unlikely event that geofencing functions are circumvented, the time sensitive QR serves to invalidate any shared QR code. A manual override functionality is implemented to allow an authorized user to manually register the attendance of users who may experience difficulties with the system or have misplaced or forgotten their UE. Once the UE's geo-coordinate is determined to fall within the lecture venue, their information is sent to the server to run final verification checks to determine if the attendance registration request should be approved. The following checks are done before final registration is approved:

- Check if the user is allowed to take the course
- Check if attendance registration is still enabled for the lecture
- Check if the attendance QR code ID has expired
- Check if the student has already marked attendance for the course.

If the above conditions are met, the attendance request is granted, and a successful notification is sent to the mobile app.

4) *IMEI registration and verification:* The proposed system implements IMEI registration and verification technique to solves the issue of proxy attendance which may occur when users log on to the system with their absent colleague's credentials to register attendance for them. When a user lunches

Algorithm 1 : Ray Casting Algorithm for Determining if a Point is Within a Polygon

```

1: Input: p is a simple polygon
2:  $G_i$  is the position of interest
3: Output: true if p contains  $G_i$ , otherwise false
4:  $count = 0$ 
5:  $s$  is an infinite ray in the  $+y$  direction, originating at  $G_i$ 
6: for each edge  $e$  in  $p$  do
7:   if  $G_i$  is within buf of  $e$  then
8:      $e_{x,buf} = e_x - 2 * buf$ 
9:   else
10:     $e_{buf} = e$ 
11:   end if
12:   if  $G_i \prec buf$  of  $e$  or  $e_{buf}$  then
13:     return false
14:   end if
15: end for

```

the mobile app for the first time, they are prompted to confirm whether to register the current UE as the primary device as illustrated in Fig. 5. If confirmed, the IMEI of the UE is requested and stored. This technique prevents fake attendance by ensuring that users can only register their attendance with their verified UE. For subsequent mobile app lunches, the IMEI of the UE is checked and compared against the stored value.

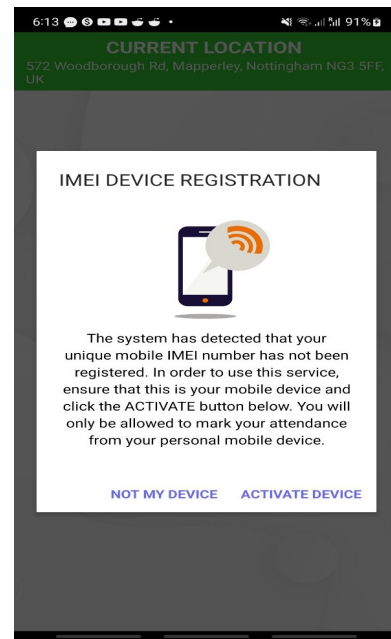

Fig. 5 IMEI registration window.

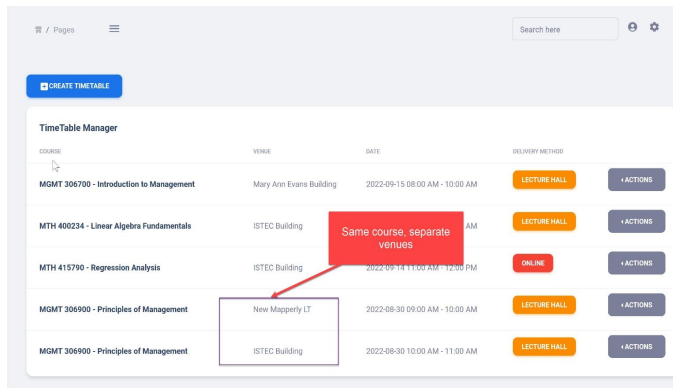

IV. EXPERIMENTAL RESULTS AND DISCUSSION

In this section, the performance of the proposed attendance monitoring system is investigated under three scenarios of attendance restriction. First, the effectiveness of geofencing restriction is tested as an end-user attempts to registering their attendance outside a specified geographic boundary of an event venue. Second, the dynamic QR code restriction is tested in a scenario where a generated QR code is sent to colleagues

in order to commit attendance fraud. Third, the capability of the attendance monitoring system to prevent registering a colleague's attendance from a their own personal UE is tested.

A. Experimental Setup

The web application is deployed on a server equipped with 3 cores and 4GB dedicated memory. The mobile app is deployed on mobile devices equipped with operating systems of Android 10 or later. Event venues named 'New Mapperly LT', 'Mary Ann Evans Building', and 'ISTEC Building' within a university environment, courses of study, event dates and times, are created by an authorized administrative user on the web application and used for testing as illustrated in Fig. 6. Two end-users are asked to register their UEs in order to register their attendance. Geofencing was implemented using the Javascript Google Maps API and location services was enabled on the UEs.

COURSE	VENUE	DATE	DELIVERY METHOD	ACTIONS
MGMT 306700 - Introduction to Management	Mary Ann Evans Building	2022-09-15 08:00 AM - 10:00 AM	LECTURE HALL	+ ACTIONS

Fig. 6 Timetable view for courses and event venues.

B. Scenario A: Geofencing Restriction

In order to test the effectiveness of the proposed attendance monitoring system to prevent proxy attendance, two event venues were created and mapped to different geolocations as shown in Fig. 6 to test geofencing restrictions. An end-user located at the New Mapperly LT venue attempts to register their attendance for both events holding at the New Mapperly LT and the ISTEC building venues. It is observed that attendance was successfully registered for the event held at the New Mapperly LT, however, the proxy attendance attempt for event held at the ISTEC building was prevented as shown in Fig. 7.

C. Scenario B: Dynamic QR Code Restriction

In order to assess the effectiveness of the dynamic QR code fraud mitigation mechanism, an end-user captured a generated QR code with their UE and sent it to another user within the same event venue. An attempt was subsequently made to register attendance registration using the shared QR code. It can be seen from the error message shown in Fig. 8 that the system successfully prevents this type of attendance fraud as the QR code generated refreshes every 20s.

Fig. 7 Effect of geofencing restriction technique.

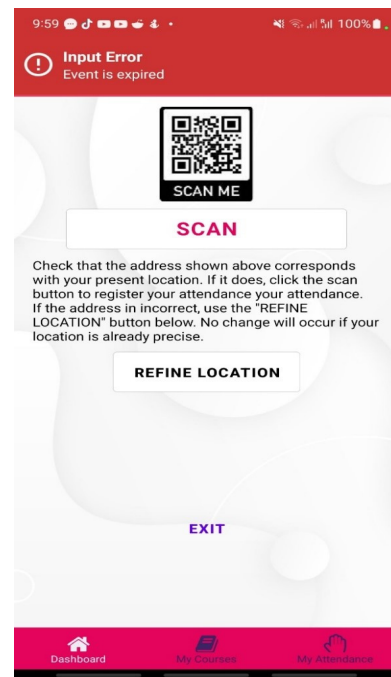

Fig. 8 Effect of dynamic QR code restriction technique.

D. Scenario C: IMEI Restriction

In order to demonstrate IMEI checks restriction, an end-user already registered on the application with their primary device attempts to register their attendance from another user's UE. It can be seen from Fig. 9 that system has effectively mitigated this fraudulent attempt as users are only allowed to register their attendance from their own personal UE.

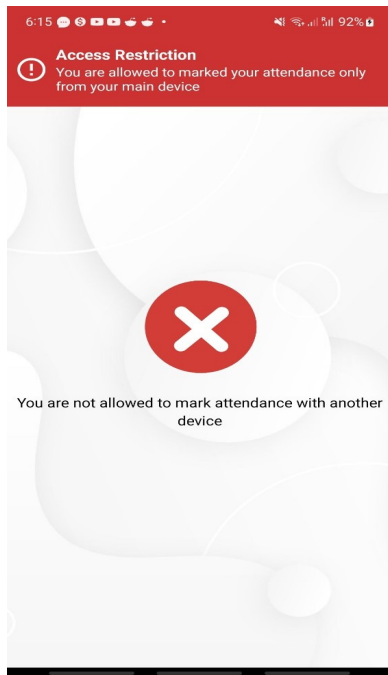

Fig. 9 Effect of IMEI restriction technique.

V. CONCLUSION

This study investigates attendance monitoring systems and proposes a fraud-resistant attendance monitoring system that utilizes a combination of geofencing, dynamic QR code and IMEI checks as preventive techniques to mitigate attendance fraud. A mobile app is developed for registering and collecting user information; and a single-page web app is built for administration and data analysis. Experimental results reveal that the solution effectively mitigates attendance fraud. End-users are effectively and securely authenticated and authorized to use the mobile and web app, and unauthorized user attempts at restricted resources are denied. Geofencing enforcement ensures that attendance registration is only available within a defined geofenced area and solves the proxy attendance problem. The dynamic QR code can only be used within a defined geofenced area, and is used only once within a set time interval to solve the problem of QR code sharing fraud. IMEI restrictions effectively restrict attendance registration to user's own personal UE and effectively eliminates the risk of buddy-punching fraud. This study is of significant importance to institutions and organizations where strict attendance compliance and reliable attendance data are of utmost importance. The efficiency of the application can be fundamentally improved by implementing an in-memory database like Memcached or Redis to cache blacklisted access and refresh tokens. The proposed system can be further enhanced by incorporating machine learning techniques to offer granular visibility into attendance patterns, highlighting those who frequently attempt to commit attendance cheating, as well as those who arrive late and leave scheduled events early. Behaviors like these in attendance data can be duly noted and rectified by the management, upholding engagement, academic achievement and optimal productivity levels in the organization.

Reverse Supply Chain Management Through a Quantity Flexibility Contract: A Case of Stochastic Remanufacturing Capacity

Changhao Zhang

Henan University of Animal Husbandry and Economy,
Zhengzhou, Henan, 450000, China

Abstract—This article investigates a two-echelon reverse supply chain (RSC) where a third-party logistics provider charges customers to return outdated products. A green manufacturer refurbishes qualified returned products through the remanufacturing process. Remanufacturing capacity is considered a stochastic variable. Under the volatility of remanufacturing capacity, some likely examined, and qualified products could not be remanufactured. If a collected product cannot be processed, it should be salvaged at a lower value and be perceived as a lost profit. In such scenarios, increasing the quantity of returned outdated products is suitable if there is a strong possibility of enough capacity in the remanufacturing process. This paper develops a stochastic model to identify the optimal order quantity under diverse contracts, including wholesale price, centralized, and quantity flexibility contracts. Under the quantity flexibility contract, the green supplier might cancel its preliminary order in a restricted quantity. Additionally, third-party logistics supplier offers a restricted quantity above the initial order to minimize understocking during peak seasons. Our numerical experiments demonstrate that the suggested quantity flexibility can coordinate the examined RSC under the volatility of remanufacturing capacity. Contrary to wholesale and centralized contracts, quantity flexibility is a more practical alternative from the perspective of participants' profitability.

Keywords—Reverse supply chain; channel coordination; uncertain remanufacturing capacity; quantity flexibility contract

I. INTRODUCTION

A reverse supply chain (RSC) comprises a series of actions that collect obsolete products from customers and return them to the original manufacturer or recycler for reprocessing or proper disposal [1]–[3]. The application of the RSC has financial, social, and environmental benefits. One of the fundamental obligations of a company to recycle its commodities is setting up an RSC; Xerox, Nike, Adidas, Sony, and Siemens are successful firms that built up their RSC [4]. Moreover, Consumers' sensitivity to environmental problems has driven corporations to highlight their recycling potential [5].

Typically, young customers in South Asia are aware of the eco-friendliness of a product's components; in some regions of the Middle East, this figure approaches 80 percent. Due to the increased environmental awareness among consumers and government intervention, many businesses have begun creating green goods [6]. Numerous goods are suitable for

remanufacturing or recycling. Electronic items, for instance, are among the most ideal for recycling due to their short life cycle, modular design, and the kind of raw material utilized [7]. For instance, 76 percent of a camera's components may be used multi times [8]. As a result, companies now put their efforts into green operations, specifically RSC, fully take advantage of their benefits.

Since 2020, the COVID-19 scenario has wreaked havoc on SCs; it produces extreme supply and demand oscillations, disrupting the corporate system. Upstream participants cannot foresee demand, and downstream participants cannot fulfill their responsibilities [9], [10]. A measure we can take for this problem is adopting coordination mechanisms [11]. SC members can set up coordinated contracts to make an SC that works well together. For example, a study by Bakhshi and Heydari (2021) demonstrated the value of investigating an option contract for coordinating the interaction between an e-retailer and a 3PL; they also compared the investigated contract with a penalty-based contract; the results show that the option contract incredibly increases the SC's total profit in comparison with other contracts. Some examples of these kinds of contracts are quantity flexibility contracts. Expressly, a great deal of research work has confirmed their applications in inventory management problems, and their findings have revealed that they can handle uncertainty well [12], [13]. Quantity flexibility contract has many capabilities and has been validated in various applications. For instance, Kord and Samouei (2023) studied a quantity flexibility contract for managing a humanitarian supply chain to buy a spot market under demand uncertainty. The results indicated the powerful performance of NPGA in terms of most evaluation indicators. The results indicated the powerful performance of NPGA in terms of most evaluation indicators.

Based on a quantity flexibility contract, a buyer can adjust its initial purchase up or down within a specified volume range. Thus, the buyer must purchase a minimum quantity, while the supplier must provide additional amounts if necessary [5], [14]. The industry can improve numerous real-world instances by implementing quantity flexibility contracts. Sun Microsystems purchases its workstations through QF contracts. Nippon Otis, a maker of elevator equipment, utilizes a quantity flexibility contract with the Tsuchiya plant, a manufacturer of components and switches. Toyota Motor Corporation, IBM, and Hewlett-Packard have also utilized quantity flexibility contracts [15].

This study aims to determine an effective strategy for stabilizing 3PL's position in an RSC. Meanwhile, this work highlights the necessity of optimal ordering decisions. In this respect, we try to answer the following questions:

QS1: What is the GS's optimal order quantity within concluded contracts?

QS2: Can the suggested quantity flexibility contract enhance the parties' profitability?

QS3: Which contract is preferred?

We evaluate a two-echelon RSC involving a green supplier who can refurbish eligible outdated products and a third-party logistics provider that collects such products from customers despite the unpredictability of remanufacturing capacity. We investigate the impact of a quantity flexibility contract in which the third-party logistics provider is the Stackelberg game leader. Under the quantity flexibility contract, the green supplier is permitted to reserve items without incurring a reservation charge and must buy a minimum amount. In contrast, the third-party logistics provider will be needed to collect additional products if required.

To the best of our knowledge, prior research has focused primarily on the significance of quantity flexibility contracts in forwarding supply chains with uncertain demand; in contrast, the current study investigates the impact of the quantity flexibility contract on an RSC with uncertain remanufacturing capacity. In other words, contrary to earlier studies, uncertainty has migrated from demand to supply. We based our model on this gap in the research.

The remainder of the article is categorized as follows: Our model setting and assumptions are illustrated in detail in Section II. Section III derives the optimum decisions in a variety of models. In Section IV, numerical analysis is used to validate the models. Section V reveals managerial insights and conclusions.

II. MODEL SETTING

A. RSC Structure

This study examines a two-echelon RSC, which includes a green supplier (GS) and a third-party logistics provider (3PL). GS recycles outdated products qualified enough to return to the market. However, the remanufacturing capacity on the GS side is susceptible to uncertainty. On the other hand, 3PL collects outdated products from consumers and returns the acceptable ones to GS after a final assessment. GS makes profits by selling remanufactured products directly through the market. Indeed, GS purchases outdated products from 3PL at the cost of c_{st} /unit and, after the recycling process, sells recycled products at the price of w /unit into the market.

In the current RSC, GS sets an order amount for 3PL and determines the order quantity. However, 3PL may not provide the whole order quantity because of the ineligible collected product. Accordingly, all qualified orders are shipped directly to GS. To sum up, GS may get fewer amounts of the placed ordered products. The parameters used in this study are summarized in Table I.

TABLE I. LISTED PARAMETERS AND DECISION VARIABLES

Parameters	Description
m	A continuous random variable with distribution function $g(\cdot)$ and cumulative function $G(\cdot)$, standing for remanufacturing capacity.
c_{st}	The unit fee paid by GS to 3PL to collect outdated products.
c_i	Inspection fee per unit of collected products at the 3PL site.
α	The clearance percentage of products inspected by 3PL.
c_m	Inventory cost of amassed products collected by 3PL.
c_r	The unit cost of refurbishing at the GS's site
c_p	Cost per unit of preparation for refurbishment by the GS.
c_s	Unit shipping cost for 3PL.
c_{tc}	Reward offered by the 3PL for the return of each outdated product.
w	The wholesale price of refurbished products.
s	The value of salvage per unit for the 3PL.
d	Downward adjustment parameter in the quantity flexibility contract.
u	Upward adjustment parameter in the quantity flexibility contract.
Decision variables	
q_w	GS's order amount for 3PL within the wholesale price contract.
q_c	GS's order amount for 3PL within the centralized contract.
q_f	GS's order amount for 3PL within the quantity flexibility contract.

B. Assumptions

The primary purpose of this study is to highlight the significance of optimum ordering/pricing choices and the management of the possible costs of overstocking or understocking in the analyzed RSC under uncertainty. Hence, the generated models include the following modeling assumptions:

Assumption 1. GS’s remanufacturing capacity is contaminated by uncertainty.

Based on Assumption 1, x is a continuous random variable with a distribution function $g(x)$ and cumulative function $G(x)$ [4].

Assumption 2. 3PL rewards customers with a per-unit fee for the return of outdated products.

Assumption 3. 3PL delivers a definite proportion of qualified collected products to GS after the final assessment.

According to the third assumption, all of the obsolete products collected by 3PL are ineligible for recycling. On the 3PL side, it is thus essential to analyze gathered products and detect discarded ones [16].

Assumption 4. Customers can buy all recycled products at a pre-set price w .

III. MATHEMATICAL MODELING

Suppliers need an ordering system to control the production/inventory process; thus, they pressure downstream partners to place their orders before the selling season. Nonetheless, uncertainties raise overstock/understock risks and discourage partners from setting early orders. Ordering in SCs may be resolved by concluding a suitable contract between two parties. Offering a reservation policy is a measure we can take to encourage GS to purchase more/earlier. To solve the problem, this research compares a regular wholesale pricing contract with a quantity flexibility contract [5] (Appendix).

A. Wholesale Price Contract

Under the wholesale price contract, each participant decides independently of the other participants’ interests. GS determines the order quantity placed for 3PL to optimize its profit, and 3PL inspects the collected products. Then, GS refurbishes the received products following the acknowledged remanufacturing capability [17]. Based on the order quantity and realized remanufacturing capacity, the profit function of GS is formulated as follows:

$$\Pi_{GS}(q_w) = \begin{cases} (w - c_r)m - (c_{st} + c_p)\alpha q_w + s(\alpha q_w - m) & \alpha q_w > m \\ (w - c_r - c_{st} - c_p)\alpha q_w & \alpha q_w < m \end{cases} \quad (1)$$

According to Eq. (1), only m units of products are remanufactured and sold if there is inadequate remanufacturing capacity; the remaining products are salvaged at a value of s ($(\alpha q_w - m) s$). Consequently, the remanufacturer’s profit function comprises income from selling m units on the market and salvage value. Moreover, A unit cost will be paid to 3PL

for each unit received, which under any condition would be αq_w . Now, the expected profit function of GS is:

$$E(\Pi_{GS}(q_w)) = (w - c_r) \left(\int_0^{\alpha q_w} m g(m) dm + \int_{\alpha q_w}^{\infty} \alpha q_w g(m) dm \right) - (c_{st} + c_p)\alpha q_w + \int_0^{\alpha q_w} s(\alpha q_w - m) g(m) dm \quad (2)$$

Proposition 1. $E(\Pi_{GS}(q_w))$ is concave in q_w and q_w^* That maximizes GS’s profit function will be calculated as follows:

$$q_w^* = \frac{G^{-1}\left(\frac{w - c_r - c_{st} - c_p}{w - c_r - s}\right)}{\alpha} \quad (3)$$

Contingent on Eq. (3), the cost of c_{st} is a criterion to determine the trade-off between overstock and understock costs. In this respect, the overstock cost is $c_{st} + c_m - w$ and the understock cost will be $w - c_r - c_{st} - c_p$. Now let us show the 3PL profit function, which is obtained as follows:

$$\Pi_T = \left(c_{st} - c_{tc} - \frac{c_i}{\alpha} - c_m - c_s \right) \alpha q_w \quad (4)$$

The profit function of 3PL reflects the revenue generated by selling outdated products to GS and the associated expenses, such as the cost of returning products, inspection, holding, and shipment. Now, we go further and investigate the centralized contract in the subsequent sections.

B. Centralized Contract

Under the centralized decision-making system, we attempt to maximize the RSC’s overall profit. Under the centralized scenario, the predicted profit function of RSC may be computed as follows:

$$\Pi_{RSC}(q_c) = \begin{cases} (w - c_r)m - c_p \alpha q_c + s(\alpha q_c - m) + \left(-c_{tc} - \frac{c_i}{\alpha} - c_m - c_s\right) \alpha q_c & \alpha q_c > m \\ (w - c_r - c_p)\alpha q_c + \left(-c_{tc} - \frac{c_i}{\alpha} - c_m - c_s\right) \alpha q_c & \alpha q_c < m \end{cases} \quad (5)$$

In Eq. (5), 3PL reviews all returned outdated items and accepts quantities that can be refurbished; following storage, the qualified outdated products are dispatched to GS. Then, GS prepares the items for refurbishing. Consequently, when there is insufficient remanufacturing capacity, as indicated by the expression $\alpha q_c > m$, only m items may be introduced into the remanufacturing process. Accordingly, the total expected profit function of RSC is determined by the following:

$$E(\Pi_{RSC}(q_c)) = (w - c_r) \left(\int_0^{\alpha q_c} m g(m) dm + \int_{\alpha q_c}^{\infty} \alpha q_c g(m) dm \right) - c_p \alpha q_c + \int_0^{\alpha q_c} s(\alpha q_c - m) g(m) dm + \left(-c_{tc} - \frac{c_i}{\alpha} - c_m - c_s\right) \alpha q_c \quad (6)$$

Proposition 2. $E(\Pi_{RSC}(q_c))$ is concave in q_c and q_c^* that maximizes RSC’s profit function will be calculated as follows:

$$q_c^* = \frac{G^{-1}\left(\frac{w - c_r - c_p - c_{tc} - \frac{c_i}{\alpha} - c_m - c_s}{w - c_r - s}\right)}{\alpha} \quad (7)$$

It should be mentioned that the primary insight gained from Proposition 2 is that $G(q_c)$ belongs to a newsvendor concern, i.e., the trade-off acquired between overstock and understock

costs is conducted depending on $(c_{tc} + \frac{c_i}{\alpha} + c_m + c_s)$ in the situation of volatile remanufacturing capacity.

C. Quantity Flexibility Contract

This section examines the scenario in which GS and 3PL implement the quantity flexibility contract. The 3PL is the leader, while the GS is the follower. The following is the order of events under this contract: (1) An offer is made for a contract with parameters (w, q_f, d, u) . w is the wholesale price following the realization of remanufacturing capacity. $0 \leq d \leq 1$ is a parameter that determines the acceptable range and gauges the flexibility. $u \geq 0$ is the upward adjustment parameter. (2) Given the contract, GS determines the reservation quantity q_f . Therefore, the permissible range is set as $[daq_f, (1+u)\alpha q_f]$. Note that GS is not required to pay the reservation fee. (3) After observing the reserved quantity, 3PL gathers outdated products at least equal to the lower limit of the permissible range, i.e., daq_f . (4) The M capacity for remanufacturing is realized. (5) 3PL delivers products to GS in accordance with M's realized capacity and after the final examination. According to the order quantity q_f and realized remanufacturing capacity, the profit function of GS will be:

$$\Pi_{GS}(q_f) = \begin{cases} wm + (-c_r - c_p)m - c_{st}daq_f + s(daq_f - m) & 0 < m < daq_f \\ wm + (-c_r - c_{st} - c_p)m & daq_f < m < (1+u)\alpha q_f \\ (w - c_r - c_{st} - c_p)(1+u)\alpha q_f & m > (1+u)\alpha q_f \end{cases} \quad (8)$$

In the first condition (i.e., $0 < m < daq_f$) of Eq. (8), the first term represents the total revenue from selling m units, the second and third terms stand for operation costs related to purchasing and refurbishing obsolete products, and the third term means the total revenue from salvaging unsold products. In the second condition ($daq_f < m < (1+u)\alpha q_f$), the first term represents the entire income from selling m units, and the second reveals the operation costs. Finally, based on the third condition ($m > (1+u)\alpha q_f$) GS sells $(1+u)\alpha q_f$ units in the market, which is the highest band of purchased products according to the concluded contract. In this regard, the expected profit function of GS will be determined as follows:

$$\begin{aligned} E(\Pi_{GS}(q_f)) &= (w - c_r - c_p) \left(\int_0^{(1+u)\alpha q_f} mg(m)dm \right. \\ &\quad + \int_{(1+u)\alpha q_f}^{\infty} (1+u)\alpha q_f g(m)dm \Big) \\ &\quad - c_{st} \left(\int_0^{daq_f} daq_f g(m)dm \right. \\ &\quad + \int_{daq_f}^{(1+u)\alpha q_f} mg(m)dm \Big) \\ &\quad + \int_{(1+u)\alpha q_f}^{\infty} (1+u)\alpha q_f g(m)dm \\ &\quad + \int_0^{daq_f} s(daq_f - m)g(m)dm \end{aligned} \quad (9)$$

The following Proposition will obtain the optimum amount of GS's order under the quantity flexibility contract.

Proposition 3. $E(\Pi_{GS}(q_f))$ is concave in q_f and q_f^* that maximizes GS's profit function will be calculated by solving the following equation:

$$\begin{aligned} (w - c_r - c_p - c_{st})(1+u)\alpha^2 q_f G((1+u)\alpha q_f) \\ - c_{st}(d\alpha)^2 q_f \left(1 - G((1+u)\alpha q_f) \right) \\ + s(d\alpha)^2 q_f G(daq_f) = 0 \end{aligned} \quad (10)$$

d is a crucial aspect of the quantity flexibility contract. Therefore, as d increases, GS decreases its order quantity. In fact, by increasing d , GS becomes reluctant to place an order with 3PL. Now let us show the 3PL profit function, which is established as follows:

$$\Pi_T = \begin{cases} (c_{st} - c_s)daq_f - (c_{tc} + \frac{c_i}{\alpha} + c_m)(1+u)\alpha q_f + s((1+u)\alpha q_f - daq_f) & 0 < m < daq_f \\ (c_{st} - c_s)m - (c_{tc} + \frac{c_i}{\alpha} + c_m)(1+u)\alpha q_f + s((1+u)\alpha q_f - m) & daq_f < m < (1+u)\alpha q_f \\ (c_{st} - c_{tc} - \frac{c_i}{\alpha} - c_m - c_s)(1+u)\alpha q_f & m > (1+u)\alpha q_f \end{cases} \quad (11)$$

As shown in Eq (11), when GS's remanufacturing capacity m is lower than daq_f , it purchases its minimum promised volume. In such circumstances, GS must salvage unsold inventory at the end of the selling season.

IV. NUMERICAL ANALYSIS

We explore various numerical experiments to show the recommended model's effectiveness. The parameters for two numerical examples are presented in Table II. The datasets utilized in the examples meet all the examined assumptions and models' criteria. The employed data are compatible with datasets applied in the prior research, mainly produced based on genuine instances. In addition, the selected values are relatively broad to be utilized for numerous items in the remanufacturing and refurbishment sector, although by scaling and specific adjustments [18] Meanwhile, equations acquired for the optimal order values are all closed-form relations that there is no need for software to solve. This study assumes that remanufacturing capacity follows a normal probability distribution $N(\mu, \sigma)$ in the first case and a uniform probability distribution $U(T1, T2)$ in the second. Table III displays the numerical findings, which include decision variables and profit functions.

In the first case, the tremendous potential of the channel is attained when all partners are handled through an interconnected solution, i.e., a centralized contract. Nevertheless, each partner seeks to advance its interests via decentralized contracts; hence, Table III indicates that the quantity flexibility contract enables all RSC participants to function nearly as a single unit. This incentive-based method has enhanced the number of orders and produced much more flexibility than the decentralized contract — the quantity flexibility contract functions as a risk-sharing strategy. Specifically, GS and 3PL share the risk of unpredictable remanufacturing capacity. By utilizing a reserving approach, GS can order obsolete items from GS with greater flexibility, increasing order volume and decreasing the likelihood of experiencing capacity instability. Results indicate that GS and 3PL will gain profit about equally if the deal is accepted.

Table IV illustrates the effect of changing d on profit functions and the GS's order quantity. Based on Table IV, as expected, by decreasing d , GS's profit under the quantity flexibility contract will increase. On the other hand, reducing d decreases the profit of 3PL under quantity flexibility.

TABLE II. AMOUNTS OF PARAMETERS

Parameters	First example	Second example
c_{st}	50	80
c_i	8	16
α	0.88	0.92
c_m	4	6
c_r	15	20
c_p	5	7
c_s	3	6
c_{tc}	20	30

$d = 0.5$	Wholesale price	140.11	1309.11	1715.58	3024.69
	Centralized	170.44	1400.87	2370.82	3771.69
	Quantity flexibility	241.88	1891.92	2892.99	4784.91

V. CONCLUSION AND FUTURE STUDIES

In this study, a reverse supply chain is built to address the problems of a stochastic remanufacturing capacity. Initially, a decentralized contract is developed in which the 3PL gives consumers a cost charge for returning outdated items. In the subsequent phase, we model a centralized contract to obtain a globally optimum solution. However, the unpredictability of the upstream remanufacturing capacity is complicated from a decentralized to a centralized contract. Developing a quantity flexibility contract that allows the green supplier to cancel its preliminary order in a restricted quantity. Additionally, 3PL offers a restricted quantity above the initial order to prevent understocking during peak seasons. Numerical examples and sensitivity analysis indicate that the suggested quantity flexibility contract not only enhances the economic

performance of each SC participant but also produces a Pareto-improving condition in which both SC participants earn higher profitability. We further demonstrate that when the quantity flexibility contract's downward adjustment parameter is low, the quantity flexibility contract is profitable for both 3PL and supplier. Thus, both prefer to participate in the quantity flexibility contract channel.

We were excused from investigating several limitations: First, it would be interesting to consider both the remanufacturing capacity and demand uncertainty and compare the results with this study. Another limitation is that we were also excused from comparing the proposed reservation-based contract (quantity flexibility) with another, such as an option contract or even a penalty-based contract.

Future research opportunities in reverse supply chain coordination might include analyzing the simultaneous effects of numerous sources of uncertainty. Another expansion may concentrate on the competitive context and use game theory to address the issue in competitive settings. In addition, how outdated items are gathered is an essential aspect of reverse logistics. Hence, this perspective might be the subject of intriguing research. Customers will be more inclined to return their used items for a discount if they can easily store out-of-date merchandise. In this study, the desire of consumers to return their outdated items is assumed to be a deterministic linear function of the provided incentive amount; however, stochastic and nonlinear processes can also be considered. Lastly, exploring the potential for outsourcing capacity and contemplating a backup manufacturer for the existing model might be examined as part of future relevant and intriguing work.

APPENDIX

Proof of Proposition 1. To prove concavity, from Eq. (1), we must determine $\frac{\partial E(\Pi_{GS}(q_w))^2}{\partial q_w^2}$. We have: $\frac{\partial E(\Pi_{GS}(q_w))^2}{\partial q_w^2} = -\alpha^2(w - c_r - c_{st})g(\alpha q_w) < 0$; therefore, GS's profit is concave in q_w . Besides, q_w^* will be obtained by first-order optimality condition, i.e., $\frac{\partial E(\Pi_{GS}(q_w))}{\partial q_w} = (w - c_r) \int_{\alpha q_w}^{\infty} g(m)dm + s \int_0^{\alpha q_w} g(m)dm - (c_{st} + c_p) = 0$. ■

Proof of Proposition 2. To show concavity, from Eq. (6), we calculate $\frac{\partial E(\Pi_{RSC}(q_c))^2}{\partial q_c^2}$. Since $-\alpha^2(w - c_r - s)g(\alpha q_c) < 0$ therefore, the RSC's profit function is strictly concave in q_c . q_c^* to be calculated through the first-order optimality state, which is $\frac{\partial E(\Pi_{RSC}(q_c))}{\partial q_c} = (w - c_r) \int_{\alpha q_c}^{\infty} g(m)dm + s \int_0^{\alpha q_c} g(m)dm + (c_r - c_p - c_{tc} - \frac{c_i}{\alpha} - c_m - c_s) = 0$. ■

Proof of Proposition 3. Since the second-order derivative of Eq. (9) in q_f is negative ($\frac{\partial E(\Pi_{GS}(q_f))^2}{\partial q_f^2} = -\alpha^2(-c_r - c_p - c_{st})g(\alpha q_w) < 0$), the $E(\Pi_{GS}(q_f))$ is concave in q_f . Now the equilibrium will be obtained by solving following equation: $(w - c_r - c_p - c_{st})(1 + u)\alpha^2 q_f G((1 + u)\alpha q_f) - c_{st}(d\alpha)^2 q_f (1 - G((1 + u)\alpha q_f)) + s(d\alpha)^2 q_f G(d\alpha q_f) = 0$

Simulation Method of Port Petrochemical Industry Throughput Development under the Background of Integration of Port, Industry and City

Tingting Zhou, Chen Guo*

College of Economics and Management, Yingkou Institute of Technology, Yingkou, 115014, China

Abstract—In order to accurately predict the changes in the throughput of port petrochemical products and facilitate the formulation of relative decisions, this paper analyzes the factors affecting the throughput of port petrochemical products in a city through the GRA method. After sorting and selection, PCA method is used for pretreatment. In the SVM algorithm, ICSO is used to obtain the best parameters and improve the prediction accuracy and efficiency. In view of the variability of future development, three development scenarios are set up to prepare for the throughput forecast of petrochemical products in a city's port. The results show that the optimization speed of ICSO algorithm is very fast. When the training iteration is 20, the best fitness value is obtained, which is 0.0572. The training effect of ICSO-SVM algorithm is good, the gap between it and the original data is small, and the overall trend is close to the original data. In the test prediction, ICSO-SVM algorithm has the best prediction effect, and its MAE, RMSE and MAPE are the smallest. The minimum MAE is 762.2, 477.0 smaller than CSO-SVM algorithm, and the latter's MAE is 1239.2. The minimum MAPE of the proposed algorithm is 1.05%, while that of CSO-SVM algorithm is 1.71%. In general, the prediction error of ICSO-SVM algorithm is smaller. After the prediction of different development scenarios, the throughput of petrochemical products in a port of a city shows an increasing trend in the next five years. This method can be applied to the development forecast of port petrochemical products and provide reference for decision-making.

Keywords—Support vector machine algorithm; port throughput; chicken swarm optimization algorithm; grey correlation analysis; petrochemical products

I. INTRODUCTION

With the continuous development of the economy, the heavy chemical industries on both sides of the Yangtze River are facing deep adjustment. Due to the low economic efficiency of the chemical siege movement, the waste of land resources and the pollution of the ecological environment have resulted in the lack of impetus for the integration and development of port clusters, petrochemical industry clusters and urban clusters, that is, it is difficult for the three to coordinate [1-3]. In order to promote the coordinated development of port, industry and city, it is necessary to analyze the development of each integrated part in depth. Some scholars choose Support Vector Machine (SVM) to predict the port throughput when studying it. In order to explore the impact of market indicators, they use this indicator as the input of the prediction model. Through experimental

tests, the model has achieved good prediction results and can predict port throughput [4]. To predict the power in the Kanto region, some scholars choose SVM algorithm to build relevant multi-network configuration predictors. After testing, the accuracy of prediction has been improved, and the test effect is good [5]. Therefore, when studying the throughput of port petrochemical products, SVM algorithm is selected as the prediction algorithm. In the analysis and processing of the factors affecting the throughput of port petrochemical products, the grey correlation analysis (GRA) and principal component analysis (PCA) are used for correlation analysis and processing to predict the throughput of port petrochemical products more accurately. By predicting the throughput of petrochemical products in ports, it is beneficial for ports to grasp the direction of business development and actively promote the rational layout of port logistics networks. The study was divided into four parts. The second part is a literature review, which introduces the research of domestic and foreign scholars on port development and port throughput, the good performance of SVM algorithm in forecasting and the relevant application research of PCA and GRA method in data analysis, among which these three methods are also suitable for port throughput forecasting research. In the third part, PCA method and GRA method are proposed to deal with the factors affecting the throughput of petrochemical products at port. ICSO-SVM algorithm is used to predict the throughput of petrochemical products at port. The fourth part carries on the empirical analysis of port petrochemical product throughput prediction, and the results show the superiority of ICSO-SVM algorithm.

II. RELATED WORK

To promote the development of the integration of port, industry and city, the transformation of petrochemical industry is necessary. Relevant parties need to adjust their industrial layout, strengthen the internal power of coordinated development, and protect the ecological environment while coordinating development. During the transformation of the petrochemical industry, some scholars simulated the development of the transportation volume of the port petrochemical industry to understand its development trend and make better decisions. In the face of the transportation problem of petrochemical products, An H and others adopted the relevant comprehensive short-term scheduling model for scheduling. They used heuristic algorithms. The data set test confirmed the superiority and low cost of this method [6]. Zhang selected the port and shipping industry of Ningbo as the

research object to study its development strategy. Taking the spatial scale as the starting point, they put forward their relevant strategic objectives, analyzed the relevant paths, and finally gave the relevant strategic integration model [7]. Wang and others analyzed the national economy and the role of port industry in it. They focus on their input and output, as well as the relevant time evolution process. They summarized relevant policy applications [8]. Ngoc et al. studied container port throughput management and applied control theory and chaos analysis. They optimize the port operation through the theory of sliding membrane control. The test verifies the effectiveness of this method [9].

Zhang et al., faced with the problem of carbon price prediction, chose the least squares SVM to predict it. When processing raw data, they choose the empirical model. The results show that the method is effective and feasible [10]. Praveena et al. detected epileptic seizures and processed the collected data through PCA dimensionality reduction by intelligent means. They use SVM to classify them. After verification, the application effect of this method is good [11]. Song et al. carried out earthquake early warning P-wave prediction on the basis of SVM. After model training, the test error of this method is small [12]. In order to predict PM2.5 of air pollution, Lai X et al. carried out relevant prediction by improving SVM algorithm on the basis of feature selection. The results confirmed the availability of this method [13]. Huang J et al. faced the problem of analyzing the factors affecting the calcination temperature of a vertical furnace, and based on orthogonal design, chose the GRA method to quantify the significant factors involved. According to the analysis results, the influence of volatile matter content is significant and is a key factor [14]. Chen C et al. used the PCA method to reduce the dimensionality of the relevant influencing factors in order to predict the phosphorus content at the endpoint of the Condi electric furnace, and input the processed results into the extreme randomization tree. The results show that the prediction effect is good [15]. Luo S et al. chose to improve the SVM algorithm when facing the problem of predicting the thermal state inside the blast furnace skull. After testing on the dataset, this method has high prediction accuracy [16].

To sum up, in the study of port throughput, there are relatively few researches on its cargo, which mainly focus on the port itself and analyze the development of the port. The researches on cargo throughput are not deep enough. In order to dig into the key factors affecting the development and change of the throughput of petrochemical products in port and obtain more accurate throughput prediction results, this study takes the throughput of petrochemical products in port as the research object and studies its development trend. Through GRA method and PCA method, the key influencing factors are dug out. Considering the good effect of SVM algorithm in prediction, the improved SVM algorithm is used to carry out relevant research, which makes the prediction technology be innovatively improved and the prediction accuracy and generalization ability of the prediction model be enhanced.

III. SIMULATION OF PORT PETROCHEMICAL INDUSTRY TRAFFIC VOLUME DEVELOPMENT BASED ON ICSO-SVM ALGORITHM UNDER THE BACKGROUND OF PORT INDUSTRY AND CITY INTEGRATION

A. Treatment of Factors affecting Port Petrochemical Product Throughput based on GRA and PCA Methods

In the continuous economic development, the integration of port and industry is an important way to develop regional economic, which is conducive to the transformation of petrochemical industry and accelerating the integration process. To understand the development trend of the petrochemical industry in the development of transportation volume, the article selects the port petrochemical product throughput as the research object and analyzes it. The change trend of the throughput of petrochemical products in a city's port in recent years is shown in Fig. 1.

In Fig. 1, the throughput of port petrochemical products in 2020 was lower than that in 2019. In 2021, the throughput of petrochemical products in the port returned to normal and increased to a certain extent, surpassing 2019. Although there were gaps in the throughput of petrochemical products in ports in different years, there was an overall growth trend. To study the causes of the changes in the throughput of port petrochemical products, this paper analyzes the influencing factors. Through consulting information and data acquisition, it is found that the throughput of port petrochemical products is affected by many factors. Based on these factors, the paper constructs a pre-selection index system of relevant influencing factors, as shown in Fig. 2.

In Fig. 2, the indicator system includes four primary indicators, namely economic and trade level (EATL), regional development vitality (RDV), population and employment level (PAEL), port infrastructure conditions (PIC), and 14 secondary indicators. In order to understand the correlation between these indicators and the throughput of port petrochemical products, the article selects the GRA method to analyze them. The greater the correlation, the stronger the corresponding correlation. In the GRA method, first set the original sequence $X'_i = [x'_i(1), x'_i(2), \dots, x'_i(n)]$, $i = 0, 1, 2, \dots, l$. The length of the number sequence is set to n , and there are $l+1$ index number sequences collected^[17-19]. The difference sequence is solved for the initial value of each sequence, and its calculation formula is shown in Eq. (1).

$$\Delta_i(k) = |x'_0(k) - x'_i(k)|, \Delta_i = (\Delta_i(1), \Delta_i(2), \dots, \Delta_i(n)) \quad (1)$$

In formula (1), Δ_i represents the difference sequence and k represents the sequence number. Solve the maximum difference and minimum difference between the two poles, as shown in Formula (2).

$$M = \max_l \max_k \Delta_i(k), M = \min_l \min_k \Delta_i(k) \quad (2)$$

In formula (2), M represents the maximum difference between the two poles, and m represents the minimum difference between the two poles. Solve the correlation coefficient $\gamma_{0i}(k)$ and calculate the correlation degree. The

calculation formula is shown in formula (3).

$$\gamma_{oi} = \frac{1}{n} \sum_{k=1}^n \gamma_{oi}(k), i = 1, 2, \dots, l \quad (3)$$

In formula (3), γ_{oi} represents the degree of correlation. The software used for correlation calculation is MATLAB. Sort the relevant results according to the order from the largest to the smallest. According to the ranking of the correlation degree obtained, 13 indicators are selected as the prediction indicators required by the article. These indicators are in the top 13 in the ranking of correlation degree and have high correlation with the throughput of port petrochemical products. Among them, the top three indicators are GDP, total import

and export of petrochemical products, and coastal berths. In particular, the correlation value corresponding to GDP is the largest. In order to better reflect the impact factors of port throughput, 13 indicators are included in the prediction model. However, the dimension of data is too large to have a certain impact on the prediction effect of SVM. Therefore, PCA method is adopted to reduce data redundancy and reduce the complexity of the problem [20-22]. It is a linear dimensionality reduction algorithm with practical significance, which can perform orthogonal transformation on high-dimensional data. The transformed data maintains the basic information of the original data. After the change of linearly related variables, the new variable formed has linear independence, which is also called principal component.

Fig. 1. Change trend of petrochemical product throughput in a port.

Fig. 2. Pre-selection index system of influencing factors.

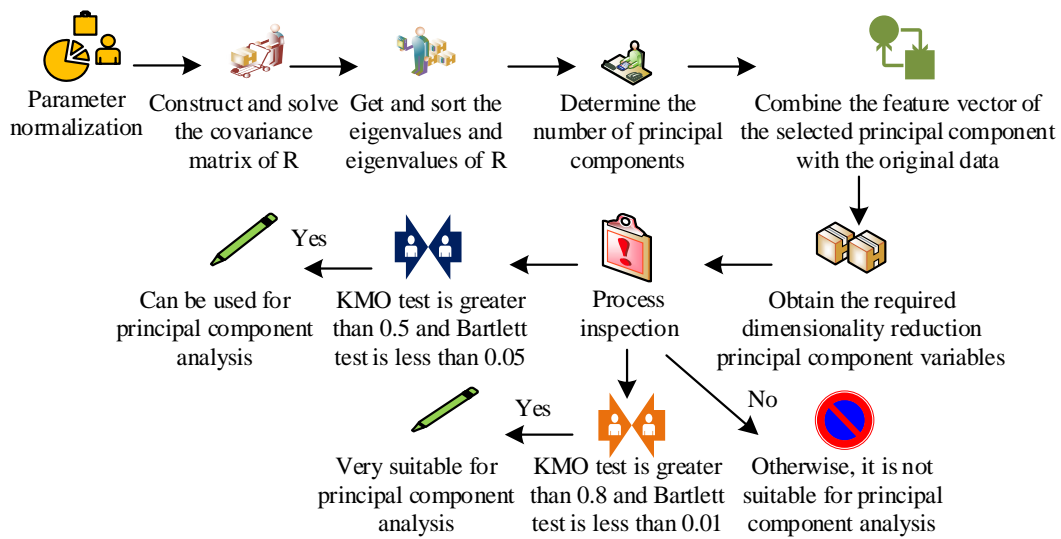

Fig. 3. Relevant process of PCA method.

PAC method first normalizes all parameters to form a normalized matrix. Secondly, it obtains the eigenvalues and eigenvectors of R by constructing and solving the covariance matrix of R, and ranks them according to the variance of principal components. The number of principal components is determined by their contribution degree and cumulative variance contribution rate, and the eigenvalues are taken as the judgment criteria, which need to exceed 1, and the contribution rate need to be no less than 85%. The feature vector of the selected principal component is combined with the original data to obtain the required dimension-reduced principal component variable. Then, there are two test methods in dimension reduction, namely, Kaiser-Meyer-Olkin (KMO) test and Bartlett test. If the value of the former test method is greater than 0.5 and the value of the latter test method is less than 0.05, the principal component analysis can be performed. If the value of the former test method is greater than 0.8, and the value of the latter test method is less than 0.01, it is particularly suitable for principal component analysis. The relevant process of PCA method is shown in Fig. 3.

After dimension reduction by PCA method, the principal components are obtained, and the correlation between the factors is eliminated, which maximizes the original main information. This method is simple, easy to implement, without parameter constraints, and has good objectivity. It can not only simplify the subsequent data processing, but also help the SVM model have better robustness. The PCA method is used to reduce the dimension of the selected 13 indicators. To better save the relevant information of the original data, the PCA method is used to process the secondary indicators under a primary indicator, and then the relevant secondary indicators of the remaining primary indicators are processed according to this method. The software used for PCA analysis is SPSS software.

B. Application of ICSO-SVM Algorithm in Throughput Prediction of Port Petrochemical Products

According to the relevant data characteristics of port petrochemical product throughput, forecasting and analysis by

SVM algorithm can effectively overcome the problems of other models. Problems include insufficient sample size and poor model stability. This method is good at processing a kind of nonlinear data, which is characterized by small samples and high dimensions. The SVM algorithm is to find an optimal hyperplane. On both sides of the plane, the samples are farthest away from it, and the classification effect and robustness of the algorithm are also better [23-24]. In the distance between sample point and hyperplane, the relevant calculation formula is shown in formula (4).

$$d = \frac{\|w^T x + b\|}{\|w\|} \quad (4)$$

In formula (4), x_i represents sample point and d represents sample interval. The normal vector is expressed as w , b means parameter. To further describe the sample interval, some training samples closest to the hyperplane on the hyperplane are found, and a formula that meets the conditions is given as formula (5).

$$\begin{cases} w^T x_i + b = 1, y_i = 1 \\ w^T x_i + b = -1, y_i = -1 \end{cases} \quad (5)$$

In formula (5), y_i represents the sample point. According to Formula (4) and Formula (5), the sum of the distance between the two support vectors and the hyperplane is $\frac{2}{\|w\|^2}$.

When this value is maximum, the corresponding sample discrimination is maximum. Analyze the nature of the sample and the degree to which it can be separated, and use the kernel function SVM as its learning method. Support vector machine regression (SVR) is widely used in classifiers. When constructing the regression function $f(x)$, set the loss boundary as ϵ . When the distance between $f(x)$ and sample is less than ϵ , an isolation band with the width of 2ϵ is formed. When the sample is in the isolation zone, the

prediction is correct. After the kernel function is applied, the relevant objective function is shown in equation (6).

$$\min \frac{\|w\|^2}{2} + C \sum_{i=1}^N \ell_\varepsilon(f(x_i) - y_i) \quad (6)$$

In formula (6), the penalty factor is expressed as C , and the ε insensitive loss function is expressed as ℓ_ε . The relevant expression is shown in Eq. (7).

$$\ell_\varepsilon = \begin{cases} 0, & \text{if } |z| \leq \varepsilon \\ |z| - \varepsilon, & \text{else} \end{cases} \quad (7)$$

In formula (7), z represents the parameter. By adding relaxation variables δ_i and $\hat{\delta}_i$, the SVR problem is transformed. Combining Lagrange multipliers α_i and $\hat{\alpha}_i$, the relevant dual problem can be obtained, and then the optimal solution of SVR problem is shown in Eq. (8).

$$f(x) = \sum_{i=1}^N (\alpha_i - \hat{\alpha}_i) K(x_i, x) + b \quad (8)$$

In formula (8), K represents the parameter. In SVM, C and kernel function width σ have a greater impact on its prediction effect. In view of this situation, radial basis function (RBF) is selected as the kernel function in this paper because of its strong generalization ability. In addition, to obtain the best parameters, the paper selects CSO algorithm for parameter optimization. Because of its poor processing effect on complex optimization problems, this paper optimizes it through two improvement strategies and obtains the improved CSO (Improved Chicken Swarm Optimization, ICSO) algorithm. Using chaos theory, the diversity of the algorithm is strengthened, and adaptive learning strategy is introduced. In the first strategy, due to the randomness of the initial population generation of CSO algorithm, it is easy to have a local optimal solution. Adding chaotic variables can avoid this situation. This variable can be generated by a specific chaotic map, and its initial population distribution range is much larger than the random variable, and can be combined with intelligent optimization methods. Among them, tent mapping is a typical method of generating chaotic sequence similar to tent, and the formula involved is shown in formula (9).

$$x''_{i+1} = \begin{cases} x''_i/a, & x''_i < a \\ (1-x''_i)/(1-a), & x''_i \geq a \end{cases} \quad (9)$$

In formula (9), x''_i and x_0 represent chaotic variables and initial variables respectively. The mapping coefficients are expressed as $a \in (0, 1)$, and a group of chaotic sequences can be obtained by x_0 iterating n times. Compared with random sequence, the data distribution characteristics of the chaotic sequence of Ten-map are relatively stable, so the corresponding x''_i is selected to replace the random number of CSO algorithm. In the adaptive learning strategy, the chicken's movement mode is improved, and the self-learning

coefficient is added, so that the direction of its movement has a certain probability towards the cock, and the relevant calculation formula of the relevant improved strategy is shown in Formula (10) and Formula (11).

$$x''_{ij}{}^{t+1} = w_i * x''_{ij}{}^t + F * (x''_{mj}{}^t - x''_{ij}{}^t) + R * (x''_{rj}{}^t - x''_{ij}{}^t) \quad (10)$$

In formula (10), w_i represents the self-learning coefficient of chicks, and x_m represents the position of hens. At the time of t , the position of the individual is expressed as x''_{ij} , the fitness of the i th hen is expressed as f_i , and the chick random following parameter is expressed as F . r represents the cock's coefficient, and R means the coefficient that follows the cock's movement, which will replace the chaotic variable.

$$w_i = \begin{cases} w_{\min} + (f_i - f_{\min}) * (w_{\max} - w_{\min}) / (f_{\text{avg}} - f_{\min}), & \text{if } f_i \leq f_{\text{avg}} \\ w_{\max}, & \text{else} \end{cases} \quad (11)$$

In formula (11), w_{\min} and w_{\max} represent the minimum and maximum weight. The maximum fitness, minimum fitness and average fitness of chicken flocks are expressed as f_{\max} , f_{\min} and f_{avg} respectively. Combined with the improved CSO algorithm, the problem to be solved is the optimal problem on the bounded two-dimensional plane. Its goal is to find the f_{\min} best individual. The individual f of the chicken flock corresponds to the mean square error of prediction, that is, to find the minimum prediction error, and then the optimal parameters of SVM can be obtained. The throughput of port petrochemical products is predicted by ICSO-SVM algorithm. The data of the first 11 years in Fig. 1 are classified as training sets, and the rest are test sets. First, data preprocessing and parameter setting are carried out. The basic model is the ε -SVR model. The system default value is 0.1. Set the ICSO algorithm parameters, as shown in Fig. 4.

In Fig. 4, according to the Ten-map chaotic algorithm, all chickens form initial positions. In the iterative process, individuals search for optimization in the search space according to their own way of movement. The individual identity is updated every 10 generations. The update is based on the current f . Keep iterating until the prediction error is less than 10-4 or the maximum iteration is reached, then the operation will be stopped. For data preprocessing, Z-core standardization method is selected, as Formula (12).

$$H' = \frac{H - \bar{H}}{\sigma} \quad (12)$$

In formula (12), H' , H and \bar{H} are mean normalized, original and original average data respectively. Mean Absolute Error (MAE) is used to evaluate the prediction effect, as Formula (13).

$$MAE = \frac{1}{T} \sum_{t=1}^T |s_t - n_t| \quad (13)$$

In formula (13), T represents the number of years, and

the real original value and predicted value of the t year are s_t and n_t respectively. The evaluation index is Mean Absolute Percentage Error (MAPE), as shown in formula (14).

$$MAPE = \frac{1}{T} \sum_{t=1}^T \left| \frac{s_t - n_t}{s_t} \right| * 100\% \quad (14)$$

The root mean square error (RMSE) as the evaluation index is shown in formula (15).

$$RMSE = \sqrt{\frac{1}{T} \sum_{t=1}^T \left| \frac{s_t - n_t}{s_t} \right|^2} \quad t \in 1, 2, \dots, T \quad (15)$$

After the prediction results are obtained, they are compared with other prediction methods to verify the reliability of the methods used in the article. Overall, the model building process is shown in Fig. 5.

In Fig. 5, several comparison models are applied to test and verify the performance of the methods used in the article. During the comparative experiment, the same data sets were used. These comparison methods are shown in Fig. 6.

After testing the method, it is applied to the throughput prediction of petrochemical products in a port of a city. Considering the uncertainty of future development, this paper uses scenario prediction method to predict the throughput of petrochemical products in a city's future port. First, according to the policy documents of a city and its development rules, different scenarios are set to reflect different development situations. The middle-aged change rate of different scenarios is set to obtain the corresponding future value. These values are entered into the model. Through the trained model, the throughput under different scenarios is predicted and the relevant outputs are obtained.

IV. PREDICTION AND ANALYSIS OF PORT PETROCHEMICAL PRODUCT THROUGHPUT

This paper uses the GRA method to deal with the impact indicators of the throughput of petrochemical products in a port of a city, so as to analyze the correlation between the various impact indicators. After processing by the GRA method, the correlation value of each indicator in the impact indicator system is shown in Fig. 7.

Fig. 7 shows that the grey correlation degree values of the impact indicators on the throughput of petrochemical products in different ports are different. Among these indicators, the grey correlation degree value of x'_{11} indicator is the largest, 0.882. The second is x'_{13} , whose grey correlation value is 0.011 less than x'_{11} . The grey correlation value of x'_{13} is 0.871. The grey correlation degree values of indicators x'_{22} , x'_{12} and x'_{24} are 0.854, 0.849 and 0.817 respectively. The

grey correlation degree value of indicator x'_{12} is 0.032 higher than x'_{24} . The index with the lowest grey correlation value of the impact index is x'_{32} , and its grey correlation value is 0.571, which is less than 0.6, that is, the urbanization rate has a weak correlation with the throughput of petrochemical products in a city's port. In addition to the urbanization rate, the other 13 impact indicators have a strong or general correlation with the throughput of petrochemical products in the port of the city. Among them, GDP, total import and export of petrochemical products, coastal berths and the throughput of petrochemical products in the port of a city have a strong correlation. GDP is the most critical impact indicator. Therefore, 13 impact indicators other than urbanization rate are selected as the input data of the prediction model. The training data selects the data from 2006 to 2016. After preprocessing, the ICSO-SVM algorithm is trained through the processed data, and the relevant results are shown in Fig. 8.

Fig. 7. Grey correlation degree value of impact index.

Fig. 8. Algorithm iterative optimization and training fitting results.

Fig. 8(a) shows the iterative optimization process of ICSO algorithm. Fig. 8(b) shows the training results of ICSO-SVM algorithm. In Fig. 8(a), the average fitness value of the ICSO algorithm is different under different iterations. The optimal fitness decreased slowly and then stabilized. When the iteration number is 12, the average fitness value of the ICSO algorithm is 0.13, which is 0.05 less than the average fitness value of the iteration number of 10. When the iteration number is 28, the average fitness value of ICSO algorithm is the largest, and its average fitness value is 0.24. For the best fitness of ICSO algorithm, when the iteration number is 10, the best fitness value is 0.0607, which is 0.0029 less than that when the iteration number is 1, and the best fitness value of the latter is 0.0636. When the iteration number is 20, the best fitness value of the ICSO algorithm is 0.0572, and the ICSO algorithm begins to converge. Therefore, the optimization speed of the proposed algorithm is fast and the error is low. In Fig. 8(b), according to the line chart of the predicted value of different years and the original data, the two fit well and the fitting result is good. In 2007, the original data was 353.71 million tons, and the forecast data was 348.09 million tons, which was 5.62 million tons less than the former. In 2008, the forecast data was 366.65 million tons, 180000 tons more than the original data. Therefore, the gap between the two is small. The prediction results of different algorithms in the test set are shown in Fig. 9.

In Fig. 9, according to the broken line of the prediction results of different algorithms, the broken line of the prediction results of the ICSO-SVM algorithm is closest to the broken line of the original data. The distance between other polylines and the polyline where the original data is located is different. In 2017, the forecast result of ICSO-SVM algorithm was 478.53 million tons, and the original data was 472.82 million tons, the former was 5.71 million tons more than the latter. In 2019, the prediction results of ICSO-SVM algorithm, CSO-SVM algorithm and PSO-SVM algorithm were 449.73 million tons, 441.03 million tons and 412.6 million tons respectively, while the original data was 453.8 million tons. The gap between the predicted results of ICSO-SVM algorithm and the original data is the smallest. In 2021, the predicted results of SVM algorithm and ICSO-SVM algorithm are 378.56 million tons and 482.05 million tons respectively, which are 110.54 million tons and 7.05 million tons less than the original data. Quantify the prediction error of the algorithm and the relevant results are shown in Fig. 10.

Fig. 9. Prediction results of different algorithms.

In Fig. 10(a), different algorithms correspond to different MAE and RMSE. In terms of MAE, the MAE of ICSO-SVM algorithm is 762.2, 477.0 smaller than CSO-SVM algorithm, and the MAE of the latter is 1239.2. The MAE of GA-SVM algorithm is 1905.0, and that of SVM algorithm is 2116.4. The maximum MAE of BP algorithm is 2473.0, which is 1710.8 larger than that of ICSO-SVM algorithm, and the latter has the minimum MAE. In terms of RMSE, the minimum RMSE of ICSO-SVM algorithm is 814.7, while the maximum RMSE of BP algorithm is 2792.4. In Fig. 10(b), the minimum MAPE of ICSO-SVM algorithm is 1.05%, which is 0.66% smaller than CSO-SVM algorithm. Therefore, ICSO-SVM algorithm has the best prediction effect. The algorithm without influencing factor analysis is 14-ICSO-SVM algorithm, and the prediction results under different pretreatment methods are shown in Fig. 11.

In Fig. 11(a), the prediction results obtained by the two pretreatment methods differ greatly. Compared with 14-ICSO-SVM algorithm, ICSO-SVM algorithm has smaller MAE and RMSE values. The MAE value of ICSO-SVM algorithm is 762.2, 1016.4 less than that of 14-ICSO-SVM algorithm, and the MAE value of the latter is 1778.6. The RMSE values of ICSO-SVM algorithm and 14-ICSO-SVM algorithm are 814.7 and 1901.7 respectively. In Fig. 11(b), the MAPE values of ICSO-SVM algorithm and 14-ICSO-SVM algorithm are 1.05% and 2.38% respectively, the latter is 1.33% higher than the former. The results further show that the GRA and PCA analysis of the data before the model prediction is conducive to reducing the prediction error. Input the influence factors after pretreatment into the trained model, and predict the throughput of petrochemical products in a city's port from 2023 to 2027 according to different development scenarios. Fig. 12 gives the results.

In Fig. 12, the predicted value under the high-speed development scenario is the largest. Under the same development scenario, the throughput of petrochemical products increased year by year. Under the low-speed development scenario, the forecast result in 2023 is 483.25 million tons, 27.14 million tons less than that in 2025. The forecast result in 2027 is 53.152 million tons. In 2026, the forecast results under the baseline development scenario and the high-speed development scenario are 528.75 million tons and 533.15 million tons respectively, 12.53 million tons and 59.33 million tons less than the corresponding development scenario in 2027.

Fig. 10. Prediction error of different algorithms.

Fig. 11. Prediction results under different pretreatment methods.

Fig. 12. Prediction results under different scenarios.

In the throughput prediction of petrochemical products at a port in a certain city, the influencing factors of throughput development will affect the prediction results. By screening out key influencing factors, the prediction results are superior to those without considering the influencing factors. Some scholars take into account the influencing factors of FDT when predicting the finish rolling discharge temperature (FDT). From the results, it can be seen that considering the influencing factors, the prediction accuracy of FDT is higher [25]. It can be seen that mining key influencing factors is beneficial for improving prediction accuracy. The model

parameters will affect the prediction accuracy of the SVM algorithm, and the more suitable the parameters are, the higher the prediction accuracy of the algorithm. Some scholars choose SVM algorithm to optimize algorithm parameters through simulated annealing algorithm when predicting student grades, in order to obtain the best parameters. After verification, the optimized SVM algorithm has better prediction performance [26]. It can be seen that optimizing parameters can improve the prediction accuracy of the algorithm. When predicting the throughput of petrochemical products, a more comprehensive and scientific consideration

of key influencing factors and optimization of SVM algorithm parameters can yield more accurate prediction results, making the obtained results more valuable for reference and providing an effective universal prediction tool for decision-makers.

V. CONCLUSION

Under the background of the integration of port and industry, to understand the development of the port petrochemical industry, this paper takes the throughput of port petrochemical products as the research object, analyzes its impact factors through the GRA method, and studies its correlation with different impact indicators. The index is sorted and selected based on the grey correlation degree, and the selected influence index is pretreated by PCA method as the input of the prediction model. The research improves the SVM algorithm through the ICSO algorithm, so as to train and test the preprocessed data. At the end of the study, the throughput of petrochemical products in the port of a city in the next five years is predicted. The results show that the optimal fitness value of ICSO algorithm is 0.0572, and the corresponding iteration number is 20. The optimization speed of the algorithm is fast and the error is low. In the training results of ICSO-SVM algorithm, the predicted value is close to the line corresponding to the original data, and the difference between the two data is small. Among the test results of different algorithms, the gap between the predicted results of ICSO-SVM algorithm and the original data is the smallest. In terms of prediction error, ICSO-SVM algorithm has the smallest MAE, RMSE and MAPE. The minimum MAE is 762.2, 1710.8 less than BP algorithm. Its minimum MAPE is 1.06%, which is 0.65% smaller than CSO-SVM algorithm. Among the different preprocessing methods, the prediction result of ICSO-SVM algorithm is better than that of 14-ICSO-SVM algorithm. The former has the lowest MAE, RMSE and MAPE. The MAPE values of ICSO-SVM algorithm and 14-ICSO-SVM algorithm are 1.05% and 2.38% respectively, and the latter is 1.33% higher than the former. Through the prediction of the throughput of petrochemical products in a city's port, its throughput is increasing year by year. Under the high-speed development scenario, the forecast result in 2027 is 592.48 million tons. Thus, the prediction effect of the method used in the article is good. In the future, more scenarios can be set, and the diversity of influencing factors can be considered to make the development scenario prediction more reasonable.
